The primary nursing diagnostic label used to describe a patient with limited or no ability to communicate verbally is *impaired verbal communication.* This is the state in which an individual experiences a decreased, delayed, or absent ability to receive, process, transmit, and use symbols (Doenges et al., 2010). A patient has defining characteristics such as the inability to articulate words, inappropriate verbalization, difficulty forming words, and difficulty comprehending, which you cluster together to form the diagnosis. This diagnosis is useful for a wide variety of patients with special problems and needs related to communication such as impaired perception, reception, and articulation. Although a patient's primary problem is impaired verbal communication, the associated difficulty in self-expression or altered communication patterns may also contribute to other nursing diagnoses:

- Anxiety
- Social isolation
- Ineffective coping
- Compromised family coping
- Powerlessness
- Impaired social interaction

The related factors for a nursing diagnosis focus on the causes of the communication disorder. In the case of impaired verbal communication, these are physiological, mechanical, anatomical, psychological, cultural, or developmental in nature. Accuracy in identifying related factors is necessary so you select interventions that effectively resolve the diagnostic problem. For example, you manage the diagnosis of *impaired verbal communication related to cultural difference (Hispanic heritage)* very differently than the diagnosis of *impaired verbal communication related to hearing loss.*

PLANNING

Once you have identified the nature of a patient's communication dysfunction, consider several factors when designing the care plan. Motivation is a factor in improving communication, and patients often require encouragement to try different approaches that involve significant change. It is especially important to involve the patient and family in decisions about the plan of care to determine whether suggested methods are acceptable. Meet basic comfort and safety needs before introducing new communication methods and techniques. Allow adequate time for practice. Participants need to be patient with themselves and one another to achieve effective communication. When the focus is on practicing communication, arrange for a quiet, private place that is free of distractions such as television or visitors. Communication aids such as a writing or picture board for a patient with a tracheostomy or a special call system for a paralyzed patient enhance communication.

Goals and Outcomes. In general, the goal of effective nursing care is that the patient experiences a sense of trust in the nurse and health care team. Expected outcomes for the patient with impaired communication are also important to identify. Outcomes are very specific and measurable and a way to determine if the broader goal is met. For example, outcomes for the patient possibly include the following:

- Patient initiates conversation about diagnosis or health care problem.
- Patient is able to attend to appropriate stimuli.
- Patient conveys clear and understandable messages with health care team.
- Patient expresses increased satisfaction with the communication process.

At times you care for patients whose difficulty in sending, receiving, and interpreting messages interferes with healthy interpersonal relationships. In this case impaired communication is a contributing factor to other nursing diagnoses such as *impaired social interaction* or *ineffective coping.* Plan interventions to help these patients improve their communication skills. Expected outcomes for a patient in this situation possibly include demonstrating the ability to appropriately express needs, feelings, and concerns; communicating thoughts and feelings more clearly; engaging in appropriate social conversation with peers and staff; and increasing feelings of autonomy and assertiveness.

Setting Priorities. It is essential to always maintain an open line of communication so a patient is able to express emergent needs or problems. This sometimes involves an intervention as simple as keeping a call light in reach for a patient restricted to bed or providing communication augmentative devices (e.g., message board or Braille computer). When you plan to have lengthy interactions with a patient, it is important to address physical care priorities so the discussion is not interrupted. Make the patient comfortable by ensuring that any symptoms are under control and elimination needs have been met.

Teamwork and Collaboration. To ensure an effective plan of care, you sometimes need to collaborate with other health care team members who have expertise in communication strategies. Speech therapists help patients with aphasia, interpreters are often necessary for patients who speak a foreign language, and mental health nurse specialists help angry or highly anxious patients to communicate more effectively.

IMPLEMENTATION

In carrying out any plan of care, use communication techniques that are appropriate for a patient's individual needs. Before learning how to adapt communication methods to help patients with serious communication impairments, it is necessary to learn the communication techniques that serve as the foundation for professional communication. It is also important to understand communication techniques that create barriers to effective interaction.

Therapeutic Communication Techniques. **Therapeutic communication** techniques are specific responses that encourage the expression of feelings and ideas and convey acceptance and respect. Learning these techniques helps you develop awareness of the variety of nursing responses available for use in different situations. Although some of the techniques seem artificial at first, skill and comfort increase with practice. Tremendous satisfaction results from developing therapeutic relationships and achieving desired patient outcomes.

Active Listening. **Active listening** means being attentive to what a patient is saying both verbally and nonverbally. Active listening facilitates patient communication. Inexperienced nurses sometimes feel the need to talk to prove they know what they are doing or to decrease anxiety (Stuart, 2009). It is often difficult at first to be quiet and really listen. Active listening enhances trust because you communicate acceptance and respect for a patient. Several nonverbal skills facilitate attentive listening. You identify them by the acronym SOLER (Townsend, 2009):

- **S**—Sit facing the patient. This posture conveys the message that you are there to listen and are interested in what the patient is saying.
- **O**—Observe an open posture (i.e., keep arms and legs uncrossed). This posture suggests that you are "open" to what the patient says. A "closed" position conveys a defensive attitude, possibly provoking a similar response in the patient.
- **L**—Lean toward the patient. This posture conveys that you are involved and interested in the interaction.
- **E**—Establish and maintain intermittent eye contact. This behavior conveys your involvement in and willingness to listen to what the patient is saying. Absence of eye contact or shifting the eyes gives the message that you are not interested in what the patient is saying.
- **R**—Relax. It is important to communicate a sense of being relaxed and comfortable with the patient. Restlessness communicates a lack of interest and a feeling of discomfort to the patient.

Sharing Observations. Nurses make observations by commenting on how the other person looks, sounds, or acts. Stating observations often helps a patient communicate without the need for extensive questioning, focusing, or clarification. This technique helps start a conversation with quiet or withdrawn persons. Do not state observations that will embarrass or anger a patient, such as telling someone, "You look a mess!" Even if you make such an observation with humor, the patient can become resentful.

Sharing observations differs from making assumptions, which means drawing unnecessary conclusions about the other person without validating them. Making assumptions puts a patient in the position of having to contradict the nurse. Examples include the nurse interpreting fatigue as depression or assuming that untouched food indicates lack of interest in meeting nutritional goals. Making observations is a gentler and safer technique: "You look tired …," "You seem different today …," or "I see you haven't eaten anything."

Sharing Empathy. **Empathy** is the ability to understand and accept another person's reality, accurately perceive feelings, and communicate this understanding to the other. To convey empathy, accurately perceive the patient's situation, communicate that understanding to the patient, and act on your understanding to help the patient (Varcarolis and Halter, 2009). To express empathy, you reflect that you understand and feel the importance of the other person's communication. Such empathetic understanding requires you to be both sensitive and imaginative, especially if you have not had similar experiences. Strive to be empathetic in every situation because it is a key to unlocking concern and communicating support for others. Statements reflecting empathy are highly effective because they tell a person that you heard both the emotional and the factual content of the communication. Empathetic statements are neutral and nonjudgmental and help establish trust in difficult situations. For example, the nurse says to an angry patient who has low mobility after a stroke, "It must be very frustrating to know what you want and not be able to do it."

Sharing Hope. Nurses recognize that hope is essential for healing and learn to communicate a "sense of possibility" to others. Appropriate encouragement and positive feedback are important in fostering hope and self-confidence and for helping people achieve their potential and reach their goals. You give hope by commenting on the positive aspects of the other person's behavior, performance, or response. Sharing a vision of the future and reminding others of their resources and strengths also strengthen hope. Reassure patients that there are many kinds of hope and that meaning and personal growth can come from illness experiences. For example, the nurse says to a patient discouraged about a poor prognosis, "I believe that you'll find a way to face your situation because I've seen your courage and creativity."

Sharing Humor. Humor is an important but often underused resource in nursing interactions. It is a coping strategy that adds perspective and helps a nurse and patient adjust to stress. The Association for Applied and Therapeutic Humor (2008) defines therapeutic humor as "any intervention that promotes health and wellness by stimulating a playful discovery, expression or appreciation of the absurdity or incongruity of life's situations." Humor provides emotional support to patients and humanizes the illness experience. Patients use humor to establish relationships with care providers; relieve anxiety about illness, diagnostic procedures, or treatments; and release anger in a socially acceptable manner (Buxman, 2008). The goals of using humor as a health care provider are to bring hope and joy to the situation and enhance a patient's well-being and the therapeutic relationship. You use humor during the orientation phase of a relationship to establish a therapeutic relationship and during the working phase as you help a patient cope with a situation.

Today it is common that nurses care for patients from different cultures. When you interact with patients who do not have a full grasp of the language, it is important to realize that they may misunderstand or misinterpret jokes and statements meant to be humorous. It is also important to recognize that, when either a nurse or patient tries to speak in another language, mistakes sometimes occur.

Dean and Major (2008) found that humor enhances teamwork, relieves tension, and helps nurses reframe difficult situations, allowing them to gain perspective. It also increases emotional flexibility, allowing nurses to shift rapidly from one situation to another. Huntley (2009) noted that humor helps nurses cope with serious situations and improves the work environment. Laughter provides a diversion from stress-related tension.

Health care professionals sometimes use a kind of dark, negative humor after difficult or traumatic situations as a way to deal with unbearable tension and stress. This coping humor has a high potential for misinterpretation as uncaring by persons not involved in the situation. For example, nursing students are sometimes offended and wonder how staff are able to laugh and joke after unsuccessful resuscitation efforts. When nurses use coping humor

within earshot of patients or their loved ones, great emotional distress results.

Sharing Feelings. Emotions are subjective feelings that result from one's thoughts and perceptions. Feelings are not right, wrong, good, or bad, although they are pleasant or unpleasant. If individuals do not express feelings, stress and illness may worsen. You help patients express emotions by making observations, acknowledging feelings, encouraging communication, giving permission to express "negative" feelings, and modeling healthy emotional self-expression. At times patients will direct their anger or frustration prompted by their illness toward you. Do not take such expressions personally. Acknowledging patients' feelings communicates that you listened to and understood the emotional aspects of their illness situation.

When you care for patients, be aware of your own emotions because feelings are difficult to hide. Students sometimes wonder whether it is helpful to share feelings with patients. Sharing emotion makes nurses seem more human and brings people closer. It is appropriate to share feelings of caring or even cry with others, as long as you are in control of the expression of these feelings and expresses them in a way that does not burden the patient or break confidentiality. Patients are perceptive and sense your emotions. It is usually inappropriate to discuss negative personal emotions such as anger or sadness with patients. A social support system of colleagues is helpful; and employee assistance programs, peer group meetings, and the use of interdisciplinary teams such as social work and pastoral care provide other means for nurses to safely express feelings away from patients.

Using Touch. Because of modern fast-paced technical environments, nurses are required more than ever to bring the sense of caring and human connection to their patients (see Chapter 7). Touch is one of the most potent forms of communication. Historically physical touch played a central role in healing (Leder and Krucoff, 2008). Nurses are privileged to experience more of this intimate form of personal contact than almost any other professional. Touch is used during procedures and assessment or to convey emotion (Playfair, 2010). It conveys many messages such as affection, emotional support, encouragement, tenderness, and personal attention. Comfort touch such as holding a hand is especially important for vulnerable patients who are experiencing severe illness with its accompanying physical and emotional losses (Fig. 24-2). When people are ill, they may feel detached from their body and become isolated from others. Touch helps them increase awareness of their body and gain connection with another person (Leder and Krucoff, 2008).

FIG. 24-2 The nurse uses touch to communicate.

Students often initially find giving intimate care to be stressful, especially when caring for patients of the opposite gender. They learn to cope with intimate contact by changing their perception of the situation. Since much of what nurses do involves touching, you need to learn to be sensitive to others' reactions to touch and use it wisely. It should be as gentle or as firm as needed and delivered in a comforting, nonthreatening manner. Sometimes you withhold touch (e.g., highly suspicious or angry persons respond negatively or even violently to a nurse's touch).

Using Silence. It takes time and experience to become comfortable with silence. Most people have a natural tendency to fill empty spaces with words, but sometimes these spaces really allow time for a nurse and patient to observe one another, sort out feelings, think about how to say things, and consider what has been communicated. Silence prompts some people to talk. It allows a patient to think and gain insight (Stuart, 2009). In general, allow a patient to break the silence, particularly when he or she has initiated it.

Silence is particularly useful when people are confronted with decisions that require much thought. For example, it helps a patient gain the necessary confidence to share the decision to refuse medical treatment. It also allows the nurse to pay particular attention to nonverbal messages such as worried expressions or loss of eye contact. Remaining silent demonstrates patience and a willingness to wait for a response when the other person is unable to reply quickly. Silence is especially therapeutic during times of profound sadness or grief.

Providing Information. Providing relevant information tells other people what they need or want to know so they are able to make decisions, experience less anxiety, and feel safe and secure. It is also an integral aspect of health teaching. It usually is not helpful to hide information from patients, particularly when they seek it. If a health care provider withholds information, the nurse clarifies the reason with him or her. Patients have a right to know about their health status and what is happening in their environment. Information of a distressing nature needs to be communicated with sensitivity, at a pace appropriate to a patient's ability to absorb it, and in general terms at first: "John, your heart sounds have changed from earlier today, and so has your blood pressure. I'll let your doctor know." A nurse provides information that enables others to understand what is happening and what to expect: "Mrs. Evans, John is getting an echocardiogram right now. This test uses painless sound waves to create a moving picture of his heart structures and valves and should tell us what is causing his murmur."

Clarifying. To check whether understanding is accurate, restate an unclear or ambiguous message to clarify the sender's meaning. In addition, ask the other person to rephrase it, explain further, or give an example of what the person means. Without clarification you may make invalid assumptions and miss valuable information. Despite efforts at paraphrasing, sometimes you do not understand the patient's message. You need to let the patient know if this is the case: "I'm not sure I understand what you mean by 'sicker than usual.' What is different now?"

Focusing. Focusing centers on key elements or concepts of a message. If conversation is vague or rambling or patients begin to repeat themselves, focusing is a useful technique. Do not use focusing if it interrupts patients while they are discussing an important issue. Rather use it to guide the direction of conversation to important areas: "We've talked a lot about your medications; now let's look more closely at the trouble you're having in taking them on time."

Paraphrasing. Paraphrasing is restating another's message more briefly using one's own words. Through paraphrasing you send feedback that lets a patient know that he or she is actively involved in the search for understanding. Practice is required to paraphrase accurately. If the meaning of a message is changed or distorted through paraphrasing, communication becomes ineffective. For example, a patient says, "I've been overweight all my life and never had any problems. I can't understand why I need to be on a diet." Paraphrasing this statement by saying, "You don't care if you're overweight," is incorrect. It is more accurate to say, "You're not convinced that you need a diet because you've stayed healthy."

Asking Relevant Questions. Nurses ask relevant questions to seek information needed for decision making. Ask only one question at a time and fully explore one topic before moving to another area. During patient assessment questions follow a logical sequence and usually proceed from general to more specific. Open-ended questions allow patients to take the conversational lead and introduce pertinent information about a topic. For example, "What's your biggest problem at the moment?" Use focused questions when more specific information is needed in an area: "How has your pain affected your life at home?" Allow patients to respond fully to open-ended questions before asking more-focused questions. Closed-ended questions elicit a yes, no, or one-word response: "How many times a day are you taking pain medication?" Although they are helpful during assessment, they are generally less useful during therapeutic exchanges.

Asking too many questions is sometimes dehumanizing. Seeking factual information does not allow a nurse or patient to establish a meaningful relationship or deal with important emotional issues. It is a way for a nurse to ignore uncomfortable areas in favor of more comfortable, neutral topics. A useful exercise is to try conversing without asking the other person a single question. By using techniques such as giving general leads ("tell me about it . . ."), making observations, paraphrasing, focusing, and providing information, you discover important information that would have remained hidden if you limited the communication process to questions alone.

Summarizing. Summarizing is a concise review of key aspects of an interaction. It brings a sense of satisfaction and closure to an individual conversation and is especially helpful during the termination phase of a nurse-patient relationship. By reviewing a conversation, participants focus on key issues and add relevant information as needed. Beginning a new interaction by summarizing a previous one helps a patient recall topics discussed and shows him or her that you analyzed their communication. Summarizing also clarifies expectations, as in this example of a nurse manager who has been working with an unsatisfied employee: "You've told me a lot of things about why you don't like this job and how unhappy you've been. We've also come up with some possible ways to make things better, and you've agreed to try some of them and let me know if any help."

Self-Disclosure. Self-disclosures are subjectively true personal experiences about the self that are intentionally revealed to another person. This is not therapy for a nurse; rather it shows patients that the nurse understands their experiences and their experiences are not unique. You choose to share experiences or feelings that are similar to those of the patient and emphasize both the similarities and differences. This kind of self-disclosure is indicative of the closeness of the nurse-patient relationship and involves a particular kind of respect for the patient. You offer it as an expression of sincerity and honesty, and it is an aspect of empathy (Stuart, 2009). Self-disclosures need to be relevant and appropriate and made to benefit the patient rather than yourself. Use them sparingly so the patient is the focus of the interaction: "That happened to me once, too. It was devastating, and I had to face some things about myself that I didn't like. I went for counseling, and it really helped. . . . What are your thoughts about seeing a counselor?"

Confrontation. When you confront someone in a therapeutic way, you help the other person become more aware of inconsistencies in his or her feelings, attitudes, beliefs, and behaviors (Stuart, 2009). This technique improves patient self-awareness and helps him or her recognize growth and deal with important issues. Use confrontation only after you have established trust, and do it gently with sensitivity: "You say you've already decided what to do, yet you're still talking a lot about your options."

Nontherapeutic Communication Techniques. Certain communication techniques hinder or damage professional relationships. These specific techniques are referred to as *nontherapeutic* or *blocking* and often cause recipients to activate defenses to avoid being hurt or negatively affected. Nontherapeutic techniques discourage further expression of feelings and ideas and engender negative responses or behaviors in others.

Asking Personal Questions. "Why don't you and John get married?" Asking personal questions that are not relevant to the situation simply to satisfy your curiosity is not appropriate professional communication. Such questions are nosy, invasive, and unnecessary. If patients wish to share private information, they will. To learn more about a patient's interpersonal roles and relationships, ask a question such as: "How would you describe your relationship with John?"

Giving Personal Opinions. "If I were you, I'd put your mother in a nursing home." When a nurse gives a personal opinion, it takes decision making away from the other person. It inhibits spontaneity, stalls problem solving, and creates doubt. Personal opinions differ from professional advice. At times people need suggestions and help to make choices. Suggestions that you present are options; the other person makes the final decision. Remember that the problem and its solution belong to the other person and not to you. A much better response is, "Let's talk about which options are available for your mother's care."

Changing the Subject. "Let's not talk about your problems with the insurance company. It's time for your walk." Changing the subject when another person is trying to communicate their story is rude and shows a lack of empathy. It tends to block further communication, and the sender then withholds important messages or fails to openly express feelings. Thoughts and spontaneity are interrupted, ideas become tangled, and information provided is sometimes inadequate. In some instances changing the subject serves as a face-saving maneuver. If this happens, reassure the patient that you will return to his or her concerns: "After your walk let's talk some more about what's going on with your insurance company."

Automatic Responses. "Older adults are always confused." "Administration doesn't care about the staff." Stereotypes are generalized beliefs held about people. Making stereotyped remarks about others reflects poor nursing judgment and threatens nurse-patient or team relationships. A cliché is a stereotyped comment such as, "You can't win them all," that tends to belittle the other person's feelings and minimize the importance of his or her message. These automatic phrases communicate that you are not taking concerns seriously or responding thoughtfully. Another kind of automatic response is parroting (i.e., repeating what the other person has said word for word). Parroting is easily overused and is not as effective as paraphrasing. A simple "oh?" gives you

time to think if the other person says something that takes one by surprise.

A nurse who is task oriented automatically makes the task or procedure the entire focus of interaction with patients, missing opportunities to communicate with them as individuals and meet their needs. Task-oriented nurses are often perceived as cold, uncaring, and unapproachable. When students first perform technical skills, it is difficult to integrate therapeutic communication because of the need to focus on the procedure. In time you learn to integrate communication with high-visibility tasks and accomplish several goals simultaneously.

False Reassurance. "Don't worry, everything will be all right." When a patient is seriously ill or distressed, you may be tempted to offer hope to the patient with statements such as "You'll be fine" or "There's nothing to worry about." When a patient is reaching for understanding, false reassurance discourages open communication. Offering reassurance not supported by facts or based in reality does more harm than good. Although you are trying to be kind, it has the secondary effect of helping you avoid the other person's distress, and it tends to block conversation and discourage further expression of feelings. A more facilitative response is, "It must be difficult not to know what the surgeon will find. What can I do to help?"

Sympathy. "I'm so sorry about your mastectomy; it must be terrible to lose a breast." **Sympathy** is concern, sorrow, or pity felt for a patient. The nurse takes on a patient's problems as if they were his or her own. Sympathy is a subjective look at another person's world that prevents a clear perspective of the issues confronting that person. If a nurse overidentifies with a patient, objectivity is lost, and the nurse is not able to help the patient work through the situation (Townsend, 2009). Although sympathy is a compassionate response to another's situation, it is not as therapeutic as empathy. A nurse's own emotional issues sometimes prevent effective problem solving and impair good judgment. A more empathetic approach is: "The loss of a breast is a major change. How do you think it will affect your life?"

Asking for Explanations. "Why are you so anxious?" Some nurses are tempted to ask the other person to explain why the person believes, feels, or has acted in a certain way. Patients frequently interpret "why" questions as accusations or think the nurse knows the reason and is simply testing them. Regardless of patient perception of your motivation, "why" questions cause resentment, insecurity, and mistrust. If you need additional information, it is best to phrase a question to avoid using the word "why." "You seem upset. What's on your mind?" is more likely to help the anxious patient communicate.

Approval or Disapproval. "You shouldn't even think about assisted suicide; it's not right." Do not impose your own attitudes, values, beliefs, and moral standards on others while in the professional helping role. Other people have the right to be themselves and make their own decisions. Judgmental responses often contain terms such as *should, ought, good, bad, right,* or *wrong.* Agreeing or disagreeing sends the subtle message that you have the right to make value judgments about patient decisions. Approving implies that the behavior being praised is the only acceptable one. Often a patient shares a decision with you, not in an effort to seek approval but to provide a means to discuss feelings. Disapproval implies that the patient needs to meet your expectations or standards. Instead help patients explore their own beliefs and decisions. The response, "I'm surprised you're considering assisted suicide. Tell me more about it," gives the patient a chance to express ideas or feelings without fear of being judged.

Defensive Responses. "No one here would intentionally lie to you." Becoming defensive in the face of criticism implies that the other person has no right to an opinion. The sender's concerns are ignored when the nurse focuses on the need for self-defense, defense of the health care team, or defense of others. When patients express criticism, listen to what they have to say. Listening does not imply agreement. You need to listen uncritically to discover reasons for a patient's anger or dissatisfaction. By avoiding a defensive attitude you are able to defuse anger and uncover deeper concerns: "You believe that people have been dishonest with you. It must be hard to trust anyone."

Passive or Aggressive Responses. "Things are bad, and there's nothing I can do about it." "Things are bad, and it's all your fault." Passive responses serve to avoid conflict or sidestep issues. They reflect feelings of sadness, depression, anxiety, powerlessness, and hopelessness. Aggressive responses provoke confrontation at the other person's expense. They reflect feelings of anger, frustration, resentment, and stress. Nurses who lack assertive skills also use triangulation, complaining to a third party rather than confronting the problem or expressing concerns directly to the source. This lowers team morale and draws others into the conflict situation. Assertive communication is a far more professional approach for the nurse to take.

Arguing. "How can you say you didn't sleep a wink when I heard you snoring all night long?" Challenging or arguing against perceptions denies that they are real and valid to the other person. It implies that the other person is lying, misinformed, or uneducated. The skillful nurse gives information or presents reality in a way that avoids argument: "You feel like you didn't get any rest at all last night, even though I thought you slept well since I heard you snoring."

Adapting Communication Techniques for the Patient with Special Needs. With our aging population more patients have difficulty communicating. Hearing loss increases with age; 47% of Americans age 75 or older have a hearing impairment (NIDCD, 2010). Vision loss affects communication and presents a challenge for the 6.5 million Americans age 65 and older who report significant vision loss (AFB, 2010). Interacting with people who have conditions that impair communication requires special thought and sensitivity. Such patients benefit greatly when you adapt communication techniques to their unique circumstances or developmental level. For example, a nurse caring for a patient with *impaired verbal communication related to cultural differences* provides a table of simple words in the patient's language. The nurse and patient use the table to help communicate about basic needs such as food, water, toileting, pain relief, and sleep. Environmental considerations and adaptive equipment improve communication with hearing-impaired individuals (Swann, 2007). Research findings suggest that many of the difficulties in communicating with patients with severe communication impairment come from the lack of an understandable nurse-patient communication system (Hemsley et al., 2001). Further research in care of adults with cerebral palsy found that successful communication between nurses and patients with complex communication needs requires the nurse's knowledge of communication assistive devices and collaboration with the patient and family (Balandin et al., 2007).

A nurse directs actions toward meeting the goals and expected outcomes identified in the plan of care, addressing both the communication impairment and its contributing factors. Box 24-9 lists many methods available to encourage, enhance, restore, or substitute for verbal communication. Be sure that a patient is physically able to use the chosen method and that it does not cause frustration by being too complicated or difficult.

BOX 24-9 COMMUNICATING WITH PATIENTS WHO HAVE SPECIAL NEEDS

Patients Who Cannot Speak Clearly (Aphasia, Dysarthria, Muteness)

- Listen attentively, be patient, and do not interrupt.
- Ask simple questions that require "yes" or "no" answers.
- Allow time for understanding and response.
- Use visual cues (e.g., words, pictures, and objects) when possible.
- Allow only one person to speak at a time.
- Encourage patient to converse.
- Let patient know if you have not understood him or her.
- Collaborate with speech therapist as needed.
- Use communication aids:

Patients Who Are Cognitively Impaired

- Use simple sentences and avoid long explanations.
- Ask one question at a time.
- Allow time for patient to respond.
- Be an attentive listener.
- Include family and friends in conversations, especially in subjects known to patient.

Patients Who Are Hearing Impaired

- Check for hearing aids and glasses.
- Reduce environmental noise.
- Get patient's attention before speaking.
- Face patient with mouth visible.
- Do not chew gum.
- Speak at normal volume—do not shout.
- Rephrase rather than repeat if misunderstood.
- Provide a sign language interpreter if indicated.

Patients Who Are Visually Impaired

- Check for use of glasses or contact lenses.
- Identify yourself when you enter room and notify patient when you leave room.
- Speak in a normal tone of voice.
- Do not rely on gestures or nonverbal communication.
- Use indirect lighting, avoiding glare.
- Use at least 14-point print.

Patients Who Are Unresponsive

- Call patient by name during interactions.
- Communicate both verbally and by touch.
- Speak to patient as though he or she can hear.
- Explain all procedures and sensations.
- Provide orientation to person, place, and time.
- Avoid talking about patient to others in his or her presence.

Patients Who Do Not Speak English

- Speak to patient in normal tone of voice.
- Establish method for patient to ask for assistance (call light or bell).
- Provide an interpreter as needed.
- Avoid using family members, especially children, as interpreters.
- Use communication board, pictures, or cards.
- Translate words from native language into English list for patient to make basic requests.
- Have dictionary (e.g., English/Spanish) available if patient can read.

Because nursing care of the older adult is ideally delivered through an interdisciplinary model, the primary goal is to establish a reliable communication system that all health care team members can understand easily. Effective communication involves adapting to special needs resulting from sensory, motor, or cognitive impairments. Encouraging older adults to share life stories and reminisce about the past has a therapeutic effect and increases their sense of well-being. Avoid sudden shifts from subject to subject. It is helpful to include a patient's family and friends and become familiar with a patient's favorite topics for conversation.

EVALUATION

Evaluate the effectiveness of your own communication by videotaping practice sessions with peers or by making process recordings—written records of your verbal and nonverbal interactions with patients. Process recording analysis reveals how to improve personal communication techniques to make them more effective. Box 24-10 contains a sample communication analysis of such a record. Analysis of a process recording enables you to evaluate the following:

- Determine whether you encouraged openness and allowed the patient to "tell his story," expressing both thoughts and feelings
- Identify any missed verbal or nonverbal cues or conversational themes
- Examine whether nursing responses blocked or facilitated the patient's efforts to communicate
- Determine whether nursing responses were positive and supportive or superficial and judgmental
- Examine the type and number of questions asked
- Determine the type and number of therapeutic communication techniques used
- Discover any missed opportunities to use humor, silence, or touch

Through the Patient's Eyes. You and your patient determine the success of the plan of care by evaluating patient communication outcomes together. You also evaluate nursing interventions to determine what strategies or interventions were effective and what patient changes resulted because of the interventions. Ask the patient if you and other members of the interdisciplinary health care team met his or her expectations. Successful nursing care related to patients' communication needs results in clear and effective communication between patients and all members of the health care team. Other outcomes include patient satisfaction and the delivery of safe care.

Patient Outcomes. If expected outcomes are not met or if progress is not satisfactory, you determine what factors influenced the outcomes, then modify the plan of care. If your evaluation data indicate a patient perceives difficulty in communicating, you explore contributing factors so they can be addressed. For example, if using a pen and paper is frustrating for a nonverbal patient whose handwriting is shaky, you revise the care plan to include use of a picture board instead. Possible questions you ask when a patient does not meet expected outcomes include:

- You seem to be having difficulty communicating right now. What do you think is contributing to this?
- You are telling me that you do not feel anxious right now, but your face appears tense. Help me better understand how you are feeling right now.

BOX 24-10 SAMPLE COMMUNICATION ANALYSIS

Nurse: "Good morning, Mr. Simpson."
(Smiles, approaches bed holding clipboard)
Acknowledged by name, social greeting to begin conversation

Patient: "What's good about it?"
(Arms crossed over chest, frowning, direct stare)
Nonverbal signs of anger

Nurse: "You sound unhappy."
(Pulls up chair and sits at bedside)
Sharing observation, nonverbal communication of availability

Patient: "You'd be unhappy, too, if nobody would answer your questions. That girl wouldn't tell me my blood sugar."
(Angry voice tone, challenging expression)
Further expression of feelings facilitated by nurse making accurate observation

Nurse: "This hospital has a fine staff, Mr. Simpson. I'm sure no one would intentionally keep information from you."
Feeling threatened and being defensive, a nontherapeutic technique

Nurse: "I'm going to test your glucose in a minute, and I'll tell you the results."
(Does test) "Your blood sugar was 350."
Providing information, demonstrating trustworthiness

Patient: "I'm so afraid complications will set in since my blood sugar is high."
(Stares out window)
Feels free to express deeper concerns, but they are hard to face

Nurse: "What kinds of things are you worried about?"
Open-ended question to seek information

Patient: "I could lose a leg, like my mother did, or go blind or have to live hooked up to a kidney machine for the rest of my life.

Nurse: "You've been thinking about all kinds of things that could go wrong, and it adds to your worry not to be told what your blood sugar is."
Summarizing to let patient "hear" what he has communicated

Patient: "I always think the worst."
(Shakes head in exasperation)
Expressing insight into his "inner dialogue"

Nurse: "I'll pass along to the tech that it's OK to tell you your glucose levels. And later this afternoon I'd like us to talk more about some things you can do to help avoid these complications and set some goals for controlling your glucose."
Providing information, encouraging collaboration and goal setting

- You seem frustrated with the use of pencil and paper to communicate. Would you like to try a letter board or a picture board and see if either of these is easier for you to use?

Evaluation of the communication process helps nurses gain confidence and competence in interpersonal skills. Becoming an effective communicator greatly increases the nurse's professional satisfaction and success. There is no skill more basic, no tool more powerful.

KEY POINTS

- Communication is a powerful therapeutic tool and an essential nursing skill that influences others and achieves positive health outcomes.
- Effective interdisciplinary communication is essential to provide safe transitions and care.
- Effective communication is critical in promoting collaboration and teamwork providing patient-centered care.
- Critical thinking facilitates communication through creative inquiry, focused self-awareness and awareness of others, purposeful analysis, and control of perceptual biases.
- Communication is most effective when the receiver and sender accurately perceive the meaning of one another's messages.
- The sender's and receiver's physical and developmental status, perceptions, values, emotions, knowledge, sociocultural background, roles, and environment all influence message transmission.
- Effective verbal communication requires appropriate intonation, clear and concise phrasing, proper pacing of statements, and proper timing and relevance of a message.
- Effective nonverbal communication complements and strengthens the message conveyed by verbal communication.
- Nurses use intrapersonal, interpersonal, transpersonal, small-group, and public interaction to achieve positive change and health goals.
- Nurses strengthen helping relationships by establishing trust, empathy, autonomy, confidentiality, and professional competence.
- Effective communication techniques are facilitative and tend to encourage the other person from openly expressing ideas, feelings, or concerns.
- Ineffective communication techniques are inhibiting and tend to block the other person's willingness to openly express ideas, feelings, or concerns.
- Blend social and informational interactions with therapeutic communication techniques to help your patients explore feelings and manage health issues.
- Older adults with sensory, motor, or cognitive impairments require the adaptation of communication techniques to compensate for their loss of function and special needs.
- Patients with impaired verbal communication require special consideration and alterations in communication techniques to facilitate sending, receiving, and interpreting messages.
- Desired outcomes for patients with impaired verbal communication include increased satisfaction with interpersonal interactions, the ability to send and receive clear messages, and attention to and accurate interpretation of verbal and nonverbal cues.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mr. Simpson is a 78-year-old patient whose wife died last year. He has been living alone. He has limited cooking skills; thus he eats out a lot. Since his wife died, his blood sugar has been poorly controlled. To help Mr. Simpson gain better blood sugar control, the dietitian came to see him. After she left, Mr. Simpson was angry and stated his desire to leave the hospital right now. He stated, "That diet person came to see me, and she doesn't know anything."

1. How would you approach Mr. Simpson? What communication techniques would you use and what would you avoid?
2. You talk with the dietitian and learn that she gave the patient information about his diet and recipes he could try. As you talk with him, you learn that the physician told him he might not be able to live alone anymore. You realize that he doesn't know how to cook. Knowing this, how would you respond to him?

3. After talking with Mr. Simpson, you determine that he is able to care for himself at home but will need some assistance. He is willing to consider various options for meal preparation. You call the physician to discuss this. Your hospital has established SBAR (Situation-Background-Assessment-Recommendation) as a standard communication tool. How do you effectively communicate your concerns and the patient's need to the physician using SBAR?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse summarizes the conversation with the patient to determine if the patient has understood him or her. This is what element of the communication process?
   1. Referent
   2. Channel
   3. Environment
   4. Feedback
2. Mrs. Jones states that she gets anxious when she thinks about giving herself insulin. How do you use your understanding of intrapersonal communication to help with this?
   1. Provide her the opportunity to practice drawing up insulin
   2. Coach her to give herself positive messages about her ability to do this
   3. Bring her written material that clearly describes the steps of insulin administration
   4. Use therapeutic communication to help her express her feeling about giving herself an injection
3. The nurse has a patient who is short of breath and calls the health care provider using SBAR (Situation-Background-Assessment-Recommendation) to help with the communication. What does the nurse first address?
   1. The respiratory rate is 28.
   2. The patient has a history of lung cancer.
   3. The patient is short of breath.
   4. He or she requests an order for a breathing treatment.
4. You are caring for Mr. Smith, who is facing amputation of his leg. During the orientation phase of the relationship, what would you do?
   1. Summarize what you have talked about in the previous sessions
   2. Review his medical record and talk to other nurses about how he is reacting
   3. Explore his feelings about losing his leg
   4. Talk with him about his favorite hobbies
5. The nurse states, "When you tell me that you're having a hard time living up to expectations, are you talking about your family's expectations?" The nurse is using which therapeutic communication technique?
   1. Providing information
   2. Clarifying
   3. Focusing
   4. Paraphrasing
6. Which of the following statements would be most likely to block communication?
   1. "You look kind of tired today."
   2. "Why do you always put so much salt on your food?"
   3. "It sounds like this has been a hard time for you."
   4. "If you use your oxygen when you walk, you may be able to walk farther."
7. You are caring for an 80-year-old woman, and you ask her a question while you are across the room washing your hands. She does not answer. What is your next action?
   1. Leave the room quietly since she evidently does not want to be bothered right now
   2. Repeat the question in a loud voice, speaking very slowly
   3. Move to her bedside, get her attention, and repeat the question while facing her
   4. Bring her a communication board so she can express her needs
8. You ask another nurse how to collect a laboratory specimen. The nurse raises her eyebrows and asks, "Why don't you figure it out?" What would be the best response?
   1. Say nothing and walk away. Find a different nurse to help you.
   2. "When you brush me off like that, it takes me even longer to do my job."
   3. "Why do you always put me down like that?"
   4. "I guess I just enjoy having you make fun of me."
9. When the nurse takes the patient's nursing history, he or she sits:
   1. Next to the patient.
   2. 4 to 12 feet from the patient.
   3. 18 inches to 4 feet from the patient.
   4. 12 inches to 3 feet from the patient.
10. When working with an older adult, the nurse remembers to avoid:
    1. Touching the patient.
    2. Allowing the patient to reminisce.
    3. Shifting quickly from subject to subject.
    4. Asking the patient how he or she feels.
11. The statement that best explains the role of collaboration with others for the patient's plan of care is which of the following?
    1. The professional nurse consults the health care provider for direction in establishing goals for patients.
    2. The professional nurse depends on the latest literature to complete an excellent plan of care for patients.
    3. The professional nurse works independently to plan and deliver care and does not depend on other staff for assistance.
    4. The professional nurse works with colleagues and the patient's family to provide combined expertise in planning care.
12. Identify behaviors that foster the development of trust. (Select all that apply.)
    1. Answer the call light promptly.
    2. Call the patient by first name unless requested otherwise.
    3. Do all the care as quickly as possible and leave the room so the patient can rest.
    4. Answer questions honestly.
    5. Demonstrate competence when doing treatments.
13. A patient with limited English proficiency is going to be discharged on new medication. How does the nurse complete the discharge teaching?
    1. Uses a dictionary to give directions for medication administration
    2. Explains the directions to the patient's 14-year-old daughter

3. Obtains an interpreter to facilitate communication of medication information
4. Uses a picture board and visual aids to communicate medication administration information

14. Your patient has just been told that she has cancer, and she is crying. Which actions facilitate therapeutic communication? (Select all that apply.)
    1. Turning on the television to her favorite show
    2. Pulling the curtain to provide privacy
    3. Offering to discuss information about her condition
    4. Asking her why she is crying
    5. Sitting quietly by her bed and hold her hand
15. Mr. Sakda emigrated from Thailand. When taking care of him, you note that he looks relaxed and smiles but seldom looks at you directly. How do you respond?
    1. Use therapeutic communication to assess for increased anxiety
    2. Sit down and position yourself closer so you are at eye level
    3. Deflect your eyes downward to show respect
    4. Continue to maintain eye contact

Answers: **1.** 4; **2.** 2; **3.** 3; **4.** 4; **5.** 2; **6.** 2; **7.** 3; **8.** 2; **9.** 3; **10.** 3; **11.** 4; **12.** 1, 4, 5; **13.** 3; **14.** 2, 3, 5; **15.** 3.

CHAPTER

25

Patient Education

OBJECTIVES

- Identify the appropriate topics that address a patient's health education needs.
- Describe the similarities and differences between teaching and learning.
- Identify the role of the nurse in patient education.
- Identify the purposes of patient education.
- Use communication principles when providing patient education.
- Describe the domains of learning.
- Identify basic learning principles.
- Discuss how to integrate education into patient-centered care.
- Differentiate factors that determine readiness to learn from those that determine ability to learn.
- Compare and contrast the nursing and teaching processes.
- Write learning objectives for a teaching plan.
- Establish an environment that promotes learning.
- Include patient teaching while performing routine nursing care.
- Use appropriate methods to evaluate learning.

Patient education is one of the most important roles for a nurse in any health care setting. Shorter hospital stays, increased demands on nurses' time, an increase in the number of chronically ill patients, and the need to give acutely ill patients meaningful information quickly emphasize the importance of quality patient education. As nurses try to find the best way to educate patients, the general public has become more assertive in seeking knowledge, understanding health, and finding resources available within the health care system. Nurses provide patients with information needed for self-care to ensure continuity of care from the hospital to the home (Falvo, 2010).

Patients have the right to know and be informed about their diagnoses, prognoses, and available treatments to help them make intelligent, informed decisions about their health and lifestyle. Part of patient-centered care is to integrate educational approaches that acknowledge patients' expertise with their own health. Creating a well-designed, comprehensive teaching plan that fits a patient's unique learning needs reduces health care costs, improves the quality of care, and ultimately changes behaviors to improve patient outcomes. Ultimately this helps patients make informed decisions about their care and become healthier and more independent (Edelman and Mandle, 2010; Villablanca et al., 2010).

STANDARDS FOR PATIENT EDUCATION

Patient education has long been a standard for professional nursing practice. All state Nurse Practice Acts recognize that patient teaching falls within the scope of nursing practice (Bastable, 2006). In addition, various accrediting agencies set guidelines for providing patient education in health care institutions. For example, The Joint Commission (TJC, 2011) sets standards for patient and family education. These standards require nurses and the health care team to assess patients' learning needs and provide education about many topics, including medications, nutrition, the use of medical equipment, pain, and the patient's plan of care. Successful accomplishment of the standards requires collaboration among health care professionals and enhances patient safety. Educational efforts should be patient-centered by taking into consideration patients' own education and experience, their desire to actively participate in the educational process, and their psychosocial, spiritual, and cultural values. It is important to document evidence of successful patient education in patients' medical records. Standards such as these help to direct your patient education.

PURPOSES OF PATIENT EDUCATION

The goal of educating others about their health is to help individuals, families, or communities achieve optimal levels of health (Edelman and Mandle, 2010). Patient education is an essential component of providing safe, patient-centered care (QSEN, 2010). In addition, providing education about preventive health care helps reduce health care costs and hardships on individuals, families, and communities. Patients now know more about health and want to be involved in health maintenance. Provide education about health and health care in places that are convenient and familiar to patients. Comprehensive patient education includes three important purposes, each involving a separate phase of health care.

Maintenance and Promotion of Health and Illness Prevention

As a nurse you are a visible, competent resource for patients who want to improve their physical and psychological well-being. In the school, home, clinic, or workplace you provide information and skills that enable patients to assume healthier behaviors. For example, in childbearing classes you teach expectant parents about physical and psychological changes in the woman and fetal development. After learning about normal childbearing, the mother who applies new knowledge is more likely to eat healthy foods, engage in physical exercise, and avoid substances that can harm the fetus. Promoting healthy behavior through education allows patients to assume more responsibility for their health (Longo et al., 2010). Greater knowledge results in better health maintenance habits. When patients become more health conscious, they are more likely to seek early diagnosis of health problems (Hawkins et al., 2011; Redman, 2007).

Restoration of Health

Injured or ill patients need information and skills to help them regain or maintain their levels of health. Patients recovering from and adapting to changes resulting from illness or injury often seek information about their condition. For example, a woman who recently had a hysterectomy asks about her pathology reports and expected length of recovery. However, some patients find it difficult to adapt to illness and become passive and uninterested in learning. As the nurse you learn to identify patients' willingness to learn and motivate interest in learning (Redman, 2007). The family often is a vital part of a patient's return to health. Family caregivers often require as much education as the patient, including information on how to perform skills within the home. If you exclude the family from a teaching plan, conflicts can occur. However, do not assume that the family should be involved; assess the patient-family relationship before providing education for family caregivers.

Coping with Impaired Functions

Not all patients fully recover from illness or injury. Many have to learn to cope with permanent health alterations. New knowledge and skills are often necessary for patients to continue activities of daily living. For example, a patient loses the ability to speak after larynx surgery and has to learn new ways of communicating. Changes in function are physical or psychosocial. In the case of serious disability such as following a stroke or a spinal cord injury, the patient's family needs to understand and accept many changes in his or her physical capabilities. The family's ability to provide support results in part from education, which begins as soon as you identify the patient's needs and the family displays a willingness to help. Teach family members to help the patient with health care management (e.g., giving medications through gastric tubes and doing passive range-of-motion exercises). Families of patients with alterations such as alcoholism, mental retardation, or drug dependence learn to adapt to the emotional effects of these chronic conditions and provide psychosocial support to facilitate the patient's health. Comparing the desired level of health with the actual state of health enables you to plan effective teaching programs.

TEACHING AND LEARNING

It is impossible to separate teaching from learning. **Teaching** is an interactive process that promotes learning. It consists of a conscious, deliberate set of actions that help individuals gain new knowledge, change attitudes, adopt new behaviors, or perform new skills (Billings and Halstead, 2009). A teacher provides information that prompts the learner to engage in activities that lead to a desired change.

Learning is the purposeful acquisition of new knowledge, attitudes, behaviors, and skills (Bastable, 2008). Complex patterns are required if the patient is to learn new skills, change existing attitudes, transfer learning to new situations, or solve problems (Redman, 2007). A new mother exhibits learning when she demonstrates how to bathe her newborn. The mother shows transfer of learning when she uses the principles she learned about bathing a newborn when she bathes her older child. Generally teaching and learning begin when a person identifies a need for knowing or acquiring an ability to do something. Teaching is most effective when it responds to the learner's needs (Redman, 2007). The teacher assesses these needs by asking questions and determining the learner's interests. Interpersonal communication is essential for successful teaching to occur (see Chapter 24).

Role of the Nurse in Teaching and Learning

Nurses have an ethical responsibility to teach their patients (Heiskell, 2010). In *The Patient Care Partnership,* the American Hospital Association (2003) indicates that patients have the right to make informed decisions about their care. The information required to make informed decisions must be accurate, complete, and relevant to patients' needs.

TJC's *Speak Up Initiatives* helps patients understand their rights when receiving medical care (TJC, 2010). The assumption is that patients who ask questions and are aware of their rights have a greater chance of getting the care they need when they need it. The program offers the following ***Speak Up*** tips to help patients become more involved in their treatment:

- **S**peak up if you have questions or concerns. If you still do not understand, ask again. It is your body, and you have a right to know.
- **P**ay attention to the care you get. Always make sure that you are getting the right treatments and medicines by the right health care professionals. Do not assume anything.
- **E**ducate yourself about your illness. Learn about the medical tests that are prescribed and your treatment plan.
- **A**sk a trusted family member or friend to be your advocate (advisor or supporter).
- **K**now which medicines you take and why you take them. Medication errors are the most common health care mistakes.
- **U**se a hospital, clinic, surgery center, or other type of health care organization that has been carefully evaluated.
- **P**articipate in all decisions about your treatment. You are the center of the health care team.

In addition, patients are advised that they have a right to be informed about the care they will receive, obtain information about care in their preferred language, know the names of their caregivers, receive treatment for pain, receive an up-to-date list of current medications, and expect that they will be heard and treated with respect.

Teach information that patients and their families need. You frequently clarify information provided by health care providers and are the primary source of information that patients need to adjust to health problems (Bastable, 2006). However, it is also important to understand patients' preferences for what they wish to learn. For example, a patient requests information about a new medication, or family members question the reason for their mother's pain. Identifying the need for teaching is easy when patients request information. However, a patient's need for teaching is often less obvious. To be an effective educator, the nurse has to do more than just pass on facts. Carefully determine what patients need to know and find the time when they are ready to learn. When nurses value and provide education, patients are better prepared to assume health care responsibilities. Nursing research about patient education supports the positive impact of patient education on patient outcomes (Box 25-1).

BOX 25-1 EVIDENCE-BASED PRACTICE

The Effectiveness of Patient Education in Self-Management of Heart Failure

PICO Question: Do patients who participate in nurse-led educational programs manage their heart failure (HF) at home better when compared with patients who do not receive formalized health education about HF management?

Evidence Summary

Patients who live with HF need education about their diagnosis and its effects on daily living to prevent multiple hospitalizations and promote optimal functioning. However, many patients do not clearly understand why they have HF or how to control it effectively. HF, especially when it is poorly controlled, negatively influences quality of life (While and Kiek, 2009). Research shows that patient education provided by nurses positively influences patient outcomes and reduces hospitalizations. Individualized patient education helps patients better manage their HF, which improves their function and quality of life. Quality nurse-directed patient education includes the following components: basic facts about HF; managing stress, depression, and social interactions; making healthy food choices; improving activity level; and managing fluid balance (Boren et al., 2009). However, successful HF management requires more than patient education. Nurses also need to implement interventions that empower patients to make informed decisions about their care. Enhancing self-efficacy positively influences quality of life and improves the ability to manage HF (Evangelista and Shinnick, 2008; While and Kiek, 2009; Yehle and Plake, 2010).

Application to Nursing Practice

- Nurse-directed patient education about lifestyle choices and management of the physical and psychosocial aspects of health and exercise, coupled with interventions that improve self-efficacy, enhance quality of life in patients with HF.
- Nurses must ensure that educational interventions and instructions match patients' health literacy abilities.
- Improving quality of life enhances functional ability in patients with HF.
- Patients who receive nurse-directed patient education improve their ability to manage their health and experience better outcomes, both physically and emotionally.

Teaching as Communication

The teaching process closely parallels the communication process (see Chapter 24). Effective teaching depends in part on effective interpersonal communication. A teacher applies each element of the communication process while providing information to learners. Thus the teacher and learner become involved together in a teaching process that increases the learner's knowledge and skills.

The steps of the teaching process are similar to those of the communication process. You use patient requests for information or perceive a need for information because of a patient's health restrictions or the recent diagnosis of an illness. Then you identify specific **learning objectives** to describe what the learner will be able to do after successful instruction.

The nurse is the sender who conveys a message to the patient. Many intrapersonal variables influence your style and approach. Attitudes, values, emotions, cultural perspective, and knowledge influence the way information is delivered. Past experiences with teaching are also helpful for choosing the best way to present necessary content.

The receiver in the teaching-learning process is the learner. A number of intrapersonal variables affect motivation and ability to learn. Patients are ready to learn when they express a desire to do so and are more likely to receive the message when they understand the content. Attitudes, anxiety, and values influence the ability to understand a message. The ability to learn depends on factors such as emotional and physical health, education, cultural perspective, patients' values about their health, the stage of development, and previous knowledge.

Effective communication involves feedback. An effective teacher provides a mechanism for evaluating the success of a teaching plan and then provides positive reinforcement (Bastable, 2008; Redman, 2007). Examples of ways to evaluate teaching sessions through feedback include having a patient demonstrate a newly learned skill or asking a patient to describe how the correct dosage schedule for a new medication will be incorporated into a daily routine. Feedback needs to show the success of the learner in achieving objectives (i.e., the learner verbalizes information or provides a return demonstration of skills learned).

DOMAINS OF LEARNING

Learning occurs in three domains: cognitive (understanding), affective (attitudes), and psychomotor (motor skills) (Bloom, 1956; Bastable, 2008). Any health topic involves one or all domains or any combination of the three. You often work with patients who need to learn in each domain. For example, patients diagnosed with diabetes need to learn how diabetes affects the body and how to control blood glucose levels for healthier lifestyles (cognitive domain). In addition, patients begin to accept the chronic nature of diabetes by learning positive coping mechanisms (affective domain). Finally, many patients living with diabetes learn to test their blood glucose levels at home. This requires learning how to use a glucose meter (psychomotor domain). The characteristics of learning within each domain influence the teaching and evaluation methods used. Understanding each learning domain prepares the nurse to select proper teaching techniques and apply the basic principles of learning (Box 25-2).

Cognitive Learning

Cognitive learning includes all intellectual behaviors and requires thinking (Bastable, 2008). In the hierarchy of cognitive behaviors the simplest behavior is acquiring knowledge, whereas the

most complex is evaluation. Cognitive learning includes the following:

- Knowledge: Learning new facts or information and being able to recall them
- Comprehension: The ability to understand the meaning of learned material
- Application: Using abstract, newly learned ideas in a concrete situation
- Analysis: Breaking down information into organized parts
- Synthesis: The ability to apply knowledge and skills to produce a new whole
- Evaluation: A judgment of the worth of a body of information for a given purpose

BOX 25-2 APPROPRIATE TEACHING METHODS BASED ON DOMAINS OF LEARNING

Cognitive

- Discussion (one-on-one or group)
  - Involves nurse and one patient or a nurse with several patients
  - Promotes active participation and focuses on topics of interest to patient
  - Allows peer support
  - Enhances application and analysis of new information
- Lecture
  - Is more formal method of instruction because it is teacher controlled
  - Helps learner acquire new knowledge and gain comprehension
- Question-and-answer session
  - Addresses patient's specific concerns
  - Assists patient in applying knowledge
- Role play, discovery
  - Allows patient to actively apply knowledge in controlled situation
  - Promotes synthesis of information and problem solving
- Independent project (computer-assisted instruction), field experience
  - Allows patient to assume responsibility for completing learning activities at own pace
  - Promotes analysis, synthesis, and evaluation of new information and skills

Affective

- Role play
  - Allows expression of values, feelings, and attitudes
- Discussion (group)
  - Allows patient to receive support from others in group
  - Helps patient learn from others' experiences
  - Promotes responding, valuing, and organization
- Discussion (one-on-one)
  - Allows discussion of personal, sensitive topics of interest or concern

Psychomotor

- Demonstration
  - Provides presentation of procedures or skills by nurse
  - Permits patient to incorporate modeling of nurse's behavior
  - Allows nurse to control questioning during demonstration
- Practice
  - Gives patient opportunity to perform skills using equipment in a controlled setting
  - Provides repetition
- Return demonstration
  - Permits patient to perform skill as nurse observes
  - Provides excellent source of feedback and reinforcement
- Independent projects, games
  - Requires teaching method that promotes adaptation and origination of psychomotor learning
  - Permits learner to use new skills

Affective Learning

Affective learning deals with expression of feelings and acceptance of attitudes, opinions, or values. Values clarification (see Chapter 22) is an example of affective learning. The simplest behavior in the hierarchy is receiving, and the most complex is characterizing (Krathwohl et al., 1964). Affective learning includes the following:

- Receiving: Being willing to attend to another person's words
- Responding: Active participation through listening and reacting verbally and nonverbally
- Valuing: Attaching worth to an object or behavior demonstrated by the learner's behavior
- Organizing: Developing a value system by identifying and organizing values and resolving conflicts
- Characterizing: Acting and responding with a consistent value system

Psychomotor Learning

Psychomotor learning involves acquiring skills that require the integration of mental and muscular activity such as the ability to walk or use an eating utensil (Redman, 2007). The simplest behavior in the hierarchy is perception, whereas the most complex is origination. Psychomotor learning includes the following:

- Perception: Being aware of objects or qualities through the use of sense organs
- Set: A readiness to take a particular action; there are three sets: mental, physical, and emotional
- Guided response: The performance of an act under the guidance of an instructor involving imitation of a demonstrated act
- Mechanism: A higher level of behavior by which a person gains confidence and skill in performing a behavior that is more complex or involves several more steps than a guided response
- Complex overt response: Smoothly and accurately performing a motor skill that requires a complex movement pattern
- Adaptation: The ability to change a motor response when unexpected problems occur
- Origination: Using existing psychomotor skills and abilities to perform a highly complex motor act that involves creating new movement patterns

BASIC LEARNING PRINCIPLES

To teach effectively and efficiently, you first need to understand how people learn (Eshleman, 2008). Motivation addresses a person's desire or willingness to learn (Redman, 2007). The patient's willingness to become involved in learning influences your teaching approach. Previous knowledge, experience, attitudes, and sociocultural factors influence a person's motivation. The ability to learn depends on physical and cognitive attributes, developmental level, physical wellness, and intellectual thought processes. An ideal learning environment allows a person to attend to instruction.

A person's learning style affects preferences for learning. People process information in the following ways: by seeing and hearing, reflecting and acting, reasoning logically and intuitively, and analyzing and visualizing. Some people learn information gradually,

whereas others learn more sporadically. Effective teaching plans include a combination of approaches that meet multiple learning styles (Billings and Halstead, 2009).

Motivation to Learn

Attentional Set. An attentional set is the mental state that allows the learner to focus on and comprehend a learning activity. Before learning anything, patients must give attention to, or concentrate on, the information to be learned. Physical discomfort, anxiety, and environmental distractions influence the ability to attend. Therefore determine the patient's level of comfort before beginning a teaching plan and ensure that the patient is able to focus on the information.

As anxiety increases, the patient's ability to pay attention often decreases. Anxiety is uneasiness or worry resulting from anticipating a threat or danger. When faced with change or the need to act differently, a person feels anxious. Learning requires a change in behavior and thus produces anxiety. A mild level of anxiety motivates learning. However, a high level of anxiety prevents learning from occurring. It incapacitates a person, creating an inability to focus on anything other than relieving the anxiety. Manage the patient's anxiety (see Chapter 37) before educating to improve the patient's comprehension and understanding of the information given (Fredericks et al., 2008).

Motivation. **Motivation** is a force that acts on or within a person (e.g., an idea, emotion, or a physical need) to cause the person to behave in a particular way (Redman, 2007). If a person does not want to learn, it is unlikely that learning will occur. Motivation sometimes results from a social, task mastery, or physical motive.

A social motive is a need for connection, social approval, or self-esteem. People normally seek out others with whom they can compare opinions, abilities, and emotions. For example, new parents often seek validation of ideas and parenting techniques from others whom they have identified as role models in their social environment or health care workers with whom they have established a relationship.

Task mastery motives are based on needs such as achievement and competence. For example, a high school senior who has diabetes begins to test blood glucose levels and make decisions about insulin dosages in preparation for leaving home and establishing independence. The ability to successfully manage diabetes provides the motivation to master the task or skill. After a person succeeds at a task, he or she is usually motivated to achieve more.

Often patient motives are physical. Some patients are motivated to return to a level of physical normalcy. For example, a patient with a below-the-knee amputation is motivated to learn how to walk with assistive devices. Knowledge that is necessary for survival, problem recognition, and critical decision making creates a stronger stimulus for learning than knowledge that merely promotes health (Bastable, 2006).

You assess a patient's motivation to learn and what the patient needs to know to promote compliance with their prescribed therapy. Unfortunately not all people are interested in maintaining health. Many do not adopt new health behaviors or change unhealthy behaviors unless they perceive a disease as a threat, overcome barriers to changing health practices, and see the benefits of adopting a healthy behavior. For example, some patients with lung disease continue to smoke. No therapy has an effect unless a person believes that health is important.

Use of Theory to Enhance Motivation and Learning. Health education often involves changing attitudes and values that are not easy to change by simply teaching facts. Therefore it is important for you to use various interventions based on theory when developing patient education plans. Because of the complexity of the patient education process, different theories and models are available to guide patient education. Using a theory that matches the patient's needs in practice will provide more effective patient education. Social learning theory provides one of the most useful approaches to patient education because it explains the characteristics of the learner and guides the educator in developing effective teaching interventions that result in enhanced learning and improved motivation (Bandura, 2001; Stonecypher, 2009).

According to social learning theory, people continuously attempt to control events that affect their lives. This allows them to attain desired outcomes and avoid undesired outcomes, resulting in improved motivation. **Self-efficacy,** a concept included in social learning theory, refers to a person's perceived ability to successfully complete a task. When people believe that they are able to execute a particular behavior, they are more likely to perform the behavior consistently and correctly (Bandura, 1997).

Self-efficacy beliefs come from four sources: enactive mastery experiences, vicarious experiences, verbal persuasion, and physiological and affective states (Bandura, 1997). Understanding the four sources of self-efficacy allows you to develop interventions to help patients adopt healthy behaviors. For example, a nurse who is wishing to teach a child recently diagnosed with asthma how to correctly use an inhaler expresses personal belief in the child's ability to use the inhaler (verbal persuasion). Then the nurse demonstrates how to use the inhaler (vicarious experience). Once the demonstration is complete, the child uses the inhaler (enactive mastery experience). As the child's wheezing and anxiety decrease after the correct use of the inhaler, he or she experiences positive feedback, further enhancing his or her confidence to use it (physiological and affective states). Interventions such as these enhance perceived self-efficacy, which in turn improves the achievement of desired outcomes.

Self-efficacy is a concept included in many health promotion theories because it often is a strong predictor of healthy behaviors and because many interventions improve self-efficacy, resulting in improved lifestyle choices (Bandura, 1997). Because of its use in theories and research studies, many evidence-based teaching interventions include a focus on self-efficacy. When nurses implement interventions to enhance self-efficacy, their patients frequently experience positive outcomes. For example, researchers associated interventions that include self-efficacy with effective management of heart failure (While and Kiek, 2009; Yehle and Plake, 2010), participation in physical activity (Ashford et al., 2010), self-management of arthritis (Nunez et al., 2009), and improved management of asthma in children (Coffman et al., 2009).

Psychosocial Adaptation to Illness. A temporary or permanent loss of health is often difficult for patients to accept. They need to grieve, and the process of grieving gives them time to adapt psychologically to the emotional and physical implications of illness. The stages of grieving (see Chapter 36) include a series of responses that patients experience during a loss such as illness. They experience these stages at different rates and sequences, depending on their self-concept before illness, the severity of the illness, and the changes in lifestyle that the illness creates. Effective, supportive care guides the patient through the grieving process.

Readiness to learn is related to the stage of grieving (Table 25-1). Patients cannot learn when they are unwilling or unable to accept the reality of illness. However, properly timed teaching facilitates adjustment to illness or disability. Identify the patient's stage of

TABLE 25-1 Relationship Between Psychosocial Adaptation to Illness, Grief, and Learning

STAGE	PATIENT'S BEHAVIOR	LEARNING IMPLICATIONS FOR NURSE AND FAMILY CAREGIVER	RATIONALE
Denial or disbelief	Patient avoids discussion of illness ("I'm fine; there's nothing wrong with me"), withdraws from others, and disregards physical restrictions. Patient suppresses and distorts information that has not been presented clearly.	Provide support, empathy, and careful explanations of all procedures while they are being done. Let patient know that you are available for discussion. Explain situation to family or significant other if appropriate. Teach in present tense (e.g., explain current therapy).	Patient is not prepared to deal with problem. Any attempt to convince or tell patient about illness results in further anger or withdrawal. Provide only information patient pursues or absolutely requires.
Anger	Patient blames and complains and often directs anger toward nurse or others.	Do not argue with patient but listen to concerns. Teach in present tense. Reassure family and significant others of patient's normalcy.	Patient needs opportunity to express feelings and anger; he or she is still not prepared to face future.
Bargaining	Patient offers to live better life in exchange for promise of better health. ("If God lets me live, I promise to quit smoking.")	Continue to introduce only reality. Teach only in present tense.	Patient is still unwilling to accept limitations.
Resolution	Patient begins to express emotions openly, realizes that illness has created changes, and begins to ask questions.	Encourage expression of feelings. Begin to share information needed for future and set aside formal times for discussion.	Patient begins to perceive need for assistance and is ready to accept responsibility for learning.
Acceptance	Patient recognizes reality of condition, actively pursues information, and strives for independence.	Focus teaching on future skills and knowledge required. Continue to teach about present occurrences. Involve family/significant other in teaching information for discharge.	Patient is more easily motivated to learn. Acceptance of illness reflects willingness to deal with its implications.

grieving on the basis of his or her behaviors. When the patient enters the stage of acceptance, the stage compatible with learning, introduce a teaching plan. Continuous assessment of the patient's behaviors determines the stages of grieving. Teaching continues as long as the patient remains in a stage conducive to learning.

Active Participation. Learning occurs when the patient is actively involved in the educational session (Edelman and Mandle, 2010). A patient's involvement in learning implies an eagerness to acquire knowledge or skills. It also improves the opportunity for the patient to make decisions during teaching sessions. For example, when teaching car seat safety during a parenting class, hold a teaching session in the parking lot where the participants park their cars. Encourage active participation by providing the learners with several different car seats for them to place in their cars. At the completion of this session, the parents are able to determine which type of car seat fits in their cars and which is the easiest to use. This provides participants with the information needed to purchase the appropriate car seat.

FIG. 25-1 The nurse uses developmentally appropriate food models to teach healthy eating behaviors to the school-age child.

Ability to Learn

Developmental Capability. Cognitive development influences the patient's ability to learn. You can be a competent teacher, but if you do not consider the patient's intellectual abilities, teaching is unsuccessful. Learning, like developmental growth, is an evolving process. You need to know the patient's level of knowledge and intellectual skills before beginning a teaching plan. Learning occurs more readily when new information complements existing knowledge. For example, measuring liquid or solid food portions requires the ability to perform mathematical calculations. Reading a medication label or discharge instructions requires reading and comprehension skills. Learning to regulate insulin dosages requires problem-solving skills.

Learning in Children. The capability for learning and the type of behaviors that children are able to learn depend on the child's maturation. Without proper physiological, motor, language, and social development, many types of learning cannot take place. However, learning occurs in children of all ages. Intellectual growth moves from the concrete to the abstract as the child matures. Therefore information presented to children needs to be understandable, and the expected outcomes must be realistic, based on the child's developmental stage (Box 25-3). Use teaching aids that are developmentally appropriate (Fig. 25-1). Learning occurs when behavior changes as a result of experience or growth (Hockenberry and Wilson, 2011).

BOX 25-3 TEACHING METHODS BASED ON PATIENT'S DEVELOPMENTAL CAPACITY

Infant
- Keep routines (e.g., feeding, bathing) consistent.
- Hold infant firmly while smiling and speaking softly to convey sense of trust.
- Have infant touch different textures (e.g., soft fabric, hard plastic).

Toddler
- Use play to teach procedure or activity (e.g., handling examination equipment, applying bandage to doll).
- Offer picture books that describe story of children in hospital or clinic.
- Use simple words such as *cut* instead of *laceration* to promote understanding.

Preschooler
- Use role play, imitation, and play to make learning fun.
- Encourage questions and offer explanations. Use simple explanations and demonstrations.
- Encourage children to learn together through pictures and short stories about how to perform hygiene.

School-Age Child
- Teach psychomotor skills needed to maintain health. (Complicated skills such as learning to use a syringe take considerable practice.)
- Offer opportunities to discuss health problems and answer questions.

Adolescent
- Help adolescent learn about feelings and need for self-expression.
- Use teaching as collaborative activity.
- Allow adolescents to make decisions about health and health promotion (safety, sex education, substance abuse).
- Use problem solving to help adolescents make choices.

Young or Middle Adult
- Encourage participation in teaching plan by setting mutual goals.
- Encourage independent learning.
- Offer information so adult understands effects of health problem.

Older Adult
- Teach when patient is alert and rested.
- Involve adult in discussion or activity.
- Focus on wellness and person's strength.
- Use approaches that enhance sensorially impaired patient's reception of stimuli (see Chapter 49).
- Keep teaching sessions short.

Adult Learning. Teaching adults differs from teaching children. Adults are able to critically reflect on their current situation and sometimes need help to see their problems and change their perspectives (Redman, 2007). Because adults become independent and self-directed as they mature, they are often able to identify their own learning needs (Billings and Halstead, 2009). Learning needs come from problems or tasks that result from real-life situations. Although adults tend to be self-directed learners, they often become dependent in new learning situations. The amount of information provided and the amount of time that is spent with the adult patient vary, depending on the patient's personal situation and readiness to learn. An adult's readiness to learn is often associated with his or her developmental stage and other events that are occurring in his or her life. Resolve any needs or issues that the patient perceives as extremely important so learning can occur.

Adults have a wide variety of personal and life experiences on which to draw. Therefore enhance adult learning by encouraging them to use these experiences to solve problems (Eshleman, 2008). Furthermore, make education patient-centered by developing educational topics and goals in collaboration with the adult patient. Adult patients are ultimately responsible for changing their own behavior. Assessing what the adult patient currently knows, teaching what the patient wants to know, and setting mutual goals improve the outcomes of patient education (Bastable, 2008).

Physical Capability. The ability to learn often depends on the patient's level of physical development and overall physical health. To learn psychomotor skills, a patient needs to possess a certain level of strength, coordination, and sensory acuity. For example, it is useless to teach a patient to transfer from a bed to a wheelchair if he or she has insufficient upper body strength. An older patient with poor eyesight or the inability to grasp objects tightly cannot learn to apply an elastic bandage. Therefore do not overestimate the patient's physical development or status. The following physical characteristics are necessary to learn psychomotor skills:

- Size (height and weight match the task to perform or the equipment to use [e.g., crutch walking])
- Strength (ability of the patient to follow a strenuous exercise program)
- Coordination (dexterity needed for complicated motor skills such as using utensils or changing a bandage)
- Sensory acuity (visual, auditory, tactile, gustatory, and olfactory; sensory resources needed to receive and respond to messages taught)

Any condition (e.g., pain or fatigue) that depletes a person's energy also impairs the ability to learn. For example, a patient who spends a morning having rigorous diagnostic studies is unlikely to be able to learn because of fatigue. Postpone teaching when an illness becomes aggravated by complications such as a high fever or respiratory difficulty. After working with a patient, assess the patient's energy level by noting the patient's willingness to communicate, the amount of activity initiated, and his or her responsiveness toward questions. Temporarily stop teaching if the patient needs rest. You achieve greater teaching success when patients are physically able to actively participate in learning.

Learning Environment

Factors in the physical environment where teaching takes place make learning either a pleasant or a difficult experience (Bastable, 2008). The ideal setting helps the patient focus on the learning task. The number of persons that the nurse teaches, the need for privacy, the room temperature, the room lighting, noise, the room ventilation, and the room furniture are important factors when choosing the setting. The ideal environment for learning is a room that is well lit and has good ventilation, appropriate furniture, and a comfortable temperature. A darkened room interferes with the patient's ability to watch your actions, especially when demonstrating a skill or using visual aids such as posters or pamphlets. A room that is cold, hot, or stuffy makes the patient too uncomfortable to focus on the information being presented.

It is also important to choose a quiet setting. A quiet setting offers privacy; infrequent interruptions are best. Provide privacy even in a busy hospital by closing cubicle curtains or taking the patient to a quiet spot. Family caregivers often need to share in discussions in the home. However, patients who are reluctant to discuss the nature of the illness when others are in the room benefit

from receiving education in a room separate from household activities such as a bedroom.

Teaching a group of patients requires a room that allows everyone to be seated comfortably and within hearing distance of the teacher. Make sure that the size of the room does not overwhelm the group. Arranging the group to allow participants to observe one another further enhances learning. More effective communication occurs as learners observe others' verbal and nonverbal interactions.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. A relationship exists between the nursing and teaching processes (Redman, 2007). During the assessment phase of the nursing process, determine the patient's health care needs (see Unit 3). At times assessment reveals a patient's need for health care information. Individualize nursing diagnoses to a patient's situation and establish a plan of care to meet desired goals and outcomes and prescribe evidence-based nursing interventions for improving or maintaining a patient's health. Evaluation determines the level of success in meeting goals of care.

While diagnosing a patient's health care problems, you often identify the need for education. When education becomes a part of the care plan, the teaching process begins. Like the nursing process, the teaching process requires assessment—in this case, analyzing the patient's learning needs, motivation, and ability to learn. A diagnostic statement specifies the information or skills that the patient requires. Develop specific learning objectives, implement appropriate patient-centered teaching strategies, and use learning principles to ensure that the patient acquires the necessary knowledge and skills. Finally, the teaching process requires an evaluation of learning based on learning objectives.

The nursing and teaching processes are not the same. The nursing process requires assessment of all sources of data to determine a patient's total health care needs. The teaching process focuses on the patient's learning needs and willingness and capability to learn. Table 25-2 compares the teaching and nursing processes.

ASSESSMENT

Through the Patient's Eyes. When providing patient education, it is important to partner with the patient to ensure safe, compassionate, and coordinated care (QSEN, 2010). During the assessment process, thoroughly assess a patient and critically analyze your findings to ensure that you make patient-centered clinical decisions required for safe nursing care. To be successful in teaching a patient, you need to assess all factors influencing the choice of relevant content, the patient's ability to learn, and the resources available for instruction. By seeing health care situations "through patients' eyes," you gain a better appreciation of their knowledge, expectations, and preferences for learning. Learning needs, identified by both you and a patient, determine the choice of teaching content. An effective assessment provides the basis for individualized patient teaching (Olsen, 2010). Box 25-4 summarizes examples of specific assessment questions to use in determining a patient's unique learning needs.

Sometimes nurses use formal educational assessment tools to determine their patients' perceived learning needs. Other times they simply identify their patients' expectations during routine assessments. Patients identify their own learning needs based on the implications of living with their illness. To meet these learning needs, assess what patients view as important information to know. When a patient feels a need to know something, he or she is likely to be receptive to information presented. For example, many parents need to know how to care for their new baby. Therefore they are often very receptive to information about baby care (e.g., how to feed the baby and make sure that he or she gets enough sleep).

Learning Needs. Determine information that is critical for patients to learn. Learning needs change, depending on a patient's current health status. Because the health status is dynamic, assessment is an ongoing activity. Assess the following:

- Information or skills needed by the patient to perform self-care and to understand the implications of a health problem—Health care team members anticipate learning needs related to specific health problems. For example, you teach a young man who has just entered high school how to perform testicular self-examination.
- Patient experiences (e.g., new or recurring problem, past hospitalization) that influence the need to learn

TABLE 25-2 Comparison of the Nursing and Teaching Processes

BASIC STEPS	NURSING PROCESS	TEACHING PROCESS
Assessment	Collect data about patient's physical, psychological, social, cultural, developmental, and spiritual needs from patient, family, diagnostic tests, medical record, nursing history, and literature.	Gather data about patient's learning needs, motivation, ability to learn, and teaching resources from patient, family, learning environment, medical record, nursing history, and literature.
Nursing diagnosis	Identify appropriate nursing diagnoses based on assessment findings.	Identify patient's learning needs on basis of three domains of learning.
Planning	Develop an individualized care plan. Set diagnosis priorities based on patient's immediate needs, expected outcomes, and patient-centered goals. Collaborate with patient on care plan.	Establish learning objectives stated in behavioral terms. Identify priorities regarding learning needs. Collaborate with patient about teaching plan. Identify type of teaching method to use.
Implementation	Perform nursing care therapies. Include patient as active participant in care. Involve family/significant other in care as appropriate.	Implement teaching methods. Actively involve patient in learning activities. Include family caregiver as appropriate.
Evaluation	Identify success in meeting desired outcomes and goals of nursing care. Alter interventions as indicated when goals are not met.	Determine outcomes of teaching-learning process. Measure patient's achievement of learning objectives. Reinforce information as needed.

BOX 25-4 NURSING ASSESSMENT QUESTIONS

Previous Learning and Identification of Learning Needs and Preferences

- What do you want to know about _____?
- What do you know about your illness and your treatment plan?
- Which experiences have you had in the past that are similar to those you are experiencing now?
- Together we can choose the best way for you to learn about your disease. How can I best help you?
- When you learn new information, do you prefer to have it given to you in pictures or written down in words?
- When you give someone directions to your house, do you tell the person how to get there, write out the instructions, or draw a map?

Self-Management

- How does (or will) your illness affect your current lifestyle?
- Which barriers currently exist that prevent you from managing your illness the way you would like to manage it?
- What role do you believe your health care providers should take in helping you manage your illness or maintain health?
- How involved do you want a family member to be in the management of your illness? Who is that family member?

Culture and Spiritual Influences

- Which cultural or spiritual beliefs do you have regarding your illness and the prescribed treatment?

For Family Caregivers

- When are you available to help, and how do you plan to help your loved one?
- Your spouse needs some help. How do you feel about learning how to assist him or her?
- Tell me how you feel about performing the care activities that your family member requires.

- Information that family caregivers require to support the patient's needs—The amount of information needed depends on the extent of the family member's role in helping the patient.

Motivation to Learn. Ask questions that identify and define the patient's motivation. These questions help to determine if the patient is prepared and willing to learn. Assess the following motivational factors:

- Behavior (e.g., attention span, tendency to ask questions, memory, and ability to concentrate during the teaching session)
- Health beliefs and sociocultural background—Sociocultural norms, values, and traditions all influence a patient's beliefs and values about health and various therapies, communication patterns, and perceptions of time (see Chapter 9).
- Perception of the severity and susceptibility of a health problem and the benefits and barriers to treatment
- Perceived ability to perform health behaviors
- Desire to learn
- Attitudes about health care providers (e.g., role of patient and nurse in making decisions)
- Learning style preference—Patients who are visual learners learn best when you use pictures and diagrams to explain information. Patients who prefer auditory learning are distracted by pictures and prefer listening to information (e.g., podcasts). Kinesthetic learners learn best while they are moving and participating in hands-on activities. Demonstrations and role playing work well with these learners (Eshleman, 2008). Patients who learn best by reasoning logically and intuitively learn better if presented with a case study that requires careful analysis and discussion with others to arrive at conclusions.

Ability to Learn. Determine the patient's physical and cognitive ability to learn. Health care providers often underestimate patients' cognitive deficits. Many factors impair the ability to learn, including fatigue, body temperature, electrolyte levels, oxygenation status, and blood glucose level. In any health care setting several of these factors often influence a patient at the same time. Assess the following factors related to the ability to learn:

- Physical strength, endurance, movement, dexterity, and coordination—Determine the extent to which the patient can perform skills. For example, have the patient manipulate equipment that will be used in self-care at home.
- Sensory deficits (see Chapter 49) that affect the patient's ability to understand or follow instruction
- Patient's reading level—This is often difficult to assess because patients who are functionally illiterate are often able to conceal it by using excuses such as not having the time or not being able to see. One way to assess a patient's reading level and level of understanding is to ask the patient to read instructions from an educational handout and then explain their meaning (see the discussion of health literacy, p. 337).
- Patient's developmental level—This influences the selection of teaching approaches (see Box 25-3).
- Patient's cognitive function, including memory, knowledge, association, and judgment
- Pain, fatigue, anxiety, or other physical symptoms that interfere with the ability to maintain attention and participate—In acute care settings a patient's physical condition can easily prevent a patient from learning.

Teaching Environment. The environment for a teaching session needs to be conducive to learning. Assess the following environmental factors:

- Distractions or persistent noise—A quiet area is essential for effective learning.
- Comfort of the room, including ventilation, temperature, lighting, furniture, and size
- Room facilities and available equipment

Resources for Learning. A patient frequently requires the support of family members or significant others. If this support is necessary, assess the readiness and ability of a family caregiver to learn the information necessary for the care of the patient. Also review resources within the home environment. Assess the following:

- Patient's willingness to have family caregivers involved in the teaching plan and provide health care—Information about the patient's health care is confidential unless the patient chooses to share it. Sometimes it is difficult for the patient to accept the help of family caregivers, especially when bodily functions are involved.
- Family caregiver's perceptions and understanding of the patient's illness and its implications—Family caregivers' perceptions should match those of the patient; otherwise conflicts occur in the teaching plan.
- Family caregiver's willingness and ability to participate in care—If the patient chooses to share information about his or her health status with family members, they need to be responsible, willing, and physically and cognitively

able to assist in care activities such as bathing or administering medications. Not all family members meet these requirements.
- Resources—These include financial or material resources such as having the ability to obtain health care equipment.
- Teaching tools, including brochures, audiovisual materials, or posters—Printed material needs to present current information that is written clearly and logically and matches the patient's reading level.

Health Literacy and Learning Disabilities. Current research shows that health literacy is a strong predictor of a person's health status (Kim and Yu, 2010; Wolf et al., 2010). The World Health Organization (2011) defines **health literacy** as the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health. Health literacy includes patients' reading and mathematics skills, comprehension, ability to make health-related decisions, and successful functioning as a consumer of health care (Speros, 2005). Persons most likely to be at risk for low health literacy include the elderly (age 65 years and older), minority populations, immigrant populations, persons of low income (approximately half of Medicare/Medicaid recipients read below the fifth-grade level), and people with chronic mental and/or physical health conditions (National Network of Libraries of Medicine, 2011).

Functional illiteracy, the inability to read above a fifth-grade level, is a major problem in America today. The National Assessment of Adult Literacy Survey (NAALS), conducted in 2003 by the National Center for Education Statistics, assessed the extent of literacy skills in Americans over the age of 16 (Kutner et al., 2006). Results from the NAALS reflected that over 75 million American adults had basic or below-basic levels of health literacy. Approximately 14% of adults could not understand a basic patient education pamphlet, and 36% could not perform moderately difficult tasks (e.g., reading a childhood vaccination chart or determining possible medication interactions from a prescription label). Older adults, men, people who did not speak English before entering school, people living below poverty level, and people without a high school education tended to have lower health literacy scores. White and Asian/Pacific Islander adults had higher literacy levels than African American, Native American/Alaska Native, and multiracial adults. Hispanic adults had the lowest levels of health literacy.

To compound the problem, the readability of printed health education material ranges from elementary school to college level. Currently printed educational materials are often above the patient's reading level (Clauson et al., 2010; MacDonald et al., 2010). Removing medical terms from health information lowers the reading level, but this often does not bring it to an acceptable level. Unfortunately health care professionals do not always address the gap between the patient's reading level and the readability of educational materials (Attwood, 2008; Rothman et al., 2009). This results in unsafe care. To ensure patient safety, all health care providers need to ensure that information is presented clearly and in a culturally sensitive manner (TJC, 2010).

Because health literacy influences how you deliver teaching strategies, it is critical for you to assess a patient's health literacy before providing instruction. Assessing health literacy is challenging, especially in busy clinical settings where there is often little time to conduct a thorough health literacy assessment. However, all health care providers need to identify problems and provide appropriate education to people who have special health literacy needs (TJC, 2010). Research shows that many Americans read and understand information that is 3 to 5 years below their last year of formal education.

Try asking patients to perform simple literacy skills. For example, can a patient read back to you a medication label correctly? After you give a simple 1-minute explanation of a diet or exercise program, can the patient explain it back to you? Can a patient correctly describe in his or her own words the information in a written handout? Most people with low health literacy say they are good readers even if they cannot read (Lee et al., 2010). You can use a variety of screening tools to test literacy. The Wide Range Achievement Test (WRAT 3) evaluates reading, spelling, and arithmetic skills for patients from 5 to 74 years of age. The Rapid Estimate of Adult Literacy in Medicine (REALM) uses pronunciation of health care terms to determine approximate reading level. The Cloze test, a test of reading comprehension, asks patients to fill in the blanks that are in a written paragraph. You also need to assess the patient's ability to understand mathematical calculations in addition to reading skills.

In addition to illiteracy, assess patients for learning disabilities that impair the ability to learn. For example, many self-care behaviors require an understanding of mathematics, including computation and fractions. If a patient's learning disability impairs the ability to effectively use mathematics skills, teaching is challenging, especially when trying to teach him or her about complex medication dosages and frequencies. Another learning disability that affects a patient's ability to learn includes attention-deficit/hyperactivity disorder (ADHD). Patients with ADHD frequently have a low threshold of frustration and difficulty recalling information and staying focused during educational sessions.

Patients who have low health literacy or learning disabilities may be ashamed of not being able to understand you and often try to mask their inability to comprehend information. Therefore make sure that you are sensitive and maintain a therapeutic relationship with your patients while assessing their ability to learn. Appreciating the unique qualities of your patients helps to ensure safe and effective patient care (QSEN, 2010).

NURSING DIAGNOSIS

After assessing information related to the patient's ability and need to learn, interpret data and cluster-defining characteristics to form diagnoses that reflect his or her specific learning needs (Box 25-5). This ensures that teaching will be goal directed and individualized. If a patient has several learning needs, the nursing diagnoses guide priority setting. When the nursing diagnosis is *deficient knowledge,* the diagnostic statement describes the specific type of learning

BOX 25-5 NURSING DIAGNOSTIC PROCESS

Deficient Knowledge (Psychomotor) Regarding Use of Crutches Related to Lack of Experience

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Have patient describe how to walk with crutches.	Patient states that he or she has not received information about use of crutches. Patient asks questions about how to use crutches.
Have patient demonstrate three-point crutch walking on level surfaces and up stairs.	Patient uses crutches inappropriately. Patient cannot go up or down stairs on crutches.

need and its cause (e.g., *deficient knowledge regarding psychomotor learning related to inexperience with medication self-administration).* Classifying diagnoses by the three learning domains helps you to focus specifically on subject matter and teaching methods. Patients often require education to support resolution of their various health problems. Examples of nursing diagnoses that indicate a need for education include the following:

- Deficient knowledge (affective, cognitive, psychomotor)
- Ineffective health maintenance
- Impaired home maintenance
- Ineffective family therapeutic regimen management
- Ineffective self-health management
- Noncompliance (with medications)

When you can manage or eliminate health care problems through education, the related factor of a diagnostic statement is *deficient knowledge.* For example, an older adult is having difficulty managing a medication regimen that involves a number of newly prescribed medications she has to take at different times of the day. The nursing diagnosis is *Ineffective self-health management* related to deficient knowledge. In this case educating the patient about her medications and the correct dosage schedules improves her ability to schedule and take them as directed. When you identify conditions that cause barriers to effective learning (e.g., nursing diagnosis of *acute pain* or *activity intolerance*), teaching is inappropriate. In these cases delay teaching until the nursing diagnosis is resolved or the health problem controlled.

PLANNING

After determining the nursing diagnoses that identify a patient's learning needs, develop a teaching plan, determine goals and expected outcomes, and involve the patient in selecting learning experiences (see the Nursing Care Plan). Expected outcomes (or learning objectives) guide the choice of teaching strategies and approaches with a patient. Patient participation ensures a more relevant, meaningful plan.

Goals and Outcomes. Goals of patient education indicate that a patient achieves a better understanding of the information provided and is able to attain health or better manage illness. If possible, include the patient when establishing learning goals and outcomes and serve as a resource in setting the minimum criteria for success. Outcomes often describe a behavior that identifies the patient's ability to do something on completion of teaching such as *will empty* colostomy bag, or *will administer* an injection. When developing outcomes, conditions or time frames need to be realistic and meet the patient's needs (e.g., "will identify the side effects of aspirin by discharge"). Consider conditions under which the patient or family will typically perform the behavior (e.g., "will walk from bedroom to bathroom using crutches").

In some health care settings nurses develop written teaching plans. The teaching plan includes topics for instruction, resources (e.g., equipment, teaching booklets, and referrals to special educational programs), recommendations for involving family, and objectives of the teaching plan. Some plans are very detailed, whereas others are in outline form. Use the plan to provide continuity of instruction. The more specific the plan, the easier it is to follow.

The setting influences the complexity of any teaching plan. In an acute care setting plans are concise and focused on the primary learning needs of the patient because there is limited time for teaching. Home care and outpatient clinic teaching plans are usually more comprehensive in scope because you often have more time to instruct patients and patients are often less anxious in outpatient settings.

Setting Priorities. Include the patient when determining priorities for patient education. Base priorities on the patient's immediate needs, nursing diagnoses, and the goals and outcomes established for him or her. Priorities also depend on what the patient perceives to be most important, his or her anxiety level, and the amount of time available to teach. A patient's learning needs are set in order of priority. For example, a patient recently diagnosed with coronary artery disease has deficient knowledge related to the illness and its implications. The patient benefits most by first learning about the correct way to take nitroglycerin and how long to wait before calling for help when chest pain occurs. Once you assist in meeting patient needs related to basic survival, you can discuss other topics such as exercise and nutritional changes.

Timing. When is the right time to teach? Before a patient enters a hospital? When a patient first enters a clinic? At discharge? At home? Each is appropriate because patients continue to have learning needs and opportunities as long as they stay in the health care system. Plan teaching activities for a time when the patient is most attentive, receptive, and alert and organize the patient's activities to provide time for rest and teaching-learning interactions.

Timing is sometimes difficult because the emphasis is often on a patient's early discharge from a hospital. For example, it takes several days after surgery for a patient to be alert and comfortable enough to learn. By the time a patient feels ready to learn, sometimes discharge is already scheduled. Therefore, to improve patient outcomes, anticipate patients' educational needs before they occur.

Although prolonged sessions cause concentration and attentiveness to decrease, make sure that teaching sessions are not too brief. The patient needs time to comprehend the information and give feedback. It is easier for him or her to tolerate and retain interest in the material during frequent sessions lasting 10 to 15 minutes. However, factors such as shorter hospital stays and lack of insurance reimbursement for outpatient education sessions often necessitate longer teaching sessions.

The frequency of sessions depends on the learner's abilities and the complexity of the material. For example, a child newly diagnosed with diabetes requires more visits to an outpatient center than the older adult who has had diabetes for 15 years and lives in a nursing home. Make sure that intervals between teaching sessions are not so long that the patient forgets information. Home care nurses frequently reinforce learning during home visits when patients are discharged from the hospital.

Organizing Teaching Material. An effective teacher carefully considers the order of information to present. When a nurse has an ongoing relationship with a patient, as in the case of home health or case management, an outline of content helps organize information into a logical sequence. Material needs to progress from simple to complex ideas because a person must learn the simple facts and concepts before learning how to make associations or complex interpretations of ideas. Staff nurses in an acute care setting will often focus on the simpler, more essential concepts, whereas home health nurses can better address complex issues. For example, to teach a woman how to feed her husband who has a gastric tube, the nurse first teaches the wife how to measure the tube feeding and manipulate the equipment. Once the wife has accomplished this, the process of administering the feeding occurs.

Begin instruction with essential content because patients are more likely to remember information that you teach early in the teaching session. For example, immediately after surgical removal of a malignant breast tumor, the patient has many learning needs. Start

NURSING CARE PLAN

Deficient Knowledge: Surgical Procedure

ASSESSMENT

Connie, a nurse in a surgeon's office, is preparing Mr. Holland for a colon resection, which is scheduled in 1 week. Mr. Holland is 75 years old and has recently been diagnosed with colorectal cancer. Connie's assessment focuses on Mr. Holland's readiness to learn and factors that affect his ability to understand the procedure and related postoperative care.

*Assessment Activities**	*Findings/Defining Characteristics*
Assess Mr. Holland's readiness to learn and ask what the surgeon has already told him about the surgery.	Mr. Holland responds, "**I can't remember what the doctor told me** at my last appointment, but **I need to know how to take care of myself.** My surgery is scheduled for next week."
Ask Mr. Holland to explain what he knows about postoperative care, including performing a return demonstration of deep breathing and coughing.	Mr. Holland is **unable to describe postoperative care or provide a return demonstration of deep breathing and coughing.**
Observe Mr. Holland's behavior during the office visit.	Mr. Holland states he is anxious but asks appropriate questions. He maintains good contact with the nurse.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Deficient Knowledge: surgical procedure related to lack of recall and exposure to information

PLANNING

Goals	*Expected Outcomes (NOC)*†
	Knowledge: Treatment Procedure
Mr. Holland will describe preoperative and postoperative care activities before surgery.	Mr. Holland will verbalize understanding of the surgical procedure, postoperative monitoring, and activity planned on the day of surgery.
Mr. Holland will participate in postoperative care during hospitalization.	Mr. Holland will demonstrate deep breathing and coughing and advance his level of physical activity after his surgery.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Learning Readiness Enhancement	
Provide a nonthreatening environment in the consultation area. Sit with the patient and encourage any questions during instruction.	The adult patient's learning is enhanced when the patient is ready to learn and when he or she perceives the information to be important. (Bastable, 2008).
Learning Facilitation	
Offer Mr. Holland multiple teaching modalities (e.g., brochure and audiotape describing preoperative and postoperative care) while explaining preoperative and postoperative care.	Providing patients with educational methods that use multiple senses is effective in educating older adults. Older adults prefer written handouts in large fonts (Meiner, 2011).
Explain postoperative care activities, including frequent monitoring and demonstrate deep breathing and coughing, and have Mr. Holland perform return demonstration.	Improving self-efficacy by using role modeling and having the patient perform behaviors enhances the successful adoption of healthy behaviors (Bandura, 1997).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Mr. Holland to describe what will happen before and after surgery.	Mr. Holland is able to state understanding of preoperative and postoperative care activities.	Mr. Holland's anxiety level has decreased, and he reports that he is ready for surgery.
Observe patient as he demonstrates deep breathing and coughing and advances his activity after surgery.	Mr. Holland is able to deep breathe and cough after surgery, but he is hesitant to advance his activity level.	Patient has not totally achieved outcome of advancing activity after surgery. Manage barriers inhibiting attainment of this outcome (e.g., pain), and continue to encourage and educate patient.

with essential information such as how to monitor the incision site for signs of infection; deal with the emotional aspects of a cancer diagnosis and complete the teaching session with informative but less critical content, including the warning signs of cancer. Repetition reinforces learning. A concise summary of key topics helps the learner remember the most important information (Bastable, 2008).

Teamwork and Collaboration. During planning choose appropriate teaching methods, encourage the patient to offer suggestions, and make referrals to other health care professionals (e.g., dietitians and physical, speech, or occupational therapists) when appropriate. The nurse is the member of the health care team primarily responsible for ensuring that all patient educational

needs are met. However, sometimes patient needs are highly complex. In these cases identify appropriate health education resources within the health care system or the community during planning. Examples of resources for patient education include diabetes education clinics, cardiac rehabilitation programs, prenatal classes, and support groups. When patients receive education and support from these types of resources, the nurse obtains a referral order when necessary, encourages patients to attend educational sessions, and reinforces information taught. Resources that specialize in a particular health need (e.g., wound care or ostomy specialists) are integral to successful patient education.

IMPLEMENTATION

The implementation of patient education depends on your ability to critically analyze assessment data when identifying learning needs and developing the teaching plan (see Care Plan). Carefully evaluate the learning objectives and determine which teaching and learning principles most effectively and efficiently assist the patient in meeting expected goals and outcomes. Implementation involves believing that each interaction with a patient is an opportunity to teach. Use evidence-based interventions to create an effective learning environment.

Maintaining Learning Attention and Participation. Active participation is key to learning. Persons learn better when more than one of the senses is stimulated. Audiovisual aids and role play are good teaching strategies. By actively experiencing a learning event, the person is more likely to retain knowledge. A teacher's actions also increase learner attention and interest. When conducting a discussion with a learner, the teacher stays active by changing the tone and intensity of his or her voice, making eye contact, and using gestures that accentuate key points of discussion. An effective teacher engages learners and talks and moves among a group rather than remaining stationary behind a lectern or table. A learner remains interested in a teacher who is actively enthusiastic about the subject under discussion.

Building on Existing Knowledge. A patient learns best on the basis of preexisting cognitive abilities and knowledge. Thus a teacher is more effective when he or she presents information that builds on a learner's existing knowledge. A patient quickly loses interest if a nurse begins with familiar information. For example, a patient who has lived with multiple sclerosis for several years is beginning a new medication that is given subcutaneously. Before teaching the patient how to prepare the medication and give the injection, the nurse asks him or her about previous experience with injections. On assessment the nurse learns that the patient's father had diabetes and the patient administered the insulin injections. The nurse individualizes the teaching plan by building on the patient's previous knowledge and experience with insulin injections.

Teaching Approaches. A nurse's approach in teaching is different from teaching methods. Some situations require a teacher to be directive. Others require a nondirective approach. An effective teacher concentrates on the task and uses teaching approaches according to the learner's needs. A learner's needs and motives frequently change over time. Thus the effective teacher is always aware of the need to modify teaching approaches.

Telling. Use the telling approach when teaching limited information (e.g., preparing a patient for an emergent diagnostic procedure). If a patient is highly anxious but it is vital for information to be given, telling is effective. When using telling, the nurse outlines the task the patient will perform and gives explicit instructions. There is no opportunity for feedback with this method.

Participating. In the participating approach the nurse and patient set objectives and become involved in the learning process together. The patient helps decide content, and the nurse guides and counsels the patient with pertinent information. In this method there is opportunity for discussion, feedback, mutual goal setting, and revision of the teaching plan. For example, a parent caring for a child with leukemia learns how to care for the child at home and recognize problems that need to be reported immediately. The parent and nurse collaborate on developing an appropriate teaching plan. After each teaching session is completed, the parent and nurse review the objectives together, determine if the objectives were met, and plan what will be covered in the next session.

Entrusting. The entrusting approach provides the patient the opportunity to manage self-care. The patient accepts responsibilities and performs tasks correctly and consistently. The nurse observes the patient's progress and remains available to assist without introducing more new information. For example, a patient has been managing diabetes well for 10 years. Because of the development of a complication, the patient now has to walk instead of jog during exercise. The patient understands how to adjust insulin when exercising to prevent hypoglycemia. The nurse instructs the patient about the newly prescribed exercise therapy and allows him or her to adjust insulin dosages independently.

Reinforcing. **Reinforcement** requires using a stimulus that increases the probability for a response. A learner who receives reinforcement before or after a desired learning behavior is likely to repeat the behavior. Feedback is a common form of reinforcement. Reinforcers are positive or negative. Positive reinforcement such as a smile or spoken approval produces desired responses. Although negative reinforcement such as frowning or criticizing decreases an undesired response, people usually respond better to positive reinforcement (Bastable, 2008). The effects of negative reinforcement are less predictable and often undesirable.

Three types of reinforcers are social, material, and activity. When a nurse works with a patient, most reinforcers are social, used to acknowledge a learned behavior (e.g., smiles, compliments, or words of encouragement). Examples of material reinforcers are food, toys, and music. These work best with young children. Activity reinforcers rely on the principle that a person is motivated to engage in an activity if he or she has the opportunity to engage in a more desirable activity after completion of the task. For example, a patient is more likely to go to a mental health counseling session if he or she is given the chance to go outside for a walk afterward.

Choosing an appropriate reinforcer involves giving careful thought and attention to individual preferences. Observing behavior often helps reveal the best reinforcer to use. Do not use reinforcers as threats. They are not effective with every patient. A young child responds more to social reinforcers than do older children or adults. In adults reinforcement is more effective when the nurse establishes a therapeutic relationship with the patient.

Incorporating Teaching with Nursing Care. Many nurses find that they are able to teach more effectively while delivering nursing care. This becomes easier as you gain confidence in your clinical skills. For example, while hanging blood you explain to the patient why the blood is necessary and the symptoms of a transfusion reaction that need to be reported immediately. Another example is explaining the side effects of a medication while administering it. An informal, unstructured style relies on the positive therapeutic relationship between nurse and patient, which fosters spontaneity in the teaching-learning process. Teaching during routine care is efficient and cost-effective (Fig. 25-2).

FIG. 25-2 Teaching postoperative care while walking with the patient uses time efficiently.

Instructional Methods. Choose instructional methods that match a patient's learning needs, the time available for teaching, the setting, the resources available, and your comfort level with teaching. Skilled teachers are flexible in altering teaching methods according to the learner's responses. An experienced teacher uses a variety of techniques and teaching aids. Do not expect to be an expert educator when first entering nursing practice. Learning to become effective in teaching takes time and practice.

When first starting to teach patients, it helps to remember that patients perceive you as an expert. However, this does not mean that they expect you to have all of the answers. It simply means that they expect that you will keep them appropriately informed. Effective nurses keep the teaching plan simple and focused on patients' needs.

One-on-One Discussion. Perhaps the most common method of instruction is one-on-one discussion. When teaching a patient at the bedside, in a physician's office, or in the home, the nurse shares information directly. You usually give information in an informal manner, allowing the patient to ask questions or share concerns. Use various teaching aids such as models or diagrams during the discussion, depending on the patient's learning needs. Use unstructured and informal discussions when helping patients understand the implications of illness and ways to cope with health stressors.

Group Instruction. Some nurses choose to teach patients in groups because of the advantages associated with group teaching. Groups are an economical way to teach a number of patients at one time, and patients are able to interact with one another and learn from the experiences of others. Learning in a group of six or less is more effective and avoids outburst behaviors. Groups also foster the development of positive attitudes that help patients meet learning objectives (Bezalel et al., 2010). Group instruction often involves both lecture and discussion. Lectures are highly structured and efficient in helping groups of patients learn standard content about a subject. A lecture does not ensure that learners are actively thinking about the material presented; thus discussion and practice sessions are essential. After a lecture, learners need the opportunity to share ideas and seek clarification. Group discussions allow patients and families to learn from one another as they review common experiences. A productive group discussion helps participants solve problems and arrive at solutions toward improving each member's health. To be an effective group leader, the nurse guides participation. Acknowledging a look of interest, asking questions, and summarizing key points foster group involvement. However, not all patients benefit from group discussions, and sometimes the physical or emotional level of wellness makes participation difficult or impossible.

Preparatory Instruction. Patients frequently face unfamiliar tests or procedures that create significant anxiety. Providing information about procedures often decreases anxiety because patients have a better idea of what to expect during the procedure, which helps to give them a sense of control. The known is less threatening than the unknown. Use the following guidelines for giving preparatory explanations:

- Describe physical sensations during a procedure. For example, when drawing a blood specimen, explain that the patient will feel a sticking sensation as the needle punctures the skin.
- Describe the cause of the sensation, preventing misinterpretation of the experience. For example, explain that a needlestick burns because the alcohol used to clean the skin enters the puncture site.
- Prepare patients only for aspects of the experience that others have commonly noticed. For example, explain that it is normal for a tight tourniquet to cause a person's hand to tingle and feel numb.

Demonstrations. Use demonstrations when teaching psychomotor skills such as preparation of a syringe, bathing an infant, crutch walking, or taking a pulse. Demonstrations are most effective when learners first observe the teacher and then, during a **return demonstration,** have the chance to practice the skill. Combine a demonstration with discussion to clarify concepts and feelings. An effective demonstration requires advanced planning:

1. Be sure that the learner can easily see each step of the demonstration. Position the learner to provide a clear view of the skill being performed.
2. Assemble and organize the equipment. Make sure that all equipment works.
3. Perform each step slowly and accurately in sequence while analyzing the knowledge and skills involved and allow the patient to handle the equipment
4. Review the rationale and steps of the procedure.
5. Encourage the patient to ask questions so he or she understands each step.
6. Judge proper speed and timing of the demonstration based on the patient's cognitive abilities and anxiety level.
7. To demonstrate mastery of the skill, have the patient perform a return demonstration under the same conditions that will be experienced at home or in the place where the skill is to be performed. For example, when a patient needs to learn to walk with crutches, the nurse simulates the home environment. If the patient's home has stairs, the patient practices going up and down a staircase in the hospital.

Analogies. Learning occurs when a teacher translates complex language or ideas into words or concepts that the patient understands. **Analogies** supplement verbal instruction with familiar images that make complex information more real and understandable. For example, when explaining arterial blood pressure, use an analogy of the flow of water through a hose. Follow these general principles when using analogies:

- Be familiar with the concept.
- Know the patient's background, experience, and culture.
- Keep the analogy simple and clear.

Role Play. During role play people are asked to play themselves or someone else. Patients learn required skills and feel more confident in being able to perform them independently. The technique involves rehearsing a desired behavior. For example, a nurse who is teaching a parent how to respond to a child's behavior pretends to be a child who is having a temper tantrum. The parent responds to the nurse who is pretending to be the child. Afterward the nurse evaluates the parent's response and determines whether an alternative approach would have been more appropriate.

Simulation. Simulation is a useful technique for teaching problem solving, application, and independent thinking. During individual or group discussion you pose a pertinent problem or situation for patients to solve. For example, patients with heart disease plan a meal that is low in cholesterol and fat. The patients in the group decide which foods are appropriate. You ask the group members to present their diet, providing an opportunity to identify mistakes and reinforce correct information.

Illiteracy and Other Disabilities. It is important to use words that a patient is able to understand. Medical jargon is confusing. Implications of low health literacy, illiteracy, and learning disabilities include an impaired ability to analyze instructions or synthesize information. In addition, many of these patients have not acquired the problem-solving skills of drawing conclusions and inferences from experience, and they do not ask questions to obtain or clarify information that has been presented. Box 25-6 summarizes nursing interventions that nurses use when caring for patients who have literacy or learning disability problems.

Sometimes patients have sensory deficits that affect how the nurse presents information (see Chapter 49). For example, patients who are deaf require a sign language interpreter. Not all people who are deaf read lips. Therefore it is very important to provide clear written materials that match the patients' reading level. Visual impairments also impact the teaching strategy used by the nurse. Many people who are blind have acute listening skills. Avoid shouting and announce your presence to patients with visual impairments before approaching them. If the patient has partial vision, use colors and a print font size (14-point font or greater) that the patient is able to see. Be sure to use proper lighting. Other helpful interventions include audiotaping teaching sessions and providing structured, well-organized instructions (Bastable, 2008).

Building Competency in Patient-Centered Care You are caring for Bob, a 47-year-old patient with type 1 diabetes who is having difficulty following a complicated medication schedule at home. He needs to take different medications, including insulin injections, several times a day. During your assessment, you find he has difficulty understanding printed teaching sheets. He admits, "I had to drop out of school when I was in eighth grade, and my vision is not as good as it used to be." What additional assessment questions and teaching strategies, approaches, and tools do you use to enhance Bob's learning and ability to take his medications as they are ordered?

Answers to questions can be found on the Evolve website.

Cultural Diversity. You must have knowledge of a patient's cultural background and beliefs and his or her ability to understand instructions in a language different from his or her native language (see Chapter 9 and Box 25-7). Cultural diversity poses a

BOX 25-6 PATIENT TEACHING

Teaching an Illiterate Patient or Patient with a Learning Disability

Objective
- Patient will perform desired behaviors accurately.

Teaching Strategies
- Establish trust with patient before beginning the teaching-learning session.
- Use simple terminology to enhance patient's understanding.
- Avoid medical jargon. If necessary, explain medical terms using basic one- or two-syllable words.
- Keep teaching sessions short and to the point and minimize distractions.
- Include the most important information at the beginning of the session.
- Relate practical information to personal experiences or real-life situations.
- Use visual cues and simple analogies when appropriate.
- Frequently ask patient for feedback to determine if he or she comprehends information.
- Ask for return demonstrations and clarify instructions when needed.
- Provide teaching materials that reflect reading level of patient, with attention given to short words and sentences, large type, and simple format (generally information written on a fifth-grade reading level is recommended for adult learners).
- Reinforce most important information at the end of the session.
- Schedule teaching sessions at frequent intervals.
- Model appropriate behavior and use role-play to help patient learn how to ask questions and ask for help effectively.

Evaluation
- Ask patient to verbalize understanding of information taught.
- Observe and evaluate patient's ability to perform desired behaviors.

Data from Bastable S: *Nurse as educator: principles of teaching and learning for nursing practice,* ed 3, Sudbury, Mass, 2008, Jones & Bartlett.

BOX 25-7 CULTURAL ASPECTS OF CARE

Patient Education

Patient education needs to be patient-centered and culturally sensitive for learning to occur. Assessing patients' preferred learning approaches and adapting education to meet patients' needs facilitates the attainment of educational outcomes. Sociocultural norms, values, and traditions often determine the importance of different health education topics and the preference of one learning approach over another. Educational efforts are especially challenging when patients and educators do not speak the same language or when written materials are not culturally sensitive and are written above patients' reading abilities.

Implications for Practice
- Establish rapport with culturally diverse patients before starting teaching sessions (Campinha-Bacote, 2009).
- Sociocultural background influences a patient's desire to learn and which information the patient perceives as important to learn (Campinha-Bacote, 2009).
- Carefully assess a patient's preference for educational delivery method to ensure successful learning.
- Nurses must have a wide variety of culturally sensitive educational resources available to them to meet the needs of diverse populations.
- When you and the patient do not speak the same language, accurate translators are necessary.

great challenge when you are trying to provide culturally sensitive care. When educating patients of different ethnic groups, be aware of the distinctive aspects of each culture, being careful not to stereotype patients (Campinha-Bacote, 2009). Collaborate with other nurses and educators to present appropriate teaching approaches, and ask the people in the cultural group to help by sharing their values and beliefs. Ethnic nurses are excellent resources who are able to provide input through their experiences to improve the care provided to members of their own community (Bastable, 2008). When patients cannot understand English, use trained and certified health care interpreters to provide health care information.

In addition, be aware of intergenerational conflict of values. This occurs when immigrant parents uphold their traditional values and their children, who are exposed to American values in social encounters, develop beliefs similar to those of their American peers. Consider this conflict in values when providing information to families or groups who have members from different generations. To enhance patient education in culturally diverse populations, know when and how to provide education while respecting cultural values. Modify teaching regarding interventions or desired behaviors to accommodate for cultural differences. Effective educational strategies often require the nurse to use different patterns of communication (Campinha-Bacote, 2009).

Using Teaching Tools. Many teaching tools are available for patient education. Selection of the right tool depends on the instructional method, the patient's learning needs, and his or her ability to learn (Table 25-3). For example, a printed pamphlet is not the best tool to use for a patient with poor reading comprehension, but an audiotape is a good choice for a patient with visual impairment.

Special Needs of Children and Older Adults. Children, adults, and older adults learn differently. You adapt teaching strategies to each learner. Children pass through several developmental stages (see Unit 2). In each developmental stage children acquire new cognitive and psychomotor abilities that respond to different types of teaching methods (Fig. 25-3). Incorporate parental input in planning health education for children.

Older adults experience numerous physical and psychological changes as they age (see Chapter 14). These changes not only increase their educational needs but also create barriers to learning unless adjustments are made in nursing interventions. Sensory changes such as visual and hearing changes require adaptation of

TABLE 25-3 Teaching Tools for Instruction

DESCRIPTION	LEARNING IMPLICATIONS
Written Materials	
Printed Material and Online Materials	
Written teaching tools available in print or online as pamphlets, booklets, brochures	Material must be easy to read. Information must be accurate and current. Method is ideal for understanding complex concepts and relationships.
Programmed Instruction	
Written sequential presentation of learning steps requiring that learners answer questions and teachers tell them whether they are right or wrong	Instruction is primarily verbal, but teacher sometimes uses pictures or diagrams. Method requires active learning, giving immediate feedback, correcting wrong answers, and reinforcing right answers. Learner works at own pace.
Computer Instruction	
Use of programmed instruction format in which computers store response patterns for learners and select further lessons on basis of these patterns (programs can be individualized)	Method requires reading comprehension, psychomotor skills, and familiarity with computer.
Nonprint Materials	
Diagrams	
Illustrations that show interrelationships by means of lines and symbols	Method demonstrates key ideas, summarizes, and clarifies key concept.
Graphs (Bar, Circle, or Line)	
Visual presentations of numerical data	Graphs help learner grasp information quickly about single concept.
Charts	
Highly condensed visual summary of ideas and facts that highlights series of ideas, steps, or events	Charts demonstrate relationship of several ideas or concepts. Method helps learners know what to do.
Pictures	
Photographs or drawings used to teach concepts in which the third dimension of shape and space is not important	Photographs are more desirable than diagrams because they more accurately portray the details of the real item.
Physical Objects	
Use of actual equipment, objects, or models to teach concepts or skills	Models are useful when real objects are too small, large, or complicated or are unavailable. Allows learners to manipulate objects that they will use later in skill.
Other Audiovisual Materials	
Slides, audiotapes, television, and videotapes used with printed material or discussion	Materials are useful for patients with reading comprehension problems and visual deficits.

FIG. 25-3 The preschool child learns not to be afraid of medical equipment by being allowed to handle the stethoscope and imitating its use.

teaching methods to enhance functioning. Older adults learn and remember effectively if the nurse paces the learning properly and if the material is relevant to the learner's needs and abilities. Although many older adults have slower cognitive function and reduced short-term memory, you facilitate learning in several ways to support behaviors that maximize the individual's capacity for self-care (Box 25-8).

Establish short-term goals when teaching older patients. Include family members who assume care for the patient. However, be sensitive to the patient's desire for assistance because offering unwanted support often results in negative outcomes and perceptions of nagging and interference. Furthermore, not all relationships between older adults and other family members are therapeutic. Because of the high incidence of abuse and neglect of older adults, assess family dynamics before including family members in educational sessions.

EVALUATION

Through the Patient's Eyes. Patient education is not complete until you evaluate outcomes of the teaching-learning process (see Care Plan). Engage patients in the evaluation process to determine if they have learned essential material. It is also important to determine if patients believe they have the information necessary to continue self-care activities within the home. This is why it is important to evaluate through the patient's eyes, respecting the type of situations patients return to after receiving care. Evaluation reinforces correct behavior, helps learners realize how to change incorrect behavior, and helps the teacher determine adequacy of teaching (Redman, 2007).

Patient Outcomes. The nurse is legally responsible for providing accurate, timely patient information that promotes continuity of care; therefore it is essential to document the outcomes of teaching. Documentation of patient teaching also supports quality improvement efforts, meets TJC's standards, and promotes third-party reimbursement. Teaching flow sheets and written plans of care (e.g., CareMaps) are excellent records that document the plan, implementation, and evaluation of learning.

BOX 25-8 FOCUS ON OLDER ADULTS

Providing Patient Education

You facilitate learning by using the following interventions when providing patient education to older adults:

- Begin and end each teaching session with the most important information.
- Present information slowly.
- Speak in a low tone of voice (lower tones are easier to hear than higher tones).
- Allow enough time for understanding the material.
- Emphasize concrete material that applies to current situations.
- Present only crucial information to avoid overwhelming the learner.
- Provide specific information in frequent, small amounts.
- Repeat important information.
- Relate new material to previous life experiences.
- Build on existing knowledge.
- Allow patients to progress at their own pace (older adults are more cautious; thus it may take longer to adopt a behavior change).
- Use group experiences if appropriate to enhance problem solving.
- If using written material, assess patient's ability to read and use information that is printed in large type and in a color that contrasts highly with the background (e.g., black 14-point print on buff-colored paper). Avoid blues and greens because they are more difficult to see.

Data from Ebersole P et al: *Toward healthy aging,* ed 7, St Louis, 2008, Mosby; Edelman CL, Mandle CL: *Health promotion throughout the lifespan,* ed 7, St Louis, 2010, Mosby.

You evaluate success by observing a patient's performance of each expected behavior. Success depends on a patient's ability to meet the established outcome and goals. Carefully phrase questions to ensure that the learner understands them and that objectives are truly measured. Questions to ask when evaluating patient education include the following:

- Were the patient's goals or outcomes realistic and observable?
- Did the patient value the information provided?
- Was the patient willing to change an existing or adopt a new behavior?
- What barriers prevented learning or change in behaviors?
- Is the patient able to perform the behavior or skill in the natural setting (e.g., home)?
- How well is the patient able to answer questions about the topic?
- If the patient is completing a log, how well does the log match what was taught?
- Does the patient continue to have problems understanding the information or performing a skill? If so, how can the nurse change the interventions to enhance knowledge or skill performance?

KEY POINTS

- The nurse ensures that patients, families, and communities receive information needed to promote, restore, and maintain optimal health.
- Teaching is most effective when it is responsive to a learner's needs.
- Teaching is a form of interpersonal communication, with the teacher and learner actively involved in a process that increases the learner's knowledge and skills.

- The ability to learn depends on a person's physical and cognitive attributes.
- The ability to attend to the learning process depends on physical comfort and anxiety levels and the presence of environmental distraction.
- A person's health beliefs influence the willingness to gain knowledge and skills necessary to maintain health.
- Use of a theory (e.g., social learning theory) or theoretical concepts (e.g., self-efficacy) enhances learning.
- Time teaching so it occurs when a patient is ready to learn.
- Patients of different age-groups require different teaching strategies because of developmental capabilities.
- Involve patients actively in all aspects of teaching plans.
- Nurses use learning objectives to set learning priorities.
- A combination of teaching methods improves the learner's attentiveness and involvement.
- A teacher is more effective when presenting information that builds on a learner's existing knowledge.
- Effective teachers use positive reinforcement.
- Older adults learn most effectively when information is paced slowly and presented in small amounts.
- Evaluate a patient's learning by observing performance of expected learning behaviors under desired conditions.
- Effective documentation describes the entire process of patient education, promotes continuity of care, and demonstrates that educational standards have been met.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

While Connie is providing preoperative teaching, she provides Mr. Holland with several teaching brochures that explain what colorectal cancer is and what to expect before, during, and after the surgery. Mr. Holland reads through the brochures and nods his head as if he understands the material.

1. To evaluate Mr. Holland's learning, Connie asks him to verbalize what he read in his own words. He has trouble describing it. Connie asks him questions about information in the brochures and discovers that he misunderstood much of the information. What do these assessment data suggest about Mr. Holland's health literacy? What special considerations does Connie need to implement at this time?
2. The surgeon comes to see Mr. Holland after surgery. A new nurse, John, is in the hospital room at this time. The surgeon tells Mr. Holland that his cancer is aggressive and that he will probably need to have chemotherapy once the incision is healed. The surgeon leaves the room. John turns to Mr. Holland. He states, "I'm sure the doctor is wrong. After all, he's a surgeon, not an oncologist." Which stage of grieving is Mr. Holland experiencing? What approach should John take in planning education for him?
3. Mr. Holland has been discharged. In planning discharge teaching, John reviews the medications Mr. Holland will be taking at home. He notices that his physician has prescribed three new medications. When John asks Mr. Holland what he understands about them, he states, "I've never heard of these medications." When John asks him to explain when he should take the medications, Mr. Holland is unable to do so correctly. What is the nursing diagnosis for this situation?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A patient needs to learn to use a walker. Which domain is required for learning this skill?
   1. Affective domain
   2. Cognitive domain
   3. Attentional domain
   4. Psychomotor domain
2. The nurse is planning to teach a patient about the importance of exercise. When is the best time for teaching to occur? (Select all that apply.)
   1. When there are visitors in the room
   2. When the patient's pain medications are working
   3. Just before lunch, when the patient is most awake and alert
   4. When the patient is talking about current stressors in his or her life
3. A patient newly diagnosed with cervical cancer is going home. The patient is avoiding discussion of her illness and postoperative orders. What is the nurse's best plan in teaching this patient?
   1. Teach the patient's spouse
   2. Focus on knowledge the patient will need in a few weeks
   3. Provide only the information that the patient needs to go home
   4. Convince the patient that learning about her health is necessary
4. The school nurse is about to teach a freshman-level high school health class about nutrition. What is the best instructional approach to ensure that the students meet the learning outcomes?
   1. Provide information using a lecture
   2. Use simple words to promote understanding
   3. Develop topics for discussion that require problem solving
   4. Complete an extensive literature search focusing on eating disorders
5. A nurse is going to teach a patient how to perform breast self-examination. Which behavioral objective does the nurse set to best measure the patient's ability to perform the examination?
   1. The patient will verbalize the steps involved in breast self-examination within 1 week.
   2. The nurse will explain the importance of performing breast self-examination once a month.
   3. The patient will perform breast self-examination correctly on herself before the end of the teaching session.
   4. The nurse will demonstrate breast self-examination on a breast model provided by the American Cancer Society.
6. A patient with chest pain is having an emergency cardiac catheterization. Which teaching approach does the nurse use in this situation?
   1. Telling approach
   2. Selling approach
   3. Entrusting approach
   4. Participating approach
7. The nurse is teaching a parenting class to a group of pregnant adolescents. The nurse pretends to be the baby's father, and the adolescent mother is asked to show how she would respond to the father if he gave her a can of beer. Which teaching approach did the nurse use?
   1. Role play
   2. Discovery

3. An analogy
4. A demonstration

8. An older adult is being started on a new antihypertensive medication. In teaching the patient about the medication, the nurse:
   1. Speaks loudly.
   2. Presents the information once.
   3. Expects the patient to understand the information quickly.
   4. Allows the patient time to express himself or herself and ask questions.
9. A patient needs to learn how to administer a subcutaneous injection. Which of the following reflects that the patient is ready to learn?
   1. Describing difficulties a family member has had in taking insulin
   2. Expressing the importance of learning the skill correctly
   3. Being able to see and understand the markings on the syringe
   4. Having the dexterity needed to prepare and inject the medication
10. A patient who is hospitalized has just been diagnosed with diabetes. He is going to need to learn how to give himself injections. Which teaching method does the nurse use?
    1. Simulation
    2. Demonstration
    3. Group instruction
    4. One-on-one discussion
11. When a nurse is teaching a patient about how to administer an epinephrine injection in case of a severe allergic reaction, he or she tells the patient to hold the injection like a dart. Which of the following instructional methods did the nurse use?
    1. Telling
    2. Analogy
    3. Demonstration
    4. Simulation
12. A nurse needs to teach a young woman newly diagnosed with asthma how to manage her disease. Which of the following topics does the nurse teach first?
    1. How to use an inhaler during an asthma attack
    2. The need to avoid people who smoke to prevent asthma attacks
    3. Where to purchase a medical alert bracelet that says she has asthma
    4. The importance of maintaining a healthy diet and exercising regularly
13. A nurse is teaching a group of young college-age women the importance of using sunscreen when going out in the sun. What type of content is the nurse providing?
    1. Simulation
    2. Restoring health
    3. Coping with impaired function
    4. Health promotion and illness prevention
14. A nurse is planning a teaching session about healthy nutrition with a group of children who are in first grade. The nurse determines that after the teaching session the children will be able to name three examples of foods that are fruits. This is an example of:
    1. A teaching plan.
    2. A learning objective.
    3. Reinforcement of content.
    4. Enhancing the children's self-efficacy.
15. A nurse is teaching a 27-year-old gentleman how to adjust his insulin dosages based on his blood sugar results. What type of learning is this?
    1. Cognitive
    2. Affective
    3. Adaptation
    4. Psychomotor

CHAPTER

26

Documentation and Informatics

OBJECTIVES

- Describe methods for interdisciplinary communication within the health care team.
- Identify purposes of a health care record.
- Discuss legal guidelines for documentation.
- Identify ways to maintain confidentiality of electronic and written records.
- Describe five quality guidelines for documentation and reporting.
- Discuss the relationship between documentation and financial reimbursement for health care.
- Describe the different methods used in record keeping.
- Discuss the advantages of standardized documentation forms.
- Identify elements to include when documenting a patient's discharge plan.
- Identify the important aspects of home care and long-term care documentation.
- Describe the purpose and content of a hand-off report.
- Explain when to take and how to verify telephone orders.
- Discuss the relationship between informatics and quality health care.
- Describe the advantages of a nursing information system.
- Identify ways to reduce data entry errors.

Documentation is anything written or printed on which you rely as record or proof of patient actions and activities. Documentation in a patient's medical record is a vital aspect of nursing practice. Nursing documentation must be accurate, comprehensive, and flexible enough to retrieve clinical data, maintain continuity of care, track patient outcomes, and reflect current standards of nursing practice. Information in the patient record provides a detailed account of the level of quality of care delivered to patients. Effective documentation ensures continuity of care, saves time, and minimizes the risk of errors.

There are several documentation systems for recording patient data. Regardless whether documentation is entered electronically or on paper, as a member of the health care team you communicate information about patients in an accurate, timely, and effective manner. The quality of patient care depends on your ability to communicate with other members of the health care team. All health care providers require the same information about patients to develop an organized, comprehensive plan of care. When a plan is not communicated to all members of the health care team, care becomes fragmented, tasks are repeated, and often delays or omissions in therapy occur.

The health care environment creates many challenges for accurately documenting and reporting the care delivered to patients. The quality of care, the standards of regulatory agencies and nursing practice, the reimbursement structure in the health care system, and legal guidelines make documentation and reporting an extremely important responsibility of a nurse. Whether the transfer of patient information occurs through verbal reports, written documents, or electronically, you need to follow basic principles to maintain confidentiality of information.

CONFIDENTIALITY

Nurses are legally and ethically obligated to keep information about patients confidential. They may not discuss a patient's examination, observation, conversation, diagnosis, or treatment with other patients or staff not involved in the patient's care. Only staff directly involved in a patient's care have legitimate access to the records. Patients frequently request copies of their medical records, and they have the right to read them. Each institution has policies to control the manner for sharing records. In most situations patients are required to give written permission for release of medical information.

Legislation to protect patient privacy for health information, the Health Insurance Portability and Accountability Act (HIPAA), governs all areas of patient information and management of that information. To eliminate barriers that could delay access to care, providers are required to notify patients of their privacy policy and make a reasonable effort to obtain written acknowledgment of this notification. HIPAA requires that disclosure or requests regarding health information are limited to the minimum necessary. This includes only the specific information required for a particular purpose. For example, if you need a patient's home telephone number to reschedule an appointment, access to the medical records is limited solely to telephone information.

Sometimes nurses use health care records for data gathering, research, or continuing education. As long as a nurse uses a record as specified and permission is granted, this is permitted. When you are a student in a clinical setting, confidentiality and compliance with HIPAA are part of professional practice. You can review your patients' medical records only for information needed to provide safe and effective patient care. For example, when you are assigned to care for a patient, you need to review the patient's medical record and plan of care. You *do not* share this information with classmates (except for clinical conferences) and *do not* access the medical records of other patients on the unit. Access to electronic health records is traceable through user log-in information. Not only is it unethical to view medical records of other patients, but breaches of confidentiality can lead to disciplinary action by employers and dismissal from work or nursing school. To protect patient confidentiality, ensure that written or electronic materials used in your student clinical practice *do not* include patient identifiers (e.g., room number, date of birth, demographic information) and *never* print material from an electronic health record for personal use.

STANDARDS

Within a health care organization there are standards that govern the type of information you document and for which you are accountable. Institutional standards or policies often dictate the frequency of documentation such as how often you record a nursing assessment or a patient's level of pain. Know the standards of your health care organization to ensure complete and accurate documentation. Nurses are expected to meet the standard of care for every nursing task they perform. Patient records can be used as evidence in a court of law if standards are not met (ANA, 2005).

In addition, your documentation needs to conform to the standards of the National Committee for Quality Assurance (NCQA) and accrediting bodies such as The Joint Commission (TJC) to maintain institutional **accreditation** and minimize liability. Usually an organization incorporates accreditation standards into its policies and revises documentation forms to suit these standards. Current documentation standards require that all patients admitted to a health care facility have an assessment of physical, psychosocial, environmental, self-care, knowledge level, and discharge planning needs. TJC standards require that your documentation be within the context of the nursing process, including evidence of patient and family teaching and discharge planning (TJC, 2011). Other standards such as HIPAA include those directed by state and federal regulatory agencies and are enforced through the Department of Justice and the Centers for Medicare and Medicaid Services (ANA, 2005).

INTERDISCIPLINARY COMMUNICATION WITHIN THE HEALTH CARE TEAM

Patient care requires effective communication among members of the health care team. Effective communication takes place along two approaches. A patient's record or chart is a confidential, permanent legal documentation of information relevant to his or her health care. The record is a continuing account of the patient's health care status and is available to all members of the health care team. All records contain the following information:

- Patient identification and demographic data
- Informed consent for treatment and procedures
- Admission data
- Nursing diagnoses or problems and nursing or interdisciplinary care plan
- Record of nursing care treatment and evaluation
- Medical history
- Medical diagnoses
- Therapeutic orders
- Medical and health discipline progress notes
- Physical assessment findings
- Diagnostic study results
- Patient education
- Summary of operative procedures
- Discharge plan and summary

Reports are oral, written, or audiotaped exchanges of information among caregivers. Common reports given by nurses include change-of-shift reports, telephone reports, hand-off reports, and incident reports. A health care provider calls a nursing unit to receive a verbal report on a patient's condition. The laboratory submits a written report providing the results of diagnostic tests and often notifies the nurse by telephone if results are critical.

Team members communicate information through discussions or conferences. For example, a discharge planning conference involves members of all disciplines (e.g., nursing, social work, dietary, medicine, and physical therapy) who meet to discuss the patient's progress toward established discharge goals. **Consultations** are another form of discussion in which one professional caregiver gives formal advice about the care of a patient to another caregiver. For example, a nurse caring for a patient with a chronic wound consults with a wound care specialist. Nurses document **referrals** (an arrangement for services by another care provider), consultations, and conferences in a patient's permanent record to allow all caregivers to plan care accordingly.

PURPOSES OF RECORDS

The patient record is a valuable source of data for all members of the health care team. Its purposes include communication, legal documentation, financial billing, education, research, and auditing/monitoring.

Communication

The patient's record is one way that health care team members communicate patient needs and progress, individual therapies, content of consultations, patient education, and discharge planning. The plan of care needs to be clear to anyone reading the chart (see Unit 3). The record is the most current and accurate continuous source of information about a patient's health care status. Information communicated in the patient's record allows health care providers to know a patient thoroughly, facilitating safe, effective, and timely patient-centered decisions. To enhance communication and promote safe patient care, you base communication on assessment findings and document patient information as you provide care (e.g., immediately after providing a nursing intervention or completing a patient assessment).

Legal Documentation

Accurate documentation is one of the best defenses for legal claims associated with nursing care (see Chapter 23). To limit nursing liability nursing documentation must indicate clearly that a patient received individualized, goal-directed nursing care based on the nursing assessment. The record must describe exactly what happened to a patient and follow agency standards. This is best achieved when you chart immediately after providing care. Even though nursing care may have been excellent, in a court of law "care not documented is care not provided."

Common charting mistakes that result in malpractice include: (1) failing to record pertinent health or drug information, (2) failing to record nursing actions, (3) failing to record that medications have been given, (4) failing to record drug reactions or changes in patients' conditions, (5) writing illegible or incomplete records, and (6) failing to document discontinued medications. Table 26-1 provides guidelines for legally sound documentation.

Reimbursement

Diagnosis-related groups (DRGs) are the basis for establishing reimbursement for patient care. A DRG is a classification based on patients' medical diagnoses. Hospitals are reimbursed a predetermined dollar amount by Medicare for each DRG. Detailed recording establishes diagnoses for determining a DRG. Your documentation clarifies the type of treatment a patient receives and supports reimbursement to the health care agency.

A medical record audit reviews financial charges used in the patient's care. Private insurance carriers and auditors from federal agencies review records to determine the reimbursement that a patient or a health care agency receives. Accurate documentation of supplies and equipment used assists in accurate and timely reimbursement.

Education

A patient's record contains a variety of information, including diagnoses, signs and symptoms of disease, successful and unsuccessful therapies, diagnostic findings, and patient behaviors. One way to learn the nature of an illness and the individual patient's response to it is to read the patient care record. No two patients have identical records, but you can identify patterns of information in records of patients who have similar health problems. With this information you learn to anticipate the type of care required for a patient.

Research

After obtaining appropriate agency approvals, nurse researchers often use patients' records for research studies to gather statistical data on the frequency of clinical disorders, complications, use of specific medical and nursing therapies, recovery from illness, and deaths. Researchers also use this information to investigate nursing interventions or health problems. For example, a nurse wants to compare a new method of pain control with a standard pain protocol using two groups of patients. The records provide data on the two types of interventions: the new method and the standard pain control. The nurse researcher collects data from the records that describe the type and dose of analgesic medications used, objective assessment data, and patients' subjective reports of pain relief. The researcher then compares the findings to determine if the new method was more effective than the standard pain control protocol. Analysis of the data contributes to evidence-based nursing practice and quality health care (see Chapter 5).

Auditing and Monitoring

Hospitals establish quality improvement programs for conducting objective, ongoing reviews of patient care. Quality improvement programs keep nurses informed of standards of nursing practice to maintain excellence in nursing care. Accrediting agencies such as TJC (2011) require quality improvement programs and set standards for the information located in a patient's record, including indications that a plan of care is developed with the patient as a participant and that discharge planning and patient education have occurred. Institutions and accrediting groups establish standards for quality care. Nurses audit records throughout the year to determine the degree to which standards of care are met and identify areas needing improvement and staff development (see Chapter 5). Nurses share deficiencies identified during monitoring with all members of the nursing staff to make changes in policy or practice.

GUIDELINES FOR QUALITY DOCUMENTATION AND REPORTING

High-quality documentation and reporting are necessary to enhance efficient, individualized patient care. Quality documentation and reporting have five important characteristics: they are factual, accurate, complete, current, and organized.

Factual

A factual record contains descriptive, objective information about what a nurse sees, hears, feels, and smells. An objective description is the result of direct observation and measurement. For example, "B/P 80/50, patient diaphoretic, heart rate 102 and regular." Avoid vague terms such as *appears, seems,* or *apparently* because these words suggest that you are stating an opinion, do not accurately communicate facts, and do not inform another caregiver of the details regarding the behaviors exhibited by a patient. Objective documentation includes observations of a patient's behaviors. For example, instead of documenting "the patient seems anxious," provide objective signs of anxiety and document "the patient's pulse rate is elevated at 110 beats/min, respiratory rate is slightly labored at 22 breaths/min, and the patient reports increased restlessness."

The only subjective data included in the record are what the patient says. When recording subjective data, document the patient's exact words within quotation marks whenever possible. For example, when he or she exhibits anxiety, you record, "Patient states, 'I feel very nervous.'" Include objective data to support subjective data so your charting is as descriptive as possible.

TABLE 26-1 Legal Guidelines for Recording

GUIDELINES	RATIONALE	CORRECT ACTION
Do not erase, apply correction fluid, or scratch out errors made while recording.	Charting becomes illegible: it appears as if you were attempting to hide information or deface a written record.	Draw single line through error, write word *error* above it, and sign your name or initials and date it. Then record note correctly.
Do not document retaliatory or critical comments about patient or care by other health care professionals. Do not enter personal opinions.	Statements can be used as evidence for nonprofessional behavior or poor quality of care.	Enter only objective and factual observations of patient's behavior; quote all patient comments.
Correct all errors promptly.	Errors in recording can lead to errors in treatment or may imply an attempt to mislead or hide evidence.	Avoid rushing to complete charting; be sure that information is accurate and complete.
Record all facts.	Record must be accurate, factual, and objective.	Be certain entry is factual and thorough. A person reading the documentation should be able to determine that patient had adequate care.
Do not leave blank spaces in nurses' notes.	Another person can add incorrect information in space.	Chart consecutively, line by line; if space is left, draw line horizontally through it and sign your name at end.
Record all written entries legibly and in black ink. Do not use felt-tip pens or erasable ink.	Illegible entries can be misinterpreted, causing errors and lawsuits; ink from felt-tip pen smudges or runs when wet and may destroy documentation; erasures are not permitted in patient charting; black ink is more legible when records are photocopied or scanned.	Never erase entries or use correction fluid and never use pencil.
If an order is questioned, record that clarification was sought.	If you perform order known to be incorrect, you are just as liable for prosecution as the health care provider.	Do not record "physician made error." Instead, chart that "Dr. Smith was called to clarify order for analgesic." Include the date and time of phone call, with whom you spoke, and the outcome.
Chart only for yourself.	You are accountable for information that you enter into a patient's record.	Never chart for someone else (exception: if caregiver has left unit for day and calls with information that needs to be documented; include date and time of entry and reference specific date and time to which you are referring and name of source of information in entry; include that information was provided via telephone).
Avoid using generalized, empty phrases such as "status unchanged" or "had good day."	This type of documentation is subjective and does not reflect patient assessment.	Use complete, concise descriptions of care so documentation is objective and factual.
Begin each entry with date and time and end with your signature and title.	This guideline ensures that correct sequence of events is recorded; signature documents who is accountable for care delivered.	Do not wait until end of shift to record important changes that occurred several hours earlier; be sure to sign each entry (e.g., Mary Marcus, RN).
For computer documentation keep your password to yourself.	This maintains security and confidentiality.	Once logged into computer, do not leave computer screen unattended. Log out when you leave the computer. Make sure that computer screen is not accessible for public viewing.

Accurate

The use of exact measurements establishes accuracy. For example, a description such as "Intake, 360 mL of water" is more accurate than "Patient drank an adequate amount of fluid." Charting that an abdominal wound is "5 cm in length without redness, drainage, or edema" is more descriptive than "large wound healing well." Accurate measurements help you determine if a patient's condition has changed.

Documentation of concise data is clear and easy to understand. It is essential to avoid the use of unnecessary words and irrelevant detail. For example, the fact that the patient is watching television is only necessary when this activity is significant to the patient's status and plan of care.

To ensure patient safety use abbreviations carefully to avoid misinterpretation. TJC's "do not use" list of abbreviations (see Chapter 31) is used by all health care providers to promote patient safety. In addition, TJC (2011) requires that health care institutions develop a list of standard abbreviations, symbols, and acronyms to be used by all members of the health care team when documenting or communicating patient care and treatment. To minimize errors spell out abbreviations in their entirety when they become confusing.

Correct spelling demonstrates a level of competency and attention to detail. Many terms can easily be misinterpreted (e.g., *dysphagia* or *dysphasia* and *dram* or *gram*). Some spelling errors result in serious treatment errors (e.g., the names of certain medications such as Lamictal and Lamisil or morphine and Numorphan are similar). Transcribe such terms carefully to ensure that the patient receives the correct medication.

All entries in medical records must be dated, and there must be a method to identify the authors of all entries (TJC, 2011). Each entry in a patient's record ends with the caregiver's full name or initials and status such as "Jane Woods, RN." When initials are used, the full name and status of the individual are found in the medical record to allow others to readily identify the individual. As a nursing student, enter your full name and nursing student (NS) abbreviation, such as "David Jones, NS. The abbreviation for *nursing student* varies between *NS* for *nursing student* or *SN* for *student nurse*. Include your educational institution when required by agency policy.

Complete

The information within a recorded entry or a report must be complete, containing appropriate and essential information. Criteria for thorough communication exist for certain health problems or nursing activities (Table 26-2). Your written entries in a patient's medical record describe the nursing care you administer and the patient's response. An example of a thorough nurse's note follows:

1915 Verbalizes sharp, throbbing pain localized along lateral side of right ankle, beginning approximately 15 minutes ago after twisting his foot on the stairs. Rates pain as 8 on a scale of 0-10. Pain increased with movement, slightly relieved with elevation. Pedal pulses equal bilaterally. Right ankle circumference 1 cm larger than left. Bilateral lower extremities warm, pale pink, skin intact, responds to tactile stimulation and capillary refill less than 3 seconds. Ice applied to right ankle. Percocet 2 tabs (PO) given for pain. States pain somewhat relieved with ice, rates pain as 6 on a scale of 0-10. Dr. M. Smith notified. Lee Turno, RN

1945 Rates pain as a 3 on a scale of 0-10. States, "The pain medication really helped." Lee Turno, RN

You frequently use flow sheets or graphic records when documenting routine activities such as daily hygiene care, vital signs, and pain assessments. Describe these data in greater detail when they are relevant such as when a change in functional ability or status occurs. For example, if your patient's blood pressure, pulse, and respirations are elevated above expected values following a walk down the hall, document additional description about the patient's status and response to the walk in the appropriate place in the medical record (e.g., nurse's notes).

Current

Timely entries are essential in a patient's ongoing care. Delays in documentation lead to unsafe patient care. To increase accuracy and decrease unnecessary duplication, many health care agencies keep records or computers near a patient's bedside to facilitate immediate documentation of information as it is collected from a patient. Document the following activities or findings at the time of occurrence:

- Vital signs
- Pain assessment
- Administration of medications and treatments
- Preparation for diagnostic tests or surgery, including preoperative checklist

TABLE 26-2 Examples of Criteria for Reporting and Recording

TOPIC	CRITERIA TO REPORT OR RECORD
Assessment	
Subjective data	Patient's description of episode in quotation marks (e.g., "I feel like an elephant is sitting on my chest, and I can't catch my breath.") Describe in patient's own words the onset, location, description of condition (severity, duration, frequency, precipitating, aggravating and relieving factors) (e.g., "The pain in my left knee started last week after I knelt on the ground. Every time I bend my knee I have a shooting pain on the inside of the knee.")
Patient behavior (e.g., anxiety, confusion, hostility)	Onset, behaviors exhibited, precipitating factors, patient's verbal behavior (e.g., pacing in room, avoiding eye contact with nurse, and repeatedly stating, "I have to go home now.")
Objective data (e.g., rash, tenderness, breath sounds)	Onset, location, description of condition (see previous criteria) (e.g., 1100: 2-cm raised pale red area noted on back of left hand)
Nursing Interventions and Evaluation	
Treatments (e.g., enema, bath, dressing change)	Time administered, equipment used (if appropriate), patient's response (objective and subjective changes) compared to previous treatment (e.g., denied incisional pain during abdominal dressing change, ambulated 300 feet in hallway without assistance)
Medication administration	Immediately after administration document: time medication given, preliminary assessment (e.g., pain level, vital signs), patient response or effect of medication; for example: 1500: Reports a "throbbing headache all over my head." Rates pain at 6 (scale 0-10). Tylenol 650 mg given PO. 1530: Patient reports pain level 2 (scale 0-10) and states "the throbbing has stopped."
Patient teaching	Information presented, method of instruction (e.g., discussion, demonstration, videotape, booklet), and patient response, including questions and evidence of understanding such as return demonstration or change in behavior
Discharge planning	Measurable patient goals or expected outcomes, progress toward goals, need for referrals

- Change in patient's status and who was notified (e.g., physician, manager, patient's family)
- Admission, transfer, discharge, or death of a patient
- Treatment for sudden change in patient's status
- Patient's response to treatment or intervention

Most health care agencies use military time, a 24-hour system that avoids misinterpretation of AM and PM times (Fig. 26-1). Instead of two 12-hour cycles in standard time, the military clock is one 24-hour time cycle. The military clock ends with midnight at 2400 and begins at 1 minute after midnight as 0001. For example, 10:22 AM is 1022 military time; 1:00 PM is 1300 military time.

Organized

Communicate information in a logical order. It is also more effective when notes are concise, clear, and to the point. To document notes about complex situations in an organized fashion think about the situation and make a list of what you need to include before beginning to enter data in the medical record. Applying critical thinking skills and the nursing process gives logic and order to nursing documentation. For example, an organized entry describes the patient's pain, your assessment and interventions, and the patient's response. Use the nursing process to give logic and organization to your documentation.

METHODS OF DOCUMENTATION

There are several documentation systems for recording patient data. Regardless whether documentation is entered electronically or on paper, each health care agency selects a documentation system that reflects its philosophy of nursing. The same system is used throughout a specific agency and may be used throughout a health care system as well.

Paper and Electronic Health Records

Traditionally health care professionals documented on paper medical records. Paper records are episode oriented, with a separate record for each patient visit to a health care agency (Hebda et al., 2009). Key information such as patient allergies, current medications, and complications from treatment may be lost from one episode of care (e.g., hospitalization or clinic visit) to the next, jeopardizing a patient's safety.

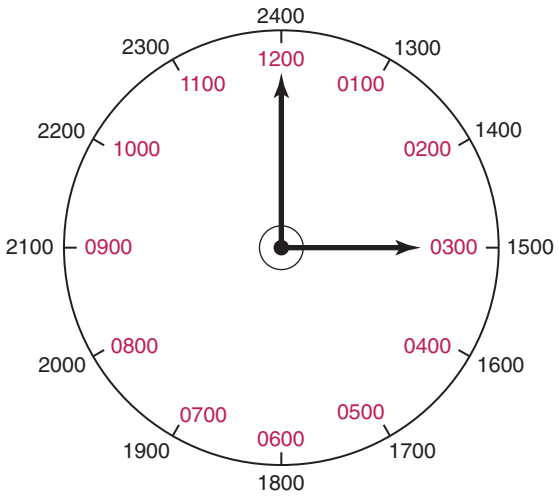

FIG. 26-1 Comparison of 24 hours of military time with the hourly positions for civilian time on the clock face.

To enhance communication among health care providers and thus patient safety, the American Recovery and Reinvestment Act of 2009 set a goal that all medical records will be kept electronically as of 2014. Many professional organizations and accrediting body initiatives also support initiation of the **electronic health record (EHR).** The EHR is an electronic record of patient health information generated whenever a patient accesses medical care in any health care delivery setting (HIMSS, 2003). Although the **electronic medical record (EMR)** contains patient data gathered in a health care setting at a specific time and place and is a part of the EHR, the two terms are frequently used interchangeably (Garets and Davis, 2005; Hebda et al., 2009).

The EHR provides access to a patient's health record information at the time and place that clinicians need it. A unique feature of an EHR is its ability to integrate all pertinent patient information into one record, regardless of the number of times a patient enters a health care system. An EHR also includes results of diagnostic studies that may include images and sound and decision support software programs. Because an unlimited number of patient records potentially can be stored within an EHR system, health care providers can access clinical data to identify quality issues, link interventions with positive outcomes, and make evidence-based decisions.

The EHR improves continuity of health care from one episode of illness to another. A clinician accesses relevant and timely information about a patient and focuses on the priority problems of care to make timely, well-informed clinical decisions. An EHR is a powerful tool because of the decision support resources it contains. For example, in a hospital setting an EHR gathers data and performs checks to support regulatory and accreditation requirements. An EHR includes tools to guide and critique medication administration (see Chapter 31) and basic decision support tools such as physician order sets and interdisciplinary treatment plans.

The ultimate development of an EHR for all patients will affect the entire health care community. Currently the American Medical Association, American Nurses Association, the HIMSS, and the American Medical Informatics Association are just some of the organizations gathering information from health care professionals to support the adoption of EHR standards (Hebda et al., 2009). All disciplines and health care organizations will benefit from the implementation of an EHR. The key advantages of an EHR for nursing include providing a means to compare ongoing clinical data about a patient with original baseline information and maintaining an ongoing record of a patient's health education. In addition, the EHR offers easier access to quality data for research and automates evidence-based guidelines.

Narrative Documentation

Narrative documentation is the traditional method for recording nursing care. It is simply the use of a story-like format to document information specific to patient conditions and nursing care. However, narrative charting has many disadvantages, including the tendency to be repetitious and time consuming and to require the reader to sort through much information to locate desired data (Box 26-1).

Problem-Oriented Medical Record

The **problem-oriented medical record (POMR)** is a method of documentation that emphasizes patients' problems. Data are organized by problem or diagnosis. Ideally each member of the health care team contributes to a single list of identified patient problems. This approach coordinates a common plan of care. The POMR has

BOX 26-1 EXAMPLES OF PROGRESS NOTES WRITTEN IN DIFFERENT FORMATS

Narrative Note

Stated "I'm dreading surgery. Last time I had a lot of pain when I got out of bed." Discussed alternatives for pain control and importance of postoperative activity. Encouraged to ask for pain medication before pain becomes severe. Stated, "I feel better prepared now." Verbalized positive effect of activity on healing and circulation.

SOAP (Subjective—Objective—Assessment—Plan)

S—"I'm worried about what it will be like after surgery."
O—Asking frequent questions about surgery. Has had no previous experience with surgery. Wife present and supportive.
A—Deficient knowledge regarding surgery related to inexperience. Patient also expressing anxiety.
P—Explain routine preoperative preparation. Demonstrate and explain rationale for turning, coughing, and deep breathing (TCDB) exercises. Provide explanation and teaching booklet on postoperative nursing care.

PIE (Problem—Intervention—Evaluation)

P—Deficient knowledge regarding surgery related to inexperience.
I—Explained normal preoperative preparations for surgery. Demonstrated TCDB exercises. Provided booklet on postoperative nursing care.
E—Demonstrated TCDB exercises correctly. Needs review of postoperative nursing care.

Focus Charting (Data—Action—Response)

D—Stated, "I'm worried about what it will be like after surgery." Asking frequent questions about surgery. Has had no previous experience with surgery. Wife present and is supportive.
A—Explained normal preoperative preparations for surgery. Demonstrated TCDB exercises. Provided booklet on postoperative nursing care.
R—Demonstrates TCDB exercises correctly. Needs review of postoperative nursing care. States, "I feel better knowing a little bit of what to expect."

the following major sections: database, problem list, care plan, and progress notes.

Database. The database section contains all available assessment information pertaining to a patient (e.g., history and physical examination, the nurse's admission history and ongoing assessment, the dietitian's assessment, laboratory reports, and radiological test results). It is the foundation for identifying patient problems and planning care. As new data become available, you revise the database. It accompanies patients through successive hospitalizations or clinic visits.

Problem List. After analyzing data, health care team members identify problems and make a single problem list. The problem list includes the patient's physiological, psychological, social, cultural, spiritual, developmental, and environmental needs. Team members list the problems in chronological order and file the list in the front of the patient's record to serve as an organizing guide for his or her care. Add new problems as you identify them. When a problem is resolved, record the date and highlight it or draw a line through the problem and its number.

Care Plan. Disciplines involved in the patient's care develop a care plan or plan of care for each problem (see Chapter 18). Nurses document the plan of care in a variety of formats. Generally these plans of care include nursing diagnoses, expected outcomes, and interventions.

Progress Notes. Health care team members monitor and record the progress of a patient's problems. Progress notes come in various formats or structured notes. One method is SOAP charting (see Box 26-1). The acronym **SOAP** stands for:

S—Subjective data (verbalizations of the patient)
O—Objective data (that which is measured and observed)
A—Assessment (diagnosis based on the data)
P—Plan (what the caregiver plans to do).

An I and E are sometimes added (i.e., **SOAPIE**) in some institutions. The I stands for intervention, and the E represents evaluation. The logic for SOAPIE notes is similar to that of the nursing process. You collect data about a patient's problems, draw conclusions, and develop a plan of care. The nurse numbers each SOAP note and titles it according to the problem on the list.

A second progress note method is the **PIE** format. It is similar to SOAP charting in its problem-oriented nature. However, PIE charting differs from the SOAP method in that it has a nursing origin, whereas SOAP originated from medical records. The format simplifies documentation by unifying the care plan and progress notes. PIE differs from SOAP notes because the narrative does not include assessment information. A nurse's daily assessment data appear on flow sheets, preventing duplication of data. The narrative note includes P—Problem, I—Intervention, and E—Evaluation. The PIE notes are numbered or labeled according to the patient's problems. Resolved problems are dropped from daily documentation after the nurse's review. Continuing problems are documented daily.

A third narrative format is **focus charting.** It involves use of **DAR** notes, which include D—Data (both subjective and objective), A—Action or nursing intervention, and R—Response of the patient (i.e., evaluation of effectiveness). A DAR note addresses patient concerns: a sign or symptom, condition, nursing diagnosis, behavior, significant event, or change in a patient's condition (see Box 26-1). Documentation follows the nursing process. Nurses broaden their thinking to include any patient concerns, not just problem areas. Focus charting incorporates all aspects of the nursing process, highlights a patient's concerns, and can be integrated into any clinical setting (Mosby, 2006).

Source Records

In a **source record** a patient's chart has a separate section for each discipline (e.g., nursing, medicine, social work, or respiratory therapy) to record data. Caregivers can easily locate the proper section of the record in which to make entries. Table 26-3 lists the components of a source record. Details about a specific problem are distributed throughout the record. For example, the nurse describes the character of abdominal pain and the use of relaxation therapy and analgesic medication in the nurses' notes. The health care provider describes the progress of the patient's bowel obstruction and the plan for surgery in a separate section of the record. The results of x-ray film examinations that show the location of the bowel obstruction are in the test results section of the record. The method by which source records are organized does not show how information from the disciplines is related or how care is coordinated to meet all of the patient's needs.

Charting by Exception

Charting by exception (CBE) focuses on documenting deviations from established norms. This approach reduces documentation time and highlights trends or changes in a patient's condition (Mosby, 2006). It is a shorthand method for documenting normal findings and routine care based on clearly defined standards of

TABLE 26-3 Organization of Traditional Source Record

SECTIONS	CONTENTS
Admission sheet	Specific demographic data about patient: legal name, identification number, gender, age, birth date, marital status, occupation and employer, health insurance, nearest relative to notify in an emergency, religious preference, name of attending physician, date and time of admission
Physician's order sheet	Record of physician's or other health care provider's orders for treatment and medications with date, time, and signature
Nurse's admission assessment	Summary of nursing history and physical examination
Graphic sheet and flow sheet	Record of repeated observations and measurements such as vital signs, daily weights, and intake and output
Medical history and examination	Results of initial examination performed by physician, including findings, family history, confirmed diagnoses, and medical plan of care
Nurses' notes	Narrative record of nursing process: assessment, nursing diagnosis, planning, implementation, and evaluation of care
Medication records	Accurate documentation of all medications administered to patient: date, time, dose, route, and nurse's signature
Progress notes	Ongoing record of patient's progress and response to medical therapy and review of disease process; often is interdisciplinary and includes documentation from health-related disciplines (e.g., health care providers, physical therapy, social work)
Other health care records	Includes results from diagnostic tests (e.g., laboratory and x-ray film results), consent forms, and sometimes documentation from health-related disciplines (e.g., radiology, social work); organization of information varies per policies of health care agency
Discharge summary	Summary of patient's condition, progress, prognosis, rehabilitation, and teaching needs at time of dismissal from hospital or health care agency

practice and predetermined criteria for nursing assessments and interventions. With standards integrated into documentation forms such as predefined normal assessment findings or predetermined interventions, a nurse then only documents significant findings or exceptions to the predefined norms. The nurse writes a progress note only when the standardized statement on the form is not met. Assessments are standardized on forms so all caregivers evaluate and document findings consistently.

The assumption with charting by exception is that all standards are met unless otherwise documented. When you see entries in the chart, you know that something out of the ordinary has occurred. Thus, when changes in a patient's condition have developed, it is easy to track them. When patients' conditions change, enter thorough and precise descriptions of the effects of these changes on patients and the actions taken.

Case Management Plan and Critical Pathways

The **case management** model of delivering care (see Chapter 2) incorporates an interdisciplinary approach to documenting patient care. Many organizations summarize the standardized plan of care into critical pathways for a specific disease or condition. **Critical pathways** are interdisciplinary care plans that include patient problems, key interventions, and expected outcomes within an established time frame. All health care team members use the same critical pathway to monitor a patient's progress during each shift or, in the case of home care, every visit.

Critical pathways eliminate nurses' notes, flow sheets, and nursing care plans because the document integrates all relevant information. Unexpected outcomes, unmet goals, and interventions not specified within the critical pathway are called **variances.** A variance occurs when the activities on the critical pathway are not completed as predicted or the patient does not meet the expected outcomes. An example of a variance is when a patient develops pulmonary complications after surgery, requiring oxygen therapy and monitoring with pulse oximetry. A positive variance occurs when a patient progresses more rapidly than expected (e.g., use of a Foley catheter is discontinued a day early). A variance analysis is necessary to review the data for trends and for developing and implementing an action plan to respond to the identified patient problems (Box 26-2). In addition, variances often result from changes in the patient's health or because of other health complications not associated with the primary reason for which the patient requires care. Once you identify a variance, you modify the patient's care to meet the needs associated with the variance. Over time health care teams sometimes revise critical pathways if similar variances reoccur.

BOX 26-2 EXAMPLE OF VARIANCE DOCUMENTATION

A 56-year-old patient is on a surgical unit 1 day after surgery. He has an elevated temperature, his breath sounds are decreased bilaterally in the bases of both lobes of the lungs, and he is slightly confused. Ordinarily 1 day after surgery the patient should be afebrile with lungs clear. The following is an example of the variance documentation for this patient.

Breath sounds diminished bilaterally at the bases. T, 100.4; P, 92; R, 28/min; oxygen sat, 84%. Daughter states he is "confused" and did not recognize her when she arrived a few minutes ago. Oxygen started at 2 L per standing orders. Will monitor pulse oximetry and vital signs every 15 minutes. Physician notified of change in status. Daughter at bedside.

COMMON RECORD-KEEPING FORMS

A variety of paper or electronic forms are available for the type of information nurses routinely document. The categories within a form are usually derived from institutional standards of practice or guidelines established by accrediting agencies.

Admission Nursing History Forms

A nurse completes a nursing history form when a patient is admitted to a nursing unit. The form guides the nurse through a complete assessment to identify relevant nursing diagnoses or problems (see Chapter 16). Data provide baseline data to compare with changes in the patient's condition.

Flow Sheets and Graphic Records

Flow sheets allow you to quickly and easily enter assessment data about a patient, including vital signs and routine repetitive care such as hygiene measures, ambulation, meals, weights, and safety and restraint checks. They provide current patient information that is accessible to all members of the health care team. Because there is a coding system for data entry, flow sheets help team members quickly see patient trends over time and decrease time spent on writing narrative notes. If an occurrence on a flow sheet is unusual or changes significantly, enter a focus note. For example, if a patient's blood pressure becomes dangerously high, first complete a focus assessment. You record your assessment and the action taken in the progress notes. Critical and acute care units commonly use flow sheets for all types of physiological data.

Patient Care Summary or Kardex

Many hospitals now have computerized systems that provide information in the form of a patient care summary that is often printed for each patient during each shift. The summary automatically updates as nurses make decisions and data (e.g., orders) are entered into the computer. In some settings a **Kardex,** a portable "flip-over" file or notebook, is kept at the nurses' station. Most Kardex forms have an activity and treatment section and a nursing care plan section that organize information for quick reference. An updated Kardex eliminates the need for repeated referral to the chart for routine information throughout the day. The patient care summary or Kardex includes the following information:

- Basic demographic data (e.g., age, religion)
- Health care provider's name
- Primary medical diagnosis
- Medical and surgical history
- Current orders from health care provider (e.g., dressing changes, ambulation, glucose monitoring)
- Nursing care plan
- Nursing orders (e.g., education sessions, symptom relief measures, counseling)
- Scheduled tests and procedures
- Safety precautions used in the patient's care
- Factors related to activities of daily living
- Nearest relative/guardian or person to contact in an emergency
- Emergency code status (e.g., indication of "do not resuscitate" order)
- Allergies

Standardized Care Plans

Some institutions use **standardized care plans** to make documentation more efficient. The plans, based on the institution's standards of nursing practice, are preprinted, established guidelines used to care for patients who have similar health problems. After completing a nursing assessment, the nurse identifies the standard care plans that are appropriate for the patient and places the plans in his or her medical record. The nurse modifies the plans to individualize the therapies. Most standardized care plans also allow a nurse to add specific goals or desired outcomes of care and the dates by which these outcomes should be achieved.

Standardized care plans are useful when conducting quality improvement audits. They also improve continuity of care among professional nurses. When they are used in a health care facility, the nurse remains responsible for providing individualized care to each patient. Standardized care plans cannot replace a nurse's professional judgment and decision making. Update care plans on a regular basis to ensure that they are current and appropriate.

Discharge Summary Forms

To save costs and ensure appropriate reimbursement, it is important to prepare patients for an effective, timely discharge from a health care institution. A patient's discharge also needs to result in desirable outcomes. Interdisciplinary discharge planning ensures that a patient leaves the hospital in a timely manner with the necessary resources (Box 26-3).

Ideally discharge planning begins at admission. By identifying discharge needs early, nursing and other health care professionals can begin planning for home care, support services, and any equipment needs at home. Nurses revise a plan of care as a patient's condition changes. Involve the patient and family in the discharge planning process so they have the necessary information and resources to return home. Discharge documentation includes medications, diet, community resources, follow-up care, and who to contact in case of an emergency or for questions.

Acuity Records

Although **acuity records** are not part of a patient's medical record, they are useful for determining the hours of care and staff required for a given group of patients. A patient's acuity level, usually determined by a computer program, is based on the type and number of nursing interventions (e.g., intravenous [IV] therapy, wound care, or ambulation assistance) required over a 24-hour period. The acuity level rates patients compared with one another. For example, an acuity system rates bathing patients from 1 (totally dependent) to 5 (independent). A patient returning from surgery requiring frequent monitoring and extensive care has an acuity level of 1 compared with another patient awaiting discharge after a successful recovery from surgery who has an acuity level of 5. Accurate acuity ratings justify overtime and the number and qualifications of staff needed to safely care for patients. The patient-to-staff ratios established for a unit depend on a composite gathering of 24-hour acuity data for each patient receiving care.

BOX 26-3 DISCHARGE SUMMARY INFORMATION

- Use clear, concise descriptions in the patient's own language.
- Provide step-by-step description of how to perform a procedure (e.g., home medication administration). Reinforce explanation with printed instructions.
- Identify precautions to follow when performing self-care or administering medications.
- Review signs and symptoms of complications that should be reported to the health care provider.
- List names and phone numbers of health care providers and community resources that the patient can contact.
- Identify any unresolved problem, including plans for follow-up and continuous treatment.
- List actual time of discharge, mode of transportation, and who accompanied the patient.

HOME CARE DOCUMENTATION

When providing home care, nurses use astute assessment skills to develop a plan of care and gather the needed information about changes in a patient's health care status. This information frequently comes from patient family members. Documentation in the home care system is different from other areas of nursing. Medicare has specific guidelines to establish eligibility for home care reimbursement. Information used for reimbursement comes from a patient's medical record. In addition, home care documentation systems provide the entire health care team with the information needed to enhance teamwork. Documentation is both the quality control and the justification for reimbursement from Medicare, Medicaid, or private insurance companies. Nurses must document all their services for payment (e.g., direct skilled care, patient instructions, skilled observation, and evaluation visits) (TJC, 2011). Information in the home care medical record includes patient assessment, referral and intake forms, interprofessional plan of care, a list of medications, and reports to third-party payers.

Some parts of the record remain in the home with the patient; other information is needed in an office setting. Thus duplication of documentation is often necessary. Agency policies indicate which forms nurses need to leave at their office versus which forms must be taken into the home. Computerized patient records are evolving to address these different needs. With the use of laptop computers, it is becoming possible for the records to be available in multiple locations, which allows greater access to information about a patient's interdisciplinary needs.

LONG-TERM HEALTH CARE DOCUMENTATION

Increasing numbers of older adults and people with disabilities in the United States require care in long-term health care facilities. Nursing personnel often face documentation challenges much different from those in the acute care setting. The Centers for Medicare and Medicaid Services (CMS) establishes guidelines related to accidents and supervision of residents of long-term care facilities. The guidelines require careful documentation for appropriate reimbursement in long-term care agencies (Senft, 2008). You assess each resident in a long-term care agency receiving funding from Medicare and Medicaid programs using the Resident Assessment Instrument/Minimum Data Set (RAI/MDS). This documentation provides standardized protocols for assessment and care planning and a minimum data set to promote quality improvement within and across facilities (Dellefield, 2007). When residents' records are reviewed for reimbursement, there is an expectation that these protocols such as skin assessments, wound care, and assisted ambulation are met. Documentation supports an interdisciplinary approach to the assessment and planning process for patients. Communication among nurses, social workers, recreational therapists, and dietitians is essential in the regulated documentation process. The fiscal support for long-term care residents hinges on the justification of nursing care as demonstrated in sound documentation of the services rendered (Dellefield, 2007).

REPORTING

Nurses communicate information about patients to help team members make appropriate decisions about patient care. It is important that any form of verbal report be timely, accurate, and relevant. Reports commonly used by nurses include hand-off, telephone, and incident reports.

Hand-Off Report

Hand-off reports happen any time one health care provider transfers care of a patient to another health care provider. The purpose of hand-off reports is to provide better continuity and individualized care for patients. For example, if you find that a patient breathes better in a certain position, you relay that information to the next nurse caring for the patient (Table 26-4). Examples of hand-off reports include change-of-shift reports and transfer reports.

Standardizing communication during hand-off reports helps ensure patient safety. Hand-off communications include up-to-date information about a patient's condition, required care, treatments, medications, services, and any recent or anticipated changes. Information during patient hand-off can be given face-to-face, in

TABLE 26-4 **Comparison of Do's and Don'ts of Hand-Off Reports**

DO'S	DON'TS
Provide only essential background information about patient (i.e., name, gender, medical diagnosis, and history).	Don't review all routine care procedures or tasks (e.g., bathing, scheduled changes).
Identify patient's nursing diagnoses or health care problems and their related causes.	Don't review all biographical information already available in written form.
Describe objective measurements or observations about patient's condition and response to health problem; emphasize recent changes.	Don't use critical comments about patient's behavior such as "Mrs. Wills is so demanding."
Share significant information about family members as it relates to patient's problems.	Don't make assumptions about relationships among family members.
Continuously review ongoing discharge plan (e.g., need for resources, patient's level of preparation to go home).	Don't engage in idle gossip.
Relay significant changes to staff in the way therapies are to be given (e.g., different position for pain relief, new medication).	Don't describe basic steps of a procedure.
Describe instructions given in teaching plan and patient's response.	Don't explain detailed content unless staff members ask for clarification.
Evaluate results of nursing or medical care measures (e.g., effect of back rub or analgesic administration).	Don't simply describe results as "good" or "poor." Be specific.
Be clear about priorities to which oncoming staff must attend.	Don't force oncoming staff to guess what to do first.

writing, or verbally such as over the telephone or via audiorecording. Regardless of the way hand-off reports are given, it is essential for staff to have an opportunity for last-minute updates, to clarify information, or to receive information on care events or changes in a patient's condition. Properly performed, a hand-off report provides an opportunity to share essential information to ensure patient safety and continuity of care (Schroeder, 2006).

An effective hand-off report is quick and efficient. A good report provides a baseline for comparisons and indicates the kind of care anticipated for the next nurse who will be caring for the patient. An organized and concise approach helps you set goals and anticipate patient needs and lessens the chance of overlooking important information. A sample format follows: background information (name, age, and medical diagnosis); primary health problem; unusual occurrences; discharge planning issues; identification of significant changes in measurable terms (e.g., pain scale); observations; findings; time when new, STAT, or prn medications were given; care required such as medications that need to be started, when to assess the effectiveness of STAT/prn medications, or when a dressing needs to be changed next; progress with teaching; interventions; and family involvement. It is especially important to report any recent changes or priority situations concerning a patient's condition. Report elements do not include normal findings or routine information retrievable from other sources or derogatory or inappropriate comments about a patient or family, which could possibly lead to legal charges if overheard by the patient or family (Benson et al., 2007). This type of language contributes to prejudicial opinions about a patient.

Telephone Reports and Orders

Telephone Reports. A registered nurse makes a telephone report when significant events or changes in a patient's condition have occurred. A telephone report needs to include clear, accurate, and concise information. About 60% of the worst type of medical errors, called *sentinel events,* relate to communication problems that often arise during telephone reports (Hemmila, 2006). Thus some institutions use SBAR, an acronym that stands for Situation-Background-Assessment-Recommendation. SBAR standardizes telephone communication of significant events or changes in a patient's condition and is a communication strategy designed to improve patient safety. For example, when describing the *situation*, you include both the admitting and secondary diagnoses and the problem your patient is having as the current issue. *Background* information includes pertinent medical history, previous laboratory tests and treatments, psychosocial issues, allergies, and current code status. For *assessment* data include significant findings in your head-to-toe physical assessment, recent vital signs, current treatment measures, restrictions, recent laboratory results and diagnostics, and pain status. Then provide your *recommendation*, in which you suggest a plan of care and what needs to be addressed (Hemmila, 2006).

Document every phone call you make to a health care provider. Documentation includes when the call was made, who made it (if you did not make the call), who was called, to whom information was given, what information was given, what information was received, and verification of the information with the provider. Health care institutions have a process for a verification "read back" when receiving information or critical test results. An example follows: "Laboratory technician J. Ignacio reported a potassium level of 5.9. Dr. Wade notified at 2030. Information transcribed and read back for verification. Ordered change in IV fluids. D_5NS 1000 mL to run at 125 mL per hour. D. Markle, RN, read back."

BOX 26-4 GUIDELINES FOR TELEPHONE AND VERBAL ORDERS

- Clearly determine the patient's name, room number, and diagnosis.
- Repeat any prescribed orders back to the physician or health care provider.
- Use clarification questions to avoid misunderstandings.
- Write TO (telephone order) or VO (verbal order), including date and time, name of patient, the complete order; sign the name of the physician or health care provider and nurse.
- Follow agency policies; some institutions require telephone (and verbal) orders to be reviewed and signed by two nurses.
- The health care provider must co-sign the order within the time frame required by the institution (usually 24 hours).

Telephone and Verbal Orders. A telephone order (TO) occurs when a health care provider gives an order over the phone to a registered nurse. A verbal order (VO) involves the health care provider giving orders to a nurse while they are standing near each other. TOs and VOs usually occur at night or during emergencies and frequently cause medical errors (Bombard, 2008). The nurse receiving a TO or VO writes down the complete order or enters it into the computer as it is being given. Then he or she reads the order back to the health care provider, called *read back,* and receives confirmation from the person who gave the order that it is correct (Bombard, 2008). An example follows: "10/16/2011: 0815, Tylenol 3, 2 tablets, every 6 hours for incisional pain. TO Dr. Knight/J. Woods, RN, read back." The health care provider later verifies the TO or VO legally by signing it within a set time (e.g., 24 hours) as set by hospital policy. TOs and VOs are used only when absolutely necessary and not for the sake of convenience. In some situations it is prudent to have a second person listen to TOs. Check agency policy. Box 26-4 provides guidelines that promote accuracy when receiving TOs.

Incident or Occurrence Reports

An incident or occurrence is any event that is not consistent with the routine operation of a health care unit or routine care of a patient. Examples of incidents include patient falls, needlestick injuries, a visitor having symptoms of illness, medication administration errors, accidental omission of ordered therapies, and circumstances that lead to injury or a risk for patient injury. Analysis of incident reports helps with the identification of trends in systems and unit operations that provide justification for changes in policies and procedures or for in-service seminars. **Incident (or occurrence) reports** are an important part of the quality improvement program of a unit (see Chapter 5).

Always contact the patient's health care provider whenever an incident happens. Note that you do not mention the incident report in the patient's medical record. Instead you document an objective description of what happened, what you observed, and the follow-up actions taken in the patient's medical record. It is important to evaluate and document the patient's response to the error or incident.

Follow agency policy when making an incident report. These reports are an important part of quality improvement. The overall goal is to identify changes needed to prevent future recurrence. File the report with the appropriate risk-management department of the agency. Analysis of incident or occurrence reports helps identify trends in an organization that provide justification for changes in policies and procedures or for in-service programs.

HEALTH INFORMATICS

Health informatics is defined by the American Medical Informatics Association (AMIA) as, "The application of computer and information science in all basic and applied biomedical sciences to facilitate the acquisition, processing, interpretation, optimal use, and communication of health-related data. The focus is the patient and the process of care, and the goal is to enhance the quality and efficiency of care provided" (Hebda et al., 2009). Nursing competence in health care informatics is becoming a priority as health care facilities adopt EMRs/EHRs and other technologies. A recent survey found that only 28% of primary care physicians in the United States used EMRs in practice (Davis et al., 2009). Another survey of 2952 hospitals in the United States reported that only 1.5% of U.S. hospitals have a comprehensive EHR system in place and 10.9% were using a basic EHR (Jha et al., 2009). Use of EMRs/EHRs is increasing as a result of the creation of the federal Health Information Technology for Economic and Clinical Health Act (HITECH) in 2009. The government will make incentive payments totaling over $27 billion over a 10-year period to health care agencies and provider's offices that adopt EHRs and use data meaningfully from the EHR to promote safe, high-quality patient care resulting in positive patient outcomes (Blumenthal, 2010). In addition, penalties will be assessed to health care facilities that do not adopt EHRs or show meaningful use of data generated from EHRs.

NURSING INFORMATICS

All nurses deal with data, information, and knowledge (Hebda et al., 2009). It is important that you know how to record, interpret, and report data and critically think and apply knowledge to use information for patient care. Data include numbers, characters, or facts that you collect according to a perceived need for analysis and possible action. You gain knowledge from gathering and using information from several sources (Hebda et al., 2009). An example is a nurse's observation of a wound's edges, color of drainage, and measurement of the length of a wound. When a nurse examines data describing the condition of the wound over time, a pattern develops showing that the wound is not healing (information). On the basis of evidence available in the scientific literature, the nurse applies knowledge of wound care principles and intervenes to manage the patient's wound.

In health care settings it is a challenge to easily access data and information about patients. This is especially true when information is recorded manually on printed forms. For example, a nurse working in risk management who is interested in investigating patient falls has to review page by page the records of patients who have fallen to identify the common factors contributing to falls. Remember that three important purposes of medical records are communication, education, and research. When a health care organization relies on handwritten patient records, the process of locating, summarizing, and comparing information is slow and difficult. Thus it becomes even more difficult to access information in a timely manner to provide or improve patient care. It also becomes difficult to locate data sources for research purposes. Furthermore, when data about patients are compared manually, it is more difficult to see the trends that help educate staff about patient care. The most efficient way to use data and information to improve quality of care, complete research, and provide education is through information technology (Institute of Medicine, 2001).

Information technology (IT) refers to the management and processing of information, generally with the assistance of computers (Hebda et al., 2009). Advances in technology allow health care agencies to move from paper-based medical records to computer-based records. A health care information system (HIS) is a group of systems used within a health care organization to support and enhance health care (Hebda et al., 2009). A HIS consists of two major types of information systems: clinical information systems (CISs) and administrative information systems. Together the two systems operate to make the entry and communication of data and information more efficient. You will find that any single health care agency uses one or several CISs and administrative information systems. For example, a small community hospital uses a nursing information system (NIS); an order entry system; and laboratory, radiology, and pharmacy systems to coordinate their core patient care services. A nurse working in such a hospital documents nursing care on a computer, locates and reviews laboratory test results, orders sterile supplies, and enters health care provider orders for x-ray films and patients' medications.

Many hospitals now use NISs to support the documentation of nursing process activities and offer resources for managing nursing care delivery. A reliable NIS is the product of nursing informatics. **Nursing informatics** is a specialty that integrates nursing science, computer science, and information science to manage and communicate data, information, and knowledge in nursing practice (American Nurses Association, 2008). It facilitates the integration of data, information, and knowledge to support patients, nurses, and other providers in decision making in all roles and settings. The application of nursing informatics results in an efficient and effective NIS. An expertly designed CIS based on nursing informatics integrates and supports clinical judgments with up-to-date evidence-based practice. An effective NIS meets two goals. First, it supports the way that nurses function and work by providing them the flexibility to use the system to view data and collect information, provide patient care, and document a patient's condition and care provided. Second, it supports and enhances nursing practice through improved access to information and clinical decision-making tools (Hebda et al., 2009).

In the fast-paced world of nursing, nursing informatics plays an important role in helping nurses make decisions more rapidly and accurately. It has revolutionized how health care providers locate or mine patient data to look for trends and patterns between patient outcomes and care provided by nurses. New technologies also allow nurses to study the effect of systems on error reduction and patient safety. Through the application of nursing informatics, practical applications of technology enhance bedside care and education.

Numerous groups, including the ANA (2008), recommend that all nurses acquire a minimal level of awareness and competence in informatics and use of IT. Competence in informatics is not the same as computer competency. To become competent in informatics you need to be able to use evolving methods of discovering, retrieving, and using information in practice (Hebda et al., 2009). This means that you learn to recognize when information is needed and have the skills to find, evaluate, and use that information effectively. For example, you need to know how to acquire, critique, and apply scientific evidence from literature databases (see Chapter 5). As a nurse you also need to know how to use clinical databases within your institution and apply the information so you can deliver high-quality, appropriate patient care.

Nursing Information Systems

A good information system that incorporates principles of nursing informatics supports the work you do. As a nurse you need to access a computer program easily, review the patient's medical history and health care provider orders, and then go to the patient's bedside to conduct a comprehensive assessment. Once you have completed the assessment, you enter data into the computer terminal at the patient's bedside and develop a plan of care from the information gathered. This allows you to quickly share the plan of care with the patient. Periodically you return to the computer to check on laboratory test results and document the therapies you administer. The computer screens and optional pop-up windows make it easy to locate information, enter and compare data, and make changes.

NISs have two designs. The nursing process design is the most traditional. It organizes documentation within well-established formats such as admission and postoperative assessment problem lists, care plans, discharge planning instructions, and intervention lists or notes. More advanced systems incorporate standardized nursing languages such as the North American Nursing Diagnosis Association (NANDA) International nursing diagnoses, the Nursing Interventions Classification (NIC), and the Nursing Outcomes Classification (NOC) into the software. For example, the documentation of nursing admission assessment findings relies on a menu-driven approach. A menu lists related commands that you select from the computer screen to complete the patient assessment. The commands direct you through various assessment categories such as a patient's medication history, nutritional status, psychosocial history, and review of systems. After you enter assessment data into a computer, a program offers menu lists for the selection of nursing diagnoses and interventions, allowing you to individualize a patient's care plan. Another example is a program for discharge instructions. After you enter the necessary information for a patient's discharge instructions, follow-up appointments, and medication information, the system generates printed copies of the instructions for you to review and give to patients on discharge. You place a copy in the patient's record. This information is also available for home care staff and the patient's health care provider.

The nursing process design includes formats for the following:

- Generation of a nursing work list that indicates routine scheduled activities related to the care of each patient
- Documentation of routine aspects of patient care such as hygiene, positioning, fluid intake and output, wound care measures, and blood glucose measurements
- Progress note entries using narrative notes, charting by exception, and flow-sheet charting
- Documentation of medication administration (see Chapter 31)

The second design model for a NIS is the protocol or critical pathway design (Hebda et al., 2009). This design offers an interdisciplinary format to manage information. All health care providers use a protocol system to document the care they provide. Evidence-based clinical protocols or critical pathways provide the formatting or design for the type of information that clinicians enter into the system. The information system allows a user to select one or more appropriate protocols for a patient. An advanced system merges multiple protocols, using a master protocol or path to direct patient care activities. Standard health care provider order sets are included in the protocols and automatically processed. The system integrates appropriate information into the medication delivery process to enhance patient safety. In addition, the system identifies variances of the anticipated outcomes on the protocols as they are charted.

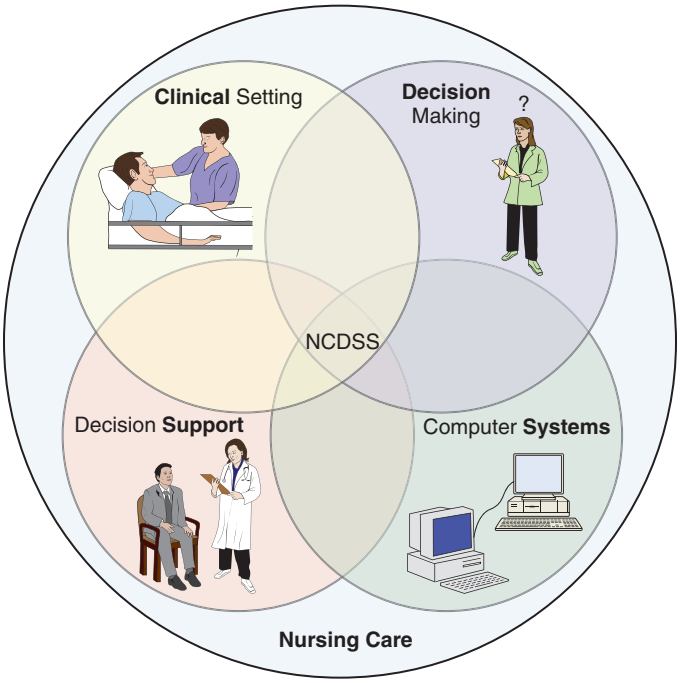

FIG. 26-2 Model of a nursing clinical decision support system (NCDSS). (Courtesy Frank Lyerla.)

This provides all caregivers the ability to analyze variances and offer an accurate clinical picture of a patient's progress.

Clinical decision support systems (CDSSs) are computerized programs used within the health care setting to support decision making (Lyerla, 2008). When used to support nursing decisions it is called a *nursing CDSS* (Fig. 26-2). A CDSS is based on "rules" and "if-then" statements, linking information and/or producing alerts, warnings, or other information to the user. The information within a CDSS is current, is evidence based, and has the ability to be updated. Information provided by a CDSS is given to the right person at the right time. For example, an effective CDSS notifies health care providers of patient allergies before ordering a medication. This enhances patient safety during the medication ordering process. CDSSs also improve nursing care. When patient assessment data are combined with patient care guidelines, nurses are better able to implement evidence-based nursing care, resulting in improved patient outcomes (Box 26-5).

Advantages of a Nursing Information System. Anecdotal reports and descriptive studies suggest that NISs offer important advantages to nurses in practice. Hebda et al. (2009) outline some specific advantages:

- Increased time to spend with patients
- Better access to information
- Enhanced quality of documentation
- Reduced errors of omission
- Reduced hospital costs
- Increased nurse job satisfaction
- Compliance with requirements of accrediting agencies (e.g., TJC)
- Development of a common clinical database

The transition to computerized documentation presents both opportunities and challenges to nurses and nurse managers. A barrier to the successful implementation of a CIS is the reluctance of some nurses and other clinical staff to accept technological advances. Often clinicians fail to understand how technology can improve the way they deliver care and enhance clinical decision

BOX 26-5 EFFECT OF CLINICAL DECISION SUPPORT SYSTEMS (CDSS) ON PATIENT OUTCOMES

PICO Question: Do nurses who work at health care agencies that use CDSS provide safer and more effective patient care when compared with nurses who work at agencies that do not use CDSS?

Evidence Summary

Nurses who provide evidence-based care at the bedside provide safe and effective care. However, one barrier to evidence-based nursing care is getting information to nurses at the bedside when they need it. Several studies investigated the effect of CDSS on patient outcomes. For example, Lyerla et al. (2010) found that nurses are more likely to follow evidence-based guidelines when caring for patients who are on ventilators when the CDSS combined interventions for ventilator-associated pneumonia with nursing assessment data. The use of CDSS is also linked with adherence to implementation of evidence-based sepsis care in intensive care units (Giuliano, Lecardo, and Staul, 2011) and completion of screening for osteoporosis in primary care settings (DeJesus et al., 2011). These studies show that CDSS that provide automatic decision support at the time and place nurses need it enhances the quality and safety of patient care. CDSS also help nurses initiate evidence-based care faster and with more accuracy, improving patient outcomes.

Application to Nursing Practice

- CDSS enhance the implementation of evidence-based practice into nursing care because they remind nurses which interventions need to be implemented for specific patients at the time the care is needed.
- Nurses need to be involved in the design and selection of CDSS to ensure that clinical decision support is provided effectively and efficiently.
- Nurses need to evaluate patient outcomes when CDSS are used. They also need to be involved in developing solutions to improve the effectiveness of CDSS when opportunities for improvement are identified.

processes. The successful implementation of a NIS requires preparation, involvement, and commitment of the entire nursing staff. The process is complex and includes more than just implementing a new technology. It is important to address educating staff, changing attitudes and cultures, and standardizing documentation and health care practices (Oroviogoicoechea et al., 2007). Successful integration requires nurses to understand the potential of informatics and IT. Although promoters of NISs suggest that adoption of computerized charting provides time saving for nursing workload, currently there is inconsistent evidence of time saved with use of electronic patient records (Choi et al., 2006).

Privacy, Confidentiality, and Security Mechanisms. Computerized documentation has legal risks. It is possible for anyone to access a computer station within a health care agency and gain information about almost any patient. Therefore protection of information and computer systems is a top priority. Confidentiality of access to computerized records is a major issue, particularly with the implementation of HIPAA. HIPAA was the first federal legislation to protect automated patient records and uniform personal health information (PHI) nationwide (Hebda et al., 2009). PHI includes individually identifiable health information such as demographic data; facts that relate to an individual's past, present, or future physical or mental health condition; provision of care; and payment for the provision of care that identifies the individual (Hebda et al., 2009).

Most security mechanisms for information systems use a combination of logical and physical restrictions to protect information and computer systems. They include measures such as firewalls and the installation of antivirus and spyware-detection software. A **firewall** is a combination of hardware and software that protects private network resources (e.g., the information system of the hospital) from outside hackers, network damage, and theft or misuse of information. For example, an automatic sign-off is a safety mechanism that logs a user off the computer system after a specified period of inactivity (Hebda et al., 2009). An automatic sign-off is used in most patient care areas and other departments that handle sensitive data.

Physical security measures include placing computers or file servers in restricted areas or using privacy filters for computer screens visible to visitors or others without access. This form of security has limited benefit, especially if an organization uses mobile wireless devices such as notebooks, tablet personal computers (PCs), and personal digital assistants (PDAs). These devices are easily misplaced or lost, falling into the wrong hands. Some organizations use motion detectors or alarms with these devices to help prevent theft.

Access or log-in codes along with passwords are frequently used for authenticating access to electronic records. A password is a collection of alphanumeric characters that a user types into a computer before accessing a program. A user usually needs to enter a password after the entry and acceptance of an access code or user name. A password does not appear on the computer screen when it is typed, nor should it be known to anyone but the user and information system administrators (Hebda et al., 2009). Strong passwords use combinations of letters, numbers, and symbols that are difficult to guess. When using a health care agency computer system, it is essential that you do not share your computer password with anyone under any circumstances. A good system requires frequent and random changes in personal passwords to prevent unauthorized persons from tampering with records. In addition, most staff have access only to patients in their work area. Some staff (e.g., administrators or risk managers) have authority to access all patient records. To protect patient privacy, health care agencies track who accesses patient records and when they access them. Disciplinary action, including loss of employment, occurs when nurses or other health care personnel inappropriately access patient information.

Handling and Disposal of Information. It is extremely important to keep medical records confidential. However, it is equally important to safeguard the information that is printed from the record or extracted for report purposes. For example, you print a copy of a nursing activities work list to use as a day planner while administering care to patients. You refer to information on the list and write notes to enter later into the computer. Information on the list is PHI, must be kept confidential, and cannot be left out for view by unauthorized persons. You destroy (e.g., shred) anything that is printed when the information is no longer needed.

Printing and faxing information from a patient's record is a primary source for the unauthorized release of information. All papers containing PHI (e.g., Social Security number, date of birth or age, patient's name or address) must be destroyed. Most agencies have shredders or locked receptacles for shredding and later incineration. Nurses also work in settings where they are responsible for erasing computer files from the hard drive that contain calendars, surgery or diagnostic procedure schedules, or other daily records that contain PHI (Hebda et al., 2009). Know and follow the disposal policies for records in the institution where you work.

Institutions need to have sound policies for the use of fax machines, specifically which type of information can be sent and

to which departments. Information that you send by fax should not exceed that requested or required for immediate clinical needs. The following are some steps to take to enhance fax security (Hebda et al., 2009):

- Confirm that fax numbers are correct before sending to be sure that you direct information properly.
- Use a cover sheet, especially if a fax machine serves a number of different users.
- Authenticate at both ends before data transmission to verify that source and destination are correct.
- Use programmed speed-dial keys to eliminate the chance of a dialing error and misdirected information.
- Place fax machines in a secure area.
- Limit machine access to designated individuals.
- Log fax transmissions. This feature is often available electronically on the machine.

Clinical Information Systems

Any clinician, including nurses, physicians, pharmacists, social workers, and therapists, uses programs available on a Clinical Information System (CIS). These programs include monitoring systems; order entry systems; and laboratory, radiology, and pharmacy systems. A monitoring system includes devices that automatically monitor and record biometric measurements (e.g., vital signs, oxygen saturation, cardiac index, and stroke volume) in critical care and specialty areas. The devices electronically send measurements directly to the nursing documentation system.

Order-entry systems allow nurses to order supplies and services from another department. An example is the ability to order sterile supplies from the central supply department. This eliminates written order forms and expedites the delivery of needed supplies to a nursing unit. **Computerized provider order entry (CPOE)** is a process by which a health care provider directly enters orders for patient care into the hospital information system. In advanced systems CPOE has built-in reminders and alerts that help a health care provider select the most appropriate medication or diagnostic test. The Institute of Medicine has instituted major initiatives to improve the quality of care and reduce medication errors. Many believe that CPOE is one answer. The direct entry of orders eliminates issues related to illegible handwriting and transcription errors. In addition, a CPOE system potentially speeds the implementation of ordered diagnostic tests and treatments, which improves staff productivity and saves money (Hebda et al., 2009) because the unit secretary no longer transcribes a written order onto a nursing order form. Orders made through CPOE are integrated within the record and sent to the appropriate departments (e.g., pharmacy or radiology).

KEY POINTS

- The medical record is a legal document and requires information describing the care that is delivered to a patient.
- The computerized health record (or electronic health record) is a digital version of a patient's medical record.
- All information pertaining to a patient's health care management that is gathered by examination, observation, conversation, or treatment is confidential.
- Access to patient records is limited to individuals involved in the care of the patient.
- Interdisciplinary communication is essential within the health care team.
- Accurate record keeping requires an objective interpretation of data with precise measurements, correct spelling, and proper use of abbreviations.
- A nurse's signature on an entry in a record designates accountability for the contents of that entry.
- Any change in a patient's condition warrants immediate documentation about the event and the action that was taken to keep a record accurate.
- The medical record is a financial record that serves as the basis for reimbursement.
- Problem-oriented medical records are organized by the patient's health care problems.
- The intent of SOAP, SOAPIE, PIE, or DAR charting formats is to organize entries in the progress notes according to the nursing process.
- Medicare guidelines for establishing a patient's home care cost reimbursement is the basis for documentation by home care nurses.
- Long-term care documentation is interdisciplinary and closely linked with fiscal requirements of outside agencies.
- Computerized Information Systems (CIS) provide information about patients in an organized and easily accessible fashion.
- The major purpose of the hand-off report is to maintain continuity of care.
- Rounds allow nurses to perform needed assessments, evaluate patients' progress, and determine the best interventions for a patient's needs.
- Always verify patient care information communicated by telephone using the "read back" process.
- A hospital information system consists of two major types of information systems: CIS and administrative information systems.
- Nursing informatics facilitates the integration of data, information, and knowledge to support patients, nurses, and other providers in decision making in all roles and settings.
- Protection of the confidentiality of patients' health information and the security of computer systems are top priorities that include log-in processes, audit trails, firewalls, data recovery processes, and policies about handling and disposing of data to protect patient information.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

David Page, an 80-year-old man, is admitted to the hospital with a diagnosis of possible pneumonia. He states that he is not feeling well and has a frequent productive cough, which is worse at night. Vital signs are: blood pressure, 150/90 mm Hg; pulse rate, 92 beats/min; respirations, 22 breaths/min. During your initial assessment he coughs violently for 40 to 45 seconds. His lungs have wheezes and rhonchi in both bases and are otherwise clear. He states, "My chest hurts when I cough, and the pain radiates into my arm."

1. Which data do you document as objective?
2. Which data are subjective?
3. The nurse documents assessment findings in an electronic documentation system in narrative format. Discuss the problems associated with this style of documentation.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A manager who is reviewing the nurses' notes in a patient's medical record finds the following entry, "Patient is difficult to care for, refuses suggestion for improving appetite." Which of the following directions does the manager give to the staff nurse who entered the note?
   1. Avoid rushing when charting an entry.
   2. Use correction fluid to remove the entry.
   3. Draw a single line through the statement and initial it.
   4. Enter only objective and factual information about the patient.
2. A new graduate nurse is providing a telephone report to a patient's health care provider and accepting telephone orders from the provider. Which of the following actions requires the new nurse's preceptor to intervene? The new nurse:
   1. Uses SBAR (Situation-Background-Assessment-Recommendation) as a format when providing the report.
   2. Gives a newly ordered medication before entering the order in the patient's medical record.
   3. Reads the orders back to the health care provider after receiving them and verifies their accuracy.
   4. Asks the preceptor to listen in on the phone conversation.
3. As you enter the patient's room, you notice that he is anxious to say something. He quickly states, "I don't know what's going on; I can't get an explanation from my doctor about my test results. I want something done about this." Which of the following is the most appropriate documentation of the patient's emotional status?
   1. The patient has a defiant attitude and is demanding his test results.
   2. The patient appears to be upset with his nurse because he wants his test results immediately.
   3. The patient is demanding and complains frequently about his doctor.
   4. The patient stated that he felt frustrated by the lack of information he received regarding his tests.
4. You are reviewing Health Insurance Portability and Accountability Act (HIPAA) regulations with your patient during the admission process. The patient states, "I've heard a lot about these HIPAA regulations in the news lately. How will they affect my care?" Which of the following is the best response?
   1. HIPAA allows all hospital staff access to your medical record.
   2. HIPAA limits the information that is documented in your medical record.
   3. HIPAA provides you with greater control over your personal health care information.
   4. HIPAA enables health care institutions to release all of your personal information to improve continuity of care.
5. A patient asks for a copy of her medical record. The best response by the nurse is to:
   1. State that only her family may read the record.
   2. Indicate that she has the right to read her record.
   3. Tell her that she is not allowed to read her record.
   4. Explain that only health care workers have access to her record.
6. Which of the following charting entries is most accurate?
   1. Patient walked up and down hallway with assistance, tolerated well.
   2. Patient up, out of bed, walked down hallway and back to room, tolerated well.
   3. Patient up, walked 50 feet and back down hallway with assistance from nurse. Spouse also accompanied patient during the walk.
   4. Patient walked 50 feet and back down hallway with assistance from nurse; HR 88 and regular before exercise, 94 and regular following exercise.
7. Match the correct entry with the appropriate SOAP (Subjective—Objective—Assessment—Plan) category.
   1. S — a. Repositioned patient on right side. Encouraged patient to use patient-controlled analgesia (PCA) device.
   2. O — b. "The pain increases every time I try to turn on my left side."
   3. A — c. Acute pain related to tissue injury from surgical incision.
   4. P — d. Left lower abdominal surgical incision, 3 inches in length, closed, sutures intact, no drainage. Pain noted on mild palpation.
8. On the nursing unit you are able to access a patient's medical record and review the education that other nurses provided to the patient during an initial hospitalization and three subsequent clinic visits. This type of feature is most common in what type of record system?
   1. Information technology.
   2. Electronic health record.
   3. Personal health information.
   4. Administrative information system.
9. You are giving a hand-off report to another nurse who will be caring for your patient at the end of your shift. Which of the following pieces of information do you include in the report? (Select all that apply.)
   1. The patient's name, age, and admitting diagnosis
   2. Allergies to food and medications
   3. Your evaluation that the patient is "needy"
   4. How much the patient ate for breakfast
   5. That the patient's pain rating went from 8 to 2 on a scale of 1 to 10 after receiving 650 mg of Tylenol
10. You are supervising a beginning nursing student who is documenting patient care. Which of the following actions requires you to intervene? The nursing student:
    1. Documented medication given by another nursing student.
    2. Included the date and time of all entries in the chart.
    3. Stood with his back against the wall while documenting on the computer.
    4. Signed all documentation electronically.
11. A group of nurses is discussing the advantages of using computerized provider order entry (CPOE). Which of the following statements indicates that the nurses understand the major advantage of using CPOE?
    1. "CPOE reduces transcription errors."
    2. "CPOE reduces the time necessary for health care providers to write orders."
    3. "Health care providers can write orders from any computer that has Internet access."
    4. "CPOE reduces the time nurses use to communicate with health care providers."

12. You are helping to design a new patient discharge teaching sheet that will go home with patients who are discharged to home from your unit. Which of the following do you need to remember when designing the teaching sheet?
    1. The new federal laws require that teaching sheets be e-mailed to patients after they are discharged.
    2. You need to use words the patients can understand when writing the directions.
    3. The form needs to be given to patients in a sealed envelope to protect their health information.
    4. The names of everyone who cared for the patient in the hospital need to be included on the form in case the patient has questions at home.
13. A nurse caring for a patient on a ventilator electronically documents the head of bed elevated at 20 degrees. Suddenly an alert warning appears on the screen warning the nurse that this patient is at a high risk for aspiration because the head of the bed is not elevated high enough. This warning is known as what type of system?
    1. Electronic health record
    2. Clinical documentation
    3. Clinical decision support system
    4. Computerized physician order entry
14. While reviewing the pulmonary section of a patient's electronic chart, the physician notices blank spaces since the initial assessment the previous day when the nurse documented that the lung assessment was within normal limits. There also are no progress notes about the patient's respiratory status in the nurse's notes. The most likely reason for this is because:
    1. The nurses forgot to document on the pulmonary system.
    2. The nurses were charting by exception.
    3. The computer is not working correctly.
    4. The physician does not have authorization to view the nursing assessment.
15. What is an appropriate way for a nurse to dispose of printed patient information?
    1. Rip several times and place in a standard trash can
    2. Place in the patient's paper-based chart
    3. Place in a secure canister marked for shredding
    4. Burn the documents

CHAPTER

27

Patient Safety

OBJECTIVES

- Discuss the importance of consensus standards for public reporting of patient safety events.
- Describe environmental hazards that pose risks to a person's safety.
- Discuss methods to reduce physical hazards and the transmission of pathogens.
- Discuss the specific risks to safety related to developmental age.
- Identify the factors to assess when a patient is in restraints.
- Describe the four categories of safety risks in a health care agency.
- Describe assessment activities designed to identify patients' physical, psychosocial, and cognitive status as it pertains to their safety.
- Identify relevant nursing diagnoses associated with risks to safety.
- Develop a nursing care plan for patients whose safety is threatened.
- Describe nursing interventions specific to a patients' age for reducing risk of falls, fires, poisonings, and electrical hazards.
- Define the knowledge, skills, and attitudes necessary to promote safety in a health care setting.

Safety, often defined as freedom from psychological and physical injury, is a basic human need. Health care provided in a safe manner and a safe community environment is essential for a patient's survival and well-being. A safe environment reduces the risk for illness and injury and helps to contain the cost of health care by preventing extended lengths of treatment and/or hospitalization, improving or maintaining a patient's functional status, and increasing the patient's sense of well-being. The Institute of Medicine's report *To Err Is Human: Building a Safer Health System* (2000) was a pivotal publication that brought patient safety to the forefront of health care in the United States. This report indicated that 44,000 to 98,000 people die each year as a result of preventable medical errors. In an effort to improve patient safety, many organizations have become devoted to developing and monitoring key health care safety initiatives and providing information to health care organizations and the public. Health care organizations foster a patient-centered safety culture by continually focusing on performance improvement endeavors, risk management findings, and safety reports; providing current reliable technology; integrating evidence-based practice into procedures; designing a safe work environment and atmosphere; and providing continuing education and access to appropriate resources for staff (Box 27-1). As part of the health care team, the nurse has the professional responsibility to be engaged in activities that support a patient-centered safety culture. Considerable emphasis has also been placed on improving the education of student nurses so they become more competent in promoting safe health care practices. The Quality and Safety Education for Nurses (QSEN) project was developed to meet the challenge of preparing future nurses who will have the knowledge, skills, and attitudes necessary to continuously improve the quality and safety of the health care systems within which they work (QSEN, 2011). The QSEN safety competency for a nurse is defined as "Minimizes risk of harm to patients and providers through both system effectiveness and individual performance." As a nurse you are responsible for incorporating critical thinking skills when using the nursing process, assessing each patient and his or her environment for hazards that threaten safety, and planning and intervening appropriately to maintain a safe environment. By doing this, you become a provider of safe acute, restorative, and continuing care and an active participant in health promotion.

SCIENTIFIC KNOWLEDGE BASE

Environmental Safety

A patient's environment includes all of the many physical and psychosocial factors that influence or affect the life and survival of that patient. This broad definition of environment crosses the

continuum of care for settings in which the nurse and patient interact such as the hospital, long-term care facility, clinic, community center, school, and home. A safe environment protects the staff as well, allowing them to function optimally. Vulnerable groups who often require help in achieving a safe environment include infants, children, older adults, the ill, the physically and mentally disabled, the illiterate, and the poor. A safe environment includes meeting basic needs, reducing physical hazards and the transmission of pathogens, and controlling pollution.

Basic Needs. Physiological needs, including the need for sufficient oxygen, nutrition, and optimum temperature, influence a person's safety. According to Maslow's hierarchy of needs, these basic needs must be met before physical and psychological safety and security can be addressed (see Chapter 6).

Oxygen. Supplemental oxygen is sometimes required to meet a person's oxygenation needs. Oxygen is not flammable, but fire needs oxygen to start and to keep burning. When more oxygen is in the air, a fire burns hotter and faster. Strict codes regulate the use and storage of medical oxygen in health care facilities. This is not necessarily true in the home environment. Hospital emergency departments see approximately 1190 thermal burns per year caused by ignitions associated with home medical oxygen (National Fire Protection Association, 2008). Smoking is by far the leading cause of burns, reported fires, deaths, and injuries involving home medical oxygen.

Be aware of factors in a patient's environment that decrease the amount of available oxygen. A common environmental hazard in the home is an improperly functioning heating system. A furnace, stove, or fireplace that is not properly vented introduces carbon monoxide into the environment. Carbon monoxide affects a person's oxygenation by binding with hemoglobin, preventing the formation of oxyhemoglobin and thus reducing the supply of oxygen delivered to tissues (see Chapter 40). Low concentrations cause nausea, dizziness, headache, and fatigue. Very high concentrations cause death after 1 to 3 minutes of exposure (National Fire Protection Association, 2010a).

Nutrition. Meeting nutritional needs adequately and safely requires environmental controls and knowledge (see Chapter 44). Health care facilities and restaurants are required to meet State Board of Health regulations. To protect consumers, commercially processed and packaged foods are subject to **Food and Drug Administration (FDA)** regulations. The FDA is a federal agency responsible for the enforcement of federal regulations regarding the manufacture, processing, and distribution of foods, drugs, and cosmetics to protect consumers against the sale of impure or dangerous substances. Although food supply in the United States is one of the safest in the world, each year about 76 million illnesses occur, more than 300,000 persons are hospitalized, and 5,000 die from foodborne illness (Centers for Disease Control and Prevention, 2009). Groups at the highest risk are children, pregnant women, older adults, and people with compromised immune systems. Foods that are inadequately prepared or stored or subject to unsanitary conditions increase the patient's risk for infections and food poisoning.

Temperature. A person's comfort zone is usually between 18.3° and 23.9° C (65° and 75° F). Temperature extremes that frequently occur during the winter and summer affect comfort, productivity, and safety. Exposure to severe cold for prolonged periods causes frostbite and accidental hypothermia. Frostbite occurs when a surface area of the skin freezes as a result of exposure to extremely cold temperatures. Hypothermia occurs when the core body temperature is 35° C (95° F) or below. Older adults, the young, patients with cardiovascular conditions, patients who have ingested drugs or alcohol in excess, and people who are homeless are at high risk for hypothermia. Exposure to extreme heat changes the electrolyte balance of the body and raises the core body temperature, resulting in heatstroke or heat exhaustion. Chronically ill patients, older adults, and infants are at greatest risk for injury from extreme heat. These patients need to avoid extremely hot, humid environments (see Chapter 29).

Physical Hazards. On average 33.5 million injuries take place each year, with the majority occurring inside or outside of the home (Centers for Disease Control and Prevention, 2010a). Physical hazards in the environment threaten a person's safety and often result in physical or psychological injury or death. Unintentional injuries are the fifth leading cause of death for Americans of all ages (National Center for Injury Prevention, 2010a). Motor vehicle accidents are the leading cause, followed by poisonings and falls. Additional hazards consist of fire and disasters. A nurse plays a role in educating patients about common safety hazards and how to prevent injury while placing emphasis on hazards to which patients are more vulnerable.

Motor Vehicle Accidents. Vehicle design and equipment such as seat belts, air bags, and laminated windshields (remain in one piece when impacted) have improved safety for vehicle occupants. State specific laws relating to young driver licensing, safety belt use, child restraint use, and motorcycle helmets exist for protection. Child safety seats and booster seats appropriate for the child's age and weight and the type of car need to be used (Fig. 27-1). The American Academy of Pediatrics (2011) recommends that all infants and toddlers ride in the back seat with a rear-facing car safety seat until they are 2 years of age or they reach the highest weight or height

allowed by the manufacturer of the car safety seat. The website of the Academy, Healthy Children, http://www.aap.org/healthtopics/carseatsafety.cfm, has information for children of all ages and the type of safety seat to use. The back seat of a car is the safest part of the vehicle in the event of a crash and prevents injury from deployment of passenger and side air bags. According to the Centers for Disease Control and Prevention (2010b), the risk of motor vehicle accidents is higher among 16- to 19-year-old drivers than any other age-group. Teens are more likely to underestimate dangerous situations or not be able to recognize hazardous situations, speed and allow shorter headways, ride with intoxicated drivers, and drive after using alcohol and drugs. Teens also have the lowest rate of seat belt use. Older drivers are keeping their licenses longer and driving more miles than in the past. Per mile traveled, fatal crash rates increase starting at age 75 and increase markedly after age 80 (Insurance Institute for Highway Safety, 2008). An older adult is not always able to quickly observe situations in which an accident is likely to occur. Decreased hearing acuity alters the ability to hear emergency vehicle sirens or vehicle horns. Because of decreased nervous system response, older adults are unable to react as quickly as they once could to avoid an accident. A decline in these skills accounts for the most common types of accidents, including right-of-way and turning accidents.

Poison. A **poison** is any substance that impairs health or destroys life when ingested, inhaled, or absorbed by the body. Almost any substance is poisonous if too much is taken. Sources in a person's home include drugs, medicines, other solid and liquid substances, and gases and vapors. Poisons often impair the function of every major organ system. Health care providers are at risk from chemicals such as toxic cleaning agents. In the home accidental poisoning is a greater risk for toddlers, preschoolers, and young school-age children, who often ingest household cleaning solutions, medications, or personal hygiene products. Emergency treatment is necessary when a person ingests a poisonous substance or comes in contact with a chemical that is absorbed through the skin. In 2008 more than 2000 people a day were seen in emergency departments after a poison incident (Centers for Disease Control and Prevention, 2010c). Specific antidotes or treatments are available only for some types of poisons. A poison control center is the best resource for patients and parents needing information about the treatment of an accidental poisoning.

Although lead has not been used in house paint or plumbing materials since the U.S. Consumer Product Safety Commission banned it in 1978, older homes in poorer communities continue to contain high lead levels. Soil and water systems are sometimes contaminated. Poisoning occurs from swallowing or inhaling lead. Fetuses, infants, and children are more vulnerable to lead poisoning than adults because their bodies absorb lead more easily and small children are more sensitive to the damaging effects of lead. Exposure to excessive levels of lead affects a child's growth or causes learning and behavioral problems and brain and kidney damage (Agency for Toxic Substances and Disease Registry, 2010).

Falls. Falls are a major public health problem. Among adults 64 years and older, falls are the leading cause of unintentional death (Centers for Disease Control and Prevention, 2010a). Numerous factors increase the risk of falls, including a history of falling, being age 65 or over, reduced vision, orthostatic hypotension, gait and balance problems, urinary incontinence, use of walking aids, and the effects of various medications (e.g., anticonvulsants, hypnotics, sedatives, certain analgesics) (Deandrea et al., 2010). Common physical hazards that lead to falls include inadequate lighting, barriers along normal walking paths and stairways, and a lack of safety devices in the home. Often a fall leads to serious injury such as fractures or internal bleeding. Patients most at risk for injury are those with bleeding tendencies resulting from disease or medical treatments and osteoporosis. Injuries frequently result from accidental contact with objects on stairs, floors, bedside tables, closet shelves, refrigerator tops, and bookshelves. Children fall from anywhere (i.e., trees, wall/fences, playground equipment, furniture, and moving objects such as skateboards and bicycles). Forces from falls lead to injury with variable severity, depending on the height of the fall, body position on impact, and impact surface.

Fire. A total of 386,500 home fires were reported in the United States in 2008, resulting in 2,755 deaths and 13,160 injuries (National Fire Protection Association, 2010b). The leading cause of fire-related death is careless smoking, especially when people smoke in bed at home. The improper use of cooking equipment and appliances, particularly stoves, is the main source for in-home fires and fire injuries. Smoke detectors and carbon monoxide detectors need to be placed strategically throughout a home. Multipurpose fire extinguishers need to be near the kitchen and any workshop areas.

Disasters. When they strike, natural disasters such as floods, tsunamis, hurricanes, tornadoes, and wildfires are a major cause of death and injury. These types of disasters result in death and leave many people homeless. Every year millions of Americans face disaster and its terrifying consequences (FEMA, 2010). Bioterrorism is another cause of disaster. Threats of this type come in the form of biological, chemical, and radiological attacks. Bioterrorism, or the use of biological agents to create fear and threat, is the most likely form of a terrorist attack to occur. Although terrorists could use any agent, health officials are most concerned with biological agents such as anthrax, smallpox, pneumonic plague, botulism, tularemia, and viral hemorrhagic fevers (American Medical Association, 2010).

Transmission of Pathogens. Pathogens and parasites pose a threat to patient safety (see Chapter 28). A **pathogen** is any microorganism capable of producing an illness. The most common means of transmission of pathogens is by the hands. For example, if an individual infected with hepatitis A does not wash his or her hands thoroughly after having a bowel movement, the risk for transmitting the disease during food preparation is great. One of the most effective methods for limiting the transmission of pathogens is the medically aseptic practice of hand hygiene (see Chapter 28). The human immunodeficiency virus (HIV), the pathogen that causes acquired immunodeficiency syndrome (AIDS), and the hepatitis B virus are transmitted through blood and other select body fluids. High-risk behaviors that include sexual contact and drug use are common risk factors for HIV. People who abuse drugs often share syringes and needles, which increase the risk of acquiring these viruses. Some states and many nonprofit organizations fund syringe exchange programs as a means to slow down the spread of infectious diseases obtained through needle sharing (Coalition for Safe Community Needle Disposal, 2010).

Immunization also reduces, and in some cases prevents, the transmission of disease from person to person. Individuals acquire active immunity by an injection of a small amount of attenuated (weakened) or dead organisms or modified toxins from the organism (toxoids) into the body. Passive immunity occurs when antibodies produced by other persons or animals are introduced into a person's bloodstream for protection against a pathogen.

Insects and rodents often carry pathogens. For example, some mosquitoes are carriers of malaria and West Nile virus. Rats and mice carry rat-bite fever. Uncontrolled mosquito and rodent populations increase the risk for these diseases. People living at the

poverty level sometimes live in unmaintained homes or housing. Rat and roach infestations are common problems. Mosquito repellant and rodent traps help eliminate this risk.

Proper disposal of human waste controls the transmission of disease and parasites. Without a satisfactory sewer and waste system in a community, the population is at risk for illnesses such as typhoid fever and hepatitis.

Pollution. A healthy environment is free of pollution. A **pollutant** is a harmful chemical or waste material discharged into the water, soil, or air. People commonly think of pollution only in terms of air, land, or water pollution; but excessive noise is also a form of pollution that presents health risks. Air pollution is the contamination of the atmosphere with a harmful chemical. Prolonged exposure to it increases the risk of pulmonary disease. In urban areas industrial waste and vehicle exhaust are common contributors to air pollution. In the home, school, or workplace, cigarette smoke is the primary cause of air pollution. Improper disposal of radioactive and bioactive waste products (e.g., dioxin) can cause land pollution. Water pollution is the contamination of lakes, rivers, and streams, usually by industrial pollutants. Water treatment facilities filter harmful contaminants from the water, but these systems sometimes contain flaws. If water becomes contaminated, the public needs to use bottled or boiled water for drinking and cooking. Flooding frequently causes damage to water treatment stations and also requires the use of bottled or boiled water.

NURSING KNOWLEDGE BASE

Factors Influencing Patient Safety

In addition to being knowledgeable about the home and health care environment and the inherent safety risks, nurses need to be familiar with a patient's developmental level; mobility, sensory, and cognitive status; lifestyle choices; and knowledge of common safety precautions. They also need to be aware of the special risks to safety that are found in health care settings.

Risks at Developmental Stages. A patient's developmental stage creates threats to safety as a result of lifestyle, cognitive and mobility status, sensory impairments, and safety awareness. With this information, you tailor safety prevention programs to the needs, preferences, and life circumstances of particular age-groups. Unfortunately all age-groups are subject to abuse. Child abuse, domestic violence, and elder abuse are serious threats to safety. Chapters 12 through 14 discuss these topics.

Infant, Toddler, and Preschooler. Injuries are the leading cause of death in children over age 1 and cause more death and disabilities than do all diseases combined (Hockenberry and Wilson, 2009). The nature of the injury sustained is closely related to normal growth and development. For example, the incidence of lead poisoning is highest in late infancy and toddlerhood. Children at this stage explore the environment and, because of their increased level of oral activity, put objects in their mouth. This increases risk for poisoning and choking. Fire often results from their curiosity in playing with matches. In addition, limited physical coordination contributes to falls from bicycles and playground equipment. Additional injuries at this age are related to riding unrestrained in a motor vehicle, drowning, and head trauma from objects. Accidents involving children are largely preventable, but parents need to be aware of specific dangers at each stage of growth and development. Accident prevention thus requires health education for parents and the removal of dangers whenever possible.

School-Age Child. When a child enters school, the environment expands to include the school, transportation to and from school, school friends, and after-school activities. School-age children are learning how to perform more complicated motor activities and often are uncoordinated. Parents, teachers, and nurses need to instruct children in safe practices to follow at school or play, including what to do if approached by strangers. Teach school-age children involved in team and contact sports the rules for playing safely and how to use protective safety equipment such as helmets and other protective gear. Head injuries are a major cause of death, with bicycle accidents being one of the major causes of such injuries (Hockenberry and Wilson, 2009). Bikes need to be the proper size for the child, and helmets must be worn (Fig. 27-2). Additional injuries in this age-group are decreased by properly using seat belts and booster seats in motor vehicles and providing pedestrian safety education.

FIG. 27-2 Proper bicycle safety equipment for school-age child.

Adolescent. As children enter adolescence, they develop greater independence and begin to develop a sense of identity and their own values. The adolescent begins to separate emotionally from his or her family, and peers generally have a stronger influence. Wide variations that swing from childlike to mature behavior are characteristic of adolescent behavior (Hockenberry and Wilson, 2009). In an attempt to relieve the tensions associated with physical and psychosocial changes and peer pressures, some adolescents engage in risk-taking behaviors such as smoking, drinking alcohol, and using drugs. This increases the incidence of accidents such as drowning and motor vehicle accidents. When adolescents learn to drive, their environment expands, and so does their potential for injury. Fortunately teen motor vehicle crashes are preventable by avoiding distractions such as using cell phones, texting, eating, and drinking while driving.

To assess for possible substance abuse, have parents look for environmental and psychosocial clues from their children. Environmental clues include the presence of drug-oriented magazines, beer and liquor bottles, drug paraphernalia and blood spots on clothing and the continual wearing of long-sleeved shirts in hot weather and dark glasses indoors. Psychosocial clues include failing grades, change in dress, increased absenteeism from school, isolation, increased aggressiveness, and changes in interpersonal relationships. Because adolescence is a time when mature sexual physical characteristics develop, some adolescents begin to have physical relationships with others that present the risk of sexually transmitted diseases.

Adult. The threats to an adult's safety are frequently related to lifestyle habits. For example, a person who uses alcohol excessively is at greater risk for motor vehicle accidents. People who smoke

long-term have a greater risk of cardiovascular or pulmonary disease as a result of the inhalation of smoke and the effect of nicotine on the circulatory system. Likewise, the adult experiencing a high level of stress is more likely to have an accident or illness such as headaches, gastrointestinal (GI) disorders, and infections.

Older Adult. The physiological changes associated with aging, effects of multiple medications, psychological factors, and acute or chronic disease increase the older adult's risk for falls and other types of accidents. Falls often result in bruises, hip fractures, or head trauma. The risk of being seriously injured in a fall increases with age. Older patients are more likely to fall in the bedroom, bathroom, and kitchen. Environmental factors such as broken stairs, icy sidewalks, inadequate lighting, throw rugs, and exposed electrical cords cause many of the accidents. Inside falls most often occur while transferring from beds, chairs, and toilets; getting into or out of bathtubs; tripping over items such as cords covered by rugs or carpets, carpet edges, or doorway thresholds; slipping on wet surfaces; and descending stairs. Fear of falling is a concern of community-dwelling older adults, and many avoid activities because of their fear (Zijlstra et al., 2007). Falls can be decreased by multiple-component group exercise, Tai Chi, having a physician or pharmacist review all medications, having an eye examination annually, and decreasing hazards in the home that increase falls (Gillespie et al., 2009).

Individual Risk Factors. Other risk factors posing threats to safety include lifestyle, impaired mobility, sensory or communication impairment, and the lack of safety awareness.

Lifestyle. Some lifestyle choices increase safety risks. People who drive or operate machinery while under the influence of chemical substances (drugs or alcohol), work at inherently dangerous jobs, or are risk takers are at greater risk of injury. In addition, people experiencing stress, anxiety, fatigue, or alcohol or drug withdrawal or those taking prescribed medications are sometimes more accident prone. Because of these factors, some people are too preoccupied to notice the source of potential accidents such as cluttered stairs or a stop sign.

Impaired Mobility. A patient with impaired mobility has many kinds of safety risks. Muscle weakness, paralysis, and poor coordination or balance are major factors in falls. Immobilization predisposes patients to additional physiological and emotional hazards, which in turn further restrict mobility and independence. Persons who are physically challenged are at greater risk for injury when entering motor vehicles and buildings that are not handicapped accessible.

Sensory or Communication Impairment. Cognitive impairments associated with delirium, dementia, and depression place patients at greater risk for injury. These conditions contribute to altered concentration and attention span, impaired memory, and orientation changes. Patients with these alterations become easily confused about their surroundings and are more likely to have falls and burns. Patients with visual, hearing, tactile, or communication impairment such as aphasia or a language barrier are not always able to perceive a potential danger or express their need for assistance (see Chapter 49).

Lack of Safety Awareness. Some patients are unaware of safety precautions such as keeping medicine or poisons away from children or reading the expiration date on food products. A complete nursing assessment, including a home inspection, helps you identify the patient's level of knowledge regarding home safety so you can correct deficiencies with an individualized nursing care plan.

Risks in the Health Care Agency. Patient safety continues to be one of the most pressing health care challenges in the nation.

BOX 27-2 THE JOINT COMMISSION 2011 NATIONAL PATIENT SAFETY GOALS FOR HOSPITALS

- Identify patients correctly.
  - Use at least two patient identifiers.
  - Eliminate transfusion errors.
- Improve staff communication.
  - Report important test results in a timely manner.
- Use medicines safely.
  - Label medications.
  - Reduce harm to patients who take anticoagulation therapy.
- Reduce the risk of health care–associated infections.
  - Meet hand hygiene guidelines.
  - Prevent multidrug-resistant organism infections.
  - Prevent central line–associated bloodstream infections.
  - Use safe practices to treat the part of the body where surgery was performed.
- Check patient medicines.
  - Identify current medicines and make sure that it is okay for patients to take any new medicines with current medicines.
  - Give a list of patient's medicines to the next provider before discharge.
  - Give a list of patient's medicines to patient and family before discharge; explain the list.
- Identify patient safety risks.
  - Identify individuals at risk for suicide.

Medical errors are the eighth leading cause of death (Agency for Healthcare Research and Quality, 2010). Medical errors happen when something that was planned as part of medical care doesn't work out or when the wrong plan was used. They occur in all health care settings. You must be aware of regulatory and organizational safety initiatives and individual patient risk factors. The Joint Commission (TJC) and the Centers for Medicare and Medicaid Services (CMS) have placed an increased emphasis on error prevention and patient safety. Their "Speak Up" campaign encourages patients to take a role in preventing health care errors by becoming active, involved, and informed participants on the health care team. For example, patients are encouraged to ask health care workers if they have washed their hands before providing care. National Patient Safety Goals of TJC (2011b) are specifically directed to reduce the risk of medical errors (Box 27-2). The goals are designed to promote specific improvements in patient safety and highlight ongoing problematic areas in health care. These evidence-based recommendations require health care facilities to focus their attention on a series of specific actions.

The National Quality Forum (NQF) (2011a) has the mission of improving the quality of health care in America by:

- Building consensus on national priorities and goals for performance improvement and working in partnership to achieve them;
- Endorsing national consensus standards for measuring and publicly reporting on performance; and
- Promoting the attainment of national goals through education and outreach programs.

Recently the NQF released its National Voluntary Consensus Standards for Public Reporting of Patient Safety Events (NQF, 2011b). The report provides a framework for publicly reporting patient safety information—including events, indicators, and

BOX 27-3 THE NATIONAL QUALITY FORUM LIST OF SERIOUS REPORTABLE EVENTS

Surgical Events
A. Surgery performed on the wrong body part
B. Surgery performed on the wrong patient
C. Wrong surgical procedure performed on a patient
D. Unintended retention of foreign object in a patient after surgery or procedure
E. Intraoperative or immediately postoperative death

Product or Device Events
A. Patient death or serious disability associated with use of contaminated drugs, devices, or biologicals provided by the health care facility
B. Patient death or serious disability associated with use or function of a device in patient care when the device is used or functions other than as intended
C. Patient death or serious disability associated with intravascular air embolism that occurs during care in a health care facility

Patient-Protection Events
A. Infant discharged to wrong person
B. Patient death or serious disability associated with patient elopement
C. Patient suicide or attempted suicide resulting in serious disability during care in a health care facility

Care-Management Events
A. Patient death or serious disability associated with medication error
B. Patient death or serious disability associated with hemolytic reaction as a result of administration of ABO/HLA-incompatible blood or blood products
C. Maternal death or serious disability associated with labor or delivery in a low-risk pregnancy during care in a health care facility
D. Patient death or serious disability associated with hypoglycemia, the onset of which occurs during care in a health care facility
E. Death or serious disability associated with failure to identify and treat hyperbilirubinemia in neonates
F. Stage III or IV pressure ulcers acquired after admission to a health care facility
G. Patient death or serious disability caused by spinal manipulative therapy
H. Artificial insemination with wrong donor sperm or wrong egg

Environmental Events
A. Patient death or serious disability associated with an electric shock during care in a health care facility
B. Any incident in which a line designated for oxygen or other gas to be delivered to a patient contains the wrong gas or is contaminated by toxic substances
C. Patient death or serious disability associated with burn incurred from any source during care in a health care facility
D. Patient death or serious disability associated with fall during care in a health care facility
E. Patient death or serious disability associated with use of restraints or bed rails during care in a health care facility

Criminal Events
A. Care provided by someone impersonating a health care provider
B. Abduction of patient of any age
C. Sexual assault on patient within or on the grounds of a health care facility
D. Death or significant injury resulting from a physical assault that occurs within or on the grounds of the facility

From National Quality Forum (NQF): *Serious reportable events in healthcare 2006 update: a consensus report,* Washington, DC, 2007, NQF p 6, accessed May 25, 2011, from http://www.qualityforum.org/Publications/2007/03/Serious_Reportable_Events_in_Healthcare-2006_Update.aspx.

measures—about health care organizations to consumers. It is important for nurses to understand the NQF standards and their intent since ultimately they influence the types of priorities that patient care organizations (e.g., hospitals, community health centers) set to improve the quality of care delivered to patients. Many of the NQF measures of patient safety (e.g., patient falls with injury, incidence of pressure ulcers, and central line bloodstream infection) are standards for judging the quality of care of health care organizations. The measures are also used by other organizations such as TJC and the CMS. Among the safety measures, the NQF endorsed a select list of serious reportable events (SREs), which was updated in 2006. The 28 events (Box 27-3) are a major focus of health care providers for patient safety initiatives. The CMS names select SREs as *Never Events* (i.e., adverse events that should never occur in a health care setting) (Department of Health and Human Services, 2008). The CMS now denies hospitals higher payment for any hospital-acquired condition resulting from or complicated by the occurrence of certain Never Events (Box 27-4). Many of the hospital-acquired conditions (e.g., fall or stage III pressure ulcer) are nurse-sensitive indicators, meaning that a nurse directly affects their development. The NQF (2010) also released 34 safe practices for better health care. Evidence supports the effectiveness of these practices in reducing the occurrence of adverse health care events.

Being aware of and engaged in activities focused on the prevention of these conditions not only enhances patient safety but also contributes to the overall success of the health care facility. The

BOX 27-4 THE 2009 CENTERS FOR MEDICARE AND MEDICAID SERVICES HOSPITAL-ACQUIRED CONDITIONS (PRESENT-ON-ADMISSION INDICATORS)

- Foreign object retained after surgery
- Air embolism
- Blood incompatibility
- Pressure ulcer stages III and IV
- Falls and trauma (fracture, dislocation, intracranial injury, crushing injury, burn, electric shock)
- Catheter-associated urinary tract infections
- Vascular catheter-associated infections
- Manifestations of poor glycemic control (diabetic ketoacidosis, nonketotic hyperosmolar coma, hypoglycemic coma, secondary diabetes with ketoacidosis, secondary diabetes with hyperosmolarity)
- Surgical site infections following:
  - Mediastinitis following coronary artery bypass graft
  - Certain orthopedic procedures (spine, neck, shoulder, elbow)
  - Bariatric surgery for obesity (laparoscopic gastric bypass, gastroenterostomy, laparoscopic gastric restrictive surgery)
- Deep vein thrombosis and pulmonary embolism following certain orthopedic procedures (total knee replacement, hip replacement)

From Centers for Medicare and Medicaid Services: *Hospital-acquired conditions,* 2010, accessed May 25, 2011, from http://www.cms.gov/HospitalAcqCond/06_Hospital-Acquired_Conditions.asp.

CMS believes that the Never Events will strengthen incentives by hospitals to develop safety practices and reduce health care costs in the long term. Health care facilities often conduct a failure mode and effect analysis (FMEA) to identify problems with processes and products before they occur.

When an actual or potential adverse event occurs, the nurse or health care provider involved completes an incident or occurrence report. An incident report is a confidential document that completely describes any patient accident occurring on the premises of a health care agency (see Chapter 23). Reporting allows the organization to identify trends/patterns throughout the facility and areas to improve. Focusing on the root cause of an event instead of the individual involved promotes a "culture of safety" that helps in specifically identifying what contributed to an error. The probability of an accident occurring declines with adherence to evidence-based principles of safety (Taylor-Adams et al., 2009).

Nurses face specific environmental risks in health care facilities. An example is the various forms of chemicals used. Chemicals found in some medications (e.g., chemotherapy), anesthetic gases, cleaning solutions, and disinfectants are potentially toxic if ingested, absorbed into the skin, or inhaled. Material safety data sheets (MSDSs) are required resources available in any health care agency (Occupational Safety and Health Administration, 1996). The MSDS provides detailed information about the chemical, health hazards imposed, first aid guidelines, and precautions for safe handling and use. MSDSs give information on the steps to take in case the material is released or spilled. Be aware of the location of the MSDSs and be knowledgeable about hazardous chemicals in your environment. Spread of pathogens also presents a risk to both nurses and other patients. Therefore always follow standard and transmission-based isolation precautions, along with proper hand hygiene (see Chapter 28).

Specific risks to a patient's safety within the health care environment include falls, patient-inherent accidents, procedure-related accidents, and equipment-related accidents. The nurse assesses for these four potential problem areas and, considering the developmental level of the patient, takes steps to prevent or minimize accidents.

Falls. Falls result in minor to severe injuries such as hip fractures or head trauma that result in reduced mobility and independence and increase the risk for premature death. Patients who have underlying disease states are more susceptible to fall-related injuries (Hughes, 2008). For example, a patient with a bleeding disorder is more likely to have an intracranial bleed; a patient with osteoporosis has a greater chance for fracture. The unfamiliar environment, acute illness, surgery, mobility status, medications, treatments, and placement of various tubes and catheters are common challenges that place patients of any age at risk of falling. Factors the nurse can influence include assessment and communication about patient risks, information access, signage, the environment, teamwork, and involving the patient and family (Dykes et al., 2009). Falls that result in injuries often extend a patient's length of stay in the health care environment, placing them at an even greater risk for other complications.

Patient-Inherent Accidents. Patient-inherent accidents are accidents (other than falls) in which the patient is the primary reason for the accident. Examples include self-inflicted cuts, injuries, and burns; ingestion or injection of foreign substances; self-mutilation or fire setting; and pinching fingers in drawers or doors. One of the more common precipitating factors for a patient-inherent accident is a seizure.

Procedure-Related Accidents. Procedure-related accidents are caused by health care providers and include medication and fluid administration errors, improper application of external devices, and accidents related to improper performance of procedures such as dressing changes or urinary catheter insertion. Nurses are able to prevent many procedure-related accidents by adhering to organizational policy and procedures and standards of nursing practice. For example, proper preparation and administration of medications, use of patient and medication bar coding, and "Smart" intravenous (IV) pumps reduce medication errors (see Chapters 31 and 41). All staff need to be aware that distractions and interruptions contribute to procedure-related accidents and need to be limited, especially during high-risk procedures such as medication administration. The potential for infection is reduced when surgical asepsis is used for sterile dressing changes or any invasive procedure such as insertion of a urinary catheter. Finally, correct use of safe patient handling techniques and equipment reduces the risk of injuries when moving and lifting patients (see Chapter 47).

Equipment-Related Accidents. Accidents that are equipment related result from the malfunction, disrepair, or misuse of equipment or from an electrical hazard. To avoid rapid infusion of IV fluids, all general-use and patient-controlled analgesic pumps need to have free-flow protection devices. To avoid accidents, do not operate monitoring or therapy equipment without adequate instruction. If faulty equipment is discovered, place a tag on it to prevent it from being used on another patient and promptly report any malfunctions. Assess potential electrical hazards to reduce the risk of electrical fires, electrocution, or injury from faulty equipment. In health care settings the clinical engineering staff make regular safety checks of equipment. Facilities must report all suspected medical device—related deaths to both the FDA and the manufacturer of the product if known (FDA, 2009). This is usually done in conjunction with the risk management department after tagging and removing the piece of equipment.

Building Competency in Safety The nurse manager on an oncology unit learns that the hospital purchased new intravenous (IV) infusion pumps or "smart pumps" that provide a mechanism to deliver chemotherapy drugs more safely. To promote a culture of safety, what does the manager do next to ensure quality safe patient care?

Answers to questions can be found on the Evolve website.

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require the nurse to anticipate necessary information, analyze the data, and make decisions regarding patient care. Critical thinking is an ongoing process. During assessment (Fig. 27-3) you consider all critical thinking elements and information about the specific patient to make appropriate nursing diagnoses.

In the case of safety, the nurse integrates knowledge from nursing and other scientific disciplines, previous experiences in caring for patients who had an injury or were at risk, critical thinking attitudes such as responsibility and discipline, and any standards of practice that are applicable. For example, the American Nurses Association (ANA) standards for nursing practice address the nurse's responsibility in maintaining patient safety. TJC (2011b) also provides standards for safety. You refer to all of this

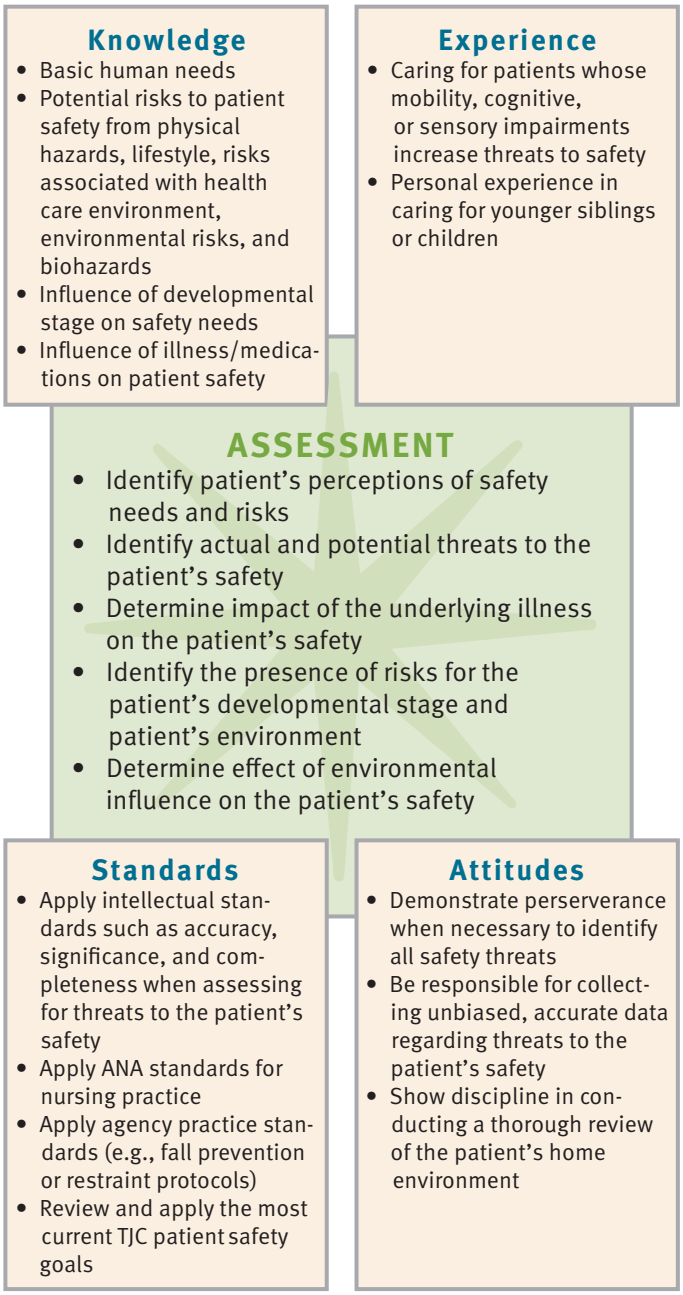

FIG. 27-3 Critical thinking model for safety assessment. *ANA,* American Nurses Association; *TJC,* The Joint Commission.

information and experience as you conduct a detailed assessment of a specific patient. For example, while assessing a specific patient's home environment, you consider typical locations within the home where dangers commonly exist. If a patient has a visual impairment, you apply previous experiences in caring for patients with visual changes to anticipate how to thoroughly assess his or her needs. Critical thinking directs you to anticipate what needs to be assessed and how to make conclusions about available data.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

BOX 27-5 NURSING ASSESSMENT QUESTIONS

Activity and Exercise
- Do you use any assistive devices such as a wheelchair, walker, or cane to help you move or get around? Did someone show you how to use them safely?
- Do you have any difficulty bathing? Dressing? Eating? Using the bathroom? Transferring out of the bed or chair?
- What type of exercise or physical activity do you get? How often?
- How do you handle meal preparation (e.g., use stove and appliances safely)?
- Do you do your own laundry? How do you do this, and where are these appliances located?
- Do you drive an automobile? When do you normally drive? How far?
- How often do you wear a safety belt when in the car?
- Have you recently been involved in a motor vehicle accident?

Medication History
- Which medications (prescription, over-the-counter, herbal) do you take?
- Has your doctor or pharmacist reviewed your medicines with you?
- Do any medications make your dizzy or light-headed?

History of Falls
- Have you ever fallen or tripped over anything in your home?
- Have you ever suffered an injury from a fall? What was it and how did it happen?
- Did you have any symptoms right before you fell? What were they?
- Which activity were you performing before the fall?

Home Maintenance and Safety
- Who does your simple home maintenance or minor home repairs?
- Who shovels your snow? Tends to your lawn?
- Do you feel safe in your home? Which things in your environment make you feel unsafe?
- Do you have someone to call in case of an emergency?
- How do you feel about modifying your home to make it safer? Do you need help finding resources to help you do this?

ASSESSMENT

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Patients generally expect to be safe in health care settings and in their homes. However, there are times when a patient's view of what is safe does not agree with that of the nurse and the standards he or she hopes to enforce. For this reason your assessment needs to be patient centered and include the patient's own perceptions of his or her risk factors, knowledge of how to adapt to such risks, and previous experience with any accidents. This is important if you need to make changes in the patient's environment. Patients usually do not purposefully put themselves in jeopardy. When they are uninformed or inexperienced, threats to their safety occur. You always need to consult patients or family members about ways to reduce hazards in their environment. To conduct a thorough patient assessment, consider possible threats to a patient's safety, including the immediate environment and any individual risk factors. Ask the patient specific questions related to safety (Box 27-5).

Nursing History. A nursing history includes data about a patient's level of wellness to determine if any underlying conditions

TABLE 27-1 Fall Assessment Tool

Fall Risk Factor Category

Scoring not completed for the following reason(s) (check any that apply).

☐ Complete paralysis or completely immobilized. Implement basic safety (low fall risk) interventions.
☐ Patient has a history of more than one fall within 6 months before admission. Implement high–fall risk interventions throughout hospitalization.
☐ Patient has experienced a fall during this hospitalization. Implement high–fall risk interventions throughout hospitalization.
☐ Patient is deemed high fall risk per protocol (e.g., seizure precautions). Implement high fall-risk interventions per protocol.

COMPLETE THE FOLLOWING AND CALCULATE FALL RISK SCORE.

IF NO BOX IS CHECKED, SCORE FOR CATEGORY IS 0	POINTS
Age (single-select) ☐ 60-69 years (1 point) ☐ 70-79 years (2 points) ☐ ≥80 years (3 points)	
Fall History (single-select) ☐ One fall within 6 months before admission (5 points)	
Elimination (Bowel and Urine) (single-select) ☐ Incontinence (2 points) ☐ Urgency or frequency (2 points) ☐ Urgency/frequency and incontinence (4 points)	
Medications: Includes PCA/Opiates, Anticonvulsants, Antihypertensives, Diuretics, Hypnotics, Laxatives, Sedatives, and Psychotropics (single-select) ☐ On one high fall–risk drug (3 points) ☐ On two or more high fall–risk drugs (5 points) ☐ Sedated procedure within past 24 hours (7 points)	
Patient Care Equipment: Any Equipment That Tethers Patient (e.g., IV Infusion, Chest Tube, Indwelling Catheters, SCDs) (single-select) ☐ One present (1 point) ☐ Two present (2 points) ☐ 3 or more present (3 points)	
Mobility (Multi-select, Choose All That Apply and Add Points Together) ☐ Requires assistance or supervision for mobility, transfer, or ambulation (2 points) ☐ Unsteady gait (2 points) ☐ Visual or auditory impairment affecting mobility (2 points)	
Cognition (Multi-select, Choose All That Apply and Add Points Together) ☐ Altered awareness of immediate physical environment (1 point) ☐ Impulsive (2 points) ☐ Lack of understanding of one's physical and cognitive limitations (4 points)	
TOTAL Moderate risk = 6-13 total points High risk = >13 total points

IV, Intravenous.

exist that pose threats to safety. For example, give special attention to assessing a patient's gait, lower-body muscle strength and coordination, balance, and vision. Consider a review of the patient's developmental status as you analyze assessment information. Also review if the patient is taking any medications or undergoing any procedures that pose risks. For example, use of diuretics increases the frequency of voiding and results in the patient having to use toilet facilities more often. Falls often occur with patients who have to get out of bed quickly because of urinary urgency.

Health Care Environment. When the patient is cared for within a health care facility, you need to determine if any hazards exist in the immediate care environment. Does the placement of equipment (e.g., drainage bags, IV pumps) or furniture pose barriers when the patient attempts to ambulate? Does positioning of the patient's bed allow him or her to easily reach items on a bedside table or stand? Does the patient need assistance with ambulation? Are there multiple tubes or IV lines? Is the call bell within reach? The nurse collaborates with clinical engineering staff to make sure that equipment functions properly and is in good condition.

Risk for Falls. Assessment of a patient's risk factors for falling is essential in determining specific needs and developing targeted interventions to prevent falls. Many different fall assessment instruments are available; use the tool chosen by your health care agency. A fall assessment tool (Table 27-1) helps you assess important risk factors. At a minimum the assessment needs to be completed on

admission, following a change in the patient's condition, after a fall, and when transferred. If it is determined that the patient is at risk for falling, regular assessment always continues. In many cases family members are important resources in assessing a patient's fall risk. Families often are able to report on the patient's level of confusion and ability to ambulate. Based on the results of a fall risk assessment, you implement multiple evidence-based interventions. It is very important to inform a patient and family members about the patient's risks. Often younger patients are not aware of how medications and treatments cause dizziness, orthostatic hypotension, or changes in balance. When patients are unaware of their risks, they are less likely to ask for assistance. If family members are informed, they will often call for help (when they are visiting patients) to be sure that patients are appropriately assisted.

Risk for Medical Errors. Be alert to factors within your own work environment that create conditions in which medical errors are more likely to occur. Studies show that overwork and fatigue cause a significant decrease in alertness and concentration, leading to errors (Trinkoff et al., 2006). It is important for you to be aware of these factors and include checks and balances when working under stress. For example, to reduce the potential for a medical error, it is essential for you to check the patient's identification by using two identifiers (e.g., name and birthday or name and account number) according to facility policy before beginning any procedure or administering a medication (see Chapter 31).

Disasters. Hospitals must be prepared to respond and care for a sudden influx of patients at the time of a community disaster. Guidelines for a disaster response are included in a facility emergency management plan. All hospitals conduct disaster drills on a routine basis. Communication is a key to any emergency management plan. Nurses must know what happened, how many patients to expect, and when patients will begin to arrive so they can prepare both themselves and their facility. Although the occurrence of a bioterrorist attack has been limited to the anthrax deaths following September 11, 2001, the threat is very real. Be prepared to make accurate and timely assessments in any type of setting. A bioterrorist attack will likely resemble a natural outbreak initially. Acutely ill patients representing the earliest cases after a covert attack seek care in emergency departments. Patients less ill at the onset of an illness possibly seek care in primary care settings. Basic epidemiological principles exist to assess whether a patient's presentation of symptoms is typical of an endemic disease or an unusual event that raises concern. Features that alert nurses to the possibility of a bioterrorism-related outbreak include the following (Dire, 2008):

- Disease (or strain) not endemic
- Unusual antibiotic resistance patterns
- Atypical clinical presentation
- Case distribution geographically (from same location) and/or temporally inconsistent
- Other inconsistent elements (e.g., number of cases, mortality and morbidity rates, deviations from disease occurrence baseline)

Patient's Home Environment. When caring for a patient in the home, a home hazard assessment is necessary. See http://homesafetycouncil.org/safetyguide for a sample home assessment guide. A thorough hazard assessment covers topics such as adequacy of lighting (inside and outdoors), presence of safety devices, placement of furniture or other items that can create barriers, condition of flooring, and safety in the kitchen and bathrooms. Know where medications and cleaning supplies are located. Walk through the home with the patient and discuss how he or she normally conducts daily activities and whether the environment poses problems. Assess for the presence of locks on doors and windows that make the home less susceptible to intruders. When assessing the adequacy of lighting, inspect the areas where the patient moves and works such as outside walkways, steps, interior halls, and doorways. Getting a sense of the patient's routines helps you recognize less obvious hazards.

Assessment for risk of food infection or poisoning includes assessing a patient's knowledge of food preparation and storage practices. For example, does a patient know to check expiration dates of prepared food and milk products? Does he or she keep foods in the refrigerator that are fresh and not spoiled? Does the patient clean fresh fruits and vegetables correctly before eating them? Assess for clinical signs of infection by conducting an examination of GI and central nervous system function, observing for a fever, and analyzing the results of cultures of feces and emesis. In the home inspect suspected food and water sources and assess the patient's handwashing practices. It is useful to ask patients when they routinely wash their hands. This then prompts a helpful discussion about the purpose and importance of handwashing.

Assessment of the environmental comfort of a patient's home includes a review of when the patient normally has heating and cooling systems serviced. Does the patient have a functional furnace or space heater? Does the home have air conditioning or fans? You need to inform patients who use space heaters of the risk for fires. Are smoke detectors, carbon monoxide detectors, and fire extinguishers present and placed strategically throughout the home and checked routinely?

When patients live in older homes, encourage them to have inspections for the presence of lead in paint, dust, or soil. Because lead also comes from the solder or plumbing fixtures in a home, patients need to have water from each faucet tested. Local health offices will help homeowners locate a trained lead inspector who takes samples from various locations and has them analyzed at a laboratory for lead content.

It is important that your assessment help individuals focus on avoiding losses and reducing their risk for injury associated with disasters. The FEMA (http://www.fema.gov/) and the American Red Cross (http://www.redcross.org/) provide nationwide education to help community members prepare for disasters of all types.

NURSING DIAGNOSIS

Gather data from your nursing assessment and analyze clusters of defining characteristics to identify relevant nursing diagnoses. Include specific related or contributing factors to individualize your nursing care (Box 27-6). For example, the nursing diagnosis *risk for injury* is sometimes related to altered mobility or sensory alteration (e.g., visual). Altered mobility leads you to select such nursing interventions as range-of-motion (ROM) exercises or teaching the proper use of safety devices such as side rails, canes, or crutches. Visual impairment as the related factor leads you to select different interventions such as keeping the area well lit; orienting the patient to the surrounding; or keeping eye glasses clean, handy, and well protected. When you do not identify the correct related factor, the use of inappropriate interventions increases a patient's risk for injury. For example, not evaluating the home environment for hazards possibly results in sending a hospitalized patient home only to return with an additional

BOX 27-6 NURSING DIAGNOSTIC PROCESS

Risk for Injury

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Observe patient's posture, range of motion, strength, balance, and body alignment.	Uncoordinated, shuffling gait Stooped posture
Ask about patient's visual acuity.	Reports difficulty seeing at night Reports "tripping" over rugs and furniture
Complete a home hazard appraisal.	Poorly lighted home Rooms filled with small items Excessive amount of furniture for size of room Rugs not secure

injury. Nursing diagnoses for patients with safety risk include the following:

- Risk for falls
- Impaired home maintenance
- Risk for injury
- Deficient knowledge
- Risk for poisoning
- Risk for suffocation
- Risk for trauma

PLANNING

Patients with actual or potential risks to safety require a nursing care plan with interventions that prevent and minimize threats to their safety. Design your interventions to help a patient feel safe to move about and interact freely within the environment. The total plan of care addresses all aspects of patient needs and uses resources of the health care team and the community when appropriate. Critically synthesize information from multiple sources (Fig. 27-4). Critical thinking ensures that the patient's plan of care integrates all that you learned about the patient and the key critical thinking elements. For example, you reflect on knowledge regarding the services that other disciplines (e.g., occupational therapy, case management) provide in helping patients return to their home environments safely. Also reflect on any previous experience when a patient benefited from safety interventions. Such experience helps you adapt approaches with each new patient. Applying critical thinking attitudes such as creativity helps you to collaborate with the patient in planning interventions that are relevant and most useful, particularly when making changes in the home environment.

Goals and Outcomes. You collaborate with the patient, family, and other members of the health care team when setting goals and expected outcomes during the planning process (see the Nursing Care Plan). The patient who is an active participant in reducing threats to safety becomes more alert to potential hazards and is more likely to adhere to the plan. Make sure that goals and outcomes for each nursing diagnosis are measurable and realistic, with consideration of the resources available to the patient. For example, in the case of the nursing diagnosis of *impaired physical mobility related to left-sided paralysis*, the goal is the patient "remains free of injury by discharge." Examples of expected outcomes include:

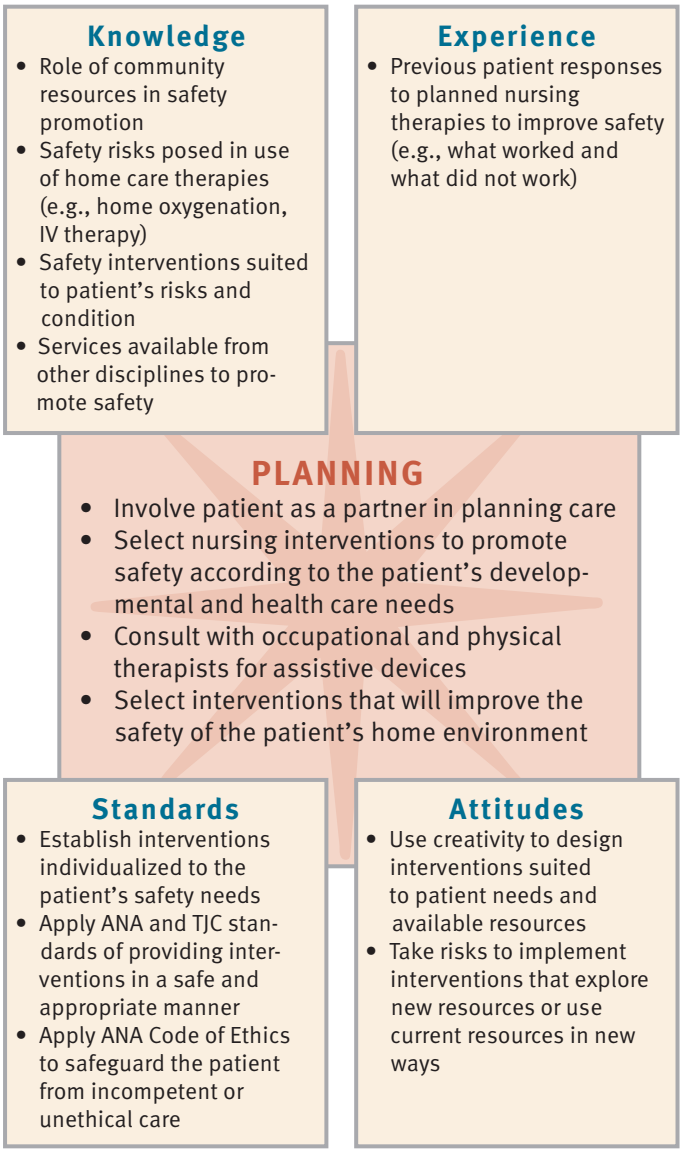

FIG. 27-4 Critical thinking model for safety planning. *ANA,* American Nurses Association; *TJC,* The Joint Commission.

- Patient uses tripod cane correctly within 24 hours.
- Patient describes approach to rise up from bed correctly with assistance by end of the teaching session today.

Setting Priorities. Prioritize a patient's nursing diagnoses and interventions to provide safe and efficient care. For example, the patient described in the concept map (Fig. 27-5) has several nursing diagnoses. The patient's mobility problem is an obvious priority because of its influence on risk for falls and skin integrity. Plan individualized interventions based on the severity of risk factors and the patient's developmental stage, level of health, lifestyle, and cultural needs (Box 27-7). Planning involves an understanding of the patient's need to maintain independence within physical and cognitive capabilities. Collaborate to establish ways of maintaining the patient's active involvement within the home and health care environment. Education of the patient and family is also an important intervention to plan for reducing safety risks over the long term.

NURSING CARE PLAN

Risk for Falls

ASSESSMENT

Mr. Key, a visiting nurse, is seeing Ms. Cohen, an 85-year-old woman, at her home. The patient is recovering from a mild stroke affecting her left side. Ms. Cohen lives alone but receives regular assistance from her daughter Peggy and son Michael, who both live within 10 miles. Mr. Key's assessment included a discussion of Ms. Cohen's health problem and how the stroke has affected her, a pertinent physical examination, and home hazard assessment.

*Assessment Activities**	*Findings/Defining Characteristics*
Ask how the stroke has affected her mobility.	She responds, "I **bump into things,** and **I'm afraid I'm going to fall.**"
Conduct a home hazard assessment.	Cabinets in kitchen are **cluttered** and full of breakable items that could fall out. **Throw rugs are on floors;** bathroom **lighting is poor** (40-watt bulbs); bathtub **lacks safety strips** or grab bars; **home is cluttered** with furniture and small objects.
Observe gait and posture.	She has **kyphosis** and a **hesitant, uncoordinated gait;** frequently holds walls for support.
Assess muscle strength.	**Left arm and leg are weaker** than right.
Assess visual acuity with corrective lenses.	She has **trouble reading and seeing familiar objects at a distance** while wearing current glasses.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Risk for falls

PLANNING

Goals	*Expected Outcomes (NOC)*†
Mrs. Cohen's family will modify the home to eliminate hazards within 1 month.	**Risk Control** Family members will reduce modifiable hazards in kitchen and hallway within 1 week. Family members will make revisions to bathroom in 1 month.
Ms. Cohen and family will be knowledgeable of potential hazards for Ms. Cohen's age-group within 1 week.	**Knowledge: Personal Safety** Ms. Cohen and daughter will identify risks for falls and prevention methods to avoid falls in home at conclusion of teaching session next week.
Ms. Cohen will express greater sense of feeling safe from falling in 1 month.	**Fall Prevention Behavior** Ms. Cohen will report improved vision with the aid of new eyeglasses in 2 weeks.
Ms. Cohen will be free of injury within 1 week.	Ms. Cohen will safely ambulate throughout the home within 1 week.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡ *Fall Prevention*	RATIONALE
Review findings from home hazard assessment with Ms. Cohen and her children and collaborate on proposed changes.	Home hazard assessment highlights extrinsic factors that lead to falls and that can be changed.
Establish a list of priorities to modify and have Ms. Cohen's son assist in installing bathroom safety devices.	Implementing home modifications based on home assessment decreases falls (Pynoos, 2010).
Discuss with Ms. Cohen and daughter the normal changes of aging, effects of recent stroke, associated risks for injury, and how to reduce risks.	Education regarding hazards reduces fear of falling (Banez, 2008).
Encourage daughter to schedule vision testing for new prescription within 2 to 4 weeks.	Improved visual acuity reduces incidence of falls (Edelman and Mandle, 2010).
Refer to physical therapist to assess need for strengthening and endurance training and use of assistive devices for kyphosis, left-sided weakness, and gait.	Exercise is effective in reducing falls and needs to include a comprehensive program combining muscle strengthening, balance, and/or endurance training for a minimum of 12 weeks (Costello, 2008)

‡Intervention classification labels from Bulechek GM, Butcher HK, Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

NURSING CARE PLAN

***Risk for Falls*—cont'd**

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Ms. Cohen and family to identify fall risks.	Ms. Cohen and family are able to identify risks during a walk through the home and expressed a greater sense of safety as a result of changes made.	Ms. Cohen and family are more knowledgeable of potential hazards.
Observe environment for elimination of hazards.	Throw rugs were removed. Lighting increased to 75 watts except in bathroom and bedroom.	Environmental hazards are partially reduced.
Reassess Ms. Cohen's visual acuity.	Ms. Cohen has new glasses and says she is able to read better and see distant objects more clearly.	Ms. Cohen's vision has improved, enabling her to ambulate more safely.
Observe Ms. Cohen's gait and posture.	Ms. Cohen's gait remains hesitant and uncoordinated; she reports that her daughter has limited time to take her to the physical therapist.	Outcome of safe ambulation is not totally achieved; help daughter develop a schedule that allows her time to take her mother to physical therapy appointments.

CONCEPT MAP

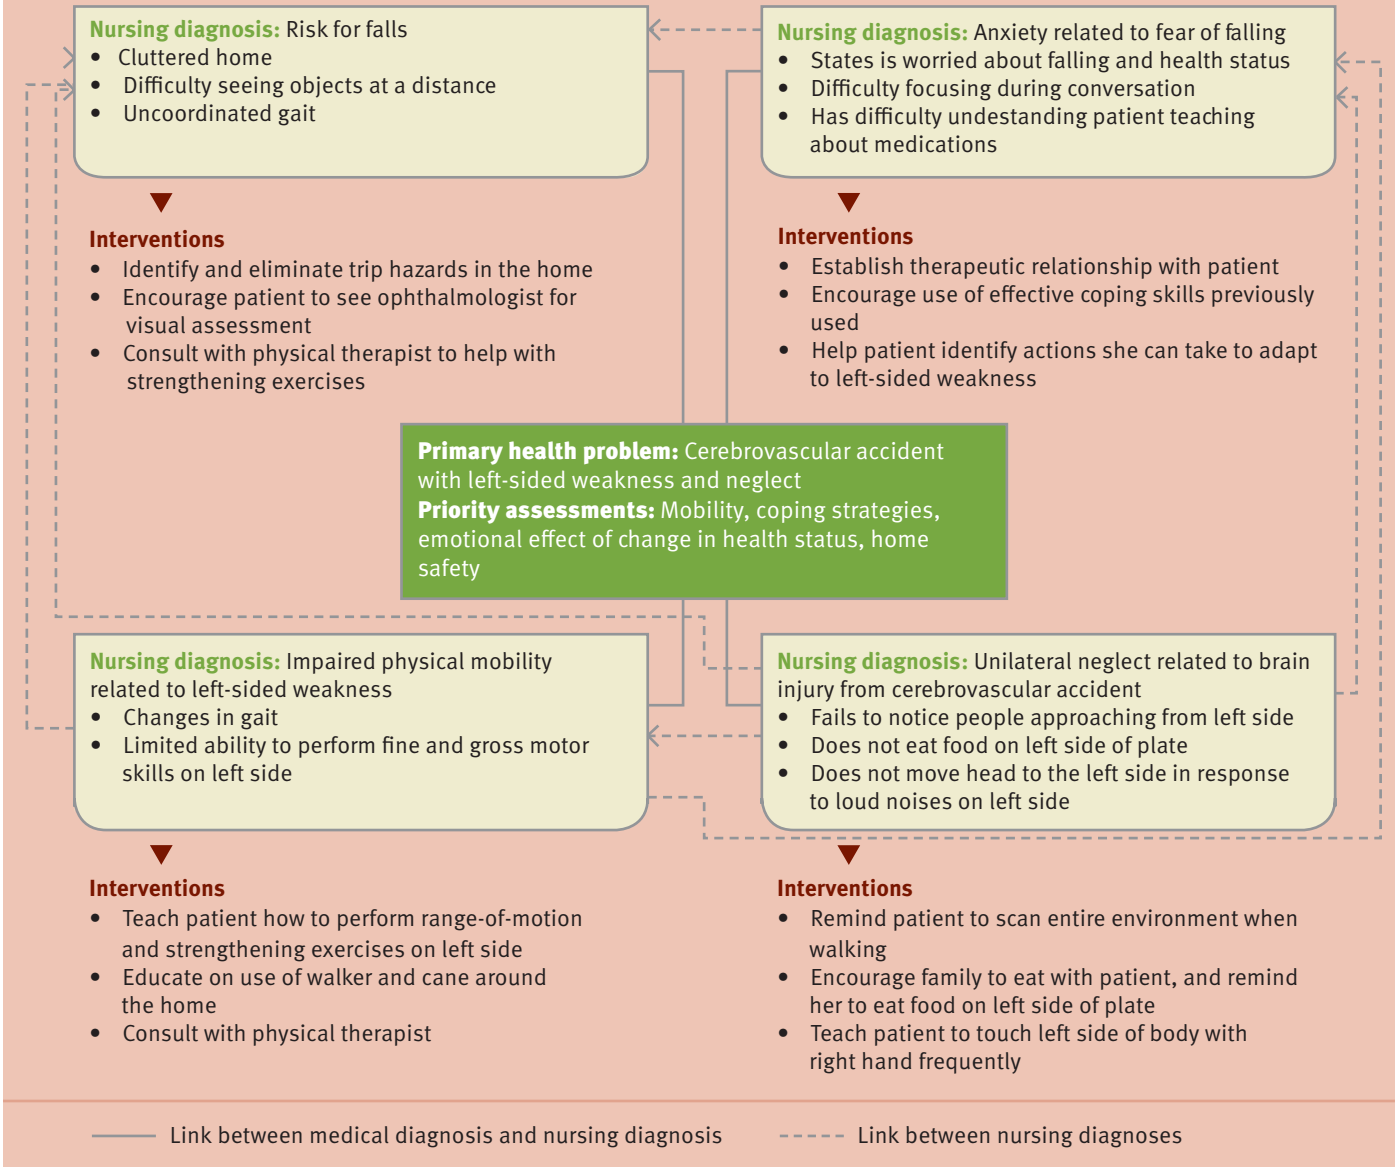

FIG. 27-5 Concept map for Ms. Cohen. *ADLs,* Activities of daily living; *CVA,* cerebrovascular accident.

BOX 27-7 CULTURAL ASPECTS OF CARE

A Patient-Centered Care Approach

Hospitalization places patients at risk for injury in an unfamiliar and confusing environment. The experience is usually at least minimally frightening. Normal life cues such as a bed without side rails and the direction one usually takes to the bathroom are absent. Thought processes and coping mechanisms are affected by illness and its accompanying emotions. Thus patients are more vulnerable to injury. This vulnerability is often intensified for patients of diverse backgrounds. It is a nurse's responsibility to diligently protect all patients, regardless of their socioeconomic status and cultural background. Most untoward events are related to failures of communication. This is especially important during assessment. Ensure you use an approach that recognizes a patient's cultural background so you ask appropriate questions to reveal health behaviors and risks. You also need to be aware of cultural beliefs about restraints when caring for patients who need restraints. Safety is enhanced when you consider patients in light of the whole person and value seeing each care situation through "the patient's eyes" and not just through your own perspective. Some specific patient-centered safety guidelines about the use of restraints follow.

Implications for Practice

- When restraints are needed, assess their meaning to the patient and the family. For example, some Asian families view the restraining of older adults as disrespectful. Similarly some survivors of war or persecution view restraints as imprisonment or punishment.
- Collaborate with family members in accommodating a patient's cultural perspectives about restraints. Removing the restraints when family members are present shows respect and caring for the patient.
- Define the protocol of the nursing unit on the use of restraints. Identify potential areas for negotiation with the patient's/family's preferences such as using a jacket versus arm restraints.

Teamwork and Collaboration. Collaboration with the patient, family, and other disciplines such as social work and occupational and physical therapy become an important part of the patient's plan of care. For example, a hospitalized patient may need to go to a rehabilitation facility to gain strength and endurance before being discharged home. Communication is essential. You communicate risk factors and the plan of care with the patient, family, and other health care providers, including other disciplines and nurses on other shifts. Permanent dry-erase boards in the patient room with patient information such as activity and level of assistance communicate information to all health care providers. A standard approach to communication such as SBAR (*S*ituation, *B*ackground, *A*ssessment, *R*ecommendation) helps you obtain and organize information (see Chapter 26).

Patients need to be able to identify, select, and know how to use resources within their community (e.g., neighborhood block homes, local police departments, and neighbors willing to check on their well-being) that enhance safety. Make sure that the patient and family understand the need for these resources and are willing to make changes that promote their safety.

IMPLEMENTATION

The QSEN (2011) project outlines recommended skills to ensure nurse competency in patient safety. Among these skills are those involving safe nursing practice during direct care:

- Demonstrate effective use of technology and standardized practices that support safety and quality.
- Demonstrate effective use of strategies to reduce risk of harm to self or others.
- Use appropriate strategies to reduce reliance on memory (such as forcing functions, checklists).

Direct your nursing interventions toward maintaining the patient's safety in all types of settings. You implement health promotion and illness prevention measures in the community setting, whereas prevention is a priority in the acute care setting.

Health Promotion. To promote an individual's health, it is necessary for the individual to be in a safe environment and practice a lifestyle that minimizes risk of injury. Edelman and Mandle (2010) describe passive and active strategies aimed at health promotion. Passive strategies include public health and government legislative interventions (e.g., sanitation and clean water laws) (see Chapter 3). Active strategies are those in which the individual is actively involved through changes in lifestyle (e.g., wearing seat belts or installing outdoor lighting) and participation in wellness programs.

Nurses participate in health promotion activities by supporting legislation, acting as positive role models, and working in community-based settings. Because environmental and community values have the greatest influence on health promotion, community and home health nurses are able to assess and recommend safety measures in the home, school, neighborhood, and workplace.

Developmental Interventions

Infant, Toddler, and Preschooler. Growing, curious children need adults to protect them from injury. Children are trusting of their environment and do not perceive themselves to be in danger. Educate parents or guardians about reducing risks of injuries to children and ways to promote safety in the home (Table 27-2). Nurses working in prenatal and postpartum settings easily incorporate safety into the care plan of the childbearing family. Community health nurses assess the home and show parents how to promote safety. Educate parents about the importance of immunizations and how they protect a child from life-threatening disease.

School-Age Child. School-age children increasingly explore their environment (see Chapter 12). They have friends outside their immediate neighborhood; and they become more active in school, church, and community activities. The school-age child needs specific teaching regarding safety in school and at play. See Table 27-2 for nursing interventions to help guide the parent in providing for the safety of the school-age child.

Adolescent. Risks to the safety of adolescents involve many factors outside the home because much of their time is spent away from home and with their peer group (see Chapter 12). Adults serve as role models for adolescents and, through providing examples, setting expectations, and providing education, help them minimize risks to their safety. This age-group has a high incidence of suicide because of feelings of decreased self-worth and hopelessness. Be aware of the risks posed at this time and be prepared to teach adolescents and their parents measures to prevent accidents and injury.

Adult. Risks to young and middle-age adults frequently result from lifestyle factors such as childrearing, high stress levels, inadequate nutrition, use of firearms, excessive alcohol intake, and substance abuse (see Chapter 13). In this fast-paced society there also appears to be more expression of anger, which can quickly precipitate accidents related to "road rage." Help adults understand their safety risks and guide them in making lifestyle modifications by

TABLE 27-2 Interventions to Promote Safety for Children and Adolescents

INTERVENTION	RATIONALE
Infants and Toddlers	
Have infants sleep on their back or side. Teach parents the mnemonic "back to sleep."	Placing infants on their back confers the lowest risk of sudden infant death syndrome (SIDS) and is the preferred position (American Academy of Pediatrics, 2005).
Do not fill cribs with pillows, large stuffed toys, or comforters. Use snug-fitting sheets.	Possibility exists for infants to become entwined in sheets and other bedding and suffocate.
Do not attach pacifiers to string or ribbon and place around a child's neck.	String or ribbon around the neck increases risk for choking.
Follow all instructions for preparing and storing formula.	Proper formula preparation and storage prevent contamination. Following product directions ensures proper concentration of formula. Undiluted formula causes fluid and electrolyte disturbances; very diluted formula does not provide sufficient nutrients.
Use large, soft toys without small parts such as buttons.	Small parts become dislodged, and choking and aspiration can occur.
Do not leave the mesh sides of playpens lowered; spaces between crib slats need to be less than 2⅜ inches (6 cm) apart.	Possibility exists for a child's head becoming wedged in the lowered mesh side or between crib slats, and asphyxiation may occur.
Never leave crib sides down or babies unattended on changing tables or in infant seats, swings, strollers, or high chairs.	Infants and toddlers roll or move and fall from changing tables or out of accessories such as infant seats or swings.
Discontinue using accessories such as infant seats and swings when the child becomes too active or physically too big and/or according to the manufacturer's directions.	When physically active or too big, the child can fall out of or tip over these accessories and suffer an injury.
Never leave a child alone in the bathroom, tub, or near any water source (e.g., pool).	Supervision reduces risk for accidental drowning.
Baby-proof the home; remove small or sharp objects and toxic or poisonous substances, including plants; install safety locks on floor-level cabinets.	Babies explore their world with their hands and mouth. Choking and poisoning can occur.
Remove plastic bags from the cleaners or grocery store from the home.	Removal reduces risk for suffocation from plastic bags.
Cover electrical outlets.	Covers reduce opportunity for crawling babies to insert objects into outlets and experience an electrical shock.
Place window guards on all windows.	Guards prevent children from falling out of windows.
Install keyless locks (e.g., deadbolts) on doors above a child's reach, even when they are standing on a chair.	Deadbolts prevent a toddler from leaving the house and wandering off. Death from exposure, car accidents, and drowning can occur. Keyless locks allow for rapid exit in case of fire.
Put children weighing less than 80 pounds or under 8 years of age in an age/weight-appropriate car seat that has been installed according to manufacturer's instructions (see Fig. 27-1). This includes car seats and booster seats. In cars with a passenger air bag, children under 12 need to be in the back seat. All passengers need to wear seat belts.	In case of a sudden stop or crash, an unrestrained child suffers severe head injuries and death.
Caregivers need to learn cardiopulmonary resuscitation (CPR) and the Heimlich maneuver.	Caregivers need to be prepared to intervene in acute emergencies such as choking.
Preschoolers	
Teach children to swim at an early age but always provide supervision near water.	Learning to swim is a useful skill that can someday save a child's life. However, all children need constant supervision near water.
Teach children how to cross streets and walk in parking lots. Instruct them to never run out after a ball or toy.	Pedestrian accidents involving young children are common.
Teach children not to talk to, go with, or accept any item from a stranger.	Avoiding strangers reduces the risk of injury and stranger abduction.
Teach children basic physical safety rules such as proper use of safety scissors, never running with an object in their mouth or hand, and never attempting to use the stove or oven unassisted.	Risk of injury is lower if children know basic safety procedures.
Teach children not to eat items found in the street or grass.	Avoiding these items reduces risk for possible poisoning.
Remove doors from unused refrigerators and freezers. Instruct children not to play or hide in a car trunk or unused appliances.	If a child cannot freely exit from appliances and car trunks, asphyxiation can occur.

Continued

TABLE 27-2 Interventions to Promote Safety for Children and Adolescents—cont'd

INTERVENTION	RATIONALE
School-Age Children	
Teach children the safe use of equipment for play and work.	The child needs to learn the safe, appropriate use of implements to avoid injury.
Teach children proper bicycle safety, including use of helmet and rules of the road.	Reduces injuries from falling off a bike or being hit by a car.
Teach children proper techniques for specific sports and the need to wear proper safety gear (e.g., helmets, eyewear, mouth guards).	Using proper sports techniques, correct equipment, and protective gear prevents injuries.
Teach children not to operate electrical equipment while unsupervised.	If an electrical mishap were to occur, no one would be available to help.
Do not allow children access to firearms or other weapons. Keep all firearms in locked cabinets.	Children are often fascinated by firearms and weapons and sometimes attempt to play with them.
Adolescents	
Encourage enrollment in driver's education classes.	Many injuries in this age-group are related to motor-vehicle accidents.
Provide information about the effects of using alcohol and drugs.	Adolescents are prone to risk-taking behaviors and are subject to peer pressures.
Refer adolescents to community and school-sponsored activities.	The adolescent needs to socialize with peers yet needs some supervision.
Encourage mentoring relationships between adults and adolescents.	Adolescents are in need of role models after whom they can pattern their behavior.
Teach them safe use of the Internet.	Avoids overuse and possible exposure to inappropriate websites.

Modified from Hockenberry M, Wilson D: *Wong's nursing care of infants and children,* ed 9, St Louis, 2011, Mosby.

BOX 27-8 FOCUS ON OLDER ADULTS

Physiological Changes of Aging and Their Effect on Patient Safety

- Older adults experience visual and hearing alterations. Encourage annual vision and hearing examinations and frequent cleaning of glasses and hearing aids as a means of preventing falls and burns.
- Some older adults have slowed reaction time. Teach patients safety tips for avoiding automobile accidents. Sometimes driving needs to be restricted to daylight hours or temporarily or permanently suspended.
- Range of motion, flexibility, and strength decrease. Encourage supervised exercise classes for older adults and teach them to seek assistance with household tasks as needed. Safety features such as grab bars in the bathroom are often necessary.
- Reflexes are slowed, and the ability to respond to multiple stimuli is reduced. Provide adequate, meaningful stimuli but prevent sensory overload.
- Nocturia and incontinence are more frequent in older adults. Institute a regular toileting schedule for the patient. A recommended frequency is every 3 hours. Give diuretics in the morning. Provide assistance, along with adequate lighting, to patients who need to go to the bathroom at night.
- Memory is sometimes impaired. Patients need to use medication organizers, which can be purchased at any drugstore at a very reasonable cost. Fill these dispensers once a week with the proper medications to be taken at a specific time during the day.
- The family plays a significant role in the care of older adults. There are 65.7 million unpaid caregivers for adults, who are mostly family members (National Alliance for Caregiving, 2011). These family caregivers spend an average of 19 hours per week providing care (National Alliance for Caregiving, 2009). Encourage the family to allow the older adult to remain as independent as possible and provide help only for those things that are especially stressful or depleted.
- The high prevalence of chronic conditions in older adults results in the use of a high number of prescription and over-the-counter medications. Coupled with age-related changes in pharmacokinetics, there is a greater risk of serious adverse effects. Medications typically prescribed for older adults include anticholinergics, diuretics, anxiolytic and hypnotic agents, antidepressants, antihypertensives, vasodilators, analgesics, and laxatives, all of which pose risks or interact to increase the risk for falls. Review the patient's drug profile to ensure that these drugs are used cautiously and assess the patient regularly for any adverse effects that increase fall risk.

referring them to resources such as classes to help quit smoking and for stress management, including employee-assistance programs. Also encourage adults to exercise regularly, maintain a healthy diet, practice relaxation techniques, and get adequate sleep.

Older Adult. Nursing interventions for older adults reduce the risk of falls and other accidents and compensate for the physiological changes of aging (Box 27-8). Most injuries to older adults involve falls, automobile accidents, and those related to burns or fires (National Center for Injury Prevention and Control, 2010b). Advancing age and the concurrent physiological changes in vision, hearing, mobility, reflexes, circulation, and the ability to make quick judgments all predispose older adults to falls (see Chapter 14). Certain disease states common to older adults such as arthritis or strokes and the effects of many medications such as sedatives, diuretics, and anticoagulants also increase the chance of injury. The American Geriatric Society (2009) developed an algorithm on prevention of falls (Fig. 27-6). Hospitalization or any unfamiliar environment, confusion, multiple medical problems, various medications, immobility concerns, urinary urgency, age-related sensory changes, and postural instability are major contributors to falling (Meiner, 2011). Provide information about neighborhood resources to help the older adult maintain an independent lifestyle. Older

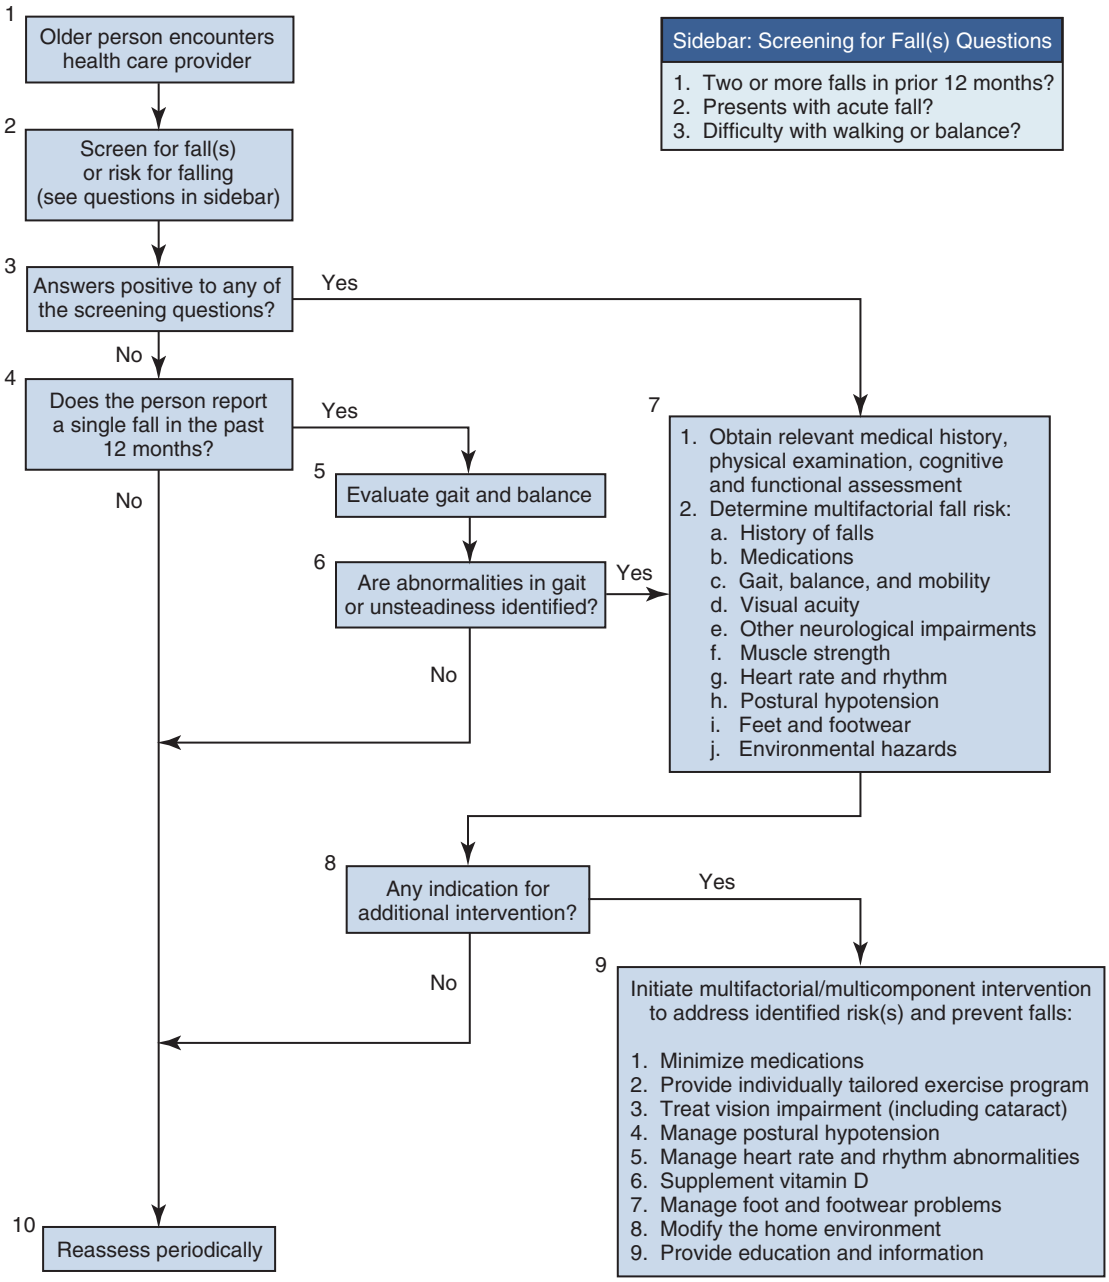

FIG. 27-6 American Geriatrics Society Clinical Practice Guideline Fall Prevention Algorithm 2010. (From American Geriatrics Society/British Geriatrics Society: *Clinical practice guideline for prevention of falls in older persons,* 2010, accessed May 25, 2011, from http://www.medcats.com/FALLS/frameset.htm.)

adults frequently relocate to new neighborhoods and need to become acquainted with new resources such as modes of transportation, church schedules, and food resources (e.g., Meals on Wheels).

Building Competency in Patient-Centered Care A 68-year-old male patient experienced a stroke 2 weeks ago. He has weakness and reduced sensation in his right leg and arm. He is returning home from the hospital and will have ongoing rehabilitation. What are this patient's risks for injury on returning home, and how does the nurse involve the family in the patient's care?

Answers to questions can be found on the Evolve website.

Educate patients regarding safe driving tips (e.g., driving shorter distances or only in daylight, using side and rearview mirrors carefully, and looking behind them toward their "blind spot" before changing lanes). If hearing is a problem, encourage the patient to keep a window rolled down while driving or reduce the volume of the radio or CD player. Counseling is often necessary to help older patients make the decision of when to stop driving. At that time help locate resources in the community that provide transportation.

Burns and scalds are also more apt to occur with older people because they sometimes forget and leave hot water running or become confused when turning the dials on a stove or other heating appliance. Nursing measures for preventing burns minimize the

risk from impaired vision. Hot water faucets and dials are color coded to make it easier for the adult to know which is hot and which is cold. Reducing the temperature of the hot water heater is also very beneficial.

Many older adults love to walk. Reduce pedestrian accidents for older adults and all other age-groups by persuading people to wear reflectors on garments when walking at night; stand on the sidewalk and not in the street when waiting to cross a street; always cross at corners and not in the middle of the block (particularly if the street is a major one); cross with the traffic light and not against it; and look left, right, and left again before entering the street or crosswalk.

Environmental Interventions. Nursing interventions directed at eliminating environmental threats include those associated with a person's basic needs and general preventive measures.

Basic Needs. Nurses contribute to a safer environment by helping patients meet basic needs related to oxygen, nutrition, and temperature. When oxygen is in use, precautions must be taken to prevent fire. Contact with heat or a spark is required to trigger combustion; therefore certain precautions are necessary, regardless of the setting where oxygen is in use. Post "No Smoking" and "Oxygen in Use" signs in patient rooms. Do not use oxygen around electrical equipment or flammable products. Store oxygen tanks upright in carts or stands to prevent tipping or falling or place the tanks flat on the floor when not in use. Check tubing for kinks that would affect the oxygen flow. Maintain oxygen at the prescribed liter flow and do not change without a health care provider's order. Additional precautions are indicated for liquid or pressurized oxygen and when traveling with home oxygen. Refer to the oxygen supplier. In the home recommend that the patient be sure to have annual inspections of heating systems, chimneys, and fuel-burning appliances. Carbon monoxide detectors are available at a reasonable cost but are not a replacement for proper use and maintenance of fuel-burning appliances.

Teach basic techniques for food handling and preparation so nutritional needs are met safely:

- Proper refrigeration, storage, and preparation of food decrease the risk of foodborne illness. Store perishable foods in refrigerators to maintain freshness.
- Wash hands before preparing foods.
- Rinse fruits and vegetables thoroughly.
- Pay attention to prevent cross-contamination of one food with another during food preparation, especially with poultry.
- Use a separate cutting board for vegetables, meats, and poultry.
- Adequately cook foods to kill any residual organisms. Refrigerate leftovers promptly. Bacteria grow quickly at room temperature.
- Have family caregivers label the date when leftovers are saved.

General Preventive Measures. Adequate lighting and security measures in and around the home, including the use of nightlights, exterior lighting, and locks on windows and doors, enable patients to reduce the risk of injury from crime. The local police department and community organizations often have safety classes available for residents to learn how to take precautions to minimize the chance of becoming involved in a crime. For example, some useful tips include always parking the car near a bright light or busy public area, carrying a whistle attached to the car keys, keeping car doors locked while driving, and always paying attention while driving to notice if anyone starts to follow the car.

BOX 27-9 PATIENT TEACHING

Prevention of Electrical Hazards

Objective

- Patient will recognize and eliminate electrical hazards in the home.

Teaching Strategies

- Discuss importance of checking for grounding of electrical appliances and other equipment.
- Provide examples of common hazards: frayed cords, damaged equipment, and overloaded outlets.
- Discuss guidelines to prevent electrical shocks:
  - Use extension cords only when necessary and use electrical tape to secure the cord to the floor, preferably against baseboards.
  - Do not run wires under carpeting.
  - Grasp the plug, not the cord, when unplugging items.
  - Keep electrical items away from water.
  - Do not operate unfamiliar equipment.
  - Disconnect items before cleaning.

Evaluation

- Have patient list electrical hazards existing in the home.
- Review steps the patient will take to eliminate these hazards.
- Check the home after the patient has had an opportunity to eliminate hazards.

Modifications in the environment easily reduce the risk of falls. To reduce the risk of injury in the home, remove all obstacles from halls and other heavily traveled areas. Necessary objects such as clocks, glasses, or tissues remain on bedside tables within reach of the patient but out of the reach of children. Take care to ensure that end tables are secure and have stable, straight legs. Place nonessential items in drawers to eliminate clutter. If small area rugs are used, secure them with a nonslip pad or skid-resistant adhesive strips. Make sure that carpeting on the stairs is secured with carpet tacks. If patients have a history of falling and live alone, recommend that they wear an electronic safety alert device. When activated by the wearer, this device alerts a monitoring site to call emergency services for assistance.

Accidental home fires typically result from smoking in bed, placing cigarettes in trash cans, grease fires, improper use of candles or space heaters, or electrical fires resulting from faulty wiring or appliances. Teach patients and families how to reduce the risk of electrical injury in the home (Box 27-9) and how to use a home fire extinguisher (Box 27-10). To reduce the risk of fires in the home, instruct patients to quit smoking or smoke outside the home. Have them inspect the condition of cooking equipment and appliances, particularly irons and stoves. For patients with visual deficits, it helps to have dials installed with large numbers or symbols on temperature controls. Make sure that smoke detectors are in strategic positions throughout the home so the alarm will alert the occupants in a home in case of fire. Make sure that all patients, even young children, are familiar with the phrase "stop, drop, and roll," which describes what to do when a person's clothing or skin is burning.

Help parents reduce the risk of accidental poisoning by teaching them to keep hazardous substances such as medications, cleaning fluids, and batteries out of the reach of children. Drug and other substance poisonings in adolescents and adults are commonly related to suicide attempts or drug experimentation. Teach parents that calling a poison control center for information before

BOX 27-10 PATIENT TEACHING

Correct Use of a Fire Extinguisher in the Home

Objective

- Patient will use a fire extinguisher in the home correctly.

Teaching Strategies

- Discuss how to choose a correct location for an extinguisher. It is recommended that one be placed on each level of the home, near an exit, in clear view, away from stoves and heating appliances, and above the reach of small children. Keep a fire extinguisher in the kitchen, near the furnace, and in the garage. Make sure that patients read instructions after purchasing the extinguisher and keep them for periodic review.
- Describe the steps to take before using the extinguisher. Attempt to fight the fire only when all occupants have left the home, the fire department has been called, the fire is confined to a small area, there is an exit route readily available, the extinguisher is the right type for the fire (see discussion in text for a description of the types of extinguishers), and the patient knows how to use it.
- Instruct the patient to memorize the mnemonic PASS: *P*ull the pin to unlock handle, *A*im low at the base of the fire, *S*queeze the handles, and *S*weep the unit from side to side (see Fig. 27-11).

Evaluation

- Patient is able to describe when it is appropriate to use a home fire extinguisher.
- Patient correctly lists the steps to take before attempting to use an extinguisher.
- Patient demonstrates correct use of the extinguisher while reciting the instructions with the mnemonic PASS.

BOX 27-11 INTERVENING IN ACCIDENTAL POISONING

1. Assess for signs or symptoms of ingestion of harmful substance such as nausea, vomiting, foaming at the mouth, drooling, difficulty breathing, sweating, and lethargy.
2. Terminate exposure to the poison by having the person empty his or her mouth of pills, plant parts, or other material.
3. If poisoning is caused by skin or eye contact, irrigate the skin or eye with copious amounts of cool tap water for 15 to 20 minutes. In the case of an inhalation exposure, safely remove the victim from the potentially dangerous environment.
4. Identify the type and amount of substance ingested to help determine the correct type and amount of antidote needed.
5. If the victim is conscious and alert, call the local poison control center or the national toll-free poison control center number (1-800-222-1222) before attempting any intervention. Poison control centers have information needed to treat poisoned patients or offer referral to treat.

   The administration of ipecac syrup is no longer recommended for routine home treatment of poisoning.
6. If the victim has collapsed or stopped breathing, call 911 for emergency transportation to the hospital. Initiate CPR if indicated until emergency personnel arrive. Ambulance personnel can provide emergency measures if needed. In addition, a parent or guardian is sometimes too upset to drive safely.
7. Position the victim with head turned to side to reduce risk for aspiration.
8. Never induce vomiting if the victim has ingested the following poisonous substances: lye, household cleaners, hair care products, grease or petroleum products, furniture polish, paint thinner, or kerosene.
9. Never induce vomiting in an unconscious or convulsing victim because vomiting increases risk for aspiration.

Modified from Hockenberry MJ, Wilson D: *Wong's essentials of pediatric nursing*, ed 8, St Louis, 2009, Mosby; American Academy of Pediatrics, Committee on Injury, Violence and Poison Prevention: Poison treatment in the home, *Pediatrics* 112 (5):1182, 2003.
CPR, Cardiopulmonary resuscitation.

attempting home remedies will save their child's life. Guidelines for accepted interventions for accidental poisonings are available to teach a parent or guardian (Box 27-11). Older adults are also at risk for poisoning because diminished eyesight may cause an accidental ingestion of a toxic substance. In addition, the impaired memory of some older adults results in an accidental overdose of prescription medications.

Be sure that medications are kept in their original containers and labeled in large print. Recommend the use of medication organizers that are filled once a week by the patient and/or family. Have patients keep poisonous substances out of the bathroom and discard old or unused medications. In the health care setting it is important for you to know how to respond when exposure to a poisonous substance occurs. In addition, adhere to guidelines for intervening in accidental poisoning. Ensure the poison control center phone number is visible near the telephone in homes with young children. In all cases of suspected poisoning, patients need to call this number immediately.

To prevent the transmission of pathogens, nurses teach aseptic practices. Medical asepsis, which includes hand hygiene and environmental cleanliness, reduces the transfer of organisms (see Chapter 28). Patients and family members need to learn thorough hand hygiene (handwashing or use of hand rub) and when to use it (e.g., before and after caring for a family member, before food preparation, before preparing a medication for a family member, after using the bathroom, and after contacting any body fluids). Patients also need to know how to dispose of infected material such as wound dressings and used needles in the home setting. Heavy plastic containers such as hard, colored plastic liquid detergent bottles are excellent for needle disposal. The Environmental Protection Agency (EPA) encourages disposal of used needles by way of community drop-off programs, household hazardous waste facilities, sharps mail-back programs, or home needle destruction devices (Coalition for Safe Community Needle Disposal, 2010). Teach patients "safe sex" practices, including abstinence, correct use of condoms, and engaging in monogamous relationships to reduce the risk for sexually transmitted infections.

Acute Care. Nurses use standard precautions for all patients to protect themselves from contact with blood and other potentially infectious body fluids (see Chapter 28). Additional specific safety measures are applicable to patients in the acute care environment. Nurses are responsible for making a patient's bedside safe. Explain and demonstrate to patients how to use the call light or intercom system and always place the call device close to the patient at the conclusion of every nurse-patient interaction. Respond quickly to call lights and bed/chair alarms. Keep the environment free from clutter around the bedside. Many health care organizations are implementing hourly rounding to reduce falls (Box 27-12). In addition, nurses sometimes apply color-coded wristbands to patients' wrists to communicate a patient's fall risk. In 2008 the American Hospital Association issued an advisory recommending that hospitals standardize wristband colors; red for patient allergies, yellow for fall risk, and purple for do-not-resuscitate preferences. This recommendation came after a

BOX 27-12 EVIDENCE-BASED PRACTICE

Effects of Nursing Rounds on Patient Safety

PICO Question: In the hospitalized adult patient, will hourly rounding compared with standard practice decrease patient falls and pressure ulcer development?

Evidence Summary

Patient falls and development of pressure ulcers are nurse-sensitive indicators. Nurses have the opportunity to reduce these adverse outcomes based on evidence-based nursing actions. Hospitalized patients often require assistance with basic activities of daily living such as eating, toileting, and mobility. Not meeting patient needs in a timely fashion decreases patient satisfaction and places patients at greater risk for injury (Meade et al., 2006). Current evidence supports a patient-centered approach to nursing care by implementing purposeful hourly rounding (Weisgram and Raymond, 2008; Ford, 2010). Hourly nursing rounds are conducted hourly during the day and evening shift and are completed at least every 2 hours during the night. Every-2-hour rounds entail rounding every 2 hours throughout the entire 24-hour period. Evidence-based nursing rounds influence safety outcomes such as checking patients for the 5 Ps: *p*ain, *p*otty, *p*osition, *p*ossessions, and *p*lan of care.

Application to Nursing Practice

- Implementation of purposeful, hourly nursing rounds improves outcomes in reducing patient falls (Weisgram and Raymond, 2008; Ford, 2010). However, in one study every-2-hour rounds did not significantly reduce falls (Meade et al., 2006).
- Implementation of hourly nursing rounds also reduces patient development of pressure ulcers (Studer Group, 2007).
- Purposeful rounding includes specific nursing actions such as addressing toileting, turning, and ensuring that possessions are within reach.
- Nurses and NAPs often share rounding responsibilities.

FIG. 27-7 Safety bars around toilets and showers.

FIG. 27-8 Wheelchair with safety locks and anti-tip bars.

near-miss incident in which a nurse working in two different hospitals placed a wrong-colored band on a patient. Many state hospital associations and communities are now standardizing colors to reduce confusion both within and across the health care organizations (American Hospital Association, 2008). The nurse takes measures to help patients avoid falls, injuries from use of restraints and side rails, fires, poisoning, and electrical hazards. Special precautions are necessary to prevent injury in patients susceptible to having seizures. Radiation injuries are also a specific safety concern. Finally be prepared to respond to a disaster emergency, including a bioterrorist attack.

Falls. Most hospitals have fall prevention protocols instituted for patients at risk for falling. For example, a patient receives a fall risk identification bracelet (yellow in color), is given information about fall risks, and receives additional nursing interventions (e.g., hourly rounding, placement on a low safety bed, yellow gown). Include family members in safety discussions. A gait belt provides a secure way to steady or guide patients who need assistance with ambulation when transferring or walking. Use additional safety equipment as needed when moving patients (see Chapter 47). When patients use assistive aids such as canes, crutches, or walkers, it is important to routinely check the condition of rubber tips and the integrity of the aid. Remove excess furniture and equipment and make sure that patients wear rubber-soled shoes or slippers for walking or transferring. Safety bars near toilets (Fig. 27-7), locks on beds and wheelchairs (Fig. 27-8), and call lights are additional safety features found in health care settings. In the health care environment frequent observations of the patient at risk for falls are important to reduce the potential for injury (Meade et al., 2006).

Restraints. Patients who are confused, disoriented, or repeatedly fall or try to remove medical devices (e.g., oxygen equipment, IV lines, or dressings) often require the temporary use of restraints to keep them safe. Restraints are not a solution to a patient problem but rather a temporary means to maintain patient safety. They are either chemical or physical. Chemical restraints are medications such as anxiolytics and sedatives used to manage a patient's behavior and are not a standard treatment or dosage for the patient's condition. A physical **restraint** is any manual method, physical or mechanical device, material, or equipment that immobilizes or reduces the ability of a patient to move his or her arms, legs, body, or head freely (TJC, 2011a). A restraint does not include devices such as orthopedically prescribed devices, surgical dressings or bandages, protective helmets, or other methods that involve physically holding a patient to conduct routine physical examinations or tests, protecting the patient from falling out of bed, or permitting the patient to participate in activities without the risk of physical harm (TJC, 2011a).

BOX 27-13 ALTERNATIVES TO RESTRAINTS

- Orient patients and families to environment; explain all procedures and treatments.
- Provide companionship and supervision; use trained sitters; adjust staffing and involve family.
- Offer diversionary activities such as music or something to hold; enlist support and input from family.
- Assign confused or disoriented patients to rooms near nurses' station and observe them frequently.
- Use calm, simple statements and physical cues as needed.
- Use de-escalation, time-out, and other verbal intervention techniques when managing aggressive behaviors.
- Provide appropriate visual and auditory stimuli (e.g., family pictures, clock, radio).
- Remove cues that promote leaving (e.g., elevators, stairs, or street clothes).
- Promote relaxation techniques and normal sleep patterns.
- Institute exercise and ambulation schedules as allowed by patient's condition; consult physical therapist for mobility and exercise programs.
- Attend frequently to needs for toileting, food, and liquid.
- Camouflage intravenous lines with clothing, stockinette, or Kling dressing.
- Evaluate all medications patient is receiving and ensure effective pain management.
- Reassess physical status and review laboratory findings.

Modified from The Joint Commission Resources: *Strategies for avoiding restraint related errors*, 2006, http://www.jcrinc.com; and Geriatric nursing resources for care of older adults: *Physical restraints*, 2006, http://www.gerontnurseonline.org/index.

The use of restraints is associated with serious complications resulting from immobilization such as pressure ulcers, pneumonia, constipation, and incontinence. In some cases death has resulted because of restricted breathing and circulation. Patients have been strangled while trying to get out of bed while restrained in a jacket or vest restraint. As a result, many health care facilities have eliminated the use of the jacket (vest) restraint (Capezuti et al., 2008). Loss of self-esteem, humiliation, and agitation are also serious concerns. Because of these risks, legislation emphasizes reducing the use of restraints. Regulatory agencies such as TJC and the CMS enforce standards for the safe use of restraint devices. The optimal goal for all patients is a restraint-free environment. Always consider and implement alternatives to restraints first. Individualize your approaches for each patient. Restraint alternatives include more frequent observations, involvement of family during visitation, frequent reorientation, and the introduction of familiar and meaningful stimuli (e.g., knitting or crocheting or looking at family photos) within the environment to reduce behaviors such as wandering that often leads to restraint use (Box 27-13).

In nursing homes, evidence shows that outcomes related to behavior issues, cognitive performance, falls, walking dependence, activities of daily living, pressure ulcers, and contractures are significantly worse when a restraint is used compared to no restraint (Castle, 2009). An interdisciplinary approach that includes individualized assessments and development of structured treatment plans reduces restraint use.

The use of restraints involves a psychological adjustment for the patient and family. If restraints are necessary, the nurse assists family members and patients by explaining their purpose, expected care while the patient is restrained, precautions taken to avoid injury, and that the restraint is temporary and protective. Informed consent from family members is sometimes required before using restraints (e.g., in long-term care settings).

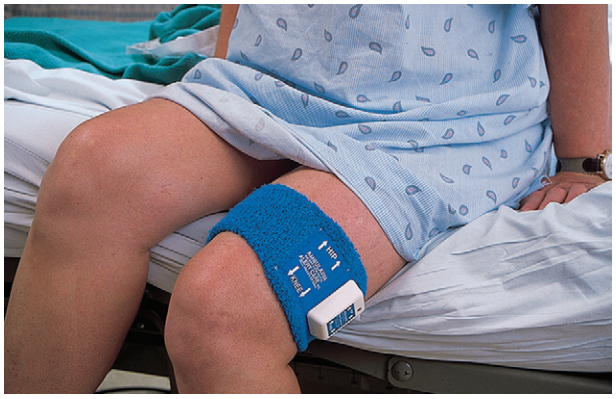

FIG. 27-9 Patient wearing an Ambularm device.

For legal purposes know agency-specific policy and procedures for appropriate use and monitoring of restraints. The use of a restraint must be clinically justified and a part of the patient's prescribed medical treatment and plan of care. A physician's order is required, based on a face-to-face assessment of the patient. The order must be current, state the type and location of restraint, and specify the duration and circumstances under which it will be used. These orders need to be renewed within a specific time frame according to the policy of the agency. In the hospital each original restraint order and renewal is limited to 4 hours for adults, 2 hours for ages 9 through 17, and 1 hour for children under age 9 (CMS, 2009; TJC, 2011a). Orders may be renewed to the time limits for a maximum of 24 consecutive hours. Restraints are not to be ordered prn (as needed). You must conduct ongoing assessment of patients who are restrained. Proper documentation, including the behaviors that necessitated the application of restraints, the procedure used in restraining, the condition of the body part restrained (e.g., circulation to hand), and the evaluation of the patient response, is essential. Restraints must be removed periodically, and the nurse assesses the patient to determine if they continue to be necessary. Skill 27-1 on pp. 388-392 includes guidelines for the proper use and application of restraints. Use of restraints must meet one of the following objectives:

- Reduce the risk of patient injury from falls
- Prevent interruption of therapy such as traction, IV infusions, nasogastric (NG) tube feeding, or Foley catheterization
- Prevent patients who are confused or combative from removing life-support equipment
- Reduce the risk of injury to others by the patient

In keeping with current safety trends, electronic devices are also sometimes used as alternatives to restraints. For example, the Ambularm, worn on the leg, signals when the leg is in a dependent position such as over the side rail or on the floor (Fig. 27-9). You also sometimes place weight-sensitive sensor mats on patients' mattresses or in the chair. An audible alarm sounds at the bedside when pressure is released off the sensor mat. The alarm often signals at the central nurses' station so staff is alerted quickly when a patient is up and out of bed. Alarms on doors also alert staff or family members when a patient who is confused, disoriented, or prone to wandering opens a door.

A less-restrictive restraint is the Posey bed (Fig. 27-10). It is a soft-sided, self-contained enclosed bed that is much less restrictive than chemical or physical restraints. It allows for freedom of

FIG. 27-10 The Posey Bed All Care Model. (Courtesy JT Posey Co, Arcadia, Calif.)

movement and thus reduces the side effects such as pressure ulcers and loss of dignity caused by physical restraints. A vinyl top covers the padded upper frame of the bed, and the nylon-net canopy surrounds the mattress and completely encloses the patient in the bed. Zippers on the four sides of the enclosure provide access to the patient. The Posey bed enclosure works well for patients who are restless and unpredictable, cognitively impaired, and at risk for injury if they were to fall or get out of bed such as patients on anticoagulant therapy at risk for intracranial bleed. The bed is also a safer alternative to side rails.

Side Rails. Side rails help to increase a patient's mobility and/or stability when in bed or moving from bed to chair. They are the most commonly used physical restraint. There are a variety of beds with different side rail designs. Basically the patient needs to have a route to exit a bed safely and maneuver freely within the bed; in this case side rails are not considered a restraint. For example, raising only the top two side rails so the lower part of the bed is open gives the patient room to exit a bed safely. Side rails used to prevent a patient such as one who is sedated from falling out of bed are not considered a restraint. Always check agency policy about the use of side rails. Be sure that a bed is in the lowest position possible when side rails are raised. Always assess the risk of using side rails compared to not using them. Check their condition; bars between the bed rails need to be closely spaced to prevent entrapment, the space between bed rails and mattress and between headboard and mattress is filled to prevent patients from falling in between, and latches securing bed rails are stable.

The use of side rails alone for a patient who is disoriented usually causes more confusion and further injury. A patient who is determined to get out of bed attempts to climb over the side rail or climbs out at the foot of the bed. Either attempt usually results in a fall or injury. Nursing interventions to reduce a patient's confusion first focus on determining and eliminating the cause of the confusion such as a response to a new medication, dehydration, or pain. Frequently nurses mistake a patient's attempt to explore his or her environment or to self-toilet as confusion. Additional safety measures include the use of a low bed with a nonskid mat placed alongside the bed on the floor. A low bed reduces the distance between the bed and floor, facilitating a roll rather than a fall from the bed.

BOX 27-14 FIRE INTERVENTION GUIDELINES FOR NURSES WORKING IN HEALTH CARE AGENCIES

- Keep the phone number for reporting fires visible on the telephone at all times.
- Know the fire drill and evacuation plan of the agency.
- Know the location of all fire alarms, exits, extinguishers, and oxygen shut-off.
- Use the mnemonic RACE to set priorities in case of fire:
  R—Rescue and remove all patients in immediate danger.
  A—Activate the alarm. Always do this before attempting to extinguish even a minor fire.
  C—Confine the fire by closing doors and windows and turning off oxygen and electrical equipment.
  E—Extinguish the fire using an appropriate extinguisher (see Fig. 27-11).

Fires. Although smoking is usually not allowed in hospital settings, smoking-related fires continue to pose a significant risk because of unauthorized smoking in the bed or bathroom. Institutional fires typically result from an electrical or anesthetic-related fire. The best intervention is to prevent fires. Nursing measures include complying with the smoking policies of the agency and keeping combustible materials away from heat sources. Box 27-14 discusses additional fire intervention guidelines for nurses in health care agencies. Regardless of where a fire occurs, it is important to have an evacuation plan in place. Know where fire extinguishers and gas shut-off valves are located and how to activate a fire alarm.

If a fire occurs in a health care agency, protect patients from immediate injury, report the exact location of the fire, contain it, and extinguish it if possible. Some agencies have fire doors that are held open by magnets and close automatically when a fire alarm sounds. It is important to keep equipment away from blocking these doors. All personnel evacuate patients when appropriate. Patients who are close to the fire, regardless of its size, are at risk of injury and need to be moved to another area. If the patient is on life support, you need to maintain his or her respiratory status manually with a bag-valve-mask device (e.g., Ambu-bag) (see Chapter 40) until he or she is moved away from the fire. Direct all ambulatory patients to walk by themselves to a safe area. In some cases they are able to help move patients in wheelchairs. You generally move bedridden patients from the scene of a fire by a stretcher, their bed, or a wheelchair. If none of these methods is appropriate, they need to be carried from the area. If you have to carry a patient, do so correctly (e.g., two-man carry). If you overextend your physical limits for lifting, injuring yourself results in further injury to the patient. If fire department personnel are on the scene, they help evacuate the patients.

After a fire is reported and patients are out of danger, nurses and other personnel take measures to contain or extinguish it such as closing doors and windows, placing wet towels along the base of doors, turning off sources of oxygen and electrical equipment, and using a fire extinguisher. Fire extinguishers are categorized as type A, used for ordinary combustibles (e.g., wood, cloth, paper, and many plastic items); type B, used for flammable liquids (e.g., gasoline, grease, paint, and anesthetic gas); and type C, used for electrical equipment. Fig. 27-11 demonstrates the process of using an extinguisher.

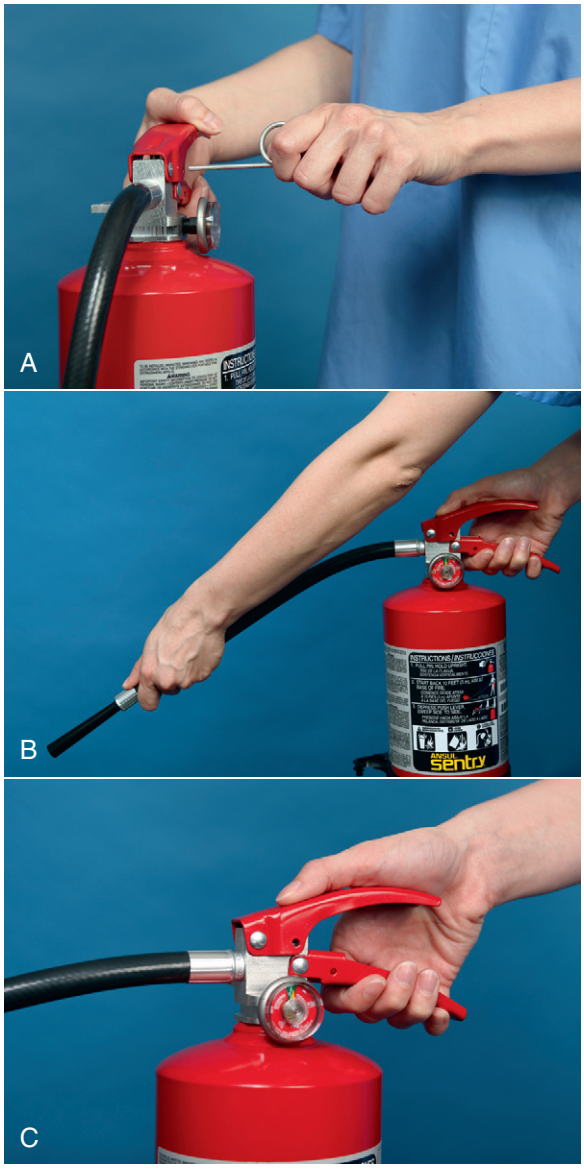

FIG. 27-11 Correct use of a fire extinguisher. A, ***P***ull pin. B, ***A***im at base of fire. C, ***S***queeze handles and ***S***weep from side to side to coat area evenly.

Electrical Hazards. Much of the equipment used in health care settings is electrical and must be well maintained. The clinical engineering departments of hospitals inspect biomedical equipment such as hospital beds, infusion pumps, or ventilators regularly. You know that a piece of equipment is safe to use when you see a safety inspection sticker with an expiration date. Decrease the risk for electrical injury and fire by using properly grounded and functional electrical equipment. The ground prong of an electrical outlet carries any stray electrical current back to the ground. Remove equipment that is not in proper working order or that sparks when plugged in for service and notify the appropriate hospital staff.

Seizures. Patients who have experienced some form of neurological injury or metabolic disturbance are at risk for a seizure. A **seizure** is hyperexcitation and disorderly discharge of neurons in the brain leading to a sudden, violent, involuntary series of muscle contractions that is paroxysmal and episodic, causing loss of consciousness, falling, tonicity (rigidity of muscles), and clonicity (jerking of muscles). A generalized tonic-clonic, or grand mal, seizure lasts approximately 2 minutes (no longer than 5) and is characterized by a cry and loss of consciousness with falling, tonicity, clonicity, and incontinence. During a fall or as a result of muscle jerking, musculoskeletal injuries can occur. Before a convulsive episode a few patients report an aura, which serves as a warning or sense that a seizure is about to occur. An **aura** is often a bright light, smell, or taste. During the seizure activity the patient often experiences shallow breathing, cyanosis, and loss of bladder and bowel control. A postictal phase follows the seizure, during which the patient has amnesia or confusion and falls into a deep sleep. A person in the community needs to be taken to a medical facility immediately if he or she has repeated seizures; if a single seizure lasts longer than 5 minutes without any sign of slowing down or is unusual in some way; if the person has trouble breathing afterwards or appears to be injured or in pain; or if recovery is different from usual (Epilepsy Foundation, 2010). Prolonged or repeated seizures indicate **status epilepticus.** This condition is a medical emergency and requires intensive monitoring and treatment. It is important that you observe the patient carefully before, during, and after the seizure so you are able to document the episode accurately. **Seizure precautions** encompass all nursing interventions to protect the patient from traumatic injury, position for adequate ventilation and drainage of oral secretions, and provide privacy and support following the seizure (see Skill 27-2 on pp. 392-294).

Radiation. Radiation is a health hazard in health care settings where radiation and radioactive materials are used in the diagnosis and treatment of patients. Hospitals have strict guidelines concerning the care of patients who are receiving radiation and radioactive materials. Be familiar with established agency protocols. To reduce your exposure to radiation, limit the time spent near the source, make the distance from the source as great as possible, and use shielding devices such as lead aprons. Staff regularly working near radiation wear devices that track the accumulative exposure to radiation.

Disasters. As a nurse, you need to be prepared to respond and care for a sudden influx of patients during a disaster. TJC (2011b) requires hospitals to have an emergency management plan that addresses identifying possible emergency situations and their probable impact, maintaining adequate amount of supplies, and a formal response plan that includes actions to be taken by staff and steps to restore essential services and resume normal operations following the emergency.

Infection control practices are critical in the event of a biological attack. Therefore you manage all patients with suspected or confirmed bioterrorism-related illnesses using standard precautions (see Chapter 28). For certain diseases such as smallpox or pneumonic plague, additional precautions such as airborne or contact isolation precautions are necessary. Most infections associated with biological agents are not transmissable from patient to patient. However, limit the transport and movement of patients to movement that is essential for treatment and care. An important aspect of care for patients who have a bioterrorism-related illness is postexposure management.

EVALUATION

Through the Patient's Eyes. Patient-centered care requires a thorough evaluation of the patient's perspective related to safety and whether his or her expectations have been met. Ask the patient questions such as "Are you satisfied with the changes made to your

home? Do you feel safer as a result of the changes? Have you had any falls or injury? Are you still afraid of falling?" Involve the family in your evaluation, especially if they live with the patient and provide assistance in the home.

Patient Outcomes. Evaluation involves monitoring the actual care delivered by the health care team based on the expected outcomes (Fig. 27-12). For each nursing diagnosis measure whether the outcomes of care have been met. If you have met the patient's goals the diagnosis is resolved, and your nursing interventions were effective and appropriate. If not, you determine whether new safety risks to the patient have developed or whether previous risks remain. For example, if the patient has a recurrent fall, reassess the conditions surrounding that fall and determine whether contributing factors can be removed or managed. The patient and family need to participate to find permanent ways to reduce risks to safety.

When patient outcomes are not met, ask the following questions:

- What factors led to your fall?
- Help me understand what makes you feel unsafe in your environment.
- What questions do you have about your safety?
- Has your health care provider recently changed your medications?
- Do you need help locating community resources to help make your home safer?
- What changes have you recently experienced that you believe contributes to your risk for falling or lack of safety?

Continually assesses the patient's and family's need for additional support services such as home care, physical therapy, counseling, and further teaching. A safe environment is essential to promoting, maintaining, and restoring health. Overall your expected outcomes include a safe physical environment and a patient whose expectations have been met, who is knowledgeable about safety factors and precautions, and who is free of injury.

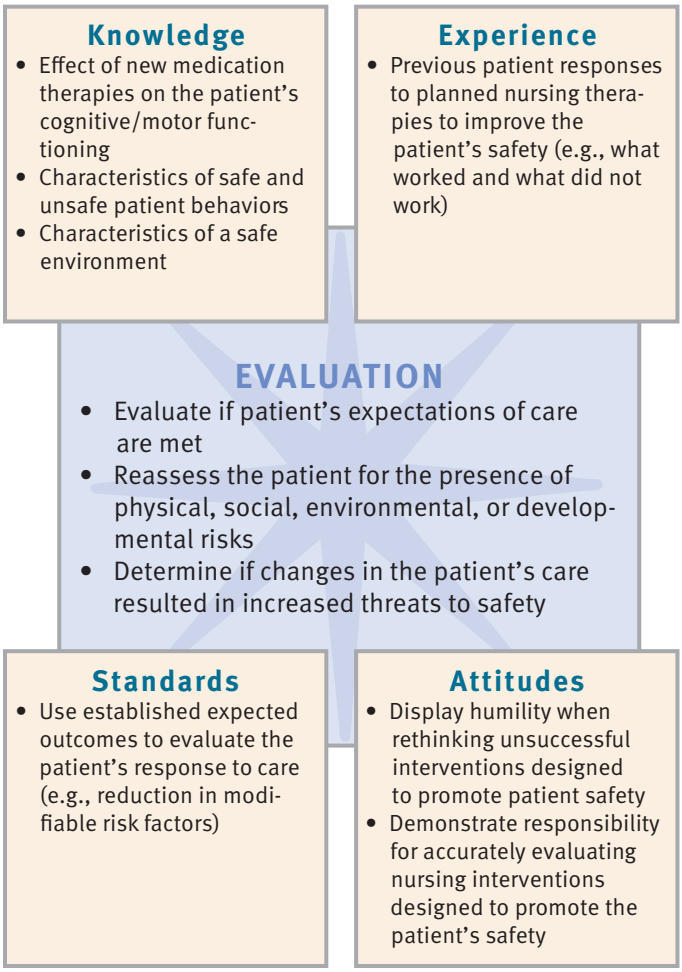

FIG. 27-12 Critical thinking model for safety evaluation.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care:

- Always try restraint alternatives before using a restraint. Involve familly in your approach.
- Protect patients from injury. Follow assessment guidelines while patients are restrained to avoid injury from inappropriate placement. Position and monitor a patient having a seizure to reduce risk of aspiration and physical injury.
- Protect patients from falling by implementing fall prevention protocols and providing patient and family education about fall prevention.

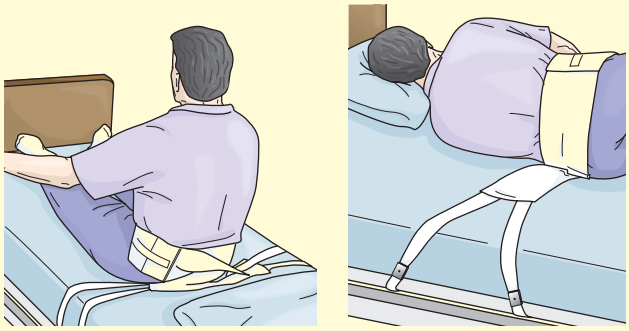
SKILL 27-1 APPLYING RESTRAINTS

View Video!

Delegation Considerations

The skill of applying restraints can be delegated to nursing assistive personnel (NAP). However, the nurse must first assess the patient's behavior, level of orientation, need for restraints, and appropriate type to use. The assessment while a restraint is in place cannot be delegated to NAP. The nurse directs NAP by:

- Reviewing correct placement of the restraint.
- Reviewing when and how to change patient's position.
- Instructing NAP to notify nurse if there is a change in skin integrity, circulation in extremities, or patient's breathing.
- Instructing to provide range of motion (ROM), nutrition and hydration, skin care, toileting, and opportunities for socialization.



Equipment

- Proper restraint
- Padding (if needed)

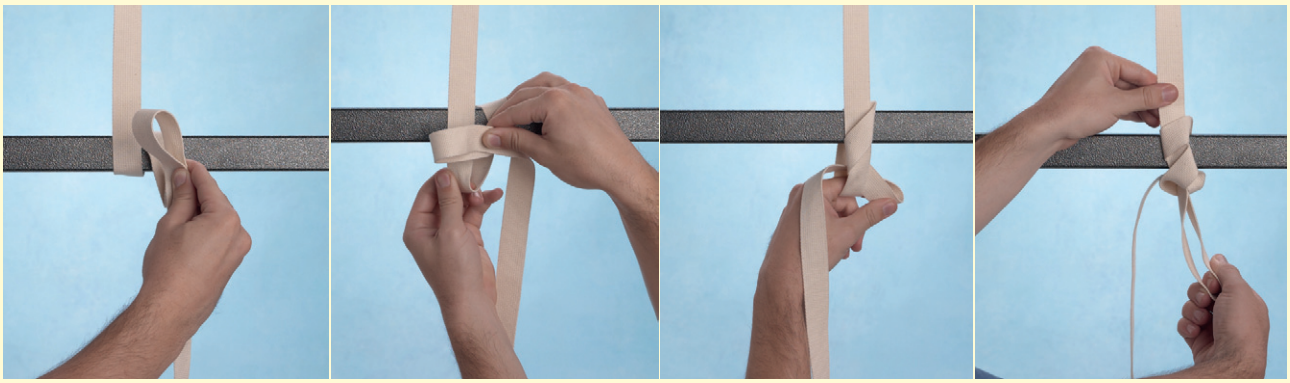
STEP	RATIONALE
ASSESSMENT	
1 Assess patient's behavior such as confusion; disorientation; agitation; restlessness; combativeness; repeated removal of tubing, dressing, or other therapeutic devices; creating a risk to other patients; and inability to follow directions.	If patient's behavior continues despite treatment or restraint alternatives, use of restraint is indicated. You use the least restrictive type of restraint.
2 Determine failure of restraint alternatives. Review agency policies regarding restraints. Check health care provider's order for purpose, type, location, and duration of restraint. Determine if signed consent for use of restraint is necessary.	A physician or licensed independent practitioner who is responsible for the care of the patient orders restraints. The physician must be authorized to order restraints by the policy of the hospital. Consult the attending physician as soon as possible if he or she did not write the original order. Unless state law is more restrictive, orders for the use of restraint for the management of violent or self-destructive behavior that jeopardizes the immediate physical safety of the patient, staff, or others is renewed within the following time frame: 4 hours for adults, 2 hours for children ages 9 through 17, and 1 hour for children under age 9. Orders are renewed to the time limits for a maximum of 24 consecutive hours (CMS, 2009; TJC, 2011a).
CLINICAL DECISION: *A physician, clinical psychologist, or other licensed independent practitioner responsible for the care of the patient evaluates the patient in person within 1 hour of the initiation of restraint used for the management of violent or self-destructive behavior that jeopardizes the physical safety of the patient, staff, or others. A registered nurse or a physician assistant may conduct the in-person evaluation if trained in accordance with the requirements and consults with the above health care provider after the evaluation as determined by hospital policy (TJC, 2011a).*	
3 Review manufacturer's instructions for restraint application before entering patient's room. Determine most appropriate size restraint.	You need to be familiar with all devices used for patient care and protection. Incorrect application of restraint device results in patient injury or death.
4 Inspect area where restraint is to be placed. Note if there is any nearby tubing or device. Assess condition of skin, sensation, adequacy of circulation, and range of joint motion.	Restraints sometimes compress and interfere with functioning of devices or tubes. Assessment provides baseline to monitor patient's response to restraint.
PLANNING	
1 Gather equipment and perform hand hygiene.	Promotes organization and reduces transmission of microorganisms.
2 Approach patient in a calm, confident manner. Identify patient using two identifiers (e.g., name and birthday or name and account number) according to facility policy.	Ensures correct patient; complies with a recommended National Patient Safety Goal (TJC, 2011a).
3 Explain what you plan to do. Provide privacy. Be sure that patient is comfortable and in correct anatomical position.	Reduces patient anxiety and promotes cooperation; positioning prevents contractures and neurovascular impairment.
IMPLEMENTATION	
1 Adjust bed to proper height and lower side rail on side of patient contact.	Allows nurse to use proper body mechanics and prevents injury during restraint application.
2 Pad skin and bony prominences (as necessary) that will be under restraint.	Reduces friction and pressure from restraint to skin and underlying tissue.
3 Apply proper-size restraint: **NOTE:** Refer to manufacturer's directions.	
a. *Belt restraint:* Have patient in sitting position. Apply belt over clothes, gown, or pajamas. Make sure that you place restraint at waist, not chest or abdomen. Remove wrinkles or creases in clothing. Bring ties through slots in belt. Help patient lie down if in bed. Avoid applying belt too tightly (see illustrations).	Restrains center of gravity and prevents patient from rolling off stretcher or sitting up while on stretcher or from falling out of bed. Tight application interferes with ventilation if belt moves up over abdomen or chest.
b. *Extremity (ankle or wrist) restraint*: Restraint designed to immobilize one or all extremities. Commercially available limb restraints are made of sheepskin with foam padding. Wrap limb restraint around wrist or ankle with soft part toward skin and secure snugly (not tightly) in place by Velcro straps or buckle. Insert two fingers under secured restraint (see illustration).	Maintain immobilization of extremity to protect patient from fall or accidental removal of therapeutic device (e.g., IV tube, Foley catheter). Tight application interferes with circulation and potentially causes neurovascular injury.

SKILL 27-1 APPLYING RESTRAINTS—cont'd

STEP	RATIONALE
CLINICAL DECISION: *Patient with wrist and ankle restraints is at risk for aspiration if placed in bed in supine position. Place patient in lateral position rather than supine.*	
c. *Mitten restraint:* Thumbless mitten device restrains patient's hands. Place hand in mitten, being sure Velcro strap(s) are around wrist and not forearm (see illustration).	Prevents patient from dislodging invasive equipment, removing dressings, or scratching but allows greater movement than a wrist restraint.
d. *Elbow restraint (freedom splint):* Restraint consists of piece of fabric with slots in which you place tongue blades. Insert patient's arm so elbow joint rests against padded area with tongue blades, keeping joint rigid (see illustration).	Commonly used with infants and children to prevent elbow flexion (e.g., when IV line placed in antecubital fossa).
CLINICAL DECISION: *This text does not address application of vest restraints. Many health care agencies ban the use of jacket (vest) restraints because of their association with fatal injuries.*	

STEP 3a *Left,* Apply belt restraint with patient sitting. *Right,* Properly applied belt restraint allows patient to turn in bed. (From Sorrentino SA: *Mosby's textbook for long-term care nursing assistants*, ed 6, St Louis, 2011, Mosby).

STEP 3b Securing an extremity restraint. Check restraint for constriction by inserting two fingers under restraint.



STEP 3c Mitten restraint. (Courtesy Posey Company, Arcadia, Calif.)

STEP 3d Freedom elbow restraint. (Courtesy Posey Company, Arcadia, Calif.)

STEP	RATIONALE
4 Attach restraint straps to portion of bed frame that moves when raising or lowering head of bed. **Do not** attach to side rails. Attach restraint to chair frame for patient in chair or wheelchair, being sure tie is out of patient's reach.	Patient will be injured if restraint is secured to side rail and it is lowered.
5 Secure restraints with quick-release tie (see illustrations). Do not tie in a knot. Be sure that tie is out of patient reach.	Allows for quick release in an emergency.

STEP 5 Posey quick-release tie. (Courtesy Posey Company, Arcadia, Calif.)

6 Assess proper placement of restraint, skin integrity, pulses, skin temperature and color, and sensation of restrained body part.	Provides baseline to later evaluate if injury develops from restraint.
7 Remove restraint at least every 2 hours (TJC, 2011a) or more frequently as determined by agency policy. If patient is violent or noncompliant, remove one restraint at a time and/or have staff assistance while removing restraints.	Removal provides opportunity to change patient's position, offer nutrients, perform full ROM, toilet, exercise patient, and assess condition of site and need for continuation.

CLINICAL DECISION: *Do not leave a patient who is violent or aggressive unattended while restraints are off.*

8 Secure call light or intercom system within reach.	Allows patient, family, or caregiver to obtain assistance quickly.
9 Leave bed or chair with wheels locked. Keep bed in lowest position.	Locked wheels prevent bed or chair from moving if patient tries to get out. If patient falls with bed in lowest position, this reduces chance of injury.
10 Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Following application, monitor patient's condition according to facility policy. Use judgment and consider patient's condition and type of restraint when selecting physical assessment measures (e.g., circulation, nutrition and hydration, ROM in extremities, vital signs, hygiene and elimination, physical and psychological status, and readiness for discontinuation). Perform visual checks if patient is too agitated (TJC, 2011a).	Frequent assessments prevent injury to patient and ensure removal of restraint at earliest possible time. Frequency of monitoring guides staff in determining appropriate intervals for evaluation based on patient's needs and condition, type of restraint used, risk associated with use of chosen intervention, and other relevant factors.
2 The physician, licensed independent practitioner (LIP), or registered nurse trained according to CMS requirements needs to evaluate patient within either 1 or 4 hours after initiation of restraints, depending on Medicare status of hospital (see agency policy).	Determines patient's immediate situation, reaction to restraints, medical and behavioral condition, and need to continue or terminate restraints (CMS, 2007)
3 After 24 hours, before writing a new order, a physician or LIP who is responsible for patient's care must see and assess patient.	Ensures that restraint application continues to be medically appropriate.
4 Observe IV catheters, urinary catheters, and drainage tubes to determine that they are positioned correctly and that therapy remains uninterrupted.	Reinsertion is uncomfortable and increases risk for infection or interrupts therapy.

SKILL 27-1 APPLYING RESTRAINTS—cont'd

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient experiences impaired skin integrity.
- Reassess need for continued use of restraint and if you can use alternative measures. If restraint is necessary to protect patient or others from injury, ensure that you applied restraint correctly and provided adequate padding.
- Check skin under restraint for abrasions and remove restraints more frequently.
- Institute appropriate skin/wound care (see Chapter 48).
- Change wet or soiled restraints to prevent skin maceration.

2 Patient has altered neurovascular status of an extremity such as cyanosis, pallor, and coldness of skin or complains of tingling, pain, or numbness.
- Remove restraint immediately and notify health care provider.

3 Patient releases restraint and suffers a fall or other traumatic injury.
- Attend to patient's immediate physical needs, inform health care provider of fall or injury, and reassess type of restraint and its correct application.

RECORDING AND REPORTING

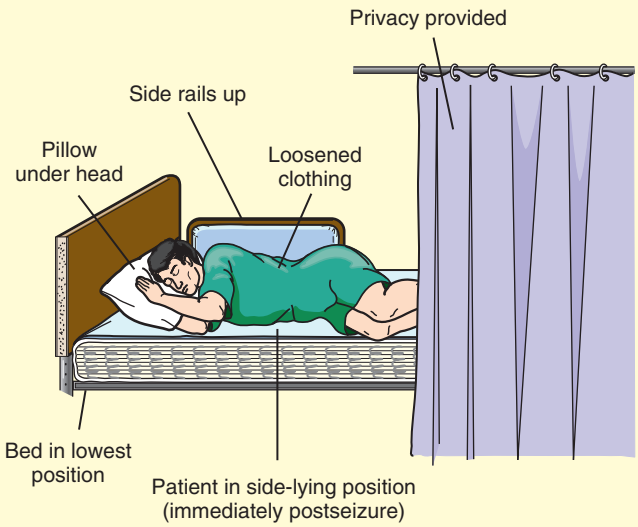
- Record patient's behavior before restraints were applied.
- Record restraint alternatives attempted and patient's response.
- Record patient's level of orientation and patient's or family member's understanding of purpose of restraint and consent (when required).
- Record reason for restraint, type of restraint used, time of starting and ending restraints, times restraint was released, and routine observations (e.g., skin color, pulses, sensation, vital signs, behavior) in nurses' notes and flow sheets.

HOME CARE CONSIDERATIONS

- A physical restraint is a device that requires a physician's order. Do not send a patient home with intent of restraining unless device is necessary to protect patient from injury. If patient's family wishes to use restraint at home, a physician's order is required, and you need to give clear instructions regarding proper application, care needed while in restraints, and complications for which to look. Carefully assess the family for competency and understanding of intent for using restraint.

SKILL 27-2 SEIZURE PRECAUTIONS

Delegation Considerations



The skill of seizure precautions cannot be delegated to nursing assistive personnel (NAP). However, the skills for making the environment safe can be delegated. The nurse directs NAP by:
- Explaining patient's prior seizure history and factors that typically trigger a seizure.
- Emphasizing not to try to restrain patient or place anything in patient's mouth.

Equipment

- Suction machine
- Oral airway
- Oral Yankauer suction catheter
- Oxygen via nasal cannula or face mask
- Stethoscope, sphygmomanometer, pulse oximeter
- Equipment for intravenous (IV) access
- Emergency medications (e.g., IV diazepam, lorazepam, valproate, phenytoin)
- Clean gloves

STEP	RATIONALE
ASSESSMENT	
1 Assess patient's seizure history and knowledge of precipitating factors. Note frequency of past seizures, presence and type of typical aura (e.g., metallic taste, perception of breeze blowing on face, or noxious odor), and body parts affected if known. Use family as resource if necessary.	Knowledge about seizure history enables you to anticipate onset of seizure activity and take appropriate safety measures.
2 Assess for medical and surgical conditions, including electrolyte disturbances such as hypoglycemia, hyperkalemia; heart disease; excess fatigue; alcohol or caffeine consumption.	These are common conditions that lead to seizures or exacerbate existing seizure condition.
3 Assess medication history and patient's adherence. Assess therapeutic drug levels of anticonvulsants if test results available.	Not taking seizure medications as prescribed and stopping them suddenly often precipitate seizure activity.
4 Inspect patient's environment for potential safety hazards (e.g., extra furniture) if seizure occurs. Keep bed in low position, side rails up at head of bed, patient in side-lying position when possible.	Protect patient from injury sustained by striking head or body on furniture or equipment.
5 Assess patient's cultural perspective about the meaning of seizures and their treatment.	Some cultures follow different caring practices for a person with seizures.
PLANNING	
1 For patients with a history of generalized seizures, have oxygen setup, suction apparatus, and clean gloves available for immediate use.	This ensures prompt intervention directed toward maintaining a patent airway.

STEP	RATIONALE
IMPLEMENTATION	
1 When seizure begins, note time, stay with patient, and call for help. Track duration of seizure. Notify health care provider immediately. Have staff member bring emergency cart to bedside.	Documents the episode accurately. Provides for patient safety. Provides access to emergency medications and IV equipment as needed.
2 Position patient safely. If standing or sitting, guide patient to floor and protect head by cradling in nurse's lap or placing a pad under head. Do not lift patient from floor to bed while seizure is in progress. Clear surrounding area of furniture. If patient is in bed, remove pillows and raise side rails.	Prevents traumatic injury. Suffocation often occurs with use of pillow.
3 If possible, turn patient onto one side, head tilted slightly forward.	Allow tongue to fall away from the airway and allow drainage of saliva.
4 If possible, provide privacy. Have staff control flow of visitors in area.	Embarrassment is common after a seizure, especially if others witnessed the seizure.
5 Do not restrain patient; hold limbs loosely if they are flailing. Place something soft under head. Loosen clothing such as collar or belt.	Prevent musculoskeletal injury. Promote free ventilatory movement of chest and abdomen.
CLINICAL DECISION: *Because injury results from forcible insertion of objects into mouth, never force apart a patient's clenched teeth. Do not place any objects into patient's mouth such as fingers, medicine, tongue depressor, or airway when teeth are clenched. Insert a bite-block or oral airway in advance if you recognize the possibility of a tonic-clonic seizure.*	
6 Maintain patient's airway and suction as needed. Check level of consciousness and oxygen saturation. Check vital signs. Provide oxygen by nasal cannula or mask if ordered. Use oral airway only if you can easily access oral cavity.	Prevent hypoxia during seizure activity.
7 Stay with patient, observing sequence and timing of seizure activity. Note the following: type of seizure; parts of body affected; if there was a loss of consciousness; presence of autonomic signs of lip smacking, mastication, or grimacing; rolling of eyes; presence of incontinence or diaphoresis; presence of apnea.	Continued observation assists in documentation, diagnosis, and treatment of seizure disorder.
8 As patient regains consciousness, reorient and reassure. Explain what happened and answer patient's questions. Stay with patient until full recovery.	Informing patients of type of seizure activity experienced assists them in participating knowledgeably in their care. Some patients remain confused for a period of time or become violent.
9 Following seizure, assist patient to position of comfort in bed with side rails up (one rail down for easy exit) and bed in lowest position (see illustration). Place call light or intercom system within reach and provide a quiet, nonstimulating environment.	Provide for continued safety. Patients are often confused and sleepy following a seizure.

STEP 9 Position of patient following seizure and when on seizure precautions.

10 Offer psychosocial support; provide time for patient to express feelings and concerns.	Patients who accept the reality of their disease integrate it into their own self-concept and have higher levels of self-esteem.
11 Perform hand hygiene.	Reduce transmission of microorganisms.

SKILL 27-2 SEIZURE PRECAUTIONS—cont'd

STEP	RATIONALE
EVALUATION	
1 Conduct a head-to-toe evaluation, including an inspection of oral cavity for breaks in mucous membranes from bites or broken teeth; look for bruising of skin or injury to bones and joints.	Determine presence of any traumatic injuries resulting from seizure activity.
CLINICAL DECISION: *If onset of seizure was not witnessed and you suspect patient fell and struck head, treat as a closed head injury or spinal injury. Place a cervical collar on patient before attempting to turn.*	
2 Evaluate patient's mental status after seizure (level of consciousness, confusion, hallucinations).	Temporary mental status changes are common following a seizure.
3 Check patient's oxygen saturation and vital signs.	Determine stability of oxygenation and circulation.
4 If possible, ask patient to verbalize feelings after seizure.	Therapeutic interaction enables patient to recognize feelings associated with having a seizure disorder.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient suffers traumatic injury.
- Continue to protect patient from further injury.
- Notify the health care provider immediately.
- Ensure environment is free of safety hazards.

2 Seizure lasts more than 5 minutes or patient has repeated seizures over 30 minutes, indicating status epilepticus.
- Establish or maintain patient's airway and administer oxygen.
- Notify health care provider immediately.
- Be prepared to call rapid response team or code blue.

3 Patient verbalizes feelings of embarrassment and humiliation.
- Offer support and allow patient to verbalize feelings.
- Encourage patient and family to participate in decision making and planning of care.

RECORDING AND REPORTING

- Record thoroughly in nurses' notes your observations before, during, and after seizure. Provide detailed description of type of seizure activity and sequence of events (e.g., presence of aura [if any], level of consciousness, posture, color, movement of extremities, incontinence, and patient's status immediately following seizure).
- Report to primary health care provider immediately as seizure begins. Status epilepticus is an emergency situation requiring immediate medical therapy.

HOME CARE CONSIDERATIONS

- Instruct family members in steps to take when patient experiences a seizure.
- Assess patient's home for environmental hazards in light of seizure condition.
- Until seizure condition is well controlled (usually for at least 1 year), make sure patient does not take a tub bath or engage in activities such as swimming unless knowledgeable family member is present. Driving is restricted until permitted by state regulations.
- Refer patient to the Epilepsy Foundation or a similar community resource for support groups.

KEY POINTS

- In the community a safe environment means that basic needs are achievable, physical hazards are reduced, transmission of pathogens and parasites is reduced, pollution is controlled, and sanitation is maintained.
- A safe health care environment is one that reduces the risk of injury, including minimizing falls, patient-inherent accidents, procedure-inherent accidents, and equipment-related accidents.
- Reduction of physical hazards in the environment includes providing adequate lighting, decreasing clutter, and securing the home.
- Reduce the transmission of pathogens through medical and surgical asepsis, immunization, adequate food sanitation, insect and rodent control, and appropriate disposal of human waste.
- Every developmental age involves specific safety risks.
- Children younger than 5 years of age are at greatest risk for home accidents that result in severe injury and death.
- The school-age child is at risk for injury at home, at school, and while traveling to and from school.
- Adolescents are at risk for injury from automobile accidents, suicide, and substance abuse.
- Threats to an adult's safety are frequently associated with lifestyle habits.
- Risks for injury for older patients are directly related to the physiological changes of the aging process.
- Nursing interventions for promoting safety are individualized for patients' developmental stage, lifestyle, and environment.
- Continually evaluate the patient's safety risk and update the nursing care plan appropriately.
- Use physical restraints only as a last resort, when patients' behavior places them or others at risk for injury.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Ms. Cohen is hospitalized for repair of a fractured hip after a fall at home. Ms. Cohen requires intravenous (IV) antibiotics after surgery. Shortly after the first dose, she became restless and started picking at her IV line and frequently attempting to get out of bed. Several restraint alternatives were attempted but, because of Ms. Cohen's restlessness, she was successful at pulling out her IV line and getting out of bed. It becomes necessary to restrain Ms. Cohen.

1. You know that a health care provider's order is required for the restraint. What are essential components of the restraint order?
2. What assessments do you need to perform on Ms. Cohen while she is restrained?
3. The physician orders a belt restraint. Your assessment of Ms. Cohen the next day reveals that during the day she is alert and pleasantly confused but not attempting to get out of bed. Do you continue use of the restraint? Explain.

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse's first action after discovering an electrical fire in a patient's room is to:
   1. Activate the fire alarm.
   2. Confine the fire by closing all doors and windows.
   3. Remove all patients in immediate danger.
   4. Extinguish the fire by using the nearest fire extinguisher.
2. A parent calls the pediatrician's office frantic about the bottle of cleaner that her 2-year-old son drank. Which of the following is the most important instruction the nurse gives to this parent?
   1. Give the child milk.
   2. Give the child syrup of ipecac.
   3. Call the poison control center.
   4. Take the child to the emergency department.
3. The nursing assessment on a 78-year-old woman reveals shuffling gait, decreased balance, and instability. On the basis of the patient's data, which one of the following nursing diagnoses indicates an understanding of the assessment findings?
   1. Activity intolerance
   2. Impaired bed mobility
   3. Acute pain
   4. Risk for falls
4. A couple is with their adolescent daughter for a school physical and state they are worried about all the safety risks affecting this age. What is the greatest risk for injury for an adolescent?
   1. Home accidents
   2. Physiological changes of aging
   3. Poisoning and child abduction
   4. Automobile accidents, suicide, and substance abuse
5. The nurse found a 68-year-old female patient wandering in the hall. The patient says she is looking for the bathroom. Which interventions are appropriate to ensure the safety of the patient? (Select all that apply.)
   1. Insert a urinary catheter.
   2. Leave a night light on in the bathroom.
   3. Ask the physician to order a restraint.
   4. Keep the bed in low position with upper and lower side rails up.
   5. Assign a staff member to stay with the patient.
   6. Provide scheduled toileting during the night shift.
   7. Keep the pathway from the bed to the bathroom clear.
6. The family of a patient who is confused and ambulatory insists that all four side rails be up when the patient is alone. What is the best action to take in this situation? (Select all that apply.)
   1. Contact the nursing supervisor.
   2. Restrict the family's visiting privileges.
   3. Ask the family to stay with the patient if possible.
   4. Inform the family of the risks associated with side-rail use.
   5. Thank the family for being conscientious and put the four rails up.
   6. Discuss alternatives with the family that are appropriate for this patient.
7. A physician writes an order to apply a wrist restraint to a patient who has been pulling out a surgical wound drain. Place the following steps for applying the restraint in the correct order.
   ___ 1. Explain what you plan to do.
   ___ 2. Wrap a limb restraint around wrist or ankle with soft part toward skin and secure.
   ___ 3. Determine that restraint alternatives fail to ensure patient's safety.
   ___ 4. Identify the patient using proper identifier.
   ___ 5. Pad the patient's wrist.
8. A child in the hospital starts to have a grand mal seizure while playing in the playroom. What is your most important nursing intervention during this situation?
   1. Begin cardiopulmonary respiration.
   2. Restrain the child to prevent injury.
   3. Place a tongue blade over the tongue to prevent aspiration.
   4. Clear the area around the child to protect the child from injury.
9. A 62-year-old woman is being discharged home with her husband after surgery for a hip fracture from a fall at home. When providing discharge teaching about home safety to this patient and her husband, the nurse knows that:
   1. A safe environment promotes patient activity.
   2. Assessment focuses on environmental factors only.
   3. Teaching home safety is difficult to do in the hospital setting.
   4. Most accidents in the older adult are caused by lifestyle factors.
10. A fragile, 87-year-old nursing home resident is admitted to the hospital with dehydration and increased confusion. The patient has upper limb restraints to prevent her from pulling out her nasogastric tube. What instructions does the nurse give to nursing assistive personnel (NAP)?
11. The nursing assessment of an 80-year-old patient who demonstrates some confusion but no anxiety reveals that the patient is a fall risk because she continues to get out of bed without help despite frequent reminders. The initial nursing intervention to prevent falls for this patient is to:
    1. Place a bed alarm device on the bed.
    2. Place the patient in a belt restraint.
    3. Provide one-on-one observation of the patient.
    4. Apply wrist restraints.
12. To ensure the safe use of oxygen in the home by a patient, which of the following teaching points does the nurse include? (Select all that apply.)

1. Smoking is prohibited around oxygen.
2. Demonstrate how to adjust the oxygen flow rate based on patient symptoms.
3. Do not use electrical equipment around oxygen.
4. Special precautions may be required when traveling with oxygen

13. How does the nurse support a culture of safety? (Select all that apply.)
    1. Completing incident reports when appropriate
    2. Completing incident reports for a near miss
    3. Communicating product concerns to an immediate supervisor
    4. Identifying the person responsible for an incident
14. You are admitting Mr. Jones, a 64-year-old patient who had a right hemisphere stroke and a recent fall. The wife stated that he has a history of high blood pressure, which is controlled by an antihypertensive and a diuretic. Currently he exhibits left-sided neglect and problems with spatial and perceptual abilities and is impulsive. He has moderate left-sided weakness that requires the assistance of two and the use of a gait belt to transfer to a chair. He currently has an intravenous (IV) line and a urinary catheter in place. What factors increase his fall risk at this time? (Select all that apply.)
    1. Smokes a pack a day
    2. Used a cane to walk at home
    3. Takes antihypertensive and diuretics
    4. History of recent fall
    5. Neglect, spatial and perceptual abilities, impulsive
    6. Requires assistance with activity, unsteady gait
    7. IV line, urinary catheter
15. At 3 AM the emergency department nurse hears that a tornado hit the east side of town. What action does the nurse take first?
    1. Prepare for an influx of patients
    2. Contract the American Red Cross
    3. Determine how to restore essential services
    4. Evacuate patients per the disaster plan

CHAPTER

28

Infection Prevention and Control

OBJECTIVES

- Explain the relationship between the chain and transmission of infection.
- Give an example of preventing infection for each element of the infection chain.
- Identify the normal defenses of the body against infection.
- Discuss the events in the inflammatory response.
- Identify patients most at risk for infection.
- Describe the signs/symptoms of a localized infection and those of a systemic infection.
- Explain conditions that promote the transmission of health care–associated infection.
- Explain the difference between medical and surgical asepsis.
- Explain the rationale for standard precautions.
- Perform proper procedures for hand hygiene.
- Explain how infection control measures differ in the home versus the hospital.
- Properly don a surgical mask, sterile gown, and sterile gloves.
- Explain procedures for each isolation category.
- Understand the definition of occupational exposure.
- Explain the postexposure process.

The incidence of patients developing infections as the direct result of contact during health care is increasing. Current trends, public awareness, and rising costs of health care have increased the importance of infection prevention and control. The Joint Commission (TJC) (2011) views this as a patient safety issue. Infection prevention and control are essential for creating a safe health care environment for patients, families, and staff. Nurses play a primary role in infection prevention and control. Patients in all health care settings are at risk for acquiring infections because of lower resistance to pathogens; increased exposure to pathogens, some of which may be resistant to most antibiotics; and **invasive** procedures. Health care workers are at risk for exposure to infections as a result of contact with patient blood, body fluids, and contaminated equipment and surfaces. By practicing basic infection prevention and control techniques, you avoid spreading pathogens to patients and sustaining an exposure when providing direct care.

Patients and their families need to be able to recognize sources of infection and understand measures used to protect themselves. Patient teaching must include basic information about infection,

the various modes of transmission, and appropriate methods of prevention.

Health care workers protect themselves from contact with infectious material, sharps injury, and/or exposure to a communicable disease by applying knowledge of the infectious process and using appropriate personal protective equipment (PPE). Diseases such as hepatitis B and C, human immunodeficiency virus (HIV) infection, acquired immunodeficiency syndrome (AIDS), tuberculosis (TB), and multidrug-resistant organisms require a greater emphasis on infection prevention and control techniques (Centers for Disease Control and Prevention [CDC], 2004, 2006).

SCIENTIFIC KNOWLEDGE BASE

Nature of Infection

An **infection** is the invasion of a susceptible host by **pathogens** or **microorganisms,** resulting in disease. It is important to know the difference between an infection and colonization. **Colonization** is the presence and growth of microorganisms within a host but without tissue invasion or damage (Tweeten, 2009). Disease or infection results only if the pathogens multiply and alter normal tissue function. Some **infectious** diseases such as viral meningitis and pneumonia have a low or no risk for transmission. Although these illnesses can be serious for the patient, they do not pose a risk to others, including caregivers.

If an infectious disease can be transmitted directly from one person to another, it is termed a **communicable disease** (Tweeten, 2009). If the pathogens multiply and cause clinical signs and symptoms, the infection is **symptomatic.** If clinical signs and symptoms are not present, the illness is termed **asymptomatic.** Hepatitis C is an example of a communicable disease that can be asymptomatic. It is most efficiently transmitted through the direct passage of blood into the skin from a percutaneous exposure, even if the source patient is asymptomatic (CDC, 2010c).

Chain of Infection

The presence of a pathogen does not mean that an infection will occur. Infection occurs in a cycle that depends on the presence of all of the following elements:

- An infectious agent or pathogen
- A reservoir or source for pathogen growth
- A port of exit from the reservoir
- A mode of transmission
- A port of entry to a host
- A susceptible host

Infection can develop if this chain remains uninterrupted (Fig. 28-1). Preventing infections involves breaking the chain of infection.

Infectious Agent. Microorganisms include bacteria, viruses, fungi, and protozoa (Table 28-1). Microorganisms on the skin are either resident or transient flora. Resident organisms (normal flora) are permanent residents of the skin, where they survive and multiply without causing illness (CDC, 2002; WHO, 2009). The potential for microorganisms or parasites to cause disease depends on the number of microorganisms present; their **virulence,** or ability to produce disease; their ability to enter and survive in the host; and the susceptibility of the host. Resident skin microorganisms are not virulent. However, they sometimes cause serious infection when surgery or other invasive procedures allow them to enter deep tissues or when a patient is severely **immunocompromised** (has an impaired immune system).

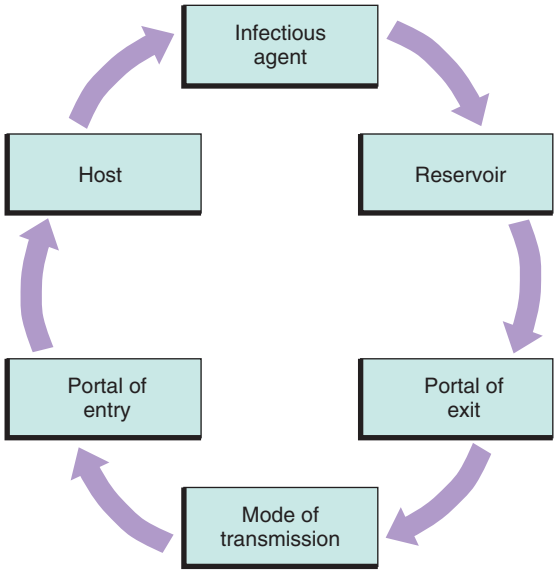

FIG. 28-1 Chain of infection.

Transient microorganisms attach to the skin when a person has contact with another person or object during normal activities. For example, when you touch a contaminated gauze dressing, transient bacteria adhere to your skin. These organisms may be readily transmitted unless removed using hand hygiene (Larson, 2005). If hands are visibly soiled with proteinaceous material, washing with soap and water is the preferred practice. If hands are not visibly soiled, use of an alcohol-based hand product or handwashing with soap and water is acceptable for disinfecting hands of health care workers (CDC, 2002; WHO, 2009).

Reservoir. A **reservoir** is a place where microorganisms survive, multiply, and await transfer to a susceptible host. Common reservoirs are humans and animals (hosts), insects, food, water, and organic matter on inanimate surfaces (fomites). Frequent reservoirs for health care–associated infections (HAIs) include health care workers, especially their hands; patients; equipment; and the environment. Human reservoirs are divided into two types: those with acute or symptomatic disease and those who show no signs of disease but are carriers of it. Humans can transmit microorganisms in either case. Animals, food, water, insects, and inanimate objects can also be reservoirs for infectious organisms. To thrive, organisms require a proper environment, including appropriate food, oxygen, water, temperature, pH, and light.

Food. Microorganisms require nourishment. Some such as *Clostridium perfringens,* the microbe that causes gas gangrene, thrive on organic matter. Others such as *Escherichia coli* consume undigested foodstuff in the bowel. Carbon dioxide and inorganic material such as soil provide nourishment for other organisms.

Oxygen. **Aerobic** bacteria require oxygen for survival and for multiplication sufficient to cause disease. Aerobic organisms cause more infections in humans than anaerobic organisms. An example of an aerobic organism is *Staphylococcus aureus.* **Anaerobic** bacteria thrive where little or no free oxygen is available. Infections deep within the pleural cavity, in a joint, or in a deep sinus tract are typically caused by anaerobes. An example of an anaerobic organism is *Clostridium difficile,* an organism that causes antibiotic-induced diarrhea.

Water. Most organisms require water or moisture for survival. For example, a frequent place for microorganisms is the moist

TABLE 28-1 Common Pathogens and Some Infections or Diseases They Produce

ORGANISM	MAJOR RESERVOIR(S)	MAJOR INFECTIONS/DISEASES
Bacteria		
Escherichia coli	Colon	Gastroenteritis, urinary tract infection
Staphylococcus aureus	Skin, hair, anterior nares, mouth	Wound infection, pneumonia, food poisoning, cellulitis
Streptococcus (beta-hemolytic group A) organisms	Oropharynx, skin, perianal area	"Strep throat," rheumatic fever, scarlet fever, impetigo, wound infection
Streptococcus (beta-hemolytic group B) organisms	Adult genitalia	Urinary tract infection, wound infection, postpartum sepsis, neonatal sepsis
Mycobacterium tuberculosis	Droplet nuclei from lungs, larynx	Tuberculosis
Neisseria gonorrhoeae	Genitourinary tract, rectum, mouth	Gonorrhea, pelvic inflammatory disease, infectious arthritis, conjunctivitis
Rickettsia rickettsii	Wood tick	Rocky Mountain spotted fever
Staphylococcus epidermidis	Skin	Wound infection, bacteremia
Viruses		
Hepatitis A virus	Feces	Hepatitis A
Hepatitis B virus	Blood and certain body fluids, sexual contact	Hepatitis B
Hepatitis C virus	Blood, certain body fluids, sexual contact	Hepatitis C
Herpes simplex virus (type 1)	Lesions of mouth or skin, saliva, genitalia	Cold sores, aseptic meningitis, sexually transmitted disease, herpetic whitlow
Human immunodeficiency virus (HIV)	Blood, semen, vaginal secretions via sexual contact	Acquired immunodeficiency syndrome (AIDS)
Fungi		
Aspergillus organisms	Soil, dust, mouth, skin, colon, genital tract	Aspergillosis, pneumonia, sepsis
Candida albicans	Mouth, skin, colon, genital tract	Candidiasis, pneumonia, sepsis
Protozoa		
Plasmodium falciparum	Blood	Malaria

Modified from Moore V: Microbiology basics. In Carrico R, editor: *APIC text of infection control and epidemiology,* Washington, DC, 2009, Association for Professionals in Infection Control and Epidemiology.

drainage from a surgical wound. Some bacteria assume a form, called a *spore,* which is resistant to drying. A common spore-forming bacterium is *C. difficile,* an organism that causes antibiotic-induced diarrhea.

Temperature. Microorganisms can live only in certain temperature ranges. Each species of bacteria has a specific temperature at which it grows best. The ideal temperature for most human pathogens is 20° to 43° C (68° to 109° F). For example, *Legionella pneumophila* grows best in water at 25° to 42° C (77° to 108° F) (Moore, 2009; Ritter, 2005). Cold temperatures tend to prevent growth and reproduction of bacteria **(bacteriostasis).** A temperature or chemical that destroys bacteria is **bactericidal.**

pH. The acidity of an environment determines the viability of microorganisms. Most microorganisms prefer an environment within a pH range of 5.0 to 7.0. Bacteria in particular thrive in urine with an alkaline pH.

Light. Microorganisms thrive in dark environments such as those under dressings and within body cavities.

Port of Exit. After microorganisms find a site to grow and multiply, they need to find a port of exit if they are to enter another host and cause disease. Ports of exit include sites such as blood, skin and mucous membranes, respiratory tract, genitourinary tract, gastrointestinal tract, and transplacental (mother to fetus).

Skin and Mucous Membranes. The skin is considered a port of exit because any break in the integrity of the skin and mucous membranes allows pathogens to exit the body. This may be exhibited by the creation of purulent drainage. The presence of purulent drainage is a potential port of exit.

Respiratory Tract. Pathogens that infect the respiratory tract such as the influenza virus are released from the body when an infected person sneezes or coughs.

Urinary Tract. Normally urine is sterile. However, when a patient has a urinary tract infection (UTI), microorganisms exit during urination.

Gastrointestinal Tract. The mouth is one of the most bacterially contaminated sites of the human body, but most of the organisms are normal floras. Organisms that are normal floras in one person can be pathogens in another. For example, organisms exit when a person expectorates saliva. In addition, gastrointestinal ports of exit include bowel elimination, drainage of bile via surgical wounds, or drainage tubes.

Reproductive Tract. Organisms such as *Neisseria gonorrhoeae* and HIV exit through a man's urethral meatus or a woman's vaginal canal during sexual contact.

Blood. The blood is normally a sterile body fluid; however, in the case of communicable diseases such as hepatitis B or C or HIV, it becomes a reservoir for pathogens.

Modes of Transmission. Each disease has a specific mode of transmission. Many times you are able to do little about the infectious agent or the susceptible host, but by practicing infection

BOX 28-1 MODES OF TRANSMISSION

Contact

Direct

- Person-to-person (fecal, oral) physical contact between source and susceptible host (e.g., touching patient feces and then touching your inner mouth or consuming contaminated food)

Indirect

- Personal contact of susceptible host with contaminated inanimate object (e.g., needles or sharp objects, dressings, environment)

Droplet

- Large particles that travel up to 3 feet during coughing, sneezing, or talking and come in contact with susceptible host

Airborne

- Droplet nuclei or residue or evaporated droplets suspended in air during coughing or sneezing or carried on dust particles

Vehicles

- Contaminated items
- Water
- Drugs, solutions
- Blood
- Food (improperly handled, stored, or cooked; fresh or thawed meats)

Vector

- External mechanical transfer (flies)
- Internal transmission such as parasitic conditions between **vector** and host such as:
  - Mosquito
  - Louse
  - Flea
  - Tick

Modified from Tweeten S: General principles of epidemiology. In Carrico R, editor: *APIC text of infection control and epidemiology,* Washington, DC, 2005, Association for Professionals in Infection Control and Epidemiology.

BOX 28-2 COURSE OF INFECTION BY STAGE

Incubation Period

Interval between entrance of pathogen into body and appearance of first symptoms (e.g., chickenpox, 10 to 21 days after exposure; common cold, 1 to 2 days; influenza, 1 to 5 days; mumps, 12 to 26 days).

Prodromal Stage

Interval from onset of nonspecific signs and symptoms (malaise, low-grade fever, fatigue) to more specific symptoms. (During this time microorganisms grow and multiply, and patient may be capable of spreading disease to others.) For example, herpes simplex begins with itching and tingling at the site before the lesion appears.

Illness Stage

Interval when patient manifests signs and symptoms specific to type of infection. For example, strep throat is manifested by sore throat, pain, and swelling; mumps is manifested by high fever, parotid and salivary gland swelling.

Convalescence

Interval when acute symptoms of infection disappear. (Length of recovery depends on severity of infection and patient's host resistance; recovery may take several days to months.)

prevention and control techniques such as hand hygiene, you interrupt the mode of transmission (Box 28-1). The same microorganism is sometimes transmitted by more than one route. For example, varicella zoster (chickenpox) is spread by the airborne route in droplet nuclei or by direct contact.

The major route of transmission for pathogens identified in the health care setting is the unwashed hands of the health care worker (CDC, 2002; Cipriano, 2007; WHO, 2009). Equipment used within the environment (e.g., a stethoscope, blood pressure cuff, or bedside commode) often becomes a source for the transmission of pathogens.

Port of Entry. Organisms enter the body through the same routes they use for exiting. For example, when a needle pierces a patient's skin, organisms enter the body if proper skin preparation is not performed first. Factors such as a depressed immune system that reduce body defenses enhance the chances of pathogens entering the body.

Susceptible Host. **Susceptibility** to an infectious agent depends on the individual's degree of resistance to pathogens. Although everyone is constantly in contact with large numbers of microorganisms, an infection does not develop until an individual becomes susceptible to the strength and numbers of the microorganisms. A person's natural defenses against infection and certain risk factors (e.g., age, nutritional status, presence of chronic disease, trauma, and smoking) affect susceptibility (resistance) (Fardo, 2009). Organisms such as *S. aureus* with resistance to key antibiotics are becoming more common in all health care settings, but especially acute care. The increased resistance is associated with the frequent and sometimes inappropriate use of antibiotics over the years in all settings (i.e., acute care, ambulatory care, clinics, and long-term care) (Arnold, 2009).

THE INFECTIOUS PROCESS

By understanding the chain of infection, you have knowledge that is vital in preventing infections. When the patient acquires an infection, observe for signs and symptoms of infection and take appropriate actions to prevent its spread. Infections follow a progressive course (Box 28-2).

If an infection is **localized** (e.g., a wound infection), the patient usually experiences localized symptoms such as pain, tenderness, and redness at the wound site. Use standard precautions, appropriate PPE, and hand hygiene when assessing the wound. The use of these precautions and hand hygiene blocks the spread of infection to other sites or other patients. An infection that affects the entire body instead of just a single organ or part is **systemic** and can become fatal if undetected and untreated.

The course of an infection influences the level of nursing care provided. The nurse is responsible for properly administering antibiotics, monitoring the response to drug therapy (see Chapter 31), using proper hand hygiene, and standard precautions. Supportive therapy includes providing adequate nutrition and rest to bolster defenses against the infectious process. The course of care for the patient often has additional effects on body systems affected by the infection.

Defenses Against Infection

The body has natural defenses that protect against infection. Normal floras, body system defenses, and inflammation are all nonspecific defenses that protect against microorganisms

TABLE 28-2 Normal Defense Mechanisms Against Infection

DEFENSE MECHANISMS	ACTION	FACTORS THAT MAY ALTER DEFENSE MECHANISMS
Skin		
Intact multilayered surface (first line of defense body against infection)	Provides barrier to microorganisms and antibacterial activity	Cuts, abrasions, puncture wounds, areas of maceration
Shedding of outer layer of skin cells	Removes organisms that adhere to outer layers of skin	Failure to bathe regularly, improper handwashing technique
Sebum	Contains fatty acid that kills some bacteria	Excessive bathing
Mouth		
Intact multilayered mucosa	Provides mechanical barrier to microorganisms	Lacerations, trauma, extracted teeth
Saliva	Washes away particles containing microorganisms	Poor oral hygiene, dehydration
	Contains microbial inhibitors (e.g., lysozyme)	
Eye		
Tearing and blinking	Provides mechanisms to reduce entry (blinking) or assist in washing away (tearing) particles containing pathogens, thus reducing dose of organisms	Injury, exposure—splash/splatter of blood or other potentially infectious material into eye
Respiratory Tract		
Cilia lining upper airway, coated by mucus	Traps inhaled microbes and sweeps them outward in mucus to be expectorated or swallowed	Smoking, high concentration of oxygen and carbon dioxide, decreased humidity, cold air
Macrophages	Engulf and destroy microorganisms that reach alveoli of lung	Smoking
Urinary Tract		
Flushing action of urine flow	Washes away microorganisms on lining of bladder and urethra	Obstruction to normal flow by urinary catheter placement, obstruction from growth or tumor, delayed micturition
Intact multilayered epithelium	Provides barrier to microorganisms	Introduction of urinary catheter, continual movement of catheter in urethra
Gastrointestinal Tract		
Acidity of gastric secretions	Prevents retention of bacterial contents	Administration of antacids
Rapid peristalsis in small intestine		Delayed motility resulting from impaction of fecal contents in large bowel or mechanical obstruction by masses
Vagina		
At puberty, normal flora causing vaginal secretions to achieve low pH	Inhibit growth of many microorganisms	Antibiotics and oral contraceptives disrupting normal flora

regardless of prior exposure. If any body defenses fail, an infection usually occurs and leads to a serious health problem.

Normal Floras. The body normally contains microorganisms that reside on the surface and deep layers of skin, in the saliva and oral mucosa, and in the gastrointestinal and genitourinary tracts. A person normally excretes trillions of microbes daily through the intestines. **Normal floras** do not usually cause disease when residing in their usual area of the body but instead participate in maintaining health.

Normal floras of the large intestine exist in large numbers without causing illness. They also secrete antibacterial substances within the walls of the intestine. The normal floras of the skin exert a protective, bactericidal action that kills organisms landing on the skin. The mouth and pharynx are also protected by floras that impair growth of invading microbes. Normal floras maintain a sensitive balance with other microorganisms to prevent infection. Any factor that disrupts this balance places a person at increased risk for acquiring a disease. For example, the use of **broad-spectrum antibiotics** for the treatment of infection can lead to **suprainfection.** A suprainfection develops when broad-spectrum antibiotics eliminate a wide range of normal flora organisms, not just those causing infection. When normal bacterial floras are eliminated, body defenses are reduced, which allows for disease-producing microorganisms to multiply, causing illness (Arnold, 2009).

Body System Defenses. A number of body organ systems have unique defenses against infection (Table 28-2). The skin, respiratory tract, and gastrointestinal tract are easily accessible to microorganisms. Pathogenic organisms can adhere to the surface skin, be inhaled into the lungs, or be ingested with food. Each organ system has defense mechanisms physiologically suited to its specific structure and function. For example, the lungs cannot completely control the entrance of microorganisms. However, the airways are lined with moist mucous membranes and hairlike projections, or cilia, that rhythmically beat to move mucus or cellular debris up to the pharynx to be expelled through swallowing.

Inflammation. The cellular response of the body to injury, infection, or irritation is termed *inflammation*. Inflammation is a protective vascular reaction that delivers fluid, blood products, and nutrients to an area of injury. The process neutralizes and eliminates pathogens or dead **(necrotic)** tissues and establishes a means of repairing body cells and tissues. Signs of localized inflammation include swelling, redness, heat, pain or tenderness, and loss of

function in the affected body part. When inflammation becomes systemic, other signs and symptoms develop, including fever, leukocytosis, malaise, anorexia, nausea, vomiting, lymph node enlargement, or organ failure.

Physical agents, chemical agents, or microorganisms trigger the inflammatory response. Mechanical trauma, temperature extremes, and radiation are examples of physical agents. Chemical agents include external and internal irritants such as harsh poisons or gastric acid. Sometimes microorganisms also trigger this response.

After tissues are injured, a series of well-coordinated events occurs. The inflammatory response includes the following:

1. Vascular and cellular responses
2. Formation of inflammatory **exudates** (fluid and cells that are discharged from cells or blood vessels [e.g., pus or serum])
3. Tissue repair

Vascular and Cellular Responses. Acute inflammation is an immediate response to cellular injury. Rapid vasodilation occurs, allowing more blood near the location of the injury. The increase in local blood flow causes the redness and localized warmth at the site of inflammation.

Injury causes tissue damage and possibly necrosis. As a result the body releases chemical mediators that increase the permeability of small blood vessels; and fluid, protein, and cells enter interstitial spaces. The accumulation of fluid appears as localized swelling **(edema).** Another sign of inflammation is pain. The swelling of inflamed tissues increases pressure on nerve endings, causing pain. As a result of physiological changes occurring with inflammation, the involved body part may have a temporary loss of function. For example, a localized infection of the hand causes the fingers to become swollen, painful, and discolored. Joints become stiff as a result of swelling, but function of the fingers returns when inflammation subsides.

The cellular response of inflammation involves white blood cells (WBCs) arriving at the site. WBCs pass through blood vessels and into the tissues. **Phagocytosis** is a process that involves the destruction and absorption of bacteria. Through the process of phagocytosis, specialized WBCs, called *neutrophils* and *monocytes,* ingest and destroy microorganisms or other small particles. If inflammation becomes systemic, other signs and symptoms develop. **Leukocytosis,** or an increase in the number of circulating WBCs, is the response of the body to WBCs leaving blood vessels. A serum WBC count is normally 5,000 to 10,000/mm^3 but typically rise to 15,000 to 20,000/mm^3 and higher during inflammation. Fever is caused by phagocytic release of pyrogens from bacterial cells, which causes a rise in the hypothalamic set point (see Chapter 29).

Inflammatory Exudate. Accumulation of fluid and dead tissue cells and WBCs forms an exudate at the site of inflammation. Exudate may be **serous** (clear, like plasma), **sanguineous** (containing red blood cells), or **purulent** (containing WBCs and bacteria). Usually the exudate is cleared away through lymphatic drainage. Platelets and plasma proteins such as fibrinogen form a meshlike matrix at the site of inflammation to prevent its spread.

Tissue Repair. When there is injury to tissue cells, healing involves the defensive, reconstructive, and maturative stages (see Chapter 48). Damaged cells are eventually replaced with healthy new cells. The new cells undergo a gradual maturation until they take on the same structural characteristics and appearance as the previous cells. If inflammation is chronic, tissue defects sometimes fill with fragile **granulation tissue.** Granulation tissue is not as strong as tissue collagen and assumes the form of scar tissue.

Health Care–Associated Infections

Patients in health care settings, especially hospitals and long-term care facilities, have an increased risk of acquiring infections. **Health care–associated infections (HAIs),** formerly called *nosocomial* or *health care–acquired infections,* result from the delivery of health services in a health care facility. They occur as the result of invasive procedures, antibiotic administration, the presence of multidrug-resistant organisms, and breaks in infection prevention and control activities.

Patients who develop HAIs often have multiple illnesses, are older adults, and are poorly nourished; thus they are more susceptible to infections. In addition, many patients have a lowered resistance to infection because of underlying medical conditions (e.g., diabetes mellitus or malignancies) that impair or damage the immune response of the body. Invasive treatment devices such as intravenous (IV) catheters or indwelling urinary catheters impair or bypass the natural defenses of the body against microorganisms. Critical illness increases patients' susceptibility to infections, especially multidrug-resistant bacteria. Meticulous hand hygiene practices, the use of chlorhexidine washes, and other advances in intensive care unit (ICU) infection prevention help to prevent these infections (Doyle et al., 2011).

Iatrogenic infections are a type of HAI from a diagnostic or therapeutic procedure. For example, procedures such as a bronchoscopy and treatment with broad-spectrum antibiotics increase the risk for certain infections (Arnold, 2009; Stricof, 2009). Use critical thinking when practicing aseptic techniques and follow basic infection prevention and control policies and procedures to reduce the risk of HAIs. Always consider the patient's risks for infection and anticipate how the approach to care increases or decreases the risk.

Health care–associated infections are exogenous or endogenous. An **exogenous infection** comes from microorganisms found outside the individual such as *Salmonella, Clostridium tetani,* and *Aspergillus.* They do not exist as normal floras. **Endogenous infection** occurs when part of the patient's flora becomes altered and an overgrowth results (e.g., staphylococci, enterococci, yeasts, and streptococci). This often happens when a patient receives broad-spectrum antibiotics that alter the normal floras. When sufficient numbers of microorganisms normally found in one body site move to another site, an endogenous infection develops. The number of microorganisms needed to cause a health care–associated infection depends on the virulence of the organism, the susceptibility of the host, and the body site affected.

The number of health care employees having direct contact with a patient, the type and number of invasive procedures, the therapy received, and the length of hospitalization influence the risk of infection. Major sites for HAIs include surgical or traumatic wounds, urinary and respiratory tracts, and the bloodstream (Box 28-3).

Health care–associated infections significantly increase costs of health care. Older adults have increased susceptibility to these infections because of their affinity to chronic disease and the aging process itself (Box 28-4). Extended stays in health care institutions, increased disability, increased costs of antibiotics, and prolonged recovery times add to the expenses both of the patient and the health care institution and funding bodies (e.g., Medicare). Often costs for HAIs are not reimbursed; as a result, prevention has a beneficial financial impact and is an important part of managed care. TJC (2011) lists several national safety goals focusing on the care of older adults (e.g., ensuring that older adults receive influenza and pneumonia vaccine or preventing infection after surgery).

BOX 28-3 SITES FOR AND CAUSES OF HEALTH CARE–ASSOCIATED INFECTIONS

Improperly performing hand hygiene increases patient risk for all types of health care–associated infections.

Urinary Tract
- Unsterile insertion of urinary catheter
- Improper positioning of the drainage tubing
- Open drainage system
- Catheter and tube becoming disconnected
- Drainage bag port touching contaminated surface
- Improper specimen collection technique
- Obstructing or interfering with urinary drainage
- Urine in catheter or drainage tube being allowed to reenter bladder (reflux)
- Repeated catheter irrigations

Surgical or Traumatic Wounds
- Improper skin preparation before surgery (e.g., shaving vs. clipping hair; not performing a preoperative bath or shower)
- Failure to clean skin surface properly
- Failure to use aseptic technique during dressing changes
- Use of contaminated antiseptic solutions

Respiratory Tract
- Contaminated respiratory therapy equipment
- Failure to use aseptic technique while suctioning airway
- Improper disposal of secretions

Bloodstream
- Contamination of intravenous (IV) fluids by tubing
- Insertion of drug additives to IV fluid
- Addition of connecting tube or stopcocks to IV system
- Improper care of needle insertion site
- Contaminated needles or catheters
- Failure to change IV access site when inflammation first appears
- Improper technique during administration of multiple blood products
- Improper care of peritoneal or hemodialysis shunts
- Improperly accessing an IV port

BOX 28-4 FOCUS ON OLDER ADULTS

Risks for Infection

- An age-related decline in immune system function, termed *immune senescence,* increases the susceptibility of the body to infection and slows overall immune response (Lesser, Paiusi, and Leips, 2006).
- Older adults are less capable of producing lymphocytes to combat challenges to the immune system. When antibodies are produced, the duration of their response is shorter, and fewer cells are produced (Fardo, 2009).
- Risks associated with the development of health care–associated infections in older patients include poor nutrition, unintentional weight loss, and low serum albumin levels (Meiner and Lueckenotte, 2006).
- After age 70 older adults appear likely to produce autoantibodies that attack parts of the body itself instead of infections (Fardo, 2009).
- Older adults experience loss and stress along with suppressed immunity related to bereavement, depression, and poor social support (Fardo, 2009).

NURSING KNOWLEDGE BASE

Body substances such as feces, urine, and wound drainage contain potentially infectious microorganisms. Health care workers are at risk for exposure to microorganisms in the hospital and/or home setting (Fauerbach, 2009). They follow specific infection prevention practices to reduce the risk of cross-contamination and transmission to other patients when caring for a patient with a known or suspected infection (CDC, 2007).

The experience of having a serious infection creates feelings of anxiety, frustration, loneliness, and anger in patients and/or their families (Calfree et al., 2008). These feelings worsen when patients are isolated to prevent transmission of a microorganism to other patients or health care staff. Isolation disrupts normal social relationships with visitors and caregivers. Patient safety is usually an additional risk for the patient on isolation precautions (Murphy, 2009). For example, an older patient with dementia is at increased risk for falling when confined in a room with the door closed. When family members fear the possibility of developing the infection, they avoid contact with the patient. Some patients perceive the simple procedures of proper hand hygiene and gown and glove use as evidence of rejection. Help patients and families reduce some of these feelings by discussing the disease process, explaining isolation procedures, and maintaining a friendly, understanding manner.

When establishing a plan of care, it is important for you to know how a patient reacts to an infection or infectious disease. The challenge is to identify and support behaviors that maintain human health or prevent infection.

Factors Influencing Infection Prevention and Control

Multiple factors influence a patient's susceptibility to infection. It is important to understand how each of these factors alone or in combination increases this risk. When more than one factor is present, the patient's susceptibility often increases, which affects length of stay, recovery time, and/or overall level of health following an illness. Understanding these factors assists in assessing and caring for a patient who has an infection or is at risk for one.

Age. Throughout life, susceptibility to infection changes. For example, an infant has immature defenses against infection. Born with only the antibodies provided by the mother, the infant's immune system is incapable of producing the necessary immunoglobulins and WBCs to adequately fight some infections. However, breastfed infants often have greater immunity than bottle-fed infants because they receive their mother's antibodies through the breast milk. As the child grows, the immune system matures; but the child is still susceptible to organisms that cause the common cold, intestinal infections, and infectious diseases such as mumps, measles, and chickenpox (if not vaccinated).

The young or middle-age adult has refined defenses against infection. Viruses are the most common cause of communicable illness in young or middle-age adults. Since 2000 there has been a major effort to vaccinate all children against all infectious diseases for which vaccines are available. Vaccine-preventable disease levels are at or near record lows (CDC, 2011). For example; hepatitis B infection in children and adolescents decreased by 89% in 2005 (CDC, 2005b).

Defenses against infection change with aging (Lesser, Paiusi, and Leips, 2006). The immune response, particularly cell-mediated immunity, declines. Older adults also undergo alterations in the structure and function of the skin, urinary tract, and

TABLE 28-3 Assessing the Risk of Infection in Adults

RISK FACTOR	CAUSES	OUTCOME
Chronic disease	COPD, heart failure, diabetes	Pneumonia, skin breakdown, venous stasis ulcers
Lifestyle—high-risk behaviors	Exposure to communicable/infectious diseases, use of IV drugs and other drugs/substances	STIs, HIV, HBV, HCV, opportunistic infections, viral infections, yeast infections, liver failure
Occupation	Miner, unemployed, homeless	Black lung disease, pneumonia, TB, poor nutritional intake, lack of access to medical care, stress
Diagnostic procedures	Invasive radiology, transplant	Multiple IV lines, immunosuppressive drugs
Heredity	Sickle cell disease, diabetes	Anemia, delayed healing
Travel history	West Nile virus, SARS, avian flu, *Hantavirus*	Meningitis, acute respiratory distress
Trauma	Fractures, internal bleeding	Sepsis, secondary infection
Nutrition	Obesity, anorexia	Impaired immune response

Modified from Tweeten SM: General principles of epidemiology. In Carrico R, editor: *APIC text of infection control and epidemiology,* Washington, DC, 2009, Association for Professionals in Infection Control and Epidemiology.
COPD, Chronic obstructive pulmonary disease; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HIV,* human immunodeficiency virus; *IV,* intravenous; *SARS,* severe acute respiratory syndrome; *STIs,* sexually transmitted infections; *TB,* tuberculosis.

lungs. For example, the skin loses its turgor, and the epithelium thins. As a result it is easier to tear or abrade the skin, which increases the potential for invasion by pathogens. In addition, older adults who are hospitalized or reside in an assisted-living or residential care facility are at risk for airborne infections. Ensuring that health care workers are vaccinated against influenza reduces the transmission of this illness in older adults (Thomas et al., 2010).

Nutritional Status. A patient's nutritional health directly influences susceptibility to infection. A reduction in the intake of protein and other nutrients such as carbohydrates and fats reduces body defenses against infection and impairs wound healing (see Chapter 48). Patients with illnesses or problems that increase protein requirements, such as extensive burns and conditions causing fever, are at further risk. Patients who have undergone surgery, for example, require increased protein. A thorough diet history is necessary. Determine a patient's normal daily nutrient intake and whether preexisting problems such as nausea, impaired swallowing, or oral pain alter food intake. Confer with a dietitian to assist in calculating the calorie count of foods ingested.

Stress. The body responds to emotional or physical stress by the general adaptation syndrome (see Chapter 37). During the alarm stage the basal metabolic rate increases as the body uses energy stores. Adrenocorticotropic hormone increases serum glucose levels and decreases unnecessary antiinflammatory responses through the release of cortisone. If stress continues or becomes intense, elevated cortisone levels result in decreased resistance to infection. Continued stress leads to exhaustion, which causes depletion in energy stores, and the body has no resistance to invading organisms. The same conditions that increase nutritional requirements such as surgery or trauma also increase physiological stress.

Disease Process. Patients with diseases of the immune system are at particular risk for infection. Leukemia, AIDS, lymphoma, and aplastic anemia are conditions that compromise a host by weakening defenses against infectious organisms. For example, patients with leukemia are unable to produce enough WBCs to ward off infection. Patients with HIV are often unable to ward off simple infections and are prone to opportunistic infections.

Patients with chronic diseases such as diabetes mellitus and multiple sclerosis are also more susceptible to infection because of general debilitation and nutritional impairment. Diseases that impair body system defenses such as emphysema and bronchitis (which impair ciliary action and thicken mucus), cancer (which alters the immune response), and peripheral vascular disease (which reduces blood flow to injured tissues) increase susceptibility to infection. Patients with burns have a high susceptibility to infection because of the damage to skin surfaces. The greater the depth and extent of the burns, the higher the risk for infection.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Determine how the patient feels about the illness or risk for infection. Assess his or her defense mechanisms, susceptibility, and knowledge of how infections are transmitted (Table 28-3). Conduct a review of systems and travel history with the patient and family to reveal any risks for exposure to a communicable disease. Immunization and vaccination history are also very useful. It is important to be thorough in assessing a patient's clinical condition. A medication history is necessary to identify medications that increase a patient's susceptibility to infection. An analysis of laboratory findings provides information about a patient's defense against infection. The early recognition of infection or risk factors helps you make the correct nursing diagnosis and establish a treatment plan.

Through the Patient's Eyes. Some patients with infection have a variety of problems. It is important to ask specific questions to determine the patient's and family's needs related to the risk for infection or disease status (Box 28-5). These needs vary from

BOX 28-5 NURSING ASSESSMENT QUESTIONS

Risk Factors
- Do you have any recent cuts or lacerations? Show me the location.
- Describe for me any illnesses or diseases that you have and those for which you receive treatment.
- Have you had any recent diagnostic testing such as cystoscopy performed?

Possible Existing Infections
- Do you have or feel like you have a fever?
- Do you have any cuts or wounds with drainage?
- Do you have any pain/burning during urination?

Medication History
- List for me the medications you are currently taking.
- Describe any over-the-counter medications or herbals that you are currently taking.

Stressors
- Tell me about any major lifestyle change occurring such as the loss of employment or place of residence, divorce, or disability.

patient to patient and include physical, psychological, social, or economic needs. Patients with chronic or serious infection, especially communicable infections such as TB or AIDS, experience psychological and social problems from self-imposed isolation or rejection by friends and family. Ask the patient how the infection affects the ability to maintain relationships and perform activities of daily living. Determine whether chronic infection has drained the patient's financial resources. Ask about his or her expectations of care and determine how much he or she wants to be involved in planning care. Some patients and their families wish to know more about the disease process, whereas others only want to know the interventions necessary to treat the infection. Encourage patients to verbalize their expectations so you are able to establish interventions to meet patients' priorities.

Status of Defense Mechanisms. Review physical assessment findings and the patient's medical condition to determine the status of normal defense mechanisms against infection. For example, any break in the skin such as an ulcer on the foot of a patient who has diabetes is a potential site for infection. Any reduction in the primary or secondary defenses of the body against infection, such as a weakened ability to cough, places a patient at increased risk.

Patient Susceptibility. As noted in a previous section, age, nutritional status, stress, and disease process are factors that influence susceptibility to infection. Gather information about each factor through your interview and the patient's and family's medical history.

Medical Therapy. Some drugs and medical therapies compromise immunity to infection. Assess your patient's medication history to determine whether he or she takes any medications that increase infection susceptibility. These include any over-the-counter medications and herbal supplements. A review of therapies received within the health care setting further reveals risks. For example, adrenal corticosteroids, prescribed for several conditions, are antiinflammatory drugs that cause protein breakdown and impair the inflammatory response against bacteria and other pathogens. Cytotoxic and antineoplastic drugs attack cancer cells but also cause the side effects of bone marrow depression and normal cell toxicity, which affects the body's response against pathogens.

Clinical Appearance. The signs and symptoms of infection may be local or systemic. Localized infections are most common in areas of skin or mucous membrane breakdown such as surgical and traumatic wounds, pressure ulcers, oral lesions, and abscesses.

To assess an area for localized infection, first inspect it for redness and swelling caused by inflammation. Because there may be drainage from open lesions or wounds, wear clean gloves. Infected drainage may be yellow, green, or brown, depending on the pathogen. For example, green nasal secretions often indicate a sinus infection. Ask the patient about pain or tenderness around the site. Some patients complain of tightness and pain caused by edema. If the infected area is large enough, movement is restricted. Gentle palpation of an infected area usually results in some degree of tenderness. Wear protective eyewear and a surgical mask when there is a risk for splash or spray with blood or body fluids.

Systemic infections cause more generalized symptoms than local infection. These symptoms often include fever, fatigue, nausea/vomiting, and malaise. Lymph nodes that drain the area of infection often become enlarged, swollen, and tender during palpation. For example, an abscess in the peritoneal cavity causes enlargement of lymph nodes in the groin. An infection of the upper respiratory tract causes cervical lymph node enlargement. If an infection is serious and widespread, all major lymph nodes may enlarge.

Systemic infections sometimes develop after treatment for localized infection has failed. Be alert for changes in the patient's level of activity and responsiveness. As systemic infections develop, an elevation in body temperature can lead to episodes of increased heart and respiratory rates and low blood pressure. Involvement of major body systems produces specific symptoms. For example, a pulmonary infection results in a productive cough with purulent sputum. A UTI results in cloudy, foul-smelling urine.

An infection does not always present with typical signs and symptoms in all patients. For example, some older adults have an advanced infection before it is identified. Because of the aging process, there is a reduced inflammatory and immune response. Older adults have increased fatigue and diminished pain sensitivity. A reduced or absent fever response often occurs from chronic use of aspirin or nonsteroidal antiinflammatory drugs. Atypical symptoms such as confusion, incontinence, or agitation may be the only symptoms of an infectious illness (Fardo, 2009). For example, as many as 20% of older adults with pneumonia do not have the typical signs and symptoms of fever, shaking, chills, and rusty productive sputum. Often the only symptoms are an unexplained increase in heart rate, confusion, or generalized fatigue. A pneumonia vaccine is available and recommended for all persons with chronic respiratory problems and those over 65 years of age.

Laboratory Data. Review laboratory data as soon as they are available. Laboratory values such as increased WBCs and/or a positive blood culture often indicate infection (Table 28-4). However, laboratory values are not enough to detect infection. You need to assess other clinical signs. A culture result may show growth of an organism in the absence of infection. For example, in the older adult bacterial growth in urine without clinical symptoms does not always indicate the presence of a UTI (Gantz, 2009). It is also important to note that laboratory values often vary from laboratory to laboratory. Be sure to know the standard range of laboratory values for the laboratory in your facility.

TABLE 28-4 Laboratory Tests to Screen for Infection

LABORATORY VALUE	NORMAL (ADULT) VALUES	INDICATION OF INFECTION
White blood cell (WBC) count	5000-10,000/mm^3	Increased in acute infection, decreased in certain viral or overwhelming infections
Erythrocyte sedimentation rate	Up to 15 mm/hr for men and 20 mm/hr for women	Elevated in presence of inflammatory process
Iron level	60-90 g/100 mL	Decreased in chronic infection
Cultures of urine and blood	Normally sterile, without microorganism growth	Presence of infectious microorganism growth
Cultures and Gram stain of wound, sputum, and throat	No WBCs on Gram stain, possible normal flora	Presence of infectious microorganism growth and WBCs on Gram stain
Differential Count (Percentage of Each Type of White Blood Cell)		
Neutrophils	55%-70%	Increased in acute **suppurative** (pus-forming) infection, decreased in overwhelming bacterial infection (older adult)
Lymphocytes	20%-40%	Increased in chronic bacterial and viral infection, decreased in sepsis
Monocytes	5%-10%	Increased in protozoan, rickettsial, and tuberculosis infections
Eosinophils	1%-4%	Increased in parasitic infection
Basophils	0.5%-1.5%	Normal during infection

BOX 28-6 NURSING DIAGNOSTIC PROCESS

Risk for Infection

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Check results of laboratory tests.	WBC count 5000/mm^3
Review current medications.	Patient receiving antibiotics and oral antidiabetic medications
Identify potential sites of infection.	IV catheter in right forearm, in place for 3 days Foley catheter draining cloudy amber-colored urine

IV, Intravenous; *WBC,* white blood cell.

NURSING DIAGNOSIS

During assessment gather objective data such as inspection of an open incision or a reduced caloric intake record and subjective data such as a patient's complaint of tenderness over a surgical wound site. Review the data carefully, looking for clusters of defining characteristics or risk factors that create a pattern. This pattern suggests a specific nursing diagnosis (Box 28-6). The following are examples of nursing diagnoses that often apply:

- Risk for infection
- Imbalanced nutrition: less than body requirements
- Impaired oral mucous membrane
- Risk for impaired skin integrity
- Social isolation
- Impaired tissue integrity
- Readiness for enhanced immunization status

It is necessary to validate data such as inspecting the integrity of a wound more carefully and to review laboratory findings to confirm a diagnosis. Success in planning appropriate nursing interventions depends on the accuracy of the diagnosis and the ability to meet the patient's needs. This requires an accurate related to factor in the diagnostic statement. For example, minimizing the risk for infection in a patient with a diagnosis of *impaired oral mucous membrane related to mouth breathing* requires proper hygiene measures, including frequent oral care. Minimizing the risk for infection in a patient with a nursing diagnosis of *imbalanced nutrition: less than body requirements related to inability to absorb nutrients* requires good nutritional support and fluid balance. The correct "related to" factor will ensure relevant and appropriate interventions for a patient.

PLANNING

Goals and Outcomes. The patient's care plan is based on each nursing diagnosis and related factor (see the Nursing Care Plan). Develop a plan that sets realistic outcomes so interventions are purposeful, direct, and measurable. When you care for a patient with broken skin who has a nursing diagnosis of *risk for infection,* implement skin and wound care measures to promote healing. The expected outcome of "absence of drainage" sets a target for measuring the patient's improvement. Common goals of care applicable to patients with infection often include the following:

- Preventing exposure to infectious organisms
- Controlling or reducing the extent of infection
- Maintaining resistance to infection
- Verbalizing understanding of infection prevention and control techniques (e.g., hand hygiene)

Patients often have multiple nursing diagnoses that are interrelated, and one diagnosis impacts on another diagnosis. A concept map for Mrs. Andrews helps to show the relationships between multiple nursing diagnoses (Fig. 28-2).

Setting Priorities. Establish priorities for each diagnosis and related goals of care. For example, you are caring for a patient with cancer who develops an open wound and is unable to tolerate solid foods. The priority of administering therapies to promote wound healing such as improved nutritional intake overrides the goal of educating the patient to assume self-care therapies at home. When the patient's condition improves, the priorities change, and patient education becomes an essential intervention.

Teamwork and Collaboration. The development of a care plan includes prevention and infection control practices from multiple disciplines. Select interventions in collaboration with the patient, the family, and others on the health care team such as the dietitian or respiratory therapist. Know the patient's sociocultural

NURSING CARE PLAN

Risk for Infection

ASSESSMENT

Mrs. Andrews has diabetes mellitus and degenerative disk disease. She had surgery on her spine late last night. She is currently experiencing pain along her incision and is having difficulty walking. Cody is the nursing student assigned to care for Mrs. Andrews. During hand-off report, Cody finds out that Mrs. Andrews needs to wear a brace when she is out of bed and is having difficulty turning herself when she is in bed. The physical therapist plans to help Mrs. Andrews transfer into a chair after breakfast.

Assessment Activities	*Findings/Defining Characteristics**
Review Mrs. Andrew's chart for laboratory data that reflects infection (e.g., white blood cell [WBC] count).	The **WBC count is 9500.**
Inspect incision area.	**Incision** edges are slightly pink; edges approximated; no drainage noted.
Review risk factors for infection.	Has had **diabetes mellitus** for past 16 years; states blood sugars have been "poorly controlled" for the past year. Dietary assessment reflects malnutrition preoperatively. Is **taking a glucocorticosteroid,** which reduces inflammation and suppresses the immune system.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Risk for infection

PLANNING

Goals	*Expected Outcomes (NOC)*†
	Immune Status
Mrs. Andrews will remain free from symptoms of infection.	Mrs. Andrews will remain afebrile. Mrs. Andrews will have no signs or symptoms of infection (e.g., incision intact; edges approximated; no redness, swelling, or drainage)
	Knowledge: Infection Management
Mrs. Andrews describes ways to prevent infection before discharge.	Mrs. Andrews will identify signs and symptoms of infection by the end of today. Mrs. Andrews will demonstrate appropriate hand hygiene before discharge. Mrs. Andrews will identify who will help assess incisional site when she goes home.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC)*, ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Infection Protection	
Teach Mrs. Andrews and family how to perform hand hygiene correctly.	Meticulous hand hygiene reduces bacterial counts on the hands (Larson, 2005). Patient can easily come in contact with organisms in the environment that can cause infection.
Instruct Mrs. Andrews to report the following to the caregiver: temperature greater than 38° C (100° F), persistent pain or redness, swelling and drainage from incision.	Signs and symptoms indicate infection.
Help Mrs. Andrews identify a family member to check the incision until it is healed, and teach the family member signs and symptoms of infection.	Mrs. Andrews will be unable to visualize incision since it is on her back; she will need a family member to help monitor healing of the surgical site.

‡Intervention classification labels from Bulecheck GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC)*, ed 5, St Louis, 2008, Mosby,

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Compare Mrs. Andrews's body temperature with baseline.	Mrs. Andrews remains afebrile and has no drainage from incision.	Mrs. Andrews has no active infection at this time.
Ask Mrs. Andrews to describe signs and symptoms to report to health care provider.	Mrs. Andrews able to identify temperature range to report. Unable to identify signs of wound infection.	Mrs. Andrews has partial understanding of signs and symptoms to report. Will require additional instruction. Offer information sheet.
Observe for signs of infection at incisional site (e.g., redness, warmth, and wound discharge).	Incision shows no signs of infection.	Incision is showing signs of healing.

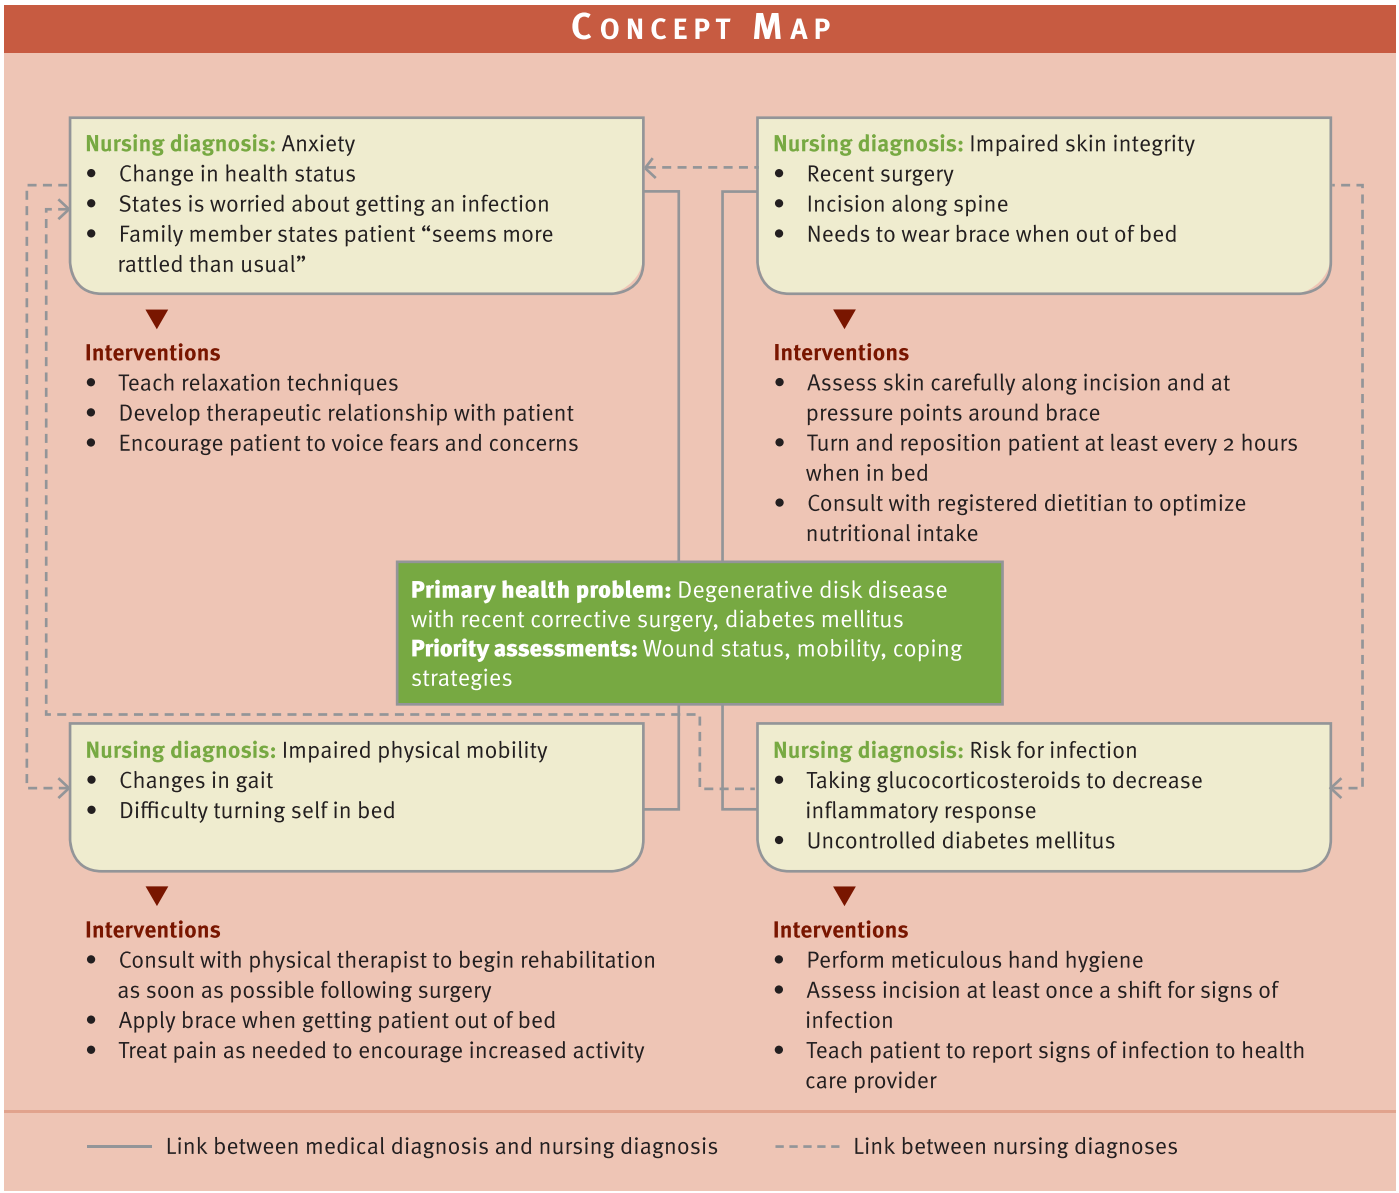

FIG. 28-2 Concept map for Mrs. Andrews.

preferences to help you in identifying the most appropriate types of interventions (Box 28-7). In addition, consult with an expert in infection control in planning the patient's care. Before discharge consult with case management to complete a home assessment and identify home health needs. Case managers work with the patient, family, and home care services to ensure that a safe discharge plan is in place.

When care continues into the patient's home, the home care nurse plans to ensure that the home environment supports good infection prevention and control practices. For example, if a patient does not have running water yet requires wound care, even simple hand hygiene with soap and water is difficult to achieve. Home health nurses instruct patients to perform hand hygiene with either bottled water and soap or alcohol-based hand products.

IMPLEMENTATION

By identifying and assessing a patient's risk factors and implementing appropriate measures, you can effectively reduce the risk of infection.

Health Promotion. Use your critical thinking skills to prevent an infection from developing or spreading. In the home and community settings, strengthen the defenses of a potential host against infection. Nutrition support, rest, maintenance of physiological protective mechanisms, and recommended immunizations protect patients. For example, an annual vaccination to protect against influenza is an important element of risk reduction.

In health care settings, implement procedures to minimize the numbers and kinds of organisms that are transmitted. Eliminating reservoirs of infection, controlling ports of exit and entry, and avoiding actions that transmit microorganisms prevent bacteria from finding a new site in which to grow. Proper use of sterile supplies, barrier precautions, standard precautions, transmission-based precautions, and hand hygiene are examples of methods to control the spread of microorganisms.

Having an infection prevention and control conscience helps you apply principles of medical and surgical asepsis. When a patient develops an infection, implement techniques and procedures to reduce the opportunity for health care personnel and other patients to be exposed to the infection. Patients with

BOX 28-7 CULTURAL ASPECTS OF CARE

Implications for Infection Control–AIDS in New York City

Various cultural and religious beliefs or practices influence patients' decisions to seek treatment for an infection or to use methods to prevent infections. One example is how sociocultural factors affect the residents of New York City who seek AIDS care. Recent research shows that HIV infection rates in New York City are significantly higher (perhaps by as much as 40%) when compared with other parts of the United States. The virus has spread in New York City at three times the national rate, making it evident that HIV education and prevention efforts are not effectively reaching New Yorkers. Auerbach and Beckerman (2010) report on the findings of a study that sought to identify the unique sociocultural needs of New York City residents who seek HIV/AIDS care. Key survey questions were aimed at identifying who receives HIV testing and why, what HIV education services were reported as being most effective, and the unique sociocultural obstacles to receiving HIV testing.

Implications for Practice

- The most helpful HIV education occurred in support groups, and the second most helpful was reading material offered in community-based settings.
- Most residents choose to get tested under the direct advice of a physician.
- Latinos tend to hold more HIV/AIDS stigma than their African-American counterparts.
- Culturally sensitive care is required to identify unique approaches to help patients be responsive to preventive care approaches, such as following safe sex habits.

Building Competency in Patient-Centered Care Mrs. Andrews was discharged home on the third postoperative day. Two weeks later she told her family that she was having increased pain in her back. She stated that she was not always wearing her back brace as instructed at the time of surgery because "it makes me sweat and itch." When she wears the brace, she frequently wipes her incision with a handkerchief to remove the perspiration and scratches it to ease the itching. Describe how to assess this patient's condition more thoroughly using a patient-centered approach.

Answers to questions can be found on the Evolve website.

communicable diseases often require specific isolation precautions to break the chain of infection.

Acute Care. Treatment of an infectious process includes eliminating the infectious organisms and supporting the patient's defenses. To identify the causative organism, the nurse collects specimens of body fluids such as sputum or drainage from infected body sites for cultures. When the disease process or causative organism is identified, the health care provider prescribes the most effective treatment.

Systemic infections require measures to prevent complications of fever (see Chapter 29). Maintaining intake of fluids prevents dehydration resulting from diaphoresis. The patient's increased metabolic rate requires an adequate nutritional intake. Rest preserves energy for the healing process.

Localized infections often require measures to assist removal of debris to promote healing. You apply principles of wound care to remove infected drainage from wound sites and support the integrity of healing wounds. When changing a dressing, wear a mask and goggles or a mask with a face shield if splashing or spraying with blood or body fluids is anticipated. Apply gloves to reduce the transmission of microorganisms into the wound (CDC, 2007). Apply special dressings to facilitate removal of drainage and promote healing of wound margins. Sometimes a surgeon will insert drainage tubes to remove infected drainage from body cavities. Use medical and surgical aseptic techniques to manage wounds and ensure correct handling of all drainage or body fluids (see Chapter 48).

During the course of infection, support the patient's body defense mechanisms. For example, if a patient has diarrhea, maintain skin integrity by frequent cleansing, application of a skin barrier cream, and frequent repositioning to prevent breakdown and the entrance of additional microorganisms. Other routine hygiene measures such as cleaning the oral cavity and bathing protect the skin and mucous membranes from invasion and overgrowth of organisms.

Asepsis. Base efforts to minimize the onset and spread of infection on the principles of aseptic technique. **Asepsis** is the absence of pathogenic (disease-producing) microorganisms. Aseptic technique refers to practices/procedures that help reduce the risk for infection. The two types of aseptic technique are medical and surgical asepsis.

Medical asepsis, or clean technique, includes procedures for reducing the number of organisms present and preventing the transfer of organisms. Hand hygiene, barrier techniques, and routine environmental cleaning are examples of medical asepsis.

Principles of medical asepsis are also commonly followed in the home; hand hygiene with soap and water before preparing food is an example. It is also important to include cultural, religious, or social beliefs of the patient and family.

After an object becomes unsterile or unclean, it is considered contaminated. In medical asepsis an area or object is considered contaminated if it contains or is suspected of containing pathogens. For example, a used bedpan, the over-bed table, and a used dressing are considered to be contaminated items.

You will learn to follow certain principles and procedures, including **standard precautions,** to prevent and control infection and its spread. Standard precautions apply to contact with blood, body fluid, nonintact skin, and mucous membranes from all patients. These precautions protect the patient and provide protection for the health care worker. A major component of patient and worker protection is hand hygiene (Skill 28-1, pp. 425-427). **Hand hygiene** includes using an instant alcohol hand antiseptic before and after providing patient care, washing hands with soap and water when they are visibly soiled, and performing a surgical scrub. **Handwashing** is the act of washing hands with soap and water, followed by rinsing under a stream of water for 15 seconds (CDC, 2002). The friction of rubbing hands together removes soil and transient organisms from the hands.

Contaminated hands of health care workers are a primary source of infection transmission in health care settings. It is recommended that health care workers have well-manicured nails and refrain from wearing artificial nails (Box 28-8) to reduce microorganism transmission. Transmission of infection occurs very easily. For example, you are performing a dressing change, and the patient's roommate asks for assistance with a blocked IV line. If you do not perform hand hygiene before handling the IV line, you transfer organisms from the patient's wound to the roommate's IV site. TJC has identified compliance with proper hand hygiene as a National Patient Safety Goal (TJC, 2011).

BOX 28-8 EVIDENCE-BASED PRACTICE

Pathogens and Artificial Fingernails

PICO Question: What are the bacterial counts on the hands of health care workers who wear artificial nails versus natural nails?

Evidence Summary

The effectiveness of hand hygiene is reduced by type and length of fingernails. Evidence shows health care workers wearing artificial nails carry more pathogenic organisms, especially gram-negative organisms and yeast, on their fingertips and at the junction of natural nail and the artificial nail. Studies also show that health care workers with chipped nail polish or artificial nails have higher numbers of bacteria on their fingertips than those without artificial nails (Rothrock, 2006). For this reason the Centers for Disease Control (CDC) hand hygiene guideline recommends that artificial nails and extenders not be worn when working with high-risk patients (CDC, 2002). In response to this recommendation, health care providers prohibit health care workers who provide direct patient care from wearing artificial nails (Rothrock, 2006; CDC 2002).

The American Association of Operating Room Nurses (AORN) also recommends prohibiting the wearing of artificial nails and extenders because their presence negatively affects the effectiveness of the surgical scrub (AORN, 2007).

The Joint Commission (TJC) listed the reduction of health care–associated infections as a National Patient Safety Goal 7 in 2007. Referring to the CDC's hand hygiene guideline of 2002, the TJC cites that avoiding the wearing of artificial nails is a category 1A recommendation. Category 1A recommendations are those backed by strong evidentiary support.

Application to Nursing Practice

- Do not wear artificial nails or extenders when performing patient care (CDC, 2002).
- Keep natural nails clean, well manicured at ¼ inch long, and free of nail gels and acrylic products.

The use of alcohol-based hand rubs is recommended by the CDC (2002) to improve hand hygiene practices, protect health care worker's hands, and reduce transmission of pathogens to patients and personnel in health care settings. Alcohols have excellent germicidal activity and are as effective as soap and water.

The CDC (2002; WHO, 2009) recommends the following:

1. When hands are visibly dirty, when soiled with blood or other body fluids, before eating, and after using the toilet, wash hands with water and either a nonantimicrobial or antimicrobial soap.
2. Wash hands if exposed to spore-forming organisms such as *Clostridium difficile* or *Bacillus anthracis*.
3. If hands are not visibly soiled (WHO, 2009), use an alcohol-based waterless antiseptic agent for routinely decontaminating hands in the following clinical situations:
   a. Before, after, and between direct patient contact (e.g., taking a pulse, lifting a patient, performing a procedure)
   b. After contact with body fluids or excretions, mucous membranes, nonintact skin, or wound dressings
   c. When moving from a contaminated to a clean body site during patient care
   d. After contact with inanimate surfaces or objects in the patient's room (e.g., over-bed table, bed linen, IV pump)
   e. Before caring for patients with severe neutropenia or other forms of severe immune suppression
   f. Before putting on sterile gloves and before inserting indwelling urinary catheters, peripheral vascular catheters, or other invasive devices
   g. After removing gloves

Instruct patients and visitors about the proper technique and times for hand hygiene. Teaching hand hygiene is particularly important if health care is to continue at home. Patients need to wash their hands before eating or handling food; after handling contaminated equipment, linen, or organic material; and after elimination. Encourage visitors to wash their hands before eating or handling food; after coming in contact with infected patients; and after handling contaminated equipment, patient furniture, or organic material (Gould et al., 2011).

You are responsible for providing the patient with a safe environment. Many hospitals are encouraging patients to follow the recommendations of The Joint Commission's "Speak Up" campaign. The Joint Commission, together with the Centers for Medicare and Medicaid Services, launched a national campaign in 2002 to urge patients to take a role in preventing health care errors by becoming active, involved, and informed participants on the health care team. The program features brochures, posters, and buttons on a variety of patient safety topics. One recommendation is to have patients speak up to be sure the health care provider has cleaned his or her hands or wears gloves.

The effectiveness of infection prevention practices depends on the conscientiousness and consistency in using effective aseptic technique by all health care providers. It is human nature to forget key procedural steps or, when hurried, to take shortcuts that break aseptic procedures. However, failure to comply with basic procedures places the patient at risk for an infection that can seriously impair recovery or lead to death.

Cleaning, Disinfection, and Sterilization. Proper cleaning, disinfection, and sterilization of contaminated objects significantly reduce and often eliminate microorganisms. In health care facilities a sterile processing department is responsible for the disinfection and sterilization of reusable supplies and equipment. However, in the home care setting sometimes the nurse has to perform these functions. Many principles of cleaning and disinfection also apply to the home.

Cleaning. Cleaning is the removal of all soil (e.g., organic and inorganic material) from objects and surfaces (Rutala and Weber, 2008, 2009). Generally cleaning involves use of water and mechanical action with detergents or enzymatic products. When an object comes in contact with an infectious or potentially infectious material, it is contaminated. If the object is disposable, it is discarded. Reusable objects need to be cleaned thoroughly before reuse and then either disinfected or sterilized according to manufacturer recommendations. Failure to follow manufacturer recommendations transfers liability from the manufacturer to the health care facility or agency if an infection results from improper processing.

Apply protective eyewear (or a face shield) and utility (dishwashing style) gloves when cleaning equipment that is soiled by organic material such as blood, fecal matter, mucus, or pus. Protective barriers provide protection from potentially infectious organisms. A brush and detergent or soap are necessary for cleaning. The following steps ensure that an object is clean:

1. Rinse contaminated object or article with cold running water to remove organic material. Hot water causes the protein in organic material to coagulate and stick to objects, making removal difficult.
2. After rinsing, wash the object with soap and warm water. Soap or detergent reduces the surface tension of water and

emulsifies dirt or remaining material. Rinse the object thoroughly.
3. Use a brush to remove dirt or material in grooves or seams. Friction dislodges contaminated material for easy removal. Open hinged items for cleaning.
4. Rinse the object in warm water.
5. Dry the object and prepare it for disinfection or sterilization if indicated by classification of the item—critical, semicritical, or noncritical.
6. The brush, gloves, and sink used to clean the equipment are considered contaminated and are cleaned and dried according to policy.

Disinfection and Sterilization. **Disinfection** describes a process that eliminates many or all microorganisms, with the exception of bacterial spores, from inanimate objects (Rutala and Weber, 2008, 2009). There are two types of disinfection: the disinfection of surfaces and high-level disinfection, which is required for some patient care items such as endoscopes and bronchoscopes. You accomplish disinfection using a chemical disinfectant or wet pasteurization (used for respiratory therapy equipment). Examples of disinfectants are alcohols, chlorines, glutaraldehydes, hydrogen peroxide, and phenols. Glutaraldehydes are caustic and toxic to tissues and pose a potential health risk. **Sterilization** is the complete elimination or destruction of all microorganisms, including spores. Steam under pressure, ethylene oxide (ETO) gas, hydrogen peroxide plasma, and chemicals are the most common sterilizing agents. ETO poses a potential health risk to staff processing with this agent, and exposure must be monitored.

The decision to clean, clean and disinfect, or sterilize depends on the intended use of the item. There are three categories of device classification (Box 28-9). Be familiar with the health care facility or agency policy and procedures for cleaning, handling, and delivering care items for eventual disinfection and sterilization. Workers in the central processing area who are specially trained in disinfection and sterilization perform most of the procedures. The following factors influence the efficacy of the disinfecting or sterilizing method:

- *Concentration of solution and duration of contact*—A weakened concentration or shortened exposure time lessens its effectiveness.
- *Type and number of pathogens*—The greater the number of pathogens on an object, the longer the required disinfecting time.
- *Surface areas to treat*—All dirty surfaces and areas need to be fully exposed to disinfecting and sterilizing agents. The type of surface is an important factor. Is the surface porous or nonporous?
- *Temperature of the environment*—Disinfectants tend to work best at room temperature.
- *Presence of soap*—Soap causes certain disinfectants to be ineffective. Thorough rinsing of an object is necessary before disinfecting.
- *Presence of organic materials*—Disinfectants become inactivated unless blood, saliva, pus, or body excretions are washed off.

Table 28-5 lists processes for disinfection and sterilization and their characteristics. Some delicate instruments requiring sterilization cannot tolerate steam and must be processed using gas or plasma.

Infection Prevention and Control—Patient Safety. Effective prevention and control of infection requires you to remain aware of the modes of transmission and ways to control them (Box 28-10). In the hospital, home, or extended care facility a patient needs a personal set of care items. Sharing bedpans, urinals, bath basins, and eating utensils easily leads to cross-infection. In facilities where health care–associated diarrhea occurs, electronic thermometers are not recommended for rectal temperatures. You usually use oral or tympanic thermometers to assess temperature (Ackley and Ladwig, 2011). Do not use electronic thermometers for patients on contact isolation.

Always be careful when handling exudate such as urine, feces, emesis, and blood. Contaminated fluids easily splash while being discarded in toilets or hoppers. These containers need to be emptied at water level to reduce the risk of splash or splatter, and gloves and protective eyewear are worn. Appropriately dispose of disposable soiled items in trash bags. Dispose of items contaminated with large amounts of blood in biohazard bags. Check the location of the biohazard bags because it varies depending on the health care facility. Handle laboratory specimens from all patients as if they were infectious and place them in designated biohazard containers or bags for transport or disposal.

Even though there is no science to show that medical waste poses a health risk, you need to be aware of the state regulations for the handling and disposal of medical (infectious) waste. Occupational Safety and Health Administration (OSHA) regulations address the handling and disposal of blood and body fluids

BOX 28-9 CATEGORIES FOR STERILIZATION, DISINFECTION, AND CLEANING

Critical Items

Items that enter sterile tissue or the vascular system present a high risk of infection if they are contaminated with microorganisms, especially bacterial spores. *Critical items* must be *sterile.* These items include:

- Surgical instruments
- Cardiac or intravascular catheters
- Urinary catheters
- Implants

Semicritical Items

Items that come in contact with mucous membranes or nonintact skin also present a risk. These objects must be free of all microorganisms (except bacterial spores). *Semicritical items* must be *high-level disinfected (HLD)* or *sterilized.* These items include:

- Respiratory and anesthesia equipment
- Endoscopes
- Endotracheal tubes
- Gastrointestinal endoscopes
- Diaphragm fitting rings

After rinsing, dry items and store in a manner to protect from damage and contamination.

Noncritical Items

Items that come in contact with intact skin but not mucous membranes must be clean. *Noncritical items* must be *disinfected.* These items include:

- Bedpans
- Blood pressure cuffs
- Bed rails
- Linens
- Stethoscopes
- Bedside trays and patient furniture
- Food utensils

TABLE 28-5 Examples of Disinfection and Sterilization Processes

CHARACTERISTICS	EXAMPLES OF USE
Moist Heat	
Steam is moist heat under pressure. When exposed to high pressure, water vapor reaches temperature above boiling point to kill pathogens and spores.	Autoclave sterilizes heat-tolerant surgical instruments and semicritical patient care items.
Chemical Sterilants—High-Level Disinfection (HLD)	
A number of chemical disinfectants are used in health care. These include alcohols, chlorines, formaldehyde, glutaraldehyde, hydrogen peroxide, iodophors, phenolics, and quaternary ammonium compounds. Each product performs in a unique manner and is used for a specific purpose.	Chemicals disinfect heat-sensitive instruments and equipment such as endoscopes, respiratory therapy equipment.
Ethylene Oxide (ETO) Gas	
This gas destroys spores and microorganisms by altering metabolic processes of cells. Fumes are released within an autoclave-like chamber. Ethylene oxide gas is toxic to humans, and aeration time varies with products.	This gas sterilizes most medical materials.
Boiling Water	
Boiling is least expensive for use in home. Bacterial spores and some viruses resist boiling. It is not used in health care facilities.	Commonly used in the home for items such as urinary catheters, suction tubes, and drainage collection devices.

that potentially pose a risk for the transmission of bloodborne pathogens. These regulations defer to state laws and regulations (OSHA, 2001a).

To control organisms exiting via the respiratory tract, cover your mouth or nose when coughing or sneezing. Teach patients, health care staff, patient's families, and visitors respiratory hygiene or **cough etiquette** (Table 28-6). The use of posters and written material explaining cough etiquette to learners is beneficial. Cough etiquette has become more important because of concerns for transmission of respiratory infections such as *Mycobacterium tuberculosis*, severe acute respiratory syndrome (SARS), and H1N1 influenza (CDC, 2005a, 2007, 2010b). The elements of a respiratory hygiene or cough etiquette include (1) covering your nose/mouth with a tissue when you cough and promptly disposing of the contaminated tissue; (2) placing a surgical mask on a patient if it does not compromise respiratory function or is applicable, which may not be feasible in pediatric populations; (3) hand hygiene after contact with contaminated respiratory secretions; and (4) spatial separation greater than 3 feet from persons with respiratory infections (CDC, 2007).

Health care personnel with upper respiratory tract infections are often placed on work restriction. Working when ill poses an additional risk to patients and co-workers. Work restriction for non–work-related illness requires the use of sick time. Work-related illness or exposures are covered by workers' compensation. Employee health and infection prevention and control services are often responsible for ensuring compliance with these guidelines.

To prevent transmission of microorganisms through indirect contact, you keep soiled items and equipment from touching your clothing. A common error is to carry dirty linen in the arms against the uniform. Use fluid-resistant linen bags or carry soiled linen with hands held out from the body. Cover laundry hampers and empty them before they become overloaded.

Many measures that control the exit of microorganisms likewise control the entrance of pathogens. Maintaining the integrity of skin and mucous membranes reduces the chances of microorganisms reaching a host. Keep the patient's skin well lubricated by using lotion as appropriate. Patients who are immobilized and debilitated are particularly susceptible to skin breakdown. Do not

BOX 28-10 INFECTION PREVENTION AND CONTROL TO REDUCE RESERVOIRS OF INFECTION

Bathing
- Use soap and water to remove drainage, dried secretions, or excess perspiration.

Dressing Changes
- Change dressings that become wet and/or soiled (see Chapter 48).

Contaminated Articles
- Place tissues, soiled dressings, or soiled linen in fluid-resistant bags for proper disposal.

Contaminated Sharps
- Place all needles, safety needles, and needleless systems into puncture-proof containers, which should be located at the site of use. Federal law requires the use of needle-safe technology. Blood tube holders are single use only (OSHA: Needlestick Safety Prevention Act of 2000, 2001b).

Bedside Unit
- Keep table surfaces clean and dry.

Bottled Solutions
- Do not leave bottled solutions open.
- Keep solutions tightly capped.
- Date bottles when opened and discard in 24 hours.

Surgical Wounds
- Keep drainage tubes and collection bags patent to prevent accumulation of serous fluid under the skin surface.

Drainage Bottles and Bags
- Wear gloves and protective eyewear if splashing or spraying with contaminated blood or body fluids is anticipated.
- Empty and dispose of drainage suction bottles according to facility policy.
- Empty all drainage systems on each shift unless otherwise ordered by a physician.
- Never raise a drainage system (e.g., urinary drainage bag) above the level of the site being drained unless it is clamped off.

TABLE 28-6 Centers for Disease Control and Prevention Isolation Guidelines

The CDC (2002; WHO, 2009) recommends the following:

1. When hands are visibly dirty, when soiled with blood or other body fluids, before eating, and after using the toilet, wash hands with either a nonantimicrobial soap or antimicrobial soap and water.
2. Wash hands if exposed to spore-forming organisms such as *Clostridium difficile* or *Bacillus anthracis*.

Standard Precautions (Tier One) for Use with All Patients

- Standard precautions apply to blood, blood products, all body fluids, secretions, excretions (except sweat), nonintact skin, and mucous membranes.
- Perform hand hygiene before, after, and between direct contact with patients. (Examples of between-contact activities are cleaning hands after a patient care activity, moving to a nonpatient care activity, and cleaning hands again before returning to perform patient contact.)
- Perform hand hygiene after contact with blood, body fluids, mucous membranes, nonintact skin, secretions, excretions or wound dressings; after contact with inanimate surfaces or articles in a patient room; and immediately after gloves are removed.
- When hands are visibly soiled or contaminated with blood or body fluids, wash them with either a nonantimicrobial soap or an antimicrobial soap and water.
- When hands are not visibly soiled or contaminated with blood or body fluids, use an alcohol-based, waterless antiseptic agent to perform hand hygiene (WHO, 2009).
- Wash hands with nonantimicrobial soap and water if contact with spores (e.g., *Clostridium difficile*) is likely to have occurred.
- Do not wear artificial fingernails or extenders if duties include direct contact with patients at high risk for infection and associated adverse outcomes.
- Wear gloves when touching blood, body fluids, secretions, excretions, nonintact skin, mucous membranes, or contaminated items or surfaces is likely. Remove gloves and perform hand hygiene between patient care encounters and when going from a contaminated to a clean body site.
- Wear personal protective equipment when the anticipated patient interaction indicates that contact with blood or body fluids may occur.
- A private room is unnecessary unless the patient's hygiene is unacceptable (e.g., uncontained secretions, excretions, or wound drainage).
- Discard all contaminated sharp instruments and needles in a puncture-resistant container. Health care facilities must make available needleless devices. Any needles should be disposed of uncapped, or a mechanical safety device is activated for recapping.
- Respiratory hygiene/cough etiquette: Have patients cover the nose/mouth when coughing or sneezing; use tissues to contain respiratory secretions and dispose in nearest waste container; perform hand hygiene after contacting respiratory secretions and contaminated objects/materials; contain respiratory secretions with procedure or surgical mask; sit at least 3 feet away from others if coughing.

Transmission-Based Precautions (Tier Two) for Use with Specific Types of Patients

CATEGORY	INFECTION/CONDITION	BARRIER PROTECTION
Airborne precautions (droplet nuclei smaller than 5 microns)	Measles, chickenpox (varicella), disseminated varicella zoster, pulmonary or laryngeal tuberculosis	Private room, negative-pressure airflow of at least 6 to 12 exchanges per hour via high-efficiency particulate air (HEPA) filtration; mask or respiratory protection device, N95 respirator (depending on condition)
Droplet precautions (droplets larger than 5 microns; being within 3 feet of the patient)	Diphtheria (pharyngeal), rubella, streptococcal pharyngitis, pneumonia or scarlet fever in infants and young children, pertussis, mumps, *Mycoplasma* pneumonia, meningococcal pneumonia or sepsis, pneumonic plague	Private room or cohort patients; mask or respirator required (depending on condition) (refer to agency policy)
Contact precautions (direct patient or environmental contact)	Colonization or infection with multidrug-resistant organisms such as VRE and MRSA, *C. difficile*, shigella, and other enteric pathogens; major wound infections; herpes simplex; scabies; varicella zoster (disseminated); respiratory syncytial virus in infants, young children or immunocompromised adults	Private room or cohort patients (see agency policy), gloves, gowns
Protective environment	Allogeneic hematopoietic stem cell transplants	Private room; positive airflow with 12 or more air exchanges per hour; HEPA filtration for incoming air; mask to be worn by patient when out of room during times of construction in area

Modified from Centers for Disease Control and Prevention, Hospital Infection Control Practice Advisory Committee: Guidelines for isolation precautions in hospitals, *MMWR Morb Mortal Wkly Rep* 57/RR-16:39, 2007.
MRSA, Methicillin-resistant *Staphylococcus aureus; VRE,* vancomycin-resistant enterococcus.

position patients on tubes or objects that cause breaks in the skin. Dry, wrinkle-free linen reduces the chances of skin breakdown. It is important to turn and position patients before their skin becomes reddened. Frequent oral hygiene prevents drying of mucous membranes. A water-soluble ointment keeps the patient's lips well lubricated.

After elimination instruct women to clean the rectum and perineum by wiping from the urinary meatus toward the rectum. Cleaning in a direction from the least to the most contaminated area helps reduce genitourinary infections. Meticulous and frequent perineal care is especially important in older adult women who wear disposable incontinence pads.

Another cause for entrance of microorganisms into a host is improper handling and management of urinary catheters and drainage sets (see Chapter 45). Keep the point of connection between a catheter and drainage tube closed and intact. As long as such systems are closed, their contents are considered sterile. Outflow spigots on drainage bags should also remain closed to

BOX 28-11 INFECTION PREVENTION AND CONTROL: PROTECTING THE SUSCEPTIBLE HOST

Protecting Normal Defense Mechanisms

- Regular bathing removes transient microorganisms from the surface of the skin. Lubrication helps keep the skin hydrated and intact.
- Perform regular oral hygiene. Saliva contains enzymes that promote digestion and has a bactericidal action to maintain control of bacteria. Flossing removes tartar and plaque that cause germ infection.
- Maintenance of adequate fluid intake promotes normal urine formation and a resultant outflow of urine to flush the bladder and urethral lining of microorganisms.
- For patients who are physically dependent or immobilized, encourage routine coughing and deep breathing to keep lower airways clear of mucus.
- Encourage proper immunization of children or adult patients who are exposed to certain infectious microorganisms. Children are vaccinated for measles, mumps, rubella, chickenpox, diphtheria, and other vaccine-preventable diseases. Adults receive one booster of tetanus-diphtheria-acellular pertussis (Tdap), annual flu vaccine, and others as recommended by the Centers for Disease Control and Prevention (CDC) (2010a). Older adults should receive pneumococcal vaccine and annual influenza vaccine.

Maintaining Healing Processes

- Promote intake of adequate fluids and a well-balanced diet containing essential proteins, vitamins, carbohydrates, and fats. The nurse also uses measures to increase the patient's appetite.
- Promote a patient's comfort and sleep so energy stores are replaced daily.
- Help the patient learn techniques to reduce stress.

prevent entrance of bacteria. Minimize movement of the catheter at the urethra by stabilizing it with tape or a securing device to reduce chances of microorganisms ascending the urethra into the bladder. Do not share urine-measuring containers among patients. Perform hand hygiene when caring for urinary drainage systems. Sometimes you care for patients with closed drainage systems that collect wound drainage, bile, or other body fluids. Make sure that the site from which a drainage tube exits remains clear of excess moisture or accumulated drainage. Keep all tubing connected throughout use and only open drainage receptacles when it is necessary to discard or measure the volume of drainage (see Chapter 48).

As a nurse you sometimes obtain specimens from drainage tubes or IV tubing ports. Disinfect tubes and ports by scrubbing the surface with alcohol or a chlorhexidine solution for 15 seconds before entering the system.

A final method for reducing the entry of microorganisms is the technique for wound cleaning. The surgical wound is considered to be sterile. To prevent entry of microorganisms into the wound, always clean outward from a wound site. When applying an antiseptic or cleaning with soap and water, wipe around the wound edge first and then clean outward away from the wound (see Chapter 48). Use clean gauze for each revolution around the circumference of the wound. A patient's resistance to infection improves as you protect normal body defenses against infection. Intervene to maintain the normal reparative processes of the body (Box 28-11). Nurses also protect themselves and others through the use of isolation precautions.

The risk of transmitting HAIs or infectious disease among patients is high, especially with an organism such as methicillin-resistant *S. aureus* (MRSA). When a patient has a suspected or known infection, health care workers are alerted and follow infection prevention and control practices. However, they are not always aware that patients have an infection. Body substances such as feces, saliva, mucus, and wound drainage always contain potentially infectious organisms.

Isolation and Isolation Precautions. Isolation is the separation and restriction of movement of ill persons with contagious diseases. Health care facilities are required to have the capability of isolating patients. For example, patients with suspected or confirmed active TB are usually placed in an airborne infection isolation room (CDC, 2007). However, not all communicable diseases require placing a patient in a special private room. You can conduct many isolation practices in standard rooms using barrier precautions.

Barrier precautions include the appropriate use of personal protective equipment (PPE) such as gowns, gloves, masks, eyewear, and other protective devices or clothing. The choice of barriers depends on the task being performed. Barrier protection applies to all patients because every patient has the potential to transmit infection via blood and body fluids and the risk for infection transmission is unknown. The CDC issued new isolation guidelines in 2007 that build on the two-tiered approach established in the 1996 guidelines.

The first and most important tier is standard precautions. The second tier addresses isolation precautions, which are based on the mode of transmission of a disease (see Table 28-6). Isolation precautions are termed *airborne, droplet, contact,* and *protective environment*. The precautions are for patients with highly transmissible pathogens. The protective environment category is designed for patients who have undergone transplants and gene therapy (CDC, 2007).

- *Contact precautions:* Used for direct and indirect contact with patients and their environment. Direct contact refers to the care and handling of contaminated body fluids. An example includes blood or other body fluids from an infected patient that enter the health care worker's body through direct contact with compromised skin or mucous membranes. Indirect contact involves the transfer of an infectious agent through a contaminated intermediate object such as contaminated instruments or hands of health care workers. The health care worker may transmit microorganisms from one patient site to another if hand hygiene is not performed between patients (CDC, 2007).
- *Droplet precautions:* Focus on diseases that are transmitted by large droplets expelled into the air and travel 3 to 6 feet from the patient. Droplet precautions require the wearing of a surgical mask when within 3 feet of the patient, proper hand hygiene, and some dedicated-care equipment. An example is a patient with influenza.
- *Airborne precautions:* Focus on diseases that are transmitted by smaller droplets, which remain in the air for longer periods of time. This requires a specially equipped room with a negative air flow referred to as an *airborne infection isolation room*. Air is not returned to the inside ventilation system but is filtered through a high-efficiency particulate air (HEPA) filter and exhausted directly to the outside. All health care personnel wear an N95 respirator every time they enter the room.
- *Protective environment:* Focuses on a very limited patient population. This form of isolation requires a specialized room with positive airflow. The airflow rate is set at greater

than 12 air exchanges per hour, and all air is filtered through a HEPA filter. Patients are not allowed to have dried or fresh flowers or potted plants in these rooms (CDC, 2007).

- When using the isolation guidelines of the CDC, refer to additional CDC documents to prevent health care–associated aspergillosis and Legionnaires' disease in immunocompromised patients and the spread of multidrug-resistant organisms (CDC, 2007).

Regardless of the type of isolation system, follow these basic principles:

- Use thorough hand hygiene before entering and leaving the room of a patient in isolation.
- Dispose of contaminated supplies and equipment in a manner that prevents spread of microorganisms to other persons as indicated by the mode of transmission of the organism.
- Apply knowledge of a disease process and the mode of infection transmission when using protective barriers.
- Protect all persons who might be exposed during transport of a patient outside the isolation room.

Psychological Implications of Isolation. When a patient requires isolation in a private room, a sense of loneliness sometimes develops because normal social relationships become disrupted. This situation can be psychologically harmful, especially for children. A recent study noted that patients in isolation suffered more depression and anxiety and were less satisfied with their care (Abad et al., 2010). Patients' body images become altered as a result of the infectious process. Some feel unclean, rejected, lonely, or guilty. Infection prevention and control practices further intensify these beliefs of difference or undesirability. Isolation disrupts normal social relationships with visitors and caregivers. Take the opportunity to listen to a patient's concerns or interests. If you rush care or show a lack of interest in a patient's needs, he or she feels rejected and even more isolated.

Before you institute isolation measures, the patient and family need to understand the nature of the disease or condition, the purposes of isolation, and steps for carrying out specific precautions. If they are able to participate in maintaining infection prevention and control practices, the chances of reducing the spread of infection increase. Teach the patient and family to perform hand hygiene and use barrier protection if appropriate. Demonstrate each procedure; be sure to give the patient and family an opportunity for practice. It is also important to explain how infectious organisms are transmitted so the patient and family understand the difference between contaminated and clean objects. Explaining and demonstrating these procedures, especially hand hygiene, helps the family to consistently practice correct hand hygiene and prescribed isolation measures (Gould et al., 2011).

Take measures to improve the patient's sensory stimulation during isolation. Make sure that the room environment is clean and pleasant. Open drapes or shades and remove excess supplies and equipment. Listen to the patient's concerns or interests. Mealtime is a particularly good opportunity for conversation. Providing comfort measures such as repositioning, a back massage, or a warm sponge bath increase physical stimulation. Depending on the patient's condition, encourage him or her to walk around the room or sit up in a chair. Recreational activities such as board games or cards are an option to keep the patient mentally stimulated.

Explain to the family the patient's risk for depression or loneliness (Abad et al., 2010). Encourage visiting family members to avoid expressions or actions that convey revulsion or disgust related to infection prevention and control practices. Discuss ways to provide meaningful stimulation.

The Isolation Environment. Private rooms used for isolation sometimes provide negative-pressure airflow to prevent infectious particles from flowing out of a room to other rooms and the air handling system. Special rooms with positive-pressure airflow are also used for highly susceptible immunocompromised patients such as recipients of transplanted organs. On the door or wall outside the room the nurse posts a card listing precautions for the isolation category in use according to health care facility policy. The card is a handy reference for health care personnel and visitors and alerts anyone who might enter the room accidentally that special precautions must be followed.

The isolation room or an adjoining anteroom needs to contain hand hygiene and PPE supplies. Soap and antiseptic (antimicrobial) solutions need to be available. Personnel and visitors perform hand hygiene before approaching the patient's bedside and again before leaving the room. If toilet facilities are unavailable, there are special procedures for handling portable commodes, bedpans, or urinals.

All patient care rooms, including those used for isolation; contain an impervious bag for soiled or contaminated linen and a trash container with plastic liners. Impervious receptacles prevent transmission of microorganisms by preventing leaking and soiling of the outside surface. A disposable rigid container needs to be available in the room to discard used sharps such as safety needles and syringes.

Remain aware of infection prevention and control techniques while working with patients in protected environments. You need to feel comfortable performing all procedures and yet remain conscious of infection prevention and control principles. Depending on the microorganism and mode of transmission, evaluate which articles or equipment to take into an isolation room. For example, the CDC (2007) recommends the dedicated use of articles such as stethoscopes, sphygmomanometers, or rectal thermometers in the isolation room of a patient infected or colonized with vancomycin-resistant enterococci. Do not use these devices on other patients unless they are first adequately cleaned and disinfected. Box 28-12 describes the procedures to perform when using shared equipment.

Personal Protective Equipment. PPE, specialized clothing or equipment worn by a health care worker for protection against infectious materials (gowns, masks or respirators, protective eyewear, and gloves), should be readily available for personnel performing patient care (CDC, 2004). The equipment to be used is task based.

Gowns. The primary reason for gowning is to prevent soiling clothes during contact with a patient. Gowns or cover-ups protect health care personnel and visitors from coming in contact with infected material and blood or body fluids. Gowns are often required depending on the expected amount of exposure to infectious material. Gowns used for barrier protection are made of a fluid-resistant material. Change gowns immediately if damaged or heavily contaminated. Isolation gowns are disposable or reusable.

Isolation gowns usually open at the back and have ties or snaps at the neck and waist to keep the gown closed and secure. Gowns need to be long enough to cover all outer garments. Long sleeves with tight-fitting cuffs provide added protection. No special technique is required for applying clean gowns as long as they are fastened securely. However, carefully remove gowns to minimize

BOX 28-12 PROCEDURAL GUIDELINES

Caring for a Patient on Isolation Precautions

Delegation Considerations

The skill of caring for a patient on isolation precautions can be delegated to nursing assistive personnel (NAP). However, it is the nurse who assesses the patient's status and isolation indications. Instruct NAP about:

- Special precautions regarding individual patient needs such as transportation to diagnostic tests.
- Precautions about bringing equipment into the patient's room

Equipment

Barrier protection determined by type of isolation—gloves, gowns, masks, protective eyewear, or face shield—that may be needed; supplies depend on procedures performed in room; sharps container; disposable blood pressure (BP) cuff

1. Assess isolation indications (e.g., patient's medical history for exposure, laboratory tests, wound drainage).
2. Review agency policies and precautions necessary for the specific isolation system and consider care measures you will perform while in patient's room.
3. Review nurses' notes or speak with colleagues regarding patient's emotional state and adjustment to isolation.
4. Perform hand hygiene and prepare all equipment that you need to take into patient's room. In some cases equipment remains in the room (stethoscope or BP cuff). Decide which isolation equipment is necessary before entering the patient's room. For example, decide if you need a gown and gloves for a patient in contact precautions or a special respirator mask for a patient on airborne precautions.
5. Prepare for entrance into isolation room:
   a. Apply cover gown, being sure that it covers all outer garments. Pull sleeves down to wrist. Tie securely at neck and waist (see illustration).

STEP 5a Tie gown at waist.

   b. Apply either surgical mask or respirator around mouth and nose. (Type depends on type of precautions and facility policy.) The nurse must have a medical evaluation and be fit tested before using a respirator (OSHA, 1995).
   c. If needed, apply eyewear or goggles snugly around face and eyes. If prescription glasses are worn, side shield may be used.
   d. Apply clean gloves. (NOTE: Wear unpowdered latex-free gloves if patient has a history of latex allergy.) Wear gloves within gown; bring glove cuffs over edge of gown sleeves (see illustration).

STEP 5d Apply gloves over gown sleeves.

6. Enter patient's room. Arrange supplies and equipment. (If equipment will be removed from room for reuse, place on clean paper towel.)
7. Explain purpose of isolation and necessary precautions to patient and family. Offer opportunity to ask questions. Assess for evidence of emotional problems that can occur from isolation.
8. Assess vital signs.
   a. If patient is infected or colonized with a resistant organism (e.g., vancomycin-resistant enterococcus [VRE], methicillin-resistant *Staphylococcus aureus* [MRSA]), equipment remains in room whenever possible. This includes stethoscope and BP cuff.
   b. If stethoscope is to be reused, clean diaphragm or bell with alcohol. Set aside on clean surface.
   c. Use individual electronic or disposable thermometer.

CLINICAL DECISION: If disposable thermometer indicates a fever, assess for other signs/symptoms. Confirm fever using an electronic thermometer (Ackley and Ladwig, 2011).

9. Administer medications (see Chapter 31).
   a. Give oral medication in wrapper or cup.
   b. Dispose of wrapper or cup in plastic-lined receptacle.
   c. Administer injection.
   d. Discard safety needle and syringe or needle into sharps container.
   e. If you are not wearing gloves and hands come into contact with contaminated article or body fluids, perform hand hygiene as soon as possible.
10. Administer hygiene, encouraging patient to discuss questions or concerns about isolation. Provide informal teaching at this time.
    a. Avoid allowing gown to become wet. Carry wash basin out away from gown; avoid leaning against any wet surface.
    b. Remove linen from bed; avoid contact with gown. Place in linen bag according to agency policy.
    c. Remove gloves and perform hand hygiene. Reglove if further care is necessary.
11. Collect specimens.
    a. Place specimen containers on clean paper towel in patient's bathroom. Follow procedure for collecting specimen of body fluids.
    b. Transfer specimen to container without soiling outside of container. Place container in plastic bag and place label on outside of bag or per

Continued

BOX 28-12 PROCEDURAL GUIDELINES

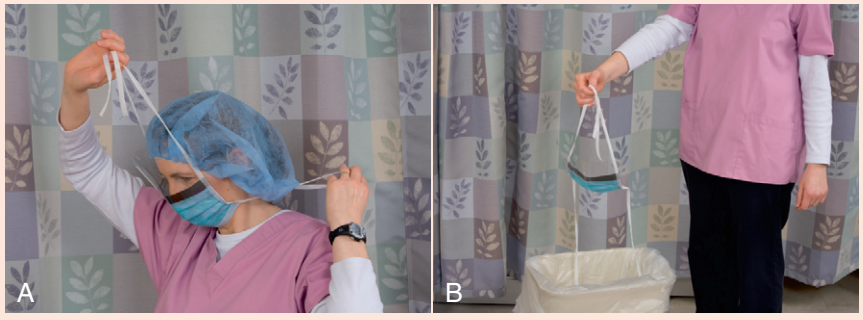
***Caring for a Patient on Isolation Precautions*—cont'd**

facility policy. Label specimen in front of patient (TJC, 2011). Perform hand hygiene and reglove if additional procedures are needed.

12. Dispose of linen and trash bags as they become full.
    a. Use sturdy, moisture-resistant single bags to contain soiled articles. Use double bag if outside of bag is contaminated.
    b. Tie bags securely at top in knot (see illustration).

STEP 12b Tie trash bag securely.

13. Remove all reusable equipment. Clean any contaminated surfaces (see health care facility or agency policy).
14. Resupply room as needed. Have a staff member outside isolation room hand you new supplies.
15. Explain to patient when you plan to return to room. Ask whether patient requires any personal care items, books, or magazines.
16. Leave isolation room. The order for removing personal protective equipment (PPE) depends on what was needed for the type of isolation. The sequence listed is based on full PPE being required.
    a. Remove gloves. Remove one glove by grasping cuff and pulling glove inside out over hand. Discard glove. With ungloved hand tuck finger inside cuff of remaining glove and pull it off, inside out (see illustration).



STEP 16a Remove glove.

    b. Remove eyewear/face shield or goggles.
    c. Untie waist and neck strings of gown. Allow gown to fall from shoulders. Remove hands from sleeves without touching outside of gown. Hold gown inside at shoulder seams and fold inside out. Discard in laundry bag if fabric or in trash can if gown is disposable.
    d. Remove mask: If mask loops over your ears, remove from ears and pull away from face. For a tie-on mask, untie *top* mask strings; hold strings; and then untie bottom strings, pull mask away from face, and drop it into trash receptacle. Do not touch outer surface of mask (see illustrations).

CLINICAL DECISION: If a patient is in isolation for airborne precautions, wait to remove mask until after you leave the patient's room and close the door.

    e. Perform hand hygiene.
    f. Leave room and close door if necessary. (Make sure that door is closed if patient is on airborne precautions.)
    g. Dispose of all contaminated supplies and equipment in a manner that prevents spread of microorganisms to other persons (see health care facility or agency policy).

STEP 16d **A,** Untie top strings of mask. **B,** Drop mask into trash.

contamination of the hands and uniform and discard them after removal.

Respiratory Protection. Wear full-face protection (with eyes, nose, and mouth covered) when you anticipate splashing or spraying of blood or body fluid into the face. Also wear masks when working with a patient placed on airborne or droplet precautions. If the patient is on airborne precautions for TB, apply an OSHA-approved respirator-style mask. The mask protects the nurse from inhaling microorganisms and small-particle droplet nuclei that remain suspended in the air from a patient's respiratory tract. The surgical mask protects a wearer from inhaling large-particle aerosols that travel short distances (3 feet). When caring for patients on droplet or airborne precautions, apply a mask (surgical or respirator) when entering the isolation room.

At times a patient who is susceptible to infection wears a mask to prevent inhalation of pathogens. Patients on droplet or airborne precautions who are transported outside of their rooms need to wear a surgical mask to protect other patients and personnel. Masks prevent transmission of infection by direct contact with mucous membranes (CDC, 2005a). A mask discourages the wearer from touching the eyes, nose, or mouth (Box 28-13).

A properly applied mask fits snugly over the mouth and nose so pathogens and body fluids cannot enter or escape through the sides. If a person wears glasses, the top edge of the mask fits below the glasses so they do not cloud over as the person exhales. Keep talking to a minimum while wearing a mask to reduce respiratory airflow. A mask that has become moist does not provide a barrier to microorganisms and is ineffective. You need to discard it. Never reuse a disposable mask. Warn patients and family members that a mask can cause a sensation of smothering. If family members become uncomfortable, they should leave the room and discard the mask.

Specially fitted respiratory protective devices (N95 respirator masks) are required when caring for patients on airborne precautions, such as patients with known or suspected TB (Fig. 28-3) (CDC, 2005a). The mask must have a higher filtration rating than regular surgical masks and be fitted snugly to prevent leakage around the sides. Be aware of health care facility policy regarding the type of respiratory protective device required. Special fit testing is required to establish the size and ability of the nurse to wear this type of mask (CDC, 2005a).

Eye Protection. Use either special glasses or goggles when performing procedures that generate splash or splatter. Examples of such procedures include irrigation of a large abdominal wound or insertion of an arterial catheter when the nurse assists a health care provider. A nurse who wears prescription glasses uses removable, reusable, or disposable side shields over them (OSHA, 2001a). Eyewear is available in the form of plastic glasses or goggles. The eyewear needs to fit snugly around the face so fluids cannot enter between the face and the glasses.

Gloves. Gloves help to prevent the transmission of pathogens by direct and indirect contact. The CDC notes that you need to wear clean gloves when touching blood, body fluid, secretions, excretions, (except sweat), moist mucous membranes, nonintact skin, and contaminated items or surfaces. Change gloves and perform hand hygiene between tasks and procedures on the same patient after contact with material that contains a high concentration of microorganisms. Remove gloves promptly after use, before touching noncontaminated items and environmental surfaces, and before going to another patient. Perform hand hygiene immediately to avoid transfer of microorganisms to other patients or environments. Because of allergy or sensitivity to latex gloves, facilities provide nonlatex gloves to reduce the incidence of health care providers developing latex allergy or sensitivity. Most facilities are working to become latex free to protect health care providers and patients.

When full PPE is necessary, first perform hand hygiene, then apply a gown, apply mask and eyewear or goggles (as needed), and end with applying gloves. Clean gloves are easy to apply and fit either hand. Pull the cuffs of the glove up over the wrists or over the cuffs of the gown. If you notice a break or tear in a glove while providing care, change gloves. If the nurse does not plan to have more contact with the patient, reapplying gloves is unnecessary. Perform hand hygiene when gloves are removed.

Instruct family members visiting patients on isolation precautions how to apply gloves properly. Demonstrate application of gloves to family members and explain the reason for the use of gloves. Emphasize the importance of performing hand hygiene after removing gloves.

BOX 28-13 PROCEDURAL GUIDELINES

Applying a Surgical Type of Mask

1. Find top edge of mask (some have a thin metal strip along edge). Pliable metal fits snugly against bridge of nose. Others offer an occlusive fit that does not require an adjustment.
2. Hold mask by top two strings or loops. Secure two top ties at top of back of head (see illustration), with ties above ears. (*Alternative:* Slip loops over each ear.)

STEP 2 Securing top two ties of a tie-on mask.

3. Tie two lower ties snugly around neck with mask well under chin (see illustration).

STEP 3 Securing lower ties of a tie-on mask.

4. Gently pinch upper metal band around bridge of nose.

NOTE: Change mask if wet, moist, or contaminated.

FIG. 28-3 N95 respirator mask with protective eyewear. (Courtesy Kimberly-Clark Health Care, Roswell, Ga.)

Specimen Collection. Many laboratory studies are often necessary when a patient is suspected of having an infectious or communicable disease (Box 28-14). You collect body fluids and secretions suspected of containing infectious organisms for culture and sensitivity tests. After a specimen is sent to a laboratory, the laboratory technologist identifies the microorganisms growing in the culture. Additional test results indicate antibiotics to which the organisms are resistant or sensitive. Sensitivity reports determine which antibiotics used in treatment are effective and need to be ordered for treatment.

You obtain all culture specimens using clean gloves and sterile equipment. Collecting fresh material such as wound drainage from the site of infection ensures that neighboring microbes do not contaminate a specimen. Seal all specimen containers tightly to prevent spillage and contamination of the outside of the container.

Bagging Trash or Linen. Bagging contaminated items prevents accidental exposure of personnel and contamination of the surrounding environment. Double bagging is not recommended. Studies demonstrate that this procedure is not necessary to prevent and control infection (CDC, 2007). The use of a single, intact, standard-size linen bag that is not overfilled and tied securely is adequate to prevent infection transmission. Check the color code of bag that your facility uses for bagging these items.

Transporting Patients. Before transferring patients to wheelchairs or stretchers, give them clean gowns to serve as robes. Patients infected with organisms transmitted by the airborne route normally leave their rooms only for essential purposes such as diagnostic procedures or surgery. When a patient has an airborne infection, he or she must wear a mask when leaving the room. Notify personnel in diagnostic or procedural areas or the operating room of the type of isolation precautions the patient requires. Some patients being transported drain body fluids onto a stretcher or wheelchair. Use an extra layer of sheets to cover the stretcher or seat of the wheelchair. Be sure to clean the equipment with an approved germicide after patient use and before another patient uses the shared equipment.

Role of the Infection Control Professional. An infection control professional is a valuable resource for assisting nurses in controlling HAIs. These professionals are specially trained in infection prevention and control. They are responsible for advising health care personnel regarding infection prevention and control practices and monitoring infections within the hospital. An infection control professional's responsibilities often include:

- Providing staff and patient education on infection prevention and control
- Developing and reviewing infection prevention and control policies and procedures
- Recommending appropriate isolation procedures
- Screening patient records for community-acquired infections that are reportable to the public health department
- Consulting with employee health departments concerning recommendations to prevent and control the spread of infection among personnel, such as TB testing

BOX 28-14 SPECIMEN COLLECTION TECHNIQUES*

View Video!

Ensure that all specimen containers used have the biohazard symbol on the outside (Pagana and Pagana, 2010).

Wound Specimen

Clean site with sterile water or saline before wound specimen collection (see Chapter 48). Apply gloves and use cotton-tipped swab or syringe to collect as much drainage as possible. Have clean test tube or culture tube on clean paper towel. After swabbing center of wound site, grasp collection tube with a paper towel. Carefully insert swab without touching outside of tube. After securing top of tube, transfer tube into biohazard bag for transport and perform hand hygiene.

Blood Specimen *(This procedure is often performed by a laboratory technician.)*

Wearing gloves, use a needle-safe syringe and culture media bottles to collect up to 10 mL of blood per culture bottle (check health care facility or agency policy). After prepping, perform venipuncture at two different sites at two different times (a minimum of 15 to 30 minutes between sets) to decrease likelihood of both specimens being contaminated with skin flora. Place blood culture bottles on a clean paper towel on bedside table or other surface; swab off bottle tops with alcohol. Inject an appropriate and equal amount of blood into the aerobic bottle (first) and anaerobic bottle (second). Transfer specimen into clean, labeled biohazard bag for transport. Remove gloves and perform hand hygiene.

Stool Specimen

Wearing gloves, use clean cup with seal top (need not be sterile) and tongue blade to collect a small amount, approximately 1 inch (2 to 3 cm), of stool. Place cup on clean paper towel in patient's bathroom. Using tongue blade, collect needed amount of feces from patient's bedpan. Transfer feces to cup without touching outside surface of cup. Dispose of tongue blade and place seal on cup. Transfer specimen into clean biohazard bag for transport. Remove gloves and perform hand hygiene.

Urine Specimen

Apply gloves and use sterile cup to collect 1 to 5 mL of urine. Place cup or tube on clean towel in patient's bathroom. If patient has a urinary catheter, use a needleless safety syringe to collect specimen from the sampling port on the catheter (see manufacturer instructions). Instruct patient to follow procedure to obtain a clean voided specimen (see Chapter 45) if not catheterized. Secure top of transfer container, label container in front of patient, and place in a biohazard bag with label attached. Remove gloves and perform hand hygiene.

*Health care facility or agency policies may differ on type of containers and amount of specimen material required.

BOX 28-15 PATIENT TEACHING

Infection Prevention and Control

Objective

- Patient will assume self-care using proper infection prevention and control techniques.

Teaching Strategies

- Instruct patient about cleaning equipment using soap and water and disinfecting with an appropriate disinfectant such as diluted bleach.
- Demonstrate proper hand hygiene, explaining that patient needs to perform before and after all treatments and when infected body fluids are contacted.
- Instruct patient in the signs and symptoms of wound infection and when to notify the health care provider.
- For patients who receive tube feedings at home, explain the importance of preparing enough formula for only 8 hours (commercially prepared) or 4 hours (home prepared). Tell patient that contaminated enteral feeding sometimes causes infections. Rinse feeding bag and tubing with mild soap and water daily and dry.
- Instruct patient to place contaminated dressings and other disposable items containing infectious body fluids in impervious plastic or brown paper bags. Place needles in metal or hard plastic containers such as coffee cans or laundry detergent bottles and tape the openings shut. *Some states have specific requirements for sharps disposal. Check local regulations.*
- Clean noticeably soiled linen separate from other laundry. Wash in warm water with detergent. There are no special recommendations for setting a dryer temperature (CDC, 2007).

Evaluation

- Ask patient or family member to describe techniques used to reduce transmission of infection.
- Have patient demonstrate select techniques.
- Ask patient to explain the risks of infection based on his or her condition.

- Gathering statistics regarding the **epidemiology** (cause and effect) of health care–associated infections
- Notifying the public health department of incidences of communicable diseases within the facility
- Consulting with all hospital departments to investigate unusual events or clusters of infection
- Monitoring antibiotic-resistant organisms in the institution

Infection Prevention and Control for Hospital Personnel. Health care workers are continually at risk for exposure to infectious microorganisms. OSHA and CDC publish rules, regulations, and guidelines to protect employees from bloodborne pathogens in the workplace. The OSHA regulations and CDC guidelines are incorporated into the policies and procedures of health care institutions and are part of regularly scheduled staff education programs.

Patient Education. Often patients need to learn to use infection prevention and control practices at home (Box 28-15). Preventive technique becomes almost second nature to the nurse who practices it daily. However, the patient is less aware of factors that promote the spread of infection or ways to prevent its transmission. The home environment may not always lend itself to infection prevention and control. Often you help a patient adapt according to the resources available to maintain hygienic techniques. Generally patients in a home care setting have a decreased risk of infection because of decreased exposure to resistant organisms such as those found in a health care facility and fewer invasive procedures. However, it is important to educate patients about infection prevention and control techniques.

Surgical Asepsis. **Surgical asepsis** or sterile technique prevents contamination of an open wound, serves to isolate the operative area from the unsterile environment, and maintains a sterile field for surgery. Surgical asepsis includes procedures used to eliminate all microorganisms, including pathogens and spores, from an object or area (Rutala and Weber, 2008, 2009). In surgical asepsis an area or object is considered contaminated if touched by any object that is not sterile. It demands the highest level of aseptic technique and requires that all areas be kept free of infectious microorganisms.

Use surgical asepsis in the following situations:

- During procedures that require intentional perforation of the patient's skin such as insertion of IV catheters or central lines
- When the integrity of the skin is broken as a result of trauma, surgical incision, or burns
- During procedures that involve insertion of catheters or surgical instruments into sterile body cavities such as insertion of a urinary catheter

Although surgical asepsis is common in the operating room, labor and delivery area, and major diagnostic areas, you also use surgical aseptic techniques at the patient's bedside (e.g., when inserting IV or urinary catheters, suctioning the tracheobronchial airway, and reapplying sterile dressings). A nurse in an operating room follows a series of steps to maintain sterile technique, including applying a mask, protective eyewear, and a cap; performing a surgical hand scrub; and applying a sterile gown and gloves. In contrast, a nurse performing a dressing change at a patient's bedside only performs hand hygiene and applies sterile gloves. For certain procedures (e.g., changing a central line dressing) the nurse also uses a mask. Regardless of the procedures followed or the setting, the nurse always recognizes the importance of strict adherence to aseptic principles (Iwamoto, 2009).

Patient Preparation. Because surgical asepsis requires exact techniques, you need to have the patient's cooperation. Certain patients fear moving or touching objects during a sterile procedure, whereas others try to assist. Explain how you will perform a procedure and what the patient can do to avoid contaminating sterile items, including the following:

- Avoid sudden movements of body parts covered by sterile drapes.
- Refrain from touching sterile supplies, drapes, or the nurse's gloves and gown.
- Avoid coughing, sneezing, or talking over a sterile area.

Certain sterile procedures last an extended time. The nurse assesses a patient's needs and anticipates factors that may disrupt a procedure. If a patient is in pain, administer ordered analgesics about a half an hour before a sterile procedure begins. Ask a patient if he or she needs to use the bathroom or a bedpan. Often patients have to assume relatively uncomfortable positions during sterile procedures. Help a patient assume the most comfortable position possible. Finally, a patient's condition sometimes results in actions or events that contaminate a sterile field. For example, a patient with a respiratory infection transmits organisms by coughing or talking. Anticipate such a problem and place a surgical mask on him or her before the procedure begins.

Principles of Surgical Asepsis. Performing sterile aseptic procedures requires a work area in which objects can be handled with minimal risk of contamination. A sterile field provides a sterile

surface for placement of sterile equipment. It is an area considered free of microorganisms and consists of a sterile kit or tray, a work surface draped with a sterile towel or wrapper, or a table covered with a large sterile drape (Church and Bjerke, 2009). When beginning a surgically aseptic procedure, nurses follow certain principles to ensure maintenance of asepsis. Failure to follow these principles places patients at risk for infection. The following principles are important:

1. *A sterile object remains sterile only when touched by another sterile object.* This principle guides a nurse in placement of sterile objects and how to handle them.
   a. Sterile touching sterile remains sterile (e.g., use sterile gloves or sterile forceps to handle objects on a sterile field).
   b. Sterile touching clean becomes contaminated (e.g., if the tip of a syringe or other sterile object touches the surface of a clean disposable glove, the object is contaminated).
   c. Sterile touching contaminated becomes contaminated (e.g., when a nurse touches a sterile object with an ungloved hand, the object is contaminated).
   d. Sterile state is questionable (e.g., when you find a tear or break in the covering of a sterile object). Discard it regardless of whether the object itself appears untouched.
2. *Only sterile objects may be placed on a sterile field.* All items are properly sterilized before use. Sterile objects are kept in clean, dry storage areas. The package or container holding a sterile object must be intact and dry. A package that is torn, punctured, wet, or open is considered unsterile.
3. *A sterile object or field out of the range of vision or an object held below a person's waist is contaminated.* Nurses never turn their back on a sterile field or a sterile tray or leave it unattended. Contamination can occur accidentally by a dangling piece of clothing, falling hair, or an unknowing patient touching a sterile object. Any object held below waist level is considered contaminated because it cannot be viewed at all times. Keep sterile objects in front with the hands as close together as possible.
4. *A sterile object or field becomes contaminated by prolonged exposure to air.* Avoid activities that create air currents such as excessive movements or rearranging linen after a sterile object or field becomes exposed. When you open sterile packages, it is important to minimize the number of people walking into an area. Microorganisms also travel by droplet through the air. Do not talk, laugh, sneeze, or cough over a sterile field or when gathering and using sterile equipment. When opening sterile packages, hold the item or piece of equipment as close as possible to the sterile field without touching the sterile surface.
5. *When a sterile surface comes in contact with a wet, contaminated surface, the sterile object or field becomes contaminated by capillary action.* If moisture leaks through the protective covering of a sterile package, microorganisms travel to the sterile object. When stored sterile packages become wet, discard the objects immediately or send the equipment for resterilization. When working with a sterile field or tray, you may have to pour sterile solutions. Any spill is a source of contamination unless on a sterile surface that moisture cannot penetrate. Urinary catheterization trays contain sterile supplies that rest in a sterile, plastic container. In contrast, if you place a piece of sterile gauze in its wrapper on a patient's bedside table and the table surface is wet, the gauze is considered contaminated.

FIG. 28-4 Placing sterile item on sterile field.

6. *Fluid flows in the direction of gravity.* A sterile object becomes contaminated if gravity causes a contaminated liquid to flow over the surface of the object. To avoid contamination during a surgical hand scrub, hold your hands above your elbows. This allows water to flow downward without contaminating your hands and fingers. The principle of water flow by gravity is also the reason for drying from fingers to elbows, with hands held up, after the scrub.
7. *The edges of a sterile field or container are considered to be contaminated.* Frequently you place sterile objects on a sterile towel, drape, or tray (Fig. 28-4). Because the edge of the drape touches an unsterile surface such as a table or bed linen, a 2.5-cm (1-inch) border around the drape is considered contaminated. Objects placed on the sterile field need to be inside this border. The edges of sterile containers become exposed to air after they are open and thus are contaminated. After you remove a sterile needle from its protective cap or after you remove forceps from a container, the objects must not touch the edge of the container.

Performing Sterile Procedures. Assemble all of the equipment that will be needed before a procedure. Have a few extra supplies available in case objects accidentally become contaminated. Do not leave a sterile area. Before a sterile procedure, explain each step so the patient can cooperate fully. If an object becomes contaminated during the procedure, do not hesitate to discard it immediately.

Donning and Removing Caps, Masks, and Eyewear. Wear a surgical mask and eyewear without a cap for any sterile procedures on a general nursing unit. Eyewear is worn as a part of standard precautions if there is a risk of fluid or blood splashing into your eyes. For sterile surgical procedures, you first apply a clean cap that covers all of your hair and then the surgical mask and eyewear. A mask must fit snugly around the face and nose. After wearing a mask for several hours, the area over the mouth and nose often becomes moist. Because moisture promotes the growth of microorganisms, change the mask if it becomes moist.

Protective glasses or goggles fit snugly around the forehead and face to fully protect the eyes. Wear eyewear only for procedures that create the risk of body fluids splashing into the eyes. Remove PPE in the following order: gloves, face shield or goggles, gown, and then mask or respirator (CDC, 2005b). After removing all PPE, perform hand hygiene.

Opening Sterile Packages. Sterile items such as syringes, gauze dressings, or catheters are packaged in paper or plastic containers and are impervious to microorganisms as long as they are dry and intact. Some institutions wrap reusable supplies (e.g., operating

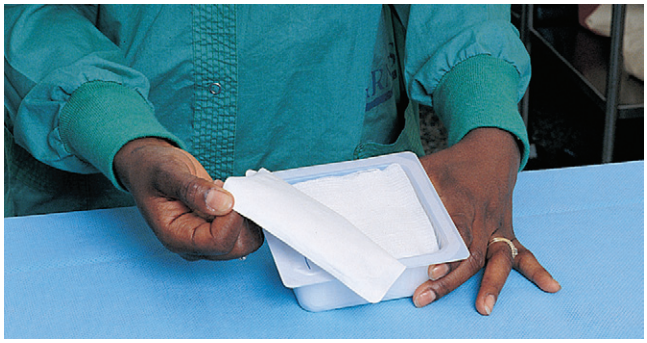


FIG. 28-5 Nurse opens sterile package on work area above waist level.

room instruments) in a double thickness of paper, linen, or muslin. These packages are permeable to steam and thus allow for steam autoclaving. Sterile items are kept in clean, enclosed storage cabinets and separated from dirty equipment.

Sterile supplies have chemical tapes indicating that a sterilization process has taken place. The tapes change color during the process. Failure of the tapes to change color means that the item is not sterile. Health care facilities follow the principles of event-related sterility, a concept that items are considered sterile if the packaging is uncompromised (Jefferson, 2009). Never use a sterile item if the packaging is open or soiled or shows evidence that the package had been wet. Before opening a sterile item, perform hand hygiene. Inspect the supplies for package integrity and sterility and assemble the supplies in the work area such as the bedside table or treatment room before opening packages. A bedside table or countertop provides a large, clean working area for opening items. Keep the work area above waist level. Do not open sterile supplies in a confined space where contamination might occur.

Opening a Sterile Item on a Flat Surface. You must open sterile packages without contaminating the contents. Commercially packaged items are usually designed so you only have to tear away or separate the paper or plastic cover. Hold the item in one hand while pulling the wrapper away with the other (Fig. 28-5). Take care to keep the inner contents sterile before use. You may use a sterile wrapper from a commercial kit or a sterile paper or linen wrapper from an institutional pack to create a sterile field on which to work. Use the inner surface of the package (except for the 1-inch (2.5-cm) border around the edges) as a sterile field to add sterile items. You can grasp the 1-inch border to maneuver the field on a table surface. See Skill 28-2 on pp. 427-431 for the steps to follow in preparing a sterile field.

Opening a Sterile Item While Holding It. To open a small sterile item, hold the package in your nondominant hand while opening the top flap and pulling it away from you. Using the dominant hand, carefully open the sides and innermost flap away from the enclosed sterile item in the same order previously mentioned. You open the item in a hand so you can pass the item to a person wearing sterile gloves or transfer the item to a sterile field.

Preparing a Sterile Field. When performing sterile procedures, you need a sterile work area that provides room for handling and placing of sterile items. A **sterile field** is an area free of microorganisms and prepared to receive sterile items. You prepare the field by using the inner surface of a sterile wrapper as the work surface or by using a sterile drape or dressing tray. After creating the surface for the sterile field, add sterile items by placing them directly on the field or transferring them with a sterile forceps (see Skill 28-2). Discard an object that comes in contact with the 1-inch (2.5-cm) border.

Sometimes you will wear sterile gloves while preparing items on a sterile field. If you do this, you can touch the entire drape, but sterile items must be handed over by an assistant. The gloves cannot touch the wrappers of sterile items.

Pouring Sterile Solutions. Often you have to pour sterile solutions into sterile containers. A bottle containing a sterile solution is sterile on the inside and contaminated on the outside; the neck of the bottle is also contaminated, but the inside of the bottle cap is considered sterile. After you remove the cap or lid, you hold it in your hand or place its sterile side (inside) up on a clean surface. This means that you are able to see the inside of the lid as it rests on the table surface. Never rest a bottle cap or lid on a sterile surface, even though the inside of the cap is sterile. The outer edge of the cap is unsterile and contaminates the surface. Placing a sterile cap down on an unsterile surface increases the chances of the inside of the cap becoming contaminated.

Hold the bottle with its label in the palm of the hand to prevent the possibility of the solution wetting and fading the label. Before pouring the solution into the container, pour a small amount (1 to 2 mL) into a disposable cap or plastic-lined waste receptacle. The discarded solution cleans the lip of the bottle. Keep the edge of the bottle away from the edge or inside of the receiving container. Pour the solution slowly to avoid splashing the underlying drape or field. Never hold the bottle so high above the container that even slow pouring causes splashing. Hold the bottle outside the edge of the sterile field.

Surgical Scrub. Patients undergoing operative procedures are at an increased risk for infection. Nurses working in operating rooms perform surgical hand antisepsis (Skill 28-3, pp. 431-433) to decrease and suppress the growth of skin microorganisms in case of glove tears. For maximum elimination of bacteria, remove all jewelry and keep the nails clean and short. Do not wear artificial nails or extenders because they often hold a greater number of bacteria (AORN, 2007; WHO, 2009). Nurses who have active skin infections, open lesions or cuts, or respiratory infections should be excluded from the surgical team.

During surgical hand antisepsis the nurse scrubs from fingertips to elbows with an antiseptic soap before each operation. The optimum duration of the surgical hand scrub is unclear, although research indicates that it probably depends on the type of antimicrobial product (CDC, 2002). The traditional scrub time in the United States for both the initial and the subsequent scrub is 5 minutes. Follow manufacturer recommendation for scrub solutions. For many years preoperative handwashing protocols required nurses to scrub with a brush. However, this practice can damage the skin. Scrubbing with a disposable sponge or combination sponge-brush reduces bacterial counts on the hands as effectively as scrubbing with a brush. However, several studies suggest that neither a brush nor a sponge is necessary to reduce bacterial counts on the hands, especially when using an alcohol-based product (CDC, 2002).

Applying Sterile Gloves. Sterile gloves are an additional barrier to bacterial transfer. There are two gloving methods: open and closed. Nurses who work on general nursing units use open gloving before procedures such as dressing changes or urinary catheter insertions. The closed-gloving method, which you perform after applying a sterile gown, is practiced in operating rooms and special treatment areas. Skills 28-4 and 28-5 (pp. 434-437) review the steps of each sterile gloving technique. Make sure to select the

proper glove size; the glove should not stretch so tightly that it can easily tear, yet it must be tight enough that you can pick up objects easily.

Donning a Sterile Gown. Nurses wear sterile gowns when assisting at the sterile field in the operating room, delivery room, and special treatment areas. It allows the nurse to handle sterile objects and also be comfortable with less risk of contamination. The sterile gown acts as a barrier to decrease shedding of microorganisms from skin surfaces into the air and thus prevents wound contamination. Nurses caring for patients with large open wounds or assisting physicians during major invasive procedures (e.g., inserting an arterial catheter) also wear sterile gowns. The circulating nurse generally does not wear one.

The nurse does not apply a sterile gown until after applying a mask and surgical cap and performing surgical handwashing. He or she picks up the gown from a sterile pack, or an assistant hands the gown to the nurse. Only a certain portion of the gown (i.e., the area from the anterior waist to, but not including, the collar and the anterior surface of the sleeves) is considered sterile. The back of the gown, the area under the arms, the collar, the area below the waist, and the underside of the sleeves are not sterile because the nurse cannot keep these areas in constant view and ensure their sterility. Skill 28-4 reviews the steps for applying a sterile gown.

EVALUATION

Measure the success of infection prevention and control techniques by determining whether you achieved the goals for reducing or preventing infection. Document the patient's response to therapies for infection prevention and control. A clear description of any signs and symptoms of systemic or local infection is necessary to give all nurses a baseline for comparative evaluation.

Through the Patient's Eyes. The patient at risk for infection needs to understand the measures needed to reduce or prevent microorganism growth and spread. Providing patients and/or family members the opportunity to discuss infection prevention and control measures or to demonstrate procedures such as hand hygiene reveals their ability to comply with therapy. Be sure that you understand the patient's perceptions of how infection spreads and how it can affect him or her as you evaluate the results of your instruction. Sometimes patients require new information, or previously instructed information needs reinforcement.

Patient Outcomes. A comparison of the patient's response such as absence of fever or wound infection are examples of expected outcomes for measuring the success of nursing interventions. Observe wounds during dressing changes to determine the degree of wound healing. Monitor patients, especially those at risk, for signs and symptoms of infection. For example, a patient who has undergone a surgical procedure is at risk for infection at the surgical site and other invasive sites such as the venipuncture site or central line sites. In addition, the patient is at risk for a respiratory tract infection as a result of decreased mobility and for a UTI if an indwelling catheter is present. Observe all invasive and surgical sites for swelling, erythema, or purulent drainage. Monitor breath sounds for changes and observe sputum character for change in color or consistency. Review laboratory test results for leukocytes. For example, leukocytosis in the urine often indicates a UTI. The absence of signs or symptoms of infection is the expected outcome of infection prevention and control.

Exposure Issues. Patients and health care personnel, including housekeepers and maintenance personnel, are at risk for acquiring infections from accidental needlesticks. After administering an injection or inserting an IV catheter, place the used needle safety device in a puncture-resistant box (see Chapter 31). Sharps boxes must be at the site of use; this is an OSHA requirement. With the passage of the Needlestick Safety and Prevention Act in 2000 (OSHA, 2001b) and the implementation of safety needle devices, incidence rate of sharps injuries decreased. All sharps must now be either needle safe or needleless. In the past a stray needle lying in bed linen or carelessly thrown into a wastebasket served as a prime source for exposure to bloodborne pathogens. Hepatitis B and C are the infections most commonly transmitted by contaminated needles (Box 28-16). Report any

BOX 28-16 HEPATITIS B VACCINATION AND FOLLOW-UP AFTER HEPATITIS C AND HUMAN IMMUNODEFICIENCY VIRUS EXPOSURE

1. Health care employers shall make available the hepatitis B vaccine and vaccination series to all employees who may have occupational exposures. If an employee declines the vaccine, he or she must sign a declination form. Evaluation and follow-up care is available to all employees who have been exposed.
2. Hepatitis B vaccinations are made available to employees within 10 working days of assignment—this means before starting to provide patient care and after receiving education and training on the vaccine.
3. A blood test (titer) is offered in some facilities 1 to 2 months after completing the three-dose vaccine series (check the health care facility or agency policy).
4. Vaccine is offered at no cost to employees. At present the vaccine does not require any boosters.
5. After exposure, no treatment is needed if there is a positive blood titer on file. If no positive titer is on file, follow the CDC guidelines.

Exposure to Hepatitis C Virus

1. If the source patient is positive for hepatitis C virus (HCV), the employee receives a baseline test.
2. At 4 weeks after exposure the employee should be offered an HCV-RNA test to determine if he or she contracted HCV.
3. If positive, the employee starts treatment.
4. There is no prophylactic treatment for HCV after exposure.
5. Early treatment for infection can prevent chronic infection.

Exposure to Human Immunodeficiency Virus

1. If the patient is positive for human immunodeficiency virus (HIV) infection, a viral load study should be performed to determine the amount of virus present in the blood.
2. If the exposure meets the CDC criteria for HIV prophylactic treatment (PEP), it should be started as soon as possible, preferably within 24 hours after the exposure (CDC, 2005b).

All medical evaluations and procedures, including the vaccine and vaccination series and evaluation after exposure (prophylaxis), are made available at no cost to at-risk employees.

A confidential written medical evaluation will be available to employees with exposure incidents.

From Occupational Safety and Health Administration: Occupational Safety and Health Act of 2001, 2001, 2005, *http://www.cdc.gov*.
CDC, Centers for Disease Control and Prevention; *RNA*, ribonucleic acid; *PEP*, postexposure prophylaxis.

contaminated needlestick immediately. Additional criteria for exposure reporting include blood or other potentially infectious materials (OPIMs) in direct contact with an open area of the skin, blood or OPIM that is splashed into a health care worker's eye or mouth or up the nose, and cuts with a sharp object that is covered with blood or OPIM.

Follow-up for risk of acquiring infection begins with source patient testing. Access to testing the source patient is stated in the testing law for each state. Some states have deemed consent, which means that the state has granted the patients consent to be tested. Other states require that the patient consent to testing for the presence of bloodborne pathogens. Know the testing policies in the facility and state where you practice. Health care facilities, agencies, and workers' compensation require the exposed employee to complete an injury report and seek appropriate treatment if needed. The need for treatment is linked to the results of a risk assessment and the testing of the patient. Test the patient for HIV, hepatitis B virus (HBV), and hepatitis C virus (HCV). If positive for HIV or HCV, testing for syphilis may be indicated because of the incidence of co-infection (CDC, 2005b, 2010c). It is required that an exposed employee be given the patient's testing results. This is *not* a violation of the Health Insurance Portability and Accountability Act (HIPAA) of 1996. Both the CDC and OSHA state that this information must be given to the exposed health care worker contingent on the health care worker's willingness to be tested.

Testing the exposed employee at the time of the exposure is not needed immediately unless required by the state testing law. If the patient tests positive for a bloodborne pathogen or if the source patient is unknown, prophylactic treatment is recommended for the employee.

Exposures also occur involving non-bloodborne pathogens. Airborne and droplet diseases also pose a risk to the non-immune nurse. The CDC (2010a) published a list of recommended immunizations and vaccinations for health care workers. The recommended vaccinations and immunizations include hepatitis B vaccine; TB testing; annual influenza vaccine; measles, mumps, rubella (MMR); chickenpox vaccine; and tetanus, diphtheria, and pertussis. Employee health should review your health history and offer appropriate prevention. Declination forms are needed if these are declined (OSHA, 2001a).

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Use clean gloves when you anticipate contact with body fluids and nonintact skin or mucous membranes when there is a risk of drainage.
- Use gown, mask, and eye protection when there is a risk for splash.
- Keep bedside table surfaces clutter free, clean, and dry when performing aseptic procedures.
- Clean all equipment that is shared between patients.
- Ensure that patients cover mouth and nose when coughing or sneezing, use tissues to contain respiratory secretions, and dispose of tissues in waste receptacle.

SKILL 28-1 HAND HYGIENE

View Video!

Delegation Considerations

The skill of hand hygiene is performed by all caregivers. Instruct all caregivers to use proper hand hygiene.

Equipment

- Antiseptic hand rub
  - Alcohol-based, waterless, antiseptic-containing emollient
- Handwashing
  - Easy-to-reach sink with warm running water
  - Antimicrobial or non-antimicrobial soap
  - Paper towels or air dryer
  - Disposable nail cleaner (optional)

STEP	RATIONALE
1 Inspect surface of your hands for breaks or cuts in skin or cuticles. Cover any skin lesions with a dressing before providing care. If lesions are too large to cover, you may be restricted from direct patient care (CDC, 2002).	Open cuts or wounds can harbor high concentrations of microorganisms. Health care facility or agency policy often prevents nurses from caring for high-risk patients if open lesions are present on hands.
2 Inspect hands for visible soiling.	If hands are visibly soiled, use soap and water until soil is removed.
3 Inspect condition of nails. Natural tips should be ¼ inch from fingertip and smooth. DO NOT WEAR artificial nails or extensions.	Subungual areas of hands harbor high concentrations of bacteria. Long nails and chipped or old polish increase the number of bacteria residing on hands. Artificial applications increase microbial load on hands (Boyce and Pittet, 2008; CDC, 2002) (see Box 28-8).
4 Push wristwatch and long uniform sleeves above wrists. Avoid wearing rings.	Provides complete access to fingers, hands, and wrists. Some studies show that skin underneath rings carry a higher bacterial load. Gram-negative bacilli, enterobacteria, and *Staphylococcus aureus* are more common under rings (Boyce and Pittet, 2008; Fagernes and Lingaas, 2009).

SKILL 28-1 HAND HYGIENE—cont'd

STEP	RATIONALE
5 Antiseptic hand rub	
a. Apply an ample amount of product to palm of one hand (see illustration).	Enough product is needed to thoroughly cover the hands.
b. Rub hands together, covering all surfaces of hands and fingers with antiseptic (see illustration).	Covering all aspects of the hands kills transient bacteria; ensures complete antimicrobial action.
c. Rub hands together for several seconds until alcohol is dry. Allow hands to dry before applying gloves.	Provides enough time for antimicrobial solution to work.
6 Handwashing using antiseptic soap	
a. Stand in front of sink, keeping hands and uniform away from sink surface. (If hands touch sink during handwashing, repeat process.)	Inside of sink is a contaminated area. Reaching over sink increases risk of touching edge, which is contaminated.
b. Turn on water. Turn faucet on or push knee pedals laterally or press pedals with foot to regulate flow and temperature (see illustration).	Knee pads within the operating room and treatment areas are preferred to prevent hand contact with faucet. Faucet handles are likely to be contaminated with organic debris and microorganisms (AORN, 2007).
c. Avoid splashing water against uniform.	Microorganisms travel and grow in moisture.
d. Regulate flow of water so temperature is warm.	Warm water removes less of the protective oils than hot water.
e. Wet hands and wrists thoroughly under running water. Keep hands and forearms lower than elbows during washing.	Hands are the most contaminated parts to be washed. Water flows from least to most contaminated area, rinsing microorganisms into the sink.
f. Apply 3 to 5 mL of antiseptic soap and rub hands together vigorously, lathering thoroughly (see illustration).	Ensures that all surface areas of the hands and fingers are cleaned.

CLINICAL DECISION: *The decision whether to use a non-antimicrobial soap, antimicrobial soap, or alcohol-based hand antiseptic depends on the procedure, the patient's immune status, and the type of infection the patient has (CDC, 2002).*

STEP 5a Apply waterless antiseptic to hands.

STEP 5b Rub hands thoroughly.

STEP 6b Turn on water.

STEP 6f Lather hands thoroughly.

STEP	RATIONALE
g. Wash hands using plenty of lather and friction for at least 15 seconds. Interlace fingers and rub palms and back of hands with circular motion at least 5 times each. Keep fingertips down to facilitate removal of microorganisms.	Soap cleans by emulsifying fat and oil and lowering surface tension. Friction and rubbing mechanically loosen and remove dirt and transient bacteria. Interlacing fingers and thumbs ensures that all surfaces are cleansed. Adequate time is needed to expose skin surfaces to antimicrobial agent.
h. Areas under fingernails are often soiled. Clean them with fingernails of other hand and additional soap with an orangewood stick (optional).	Areas under nails are often highly contaminated, which increases the risk of infection for the nurse or patient.
i. Rinse hands and wrists thoroughly, keeping hands down and elbows up (see illustration).	Rinsing mechanically washes away dirt and microorganisms.
j. Dry hands thoroughly from fingers to wrists and forearms with paper towel, single-use cloth, or warm air dryer.	Drying from cleanest (fingertips) to least clean (forearms) area avoids contamination. Drying hands prevents chapping and roughened skin.
k. If used, discard paper towel in proper receptacle.	Prevents transfer of microorganisms.
l. Turn off water with foot or knee pedals. To turn off hand faucet, using clean, dry paper towel; avoid touching handles with hands (see illustration).	Wet towel and hands allow transfer of pathogens from faucet to hands. Faucet handles are contaminated.

STEP 6i Rinse hands.

STEP 6l Turn off faucet.

HOME CARE CONSIDERATIONS

- Evaluate the handwashing facilities in the home to determine the potential for contamination, how close the facilities are to the patient, and available supplies in the area.
- Evaluate the availability of warm running water and soap when conducting home visits and anticipate the need for alternative handwashing products such as alcohol-based hand rubs and/or detergent-containing towels.
- Instruct the patient and primary caregiver in proper techniques and situations for handwashing.

SKILL 28-2 PREPARATION OF STERILE FIELD

View Video!

Delegation Considerations

The skill of preparing a sterile field cannot be delegated to nursing assistive personnel (NAP). A surgical technician may prepare a sterile field as indicated by health care facility policy.

Equipment

- Sterile pack (commercial or institution wrapped)
- Sterile drape to be used as a sterile field
- Sterile gloves (optional, check agency policy)
- Sterile solution and equipment specific to the procedure
- Waist-high table or countertop surface
- Appropriate PPE (see agency policy)

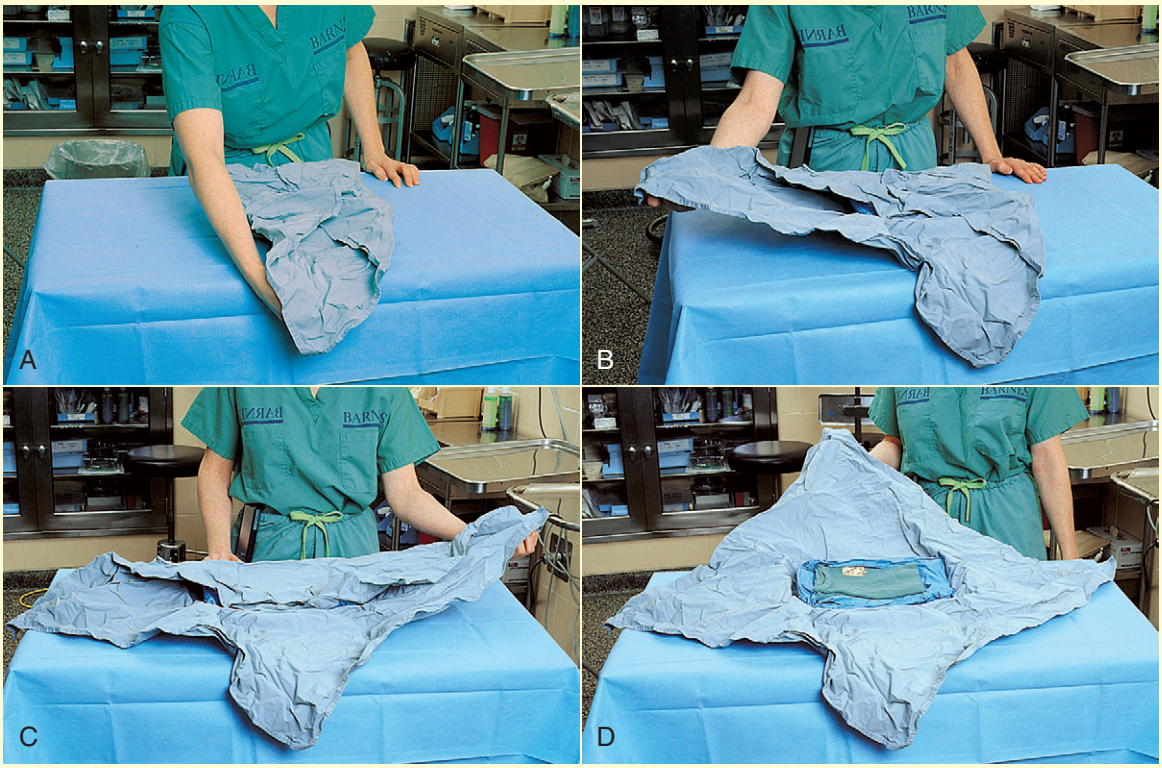
STEP	RATIONALE
1 Apply personal protective equipment as needed (consult agency policy).	Controls the spread of microorganisms.
2 Complete all priority care tasks before beginning procedure.	Sterile field should be prepared as close as possible to time of use (AORN, 2007).
3 Ask visitors to step out of room briefly during procedure.	Traffic and movement increase potential for spread of microorganisms through air currents.

SKILL 28-2 PREPARATION OF STERILE FIELD—cont'd

STEP	RATIONALE
4 Select a clean, dry work surface above waist level.	A sterile object held below the waist is contaminated.
5 Assemble necessary equipment and check expiration dates or labels and condition of supply packaging for sterility of equipment.	Preparation of equipment in advance prevents break in technique. Equipment that has evidence of previously being open, soiled, or wet is considered unsterile.
6 Perform hand hygiene.	Reduces transmission of microorganisms.
7 Prepare sterile field.	
a. Sterile commercial kit or tray containing sterile items	
(1) Place sterile kit or pack containing sterile items on work surface.	Ensures sterility of packaged drape.
(2) Open outside cover and remove kit from dust cover. Place on work surface.	Inner kit remains sterile.
(3) Grasp outer edge of tip of outermost flap.	Outer surface of package is considered unsterile. There is a 2.5-cm (1-inch) border around any sterile drape or wrap that is considered unsterile.
(4) Open outermost flap away from body, keeping arm outstretched and away from the sterile field (see illustration).	Reaching over sterile field contaminates it.
(5) Grasp outer edge of first side of flap.	Outer border is considered unsterile.
(6) Open side flap, pulling to side and allowing it to lie flat on table surface (see illustration). Keep arm to the side and do not extend it over the sterile surface.	Drape or flap should lie flat so it will not accidentally rise up and contaminate inner surface or the sterile items placed on its surface.
(7) Grasp outer edge of second side flap. Repeat for opening second side of package, pulling out to side (see illustration).	
(8) Grasp outer edge of last and innermost flap.	
(9) Stand away from sterile package and pull flap back, allowing it to fall flat on work surface (see illustration).	Reaching over sterile field contaminates it.

STEP 7a(4) Open outermost flap of sterile kit away from body.

STEP 7a(6) Open first side flap, pulling to side.



STEP 7a(7) Open second side flap, pulling to side.

STEP 7a(9) Open last and innermost flap, standing away from sterile field.

STEP	RATIONALE
b. Sterile linen-wrapped package	
(1) Place package on work surface.	
(2) Remove sterilization tape and seal and unwrap both layers, following Steps 7a (1) to (9) as with sterile kit (see illustrations).	
(3) Use opened package wrapper as a sterile field.	Inner surface of wrapper is considered sterile.

STEP 7b(2) **A,** Nurse opens the top flap away from the body. **B,** Nurse's arm is kept out away from the sterile field while opening a side flap. **C,** Nurse opens second side flap, keeping arm away from sterile field. **D,** Nurse opens back flap.

c. Sterile drape	
(1) Place pack containing sterile drape on work surface. Follow Steps 7a (1) to (9) to open.	Ensures sterility of packaged drape.
(2) Apply sterile glove.	
NOTE: This is an option, depending on health care facility policy. You may touch outer 1-inch border of drape without wearing gloves.	
(3) Grasp folded top edge of drape with fingertips of one hand. Gently lift drape up from its wrapper without touching any object.	If sterile object touches any nonsterile object, it becomes contaminated.
(4) Allow drape to unfold, keeping it above waist, and work surface and away from body. (Carefully discard outer wrapper with other hand.)	Object held below person's waist or above chest is contaminated.

SKILL 28-2 PREPARATION OF STERILE FIELD—cont'd

STEP	RATIONALE
(5) With other hand grasp adjacent corner of drape. Hold drape straight over work surface (see illustration).	Drape can now be properly placed with two hands.
(6) Holding drape, first position bottom half over top half of intended work surface (see illustration).	Prevents nurse from reaching over sterile field.
(7) Allow top half of drape to be placed over bottom half of work surface (see illustration).	A flat sterile surface is now available for placement of sterile items.
8 Adding sterile items	
a. Open sterile item (following package directions) while holding outside wrapper in nondominant hand.	Frees dominant hand for unwrapping outer wrapper.
b. Carefully peel wrapper onto nondominant hand.	Item remains sterile. Inner surface of wrapper covers hand, making it sterile.
c. Being sure wrapper does not fall down on sterile field, place item onto field at angle. *Do not hold arm over sterile field* (see illustration).	Prevents reaching over field and contaminating its surface.
d. Dispose of outer wrapper.	Prevents accidental contamination of sterile field.

STEP 7c(5) Hold drape straight up and away from body.

STEP 7c(6) Lay bottom half over work surface.

STEP 7c(7) Place top half of drape over work surface.

STEP 8c Add item to sterile field.

STEP	RATIONALE
9 Pour sterile solution	
a. Verify contents and expiration date of solution.	Ensures proper solution and sterility of contents.
b. Be sure receptacle for solution is located near or on sterile work surface edge. Sterile kits have cups or plastic molded sections into which you can pour fluids.	Prevents reaching over sterile field.
c. Remove sterile seal and cap from bottle in an upward motion. With solution bottle held away from sterile field, with the label facing up and the bottle lip 1 to 2 inches above inside of receiving container, slowly pour contents into container (see illustration).	Prevents contamination of bottle lip and keeps inside of cap sterile. Edge and outside of bottle are considered contaminated. Slow pouring prevents splashing liquids, which causes fluid permeation of sterile barrier (called *strike through*) and results in contamination

STEP 9c Pour solution into receiving container on sterile field.

10 Perform procedure using sterile technique.	Prevents transmission of infection to patient.

RECORDING AND REPORTING

- It is not necessary to record or report this procedure.

SKILL 28-3 SURGICAL HAND ASEPSIS

Delegation Considerations

The skill of surgical hand asepsis can be delegated to properly trained surgical technicians (know the state Nurse Practice Act).

Equipment

- Deep sink with foot or knee controls for dispensing water and soap (faucets should be high enough for hands and forearms to fit comfortably)
- Antimicrobial agent approved by the health care facility
- Surgical scrub sponge with plastic nail pick (optional)
- Paper face mask, cap or hood, surgical shoe covers
- Sterile towel
- Sterile pack containing sterile gown
- Protective eyewear (glasses or goggles)

STEP	RATIONALE
1 Consult manufacturer policy regarding required length of time and antiseptic to use for hand antisepsis.	Guidelines vary regarding ideal time needed and antiseptic to use for surgical scrub.
2 Remove bracelets, rings, and watches.	Jewelry may harbor or protect microorganisms from removal. Allergic skin reactions may occur as a result of scrub agent or glove powder accumulating under jewelry.
3 Be sure that fingernails are short, clean, and healthy. Artificial nails should be removed. Natural nails should be less than ¼ inch long.	Long nails and chipped or old polish increase number of bacteria residing on nails. Long fingernails can puncture gloves, causing contamination. Artificial nails are known to harbor gram-negative microorganisms and fungus (AORN, 2007; CDC, 2002).

CLINICAL DECISION: *Remove nail polish if chipped or worn longer than 4 days because it likely will harbor microorganisms (AORN, 2007).*

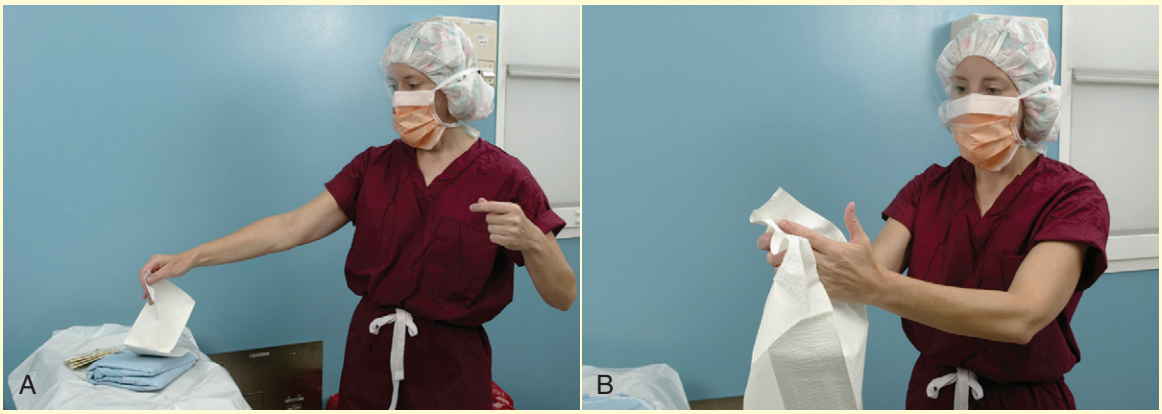
SKILL 28-3 SURGICAL HAND ASEPSIS—cont'd

STEP	RATIONALE
4 Inspect condition of cuticles, hands, and forearms for abrasions, cuts, or open lesions.	These conditions increase likelihood of more microorganisms residing on skin surfaces. Broken skin permits microorganisms to enter layers of the skin, providing deeper microbial breeding grounds (AORN, 2007).
5 Apply surgical shoe covers, cap or hood, face mask, and protective eyewear.	Mask prevents escape into air of microorganisms that can contaminate hands. Other protective wear prevents exposure to blood and body fluid splashes during the procedure.
6 Turn on water using knee or foot controls and adjust to comfortable temperature.	Knee or foot controls prevent contamination of hands after scrub.
7 Prescrub wash/rinse: Wet hands and arms under running lukewarm water and lather with detergent to 5 cm (2 inches) above elbows. (Hands need to be above elbows at all times.)	Water runs by gravity from fingertips to elbows. Hands become cleanest part of upper extremity. Keeping hands elevated allows water to flow from least to most contaminated areas. Washing a wide area reduces risk of contaminating overlying gown that the nurse later applies.
8 Rinse hands and arms thoroughly under running water. **Remember to keep hands above elbows.**	Rinsing removes transient bacteria from fingers, hands, and forearms.
9 Under running water clean under nails of both hands with nail pick. Discard after use (see illustration).	Removes dirt and organic material that harbor large numbers of microorganisms.
10 Surgical hand scrub (with brush)	
a. Wet clean sponge and apply antimicrobial agent. Visualize each finger, hand, and arm as having four sides. Wash all four sides effectively. Scrub the nails of one hand with 15 strokes. Scrub the palm, each side of thumb and fingers, and posterior side of hand with 10 strokes each (see illustration).	Friction loosens resident bacteria that adhere to skin surfaces. Ensures coverage of all surfaces. Scrubbing is performed from cleanest area (hands) to marginal area (upper arms).
b. Divide the arm mentally into thirds: scrub each third 10 times (AORN, 2007) (see illustration). Some health care facility policies require scrub by time rather than 10 strokes. Rinse brush and repeat sequence for the other arm. A two-brush method may be substituted (check health care facility policy).	Eliminates transient microorganisms and reduces resident hand flora.
c. Discard brush. Flex arms and rinse from fingertips to elbows in one continuous motion, allowing water to run off at elbow (see illustration).	Hands remain the cleanest part of upper extremities.

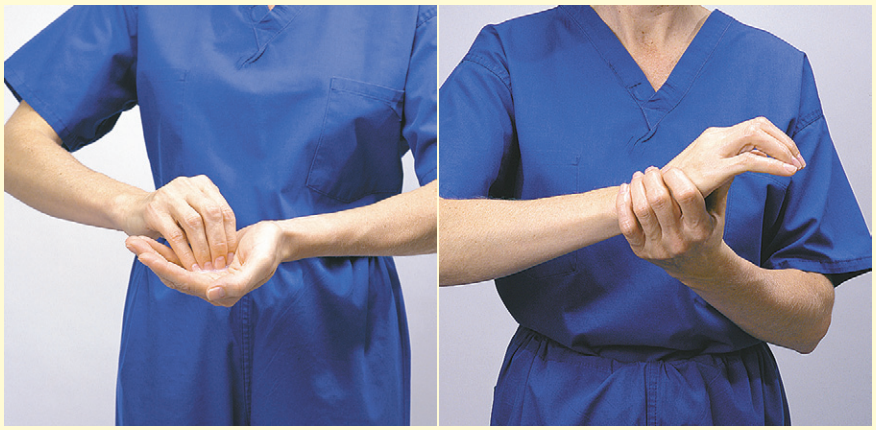
STEP 9 Clean under fingernails.

STEP 10a Scrub side of fingers.

STEP 10b Scrub forearms.



STEP 10c Rinse arms.



STEP	RATIONALE
d. Turn off water with foot or knee control, with hands elevated in front of and away from body. Enter operating room suite by backing into room.	Keeps hands free of microorganisms.
e. Approach sterile setup; grasp sterile towel, taking care not to drip water onto sterile setup.	Water contaminates sterile setup.
f. Bending slightly at waist, keeping hands and arms above waist and outstretched, grasp one end of sterile towel and dry one hand, moving from fingers to elbow in a rotating motion (see illustration).	Avoids sterile towel from contacting unsterile scrub attire and transferring contamination to hands. Dry skin from cleanest (hands) to least clean (elbows).
g. Repeat drying method for other hand by carefully reversing towel or using a new sterile towel.	Prevents accidental contamination.
h. Drop towel into linen hamper or circulating nurse's hand.	Prevents accidental contamination.
11 *Optional:* Brushless antiseptic hand rub	
a. After prescrub wash, dry hands and forearms thoroughly with paper towel.	Promotes reduction in microorganisms on all surfaces of hands and arms.
b. Dispense 2 mL of antimicrobial agent hand preparation into palm of one hand. Dip fingertips of opposite hand into hand preparation and work it under nails. Spread remaining hand preparation over hand and up to just above elbow, covering all surfaces (see illustration).	
c. Using another 2 mL of hand preparation, repeat with other hand.	
d. Dispense another 2 mL of hand preparation into either hand and reapply to all aspects of both hands up to wrist. Allow to dry before donning gloves.	Ensures complete antiseptic coverage of all hand surfaces.
12 Proceed with sterile gowning (see Skill 28-4).	

RECORDING AND REPORTING

- It is not necessary to record or report this procedure.
- Report any skin dermatitis to employee health or infection control per agency policy.

STEP 10f **A,** Grasp sterile towel. **B,** Drying sequence.

STEP 11b Application of antimicrobial agent for brushless hand scrub. Nurse using 3M Avagard. (Photos courtesy of 3M Health Care.)

SKILL 28-4 APPLYING A STERILE GOWN AND PERFORMING CLOSED GLOVING

Delegation Considerations

Applying a sterile gown and closed gloving can be delegated to a properly trained surgical technician (know the state Nurse Practice Act).

Equipment

- Package of proper-size sterile gloves (latex free if nurse or patient has sensitivity or allergy)
- Sterile pack containing sterile gown
- Clean, flat, dry surface
- Paper face masks, cap or hood, surgical shoe covers
- Protective eyewear/face shield

STEP	RATIONALE
APPLYING STERILE GOWN	
1 Before entering operating room or treatment area, apply cap, face mask, eyewear, and foot covers (paper or cloth covers fit over work shoes).	Prevents hair and air droplet nuclei from contaminating sterile work areas. Eyewear protects mucous membranes of eye. Foot covers reduce contamination from shoes.
2 Perform thorough surgical hand wash (see Skill 28-3).	Removes transient and resident bacteria from fingers, hands, and forearms.
3 Circulating nurse assists by opening sterile pack containing sterile gown (folded inside out).	Outer surface of gown remains sterile.
4 Circulating nurse prepares glove package by peeling outer wrapper open while keeping inner contents sterile. Places inner glove package on sterile field created by sterile outer wrapper.	Keeps gloves sterile and allows nurse who has scrubbed to handle sterile items.
5 Reach down to sterile gown package; lift folded gown directly upward and step back away from table.	Provides wide margin of safety, avoiding contamination of gown.
6 Holding folded gown, locate neckband. With both hands grasp inside front of gown just below neckband.	Clean hands can touch inside of gown without contaminating outer surface.
7 Allow gown to unfold, keeping inside of gown toward body. Do not touch outside of gown with bare hands.	Outside of gown is sterile surface.
8 With hands at shoulder level, slip both arms into armholes simultaneously (see illustration). Ask circulating nurse to bring gown over your shoulders by reaching inside to arm seams and pulling gown on, leaving sleeves covering hands.	Careful application prevents contamination. Gown covers hands to prepare for closed gloving.
9 Have circulating nurse securely tie back of gown at neck and waist (see illustration). (If gown is wraparound style, do not touch sterile flap to cover it until you are gloved.)	Gown must completely enclose underlying garments.

STEP 8 Place arms in sleeves.

STEP 9 Circulating nurse ties scrub gown.

STEP	RATIONALE
PERFORMING CLOSED GLOVING	
10 Closed gloving	
a. With hands covered by gown sleeves, open inner sterile glove package (see illustration).	Hands remain clean. Sterile gown cuff touches sterile glove surface.
b. With dominant hand inside gown cuff, pick up glove for nondominant hand by grasping folded cuff.	Sterile gown touches sterile glove.
c. Extend nondominant forearm with palm up and place palm of glove against palm of nondominant hand. Glove fingers point toward elbow.	Positions glove for application over cuffed hand, keeping glove sterile.
d. Grasp back of glove cuff with covered dominant hand and turn glove cuff over end of nondominant hand and gown cuff (see illustration).	Seal created by glove cuff over gown prevents exit of microorganisms over operative sterile field.
e. Grasp top of glove and underlying gown sleeve with covered dominant hand. Carefully extend fingers into glove, being sure that glove cuff covers gown cuff.	
f. Glove dominant hand in same manner, reversing hands (see illustration). Use gloved nondominant hand to pull on glove. Keep hand inside sleeve (see illustrations).	Sterile touches sterile.
g. Be sure that fingers are fully extended into both gloves.	Ensures that nurse has full dexterity while using gloved hand.

STEP 10a Scrub nurse opens glove package.

STEP 10d Glove is applied to left hand as right hand remains inside cuff.

STEP 10f Second glove is applied.

SKILL 28-4 APPLYING A STERILE GOWN AND PERFORMING CLOSED GLOVING—cont'd

STEP	RATIONALE
11 For wraparound sterile gowns: take gloved hand and release fastener or ties in front of gown.	Front of gown is sterile.
12 Hand paper tab connected to sterile tie to circulating nurse, who is nonsterile (see illustration). Circulating nurse stands still as you turn completely around to left, allowing for margin of safety as gown wraps around and covers your back. Take back sterile tie from circulating nurse and secure tie to gown.	Contact with team member could contaminate gown and gloves. Gown must enclose undergarments.

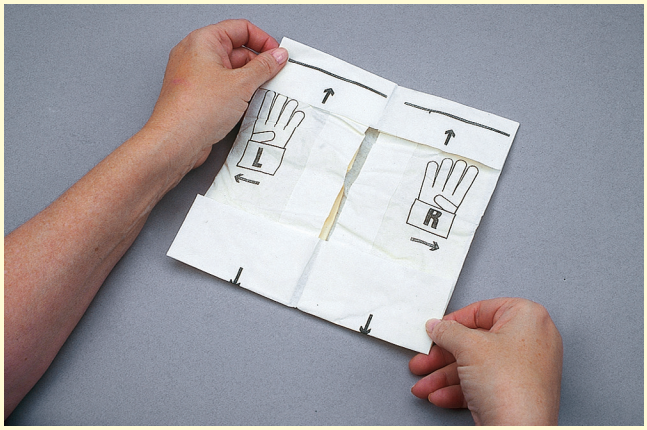
STEP 12 Hand tie to sterile team member.

RECORDING AND REPORTING

- It is not necessary to record or report this procedure.

SKILL 28-5 OPEN GLOVING

View Video!



Delegation Considerations

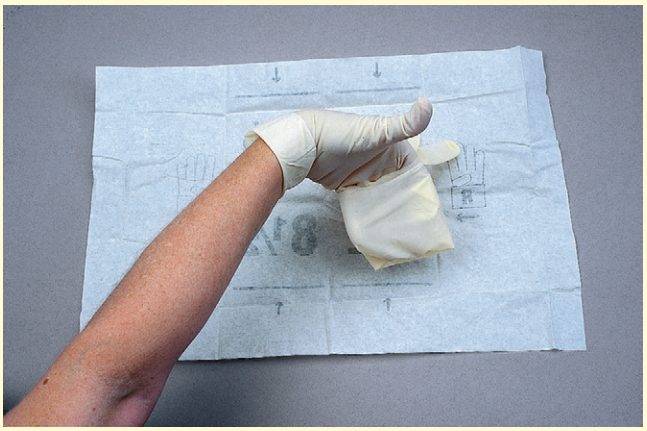
The skill of open gloving can be delegated when personnel are trained to perform a sterile procedure.

Equipment

- Sterile gloves (proper size)

STEP	RATIONALE
1 Perform thorough hand hygiene.	Removes bacteria from skin surfaces and reduces transmission of infection.
2 Remove outer glove package wrapper by carefully separating and peeling apart sides.	Prevents inner glove package from accidentally opening and touching contaminated objects.
3 Grasp inner package and lay it on clean, flat surface just above waist level. Open package, keeping gloves on wrappers inside surface (see illustration).	Sterile object held below waist is contaminated. Inner surface of glove package is sterile.

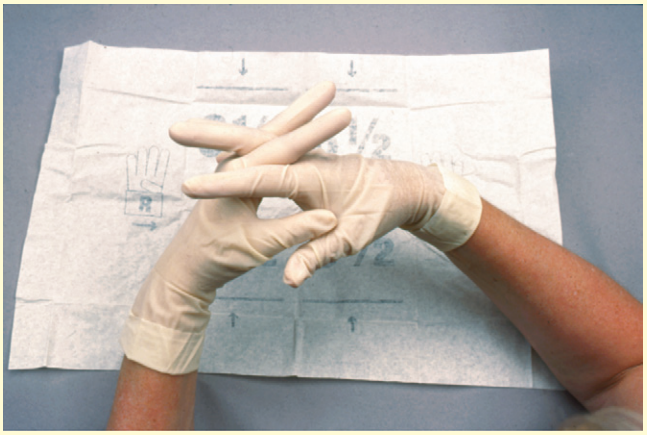
STEP 3 Open package.



STEP	RATIONALE
4 Identify right and left glove. Each glove has cuff approximately 5 cm (2 inches) wide. Glove dominant hand first.	Proper identification of gloves prevents contamination by improper fit. Gloving of dominant hand first improves dexterity.
5 With thumb and first two fingers of nondominant hand, grasp edge of cuff of glove for dominant hand. Touch only inside surface of glove.	Inner edge of cuff lies against skin and thus is not sterile.
6 Carefully pull glove over dominant hand, leaving cuff and being sure that it does not roll up wrist. Be sure that thumb and fingers are in proper spaces (see illustration).	If outer surface of glove touches hand or wrist, it is contaminated.
7 With gloved dominant hand, slip fingers underneath cuff of second glove (see illustration).	Cuff protects gloved fingers. Sterile touching sterile prevents glove contamination.
8 Carefully pull second glove over nondominant hand. Do not allow fingers and thumb of gloved dominant hand to touch any part of exposed nondominant hand. Keep thumb of dominant hand abducted back (see illustration).	Contact of gloved hand with exposed hand results in contamination.
9 After second glove is on, interlock fingers of gloved hands and hold away from body above waist level until beginning procedure (see illustration).	Prevents accidental contamination from hand movement.
GLOVE DISPOSAL	
10 Grasp outside of one cuff with other gloved hand; avoid touching wrist. Pull halfway down palm of hand. Take thumb of half-ungloved hand and place under cuff of other glove.	Minimizes contamination of underlying skin.
11 Pull glove off, turning it inside out. Discard in receptacle.	Outside of glove does not touch skin surface.
12 Take fingers of bare hand and tuck inside remaining glove cuff. Peel glove off, inside out. Discard in receptacle.	

RECORDING AND REPORTING

- It is not necessary to record or report this procedure.



STEP 6 Pull glove over dominant hand.

STEP 7 Slip fingers underneath cuff of second glove.

STEP 8 Pull second glove over nondominant hand.

STEP 9 Hands are interlocked.

KEY POINTS

- Hand hygiene is the most important technique to use in preventing and controlling transmission of infection.
- The potential for microorganisms to cause disease depends on the number of organisms, virulence, ability to enter and survive in a host, and susceptibility of the host.
- Normal body floras help to resist infection by releasing antibacterial substances and inhibiting multiplication of pathogenic microorganisms.
- The signs of local inflammation and infection are identical.
- An infection can develop as long as the six elements composing the infection chain are uninterrupted.
- Microorganisms are transmitted by direct and indirect contact, airborne spread, and vectors and contaminated articles.
- Increasing age, poor nutrition, stress, inherited conditions, chronic disease, and treatments or conditions that compromise the immune response increase susceptibility to infection.
- The major sites for health care–associated infections include the urinary and respiratory tracts, bloodstream, and surgical or traumatic wounds.
- The CDC now recommends use of alcohol-based waterless antiseptics as an alternative to handwashing unless hands are visibly soiled.
- Invasive procedures, medical therapies, long hospitalization, and contact with health care personnel increase a hospitalized patient's risk for acquiring a health care–associated infection.
- Isolation practices may prevent personnel and patients from acquiring infections and transmission of microorganisms to other persons.
- Standard precautions use generic barrier techniques when caring for all patients.
- Proper cleaning requires mechanical removal of all soil from an object or area.
- A patient in isolation is subject to sensory deprivation because of the restricted environment.
- An infection prevention and control professional monitors the incidence of infection within an institution and provides educational and consulting services.
- Surgical asepsis requires more stringent techniques than medical asepsis and is directed at eliminating microorganisms.
- If the skin is broken or if an invasive procedure into a body cavity normally free of microorganisms is performed, follow surgical aseptic practices.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Andrews did well after her spinal surgery and was discharged home on the third postoperative day. Two weeks later she told her family that she was having increased pain in her back. She stated that she was not always wearing her back brace as instructed at the time of surgery because "it makes me sweat and itch." When she wears the brace, she frequently wipes over her incision with a handkerchief to remove the perspiration and scratches it to ease the itching. Her daughter noted that the incision was reddened with a small amount of drainage coming from the site. Mrs. Andrews was readmitted, and an incision and drainage of the back wound were performed.

1. What do you need to include when assessing the wound for infection?
2. If Mrs. Andrews were to develop a systemic infection as a result of the localized wound infection, which assessments would you expect to find? Explain your answers.
3. Which methods of infection control do you need to use when caring for Mrs. Andrews?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. If an infectious disease can be transmitted directly from one person to another, it is a:
   1. Susceptible host.
   2. Communicable disease.
   3. Port of entry to a host.
   4. Port of exit from the reservoir.
2. Which is the most likely means of transmitting infection between patients?
   1. Exposure to another patient's cough
   2. Sharing equipment among patients
   3. Disposing of soiled linen in a shared linen bag
   4. Contact with a health care worker's hands
3. Identify the interval when a patient progresses from nonspecific signs to manifesting signs and symptoms specific to a type of infection.
   1. Illness stage
   2. Convalescence
   3. Prodromal stage
   4. Incubation period
4. Which of the following is the most *effective* way to break the chain of infection?
   1. Hand hygiene
   2. Wearing gloves
   3. Placing patients in isolation
   4. Providing private rooms for patients
5. A family member is providing care to a loved one who has an infected leg wound. What would you instruct the family member to do after providing care and handling contaminated equipment or organic material?
   1. Wear gloves before eating or handling food.
   2. Place any soiled materials into a bag and double bag it.
   3. Have the family member check with the doctor about need for immunization.
   4. Perform hand hygiene after care and/or handling contaminated equipment or material.
6. A patient is isolated for pulmonary tuberculosis. The nurse notes that the patient seems to be angry, but he knows that this is a normal response to isolation. Which is the best intervention?
   1. Provide a dark, quiet room to calm the patient.
   2. Reduce the level of precautions to keep the patient from becoming angry.
   3. Explain the reasons for isolation procedures and provide meaningful stimulation.
   4. Limit family and other caregiver visits to reduce the risk of spreading the infection.
7. The nurse wears a gown when:
   1. The patient's hygiene is poor.
   2. The nurse is assisting with medication administration.

3. The patient has acquired immunodeficiency syndrome (AIDS) or hepatitis.
4. Blood or body fluids may get on the nurse's clothing from a task that he or she plans to perform.

8. The nurse has redressed a patient's wound and now plans to administer a medication to the patient. Which is the correct infection control procedure?
   1. Leave the gloves on to administer the medication.
   2. Remove gloves and administer the medication.
   3. Remove gloves and perform hand hygiene before administering the medication.
   4. Leave the medication on the bedside table to avoid having to remove gloves before leaving the patient's room.
9. When a nurse is performing surgical hand asepsis, the nurse must keep hands:
   1. Below elbows.
   2. Above elbows.
   3. At a 45-degree angle.
   4. In a comfortable position.
10. What is the best method to sterilize a straight urinary catheter and suction tube in the home setting?
    1. Use an autoclave.
    2. Use boiling water.
    3. Use ethylene oxide gas.
    4. Use chemicals for disinfection.
11. A patient has an indwelling urinary catheter. Why does an indwelling urinary catheter present a risk for urinary tract infection?
    1. It keeps an incontinent patient's skin dry.
    2. It can get caught in the linens or equipment.
    3. It obstructs the normal flushing action of urine flow.
    4. It allows the patient to remain hydrated without having to urinate.
12. Put the following steps for removal of protective barriers after leaving an isolation room in order:
    1. Untie top, then bottom mask strings and remove from face.
    2. Untie waist and neck strings of gown. Allow gown to fall from shoulders and discard. Remove gown, rolling it onto itself without touching the contaminated side.
    3. Remove gloves.
    4. Remove eyewear or goggles.
    5. Perform hand hygiene.
13. Your ungloved hands come in contact with the drainage from your patient's wound. What is the correct method to clean your hands?
    1. Wash them with soap and water.
    2. Use an alcohol-based hand cleaner.
    3. Rinse them and use the alcohol-based hand cleaner.
    4. Wipe them with a paper towel.
14. A patient's surgical wound has become swollen, red, and tender. You note that the patient has a new fever and leukocytosis. What is the best immediate intervention?
    1. Notify the health care provider and use surgical technique to change the dressing.
    2. Reassure the patient and recheck the wound later.
    3. Notify the health care provider and support the patient's fluid and nutritional needs.
    4. Alert the patient and caregivers to the presence of an infection to ensure care after discharge.
15. While preparing to do a sterile dressing change, a nurse accidentally sneezes over the sterile field that is on the over-the-bed table. Which of the following principles of surgical asepsis, if any, has the nurse violated?
    1. When a sterile field comes in contact with a wet surface, the sterile field is contaminated by capillary action.
    2. Fluid flows in the direction of gravity.
    3. A sterile field becomes contaminated by prolonged exposure to air.
    4. None of the principles were violated.

Answers: **1.** 2; **2.** 4; **3.** 3; **4.** 1; **5.** 4; **6.** 3; **7.** 4; **8.** 3; **9.** 2; **10.** 2; **11.** 3; **12.** 3, 4, 2, 1, 5; **13.** 1; **14.** 3; **15.** 3.

CHAPTER

29

Vital Signs

OBJECTIVES

- Explain the principles and mechanisms of thermoregulation.
- Describe nursing measures that promote heat loss and heat conservation.
- Discuss physiological changes associated with fever.
- Accurately assess body temperature, pulse, respirations, oxygen saturation, and blood pressure.
- Explain the physiology of normal regulation of blood pressure, pulse, oxygen saturation, and respirations.
- Describe factors that cause variations in body temperature, pulse, oxygen saturation, respirations, and blood pressure.
- Describe cultural and ethnic variations with blood pressure assessment.
- Identify ranges of acceptable vital sign values for an infant, a child, and an adult.
- Explain variations in technique used to assess an infant's, a child's, and an adult's vital signs.
- Describe the benefits and precautions involving self-measurement of blood pressure.
- Identify when to take vital signs.
- Accurately record and report vital sign measurements.
- Appropriately delegate measurement of vital signs to nursing assistive personnel.

The most frequent measurements obtained by health care providers are those of temperature, pulse, blood pressure (BP), respiratory rate, and oxygen saturation. As indicators of health status, these measures indicate the effectiveness of circulatory, respiratory, neural, and endocrine body functions. Because of their importance they are referred to as **vital signs.** Pain, a subjective symptom, is often called the fifth vital sign and is frequently measured with the others (see Chapter 43). Measurement of vital signs provides data to determine a patient's usual state of health (baseline data). Many factors such as the temperature of the environment, the patient's physical exertion, and the effects of illness cause vital signs to change, sometimes outside an acceptable range. Assessment of vital signs provides data to identify nursing diagnoses, implement planned interventions, and evaluate outcomes of care. An alteration in vital signs signals a change in physiological function and the need for medical or nursing intervention.

Vital signs are a quick and efficient way of monitoring a patient's condition or identifying problems and evaluating his or her response to intervention. When you learn the physiological variables influencing vital signs and recognize the relationship of their changes to other physical assessment findings, you can make precise

BOX 29-1 VITAL SIGNS

Acceptable Ranges for Adults

Temperature Range: 36° to 38° C (96.8° to 100.4° F)
Average oral/tympanic: 37° C (98.6° F)
Average rectal: 37.5° C (99.5° F)
Average axillary: 36.5° C (97.7° F)

Pulse
60 to 100 beats/min

Respirations
12 to 20 breaths/min

Blood Pressure
Average: <120/<80 mm Hg
Pulse pressure: 30 to 50 mm Hg

BOX 29-2 WHEN TO MEASURE VITAL SIGNS

- On admission to a health care facility
- When assessing a patient during home care visits
- In a hospital on a routine schedule according to the health care provider's order or hospital standards of practice
- Before and after a surgical procedure or invasive diagnostic procedure
- Before, during, and after a transfusion of blood products
- Before, during, and after the administration of medication or therapies that affect cardiovascular, respiratory, or temperature-control functions
- When a patient's general physical condition changes (e.g., loss of consciousness or increased intensity of pain)
- Before and after nursing interventions influencing a vital sign (e.g., before a patient previously on bed rest ambulates or before a patient performs range-of-motion exercises)
- When a patient reports nonspecific symptoms of physical distress (e.g., feeling "funny" or "different")

determinations about a patient's health problems. Vital signs and other physiological measurements are the basis for clinical decision making and problem solving.

GUIDELINES FOR MEASURING VITAL SIGNS

Vital signs are a part of the assessment database. You include them in a complete physical assessment (see Chapter 30) or obtain them individually to assess a patient's condition. Establishing a database of vital signs during a routine physical examination serves as a baseline for future assessments. The patient's needs and condition determine when, where, how, and by whom vital signs are measured. You need to measure them correctly, and at times you appropriately delegate their measurement. You also need to know expected values (Box 29-1), interpret your patient's values, communicate findings appropriately, and begin interventions as needed. Use the following guidelines to incorporate measurements of vital signs into nursing practice:

- The nurse caring for the patient is responsible for measurement of vital signs. Although you sometimes delegate measurement of selected vital signs (i.e., in stable patients), as a nurse you need to analyze them to interpret their significance and make decisions about interventions.
- Ensure that equipment is functional and appropriate for the size and age of the patient. Equipment used to measure vital signs (e.g., a thermometer) needs to work properly to obtain accurate findings.
- Select equipment based on the patient's condition and characteristics (e.g., do not use an adult-size BP cuff for a child).
- Know the patient's usual range of vital signs. These values can differ from the acceptable range for that age or physical state. The patient's usual values serve as a baseline for comparison with later findings. Thus you are able to detect a change in condition over time.
- Determine the patient's medical history, therapies, and prescribed medications. Some illnesses or treatments cause predictable changes in vital signs. Some medications affect one or more vital signs.
- Control or minimize environmental factors that affect vital signs. For example, assessing the patient's temperature in a warm, humid room may yield a value that is not a true indicator of his or her condition.
- Use an organized, systematic approach when taking vital signs. Each procedure requires a step-by-step approach to ensure accuracy.
- Based on the patient's condition, collaborate with health care providers to decide the frequency of vital sign assessment. In the hospital, health care providers order a minimum frequency of vital sign measurements for each patient. Following surgery or treatment intervention you measure vital signs more frequently to detect complications. In a clinic or outpatient setting you take vital signs before the health care provider examines the patient and after any invasive procedures. As a patient's physical condition worsens, it is often necessary to monitor vital signs as often as every 5 to 10 minutes. The nurse is responsible for judging whether more frequent assessments are necessary (Box 29-2).
- Use vital sign measurements to determine indications for medication administration. For example, give certain cardiac drugs only within a range of pulse or BP values. Administer antipyretics when temperature is elevated outside of the acceptable range for the patient. Know the acceptable ranges for your patients before administering medications.
- Analyze the results of vital sign measurement. Vital signs are not interpreted in isolation. You need to also know related physical signs or symptoms and be aware of the patient's ongoing health status.
- Communicate significant changes in vital signs to the patient's health care provider or the charge nurse. Document findings and compare with baseline measurements to identify significant changes. When vital signs appear abnormal, have another nurse or health care provider repeat the measurement to verify readings.
- Instruct the patient or family caregiver in vital sign assessment and the significance of findings.

BODY TEMPERATURE

Physiology

Body temperature is the difference between the amount of heat produced by body processes and the amount of heat lost to the external environment.

Heat produced – Heat lost = Body temperature

Despite extremes in environmental conditions and physical activity, temperature-control mechanisms of humans keep body **core temperature** (temperature of the deep tissues) relatively constant (Fig. 29-1). However, surface temperature varies, depending on blood flow to the skin and the amount of heat lost to the external environment. Because of these surface temperature changes, the

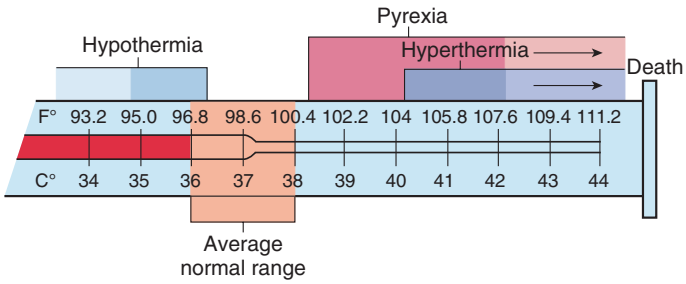

FIG. 29-1 Ranges of normal temperature values and abnormal body temperature alterations.

acceptable temperature of humans ranges from 36° to 38° C (96.8° to 100.4° F). Bodily tissues and cells function best within the relatively narrow temperature range.

The site of temperature measurement (oral, rectal, axillary, tympanic membrane, temporal artery, esophageal, pulmonary artery, or even urinary bladder) is one factor that determines a patient's temperature. For healthy young adults the average oral temperature is 37° C (98.6° F). In clinical practice you learn the temperature range of individual patients. No single temperature is normal for all people.

The measurement of body temperature aims to obtain a representative average temperature of core body tissues. Sites reflecting core temperatures are more reliable indicators of body temperature than those reflecting surface temperatures. In addition, the temperature value obtained often differs, depending on the measurement site.

Regulation. Physiological and behavioral mechanisms regulate the balance between heat lost and heat produced, or **thermoregulation.** For the body temperature to stay constant and within an acceptable range, various mechanisms maintain the relationship between heat production and heat loss. Apply knowledge of temperature-control mechanisms to promote temperature regulation.

Neural and Vascular Control. The hypothalamus, located between the cerebral hemispheres, controls body temperature the same way a thermostat works in the home. A comfortable temperature is the "set point" at which a heating system operates. In the home a drop in environmental temperature activates the furnace, whereas a rise in temperature shuts the system down.

The hypothalamus senses minor changes in body temperature. The anterior hypothalamus controls heat loss, and the posterior hypothalamus controls heat production. When nerve cells in the anterior hypothalamus become heated beyond the set point, impulses are sent out to reduce body temperature. Mechanisms of heat loss include sweating, vasodilation (widening) of blood vessels, and inhibition of heat production. The body redistributes blood to surface vessels to promote heat loss.

If the posterior hypothalamus senses that body temperature is lower than the set point, the body initiates heat-conservation mechanisms. Vasoconstriction (narrowing) of blood vessels reduces blood flow to the skin and extremities. Compensatory heat production is stimulated through voluntary muscle contraction and muscle shivering. When vasoconstriction is ineffective in preventing additional heat loss, shivering begins. Disease or trauma to the hypothalamus or the spinal cord, which carries hypothalamic messages, causes serious alterations in temperature control.

Heat Production. Thermoregulation depends on the normal function of heat production processes. Heat produced by the body is a by-product of metabolism, which is the chemical reaction in all body cells. Food is the primary fuel source for metabolism. Activities requiring additional chemical reactions increase the metabolic rate. As metabolism increases, additional heat is produced. When metabolism decreases, less heat is produced. Heat production occurs during rest, voluntary movements, involuntary shivering, and nonshivering thermogenesis.

- Basal metabolism accounts for the heat produced by the body at absolute rest. The average **basal metabolic rate (BMR)** depends on the body surface area. Thyroid hormones also affect the BMR. By promoting the breakdown of body glucose and fat, thyroid hormones increase the rate of chemical reactions in almost all cells of the body. When large amounts of thyroid hormones are secreted, the BMR can increase 100% above normal. The absence of thyroid hormones reduces the BMR by half, causing a decrease in heat production. The male sex hormone testosterone increases BMR. Men have a higher BMR than women.
- Voluntary movements such as muscular activity during exercise require additional energy. The metabolic rate increases during activity, sometimes causing heat production to increase up to 50 times normal.
- **Shivering** is an involuntary body response to temperature differences in the body. The skeletal muscle movement during shivering requires significant energy. Shivering sometimes increases heat production 4 to 5 times greater than normal. The heat that is produced helps equalize the body temperature, and the shivering ceases. In vulnerable patients shivering seriously drains energy sources, resulting in further physiological deterioration.
- **Nonshivering thermogenesis** occurs primarily in neonates. Because neonates cannot shiver, a limited amount of vascular brown tissue, present at birth, is metabolized for heat production.

Heat Loss. Heat loss and heat production occur simultaneously. Skin structure and exposure to the environment result in constant, normal heat loss through radiation, conduction, convection, and evaporation.

Radiation is the transfer of heat from the surface of one object to the surface of another without direct contact between the two. As much as 85% of the surface area of the human body radiates heat to the environment. Peripheral vasodilation increases blood flow from the internal organs to the skin to increase radiant heat loss. Peripheral vasoconstriction minimizes radiant heat loss. Radiation increases as the temperature difference between the objects increases. Radiation heat loss can be considerable during surgery when the patient's skin is exposed to a cool environment. However, if the environment is warmer than the skin, the body absorbs heat through radiation.

The patient's position enhances radiation heat loss (e.g., standing exposes a greater radiating surface area, and lying in a fetal position minimizes heat radiation). Help promote heat loss through radiation by removing clothing or blankets. Covering the body with dark, closely woven clothing decreases the amount of heat lost from radiation.

Conduction is the transfer of heat from one object to another with direct contact. Solids, liquids, and gases conduct heat through contact. When the warm skin touches a cooler object, heat is lost. Conduction normally accounts for a small amount of heat loss. Applying an ice pack or bathing a patient with a cool cloth increases conductive heat loss. Applying several layers of clothing reduces conductive loss. The body gains heat by conduction when it makes

contact with materials warmer than skin temperature (e.g., application of an aquathermia pad).

Convection is the transfer of heat away by air movement. A fan promotes heat loss through convection. Convective heat loss increases when moistened skin comes into contact with slightly moving air.

Evaporation is the transfer of heat energy when a liquid is changed to a gas. The body continuously loses heat by evaporation. Approximately 600 to 900 mL a day evaporates from the skin and lungs, resulting in water and heat loss. By regulating perspiration or sweating, the body promotes additional evaporative heat loss. When body temperature rises, the anterior hypothalamus signals the sweat glands to release sweat through tiny ducts on the surface of the skin. Sweat evaporates, resulting in heat loss. During physical exercise over 80% of the heat produced is lost by evaporation (Lim, Byrne, and Lee, 2008).

Diaphoresis is visible perspiration primarily occurring on the forehead and upper thorax, although you can see it in other places on the body. For each hour of exercise in hot conditions approximately 1 L of body fluid is lost in sweat (Lim, Byrne, and Lee, 2008). Excessive evaporation causes skin scaling and itching and drying of the nares and pharynx. A lowered body temperature inhibits sweat gland secretion. People who have a congenital absence of sweat glands or a serious skin disease that impairs sweating are unable to tolerate warm temperatures because they cannot cool themselves adequately.

Skin in Temperature Regulation. The skin regulates temperature through insulation of the body, vasoconstriction (which affects the amount of blood flow and heat loss to the skin), and temperature sensation. The skin, subcutaneous tissue, and fat keep heat inside the body. Persons with more body fat have more natural insulation than do slim and muscular people.

The way the skin controls body temperature is similar to the way an automobile radiator controls engine temperature. An automobile engine generates a great deal of heat. Water is pumped through the engine to collect the heat and carry it to the radiator, where a fan transfers the heat from the water to the outside air. In the human body the internal organs produce heat; during exercise or increased sympathetic stimulation the amount of heat produced is greater than the usual core temperature. Blood flows from the internal organs, carrying heat to the body surface. The skin has many blood vessels, especially the areas of the hands, feet, and ears. Blood flow through these vascular areas of the skin varies from minimal flow to as much as 30% of the blood ejected from the heart. Heat transfers from the blood, through vessel walls, to the surface of the skin and is lost to the environment through the heat-loss mechanisms. The core temperature of the body remains within safe limits.

The degree of vasoconstriction determines the amount of blood flow and heat loss to the skin. If the core temperature is too high, the hypothalamus inhibits vasoconstriction. As a result, blood vessels dilate, and more blood reaches the surface of the skin. On a hot, humid day the blood vessels in the hands are dilated and easily visible. In contrast, if the core temperature becomes too low, the hypothalamus initiates vasoconstriction, and blood flow to the skin lessens to conserve heat.

Behavioral Control. Healthy individuals are able to maintain comfortable body temperature when exposed to temperature extremes. The ability of a person to control body temperature depends on (1) the degree of temperature extreme, (2) the person's ability to sense feeling comfortable or uncomfortable, (3) thought processes or emotions, and (4) the person's mobility or ability to remove or add clothes. Individuals are unable to control body temperature if any of these abilities is lost. For example, infants are able to sense uncomfortable warm conditions but need assistance in changing their environment. Older adults sometimes need help in detecting cold environments and minimizing heat loss. Illnesses, a decreased level of consciousness, or impaired thought processes result in an inability to recognize the need to change behavior for temperature control. When temperatures become extremely hot or cold, health-promoting behaviors such as removing or adding clothing have a limited effect on controlling temperature.

Factors Affecting Body Temperature

Many factors affect body temperature. Changes in body temperature within an acceptable range occur when physiological or behavioral mechanisms alter the relationship between heat production and heat loss. Be aware of these factors when assessing temperature variations and evaluating deviations from normal.

Age. At birth the newborn leaves a warm, relatively constant environment and enters one in which temperatures fluctuate widely. Temperature-control mechanisms are immature. An infant's temperature responds drastically to changes in the environment. Take extra care to protect newborns from environmental temperatures. Provide adequate clothing, and avoid exposing infants to temperature extremes. A newborn loses up to 30% of body heat through the head and therefore needs to wear a cap to prevent heat loss. When protected from environmental extremes, the newborn's body temperature is usually within 35.5° to 37.5° C (95.9° to 99.5° F).

Temperature regulation is unstable until children reach puberty. The usual temperature range gradually drops as individuals approach older adulthood. The older adult has a narrower range of body temperatures than the younger adult. Oral temperatures of 35° C (95° F) are sometimes found in older adults in cold weather. However, the average body temperature of older adults is approximately 36° C (96.8° F). Older adults are particularly sensitive to temperature extremes because of deterioration in control mechanisms, particularly poor vasomotor control (control of vasoconstriction and vasodilation), reduced amounts of subcutaneous tissue, reduced sweat gland activity, and reduced metabolism.

Exercise. Muscle activity requires an increased blood supply and carbohydrate and fat breakdown. Any form of exercise increases metabolism and heat production and thus body temperature. Prolonged strenuous exercise such as long-distance running temporarily raises body temperature.

Hormone Level. Women generally experience greater fluctuations in body temperature than men. Hormonal variations during the menstrual cycle cause body temperature fluctuations. Progesterone levels rise and fall cyclically during the menstrual cycle. When progesterone levels are low, the body temperature is a few tenths of a degree below the baseline level. The lower temperature persists until ovulation occurs. During ovulation greater amounts of progesterone enter the circulatory system and raise the body temperature to previous baseline levels or higher. These temperature variations help to predict a woman's most fertile time to achieve pregnancy.

Body temperature changes also occur in women during menopause (cessation of menstruation). Women who have stopped menstruating often experience periods of intense body heat and sweating lasting from 30 seconds to 5 minutes. During these periods often intermittent skin temperature increases up to 4° C (7.2° F), referred to as hot flashes. This is caused by the instability of the vasomotor controls for vasodilation and vasoconstriction.

Circadian Rhythm. Body temperature normally changes 0.5° to 1° C (0.9° to 1.8° F) during a 24-hour period. However, temperature is one of the most stable rhythms in humans. The temperature is usually lowest between 1:00 and 4:00 AM (Fig. 29-2). During the day body temperature rises steadily until a maximum temperature value at about 4:00 PM and then declines to early-morning levels (Henker and Carlson, 2007). Temperature patterns are not automatically reversed in people who work at night and sleep during the day. It takes 1 to 3 weeks for the cycle to reverse. In general, the circadian temperature rhythm does not change with age.

Stress. Physical and emotional stress increase body temperature through hormonal and neural stimulation. These physiological changes increase metabolism, which increases heat production. A patient who is anxious about entering a hospital or a health care provider's office often has a higher normal temperature.

Environment. Environment influences body temperature. When placed in a warm room a patient may be unable to regulate body temperature by heat-loss mechanisms, and the body temperature may elevate. If the patient were outside in the cold without warm clothing, body temperature may be low as a result of extensive radiant and conductive heat loss. Environmental temperatures affect infants and older adults more often because their temperature-regulating mechanisms are less efficient.

Temperature Alterations. Changes in body temperature outside the usual range are related to excessive heat production, excessive heat loss, minimal heat production, minimal heat loss, or any combination of these alterations.

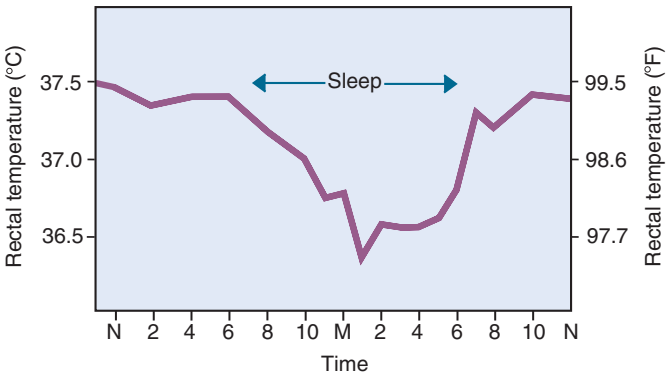

FIG. 29-2 Temperature cycle for 24 hours.

Fever. **Fever,** or **pyrexia,** occurs because heat-loss mechanisms are unable to keep pace with excessive heat production, resulting in an abnormal rise in body temperature. A fever is usually not harmful if it stays below 39° C (102.2° F). A single temperature reading does not always indicate a fever. In addition to physical signs and symptoms of infection, fever determination is based on several temperature readings at different times of the day compared with the usual value for that person at that time.

A true fever results from an alteration in the hypothalamic set point. **Pyrogens** such as bacteria and viruses elevate body temperature. Pyrogens act as antigens, triggering immune system responses. The hypothalamus reacts to raise the set point, and the body responds by producing and conserving heat. Several hours pass before the body temperature reaches the new set point. During this period a person experiences chills, shivers, and feels cold, even though the body temperature is rising (Fig. 29-3). The chill phase resolves when the new set point, a higher temperature, is achieved. During the next phase, the plateau, the chills subside, and the person feels warm and dry. If the new set point is "overshot" or the pyrogens are removed (e.g., destruction of bacteria by antibiotics), the third phase of a **febrile** episode occurs. The hypothalamus set point drops, initiating heat loss responses. The skin becomes warm and flushed because of vasodilation. Diaphoresis assists in evaporative heat loss. When the fever "breaks," the patient becomes **afebrile.**

Fever is an important defense mechanism. Mild temperature elevations as high as 39° C (102.2° F) enhance the immune system of the body. During a febrile episode white blood cell production is stimulated. Increased temperature reduces the concentration of iron in the blood plasma, suppressing the growth of bacteria. Fever also fights viral infections by stimulating interferon, the natural virus-fighting substance of the body.

Fevers and fever patterns serve a diagnostic purpose. Fever patterns differ, depending on the causative pyrogen (Box 29-3). The increase or decrease in pyrogen activity results in fever spikes and declines at different times of the day. The duration and degree of fever depend on the strength of the pyrogen and the ability of the individual to respond. The term **fever of unknown origin (FUO)** refers to a fever with an undetermined cause.

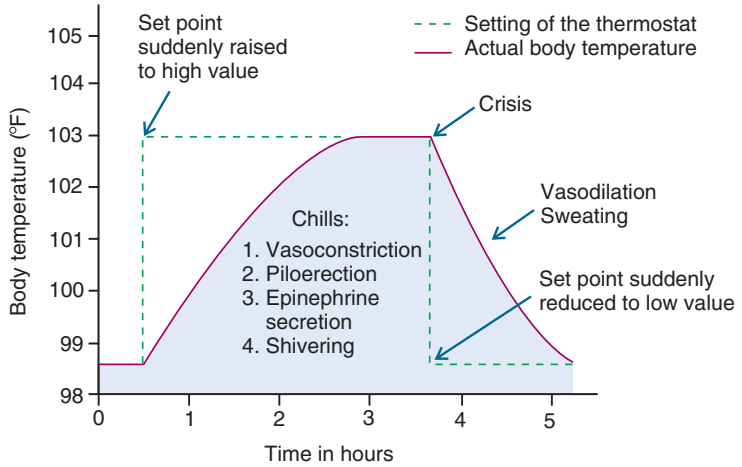

FIG. 29-3 Effect of changing set point of hypothalamic temperature control during a fever. (Modified from Guyton AC, Hall JE: *Textbook of medical physiology,* ed 12, Philadelphia, 2011, Saunders.)

BOX 29-3 PATTERNS OF FEVER

Sustained: A constant body temperature continuously above 38° C (100.4° F) that has little fluctuation

Intermittent: Fever spikes interspersed with usual temperature levels (Temperature returns to acceptable value at least once in 24 hours.)

Remittent: Fever spikes and falls without a return to normal temperature levels.

Relapsing: Periods of febrile episodes and periods with acceptable temperature values (Febrile episodes and periods of normothermia are often longer than 24 hours.)

During a fever cellular metabolism increases, and oxygen consumption rises. Body metabolism increases 10% for every degree Celsius of temperature elevation (Henker and Carlson, 2007). Heart and respiratory rates increase to meet the metabolic needs of the body for nutrients. The increased metabolism uses energy that produces additional heat. If a patient has a cardiac or respiratory problem, the stress of a fever is great. A prolonged fever weakens a patient by exhausting energy stores. Increased metabolism requires additional oxygen. If the body cannot meet the demand for additional oxygen, cellular hypoxia (inadequate oxygen) occurs. Myocardial hypoxia produces angina (chest pain). Cerebral hypoxia produces confusion. Interventions during a fever include oxygen therapy. When water loss through increased respiration and diaphoresis is excessive, the patient is at risk for fluid volume deficit. Dehydration is a serious problem for older adults and children with low body weight. Maintaining optimum fluid volume status is an important nursing action (see Chapter 41).

Hyperthermia. An elevated body temperature related to the inability of the body to promote heat loss or reduce heat production is **hyperthermia.** Whereas fever is an upward shift in the set point, hyperthermia results from an overload of the thermoregulatory mechanisms of the body. Any disease or trauma to the hypothalamus impairs heat-loss mechanisms. **Malignant hyperthermia** is a hereditary condition of uncontrolled heat production that occurs when susceptible people receive certain anesthetic drugs.

Heatstroke. Heat depresses hypothalamic function. Prolonged exposure to the sun or a high environmental temperature overwhelms the heat-loss mechanisms of the body. These conditions cause **heatstroke,** defined as a body temperature of 40° C (104° F) or more (Lewis, 2007). Heatstroke is a dangerous heat emergency with a high mortality rate. Patients at risk include the very young or very old and those who have cardiovascular disease, hypothyroidism, diabetes, or alcoholism. Also at risk are those who take medications that decrease the ability of the body to lose heat (e.g., phenothiazines, anticholinergics, diuretics, amphetamines, and beta-adrenergic receptor antagonists) and those who exercise or work strenuously (e.g., athletes, construction workers, and farmers).

Signs and symptoms of heatstroke include giddiness, confusion, delirium, excess thirst, nausea, muscle cramps, visual disturbances, and even incontinence. Vital signs reveal a body temperature sometimes as high as 45° C (113° F), with an increase in heart rate (HR) and lowering of BP. The most important sign of heatstroke is hot, dry skin. Victims of heatstroke do not sweat because of severe electrolyte loss and hypothalamic malfunction. If the condition progresses, the patient with heatstroke becomes unconscious, with fixed, nonreactive pupils. Permanent neurological damage occurs unless cooling measures are rapidly started.

Heat Exhaustion. **Heat exhaustion** occurs when profuse diaphoresis results in excess water and electrolyte loss. Caused by environmental heat exposure, the patient exhibits signs and symptoms of fluid volume deficit (see Chapter 41). First aid includes transporting him or her to a cooler environment and restoring fluid and electrolyte balance.

TABLE 29-1 Classification of Hypothermia

	CELSIUS	FAHRENHEIT
Mild	34°-36°	93.2°-96.8°
Moderate	30°-34°	86.0°-93.2°
Severe	<30°	<86°

Hypothermia. Heat loss during prolonged exposure to cold overwhelms the ability of the body to produce heat, causing hypothermia. **Hypothermia** is classified by core temperature measurements (Table 29-1). It is sometimes unintentional such as falling through the ice of a frozen lake. Occasionally hypothermia is intentionally induced during surgical or emergency procedures to reduce metabolic demand and the need of the body for oxygen.

Accidental hypothermia usually develops gradually and goes unnoticed for several hours. When skin temperature drops below 35° C (95° F), the patient suffers uncontrolled shivering, loss of memory, depression, and poor judgment. As the body temperature falls below 34.4° C (94° F), HR, respiratory rate, and BP fall. The skin becomes cyanotic. Patients experience cardiac dysrhythmias, loss of consciousness, and unresponsiveness to painful stimuli if hypothermia progresses. In cases of severe hypothermia a person demonstrates clinical signs similar to those of death (e.g., lack of response to stimuli and extremely slow respirations and pulse). When you suspect hypothermia, assessment of core temperature is critical. A special low-reading thermometer is required because standard devices do not register below 35° C (95° F).

Frostbite occurs when the body is exposed to subnormal temperatures. Ice crystals form inside the cell, and permanent circulatory and tissue damage occurs. Areas particularly susceptible to frostbite are the earlobes, tip of the nose, and fingers and toes. The injured area becomes white, waxy, and firm to the touch. The patient loses sensation in the affected area. Interventions include gradual warming measures, analgesia, and protection of the injured tissue.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. Knowledge of the physiology of body temperature regulation is essential to assess and evaluate a patient's response to temperature alterations and intervene safely. Implement independent measures to increase or minimize heat loss, promote heat conservation, and increase comfort. These measures complement the effects of medically ordered therapies during illness. You also provide education to family members, parents of children, or other caregivers.

ASSESSMENT

Through the Patient's Eyes. During the assessment process thoroughly assess each patient, explore his or her beliefs and experiences, and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Sites. Core and surface body temperature can be measured at several sites. Intensive care units use the core temperatures of the pulmonary artery, esophagus, and urinary bladder. These measurements require the use of continuous invasive devices placed in body cavities or organs and continually display readings on an electronic monitor.

Use a thermometer to obtain intermittent temperature measurements from the mouth, rectum, tympanic membrane, temporal artery, and axilla. You can also apply noninvasive chemically prepared thermometer patches to the skin. Oral, rectal, axillary, and skin temperature sites rely on effective blood circulation at the measurement site. The heat of the blood is conducted to the thermometer probe. Tympanic temperature relies on the radiation of body heat to an infrared sensor. Because the tympanic membrane shares the same arterial blood supply as the hypothalamus, it is a core temperature. Temporal artery measurements detect the temperature of cutaneous blood flow.

To ensure accurate temperature readings, measure each site correctly (see Skill 29-1 on pp. 467-471). The temperature obtained varies, depending on the site used, but it is usually between 36° C (96.8° F) and 38° C (100.4° F). Rectal temperatures are usually 0.5° C (0.9° F) higher than oral temperatures, and axillary temperatures are usually 0.5° C (0.9° F) lower than oral temperatures. Each of the common temperature measurement sites has advantages and disadvantages (Box 29-4). Choose the safest and most accurate site for the patient. When possible, use the same site when repeated measurements are necessary.

Thermometers. Two types of thermometers are available for measuring body temperature: electronic and disposable. The mercury-in-glass thermometer, once the standard device, has been eliminated from health care facilities because of the environmental hazards of mercury. However, some patients still use mercury-in-glass thermometers at home. When you find a mercury-in-glass thermometer in the home, teach the patient about safer temperature devices and encourage the disposal of mercury products at appropriate neighborhood hazardous disposal locations.

Each device measures temperature using the **Celsius** or **Fahrenheit** scale. Electronic thermometers convert the temperature scales by activating a switch. When it is necessary to convert temperature readings, use the following formulas:

1. To convert Fahrenheit to Celsius, subtract 32 from the Fahrenheit reading and multiply the result by 5/9.

$$C = (F - 32) \times 5/9$$

Example: $40°\ C = (104°\ F - 32) \times 5/9$

2. To convert Celsius to Fahrenheit, multiply the Celsius reading by 9/5 and add 32 to the product.

$$F = (9/5 \times °C) + 32$$

Example: $104°\ F = (9/5 \times 40°\ C) + 32°$

Electronic Thermometer. The electronic thermometer consists of a rechargeable battery-powered display unit, a thin wire cord, and a temperature-processing probe covered by a disposable probe cover (Fig. 29-4). Separate unbreakable probes are available for oral and rectal use. You can also use the oral probe for axillary temperature measurement. Electronic thermometers provide two modes of operation: a 4-second predictive temperature and a 3-minute standard temperature. In day-to-day clinical situations most nurses use the 4-second predictive mode. A sound signals, and a reading appears on the display unit when the peak temperature reading has been measured.

FIG. 29-4 Electronic thermometer. Blue probe is for oral or axillary use. Red probe is for rectal use.

FIG. 29-5 Temporal artery thermometer scanning child's forehead.

Another form of electronic thermometer is used exclusively for tympanic temperature. An otoscope-like speculum with an infrared sensor tip detects heat radiated from the tympanic membrane. Within seconds of placement in the auditory canal, a sound signals, and a reading appears on the display unit when the peak temperature reading has been measured (Box 29-5).

Another form of electronic thermometer measures the temperature of the superficial temporal artery. A handheld scanner with an infrared sensor tip detects the temperature of cutaneous blood flow by sweeping the sensor across the forehead and just behind the ear (Fig. 29-5). After scanning is complete, a reading appears on the display unit. Temporal artery temperature is a reliable noninvasive measure of core temperature (Box 29-6).

The greatest advantages of electronic thermometers are that their readings appear within seconds and they are easy to read. The plastic sheath is unbreakable and ideal for children. Their expense is a major disadvantage. Maintaining cleanliness of the probes is an important consideration. For example, if not properly cleaned between patients, gastrointestinal contamination of the rectal probe causes disease transmission. Wipe the thermometer daily with alcohol and the thermometer probe with an alcohol swab after each patient, paying particular attention to the ridges where the probe cover is secured to the probe.

Chemical Dot Thermometers. Single-use or reusable chemical dot thermometers (Fig. 29-6) are thin strips of plastic with a

BOX 29-4 ADVANTAGES AND DISADVANTAGES OF SELECT TEMPERATURE MEASUREMENT SITES

SITE ADVANTAGES	SITE LIMITATIONS
Oral	
Easily accessible—requires no position change	Causes delay in measurement if patient recently ingested hot/cold fluids or foods, smoked, or is receiving oxygen by mask/cannula
Comfortable for patient	Not for patients who had oral surgery, trauma, history of epilepsy, or shaking chills
Provides accurate surface temperature reading	Not for infants, small children, or patients who are confused, unconscious, or uncooperative
Reflects rapid change in core temperature	Risk of body fluid exposure
Reliable route to measure temperature in patients who are intubated	
Tympanic Membrane	
Easily accessible site	More variability of measurement than with other core temperature devices (Lawson, Bridges, and Ballou, 2007)
Minimal patient repositioning required	Requires removal of hearing aids before measurement
Obtained without disturbing, waking, or repositioning patients	Requires disposable sensor cover with only one size available
Used for patients with tachypnea without affecting breathing	Otitis media and cerumen impaction distorts readings (Lawson et al., 2007)
Provides accurate core reading because eardrum close to hypothalamus; sensitive to core temperature changes	Not used in patients who have had surgery of the ear or tympanic membrane
Very rapid measurement (2 to 5 seconds)	Does not accurately measure core temperature changes during and after exercise
Unaffected by oral intake of food or fluids or smoking	Does not obtain continuous measurement
Used in newborns to reduce infant handling and heat loss	Affected by ambient temperature devices such as incubators, radiant warmers, and facial fans
	When used in neonates, infants, and children under 3 years old, use care to position device correctly because anatomy of ear canal makes it difficult to position
	Inaccuracies reported caused by incorrect positioning of handheld unit
Rectal	
Sometimes considered to be more reliable when oral temperature cannot be obtained	Lags behind core temperature during rapid temperature changes (Henker and Carlson, 2007)
	Not for patients with diarrhea, rectal disorders, or bleeding tendencies or those who had rectal surgery
	Requires positioning and is often source of patient embarrassment and anxiety
	Risk of body fluid exposure
	Requires lubrication
	Not for routine vital signs in newborns
	Readings influenced by impacted stool
Axilla	
Safe and inexpensive	Long measurement time
Used with newborns and unconscious patients	Underestimates core temperature (Lawson et al., 2007)
	Requires continuous positioning by nurse
	Measurement lags behind core temperature during rapid temperature changes
	Not recommended to detect fever in infants and young children (Lim, Byrne, and Lee, 2008)
	Requires exposure of thorax, which results in temperature loss, especially in newborns
	Affected by exposure to environment, including time to place thermometer
Skin	
Inexpensive	Measurement lags behind other sites during temperature changes, especially during hyperthermia
Provides continuous reading	Adhesion impaired by diaphoresis or sweat
Safe and noninvasive	Reading affected by environmental temperature
Used for neonates	Cannot be used for patients with allergy to adhesive
Temporal Artery	
Easy to access without position change	Inaccurate with head covering or hair on forehead
Very rapid measurement	Affected by skin moisture such as diaphoresis or sweating
No risk of injury to patient or nurse	
Eliminates need to disrobe or be unbundled	
Comfortable for patient	
Used in premature infants, newborns, and children	
Reflects rapid change in core temperature	
Sensor cover not required	

BOX 29-5 EVIDENCE-BASED PRACTICE

Comparing Temperatures at Different Measurement Sites

PICO Question: Are tympanic thermometers compared with oral or temporal thermometers accurate in measuring body temperature in hospitalized patients?

Evidence Summary

Numerous devices and sites for measuring temperature allow you to select the best approach for the clinical condition of the patient. As the patient's condition changes, obtaining a temperature using a different temperature device for a different site is sometimes needed. Oral, tympanic, and temporal thermometers are the most frequently used devices for medical and surgical adult and pediatric patients. To safely substitute a temperature measurement from one site to another, the temperature agreement needs to be within 1° C (1.8° F). The reliability of the tympanic membrane thermometer has been questioned (Lawson et al., 2007). A study of postoperative patients reported that nearly 20% of the patients had at least a 2° C (3.6° F) difference between tympanic and oral temperature measurements (Frommelt, Ott, and Hays, 2008). In a study of the tympanic and temporal temperatures of 178 acute care patients, over 40% of the patients' two temperatures differed more than 1° C (1.8° F) (Woodrow et al., 2006). In another study five trained data collectors obtained tympanic and temporal temperatures of over 200 preoperative and postoperative patients. Although 63% of the temperatures were within a 0.5° C (0.9° F) difference, the temperatures varied by over 1° C (1.8° F) in 13% of patients (Fetzer and Lawrence, 2008).

The unreliability of the tympanic thermometer is attributed to errors in technique and patient characteristics such as the presence of cerumen. Research shows a lack of agreement among commonly used temperature devices. Selection of the site to obtain a patient's temperature is a nursing responsibility. When evaluating temperature over time, measurements obtained from different sites are not interchangeable. Use values from a consistent site when trending temperatures.

Application to Nursing Practice

- Always record the site of a temperature measurement with the temperature.
- Do not compare an oral temperature taken at one time with a tympanic or temporal artery temperature taken earlier or later.
- There is no agreement as to the most accurate noninvasive temperature measurement site.

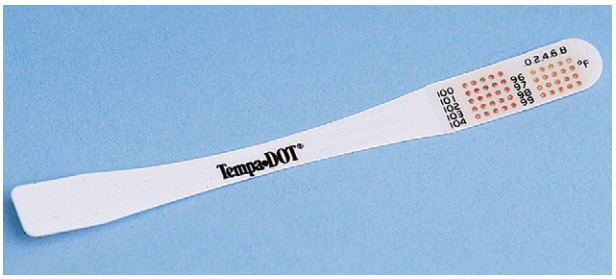

FIG. 29-6 Disposable, single-use thermometer strip.

temperature sensor at one end. The sensor consists of a matrix of chemically impregnated dots that change color at different temperatures. In the Celsius version there are 50 dots, each representing a temperature increment of 0.1° C, over a range of 35.5° C to 40.4° C. The Fahrenheit version has 45 dots with increments of 0.2° F and a range of 96° F to 104.8° F. Chemical dots on the thermometer change color to reflect temperature reading, usually within 60 seconds. Most are for single use. In one reusable brand for a single patient the chemical dots return to the original color within a few seconds. Chemical dot thermometers are usually for oral temperatures. You also use them at axillary or rectal sites, covered by a plastic sheath at the latter site, with a placement time of 3 minutes. Chemical dot thermometers are useful for screening temperatures, especially in infants and young children and patients who are intubated. Because chemical dot thermometers often underestimate oral temperature by 0.4° C (0.7° F) or more, use electronic thermometers to confirm measurements made with a chemical dot thermometer when treatment decisions are involved. Chemical dot thermometers are useful when caring for patients on protective isolation to avoid the need to take electronic instruments into patient rooms (see Chapter 28).

Another disposable thermometer useful for screening temperature is a temperature-sensitive patch or tape. Applied to the forehead or abdomen, chemical sensitive areas of the patch change color at different temperatures.

BOX 29-6 PROCEDURAL GUIDELINES

Measurement of Temporal Artery Temperature

Delegation Considerations

The skill of measuring temporal artery temperature can be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Obtain temperature for select patient with ordered frequency.
- Report abnormalities to the nurse for further assessment.

Equipment

Temporal artery thermometer, alcohol wipes (optional), probe cover (optional).

1. Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy.
2. Perform hand hygiene.
3. Ensure that forehead is dry; wipe with towel if needed.
4. Place probe flush on patient's forehead to avoid measuring ambient temperature.
5. Press red scan button with your thumb. Continuous scanning for highest temperature occurs until you release button.
6. Slowly slide thermometer straight across forehead while keeping probe flush on skin.
7. Keeping scan button pressed, lift probe from forehead and touch it to neck just behind earlobe (area where perfume is typically applied).
8. While scanning, a clicking sound occurs and stops when peak temperature is reached.
9. Release scan button; read and record temperature. Reading remains on for 15 seconds after you release the button.
10. Clean probe with alcohol wipe or remove and dispose of probe cover if used.
11. Perform hand hygiene.
12. Discuss findings with patient as needed.
13. Compare measurement with patient baseline and acceptable values.
14. Record temperature on nurses' notes, vital sign flow sheet, or electronic medical record.

NURSING DIAGNOSIS

After concluding your assessment, cluster defining characteristics to form a nursing diagnosis (Box 29-7). For example, an increase in body temperature, flushed skin, skin warm to touch, and tachycardia indicate the diagnosis of *hyperthermia.* State the nursing diagnosis as either an at-risk or actual temperature alteration.

BOX 29-7 NURSING DIAGNOSTIC PROCESS

Ineffective Thermoregulation Related to Aging and Inability to Adapt to Environmental Temperature

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Obtain vital signs, including temperature, pulse (see Skill 29-2), respirations (see Skill 29-3), SpO_2 (see Skill 29-4).	Increased body temperature above usual range Tachycardia Tachypnea Hypoxemia
Palpate skin.	Warm, dry skin
Observe patient's appearance and behavior while talking and resting.	Restlessness Confusion Flushed appearance
Review medical history.	Found in unventilated apartment during heat wave; 85 years old with history of dementia

Implement actions to minimize or eliminate the risk factors if the patient has risk factors for temperature alterations. Examples of nursing diagnoses for patients with body temperature alterations include the following:

- Risk for imbalanced body temperature
- Hyperthermia
- Hypothermia
- Ineffective thermoregulation

Once you determine a diagnosis, accurately select the related factor or etiology. The related factor allows you to select appropriate nursing interventions. In the example of hyperthermia, a related factor of vigorous activity results in much different interventions than a related factor of decreased ability to perspire.

PLANNING

During planning integrate the knowledge gathered from assessment and the patient history to develop an individualized plan of care (see the Nursing Care Plan). Match the patient's needs with interventions that are supported and recommended in the clinical research literature.

Goals and Outcomes. The plan of care for a patient with alteration in temperature includes realistic and individualized goals along with relevant outcomes. This requires collaboration with the patient and family in setting goals and outcomes and selecting nursing interventions. Establish expected outcomes to gauge progress toward returning the body temperature to an acceptable range. In cases in which the temperature alteration requires helping patients modify their environment, goals may be long term (e.g., obtaining appropriate clothing to wear in cold weather). Short-term goals such as regaining normal range of body temperature improve patient health. In the example of a patient who has an elevated fever and excessive diaphoresis, the goal of care is attaining fluid and electrolyte balance. The outcome is that patient intake and output will be equal for the next 24 hours.

Setting Priorities. Set priorities of care with regard to the extent that the temperature alteration affects a patient. The severity of a temperature alteration and its effects, together with the patient's general health status, influence your priorities in his or her care. Safety is a top priority. Often other medical problems complicate the care plan. For instance, body temperature imbalance affects body requirements for fluids. Patients with heart problems often have difficulty tolerating required fluid replacement therapy.

Teamwork and Collaboration. Patients at risk for imbalanced body temperature require an individualized care plan directed at maintaining normothermia and reducing risk factors. For example, it is important to establish the outcome that the patient can explain appropriate actions to take and available community resources to use (e.g., cooling stations) during a heat wave. Teach the patient and caregiver the importance of thermoregulation and actions to take during excessive environmental heat. Education is particularly important for parents, who need to know how to take action at home and whom to call (e.g., health care provider's office, home care nurse) when an infant or child develops a temperature imbalance.

IMPLEMENTATION

Health Promotion. By maintaining balance between heat production and heat loss you promote the health of patients at risk for imbalanced body temperature. Consider patient activity, temperature of the environment, and clothing. Teach patients to avoid strenuous exercise in hot, humid weather; drink fluids such as water or clear fruity juices before, during, and after exercise; and wear light, loose-fitting, light-colored clothes. Also teach patients to avoid exercising in areas with poor ventilation, wear a protective covering over the head when outdoors, and expose themselves to hot climates gradually.

Prevention is the key for patients at risk for hypothermia. It involves educating patients, family members, and friends. Patients at risk include the very young; the very old; and people debilitated by trauma, stroke, diabetes, drug or alcohol intoxication, and sepsis. Patients who are mentally ill or handicapped sometimes fall victim to hypothermia because they are unaware of the dangers of cold conditions. People without adequate home heating, shelter, diet, or clothing are also at risk. Fatigue, dark skin color, malnutrition, and hypoxemia also contribute to the risk of frostbite.

Acute Care

Fever. When an elevated body temperature develops, initiate interventions to treat fever. The objective of therapy is to increase heat loss, reduce heat production, and prevent complications. The choice of interventions depends on the cause; adverse effects; and the strength, intensity, and duration of the temperature elevation. Nurses are essential in assessing and implementing temperature-reducing strategies (Box 29-8). The health care provider attempts to determine the cause of the elevated temperature by isolating the causative pyrogen. Sometimes it is necessary to obtain culture specimens for laboratory analysis such as urine, blood, sputum, and wound sites (see Chapter 28). Some antibiotic medications are ordered to be given after the cultures have been obtained. Administering antibiotics destroys pyrogenic bacteria and eliminates body stimulus for the elevated temperature.

Most fevers in children are of a viral origin, last only briefly, and have limited effects. However, children still have immature temperature-control mechanisms, and temperatures can rise rapidly. Dehydration and febrile seizures occur during rising temperatures of children between 6 months and 3 years of age. Febrile seizures are unusual in children more than 5 years of age. The extent of the temperature, often exceeding 38.8° C (101.8° F), seems to be a more important factor than the rapidity of the temperature increase. Children are at particular risk for fluid volume deficit because they can quickly lose large amounts of fluids in proportion

NURSING CARE PLAN

Hyperthermia

ASSESSMENT

Mr. Coburn is a 56-year-old school teacher who arrives at the outpatient clinic with malaise. His medical history includes a past urinary tract infection. Several of his students have been out of school lately with colds. He has been feeling poorly for the past 3 days.

Assessment Activities	*Findings/Defining Characteristics**
Palpate skin.	Mr. Coburn's skin is **warm and dry** to touch.
Observe patient's behavior while talking and resting.	Mr. Coburn appears to have labored breathing. His face is **flushed.**
Obtain vital signs.	Blood pressure right arm 116/62 mm Hg, left arm 114/64 mm Hg; right radial pulse **128 beats/min,** regular and bounding; respiratory rate **26 breaths/min;** SpO_2 98% on room air; oral temperature **39.2° C** (102.6° F).
Review medical history.	He admits to smoking one pack of cigarettes per day and recently began expectorating **yellow-green sputum.** He has been **tired** for the past 3 days and on rising in the morning has been dizzy.

***Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Hyperthermia related to infectious process

PLANNING

Goals	*Expected Outcomes (NOC)*†
	Thermoregulation
Mr. Coburn will regain normal range of body temperature within next 24 hours.	Body temperature will decline at least 1° C (1.8° F) within next 8 hours.
Mr. Coburn will state a sense of comfort and rest within next 48 hours.	Patient will verbalize increased satisfaction with rest and sleep pattern. Patient will report increase in energy level within next 3 days.
Mr. Coburn's fluid and electrolyte balance will be maintained during next 3 days.	Intake will equal output within next 24 hours. No evidence of postural hypotension during ambulation.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Fever Treatment	
Instruct Mr. Coburn to reduce external coverings and keep clothing and bed linen dry.	Promotes heat loss through conduction and convection.
Instruct Mr. Coburn to use ordered antipyretic medications safely when needed for comfort.	Antipyretics reduce set point (Lehne, 2010).
Instruct Mr. Coburn to limit physical activity and increase frequency of rest periods over next 2 days.	Activity and stress increase metabolic rate, contributing to heat production.
Instruct Mr. Coburn to increase oral fluids of choice to 8 to 10 8-oz glasses of fluid daily.	Increased metabolic rate and diaphoresis associated with fever causes loss of body fluids (Hockenberg, 2008).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Obtain body temperature measurement.	Body temperature 37.8° C (100.0° F).	Body temperature within normal limits.
Obtain orthostatic blood pressure measurements.	Blood pressure measurements lying, sitting, and standing are within 5 mm Hg of each other.	No evidence of postural hypotension.
Ask Mr. Coburn if his energy level has changed since the last visit.	He responds, "I am sleeping much better and have returned to work with a lot more energy."	Improved rest and sleep pattern and increased energy level.

BOX 29-8 NURSING INTERVENTIONS FOR PATIENTS WITH A FEVER

Interventions (Unless Contraindicated)

- Obtain blood cultures (before beginning antibiotics) if ordered. Obtain blood specimens to coincide with temperature spikes when the antigen-producing organism is most prevalent.
- Minimize heat production: reduce the frequency of activities that increase oxygen demand such as excessive turning and ambulation; allow rest periods; limit physical activity.
- Maximize heat loss: reduce external covering on patient's body without causing shivering; keep clothing and bed linen dry.
- Satisfy requirements for increased metabolic rate: provide supplemental oxygen therapy as ordered to improve oxygen delivery to body cells; provide measures to stimulate appetite and offer well-balanced meals; provide fluids (at least 8 to 10 8-oz glasses for patients with normal cardiac and renal function) to replace fluids lost through insensible water loss and sweating.
- Promote patient comfort: encourage oral hygiene because oral mucous membranes dry easily from dehydration; control temperature of the environment without inducing shivering; apply damp cloth to patient's forehead.
- Identify onset and duration of febrile episode phases: examine previous temperature measurements for trends.
- Initiate health teaching as indicated.
- Control environmental temperature to 21° to 27° C (70° to 80° F).

to their body weight. It is important to maintain accurate intake and output records, weigh the patient daily, and encourage fluids.

Sometimes a fever is a hypersensitivity response to a drug. Drug fevers are often accompanied by other allergy symptoms such as rash or pruritus (itching). Treatment involves withdrawing the medication.

Antipyretics are medications that reduce fever. Nonsteroidal antiinflammatory drugs such as acetaminophen, salicylates, indomethacin, and ketorolac reduce fever by increasing heat loss. Corticosteroids reduce heat production by interfering with the immune system and mask signs of infection. They are not used to treat a fever. However, they can suppress fever in response to a pyrogen.

Nonpharmacological therapy for fever uses methods that increase heat loss by evaporation, conduction, convection, or radiation. Make sure that nursing measures to enhance body cooling do not stimulate shivering. Shivering is counterproductive and increases energy expenditure up to 400%. Tepid sponge baths, bathing with alcohol-water solutions, applying ice packs to axillae and groin areas, and cooling fans were previously used to reduce fever; however, avoid these therapies because they lead to shivering. There is no advantage of these methods over antipyretic medications.

Blankets cooled by circulating water delivered by motorized units increase conductive heat loss. Follow manufacturer instructions for applying these hypothermia blankets because of the risk for skin breakdown and "freeze burns." Placing a bath blanket between the patient and the hypothermia blanket and wrapping distal extremities (fingers, toes, and genitalia) reduces the risk of injury to the skin and tissue from hypothermia therapy. Wrapping the patient's extremities reduces the incidence and intensity of shivering. Medications such as meperidine or butorphanol reduce shivering.

Heatstroke. Heatstroke is an emergency situation. First aid treatment includes moving the patient to a cooler environment, removing excess body clothing, placing cool wet towels over the skin, and using oscillating fans to increase convective heat loss. Emergency medical treatment includes intravenous (IV) fluids, irrigating the stomach and lower bowel with cool solutions, and hypothermia blankets.

Hypothermia. The priority treatment for hypothermia is to prevent a further decrease in body temperature. Removing wet clothes, replacing them with dry ones, and wrapping patients in blankets are key nursing interventions. In emergencies away from a health care setting, have the patient lie under blankets next to a warm person. A conscious patient benefits from drinking hot liquids such as soup and avoiding alcohol and caffeinated fluids. It is also helpful to keep the head covered, place the patient near a fire or in a warm room, or place heating pads next to areas of the body (head and neck) that lose heat the quickest.

Restorative and Continuing Care. Educate the patient with a fever about the importance of taking and continuing any antibiotics as directed until the course of treatment is completed. Children and older adults are at risk for fluid volume deficit because they can quickly lose large amounts of fluids in proportion to their body weight. Identifying preferred fluids and encouraging oral fluid intake is an important ongoing nursing intervention.

EVALUATION

Through the Patient's Eyes. Evaluate your patient's perspectives about the care provided. Is he or she satisfied with the outcomes of care or does the care plan need to be modified? Including the patient in the evaluation demonstrates that you value his or her perspective and contributes to patient safety.

Patient Outcomes. Evaluate all nursing interventions by comparing the patient's actual response to the expected outcomes of the care plan. Determine if goals of care were met and make revisions to the care plan when necessary. After any intervention measure the patient's temperature to evaluate for change. In addition, use other evaluative measures such as palpating the skin and assessing pulse and respirations. If therapies are effective, body temperature returns to an acceptable range, other vital signs stabilize, and the patient reports a sense of comfort.

PULSE

The pulse is the palpable bounding of blood flow noted at various points on the body. Blood flows through the body in a continuous circuit. The pulse is an indicator of circulatory status.

Physiology and Regulation

Electrical impulses originating from the sinoatrial (SA) node travel through heart muscle to stimulate cardiac contraction. Approximately 60 to 70 mL of blood enters the aorta with each ventricular contraction (stroke volume). With each stroke volume ejection, the walls of the aorta distend, creating a pulse wave that travels rapidly toward the distal ends of the arteries. The pulse wave moves 15 times faster through the aorta and 100 times faster through the small arteries than the ejected volume of blood. When a pulse wave reaches a peripheral artery, you can feel it by palpating the artery lightly against underlying bone or muscle. The pulse is the palpable bounding of the blood flow in the peripheral artery. The number of pulsing sensations occurring in 1 minute is the pulse rate.

The volume of blood pumped by the heart during 1 minute is the **cardiac output,** the product of HR and the stroke volume (SV) of the ventricle. In an adult the heart normally pumps 5000 mL of blood per minute. A change in HR or stroke volume does not

TABLE 29-2 **Pulse Sites**

SITE	LOCATION	ASSESSMENT CRITERIA
Temporal	Over temporal bone of head, above and lateral to eye	Easily accessible site used to assess pulse in children
Carotid	Along medial edge of sternocleidomastoid muscle in neck	Easily accessible site used during physiological shock or cardiac arrest when other sites are not palpable
Apical	Fourth to fifth intercostal space at left midclavicular line	Site used to auscultate for apical pulse
Brachial	Groove between biceps and triceps muscles at antecubital fossa	Site used to assess status of circulation to lower arm and auscultate blood pressure
Radial	Radial or thumb side of forearm at wrist	Common site used to assess character of pulse peripherally and assess status of circulation to hand
Ulnar	Ulnar side of forearm at wrist	Site used to assess status of circulation to hand; also used to perform an Allen's test
Femoral	Below inguinal ligament, midway between symphysis pubis and anterior superior iliac spine	Site used to assess character of pulse during physiological shock or cardiac arrest when other pulses are not palpable; used to assess status of circulation to leg
Popliteal	Behind knee in popliteal fossa	Site used to assess status of circulation to lower leg
Posterior tibial	Inner side of ankle, below medial malleolus	Site used to assess status of circulation to foot
Dorsalis pedis	Along top of foot, between extension tendons of great and first toe	Site used to assess status of circulation to foot

always change the output of the heart or the amount of blood in the arteries. For example, if a person's HR is 70 beats/min and the stroke volume is 70 mL, the cardiac output is 4900 mL per minute (70 beats/min times 70 mL per beat). If the HR drops to 60 beats/min and the stroke volume rises to 85 mL per beat, the cardiac output increases to 5100 mL or 5.1 L per minute (60 beats/min times 85 mL per beat).

Mechanical, neural, and chemical factors regulate the strength of ventricular contraction and its stroke volume. But when these factors are unable to alter stroke volume, a change in HR results in a change in cardiac output, which affects BP. As HR increases, there is less time for the heart to fill. As HR increases without a change in stroke volume, BP decreases. As HR slows, filling time is increased, and BP increases. The inability of BP to respond to increases or decreases in HR indicates a possible health problem. Report this to the health care provider.

An abnormally slow, rapid, or irregular pulse alters cardiac output. Assess the ability of the heart to meet the demands of body tissue for nutrients by palpating a peripheral pulse or using a stethoscope to listen to heart sounds (apical rate).

Assessment of Pulse

You can assess any artery for pulse rate, but you typically use the radial artery because it is easy to palpate. When a patient's condition suddenly worsens, the carotid site is recommended for quickly finding a pulse. The heart continues delivering blood through the carotid artery to the brain as long as possible. When cardiac output declines significantly, peripheral pulses weaken and are difficult to palpate.

The radial and apical locations are the most common sites for pulse rate assessment. Use the radial pulse to teach patients how to monitor their own HRs (e.g., athletes, persons taking heart medications, and patients starting a prescribed exercise regimen). If the radial pulse is abnormal or intermittent resulting from dysrhythmias or if it is inaccessible because of a dressing or cast, assess the apical pulse. When a patient takes medication that affects the HR, the apical pulse provides a more accurate assessment of heart function. The brachial or apical pulse is the best site for assessing an infant's or young child's pulse because other peripheral pulses are deep and difficult to palpate accurately.

Assessment of other peripheral pulse sites such as the brachial or femoral artery is unnecessary when routinely obtaining vital signs. You assess other peripheral pulses when conducting a complete physical, when surgery or treatment has impaired blood flow to a body part, or when there are clinical indications of impaired peripheral blood flow (see Chapter 30). Table 29-2 summarizes pulse sites and criteria for measurement. Skill 29-2 on pp. 472-475 outlines pulse rate assessment.

Use of a Stethoscope. Assessing the apical rate requires a stethoscope. The five major parts of the stethoscope are the earpieces, binaurals, tubing, bell chest piece, and diaphragm chest piece (Fig. 29-7).

The plastic or rubber earpieces should fit snugly and comfortably in your ears. The binaurals should be angled and strong enough so the earpieces stay firmly in the ears without causing discomfort. To ensure the best reception of sound, the earpieces follow the contour of the ear canal pointing toward the face when the stethoscope is in place.

The polyvinyl tubing is flexible and 30 to 40 cm (12 to 18 inches) in length. Longer tubing decreases the transmission of sound waves. Thick-walled and moderately rigid tubing eliminates transmission of environmental noise and prevents the tubing from kinking, which distorts sound wave transmission. Stethoscopes have single or dual tubes.

The chest piece consists of a bell and a diaphragm that you rotate into position. The diaphragm or bell needs to be in proper position during use to hear sounds through the stethoscope. To test the position of the chest piece, tap lightly on the diaphragm to determine which side is functioning. The diaphragm is the circular, flat portion of the chest piece covered with a thin plastic disk. It transmits high-pitched sounds created by the high-velocity movement of air and blood. Auscultate bowel, lung, and heart sounds

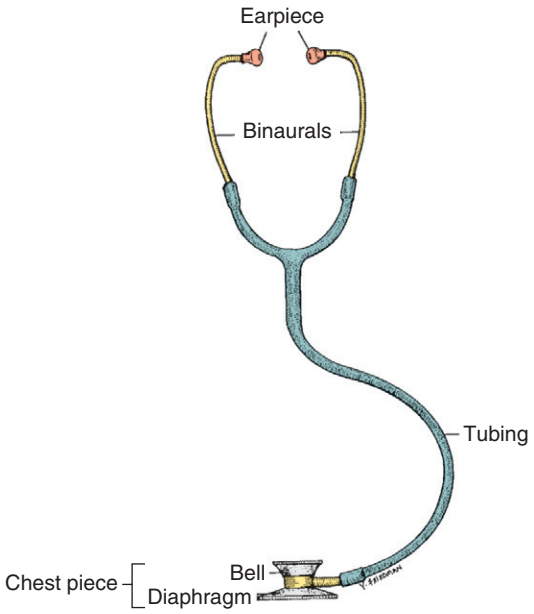

FIG. 29-7 Parts of stethoscope.

FIG. 29-8 Positioning diaphragm of stethoscope firmly and securely when auscultating high-pitched heart sounds.

using the diaphragm. Always place the stethoscope directly on the skin because clothing obscures the sound. Position the diaphragm to make a tight seal and press firmly against the patient's skin (Fig. 29-8).

The bell is the bowl-shaped chest piece usually surrounded by a rubber ring. The ring avoids chilling patients with cold metal when placed on the skin. The bell transmits low-pitched sounds created by the low-velocity movement of blood. Auscultate heart and vascular sounds using the bell. Apply the bell lightly, resting the chest piece on the skin (Fig. 29-9).

Compressing the bell against the skin reduces low-pitched sound amplification and creates a "diaphragm of skin." Some stethoscopes have one chest piece that combines features of the bell and diaphragm. When you use light pressure, the chest piece is a bell; exerting more pressure converts the bell into a diaphragm.

The stethoscope is a delicate instrument and requires proper care for optimal function. Remove the earpieces regularly and clean them of cerumen (earwax). Clean the bell and diaphragm of dust, lint, and body oils. Clean the tubing with mild soap and water between patients.

FIG. 29-9 Positioning bell of stethoscope lightly on skin to hear low-pitched heart sounds.

TABLE 29-3 Acceptable Ranges of Heart Rate

AGE	HEART RATE (BEATS/MIN)
Infant	120-160
Toddler	90-140
Preschooler	80-110
School-age child	75-100
Adolescent	60-90
Adult	60-100

Character of the Pulse

Assessment of the radial pulse includes measuring the rate, rhythm, strength, and equality. When auscultating an apical pulse, assess rate and rhythm only.

Rate. Before measuring a pulse, review the patient's baseline rate for comparison (Table 29-3). Some practitioners prefer to make baseline measurements of the pulse rate as a patient assumes a sitting, standing, and lying position. Postural changes affect the pulse rate because of alterations in blood volume and sympathetic activity. The HR temporarily increases when a person changes from a lying to a sitting or standing position.

When assessing the pulse, consider the variety of factors influencing the pulse rate (Table 29-4). A single factor or a combination of these factors often causes significant changes. If you detect an abnormal rate while palpating a peripheral pulse, the next step is to assess the apical rate. The apical rate requires auscultation of heart sounds, which provides a more accurate assessment of cardiac contraction.

Assess the apical rate by listening to heart sounds (see Chapter 30). Identify the first and second heart sounds (S_1 and S_2). At normal slow rates S_1 is low pitched and dull, sounding like a "lub." S_2 is higher pitched and shorter, creating the sound "dub." Count each set of "lub-dub" as one heartbeat. Using the diaphragm or bell of the stethoscope, count the number of lub-dubs occurring in 1 minute.

Peripheral and apical pulse rate assessment often reveals variations in HR. Two common abnormalities in pulse rate are tachycardia and bradycardia. **Tachycardia** is an abnormally elevated HR,

TABLE 29-4 Factors Influencing Pulse Rate

FACTOR	INCREASES PULSE RATE	DECREASES PULSE RATE
Exercise	Short-term exercise	Heart conditioned by long-term exercise, resulting in lower resting pulse and quicker return to resting level after exercise
Temperature	Fever and heat	Hypothermia
Emotions	Sympathetic stimulation increased by acute pain and anxiety, affecting heart rate; effect of chronic pain on heart rate varies	Parasympathetic stimulation increased by unrelieved severe pain affecting heart rate; relaxation
Drugs	Positive chronotropic drugs such as epinephrine	Negative chronotropic drugs such as digitalis; beta-adrenergic and calcium channel blockers
Hemorrhage	Sympathetic stimulation increased by loss of blood	
Postural changes	Standing or sitting	Lying down
Pulmonary conditions	Diseases causing poor oxygenation such as asthma, chronic obstructive pulmonary disease (COPD)	

above 100 beats/min in adults. **Bradycardia** is a slow rate, below 60 beats/min in adults.

An inefficient contraction of the heart that fails to transmit a pulse wave to the peripheral pulse site creates a **pulse deficit.** To assess a pulse deficit you and a colleague assess radial and apical rates simultaneously and then compare rates. The difference between the apical and radial pulse rates is the pulse deficit. For example, an apical rate of 92 with a radial rate of 78 leaves a pulse deficit of 14 beats. Pulse deficits are often associated with abnormal rhythms.

Rhythm. Normally a regular interval occurs between each pulse or heartbeat. An interval interrupted by an early or late beat or a missed beat indicates an abnormal rhythm or **dysrhythmia.** A dysrhythmia threatens the ability of the heart to provide adequate cardiac output, particularly if it occurs repetitively. You identify a dysrhythmia by palpating an interruption in successive pulse waves or auscultating an interruption between heart sounds. If a dysrhythmia is present, assess the regularity of its occurrence and auscultate the apical rate (see Chapter 30). Dysrhythmias are described as regularly irregular or irregularly irregular.

To document a dysrhythmia, the health care provider often orders an electrocardiogram, Holter monitor, or telemetry monitor. An electrocardiogram records the electrical activity of the heart for a 12-second interval. This test requires placement of electrodes across a patient's chest followed by recording of the heart rhythm. The patient wears the Holter monitor, which records and stores 24 hours of electrical activity. Access to the information recorded is not available until after the 24 hours have passed and the data are reviewed. Cardiac telemetry provides continuous monitoring of the electrical activity of the heart transmitted to a stationary monitor. Telemetry permits continuous observation of heart rhythm during all of a patient's daily activities and thus allows for immediate treatment if the rhythm becomes erratic or unstable.

Children often have a sinus dysrhythmia, which is an irregular heartbeat that speeds up with inspiration and slows with expiration. This is a normal finding that you can verify by having the child hold his or her breath; the HR usually becomes regular.

Strength. The strength or amplitude of a pulse reflects the volume of blood ejected against the arterial wall with each heart contraction and the condition of the arterial vascular system leading to the pulse site. Normally the pulse strength remains the same with each heartbeat. Document the pulse strength as bounding (4+); full or strong (3+); normal and expected (2+); diminished or barely palpable (1+); or absent (0). Include assessment of pulse strength in the assessment of the vascular system (see Chapter 30).

Equality. Assess radial pulses on both sides of the peripheral vascular system, comparing the characteristics of each. A pulse in one extremity is sometimes unequal in strength or absent in many disease states (e.g., thrombus [clot] formation, aberrant blood vessels, cervical rib syndrome, or aortic dissection). Assess all symmetrical pulses simultaneously except for the carotid pulse. Never measure the carotid pulses simultaneously because excessive pressure occludes blood supply to the brain.

Nursing Process and Pulse Determination

Pulse assessment determines the general state of cardiovascular health and the response of the body to other system imbalances. Tachycardia, bradycardia, and dysrhythmias are defining characteristics of many nursing diagnoses, including the following:

- Activity intolerance
- Anxiety
- Decreased cardiac output
- Fear
- Deficient/excess fluid volume
- Impaired gas exchange
- Hyperthermia
- Hypothermia
- Acute pain
- Ineffective peripheral tissue perfusion

The nursing care plan includes interventions based on the nursing diagnosis identified and the related factors. For example, the defining characteristics of an abnormal HR, exertional dyspnea, and a patient's verbal report of fatigue lead to a diagnosis of *activity intolerance.* When the related factor is *inactivity following a prolonged illness,* interventions focus on increasing the patient's daily exercise routine. Once the plan is implemented, evaluate patient outcomes by assessing his or her pulse.

RESPIRATION

Human survival depends on the ability of oxygen (O_2) to reach body cells and carbon dioxide (CO_2) to be removed from the cells. Respiration is the mechanism the body uses to exchange gases

between the atmosphere and the blood and the blood and the cells. Respiration involves **ventilation** (the movement of gases in and out of the lungs), **diffusion** (the movement of oxygen and carbon dioxide between the alveoli and the red blood cells), and **perfusion** (the distribution of red blood cells to and from the pulmonary capillaries). Analyzing respiratory efficiency requires integrating assessment data from all three processes. Assess ventilation by determining respiratory rate, depth, and rhythm. Assess diffusion and perfusion by determining oxygen saturation.

Physiological Control

Breathing is generally a passive process. Normally a person thinks little about it. The respiratory center in the brainstem regulates the involuntary control of respirations. Adults normally breathe in a smooth, uninterrupted pattern 12 to 20 times a minute.

The body regulates ventilation using levels of CO_2, O_2, and hydrogen ion concentration (pH) in the arterial blood. The most important factor in the control of ventilation is the level of CO_2 in the arterial blood. An elevation in the CO_2 level causes the respiratory control system in the brain to increase the rate and depth of breathing. The increased ventilatory effort removes excess CO_2 (hypercarbia) by increasing exhalation. However, patients with chronic lung disease have ongoing hypercarbia. For these patients chemoreceptors in the carotid artery and aorta become sensitive to **hypoxemia,** or low levels of arterial O_2. If arterial oxygen levels fall, these receptors signal the brain to increase the rate and depth of ventilation. Hypoxemia helps to control ventilation in patients with chronic lung disease. Because low levels of arterial O_2 provide the stimulus that allows a patient to breathe, administration of high oxygen levels is fatal for patients with chronic lung disease.

Mechanics of Breathing

Although breathing is normally passive, muscular work is involved in moving the lungs and chest wall. Inspiration is an active process. During inspiration the respiratory center sends impulses along the phrenic nerve, causing the diaphragm to contract. Abdominal organs move downward and forward, increasing the length of the chest cavity to move air into the lungs. The diaphragm moves approximately 1 cm (⅜ inch), and the ribs retract upward from the midline of the body approximately 1.2 to 2.5 cm (½ to 1 inch). During a normal, relaxed breath, a person inhales 500 mL of air. This amount is referred to as the tidal volume. During expiration the diaphragm relaxes, and the abdominal organs return to their original positions. The lung and chest wall return to a relaxed position (Fig. 29-10). Expiration is a passive process. Sighing interrupts the normal rate and depth of ventilation, **eupnea.** The sigh, a prolonged deeper breath, is a protective physiological mechanism for expanding small airways and alveoli not ventilated during a normal breath.

The accurate assessment of respirations depends on the recognition of normal thoracic and abdominal movements. During quiet breathing the chest wall gently rises and falls. Contraction of the intercostal muscles between the ribs or contraction of the muscles in the neck and shoulders (the accessory muscles of breathing) is not visible. During normal quiet breathing diaphragmatic movement causes the abdominal cavity to rise and fall slowly.

Assessment of Ventilation

Respirations are the easiest of all vital signs to assess, but they are often the most haphazardly measured. Do not estimate respirations. Accurate measurement requires observation and palpation of chest wall movement.

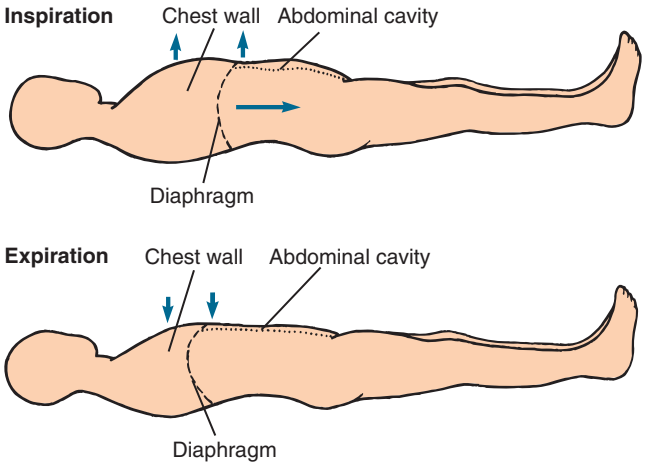

FIG. 29-10 Illustration of diaphragmatic and chest wall movement during inspiration and expiration.

A sudden change in the character of respirations is important. Because respiration is tied to the function of numerous body systems, consider all variables when changes occur (Box 29-9). For example, a drop in respirations occurring in a patient after head trauma often signifies injury to the brainstem. Abdominal trauma injures the phrenic nerve, which is responsible for diaphragmatic contraction.

Do not let a patient know that you are assessing respirations. A patient aware of the assessment can alter the rate and depth of breathing. Assess respirations immediately after measuring pulse rate, with your hand still on the patient's wrist as it rests over the chest or abdomen. When assessing a patient's respirations, keep in mind the patient's usual ventilatory rate and pattern, the influence any disease or illness has on respiratory function, the relationship between respiratory and cardiovascular function, and the influence of therapies on respirations. The objective measurements of respiratory status include the rate and depth of breathing and the rhythm of ventilatory movements (Skill 29-3 on pp. 476-478).

Respiratory Rate. Observe a full inspiration and expiration when counting ventilation or respiration rate. The usual respiratory rate varies with age (Table 29-5). The usual range of respiratory rate declines throughout life.

The apnea monitor is a device that aids respiratory rate assessment. This device uses leads attached to a patient's chest wall that sense movement. The absence of chest wall movement triggers the apnea alarm. Apnea monitoring is used frequently with infants in the hospital and at home to observe patients at risk for prolonged apneic events.

Ventilatory Depth. Assess the depth of respirations by observing the degree of excursion or movement in the chest wall. Describe ventilatory movements as deep, normal, or shallow. A deep respiration involves a full expansion of the lungs with full exhalation. Respirations are shallow when only a small quantity of air passes through the lungs and ventilatory movement is difficult to see. Use more objective techniques if you observe that chest excursion is unusually shallow (see Chapter 30). Table 29-6 summarizes types of breathing patterns.

Ventilatory Rhythm. Determine breathing pattern by observing the chest or the abdomen. Diaphragmatic breathing results from the contraction and relaxation of the diaphragm, and you observe it best by watching abdominal movements. Healthy

BOX 29-9 FACTORS INFLUENCING CHARACTER OF RESPIRATIONS

Exercise
- Exercise increases rate and depth to meet the body's need for additional oxygen and to rid the body of CO_2.

Acute Pain
- Pain alters rate and rhythm of respirations; breathing becomes shallow.
- Patient inhibits or splints chest wall movement when pain is in area of chest or abdomen.

Anxiety
- Anxiety increases respiration rate and depth as a result of sympathetic stimulation.

Smoking
- Chronic smoking changes pulmonary airways, resulting in increased rate of respirations at rest when not smoking.

Body Position
- A straight, erect posture promotes full chest expansion.
- A stooped or slumped position impairs ventilatory movement.
- Lying flat prevents full chest expansion.

Medications
- Opioid analgesics, general anesthetics, and sedative hypnotics depress rate and depth.
- Amphetamines and cocaine sometimes increase rate and depth.
- Bronchodilators slow rate by causing airway dilation.

Neurological Injury
- Injury to brainstem impairs respiratory center and inhibits respiratory rate and rhythm.

Hemoglobin Function
- Decreased hemoglobin levels (anemia) reduce oxygen-carrying capacity of the blood, which increases respiratory rate.
- Increased altitude lowers amount of saturated hemoglobin, which increases respiratory rate and depth.
- Abnormal blood cell function (e.g., sickle cell disease) reduces ability of hemoglobin to carry oxygen, which increases respiratory rate and depth.

TABLE 29-5 Acceptable Ranges of Respiratory Rate

AGE	RATE (BREATHS/MIN)
Newborn	35-40
Infant (6 months)	30-50
Toddler (2 years)	25-32
Child	20-30
Adolescent	16-20
Adult	12-20

men and children usually demonstrate diaphragmatic breathing. Women tend to use thoracic muscles to breathe, assessed by observing movements in the upper chest. Labored respirations usually involve the accessory muscles of respiration visible in the neck. When something such as a foreign body interferes with the movement of air in and out of the lungs, the intercostal spaces retract

TABLE 29-6 Alterations in Breathing Pattern

ALTERATION	DESCRIPTION
Bradypnea	Rate of breathing is regular but abnormally slow (less than 12 breaths/min).
Tachypnea	Rate of breathing is regular but abnormally rapid (greater than 20 breaths/min).
Hyperpnea	Respirations are labored, increased in depth, and increased in rate (greater than 20 breaths/min) (occurs normally during exercise).
Apnea	Respirations cease for several seconds. Persistent cessation results in respiratory arrest.
Hyperventilation	Rate and depth of respirations increase. Hypocarbia sometimes occurs.
Hypoventilation	Respiratory rate is abnormally low, and depth of ventilation is depressed. Hypercarbia sometimes occurs.
Cheyne-Stokes respiration	Respiratory rate and depth are irregular, characterized by alternating periods of apnea and hyperventilation. Respiratory cycle begins with slow, shallow breaths that gradually increase to abnormal rate and depth. The pattern reverses; breathing slows and becomes shallow, climaxing in apnea before respiration resumes.
Kussmaul's respiration	Respirations are abnormally deep, regular, and increased in rate.
Biot's respiration	Respirations are abnormally shallow for two to three breaths followed by irregular period of apnea.

during inspiration. A longer expiration phase is evident when the outward flow of air is obstructed (e.g., asthma).

With normal breathing a regular interval occurs after each respiratory cycle. Infants tend to breathe less regularly. The young child often breathes slowly for a few seconds and then suddenly breathes more rapidly. While assessing respirations, estimate the time interval after each respiratory cycle. Respiration is regular or irregular in rhythm.

Building Competency in Safety You are caring for Mrs. Larkam, a 28-year-old patient with type 1 diabetes who is admitted for pneumonia. Mrs. Larkam is also 7½ months' pregnant with her first child. She requires oxygen via humidified face mask at 28%. Which vital signs do you delegate to nursing assistive personnel (NAP), and in what order should the vital signs be obtained? Which device should be used to obtain her temperature? Positioning is important for Mrs. Larkam to improve her lung function. How do you reposition her when vital signs are obtained?

Answers to questions can be found on the Evolve website.

Assessment of Diffusion and Perfusion

Evaluate the respiratory processes of diffusion and perfusion by measuring the **oxygen saturation** of the blood. Blood flow through the pulmonary capillaries provides red blood cells for oxygen attachment. After oxygen diffuses from the alveoli into the pulmonary blood, most of the oxygen attaches to hemoglobin molecules

FIG. 29-11 Portable pulse oximeter with digit probe.

in red blood cells. Red blood cells carry the oxygenated hemoglobin molecules through the left side of the heart and out to the peripheral capillaries, where the oxygen detaches, depending on the needs of the tissues.

The percent of hemoglobin that is bound with oxygen in the arteries is the percent of saturation of hemoglobin (or SaO_2). It is usually between 95% and 100%. SaO_2 is affected by factors that interfere with ventilation, perfusion, or diffusion (see Chapter 40). The saturation of venous blood (SvO_2) is lower because the tissues have removed some of the oxygen from the hemoglobin molecules. Factors that interfere with or increase tissue oxygen demand affect the usual value for SvO_2, which is 70%.

Measurement of Arterial Oxygen Saturation. A pulse oximeter permits the indirect measurement of oxygen saturation (Skill 29-4 on pp. 478-480). The pulse oximeter is a probe with a light-emitting diode (LED) and photodetector connected by cable to an oximeter (Fig. 29-11). The LED emits light wavelengths that the oxygenated and deoxygenated hemoglobin molecules absorb differently. The photodetector detects the amount of oxygen bound to hemoglobin molecules, and the oximeter calculates the pulse saturation (SpO_2). SpO_2 is a reliable estimate of SaO_2 when the SaO_2 is over 70%. Values obtained with pulse oximetry are less accurate at saturations less than 70%.

The photodetector is in the oximeter probe. Selecting the appropriate probe is important to reduce measurement error. Digit probes are spring loaded and conform to various sizes. Earlobe probes have greater accuracy at lower saturations and are least affected by peripheral vasoconstriction. You can apply disposable sensor pads to a variety of sites, including the bridge of an adult's nose or the sole of an infant's foot. Factors that affect light transmission or peripheral arterial pulsations affect the ability of the photodetector to measure SpO_2 (Box 29-10). An awareness of these factors allows accurate interpretation of abnormal SpO_2 measurements.

Nursing Process and Respiratory Vital Signs

Measurement of respiratory rate, pattern, and depth, along with SpO_2, assesses ventilation, diffusion, and perfusion. You also conduct other assessments to measure respiratory status (see Chapter 30). Use assessment data to determine the nature of a patient's problem. Respiratory assessment data are defining characteristics of many nursing diagnoses, including the following:

- Activity intolerance
- Ineffective airway clearance
- Anxiety
- Ineffective breathing pattern
- Impaired gas exchange
- Acute pain
- Ineffective peripheral tissue perfusion
- Dysfunctional ventilatory weaning response

The nursing care plan includes interventions based on the nursing diagnosis identified and the related factors. For example, the defining characteristics of tachycardia, changes in depth of respirations, use of accessory muscles, dyspnea, and a decline in SpO_2 lead to a diagnosis of *impaired gas exchange.* Related factors could include an infectious process or a history of chronic obstructive lung disease with a 30–pack-year history of smoking. You select interventions based on the related factor. After intervening, evaluate patient outcomes by assessing the respiratory rate, ventilatory depth, rhythm, and SpO_2.

BOX 29-10 FACTORS AFFECTING DETERMINATION OF PULSE OXYGEN SATURATION (SpO_2)

Interference with Light Transmission

- Outside light sources interfere with ability of oximeter to process reflected light.
- Carbon monoxide (caused by smoke inhalation or poisoning) artificially elevates SpO_2 by absorbing light similar to oxygen.
- Patient motion interferes with ability of oximeter to process reflected light.
- Jaundice interferes with ability of oximeter to process reflected light.
- Intravascular dyes (methylene blue) absorb light similar to deoxyhemoglobin and artificially lower saturation.
- Nail polish, artificial nails, or metal studs in nails can interfere with light absorption and the ability of the oximeter to process reflected light (Cicek et al., 2010).
- Dark skin pigment sometimes results in signal loss or overestimation of saturation.

Interference with Arterial Pulsations

- Peripheral vascular disease (atherosclerosis) reduces pulse volume.
- Hypothermia at assessment site decreases peripheral blood flow.
- Pharmacological vasoconstrictors (e.g., epinephrine) decrease peripheral pulse volume.
- Low cardiac output and hypotension decrease blood flow to peripheral arteries.
- Peripheral edema obscures arterial pulsation.
- Tight probe records venous pulsations in finger that compete with arterial pulsations.

BLOOD PRESSURE

Blood pressure is the force exerted on the walls of an artery by the pulsing blood under pressure from the heart. Blood flows throughout the circulatory system because of pressure changes. It moves from an area of high pressure to one of low pressure. Systemic or arterial BP, the BP in the system of arteries in the body, is a good indicator of cardiovascular health. The contraction of the heart forces the blood under high pressure into the aorta. The peak of maximum pressure when ejection occurs is the **systolic pressure.** When the ventricles relax, the blood remaining in the arteries exerts a minimum or **diastolic pressure.** Diastolic pressure is the minimal pressure exerted against the arterial walls at all times.

The standard unit for measuring BP is millimeters of mercury (mm Hg). The measurement indicates the height to which the BP raises a column of mercury. Record BP with the systolic reading before the diastolic reading (e.g., 120/80). The difference between systolic and diastolic pressure is the **pulse pressure.** For a BP of 120/80, the pulse pressure is 40.

Physiology of Arterial Blood Pressure

Blood pressure reflects the interrelationships of cardiac output, peripheral vascular resistance, blood volume, blood viscosity, and artery elasticity. Your knowledge of these hemodynamic variables helps in the assessment of BP alterations.

Cardiac Output. The BP depends on the cardiac output. When volume increases in an enclosed space such as a blood vessel, the pressure in that space rises. Thus, as cardiac output increases, more blood is pumped against arterial walls, causing the BP to rise. Cardiac output increases as a result of an increase in HR, greater heart muscle contractility, or an increase in blood volume. Changes in HR occur faster than changes in heart muscle contractility or blood volume. A rapid or significant increase in HR decreases the filling time of the heart. As a result BP decreases.

Peripheral Resistance. The BP depends on peripheral vascular resistance. Blood circulates through a network of arteries, arterioles, capillaries, venules, and veins. Arteries and arterioles are surrounded by smooth muscle that contracts or relaxes to change the size of the lumen. The size of arteries and arterioles changes to adjust blood flow to the needs of local tissues. For example, when a major organ needs more blood, the peripheral arteries constrict, decreasing their supply of blood. More blood becomes available to the major organ because of the resistance change in the periphery. Normally arteries and arterioles remain partially constricted to maintain a constant flow of blood. Peripheral vascular resistance is the resistance to blood flow determined by the tone of vascular musculature and diameter of blood vessels. The smaller the lumen of a vessel, the greater is the peripheral vascular resistance to blood flow. As resistance rises, arterial BP rises. As vessels dilate and resistance falls, BP drops.

Blood Volume. The volume of blood circulating within the vascular system affects BP. Most adults have a circulating blood volume of 5000 mL. Normally the blood volume remains constant. However, an increase in volume exerts more pressure against arterial walls. For example, the rapid, uncontrolled infusion of IV fluids elevates BP. When circulating blood volume falls, as in the case of hemorrhage or dehydration, BP falls.

Viscosity. The thickness or viscosity of blood affects the ease with which blood flows through small vessels. The **hematocrit,** or percentage of red blood cells in the blood, determines blood viscosity. When the hematocrit rises and blood flow slows, arterial BP increases. The heart contracts more forcefully to move the viscous blood through the circulatory system.

Elasticity. Normally the walls of an artery are elastic and easily distensible. As pressure within the arteries increases, the diameter of vessel walls increases to accommodate the pressure change. Arterial distensibility prevents wide fluctuations in BP. However, in certain diseases such as arteriosclerosis, the vessel walls lose their elasticity and are replaced by fibrous tissue that cannot stretch well. Reduced elasticity results in greater resistance to blood flow. As a result, when the left ventricle ejects its stroke volume, the vessels no longer yield to pressure. Instead a given volume of blood is forced through the rigid arterial walls, and the systemic pressure rises. Systolic pressure is more significantly elevated than diastolic pressure as a result of reduced arterial elasticity.

TABLE 29-7 Average Optimal Blood Pressure for Age

AGE	BLOOD PRESSURE (mm Hg)
Newborn (3000 g [6.6 lb])	40 (mean)
1 month	85/54
1 year	95/65
6 years*	105/65
10-13 years*	110/65
14-17 years*	119/75
18 years and older	<120/<80

From National High Blood Pressure Education Program (NHBPEP); National Heart, Lung, and Blood Institute; National Institutes of Health: The seventh report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure, *JAMA* 289(19):2560, 2003.

*In children and adolescents hypertension is defined as blood pressure that on repeated measurement is at the 95th percentile or greater adjusted for age, height, and gender (NHBPEP, 2003).

Each hemodynamic factor significantly affects the others. For example, as arterial elasticity declines, peripheral vascular resistance increases. The complex control of the cardiovascular system normally prevents any single factor from permanently changing the BP. For example, if the blood volume falls, the body compensates with an increased vascular resistance.

Factors Influencing Blood Pressure

BP is not constant. Many factors continually influence it. One measurement cannot adequately reflect a patient's usual BP. Even under the best conditions, it changes from heartbeat to heartbeat. Blood pressure trends, not individual measurements, guide nursing interventions. Understanding these factors ensures a more accurate interpretation of BP readings.

Age. Normal BP levels vary throughout life (Table 29-7). BP increases during childhood. Evaluate the level of a child's or adolescent's BP with respect to body size and age. An infant's BP ranges from 65 to 115/42 to 80 mm Hg. The normal BP for a 7-year-old is 87 to 117/48 to 64 mm Hg. Larger children (heavier and/or taller) have higher BPs than smaller children of the same age. During adolescence BP continues to vary according to body size.

An adult's BP tends to rise with advancing age. The optimal BP for a healthy, middle-age adult is less than 120/80 mm Hg. Values of 120 to 139/80 to 89 mm Hg are considered prehypertension (NHBPEP, 2003) (Table 29-8). Older adults often have a rise in systolic pressure related to decreased vessel elasticity; however, BP greater than 140/90 is defined as hypertension and increases an older adult's risk for hypertension-related illness.

Stress. Anxiety, fear, pain, and emotional stress result in sympathetic stimulation, which increases HR, cardiac output, and vascular resistance. The effect of sympathetic stimulation increases BP. Anxiety raises BP as much as 30 mm Hg.

Ethnicity. The incidence of hypertension (high BP) is higher in African Americans than in European Americans. African Americans tend to develop more severe hypertension at an earlier age and have twice the risk for complications such as stroke and heart attack. Genetic and environmental factors are often contributing factors. Hypertension-related deaths are also higher among African Americans.

Gender. There is no clinically significant difference in BP levels between boys and girls. After puberty males tend to have

higher BP readings. After menopause women tend to have higher BP levels than men of similar age.

Daily Variation. Blood pressure varies throughout the day, with lower BP during sleep between midnight and 3:00 AM. Between 3:00 AM and 6:00 AM there is a slow and steady rise in BP. When a patient awakens, there is an early-morning BP surge. It is highest during the day between 10:00 AM and 6 PM. No two persons have the same pattern or degree of variation.

Medications. Some medications directly or indirectly affect BP. Before BP assessment ask whether the patient is receiving antihypertensive or other cardiac medications, which lower BP (Table 29-9). Another class of medications affecting BP is opioid analgesics, which can lower it. Vasoconstrictors and an excess volume of IV fluids increase it.

Activity and Weight. A period of exercise can reduce BP for several hours afterwards. Older adults often experience a 5- to 10-mm fall in BP about 1 hour after eating. An increase in oxygen demand by the body during activity increases BP. Inadequate exercise frequently contributes to weight gain, and obesity is a factor in the development of hypertension.

Smoking. Smoking results in vasoconstriction, a narrowing of blood vessels. BP rises when a person smokes and returns to baseline about 15 minutes after stopping smoking.

Hypertension

The most common alteration in BP is **hypertension.** Hypertension is often asymptomatic. Prehypertension is diagnosed in adults when an average of two or more diastolic readings on at least two subsequent visits are between 80 and 89 mm Hg or when the average of multiple systolic BPs on two or more subsequent visits is between 120 and 139 mm Hg. Diastolic readings greater than 90 mm Hg and systolic readings greater than 140 mm Hg (NHBPEP, 2003) define hypertension. Categories of hypertension have been developed (see Table 29-8) and determine medical intervention. One elevated BP measurement does not qualify as a diagnosis of hypertension. However, if a high reading during the first BP measurement (e.g., 150/90 mm Hg) is obtained, the patient is encouraged to return for another checkup within 2 months (Table 29-10).

TABLE 29-8 Classification of Blood Pressure for Adults Ages 18 and Older

CATEGORY	SYSTOLIC (mm Hg)*		DIASTOLIC (mm Hg)*
Normal	<120		<80
Prehypertension†	120-139	or	80-89
Stage 1 hypertension	140-159	or	90-99
Stage 2 hypertension	≥160	or	≥100

Data from National High Blood Pressure Education Program (NHBPEP); National Heart, Lung, and Blood Institute; National Institutes of Health: The seventh report of the Joint National Committee on Detection, Evaluation and Treatment of High Blood Pressure, *JAMA* 289(19):2560, 2003.
*Treatment based on highest category.
†Based on the average of two or more readings taken at each of two or more visits after an initial screening. Patient should not be taking antihypertensive drugs or be acutely ill. When systolic and diastolic blood pressures fall into different categories, select the higher category to classify the individual's blood pressure status. For example, classify 160/92 mm Hg as stage 2 hypertension.

TABLE 29-10 Recommendations for Blood Pressure Follow-up

INITIAL BLOOD PRESSURE	FOLLOW-UP RECOMMENDED*
Normal	Recheck in 2 years.
Prehypertension	Recheck in 1 year.†
Stage 1 hypertension	Confirm within 2 months.†
Stage 2 hypertension	Evaluate or refer to source of care within 1 month. For those with higher pressure (e.g., >180/110 mm Hg), evaluate and treat immediately or within 1 week, depending on clinical situation and complications.

Data from National High Blood Pressure Education Program (NHBPEP); National Heart, Lung, and Blood Institute; National Institutes of Health: The seventh report of the Joint National Committee on Detection, Evaluation and Treatment of High Blood Pressure, *JAMA* 289(19):2560, 2003.
*Modify the scheduling of follow-up according to reliable information about past blood pressure measurements, other cardiovascular risk factors, or target organ damage.
†Provide advice about lifestyle modifications.

TABLE 29-9 Antihypertensive Medications

MEDICATION TYPE	NAMES	ACTION
Diuretics	Furosemide (Lasix), spironolactone (Aldactone), metolazone, polythiazide, benzthiazide	Lowers blood pressure by reducing resorption of sodium and water by the kidneys, thus lowering circulating fluid volume
Beta-adrenergic blockers	Atenolol (Tenormin), nadolol (Corgard), timolol maleate (Blocadren), propranolol (Inderal)	Combines with beta-adrenergic receptors in the heart, arteries, and arterioles to block response to sympathetic nerve impulses; reduces heart rate and thus cardiac output
Vasodilators	Hydralazine hydrochloride (Apresoline), minoxidil (Loniten)	Acts on arteriolar smooth muscle to cause relaxation and reduce peripheral vascular resistance
Calcium channel blockers	Diltiazem (Cardizem, Dilacor XR), verapamil hydrochloride (Calan SR), nifedipine (Procardia), nicardipine (Cardene)	Reduces peripheral vascular resistance by systemic vasodilation
Angiotensin-converting enzyme (ACE) inhibitors	Captopril (Capoten), enalapril (Vasotec), lisinopril (Prinivil, Zestril), benazepril (Lotensin)	Lowers blood pressure by blocking the conversion of angiotensin I to angiotensin II, preventing vasoconstriction; reduces aldosterone production and fluid retention, lowering circulating fluid volume
Angiotensin-II receptor blockers (ARBs)	Losartan (Cozaar), olmesartan (Benicar)	Lowers blood pressure by blocking the binding of angiotensin II, which prevents vasoconstriction

Hypertension is associated with thickening and loss of elasticity in the arterial walls. Peripheral vascular resistance increases within thick and inelastic vessels. The heart continually pumps against greater resistance. As a result blood flow to vital organs such as the heart, brain, and kidney decreases.

Persons with a family history of hypertension are at significant risk. Modifiable risk factors include obesity, cigarette smoking, heavy alcohol consumption, and high sodium (salt) intake. Sedentary lifestyle and continued exposure to stress are also linked to hypertension. The incidence of hypertension is greater in patients with diabetes, older adults, and African Americans. It is a major factor underlying deaths from strokes and is a contributing factor to myocardial infarctions (heart attacks). When patients are diagnosed with hypertension, educate them about BP values, long-term follow-up care and therapy, the usual lack of symptoms (the fact that it may not be "felt"), the ability of therapy to control but not cure it, and a consistently followed treatment plan that ensures a relatively normal lifestyle (NHBPEP, 2003).

Hypotension

Hypotension is present when the systolic BP falls to 90 mm Hg or below. Although some adults have a low BP normally, for most people low BP is an abnormal finding associated with illness.

Hypotension occurs because of the dilation of the arteries in the vascular bed, the loss of a substantial amount of blood volume (e.g., hemorrhage), or the failure of the heart muscle to pump adequately (e.g., myocardial infarction). Hypotension associated with pallor, skin mottling, clamminess, confusion, increased HR, or decreased urine output is life threatening and is reported to a health care provider immediately.

Orthostatic hypotension, also referred to as **postural hypotension,** occurs when a normotensive person develops symptoms and low BP when rising to an upright position. When a healthy individual changes from a lying–to sitting–to standing position, the peripheral blood vessels in the legs constrict. When standing the lower-extremity vessels constrict, preventing the pooling of blood in the legs caused by gravity. Thus an individual normally does not feel any symptoms when standing. In contrast, when patients have a decreased blood volume, their blood vessels are already constricted. When a patient with volume depletion stands, there is a significant drop in BP with an increase in HR to compensate for the drop in cardiac output. Patients who are dehydrated, anemic, or have experienced prolonged bed rest or recent blood loss are at risk for orthostatic hypotension. Some medications cause orthostatic hypotension if misused, especially in older adults or young patients. Always measure BP before administering such medications.

Assess for orthostatic hypotension during measurements of vital signs by obtaining BP and pulse with the patient supine, sitting, and standing. Obtain BP readings 1 to 3 minutes after the patient changes position. In most cases orthostatic hypotension is detected within a minute of standing. If it occurs, assist the patient to a lying position and notify the health care provider or nurse in charge. While obtaining orthostatic measurements, observe for other symptoms of hypotension such as fainting, weakness, or light-headedness. When recording orthostatic BP measurements, record the patient's position in addition to the BP measurement (e.g., 140/80 mm Hg supine, 132/72 mm Hg sitting, 108/60 mm Hg standing). The skill of orthostatic measurements requires critical thinking and ongoing nursing judgment when determining a patient's response to repositioning. Do not delegate this procedure.

Measurement of Blood Pressure

Arterial BP measurements are obtained either directly (invasively) or indirectly (noninvasively). The direct method requires the insertion of a thin catheter into an artery. Tubing connects the catheter with electronic hemodynamic monitoring equipment. The monitor displays a constant arterial pressure waveform and reading. Because of the risk of sudden blood loss from an artery, invasive BP monitoring is used only in intensive-care settings. The common indirect method requires a sphygmomanometer and stethoscope. Auscultation or palpation with auscultation is the most widely used technique (Skill 29-5 on pp. 480-484).

Blood Pressure Equipment. Before assessing BP, make sure that you are comfortable using a sphygmomanometer and stethoscope. A **sphygmomanometer** includes a pressure manometer, an occlusive cloth or vinyl cuff that encloses an inflatable rubber bladder, and a pressure bulb with a release valve that inflates the bladder (Fig. 29-12). The aneroid manometer has a glass-enclosed circular gauge containing a needle that registers millimeter calibrations. Before using the aneroid model, make sure that the needle points to zero and that the manometer is correctly calibrated. Aneroid sphygmomanometers require biomedical calibration every 6 months to verify their accuracy.

Cloth or disposable vinyl compression cuffs contain an inflatable bladder and come in different sizes. The size selected is proportional to the circumference of the limb being assessed (Fig. 29-13). Ideally the width of the cuff is 40% of the circumference (or 20% wider than the diameter) of the midpoint of the limb on which the cuff is used to measure BP. The bladder, enclosed by the cuff, encircles at least 80% of the upper arm of an adult and the entire arm of a child. Place the lower edge of the cuff above the antecubital fossa, allowing room for positioning the stethoscope bell or diaphragm. Many adults require a large adult cuff. Using the forearm when a larger cuff is not readily available is not recommended. An improperly fitting cuff causes inaccurate BP measurements (Table 29-11).

The release valve of the sphygmomanometer needs to be clean and freely movable in either direction. A closed valve holds the pressure constant. A sticky valve makes pressure cuff deflation hard to regulate.

FIG. 29-12 Wall-mounted aneroid sphygmomanometer.

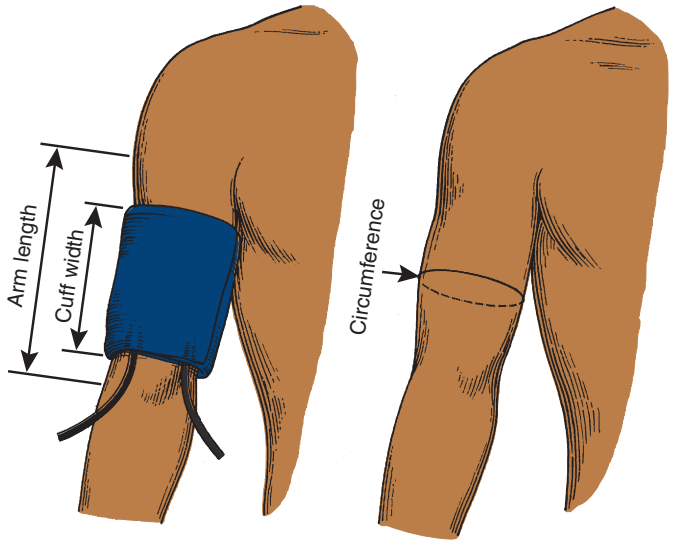

FIG. 29-13 Guidelines for proper blood pressure cuff size. Cuff width 20% more than upper-arm diameter or 40% of circumference and two thirds of arm length.

TABLE 29-11 Common Errors in Blood Pressure Assessment

ERROR	EFFECT
Bladder or cuff too wide	False-low reading
Bladder or cuff too narrow or too short	False-high reading
Cuff wrapped too loosely or unevenly	False-high reading
Deflating cuff too slowly	False-high diastolic reading
Deflating cuff too quickly	False-low systolic and false-high diastolic reading
Arm below heart level	False-high reading
Arm above heart level	False-low reading
Arm not supported	False-high reading
Stethoscope that fits poorly or impairment of examiner's hearing, causing sounds to be muffled	False-low systolic and false-high diastolic reading
Stethoscope applied too firmly against antecubital fossa	False-low diastolic reading
Inflating too slowly	False-high diastolic reading
Repeating assessments too quickly	False-high systolic reading
Inadequate inflation level	False-low systolic reading
Multiple examiners using different Korotkoff sounds for diastolic readings	False-high systolic and false-low diastolic reading

Auscultation. The best environment for BP measurement by auscultation is a quiet room at a comfortable temperature. Although the patient may lie or stand, sitting is the preferred position. In most cases BP readings obtained with the patient in the supine, sitting, and standing positions are similar.

The patient's position during routine BP determination needs to be the same during each measurement to permit a meaningful comparison of values. Before obtaining the patient's BP, attempt to control factors responsible for artificially high readings such as pain, anxiety, or exertion. The patient's perception that the physical or interpersonal environment is stressful affects the BP measurement. BP measurements taken at the patient's place of employment or in a health care provider's office are higher than those taken at the patient's home.

During the initial assessment obtain and record the BP in both arms. Normally there is a difference of 5 to 10 mm Hg between the arms. In subsequent assessments measure the BP in the arm with the higher pressure. Pressure differences greater than 10 mm Hg indicate vascular problems and are reported to the health care provider or nurse in charge.

Ask the patient to state his or her usual BP. If the patient does not know, inform him or her after measuring and recording it. This is a good opportunity to educate a patient about optimal values of BP, risk factors for developing hypertension, and dangers of hypertension.

Indirect measurement of arterial BP works on a basic principle of pressure. Blood flows freely through an artery until an inflated cuff applies pressure to tissues and causes the artery to collapse. After releasing the cuff pressure, the point at which blood flow returns and sound appears through auscultation is the systolic pressure.

In 1905 Korotkoff, a Russian surgeon, first described the sounds heard over an artery distal to the BP cuff. The first Korotkoff sound is a clear rhythmical tapping corresponding to the pulse rate that gradually increases in intensity. *Onset of the sound corresponds to the systolic pressure.* A blowing or swishing sound occurs as the cuff continues to deflate, resulting in the second Korotkoff sound. As the artery distends there is turbulence in blood flow. The third Korotkoff sound is a crisper and more intense tapping. The fourth Korotkoff sound becomes muffled and low pitched as the cuff is further deflated. At this point the cuff pressure has fallen below the pressure within the vessel walls; *this sound is the diastolic pressure in infants and children.* The fifth Korotkoff sound marks the disappearance of sound. *In adolescents and adults the fifth sound corresponds with the diastolic pressure* (Fig. 29-14). In some patients the sounds are clear and distinct. In others only the beginning and ending sounds are clear.

The American Heart Association recommends recording two numbers for a BP measurement: the point on the manometer when you hear the first sound for systolic and the point on the manometer when you hear the fifth sound for diastolic. Some institutions recommend recording the point when you hear the fourth sound as well, especially for patients with hypertension. Divide the numbers by slashed lines (e.g., 120/70 or 120/100/70). Note the arm used to measure the BP (e.g., right arm [RA] 130/70) and the patient's position (e.g., sitting).

BP assessment results in many medical decisions and nursing interventions. Obtaining an accurate measurement is essential. There are several sources for error (see Table 29-11). When you are unsure of a reading, have a colleague reassess the BP.

Assessment in Children. All children 3 years of age through adolescence need to have BP checked at least annually. BP in children changes with growth and development. Help parents understand the importance of this routine screening to detect children who are at risk for hypertension. The measurement of BP in infants and children is difficult for several reasons:

- Different arm size requires careful and appropriate cuff size selection. Do not choose a cuff based on the name of the cuff. An "infant" cuff is often too small for some infants.
- Readings are difficult to obtain in restless or anxious infants and children. Allow at least 15 minutes for children to

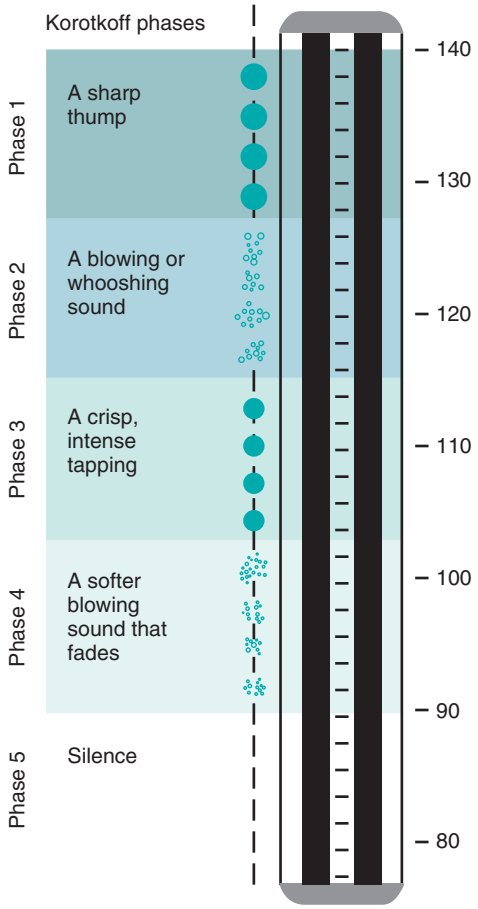

FIG. 29-14 The sounds auscultated during blood pressure measurement can be differentiated into five Korotkoff phases. In this example blood pressure is 140/90 mm Hg.

recover from recent activities and become less apprehensive. Preparing the child for the unusual sensation of the BP cuff increases cooperation. Most children understand the analogy of a "tight hug on your arm."

- Placing the stethoscope too firmly on the antecubital fossa causes errors in auscultation.
- Korotkoff sounds are difficult to hear in children because of low frequency and amplitude. A pediatric stethoscope bell is often helpful.

Ultrasonic Stethoscope. When you are unable to auscultate sounds because of a weakened arterial pulse, you can use an ultrasonic stethoscope (see Chapter 30). This stethoscope allows you to hear low-frequency systolic sounds. You frequently use this device when measuring the BP of infants and children and low BP in adults.

Palpation. Indirect measurement of BP by palpation is useful for patients whose arterial pulsations are too weak to create Korotkoff sounds. Severe blood loss and decreased heart contractility are examples of conditions that result in BPs too low to auscultate accurately. In these cases you can assess the systolic BP by palpation (Box 29-11). The diastolic BP is difficult to determine by palpation. When using the palpation technique, record the systolic value and how you measured it (e.g., RA 90/-, palpated, supine).

You can use the palpation technique along with auscultation. In some patients with hypertension the sounds usually heard over the brachial artery when the cuff pressure is high disappear as pressure is reduced and then reappear at a lower level. This temporary

BOX 29-11 PROCEDURAL GUIDELINES

Palpating Systolic Blood Pressure

Delegation Considerations

The skill of palpation of blood pressure (BP) cannot be delegated to nursing assistive personnel.

Equipment

Sphygmomanometer

1. Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.
2. Perform hand hygiene.
3. Apply BP cuff to extremity selected for measurement.
4. Continually palpate pulse of brachial, radial, or popliteal artery with fingertips of one hand.
5. Inflate BP cuff 30 mm Hg above point at which you no longer can palpate the pulse.
6. Slowly release valve and deflate cuff, allowing manometer needle mercury to fall 2 mm Hg per second.
7. Note point on manometer when pulse is again palpable; this is the systolic BP.
8. Deflate cuff rapidly and completely. Remove cuff from patient extremity unless you need to repeat the measurement.
9. Perform hand hygiene.
10. Record BP as systolic/-, palpated (e.g., BP 108/-, palpated) on vital sign flow sheet, in nurses' notes, or electronic medical record. Report abnormal findings to nurse in charge or health care provider.

disappearance of sound is the **auscultatory gap.** It typically occurs between the first and second Korotkoff sounds. The gap in sound covers a range of 40 mm Hg and thus causes an underestimation of systolic pressure or overestimation of diastolic pressure. The examiner needs to be certain to inflate the cuff high enough to hear the true systolic pressure before the auscultatory gap. Palpation of the radial artery helps to determine how high to inflate the cuff. The examiner inflates the cuff 30 mm Hg above the pressure at which the radial pulse was palpated. Record the range of pressures in which the auscultatory gap occurs (e.g., BP RA 180/94 mm Hg with an auscultatory gap from 180 to 160 mm Hg, sitting).

Lower-Extremity Blood Pressure. Dressings, casts, IV catheters, or arteriovenous fistulas or shunts make the upper extremities inaccessible for BP measurement. You then need to obtain the BP in a lower extremity. Comparing upper-extremity BP with that in the legs is also necessary for patients with certain cardiac and BP abnormalities. The popliteal artery, palpable behind the knee in the popliteal space, is the site for auscultation. The cuff needs to be wide and long enough to allow for the larger girth of the thigh. Placing the patient in a prone position is best. If such a position is impossible, ask the patient to flex the knee slightly for easier access to the artery. Position the cuff 2.5 cm (1 inch) above the popliteal artery, with the bladder over the posterior aspect of the midthigh (Fig. 29-15). The procedure is identical to brachial artery auscultation. Systolic pressure in the legs is usually higher by 10 to 40 mm Hg than in the brachial artery, but the diastolic pressure is the same.

Electronic Blood Pressure Devices. Many different styles of electronic BP machines are available to determine BP automatically (Fig. 29-16). Electronic BP machines rely on an electronic sensor to detect the vibrations caused by the rush of blood through an artery (Box 29-12). Use electronic devices when frequent BP assessment is necessary such as in patients who are critically ill or unstable, during or after invasive procedures, or when therapies

BOX 29-12 PROCEDURAL GUIDELINES

Electronic Blood Pressure Measurement

Delegation Considerations

The skill of obtaining an electronic blood pressure (BP) measurement can be delegated to nursing assistive personnel (NAP). However, an RN must first verify that the patient is stable and does not need to be closely monitored for evaluating response to medications. Instruct the NAP to:

- Select appropriate limb for BP measurement.
- Select appropriate-size BP cuff for designated limb.
- Obtain BP measurement for select patient with ordered frequency.
- Report abnormalities to nurse for further assessment.

Equipment

Electronic BP machine, BP cuff of appropriate size as recommended by manufacturer.

1. Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.
2. Determine appropriateness of using electronic BP measurement. Patients with irregular heart rate, peripheral vascular disease, seizures, tremors, and shivering are not candidates for this device (Bern et al., 2007).
3. Determine best site for cuff placement (see Skill 29-5, Step 3).
4. Perform hand hygiene. Assist patient to comfortable position, either lying or sitting. Plug in device and place it near patient, ensuring that connector hose between cuff and machine will reach.
5. Locate on/off switch and turn machine on to enable device to self-test computer systems.
6. Select appropriate cuff size for patient extremity (see Table 29-11) and appropriate cuff for machine. Electronic BP machines are vulnerable to error among older adults and obese patients (Heinemann et al., 2008). Electronic BP cuff and machine are matched by the manufacturer and are not interchangeable.
7. Expose extremity for measurement by removing restrictive clothing to ensure proper cuff application. Do not place BP cuff over clothing.
8. Prepare BP cuff by manually squeezing all the air out of cuff and connecting it to connector hose.
9. Wrap flattened cuff snugly around extremity, verifying that only one finger fits between cuff and patient's skin. Make sure that "artery" arrow marked on outside of cuff is placed correctly (see illustration for Skill 29-5, Step 4).
10. Verify that connector hose between cuff and machine is not kinked. Kinking prevents proper inflation and deflation of cuff.
11. Following manufacturer directions, set frequency control of automatic or manual and press start button. The first BP measurement pumps cuff to pressure of approximately 180 mm Hg. After this pressure is reached, the machine begins a deflation sequence that determines BP. The first reading determines peak pressure inflation for additional measurements.

    CLINICAL DECISION: If unable to obtain BP with electronic device, verify machine connections (e.g., plugged into working electrical outlet, hose-cuff connections tight, machine on, correct cuff). Repeat electronic BP; if unable to obtain, use auscultatory technique (see Skill 29-5).

12. When deflation is complete, digital display provides most recent values and flash time in minutes that has elapsed since measurement occurred.
13. Set frequency of BP measurements and upper and lower alarm limits for systolic, diastolic, and mean BP readings. Intervals between BP measurements are set from 1 to 90 minutes. Determine measurement frequency and alarm limits based on patient's acceptable range of BP, nursing judgment, and health care provider order.
14. Obtain additional readings at any time by pressing start button. (Sometimes you need these for unstable patients.) Pressing cancel button immediately deflates cuff.
15. If frequent BP determinations are necessary, leave cuff in place. Remove cuff at least every 2 hours to assess underlying skin integrity and, if possible, alternate BP sites. Patients with abnormal bleeding tendencies are at risk for microvascular rupture from repeated inflations. When patient no longer requires electronic BP machine, clean BP cuff according to facility policy to reduce transmission of microorganisms.
16. Compare electronic BP readings with auscultatory BP to verify accuracy of electronic BP device.
17. Record BP and site assessed on vital sign flow sheet, in nurses' notes, or electronic medical record (per agency policy). Record any signs of BP alterations in nurses' notes. Report abnormal findings to nurse in charge or health care provider.

BOX 29-13 PATIENT CONDITIONS NOT APPROPRIATE FOR ELECTRONIC BLOOD PRESSURE MEASUREMENT

- Irregular heart rate
- Peripheral vascular obstruction (e.g., clots, narrowed vessels)
- Shivering
- Seizures
- Excessive tremors
- Inability to cooperate
- Blood pressure less than 90 mm Hg systolic

require frequent monitoring (e.g., IV heart and BP medications). Box 29-13 lists conditions that are not appropriate for automatic BP devices.

The advantages of automatic devices are the ease of use and efficiency when repeated or frequent measurements are indicated. The ability to use a stethoscope is not necessary. However, automatic devices are more sensitive to outside interference and susceptible to error. Most electronic BP devices are unable to process sounds or vibrations of low BP. The range of device sophistication also makes BP measurement comparisons difficult. The use of automatic BP devices permits assessment of BP during interpersonal interactions. Talking to a patient while assessing the BP increases readings 10% to 40%.

Self-Measurement of Blood Pressure. Improved technology in electronic monitoring devices allows individuals to measure their own BPs in their home with the push of a button. The portable home devices include the aneroid sphygmomanometer and electronic digital readout devices that do not require use of a stethoscope. The electronic devices are easier to manipulate but require frequent recalibration, more than once a year. Because of their sensitivity, improper cuff placement or movement of the arm causes electronic devices to give incorrect readings.

Stationary automatic BP devices are often found in public places such as grocery stores, fitness clubs, airports, or work sites. Users simply rest their arms within the inflatable cuff of the machine, which contains a pressure sensor. The cuff fits over clothing. A visual display tells users their BP within 60 to 90 seconds. The reliability of the stationary machines is limited. BP values vary by 5 to 10 mm Hg or more (for both systolic and diastolic values) compared with pressures taken with a manual sphygmomanometer.

Self-measurement of BP has several benefits. Sometimes elevated BP is detected in persons previously unaware of a problem. Persons with prehypertension provide information about the pattern of BP values to their health care provider. Patients with hypertension benefit from participating actively in their treatment through self-monitoring, which helps adherence with treatment. The disadvantages of self-measurement include improper use of the device and risk of inaccurate readings. Some patients are needlessly alarmed with one elevated reading. Some patients with hypertension become overly conscious of their BP and inappropriately self-adjust medications.

Consumers can learn to use self-measurement devices if they have the information needed to perform the procedure correctly and if they know when to seek medical attention. Advise patients of possible inaccuracies in the BP devices, help them understand the meaning and implications of readings, and teach them proper measurement techniques. Encourage them to record the date of their BP readings to assess BP over time and share findings with their health care provider.

BOX 29-14 PATIENT TEACHING

Health Promotion

Objective

- Patient verbalizes measures to promote health.

Teaching Strategies

- Explain measures to prevent body temperature alterations.
- Instruct patients on risk factors for hypothermia, frostbite, and heat stroke. Demonstrate self-assessment of heart rate using the carotid pulse. Patients taking certain prescribed cardiac medications need to learn to assess their own pulse rate to detect side effects of medications. Patients undergoing cardiac rehabilitation need to learn to assess their own pulse rate to determine their response to exercise.
- Instruct patients on normal blood pressure values, risk factors for hypertension, usual lack of hypertension symptoms, ability of therapy to control but not cure, and benefits of a consistently followed hypertension treatment plan.
- Demonstrate how to obtain blood pressure to the patient's family caregiver using an appropriate-size blood pressure cuff for home use at the same time each day, after patient has had a brief rest, and the same position and arm each time pressure is taken.
- Instruct patient on signs and symptoms of hypoxemia.
- Instruct patient on the effect of cigarette smoking on oxygen saturation.

Evaluation

- Observe patient's ability to initiate preventive health measures to prevent body temperature alterations.
- Assess patient's accuracy in obtaining pulse rate.
- Assess family caregiver's accuracy in obtaining blood pressure.

Nursing Process and Blood Pressure Determination

The assessment of BP along with pulse assessment evaluates the general state of cardiovascular health and responses to other system imbalances. Hypotension, hypertension, orthostatic hypotension, and narrow or wide pulse pressures are defining characteristics of certain nursing diagnoses, including the following:

- Activity intolerance
- Anxiety
- Decreased cardiac output
- Deficient/excess fluid volume
- Risk for injury
- Acute pain
- Ineffective peripheral tissue perfusion

The nursing care plan includes interventions based on the nursing diagnosis identified and the related factors. For example, the defining characteristics of hypotension, dizziness, pulse deficit, and dysrhythmia lead to a diagnosis of *decreased cardiac output.* Related factors might include poor oral intake, excessive heat exposure, and a history of valvular heart disease. The related factor guides the choice of nursing interventions. Evaluate patient outcomes by assessing the BP following each intervention.

HEALTH PROMOTION AND VITAL SIGNS

The emphasis on health promotion and maintenance and discharge from hospital settings has resulted in an increase in the need for patients and their families to monitor vital signs in the home. Teaching considerations affect all vital sign measurements. Incorporate them within the patient's plan of care (Box 29-14).

BOX 29-15 FOCUS ON OLDER ADULTS

Factors Affecting Vital Signs of Older Adults

Temperature

- The temperature of older adults is at the lower end of the normal temperature range, 36° to 36.8° C (96.8° to 98.3° F) orally and 36.6° to 37.2° C (98° to 99° F) rectally. Therefore temperatures considered within normal range sometimes reflect a fever in an older adult. In an older adult fever is present when a single oral temperature is over 37.8° C (100° F); repeated oral temperatures are over 37.2° C (99° F); rectal temperatures are over 37.5° C (99.5° F); or temperature has increased more than 1° C (2° F) over baseline (High et al., 2009).
- Older adults are very sensitive to slight changes in environmental temperature because their thermoregulatory systems are not as efficient.
- A decrease in sweat gland reactivity in the older adult results in a higher threshold for sweating at high temperatures, which leads to hyperthermia and heatstroke.
- Be especially attentive to subtle temperature changes and other manifestations of fever in this population such as tachypnea, anorexia, falls, delirium, and overall functional decline.
- With aging loss of subcutaneous fat reduces the insulating capacity of the skin; older men are especially high risk for hypothermia.

Pulse Rate

- If it is difficult to palpate the pulse of an obese older adult, a Doppler device provides a more accurate reading.
- The older adult has a decreased heart rate at rest.
- It takes longer for the heart rate to rise in the older adult to meet sudden increased demands that result from stress, illness, or excitement. Once elevated, the pulse rate of an older adult takes longer to return to normal resting rate.
- When assessing the apical rate of an older woman, the breast tissue is gently lifted, and the stethoscope placed at the fifth intercostal space (ICS) or the lower edge of the breast.
- Heart sounds are sometimes muffled or difficult to hear in older adults because of an increase in air space in the lungs.

Blood Pressure

- Older adults often have decreased upper arm mass, which requires special attention to selection of blood pressure cuff size.
- Older adults sometimes have an increase in systolic pressure related to decreased vessel elasticity while the diastolic pressure remains the same, resulting in a wider pulse pressure.
- Instruct older adults to change position slowly and wait after each change to avoid postural hypotension and prevent injuries.

Respirations

- Aging causes ossification of costal cartilage and downward slant of ribs, resulting in a more rigid rib cage, which reduces chest wall expansion. Kyphosis and scoliosis that occur in older adults also restrict chest expansion and decrease tidal volume.
- Older adults depend more on accessory abdominal muscles during respiration than on weaker thoracic muscles.
- The respiratory system matures by the time a person reaches 20 years of age and begins to decline in healthy people after the age of 25. Despite this decline older adults are able to breathe effortlessly as long as they are healthy. However, sudden events that require an increased demand for oxygen (e.g., exercise, stress, illness) create shortness of breath in the older adult.
- Identifying an acceptable pulse oximeter probe site is difficult with older adults because of the likelihood of peripheral vascular disease, decreased cardiac output, cold-induced vasoconstriction, and anemia.

When considering how to teach patients and their families about vital sign measurements and their importance and significance, a patient's age is an important factor. With an increase in the older-adult population there is a greater need for family caregivers to be aware of changes that are unique to older adults. Box 29-15 identifies some of these variations.

RECORDING VITAL SIGNS

Special electronic and paper graphic flow sheets exist for recording vital signs (see Chapter 26). Identify institution procedure for documenting on a graphic. In addition to the actual vital sign values, record in the nurses' notes any accompanying or precipitating symptoms such as chest pain and dizziness with abnormal BP, shortness of breath with abnormal respirations, cyanosis with hypoxemia, or flushing and diaphoresis with elevated temperature. Document any interventions initiated as a result of vital sign measurement such as administration of oxygen therapy, hydration, or an antihypertensive medication.

Patients being managed on critical paths or CareMaps often have vital sign values listed as outcomes. If a vital sign value is above or below the anticipated outcomes, write a variance note to explain the nature of the variance and the nursing course of action. For example, a CareMap for a patient who has undergone lung surgery often has an outcome during the postoperative period of "afebrile." If the patient has a fever, the nurse's variance note addresses possible sources of fever (e.g., retained pulmonary secretions) and nursing interventions (e.g., increased suctioning, postural drainage, or hydration).

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient-centered care.

- Devices for measuring vital signs are often shared among patients. Cleaning each device carefully between patients decreases patients' risk of infection.
- BP cuffs and pulse oximetry sensors can apply excessive pressure on fragile skin. Rotating sites during repeated measurements decreases risk for skin breakdown.
- Analyze the trends for measuring vital signs and report abnormal findings to the health care provider.
- Determine frequency of measuring vital signs based on the patient's condition.

SKILL 29-1 MEASURING BODY TEMPERATURE

View Video!

Delegation Considerations

The skill of temperature measurement can be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Select appropriate route and device to measure temperature.
- Take appropriate precautions when properly positioning the patient for rectal temperature measurement.
- Consider specific patient-related factors that falsely raise or lower temperature.
- Obtain temperature measurement at ordered frequency.
- Be aware of the usual values for patient.
- Report abnormalities to the nurse for further assessment.

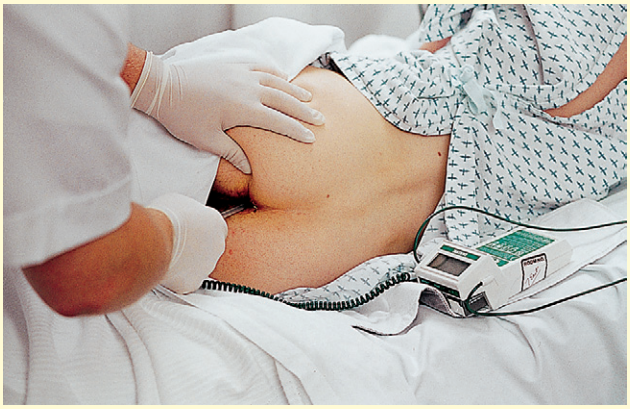
Equipment

- Appropriate thermometer (see Box 29-4)
- Soft tissue or wipe
- Lubricant (for rectal measurements only)
- Pen, vital sign flow sheet, or record or patient's electronic medical record
- Clean gloves, plastic thermometer sleeve, disposable probe or sensor cover
- Towel

STEP	RATIONALE
ASSESSMENT	
1 Assess for signs and symptoms of temperature alterations and factors that influence body temperature.	Physical signs and symptoms indicate abnormal temperature. Enables you to accurately assess the nature of variations.
2 Determine previous activity that interferes with accuracy of temperature measurement. When taking oral temperature, wait 20 to 30 minutes before measuring temperature if patient has smoked or ingested hot or cold liquids or foods.	Smoking, mouth breathing, and oral intake cause false oral temperature readings (Henker and Carlson, 2007).
3 Determine appropriate temperature site and device for patient.	Site is chosen based on advantages and disadvantages of each site (see Box 29-4). Use disposable single-use thermometer for patient on isolation precautions.
PLANNING	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Explain route by which temperature will be taken and importance of maintaining proper position until reading is complete.	Patients are often curious about such measurements and need to be cautioned against prematurely removing thermometer to read results.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Assist patient in assuming comfortable position that provides easy access to temperature measurement site.	Ensures comfort and accuracy of temperature reading.
3 Obtain temperature reading.	
a. **Oral temperature measurement with electronic thermometer**	
(1) Apply clean gloves (optional).	Use of oral probe cover, which you can remove without physical contact, minimizes need to wear gloves.
(2) Remove thermometer pack from charging unit. Attach oral thermometer probe stem (blue tip) to thermometer unit. Grasp top of probe stem, being careful not to apply pressure on the ejection button.	Charging provides battery power. Ejection button releases plastic probe cover from probe stem.

SKILL 29-1 MEASURING BODY TEMPERATURE—cont'd

STEP	RATIONALE
(3) Slide disposable plastic probe cover over thermometer probe stem until cover locks in place (see illustrations).	Soft plastic cover will not break in patient's mouth and prevents transmission of microorganisms between patients.
(4) Ask patient to open mouth; gently place thermometer probe under tongue in posterior sublingual pocket lateral to center of lower jaw (see illustration).	Heat from superficial blood vessels in sublingual pocket produces temperature reading. With electronic thermometer, temperatures in right and left posterior sublingual pocket are significantly higher than in area under front of tongue.
(5) Ask patient to hold thermometer probe with lips closed.	Closed lips maintain proper position of thermometer during recording.
(6) Leave thermometer probe in place until audible signal indicates completion and temperate reading appears on digital display; remove thermometer probe from under patient's tongue.	Probe needs to stay in place until signal occurs to ensure accurate reading.
(7) Push ejection button on thermometer probe stem to discard plastic probe cover into appropriate receptacle.	Reduces transmission of microorganisms.
(8) Return thermometer probe stem to storage position of recording unit.	Storage position protects probe stem. Returning probe stem automatically causes digital reading to disappear.
(9) If gloves are worn, remove and dispose in appropriate receptacle. Perform hand hygiene.	Hand hygiene reduces transmission of microorganisms.
(10) Return thermometer to charger.	Charger maintains battery charge.



STEP 3a(3) Disposable plastic cover is placed over probe.

STEP 3a(4) Probe under tongue in posterior sublingual pocket.

STEP	RATIONALE
b. Rectal temperature measurement with electronic thermometer	
(1) Draw curtain around bed and/or close room door. Assist patient to Sims' position with upper leg flexed. Move aside bed linen to expose only anal area. Keep patient's upper body and lower extremities covered with sheet or blanket.	Maintains patient's privacy, minimizes embarrassment, and promotes comfort. Exposes anal area for correct thermometer placement.
(2) Apply clean gloves.	Maintains standard precautions when exposed to items soiled with body fluids (e.g., feces).
(3) Remove thermometer pack from charging unit. Attach rectal probe stem (red tip) to thermometer unit. Grasp top of probe stem, being careful not to apply pressure on the ejection button.	Charging provides battery power. Ejection button releases plastic cover from probe stem.
(4) Slide disposable plastic probe cover over thermometer probe stem until cover locks in place.	Soft plastic probe cover prevents transmission of microorganisms between patients.
(5) Squeeze liberal portion of lubricant on tissue. Dip end of probe cover into lubricant, covering 2.5 to 3.5 cm (1 to 1½ inches) for adult.	Lubrication minimizes trauma to rectal mucosa during insertion. Tissue avoids contamination of remaining lubricant in container.
(6) With nondominant hand, separate patient's buttocks to expose anus. Ask patient to breathe slowly and relax.	Fully exposes anus for thermometer insertion. Relaxes anal sphincter for easier thermometer insertion.
(7) Gently insert thermometer probe into anus in direction of umbilicus 2.5 to 3.5 cm (1 to 1½ inches) for adult. Do not force thermometer.	Ensures adequate exposure against blood vessels in rectal wall.
CLINICAL DECISION: *If you cannot adequately insert thermometer into rectum, remove it and consider alternative method for obtaining temperature.*	
(8) Once positioned, hold thermometer probe in place (see illustration) until audible signal indicates completion and patient's temperature appears on digital display; remove thermometer probe from anus.	Probe needs to stay in place until signal occurs to ensure accurate reading.

STEP 3b(8) Probe position in anus.

(9) Push ejection button on thermometer stem to discard plastic probe cover into appropriate receptacle. Wipe probe stem with alcohol swab, paying particular attention to ridges where probe stem cover connects to probe.	Reduces transmission of microorganisms.
(10) Return thermometer probe stem to storage position of recording unit.	Protects probe stem from damage. Returning probe stem automatically causes digital reading to disappear.
(11) Wipe patient's anal area with soft tissue to remove lubricant or feces and discard tissue. Help patient assume a comfortable position.	Provides for comfort and hygiene.
(12) Remove and dispose of gloves in appropriate receptacle. Perform hand hygiene.	Reduces transmission of microorganisms.
(13) Return thermometer to charger. Verify that charger and probes are wiped with alcohol daily.	Maintains battery charge of thermometer unit. Reduces transmission of microorganisms.
c. Axillary temperature measurement with electronic thermometer	
(1) Draw curtain around bed and/or close door. Assist patient to a supine or sitting position. Move clothing or gown away from shoulder and arm.	Maintains patient's privacy, minimizes embarrassment. Position provides easy access to axilla. Exposes axilla for correct thermometer probe placement.
(2) Remove thermometer pack from charging unit. Be sure that oral probe stem (blue tip) is attached to thermometer unit. Grasp top of thermometer probe stem, being careful not to apply pressure on ejection button.	Charging provides battery power. Ejection button releases plastic cover from probe.
(3) Slide disposable plastic probe cover over thermometer stem until cover locks in place.	Soft plastic probe cover prevents transmission of microorganisms between patients.

SKILL 29-1 MEASURING BODY TEMPERATURE—cont'd

STEP	RATIONALE
(4) Raise patient's arm away from torso; inspect for skin lesion and excessive perspiration. Insert thermometer probe into center of axilla, lower arm over probe, and place arm across patient's chest (see illustration).	Maintains proper position of probe against blood vessels in axilla.

STEP 3c(4) Thermometer tip in axilla.

CLINICAL DECISION: *Do not use axilla if skin lesions are present because lesions alter local temperature and areas are painful to touch.*

(5) Once positioned, hold thermometer probe in place until audible signal occurs and temperature appears on digital display. Remove thermometer probe from axilla.	Thermometer probe needs to stay in place until signal occurs to ensure accurate reading.
(6) Push ejection button on thermometer stem to discard plastic probe cover into appropriate receptacle.	Reduces transmission of microorganisms.
(7) Return thermometer stem to storage position of recording unit.	Storage position protects stem. Returning probe automatically causes digital reading to disappear.
(8) Help patient assume a comfortable position, replacing linen or gown.	Restores comfort and promotes privacy.
(9) Perform hand hygiene.	Reduces transmission of microorganisms.
(10) Return thermometer to charger.	Maintains battery charge.
d. Tympanic membrane temperature with electronic infrared thermometer	
(1) Help patient assume comfortable position with head turned toward side away from you. If patient has been lying on one side, use upper ear.	Ensures comfort and exposes auditory canal for accurate temperature measurement. Heat trapped in lower ear causes false-high temperature readings.
(2) Note if there is obvious earwax in patient's ear canal.	Earwax on lens cover blocks a clear optical pathway. It can lower tympanic temperature by 0.3° C (0.6° F). Switch to other ear or select alternative measurement site if needed.
(3) Remove thermometer handheld unit from charging base, being careful not to apply pressure to ejection button.	Base provides battery power. Removal of handheld unit from base prepares it to measure temperature. Ejection button releases plastic probe cover from thermometer tip.
(4) Slide clean disposable speculum cover over otoscope-like lens tip until it locks into place. Do not touch lens cover.	Soft plastic probe cover prevents transmission of microorganisms between patients. Lens cover needs to be free of dust, fingerprints, or earwax to ensure clear optical pathway.
(5) If right-handed, obtain temperature from patient's right ear; left-handed people obtain temperature from patient's left ear.	The less acute the angle of approach, the better the probe will seal inside the auditory canal.
(6) Insert infrared speculum into ear canal following manufacturer instructions for tympanic probe positioning:	Ear tug straightens external auditory canal, allowing maximum exposure of the tympanic membrane (Hockenberry and Wilson, 2007).
a. Pull ear pinna backward, up, and out for an adult. For children 3 years and younger, point covered probe toward midpoint between eyebrow and side burns. For children older than 3 years, pull pinna up and back (Hockenberry and Wilson, 2007).	Correctly positioning speculum tip with respect to ear canal ensures accurate readings.

STEP	RATIONALE
b. Move thermometer in a figure-eight pattern.	Some manufacturers recommend movement of the speculum tip in a figure-eight pattern, which allows the sensor to detect maximum tympanic membrane heat radiation.
c. Fit speculum tip snugly into canal and do not move (see illustration), pointing speculum tip toward nose.	Gentle pressure seals ear canal from ambient temperature, which alters readings as much as 2.8° C (5° F). Operator error leads to false-low temperatures.

STEP 3d(6)c Tympanic thermometer with probe cover inserted into auditory canal.

(7) Once positioned, press scan button on handheld unit. Leave speculum in place until audible signal indicates completion and patient's temperature appears on digital display.	Pressing scan button causes detection of infrared energy. Speculum needs to stay in place until signal occurs to ensure accurate reading.
(8) Carefully remove speculum from auditory meatus.	Prevents rubbing of sensitive outer ear lining.
(9) Push ejection button on handheld unit to discard speculum cover into appropriate receptacle.	Reduces transmission of microorganisms. Automatically causes digital reading to disappear.
(10) If temperature is abnormal or a second reading is necessary, replace speculum cover and wait 2 to 3 minutes before repeating measurement in same ear. Repeat measurement in other ear or try an alternative temperature site or instrument.	Time allows ear canal to regain usual temperature.
(11) Return handheld unit to charging base.	Protects sensor tip from damage.
(12) Help patient to get into a comfortable position.	Restores comfort and sense of well-being.
(13) Perform hand hygiene.	Reduces transmission of microorganisms.
4 Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.

EVALUATION

1 If temperature is assessed for first time, establish temperature as baseline if it is within normal range.	Used to compare future temperature measurements.
2 Compare temperature reading with patient's previous baseline and acceptable temperature range for his or her age-group.	Body temperature fluctuates within narrow range; comparison reveals presence of abnormality. Improper placement or movement of thermometer causes inaccuracies. Second measurement confirms initial findings of abnormal body temperature.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Temperature 1° C (1.8° F) above usual range
- Assess possible sites (e.g., central line catheter, wounds) for localized infection and related data suggesting a systemic infection.
- Follow interventions listed in Box 29-8.

2 Fever persists or reaches unacceptable level as defined by health care provider.
- Notify health care provider and administer antipyretics and antibiotics as ordered.

3 Temperature 1° C (1.8° F) below usual range
- Remove any drafts, wet clothing, or linen.
- Apply extra blankets and, unless contraindicated, offer warm liquids.
- Monitor apical pulse rate and rhythm because hypothermia causes bradycardia and dysrhythmias.

RECORDING AND REPORTING

- Record temperature in nurses' notes or vital sign flow sheet. Document measurement of temperature after administration of specific therapies in narrative form in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider.

HOME CARE CONSIDERATIONS

- Assess temperature and ventilation of patient's environment to determine existence of any environmental condition that influences patient's temperature.

SKILL 29-2 ASSESSING THE RADIAL AND APICAL PULSES

View Video!

Delegation Considerations

The skill of pulse measurement can be delegated to nursing assistive personnel (NAP) if the patient is stable and not at high risk for acute or serious cardiac problems. Instruct the NAP to:

- Consider specific factors related to patient history, usual values, or risk for irregular pulse.
- Obtain appropriate pulse measurements and position for select patient.
- Report specific abnormalities to the nurse for further assessment.

Equipment

- Stethoscope (apical pulse only)
- Wristwatch with second hand or digital display
- Pen, vital sign flow sheet, or patient's electronic health record
- Alcohol swab

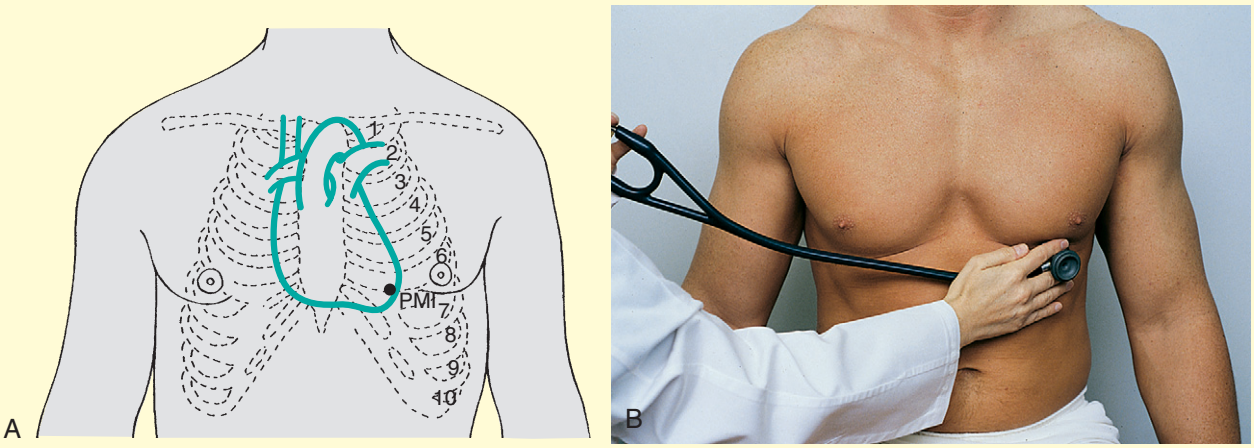
STEP	RATIONALE
ASSESSMENT	
1 Determine need to assess radial or apical pulse:	Nurse uses clinical judgment to determine need for assessment.
a. Assess for any risk factors for pulse alterations. • History of heart disease • Cardiac dysrhythmias • Onset of sudden chest pain or acute pain from any site • Invasive cardiovascular diagnostic tests • Surgery • Sudden infusion of large volume of intravenous (IV) fluid • Internal or external hemorrhage, dehydration • Administration of medications that alter cardiac function	These conditions place patients at risk for pulse alterations. A history of peripheral vascular disease often alters pulse rate and quality.
b. Assess for signs and symptoms of altered stroke volume and cardiac output such as dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations (person's unpleasant awareness of heartbeat), jugular venous distention, edema of dependent body parts, cyanosis, or pallor of skin (see Chapter 40).	Physical signs and symptoms indicate alteration in cardiac function.
c. Assess for signs and symptoms of peripheral vascular disease such as pale, cool extremities; thin, shiny skin with decreased hair growth; thickened nails.	Physical signs and symptoms indicate alteration in local arterial blood flow.
2 Assess for factors that influence pulse rate and rhythm: age, exercise, position changes, fluid balance, medications, temperature, and sympathetic stimulation.	Allows for accurate assessment of presence and significance of pulse alterations. Acceptable range of pulse rate changes with age (see Table 29-3).
3 Determine patient's previous baseline pulse rate if available in his or her medical record.	Allows for accurate assessment of change in condition and provides comparison with future apical pulse measurements.
4 Determine if patient has latex allergy.	If patient has latex allergy, verify that stethoscope is latex free.
PLANNING	
1 Explain that you will assess pulse or heart rate. Encourage patient to relax and not speak. If patient was active, wait 5 to 10 minutes before assessing pulse.	Activity and anxiety elevate heart rate. Patient's voice interferes with your ability to hear sound when assessing apical rate. Obtaining pulse rates at rest allows for objective comparison of values.
2 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Ensures correct patient. Complies with recommended National Patient Safety Goals (TJC, 2011).
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 If necessary, draw curtain around bed and/or close door.	Maintains privacy.
3 Obtain pulse measurement.	

STEP	RATIONALE
a. Radial pulse	
(1) Help patient get into supine or sitting position.	Provides easy access to pulse sites.
(2) If supine, place patient's forearm straight alongside body or across lower chest or upper abdomen with wrist extended straight (see illustration). If sitting, bend patient's elbow 90 degrees and support lower arm on chair or on your arm.	Relaxed position of lower arm and slight flexion of wrist promote exposure of artery to palpation without restriction.
(3) Place tips of first two or middle three fingers of hand over groove along radial or thumb side of patient's inner wrist. Slightly extend wrist with palm down until you note strongest pulse (see illustration).	Fingertips are most sensitive parts of hand to palpate arterial pulsation. Your thumb has a pulsation that interferes with accuracy.
(4) Lightly compress against radius, obliterate pulse initially, and then relax pressure so pulse becomes easily palpable.	Pulse is more accurately assessed with moderate pressure. Too much pressure occludes pulse and impairs blood flow.
(5) Determine strength of pulse. Note whether thrust of vessel against fingertips is bounding (4+), full/strong (3+), normal/expected (2+), diminished or barely palpable (1+), or absent (0).	Strength reflects volume of blood ejected against arterial wall with each heart contraction. Accurate description of strength improves communication among nurses and other health care providers.
(6) After feeling a regular pulse, look at the second hand of a watch and begin to count rate: count the first beat after the second hand hits the number on the dial; count as one, then two, and so on.	Determine rate only after knowing that you can palpate pulse. Timing begins with zero. Count of one is first beat palpated after timing begins.
(7) If pulse is regular, count rate for 30 seconds and multiply total by 2.	A 30-second count is accurate for rapid, slow, or regular pulse rates.
(8) If pulse is irregular, count rate for 1 minute (60 seconds). Assess frequency and pattern of irregularity. Compare radial pulses bilaterally.	Inefficient contraction of heart fails to transmit pulse wave, interfering with cardiac output, resulting in irregular pulse. Longer time ensures accurate count.

CLINICAL DECISION: *If pulse is irregular, do an apical/radial pulse assessment to detect a pulse deficit. Count apical pulse (see Step 3b) while a colleague counts radial pulse. Begin apical pulse count out loud to simultaneously assess pulses. If pulse count differs by more than 2, a pulse deficit exists, which sometimes indicates alterations in cardiac output.*

b. Apical pulse	
(1) Clean earpieces and diaphragm of stethoscope with alcohol swab.	Reduces transmission of microorganisms.
(2) Draw curtain around bed and/or close door.	Provides privacy and minimizes embarrassment.
(3) Help patient to supine or sitting position. Move aside bed linen and gown to expose sternum and left side of chest.	Exposes portion of chest wall for selection of auscultatory site.
(4) Locate anatomical landmarks to identify the point of maximal impulse (PMI), also called the apical impulse (see illustrations A-D). Heart is located behind and to left of sternum with base at top and apex at bottom. Find angle of Louis just below suprasternal notch between sternal body and manubrium; feels like a bony prominence (illustration A). Slip fingers down each side of angle to find second intercostal space (ICS) (illustration B). Carefully move fingers down left side of sternum to fifth ICS (illustration C) and laterally to the left midclavicular line (MCL) (illustration D). A light tap felt within an area 1 to 2 cm (½ to 1 inch) of the PMI is reflected from the apex of the heart.	Use of anatomical landmarks allows correct placement of stethoscope over apex of heart, enhancing ability to hear heart sounds clearly. If unable to palpate the PMI, reposition patient on left side. In the presence of serious heart disease, the PMI is located to the left of the MCL or at the sixth ICS.

STEP 3a(2) Pulse check with patient's forearm at side with wrist extended.



STEP 3a(3) Hand placement for pulse checks.

SKILL 29-2 ASSESSING THE RADIAL AND APICAL PULSES—cont'd

STEP	RATIONALE
(5) Place diaphragm of stethoscope in palm of hand for 5 to 10 seconds.	Warming of metal or plastic diaphragm prevents patient from being startled and promotes comfort.
(6) Place diaphragm of stethoscope over PMI at fifth ICS at left MCL and auscultate for normal S_1 and S_2 heart sounds (heard as "lub-dub") (see illustrations).	Allow stethoscope tubing to extend straight without kinks that would distort sound transmission. Normal sounds S_1 and S_2 are high pitched and best heard with the diaphragm.

STEP 3b(4) **A,** Locating angle of Louis. **B,** Locating second intercostal space (ICS). **C,** Locating fifth ICS. **D,** Identifying midclavicular line (MCL).

STEP 3b(6) **A,** Location of point of maximal impulse (PMI) in adult. **B,** Stethoscope over PMI.

STEP	RATIONALE
(7) When you hear S_1 and S_2 with regularity, use second hand of watch and begin to count rate: when sweep hand hits number 12 on dial, start counting with zero, then one, two, and so on.	Determine apical rate accurately only after you are able to auscultate sounds clearly. Timing begins with zero. Count of one is first sound auscultated after timing begins.
(8) If apical rate is regular, count for 30 seconds and multiply by 2.	Regular rate is accurate when measured for 30 seconds.

CLINICAL DECISION: *If heart rate is irregular or patient is receiving cardiovascular medication, count for 1 minute (60 seconds). Irregular rate is more accurately assessed when measured over a longer interval.*

(9) Note if heart rate is irregular and describe pattern or irregularity (S_1 and S_2 occurring early or later after previous sequence of sounds [e.g., every third or every fourth beat is skipped]).	Regular occurrence of dysrhythmia within 1 minute indicates inefficient contraction of heart and alteration in cardiac output.
(10) Replace patient's gown and bed linen; help patient return to comfortable position.	Restores comfort and promotes sense of well-being.
(11) Perform hand hygiene.	Reduces transmission of microorganisms.
(12) Clean earpieces and diaphragm of stethoscope with alcohol swab routinely after each use.	Prevents transmission of microorganisms.
4 Perform hand hygiene.	Reduces transmission of microorganisms.
5 Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.

EVALUATION

1 Compare readings with previous baseline and/or acceptable range of heart rate for patient's age (see Table 29-3).	Evaluates for change in condition and alterations.
2 Compare peripheral pulse rate with apical rate and note discrepancy.	Differences between measurements indicate pulse deficit and warn of cardiovascular compromise. Abnormalities often require therapy.
3 Compare radial pulse equality and note discrepancy.	Differences between radial arteries indicate compromised peripheral vascular system.
4 Correlate pulse rate with data obtained from blood pressure and related signs and symptoms (palpitations, dizziness).	Pulse rate and blood pressure are interrelated.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Radial pulse is weak, thready, or difficult to palpate.
- Assess both radial pulses and compare findings. Local obstruction to one extremity (e.g., clot, edema) decreases peripheral blood flow.
- Assess for swelling in surrounding tissues or other reason causing decreased peripheral blood flow (e.g., dressing, cast).
- Perform complete assessment of all peripheral pulses (see Chapter 30).
- Observe for symptoms associated with decreased tissue perfusion, including pallor and cool skin temperature of tissue distal to the weak pulse.
- Measure apical and radial pulse simultaneously to determine presence of pulse deficit.
- Assess for signs and symptoms associated with altered tissue perfusion, including pallor and cool skin temperature distal to the weak pulse.
- Have a second nurse assess pulses.

2 Apical pulse is greater than expected normal value (e.g., rate greater than 100 beats/min [tachycardia] in an adult; see Table 29-3).
- Identify related data, including fever, anxiety, pain, recent exercise, hypotension, decreased oxygenation, or dehydration.
- Observe for signs and symptoms of inadequate cardiac output, including fatigue, chest pain, orthopnea, cyanosis, and dizziness.

3 Apical pulse is less than expected normal value (e.g., rate less than 60 beats/min [bradycardia] in an adult; see Table 29-3).
- Observe for factors that alter heart rate such as digoxin and antidysrhythmics: it is sometimes necessary to withhold prescribed medications until the health care provider is able to evaluate the need to adjust dosage.
- Observe for signs and symptoms of inadequate cardiac output, including fatigue, chest pain, orthopnea, cyanosis, dizziness.

RECORDING AND REPORTING

- Record pulse rate with assessment site in nurses' notes or vital signs flow sheet. Document pulse rate after administration of specific therapies in narrative form in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider immediately.

HOME CARE CONSIDERATIONS

- Assess home environment to determine room that affords quiet environment for auscultating apical rate.

SKILL 29-3 ASSESSING RESPIRATIONS

View Video!

Delegation Considerations

The skill of respiration measurement can be delegated to nursing assistive personnel (NAP) unless the patient is considered unstable. Instruct NAP to:

- Consider specific factors related to patient history that increase risk for increased, decreased, or irregular respirations.
- Obtain respiration measurements at appropriate times as determined by agency policy, health care provider's order, or patient condition such as onset of labored breathing or statement of breathing difficulty.
- Report respiratory abnormalities to the nurse immediately for further assessment.

Equipment

- Wristwatch with second hand or digital display
- Pen, vital sign flow sheet or record, or electronic health record

STEP	RATIONALE
ASSESSMENT	
1 Determine need to assess patient's respirations:	Nurse uses clinical judgment to determine need for assessment.
a. Identify risk factors for respiratory alterations, including: • Fever, pain, anxiety • Diseases of chest wall or muscles • Constrictive chest or abdominal dressings • Gastric distention • Pulmonary disease (emphysema, bronchitis, asthma, pneumonia, acute bronchitis) • Traumatic injury to chest wall with or without collapse of underlying lung tissue • Presence of a chest tube • Pulmonary edema and emboli • Head injury with damage to brainstem • Anemia	Conditions that place patient at risk for ventilatory and respiratory alterations are detected by changes in respiratory rate, depth, and rhythm.
b. Assess for signs and symptoms of respiratory alterations such as bluish or cyanotic appearance of nail beds, lips, mucous membranes, and skin; restlessness, irritability, confusion, reduced level of consciousness; pain during inspiration; labored or difficult breathing; adventitious breath sounds (see Chapter 30) or inability to breathe spontaneously; thick, frothy, blood-tinged, or copious sputum produced on coughing.	Physical signs and symptoms indicate alterations in respiratory status.
2 Assess pertinent laboratory values:	
a. **Arterial blood gases (ABGs):** Normal ABGs (values vary slightly among institutions): • pH: 7.35-7.45 • $PaCO_2$: 35-45 mm Hg • PaO_2: 80-100 mm Hg • SaO_2: 95%-100%	Arterial blood gases measure arterial blood pH; partial pressure of O_2 and CO_2; and arterial O_2 saturation, which reflects patient's oxygenation status.
b. **Pulse oximetry (SpO_2):** Acceptable SpO_2 ranges from 95% to 100%; however, a value of less than 90% is considered hypoxemia; values below 90% are acceptable for certain chronic disease conditions (see Skill 29-4).	SpO_2 less than 90% is often accompanied by changes in respiratory rate, depth, and rhythm.
c. **Complete blood count (CBC):** Normal CBC for adults (values vary among institutions): • *Hemoglobin:* 14 to 18 g/100 mL, males; 12 to 16 g/100 mL, females • *Hematocrit:* 42% to 52%, males; 37% to 47%, females • *Red blood cell count:* 4.7 to 6.1 million/mm^3, males; 4.2 to 5.4 million/mm^3, females (Pagana and Pagana, 2011)	Complete blood count measures red blood cell count; volume of red blood cells; and concentration of hemoglobin, which reflects patient's capacity to carry O_2.
3 Assess for factors that influence respirations (see Box 29-9).	Allows you to control for factors that can affect measurement.
4 Determine previous baseline respiratory rate (if available) from patient's record.	Allows you to assess for change in condition. Provides comparison with future respiratory measurements.
PLANNING	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Plan to assess respirations after measuring pulse in an adult.	Inconspicuous assessment of respirations immediately after pulse assessment prevents patient from consciously or unintentionally altering rate and depth of breathing.

STEP	RATIONALE
IMPLEMENTATION	
1 Perform hand hygiene. Draw curtain around bed and/or close door.	Prevents transmission of microorganisms. Maintains privacy.
2 Be sure that patient is in comfortable position, preferably sitting or lying with head of bed elevated 45 to 60 degrees. Be sure that patient's chest is visible. If necessary, move bed linen or gown.	Sitting erect promotes full ventilatory movement. Ensures clear view of chest wall and abdominal movements.
3 Place patient's arm in relaxed position across abdomen or lower chest or place your hand directly over patient's upper abdomen (see illustration).	A similar position used during pulse assessment allows respiratory rate assessment to be inconspicuous. Patient's hand or your hand rises and falls during respiratory cycle.

STEP 3 Nurse's hand over patient's abdomen to check respiration.

4 Observe complete respiratory cycle (one inspiration and one expiration).	Rate is accurately determined only after you have observed a respiratory cycle.
5 After you observe a cycle, look at second hand of watch and begin to count rate: when sweep hand hits number on dial, begin time frame, counting one with first full respiratory cycle.	Timing begins with count of one. Respirations occur more slowly than pulse; thus timing does not begin with zero.
6 If rhythm is regular, count number of respirations in 30 seconds and multiply by 2. If rhythm is irregular, less than 12, or greater than 20, count for 1 full minute.	Respiratory rate is equivalent to number of respirations per minute. Suspected irregularities require assessment for at least 1 minute (see Table 29-6).
7 Note depth of respirations subjectively assessed by observing degree of chest wall movement while counting rate. You also objectively assess depth by palpating chest wall excursion or auscultating the posterior thorax after rate has been counted (see Chapter 30). Describe depth as shallow, normal, or deep.	Character of ventilatory movement reveals specific disease states that restrict volume of air from moving into and out of the lungs.
8 Note rhythm of ventilatory cycle. Normal breathing is regular and uninterrupted. Do not confuse sighing with abnormal rhythm.	Character of ventilations reveals specific types of alterations. Periodically people unconsciously take single deep breaths or sighs to expand small airways prone to collapse.

CLINICAL DECISION: *An irregular respiratory pattern or occurrence of periods of apnea (cessation of respiration for several seconds) is a symptom of underlying disease in the adult and must be reported to the nurse in charge or health care provider. The patient requires further assessment (see Chapter 30) and needs immediate intervention. An irregular respiratory rate and short apneic spells are normal for newborns.*

9 Replace bed linen and patient's gown.	Restores comfort and promotes sense of well-being.
10 Perform hand hygiene.	Reduces transmission of microorganisms.
11 Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.
EVALUATION	
1 If assessing respirations for first time, establish rate, rhythm, and depth as baseline if within normal range.	Used to compare future respiratory assessment.
2 Compare respirations with patient's previous baseline and normal rate, rhythm, and depth.	Allows nurse to assess for changes in patient's condition and presence of respiratory alterations.
3 Correlate respiratory rate, depth, and rhythm with data obtained from pulse oximetry and arterial blood gas measurements if available.	Ventilation, perfusion, and diffusion are interrelated.

SKILL 29-3 ASSESSING RESPIRATIONS—cont'd

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient has respiratory rate that is outside of expected normal values (e.g., less than 12 (bradypnea) or above 20 (tachypnea) breaths/min in an adult; see Table 29-5). Breathing pattern is irregular. Depth of respirations increase or decrease: patient feels short of breath.
- Observe for related factors, such as obstructed airway; assess for abnormal breath sounds, productive cough, restlessness, irritability, anxiety, confusion (see Chapter 30).
- Assist patient to supported sitting position (semi- or high-Fowler's) unless contraindicated, which improves ventilation.
- Provide oxygen as ordered (see Chapter 30).
- Assess for environmental factors that influence patient's respiratory rate such as secondhand smoke and poor room ventilation, and make corrections.

RECORDING AND REPORTING

- Record respiratory rate and character in nurses' notes or vital sign flow sheet.
- Record abnormal depth and rhythm in narrative form in nurses' notes.
- Document measurement of respiratory rate after administration of specific therapies in narrative form in nurses' notes.
- Indicate type and amount of oxygen therapy if used by patient during assessment. Document respiratory assessment after administration of specific therapies in narrative form in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider immediately.

HOME CARE CONSIDERATIONS

- Assess for environmental factors in the home that influence patient's respiratory rate such as secondhand smoke, poor ventilation, or gas fumes.

SKILL 29-4 MEASURING OXYGEN SATURATION (PULSE OXIMETRY)

View Video!

Delegation Considerations

The skill of oxygen saturation measurement can be delegated to nursing assistive personnel (NAP) unless patient is unstable. Instruct the NAP to:
- Report to the nurse immediately any SpO_2 reading lower than 90%, which the nurse confirms.
- Obtain oxygen saturation at appropriate times as determined by agency policy, health care provider's order, or patient condition such as onset of labored breathing or cyanosis.
- Select appropriate sensor site, probe, and patient position for measurement of oxygen saturation.
- Refrain from using pulse oximetry as an assessment of heart rate because the oximeter does not detect an irregular pulse.

Equipment

- Oximeter
- Oximeter probe appropriate for patient and recommended by manufacturer
- Acetone or nail polish remover if needed
- Pen, vital sign flow sheet or record form, or patient's electronic medical record

STEP	RATIONALE
ASSESSMENT	
1 Determine need to measure patient's oxygen saturation:	Clinical judgment determines need for assessment. Certain conditions place patients at risk for decreased oxygen saturation.
a. Identify risk factors of decreased oxygen saturation, including: acute or chronic compromised respiratory function, recovery from general anesthesia or conscious sedation, traumatic injury to chest wall with or without collapse of underlying lung tissue, ventilator dependence, changes in supplemental oxygen therapy.	
b. Assess for signs and symptoms of alterations in oxygen saturation such as altered respiratory rate, depth, or rhythm; adventitious breath sounds (see Chapter 30); cyanotic appearance of nail beds, lips, mucous membranes, and skin; restlessness, irritability, confusion; reduced level of consciousness; labored or difficult breathing.	Physical signs and symptoms often indicate abnormal oxygen saturation.
2 Assess for factors that normally influence measurement of SpO_2 (see Box 29-10) in addition to oxygen therapy, hemoglobin level, body temperature, and medications such as bronchodilators.	Allows nurse to accurately assess oxygen saturation variations.
3 Determine previous baseline SpO_2 (if available) from patient's record.	Baseline information provides basis for comparison and assists in assessment of current status and evaluation of interventions.
4 Determine most appropriate patient-specific site (e.g., finger, earlobe) for sensor probe placement by measuring capillary refill (see Chapter 30). If capillary refill is greater than 3 seconds, select alternate site.	Sensor requires pulsating vascular bed to identify hemoglobin molecules that absorb emitted light. Changes in SpO_2 are reflected in circulation of finger capillary bed within 30 seconds and capillary bed of earlobe within 5-10 seconds.

STEP	RATIONALE
a. Site needs to have adequate local circulation and be free of moisture.	Moisture prevents the sensor from detecting SpO_2 levels.
b. Place probe on finger free of polish or artificial nail.	Artificial nails and certain nail polish colors alter readings (Cicek et al., 2010).
c. If tremors are present, use earlobe as site.	Motion artifact is most common cause of inaccurate readings (Mininni, 2009).
d. If patient is obese, clip-on probe may not fit properly; obtain a single-use (tape-on) probe.	
5 Determine if patient has a latex allergy.	Do not use adhesive sensors if patient has a latex allergy.
PLANNING	
1 Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Explain purpose of procedure and how you measure oxygen saturation to patient. Instruct patient to breathe normally.	Promotes patient cooperation and increases compliance. Prevents large fluctuations in minute ventilation and possible error in SpO_2 readings.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Position patient comfortably. When using finger as monitoring site, support lower arm.	Ensures probe positioning and decreases motion artifact that interferes with SpO_2 determination.
3 Instruct patient to breathe normally.	Prevents large fluctuations in respiratory rate and depth and possible changes in SpO_2.
4 When using finger as monitoring site, remove any fingernail polish with acetone. Acrylic nails without polish do not interfere with SpO_2 determination.	Ensures accurate readings. Opaque coatings decrease light transmission; nail polish containing blue pigment absorbs light emissions and falsely alters saturation.
5 Attach sensor probe to monitoring site. Instruct patient that clip-on probe feels like a clothespin on finger but will not hurt.	Pressure spring tension of sensor probe on peripheral digit or earlobe is unexpected.
CLINICAL DECISION: *Do not attach probe to finger, ear, or bridge of nose if area is edematous or skin integrity is compromised. Do not attach probe to fingers that are hypothermic. Select ear or bridge of nose if adult patient has history of peripheral vascular disease. Do not use earlobe and bridge of nose sensors for infants and toddlers because of skin fragility. Do not use disposable adhesive probes if patient has latex allergy. Do not place sensor on same extremity as electronic blood pressure cuff because blood flow to finger is temporarily interrupted when cuff inflates and causes inaccurate readings that trigger alarms.*	
6 Once sensor is in place, turn on oximeter by activating power. Observe pulse waveform/intensity display and audible beep. Correlate oximeter pulse rate with patient's radial pulse. Differences require reevaluation of oximeter probe placement and may require reassessment of pulse rates.	Pulse waveform/intensity display enables detection of valid pulse or presence of interfering signal. Pitch of audible beep is proportional to SpO_2 value. Double-checking pulse rate ensures oximeter accuracy. Oximeter pulse rate, patient's radial pulse, and apical pulse rate should be the same. Any difference requires reevaluation of oximeter sensor probe placement and reassessment of pulse rates.
7 Leave probe in place until oximeter readout reaches constant value and pulse display reaches full strength during each cardiac cycle. Inform patient that oximeter will alarm if probe falls off or patient moves probe. Read SpO_2 on digital display.	Reading takes 10 to 30 seconds, depending on site selected.
8 If continuous SpO_2 monitoring is necessary, verify SpO_2 alarm limits and volume, which are preset by the manufacturer at a low of 85% and a high of 100%. Determine limits for SpO_2 and pulse rate alarms based on each patient's condition. Verify that alarms are on. Assess skin integrity every 2 hours under sensor probe. Relocate sensor probe at least every 24 hours or more frequently if skin integrity is altered or tissue perfusion compromised.	Alarms are set at appropriate limits and volumes to avoid frightening patients and visitors. Sensor probe tension and sensitivity to disposable sensor probe adhesive cause skin irritation and lead to disruption of skin integrity.
9 Help patient return to comfortable position.	Restores comfort and promotes sense of well-being.
10 Perform hand hygiene.	Reduces transmission of microorganisms.
11 Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.
12 If planning intermittent or spot-checking SpO_2 measurements, remove probe and turn oximeter power off. Store probe in appropriate location.	Batteries will run out if oximeter is left on. Sensor probes are expensive and vulnerable to damage.
EVALUATION	
1 Compare SpO_2 readings with patient baseline and acceptable values.	Comparison reveals presence of abnormality.
2 Correlate SpO_2 with SaO_2 obtained from arterial blood gas measurements (see Chapter 41) if available.	Documents reliability of noninvasive assessment.
3 Correlate SpO_2 reading with data obtained from respiratory rate, depth, and rhythm assessment (see Skill 29-3).	Measurements assessing ventilation, perfusion, and diffusion are interrelated.
4 During continuous monitoring assess skin integrity underneath probe at least every 2 hours based on patient's peripheral circulation.	Prevents tissue ischemia.

SKILL 29-4 MEASURING OXYGEN SATURATION (PULSE OXIMETRY)—cont'd

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 SpO_2 is less than 90%.
- Verify that oximeter probe is intact and outside light transmission does not influence measurement.
- Observe for signs and symptoms of decreased oxygenation: anxiety, restlessness, tachycardia, cyanosis.
- Verify that supplemental oxygen delivery system is delivered as ordered and functioning properly.
- Observe for and minimize factors that decrease SpO_2 such as lung secretions, increased activity, and hyperthermia.
- Assist patient to a position that maximizes ventilatory effort (e.g., place an obese patient in a high-Fowler's position).
- Notify nurse in charge or health care provider immediately.

2 Pulse rate indicated on the oximeter is less than patient's radial or apical pulse.
- Reposition sensor probe to an alternative site with increased blood flow.
- Assess patient for signs of altered cardiac output (e.g., decreased blood pressure, cool skin, confusion).

RECORDING AND REPORTING

- Record SpO_2 value on nurses' notes or vital sign flow sheet.
- Indicate type and amount of oxygen therapy used by patient during assessment.
- Record signs and symptoms of oxygen desaturation in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider immediately.
- Document oxygen saturation after administration of specific therapies in narrative form in nurses' notes.
- Record in nurses' notes patient's use of continuous or intermittent pulse oximetry. Documents use of equipment for third-party payers.

HOME CARE CONSIDERATIONS

- Pulse oximetry is used in home care to noninvasively monitor oxygen therapy or changes in oxygen therapy.
- Instruct family caregivers to examine oximeter site before applying sensor.
- Instruct family caregivers on procedure to implement when oxygen saturation is not within acceptable values.

SKILL 29-5 MEASURING BLOOD PRESSURE

View Video!

Delegation Considerations

The skill of blood pressure (BP) measurement can be delegated to nursing assistive personnel (NAP) unless the patient is considered unstable. Instruct the NAP to:
- Obtain BP measurement at appropriate times as determined by agency policy, health care provider's order, or patient condition.
- Select appropriate limb for BP measurement.
- Select appropriate-size BP cuff for designated limb.
- Consider specific patient-related factors that influence BP and risk of orthostatic hypotension.
- Report abnormalities to the nurse for further assessment immediately.

Equipment

- Aneroid sphygmomanometer
- Cloth or disposable vinyl pressure cuff of appropriate size for patient's extremity
- Stethoscope
- Alcohol swab
- Pen, vital sign flow sheet or record form, or electronic medical record

STEP	RATIONALE
ASSESSMENT	
1 Determine need to assess patient's BP:	Nurse uses clinical judgment to determine need for assessment.
a. Identify risk factors, including: • History of cardiovascular or renal disease, diabetes • Circulatory shock (hypovolemic, septic, cardiogenic, or neurogenic) • Acute or chronic pain • Rapid intravenous infusion of fluids or blood products • Increased intracranial pressure • Toxemia of pregnancy	Conditions place patients at risk for BP alteration.
b. Observe for signs and symptoms of BP alterations: **(1)** High BP (hypertension): headache (usually occipital), flushing of face, nosebleed, and fatigue in older adults **(2)** Low BP (hypotension): dizziness, mental confusion; restlessness; pale, dusky, or cyanotic skin and mucous membranes; cool, mottled skin over extremities	Physical signs and symptoms often indicate alterations in BP. High BP is often asymptomatic until pressure is very high.

STEP	RATIONALE
2 Assess for factors that affect BP (see Table 29-11)	Allows you to ensure that BP measurement is accurate.
3 Determine best site for BP assessment. Avoid applying cuff to extremity when intravenous fluids are infusing, an arteriovenous shunt or fistula is present, breast or axillary surgery has been performed on that side, or extremity has been traumatized or diseased or requires a cast or bulky bandage. Use lower extremities when brachial arteries are inaccessible.	Inappropriate site selection results in poor amplification of sounds, causing inaccurate readings. Application of pressure from inflated bladder temporarily restricts blood flow and further compromises circulation in extremity that already has impaired blood flow.
4 Determine previous baseline BP (if available) from patient's record.	Allows nurse to assess for change in condition. Provides comparison with future BP measurements.
5 Determine if patient has latex allergy.	Verify that stethoscope and BP cuff are latex free if patient has latex allergy.
PLANNING	
1 Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Explain to patient that you will assess BP. Have patient rest at least 5 minutes before measuring BP sitting or lying down; wait 1 minute if patient is standing. When possible, have patient sit in a chair (NHBPEP, 2003). Ask patient not to speak while measuring BP.	Allows patient to relax and helps to avoid falsely elevated readings. When assessed at rest, BP readings taken at different times are comparable. Talking to patient when assessing BP increases readings 10% to 40%.
3 Be sure that patient has not ingested caffeine or smoked for 30 minutes before BP measurement.	Caffeine or nicotine causes false BP elevations. Smoking immediately increases BP and lasts up to 15 minutes; caffeine increases BP up to 3 hours.
4 Assist patient to sitting position if appropriate. Be sure that room is warm, quiet, and relaxing.	Maintains patient comfort during measurement. Sitting is preferred to lying. Diastolic pressure measured with sitting is approximately 5 mm Hg higher than when measured supine. Patient perceptions of stressful environment affect BP measurement. Talking and background noise result in inaccurate measurements.
5 Select appropriate cuff size.	Improper cuff size results in inaccurate readings (see Table 29-11). If cuff is too small, it tends to come loose when being inflated or results in false-high readings. If the cuff is too large, you may obtain false-low readings.
IMPLEMENTATION	
1 Perform hand hygiene and clean stethoscope earpieces and diaphragm with alcohol swab.	Reduces transmission of microorganisms.
2 Position patient. **a.** Arm: Position patient sitting or lying, position his or her forearm at heart level. Turn palm up (see illustration). If sitting, instruct patient to keep feet flat on floor without crossing legs. **b.** Thigh: Position patient lying with thigh flat (provide support as needed). Have knee slightly flexed.	If arm is extended and not supported, patient performs isometric exercise that increases diastolic pressure. Placing arm above level of heart causes false-low reading 2 mm Hg for each inch above heart level. Leg crossing falsely increases systolic BP. Even in the supine position a diastolic pressure increases BP up to 3 to 4 mm Hg for each 5-cm (1.97-in) change in heart level.
3 Expose extremity (arm or leg) fully by removing constricting clothing.	Ensures proper cuff application. Do not place BP cuff over clothing. Tight clothing causes congestion of blood and can falsely elevate BP readings.

STEP 2a Patient's forearm supported in bed.

SKILL 29-5 MEASURING BLOOD PRESSURE—cont'd

STEP	RATIONALE
4 Palpate brachial artery (arm) (see illustration) or popliteal artery (leg). With cuff fully deflated, apply bladder of cuff above artery by centering arrows marked on cuff over artery. If there are no center arrows on cuff, estimate the center of the bladder and place it over artery. Position cuff 2.5 cm (1 inch) above site of pulsation (antecubital or popliteal space). Wrap cuff evenly and snugly around extremity (see illustrations).	Inflating bladder directly over artery ensures that proper pressure is applied during inflation. Loose-fitting cuff causes false-high readings.
5 Position manometer gauge no farther than 1 m (approximately 1 yard) away.	Looking up or down at scale results in inaccurate readings.
6 Measure BP.	
a. Two-step methods	
(1) Relocate brachial pulse. Palpate artery distal to cuff with fingertips of nondominant hand while inflating cuff rapidly to pressure 30 mm Hg above point at which pulse disappears. Slowly deflate cuff and note point when pulse reappears. Deflate cuff fully and wait 30 seconds.	Estimating systolic pressure prevents false low readings. Determine maximal inflation point for accurate reading by palpation. If unable to palpate artery because of weakened pulse, use an ultrasonic stethoscope (see Chapter 30). Completely deflating cuff prevents venous congestion and false-high readings.
(2) Place stethoscope earpieces in ears and be sure that sounds are clear, not muffled.	Each earpiece follows angle of ear canal to facilitate hearing.

STEP 4 **A,** Nurse palpating patient's brachial artery. **B,** Center bladder cuff above artery. **C,** Blood pressure cuff wrapped around upper arm.

STEP	RATIONALE
(3) Relocate brachial or popliteal artery and place bell or diaphragm chest piece of stethoscope over it. Do not allow chest piece to touch cuff or clothing (see illustration).	Proper stethoscope placement ensures best sound reception. Stethoscope improperly positioned causes muffled sounds that often result in false-low systolic and false-high diastolic readings.
(4) Close valve of pressure bulb clockwise until tight.	Tightening valve prevents air leak during inflation.
(5) Quickly inflate cuff to 30 mm Hg above palpated systolic pressure (patient's estimated systolic pressure) (see illustration).	Rapid inflation ensures accurate measurement of systolic pressure.
(6) Slowly release pressure bulb valve and allow needle of manometer gauge to fall at rate of 2 to 3 mm Hg/sec. Make sure that there are no extraneous sounds.	Too-rapid or too-slow decline in pressure causes inaccurate readings. Noise interferes with precise determination of Korotkoff phases.
(7) Note point on manometer when you hear first clear sound. Sound slowly increases in intensity.	First Korotkoff sound reflects systolic BP.
(8) Continue to deflate cuff, noting point at which muffled or dampened sound appears.	Fourth Korotkoff sound involves distinct muffling of sounds and is an indicator of diastolic pressure in children (NHBPEP, 2003).
(9) Continue to deflate cuff gradually, noting point at which sound disappears in adults. Listen for 10 to 20 mm Hg after last sound and allow remaining air to escape quickly.	Beginning of fifth Korotkoff sound is indicator of diastolic pressure in adults (NHBPEP, 2003). Continuous cuff inflation causes arterial occlusion, resulting in numbness and tingling of patient's arm.
b. One-step method	
(1) Place stethoscope earpieces in ears and be sure sounds are clear, not muffled.	Each earpiece follows angle of ear canal to facilitate hearing.
(2) Relocate brachial or popliteal artery and place bell or diaphragm chest piece of stethoscope over it. Do not allow chest piece to touch cuff or clothing.	Proper stethoscope placement ensures optimal sound reception. Stethoscope improperly positioned causes muffled sounds that result in false-low systolic and false-high diastolic readings.
(3) Close valve of pressure bulb clockwise until tight. Quickly inflate cuff to 30 mm Hg above patient's usual systolic pressure.	Tightening of valve prevents air leak during inflation. Inflation above systolic level ensures accurate measurement of systolic BP.
(4) Slowly release pressure bulb valve and allow needle of manometer gauge to fall at rate of 2 to 3 mm Hg/sec.	Too-rapid or too-slow decline in pressure causes inaccurate readings.
(5) Note point on manometer when you hear first clear sound. Sound slowly increases in intensity.	First Korotkoff sound reflects systolic pressure.
(6) Continue to deflate cuff, noting point at which muffled or dampened sound appears.	Fourth Korotkoff sound involves distinct muffling of sounds and indicates diastolic pressure in children (NNBPEP, 2003).
(7) While gradually deflating cuff, note point at which sound disappears in adults. Listen for 10 to 20 mm Hg after last sound and allow remaining air to escape quickly.	Beginning of fifth Korotkoff sound indicates diastolic pressure in adults (NHBPEP, 2003). Continuous cuff inflation causes arterial occlusion, resulting in numbness and tingling of patient's arm.
7 American Heart Association recommends average of two sets of BP measurement, 2 minutes apart. Use second set of BP measurements as baseline. If readings are different by more than 5 mm Hg, additional readings are necessary.	Two sets of BP measurements help to prevent false positives based on patient's sympathetic response (alert reaction). Averaging minimizes effect of anxiety, which often causes first reading to be higher than subsequent measurements.
8 Remove cuff from extremity unless you need to repeat measurement. If this is first assessment of patient, repeat BP assessment on other extremity.	Comparison of BP in both extremities detects circulation problems. (Normal difference of 5 to 10 mm Hg exists between extremities.)
9 Help patient return to comfortable position and cover upper arm if previously clothed.	Restores comfort and promotes sense of well-being.
10 Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.
11 Perform hand hygiene.	Reduces transmission of microorganisms.

STEP 6a(3) Stethoscope over brachial artery to measure BP.

STEP 6a(5) Inflating BP cuff.

SKILL 29-5 MEASURING BLOOD PRESSURE—cont'd

STEP	RATIONALE
EVALUATION	
1 Compare reading with previous baseline and/or acceptable value of BP for patient's age.	Evaluates for change in condition and cardiovascular alterations.
2 Compare BP in both arms or both legs.	If using upper extremities, use arm with higher pressure for subsequent assessments unless contraindicated.
3 Correlate BP with data obtained from pulse assessment and related cardiovascular signs and symptoms.	BP and heart rate are interrelated.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Unable to obtain BP reading
- Determine that no immediate crisis is present by obtaining pulse and respiratory rate.
- Assess for signs of decreased cardiac output; if present, notify nurse in charge or health care provider immediately.
- Use alternative sites or procedures to obtain BP: auscultate BP in lower extremity, use a Doppler ultrasonic instrument, implement palpation method to obtain systolic BP.
- Repeat BP measurement with sphygmomanometer. Electronic BP devices are less accurate in low–blood flow conditions.

2 BP is not sufficient for adequate perfusion and oxygenation of tissues.
- Compare BP value to baseline. A systolic reading of 90 mm Hg is an acceptable value for some patients.
- Position patient in supine position to enhance circulation and restrict activity if it is decreasing BP.
- Assess for signs and symptoms of hypotension such as tachycardia; weak, thready pulse; weakness, dizziness, confusion; cool, pale, dusky or cyanotic skin.
- Notify nurse in charge or health care provider immediately.
- Increase rate of intravenous infusion or administer vasoconstricting drugs if ordered.

3 BP is above acceptable range.
- Repeat BP measurement in other arm and compare findings. Verify correct selection and placement of cuff.
- Ask nurse colleague to repeat measurement in 1 to 2 minutes.
- Observe for related symptoms, although symptoms are sometimes not apparent until BP is extremely elevated.
- Report elevated BP to nurse in charge or health care provider to initiate appropriate evaluation and treatment.
- Administer antihypertensive medications as ordered.

4 Patent has a difference of more than 20 mm Hg systolic or diastolic when comparing BP measurements on upper extremities.
- Report abnormal findings to nurse in charge or health care provider.

RECORDING AND REPORTING

- Record BP in nurses' notes or vital sign flow sheet. BP measurement after administration of specific therapies needs to be documented in narrative form in nurses' notes.
- Record any signs or symptoms of BP alterations in narrative form in nurses' notes.
- Document measurement of BP after administration of specific therapies in narrative form in nurses' notes.
- Report abnormal findings to nurse in charge or health care provider immediately.

HOME CARE CONSIDERATIONS

- Assess home noise level to determine room that provides most quiet environment for assessing BP.
- Consider electronic BP cuff for home if patient has hearing difficulties, sufficient financial resources, and adequate dexterity.

KEY POINTS

- Measurement of vital signs includes the physiological measurement of temperature, pulse, BP, respirations, and oxygen saturation.
- Nurses measure vital signs as part of a complete physical examination or in a review of a patient's condition.
- Nurses assess changes in vital signs with other physical assessment findings, using clinical judgment to determine measurement frequency.
- Knowledge of the factors influencing vital signs assists in determining and evaluating abnormal values.
- Vital signs provide a basis for evaluating response to nursing interventions.
- Measure vital signs when the patient is inactive and the environment is controlled for comfort.
- Nurses help patients maintain body temperature by initiating interventions that promote heat loss, production, or conservation.
- A fever is one of the normal defense mechanisms of the body.
- Measurement of temperature using the temporal artery is the least invasive, most accurate method of obtaining core temperature.
- Respiratory assessment includes determining the effectiveness of ventilation, perfusion, and diffusion.
- Assessment of respiration involves observing ventilatory movements through the respiratory cycle.

- Variables affecting ventilation, perfusion, and diffusion influence oxygen saturation.
- To assess cardiac function, it is easy to measure pulse rate and rhythm using the radial or apical pulses.
- Hypertension is diagnosed only after an average of readings made during two or more subsequent visits reveals an elevated BP.
- Improper selection and application of the BP measurement cuff results in errors in BP measurement.
- Changes in one vital sign often influence characteristics of the other vital signs.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mr. Coburn, the 56-year-old school teacher who was seen earlier in the week for hyperthermia, arrives at the walk-in health center complaining of feeling dizzy and nauseated. You immediately note that he appears to be having some difficulty catching his breath during coughing spells. A new graduate nurse takes Mr. Coburn's admitting vital signs as: pulse 122, RR 14, BP 88/50 RA, tympanic temperature 38° C (100.4° F), SpO_2 92%. As you enter Mr. Coburn's room the electronic BP machine alarm is sounding. You note that it is flashing "72 systolic" with no diastolic reading. Mr. Coburn is turned on his right side, and his eyes are closed. His respirations appear labored.

1. List in order of priority your first five interventions.
2. Which vital signs should you reassess and which methods should you use?
3. Which hourly vital signs should you delegate to a NAP?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A 52-year-old woman is admitted with dyspnea and discomfort in her left chest with deep breaths. She has smoked for 35 years and recently lost over 10 pounds. Her vital signs on admission are: HR 112, BP 138/82, RR 22, tympanic temperature 36.8° C (98.2° F), and oxygen saturation 94%. She is receiving oxygen at 2 L via a nasal cannula. Which vital sign reflects a positive outcome of the oxygen therapy?
   1. Temperature: 37° C (98.6° F)
   2. Radial pulse: 112
   3. Respiratory rate: 24
   4. Oxygen saturation: 96%
   5. Blood pressure: 134/78
2. The licensed practice nurse (LPN) provides you with the change-of-shift vital signs on four of your patients. Which patient do you need to assess first?
   1. 84-year-old man recently admitted with pneumonia, RR 28, SpO_2 89%
   2. 54-year-old woman admitted after surgery for fractured arm, BP 160/86 mm Hg, HR 72
   3. 63-year-old man with venous ulcers from diabetes, temperature 37.3° C (99.1° F), HR 84
   4. 77-year-old woman with left mastectomy 2 days ago, RR 22, BP 148/62
3. A 56-year-old patient with diabetes admitted for community-acquired pneumonia has a temperature of 38.2° C (100.8° F) via the temporal artery. Which additional assessment data are needed in planning interventions for the patient's infection? (Select all that apply.)
   1. Heart rate
   2. Presence of diaphoresis
   3. Smoking history
   4. Respiratory rate
   5. Recent bowel movement
   6. Blood pressure in right arm
   7. Patient's normal temperature
   8. Blood pressure in distal extremity
4. A 55-year-old widowed patient was in a motor vehicle accident and is admitted to a surgical unit after repair of a fractured left arm and left leg. She also has a laceration on her forehead. An intravenous (IV) line is infusing in the right antecubital fossa, and pneumatic compression stockings are on the right lower leg. She is receiving oxygen via a simple face mask. What sites do you instruct the nursing assistant to use for obtaining the patient's blood pressure and temperature?
   1. Right antecubital and tympanic membrane
   2. Right popliteal and right axillae
   3. Left antecubital and oral
   4. Left popliteal and temporal artery
5. A patient has been transferred to your unit from the respiratory intensive care unit, where he has been for the past 2 weeks recovering from pneumonia. He is receiving oxygen via 4 L nasal cannula. His respiratory rate is 26 breaths/min, and his oxygen saturation is 92%. In planning his care, which information is most helpful in determining your priority nursing interventions?
   1. Activity order
   2. Medication list
   3. Baseline vital signs
   4. Patient's perception of dyspnea
6. During a patient's routine annual physical, she tells you that she has noted that her heart feels like it's "racing," usually in the later morning, early afternoon, or just before she goes to bed. Her radial pulse rate is 68 beats/min and regular; her blood pressure is 134/82 mm Hg. What additional information is helpful in evaluating the patient's racing heart? (Select all that apply.)
   1. Dietary habits
   2. Medication list
   3. Exercise regimen
   4. Age, weight, and height
7. You observe a nursing student taking a blood pressure (BP) on a patient. The patient's BP range over the past 24 hours is 132/64 to 126/72 mm Hg. The student used a BP cuff that was too narrow for the patient. Which of the following BP readings made by the student is most likely caused by the incorrect choice of BP cuff?
   1. 96/40 mm Hg
   2. 110/66 mm Hg
   3. 130/70 mm Hg
   4. 156/82 mm Hg
8. As you are obtaining the oxygen saturation on a 19-year-old college student with severe asthma, you note that she has black nail polish on her nails. You remove the polish from one nail, and she asks you why her nail polish had to be removed. Your best reply is:
   1. Nail polish attracts microorganisms and contaminates the finger sensor.
   2. Nail polish increases oxygen saturation.
   3. Nail polish interferes with sensor function.
   4. Nail polish creates excessive heat in sensor probe.

9. A patient has been hospitalized for the past 48 hours with a fever of unknown origin. His medical record indicates tympanic temperatures of 38.7° C (101.6° F) (0400), 36.6° C (97.9° F) (0800), 36.9° C (98.4° F) (1200), 37.6° C (99.6° F) (1600), and 38.3° C (100.9° F) (2000). How would you describe this pattern of temperature measurements?
    1. Usual range of circadian rhythm measurements
    2. Sustained fever pattern
    3. Intermittent fever pattern
    4. Resolving fever pattern
10. A patient presents in the clinic with dizziness and fatigue. The nursing assistant reports a very slow radial pulse of 44. What is your priority intervention?
    1. Request that the nursing assistant repeat the pulse check
    2. Call for a stat electrocardiogram (ECG)
    3. Assess the patient's apical pulse and evidence of a pulse deficit
    4. Prepare to administer cardiac-stimulating medications
11. Which of the following patients is most at risk for tachycardia?
    1. A healthy professional tennis player
    2. A patient admitted with hypothermia
    3. A patient with a fever of 39.4° C (103° F)
    4. A 90-year-old male taking beta blockers
12. Which of the following patients is at most risk for tachypnea? (Select all that apply.)
    1. Patient just admitted with four rib fractures
    2. Woman who is 9 months' pregnant
    3. Adult who has consumed alcoholic beverages
    4. Adolescent awaking from sleep
13. The following blood pressures, taken 6 months apart, were recorded from patients screened by the nurse at the assisted-living facility. Which patient should be referred to the health care provider for hypertension evaluation?
    1. 120/80, 118/78, 124/82
    2. 128/84, 124/86, 128/88
    3. 148/82, 148/78, 134/86
    4. 154/78, 118/76, 126/84
14. A patient is admitted for dehydration caused by pneumonia and shortness of breath. He has a history of heart disease and cardiac dysrhythmias. The nursing assistant tells you his admitting vital signs. Which measurement should you reassess? (Select all that apply.)
    1. Right arm BP: 120/80
    2. Radial pulse rate: 72 and irregular
    3. Temporal temperature: 37.4° C (99.3° F)
    4. Respiratory rate: 28
    5. Oxygen saturation: 99%
15. A patient returns to your postoperative unit following surgery for right shoulder rotator cuff repair. The licensed practical nurse (LPN) reports that she had difficulty obtaining the patient's heart rate from his right radial pulse. What is your best response?
    1. Assess the patient's apical pulse to obtain the heart rate.
    2. Obtain the heart rate from right and left radial sites.
    3. Obtain the heart rate using the oximeter probe.
    4. Perform a complete assessment of all pulses.

Answers: **1.** 4; **2.** 1; **3.** 1, 2, 4, 7; **4.** 2; **5.** 3; **6.** 1, 2; **7.** 4; **8.** 3; **9.** 3; **10.** 3; **11.** 3; **12.** 1, 2; **13.** 3; **14.** 2, 4, 5; **15.** 4.

CHAPTER

30

Health Assessment and Physical Examination

OBJECTIVES

- Discuss the purposes of physical assessment.
- Discuss how cultural diversity influences a nurse's approach to and findings from a health assessment.
- List techniques for preparing a patient physically and psychologically before and during an examination.
- Describe interview techniques used to enhance communication during history taking.
- Make environmental preparations before an examination.
- Identify data to collect from the nursing history before an examination.
- Demonstrate the techniques used with each physical assessment skill.
- Discuss normal physical findings in a young, middle-age, and older adult.
- Discuss ways to incorporate health promotion and health teaching into the examination.
- Identify ways to use physical assessment skills during routine nursing care.
- Describe physical measurements made in assessing each body system.
- Identify self-screening examinations commonly performed by patients.
- Identify preventive screenings and the appropriate age(s) for each screening to occur.

The health assessment and physical examination are the first steps toward providing safe and competent nursing care. The nurse is in a unique position to determine each patient's current health status, distinguish variations from the norm, and recognize improvements or deterioration in his or her condition. As a nurse, you must be able to recognize and interpret each patient's behavioral and physical presentation. By performing health assessments and physical examinations, you will identify health patterns and evaluate each patient's response to treatments and therapies.

Nurses gather assessment data about patients' past and current health conditions in a variety of ways, using a comprehensive or focused approach, depending on the patient situation. Assessments are performed at health fairs, at screening clinics, in a health provider's office, in acute care agencies, or in patients' homes. Depending on the outcome of an assessment, a nurse considers evidence-based recommendations for care based on a patient's values, the health provider's clinical expertise, or own personal experience.

A complete health assessment involves a nursing history (see Chapter 16) and behavioral and physical examination. Through the health history interview you gather subjective data about a patient's condition. You obtain objective data while observing a patient's behavior and overall presentation. You identify additional objective data through a head-to-toe body system review during the physical examination. Your clinical judgments are based on all of the gathered data to create a plan of care for each situation. With accurate data you create a patient-centered care plan, identifying the nursing diagnoses, desired patient outcomes, and nursing interventions. Continuity in health care improves when you evaluate a patient by making ongoing, objective, and comprehensive assessments.

PURPOSES OF THE PHYSICAL EXAMINATION

A physical examination is conducted as an initial evaluation in triage for emergency care; for routine screening to promote wellness behaviors and preventive health care measures; to determine eligibility for health insurance, military service, or a new job; or to admit a patient to a hospital or long-term care facility. After considering the patient's current condition, a nurse selects a focused physical examination on a specific system or area. For example, when a patient is having a severe asthma episode, the nurse first focuses on the pulmonary and cardiovascular systems so treatments can begin immediately. When the patient is no longer at risk for a bad outcome or injury, the nurse performs a more comprehensive examination of other body systems.

For patients who are hospitalized, a nurse integrates the collection of physical assessment data during routine patient care, validating findings with what is known about the patient's health history. For example, on entering a patient's room a nurse may notice behavioral patient cues that indicate comfort, anxiety, or sadness; assess the skin during the bed bath; or assess physical movements and swallowing abilities while administering medications. Use physical examination to do the following:

- Gather baseline data about the patient's health status.
- Support or refute subjective data obtained in the nursing history.
- Identify and confirm nursing diagnoses.
- Make clinical decisions about a patient's changing health status and management.
- Evaluate the outcomes of care.

Cultural Sensitivity

Respect the cultural differences among patients from a variety of backgrounds when completing an examination. It is important to remember that cultural differences influence patient behaviors. Consider the patient's health beliefs, use of alternative therapies, nutrition habits, relationships with family, and comfort with physical closeness during the examination and history. These factors will affect your approach as well as the type of findings you might expect.

Be culturally aware and avoid stereotyping on the basis of gender or race. There is a difference between cultural characteristics and physical characteristics. Learn to recognize common characteristics and disorders among members of ethnic populations within the community. It is equally important to recognize variations in physical characteristics such as in the skin and musculoskeletal system, which are related to racial variables. By recognizing cultural diversity, you show respect for each patient's uniqueness, leading to higher-quality care and improved clinical outcomes (see Chapter 9).

PREPARATION FOR EXAMINATION

Physical examination is a routine part of a nurse's patient assessment. In many care settings a head-to-toe physical assessment is required daily. You perform a reassessment when a patient's condition changes as it improves or worsens. In some health care settings such as during a home health visit a focused physical examination is preferred. Proper preparation of the environment, equipment, and patient ensures a smooth physical examination with few interruptions. A disorganized approach causes errors and incomplete findings. Safety for confused patients should be a priority; never leave a confused or combative patient alone during an examination.

Infection Control

Some patients present with open skin lesions, infected wounds, or other communicable diseases. Use standard precautions throughout an examination (see Chapter 28). When an open sore or microorganism is present, wear gloves to reduce contact with contaminants. If a patient has excessive drainage or there is a risk of splattering from a wound, additional personal protective equipment such as an isolation gown or eye shield should be used. Follow agency hand hygiene policies before initiating and after completing a physical assessment.

Although most health care agencies make nonlatex gloves available, it is your responsibility to identify latex allergies in patients and use equipment items that are latex free. By recognizing risk factors for latex allergies, the patient remains free of a natural rubber latex (NRL) allergy response. Two types of allergic responses appear with NRL. The most immediate is an immunological reaction type 1 response, for which the body develops antibodies known as *immunoglobulin E* that can lead to an anaphylactic response. Atopy occurs when there is an increased tendency for the body to form antibodies as a result of the immune response. The second is the allergic contact dermatitis type 4 response, which causes a delayed reaction that appears 12 to 48 hours after exposure (Bundesen, 2008). Both require prior exposure to the substance to which the body reacts. The severity of the response varies among individuals. Table 30-1 provides a short list of products that contain latex and suggests available alternatives.

Environment

A respectful, considerate physical examination requires privacy. In the acute setting, nurses perform assessments in a patient's room. Examination rooms are used in clinics or office settings. In the home the examination is performed in a space where privacy can be established such as the patient's bedroom.

Examination spaces need to be well equipped for any procedures. Adequate lighting is necessary to properly illuminate body parts. The hospital patient room can be secured for privacy so patients are comfortable discussing their condition. Eliminate extra noise and take precautions to prevent interruptions from others. The room must be warm enough to maintain comfort.

Depending on the body part being assessed, it may be difficult to perform a selected assessment skill when a patient is in bed or on a stretcher. Special examination tables make positioning easier and body areas more easily accessible. By assisting patients on and off the examination table, injury can be avoided, and falls prevented. Examination tables can be uncomfortable; elevate the head of the table about 30 degrees. A small pillow helps with head and neck comfort. If the examination is completed in the patient room, raise the patient's bed to be able to reach him or her more easily.

TABLE 30-1 Products Containing Latex and Nonlatex Substitutes*

PRODUCTS CONTAINING LATEX	NONLATEX SUBSTITUTES
Medical Equipment	
Disposable gloves	Vinyl, nitrile, or neoprene gloves
Blood pressure cuffs	Covered cuffs
Stethoscope tubing	Covered tubing
Intravenous injection ports	Needleless system, stopcocks, covered latex ports
Tourniquets	Latex-free or cloth-covered tourniquets
Syringes	Glass syringes
Adhesive tape	Nonlatex tapes
Oral and nasal airways	Nonlatex tubes
Endotracheal tubes	Hard plastic tubes
Catheters	Silicone catheters
Eye goggles	Silicone eye goggles
Anesthesia masks	Silicone masks
Respirators	Nonlatex respirators
Rubber aprons	Cloth-covered aprons
Wound drains	Silicone drains
Medication vial stoppers	Stoppers removed
Household Items	
Rubber bands	String; latex-free bands
Erasers	Silicone erasers
Motorcycle and bicycle handgrips	Handgrips removed or covered
Carpeting	Other types of flooring
Swimming goggles	Silicone construction
Shoe soles	Leather shoes
Expandable fabric (e.g., waistbands)	Fabric removed or covered
Dishwashing gloves	Vinyl gloves
Condoms	Nonlatex condoms
Diaphragms	Synthetic rubber diaphragms
Balloons	Mylar balloons
Pacifiers and baby bottle nipples	Silicone, plastic, or nonlatex pacifiers and nipples

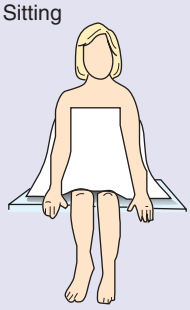
Modified from American Latex Allergy Association: *Literature review on latex-food cross-reactivity, 1991-2006,* 2011, http://www.latexallergyresources.org/topics/CrossReactiveAllergens.cfm. Accessed September 8, 2011; and Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby;
*This list is intended to provide examples of products and alternatives. It is not complete.

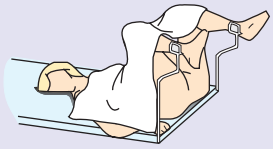
BOX 30-1 EQUIPMENT AND SUPPLIES FOR PHYSICAL ASSESSMENT

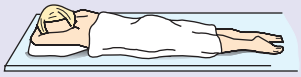
- Cervical brush or broom devices (if needed)
- Cotton applicators
- Disposable pad/paper towels
- Drapes/cover
- Eye chart (e.g., Snellen chart)
- Flashlight and spotlight
- Forms (e.g., physical, laboratory)
- Nonlatex gloves (clean)
- Gown for patient
- Ophthalmoscope
- Otoscope
- Papanicolaou (Pap) liquid preparation (if needed)
- Percussion (reflex) hammer
- Pulse oximeter
- Ruler
- Scale with height measurement rod
- Specimen containers, slides, wooden or plastic spatula, and cytological fixative (if needed)
- Sphygmomanometer and cuff
- Sterile swabs
- Stethoscope
- Tape measure
- Thermometer
- Tissues
- Tongue depressors
- Tuning fork
- Vaginal speculum (if needed)
- Water-soluble lubricant
- Watch with second hand or digital display

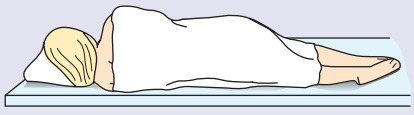
Equipment

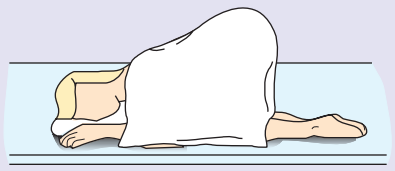
Perform hand hygiene thoroughly before handling equipment and starting an examination. Arrange any necessary equipment so that it is readily available and easy to use. Prepare equipment as appropriate (e.g., warm the diaphragm of the stethoscope between the hands before applying it to the skin). Be sure that equipment functions properly before using it (e.g., ensure that the ophthalmoscope and otoscope have good batteries and light bulbs). Box 30-1 lists typical equipment used during a physical examination.











Physical Preparation of the Patient

To show respect for a patient, ensure that physical comfort needs are met. Before starting, ask if the patient needs to use the restroom. An empty bladder and bowel facilitate examination of the abdomen, genitalia, and rectum. Collection of urine or fecal specimens occurs at this time if needed.

Physical preparation involves making certain that patient privacy is maintained with proper dress and draping. The patient in the hospital likely is wearing only a simple gown. In the clinic or health care provider's office the patient needs to undress and usually is provided a disposable paper cover or paper gown. If the examination is limited to certain body systems, it is not always necessary for the patient to undress completely. Provide the patient privacy and plenty of time to undress to avoid embarrassment. After changing into the recommended gown or cover, the patient sits or lies down on the examination table with a light drape over the lap or lower trunk. Make sure that he or she stays warm by eliminating drafts, controlling room temperature, and providing warm blankets. Routinely ask if he or she is comfortable.

Positioning. During the examination ask the patient to assume proper positions so body parts are accessible and he or she stays comfortable. Table 30-2 lists the preferred positions for each part of the examination and contains figures illustrating the positions. Patients' abilities to assume positions depend on their physical strength, mobility, ease of breathing, age, and degree of wellness. After explaining the positions, help the patient to assume them. Take care to maintain respect and show consideration by adjusting the drapes so that only the area examined is accessible. During the examination a patient may need to assume more than one position. To decrease the number of position changes, organize the examination so all techniques requiring a sitting position are completed first, followed by those that require a supine position next, and so forth. Use extra care when positioning older adults with disabilities and limitations.

TABLE 30-2 **Positions for Examination**

POSITION	AREAS ASSESSED	RATIONALE	LIMITATIONS
Sitting 	Head and neck, back, posterior thorax and lungs, anterior thorax and lungs, breasts, axillae, heart, vital signs, and upper extremities	Sitting upright provides full expansion of lungs and better visualization of symmetry of upper body parts.	Physically weakened patient is sometimes unable to sit. Use supine position with head of bed elevated instead.
Supine 	Head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen, extremities, pulses	This is most normally relaxed position. It provides easy access to pulse sites.	If patient becomes short of breath easily, raise the head of bed.
Dorsal recumbent 	Head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen	Position is for abdominal assessment because it promotes relaxation of abdominal muscles.	Patients with painful disorders are more comfortable with knees flexed.
Lithotomy* 	Female genitalia and genital tract	Position provides maximal exposure of female genitalia and facilitates insertion of vaginal speculum.	Lithotomy position is embarrassing and uncomfortable; thus examiner minimizes time that patient spends in it. Keep patient well draped.
Sims' 	Rectum and vagina	Flexion of hip and knee improves exposure of rectal area.	Joint deformities hinder patient's ability to bend hip and knee.
Prone 	Musculoskeletal system	Position is only for assessing extension of hip joint, skin, buttocks.	Patients with respiratory difficulties do not tolerate this position well.
Lateral recumbent 	Heart	Position aids in detecting murmurs.	Patients with respiratory difficulties do not tolerate this position well.
Knee-chest* 	Rectum	Position provides maximal exposure of rectal area.	This position is embarrassing and uncomfortable.

*Some patients with arthritis or other joint deformities are unable to assume this position.

Psychological Preparation of a Patient

Many patients find an examination stressful or tiring, or they experience anxiety about possible findings. A thorough explanation of the purpose and steps of each assessment lets a patient know what to expect and how to cooperate. Adapt explanations to the patient's level of understanding and encourage him or her to ask questions and comment on any discomfort. Convey an open, professional approach while remaining relaxed. A quiet, formal demeanor inhibits the patient's ability to communicate, but a style that is too casual may cause him or her to doubt an examiner's competence (Seidel et al., 2011).

Consider cultural or social norms when performing an examination on a person of the opposite gender. When this situation occurs, another person of the patient's gender or a culturally approved family member needs to be in the room. By taking this step you demonstrate cultural awareness for a patient's individual needs. As a side benefit, the second person acts as a witness to the conduct of the examiner and the patient should any question arise.

During the examination, watch the patient's emotional responses by observing whether his or her facial expressions show fear or concern or if body movements indicate anxiety. When you remain calm, the patient is more likely to relax. Especially if the patient is weak or elderly, it is necessary to pace the examination, pausing at intervals to ask how he or she is tolerating the assessment. If the patient feels alright, the examination can proceed. However, do not force the patient to cooperate based on your schedule. Postponing the examination is advantageous because the findings may be more accurate when the patient can cooperate and relax.

Assessment of Age-Groups

It is necessary to use different interview styles and approaches to physical examination for patients of different age-groups. Your approach will vary with each group. When assessing children, show sensitivity and anticipate the child's perception of the examination as a strange and unfamiliar experience. Routine pediatric examinations focus on health promotion and illness prevention, particularly for the care of well children who receive competent parenting and have no serious health problems (Josephson and AACAP Work Group, 2007). This examination focuses on growth and development, sensory screening, dental examination, and behavioral assessment. Children who are chronically ill or disabled and foster, foreign-born, or adopted children sometimes require additional examination visits. When examining children, the following tips help in data collection:

- Gather all or part of the history on infants and children from parents or guardians.
- Perform the examination in a nonthreatening area; provide time for play to become acquainted.
- Because parents sometimes think the examiner is testing them, offer support during the examination and do not pass judgment.
- Call children by their first name and address the parents as "Mr., Mrs., or Ms." rather than by their first name unless instructed differently.
- Use open-ended questions to allow parents to share more information and describe more of the children's problems. This also allows observation of parent-child interactions. You can interview older children, who often provide details about their health history and severity of symptoms.
- Treat adolescents as adults and individuals because they tend to respond best when treated as such.
- Remember that adolescents have the right to confidentiality. After talking with parents about historical information, speak alone with adolescents.

A comprehensive health assessment and examination of older adults includes physical data, developmental stage, family relationships, religious and occupational pursuits, and a review of the patient's cognitive, affective, and social level (Kresevic, 2008). An important aspect is to assess the patient's ability to perform basic activities of daily living (e.g., bathing, grooming) and complex instrumental activities of daily living (e.g., making phone call).

Throughout the examination recognize that with advancing age the body does not demonstrate obvious injury or disease as vigorously as younger patients and older adults do not always exhibit the expected signs and symptoms (Meiner, 2011). Characteristically older adults present with subtle or atypical signs and symptoms. Principles to follow during examination of an older adult include the following:

- Do not stereotype about aging patients' level of cognition. Most older adults are able to adapt to change and learn about their health. Similarly most are reliable historians.
- Recognize that some older adults have sensory or physical limitations that affect how quickly they can be interviewed and examinations can be conducted. It might be necessary to plan for more than one examination session. Sometimes it helps to give patients an initial health questionnaire before they come to a clinic or office.
- Perform the examination with adequate space; this is especially important for patients with mobility aids such as a cane or walker.
- During the examination use patience, allow for pauses, and observe for details. Recognize normal physiological and behavioral changes that are characteristic of later life.
- Certain types of health information are stressful for older patients to give. Some view illness as a threat to independence and a step toward institutionalization.
- Be aware of the location of the closest bathroom facility in case the patient has an urgent need to eliminate.
- Be alert to signs of increasing fatigue such as sighing, grimacing, irritability, leaning against objects for support, and drooping head and shoulders.

ORGANIZATION OF THE EXAMINATION

You will conduct a physical examination by assessing each body system. Use judgment to ensure that an examination is relevant and includes the correct assessments. Patients with focused symptoms or needs require only parts of an examination; thus, when a patient comes to a clinic with symptoms of a severe chest cold, a neurological assessment should not be required. A patient entering the emergency department with acute abdominal symptoms requires assessment of the body systems most at risk for being abnormal. However, when a patient is admitted to the hospital, you will perform a complete examination at the time of admission and at least once each day. Agency guidelines may define the components of a complete examination (see agency policy). A patient in the community seeks screening for specific conditions, often dependent on the patient's age or health risks listed in Table 30-3.

Any physical examination should follow a systematic routine to avoid missing important findings. A head-to-toe approach includes all body systems, and the examiner recalls and performs each step in a predetermined order. For an adult the examination begins with an assessment of the head and neck and progresses methodically

TABLE 30-3 **Recommended Preventive Screenings**

DISEASE/CONDITION	AGE-GROUP	SCREENING MEASURES
Breast cancer*	Ages 20 to 39	Monthly breast self-examination (BSE). Clinical breast examination by health care professional every 3 years
	Ages 40 and up	Monthly BSE Annual clinical breast examination by health care professional Annual mammograms (Women at increased risk need to speak to health care provider regarding screening options.)
Colon/rectal cancer*	Ages 50 and up	Men and women need to have one of the following: fecal occult blood test (FOBT) or fecal immunochemical test (FIT) annually or flexible sigmoidoscopy (FSIG) every 5 years; the combination of FOBT or FIT annually and an FSIG every 5 years is preferred over either of the previous options; or double-contrast barium enema every 5 years; or colonoscopy every 10 years. They also need a digital rectal examination at the same time. Earlier screening is necessary if risk factors exist.
Ear disorders	All ages Over age 65	Periodic hearing checks as needed Regular hearing checks
Eye disorders	Age 40 and under	Complete eye examination every 3 to 5 years (more if positive history for eye disease [e.g., diabetes])
	Ages 40 to 64	Complete eye examination every 2 years to screen for conditions that may go unnoticed (e.g., glaucoma)
	Age 65 and up	Complete eye examination every year
Heart/vascular disorders	Men age 45 to 65 Women age 45 to 65	Regular measurement of total blood cholesterol levels, lipids, and triglycerides; blood pressure screenings (If patient has risk factors for coronary artery disease [CAD], blood pressure screening needs to begin at age 20-35 for men, 20-45 for women.)
Obesity	All ages	Periodic height and weight measurements
Oral cavity/pharyngeal disorders/cancer	All ages (children, adults, older adults)	Regular dental examinations every 6 months
Ovarian cancer*	Age 18 and up or on becoming sexually active	Annual pelvic examinations by health care provider (This screening occasionally detects ovarian cancer in its advanced stage. Those at high risk need to have a thorough pelvic examination, a transvaginal ultrasound, and a blood test [tumor marker CA 125]).
Prostate cancer*	Ages 50 and up	Men who have at least a 10-year life expectancy need to have a digital rectal examination (DRE) and prostate-specific antigen (PSA) blood test annually. Men at high risk require earlier screening.
Skin cancer*	Ages 20 to 40 Over 40	See specialist every 3 years Annual skin checkups with biopsy of suspicious lesions
Testicular cancer*	Age 15 and up	Monthly testicular self-examination (TSE)
Uterine cancer*	Screening begins 3 years after having vaginal intercourse but not later than age 21	Annual pelvic examination by health care provider plus annual Papanicolaou (Pap) test
Cervical cancer	Screening begins 3 years after vaginal intercourse but not later than age 21	Annual pelvic examination by health care provider, plus an annual Pap test (At age 30 or after, those who have had three normal tests consecutively may be screened every 2 to 3 years. If patient has risk factors, screening needs to occur more frequently. Contact health care provider.)
Endometrial cancer	Same as for cervical cancer	Endometrial biopsy at age 35 for high-risk patients (those with or at risk for hereditary nonpolyposis colon cancer [HNPCC]) (At menopause women at average and high risk need to be informed about signs and symptoms to report.)

*Data from American Cancer Society: *Cancer facts and figures 2011,* Atlanta, 2011, The Society; website for further information on preventative screenings: *Guide to clinical preventive services,* AHRQ Publication No. 05-0570, Rockville, Md, 2011, Agency for Healthcare Research and Quality, http://www.ahrp.gov/.

down the body to incorporate all body systems. The following tips help keep an examination well organized:

- Compare both sides of the body for symmetry. A degree of asymmetry is normal (e.g., the biceps muscles in the dominant arm are sometimes more developed than the same muscles in the nondominant arm).
- If the patient is seriously ill, first assess the systems of the body most at risk for being abnormal. For example, a patient with chest pain first undergoes a cardiovascular assessment.
- If the patient becomes fatigued, offer rest periods between assessments.
- Perform painful procedures near the end of an examination.
- Record assessments in specific terms in the electronic or paper record. A standard form allows for recording information in the same sequence that it is gathered.
- Use common and accepted medical terms and abbreviations to keep notes accurate, brief, and concise.
- Record quick notes during the examination to avoid delays. Complete any larger documentation notes at the end of the examination.

TECHNIQUES OF PHYSICAL ASSESSMENT

The four techniques used in a physical examination are inspection, palpation, percussion, and auscultation.

Inspection

To inspect, carefully look, listen, and smell to distinguish normal from abnormal findings. To do so, you must be aware of any personal visual, hearing, or olfactory deficits. It is important to deliberately practice this skill and learn to recognize all of the possible pieces of data that can be gathered through inspection alone. **Inspection** occurs when interacting with a patient, watching for nonverbal expressions of emotional and mental status. Physical movements and structural components can also be identified in such an informal way. Most important, be deliberate and pay attention to detail. Follow these guidelines to achieve the best results during inspection:

- Make sure that adequate lighting is available, either direct or tangential.
- Use a direct lighting source (e.g., a penlight or lamp) to inspect body cavities.
- Inspect each area for size, shape, color, symmetry, position, and abnormality.
- Position and expose body parts as needed so all surfaces can be viewed but privacy can be maintained.
- When possible, check for side-to-side symmetry by comparing each area with its match on the opposite side of the body.
- Validate findings with the patient.

While assessing a patient, recognize the nature and source of body odors (Table 30-4). An unusual odor often indicates an underlying pathology. **Olfaction** helps to detect abnormalities that cannot be recognized by any other means. For example, when a patient's breath has a sweet, fruity odor, assess for signs of diabetes. Continue to inspect various parts of the body during the physical examination. Palpation may be used concurrently with inspection, or it may follow in a more deliberate fashion.

Palpation

Palpation involves using the sense of touch to gather information. Through touch you make judgments about expected and unexpected findings of the skin or underlying tissue, muscle, and bones.

TABLE 30-4 Assessment of Characteristic Odors

ODOR	SITE OR SOURCE	POTENTIAL CAUSES
Alcohol	Oral cavity	Ingestion of alcohol, diabetes
Ammonia	Urine	Urinary tract infection, renal failure
Body odor	Skin, particularly in areas where body parts rub together (e.g., underarms and under breasts)	Poor hygiene, excess perspiration (hyperhidrosis), foul-smelling perspiration (bromhidrosis)
	Wound site	Wound abscess
	Vomitus	Abdominal irritation, contaminated food
Feces	Vomitus/oral cavity (fecal odor)	Bowel obstruction
	Rectal area	Fecal incontinence
Foul-smelling stools in infant	Stool	Malabsorption syndrome
Halitosis	Oral cavity	Poor dental and oral hygiene, gum disease
Sweet, fruity ketones	Oral cavity	Diabetic acidosis
Stale urine	Skin	Uremic acidosis
Sweet, heavy, thick odor	Draining wound	*Pseudomonas* (bacterial) infection
Musty odor	Casted body part	Infection inside cast
Fetid, sweet odor	Tracheostomy or mucus secretions	Infection of bronchial tree (*Pseudomonas* bacteria)

For example, you palpate the skin for temperature, moisture, texture, turgor, tenderness, and thickness and the abdomen for tenderness, distention, or masses. Use different parts of the hand to detect different characteristics (Table 30-5). The palmar surface of the hand and finger pads is more sensitive than the fingertips and should be used to determine position, texture, size, consistency, masses, fluid, and crepitus (Fig. 30-1, *A*). Assess body temperature by using the dorsal surface or back of the hand (Fig. 30-1, *B*). The palmar surface of the hand and fingers (Fig. 30-1, *C*) is more sensitive to vibration. Measure position, consistency, and turgor by lightly grasping the body part with the fingertips (Fig. 30-1, *D*).

Touching the patient is a personal experience for both you and the patient. Display respect and concern throughout the examination. Before palpating consider the patient's condition and ability to tolerate the assessment techniques, paying close attention to areas that are painful or tender. In addition, always be conscious of the environment and any threats to the patient's safety.

Prepare for palpation by warming hands, keeping fingernails short and using a gentle approach. Palpation proceeds slowly, gently, and deliberately. The patient needs to be guided to relax and feel comfortable since tensed muscles make assessment more difficult. To promote relaxation, have him or her take slow, deep breaths and place both arms along the sides of the body. Ask the patient to point to more sensitive areas, watching for nonverbal signs of discomfort. *Palpate tender areas last.*

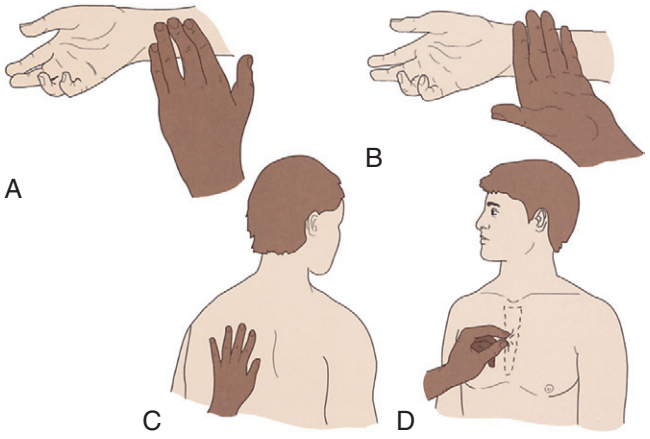


FIG. 30-1 **A,** Radial pulse is detected with the pads of fingertips, the most sensitive part of the hand. **B,** Dorsum of the hand detects temperature variations in skin. **C,** The bony part of the palm at the base of the fingers detects vibrations. **D,** Skin is grasped with the fingertips to assess turgor.

TABLE 30-5 Examples of Characteristics Measured by Palpation

AREA EXAMINED	CRITERIA MEASURED	PORTION OF HAND TO USE
Skin	Temperature	Dorsum of hand/fingers
	Moisture Texture	Palmar surface
	Turgor and elasticity	Grasping with fingertips
	Tenderness Thickness	Palmar surface
Organs (e.g., liver and intestine)	Size Shape Tenderness Absence of masses	Entire palmar surface of hand or palmar surface of fingers
Glands (e.g., thyroid and lymph)	Swelling Symmetry and mobility	Pads of fingers
Blood vessels (e.g., carotid or femoral artery)	Pulse amplitude Elasticity Rate Rhythm	Palmar surface/pads of fingertips
Thorax	Excursion	Palmar surface
	Tenderness	Finger pads/palmar surface of fingers
	Fremitus	Palmar or ulnar surface of entire hand

Two types of palpation are used for physical examination, light and deep. Light palpation is performed by placing the hand on the body part being examined; it also involves pressing inward about 1 cm (½ inch). Light, superficial palpation of structures such as the abdomen gives the patient the chance to identify areas of tenderness (Fig. 30-2, *A*). Inquire about areas of tenderness and assess them further for potentially serious pathologies. Deep palpation is used to examine the condition of organs such as those in the abdomen (Fig. 30-2, *B*). Depress the area under examination approximately 4 cm (2 inches) (Seidel et al., 2011), using one or both hands (bimanually). When using bimanual palpation, relax

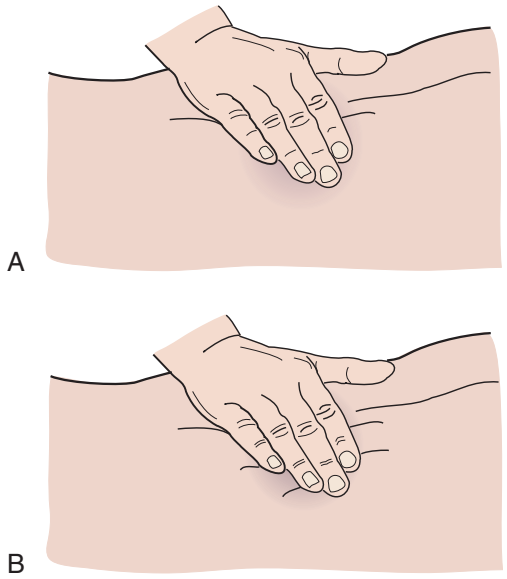

FIG. 30-2 **A,** During light palpation gentle pressure against underlying skin and tissues can detect areas of irregularity and tenderness. **B,** During deep palpation depress tissue to assess the condition of underlying organs.

one hand (sensing hand) and place it lightly over the patient's skin. The other hand (active hand) helps apply pressure to the sensing hand. The lower hand does not exert pressure directly and thus remains sensitive to detect organ characteristics. For safety deep palpation should be observed by your clinical instructor when you first attempt the procedure.

Percussion

Percussion involves tapping the skin with the fingertips to vibrate underlying tissues and organs. The vibration travels through body tissues, and the character of the resulting sound reflects the density of the underlying tissue. The denser the tissue, the quieter the sound. By knowing how various densities influence sound, it is possible to locate organs or masses, map their edges, and determine their size. An abnormal sound suggests a mass or substance such as air or fluid within an organ or body cavity. The skill of percussion is used more often by advanced practice nurses than by nurses in daily practice at the bedside.

Auscultation

Auscultation involves listening to sounds the body makes to detect variations from normal. Some sounds such as speech and coughing can be heard without additional equipment, but a stethoscope is necessary to hear internal body sounds.

Internal body sounds are created by blood, air, or gastric contents as they move against the body structures. For example, normal heart sounds are created when the heart valves close, moving blood to the next portion of the cardiovascular system. Normal sounds for each body system are discussed later in this chapter. Learn to recognize abnormal sounds after learning normal variations. Becoming more proficient in auscultation occurs by knowing the types of sounds each body structure makes and the location in which the sounds are heard best.

To auscultate internal sounds you need to hear well, have a good stethoscope, and know how to use it properly. Nurses with hearing disorders can obtain stethoscopes with extra sound amplification.

Chapter 29 describes the parts of the stethoscope and its general use. The bell is best for hearing low-pitched sounds such as vascular and certain heart sounds, and the diaphragm is best for listening to high-pitched sounds such as bowel and lung sounds.

By practicing with the stethoscope, you become proficient at using it and realize when sounds are clear and when there are extraneous sounds. Extraneous sounds created by rubbing against the tubing or chest piece interfere with auscultation of body organ sounds. By deliberately producing these sounds, you learn to recognize and disregard them during the actual examination. Box 30-2 contains ways to practice using and techniques for caring for the stethoscope. Describe any sound you hear using the following characteristics:

- Frequency indicates the number of sound wave cycles generated per second by a vibrating object. The higher the frequency, the higher the pitch of a sound and vice versa.
- Loudness refers to the amplitude of a sound wave. Auscultated sounds range from soft to loud.
- Quality refers to sounds of similar frequency and loudness from different sources. Terms such as *blowing* or *gurgling* describe the quality of sound.
- Duration means the length of time that sound vibrations last. The duration of sound is short, medium, or long. Layers of soft tissue dampen the duration of sounds from deep internal organs.

Auscultation requires concentration and practice. While listening, know which sounds are normally produced in certain parts of the body and what causes the sounds. Normal sounds will be discussed in each body system section of this chapter. After understanding the cause and character of normal auscultated sounds, it becomes easier to recognize abnormal sounds and their origins.

GENERAL SURVEY

When a patient first enters the examination room, observe his or her walk and general appearance and be attentive to his or her behavior and dress. A general survey, or appraisal, of the patient's presentation and behavior provides information about characteristics of an illness, the patient's ability to function independently, body image, emotional state, recent changes in weight, and developmental status. If there are abnormalities or problems, assess the affected body system more closely during the full examination.

General Appearance and Behavior

Assess appearance and behavior while preparing the patient for the examination. For this review include:

- *Gender and race:* A person's gender affects the type of examination performed and the order of the assessments. Different physical features are related to gender and race. Certain illnesses are more likely to affect a specific gender or race (e.g., the incidence of skin cancer is more common in whites than in blacks, prostate cancer is higher in black men than in white men, and cancer of the bladder is four times higher in men than women) (American Cancer Society [ACS], 2011).
- *Age:* Age influences normal physical characteristics and a person's ability to participate in some parts of the examination.
- *Signs of distress:* Sometimes obvious signs or symptoms indicate pain (grimacing, splinting painful area), difficulty breathing (shortness of breath, sternal retractions), or anxiety. Set priorities and examine the related physical areas first.

BOX 30-2 USE AND CARE OF THE STETHOSCOPE

- Ensure that the earpiece follows the contour of the ear canals. Learn which fit is best for you by comparing amplification of sounds with the earpieces in both directions.
- Place the earpieces in your ears with the tips turned toward the face. *Lightly* blow into the diaphragm. Again place the earpieces in your ears, this time with the ends turned toward the back of the head. *Lightly* blow into the diaphragm. You will find that you hear clearer sounds with the earpiece turned toward the face. After you have learned the right fit for the loudest amplification, wear the stethoscope the same way each time.
- Put on the stethoscope and *lightly* blow into the diaphragm. If the sound is barely audible, *lightly* blow into the bell. Sound is carried through only one part of the chest piece at a time. If the sound is greatly amplified through the diaphragm, the diaphragm is in position for use. If the sound is barely audible through the diaphragm, the bell is in position for use. Rotation of the diaphragm and bell places the chest piece in the desired position. Leave the diaphragm in position for the next exercise.
- Place the diaphragm over the anterior part of your chest. Ask a friend to speak in a normal conversational tone. Environmental noise seriously detracts from hearing the noise created by body organs. When using a stethoscope, the patient and the examiner need to remain quiet.
- Put on the stethoscope and gently tap the tubing. It is often difficult to avoid stretching or moving the stethoscope tubing. The examiner is in a position so the tubing hangs free. Moving or touching the tubing creates extraneous sounds.
- *Care of the stethoscope:* Remove earpieces regularly and clean; remove cerumen (earwax). Keep the bell and diaphragm free of dust, lint, and body oils. Keep the tubing away from any body oils. Avoid draping the stethoscope around the neck next to the skin. Clean by wiping the entire stethoscope (e.g., diaphragm, tubing) with alcohol or soapy water. Be sure to dry all parts thoroughly. Follow the manufacturer's recommendations.
- *Infection control:* Harmful bacteria such as gram-positive bacilli, methicillin-resistant *Staphylococcus aureus* (MRSA), nonaureus *Staphylococcus, Enterobacter cloacae,* and methicillin-sensitive *S. aureus* can be transferred from patient to patient when using portable equipment such as stethoscopes. Clean the stethoscope (diaphragm/bell) *before* reuse on another patient. Using a disinfectant such as isopropyl alcohol (with or without chlorhexidine), benzalkonium, or sodium hypochlorite is effective in reducing the number of bacterial colonies. Hand foam serves this purpose well. Earpieces of stethoscopes are sources of transferable bacteria. When you inadvertently touch your ears and care for the patient, potential pathogens could contaminate the earpieces. Using hand hygiene before and after patient contact decreases the risk of transmitting microorganisms from your ear to your patient. Follow institution infection control guidelines, especially contact precautions, to decrease this risk (Lecat et al., 2009).

- *Body type:* Observe if the patient appears trim and muscular, obese, or excessively thin. Body type reflects the level of health, age, and lifestyle.
- *Posture:* Normal standing posture shows an upright stance with parallel alignment of the hips and shoulders. Normal sitting posture involves some degree of rounding of the shoulders. Observe whether the patient has a slumped, erect, or bent posture, which reflects mood or pain. Changes in older adult physiology often result in a stooped, forward-bent posture, with the hips and knees somewhat flexed and the arms bent at the elbows.

- *Gait:* Observe as the patient walks into the room or stands at the bedside (if the patient is ambulatory). Note whether movements are coordinated or uncoordinated. A person normally walks smoothly, with the arms swinging freely at the sides and the head and face leading the body.
- *Body movements:* Observe whether movements are purposeful, noting any tremors involving the extremities. Determine if any body parts are immobile.
- *Hygiene and grooming:* Note the patient's level of cleanliness by observing the appearance of the hair, skin, and fingernails. Determine if his or her clothes are clean. Grooming depends on the patient's cognitive and emotional function, daily or social activities, and occupation. Observe for excessive use of cosmetics or colognes that could indicate a change in self-perception.
- *Dress:* Culture, lifestyle, socioeconomic level, and personal preference affect the selection and wearing of clothing. However, you should assess whether or not the clothing is appropriate for the temperature, weather conditions, or setting. Depressed or mentally ill people may not be able to select proper clothing, and an older adult might tend to wear extra clothing because of sensitivity to cold.
- *Body odor:* An unpleasant body odor can result from physical exercise, poor hygiene, or certain disease states. Validate any odors that might indicate a health problem.
- *Affect and mood:* Affect is a person's feelings as he or she appears to others. Patients express mood or emotional state verbally and nonverbally. Determine whether or not verbal expressions match nonverbal behavior and if the mood is appropriate for the situation. By maintaining eye contact you can observe facial expressions while asking questions.
- *Speech:* Normal speech is understandable and moderately paced and shows an association with the person's thoughts. However, emotions or neurological impairment sometimes causes rapid or slowed speech. Observe whether the patient speaks in a normal tone with clear inflection of words.
- *Signs of patient abuse:* During the examination observe if the patient fears his or her spouse or partner, a caregiver, a parent, or an adult child. Abuse of children, women, and older adults is a growing health problem. Consider any obvious physical injury or neglect as signs of possible abuse (e.g., evidence of malnutrition or presence of bruising on the extremities or trunk). Abuse occurs in many forms: physical, mental or emotional, sexual, social, and financial or economic. Observe the behavior of the individual for any signs of frustration, explanations that do not fit his or her physical presentation, or signs of injury. Most states mandate a report to a social service center when abuse or neglect is suspected (Box 30-3). It is difficult to detect abuse because victims often do not complain or report that they are in an abusive situation (Cohen et al., 2007). If abuse is suspected, find a way to interview the patient in private; patients are more likely to reveal any problems when the suspected abuser is absent from the room. It is imperative that you help the patient find safe housing or seek protection from the abuser since the risk for further abuse is high once the victim has reported it or tries to leave the abusive situation.
- *Substance abuse:* Unusual or inconsistent behavior may be an indicator of substance abuse, which can affect all socioeconomic groups. Although a single patient visit to a clinic does not always reveal the problem, unusual behaviors should be investigated further to reveal behaviors that should be confirmed with a well-focused history and physical examination. Always approach the patient in a caring and nonjudgmental way; substance abuse involves both emotional and lifestyle issues. Box 30-4 lists characteristics of patients who should be further assessed for potential substance abuse. The CAGE questionnaire provides a useful set of questions to guide assessment. CAGE is an acronym for the following:
  - Have you ever felt the need to **Cut down** on your drinking or drug use?
  - Have people **Annoyed** you by criticizing your drinking or drug use?
  - Have you ever felt bad or **Guilty** about your drinking or drug use?
  - Have you ever used or had a drink first thing in the morning as an **Eye-opener** to steady your nerves or feel normal?

If two or more of the CAGE questions are positive, be aware that substance abuse is likely and the patient needs guidance and encouragement to seek treatment. Among older adults risk factors for development of alcohol-related problems include chronic medical disorders, sleep disorders, social isolation, loneliness, bereavement, and acute or chronic pain. Older women appear to abuse alcohol more often than elderly men (Boyle and Davis, 2006).

Vital Signs

After completing the general survey, measure the patient's vital signs (see Chapter 29). Measurement of vital signs is more accurate if completed before beginning positional changes or movements. If there is a chance that the vital signs are skewed when first measured, recheck them later during the rest of the examination. Pain, considered the fifth vital sign, should also be assessed.

Height and Weight

Height and weight reflect a person's general health status. Standardized tables help reveal the normal expected adult weight for a given height (Table 30-6). Assess every patient to identify if he or she is at a healthy weight, overweight, or obese. Weight is routinely measured during health screenings, visits to physicians' offices or clinics, and on admission to the hospital. Infants and children are measured for both height and weight at each health care visit to assess for healthy growth and development. If older adults are underweight, difficulty with feeding and other functional activities is a possibility. Measuring height and weight of older adults, along with obtaining a dietary history, shows risk factors for chronic diseases (Box 30-5).

Assess trends in weight changes compared with height for signs of poor health. Assessments screen for abnormal weight changes. A patient's weight normally varies daily because of fluid loss or retention. However, a downward trend in a frail older adult indicates that there is a serious reduction in nutritional reserves. The nursing history helps to focus on possible causes for a change in weight (Table 30-7). Ask the patient to report current height and weight, along with a history of any substantial weight gain or loss. A weight gain of 5 pounds (2.3 kg) in 1 day indicates fluid-retention problems. A weight loss is considered significant if the patient has lost more than 5% of body weight in a month or 10% in 6 months.

When a patient is hospitalized, daily weight is measured at the same time of day, on the same scale, with approximately the same clothes. This allows an objective comparison of subsequent weights. Accuracy of weight measurement is important because health care

BOX 30-3 CLINICAL INDICATORS OF ABUSE

PHYSICAL FINDINGS	BEHAVIORAL FINDINGS
Child Abuse	
Blood on underclothing	Fear of certain people or places
Pain, itching, or unusual odor in genital area	Play activities recreate the abuse situation
Genital injuries	Regressed behavior
Difficulty sitting or walking	Sexual acting out
Pain while urinating; recurrent urinary tract infections	Knowledge of explicit sexual matters
Foreign bodies in rectum, urethra, or vagina	Preoccupation with others' or own genitals
Sexually transmitted infections	Profound and rapid personality changes
Pregnancy in young adolescent	Rapidly declining school performance
	Poor relationship with peers
Intimate Partner Violence	
Injuries and trauma inconsistent with reported cause	Overuse of health services
Multiple injuries involving head, face, neck, breasts, abdomen, and genitalia (black eyes, orbital fractures, broken nose, fractured skull, lip lacerations, broken teeth, vaginal tears)	Attempted suicide
	Eating or sleeping disorders
X-ray films showing old and new fractures in different stages of healing	Anxiety and panic attacks
Abrasions, lacerations, bruises/welts	Pattern of substance abuse (follows physical abuse)
Burns from cigarettes or other	Low self-esteem
Human bites	Depression
Unexplained injuries (e.g., bruises, fractures, and welts)	Sense of helplessness
Strangulation marks on neck from rope burns or bruises; throat pain, voice changes, trouble swallowing; damage to hyoid bone	Guilt
	Increased forgetfulness
	Stress-related complaints (headache, anxiety)
	Financial dependence on abuser
	Isolation from others
Older-Adult Abuse	
Injuries and trauma inconsistent with reported cause (scratch, bruise, or bite)	Dependent on caregiver
Hematomas, bruises at various stages of resolution	Physically and/or cognitively impaired
Unexplained bruises or welts, pattern bruises	Combative, verbally aggressive
Immersion burns	Wandering
Bruises, chafing, excoriation on wrist or legs (restraints)	Minimal social support
Burns from cigarettes or ropes	Prolonged interval between injury and medical treatment
Fractures inconsistent with cause described	Life circumstances do not match size of the patient's estate
Dried blood	Uncommunicative or isolated
Overmedication or undermedication	
Exposure to severe weather, cold or hot	
Torn, bloody underwear or vaginal and anal bruises	
Sunken eyes or loss of weight	
Extreme thirst	
Bed sores	

Data from Hockenberry MJ, Wilson P: *Wong's nursing care of infants and children*, ed 9, St Louis, 2011, Mosby; Krieger CL: Intimate partner violence, *Nurs Women's Health* 12(3):225, 2008; Muehlbauer M, Crane PA: Elder abuse and neglect, *J Psychosocial Nurs* 44(11):43; Westley C: Elder mistreatment: a self-learning module, *Medsurg Nurs* 14(2):133, 2005.

providers base medical and nursing decisions (e.g., drug dosage, medications) on changes.

Several different scales are available for use. Patients capable of bearing their own weight use a standing scale. The standard platform scale is calibrated by moving the large and small weights to zero. By adjusting the calibrating knob, the balance beam is leveled and steadied. The patient stands on the scale platform and remains still as the nurse adjusts the largest solid weight to the 50-pound or 22.5-kg increment under the patient's weight. Next the smaller weight is moved to balance the scale at the nearest ¼ pound or 0.1 kg (Seidel et al., 2011). Electronic scales automatically display the weight within seconds. They are calibrated automatically each time they are used.

Bed and chair scales are available for patients who are unable to bear weight. Newer electronic hospital beds have built-in electronic scales for weighing patients who are not able to get out of bed.

You can use a basket or platform scale to weigh infants. After removing the infant's clothing, weigh him or her in dry disposable diapers. Adjust the measurement later for the weight of the diaper, ensuring an accurate reading. Keep the room warm to prevent chills. Place a light cloth or paper on the surface of the infant scale to prevent cross-infection from urine or feces. When placing an infant in a basket or on a platform, hold a hand lightly above him or her to detect movements and prevent accidental falls. Measure an infant's weight in both ounces and grams.

BOX 30-4 BEHAVIORS THAT ARE SUSPICIOUS FOR SUBSTANCE ABUSE

Among Adolescents: Agitation, inappropriate behavior, poor coordination, seizure, respiratory depression, coma, asphyxiation, aspiration, pulmonary edema, cardiac arrhythmias, immune system impairment, self-inflicted trauma, and suicidal ideation

Red Flags:

- The risk of suicide, seizures, and violent behavior is high among substance abusers.
- Intoxicated patients—particularly those with phencyclidine (PCP) or methamphetamine intoxication—are at significant risk for becoming agitated and violent, placing themselves and others at risk for injury.

Observe for combinations or repetition of these behaviors:

- Frequently misses appointments
- Frequently requests written excuses for absence from work
- Chief complaints of insomnia, "bad nerves," or pain that does not fit a particular pattern
- Reports lost prescriptions (e.g., tranquilizers or pain medications) or asks for frequent refills
- Frequent emergency department visits
- History of changing health care providers or brings in medication bottles prescribed by several different providers
- History of gastrointestinal bleeds, peptic ulcers, pancreatitis, cellulitis, or frequent pulmonary infections
- Frequent sexually transmitted infections (STIs), complicated pregnancies, multiple abortions, or sexual dysfunction
- Complaints of chest pains or palpitations or has a history of admissions to rule out heart attacks
- History of activities that place the patient at risk for human immunodeficiency virus (HIV) infections (multiple partners, multiple rapes)
- Family history of addiction; history of childhood sexual, physical, or emotional abuse; or social and financial or marital problems
- Intimate partner violence

Data from American Psychiatric Association: *Diagnostic and statistical manual of mental disorders*, ed 4, text revision, Washington, DC, 2000, The Association; American Society of Addiction Medicine and Widlitz M, Marin D: Substance abuse in older adults: an overview, *Geriatrics* 57(12):29, 2002; and Walsh K et al: Examining the interface between substance misuse and intimate partner violence, *Substance Abuse Res Treatment* 3:25, 2009.

BOX 30-5 DIETARY HISTORY FOR OLDER ADULTS

- Does the older adult need or have help shopping for or preparing meals?
- Is income adequate for food purchasing? Food stamps or public assistance required?
- Does the patient ever skip meals?
- Are the five primary food groups from the food guide pyramid represented in the daily diet (see Chapter 44) (USDA and USDHHS, 2010)?
- Does the older adult take nutritional supplements such as multivitamins?
- Does the older adult take any medication affecting appetite or absorption of nutrients?
- Does the older adult have any religious or cultural beliefs and practices that influence diet?
- Does the older adult have a special diet, food intolerances, or allergies? Does the patient's diet contain an unusual amount of alcohol, sweets, or fried food?
- Does the older adult have problems with chewing, swallowing, or salivation?
- Does the older adult have gastrointestinal problems that interfere with food intake?

Data from Meiner SE: *Gerontologic nursing,* ed 4, St Louis, 2011, Mosby; Moore MC: *Pocket guide to nutritional assessment and care,* ed 5, St Louis, 2005, Mosby; and US Department of Agriculture and US Department of Health and Human Services: *Dietary guidelines for Americans, 2010,* ed 7, Washington, DC, 2010, US Government Printing Office.

Measure height in patients capable of standing by having them remove their shoes. The standing surface should be clean. Use a measuring rod attached vertically to a weight scale, or use a tape ruler on the wall. As the patient stands erect, place a flat surface on his or her head that is even with the vertical measure. Then read the number on the scale or ruler that indicates his or her height in centimeters or inches.

Remove the shoes of a nonweight-bearing patient and position the patient (such as an infant) supine on a firm surface. When measuring an infant, hold his or her head and make sure that his or her legs are straight at the knees. After positioning the infant, use a tape measure to measure length from the head to the bottom of the feet (Fig. 30-3). Record the infant's length to the nearest 0.5 cm or ¼ inch.

FIG. 30-3 Measurement of infant length. (From Murray SS, McKinney ES: *Foundations of maternal-newborn and women's health nursing,* ed 5, St Louis, 2010, Saunders.)

SKIN, HAIR, AND NAILS

The **integumentary system** refers to the skin, hair, scalp, and nails. To assess the integument, you first gather a health history to guide your examination and use the techniques of inspection and palpation.

Skin

Begin an assessment of the skin by focusing on the health history questions found in Table 30-8. The physical examination begins with an inspection of all visible skin surfaces; the less visible surfaces are assessed when you examine other body systems. Use the senses of sight, smell, and touch while performing inspection and palpation of the skin.

Assessment of the skin reveals the patient's health status related to oxygenation, circulation, nutrition, local tissue damage, and hydration. Check the condition of the patient's integument to determine the need for nursing care. For example, assessment findings can help determine the type of hygiene measures required to maintain integrity of the integument (see Chapter 39). Adequate

TABLE 30-7 Nursing History for Weight Assessment

ASSESSMENT	RATIONALE
Ask about total weight lost or gained; compare with usual weight; note time period for loss (e.g., gradual, sudden, desired, or undesired).	Assessment determines severity of problem and reveals if weight change is related to disease process, change in eating pattern, or pregnancy.
If weight loss desired, ask about eating habits, diet plan followed, food preparation, calorie intake, appetite, exercise pattern, support group participation, weight goal.	Assessment helps to determine appropriateness of diet plan followed.
If weight loss undesired, ask about anorexia; vomiting; diarrhea; thirst; frequent urination; and change in lifestyle, activity, and stress levels.	Assessment focuses on problems that cause weight loss (e.g., gastrointestinal problems).
Assess if patient has noted changes in social aspects of eating: more meals in restaurants, rushing to eat meals, stress at work, or skipping meals.	Lifestyle changes sometimes contribute to weight changes.
Assess if patient takes chemotherapy, diuretics, insulin, fluoxetine, prescription and nonprescription appetite suppressants, laxatives, oral hypoglycemics, or herbal supplements (weight loss); steroids, oral contraceptives, antidepressants, insulin (weight gain).	Weight gain or loss is a side effect of these medications.
Assess for preoccupation with body weight or body shape such as fasting, never feeling thin enough, unusually strict caloric intake or restrictions, laxative abuse, induced vomiting, amenorrhea, excessive exercise, alcohol intake.	Excesses indicate an eating disorder.

nutrition and hydration become goals of therapy if there is an alteration in the integumentary status (see Chapter 44).

Every patient has a risk for skin impairment during administration of care in a hospital setting. Risk increases if there is pressure against the skin when the patient is immobile, from reactions to various medications used in treatment, and from moisture if the patient is incontinent. At high risk are patients who are neurologically impaired or chronically ill or have had orthopedic or vascular injuries. Also at higher risk are patients with diminished mental status, poor tissue oxygenation, low cardiac output, or inadequate nutrition. Patients who are homebound, in nursing homes, or extended care facilities are often at risk for similar problems, depending on their level of mobility and the presence of chronic illness. Routinely assess the skin of all at-risk patients to look for primary or initial lesions that develop. Without proper care primary lesions can deteriorate to become secondary lesions that require

TABLE 30-8 Nursing History for Skin Assessment

ASSESSMENT	RATIONALE
Ask patient about history of changes in skin: dryness, pruritus, sores, rashes, lumps, color, texture, odor, and lesion that does not heal.	Patient is best source to recognize change. Usually skin cancer is first noticed as a localized change in skin color.
Consider if patient has the following history: fair, freckled, ruddy complexion; light-colored hair or eyes; tendency to burn easily.	Characteristics are risk factors for skin cancer.
Determine whether patient works or spends excessive time outside. If so, ask whether patient wears sunscreen and the level of protection.	Exposed areas such as face and arms are more pigmented than rest of body. The American Cancer Society (2011) recommends use of sunscreen.
Determine whether patient has noted lesions, rashes, or bruises.	Most skin changes do not develop suddenly. Change in character of lesion possibly indicates cancer. Bruising indicates trauma or bleeding disorder.
Question patient about frequency of bathing and type of soap used.	Excessive bathing and use of harsh soaps cause dry skin.
Ask if patient has had recent trauma to skin.	Some injuries cause bruising and changes in skin texture.
Determine whether patient has history of allergies.	Skin rashes commonly occur from allergies.
Ask if patient uses topical medications or home remedies on skin.	Incorrect use of topical agents causes inflammation or irritation.
Ask if patient goes to tanning parlors, uses sunlamps, or takes tanning pills.	Overexposure of skin to these irritants can cause skin cancer.
Ask if patient has family history of serious skin disorders such as skin cancer or psoriasis.	Family history can reveal information about patient's condition.
Determine if patient works with creosote, coal, tar, petroleum products, arsenic compounds, or radium.	Exposure to these agents creates risk for skin cancer.

more extensive nursing care. For example, the development of a pressure ulcer lengthens a hospital stay unless it is prevented or discovered and treated early (see Chapter 48).

Adequate lighting is required when assessing the skin. Daylight is the best choice to identify variations in skin color, especially for detecting skin changes in dark-skinned patients. When sunlight is not available, fluorescent lighting is the next best choice. Room temperature also affects skin assessment. A room that is too warm causes superficial vasodilation, resulting in increased redness of the skin. A cool environment causes the sensitive patient to develop cyanosis around the lips and nail beds (Seidel et al., 2011).

Although you inspect the skin over each part of the body during an examination, it is helpful to make a brief but careful overall visual sweep of the entire body. This approach provides a good idea of the distribution and extent of any lesions and the overall symmetry of skin color. Inspect all skin surfaces, making a point to do so when examining other body systems. Often overlooked, inspection of the feet is absolutely essential for patients with poor circulation or diabetes. If any abnormalities are found during an examination, palpate the involved areas. Use disposable gloves for palpation if open, moist, or draining lesions are present.

Throughout the examination remain alert for skin odors. White and black adolescents and adults ordinarily have body odor because they have a greater number of functioning apocrine glands. In contrast, Asians and Native Americans/American Indians often do not (Seidel et al., 2011). Fig. 30-4 illustrates a normal cross-section of the skin.

Color. Skin color varies from body part to body part and from person to person. Despite individual variations, it is usually uniform over the body. Table 30-9 lists common variations. Normal skin pigmentation ranges in tone from ivory or light pink to ruddy pink in light skin and from light to deep brown or olive in dark skin. In older adults **pigmentation** increases unevenly, causing discolored skin. While inspecting the skin be aware that cosmetics or tanning agents sometimes mask normal skin color.

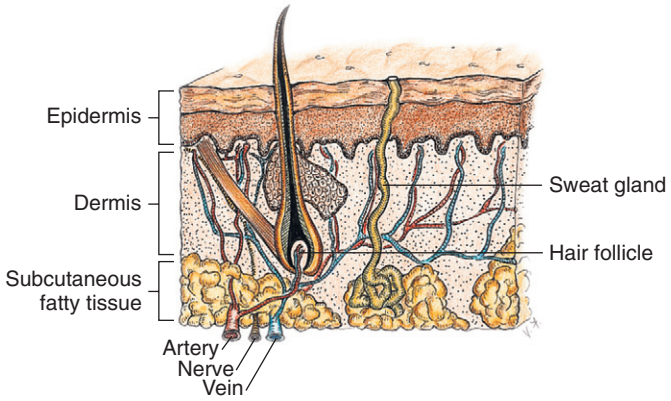

FIG. 30-4 A cross-section of the skin reveals three layers: epidermis, dermis, and subcutaneous fatty tissues.

The assessment of color first involves areas of the skin not exposed to the sun such as the palms of the hands. Note if the skin is unusually pale or dark. Areas exposed to the sun such as the face and arms are darker. It is more difficult to note changes such as pallor or cyanosis in patients with dark skin. Usually color hues are most evident in the palms, soles of the feet, lips, tongue, and nail beds. Areas of increased color (hyperpigmentation) and decreased color (hypopigmentation) are common. Skin creases and folds are darker than the rest of the body in the dark-skinned patient.

Inspect sites where abnormalities are more easily identified. For example, pallor is more evident in the face, buccal (mouth) mucosa, conjunctiva, and nail beds. Observe for **cyanosis** (bluish discoloration) in the lips, nail beds, palpebral conjunctivae, and palms. In recognizing pallor in the dark-skinned patient, observe that normal brown skin appears to be yellow-brown and normal black skin appears to be ashen gray. Also assess the lips, nail beds, and mucous membranes for generalized pallor; if pallor is present, the mucous

TABLE 30-9 Skin Color Variations

COLOR	CONDITION	CAUSES	ASSESSMENT LOCATIONS
Bluish (cyanosis)	Increased amount of deoxygenated hemoglobin (associated with hypoxia)	Heart or lung disease, cold environment	Nail beds, lips, mouth, skin (severe cases)
Pallor (decrease in color)	Reduced amount of oxyhemoglobin Reduced visibility of oxyhemoglobin resulting from decreased blood flow	Anemia Shock	Face, conjunctivae, nail beds, palms of hands Skin, nail beds, conjunctivae, lips
Loss of pigmentation	Vitiligo	Congenital or autoimmune condition causing lack of pigment	Patchy areas on skin over face, hands, arms
Yellow-orange (jaundice)	Increased deposit of bilirubin in tissues	Liver disease, destruction of red blood cells	Sclera, mucous membranes, skin
Red (erythema)	Increased visibility of oxyhemoglobin caused by dilation or increased blood flow	Fever, direct trauma, blushing, alcohol intake	Face, area of trauma, sacrum, shoulders, other common sites for pressure ulcers
Tan-brown	Increased amount of melanin	Suntan, pregnancy	Areas exposed to sun: face, arms, areolas, nipples

membranes are ashen gray. Assessment of cyanosis in the dark-skinned patient requires observing areas where pigmentation occurs the least (conjunctiva, sclera, buccal mucosa, tongue, lips, nail beds, and palms and soles). In addition, verify these findings with clinical manifestations (Seidel et al., 2011).

The best site to inspect for **jaundice** (yellow-orange discoloration) is on the patient's sclera. You can see normal reactive hyperemia, or redness, most often in regions exposed to pressure such as the sacrum, heels, and greater trochanter. Inspect for any patches or areas of skin color variation. Localized skin changes such as pallor or **erythema** (red discoloration) indicate circulatory changes. For example, an area of erythema is caused by localized vasodilation resulting from a sunburn, inflammation, or fever. It is difficult to observe erythema in the dark-skinned patient; thus palpate the area for heat and warmth to note the presence of skin inflammation. Compare the area with a different part of the skin to detect a difference in temperature. An area of an extremity that appears unusually pale results from arterial occlusion or edema. Be sure to ask if the patient has noticed any changes in skin coloring.

There is also a pattern of findings associated with patients who are chemically dependent or intravenous (IV) drug abusers (Table 30-10). It is sometimes difficult to recognize signs and symptoms through an isolated examination. A patient who takes repeated IV injections has edematous, reddened, and warm areas along the arms and legs. This pattern suggests recent injections. Evidence of old injection sites appears as hyperpigmented and shiny or scarred areas.

TABLE 30-10 Physical Findings of the Skin Indicative of Substance Abuse

SKIN FINDING	COMMONLY ASSOCIATED DRUG
Diaphoresis	Sedative hypnotic (including alcohol)
Spider angiomas	Alcohol, stimulants
Burns (especially fingers)	Alcohol
Needle marks	Opioids
Contusion, abrasions, cuts, scars	Alcohol, other sedative hypnotics, intravenous (IV) opioids
"Homemade" tattoos	Cocaine, IV opioids (prevents detection of injection sites)
Vasculitis	Cocaine
Red, dry skin	Phencyclidine (PCP)

Data from Brewer JD et al: Cocaine abuse: dermatologic manifestations and therapeutic approaches, *J Am Acad Dermatol* 59:483, 2008; McKenry L et al: *Mosby's pharmacology in nursing*, ed 22, St Louis, 2006, Mosby; and Smith DE, Seymour RB: *Clinician's guide to substance abuse*, New York, 2001, McGraw-Hill.

Moisture. The hydration of skin and mucous membranes helps to reveal body fluid imbalances, changes in the environment of the skin, and regulation of body temperature. Moisture refers to wetness and oiliness. The skin is normally smooth and dry. Skinfolds such as the axillae are normally moist. Minimal perspiration or oiliness is often present (Seidel et al., 2011). Increased perspiration can be associated with activity, exposure to warm environments, obesity, anxiety, or excitement. Use ungloved fingertips to palpate skin surfaces. Observe for dullness, dryness, crusting, and flaking that resembles dandruff when the skin surface is lightly rubbed. Excessively dry skin is common in older adults and persons who use excessive amounts of soap during bathing (Meiner, 2011). Other factors causing dry skin include lack of humidity, exposure to sun, smoking, stress, excessive perspiration, and dehydration. Excessive dryness worsens existing skin conditions such as eczema and dermatitis.

Temperature. The temperature of the skin depends on the amount of blood circulating through the dermis. Increased or decreased skin temperature indicates an increase or decrease in blood flow. An increase in skin temperature often accompanies localized erythema or redness of the skin. A reduction in skin temperature often accompanies pallor and reflects a decrease in blood flow. It is important to remember that a cold exam room can cause changes in the patient's skin temperature and color.

Accurately assess temperature by palpating the skin with the dorsum or back of the hand. Compare symmetrical body parts. Normally the skin temperature is warm. Sometimes it is the same throughout the body, and other times it varies in one area. Always assess skin temperature for patients at risk of having impaired

circulation such as after a cast application or vascular surgery. You can identify a stage I pressure ulcer early by noting warmth over an area of erythema on the skin (see Chapter 48).

Texture. Texture refers to the character of the surface of the skin and how the deeper layers feel. By palpating lightly with the fingertips, you determine whether the patient's skin is smooth or rough, thin or thick, tight or supple, and **indurated** (hardened) or soft. The texture of the skin is normally smooth, soft, even, and flexible in children and adults. However, the texture is usually not uniform throughout, with thicker texture over the palms of the hand and soles of the feet. In older adults the skin becomes wrinkled and leathery because of a decrease in collagen, subcutaneous fat, and sweat glands.

Localized skin changes result from trauma, surgical wounds, or lesions. When there are irregularities in texture such as scars or indurations, ask the patient about recent injury to the skin. Deeper palpation sometimes reveals irregularities such as tenderness or localized areas of induration, which can be caused by repeated injections.

Turgor. **Turgor** refers to the elasticity of the skin. Normally the skin loses its elasticity with age, but fluid balance can also affect skin turgor. Edema or dehydration diminishes turgor. To assess skin turgor, grasp a fold of skin on the back of the forearm or sternal area with the fingertips and release (Fig. 30-5). Since the skin on the back of the hand is normally loose and thin, turgor is not reliably assessed at that site (Seidel et al., 2011). Normally the skin lifts easily and falls immediately back to its resting position. When turgor is poor, it stays pinched and shows tenting. Evaluate the ease with which the skin moves and the speed at which it returns to its resting state. Failure of the skin to reassume its normal contour or shape indicates dehydration. The patient with poor skin turgor does not have resilience to the normal wear and tear on the skin, and a decrease in turgor predisposes the patient to skin breakdown.

FIG. 30-5 Assessment for skin turgor. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

Vascularity. The circulation of the skin affects color in localized areas and leads to the appearance of superficial blood vessels. Vascularity occurs in localized pressure areas when patients remain in one position. Vascularity appears reddened, pink or pale (see Chapter 48). With aging, capillaries become fragile and more easily injured. **Petechiae** are nonblanching, pinpoint-size, red or purple spots on the skin caused by small hemorrhages in the skin layers. Many petechiae have no known cause, but some may indicate serious blood-clotting disorders, drug reactions, or liver disease.

Edema. Areas of the skin become swollen or edematous from a buildup of fluid in the tissues. Direct trauma and impairment of venous return are two common causes of **edema.** Inspect edematous areas for location, color, and shape. The formation of edema separates the surface of the skin from the pigmented and vascular layers, masking skin color. Edematous skin also appears stretched and shiny. Palpate edematous areas to determine mobility, consistency, and tenderness. When pressure from the examiner's fingers leaves an indentation in the edematous area, it is called *pitting edema*. To assess the degree of pitting edema, press the edematous area firmly with the thumb for several seconds and release. The depth of pitting, recorded in millimeters, determines the degree of edema (Seidel et al., 2011). For example, 1+ edema equals a 2-mm depth, 2+ edema equals a 4-mm depth, 3+ equals 6 mm, and 4+ equals 8 mm (Fig. 30-6).

Lesions. The term *lesion* refers broadly to any unusual finding of the skin surface. Normally the skin is free of lesions, except for common freckles or age-related changes such as skin tags, senile keratosis (thickening of skin), cherry angiomas (ruby red papules), and atrophic warts. Lesions that are primary occur as an initial spontaneous sign of a pathological process such as with an insect bite. Secondary lesions result from later formation or trauma to a primary lesion such as occurs with a pressure ulcer. When you find a lesion, collect standard information about its color, location, texture, size, shape, type, grouping (clustered or linear), and distribution (localized or generalized). Next observe for any exudate, odor, amount, and consistency. Measure the size of the lesion in centimeters by using a small, clear, flexible ruler. Measure each lesion for height, width, and depth.

Palpation helps determine the mobility, contour (flat, raised, or depressed), and consistency (soft or indurated) of a lesion. Certain types of lesions present characteristic patterns. For example, a tumor is usually an elevated, solid lesion larger than 2 cm. Primary

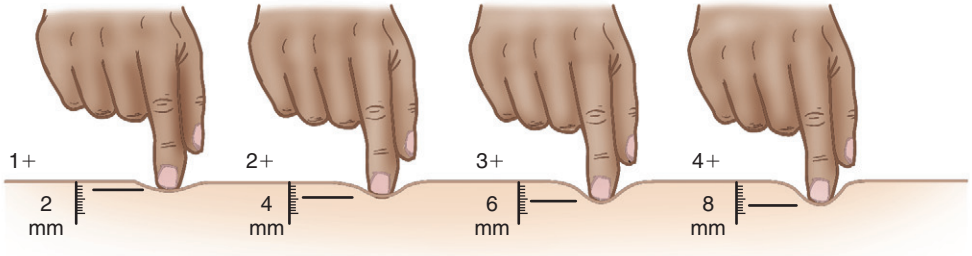

FIG. 30-6 Assessing for pitting edema. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

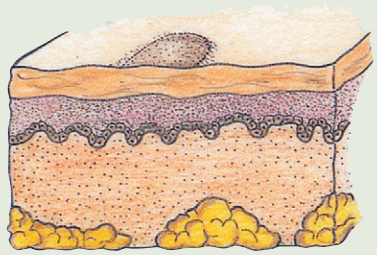
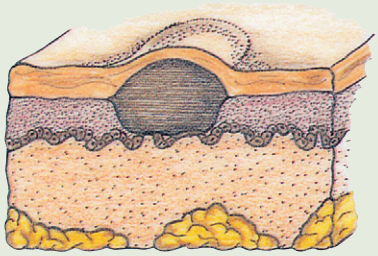
lesions such as macules and nodules come from some stimulus to the skin (Box 30-6). Secondary lesions such as ulcers occur as alterations in primary lesions. After you identify a lesion, closely inspect it in good lighting. Palpate gently, covering the entire area of the lesion. If it is moist or draining fluid, wear gloves during palpation and pay attention to whether or not the patient identifies any areas of tenderness.

Skin (cutaneous) malignancies are the most common neoplasms in patients. For this reason the examiner should incorporate a thorough skin assessment on all patients. Cancerous lesions have distinct features and over time undergo changes in color and size (Box 30-7). Basal cell carcinoma is most common in sun-exposed areas and frequently occurs with a history of sun-damaged skin; it almost never spreads to other parts of the body. Squamous cell carcinoma is more serious than basal cell and develops on the outer layers of sun-exposed skin; these cells may travel to lymph nodes and throughout the body. Malignant melanoma, a skin cancer that develops from melanocytes, begins as a mole or other area that has changed in appearance and is usually located on normal skin; in African Americans (more than in other races), it can also appear under fingernails or on the palms of the hands and soles of the feet. Use the *ABCD* mnemonic to assess the skin for any type of carcinoma (ACS, 2011):



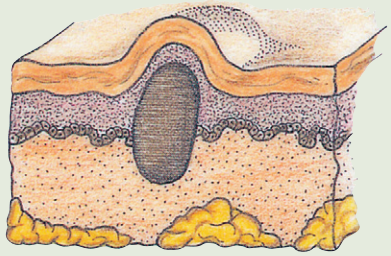
- ***A***symmetry—look for an uneven shape
- ***B***order irregularity—look for edges that are blurred, notched, or ragged
- ***C***olor—look for pigmentation that is not uniform; variegated areas of blue, black, and brown and areas of pink, white, gray, blue, or red are abnormal
- ***D***iameter—look for areas greater than the size of a typical pencil eraser

Report abnormal lesions to the health care provider for further examination. Since ultraviolet light of the sun or tanning beds increase the risk for development of skin cancers, teach patients about the risks that exist. They should be taught how to perform a skin self-examination, using the best-quality teaching materials (Box 30-8).

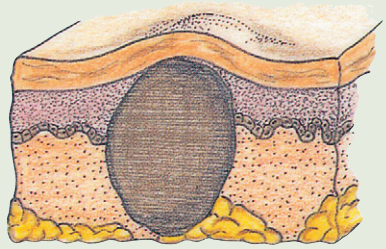


Hair and Scalp

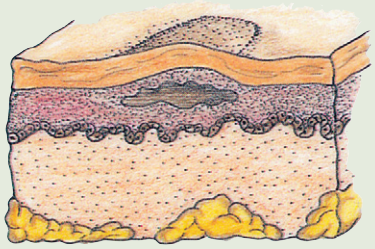
Two types of hair cover the body: soft, fine, vellus hair, which covers the body; and coarse, long, thick terminal hair, which is easily visible on the scalp, axillae, and pubic areas and in the beard on men. First,



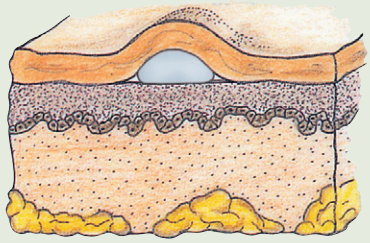
BOX 30-6 TYPES OF PRIMARY SKIN LESIONS



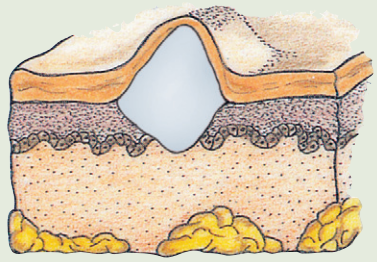
Macule: Flat, nonpalpable change in skin color; smaller than 1 cm (e.g., freckle, petechiae)



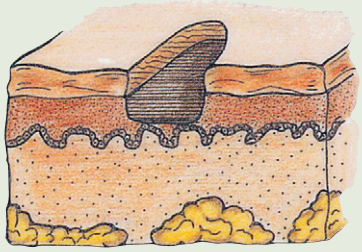
Papule: Palpable, circumscribed, solid elevation in skin; smaller than 1 cm (e.g., elevated nevus)



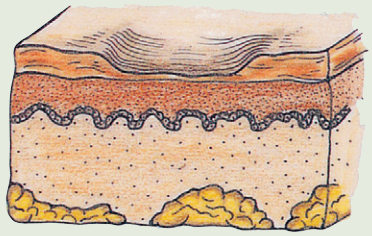
Nodule: Elevated solid mass, deeper and firmer than papule; 1-2 cm (e.g., wart)



Tumor: Solid mass that extends deep through subcutaneous tissue; larger than 1-2 cm (e.g., epithelioma)



Wheal: Irregularly shaped, elevated area or superficial localized edema; varies in size (e.g., hive, mosquito bite)



Vesicle: Circumscribed elevation of skin filled with serous fluid, smaller than 1 cm (e.g., herpes simplex, chickenpox)

Pustule: Circumscribed elevation of skin similar to vesicle but filled with pus; varies in size (e.g., acne, staphylococcal infection)

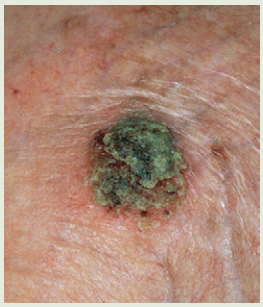
Ulcer: Deep loss of skin surface that extends to dermis and frequently bleeds and scars; varies in size (e.g., venous stasis ulcer)

Atrophy: Thinning of skin with loss of normal skin furrow, with skin appearing shiny and translucent; varies in size (e.g., arterial insufficiency)

BOX 30-7 SKIN MALIGNANCIES

Basal Cell Carcinoma

0.5- to 1-cm crusted lesion that is flat or raised and has a rolled, somewhat scaly border



Frequently appearance of underlying, widely dilated blood vessels within the lesion

Squamous Cell Carcinoma

Occurs more often on mucosal surfaces and nonexposed areas of skin than basal cell

0.5- to 1.5-cm scaly lesion sometimes ulcerated or crusted; appears frequently and grows more rapidly than basal cell

Melanoma

0.5- to 1-cm brown, flat lesion; appears on sun-exposed or nonexposed skin; variegated pigmentation, irregular borders, and indistinct margins

Ulceration, recent growth, or recent changes in long-standing mole are ominous signs

Illustrations from Belcher AE: *Cancer nursing*, St Louis, 1992, Mosby; Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy*, ed 3, St Louis, 1996, Mosby; and Zitelli B, Davis H: *Atlas of pediatric physical diagnosis*, ed 2, St Louis, 1991, Mosby.

obtain health history information listed in Table 30-11. Prepare to inspect the condition and distribution of hair and the integrity of the scalp by first obtaining a good light source. In addition, hair assessment occurs during all portions of the examination.

Inspection. During inspection explain that it is necessary to separate parts of the hair to detect abnormalities. Wear a pair of clean gloves if open lesions or lice are noted.

TABLE 30-11 Nursing History for Hair and Scalp Assessment

ASSESSMENT	RATIONALE
Ask patient if he or she is wearing a wig or hairpiece and ask him or her to remove it.	Wigs or hairpieces interfere with inspection of hair and scalp. (Patient sometimes requests to omit this part of examination.)
Determine if patient has noted change in growth or loss of hair; change in texture or color.	Change often occurs slowly over time.
Identify type of hair care products used for grooming.	Excessive use of chemical agents and burning of hair causes drying and brittleness.
Determine if patient has recently had chemotherapy (drugs that cause hair loss) or taken a vasodilator (minoxidil) for hair growth.	Chemotherapeutic agents kill cells that rapidly multiply such as tumor and normal hair cells. Minoxidil causes excessive hair growth.
Has patient noted changes in diet or appetite?	Nutrition influences condition of hair.

First inspect the color, distribution, quantity, thickness, texture, and lubrication of body hair. Scalp hair is coarse or fine and curly or straight; and it should be shiny, smooth, and pliant. While separating sections of scalp hair, observe characteristics of color and coarseness. Color varies from very light blond to black to gray and is sometimes altered by rinses or dyes. In older adults the hair becomes dull gray, white, or yellow.

Be aware of the normal distribution of hair growth in a man and a woman. At puberty an increase in the amount and distribution of hair occurs for both genders. During the aging process the hair may thin over the scalp, axillae, and pubic areas. For older men, facial hair decreases. A woman with hirsutism has hair growth on the upper lip, chin, and cheeks, with vellus hair becoming coarser over the body. This may be related to an endocrine disorder. For some a change in hair growth negatively affects body image and emotional well-being. The amount of hair covering the extremities is sometimes reduced as a result of aging, or it could result from arterial insufficiency that could reduce hair growth over the lower extremities. In the United States and some other cultures, women commonly shave their legs and axilla, although shaving remains a matter of personal preference among women from all cultures.

Assess for causes of changes in the thickness, texture, and lubrication of scalp hair. At times these are a result of febrile illnesses or scalp diseases that result in hair loss. Conditions such as thyroid disease alter the condition of the hair, making it fine and brittle. Hair loss **(alopecia)** or thinning of the hair is usually related to genetic tendencies or endocrine disorders such as diabetes, thyroiditis, and even menopause. Poor nutrition causes stringy, dull, dry, and thin hair. The oil of sebaceous glands lubricates the hair, but excessively oily hair is associated with androgen hormone stimulation. Dry, brittle hair occurs with aging and excessive use of chemical agents.

Normally the scalp is smooth and inelastic, with even coloration. Carefully separate strands of hair and thoroughly inspect the scalp for lesions, which are not easy to notice in thick hair. Note

BOX 30-8 EVIDENCE-BASED PRACTICE

Skin Assessment

PICO Question: Is skin cancer detected early in patients at high risk for melanoma when they undergo annual full body skin examinations by health providers versus being taught self-examination with periodic check-ups?

Evidence Summary

The rates of melanoma and nonmelanoma skin cancers have been steadily increasing for the past 30 years, probably a result of increased cumulative ultraviolet exposure (ACS, 2011; Ridky, 2007). By identifying, treating, and removing nonmelanoma types early, the patient avoids repeated or extensive surgery (American Cancer Society [ACS], 2011).

In contrast, melanoma is the leading cause of death from skin cancer. Melanoma is most treatable when it is found in its thin, early stage, although patients who experience melanoma are at risk for future recurrence (Wolff et al., 2009). If the cancer spreads beyond the lymph nodes to body organs, the disease is fatal.

The ACS (2011) recommends that people engage in regular skin self-examination (SSE) for early identification and treatment. Comprehensive SSE may lead to earlier diagnosis of new or recurrent disease. Women who have positive body image and older women are more likely to perform skin SSE (Chait et al., 2009). Whole body screening by a health care provider is often recommended.

According to the U.S. Preventive Services Task Force, evidence showing that there is a benefit to whole body screening as a way to effectively reduce morbidity and mortality from melanoma is lacking (Wolff et al., 2009). The National Guideline Clearinghouse suggests that full-body screening may be beneficial for people who have a high risk because a first-degree relative had melanoma or because there is a personal history of skin cancer, organ transplantation, or long-term treatment with ultraviolet light for psoriasis (Marret et al., 2007). Further study needs to be done to fully know whether the cost, time, and accuracy of skin cancer screening warrant recommending it for the general public.

Application to Nursing Practice

- Instruct patient to conduct a complete monthly SSE, noting moles, blemishes, and birthmarks. Instruct to inspect all skin surfaces:
  - Perform the examination after a bath or shower, including a head-to-toe check.
  - Use a well-lit room and mirrors to examine all skin surfaces; enlisting a partner's help significantly increases the chance that the self-examination is thorough (Loescher et al., 2006).
- Instruct patient to report to their health care provider any change in size or color of moles or skin lesions or a sore that does not heal, starts to bleed, ooze or feel different (swollen, hard, lumpy, itchy, or tender to the touch). Especially instruct older adults, who tend to have delayed wound healing.
- Use supportive communication (Glanz et al., 2010, Mujumdar et al., 2009) to inform your patients of ways to prevent skin cancer by avoiding overexposure to the sun.
- Wear wide-brimmed hats and long sleeves.
- Apply broad-spectrum sunscreens with skin protection factor (SPF) of 15 or greater to protect against ultraviolet B (UVB) and ultraviolet A (UVA) rays approximately 15 minutes before going into the sun and after swimming or perspiring.
- Avoid tanning under the direct sun at midday (10 AM to 4 PM).
- Do not use indoor sunlamps, tanning parlors, or tanning pills.
- Inform patients who are on medications that make the skin more sensitive to the sun (e.g., oral contraceptives, antibiotics, antiinflammatories, antihypertensives, immunosuppressives) to take extra precautions when spending time in the sun.
- Inform patients to protect their children from the sun. Severe sunburns in childhood greatly increase melanoma risk later in life (ACS, 2011).
- Encourage all women to perform SSE, show respect for those who have a poorer body image as it relates to body mass index, and encourage and support feelings surrounding self-inspection (Chait et al., 2009).
- Teach patients to avoid very dry skin by avoiding hot water, harsh soaps, and drying agents such as rubbing alcohol; using a super-fatted (Dove) soap; and patting, not rubbing, the skin after bathing.
- Apply moisturizers to the skin regularly to reduce itching and drying and wear cotton clothing.

the characteristics of any scalp lesion. For lumps or bruises, ask if the patient has experienced recent head trauma. Moles on the scalp are common, but they can bleed as a result of vigorous combing or brushing. Dandruff or psoriasis frequently causes scaliness or dryness of the scalp.

Careful inspection of hair follicles on the scalp and pubic areas can reveal lice or other parasites. The three types of lice are *Pediculus humanus capitis* (head lice), *Pediculus humanus corporis* (body lice), and *Pediculus pubis* (crab lice). The presence of lice does not mean a person practices poor hygiene. Lice spread easily, especially among children who play closely together. Head and crab lice attach their eggs to hair. The tiny eggs look like oval particles of dandruff, although the lice themselves are difficult to see (Fig. 30-7). Head and body lice are very small with grayish-white bodies, whereas crab lice have red legs. To better identify infestations, observe for small, red, pustular eruptions in the hair follicles and areas where skin surfaces meet, such as behind the ears and in the groin. A person often has intense itching of the scalp, especially on the back of the head or neck. Combing with a fine-tooth comb reveals the small oval-shaped lice; discovery of lice requires immediate treatment. Teach the patient to perform best hair and scalp hygiene practices (Box 30-9).

FIG. 30-7 Head lice. Numerous white nits attached to hairs. (From Weston WL et al: *Color textbook of pediatric dermatology,* ed 4, St Louis, 2007, Mosby.)

BOX 30-9 PATIENT TEACHING

Hair and Scalp Assessment

Objective

- Patient will perform proper hygiene practices for care of the hair and scalp.

Teaching Strategies

- Instruct patient about basic hygiene practices for hair and scalp care.
- Instruct patients who have head lice to shampoo thoroughly with pediculicide (shampoo available at drugstores) in cold water at a basin or sink. Do not use a tub or shower, where the medication can reach other body parts. Comb thoroughly with a fine-tooth comb (following product directions), and discard comb. *Caution: Do not use products containing Lindane, a toxic ingredient known to cause adverse reactions.* Repeat shampoo treatment 12 to 24 hours later.
- After shampooing, remove any detectable nits or nit cases with tweezers or a metal nit comb. A dilute solution of vinegar and water helps loosen nits.
- Instruct patients and parents about ways to reduce transmission of lice:
  - Do not share hair brushes, combs, hair pieces, hats, bedding, towels, or clothing with someone who has head lice.
  - Vacuum all rugs, car seats, pillows, furniture, and flooring thoroughly and discard vacuum bag.
  - Seal nonwashable items in plastic bags for 14 days if unable to dry-clean or vacuum.
  - Use thorough hand hygiene practices.
  - Launder all clothing, linen, and bedding in hot water and detergent, then dry in a hot dryer for at least 30 minutes. Dry-clean nonwashable items.
  - Do not use insecticide.
  - Instruct patient to notify his or her partner if lice were sexually transmitted.
  - Avoid physical contact with infested individuals and their belongings, especially clothing and bedding.
  - Soak any comb or brush used to remove lice for 15 minutes in very hot ammonia water (1 tsp ammonia to 2 cups hot water) or boiling water for 10 minutes.

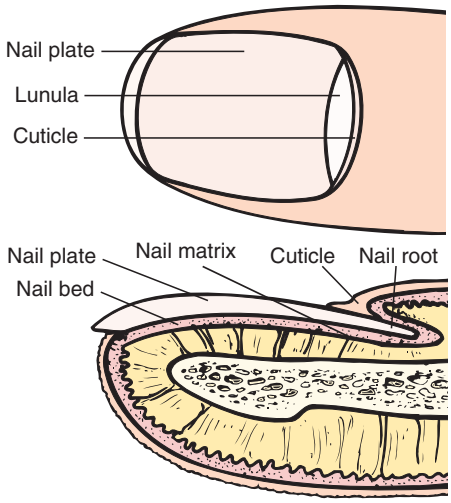
Evaluation

- Have patient describe methods used to care for the hair and scalp.
- Have patient explain the steps to take to reduce lice transmission in the home.

Data from Heyman DL, editor: *Control of communicable diseases manual,* Washington, DC, 2009, American Public Health Association; and National Pediculosis Association: *Child care provider's guide to controlling head lice,* 2005, http://www.headlice.org. Accessed September 8, 2011.

TABLE 30-12 Nursing History for Nail Assessment

ASSESSMENT	RATIONALE
Ask if patient has experienced recent trauma or changes in nails (splitting, breaking, discoloration, thickening).	Trauma changes shape and growth of nail. Systemic conditions cause changes in color, growth, and shape.
Has the patient had other symptoms of pain, swelling, presence of systemic disease with fever, or psychological or physical stress?	Alterations sometimes occur slowly over time.
Question patient's nail care practices. Determine if patient has acrylic nails or silk wraps.	Change in nails can be caused by local or systemic problem. Acrylic nails and silk wraps are areas for fungal growth.
Determine if patient has risks for nail or foot problems (e.g., diabetes, peripheral vascular disease, older adulthood, obesity).	Chemical agents cause drying of nails. Improper care damages nails and cuticles. Vascular changes associated with diabetes and peripheral vascular disease reduce blood flow to peripheral tissues; foot lesions and thickened nails are common. Some older adults have trouble performing foot and nail care because of poor vision, lack of coordination, or inability to bend over. Obese patients have difficulty bending.



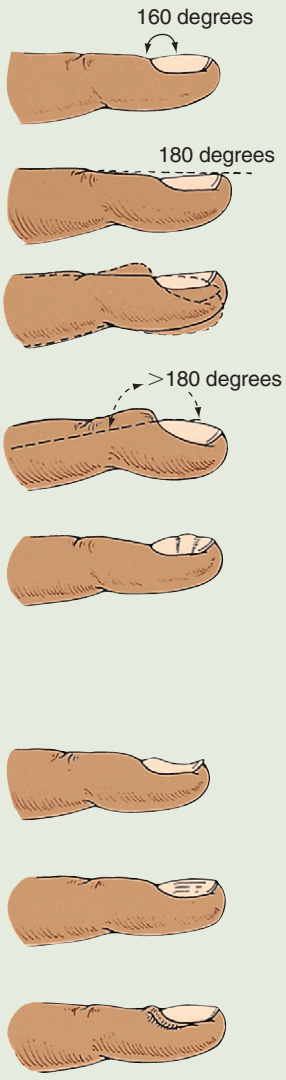


FIG. 30-8 Components of nail unit. (From Lewis SL et al: *Medical-surgical nursing,* ed 8, St Louis, 2011, Mosby.)

Nails

The condition of the nails reflects general health, state of nutrition, a person's occupation, and habits of self-care. Before assessing the nails, gather a brief history (Table 30-12). The most visible portion of the nail is the nail plate, the transparent layer of epithelial cells covering the nail bed (Fig. 30-8). The vascularity of the nail bed creates the underlying color of the nail. The semilunar whitish area at the base of the nail bed is called the *lunula,* from which the nail plate grows.

Inspection and Palpation. Inspect the nail bed for color, length, symmetry, cleanliness, and configuration. The shape and condition of the nails can give clues to pathophysiological problems. Assess the thickness and shape of the nail, the texture of the nail, the angle between the nail and the nail bed, and the condition of the lateral and proximal nail folds around the nail. When inspecting the nails, you gather a sense about the patient's hygiene practices. The nails are normally transparent, smooth, well rounded, and convex, with a nail bed angle of about 160 degrees (Box 30-10). A larger angle and softening of the nail bed indicate chronic oxygenation problems. The surrounding cuticles are smooth, intact, and without inflammation. When you assess for basic care of the nails, you recognize that nail biting, stains, and jagged edges either represent poor nail care or are caused by habits or occupational exposure to grease or dirt. Jagged, bitten, or broken nail edges or cuticles predispose a patient to localized infection.

BOX 30-10 ABNORMALITIES OF THE NAIL BED

Normal nail: Approximately 160-degree angle between nail plate and nail

Clubbing: Change in angle between nail and nail base (eventually larger than 180 degrees); nail bed softening with nail flattening; often enlargement of fingertips
Causes: Chronic lack of oxygen: heart or pulmonary disease

Beau's lines: Transverse depressions in nails indicating temporary disturbance of nail growth (nail grows out over several months).
Causes: Systemic illness such as severe infection; nail injury

Koilonychia (spoon nail): Concave curves
Causes: Iron deficiency anemia, syphilis, use of strong detergents

Splinter hemorrhages: Red or brown linear streaks in nail bed
Causes: Minor trauma, subacute bacterial endocarditis, trichinosis

Paronychia: Inflammation of skin at base of nail
Causes: Local infection, trauma

BOX 30-11 PATIENT TEACHING

Nail Assessment

Objective
- Patient will properly care for fingernails, feet, and toenails.

Teaching Strategies
- Instruct patient to cut nails only after soaking them about 10 minutes in warm water. (**Exception:** Patients with diabetes or peripheral vascular disease are warned against soaking nails because this dries out the hands and feet; dry skin leads to infection.)
- Caution patient against over-the-counter preparations to treat corns, calluses, or ingrown toenails.
- Instruct patient to cut nails straight across and even with tops of fingers or toes. If patient has diabetes, tell him or her to file rather than cut nails (see Chapter 39).
- Instruct patient to shape nails with a file or emery board.
- If patient has diabetes:
  - Wash feet daily in warm water and carefully dry them, especially between the toes. Inspect feet each day in good lighting, looking for dry places and cracks in skin. Soften dry feet by applying a cream or lotion such as Nivea, Eucerin, or Alpha Keri.
  - Do not put lotion between toes; moisture between toes allows microorganisms to grow, leading to infections.
  - Caution patient against using sharp objects to poke or dig under toenail or around the cuticle.
  - Have patient see a podiatrist for treatment of ingrown toenails and nails that are thick or tend to split.

Evaluation
- Inspect nails during the next home visit.
- Have patient explain steps to take to avoid injury.

When palpating, expect to find a firm nail base and check for any abnormalities such as erythema or swelling. For patients with impaired circulation, especially observe for early signs of infection or open lesions. To palpate, gently grasp the patient's finger and observe the color of the nail bed. The nail bed and nails appear pink with white nail tips in white patients. In darker-skinned patients the nail beds are darkly pigmented with a blue or reddish hue. A brown or black pigmentation is normal with longitudinal streaks (Fig. 30-9). Trauma, cirrhosis, diabetes mellitus, and hypertension cause splinter hemorrhages. Vitamin, protein, and electrolyte changes cause various lines or bands to form on the nail beds.

Nails normally grow at a constant rate, but direct injury or generalized disease changes growth patterns. With aging the nails of the fingers and toes become harder and thicker. Longitudinal striations develop, and the rate of nail growth slows. Nails become more brittle, dull, and opaque and turn yellow in older adults with insufficient calcium. In addition, the cuticle becomes less thick and wide.

Calluses and corns are commonly found on the toes or fingers. A callus is flat and painless, resulting from a thickening of the epidermis. Friction and pressure from shoes cause corns, usually over bony prominences. During the examination instruct the patient in proper nail care (Box 30-11).

FIG. 30-9 Pigmented bands in nail of patient with dark skin. (From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy,* ed 5, St Louis, 2010, Mosby.)

HEAD AND NECK

An examination of the head and neck includes assessment of the head, eyes, ears, nose, mouth, pharynx, and neck (lymph nodes, carotid arteries, thyroid gland, and trachea). During assessment of

TABLE 30-13 Nursing History for Head Assessment

ASSESSMENT	RATIONALE
Determine if patient experienced recent head trauma. If so, assess state of consciousness after injury (immediately on return and 5 minutes later), duration of unconsciousness, and predisposing factors (e.g., seizure, poor vision, blackout).	Trauma is major cause for lumps, bumps, cuts, bruises, or deformities of scalp or skull. Loss of consciousness following head injury indicates possible brain injury.
Ask if patient has history of headache; note onset, duration, character, pattern, and associated symptoms.	Character of headache helps to reveal causative factors such as sinus infection, migraine, or neurological disorders.
Determine length of time patient has experienced neurological symptoms.	Duration of signs or symptoms reveals severity of problem.
Review patient's occupational history for use of safety helmets.	Nature of some occupations creates a risk for head injury.
Ask if patient participates in contact sports, cycling, rollerblading, or skateboarding.	These activities require use of safety helmets.

peripheral arteries also assess the carotid arteries. Assessment of the head and neck uses inspection, palpation, and auscultation, with inspection and palpation often used simultaneously.

Head

Inspection and Palpation. The nursing history screens for intracranial injury and local or congenital deformities (Table 30-13). Inspect the patient's head, noting the position, size, shape, and contour. The head is normally held upright and midline to the trunk. Holding it tilted to one side acts as a behavioral indicator of a potential unilateral hearing or visual loss or is a physical indicator of muscle weakness in the neck. A horizontal jerking or bobbing indicates a tremor.

Note the patient's facial features, looking at the eyelids, eyebrows, nasolabial folds, and mouth for shape and symmetry. It is normal for slight asymmetry to exist. If there is facial asymmetry, note if all features on one side of the face are affected or if only a portion of the face is involved. Various neurological disorders (e.g., facial nerve paralysis) affect different nerves that innervate muscles of the face.

Examine the size, shape, and contour of the skull. The skull is generally round with prominences in the frontal area anteriorly and the occipital area posteriorly. Trauma typically causes local skull deformities. In infants a large head results from congenital anomaly or the buildup of cerebrospinal fluid in the ventricles (hydrocephalus). Some adults have enlarged jaws and facial bones resulting from acromegaly, a disorder caused by excessive secretion of growth hormone. Palpate the skull for nodules or masses. Gently rotate the fingertips down the midline of the scalp and along the sides of the head to identify abnormalities. Palpate the temporomandibular joint (TMJ) space bilaterally. Place the fingertips just anterior to the tragus of each ear. The fingertips should slip into the joint space as the patient's mouth opens to gently palpate the joint spaces. Normally the movements should be smooth, although it is not unusual to hear or feel a clicking or snapping in the TMJ (Seidel et al., 2011).

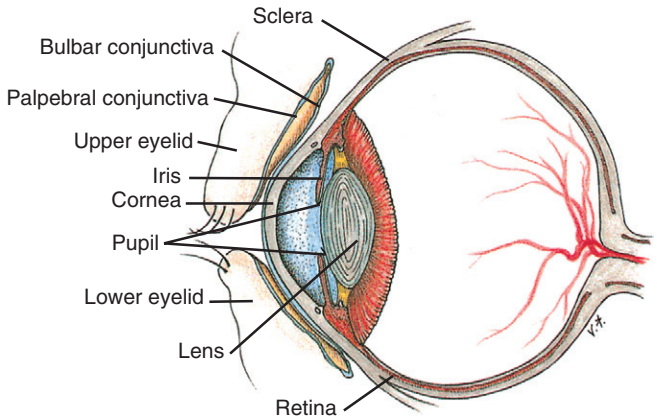

FIG. 30-10 Cross-section of eye.

Eyes

Examination of the eyes includes assessment of visual acuity, visual fields, extraocular movements, and external and internal eye structures. Fig. 30-10 shows a cross-section of the eye. The eye assessment detects visual alterations and determines the general level of assistance that patients require when ambulating or performing self-care activities. Some patients with visual problems also need special aids for reading educational materials or instructions (e.g., medication labels). Table 30-14 reviews the nursing history for an eye examination. Box 30-12 describes common types of visual problems.

Visual Acuity. The assessment of visual acuity (i.e., the ability to see small details) tests central vision. The easiest way to assess near vision is to ask patients to read printed material under adequate lighting. If patients wear glasses, make sure that they wear them during the assessment. Determine the language the patient speaks and his or her reading ability. Asking patients to read aloud helps to determine literacy. If the patient has difficulty reading, move to the next step.

Assessment of distant vision requires using a Snellen chart (paper chart or projection screen). The chart should be well lighted. Test vision without corrective lenses first. Have the patient sit or stand 6.1 m (20 feet) away from the chart and try to read all of the letters beginning at any line with both eyes open. Then have the patient read the line with each eye separately (patient covers the opposite eye with an index card or eye cover to avoid applying pressure to the eye). Note the smallest line for which the patient is able to read all of the letters correctly and record the visual acuity for that line. Repeat the test with the patient wearing corrective lenses. Complete the test rapidly enough so the patient does not memorize the chart (Seidel et al., 2011). If a patient is unable to read, use an *E* chart or one with pictures of familiar objects. Instead of reading letters, patients tell which direction each *E* is pointing or the name of the object.

The Snellen chart has standardized numbers at the end of each line of the chart. The numerator is the number 20, or the distance the patient stands from the chart. The denominator is the distance from which the normal eye is able to read the chart. Normal visual acuity is 20/20. The larger the denominator, the poorer the patient's visual acuity. For example, a value of 20/40 means that the patient, standing 20 feet away, can read a line that a person with normal vision can read from 40 feet away. Record visual acuity for each eye and both eyes, and record whether the test was performed with or without correction (including glasses or contact lenses).

TABLE 30-14 Nursing History for Eye Assessment

ASSESSMENT	RATIONALE
Determine if patient has history of eye disease, (e.g., glaucoma, retinopathy, cataracts), eye trauma, diabetes, hypertension, or eye surgery.	Some diseases or trauma cause risk for partial or complete visual loss. Patient may have had surgery for a visual disorder.
Determine problems that prompted patient to seek health care. Ask patient about eye pain, photophobia (sensitivity to light), burning or itching, excess tearing or crusting, diplopia (double vision) or blurred vision, awareness of a "film" or "curtain" over field of vision, floaters (small, black spots that seem to float across field of vision), flashing lights, or halos around lights.	Common symptoms of eye disease indicate need for health care provider.
Determine whether there is family history of eye disorders or diseases.	Certain eye problems such as glaucoma or retinitis pigmentosa are inherited.
Review patient's occupational history and recreational hobbies. Are safety glasses worn?	Performance of close, intricate work causes eye fatigue. Working with computers causes eye strain. Certain occupational tasks (e.g., working with chemicals) and recreational activities (e.g., fencing, motorcycle riding) place people at risk for eye injury unless they take precautions.
Ask patient if he or she wears glasses or contacts and, if so, how often.	Patients need to wear glasses or contacts during certain portions of examination for accurate assessment.
Determine when patient last visited ophthalmologist or optometrist.	Date of last eye examination reveals level of preventive care patient takes.
Assess medications patient is taking, including eye drops or ointment.	Determines need to assess patient's knowledge of medications. Certain medications cause visual symptoms.

BOX 30-12 COMMON EYE AND VISION PROBLEMS

Hyperopia
Hyperopia is farsightedness, a refractive error in which rays of light enter the eye and focus behind the retina. Persons are able to clearly see distant objects but not close objects.

Myopia
Myopia is nearsightedness, a refractive error in which rays of light enter the eye and focus in front of the retina. Persons are able to clearly see close objects but not distant objects.

Presbyopia
Presbyopia is impaired near vision in middle-age and older adults, caused by loss of elasticity of the lens and associated with the aging process.

Retinopathy
Retinopathy is a noninflammatory eye disorder resulting from changes in retinal blood vessels. It is a leading cause of blindness.

Strabismus
Strabismus is a (congenital) condition in which both eyes do not focus on an object simultaneously; these eyes appear crossed. Impairment of the extraocular muscles or their nerve supply causes strabismus.

Cataracts
A cataract is an increased opacity of the lens, which blocks light rays from entering the eye. Cataracts sometimes develop slowly and progressively after age 35 or suddenly after trauma. Cataracts are one of the most common eye disorders. Most older adults (65 years old and older) have some evidence of visual impairment from cataracts.

Glaucoma
Glaucoma is intraocular structural damage resulting from elevated intraocular pressure. Obstruction of the outflow of aqueous humor causes this. Without treatment the disorder leads to blindness.

Macular Degeneration
Macular degeneration is blurred central vision often occurring suddenly, caused by a progressive degeneration of the center of the retina. It is the most common visual impairment of individuals over age 50 and the most common cause of blindness in older adults. There is no cure.

If patients cannot read even the largest letters or figures of a Snellen chart, test their ability to count upraised fingers or distinguish light. Hold a hand 30 cm (1 foot) from the patient's face and have him or her count the upraised fingers. To check light perception shine a penlight into the eye and turn off the light. If the patient notes when the light is turned on or off, light perception is intact.

Assess near vision by asking the patient to read a handheld card containing a vision screening chart. The patient holds the card a comfortable distance (5 to 6 cm [about 12½ to 14 inches]) from the eyes and reads the smallest line possible. This portion of the examination is a good time to discuss the need for routine eye examinations (Box 30-13).

Extraocular Movements. Six small muscles guide the movement of each eye. Both eyes move parallel to one another in each of the six directions of gaze (Fig. 30-11). To assess extraocular movements the patient sits or stands, and the nurse faces the patient from 60 cm (2 feet) away. The nurse holds a finger at a comfortable distance (15 to 30 cm [6 to 12 inches]) from the patient's eyes. While the patient maintains his or her head in a fixed position facing forward, the nurse directs him or her to follow with the eyes only as the nurse's finger moves to the right, left, and diagonally up and down to the left and right. The nurse moves the finger smoothly and slowly within the normal field of vision.

As the patient gazes in each direction, observe for parallel eye movement, the position of the upper eyelid in relation to the iris, and the presence of abnormal movements. As the eyes move through each direction of gaze, the upper eyelid covers the iris only slightly. **Nystagmus,** an involuntary, rhythmical oscillation of the eyes, occurs as a result of local injury to eye muscles and supporting structures or a disorder of the cranial nerves innervating the

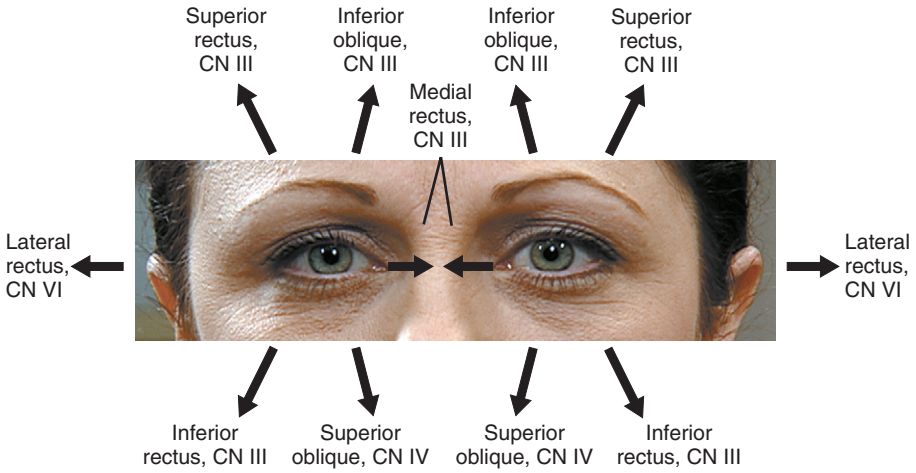

FIG. 30-11 Six directions of gaze. Direct patient to follow finger movement through each gaze. *CN,* Cranial nerve. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

BOX 30-13 PATIENT TEACHING

Eye Assessment

Objective

- Patient will follow recommendations for regular eye examinations and prevention of injury.

Teaching Strategies

- Explain recommended frequency for eye testing with a Snellen chart and examination (see Table 30-3).
- Describe the typical symptoms of eye disease.
- Instruct older adult to take the following precautions because of normal vision changes: avoid or use caution while driving at night, increase lighting in the home to reduce risk of falls, and paint the first and last steps of a staircase and the edge of each of the other steps a bright color to aid depth perception.
- Remind patient that wearing protective eyewear prevents injury from debris and splashes.

Evaluation

- Ask patient or family member to report on patient's most recent visit to an ophthalmologist.
- Have patient describe when to have an eye examination.
- Ask patient to describe common symptoms of eye disease.
- Observe the home environment of a patient with visual deficits.

Modified from Agency for Healthcare Research and Quality: *Guide to clinical preventive services,* Rockville, Md, 2010, AHRQ, http://www.uspreventiveservicestaskforce.org/uspstf09/visualscr/viseldrs.pdf.

muscles. Initiate nystagmus in patients with normal eye movements by having them gaze to the far left or right.

Visual Fields. As a person looks straight ahead, he or she is normally able to see all objects in the periphery. To assess visual fields direct the patient to stand or sit 60 cm (2 feet) away at eye level. The patient gently closes or covers one eye (e.g., the left) and looks at your eye directly opposite. You close your opposite eye (in this case the right) so the field of vision is superimposed on that of the patient. Next move a finger equidistant between you and the patient outside the field of vision and slowly bring it back into the visual field. The patient reports when he or she is able to see the finger. If you see the finger before the patient does, a portion of the patient's visual field is reduced. To test temporal field vision, hold an object or your finger slightly behind the patient. Repeat the procedure for each field of vision for the other eye. Patients with visual field problems are at risk for injury because they cannot see all of the objects in front of them. Older adults commonly have loss of peripheral vision caused by changes in the lens.

External Eye Structures. To inspect external eye structures, stand directly in front of the patient at eye level and ask him or her to look at your face.

Position and Alignment. Assess the position of the eyes in relation to one another. Normally they are parallel to one another. Bulging eyes (exophthalmos) usually indicate hyperthyroidism. Crossed eyes (strabismus) result from neuromuscular injury or inherited abnormalities. Tumors or inflammation of the orbit often cause abnormal eye protrusion.

For the remainder of the eye examination have the patient remove contact lenses.

Eyebrows. Inspect the eyebrows for size, extension, texture of hair, alignment, and movement. Normally the eyebrows are symmetrical. Coarseness of hair and failure to extend beyond the temporal canthus possibly reveals hypothyroidism. Thin brows possibly are a result of waxing or plucking. Aging causes loss of the lateral third of the eyebrows. To assess movement, ask the patient to raise and lower the eyebrows. The brows normally raise and lower symmetrically. An inability to move the eyebrows indicates a facial nerve paralysis (cranial nerve VII).

Eyelids. Inspect the eyelids for position; color; condition of the surface; condition and direction of the eyelashes; and the patient's ability to open, close, and blink. When the eyes are open in a normal position, the lids cover the sclera above the iris but not the pupil. The lids are also close to the eyeball. An abnormal drooping of the lid over the pupil is called **ptosis** (pronounced "toe-sis"), caused by edema or impairment of the third cranial nerve. In the older adult ptosis results from a loss of elasticity that accompanies aging. The nurse observes for defects in the position of the lid margins. An older adult frequently has lid margins that turn out **(ectropion)** or in **(entropion).** Entropion sometimes leads to the lashes of the lid irritating the conjunctiva and cornea, increasing

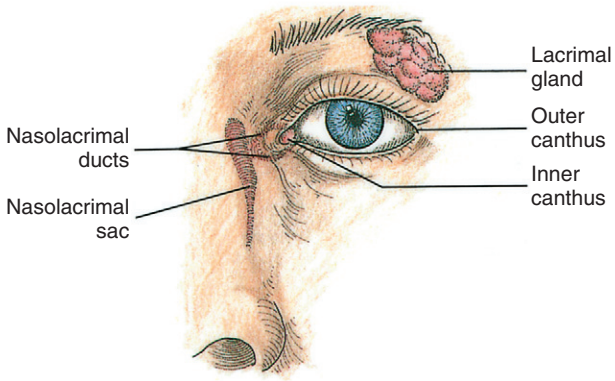

FIG. 30-12 The lacrimal apparatus secretes and drains tears, which moisten and lubricate eye structures.

the risk of infection. Normally the eyelashes are distributed evenly and curved outward away from the eye. An erythematous or yellow lump (hordeolum or sty) on the follicle of an eyelash indicates an acute suppurative inflammation.

To inspect the surface of the upper lids ask the patient to close his or her eyes while observing for tremors of the lids. The lids are normally smooth and the same color as the surrounding skin. Redness indicates inflammation or infection. Lid edema is sometimes caused by allergies or heart or kidney failure. Edema of the eyelids prevents them from closing. Inspect any lesions for typical characteristics and discomfort or drainage. Wear clean gloves if drainage is present.

The lids normally close symmetrically. Their failure to close exposes the cornea to drying. This condition is common in unconscious patients or those with facial nerve paralysis. To inspect the lower lids, ask the patient to open the eyes again while the nurse looks for the same characteristics noted for the upper lids. Normally a patient blinks involuntarily and bilaterally up to 20 times a minute. The blink reflex lubricates the cornea. Report absent, infrequent, rapid, or monocular (one-eyed) blinking.

Lacrimal Apparatus. The lacrimal gland (Fig. 30-12), located in the upper outer wall of the anterior part of the orbit, is responsible for tear production. Tears flow from the gland across the surface of the eye to the lacrimal duct, which is in the nasal corner or inner canthus of the eye. The lacrimal gland is sometimes the site of tumors or infections and should be inspected for edema and redness. Palpate the gland gently to detect tenderness; normally tenderness cannot be felt.

The nasolacrimal duct sometimes becomes obstructed, blocking the flow of tears. Observe for evidence of edema in the inner canthus. Gentle palpation of the duct at the lower eyelid just inside the lower orbital rim causes a regurgitation of tears.

Conjunctivae and Sclerae. The bulbar conjunctiva covers the exposed surface of the eyeball up to the outer edge of the cornea. Observe the sclera under the bulbar conjunctiva; it normally has the color of white porcelain in light-skinned patients and is light yellow in dark-skinned patients. Sclerae become pigmented and appear either yellow or green if liver disease is present.

Take care when inspecting the conjunctivae. For adequate exposure of the bulbar conjunctiva, retract the eyelids without placing pressure directly on the eyeball. Gently retract both lids, with the thumb and index finger pressed against the lower and upper bony orbits. Ask the patient to look up, down, and from side to side. Many patients begin to blink, making the examination difficult.

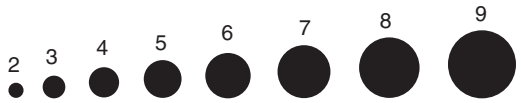

FIG. 30-13 Chart depicting pupillary size in millimeters.

Inspect for color, texture, and the presence of edema or lesions. Normally the conjunctivae are free of erythema. The presence of redness indicates an allergic or infectious **conjunctivitis.** Bright red blood in a localized area surrounded by normal-appearing conjunctiva usually indicates subconjunctival hemorrhage. Conjunctivitis is a highly contagious infection. It is easy to spread the crusty drainage that collects on eyelid margins from one eye to the other. Wear clean gloves during the examination. Performing proper hand hygiene is necessary before and after the examination.

Corneas. The cornea is the transparent, colorless portion of the eye covering the pupil and iris. From a side view, it looks like the crystal of a wristwatch. While the patient looks straight ahead, inspect the cornea for clarity and texture while shining a penlight obliquely across its entire surface. The cornea is normally shiny, transparent, and smooth. In older adults it loses its luster. Any irregularity in the surface indicates an abrasion or tear that requires further examination by a health care provider. Both conditions are very painful. Note the color and details of the underlying iris. In an older adult the iris becomes faded. A thin white ring along the margin of the iris, called an **arcus senilis,** is common with aging but is abnormal in anyone under age 40. To test for the corneal blink reflex, see the cranial nerve test section of this chapter.

Pupils and Irises. Observe the pupils for size, shape, equality, accommodation, and reaction to light. They are normally black, round, regular, and equal in size (3 to 7 mm in diameter) (Fig. 30-13). The iris should be clearly visible.

Cloudy pupils indicate cataracts. Dilated pupils result from glaucoma, trauma, neurological disorders, eye medications (e.g., atropine), or withdrawal from opioids. Inflammation of the iris or use of drugs (e.g., pilocarpine, morphine, or cocaine) causes constricted pupils. Pinpoint pupils are a common sign of opioid intoxication. Shining a beam of light through the pupil and onto the retina stimulates the third cranial nerve, causing the muscles of the iris to constrict. Any abnormality along the nerve pathways from the retina to the iris alters the ability of the pupils to react to light. Changes in intracranial pressure, lesions along the nerve pathways, locally applied ophthalmic medications, and direct trauma to the eye alter pupillary reaction.

Test pupillary reflexes (to light and accommodation) in a dimly lit room. Instruct the patient to avoid looking directly at the light. While the patient looks straight ahead, bring a penlight from the side of his or her face, directing the light onto the pupil (Fig. 30-14). A directly illuminated pupil constricts, and the opposite pupil constricts consensually. Observe the quickness and equality of the reflex. Repeat the examination for the opposite eye.

To test for accommodation, ask the patient to gaze at a distant object (the far wall) and then at a test object (finger or pencil) held approximately 10 cm (4 inches) from the bridge of his or her nose. The pupils normally converge and accommodate by constricting when looking at close objects. The pupillary responses are equal. Testing for accommodation is only important if the patient has a defect in the pupillary response to light (Seidel et al., 2011). If assessment of pupillary reaction is normal in all tests, record the abbreviation **PERRLA** (pupils equal, round, reactive to light, and accommodation).

FIG. 30-14 **A,** To check pupillary reflexes the nurse first holds the penlight to the side of the patient's face. **B,** Illumination of the pupil causes pupillary constriction.

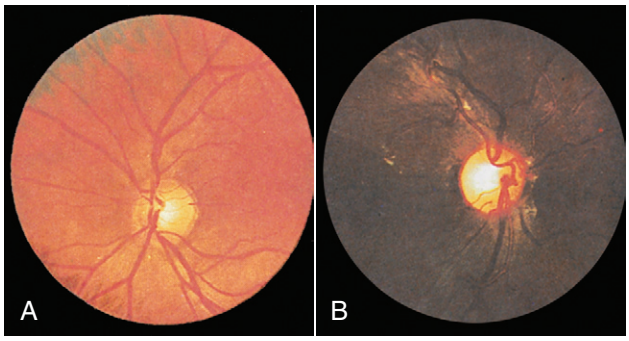

FIG. 30-15 Fundus of white patient **(A)** and black patient **(B)**. (Courtesy MEDCOM, Cypress, Calif.)

Internal Eye Structures. The examination of the internal eye structures through the use of an ophthalmoscope is beyond the scope of new graduate nurses' practice. Advanced nurse practitioners use the ophthalmoscope to inspect the fundus (Fig. 30-15), which includes the retina, choroid, optic nerve disc, macula, fovea centralis, and retinal vessels. Patients in greatest need of an examination are those with diabetes, hypertension, and intracranial disorders.

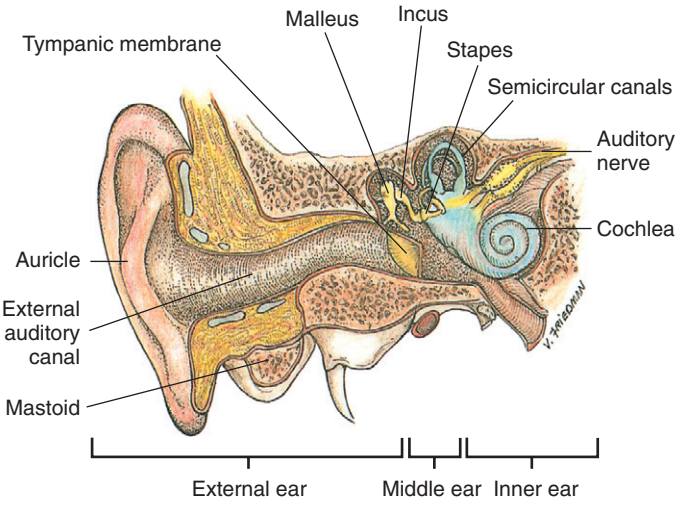

FIG. 30-16 Structures of external, middle, and inner ear.

Ears

The ear assessment determines the integrity of ear structures and hearing acuity. The three parts of the ear are the external, middle, and inner ear (Fig. 30-16). Inspect and palpate external ear structures, which consist of the auricle, outer ear canal, and tympanic membrane (eardrum). The ear canal is normally curved and approximately 2.5 cm (1 inch) long in an adult. It is lined with skin containing fine hairs, nerve endings, and glands secreting cerumen. The middle ear is inspected with an otoscope. It is an air-filled cavity containing the three bony ossicles (malleus, incus, and stapes). The eustachian tube connects the middle ear to the nasopharynx. Pressure between the outer atmosphere and the middle ear is stabilized through the eustachian tube. Finally the inner ear is tested by measuring the patient's hearing acuity. The inner ear contains the cochlea, vestibule, and semicircular canals. Assessing the ears determines the integrity of ear structures and the condition of hearing. Use nursing history data to identify patients' risks for hearing disorders (Table 30-15).

Understanding the mechanisms for sound transmission helps identify the nature of hearing disorders. Sound travels through the ear by air and bone conduction. Nerve impulses from the cochlea travel to the auditory (eighth cranial nerve) and the cerebral cortex. Disorders of the ear result from several types of problems, including mechanical dysfunction (blockage by cerumen or foreign body), trauma (foreign bodies or noise exposure), neurological disorders (auditory nerve damage), acute illnesses (viral infection), and toxic effects of medications.

Auricles. With the patient sitting comfortably, inspect the size, shape, symmetry, landmarks, position, and color of the auricle (Fig. 30-17). The auricles are normally of equal size and level with one another. The upper point of attachment is in a straight line with the lateral canthus, or corner of the eye. The position of the auricle is almost vertical. Ears that are low set or at an unusual angle are a sign of chromosome abnormality such as Down syndrome. Ear color is usually the same as that of the face, without moles, cysts, deformities, or nodules. Redness is a sign of inflammation or fever. Extreme pallor indicates frostbite.

Palpate the auricles for texture, tenderness, and skin lesions. Auricles are normally smooth and without lesions. If the patient complains of pain, gently pull the auricle, press on the tragus, and palpate behind the ear over the mastoid process. If palpating the

TABLE 30-15 Nursing History for Ear Assessment

ASSESSMENT	RATIONALE
Ask if patient has experienced ear pain, itching, discharge, vertigo, tinnitus (ringing in ears), or change in hearing.	These signs and symptoms indicate infection or hearing loss.
Assess risks for hearing problem. *Infants/children:* Hypoxia at birth, meningitis, birth weight less than 1500 g, family history of hearing loss, congenital anomalies of skull or face, nonbacterial intrauterine infections (rubella, herpes), maternal drug use, excessively high bilirubin, head trauma *Adults:* Exposure to industrial or recreational noise, genetic disease (Ménière's disease), neurodegenerative disorder	Risk factors predispose patient to permanent hearing loss. It is difficult to assess infant's hearing status with examination only.
Determine patient's exposure to loud noises at work and availability of protective devices.	Prolonged noise exposure causes temporary or permanent hearing loss.
Note behaviors indicative of hearing loss such as failure to respond when spoken to, requests to repeat comments, leaning forward to hear, and child's inattentiveness or use of monotonous voice tone.	Persons with hearing loss cope with sensory deficit through a variety of behavioral cues.
Assess if patient takes large doses of aspirin or other ototoxic drugs (e.g., aminoglycosides, furosemide, streptomycin, cisplatin, ethacrynic acid).	Medications have side effects of hearing loss.
Determine whether patient uses hearing aid.	Determination allows nurse to assess ability to care for device and adjust voice tone to communicate.
If patient had recent hearing problem, note onset, contributing factors, affected ear, and effect on activities of daily living.	Helps determine nature and severity of hearing problem.
Determine whether patient has repeated history of cerumen buildup in ear.	Cerumen impaction is common cause for conduction deafness.

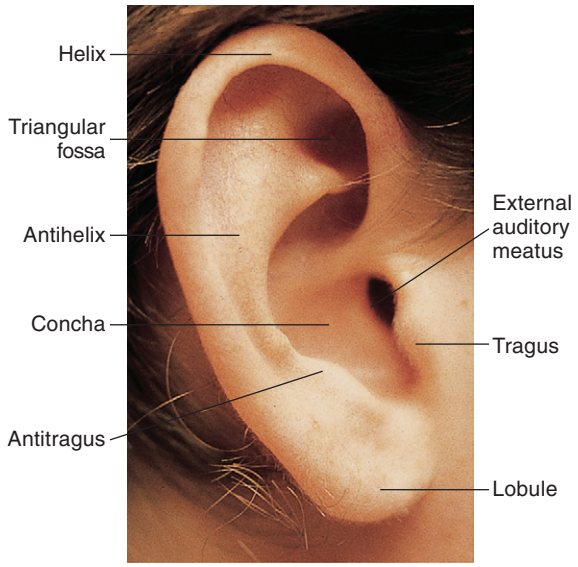

FIG. 30-17 Anatomical structures of auricle. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

external ear increases the pain, an external ear infection is likely. If palpating the auricle and tragus does not influence the pain, the patient possibly has a middle ear infection. Tenderness in the mastoid area indicates mastoiditis.

Inspect the opening of the ear canal for size and presence of discharge. If discharge is present, wear clean gloves. A swollen or occluded meatus is not normal. A yellow, waxy substance called **cerumen** is common. Yellow or green, foul-smelling discharge indicates infection or a foreign body.

Ear Canals and Eardrums. Observe the deeper structures of the external and middle ear with the use of an otoscope. A special ear speculum attaches to the handle of the ophthalmoscope. For best visualization select the largest speculum that fits comfortably in the patient's ear. Before inserting the speculum, check for foreign bodies in the opening of the auditory canal.

Make sure that the patient avoids moving the head during the examination to avoid damage to the canal and tympanic membrane. Infants and young children might need to be held securely to prevent movement. Lay infants supine with head turned to one side and arms held securely at the sides. Have young children sit on their parents' laps with their legs held between the parents' knees.

Turn on the otoscope by rotating the dial at the top of the handle. To insert the speculum properly, ask the patient to tip the head slightly toward the opposite shoulder. Hold the handle of the otoscope in the space between the thumb and index finger, supported on the middle finger. This leaves the ulnar side of the hand to rest against the patient's head, stabilizing the otoscope as you insert it into the canal (Seidel et al., 2011). There are two ways to grip the otoscope: (1) hold the handle along the patient's face with the fingers against the face or neck; and (2) lightly brace the inverted otoscope against the side of the patient's head or cheek. This latter grip, used with children, prevents accidental movement of the otoscope deeper into the ear canal. Insert the scope while pulling the auricle upward and backward in the adult and older child (Fig. 30-18). This maneuver straightens the ear canal. For infants the auricle should be pulled down and back.

Insert the speculum slightly down and forward 1 to 1.5 cm (½ inch) into the ear canal. Take care not to scrape the sensitive lining, which is painful. The ear canal normally has little cerumen and is uniformly pink with tiny hairs in the outer third of the canal. Observe for color, discharge, scaling, lesions, foreign bodies, and

FIG. 30-18 Otoscopic examination. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

BOX 30-14 PATIENT TEACHING

Ear Assessment

Objective

- Patient will follow preventive guidelines for screening of hearing loss and proper cleaning technique for the ears.

Teaching Strategies

- Instruct patient in the proper way to clean the outer ear (see Chapter 39), avoiding use of cotton-tipped applicators and sharp objects such as hairpins, which cause impaction of cerumen deep in the ear canal or trauma.
- Tell patient to avoid inserting pointed objects into the ear canal.
- Encourage patients over age 65 to have regular hearing checks. Explain that a reduction in hearing is a normal part of aging (see Chapter 49).
- Instruct family members of patients with hearing loss to avoid shouting, speak in low tones, and be sure that patient is able to see the speaker's face.

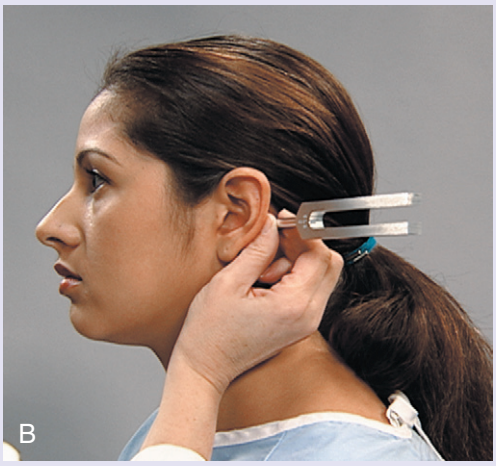
Evaluation

- Ask patient to explain the proper technique for cleaning the ears.
- In a follow-up visit question patient about frequency of hearing checks.
- Observe patient with hearing loss interacting with family members.

cerumen. Normally cerumen is dry (light brown to gray and flaky) or moist (dark yellow or brown) and sticky. Dry cerumen is common in Asians and Native Americans (Seidel et al., 2011). A reddened canal with discharge is a sign of inflammation or infection. In other adults accumulated cerumen is a common problem; buildup creates a mild hearing loss. During the examination ask the patient about methods he or she uses to clean the ear canal (Box 30-14).

The light from the otoscope allows visualization of the tympanic membrane. Know the common anatomical landmarks and their appearances (Fig. 30-19). Gently move the otoscope so the entire tympanic membrane and its periphery are visible. Because the tympanic membrane is angled away from the ear canal, the light from the otoscope appears as a cone shape rather than a circle. A ring of fibrous cartilage surrounds the oval membrane. The umbo is near the center of the membrane, behind which is the attachment of the malleus. The underlying short process of the malleus creates a knoblike structure at the top of the drum. Check carefully to make sure that there are no tears or breaks in the membrane. The normal tympanic membrane is translucent, shiny, and pearly gray. It is free from tears or breaks. A pink or red bulging membrane indicates inflammation. A white color reveals pus behind it. The membrane is taut, except for the small triangular pars flaccida near the top. If cerumen is blocking the tympanic membrane, warm water irrigation safely removes the wax.

Hearing Acuity. A patient with a hearing loss often fails to respond to conversation. The three types of hearing loss are conduction, sensorineural, and mixed. A conduction loss interrupts sound waves as they travel from the outer ear to the cochlea of the inner ear because the sound waves are not transmitted through the outer and middle ear structures. For example, causes of a conduction loss include swelling of the auditory canal and tears in the tympanic membrane. A sensorineural loss involves the inner ear, auditory nerve, or hearing center of the brain. Sound is conducted through the outer and middle ear structures, but the continued transmission of sound becomes interrupted at some point beyond the bony ossicles. A mixed loss involves a combination of conduction and sensorineural loss. Patients working or living around loud noises are at risk for hearing loss. In addition, adolescents are at risk for premature hearing loss from continued exposure to loud music in their car or home or at concert events. Hearing loss among adolescents is increasing, especially among those with high levels of noise exposure such as from loud music (Shargorodsky et al., 2010).



Older adults experience an inability to hear high-frequency sounds and consonants (e.g., *S, Z, T,* and *G*). Deterioration of the cochlea and thickening of the tympanic membrane cause older adults to gradually lose hearing acuity. They are especially at risk for hearing loss caused by **ototoxicity** (injury to auditory nerve) resulting from high maintenance doses of antibiotics (e.g., aminoglycosides).

To conduct a hearing assessment, have the patient remove any hearing aid if worn. Note his or her response to questions. Normally he or she responds without excessive requests to have the questions repeated. If a hearing loss is suspected, check the patient's response to the whispered voice. Test one ear at a time while the patient occludes the other ear with a finger. Ask him or her to gently move the finger up and down during the test in response to the whispered sound. While standing 30 to 60 cm (1 to 2 feet) from the testing ear, speak while covering the mouth so the patient is

TABLE 30-16 **Tuning Fork Tests**

TESTS AND STEPS	RATIONALE
Weber's Test (Lateralization of Sound)	
Hold fork at its base and tap it lightly against heel of palm. Place base of vibrating fork on midline vertex of patient's head or middle of forehead (see illustration *A*). Ask patient if he or she hears the sound equally in both ears or better in one ear (lateralization).	Patient with normal hearing hears sound equally in both ears. In conduction deafness sound is heard best in impaired ear. In sensorineural hearing loss, sound is heard better in normal ear.
Rinne Test (Comparison of Air and Bone Conduction)	
Place stem of vibrating tuning fork against patient's mastoid process (see illustration *B*). Begin counting the interval with your watch. Ask patient to tell you when he or she no longer hears the sound; note number of seconds. Quickly place still-vibrating tines 1 to 2 cm (½ to 1 inch) from ear canal and ask patient to tell you when he or she no longer hears the sound (see illustration *C*). Continue counting time the sound is heard by air conduction. Compare number of seconds the sound is heard by bone conduction versus air conduction.	Patient should hear air-conducted sound twice as long as bone-conducted sound (2:1 ratio). For example, if patient hears bone-conducted sound for 10 seconds, he or she should hear air-conducted sound for an additional 10 seconds. In conduction deafness, patient hears bone conduction longer than air conduction in affected ear. In sensorineural loss, patient hears air conduction longer than bone conduction in affected ear, but at less than a 2:1 ratio (Seidel et al., 2011).

Illustrations from Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.

unable to read lips. After exhaling fully, whisper softly toward the unoccluded ear, reciting random numbers with equally accented syllables such as *nine-four-ten.* If necessary, gradually increase voice intensity until the patient correctly repeats the numbers. Then test the other ear for comparison. Seidel et al. (2011) report that patients normally hear numbers clearly when whispered, responding correctly at least 50% of the time.

If a hearing loss is present, test the hearing using a tuning fork. A tuning fork of 256 to 512 hertz (Hz) is most commonly used. The tuning fork allows for comparison of hearing by bone conduction with that of air conduction. Hold the base of the tuning fork with one hand without touching the tines. Tap the fork lightly against the palm of the other hand to set the fork in vibration (Table 30-16).

TABLE 30-17 Nursing History for Nose and Sinus Assessment

ASSESSMENT	RATIONALE
Ask if patient has had trauma to nose.	Trauma causes septal deviation and asymmetry of external nose.
Ask if patient has history of allergies, nasal discharge, epistaxis (nosebleeds), or postnasal drip.	History is useful in determining source or nature of nasal and sinus drainage.
If there is history of nasal discharge, assess color, amount, odor, duration, and associated symptoms (e.g., sneezing, nasal congestion, obstruction, or mouth breathing).	Aids in ruling out presence of infection, allergy, or drug use.
Assess for history of nosebleed, including site, frequency, amount of bleeding, treatment, and difficulty stopping bleeding.	Characteristics sometimes reveal trauma, medication use, or excessive dryness as causative factors.
Ask if patient uses nasal spray or drops, including amount, frequency, and duration of use.	Overuse of over-the-counter nasal preparations causes physical change in mucosa.
Ask if patient snores at night or has difficulty breathing.	Difficulty breathing or snoring indicates septal deviation or obstruction.

Nose and Sinuses

Assess the integrity of the nose and sinuses by using inspection and palpation. The patient sits during the examination. A penlight allows for gross examination of each naris. A more detailed examination requires use of a nasal speculum to inspect the deeper nasal turbinates. Do not use a speculum unless a qualified practitioner such as a nurse educator or an advanced practice nurse is present. Table 30-17 lists components of the nursing history.

Nose. When inspecting the external nose, observe for shape, size, skin, color, and the presence of deformity or inflammation. The nose is normally smooth and symmetrical with the same skin color as the face. Recent trauma sometimes causes edema and discoloration. If swelling or deformities exist, gently palpate the ridge and soft tissue of the nose by placing one finger on each side of the nasal arch and gently moving the fingers from the nasal bridge to the tip. Note any tenderness, masses, or underlying deviations. Nasal structures are usually firm and stable.

Air normally passes freely through the nose when a person breathes. To assess patency of the nares, place a finger on the side of the patient's nose and occlude one naris. Ask the patient to breathe with the mouth closed. Repeat the procedure for the other naris.

While illuminating the anterior nares, inspect the mucosa for color, lesions, discharge, swelling, and evidence of bleeding. If discharge is present, apply gloves. Normal mucosa is pink and moist without lesions. Pale mucosa with clear discharge indicates allergy. A mucoid discharge indicates rhinitis. A sinus infection results in yellowish or greenish discharge. Habitual use of intranasal cocaine and opioids causes puffiness and increased vascularity of the nasal mucosa. For the patient with a nasogastric tube, routinely check for local skin breakdown **(excoriation)** of the naris, characterized by redness and skin sloughing.

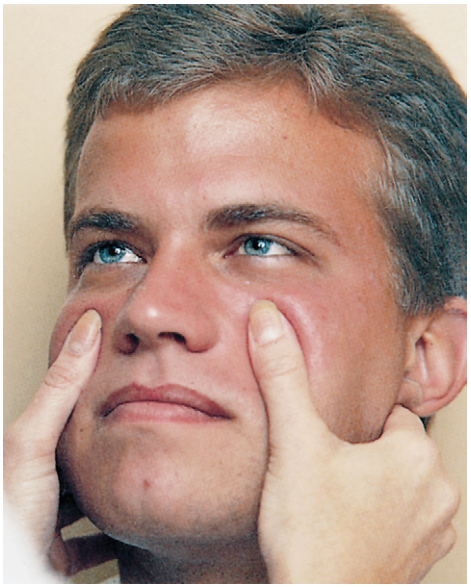


FIG. 30-20 Palpation of maxillary sinuses.

To view the septum and turbinates, have the patient tip the head back slightly to provide a clear view. Illuminate the septum and observe for alignment, perforation, or bleeding. Normally the septum is close to the midline and thicker anteriorly than posteriorly. The turbinates are covered with mucous membranes that warm and moisten inspired air. Normal mucosa is pink and moist, without lesions. A deviated septum obstructs breathing and interferes with passage of a nasogastric tube. Perforation of the septum often occurs after repeated use of intranasal cocaine. Note any **polyps** (tumorlike growths) or purulent drainage.

Sinuses. Examination of the sinuses involves palpation. In cases of allergies or infection, the interior of the sinuses becomes inflamed and swollen. The most effective way to assess for tenderness is by externally palpating the frontal and maxillary facial areas (Fig. 30-20). Palpate the frontal sinus by exerting pressure with the thumb up and under the patient's eyebrow. Gentle, upward pressure elicits tenderness easily if sinus irritation is present. Do not apply pressure to the eyes. If sinus tenderness is present, the sinuses may be transilluminated. However this procedure requires advanced experience. Box 30-15 describes teaching guidelines during nose and sinus assessment.

Mouth and Pharynx

Assess the mouth and pharynx to detect signs of overall health; determine oral hygiene needs; and determine therapies needed for patients with dehydration, restricted intake, oral trauma, or oral airway obstruction. To assess the oral cavity use a penlight and tongue depressor or gauze square. Wear clean gloves during the examination. Have the patient sit or lie down. Assess the oral cavity also while administering oral hygiene (see Chapter 39). Table 30-18 describes the nursing history for assessment of the mouth and pharynx.

Lips. Inspect the lips for color, texture, hydration, contour, and lesions. With the patient's mouth closed, view the lips from end to end. Normally they are pink, moist, symmetrical, and smooth (Fig. 30-21). Lip color in the dark-skinned patient varies from pink to plum. Have female patients remove their lipstick before the examination. Anemia causes pallor of the lips, with cyanosis caused by

TABLE 30-18 Nursing History for Mouth and Pharyngeal Assessment

ASSESSMENT	RATIONALE
Determine if patient wears dentures or retainers and if they are comfortable.	Patient needs to remove dentures to visualize and palpate gums. Ill-fitting dentures chronically irritate mucosa and gums.
Determine if patient has had recent change in appetite or weight.	Symptoms result from painful mouth conditions or poor hygiene.
Determine if patient uses tobacco products:	
• Smoking cigarette, cigar, or pipe	Smoking these products increases risk for lung, oral cavity, larynx, and esophageal cancers (American Cancer Society [ACS], 2011).
• Smokeless tobacco: use of chewing tobacco and snuff	Smokeless tobacco causes various cancers and noncancerous oral disorders. Long-term snuff users have increased risk for cancer of the gums and cheeks (ACS, 2011).
Review history for alcohol consumption.	Oral and pharyngeal cancers are more common in alcohol users than nonalcohol users. Combine tobacco with heavy use of alcohol, the risk is significantly increased, as the two act synergistically. Those who both smoke and drink, have a 15 times greater risk of developing oral cancer than others (Oral Cancer Foundation, 2011). Effects of alcohol are also independent of tobacco use.
Assess dental hygiene practices, including use of fluoride toothpaste, frequency of brushing and flossing, and frequency of dental visits.	Assessment reveals patient's need for education and/or financial support. Periodontal disease has a higher prevalence in older adults who have history of high plaque buildup, use tobacco, and visit the dentist infrequently.
Ask if patient has pain from chewing or eating. If so, ask if mouth lesions are present, including duration and associated symptoms.	Pain is often associated with broken tooth, teeth grinding, or temporomandibular joint problems. Extra care is needed during oral hygiene administration.
Review the patient's medical history for a previous diagnosis of the human papilloma virus.	The human papilloma virus, particularly HPV16, has been definitively implicated in oral cancers, particularly those that occur in the back of the mouth (oropharynx, base of tongue, tonsillar pillars and crypt, as well as the tonsils themselves) (Oral Cancer Foundation, 2011).

FIG. 30-21 Lips are normally pink, symmetrical, smooth, and moist.

respiratory or cardiovascular problems. Cherry-colored lips indicate carbon monoxide poisoning. Any lesions should be evaluated for the potential of being an infection, irritation, or skin cancer.

Buccal Mucosa, Gums, and Teeth. Ask the patient to clench the teeth and smile to observe teeth occlusion. The upper molars normally rest directly on the lower molars, and the upper incisors slightly override the lower incisors. A symmetrical smile reveals normal facial nerve function.

BOX 30-15 PATIENT TEACHING

Nose and Sinus Assessment

Objective

- Patient will explain self-care measures to address and minimize loss of olfaction.

Teaching Strategies

- Caution patient against overuse of over-the-counter nasal sprays, which leads to "rebound" effect, causing excess nasal congestion.
- Instruct parents in care of a child with nosebleeds: have child sit up and lean forward to avoid aspiration of blood, apply pressure to the anterior nose with the thumb and forefinger as the child breathes through the mouth, and apply ice or a cold cloth to the bridge of the nose if pressure fails to stop bleeding.
- Instruct older adults with loss of olfaction to follow safety precautions:
  - Install smoke detectors on each floor of their home.
  - Ask others to advise them when food smells pungent.
- Instruct older adults to always check dated labels on food to ensure against spoilage.

Evaluation

- Have patient explain proper use of over-the-counter nasal sprays.
- Have parents demonstrate and describe technique for stopping a nosebleed.
- Inspect patient's home during visit and look for smoke detectors. Ask to check some food items in the refrigerator.

BOX 30-16 PATIENT TEACHING

Mouth and Pharyngeal Assessment

Objective

- Patient will practice proper oral hygiene/dental care measures and identify symptoms of oral cancer.

Teaching Strategies

- Discuss proper techniques for oral hygiene, including brushing and flossing (see Chapter 39).
- Explain the early warning signs of oral cavity and pharynx cancer that should be checked by a health care professional, including a mouth sore that bleeds easily and does not heal, a lump or thickening in the cheek, a white or red patch on the mucosa that persists, a sore throat or a feeling that something is caught in the throat, numbness of the tongue or other area of the mouth, or a swelling of the jaw that causes dentures to not fit (Oral Cancer Foundation, 2011).
- Late symptoms of oral cancer are difficulty chewing, swallowing, or moving the tongue or jaw (ACS, 2011).
- Encourage regular dental examination every 6 months for children, adults, and older adults.

Evaluation

- Ask patient to demonstrate brushing.
- Have patient identify when to have regular dental checkups.
- Have patient identify the warning signs of oral cavity and pharynx cancer that require further evaluation by a health care provider.

Inspect the teeth to determine the quality of dental hygiene (Box 30-16). Note the position and alignment of the teeth. To examine the posterior surface of the teeth, have the patient open the mouth with the lips relaxed. Use a tongue depressor to retract the lips and cheeks, especially when viewing the molars. Note the color of teeth and presence of dental caries (cavities), tartar, and extraction sites. Normal, healthy teeth are smooth, white, and shiny. A chalky white discoloration of the enamel is an early indication of caries formation. Brown or black discolorations indicate the formation of caries. A stained yellow color is from tobacco use; coffee, tea, and colas cause a brown stain. In the older adult loose or missing teeth are common because bone resorption increases. An older adult's teeth often feel rough when tooth enamel calcifies. Yellow or darkened teeth are also common in the older adult because of the general wear and tear that exposes the darker underlying dentin.

To view the mucosa and gums, ask the patient to first remove any dental appliance. View the inner oral mucosa by having the patient open and relax the mouth slightly and then gently retract his or her lower lip away from the teeth (Fig. 30-22). Repeat this process for the upper lip. Inspect the mucosa for color; hydration; texture; and lesions such as ulcers, abrasions, or cysts. Normally the mucosa is glistening, pink, smooth, and moist. Some common small, yellow-white raised lesions on the buccal mucosa and lips are Fordyce spots, or ectopic sebaceous glands (Seidel et al., 2011). If lesions are present, palpate them gently with a gloved hand for tenderness, size, and consistency.

To inspect the buccal mucosa, ask the patient to open the mouth and then gently retract the cheeks with a tongue depressor (Fig. 30-23). View the surface of the mucosa from right to left and top to bottom. A penlight illuminates the most posterior portion of the mucosa. Normal mucosa is glistening, pink, soft, moist, and smooth. Varying shades of hyperpigmentation are normal in 10% of whites after age 50 and as many as 90% of blacks by the same age. For patients with normal pigmentation, the buccal mucosa is a good site to inspect for jaundice and pallor. In older adults the mucosa is normally dry because of reduced salivation. Thick white patches (leukoplakia) are often a precancerous lesion seen in heavy smokers and alcoholics. Palpate for any buccal lesions by placing the index finger within the buccal cavity and the thumb on the outer surface of the cheek. Patients who smoke cigarettes, cigars, or pipes and those who use smokeless tobacco have an increased risk of oral, pharyngeal, laryngeal, and esophageal cancer. These individuals may have leukoplakia or other lesions anywhere in their oral cavity (e.g., lips, gums, or tongue) at an early age.

FIG. 30-22 Inspection of inner oral mucosa of lower lip.

FIG. 30-23 Retraction of buccal mucosa allows for clear visualization.

Inspect the gums (gingivae) for color, edema, retraction, bleeding, and lesions while retracting the cheeks. Healthy gums are pink, smooth, and moist and fit tightly around each tooth. Dark-skinned patients often have patchy pigmentation. In older adults the gums are usually pale. Using clean gloves, palpate the gums to assess for lesions, thickening, or masses. Normally there is no tenderness. Spongy gums that bleed easily indicate periodontal disease and vitamin C deficiency. If the patient has loose or mobile teeth, swollen gums, or pockets containing debris at the tooth margins, a dental referral should be considered to check for periodontal disease or gingivitis.

Tongue and Floor of Mouth. Carefully inspect the tongue on all sides and the floor of the mouth. Have the patient relax the

FIG. 30-24 The undersurface of the tongue is highly vascular.

FIG. 30-25 The hard palate is located anteriorly in the roof of the mouth.

mouth and stick the tongue out halfway. Note any deviation, tremor, or limitation in movement. This tests hypoglossal nerve function. If the patient protrudes the tongue too far, it elicits the gag reflex. When the tongue protrudes, it lays midline. To test for tongue mobility, ask the patient to raise it up and move it from side to side. It should move freely.

Using a penlight for illumination, examine the tongue for color, size, position, texture, and coatings or lesions. A normal tongue is medium or dull red in color, moist, slightly rough on the top surface, and smooth along the lateral margins. The undersurface of the tongue and the floor of the mouth are highly vascular (Fig. 30-24). Take extra care to inspect this area, a common site for oral cancer lesions. The patient lifts the tongue by placing its tip on the palate behind the upper incisors. Inspect for color, swelling, and lesions such as nodules or cysts. The ventral surface of the tongue is pink and smooth, with large veins between the frenulum folds. To palpate the tongue, explain the procedure and ask the patient to protrude it. Grasp the tip with a gauze square and gently pull it to one side. With a gloved hand palpate the full length of the tongue and the base for any areas of hardening or ulceration. Varicosities (swollen, tortuous veins) are common in the older adult and rarely cause problems.

Palate. Have the patient extend the head backward, holding the mouth open to inspect the hard and soft palates. The hard palate, or roof of the mouth, is located anteriorly. The whitish hard palate is dome shaped. The soft palate extends posteriorly toward the pharynx. It is normally light pink and smooth. Observe the palates for color, shape, texture, and extra bony prominences or defects (Fig. 30-25). A bony growth, or exostosis, between the two palates is common.

Pharynx. Perform an examination of pharyngeal structures to rule out infection, inflammation, or lesions. Have the patient tip the head back slightly, open the mouth wide, and say "ah" while you place the tip of a tongue depressor on the middle third of the tongue. Take care not to press the lower lip against the teeth. By placing the tongue depressor too far anteriorly, the posterior part of the tongue mounds up, obstructing the view. Placing the tongue depressor on the posterior tongue elicits the gag reflex.

With a penlight, first inspect the uvula and soft palate (Fig. 30-26). Both structures, which are innervated by the tenth cranial (vagus) nerve, should rise centrally as the patient says "ah." Examine the anterior and posterior pillars, soft palate, and uvula. View the tonsils in the cavities between the anterior and posterior pillars and note the presence or absence of tissue. The posterior pharynx is

FIG. 30-26 A penlight and tongue depressor allow the visualization of the uvula and posterior soft palate.

behind the pillars. Normally pharyngeal tissues are pink and smooth and well hydrated. Small irregular spots of lymphatic tissue and small blood vessels are normal. Note edema, petechiae (small hemorrhages), lesions, or exudate. The back of the pharynx is a common site for oral cancer (Oral Cancer Foundation, 2011). Patients with chronic sinus problems frequently exhibit a clear exudate that drains along the wall of the posterior pharynx. Yellow or green exudate indicates infection. A patient with a typical sore throat has a red and edematous uvula and tonsillar pillars with possible presence of yellow exudate.

Neck

Assessment of the neck includes assessing the neck muscles, lymph nodes of the head and neck, carotid arteries, jugular veins, thyroid gland, and trachea (Fig. 30-27). You may postpone the examination of the jugular veins and carotid arteries until the vascular system assessment. Inspect and palpate the neck to determine the integrity of its structures and examine the lymphatic system. An abnormality of superficial lymph nodes sometimes reveals the presence of an infection or **malignancy.** Examine the lymphatic system region by region during the assessment of other body systems (head and neck, breast, genitalia, and extremities). Examination of the thyroid gland and trachea also aids in ruling out malignancies. Perform this examination with the patient sitting. The sternocleidomastoid

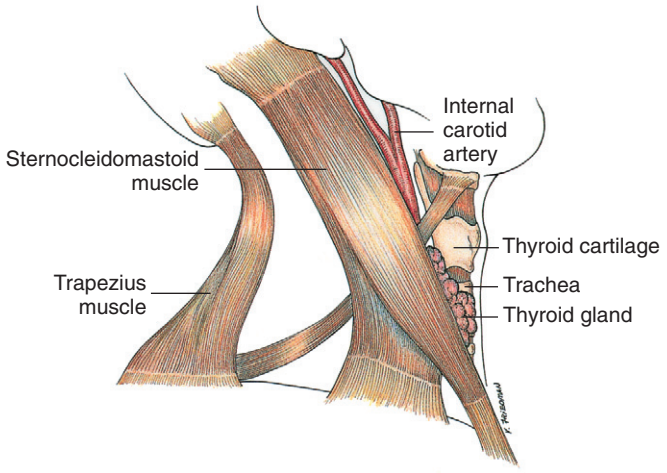

FIG. 30-27 Anatomical position of major neck structures. Note triangles formed by the sternocleidomastoid muscle, lower jaw, and anterior neck anteriorly and the sternocleidomastoid muscle, trapezius muscle, and lower neck posteriorly.

and trapezius muscles outline the areas of the neck, dividing each side of the neck into two triangles. The anterior triangle contains the trachea, thyroid gland, carotid artery, and anterior cervical lymph nodes. The posterior triangle contains the posterior lymph nodes. Table 30-19 reviews the nursing history for the head and neck examination.

Neck Muscles. First inspect the neck in the usual anatomical position, with slight hyperextension. Observe for symmetry of the neck muscles. Ask the patient to flex the neck with the chin to the chest, hyperextend the neck backward, and move the head laterally to each side and then sideways with the ear moving toward the shoulder. This tests the sternocleidomastoid and trapezius muscles. The neck normally moves without discomfort. Perform other tests for muscle strength and function during assessment of the musculoskeletal system.

Lymph Nodes. An extensive system of lymph nodes collects lymph from the head, ears, nose, cheeks, and lips (Fig. 30-28). The immune system protects the body from foreign antigens, removes damaged cells from the circulation, and provides a partial barrier to growth of malignant cells within the body. Assessing the lymph nodes requires competence when caring for patients with suspected immunoincompetence, which is often linked to allergies, human immunodeficiency virus (HIV) infection, autoimmune disease (e.g., lupus erythematosus), or serious infection.

With the patient's chin raised and head tilted slightly, first inspect the area where lymph nodes are distributed and compare both sides. This position stretches the skin slightly over any possible enlarged nodes. Inspect visible nodes for edema, erythema, or red streaks. Nodes are not normally visible.

Use a methodical approach to palpate the lymph nodes to avoid overlooking any single node or chain. The patient relaxes with the neck flexed slightly forward. Inspect and palpate both sides of the neck for comparison. During palpation either face or stand to the side of the patient for easy access to all nodes. Use the pads of the middle three fingers of each hand to gently palpate in a circular motion over the nodes (Fig. 30-29). Check each node methodically in the following sequence: occipital nodes at the base of the skull, postauricular nodes over the mastoid, preauricular nodes just in front of the ear, retropharyngeal nodes at the angle of the mandible,

TABLE 30-19 Nursing History for Neck Assessment

ASSESSMENT	RATIONALE
Assess for history of recent cold, infection, or enlarged lymph nodes or exposure to radiation or toxic chemicals.	Colds or infections cause temporary or permanent lymph node enlargement. Lymph nodes are also enlarged in various diseases such as cancer.
If there is an enlarged lymph node, consider reviewing history of intravenous drug use, hemophilia, sexual contact with persons infected with human immunodeficiency virus (HIV), history of blood transfusion, multiple and indiscriminate sexual contacts, or male with homosexual or bisexual activities.	These are risk factors for HIV infection.
Ask if patient has had history of neck pain with restriction in movement.	This indicates muscle strain, head injury, local nerve injury, or enlarged or swollen lymph node.
Ask if patient has had change in temperature preference (more or less clothing); swelling in neck; change in texture of hair, skin, or nails; or change in emotional stability.	Symptoms indicate thyroid disease.
Ask if patient has history of hypothyroidism or hyperthyroidism, takes thyroid medication, or has a family history of thyroid disease.	Disease or medications influence tissue growth of gland.
Review medical history of pneumothorax (collapsed lung) or bronchial tumor.	Conditions place patient at risk for tracheal displacement or lateral deviation.

submandibular nodes, and submental nodes in the midline behind the mandibular tip. Try to detect enlargement and note the location, size, shape, surface characteristics, consistency, mobility, tenderness, and warmth of the nodes. If the skin is mobile, move it over the area of the nodes. It is important to press underlying tissue in each area and not simply move the fingers over the skin. However, if you apply excessive pressure, you miss small nodes and destroy palpable nodes.

To palpate supraclavicular nodes, ask the patient to bend the head forward and relax the shoulders. Palpate these nodes by hooking the index and third finger over the clavicle lateral to the sternocleidomastoid muscle. Palpate the deep cervical nodes only with the fingers hooked around the sternocleidomastoid muscle.

Normally lymph nodes are not easily palpable. However, small, mobile, nontender nodes are common. Lymph nodes that are large, fixed, inflamed, or tender indicate a problem such as local infection, systemic disease, or neoplasm (Seidel et al., 2011) (Box 30-17). When you find enlarged nodes, explore the adjacent areas and regions drained by the nodes. Tenderness almost always indicates inflammation. A problem involving a lymph node of the head and neck means an abnormality in the mouth, throat, abdomen, breasts, thorax, or arms. These are the areas drained by the head and neck nodes.

Thyroid Gland. The thyroid gland lies in the anterior lower neck, in front of and to both sides of the trachea. The gland is fixed

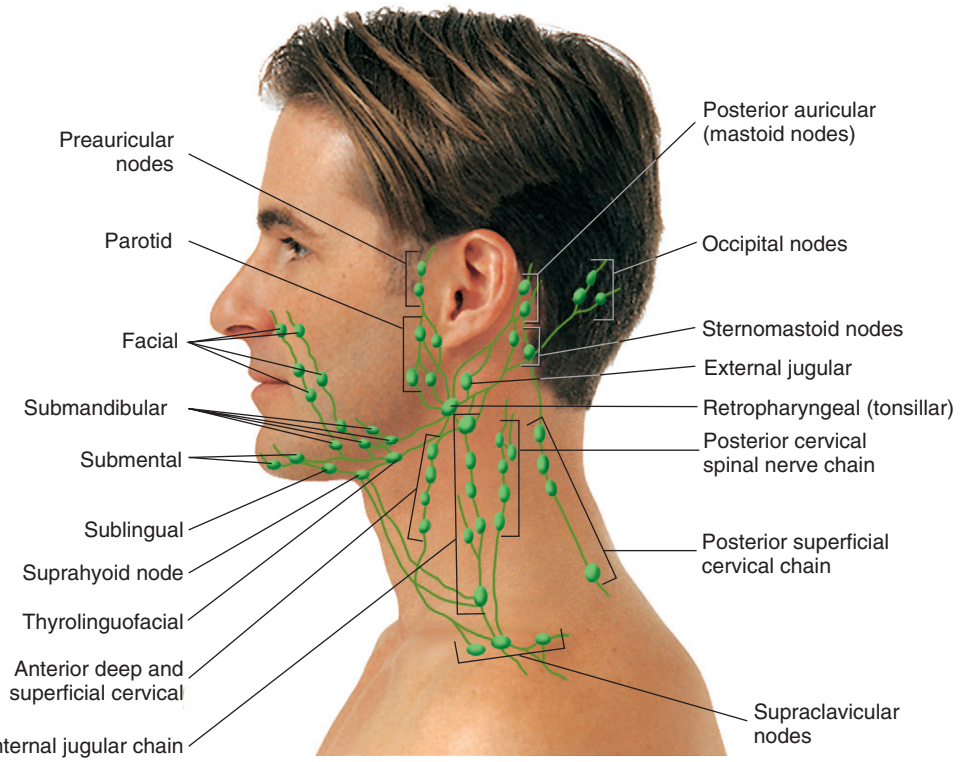

FIG. 30-28 Palpable lymph nodes in the head and neck. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

FIG. 30-29 Supraclavicular lymph node palpation.

BOX 30-17 PATIENT TEACHING

Neck Assessment

Objective

- Patient will take proper preventive action if he or she notices a mass in the neck.

Teaching Strategies

- Stress importance of regular compliance with medication schedule to patients with thyroid disease.
- Instruct patient about the lymph nodes and how infection commonly causes node tenderness and mild enlargement.
- Instruct patient to call a health care provider when he or she notices a fixed, enlarged lump or mass in the neck.
- Teach patient risk factors for HIV infection and other sexually transmitted diseases.

Evaluation

- Have patient explain when to notify a physician about a neck mass.

HIV, Human immunodeficiency virus.

to the trachea, with the isthmus overlying the trachea and connecting the two irregular, cone-shaped lobes (Fig. 30-30). Inspect the lower neck overlying the thyroid gland for obvious masses, symmetry, and any subtle fullness at the base of the neck. Ask the patient to hyperextend the neck, which helps tighten the skin for better visualization. Offer the patient a glass of water, and, while observing the neck, have him or her swallow. This maneuver helps to visualize an abnormally enlarged thyroid. Normally the thyroid cannot be visualized.

Advanced practice nurses examine the thyroid by palpating for more subtle masses; this technique is not discussed here.

Carotid Artery and Jugular Vein. This portion of the examination is described under examination of the vascular system (see later section).

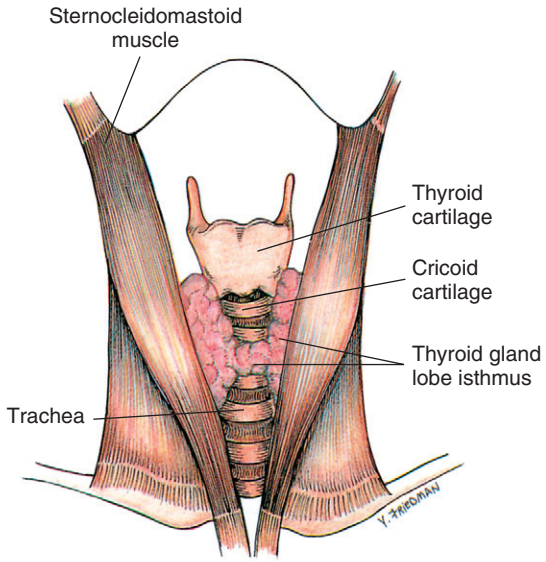

FIG. 30-30 Anatomical position of thyroid gland.

Trachea. The trachea is a part of the upper respiratory system that you directly palpate. It is normally located in the midline above the suprasternal notch. Masses in the neck or mediastinum and pulmonary abnormalities cause displacement laterally. Have the patient sit or lie down during palpation. Determine the position of the trachea by palpating at the suprasternal notch, slipping the thumb and index fingers to each side. Note if the finger and thumb shift laterally. Do not apply forceful pressure because this elicits coughing.

THORAX AND LUNGS

Accurate physical assessment of the thorax and lungs requires review of the ventilatory and respiratory functions of the lungs. If disease is affecting the lungs, it affects other body systems as well. For example, reduced oxygenation causes changes in mental alertness because of the sensitivity of the brain to lowered oxygen levels. Use data from all body systems to determine the nature of pulmonary alterations. You will use inspection, palpation, and auscultation to examine the thorax and lungs. Diagnostic equipment such as x-ray films, magnetic resonance imaging (MRI, and computed tomography (CT) scans create little need for the use of percussion as an assessment measure. Risk factors for lung disease are reviewed at the time of respiratory assessment (Box 30-18).

Before assessing the thorax and lungs, be familiar with the landmarks of the chest (Fig. 30-31, *A* to *C*). These landmarks help you identify findings and use assessment skills correctly. The patient's nipples, angle of Louis, suprasternal notch, costal angle, clavicles, and vertebrae are key landmarks that provide a series of imaginary lines for sign identification. Keep a mental image of the location of the lobes of the lung and the position of each rib (Fig. 30-32, *A* to *C*). The proper orientation to anatomical structures ensures a thorough assessment of the anterior, lateral, and posterior thorax.

Locating the position of each rib is critical to visualizing the lobe of the lung being assessed. To begin, locate the angle of Louis at the manubriosternal junction. The angle is a visible and palpable angulation of the sternum and is the point at which the second rib articulates with the sternum. Count the ribs and intercostal spaces (between the ribs) from this point. The number of each intercostal space corresponds with that of the rib just above it. The spinous process of the third thoracic vertebra and the fourth, fifth, and sixth ribs help to locate the lobes of the lung laterally. The lower lobes project laterally and anteriorly (Fig. 30-32, *B*). Posteriorly the tip or inferior margin of the scapula lies approximately at the level of the seventh rib (Fig. 30-32, *C*). After identifying the seventh rib, count upward to locate the third thoracic vertebra and align it with the inner borders of the scapula to locate the posterior lobes.

The examination requires the patient to be undressed to the waist, with good lighting. Assess patients at risk for pulmonary problems such as the patient confined to bed rest or with chest pain who cannot fully expand the lungs. The examination begins with the patient sitting for assessment of the posterior and lateral chest. Have him or her sit or lie down for assessment of the anterior chest. Table 30-20 reviews the nursing history for lung examination.

BOX 30-18 PATIENT TEACHING

Lung Assessment

Objective

- Patients of all age-groups will practice preventive care measures for lung health.

Teaching Strategies

- Explain risk factors for chronic lung disease and lung cancer, including cigarette smoking, history of smoking for over 20 years; exposure to environmental pollution; and radiation exposure from occupational, medical, and environmental sources. Exposure to radon and asbestos also increases risk. Other risk factors include exposure to certain metals (e.g., arsenic, cadmium, chromium), some organic chemicals, and tuberculosis. Exposure to secondhand cigarette smoke increases risk for nonsmokers (ACS, 2011).
- Share brochures on lung cancer, asthma, and COPD from American Cancer Society with patient and family.
- Instruct patient with asthma to identify and tell which triggers cause asthma episodes.
- Discuss warning signs of lung cancer such as a persistent cough, sputum streaked with blood, chest pains, and recurrent attacks of pneumonia or bronchitis.
- Counsel older adult on benefits of receiving influenza and pneumonia vaccinations because of a greater susceptibility to respiratory infection.
- Instruct patient with COPD in coughing and pursed-lip breathing exercises.
- Refer persons at risk for tuberculosis who visit clinics or health care centers for skin testing.

Evaluation

- Have patient describe risk factors for lung disease and cancer.
- Ask patient to identify any known risks for cancer.
- Ask patient to name warning signs of lung cancer.
- In a follow-up visit review patient's immunization record.
- Observe patient performing breathing exercises and coughing.

COPD, chronic obstructive pulmonary disease.

Posterior Thorax

Begin examination of the posterior thorax by observing for any signs or symptoms in other body systems that indicate pulmonary problems. Reduced mental alertness, nasal flaring, somnolence, and cyanosis are examples of assessed signs that indicate oxygenation problems. Inspect the posterior thorax by observing the shape and symmetry of the chest from the patient's back and front.

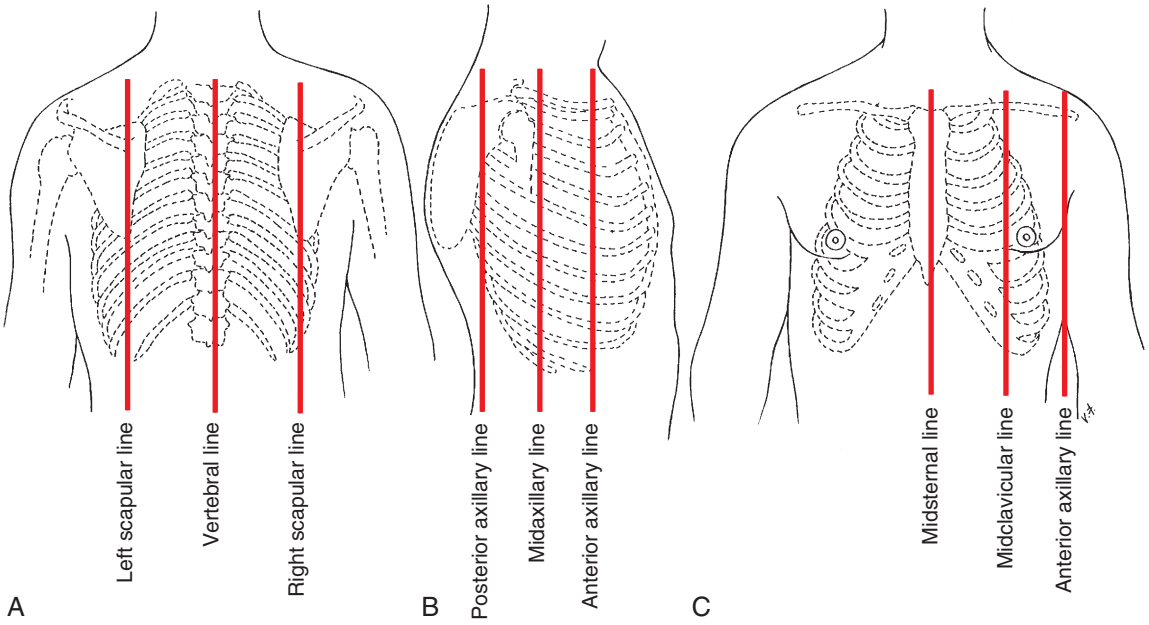

FIG. 30-31 Anatomical chest wall landmarks. **A,** Posterior chest landmarks. **B,** Lateral chest landmarks. **C,** Anterior chest landmarks.

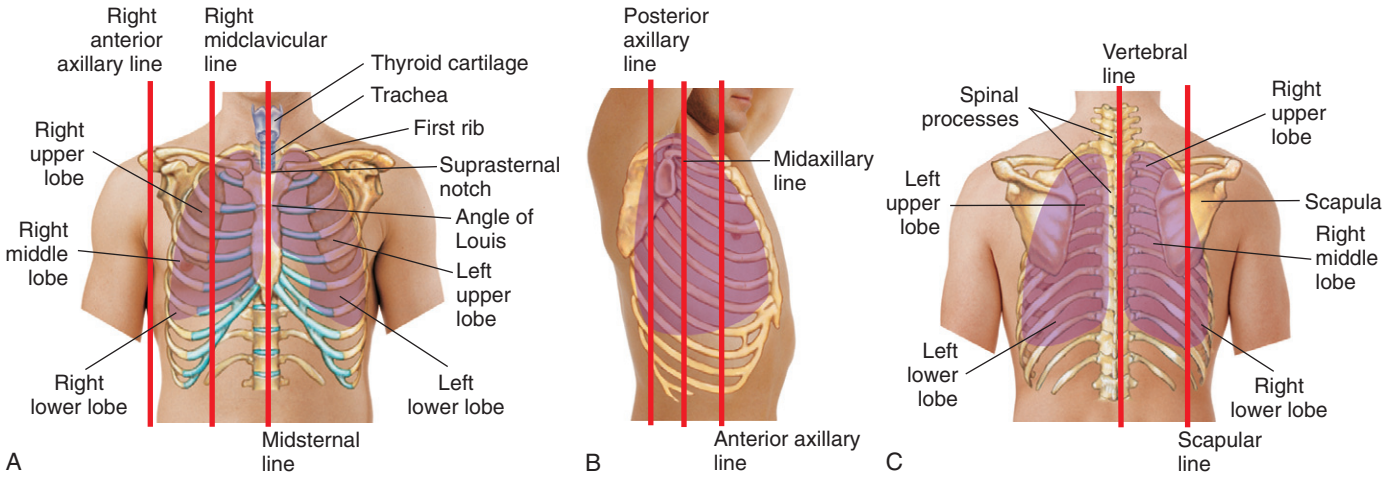

FIG. 30-32 Position of lung lobes in relation to anatomical landmarks. **A,** Anterior position. **B,** Lateral position. **C,** Posterior position. (From Seidel HM, et al: *Mosby's guide to physical examination, ed 7,* St Louis, 2011, Mosby.)

Note the anteroposterior diameter. Body shape or posture significantly impairs ventilatory movement. Normally the chest contour is symmetrical, with the anteroposterior diameter one third to one half of the transverse, or side-to-side, diameter. A barrel-shaped chest (anteroposterior diameter equals transverse diameter) characterizes aging and chronic lung disease. Infants have an almost round shape. Congenital and postural alterations cause abnormal contours. Some patients lean over a table or splint the side of the chest because of a breathing problem. Splinting or holding the chest wall because of pain causes a patient to bend toward the side affected. Such a posture impairs ventilatory movement.

Standing at a midline position behind the patient, look for deformities, position of the spine, slope of the ribs, retraction of the intercostal spaces during inspiration, and bulging of the intercostal spaces during expiration. The scapulae are normally symmetrical and closely attached to the thoracic wall. The normal spine is straight without lateral deviation. Posteriorly the ribs tend to slope across and down. The ribs and intercostal spaces are easier to see in a thin person. Normally no bulging or active movement occurs within the intercostal spaces during breathing. Bulging indicates that the patient is using great effort to breathe.

Also assess the rate and rhythm of breathing (see Chapter 29). Observe the thorax as a whole. It normally expands and relaxes regularly with equality of movement bilaterally. In healthy adults the normal respiratory rates vary from 12 to 20 respirations per minute.

Palpation of the posterior thorax provides further information about a patient's health status. Palpate the thoracic muscles and skeleton for lumps, masses, pulsations, and unusual movement. If the patient voices pain or tenderness, avoid deep palpation. Fractured rib fragments could be displaced against vital organs. Normally the chest wall is not tender. If there is a suspicious mass or

TABLE 30-20 Nursing History for Lung Assessment

ASSESSMENT	RATIONALE
Assess history of tobacco or marijuana use, including type of tobacco, duration and amount (Pack-years = Number of years smoking × Number of packs per day), age started, and efforts to quit and length of time since smoking stopped.	Smoking is a risk factor for lung cancer, heart disease, cerebrovascular disease, emphysema, or chronic bronchitis. It accounts for a significant percentage of all cancer deaths. It increases the risk for 15 types of cancer (American Cancer Society, 2010).
Ask if patient has had a *persistent cough* (productive or nonproductive), *sputum streaked with blood, voice change, chest pain,* shortness of breath, **orthopnea,** dyspnea during exertion or at rest, poor activity tolerance, or *recurrent attacks of pneumonia or bronchitis.*	Symptoms of cardiopulmonary alterations help localize objective physical findings. (Warning signals for lung cancer are in italic type.) The diaphragm of the lungs expands more easily when the individual is sitting upright, as for patients who must be in an upright position to breathe.
Determine if patient works in environment containing pollutants (e.g., asbestos, arsenic, coal dust) or requiring exposure to radiation. Does patient have exposure to secondhand smoke?	These risk factors increase chance for various lung diseases.
Review history for known or suspected human immunodeficiency virus (HIV) infection; substance abuse; low income; or being a resident or employee of nursing home or shelter, homeless, recent prison inmate, family member of tuberculosis (TB) patient, or immigrant to the United States from a country where TB is prevalent (Frakes and Evans, 2004).	These are risk factors for TB.
Ask if patient has history of persistent cough, hemoptysis, unexplained weight loss, fatigue, night sweats, or fever.	These are risk factors for both TB and HIV infection.
Does patient have history of chronic hoarseness?	Hoarseness indicates laryngeal disorder or abuse of cocaine or opioids (sniffing).
Assess history of allergies to pollens, dust, or other airborne irritants and to foods, drugs, or chemical substances.	Symptoms such as choking feeling, bronchospasm with respiratory stridor, wheezes on auscultation, and dyspnea are often caused by allergic response.
Review family history for cancer, TB, allergies, or chronic obstructive pulmonary disease.	Conditions place patient at risk for lung disease.
Ask if patient has had a pneumonia or influenza vaccine and a TB test; if not, educate him or her on need to do so.	The very young, the very old, and those with chronic respiratory problems or immunosuppressive diseases are at increased risk for respiratory disease.

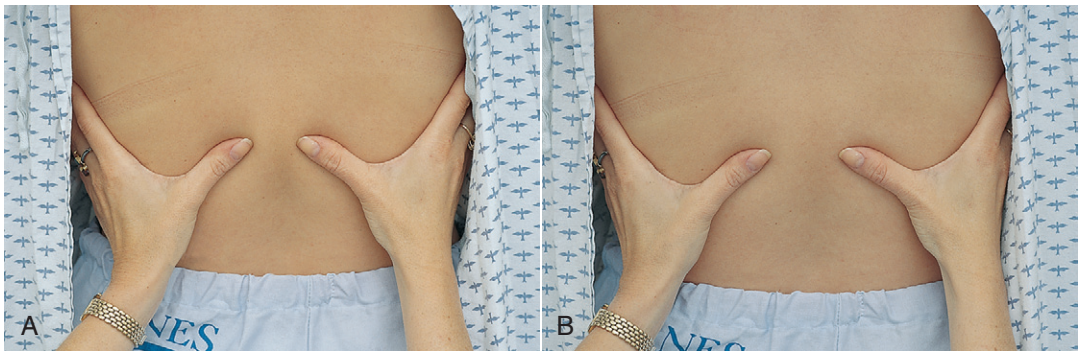

FIG. 30-33 A, Hand position for palpation of posterior thorax excursion. **B,** As patient inhales, movement of chest excursion separates thumbs.

swollen area, lightly palpate it for size, shape, and the typical qualities of a lesion.

To measure chest excursion or depth of breathing, stand behind the patient and place the thumbs along the spinal processes at the tenth rib, with the palms lightly contacting the posterolateral surfaces. Place thumbs 5 cm (2 inches) apart, pointing toward the spine with fingers pointing laterally (Fig. 30-33, *A*). Press the hands toward the spine so a small skinfold appears between the thumbs. Do not slide the hands over the skin. Instruct the patient to exhale and then take a deep breath. Note movement of the thumbs during inhalation (Fig. 30-33, *B*). Chest excursion is symmetrical, separating the thumbs 3 to 5 cm (1¼ to 2 inches). Reduced chest excursion may be caused by pain, postural deformity, or fatigue. In older adults chest movement normally declines because of costal cartilage calcification and respiratory muscle atrophy.

During speech the sound created by the vocal cords is transmitted through the lung to the chest wall. The sound waves create vibrations that you palpate externally. These vibrations are called **vocal or tactile fremitus.** The accumulation of mucus, the collapse of lung tissue, or the presence of one or more lung lesions blocks the vibrations from reaching the chest wall.

To palpate for tactile fremitus, place the palmar surfaces of the fingers or the ulnar part of the hand over symmetrical intercostal spaces, beginning at the lung apex (Fig. 30-34, *A*) and using a firm,

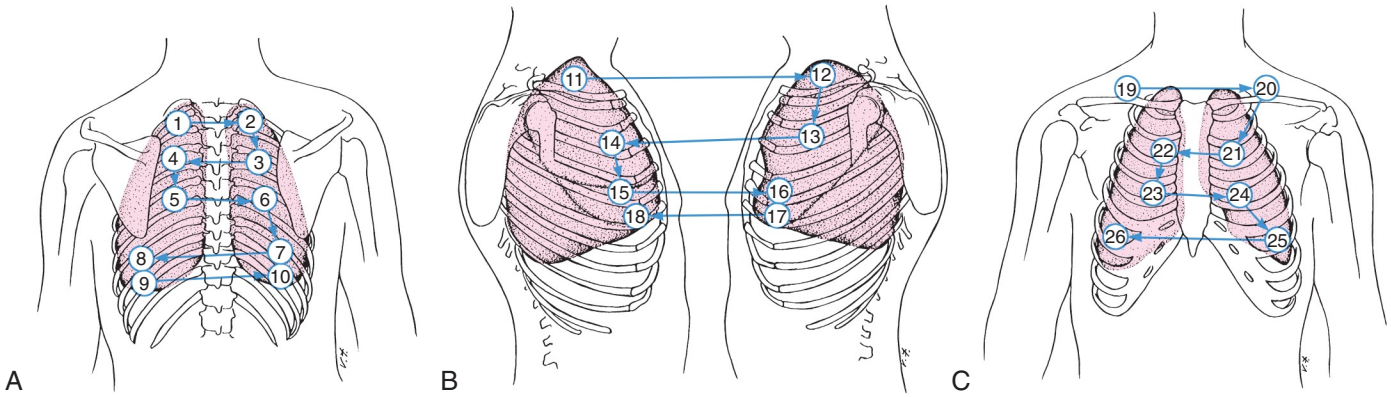

FIG. 30-34 A to **C,** A systematic pattern (posterior-lateral-anterior) is followed when palpating and auscultating the thorax.

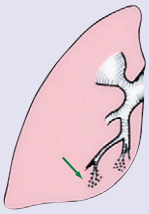
light touch. Ask the patient to say "ninety-nine" or "one-one-one." Palpate both sides simultaneously and symmetrically (from top to bottom) for comparison or use one hand, quickly alternating between the two sides (Seidel et al., 2011). Normally a faint vibration is present as the patient speaks. If fremitus is faint, ask the patient to speak in a louder or lower tone of voice. Normally fremitus is symmetrical. Vibrations are strongest at the top, near the level of the tracheal bifurcation. Strong vibrations through the chest wall occur in crying infants.

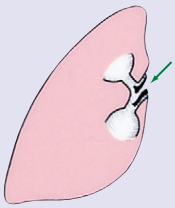
Auscultation assesses the movement of air through the tracheobronchial tree and detects mucus or obstructed airways. Normally air flows through the airways in an unobstructed pattern. Recognizing the sounds created by normal airflow allows you to detect sounds caused by airway obstruction. Follow the same systematic approach when listening that was used for palpation (see Fig. 30-34, *A*).

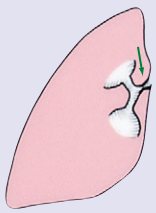
Place the diaphragm of the stethoscope firmly on the skin, over the posterior chest wall between the ribs (Fig. 30-35). The patient folds the arms in front of the chest and keeps the head bent forward while taking slow, deep breaths with the mouth slightly open. Listen to an entire inspiration and expiration at each position of the stethoscope. If sounds are faint, as in the obese patient, ask the patient to breathe harder and faster temporarily. Breath sounds are much louder in children because of their thin chest walls. The bell works best in children because of a child's small chest. Auscultate for normal breath sounds and abnormal or **adventitious sounds.** Normal breath sounds differ in character, depending on the area you are auscultating. Bronchovesicular and vesicular sounds are normally heard over the posterior thorax (Table 30-21).

Abnormal sounds result from air passing through moisture, mucus, or narrowed airways. They also result from alveoli suddenly reinflating or an inflammation between the pleural linings of the lung. Adventitious sounds often occur superimposed over normal sounds. The four types of adventitious sounds are crackles, rhonchi, wheezes, and pleural friction rub. A specific entity causes each sound, and each has typical auditory features (Table 30-22). During auscultation note the location and characteristics of the sounds and listen for the absence of breath sounds (found in patients with collapsed or surgically removed lobes).

If there are abnormalities in tactile fremitus or auscultation, perform the vocal resonance tests (spoken and whispered voice sounds). Place the stethoscope over the same locations used to assess breath sounds and have the patient say "ninety-nine" in a normal voice tone. Normally the sound is muffled. If fluid is







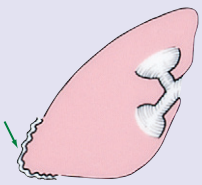


FIG. 30-35 Use the diaphragm of the stethoscope to auscultate breath sounds. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

TABLE 30-21 Normal Breath Sounds

DESCRIPTION	LOCATION	ORIGIN
Vesicular		
Vesicular sounds are soft, breezy, and low pitched. Inspiratory phase is 3 times longer than expiratory phase.	Best heard over periphery of lung (except over scapula)	Created by air moving through smaller airways
Bronchovesicular		
Bronchovesicular sounds are blowing sounds that are medium pitched and of medium intensity. Inspiratory phase is equal to expiratory phase.	Best heard posteriorly between scapulae and anteriorly over bronchioles lateral to sternum at first and second intercostal spaces	Created by air moving through large airways
Bronchial		
Bronchial sounds are loud and high pitched with hollow quality. Expiration lasts longer than inspiration (3:2 ratio).	Heard only over trachea	Created by air moving through trachea close to chest wall

TABLE 30-22 Adventitious Breath Sounds

SOUND	SITE AUSCULTATED	CAUSE	CHARACTER
Crackles 	Are most common in dependent lobes: right and left lung bases	Random, sudden reinflation of groups of alveoli; disruptive passage of air through small airways	Fine crackles are high-pitched fine, short; interrupted crackling sounds heard during end of inspiration; usually not cleared with coughing. Medium crackles are lower; moister sounds heard during middle of inspiration; not cleared with coughing. Coarse crackles are loud, bubbly sounds heard during inspiration; not cleared with coughing.
Rhonchi (sonorous wheeze) 	Are primarily heard over trachea and bronchi; if loud enough, able to be heard over most lung fields	Muscular spasm, fluid, or mucus in larger airways; new growth or external pressure causing turbulence	Loud, low-pitched, rumbling coarse sounds are heard either during inspiration or expiration; sometimes cleared by coughing.
Wheezes (sibilant wheeze) 	Heard over all lung fields	High-velocity airflow through severely narrowed or obstructed airway	High-pitched, continuous musical sounds are like a squeak heard continuously during inspiration or expiration; usually louder on expiration.
Pleural friction rub 	Heard over anterior lateral lung field (if patient is sitting upright)	Inflamed pleura; parietal pleura rubbing against visceral pleura	Dry, rubbing, or grating quality is heard during inspiration or expiration; does not clear with coughing; heard loudest over lower lateral anterior surface.

Data from Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.

compressing the lung, the vibrations from the patient's voice are transmitted to the chest wall, and the sound becomes clear (bronchophony). Then ask the patient to whisper "ninety-nine." The whispered voice is usually faint and indistinct. Certain lung abnormalities cause the whispered voice to become clear and distinct (whispered pectoriloquy).

Lateral Thorax

Extend the assessment of the posterior thorax to the lateral sides of the chest. The patient sits during examination of the lateral chest. Have the patient raise the arms to improve access to lateral thoracic structures. Use inspection, palpation, and auscultation skills to examine the lateral thorax (see Fig. 30-34, *B*). Do not assess excursion laterally. Normally the breath sounds you hear are vesicular.

Anterior Thorax

Inspect the anterior thorax for the same features as the posterior thorax. The patient sits or lies down with the head elevated. Observe the accessory muscles of breathing: sternocleidomastoid, trapezius, and abdominal muscles. The accessory muscles move little with normal passive breathing. However, patients who use a great deal of effort to breathe as a result of strenuous exercise or pulmonary disease (e.g., chronic obstructive pulmonary disease) rely on the accessory and abdominal muscles to contract, thereby leading to inspiration and expiration. Some patients who require great effort produce a grunting sound.

Observe the width of the costal angle. It is usually larger than 90 degrees between the two costal margins. Observe the breathing pattern. Normal breathing is quiet and barely audible near the open mouth. You most often assess respiratory rate and rhythm

TABLE 30-23 Nursing History for Heart Assessment

ASSESSMENT	RATIONALE
Determine history of smoking, alcohol intake, caffeine intake, use of prescriptive and recreational drugs, exercise habits, and dietary patterns and intake (including fat and sodium intake).	Smoking; alcohol ingestion; cocaine use; lack of regular exercise; intake of foods high in carbohydrates, fats, and cholesterol are risk factors for cardiovascular disease. Caffeine can cause heart dysrhythmias.
Determine if patient is taking medications for cardiovascular function (e.g., antidysrhythmics, antihypertensives) and if he or she knows their purpose, dosage, and side effects.	Knowledge allows nurse to assess compliance with drug therapies. Medications sometimes affect vital sign values.
Assess for chest pain or discomfort, palpitations, excess fatigue, cough, dyspnea, leg pain or cramps, edema of feet, cyanosis, fainting, and orthopnea. Ask if symptoms occur at rest or during exercise.	These are key symptoms of heart disease. Cardiovascular function is sometimes adequate during rest but not during exercise. Positions affect how well lungs can expand.
If patient reports chest pain, determine if it is cardiac in nature. Anginal pain is usually a deep pressure or ache that is substernal and diffuse, radiating to one or both arms, neck, or jaw.	Assessment determines nature of pain and need to initiate care immediately.
Determine whether patient has a stressful lifestyle. What physical demands and/or emotional stress exist?	Repeated exposure to stress increases risk for heart disease.
Assess family history for heart disease, diabetes, high cholesterol levels, hypertension, stroke, or rheumatic heart disease.	Factors increase risk for heart disease.
Ask patient about history of heart trouble (e.g., heart failure, congenital heart disease, coronary artery disease, dysrhythmias, murmurs).	Knowledge reveals patient's level of understanding of condition. Preexisting condition influences examination techniques used and findings to expect.
Determine whether patient has preexisting diabetes, lung disease, obesity, or hypertension.	These disorders alter heart function.

anteriorly (see Chapter 29). The male patient's respirations are usually diaphragmatic, whereas a female's are more costal. Accurate assessment occurs as the patient breathes passively.

Palpate the anterior thoracic muscles and skeleton for lumps, masses, tenderness, or unusual movement. The sternum and xiphoid are relatively inflexible. Place the thumbs parallel approximately along the costal margin 6 cm (2½ inches) apart with the palms touching the anterolateral chest. Push the thumbs toward the midline to create a skinfold. As the patient inhales deeply, the thumbs normally separate approximately 3 to 5 cm (1¼ to 2 inches), with each side expanding equally.

Assess tactile fremitus over the anterior chest wall. Anterior findings differ from posterior findings because of the heart and female breast tissue. Fremitus is felt next to the sternum at the second intercostal space, at the level of the bronchial bifurcation. It decreases over the heart, lower thorax, and breast tissue.

Auscultation of the anterior thorax follows a systematic pattern (see Fig. 30-34, *C*) comparing right and left sides. This is important so lung sounds in one region on one side of the body can be compared with sounds in the same region on the opposite side of the body.

If possible, have the patient sit to maximize chest expansion. Give special attention to the lower lobes, where mucus secretions commonly gather. Listen for bronchovesicular and vesicular sounds above and below the clavicles and along the lung periphery. In addition, auscultate for bronchial sounds, which are loud, high pitched, and hollow sounding, with expiration lasting longer than inspiration (3:2 ratio). This sound is normally heard over the trachea.

HEART

Compare the assessment of heart function with findings from the vascular assessment (see later section). Alterations in either system sometimes manifest as changes in the other. Some patients with signs or symptoms of heart (cardiac) problems have a life-threatening condition requiring immediate attention. In this case act quickly and conduct only the portions of the examination that are absolutely necessary. Conduct a more thorough assessment when the patient is more stable. The nursing history (Table 30-23) provides data to help interpret physical findings.

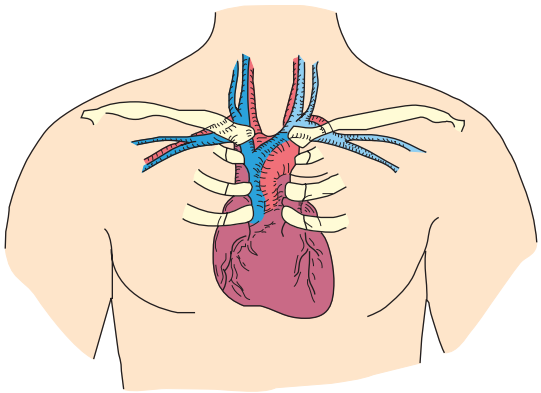

FIG. 30-36 Anatomical position of heart.

Assess cardiac function through the anterior thorax. Form a mental image of the exact location of the heart (Fig. 30-36). In the adult it is located in the center of the chest (precordium), behind and to the left of the sternum, with a small section of the right atrium extending to the right of the sternum. The base of the heart is the upper portion, and the apex is the bottom tip. The surface of the right ventricle composes most of the anterior surface of the heart. A section of the left ventricle shapes the left anterior side of the apex. The apex actually touches the anterior chest wall at approximately the fourth to fifth intercostal space just medial to the left midclavicular line. This is the **apical impulse or point of maximal impulse (PMI).**

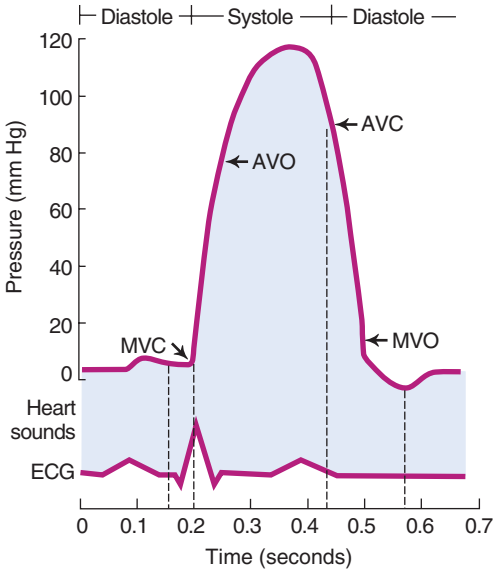

FIG. 30-37 Cardiac cycle. *AVC,* Aortic valve closes; *AVO,* aortic valve opens; *ECG,* electrocardiogram; *MVC,* mitral valve closes; *MVO,* mitral valve opens.

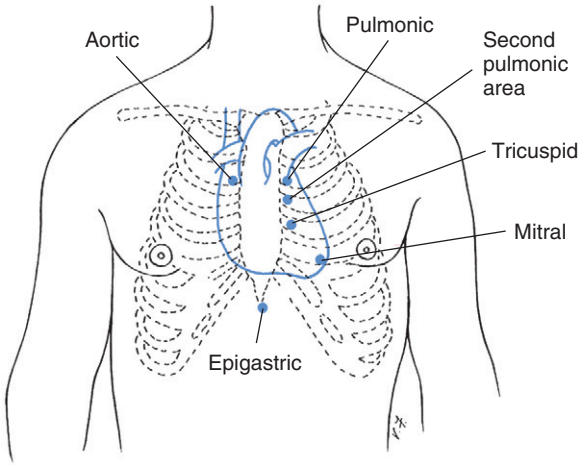

FIG. 30-38 Anatomical sites for assessment of cardiac function.

An infant's heart is positioned more horizontally. The apex of the heart is at the third or fourth intercostal space, just to the left of the midclavicular line. By the age of 7 a child's PMI is in the same location as the adult's. In tall, slender persons the heart hangs more vertically and is positioned more centrally. In shorter or stockier individuals the heart tends to lie more to the left and horizontally (Seidel et al., 2011).

To assess heart function, a clear understanding of the cardiac cycle and associated physiological events is of utmost importance (Fig. 30-37). The heart normally pumps blood through its four chambers in a methodical, even sequence. Events on the left side occur just before those on the right. As blood flows through each chamber, the valves open and close, the pressures within chambers rise and fall, and the chambers contract. Each event creates a physiological sign. Both sides of the heart function in a coordinated fashion.

There are two phases to the cardiac cycle: systole and diastole. During systole the ventricles contract and eject blood from the left ventricle into the aorta and from the right ventricle into the pulmonary artery. During diastole the ventricles relax, and the atria contract to move blood into the ventricles and fill the coronary arteries.

Heart sounds occur in relation to physiological events in the cardiac cycle. As systole begins, ventricular pressure rises and closes the mitral and tricuspid valves. Valve closure causes the first heart sound (S_1), often described as "lub." The ventricles then contract, and blood flows through the aorta and pulmonary circulation. After the ventricles empty, ventricular pressure falls below that in the aorta and pulmonary artery. This allows the aortic and pulmonic valves to close, causing the second heart sound (S_2), described as "dub." As ventricular pressure continues to fall, it drops below that of the atria. The mitral and tricuspid valves reopen to allow ventricular filling. When the heart attempts to fill an already distended ventricle, a third heart sound (S_3) can be heard, as with heart failure. An S_3 is considered abnormal in adults over 30 years of age but can often be heard normally in children and young adults. It can also be present among women in the late stages of pregnancy. A fourth heart sound (S_4) occurs when the atria contract to enhance ventricular filling. An S_4 is often heard in healthy older adults, children, and athletes; but it is not normal in adults. Because S_4 also indicates an abnormal condition, report it to a health care provider.

Inspection and Palpation

Make the patient relaxed and comfortable before the examination. Explain the procedure to relieve his or her anxiety. An anxious or uncomfortable patient has mild tachycardia, which leads to inaccurate findings.

Use the skills of inspection and palpation simultaneously. Begin the examination with the patient in the supine position or the upper body elevated 45 degrees because patients with heart disease frequently suffer shortness of breath while lying flat. Stand at the patient's right side. Do not let the patient talk, especially when auscultating heart sounds. Good lighting in the room is essential.

Direct your attention to the anatomical sites best suited for assessment of cardiac function. During inspection and palpation look for visible pulsations and exaggerated lifts and palpate for the apical impulse and any source of vibrations (thrills). Follow an orderly sequence, beginning with assessment of the base of the heart and moving toward the apex. First inspect the angle of Louis, which lies between the sternal body and manubrium, and feel the ridge in the sternum approximately 5 cm (2 inches) below the sternal notch. Slip the fingers along the angle on each side of the sternum to feel adjacent ribs. The intercostal spaces are just below each rib. The second intercostal space allows identification of each of the six anatomical landmarks (Fig. 30-38). The second intercostal space on the right is the aortic area, and the left second intercostal space is the *pulmonic area*. You need to use deeper palpation to feel the spaces in obese or heavily muscled patients. After locating the pulmonic area, move the fingers down the patient's left sternal border to the third intercostal space, called the *second pulmonic area*. The *tricuspid area* is located at the fourth or fifth intercostal space along the sternum. To find the *apical or mitral area*, locate the fifth intercostal space just to the left of the sternum and move the fingers laterally to the left midclavicular line. Locate the apical area with the palm of the hand or the fingertips. Normally you feel the apical impulse as a light tap in an area 1 to 2 cm (½ to ¾ inch) in diameter at the apex (Fig. 30-39). Another

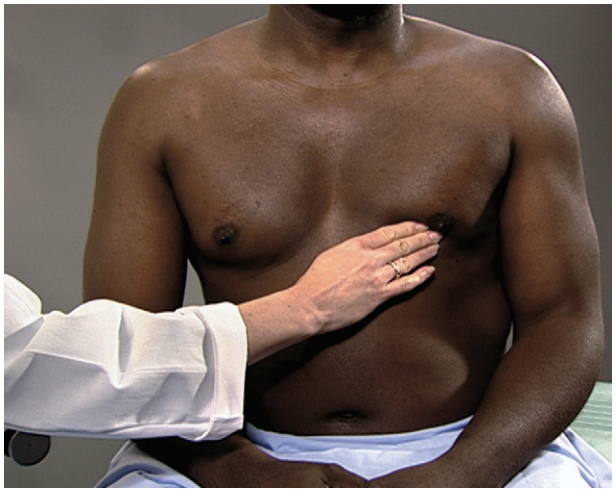

FIG. 30-39 Palpation of apical pulse. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

landmark is the epigastric area at the tip of the sternum. Palpate there if you suspect aortic abnormalities.

Locate the six anatomical landmarks of the heart and inspect and palpate each area. Look for the appearance of pulsations, viewing each area over the chest at an angle to the side. Normally pulsations are not seen, except perhaps at the PMI in thin patients or at the epigastric area as a result of abdominal aorta pulsation. Use the proximal halves of the four fingers together and alternate this with the ball of the hand to palpate for pulsations. Touch the areas gently to allow movements to lift the hand. Normally no pulsations or vibrations are felt in the second, third, or fourth intercostal spaces. Loud murmurs cause a vibration. Time palpated pulsations or vibrations and their occurrence in relation to systole or diastole by auscultating heart sounds simultaneously.

The apical impulse or PMI is easily felt. If you cannot locate it with the patient in a supine position, have him or her roll onto the left side, moving the heart closer to the chest wall. Estimate the size of the heart by noting the diameter of the PMI and its position relative to the midclavicular line. In cases of serious heart disease, the cardiac muscle enlarges, with the PMI found to the left of the midclavicular line. The PMI is sometimes difficult to find in the older adult because the chest deepens in its anteroposterior diameters. It is also difficult to find in muscular or overweight patients. An infant's PMI is located near the third or fourth intercostal space. It is easy to palpate because of the child's thin chest wall.

Auscultation

Auscultation of the heart detects normal heart sounds, extra heart sounds, and murmurs. Concentrate on detecting low-intensity sounds created by valve closures. To begin auscultation eliminate all sources of room noise and explain the procedure to reduce the patient's anxiety. Follow a systematic pattern, beginning at the aortic area and inching the stethoscope across each of the anatomical sites. Listen for the complete cycle ("lub-dub") of heart sounds clearly at each location. Repeat the sequence using the bell of the stethoscope. Sometimes you will have a patient assume three different positions during the examination to hear sounds clearly (Fig. 30-40, *A* to *C*): sitting up and leaning forward (good for all areas and to hear high-pitched murmurs), supine (good for all areas), and left lateral recumbent (good for all areas; best position to hear low-pitched sounds in diastole).

FIG. 30-40 Sequence of patient positions for heart auscultation. **A,** Sitting. **B,** Supine. **C,** Left lateral recumbent. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

Learn to identify the first (S_1) and second (S_2) heart sounds. At normal rates S_1 occurs after the long diastolic pause and preceding the short systolic pause. S_1 is high pitched, dull in quality, and heard best at the apex. If it is difficult to hear S_1, time it in relation to the carotid pulsation. S_2 follows the short systolic pause and precedes the long diastolic pause; it is best heard at the aortic area.

Auscultate for rate and rhythm after hearing both sounds clearly. Each combination of S_1 and S_2 or "lub-dub" counts as one heartbeat. Count the rate for 1 minute and listen for the interval between S_1 and S_2 and then the time between S_2 and the next S_1. A regular rhythm involves regular intervals of time between each sequence of beats. There is a distinct silent pause between S_1 and S_2. Failure of the heart to beat at regular successive intervals is a **dysrhythmia.** Some dysrhythmias are life threatening.

When assessing an irregular heart rhythm, compare apical and radial pulse rates simultaneously to determine if a pulse deficit exists. Auscultate the apical pulse first and then immediately palpate the radial pulse (one-examiner technique). Assess the apical and radial rates at the same time when two examiners are present. When a patient has a pulse deficit, the radial pulse is slower than the apical pulse because ineffective contractions fail to send pulse waves to the periphery. Report a difference in pulse rates to the health care provider immediately.

Assess for extra heart sounds at each auscultatory site. Use the bell of the stethoscope and listen for low-pitched extra heart sounds such as S_3 and S_4 gallops, clicks, and rubs. Auscultate over all anatomical areas. S_3, or a **ventricular gallop,** occurs after S_2. It is caused by a premature rush of blood into a ventricle that is stiff or dilated as a result of heart failure and hypertension. The combination of S_1, S_2, and S_3 sounds like "Ken-tuck'-y."

S_4, or an atrial gallop, occurs just before S_1 or ventricular systole. The sound of an S_4 is similar to that of "Ten'-es-see." Physiologically it is caused by an atrial contraction pushing against a ventricle that is not accepting blood because of heart failure or other alterations. You can hear extra heart sounds more easily with the patient lying on the left side and the stethoscope at the apical site.

The final portion of the examination includes assessment for heart murmurs. **Murmurs** are sustained swishing or blowing sounds heard at the beginning, middle, or end of the systolic or diastolic phase. They are caused by increased blood flow through a normal valve, forward flow through a stenotic valve or into a dilated vessel or heart chamber, or backward flow through a valve that fails to close. A murmur is asymptomatic or a sign of heart disease (Box 30-19). They are common in children. Keep the following factors in mind when auscultating to detect murmurs:

- When a murmur is detected, auscultate the mitral, tricuspid, aortic, and pulmonic valve areas for placement in the cardiac cycle (timing); the place it is heard best (location); radiation; loudness; pitch; and quality.
- If a murmur occurs between S_1 and S_2, it is a systolic murmur.
- If it occurs between S_2 and the next S_1, it is a diastolic murmur.
- The location of a murmur is not necessarily directly over the valves. Experience with hearing murmurs helps with better understanding of where each type of murmur is best heard. For example, mitral murmurs are best heard at the apex of the heart.
- To assess for radiation, listen over areas in addition to where it is heard best. Murmurs can also be heard over the neck or back.
- Intensity or loudness is related to the rate of blood flow through the heart or the amount of blood regurgitated. Feel for a thrust or intermittent palpable sensation at the auscultation site in serious murmurs. A **thrill** is a continuous palpable sensation that resembles the purring of a cat. Intensity is recorded using the following grades (Seidel et al., 2011):

  Grade 1: Barely audible in a quiet room
  Grade 2: Clearly audible but quiet
  Grade 3: Moderately loud
  Grade 4: Loud, with associated thrill
  Grade 5: Very loud, thrill easily palpable
  Grade 6: Louder, may be heard without stethoscope; thrill palpable and visible

- A murmur is low, medium, or high in pitch, depending on the velocity of blood flow through the valves. A low-pitched murmur is best heard with the bell of the stethoscope. If the murmur is best heard with the diaphragm, the murmur is high pitched.

  The quality of a murmur refers to its characteristic pattern and sound. A crescendo murmur starts softly and builds in loudness. A decrescendo murmur starts loudly and becomes less intense.

BOX 30-19 PATIENT TEACHING

Heart Assessment

Objective

- Patient will describe risk factors for heart disease and take appropriate steps to eliminate risks from lifestyle.

Teaching Strategies

- Explain risk factors for heart disease, including high dietary intake of saturated fat or cholesterol, lack of regular aerobic exercise, smoking, excess weight, stressful lifestyle, hypertension, and family history of heart disease.
- Refer patient (if appropriate) to resources available for controlling or reducing risks (e.g., nutritional counseling, exercise class, stress reduction programs).
- Teach patient to reduce dietary intake of cholesterol and saturated fats. Explain that approximately 70% to 75% of saturated fatty acids come from meats, poultry, fish, and dairy products. The American Heart Association (2011) recommends a diet that includes an intake that limits total fat to less than 25% to 35% of total calories, saturated fats to less than 7% of daily calories, trans fats to less than 1% of calories, and cholesterol to less than 300 mg/day.
- Encourage patient to have total blood cholesterol levels and triglycerides measured regularly. Desirable levels are less than 200 mg/100 mL. You need more than one cholesterol measurement to assess the blood cholesterol level accurately. Low-density lipoprotein (LDL) cholesterol is the major component of atherosclerotic plaques. Separate measurement of LDL cholesterol is wise in a patient with high total blood cholesterol levels. In an individual with no other risk factors, an LDL cholesterol level of 160 mg/100 mL or higher is high risk (Moore, 2005).
- Encourage patient to discuss with health care provider the need for periodic C-reactive protein (CRP) testing. CRP levels assess a patient's risk for cardiovascular disease.
- Advise patient to avoid cigarette smoke because nicotine causes vasoconstriction.
- Advise patient to quit smoking because this lowers the risk for coronary heart disease and coronary vascular disease (ACS, 2011).
- Patients who are at risk benefit from taking a daily low dose of aspirin. Consult health care provider before starting therapy.

Evaluation

- Ask patient to identify risk factors for heart disease.
- Have patient develop a meal plan low in saturated fat and cholesterol.
- Check patient's cholesterol level during follow-up appointments at the clinic or physician's office.
- Ask patient to describe ways he or she has chosen to reduce cardiac risk factors.

TABLE 30-24 Nursing History for Vascular Assessment

ASSESSMENT	RATIONALE
Determine if patient experiences leg cramps; numbness or tingling in extremities; sensation of cold hands or feet; pain in legs; or swelling or cyanosis of feet, ankles, or hand.	These signs and symptoms indicate vascular disease.
If patient experiences leg pain or cramping in lower extremities, ask if walking or standing for long periods or during sleep aggravate or relieve it.	Relationship of symptoms to exercise clarifies whether problem is vascular or musculoskeletal. Pain caused by vascular condition tends to increase with activity. Musculoskeletal pain usually is not relieved when exercise ends.
Ask patients if they wear tight-fitting garters, socks, or hosiery and sit or lie in bed with legs crossed.	Tight hosiery around lower extremities and crossing legs can impair venous return.
Reconsider previous heart risk factors (e.g., smoking, exercise, nutritional problems).	These predispose patient to vascular disease.
Assess medical history for heart disease, hypertension, phlebitis, diabetes, or varicose veins.	Circulatory and vascular disorders influence findings gathered during examination.

VASCULAR SYSTEM

Examination of the vascular system includes measuring the blood pressure (see Chapter 29) and assessing the integrity of the peripheral vascular system. Table 30-24 reviews the nursing history data collected before the examination. Use the skills of inspection, palpation, and auscultation. Perform portions of the vascular examination during other body system assessments. For example, check the carotid pulse after palpating the cervical lymph nodes. Note signs and symptoms of arterial and venous insufficiency when assessing the skin.

Blood Pressure

When auscultating blood pressure, know that readings between the arms vary by as much as 10 mm Hg and tend to be higher in the right arm (Seidel et al., 2011). Always record the higher reading. Repeated systolic readings that differ by 15 mm Hg or more suggest atherosclerosis or disease of the aorta.

Carotid Arteries

When the left ventricle pumps blood into the aorta, the arterial system transmits pressure waves. The carotid arteries reflect heart function better than peripheral arteries because their pressure correlates with that of the aorta. The carotid artery supplies oxygenated blood to the head and neck (Fig. 30-41). The overlying sternocleidomastoid muscle protects it.

To examine the carotid arteries, have the patient sit or lie supine with the head of the bed elevated 30 degrees. Examine one carotid artery at a time. If both arteries are occluded simultaneously during palpation, the patient loses consciousness as a result of inadequate circulation to the brain. Do not palpate or massage the carotid

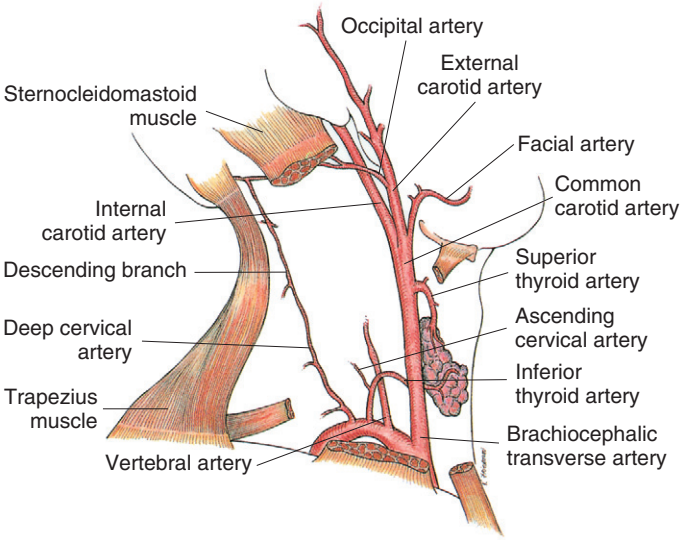

FIG. 30-41 Anatomical position of carotid artery.

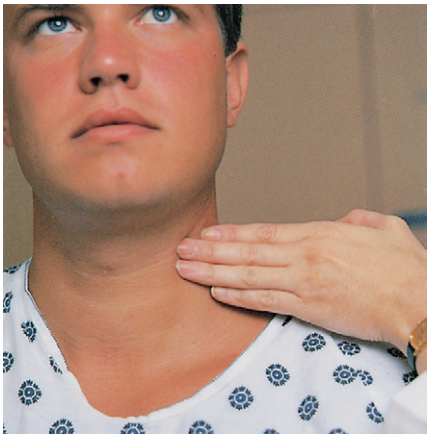

FIG. 30-42 Palpation of internal carotid artery along margin of sternocleidomastoid muscle.

arteries vigorously because the carotid sinus is located at the bifurcation of the common carotid arteries in the upper third of the neck. This sinus sends impulses along the vagus nerve. Its stimulation causes a reflex drop in heart rate and blood pressure, which causes **syncope** or circulatory arrest. This is a particular problem for older adults.

Begin inspection of the neck for obvious pulsation of the artery. Have the patient turn the head slightly away from the artery being examined. Sometimes the wave of the pulse is visible. The carotid is the only site for assessing the quality of a pulse wave. An absent pulse wave indicates arterial occlusion (blockage) or **stenosis** (narrowing).

To palpate the pulse ask the patient to look straight ahead or turn the head slightly toward the side you are examining. Turning relaxes the sternocleidomastoid muscle. Slide the tips of the index and middle fingers around the medial edge of the sternocleidomastoid muscle. Gently palpate to avoid occlusion of circulation (Fig. 30-42).

The normal carotid pulse is localized and strong rather than diffuse. It has a thrusting quality. As the patient breathes,

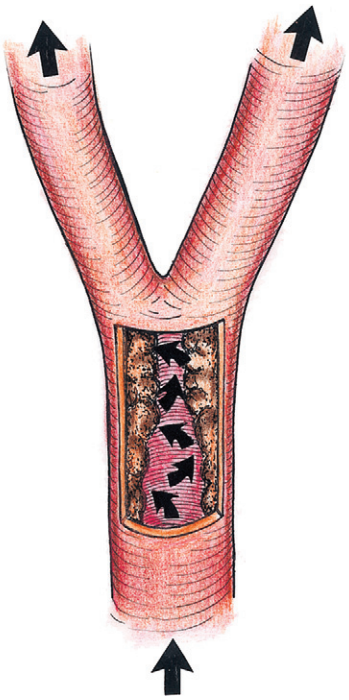

FIG. 30-43 Occlusion or narrowing of the carotid artery disrupts normal blood flow. The resultant turbulence creates a sound (bruit) that is auscultated.

FIG. 30-44 Auscultation for carotid artery bruit. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

no change occurs. Rotation of the neck or a shift from a sitting to a supine position does not change the quality of the carotid impulse. Both carotid arteries are normally equal in pulse rate, rhythm, and strength and are equally elastic. Diminished or unequal carotid pulsations indicate atherosclerosis or other forms of arterial disease.

The carotid is the most commonly auscultated pulse. Auscultation is especially important for middle-age or older adults or patients suspected of having cerebrovascular disease. When the lumen of a blood vessel is narrowed, it disturbs blood flow. As blood passes through the narrowed section, it creates turbulence, causing a blowing or swishing sound. The blowing sound is called a **bruit** (pronounced "brew-ee") (Fig. 30-43).

Place the bell of the stethoscope over the carotid artery at the lateral end of the clavicle and the posterior margin of the sternocleidomastoid muscle. Have the patient turn his or her head slightly away from the side being examined (Fig. 30-44). Ask him or her to hold the breath for a moment so breath sounds do not obscure a bruit. Normally you do not hear any sounds during carotid auscultation. Palpate the artery lightly for a thrill (palpable bruit) if you hear a bruit.

Jugular Veins

The most accessible veins for examination are the internal and external jugular veins in the neck. Both veins drain bilaterally from the head and neck into the superior vena cava. The external jugular vein lies superficially and is just above the clavicle. The internal jugular vein lies deeper, along the carotid artery.

It is best to examine the right internal jugular vein because it follows a more direct anatomical path to the right atrium of the heart. The column of blood inside the internal jugular vein serves as a manometer, reflecting pressure in the right atrium. The higher the column, the greater is the venous pressure. Raised venous pressure reflects right-sided heart failure.

Normally, when a patient lies in the supine position, the external jugular vein distends and becomes easily visible. In contrast, the jugular veins normally flatten when the patient changes to a sitting or standing position. However, for some patients with heart disease the jugular veins remain distended when sitting.

To measure venous pressure, first inspect the jugular veins. Venous pressure is influenced by blood volume, the capacity of the right atrium to receive blood and send it to the right ventricle and the ability of the right ventricle to contract and force blood into the pulmonary artery. Any factor resulting in greater blood volume within the venous system results in elevated venous pressure. Assess venous pressure by using the following steps:

1. Ask the patient to lie supine with the head elevated 30 to 45 degrees (semi-Fowler's position).
2. Expose the neck and upper thorax. Use a pillow to align the head. Avoid neck hyperextension or flexion to ensure that the vein is not stretched or kinked (Fig. 30-45).
3. Usually pulsations are not evident with the patient sitting up. As he or she slowly leans back into a supine position, the level of venous pulsations begins to rise above the level of the manubrium as much as 1 or 2 cm (½ to 1 inch) as the patient reaches a 45-degree angle. Measure venous pressure by measuring the vertical distance between the angle of Louis and the highest level of the visible point of the internal jugular vein pulsation.
4. Use two rulers. Line up the bottom edge of a regular ruler with the top of the area of pulsation in the jugular vein. Then take a centimeter ruler and align it perpendicular to the first ruler at the level of the sternal angle. Measure in centimeters the distance between the second ruler and the sternal angle (Fig. 30-46).
5. Repeat the same measurement on the other side. Bilateral pressures higher than 2.5 cm (1 inch) are considered elevated and are a sign of right-sided heart failure. One-sided pressure elevation is caused by obstruction.

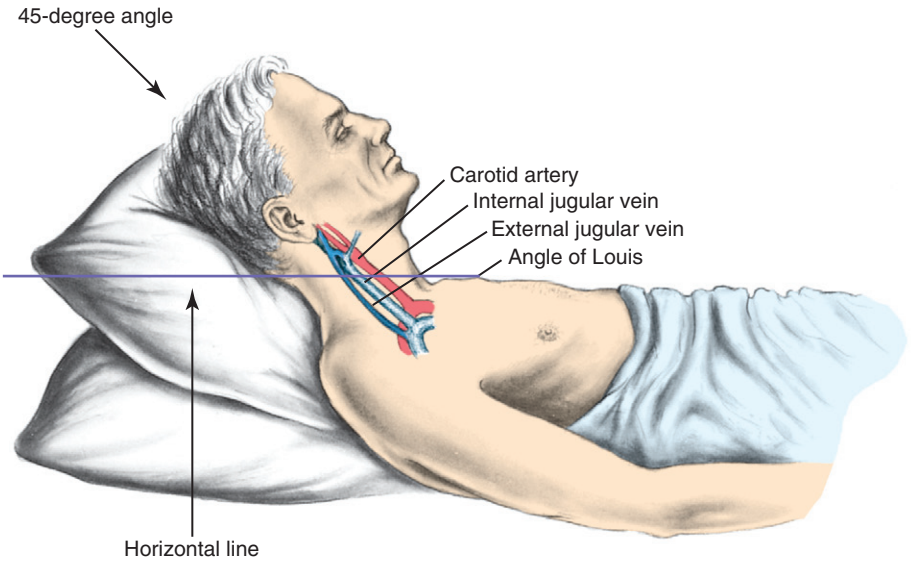

FIG. 30-45 Position of patient to assess jugular vein distention. (From Thompson JM et al: *Mosby's manual of clinical nursing,* ed 5, St Louis, 2001, Mosby.)

FIG. 30-46 Measuring jugular venous pressure. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

TABLE 30-25 Indicators for Assessing Local Blood Flow

INDICATOR	RATIONALE
Systemic diseases (e.g., arteriosclerosis, atherosclerosis, diabetes).	Diseases result in changes in integrity of walls of arteries and smaller blood vessels.
Coagulation disorders (e.g., thrombosis, embolus).	Blood clot causes mechanical obstruction to blood flow.
Local trauma or surgery (e.g., contusion, fracture, vascular surgery).	Direct manipulation of vessels or localized edema impairs blood flow.
Application of constricting devices (e.g., casts, dressings, elastic bandages, restraints).	Constriction causes tourniquet effect, impairing blood flow to areas below site of constriction.

Peripheral Arteries and Veins

To examine the peripheral vascular system, first assess the adequacy of blood flow to the extremities by measuring arterial pulses and inspecting the condition of the skin and nails. Next, assess the integrity of the venous system. Assess the arterial pulses in the extremities to determine sufficiency of the entire arterial circulation.

Factors such as coagulation disorders, local trauma or surgery, constricting casts or bandages, and systemic diseases impair circulation to the extremities (Table 30-25). Discuss risk factors and ways to monitor for circulatory problems with the patient (Box 30-20).

Peripheral Arteries. Examine each peripheral artery using the distal pads of your second and third fingers. The thumb helps anchor the brachial and femoral artery. Apply firm pressure but avoid occluding a pulse. When a pulse is difficult to find, it helps to vary pressure and feel all around the pulse site. Be sure not to palpate your own pulse.

Routine vital signs usually include assessment of the rate and rhythm of the radial artery because it is easily accessible. Count the pulse for either 30 seconds or a full minute, depending on the character of the pulse (see Chapter 29). Always count an irregular pulse for 60 seconds. With palpation, normally feel the pulse wave at regular intervals. When an interval is interrupted by an early, a late, or a missed beat, the pulse rhythm is irregular. During cardiac emergencies health care providers usually assess the carotid artery because it is accessible and most useful in evaluating heart activity. To check local circulatory status of tissues (e.g., when a leg cast is in place or following vascular surgery), palpate the peripheral arteries long enough to note that a pulse is present.

Assess each peripheral artery for elasticity of the vessel wall, strength, and equality. The arterial wall is normally elastic, making it easily palpable. After depressing the artery, it springs back to shape when releasing the pressure. An abnormal artery is hard, inelastic, or calcified.

The strength of a pulse is a measurement of the force at which blood is ejected against the arterial wall. Some examiners use a scale rating from 0 to 4+ for the strength of a pulse (Seidel et al., 2011):

BOX 30-20 PATIENT TEACHING

Vascular Assessment

Objective

- Patient with vascular insufficiency will avoid activities that worsen circulatory status.

Teaching Strategies

- Instruct patient with risk or evidence of vascular insufficiency in the lower extremities to avoid tight clothing over the lower body or legs, avoid sitting or standing for long periods, avoid sitting with legs crossed, walk regularly, and elevate feet when sitting.
- Advise patient to avoid or stop cigarette smoking because nicotine causes vasoconstriction. Offer a referral to a reliable stop smoking program.
- Identify patient with hypertension about the benefits of regular monitoring of blood pressure (daily, weekly, or monthly). Teach patient how to use home monitoring kits.

Evaluation

- Ask patient to identify if blood pressure reading is within normal limits for age.
- Have patient with vascular insufficiency describe precautions to take to avoid further circulatory deficiency.
- Have patient demonstrate self-monitoring of blood pressure.

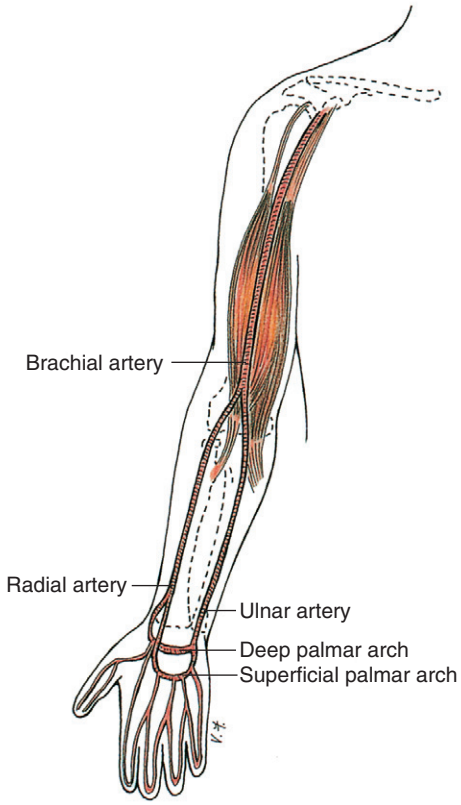

FIG. 30-47 Anatomical positions of brachial, radial, and ulnar arteries.

0: Absent, not palpable
1+: Pulse diminished, barely palpable
2+: Expected/normal
3+: Full pulse, increased
4+: Bounding pulse

Measure all peripheral pulses for equality and symmetry. Compare the left radial pulse with that of the right and so on. Lack of symmetry indicates impaired circulation such as a localized obstruction or an abnormally positioned artery.

In the upper extremities the brachial artery channels blood to the radial and ulnar arteries of the forearm and hand. If circulation in this artery becomes blocked, the hands do not receive adequate blood flow. If circulation in the radial or ulnar arteries becomes impaired, the hand still receives adequate perfusion. An interconnection between the radial and ulnar arteries guards against arterial occlusion (Fig. 30-47).

To locate pulses in the arm have the patient sit or lie down. Find the radial pulse along the radial side of the forearm at the wrist. Thin individuals have a groove lateral to the flexor tendon of the wrist. Feel the radial pulse with light palpation in the groove (Fig. 30-48). The ulnar pulse is on the opposite side of the wrist and feels less prominent (Fig. 30-49). Palpate the ulnar pulse only when evaluating arterial insufficiency to the hand.

FIG. 30-48 Palpation of radial pulse.

To palpate the brachial pulse, find the groove between the biceps and triceps muscle above the elbow at the antecubital fossa (Fig. 30-50). The artery runs along the medial side of the extended arm. Palpate it with the fingertips of the first three fingers in the muscle groove.

The femoral artery is the primary artery in the leg, delivering blood to the popliteal, posterior tibial, and dorsalis pedis arteries (Fig. 30-51). An interconnection between the posterior tibial and dorsalis pedis arteries guards against local arterial occlusion.

Find the femoral pulse with the patient lying down with the inguinal area exposed (Fig. 30-52). The femoral artery runs below the inguinal ligament, midway between the symphysis pubis and the anterosuperior iliac spine. Sometimes deep palpation is necessary to feel the pulse. Bimanual palpation is effective in obese patients. Place the fingertips of both hands on opposite sides of the pulse site. Feel a pulsatile sensation when the arterial pulsation pushes the fingertips apart.

The popliteal pulse runs behind the knee. Have the patient slightly flex the knee with the foot resting on the examination table or assume a prone position with the knee slightly flexed (Fig. 30-53). Instruct him or her to keep leg muscles relaxed. Palpate with the fingers of both hands deeply into the popliteal fossa, just lateral to the midline. The popliteal pulse is difficult to locate.

FIG. 30-49 Palpation of ulnar pulse.

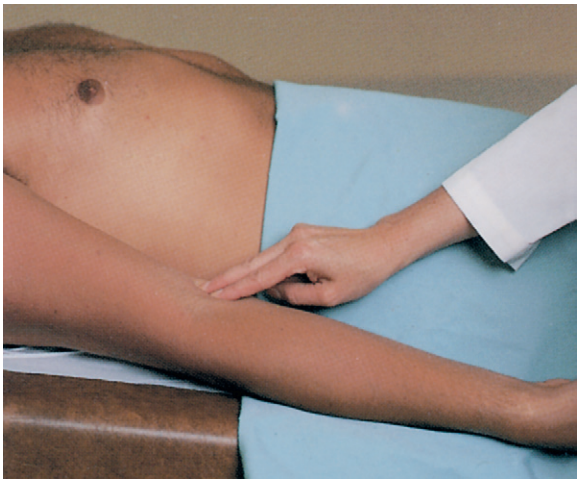

FIG. 30-50 Palpation of brachial pulse.

With the patient's foot relaxed, locate the dorsalis pedis pulse. The artery runs along the top of the foot in line with the groove between the extensor tendons of the great toe and first toe (Fig. 30-54). To find the pulse, place the fingertips between the first and second toes and slowly move up the dorsum of the foot. This pulse is sometimes congenitally absent.

Find the posterior tibial pulse on the inner side of each ankle (Fig. 30-55). Place the fingers behind and below the medial malleolus (ankle bone). With the foot relaxed and slightly extended, palpate the artery.

Ultrasound Stethoscopes. If a pulse is difficult to palpate, an ultrasound (Doppler) stethoscope is a useful tool that amplifies the sounds of a pulse wave. Factors that weaken a pulse or make palpation difficult include obesity, reduction in the stroke volume of the heart, diminished blood volume, or arterial obstruction. Apply a thin layer of transmission gel to the patient's skin at the pulse site or directly onto the transducer tip of the probe. Turn on the volume control and place the tip of the transducer at a 45- to 90-degree angle on the skin (Fig. 30-56). Move the transducer until you hear a pulsating "whooshing" sound that indicates that arterial blood flow is present.

Tissue Perfusion. The condition of the skin, mucosa, and nail beds offers useful data about the status of circulatory blood flow.

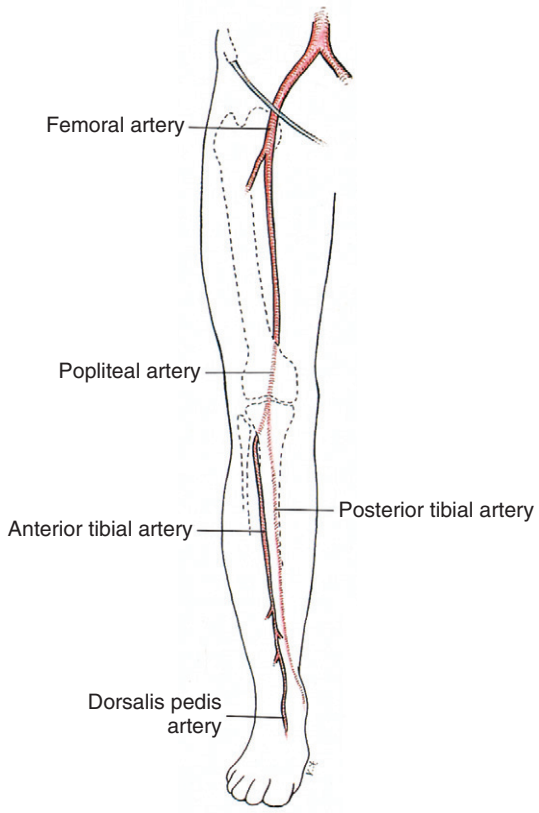

FIG. 30-51 Anatomical position of femoral, popliteal, dorsalis pedis, and posterior tibial arteries.

FIG. 30-52 Palpation of femoral pulse.

FIG. 30-53 Palpation of popliteal pulse.

FIG. 30-54 Palpation of dorsalis pedis pulse.

FIG. 30-55 Palpation of posterior tibial pulse.

FIG. 30-56 Ultrasound stethoscope in position on the pedal pulse.

TABLE 30-26 Signs of Venous and Arterial Insufficiency

ASSESSMENT CRITERION	VENOUS	ARTERIAL
Color	Normal or cyanotic	Pale; worsened by elevation of extremity; dusky red when extremity is lowered
Temperature	Normal	Cool (blood flow blocked to extremity)
Pulse	Normal	Decreased or absent
Edema	Often marked	Absent or mild
Skin changes	Brown pigmentation around ankles	Thin, shiny skin; decreased hair growth; thickened nails

Examine the face and upper extremities, looking at the color of the skin, mucosa, and nail beds. The presence of cyanosis requires special attention. Heart disease sometimes causes central cyanosis, which indicates poor arterial oxygenation. Some characteristics of this are a bluish discoloration of the lips, mouth, and conjunctivae. Blue lips, earlobes, and nail beds are signs of peripheral cyanosis, which indicates peripheral vasoconstriction. When cyanosis is present, consult with a health care provider to request laboratory testing of oxygen saturation to determine the severity of the problem. Examination of the nails involves inspection for **clubbing,** a bulging of the tissues at the nail base. Clubbing is caused by insufficient oxygenation at the periphery resulting from conditions such as chronic emphysema and congenital heart disease.

Inspect the lower extremities for changes in color, temperature, and condition of the skin, indicating either arterial or venous alterations (Table 30-26). This is a good time to ask the patient about any history of pain in the legs. If an arterial occlusion is present, the patient has signs resulting from an absence of blood flow. Pain is distal to the occlusion. The five *P*s—pain, pallor, pulselessness, paresthesias, and paralysis—characterize an occlusion. Venous congestion causes tissue changes that indicate an inadequate circulatory flow back to the heart.

During examination of the lower extremities, also inspect skin and nail texture; hair distribution on the lower legs, feet, and toes; the venous pattern; and scars, pigmentation, or ulcers. Palpate the legs and feet for color and temperature. Capillary refill, traditionally used to determine adequacy of peripheral blood flow to the digits, has limited value. More useful information is gained from grading pulses, assessing for color and warmth, and assessing pulses with a Doppler (Dufault et al., 2008).

The absence of hair growth over the legs indicates circulatory insufficiency. Remember not to confuse absence of hair on the legs with shaved legs. In addition, men who wear tight-fitting dress socks or jeans may have less hair on their calves. Chronic recurring ulcers of the feet or lower legs are a serious sign of circulatory insufficiency and require a health care provider's intervention.

Peripheral Veins. Assess the status of the peripheral veins by asking the patient to assume sitting and standing positions. Assessment includes inspection and palpation for varicosities, peripheral edema, and phlebitis. Varicosities are superficial veins that become dilated, especially when the legs are in a dependent position. They are common in older adults because the veins normally fibrose, dilate, and stretch. They are also common in people who stand for

prolonged periods. Varicosities in the anterior or medial part of the thigh and the posterolateral part of the calf are abnormal.

Dependent edema around the area of the feet and ankles is a sign of venous insufficiency or right-sided heart failure. It is common in older adults and people who spend a lot of time standing (e.g., waitresses, security guards, and nurses). To assess for pitting edema, use the index finger to press firmly for several seconds and release over the medial malleolus or the shins. A depression left in the skin indicates edema. Grading 1+ through 4+ characterizes the severity of the edema (see Fig. 30-6).

Phlebitis is an inflammation of a vein that occurs commonly after trauma to the vessel wall, infection, immobilization, and prolonged insertion of IV catheters. To assess for phlebitis in the leg, inspect the calves for localized redness, tenderness, and swelling over vein sites. Gentle palpation of calf muscles reveals warmth, tenderness, and firmness of the muscle. Unilateral edema of the affected leg is one of the most reliable findings of phlebitis. Determine if dorsiflexion of the foot (Homans' sign) causes pain in the calf. However, Homans' sign is not always a reliable indicator of phlebitis or deep vein thrombosis (DVT) and is present in other conditions (Seidel et al., 2011). Performing the Homans' sign test is contraindicated in patients with DVT. If a clot is present in the leg, it may become dislodged from its original site during this test, resulting in a pulmonary embolism.

Lymphatic System

Assess the lymphatic drainage of the lower extremities during examination of the vascular system or during the female or male genital examination. Superficial and deep nodes drain the legs, but only two groups of superficial nodes are palpable. With the patient supine, palpate the area of the superficial inguinal nodes in the groin area (Fig. 30-57, *A*). Then move the fingertips toward the inner thigh, feeling for any inferior nodes. Use a firm but gentle pressure when palpating over each lymphatic chain. Multiple nodes are not normally palpable, although a few soft, nontender nodes are not unusual. Enlarged, hardened, tender nodes reveal potential sites of infection or metastatic disease.

In the upper extremities lymph is carried by the collecting ducts from the upper extremities to the subclavian lymphatic trunk. To assess this lymph system, gently palpate the epitrochlear nodes, located on the medial aspect of the arms near the antecubital fossa (Fig. 30-57, *B*). The proximal portion of the upper-extremity lymph system is located in the axilla and is usually assessed during examination of the breasts.

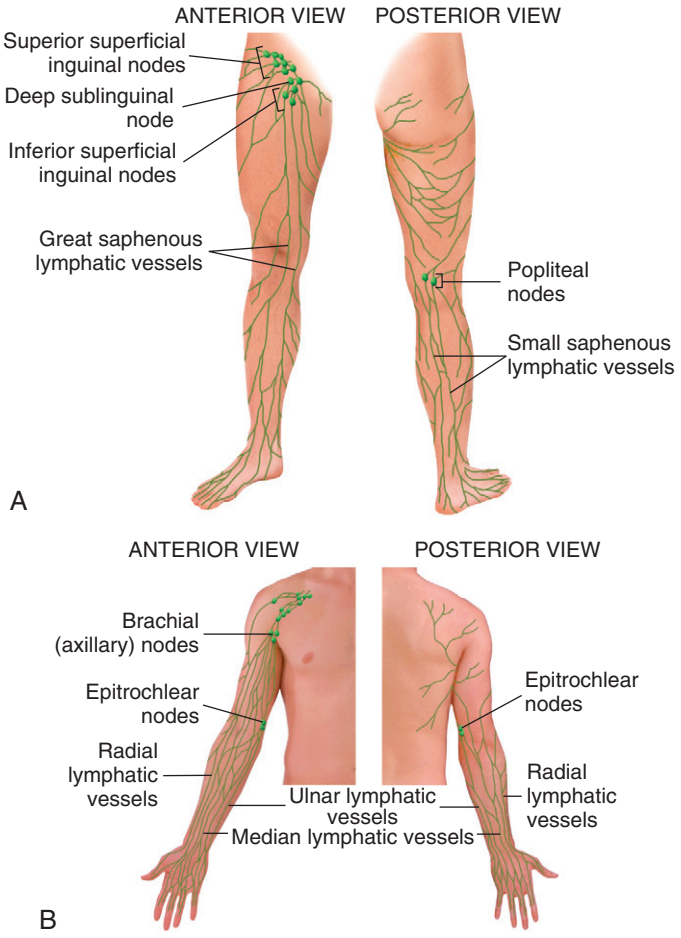

FIG. 30-57 A, Lymphatic drainage for the lower extremities. **B,** Lymphatic drainage for upper extremities. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

BREASTS

It is important to examine the breasts of both female and male patients. Men have a small amount of glandular tissue, a potential site for the growth of cancer cells, in the breast. In contrast, the majority of the female breast is glandular tissue.

Female Breasts

New cases of invasive breast cancer were predicted to affect 230,480 women in the United States in 2011, with 2140 new cases expected in men (ACS, 2011). The disease is second to lung cancer as the leading cause of death in women with cancer. Early detection is the key to cure. A major responsibility for nurses is to teach patients health behaviors such as breast self-examination (BSE) (Box 30-21).

If the patient already performs BSE, assess the method she uses and times she does the examination in relation to her menstrual cycle. The best time for a BSE is the fourth through seventh day of the menstrual cycle or right after the menstrual cycle ends, when the breast is no longer swollen or tender from hormone elevations. If the woman is postmenopausal, advise her to check her breasts on the same day each month. The pregnant woman should also check her breasts on a monthly basis.

Older women require special attention when reviewing the need for regular BSE. Fixed incomes limit many older women; thus they fail to pursue regular clinical breast examination and mammography. Unfortunately many older women ignore changes in their breasts, assuming that they are a part of aging. In addition, physiological factors affect the ease with which older women perform a BSE. Musculoskeletal limitations, diminished peripheral sensation, reduced eyesight, and changes in joint range of motion (ROM) limit palpation and inspection abilities. Find resources for older women, including free screening programs. Teach family members to perform the patient's examination.

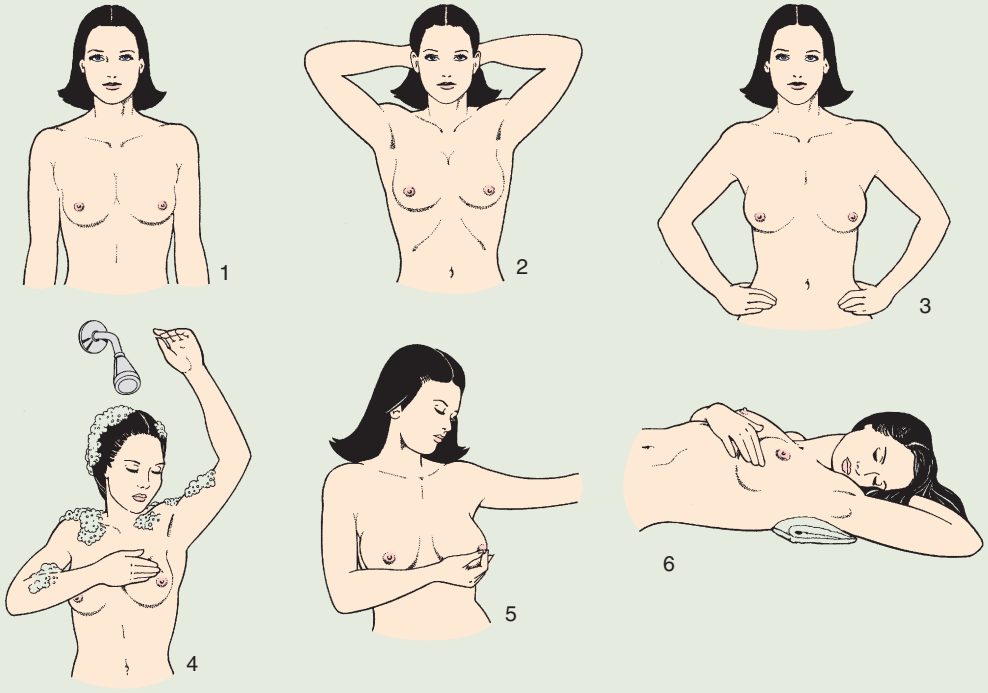
The American Cancer Society (ACS, 2011) recommends the following guidelines for the early detection of breast cancer:

- Monthly BSE is an option for women in their 20s.
- Women 20 years of age and older need to report any breast changes to a health care provider immediately.
- Women need a clinical breast examination by a health care provider every 3 years from ages 20 to 40 and annually for women over age 40.

BOX 30-21 BREAST SELF-EXAMINATION

Patients should perform breast self-examination (BSE) once a month to become familiar with the usual appearance and feel of both breasts. Familiarity makes it easier to notice any changes in the breast from one month to another. Early discovery of a change from baseline is the purpose of BSE.

If menstruating, the best time to do BSE is 2 or 3 days after the monthly period ends, when breasts are least likely to be tender or swollen. If no longer menstruating, pick a day such as the first day of the month as a reminder to do BSE. Instructions for BSE:



1. Stand before a mirror. Inspect both breasts for anything unusual such as discharge from the nipples, puckering, dimpling, or scaling of the skin.

The next two steps are designed to emphasize any change in the shape or contour of the breasts. During each step the patient will feel chest muscles tighten.

2. Watching closely in the mirror, clasp hands behind the head, and swing elbows forward.
3. Press hands firmly on hips and bow slightly toward the mirror while pulling shoulders and elbows forward.

Some women do the next part of the examination in the shower. Fingers glide over soapy skin, making it easy to appreciate the texture underneath.

4. Raise the left arm. Use three or four fingers of the right hand to explore the left breast firmly, carefully, and thoroughly. Beginning at the outer edge, press the flat part of the fingers in small circles, moving the circles slowly around the breast. Gradually work toward the nipple. Be sure to cover the entire breast. Pay special attention to the area between the breast and the armpit, including the armpit itself. Feel for any unusual lump or mass under the skin.
5. Gently squeeze the nipple and look for discharge. Repeat the examination on the right breast.
6. Repeat steps 4 and 5 lying down. Lie flat on back, right arm over the head and a pillow or folded towel under the right shoulder. This position flattens the breast and makes it easier to examine. Use the same circular motion described earlier.
7. Repeat on the right breast.

From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.

- Women with a family history of breast cancer need an annual examination by a health care provider.
- Asymptomatic women need a screening mammogram by age 40; women age 40 and over need to have a mammogram annually.
- For women at increased risk, the ACS recommends talking with the health care provider for screening options and additional testing.

The patient's history (Table 30-27) reveals normal developmental changes and signs of breast disease. Because of its glandular structure, the breast undergoes changes during a woman's life. Knowing these changes (Box 30-22) allows complete and accurate assessment. Encourage both men and women to observe their breasts for changes.

Inspection. Have the patient remove the top gown or drape to allow simultaneous visualization of both breasts. Have her stand or sit with her arms hanging loosely at her sides. If possible, place a mirror in front of her during inspection so she sees what to look for when performing a BSE. To recognize abnormalities the patient needs to be familiar with the normal appearance of her breasts. Describe observations or findings in relation to imaginary lines that divide the breast into four quadrants and a tail. The lines cross at the center of the nipple. Each tail extends outward from the upper outer quadrant (Fig. 30-58).

Inspect the breasts for size and symmetry. Normally they extend from the third to the sixth ribs, with the nipple at the level of the fourth intercostal space. It is common for one breast to be smaller. However, inflammation or a mass causes a difference in size. As a

TABLE 30-27 Nursing History for Breast Assessment

ASSESSMENT	RATIONALE
Determine if woman is over age 40; has a personal or family history of breast cancer, early-onset menarche (before age 13), or late-age menopause (after age 50); has never had children or gave birth to first child after age 30; or has recently used oral contraceptives.	These are risk factors for breast cancer (American Cancer Society [ACS], 2011).
Ask if patient (both sexes) has noticed lump, thickening, pain, or tenderness of breast; discharge, distortion, retraction, or scaling of the nipple; or change in size of breast.	Potential signs and symptoms of breast cancer allow nurse to focus on specific areas of breast during assessment.
Determine patient's use of medications (oral contraceptives, digitalis, diuretics, steroids, or estrogen). Determine his or her caffeine intake.	Some medications cause nipple discharge. Hormones and caffeine cause fibrocystic changes in breast.
Determine patient's level of activity, alcoholic intake, and weight.	Breast cancer incidence rates correlate with being overweight or obese (postmenopausal), physical inactivity, and consumption of one or more alcoholic beverages per day (ACS, 2011).
Ask if patient performs monthly breast self-examination (BSE). If so, determine time of month she performs examination in relation to menstrual cycle. Have her describe or demonstrate method used.	Nurse's role is to educate patient about breast cancer and techniques for BSE.
If patient reports a breast mass, ask about length of time since she first noticed the lump. Does lump come and go, or is it always present? Have there been changes in the lump (e.g., size, relationship to menses), and are there associated symptoms?	Assessment helps to determine nature of mass (e.g., breast cancer vs. fibrocystic disease).

BOX 30-22 NORMAL CHANGES IN THE BREAST DURING A WOMAN'S LIFE SPAN

Puberty (8 to 20 Years)
Breasts mature in five stages. One breast may grow more rapidly than the other. The ages at which changes occur and rate of developmental progression vary.

Stage 1 (Preadolescent)
This stage involves elevation of the nipple only.

Stage 2
The breast and nipple elevate as a small mound, and the areolar diameters enlarge.

Stage 3
There is further enlargement and elevation of the breast and areola, with no separation of contour.

Stage 4
The areola and nipple project into the secondary mound above the level of the breast (does not occur in all girls).

Stage 5 (Mature Breast)
Only the nipple projects, and the areola recedes (varies in some women).

Young Adulthood (20 to 30 Years)
Breasts reach full (nonpregnant) size. Shape is generally symmetrical. Breasts are sometimes unequal in size.

Pregnancy
Breast size gradually enlarges to 2 to 3 times the previous size. Nipples enlarge and become erect. Areolas darken, and diameters increase. Superficial veins become prominent. The nipples expel a yellowish fluid (colostrum).

Menopause
Breasts shrink. Tissue becomes softer, sometimes flabby.

Older Adulthood
Breasts become elongated, pendulous, and flaccid as a result of glandular tissue atrophy. The skin of the breasts tends to wrinkle, appearing loose and flabby.

Nipples become smaller and flatter and lose erectile ability. They sometimes invert because of shrinkage and fibrotic changes.

Data from Ebersole P et al: *Toward healthy aging,* ed 7, St Louis, 2008, Mosby; Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 9, St Louis, 2011, Mosby; and Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.

woman becomes older, the ligaments supporting the breast tissue weaken, causing the breasts to sag and the nipples to lower.

Observe the contour or shape of the breasts and note masses, flattening, retraction, or dimpling. Breasts vary in shape from convex to pendulous or conical. Retraction or dimpling can result from invasion of underlying ligaments by tumors. The ligaments fibrose and pull the overlying skin inward toward the tumor. Edema also changes the contour of the breasts. To bring out retraction or changes in the shape of breasts, ask the patient to assume three positions: raise arms above the head, press hands against the hips, and extend arms straight ahead while sitting and leaning forward. Each maneuver causes a contraction of the pectoral muscles, which accentuates the presence of any retraction.

Carefully inspect the skin for color; venous pattern; and the presence of lesions, edema, or inflammation. Lift each breast when necessary to observe lower and lateral aspects for color and texture changes. The breasts are the color of neighboring skin, and venous patterns are the same bilaterally. Venous patterns are easily visible in thin or pregnant women. Women with large breasts often have redness and excoriation of the undersurfaces caused by rubbing of skin surfaces.

Inspect the nipple and areola for size, color, shape, discharge, and the direction in which the nipples point. The normal areolas are round or oval and nearly equal bilaterally. Color ranges from pink to brown. In light-skinned women the areola turns brown during pregnancy and remains dark. In dark-skinned women the areola is brown before pregnancy (Seidel et al., 2011). Normally the nipples point in symmetrical directions, are everted, and have

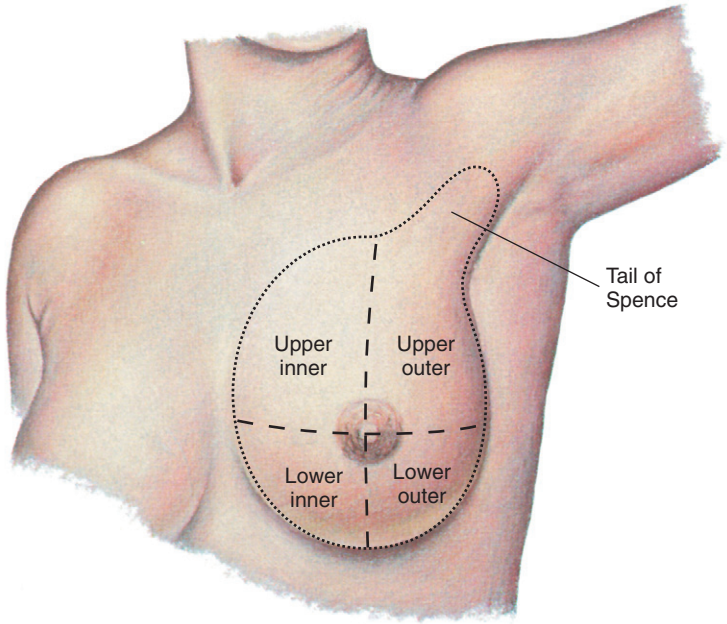


FIG. 30-58 Quadrants of left breast and axillary tail of Spence. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 6, St Louis, 2006, Mosby.)

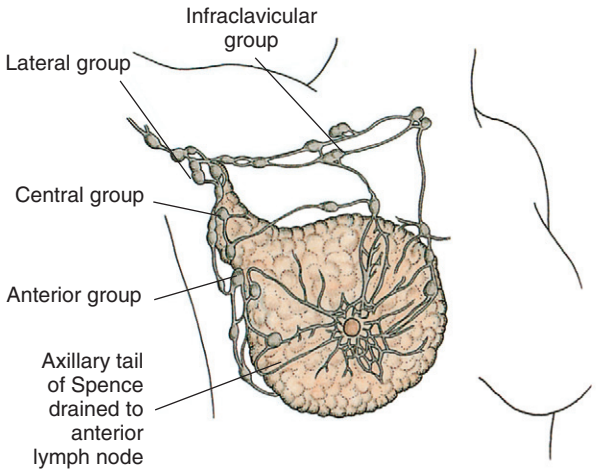

FIG. 30-59 Anatomical position of axillary and clavicular lymph nodes.

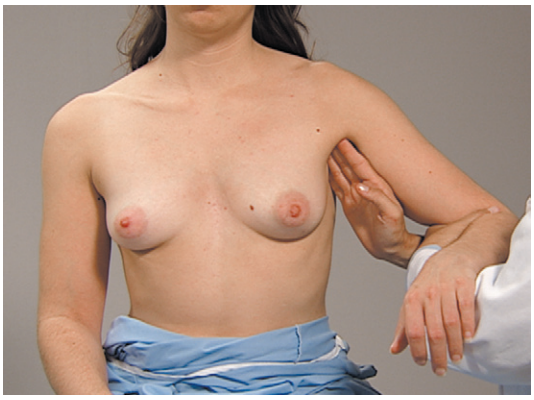

FIG. 30-60 Support patient's arm and palpate axillary lymph nodes. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

no drainage. If the nipples are inverted, ask if this has been a lifetime history. A recent inversion or inward turning of the nipple indicates an underlying growth. Rashes or ulcerations are not normal on the breast or nipples. Note any bleeding or discharge from the nipple. Clear yellow discharge 2 days after childbirth is common. While inspecting the breasts, explain the characteristics you see. Teach the patient the significance of abnormal signs or symptoms.

Palpation. Palpation assesses the condition of underlying breast tissue and lymph nodes. Breast tissue consists of glandular tissue, fibrous supportive ligaments, and fat. Glandular tissue is organized into lobes that end in ducts that open onto the surface of the nipple. The largest portion of glandular tissue is in the upper outer quadrant and tail of each breast. Suspensory ligaments connect to skin and fascia underlying the breast to support the breast and maintain its upright position. Fatty tissue is located superficially and to the sides of the breast.

A large portion of lymph from the breasts drains into axillary lymph nodes. If cancerous lesions metastasize (spread), the nodes commonly become involved. Study the location of supraclavicular, infraclavicular, and axillary nodes (Fig. 30-59). The axillary nodes drain lymph from the chest wall, breasts, arms, and hands. A tumor of one breast sometimes involves nodes on the same and opposite sides.

To palpate the lymph nodes have the patient sit with her arms at her sides and muscles relaxed. While facing the patient and standing on the side you are examining, support her arm in a flexed position, and abduct it from the chest wall. Place the free hand against the patient's chest wall and high in the axillary hollow. With the fingertips press gently down over the surface of the ribs and muscles. Palpate the axillary nodes with the fingertips, gently rolling soft tissue (Fig. 30-60). Palpate four areas of the axilla: at the edge of the pectoralis major muscle along the anterior axillary line, the chest wall in the midaxillary area, the upper part of the humerus, and the anterior edge of the latissimus dorsi muscle along the posterior axillary line.

FIG. 30-61 **A,** The patient lies flat with arm abducted and hand under head to help flatten breast tissue evenly over the chest wall. **B,** Each breast is palpated in a systematic fashion. (**B** from Seidel HM et al: *Mosby's guide to physical examination,* ed 6, St Louis, 2006, Mosby.)

Normally lymph nodes are not palpable. Carefully assess each area and note their number, consistency, mobility, and size. One or two small, soft, nontender palpable nodes are normal. An abnormal palpable node feels like a small mass that is hard, tender, and immobile. Continue to palpate along the upper and lower clavicular ridges. Reverse the procedure for the patient's other side.

It is sometimes difficult for a patient to learn to palpate for lymph nodes. Lying down with the arm abducted makes the area more accessible. Instruct the patient to use her left hand for the right axillary and clavicular areas. Take the patient's fingertips and move them in the proper fashion. Then have the patient use her right hand to palpate for nodes on the left side.

With the patient lying supine and one arm under the head and neck (alternating with each breast), palpate her breast tissue. The supine position allows the breast tissue to flatten evenly against the chest wall. The position of the arm and hand further stretches and positions breast tissue evenly (Fig. 30-61, *A*). Place a small pillow or towel under the patient's shoulder blade to further position breast tissue. Palpate the tail of Spence (Fig. 30-61, *B*).

The consistency of normal breast tissue varies widely. The breasts of a young patient are firm and elastic. In an older patient the tissue sometimes feels stringy and nodular. A patient's familiarity with the texture of her own breasts is very important. Patients gain familiarity through monthly BSE (Box 30-23).

If the patient complains of a mass, examine the opposite breast to ensure an objective comparison of normal and abnormal tissue. Use the pads of the first three fingers to compress breast tissue gently against the chest wall, noting tissue consistency. Perform palpation systematically in one of three ways: (1) clockwise or counterclockwise, forming small circles with the fingers along each quadrant and the tail; (2) using a vertical technique with the fingers moving up and down each quadrant; or (3) palpating from the center of the breast in a radial fashion, returning to the areola to begin each spoke (Fig. 30-62, *A* to *C*). Whichever approach you use, be sure to cover the entire breast and tail, directing attention to any areas of tenderness. Use a bimanual technique when palpating large, pendulous breasts. Support the inferior portion of the breast in one hand while using the other hand to palpate breast tissue against the supporting hand.

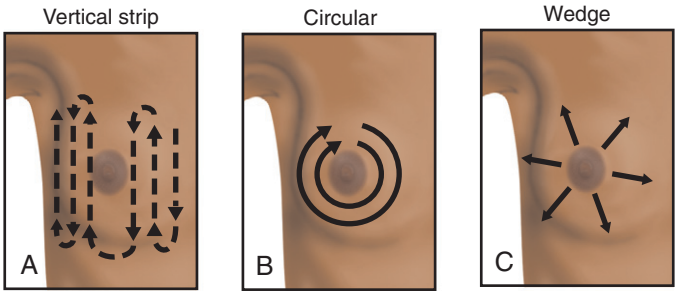

FIG. 30-62 Various methods for palpation of breast. **A,** Palpate from top to bottom in vertical strips. **B,** Palpate in concentric circles. **C,** Palpate out from center in wedge sections. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

BOX 30-23 PATIENT TEACHING

Female Breast Assessment

Objective

- Patient will follow prevention and detection practices to ensure breast health.

Teaching Strategies

- Have patient perform return demonstration of breast self-examination (BSE) and offer the opportunity to ask questions.
- Explain recommended frequency of mammography and assessment by a health care provider.
- Discuss signs and symptoms of breast cancer.
- Discuss signs and symptoms of benign (fibrocystic) breast disease.
- Inform a woman who is obese or has a family history of breast cancer that she is at higher risk for the disease (ACS, 2011). Encourage dietary changes, including limiting meat consumption to well-trimmed, lean beef, pork, or lamb; removing skin from cooked chicken before eating it; selecting tuna and salmon packed in water and not oil; and using low-fat dairy products.
- Encourage patient to reduce intake of caffeine and theophyllines. Although this approach is controversial, it can reduce symptoms of benign (fibrocystic) breast disease.

Evaluation

- Have patient demonstrate BSE.
- During follow-up visit, determine whether patient has had mammography performed.
- Ask patient to explain frequency of mammography.
- Have patient describe signs and symptoms of breast cancer compared with benign (fibrocystic) breast disease.

During palpation note the consistency of breast tissue. It normally feels dense, firm, and elastic. With menopause breast tissue shrinks and becomes softer. The lobular feel of glandular tissue is normal. The lower edge of each breast sometimes feels firm and hard. This is the normal inframammary ridge and not a tumor. It helps to move the patient's hand so she can feel normal tissue variations. Palpate abnormal masses to determine location in relation to quadrants, diameter in centimeters, shape (e.g., round or discoid), consistency (soft, firm, or hard), tenderness, mobility, and discreteness (clear or unclear boundaries).

Cancerous lesions are hard, fixed, nontender, irregular in shape, and usually unilateral. A common benign condition of the breast is benign (fibrocystic) breast disease. Bilateral lumpy, painful breasts and sometimes nipple discharge characterize this condition. Symptoms are more apparent during the menstrual period. When palpated the cysts (lumps) are soft, well differentiated, and movable. Deep cysts feel hard.

Give special attention to palpating the nipple and areola. Palpate the entire surface gently. Use the thumb and index finger to compress the nipple and note any discharge. During the examination of the nipple and areola, the nipple sometimes becomes erect with wrinkling of the areola. These changes are normal. Continue by positioning the patient and examining the other breast.

After completing the examination, have the patient demonstrate self-palpation. Observe the patient's technique and emphasize the importance of a systematic approach. Urge the patient to see her health care provider if she discovers an abnormal mass during routine monthly BSE. She also needs to know all of the signs and symptoms of breast cancer.

Male Breasts

Examination of the male breast is relatively easy. Inspect the nipple and areola for nodules, edema, and ulceration. An enlarged male breast results from obesity or glandular enlargement. Breast enlargement in young males results from steroid use. Fatty tissue feels soft, whereas glandular tissue is firm. Use the same techniques to palpate for masses used in examination of the female breast. Because breast cancer in men is relatively rare, routine self-examinations are unnecessary. However, men who have a first-degree relative (e.g., mother or sister) with breast cancer, are at risk for breast cancer and need to palpate their breasts at regular intervals. Men at high risk may be scheduled by their health care provider for routine mammograms.

ABDOMEN

The abdominal examination is complex because of the number of organs located within and near the abdominal cavity. A thorough nursing history (Table 30-28) helps interpret physical signs. The examination includes an assessment of structures of the lower

TABLE 30-28 Nursing History for Abdominal Assessment

ASSESSMENT	RATIONALE
If patient has abdominal or low back pain, assess character of pain in detail (location, onset, frequency, precipitating factors, aggravating factors, type of pain, severity, course).	Pattern of characteristics of pain helps determine its source.
Carefully observe patient's movement and position, including lying still with knees drawn up, moving restlessly to find comfortable position, and lying on one side or sitting with knees drawn to chest.	Positions assumed by patient reveal nature and source of pain, including peritonitis, renal stone, and pancreatitis.
Assess normal bowel habits and stool character; ask if patient uses laxatives.	Data compared with physical findings help identify cause and nature of elimination problems.
Determine if patient has had abdominal surgery, trauma, or diagnostic tests of gastrointestinal (GI) tract.	Surgical or traumatic alterations of abdominal organs cause changes in expected findings (e.g., position of underlying organs). Diagnostic tests change character of stool.
Assess if patient has had recent weight changes or intolerance to diet (e.g., nausea, vomiting, cramping, especially in last 24 hours).	Data possibly indicate alterations in upper GI tract (stomach or gallbladder) or lower colon.
Assess for difficulty in swallowing, belching, flatulence (gas), bloody emesis (hematemesis), black or tarry stools (melena), heartburn, diarrhea, or constipation.	These characteristic signs and symptoms indicate GI alterations.
Ask if patient takes antiinflammatory medication (e.g., aspirin, ibuprofen, steroids) or antibiotics.	Pharmacological agents cause GI upset or bleeding.
Ask patient to locate tender areas before examination begins.	Assess painful areas last to minimize discomfort and anxiety.
Inquire about family history of cancer, kidney disease, alcoholism, hypertension, or heart disease.	Data possibly reveal risk for alterations identifiable during examination.
Determine if female patient is pregnant; note last menstrual period.	Pregnancy causes changes in abdominal shape and contour.
Assess patient's usual intake of alcohol.	Chronic alcohol ingestion causes gastrointestinal and liver problems.
Review patient's history for the following: health care occupation, hemodialysis, intravenous drug user, household or sexual contact with hepatitis B virus (HBV) carrier, heterosexual person with more than one sex partner in previous 6 months, sexually active homosexual or bisexual male, international traveler in area of high HBV infection rate.	Risk factors for HBV exposure.

gastrointestinal (GI) tract in addition to the liver, stomach, uterus, ovaries, kidneys, and bladder. Abdominal pain is one of the most common symptoms that patients report when seeking medical care. An accurate assessment requires matching patient history data with a careful assessment of the location of physical symptoms.

Assess the organs anteriorly and posteriorly. A system of landmarks help map out the abdominal region. The xiphoid process (tip of the sternum) is the upper boundary of the anterior abdominal region. The symphysis pubis marks the lower boundary. Divide the abdomen into four imaginary quadrants (Fig. 30-63, *A*); refer to assessment findings and record them in relation to each quadrant. Posteriorly the lower ribs and heavy back muscles protect the kidneys, which are located from the T12 to L3 vertebrae (Fig. 30-63, *B*). The costovertebral angle formed by the last rib and vertebral column is a landmark used during kidney palpation.

During the abdominal examination the patient needs to relax. A tightening of abdominal muscles hinders palpation. Ask the patient to void before beginning. Be sure that the room is warm and drape upper chest and legs. The patient lies supine or in a dorsal recumbent position with the arms at the sides and knees slightly bent. Place small pillows beneath the knees. If the patient places the arms under the head, the abdominal muscles tighten. Proceed calmly and slowly, being sure that there is adequate lighting. Expose the abdomen from just above the xiphoid process down to the symphysis pubis. Warm hands and stethoscope further promote relaxation. Ask the patient to report pain and point out tender areas. Assess tender areas last.

The order of an abdominal examination differs slightly from previous assessments. Begin with inspection and follow with auscultation. By using auscultation before palpation there is less chance of altering the frequency and character of bowel sounds. Be sure to have a tape measure and marking pen available during the examination.

Inspection

Make it a habit to observe the patient during routine care activities. Note his or her posture and look for evidence of abdominal splinting: lying with the knees drawn up or moving restlessly in bed. A patient free from abdominal pain does not guard or splint the abdomen. To inspect the abdomen for abnormal movement or shadows, stand on the patient's right side and inspect from above the abdomen. After sitting or stooping down to look across the abdomen, assess abdominal contour. Direct the examination light over the abdomen.

Skin. Inspect the skin over the abdomen for color, scars, venous patterns, lesions, and **striae** (stretch marks). The skin is subject to the same color variations as the rest of the body. Venous patterns are normally faint, except in thin patients. Striae result from stretching of tissue by obesity or pregnancy. Artificial openings indicate drainage sites resulting from surgery (see Chapter 50) or an ostomy (see Chapters 45 and 46). Scars reveal evidence of past trauma or surgery that has created permanent changes in underlying organ anatomy. Bruising indicates accidental injury, physical abuse, or a type of bleeding disorder. If needle marks or bruises are present, ask if the patient self-administers injections (e.g., low-molecular-weight heparin or insulin). Unexpected findings include generalized color changes such as jaundice or cyanosis. Shiny abdominal skin with a taut (tight) appearance can indicate ascites.

Umbilicus. Note the position; shape; color; and signs of inflammation, discharge, or protruding masses. A normal umbilicus is flat or concave with the color the same as that of the surrounding skin. Underlying masses cause displacement of the umbilicus. An everted (pouched-out) umbilicus usually indicates distention. Hernias (protrusion of abdominal organs through the muscle wall) cause upward protrusion of the umbilicus. Normally the umbilical area does not emit discharge.

Contour and Symmetry. Inspect for contour, symmetry, and surface motion of the abdomen, noting any masses, bulging, or distention. A flat abdomen forms a horizontal plane from the xiphoid process to the symphysis pubis. A round abdomen protrudes in a convex sphere from the horizontal plane. A concave abdomen appears to sink into the muscular wall. Each of these findings is normal if the shape of the abdomen is symmetrical. In older adults there is often an overall increased distribution of adipose tissue. The presence of masses on only one side, or asymmetry, possibly indicates an underlying pathological condition.

Intestinal gas, a tumor, or fluid in the abdominal cavity causes **distention** (swelling). When distention is generalized, the entire abdomen protrudes. The skin often appears taut, as if it were stretched over the abdomen. When gas causes distention, the flanks (side muscles) do not bulge. However, if fluid is the source of the problem, the flanks bulge. Ask the patient to roll onto one side. A protuberance forms on the dependent side if fluid is the cause of the distention. Ask the patient if the abdomen feels unusually tight.

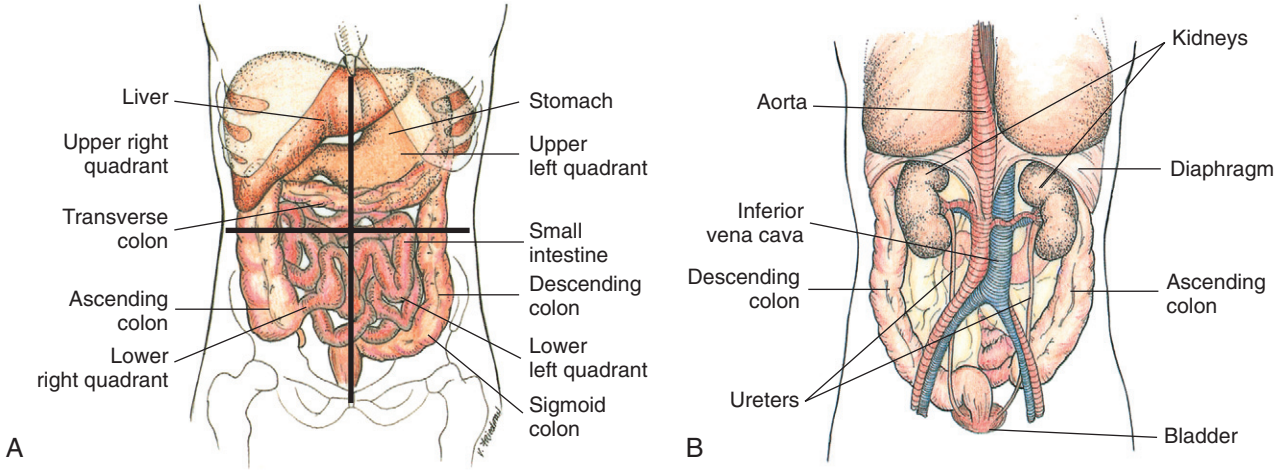

FIG. 30-63 **A,** Anterior view of abdomen divided by quadrants. **B,** Posterior view of abdominal section.

Be careful not to confuse distention with obesity. In obesity the abdomen is large, rolls of adipose tissue are often present along the flanks, and the patient does not complain of tightness in the abdomen. If distention is expected, measure the abdomen by placing a tape measure around it at the level of the umbilicus (this may require the patient to roll side-to-side as you position the tape measure). Consecutive measurements show any increase or decrease in distention. Use a marking pen to indicate the location of the tape measure.

Enlarged Organs or Masses. Observe the contour of the abdomen while asking the patient to take a deep breath and hold it. Normally the contour remains smooth and symmetrical. This maneuver forces the diaphragm downward and reduces the size of the abdominal cavity. Any enlarged organs in the upper abdominal cavity (e.g., liver or spleen) descend below the rib cage to cause a bulge. Perform a closer examination with palpation. To evaluate the abdominal musculature have the patient raise the head. This position causes superficial abdominal wall masses, hernias, and muscle separations to become more apparent.

Movement or Pulsations. Inspect for movement. Normally men breathe abdominally, and women breathe more costally. A patient with severe pain has diminished respiratory movement and tightens the abdominal muscles to guard against the pain. Closely inspect for peristaltic movement and aortic pulsation by looking across the abdomen from the side. These movements are visible in thin patients; otherwise no movement is present.

Auscultation

Auscultate before palpation during the abdominal assessment because manipulation of the abdomen alters the frequency and intensity of bowel sounds. Ask patients not to talk. Patients with GI tubes connected to suction need them temporarily turned off before beginning an examination.

Bowel Motility. **Peristalsis,** or the movement of contents through the intestines, is a normal function of the small and large intestine. Bowel sounds are the audible passage of air and fluid that peristalsis creates. Place the warmed diaphragm of the stethoscope lightly over each of the four quadrants. Normally air and fluid move through the intestines, creating soft gurgling or clicking sounds that occur irregularly 5 to 35 times per minute (Seidel et al., 2011). Sounds usually last ½ second to several seconds. It normally takes 5 to 20 seconds to hear a bowel sound. However, it takes 5 minutes of continuous listening before determining that bowel sounds are absent (Seidel et al., 2011). Auscultate all four quadrants to be sure that you do not miss any sounds. The best time to auscultate is between meals. Sounds are generally described as normal, audible, absent, hyperactive, or hypoactive. Absent sounds indicate a lack of peristalsis, possibly the result of late-stage bowel obstruction; paralytic ileus; or peritonitis. Normally absent or hypoactive bowel sounds occur after surgery following general anesthesia. Hyperactive sounds are loud, "growling" sounds called **borborygmi,** which indicate increased GI motility. Inflammation of the bowel, anxiety, diarrhea, bleeding, excessive ingestion of laxatives, and reaction of the intestines to certain foods cause increased motility. Teach patients practices to promote normal elimination patterns (Box 30-24).

Vascular Sounds. Bruits indicate narrowing of the major blood vessels and disruption of blood flow. The presence of bruits in the abdominal area can reveal aneurysms or stenotic vessels. Use the bell of the stethoscope to auscultate in the epigastric region and each of the four quadrants. Normally there are no vascular sounds over the aorta (midline through the abdomen) or femoral arteries (lower quadrants). You can hear renal artery bruits by placing the stethoscope over each upper quadrant anteriorly or over the costovertebral angle posteriorly. Report a bruit immediately to a health care provider.

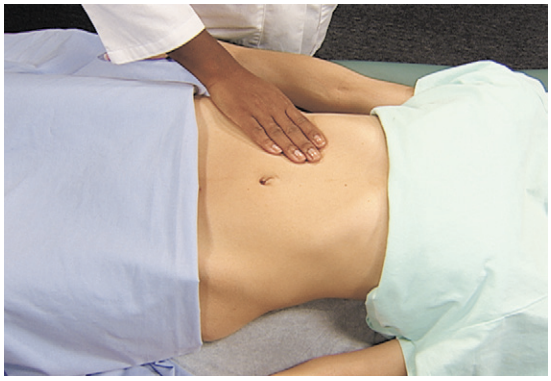

FIG. 30-64 Light palpation of abdomen. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

BOX 30-24 PATIENT TEACHING

Abdominal Assessment

Objective

- Patient will maintain normal bowel elimination.

Teaching Strategies

- Explain factors that promote normal bowel elimination such as diet, regular exercise, limited use of over-the-counter drugs causing constipation, establishment of regular elimination schedule, and a good fluid intake (see Chapter 46). Stress importance for older adults.
- Caution patients about dangers of excessive use of laxatives or enemas.
- Instruct patient to have acute abdominal pain evaluated by a health care provider.

Evaluation

- Reassess patient's bowel elimination pattern and stool character after therapies begin.
- Observe patient using pain-relief measures and reassess character of pain.

Kidney Tenderness. With the patient sitting or standing erect, use direct or indirect percussion to assess for kidney inflammation. You might require an advanced practice nurse to help you with this skill. With the ulnar surface of the partially closed fist, percuss posteriorly the costovertebral angle at the scapular line. If the kidneys are inflamed, the patient feels tenderness during percussion.

Palpation

Palpation primarily detects areas of abdominal tenderness, distention, or masses. As your skill base increases, learn to palpate for specific organs by using light and deep palpation.

Use light palpation over each abdominal quadrant to detect areas of tenderness. Initially avoid areas previously identified as problem spots. Lay the palm of the hand with fingers extended and approximated lightly on the abdomen. Explain the maneuver to the patient and, with the palmar surface of the fingers, depress approximately 1.3 cm (½ inch) in a gentle dipping motion (Fig. 30-64). Avoid quick jabs and use smooth, coordinated movements. If the

FIG. 30-65 Deep palpation of abdomen. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

patient is ticklish, first place his or her hand on the abdomen with your hand on the patient's; continue this until the patient tolerates palpation.

Use a systematic palpation approach for each quadrant and assess for muscular resistance, distention, tenderness, and superficial organs or masses. Observe the patient's face for signs of discomfort. The abdomen is normally smooth with consistent softness and nontender without masses. In contrast to firm muscles found among young adults, an older adult often lacks abdominal tone. Guarding or muscle tenseness sometimes occurs while palpating a sensitive area. If tightening remains after the patient relaxes, peritonitis, acute cholecystitis, or appendicitis is sometimes the cause. It is easy to detect a distended bladder with light palpation. Normally the bladder lies below the umbilicus and above the symphysis pubis. Routinely check for a distended bladder if the patient has been unable to void (e.g., because of anesthesia or sedation) or has been incontinent or if an indwelling urinary catheter is not draining well.

With practice and experience perform deep palpation to delineate abdominal organs and detect less obvious masses. You need short fingernails. It is important for the patient to be relaxed while the hands depress approximately 2.5 to 7.5 cm (1 to 3 inches) into the abdomen (Fig. 30-65). Never use deep palpation over a surgical incision or over extremely tender organs. It is also unwise to use palpation on abnormal masses. Deep pressure causes tenderness in a healthy patient over the cecum, sigmoid colon, aorta, and the midline near the xiphoid process (Seidel et al., 2011).

Survey each quadrant systematically. Palpate masses for size, location, shape, consistency, tenderness, pulsation, and mobility. Test for rebound tenderness by pressing a hand slowly and deeply into the involved area and letting go quickly. The test is positive if the patient feels pain with the release of the hand. Rebound tenderness occurs in patients with peritoneal irritation such as occurs in appendicitis; pancreatitis; or any peritoneal injury causing bile, blood, or enzymes to enter the peritoneal cavity.

Aortic Pulsation. Palpate with the thumb and forefinger of one hand deeply into the upper abdomen just left of the midline to assess aortic pulsation. Normally a pulsation is transmitted forward. If the aorta is enlarged because of an aneurysm (localized dilation of a vessel wall), the pulsation expands laterally. Do not palpate a pulsating abdominal mass. When enlargement from an aneurysm is present, only lightly palpate this area, referring the finding to the health care provider. In obese patients it is often necessary to palpate with both hands, one on each side of the aorta.

FEMALE GENITALIA AND REPRODUCTIVE TRACT

Examination of the female genitalia is embarrassing to a patient unless you use a calm, relaxed approach. The gynecological examination is one of the most difficult experiences for adolescents. A person's cultural background further adds to apprehension. For example, female Mexican Americans have a strong social value that women do not expose their bodies to men or even to other women. Similarly, Chinese Americans believe that the examination of genitalia is offensive. Provide a thorough explanation of the reason for the procedures used in the examination. The lithotomy position assumed during the examination is an added source of embarrassment. A patient is more comfortable when you use correct positioning and draping. Be sure to explain each portion of the examination in advance so patients anticipate necessary actions. Adolescents sometimes choose to have parents present in the examination room.

Sometimes a patient requires a complete examination of the female reproductive organs, including assessing the external genitalia and performing a vaginal examination. You can examine external genitalia while performing routing hygiene measures or when preparing to insert a urinary catheter. An internal examination is part of each woman's preventive health care because ovarian cancer causes more deaths than any other cancer of the female reproductive system (ACS, 2011).

Adolescents and young adults are examined because of the growing incidence of sexually transmitted infections (STIs). The average age of menarche among young girls has declined, and the majority of male and female teenagers are sexually active by age 19 (Hockenberry and Wilson, 2011). It is important to assess a patient's level of anxiety when obtaining the nursing history (Table 30-29). Combine rectal and anal assessments with the pelvic examination since the patient is situated in a lithotomy or dorsal recumbent position.

Preparation of the Patient

The beginning nurse is often responsible for assisting a patient's health care provider with the examination. For a complete examination the following equipment is needed: examination table with stirrups, vaginal speculum of correct size, adjustable light source, sink, clean disposable gloves, sterile cotton swabs, glass slides, plastic or wooden spatula, cervical brush or broom device, cytological fixative, and culture plates or media (Seidel et al., 2011).

Make sure that the equipment is ready before the examination begins. Ask the patient to empty her bladder so the uterus and ovaries are readily palpable. Often it is necessary to collect a urine specimen. Assist the patient to the lithotomy position in bed or on an examination table for the external genitalia assessment. Assist her into stirrups for a speculum examination. Have a woman stabilize each foot in a stirrup and have her slide the buttocks down to the edge of the examining table. Place a hand at the edge of the table and instruct the patient to move until touching the hand. The patient's arms should be at her sides or folded across the chest to prevent tightening of abdominal muscles.

Some women suffering from pain or deformity of the joints are unable to assume a lithotomy position. In this situation it is necessary to have the patient abduct only one leg or have another assist in separating the patient's thighs. In addition, use the side-lying position with the patient on the left side with the right thigh and knee drawn up to her chest.

Give a square drape or sheet to the patient. She holds one corner over her sternum, the adjacent corners fall over each knee, and the

TABLE 30-29 Nursing History for Female Genitalia and Reproductive Tract Assessment

ASSESSMENT	RATIONALE
Determine if patient has had previous illness or surgery involving reproductive organs, including STIs.	Illness or surgery influences appearance and position of organs being examined.
Determine if patient has received HPV vaccine.	HPV increases patient's risk for development of cervical cancer.
Review menstrual history, including age at menarche, frequency and duration of menstrual cycle, character of flow (e.g., amount, presence of clots), presence of dysmenorrhea (painful menstruation), pelvic pain, dates of last two menstrual periods, and premenstrual symptoms.	This information helps to reveal level of reproductive health, including normalcy of menstrual cycle.
Ask patient to describe obstetrical history, including each pregnancy and history of abortions or miscarriages.	Observed physical findings vary, depending on woman's history of pregnancy.
Determine whether patient uses safe sex practices; have patient describe current and past contraceptive practices and problems encountered. Discuss risk of STIs and HIV infection.	Use of certain types of contraceptives influences reproductive health (e.g., sensitivity reaction to spermicidal jelly). Sexual history reveals risk for and understanding of STIs.
Assess if patient has signs and symptoms of vaginal discharge, painful or swollen perianal tissues, or genital lesions.	These signs and symptoms may indicate STI or other pathological condition.
Determine if patient has symptoms or history of genitourinary problems, including burning during urination, frequency, urgency, nocturia, hematuria, incontinence, or stress incontinence (see Chapter 45).	Urinary problems are associated with gynecological disorders, including STIs.
Ask if patient has had signs of bleeding outside of normal menstrual period or after menopause or has had unusual vaginal discharge.	These are warning signs for cervical and endometrial cancer or vaginal infection.
Determine if patient has history of HPV (condyloma acuminatum, herpes simplex, or cervical dysplasia); has multiple sex partners; smokes cigarettes; has had multiple pregnancies; or was young at first intercourse.	These are risk factors for cervical cancer (ACS, 2011).
Determine if patient is older than 40, obese, and has history of ovarian dysfunction, breast or endometrial cancer, irradiation of pelvic organs, or endometriosis; has family history of ovarian, breast, or colon cancer; has history of infertility or nulliparity; or use of estrogen (alone) hormone replacement therapy.	These are risk factors for ovarian cancer (ACS, 2011).
Determine if patient is postmenopausal, obese, or infertile; had early menarche; had late menopause; has history of hypertension, diabetes, gallbladder disease, or polycystic ovary disease; has family history of endometrial, breast, or colon cancer; or has a history of estrogen-related exposure (estrogen replacement therapy, tamoxifen use).	These are risk factors for endometrial cancer (ACS, 2011).

HIV, Human immunodeficiency virus; *HPV,* human papillomavirus (HPV) vaccine; *STI,* sexually transmitted infection.

fourth corner covers the perineum. After the examination begins, lift the drape over the perineum. A male examiner always needs to have a female attendant present during the examination, whereas a female examiner may choose to work alone. An additional female should be present if the patient requests it.

External Genitalia

Make sure that the perineal area is well illuminated. Follow standard precautions and wear clean gloves to prevent contact with infectious organisms. The perineum is sensitive and tender; do not touch the area suddenly without warning the patient. It is best to touch the inner thigh first before touching it.

While sitting at the end of the examination table or bed, inspect the quantity and distribution of hair growth. Preadolescents have no pubic hair. During adolescence hair grows along the labia, becoming darker, coarser, and curlier. In an adult hair grows in a triangle over the female perineum and along the medial surfaces of the thighs. The underlying skin is free of inflammation, irritation, or lesions.

Inspect surface characteristics of the labia majora. The skin of the perineum is smooth, clean, and slightly darker than other skin. The mucous membranes appear dark pink and moist. The labia majora can be gaping or closed, appear dry or moist, and are usually symmetrical. After childbirth the labia majora separate, causing the labia minora to become more prominent. When a woman reaches menopause, the labia majora become thinned; they become atrophied in older age. The labia majora are normally without inflammation, edema, lesions, or lacerations.

To inspect the remaining external structures, use your nondominant hand and gently place the thumb and index finger inside the labia minora and retract the tissues outwardly (Fig. 30-66). Be sure to have a firm hold to avoid repeated retraction against the sensitive tissues. Use the other hand to palpate the labia minora between the thumb and second finger. On inspection the labia minora are normally thinner than the labia majora, and one side is sometimes larger. The tissue feels soft on palpation and without tenderness. The size of the clitoris varies, but it normally does not exceed 2 cm in length and 0.5 cm in width. Look for atrophy, inflammation, or adhesions. If inflamed, the clitoris is a bright cherry red. In young women it is a common site for syphilitic lesions, or chancres, which appear as small open ulcers that drain serous material.

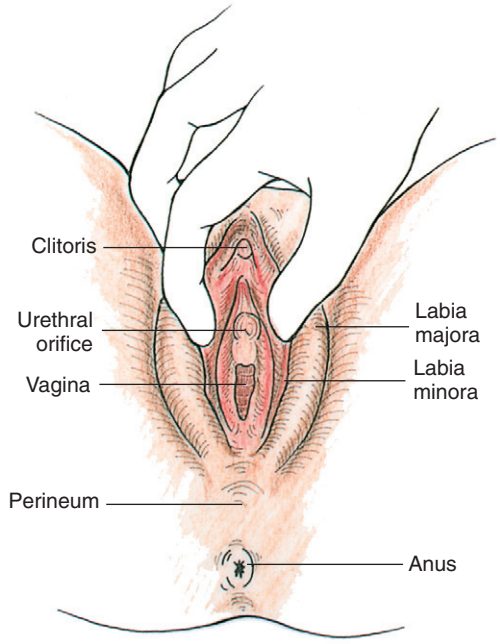

FIG. 30-66 Female external genitalia.

Inspect the urethral orifice carefully for color and position. It is normally intact without inflammation. The urethral meatus is anterior to the vaginal orifice and is pink. It appears as a small slit or pinhole opening just above the vaginal canal. Note any discharge, polyps, or fistulas.

Inspect the vaginal orifice for inflammation, edema, discoloration, discharge, and lesions. Normally the opening is a thin, vertical slit; and the tissue is moist. While inspecting the vaginal orifice, note the condition of the hymen, which is just inside the opening. In the virgin female the hymen restricts the opening of the vagina, but the tissue retracts or disappears after sexual intercourse.

Inspect the anus, looking for lesions and hemorrhoids (see rectal examination). After completion of the external examination, dispose of examination gloves and offer the patient soft disposable cloths for perineal hygiene.

Patients who are at risk for contracting an STI need to learn to perform a genital self-examination (Box 30-25). The purpose of the examination is to detect any signs or symptoms of an STI. Many persons do not know that they have an STI (e.g., chlamydia), and some STIs (e.g., syphilis) remain undetected for years.

Speculum Examination of Internal Genitalia

An examination of the internal genitalia requires much skill and practice. Advanced nurse practitioners and primary care providers perform this examination. As a nursing student you observe the procedure or assist the examiner by helping the patient with positioning, handing off specimen supplies, and providing emotional support for the patient.

The examination involves use of a plastic or metal speculum consisting of two blades and an adjustment device. The examiner inserts the speculum into the vagina to assess the internal genitalia for cancerous lesions and other abnormalities. During the examination the examiner collects a specimen for a Papanicolaou (Pap) test for cervical and vaginal cancer. The cervix is inspected for color, position, size, surface characteristics, and discharge (Seidel et al., 2011).

BOX 30-25 PATIENT TEACHING

Female Genitalia and Reproductive Tract Assessment

Objective

- Patient will use measures to maintain sexual health and prevent acquisition and transmission of sexually transmitted infections (STIs).

Teaching Strategies

- Instruct patient about purpose and recommended frequency of Papanicolaou (Pap) smears and gynecological examinations. Explain that the Pap smear is relatively painless and needed annually with a pelvic examination for women who are sexually active or over the age of 21. Patients are screened more often if certain risk factors exist such as a weak immune system, multiple sex partners, smoking, and a history of infections (e.g., human papillomavirus [HPV]).
- Counsel patient with an STI about the implications of diagnosis and treatment.
- Recommend the HPV vaccine for females ages 9 to 26 years to prevent cervical cancer (American Cancer Society [ACS], 2011; Centers for Disease Control and Prevention, 2011). The HPV vaccine prevents the most common types of HPV that cause cervical cancer and genital warts. It is given as a 3-dose vaccine.
- Instruct in genital self-examination (GSE). Using a mirror, position self to examine the area covered by the pubic hair. Spread the hair apart, looking for bumps, sores, or blisters. Also look for any warts, which appear as small, bumpy spots and enlarge to fleshy, cauliflower-like lesions. Next spread the outer vaginal lips apart and look at the clitoris for bumps, blisters, sores, or warts. Look at both sides of the inner vaginal lips. Inspect the area around the urinary and vaginal opening for bumps, blisters, sores, or warts.
- Explain warning signs of STIs: pain or burning on urination, pain during sex, pain in pelvic area, bleeding between menstruation, itchy rash around vagina, and abnormal vaginal discharge.
- Teach measures to prevent STIs: male partner's use of condoms, restricting number of sexual partners, avoiding sex with persons who have several other partners, and perineal hygiene measures.
- Tell patients with an STI to inform sexual partners of the need for an examination.
- Reinforce the importance of performing perineal hygiene (as appropriate).

Evaluation

- Ask patient to explain when she should routinely have a gynecological examination and Pap test.
- Have patient describe ways to prevent transmission of STIs.
- For patient with an STI, determine during follow-up visit if patient has followed safe sexual practices (use nonthreatening inquiry).

MALE GENITALIA

An examination of the male genitalia assesses the integrity of the external genitalia (Fig. 30-67), inguinal ring, and canal. Because the incidence of STIs in adolescents and young adults is high, an assessment of the genitalia needs to be a routine part of any health maintenance examination for this age-group (Box 30-26). The examination begins by having the patient void. Make sure the examination room is warm. Have the patient lie supine with the chest, abdomen, and lower legs draped or stand during the examination. Apply clean gloves.

Use a calm, gentle approach to lessen the patient's anxiety. The position and exposure of the body during the examination is embarrassing for some men. To minimize his anxiety, it often helps

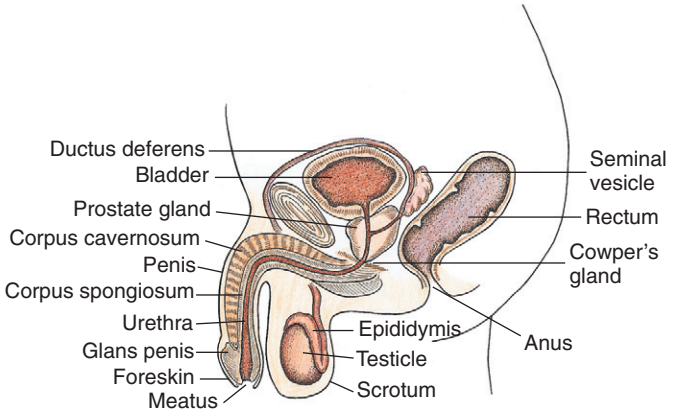

FIG. 30-67 External and internal male sex organs.

BOX 30-26 PATIENT TEACHING

Male Genitalia Assessment

Objective

- Patient will use measures to maintain sexual health and prevent acquisition and transmission of sexually transmitted infections (STIs).

Teaching Strategies

- Teach patient how to perform genital self-examination (see Box 30-27).
- Counsel patient who has an STI about diagnosis implications and treatment.
- Explain warning signs of STIs: pain on urination and during sex, abnormal penile discharge (different from usual), swollen lymph nodes, or rash or ulcer on skin or genitalia.
- Teach measures to prevent STIs: use of condoms, avoiding sex with infected partner, restricting number of sexual partners, avoiding sex with persons who have multiple partners, and using regular perineal hygiene.
- Recommend HPV vaccine for males ages 9 to 26 years. Boys and young men may choose to get this vaccine to prevent genital warts and anal cancer (CDC, 2011).
- Tell patients with an STI to inform their sexual partners of the need to have an examination.
- Instruct patient to seek treatment as soon as possible if partner becomes infected with an STI.

Evaluation

- Ask patient to describe methods for preventing and treating STIs.
- During a follow-up visit determine whether patient with an STI has used safe sex practices.

TABLE 30-30 Nursing History for Male Genitalia Assessment

ASSESSMENT	RATIONALE
Review normal urinary elimination pattern, including frequency of voiding; history of nocturia; character and volume of urine; daily fluid intake; symptoms of burning, urgency, and frequency; difficulty starting stream; and hematuria (see Chapter 45).	Urinary problems are directly associated with genitourinary problems because of anatomical structure of men's reproductive and urinary systems.
Assess patient's sexual history and use of safe sex habits (multiple partners, infection in partners, failure to use condom).	Sexual history reveals risk for and understanding of sexually transmitted diseases (STIs) and human immunodeficiency virus (HIV).
Determine if patient has received the HPV vaccine.	HPV is associated with genital warts in men and can lead to cervical cancer in females (CDC, 2011).
Determine if patient has had previous surgery or illness involving urinary or reproductive organs, including STI.	Alterations resulting from disease or surgery are sometimes responsible for symptoms or changes in organ structure or function.
Ask if patient has noted penile pain or swelling, genital lesions, or urethral discharge.	These signs and symptoms may indicate STI.
Determine if patient has noticed heaviness or painless enlargement of testis or irregular lumps.	These signs and symptoms are early warning signs for testicular cancer.
If patient reports an enlargement in inguinal area, assess if it is intermittent or constant, associated with straining or lifting, and painful and whether pain is affected by coughing, lifting, or straining at stool.	Signs and symptoms reflect potential inguinal hernia.
Ask if patient has difficulty achieving erection or ejaculation; also review whether patient is taking diuretics, sedatives, antihypertensives, or tranquilizers.	These medications influence sexual performance.

to offer explanations of the steps of examination so he anticipates all actions. Manipulate the genitalia gently to avoid causing erection or discomfort. Obtain a thorough history (Table 30-30) before the examination, ensuring that the assessment is complete.

Sexual Maturity

First note the sexual maturity of the patient by observing the size and shape of the penis and testes; the size, color, and texture of the scrotal skin; and the character and distribution of pubic hair. The testes first increase in size in preadolescence. During this time there is no pubic hair. By the end of puberty, the testes and penis enlarge to adult size and shape, and scrotal skin darkens and becomes wrinkled. With puberty hair is coarse and abundant in the pubic area. The penis has no hair, and the scrotum has very little hair (Fig. 30-68, *A* and *B*). Also inspect the skin covering the genitalia for lice, rashes, excoriations, or lesions. Normally it is clear, without lesions.

Penis

To inspect penile surfaces, manipulate the genitalia or have the patient assist. Inspect the shaft, corona, prepuce (foreskin), glans, and urethral meatus. The dorsal vein is apparent on inspection. In uncircumcised males retract the foreskin to reveal the glans and urethral meatus. The foreskin usually retracts easily. A small amount of white, thick smegma sometimes collects under this

BOX 30-27 MALE GENITAL SELF-EXAMINATION

All men 15 years and older need to perform this examination monthly using the following steps.

Genital Examination

- Perform the examination after a warm bath or shower when the scrotal skin is less thick.
- Stand naked in front of a mirror, hold the penis in your hand, and examine the head. Pull back the foreskin if uncircumcised to expose the glans.
- Inspect and palpate the entire head of the penis in a clockwise motion, looking carefully for any bumps, sores, or blisters (bumps and blisters may be light colored or red, resemble pimples).
- Look also for any genital warts (see illustration).
- Look at the opening (urethral meatus) at the end of the penis for discharge.
- Look along the entire shaft of the penis for the same signs.
- Be sure to separate pubic hair at the base of the penis and carefully examine the skin underneath.

Testicular Self-Examination

- Look for swelling or lumps in the skin of the scrotum while looking in the mirror.
- Use both hands, placing the index and middle fingers under the testicles and the thumb on top (see illustration).
- Gently roll the testicle, feeling for lumps, swelling, soreness, or a harder consistency.
- Find the epididymis (a cordlike structure on the top and back of the testicle; it is not a lump).
- Feel for small, pea-size lumps on the front and side of the testicle. Abnormal lumps are usually painless.
- Call your health care provider for abnormal findings.

Illustrations from Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.

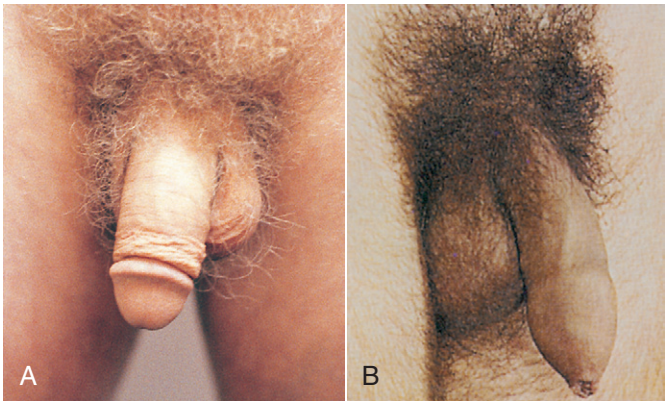

FIG. 30-68 Appearance of male genitalia. **A,** Circumcised. **B,** Uncircumcised. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

foreskin. Obtain a culture if abnormal discharge is present. The urethral meatus is slitlike in appearance and positioned on the ventral surface just millimeters from the tip of the glans. In some congenital conditions the meatus is displaced along the penile shaft. The area between the foreskin and glans is a common site for venereal lesions. Gently compress the glans between the thumb and index finger; this opens the urethral meatus for inspection of lesions, edema, and inflammation. Normally the opening is glistening and pink without discharge. Palpate any lesion gently to note tenderness, size, consistency, and shape. When inspection and palpation of the glans is complete, pull the foreskin down to its original position.

Continue by inspecting the entire shaft of the penis, including the undersurface, looking for lesions, scars, or edema. Palpate the shaft between the thumb and first two fingers to detect localized areas of hardness or tenderness. A patient who has lain in bed for a prolonged time sometimes develops dependent edema in the penis shaft.

It is important for any male patient to learn to perform a genital self-examination to detect signs or symptoms of STIs, especially men who have had more than one sexual partner or whose partner has had other partners. Men may have an STI but not be aware of it; self-examination is a routine part of self-care (Box 30-27).

Scrotum

Be particularly cautious while inspecting and palpating the scrotum because the structures lying within the scrotal sac are very sensitive. The scrotum is divided internally into two halves. Each half contains a testicle, epididymis, and the vas deferens, which travels

upward into the inguinal ring. Normally the left testicle is lower than the right. Inspect the size, shape, and symmetry of the scrotum while observing for lesions or edema. Gently lift the scrotum to view the posterior surface. The scrotal skin is usually loose, and the surface is coarse. The scrotal skin is more deeply pigmented than body skin. Tightening of the skin or loss of wrinkling reveals edema. The size of the scrotum normally changes with temperature variations because the dartos muscle contracts in cold and relaxes in warm temperatures. Lumps in the scrotal skin are commonly sebaceous cysts.

Testicular cancer is a solid tumor common in young men ages 18 to 34 years. Early detection is critical. Explain testicular self-examination (see Box 30-27) while examining the patient. The testes are normally sensitive but not tender. The underlying testicles are normally ovoid and approximately 2 to 4 cm (1 to 1½ inch) in size. Gently palpate the testicles and epididymis between the thumb and first two fingers. The testes feel smooth, rubbery, and free of nodules. The epididymis is resilient. Note the size, shape, and consistency of the organs. The most common symptoms of testicular cancer are a painless enlargement of one testis and the appearance of a palpable, small, hard lump, about the size of a pea, on the front or side of the testicle. In the older adult the testicles decrease in size and are less firm during palpation. Continue to palpate the vas deferens separately as it forms the spermatic cord toward the inguinal ring, noting nodules or swelling. It normally feels smooth and discrete.

Inguinal Ring and Canal

The external inguinal ring provides the opening for the spermatic cord to pass into the inguinal canal. The canal forms a passage through the abdominal wall, a potential site for hernia formation. A hernia is a protrusion of a portion of intestine through the inguinal wall or canal. Sometimes an intestinal loop enters the scrotum. Have the patient stand during this part of the examination.

During inspection ask the patient to strain or bear down. The maneuver helps to make a hernia more visible. Look for obvious bulging in the inguinal area.

Complete the examination by palpating for inguinal lymph nodes. Normally small, nontender, mobile horizontal nodes are palpable. Any abnormality indicates local or systemic infection or malignant disease.

RECTUM AND ANUS

A good time to perform the rectal examination is after the genital examination. Usually this examination is not performed for young children or adolescents. It detects colorectal cancer in its early stages. The rectal examination also detects prostatic tumors in men. Collect a health history (Table 30-31) to detect the patient's risk for bowel or rectal disease (men and women) or prostatic disease (men). Teach the patient about the purpose of the examination (Box 30-28).

The rectal examination is uncomfortable; thus explaining all steps helps a patient relax. Use a calm, slow-paced, gentle approach during the examination. Female patients remain in the dorsal recumbent position following genitalia examination or they assume a side-lying (Sims') position. The best way to examine men is to have the patient stand and bend over forward with hips flexed and upper body resting across an examination table. Examine a nonambulatory patient in the Sims' position. Use nonlatex clean gloves.

TABLE 30-31 Nursing History for Rectal and Anal Assessment

ASSESSMENT	RATIONALE
Determine whether patient has experienced bleeding from rectum, black or tarry stools (melena), rectal pain, or change in bowel habits (constipation or diarrhea).	These are warning signs of colorectal cancer* or other gastrointestinal alterations.
Determine whether patient has personal or strong family history of colorectal cancer, polyps, or chronic inflammatory bowel disease. Ask if patient is over age 40.	These are risk factors for colorectal cancer.*
Assess dietary habits, including high fat intake, diet high in processed or red meats, or deficient fiber content (inadequate fruits and vegetables).	Bowel cancer is often linked to dietary intake of fat or insufficient fiber intake.*
Determine if patient is obese, is physically inactive, smokes, or consumes alcohol.	These are risk factors for colorectal cancer.
Determine whether patient has undergone screening for colorectal cancer (digital examination, fecal occult blood test, flexible sigmoidoscopy, and colonoscopy).	Undergoing this screening reflects understanding and compliance with preventive health care measures.
Assess medication history for use of laxatives or cathartic medications.	Repeated use causes diarrhea and eventual loss of intestinal muscle tone.
Assess for use of codeine or iron preparations.	Codeine causes constipation. Iron turns the color of feces black and tarry.
Ask male patient if he has experienced weak or interrupted urine flow, inability to urinate, difficulty in starting or stopping urine flow, polyuria, nocturia, hematuria, or dysuria. Does patient have continuing pain in lower back, pelvis, or upper thighs?	These are warning signs of prostatic cancer.* Symptoms also suggest infection or prostate enlargement.

*Data from American Cancer Society: *Cancer facts and figures 2006,* Atlanta, 2010, The Society.

Inspection

Using the nondominant hand, gently retract the buttocks to view the perianal and sacrococcygeal areas. Perianal skin is smooth, more pigmented, and coarser than skin over the buttocks. Inspect anal tissue for skin characteristics, lesions, external hemorrhoids (dilated veins that appear as reddened protrusions), ulcers, fissures and fistulas, inflammation, rashes, or excoriation. Anal tissues are moist and hairless, and the voluntary external muscle sphincter holds the anus closed. Next ask a patient to bear down as though having a bowel movement. Any internal hemorrhoids or fissures appear at this time. Use clock reference (e.g., 3 o'clock or 8 o'clock) to describe location of findings. Normally there is no protrusion of tissue.

Digital Palpation

Examine the anal canal and sphincters with digital palpation, and in male patients palpate the prostate gland to rule out enlargement. Usually advanced practitioners perform this portion of the examination. This technique is not discussed here.

BOX 30-28 PATIENT TEACHING

Rectal and Anal Assessment

Objective

- Patient will be able to identify symptoms of colorectal and prostatic cancer.

Teaching Strategies

- Discuss the guidelines of the American Cancer Society (ACS) (2011) for early detection of colorectal cancer.
- Beginning at age 50, both men and women should follow one of these testing schedules:
  - Tests that find polyps and cancer
    - Flexible sigmoidoscopy every 5 years, or
    - Colonoscopy every 10 years, or
    - Double-contrast barium enema every 5 years, or
    - CT colonography (virtual colonoscopy) every 5 years
  - Tests that primarily find cancer
    - Yearly fecal occult blood test (gFOBT), or
    - Yearly fecal immunochemical test (FIT) every year, or
    - Stool DNA test (sDNA), interval uncertain
- Individuals at increased risk should discuss options with their health care provider.
- Discuss warning signs of colorectal cancer (see Table 30-31).
- Discuss with male patient the ACS guidelines (2011) for early detection of prostate cancer:
  - Digital rectal examination performed annually after age 50
  - Annual prostate-specific antigen (PSA) blood test for men age 50 and over
  - Prostate ultrasound testing if results of either digital rectal examination or PSA test is suspicious
  - Need for African American men or those with a first-degree relative diagnosed with prostate cancer to begin testing at age 45
- Discuss warning signs of prostate cancer.

Evaluation

- During follow-up visit determine whether patient has had a rectal examination performed.
- Have patient explain warning signs of colorectal and prostate cancer.

MUSCULOSKELETAL SYSTEM

The musculoskeletal assessment can be performed as a separate examination or integrated with other parts of the total physical examination. In addition, you can assess the patient's movements while performing other nursing care measures such as bathing or positioning. The assessment of musculoskeletal function focuses on determining range of joint motion, muscle strength and tone, and joint and muscle condition. Assessing musculoskeletal integrity is especially important when a patient reports pain or loss of function in a joint or muscle. Because muscular disorders are often the result of neurological disease, you may choose to perform a simultaneous neurological assessment.

While examining a patient's musculoskeletal function, visualize the anatomy of bone and muscle placement and joint structure (see Chapter 47). Joints vary in degree of mobility, depending on the type of joint.

For a complete examination expose the muscles and joints so they are free to move. Have the patient assume a sitting, supine, prone, or standing position while assessing specific muscle groups. Table 30-32 lists the information gathered in the nursing history.

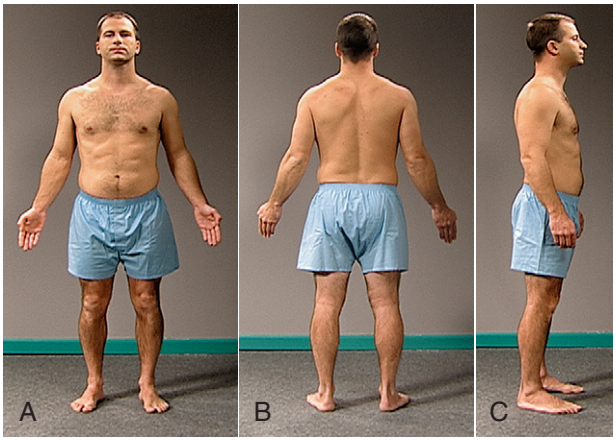

FIG. 30-69 Inspection of overall body posture. **A,** Anterior view. **B,** Posterior view. **C,** Lateral view. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

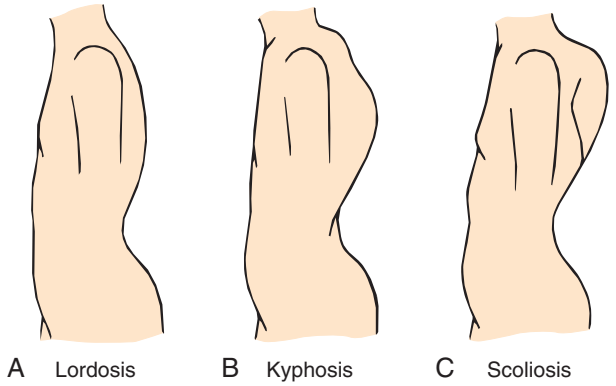

FIG. 30-70 Common postural abnormalities. **A,** Lordosis. **B,** Kyphosis. **C,** Scoliosis.

General Inspection

Observe the patient's gait when entering the examination room. When the patient is unaware of the nature of your observation, gait is more natural. Later, a more formal test has the patient walk in a straight line away from and return to the point of origin. Note how the patient walks, sits, and rises from a sitting position. Normally patients walk with the arms swinging freely at the sides and the head leading the body. Older adults often walk with smaller steps and a wider base of support. Note foot dragging, limping, shuffling, and the position of the trunk in relation to the legs.

Observe the patient from the side and while facing the patient in a standing position. The normal standing posture is upright with parallel alignment of the hips and shoulders (Fig. 30-69, *A* to *C*). There is an even contour of the shoulders, level scapulae and iliac crests, alignment of the head over the gluteal folds, and symmetry of extremities. While observing from the side of the patient, note the normal cervical, thoracic, and lumbar curves. Holding the head erect is normal. As the patient sits, some degree of rounding of the shoulders is normal. Older adults tend to assume a stooped, forward-bent posture with the hips and knees somewhat flexed and arms bent at the elbows, raising the level of the arms.

Common postural abnormalities include lordosis, kyphosis, and scoliosis (Fig. 30-70, *A* to *C*). **Kyphosis,** or hunchback, is an

TABLE 30-32 Nursing History for Musculoskeletal Assessment

ASSESSMENT	RATIONALE
Determine if patient is involved in competitive sports (particularly involving collision and contact), fails to warm up adequately, is in poor physical condition, or has had a rapid growth spurt (adolescents).	These are risk factors for sports injury.
Review patient history for use of alcohol and/or caffeine; cigarette smoking; constant dieting; calcium intake less than 500 mg daily; thin and light body frame; nulliparous status; menopause before age 45; estrogen deficiency; postmenopause status; family history of osteoporosis; white, Asian, Native American, or northern European ancestry; advanced age; history of fractures/falls; inadequate calcium intake and vitamin D; sedentary lifestyle; chronic diseases (Cushing's hyperthyroidism and hypothyroidism, malabsorption/malnutrition disorders, neoplasm); long-term use of corticosteroids, methotrexate, phenytoin, aluminum-containing antacids; lack of weight-bearing exercise; lack of exposure to sunlight (Walker, 2010).	These are risk factors for osteoporosis.
Ask patient to describe history of problems in bone, muscle, or joint function (e.g., recent fall, trauma, lifting of heavy objects, history of bone or joint disease with sudden or gradual onset, location of alteration).	History helps to assess nature of musculoskeletal problem.
Assess nature and extent of pain, including location, duration, severity, predisposing and aggravating factors, relieving factors, and type.	Pain frequently accompanies alterations in bone, joints, or muscle. This has implications not only for comfort, but also for ability to perform activities of daily living.
Assess patient's normal activity pattern, including type of exercise routinely performed.	Provides baseline in assessment. Sedentary lifestyle and lack of appropriate exercise increase bone loss and risk of fractures.
Determine how alteration influences ability to perform activities of daily living (e.g., bathing, feeding, dressing, toileting, ambulating) and social functions (e.g., household chores, work, recreation, sexual activities).	The extent to which patient is able to perform self-care determines the level of nursing care. Type and degree of restriction in continuing social activities influence topics for patient education and ability of nurse to identify alternative ways to maintain function.
Assess height loss of woman over age 50 by subtracting current height from recall of maximum adult height.	Measurement is useful screening tool to predict osteoporosis.

BOX 30-29 PATIENT TEACHING

Health Promotion to Prevent Osteoporosis in Women

Objective

- Patient will follow measures to prevent or minimize osteoporosis.

Teaching Strategies

- Recommend women age 65 and older for routine screening for osteoporosis. Recommend men for screening as well; they are equally at risk for development of osteoporosis as they age.
- To reduce bone demineralization, instruct older adults in a proper exercise program (e.g., weight-bearing, muscle-strengthening, and balance-training exercises) to be followed 3 or more times a week.
- Encourage intake of calcium to meet the recommended daily allowance. Increased vitamin D aids calcium absorption.
- Recommendation for calcium supplements for adults over age 25 is 1000 to 1500 mg/day. Instruct patient to take no more than 600 mg of calcium at one time.
- Instruct older adults and those with osteoporosis in proper body mechanics and range-of-motion and moderate weight-bearing exercises (e.g., swimming and walking) to minimize trauma and subsequent fracture of bones.
- Instruct older patients to pace activities to compensate for loss in muscle strength.

Evaluation

- Observe patient's posture.
- Ask patient to describe therapies for preventing osteoporosis.
- Observe patient perform range-of-motion exercises.
- Have patient keep log of regular weight-training exercises.

exaggeration of the posterior curvature of the thoracic spine. This postural abnormality is common in older adults. **Lordosis,** or swayback, is an increased lumbar curvature. A lateral spinal curvature is called **scoliosis.** Loss of height is frequently the first clinical sign of osteoporosis, in which height loss occurs in the trunk as a result of vertebral fracture and collapse. **Osteoporosis** is a systemic skeletal condition that is noted to have both decreased bone mass and deterioration of bone tissue, making bones fragile and at risk for fracture (Nelson et al., 2010). Osteopenia, characterized by low bone mass of the hip, puts persons at risk for osteoporosis, fractures, and potential complications later in life. Approximately 80% of people with osteoporosis are women; approximately 20% of the time the disease affects men. It affects any age-group, including children. Patients should be taught ways to reduce the chance of developing this disease (Box 30-29).

During general inspection look at the extremities for overall size, gross deformity, bony enlargement, alignment, and symmetry. Normally there is bilateral symmetry in length, circumference, alignment, and position and in the number of skinfolds (Seidel et al., 2011). A general review pinpoints areas requiring specialized assessment.

Palpation

Apply gentle palpation to all bones, joints, and surrounding muscles during a complete examination. For a focused assessment only examine the involved area. Note any heat, tenderness, edema, or resistance to pressure. The patient should not feel any discomfort when you palpate. Muscles should be firm.

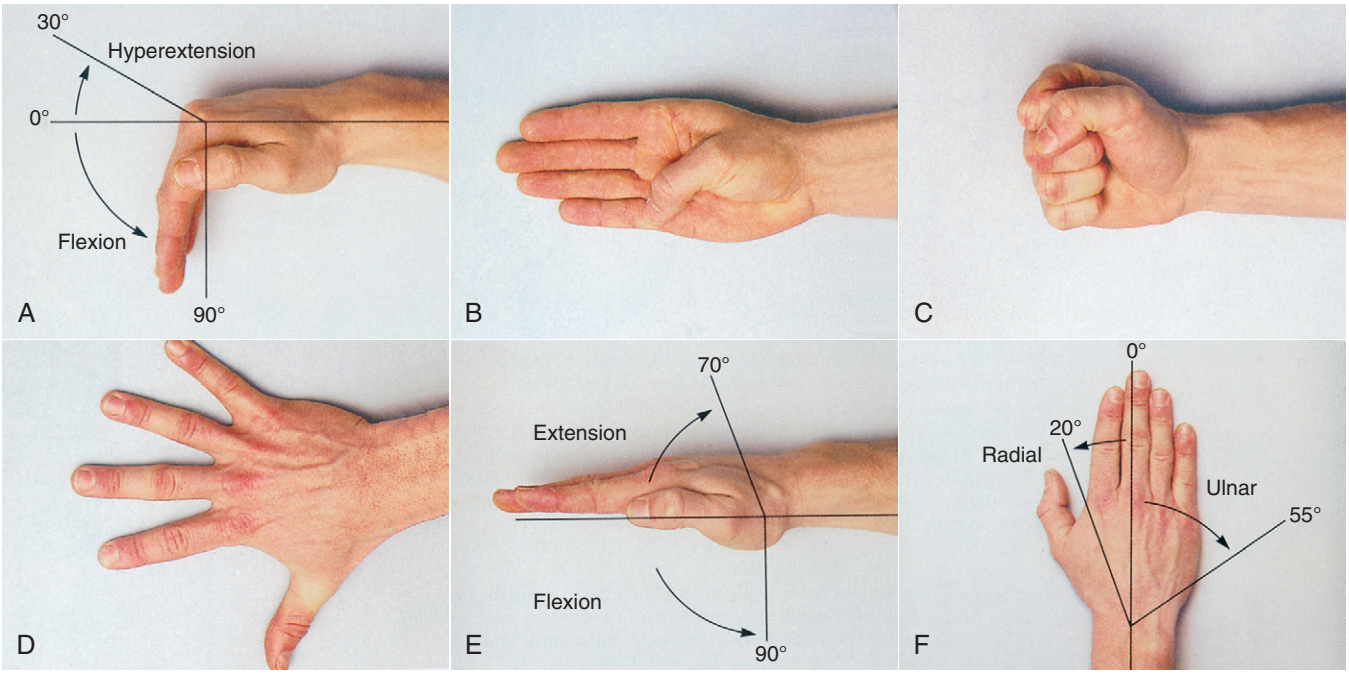

FIG. 30-71 Range of motion of hand and wrist. **A,** Metacarpophalangeal flexion and hyperextension. **B,** Finger flexion: thumb to each fingertip and to the base of the little finger. **C,** Finger flexion, fist formation. **D,** Finger abduction. **E,** Wrist flexion and hyperextension. **F,** Wrist radial and ulnar movement. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

Range of Joint Motion

The examination includes comparison of both active and passive ROM. Ask the patient to put each major joint through active and passive full ROM (see Chapter 47). Learn the correct terminology for the movements that the joints are capable of making (Table 30-33) and teach the patient how to move through each ROM. Demonstrate ROM to the patient when possible. To assess ROM passively, ask the patient to relax and then passively move the extremities through their ROM. Compare the same body parts for equality in movement. Fig. 30-71, *A* to *F*, shows an example of ROM positions for the hand and wrist. Do not force a joint into a painful position. Know the normal range of each joint and the extent to which you can move the patient's joints. ROM is equal between contralateral joints. Ideally assess the patient's normal range to determine a baseline for assessing later change.

A **goniometer,** frequently used by physical and occupational therapists, measures the precise degree of motion in a particular joint and is mainly for patients who have a suspected reduction in joint movement. The instrument has two flexible arms with a 180-degree protractor in the center. Position the center of the protractor at the center of the joint you are measuring (Fig. 30-72). The arms extend along the body parts on each side of the protractor. Measure the joint angle before moving the joint. After taking the joint through a full ROM, measure the angle again to determine the degree of movement. Compare the reading with the normal degree of joint movement.

Joints are typically free from stiffness, instability, swelling, or inflammation. There should be no discomfort when applying pressure to bones and joints. In older adults joints often become swollen and stiff with reduced ROM resulting from cartilage erosion and fibrosis of synovial membranes (see Chapter 47). If a joint appears swollen and inflamed, palpate it for warmth.

TABLE 30-33 Terminology for Normal Range-of-Motion Positions

TERM	RANGE OF MOTION	EXAMPLES OF JOINTS
Flexion	Movement decreasing angle between two adjoining bones; bending of limb	Elbow, fingers, knee
Extension	Movement increasing angle between two adjoining bones	Elbow, knee, fingers
Hyperextension	Movement of body part beyond its normal resting extended position	Head
Pronation	Movement of body part so front or ventral surface faces downward	Hand, forearm
Supination	Movement of body part so front or ventral surface faces upward	Hand, forearm
Abduction	Movement of extremity away from midline of body	Leg, arm, fingers
Adduction	Movement of extremity toward midline of body	Leg, arm, fingers
Internal rotation	Rotation of joint inward	Knee, hip
External rotation	Rotation of joint outward	Knee, hip
Eversion	Turning of body part away from midline	Foot
Inversion	Turning of body part toward midline	Foot
Dorsiflexion	Flexion of toes and foot upward	Foot
Plantar flexion	Bending of toes and foot downward	Foot

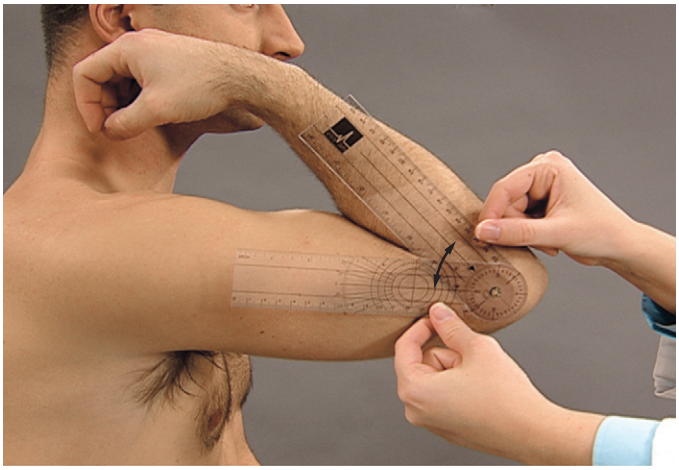

FIG. 30-72 The patient flexes the arm; the goniometer measures joint range of motion. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

FIG. 30-73 Assessing muscle tone.

TABLE 30-34 Maneuvers to Assess Muscle Strength

MUSCLE GROUP	MANEUVER
Neck (sternocleidomastoid)	Place hand firmly against patient's upper jaw. Ask patient to turn head laterally against resistance.
Shoulder (trapezius)	Place hand over midline of patient's shoulder, exerting firm pressure. Have patient raise shoulders against resistance.
Elbow	
Biceps	Pull down on forearm as patient attempts to flex arm.
Triceps	As you flex patient's arm, apply pressure against forearm. Ask patient to straighten arm.
Hip	
Quadriceps	When patient is sitting, apply downward pressure to thigh. Ask patient to raise leg up from table.
Gastrocnemius	Patient sits while examiner holds shin of flexed leg. Ask patient to straighten leg against resistance.

TABLE 30-35 Muscle Strength

	SCALES		
MUSCLE FUNCTION LEVEL	GRADE	% NORMAL	LOVETT SCALE
No evidence of contractility	0	0	0 (zero)
Slight contractility, no movement	1	10	T (trace)
Full range of motion, gravity eliminated*	2	25	P (poor)
Full range of motion with gravity	3	50	F (fair)
Full range of motion against gravity, some resistance	4	75	G (good)
Full range of motion against gravity, full resistance	5	100	N (normal)

Modified from Walker J: The role of the nurse in the management of osteoporosis, *Br J Nurs* 19(19):1243, 2010.
*Passive movement.

Muscle Tone and Strength

Assess muscle strength and tone during ROM measurement. Integrate these findings with those from the neurological assessment. Note muscle tone, the slight muscular resistance felt as you move the relaxed extremity passively through its ROM.

Ask the patient to allow an extremity to relax or hang limp. This is often difficult, particularly if the patient feels pain in it. Support the extremity and grasp each limb, moving it through the normal ROM (Fig. 30-73). Normal tone causes a mild, even resistance to movement through the entire range.

If a muscle has increased tone, or **hypertonicity,** there is considerable resistance with any sudden passive movement of a joint. Continued movement eventually causes the muscle to relax. A muscle that has little tone **(hypotonicity)** feels flabby. The involved extremity hangs loosely in a position determined by gravity.

For assessment of muscle strength, have the patient assume a stable position. He or she performs maneuvers demonstrating strength of major muscle groups (Table 30-34). Use a grading scale of "0 to 5" to compare symmetrical muscle pairs for strength (Table 30-35). The arm on the dominant side normally is stronger than the arm on the nondominant side. In older adults a loss of muscle mass causes bilateral weakness, but muscle strength remains greater in the dominant arm or leg.

Examine each muscle group. Ask the patient to first flex the muscle you are examining and then to resist when you apply an opposing force against that flexion. It is important to not allow the patient to move the joint. Gradually increase pressure to a muscle group (e.g., elbow extension). Have the patient resist the pressure you apply by attempting to move against resistance (e.g., elbow flexion) until instructed to stop. Vary the amount of pressure applied and observe the joint move. If you identify a weakness, compare the size of the muscle with its opposite counterpart by measuring the circumference of the muscle body with a tape measure. A muscle that has **atrophied** (reduced in size) feels soft and boggy when palpated.

TABLE 30-36 Nursing History for Neurological Assessment

ASSESSMENT	RATIONALE
Determine if patient uses analgesics, alcohol, sedatives, hypnotics, antipsychotics, antidepressants, nervous system stimulants, or recreational drugs.	These medications alter level of consciousness or cause behavioral changes. Abuse sometimes causes tremors, ataxia, and changes in peripheral nerve function.
Determine if patient has recent history of seizures/convulsions: clarify sequence of events (aura, fall to ground, motor activity, loss of consciousness); character of any symptoms; and relationship of seizure to time of day, fatigue, or emotional stress.	Seizure activity often originates from central nervous system alteration. Characteristics of seizure help determine its origin.
Screen patient for symptoms of headache, tremors, dizziness, vertigo, numbness or tingling of body part, visual changes, weakness, pain, or changes in speech. Presence of any symptom requires more detailed review (onset, severity, precipitating factors or sequence of events).	These symptoms frequently originate from alterations in central or peripheral nervous system function. Identification of specific patterns aids in diagnosis of pathological condition.
Discuss with patient's family any recent changes in patient's behavior (e.g., increased irritability, mood swings, memory loss, change in energy level).	Behavioral changes sometimes result from intracranial pathological states.
Assess patient for history of change in vision, hearing, smell, taste, or touch.	Major sensory nerves originate from brainstem. These symptoms help to localize nature of problem.
If an older patient displays sudden acute confusion (delirium), review history for drug toxicity (anticholinergics, diuretics, digoxin, cimetidine, sedatives, antihypertensives, antiarrhythmics), serious infections, metabolic disturbances, heart failure, and severe anemia.	Delirium is one of the most common mental disorders in older persons. Condition is always potentially reversible (see Box 30-31).
Review past history for head or spinal cord injury, meningitis, congenital anomalies, neurological disease, or psychiatric counseling.	Factors cause neurological symptoms or behavioral changes to develop, focusing assessment on possible cause.

NEUROLOGICAL SYSTEM

The neurological system is responsible for many functions, including initiation and coordination of movement, reception and perception of sensory stimuli, organization of thought processes, control of speech, and storage of memory. A close integration exists between the neurological system and all other body systems. For example, urine production relies in part on the adequacy of blood flow to the kidneys, and the size of arterioles supplying the kidneys is under neural control.

A full assessment of neurological function requires much time and attention to detail. For efficiency, integrate neurological measurements with other parts of the physical examination. For example, test cranial nerve function while assessing the head and neck. Observe mental and emotional status during the initial interview.

Consider many variables when deciding the extent of the neurological examination. A patient's level of consciousness influences his or her ability to follow directions. General physical status influences tolerance to assessment. A patient's chief complaint also helps determine the need for a thorough neurological assessment. If a patient complains of headache or a recent loss of function in an extremity, he or she needs a complete neurological review. Table 30-36 lists the data collected in the nursing history. You will need the following items for a complete examination:

- Reading material
- Vials containing aromatic substances (e.g., vanilla extract and coffee)
- Opposite tip of cotton swab or tongue blade broken in half
- Snellen eye chart
- Penlight
- Vials containing sugar or salt
- Tongue blade
- Two test tubes, one filled with hot water and the other with cold water
- Cotton balls or cotton-tipped applicators
- Tuning fork
- Reflex hammer

Mental and Emotional Status

You learn a great deal about mental capacities and emotional state simply by interacting with a patient. Ask questions during an examination to gather data and observe the appropriateness of emotions and thoughts. Special assessment tools are designed to assess a patient's mental status. The Mini-Mental State Examination (MMSE) is an instrument developed by Folstein et al. (1975) that measures orientation and cognitive function. The questions in Box 30-30 offer examples of questions found on the MMSE. The maximum score on the MMSE is 30. Patients with scores of 21 or less generally reveal cognitive impairment requiring further evaluation.

To ensure an objective assessment, consider a patient's cultural and educational background, values, beliefs, and previous experiences. Such factors influence response to questions. An alteration in mental or emotional status reflects a disturbance in cerebral functioning. The cerebral cortex controls and integrates intellectual and emotional functioning. Primary brain disorders, medication, and metabolic changes are examples of factors that change cerebral function.

Delirium is an acute mental disorder that occurs among hospitalized patients. Obtain a thorough history of a patient's behavior before delirium develops so as to recognize the condition early. Family members are usually a good resource. Among older adults delirium most often presents within the first 48 to 72 hours of hospital admission (Rigney, 2010). It is an acute mental disorder characterized by confusion, disorientation, and restlessness. It is

BOX 30-30 MINI-MENTAL STATE EXAMINATION SAMPLE QUESTIONS

- Orientation to time
  "What is the date?"
- Registration
  "Listen carefully. I am going to say three words. Say them back after I stop. Ready? Here they are . . .
  HOUSE (pause), CAR (pause), LAKE (pause). Now repeat these words back to me."
  (Repeat up to 5 times but score only the first trial.)
- Naming
  "What is this?" (Point to a pencil or pen.)
- Reading
  "Please read this and do what it says." (Show examinee the words on the stimulus form.)

BOX 30-31 CLINICAL CRITERIA FOR DELIRIUM

Definition: An acute disturbance of consciousness that is accompanied by a change in cognition. It is not caused by a preexisting or evolving dementia. Delirium develops over a short period of time, usually hours to days, and tends to fluctuate during the course of the day. It is usually a direct physiological consequence of a general medical condition. It is most common in older adults but occurs occasionally in younger patients.

- There is reduced clarity of awareness of the environment.
- Ability to focus, sustain, or shift attention is impaired (questions must be repeated).
- Irrelevant stimuli easily distract the person.
- There is an accompanying change in cognition (memory impairment, disorientation, or language disturbance).
- Recent memory is commonly affected.
- Disorientation usually occurs, with patient disoriented to time, place, or person.
- Language disturbance involves impaired ability to name objects or ability to write; speech is sometimes rambling.
- Perceptual disturbances include misinterpretations, delusions, or visual and auditory hallucinations. Neurological signs include tremor, unsteady gait, asterixis, or myoclonus.

often a sign of an impending or underlying physical illness in older adults (Flood and Buckwalter, 2009). The acute condition differs from dementia, a more progressive, organic mental disorder such as Alzheimer's disease. You need to recognize the difference so you can try to learn the underlying cause of delirium. Fortunately the condition often reverses when it is correctly assessed and the underlying cause is treated (i.e., central nervous system [CNS], metabolic, and cardiopulmonary disorders; systemic illnesses; and sensory deprivation or overload). To avoid misdiagnosis you need to adequately assess mental status. Frequently patients who develop delirium are labeled with "sundown syndrome" because the delirium frequently worsens at night. Many practitioners mistake this as being common with old age. Be aware that children are vulnerable to delirium from causes such as infection, drugs, serious trauma, autoimmune disorders, general anesthesia, and after transplant (Hatherill and Fisher, 2010). Box 30-31 summarizes clinical criteria for delirium.

Level of Consciousness. A person's level of consciousness exists along a continuum from full awakening, alertness, and cooperation to unresponsiveness to any form of external stimuli. Talk with the patient, asking questions about events involving his or her concerns about any health problems. A fully conscious patient responds to questions quickly and expresses ideas logically. With a lowering of a patient's consciousness, use the Glasgow Coma Scale (GCS) for an objective measurement of consciousness on a numerical scale (Table 30-37). The patient needs to be as alert as possible before testing. Take care when using the scale if the patient has sensory losses (e.g., vision or hearing). The GCS allows evaluation of a patient's neurological status over time. The higher the score, the better the patient's neurological function. Ask short, simple questions such as "What is your name?" "Where are you?" and "What day is this?" Also ask the patient to follow simple commands such as "Move your toes."

If the patient is not conscious enough to follow commands, try to elicit the pain response. Apply firm pressure with the thumb over the root of the patient's fingernail. The normal response to the painful stimuli is withdrawal of the body part from the stimulus. A patient with serious neurological impairment exhibits abnormal posturing in response to pain. A flaccid response indicates the absence of muscle tone in the extremities and severe injury to brain tissue.

TABLE 30-37 Glasgow Coma Scale

(The total score is the sum of the scores in the three categories)

ACTION	RESPONSE	SCORE
Eyes open	Spontaneously	4
	To speech	3
	To pain	2
	None	1
Best verbal response	Oriented	5
	Confused	4
	Inappropriate words	3
	Incomprehensible sounds	2
	None	1
Best motor response	Obeys commands	6
	Localized pain	5
	Flexion withdrawal	4
	Abnormal flexion	3
	Abnormal extension	2
	Flaccid	1
	TOTAL SCORE	**3 to 15**

Behavior and Appearance. Behavior, moods, hygiene, grooming, and choice of dress reveal pertinent information about mental status. Remain perceptive of a patient's mannerisms and actions during the entire physical assessment. Note nonverbal and

verbal behaviors. Does the patient respond appropriately to directions? Does his or her mood vary with no apparent cause? Does he or she show concern about appearance? Is his or her hair clean and neatly groomed, and are the nails trim and clean? The patient should behave in a manner expressing concern and interest in the examination. He or she should make eye contact with you and express appropriate feelings that correspond to the situation. Normally the patient shows some degree of personal hygiene.

Choice and fit of clothing reflect socioeconomic background or personal taste rather than deficiency in self-concept or self-care. Avoid being judgmental and focus assessment on the appropriateness of clothing for the weather. Older adults sometimes neglect their appearance because of a lack of energy, finances, or reduced vision.

Language. Normal cerebral function allows a person to understand spoken or written words and express the self through written words or gestures. Assess the patient's voice inflection, tone, and manner of speech. Normally a patient's voice has inflections, is clear and strong, and increases in volume appropriately. Speech is fluent. When communication is clearly ineffective (e.g., omission or addition of letters and words, misuse of words, or hesitations), assess for **aphasia.** Injury to the cerebral cortex results in aphasia.

The two types of aphasia are sensory (or receptive) and motor (or expressive). With receptive aphasia a person cannot understand written or verbal speech. With expressive aphasia a person understands written and verbal speech but cannot write or speak appropriately when attempting to communicate. A patient sometimes suffers a combination of receptive and expressive aphasia. Assess language capabilities when it is clear that a patient is communicating ineffectively. Some simple assessment techniques include the following:

- Point to a familiar object, and ask the patient to name it.
- Ask the patient to respond to simple verbal and written commands such as "Stand up" or "Sit down."
- Ask the patient to read simple sentences out loud.

Normally a patient names objects correctly, follows commands, and reads sentences correctly.

Intellectual Function

Intellectual function includes memory (recent, immediate, and past), knowledge, abstract thinking, association, and judgment. Testing each aspect of function involves a specific technique. However, because cultural and educational background influences the ability to respond to test questions, do not ask questions related to concepts or ideas with which a patient is unfamiliar.

Memory. Assess immediate recall and recent and remote memory. Patients demonstrate immediate recall by repeating a series of numbers (e.g., *7, 4, 1*) in the order they are presented or in reverse order. Patients normally recall a series of five to eight digits forward and four to six digits backward.

First ask to test the patient's memory. Then state clearly and slowly the name of three unrelated objects. After mentioning all three, ask the patient to repeat each. Continue until he or she is successful. Later in the assessment, ask the patient to repeat the three words again. He or she should be able to identify them. Another test for recent memory involves asking the patient to recall events occurring during the same day (e.g., what was eaten for breakfast). Validate information with a family member.

To assess past memory, ask the patient to recall his or her mother's maiden name, a birthday, or a special date in history. It is best to ask open-ended rather than simple yes/no questions. A patient usually has immediate recall of such information. With older adults do not interpret hearing loss as confusion. Good communication techniques are essential throughout the examination to ensure that a patient clearly understands all directions and testing.

Knowledge. Assess knowledge by asking how much the patient knows about his or her illness or the reason for seeking health care. A knowledge assessment allows you to determine a patient's ability to learn or understand. If there is an opportunity to teach, test a patient's mental status by asking for feedback during a follow-up visit.

Abstract Thinking. Interpreting abstract ideas or concepts reflects the capacity for abstract thinking. For an individual to explain common phrases such as "A stitch in time saves nine" or "Don't count your chickens before they're hatched" requires a higher level of intellectual function. Note whether a patient's explanations are relevant and concrete. A patient with altered mental status probably interprets the phrase literally or merely rephrases the words.

Association. Another higher level of intellectual functioning involves finding similarities or associations between concepts: a dog is to a beagle as a cat is to a Siamese. Name related concepts and ask the patient to identify their associations. Ask questions that are appropriate to the patient's level of intelligence, using simple concepts.

Judgment. Judgment requires a comparison and evaluation of facts and ideas to understand their relationships and form appropriate conclusions. Attempt to measure the patient's ability to make logical decisions with questions such as "Why did you seek health care?" or "What would you do if you became ill at home?" Normally a patient makes logical decisions.

Cranial Nerve Function

To assess cranial nerve function, you may test all 12 cranial nerves, a single nerve, or related group of nerves. A dysfunction in one nerve reflects an alteration at some point along the distribution of the cranial nerve. Measurements used to assess the integrity of organs within the head and neck also assess cranial nerve function. A complete assessment involves testing the 12 cranial nerves in their numerical order. To remember the order of the nerves, use this simple phrase, "On old Olympus' towering tops, a Finn and German viewed some hops." The first letter of each word in the phrase is the same as the first letter of the names of the cranial nerves listed in order (Table 30-38).

Sensory Function

The sensory pathways of the CNS conduct sensations of pain, temperature, position, vibration, and crude and finely localized touch. Different nerve pathways relay the sensations. Most patients require only a quick screening of sensory function unless there are symptoms of reduced sensation, motor impairment, or paralysis. The risk of skin breakdown is greater in a patient with impaired sensation. When assessing decreased sensation, complete a skin and tissue assessment of the area affected by the sensory loss. In addition, teach the patient to avoid pressure, thermal, and/or chemical trauma to the area.

Normally a patient has sensory responses to all stimuli that are tested. He or she feels sensations equally on both sides of the body in all areas. Assess the major sensory nerves by knowing the sensory dermatome zones (Fig. 30-74, *A* and *B*). Some areas of the skin are innervated by specific dorsal root cutaneous nerves. For example, if assessment reveals reduced sensation when checking for light touch along an area of the skin (e.g., the lower neck), this

TABLE 30-38 Cranial Nerve Function and Assessment

NUMBER	NAME	TYPE	FUNCTION	METHOD
I	Olfactory	Sensory	Sense of smell	Ask patient to identify different nonirritating aromas such as coffee and vanilla.
II	Optic	Sensory	Visual acuity	Use Snellen chart or ask patient to read printed material while wearing glasses.
III	Oculomotor	Motor	Extraocular eye movements: inward, up and inward, up and outward, down and outward	Assess six directions of gaze.
			Pupil constriction and dilation	Measure pupillary reaction to light reflex and accommodation.
			Opening the eye	
IV	Trochlear	Motor	Downward, inward eye movements	Assess six directions of gaze.
V	Trigeminal	Sensory and motor	Sensory nerve to skin of face	Lightly touch cornea with wisp of cotton. Assess corneal reflex. Measure sensation of light pain and touch across skin of face.
			Motor nerve to muscles of jaw	Palpate temples as patient clenches teeth.
VI	Abducens	Motor	Lateral movement of eyeballs	Assess six directions of gaze.
VII	Facial	Sensory and motor	Facial expression	As patient smiles, frowns, puffs out cheeks, and raises and lowers eyebrows, look for asymmetry.
			Taste	Have patient identify salty or sweet taste on front of tongue.
VIII	Auditory	Sensory	Hearing	Assess ability to hear spoken word.
IX	Glossopharyngeal	Sensory and motor	Taste	Ask patient to identify sour or sweet taste on back of tongue.
			Ability to swallow	Use tongue blade to elicit gag reflex.
X	Vagus	Sensory and motor	Sensation of pharynx	Ask patient to say "ah." Observe movement of palate and pharynx.
			Movement of vocal cords	Assess speech for hoarseness.
XI	Spinal accessory	Motor	Movement of head and shoulders	Ask patient to shrug shoulders and turn head against passive resistance.
XII	Hypoglossal	Motor	Position of tongue	Ask patient to stick out tongue to midline and move it from side to side.

BOX 30-32 PATIENT TEACHING

Neurological Assessment

Objective

- Patient and family or significant others will understand relationship of patient's behavioral and mental changes to physical status.

Teaching Strategies

- Explain to family caregiver the implications of any behavioral or mental impairment shown by patient.
- If patient has sensory or motor impairments, explain measures to ensure safety (e.g., use of ambulation aids or safety bars in bathrooms or stairways).
- Teach older adult to plan enough time to complete tasks because reaction time is slow.
- Teach older adult to observe skin surfaces for areas of trauma since pain perception is reduced.

Evaluation

- Ask family member to discuss patient behaviors that result from neurological impairments.
- Have patient explain safety measures used to avoid injury from sensory and motor limitations.
- Have older patient explain reason for inspecting skin surface routinely.

determines in general where a neurological lesion exists (e.g., fourth cervical spinal cord segment).

Perform all sensory testing with the patient's eyes closed so he or she is unable to see when or where a stimulus touches the skin (Table 30-39). Then touch the patient's skin in a random, unpredictable order to maintain his or her attention and prevent detection of a predictable pattern. Ask the patient to describe when, what, and where he or she feels each stimulus. Compare symmetrical areas of the body while applying stimuli to the patient's arms, trunk, and legs.

Motor Function

An examination of motor function includes assessments made during the musculoskeletal examination. In addition, the nurse assesses cerebellar function. The cerebellum coordinates muscular activity, maintains balance and equilibrium, and controls posture.

Coordination. To avoid confusion, demonstrate each maneuver and then have the patient repeat it, observing for smoothness and balance in his or her movements (Box 30-32). In older adults normally slow reaction time causes movements to be less rhythmical.

To assess fine-motor function, have the patient extend the arms out to the sides and touch each forefinger alternately to the nose

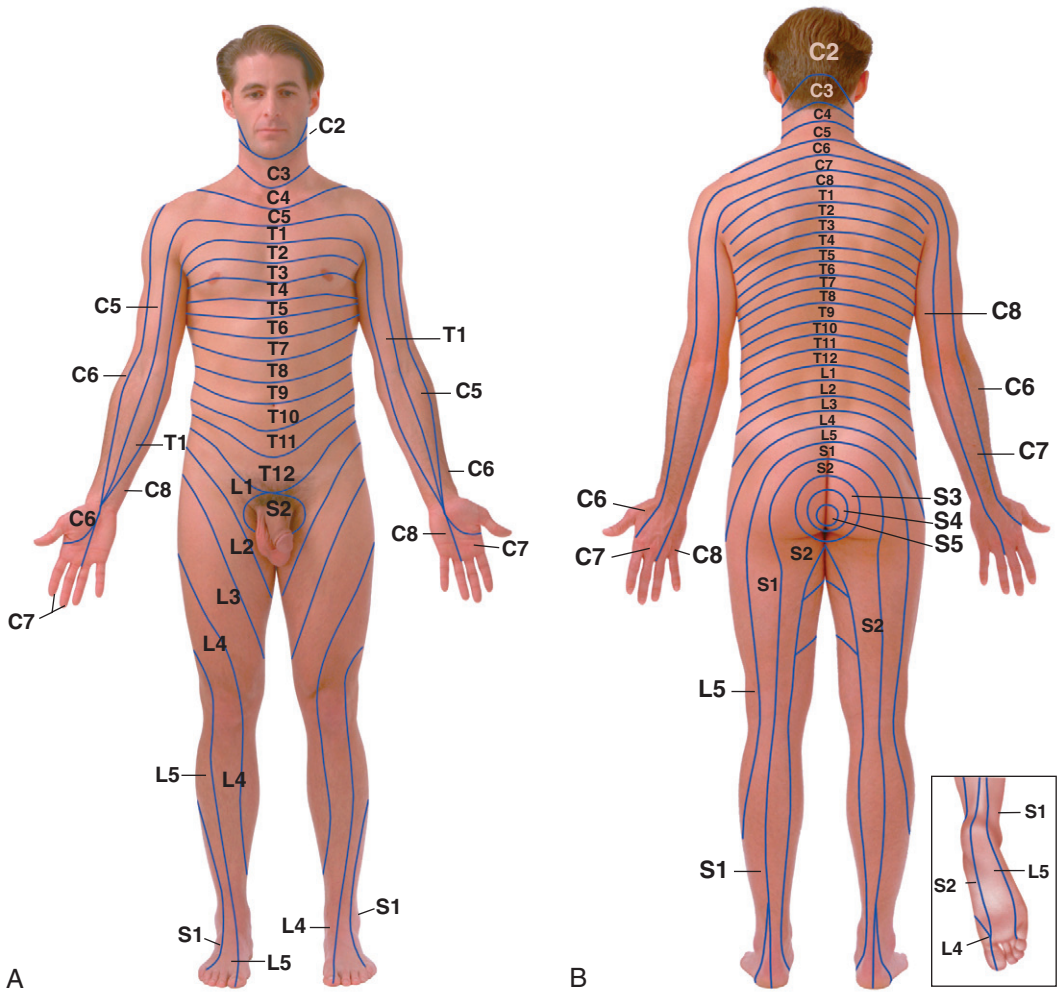

FIG. 30-74 Dermatomes of body (body surface areas innervated by particular spinal nerves); C1 usually has no cutaneous distribution. **A,** Anterior view. **B,** Posterior view. It appears that there is a distinct separation of surface area controlled by each dermatome, but there is almost always overlap between spinal nerves. (From Seidel HM et al: *Mosby's guide to physical examination,* ed 7, St Louis, 2011, Mosby.)

(first with eyes open, then with eyes closed). Normally a patient alternately touches the nose smoothly. Performing rapid, rhythmical, alternating movements demonstrates coordination in the upper extremities. While sitting, the patient begins by patting the knees with both hands. Then he or she alternately turns up the palm and back of the hands while continuously patting the knees. Normally patients perform the maneuver smoothly and regularly with increasing speed.

An additional maneuver for upper-extremity coordination involves touching each finger with the thumb of the same hand in rapid sequence. A patient moves from the index finger to the little finger and back, with one hand tested at a time. The dominant hand is slightly less awkward when performing this movement. Movement is smooth and in succession.

Test lower-extremity coordination with the patient lying supine, legs extended. Place a hand at the ball of the patient's foot. The patient taps the hand with the foot as quickly as possible. Test each foot for speed and smoothness. The feet do not move as rapidly or evenly as the hands.

Balance. Use one or two of the following tests to assess balance and gross-motor function. When examining the older adult for balance and equilibrium, be aware of the risk for falls. Some older adults need help with this portion of the examination.

Have the patient perform a Romberg's test by standing with feet together, arms at the sides, both with eyes open and eyes closed. Protect the patient's safety by standing at the side, observe for swaying. Expect slight swaying of the body in the Romberg's test. A loss of balance (positive Romberg) causes a patient to fall to the side. Normally he or she does not break the stance.

Have the patient close the eyes, with arms held straight at the sides, and stand on one foot and then the other. Normally patients are able to maintain balance for 5 seconds with slight swaying. Another test involves asking the patient to walk a straight line by placing the heel of one foot directly in front of the toes of the other foot.

Reflexes

Eliciting reflex reactions provides data about the integrity of sensory and motor pathways of the reflex arc and specific spinal cord segments. Assessment of reflexes does not determine higher neural center functioning. Fig. 30-75 traces the pathway of the reflex arc. Each muscle contains a small sensory unit called a *muscle*

TABLE 30-39 Assessment of Sensory Nerve Function

FUNCTION	EQUIPMENT	METHOD	PRECAUTIONS
Pain	Broken tongue blade or wooden end of cotton applicator	Ask patients to voice when they feel dull or sharp sensation. Alternately apply sharp and blunt ends of tongue blade to surface of skin. Note areas of numbness or increased sensitivity.	Remember that areas where skin is thick such as heel or sole of foot are less sensitive to pain.
Temperature	Two test tubes, one filled with hot water and another with cold	Touch skin with tube. Ask patient to identify hot or cold sensation.	Omit test if pain sensation is normal.
Light touch	Cotton ball or cotton-tip applicator	Apply light wisp of cotton to different points along surface of skin. Ask patients to voice when they feel a sensation.	Apply at areas where skin is thin or more sensitive (e.g., face, neck, inner aspect of arms, top of feet and hands).
Vibration	Tuning fork	Apply stem of vibrating fork to distal interphalangeal joint of fingers and interphalangeal joint of great toe, elbow, and wrist. Have patients voice when and where they feel vibration.	Be sure that patient feels vibration and not merely pressure.
Position		Grasp finger or toe, holding it by its sides with thumb and index finger. Alternate moving finger or toe up and down. Ask patient to state when finger is up or down. Repeat with toes.	Avoid rubbing adjacent appendages as you move finger or toe. Do not move joint laterally; return to neutral position before moving again.
Two-point discrimination	Two broken tongue blades	Lightly apply one or both tongue blade tips simultaneously to the surface of the skin. Ask patients whether they feel one or two pricks. Find the distance at which patient can no longer distinguish two points.	Apply blade tips to same anatomical site (e.g., fingertips, palm of hand, or upper arms). Minimum distance at which patient discriminates two points varies (2 to 8 mm on fingertips).

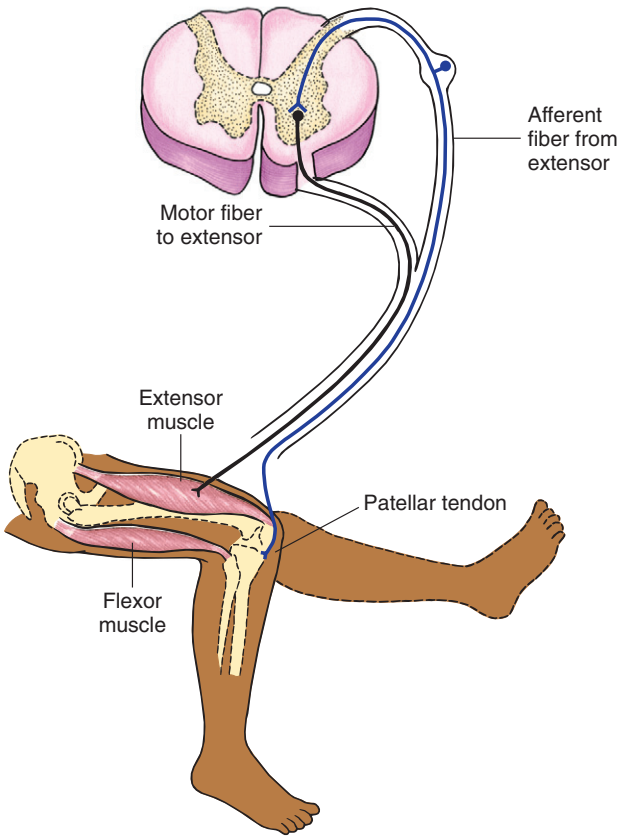

FIG. 30-75 Pathway of the reflex arc.

spindle, which controls muscle tone and detects changes in the length of muscle fibers. Tapping a tendon with a reflex hammer stretches the muscle and tendon, lengthening the spindle. The spindle sends nerve impulses along afferent nerve pathways to the dorsal horn of the spinal cord segment. Within milliseconds the impulses reach the spinal cord and synapse to travel to the efferent motor neuron in the spinal cord. A motor nerve sends the impulses back to the muscle, causing the reflex response.

The two categories of normal reflexes are deep tendon reflexes, elicited by mildly stretching a muscle and tapping a tendon, and cutaneous reflexes, elicited by stimulating the skin superficially. Grade reflexes as follows (Seidel et al., 2011):

0: No response
1+: Sluggish or diminished
2+: Active or expected response
3+: More brisk than expected, slightly hyperactive
4+: Brisk and hyperactive with intermittent or transient clonus

When assessing reflexes have the patient relax as much as possible to avoid voluntary movement or tensing of muscles. Position the limbs to slightly stretch the muscle being tested. Hold the reflex hammer loosely between the thumb and fingers so it is able to swing freely and tap the tendon briskly (Fig. 30-76). Compare the responses on corresponding sides. Normally the older adult presents with diminished reflexes. Reflexes are hyperactive in patients with alcohol, cocaine, or opioid intoxication. Table 30-40 summarizes common deep tendon and cutaneous reflexes.

AFTER THE EXAMINATION

Record findings from the physical assessment either during the examination or when it is completed. Special forms are available to record data. Review all findings before helping the patient dress

FIG. 30-76 Position for eliciting patellar tendon reflex. The lower leg normally extends.

in case it is necessary to recheck any information or gather additional data. Integrate physical assessment findings into the plan of care.

After completing the assessment give the patient time to dress. The hospitalized patient sometimes needs help with hygiene and returning to bed. When the patient is comfortable, it helps to share a summary of the assessment findings. If the findings have revealed serious abnormalities such as a mass or highly irregular heart rate, consult the patient's health care provider before revealing them. It is the health care provider's responsibility to make definitive medical diagnoses. Explain the type of abnormality found and the need for the health care provider to conduct an additional examination.

Delegate cleaning the examination area to support staff if needed. Use infection control practice to remove materials or instruments soiled with potentially infectious wastes. If the patient's bedside was the examination site, clear away soiled items from the bedside table and make sure that the bed linen is dry and clean. A patient appreciates a clean gown and the opportunity to wash the face and hands. Afterward be sure to perform hand hygiene.

Be sure to record a complete assessment. If you delayed entering any items into the assessment form, record them at this time to avoid forgetting any important information. If you made entries periodically during the examination, review them for accuracy and thoroughness. Communicate significant findings to appropriate medical and nursing personnel, either verbally or in the patient's written care plan.

KEY POINTS

- Baseline assessment findings reflect a patient's functional abilities and serve as the basis for comparison with subsequent assessment findings.
- Physical assessment of a child or infant requires the application of the principles of growth and development.
- Recognize that the normal process of aging affects physical findings collected from an older adult.
- Integrate patient teaching throughout the examination to help patients learn about health promotion, disease prevention, and skills to help with any current health issue.

TABLE 30-40 Assessment of Common Reflexes

TYPE	PROCEDURE	NORMAL REFLEX
Deep Tendon Reflexes		
Biceps	Flex patient's arm up to 45 degrees at elbow with palms down. Place your thumb in antecubital fossa at base of biceps tendon and your fingers over biceps muscle. Strike biceps tendon with reflex hammer.	Flexion of arm at elbow
Triceps	Flex patient's arm at elbow, holding arm across chest, or hold upper arm horizontally and allow lower arm to go limp. Strike triceps tendon just above elbow.	Extension at elbow
Patellar	Have patient sit with legs hanging freely over side of table or chair or have him or her lie supine and support knee in a flexed 90-degree position. Briskly tap patellar tendon just below patella.	Extension of lower leg
Achilles	Have patient assume same position as for patellar reflex. Slightly dorsiflex patient's ankle by grasping toes in palm of your hand. Strike Achilles tendon just above heel at ankle malleolus.	Plantar flexion of foot
Cutaneous Reflexes		
Plantar	Have patient lie supine with legs straight and feet relaxed. Take handle end of reflex hammer and stroke lateral aspect of sole from heel to ball of foot, curving across ball of foot toward big toe.	Plantar flexion of all toes
Abdominal	Have patient stand or lie supine. Stroke abdominal skin with base of cotton applicator over lateral borders of rectus abdominis muscle toward midline. Repeat test in each abdominal quadrant.	Contraction of rectus abdominis muscle with pulling of umbilicus toward stimulated side

- Inspection includes visual and olfaction and requires good lighting; full view of the body part; and a careful, systematic approach that compares a body part with its counterpart on the opposite side of the body.
- Palpation involves the use of parts of the hand to detect different types of physical characteristics.
- Use auscultation to assess the character of sounds created in various body organs.
- Perform a physical examination only after proper preparation of the environment and equipment and after preparing the patient physically and psychologically.
- Throughout the examination keep the patient warm, comfortable, and informed of each step of the process.
- A competent examiner is systematic while combining assessment of different body systems simultaneously.
- Information from the history helps to focus on body systems likely to be affected.

- When assessing a seriously ill patient, first concentrate on the body systems most affected.
- Creating a mental image of internal organs in relation to external anatomical landmarks enhances accuracy in assessing the thorax, heart, and abdomen.
- When assessing heart sounds, imagine events occurring during the cardiac cycle.
- Never palpate both of the carotid arteries simultaneously.
- When examining a woman's breasts, explain the techniques for breast self-examination.
- The order of the abdominal assessment is inspection, auscultation, percussion (if used), and palpation.
- During assessment of the genitalia explain the technique for genital self-examination.
- Conduct an assessment of musculoskeletal function when observing a patient ambulate or participate in other active movements.
- Assess mental and emotional status by interacting with a patient throughout the examination.
- At the end of the examination provide for the patient's comfort and then document a detailed summary of physical assessment findings.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You receive morning report for Ms. Malone, age 63, admitted to the hospital yesterday with fatigue, a cough, and dyspnea; she is diagnosed with chronic heart failure. She states that she had increasing difficulty with shortness of breath and swelling in her legs. Pedal pulses are +1 bilaterally. On auscultation you hear bilateral crackles in the lung bases and an S_3 gallop when auscultating the heart. Respiratory rate is 18; heart rate is 84 and regular. The patient has an occasional nonproductive cough. She is receiving 2 L of oxygen by nasal cannula.

1. During the assessment Ms. Malone reports that she had difficulty breathing during the night while lying flat. Which assessment approach should the nurse take first?
   1. Raise the head of the bed up to a 45-degree angle to auscultate the lungs.
   2. Auscultate for adventitious sounds in the lung bases.
   3. Assess the patency of the nasal sinuses.
   4. Palpate legs to determine whether there is increased edema from circulating blood volume.
2. When examining Ms. Malone's lower extremities, you note bilateral pedal edema of +2. Which statement by the patient shows that she correctly understands this finding?
   1. "I ate too many fruits and vegetables with vitamin C, and that causes me to retain water."
   2. "I know that when my heart condition is not well controlled, my feet swell."
   3. "My parents both had foot swelling as they aged, and that's why my feet swell too."
   4. "When my heart isn't strong, the circulation doesn't get down to my feet."
3. After receiving medications to manage her heart failure, you return to reassess Ms. Malone's cardiac status. Select the techniques you use to correctly examine her lungs. (Select all that apply.)
   1. Listen to an entire inspiration and expiration.
   2. Place the diaphragm of the stethoscope over the ribs.
   3. Begin auscultation at the apex, moving downward, auscultating the entire right lung and then the left.
   4. If you auscultate an abnormal breath sound, check for the presence of bronchophony.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse prepares to conduct a general survey on an adult patient. Which assessment is performed first while the nurse initiates the nurse-patient relationship?
   1. Appearance and behavior
   2. Measurement of vital signs
   3. Observing specific body systems
   4. Conducting a detailed health history
2. The nurse is teaching a young mother to palpate her 8-year-old child to quickly evaluate if the child has a fever. Which information is important for the nurse to include?
   1. Place the palm of the hand on the child's back.
   2. Lightly touch the child's forehead with the fingertips.
   3. Place the back of your hand against the child's forehead and then on the back of the neck.
   4. Use the pads of your fingers and press against the child's neck and over the thorax.
3. While assessing the adult patient's lungs, the nurse identifies the following assessment findings. Which finding should be reported to the health care provider?
   1. Respiratory rate: 14
   2. Pain reported when palpating posterior lower thorax
   3. Thorax rising and falling symmetrically for right and left lungs
   4. Vesicular breath sounds heard with auscultation of peripheral lung fields
4. The nurse is teaching a young female patient to practice good skin health. Which information is important for the nurse to include?
   1. Avoid sunbathing between 3 PM and 7 PM.
   2. Oral contraceptives and antiinflammatories make the skin more sensitive to the sun.
   3. Call the health care provider for the presence of a mole on an arm or leg that appears uniformly brown.
   4. Wear sunscreen with an SPF of 30 or greater if using a sunlamp or tanning parlor.
5. As a nurse prepares to provide morning care and treatments, it is important to question a patient about a latex allergy before which intervention? (Select all that apply.)
   1. Applying adhesive tape to anchor a nasogastric tube
   2. Inserting a rubber Foley catheter into the patient's bladder
   3. Providing oral hygiene using a standard toothbrush and toothpaste
   4. Giving an injection using plastic syringes with rubber-coated plungers
   5. Applying a transparent wound dressing
6. The nurse is assessing a patient who returned 3 hours ago from a cardiac catheterization, during which the large catheter was inserted into the patient's femoral artery in the right groin. Which assessment finding would require immediate follow-up?
   1. Palpation of a femoral pulse with a heart rate of 76
   2. Auscultation of a heart murmur over the left thorax

3. Identification of mild bruising at the catheter insertion site
4. Palpation of a right dorsalis pedis pulse with strength of +1

7. The patient reports having a sore throat, coughing, and sneezing. While performing a focused assessment, which finding supports the patient's reported symptoms related to upper respiratory infection?
   1. Buccal mucosa is moist and dark pink.
   2. Respiratory rate is 18, rhythm is even.
   3. Retropharyngeal lymph nodes are enlarged and firm.
   4. Inspection with a tongue depressor on the posterior tongue causes gagging.
8. The nurse is teaching a patient with poor arterial circulation about checking blood flow in the legs. Which information should the nurse include? (Select all that apply.)
   1. A normal pulse on the top of the foot indicates adequate blood flow to the foot.
   2. To locate the dorsalis pedis pulse, take the fingers and palpate behind the knee
   3. When there is poor arterial blood flow, the leg is generally warm to the touch.
   4. Loss of hair on the lower leg indicates a long-term problem with arterial blood flow.
9. How should the patient be positioned to best palpate for lumps or tumors during an examination of the right breast?
   1. Supine with both arms overhead with palms upward
   2. Sitting with hands clasped just above the umbilicus
   3. Supine with the right arm abducted and hand under the head and neck
   4. Lying on the right side, adducting the right arm on the side of the body
10. The nurse is planning a staff education conference about abdominal assessment. Which point is important for the nurse to include?
    1. The aorta can be felt using deep palpation in the upper abdomen near the midline.
    2. The patient should be sitting to best determine the contour and shape of the abdomen.
    3. Always wear gloves when palpating the skin on the patient's abdomen.
    4. Avoid palpating the abdomen if the patient reports any discomfort or feelings of fullness.
11. The nurse is teaching a patient how to perform a testicular self-examination. Which statement by the nurse is correct?
    1. "The testes are normally round and feel smooth and rubbery."
    2. "The best time to do a testicular self-examination is before your bath or shower."
    3. "Perform a testicular self-examination weekly to detect signs of testicular cancer."
    4. "Since you are over 40 years old, you are in the highest risk group for testicular cancer."
12. The patient is assessed for range of joint movement. He or she is unable to move the right arm above the shoulder. How should the nurse document this finding?
    1. Patient was not able to flex arm at shoulder.
    2. Extension of right arm is limited.
    3. Patient's abduction of right arm was limited to 100 degrees.
    4. Internal rotation of right arm is limited to less than 90 degrees.
13. The nurse plans to assess the patient's abstract reasoning. Which task should the nurse ask the patient to perform?
    1. "Tell me where you are."
    2. "What can you tell me about your illness?"
    3. "Repeat these numbers back to me: 7…5…8."
    4. "What does this mean: 'A stitch in time saves nine?'"
14. The nurse teaches a patient about cranial nerves to help explain why the patient's right side of the mouth droops instead of moving up into a smile. What nerve does the nurse explain to the patient?
    1. VII—Facial
    2. V—Trigeminal
    3. XII—Hypoglossal
    4. XI—Spinal accessory
15. The nurse is planning to teach the student nurse how to assess the hydration status of an older adult. Which techniques are appropriate for this situation? (Select all that apply.)
    1. Inspect the lips and mucous membranes to determine if they are moist.
    2. Pinch the skin on the back of the hand to see if the skin tents.
    3. Check the patient's pulse and blood pressure.
    4. Weigh the patient daily.

Answers: **1.** 1; **2.** 3; **3.** 2; **4.** 2; **5.** 1, 2, 4; **6.** 4; **7.** 3; **8.** 1, 4; **9.** 3; **10.** 1; **11.** 1; **12.** 3; **13.** 4; **14.** 1; **15.** 1, 3, 4.

CHAPTER

31

Medication Administration

OBJECTIVES

- Discuss the nurse's role and responsibilities in medication administration.
- Describe the physiological mechanisms of medication action.
- Differentiate among different types of medication actions.
- Discuss developmental factors that influence pharmacokinetics.
- Discuss factors that influence medication actions.
- Discuss methods used to educate patients about prescribed medications.
- Compare and contrast the roles of the prescriber, pharmacist, and nurse in medication administration.
- Implement nursing actions to prevent medication errors.
- Describe factors to consider when choosing routes of medication administration.
- Calculate prescribed medication doses correctly.
- Discuss factors to include in assessing a patient's needs for and response to medication therapy.
- Identify the six rights of medication administration and apply them in clinical settings.
- Correctly and safely prepare and administer medications.

Patients with acute or chronic health problems restore or maintain their health using a variety of strategies. One of these strategies is medication, a substance used in the diagnosis, treatment, cure, relief, or prevention of health problems. No matter where they receive their health care—hospitals, clinics, or home—nurses play an essential role in safe medication preparation, administration, and evaluation of medication effects. When patients cannot administer their own medications at home, family members, friends, or home care personnel are often responsible for medication administration. In all settings, nurses are responsible for evaluating the effects of medications on the patient's ongoing health status, teaching them about their medications and side effects, ensuring adherence to the medication regimen, and evaluating the patient's and family caregiver's ability to self-administer medications.

SCIENTIFIC KNOWLEDGE BASE

Medications are frequently used to manage diseases. Because medication administration and evaluation are a critical part of nursing practice, nurses need to have knowledge about the actions and effects of the medications taken by their patients. Administering medications safely requires an understanding of legal aspects of

health care, pharmacology, pharmacokinetics, the life sciences, pathophysiology, human anatomy, and mathematics.

Medication Legislation and Standards

Federal Regulations. The U.S. government regulates the pharmaceutical industry to protect the health of the people by ensuring that medications are safe and effective. The first American law to regulate medications was the Pure Food and Drug Act. This law simply requires all medications to be free of impure products. Subsequent legislation has set standards related to safety, potency, and efficacy. Enforcement of medication laws currently rests with the Food and Drug Administration (FDA), which ensures that all medications on the market undergo vigorous testing before they are sold to the public. Federal medication law extends and refines controls on medication sales and distribution; testing, naming, and labeling; and the regulation of controlled substances. Official publications such as the *United States Pharmacopeia* (USP) and the *National Formulary* set standards for medication strength, quality, purity, packaging, safety, labeling, and dose form. In 1993 the FDA instituted the MedWatch program. This voluntary program encourages nurses and other health care professionals to report when a medication, product, or medical event causes serious harm to a patient by completing the MedWatch form. The form is available on the MedWatch website (USFDA, 2010).

State and Local Regulation of Medication. State and local medication laws must conform to federal legislation. States often have additional controls, including control of substances not regulated by the federal government. Local governmental bodies regulate the use of alcohol and tobacco.

Health Care Institutions and Medication Laws. Health care agencies establish individual policies to meet federal, state, and local regulations. The size of the agency, the types of services it provides, and the types of professional personnel it employs influence these policies. Agency policies are often more restrictive than governmental controls. For example, a common agency policy is the automatic discontinuation of narcotics after a set number of days. Although a prescriber can reorder the narcotic, this policy helps to control unnecessarily prolonged medication therapy and requires the prescriber to review the need for this class of medication on a regular basis.

Medication Regulations and Nursing Practice. State Nurse Practice Acts (NPAs) have the most influence over nursing practice by defining the scope of nurses' professional functions and responsibilities. Most NPAs are purposefully broad so nurses' professional responsibilities are not limited. Health care agencies often interpret specific actions allowed under NPAs; but they are not able to modify, expand, or restrict the intent of the act. The primary intent of NPAs is to protect the public from unskilled, undereducated, and unlicensed personnel.

The nurse is responsible for following legal provisions when administering controlled substances such as opioids, which are carefully controlled through federal and state guidelines. Violations of the Controlled Substances Act are punishable by fines, imprisonment, and loss of nurse licensure. Hospitals and other health care agencies have policies for the proper storage and distribution of narcotics (Box 31-1).

BOX 31-1 GUIDELINES FOR SAFE NARCOTIC ADMINISTRATION AND CONTROL

- Store all narcotics in a locked, secure cabinet or container. (Computerized, locked cabinets are preferred.)
- Frequently count narcotics with the opening of narcotic drawers and/or at shift change.
- Report discrepancies in narcotic counts immediately.
- Use a special inventory record each time a narcotic is dispensed. Records are often kept electronically and provide an accurate ongoing count of narcotics used, wasted, and remaining.
- Use the record to document the patient's name, date, time of medication administration, name of medication, dose, and signature of nurse dispensing the medication.
- A second nurse witnesses disposal of the unused portion if a nurse gives only part of a dose of a controlled substance. If paper records are kept, both nurses sign their names on the form. Computerized systems record the nurses' names electronically. Follow agency policy for appropriate waste of narcotics. Do not place wasted portions of medications in sharps containers.

Pharmacological Concepts

Medication Names. Some medications have as many as three different names. The chemical name of a medication provides an exact description of its composition and molecular structure. Nurses rarely use chemical names in clinical practice. An example of a chemical name is *N*-acetyl-para-aminophenol, which is commonly known as Tylenol. The manufacturer who first develops the medication gives the generic or nonproprietary name, with United States Adopted Names (USAN) Council approval (AMA, 2010). Acetaminophen is an example of a generic name. It is the generic name for Tylenol. The generic name becomes the official name listed in official publications such as the USP. The trade name, brand name, or proprietary name is the name under which a manufacturer markets a medication. The trade name has the symbol (™) at the upper right of the name, indicating that the manufacturer has trademarked the name of the medication (e.g., Panadol,™ Tempra,™ and St. Joseph Aspirin-Free Fever Reducer for Children™).

Manufacturers choose trade names that are easy to pronounce, spell, and remember. Many companies produce the same medication, and similarities in trade names are often confusing. Therefore be careful to obtain the exact name and spelling for each medication you administer to your patients. Because similarities in drug names are a common cause of medical errors, The Institute for Safe Medication Practices (ISMP) (2010a) (http://www.ismp.org/Tools/confuseddrugnames.pdf) and The Joint Commission (TJC) (2011a) (http://www.jointcommission.org/standards_information/npsgs.aspx) publish a list of medications that are frequently confused with one another. TJC's list includes recommendations to prevent mixing these medications.

Classification. Medication classification indicates the effect of the medication on a body system, the symptoms the medication relieves, or its desired effect. Usually each class contains more than one medication that is used for the same type of health problem. For example, patients who have asthma often take a variety of medications to control their illness such as beta$_2$-adrenergic agonists. The *beta$_2$-adrenergic* classification contains at least eight different medications (Lehne, 2010). Some are part of more than one class. For example, aspirin is an analgesic, an antipyretic, and an antiinflammatory medication.

Medication Forms. Medications are available in a variety of forms, or preparations. The form of the medication determines its route of administration. The composition of a medication enhances its absorption and metabolism. Many medications come in several

TABLE 31-1 Forms of Medication

FORM	DESCRIPTION
Medication Forms Commonly Prepared for Administration by Oral Route	
Solid Forms	
Caplet	Shaped like capsule and coated for ease of swallowing
Capsule	Medication encased in gelatin shell
Tablet	Powdered medication compressed into hard disk or cylinder; in addition to primary medication, contains binders (adhesive to allow powder to stick together), disintegrators (to promote tablet dissolution), lubricants (for ease of manufacturing), and fillers (for convenient tablet size)
Enteric-coated tablet	Coated tablet that does not dissolve in stomach; coatings dissolve in intestine, where medication is absorbed
Liquid Forms	
Elixir	Clear fluid containing water and/or alcohol; often sweetened
Extract	Syrup or dried form of pharmacologically active medication, usually made by evaporating solution
Aqueous solution	Substance dissolved in water and syrups
Aqueous suspension	Finely divided drug particles dispersed in liquid medium; when suspension is left standing, particles settle to bottom of container
Syrup	Medication dissolved in a concentrated sugar solution
Other Oral Forms and Terms Associated with Oral Preparations	
Troche (lozenge)	Flat, round tablets that dissolve in mouth to release medication; not meant for ingestion
Aerosol	Aqueous medication sprayed and absorbed in mouth and upper airway; not meant for ingestion
Sustained release	Tablet or capsule that contains small particles of a medication coated with material that requires a varying amount of time to dissolve
Medication Forms Commonly Prepared for Administration by Topical Route	
Ointment (salve or cream)	Semisolid, externally applied preparation, usually containing one or more medications
Liniment	Usually contains alcohol, oil, or soapy emollient applied to skin
Lotion	Liquid suspension that usually protects, cools, or cleanses skin
Paste	Thick ointment; absorbed through skin more slowly than ointment; often used for skin protection
Transdermal disk or patch	Medicated disk or patch absorbed through skin slowly over long period of time (e.g., 24 hours, 1 week)
Medication Forms Commonly Prepared for Administration by Parenteral Route	
Solution	Sterile preparation that contains water with one or more dissolved compounds
Powder	Sterile particles of medication that are dissolved in a sterile liquid (e.g., water, normal saline) before administration
Medication Forms Commonly Prepared for Instillation Into Body Cavities	
Intraocular disk	Small, flexible oval (similar to contact lens) consisting of two soft, outer layers and a middle layer containing medication; slowly releases medication when moistened by ocular fluid
Suppository	Solid dosage form mixed with gelatin and shaped in form of pellet for insertion into body cavity (rectum or vagina); melts when it reaches body temperature, releasing medication for absorption

forms such as tablets, capsules, elixirs, and suppositories. When administering a medication, be certain to use the proper form (Table 31-1).

Pharmacokinetics As the Basis of Medication Actions

For medications to be therapeutic they must be taken into a patient's body; be absorbed and distributed to cells, tissues, or a specific organ; and alter physiological functions. **Pharmacokinetics** is the study of how medications enter the body, reach their site of action, metabolize, and exit the body. Use knowledge of pharmacokinetics when timing medication administration, selecting the route of administration, considering the patient's risk for alterations in medication action, and evaluating the patient's response.

Absorption. **Absorption** is the passage of medication molecules into the blood from the site of medication administration. Factors that influence absorption are the route of administration, ability of the medication to dissolve, blood flow to the site of administration, body surface area (BSA), and lipid solubility of medication.

Route of Administration. Each route of medication administration has a different rate of absorption. When applying medications on the skin, absorption is slow because of the physical makeup of the skin. Medications placed on the mucous membranes and respiratory airways are absorbed quickly because these tissues contain many blood vessels. Because orally administered medications pass through the gastrointestinal (GI) tract, the overall rate of absorption is usually slow. Intravenous (IV) **injection** produces the most rapid absorption because medications are immediately available when they enter the systemic circulation.

Ability of the Medication to Dissolve. The ability of an oral medication to dissolve depends largely on its form or preparation. The body absorbs solutions and suspensions already in a liquid state

more readily than tablets or capsules. Acidic medications pass through the gastric mucosa rapidly. Medications that are basic are not absorbed before reaching the small intestine.

Blood Flow to the Site of Administration. Medications are absorbed as blood comes in contact with the site of administration. The richer the blood supply to the site of administration, the faster the medication is absorbed.

Body Surface Area. When a medication comes in contact with a large surface area, it is absorbed at a faster rate. This helps explain why the majority of medications are absorbed in the small intestine rather than the stomach.

Lipid Solubility. Because the cell membrane has a lipid layer, highly lipid-soluble medications cross cell membranes easily and are absorbed quickly. Another factor that often affects medication absorption is whether or not food is in the stomach. Some oral medications are absorbed more easily when administered between meals because food changes the structure of a medication and sometimes impairs its absorption. When some medications are administered together, they interfere with one another, which impairs the absorption of both medications.

Safe medication administration requires knowledge of factors that alter or impair absorption of prescribed medications. You need an understanding of medication pharmacokinetics, the patient's health history, the physical examination, and knowledge gained through daily interactions with patients. Use this knowledge to ensure that you administer medications at the correct time for best absorption. When medications interact with food, know which medications must be administered before or between meals or on an empty stomach. When medications interact with one another, ensure that they are not given at the same time. Consult and collaborate with the patient's prescribers to ensure that the patient achieves the therapeutic effect of all medications. Before administering any medication, check pharmacology books, drug references, or package inserts or consult with pharmacists to identify medication-medication or medication-food interactions.

Distribution. After a medication is absorbed, it is distributed within the body to tissues and organs and ultimately to its specific site of action. The rate and extent of distribution depend on the physical and chemical properties of the medication and the physiology of the person taking it.

Circulation. Once a medication enters the bloodstream, it is carried throughout the tissues and organs. How fast it reaches the site depends on the vascularity of the various tissues and organs. Conditions that limit blood flow or blood perfusion inhibit the distribution of a medication. For example, patients with heart failure have impaired circulation, which slows medication delivery to the intended site of action. Therefore the efficacy of medications in these patients is often delayed or altered.

Membrane Permeability. Membrane permeability refers to the ability of the medication to pass through tissues and membranes to enter target cells. To be distributed to an organ, a medication has to pass through all of the tissues and biological membranes of the organ. Some membranes serve as barriers to the passage of medications. For example, the blood-brain barrier allows only fat-soluble medications to pass into the brain and cerebral spinal fluid. Therefore central nervous system infections often require treatment with antibiotics injected directly into the subarachnoid space in the spinal cord. Some older patients experience adverse effects (e.g., confusion) as a result of the change in the permeability of the blood-brain barrier, with easier passage of fat-soluble medications. The placental membrane also has a nonselective barrier to medications. Fat-soluble and nonfat-soluble agents often cross the placenta and produce fetal deformities. After birth neonates often experience respiratory depression and withdrawal symptoms when their mothers use or abuse narcotics.

Protein Binding. The degree to which medications bind to serum proteins such as albumin affects their distribution. Most medications partially bind to albumin. Medications bound to albumin cannot exert pharmacological activity. The unbound or "free" medication is its active form. Older adults have a decrease in albumin, probably caused by a change in liver function. The same is true for patients with liver disease or malnutrition. In both examples patients are at risk for an increase in medication activity, toxicity, or both.

Metabolism. After a medication reaches its site of action, it becomes metabolized into a less active or inactive form that is easier to excrete. **Biotransformation** occurs under the influence of enzymes that **detoxify,** break down, and remove biologically active chemicals. Most biotransformation occurs within the liver, although the lungs, kidneys, blood, and intestines also metabolize medications. The liver is especially important because its specialized structure oxidizes and transforms many toxic substances. The liver degrades many harmful chemicals before they become distributed to the tissues. If a decrease in liver function occurs such as with aging or liver disease, a medication is usually eliminated more slowly, resulting in its accumulation. Patients are at risk for medication toxicity if organs that metabolize medications are not functioning correctly. For example, a small sedative dose of a barbiturate sometimes causes a patient with liver disease to lapse into a coma.

Excretion. After medications are metabolized, they exit the body through the kidneys, liver, bowel, lungs, and exocrine glands. The chemical makeup of a medication determines the organ of excretion. Gaseous and volatile compounds such as nitrous oxide and alcohol exit through the lungs. Deep breathing and coughing (see Chapter 40) help patients eliminate anesthetic gases more rapidly after surgery. The exocrine glands excrete lipid-soluble medications. When medications exit through sweat glands, the skin often becomes irritated, requiring you to instruct patients in good hygiene practices (see Chapter 39). If a medication is excreted through the mammary glands, there is a risk that a nursing infant will ingest the chemicals. Check the safety of any medication used in breastfeeding women.

The GI tract is another route for medication excretion. Medications that enter the hepatic circulation are broken down by the liver and excreted into the bile. After chemicals enter the intestines through the biliary tract, the intestines resorb them. Factors that increase peristalsis (e.g., laxatives and enemas) accelerate medication excretion through the feces, whereas factors that slow peristalsis (e.g., inactivity and improper diet) often prolong the effects of a medication.

The kidneys are the main organs for medication excretion. Some medications escape extensive metabolism and exit unchanged in the urine. Others undergo biotransformation in the liver before the kidneys excrete them. If renal function declines, a patient is at risk for medication toxicity. When the kidney cannot adequately excrete a medication, it is necessary to reduce the dose. Maintenance of an adequate fluid intake (8 to 9 cups, or about 2 L of water/day) promotes proper elimination of medications for the average adult.

Types of Medication Action

Medications vary considerably in the way they act and their types of action. Patients do not always respond in the same way to each successive dose of a medication. Sometimes the same medication

causes very different responses in different patients. Therefore it is essential to understand all the effects that medications have on patients.

Therapeutic Effects. The **therapeutic effect** is the expected or predicted physiological response that a medication causes. Each medication has a desired therapeutic effect. For example, nitroglycerin reduces cardiac workload and increases myocardial oxygen supply. Some medications have more than one therapeutic effect. For example, prednisone, a steroid, decreases swelling, inhibits inflammation, reduces allergic responses, and prevents rejection of transplanted organs. Knowing the desired therapeutic effect for each medication allows you to provide patient education and accurately evaluate its desired effect.

Side Effects/Adverse Effects. Every medication has a potential to harm a patient. **Side effects** are predictable and often unavoidable secondary effects produced at a usual therapeutic dose. They are either harmless or cause injury. For example, some antihypertensive medications cause impotence in men. If the side effects are serious enough to negate the beneficial effects of the therapeutic action of the medication, the prescriber discontinues the medication. Patients often stop taking medications because of side effects. **Adverse effects** are unintended, undesirable, and often unpredictable severe responses to medication. Some adverse effects are immediate, whereas others take weeks or months to develop. Early recognition is important. When adverse responses to medications occur, the prescriber discontinues the medication immediately. Health care providers report adverse effects to the FDA using the MedWatch program (USFDA, 2010).

Toxic Effects. **Toxic effects** develop after prolonged intake of a medication or when a medication accumulates in the blood because of impaired metabolism or excretion. Excess amounts of a medication within the body sometimes have lethal effects, depending on its action. For example, toxic levels of morphine, an opioid, cause severe respiratory depression and death. Antidotes are available to treat specific types of medication toxicity. For example, naloxone (Narcan), an opioid antagonist, reverses the effects of opioid toxicity.

Idiosyncratic Reactions. Medications sometimes cause unpredictable effects such as an **idiosyncratic reaction,** in which a patient overreacts or underreacts to a medication or has a reaction different from normal. For example, a child who receives diphenhydramine (Benadryl), an antihistamine, becomes extremely agitated or excited instead of drowsy. It is not always possible to predict if a patient will have an idiosyncratic response to a medication.

Allergic Reactions. Allergic reactions also are unpredictable responses to a medication. Some patients become immunologically sensitized to the initial dose of a medication. With repeated administration the patient develops an allergic response to it, its chemical preservatives, or a metabolite. The medication or chemical acts as an antigen, triggering the release of the antibodies in the body. A patient's **medication allergy** symptoms vary, depending on the individual and the medication (Table 31-2). Among the different classes of medications, antibiotics cause a high incidence of allergic reactions. Severe or **anaphylactic reactions,** which are life threatening, are characterized by sudden constriction of bronchiolar muscles, edema of the pharynx and larynx, and severe wheezing and shortness of breath. Immediate medical attention is required to treat anaphylactic reactions. A patient with a known history of an allergy to a medication needs to avoid exposure to that medication in the future and wear an identification bracelet or medal (Fig. 31-1), which alerts nurses and physicians to the allergy if the patient is unconscious when receiving medical care.

TABLE 31-2 Mild Allergic Reactions

SYMPTOM	DESCRIPTION
Urticaria	Raised, irregularly shaped skin eruptions with varying sizes and shapes; eruptions have reddened margins and pale centers
Rash	Small, raised vesicles that are usually reddened; often distributed over entire body
Pruritus	Itching of skin; accompanies most rashes
Rhinitis	Inflammation of mucous membranes lining nose; causes swelling and clear, watery discharge

FIG. 31-1 Allergy identification bracelet and medal.

Medication Interactions

When one medication modifies the action of another, a **medication interaction** occurs. Medication interactions are common in individuals taking several medications. Some medications increase or diminish the action of others and may alter the way another medication is absorbed, metabolized, or eliminated from the body. When two medications have a **synergistic effect,** their combined effect is greater than the effect of the medications when given separately. For example, alcohol is a central nervous system depressant that has a synergistic effect on antihistamines, antidepressants, barbiturates, and narcotic analgesics. Sometimes a medication interaction is desired. Prescribers often combine medications to create an interaction that has a beneficial effect. For example, a patient with high blood pressure takes several medications such as diuretics and vasodilators that act together to control the blood pressure when one medication is not effective on its own.

Timing of Medication Dose Responses

Medications administered intravenously enter the bloodstream and act immediately, whereas medications given in other routes take time to enter the bloodstream and have an effect. The quantity and distribution of a medication in different body compartments change constantly. Medications are ordered at various times, depending on when their response begins, becomes most intense, and ceases.

The minimum effective concentration (MEC) is the plasma level of a medication below which the effect of the medication does

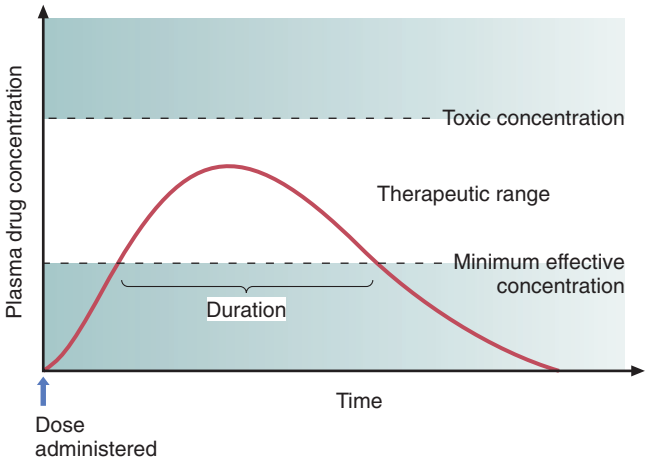

FIG. 31-2 The therapeutic range of a medication occurs between the minimum effective concentration and the toxic concentration. (From Lehne RA: *Pharmacology for nursing care,* ed 7, St Louis, 2010, Saunders.)

not occur. The toxic concentration is the level at which toxic effects occur. When a medication is prescribed, the goal is to achieve a constant blood level within a safe therapeutic range, which falls between the MEC and the toxic concentration (Fig. 31-2). When a medication is administered repeatedly, its serum level fluctuates between doses. The highest level is called the **peak** concentration, and the lowest level is called the **trough** concentration. After reaching its peak, the serum concentration of the medication falls progressively. With IV **infusions** the peak concentration occurs quickly, but the serum level also begins to fall immediately. Some medication doses (e.g., vancomycin) are based on peak and trough serum levels. The trough level is generally drawn 30 minutes before administering the drug, and the peak level is drawn whenever the drug is expected to reach its peak concentration. The time it takes for a drug to reach its peak concentration varies, depending on the pharmacokinetics of the medication.

All medications have a **biological half-life,** which is the time it takes for excretion processes to lower the amount of unchanged medication by half. A medication with a short half-life needs to be given more frequently than a medication with a longer half-life. The half-life does not change, no matter how much medication is given. For example, if the nurse gives 1 g of a medication that has a half-life of 8 hours, the patient excretes 500 mg of the medication in 8 hours. In the next 8 hours the patient excretes 250 mg. This process continues until the medication is totally eliminated from the body.

To maintain a therapeutic plateau the patient must receive regular fixed doses. For example, current evidence shows that pain medications are most effective when they are given around the clock (ATC) rather than when the patient intermittently complains of pain because ATC allows the body to maintain an almost constant level of pain medication. After an initial medication dose, the patient receives each successive dose when the previous dose reaches its half-life.

Safe drug administration involves adherence to prescribed doses and dosage schedules (Table 31-3). Some agencies set schedules for medication administration. However, nurses are able to alter this schedule based on knowledge about a medication. For example, at some agencies medications that are to be taken once a day are given at 9:00 AM. However, if a medication works best when given before bedtime, the nurse administers it before the patient goes to sleep. In addition, acute care agencies use guidelines from the Institute for Safe Medication Practices (CMS, 2011; ISMP, 2011) to determine safe, effective, and timely administration of scheduled medications. According to the ISMP guidelines, hospitals need to determine which medications are time-critical and which are non–time-critical. Time-critical medications are medications in which early or delayed administration of maintenance doses (more than 30 minutes before or after the scheduled dose) will most likely cause harm or result in subtherapeutic responses in a patient. Non–time-critical medications include medications in which the timing of administration will most likely not affect the desired effect of the medication if given 1 to 2 hours before or after its scheduled time. You need to administer time-critical medications at a precise time or within 30 minutes before or after the scheduled time. You administer medications identified as non–time-critical within 1 to 2 hours of their scheduled time. Follow your agency's medication administration policies about the timing of medications to ensure you administer medications at the right time (CMS, 2011; ISMP, 2011).

When teaching patients about dosage schedules, use language that is familiar to the patient. For example, when teaching a patient about medication dosing twice a day, instruct him or her to take it in the morning and again in the evening. Use knowledge about the time intervals and terms used to describe medication actions to anticipate the effect of a medication and educate the patient about when to expect a response (Table 31-4).

TABLE 31-3 Common Dosage Administration Schedules

DOSAGE SCHEDULE	ABBREVIATION
Before meals	AC, ac
As desired	ad lib
At bedtime	"nightly" or "at bedtime"
After meals	PC, pc
Whenever there is a need	prn
Every morning, every AM	qAM
Every day	Daily
Give immediately	STAT, stat

TABLE 31-4 Terms Associated with Medication Actions

TERM	MEANING
Onset	Time it takes after a medication is administered for it to produce a response
Peak	Time it takes for a medication to reach its highest effective concentration
Trough	Minimum blood serum concentration of medication reached just before the next scheduled dose
Duration	Time during which the medication is present in concentration great enough to produce a response
Plateau	Blood serum concentration of a medication reached and maintained after repeated fixed doses

TABLE 31-5 Factors Influencing Choice of Administration Routes

ADVANTAGES	DISADVANTAGES OR CONTRAINDICATIONS
Oral, Buccal, Sublingual Routes	
Convenient and comfortable for patient Economical Easy to administer Often produce local or systemic effects Rarely cause anxiety for patient.	Oral route is avoided when patient has alterations in gastrointestinal function (e.g., nausea, vomiting), reduced motility (after general anesthesia or bowel inflammation), and surgical resection of gastrointestinal tract. Oral administration is contraindicated in patients unable to swallow (e.g., patients with neuromuscular disorders, esophageal strictures, mouth lesions). Oral administration is contraindicated in unconscious or confused patient who is unable or unwilling to swallow or hold medication under tongue. Oral medications cannot be administered when patients have gastric suction; are contraindicated before some tests or surgery. Oral medications sometimes irritate lining of gastrointestinal tract, discolor teeth, or have unpleasant taste. Gastric secretions destroy some medications.
Subcutaneous, Intramuscular (IM), Intravenous (IV), Intradermal (ID) Routes	
Provide means of administration when oral medications are contraindicated More rapid absorption than with topical or oral routes IV infusion provides medication delivery when patient is critically ill or long-term therapy is necessary; if peripheral perfusion is poor, IV route preferred over injections	There is risk of introducing infection, and some medications are expensive. Some patients experience pain from repeated needlesticks. Subcutaneous, IM, and ID routes are avoided in patients with bleeding tendencies. There is risk of tissue damage. IM and IV routes have higher absorption rates, thus placing patient at higher risk for reactions. They often cause considerable anxiety in many patients, especially children.
Skin	
Primarily provides local effect Painless Limited side effects	Patients with skin abrasions are at risk for rapid medication absorption and systemic effects. Medications are absorbed through skin slowly.
Transdermal	
Prolonged systemic effects with limited side effects	Medication leaves oily or pasty substance on skin and sometimes soils clothing.
Mucous Membranes*	
Therapeutic effects provided by local application to involved sites Aqueous solutions readily absorbed and capable of causing systemic effects Potential route of administration when oral medications are contraindicated	Mucous membranes are highly sensitive to some medication concentrations. Patient with ruptured eardrum cannot receive ear irrigations. Insertion of rectal and vaginal medication often causes embarrassment. Rectal suppositories contraindicated if patient has had rectal surgery or if active rectal bleeding is present.
Inhalation	
Provides rapid relief for local respiratory problems Used for introduction of general anesthetic gases	Some local agents cause serious systemic effects.

*Includes eyes, ears, nose, vagina, rectum, and ostomy.

Routes of Administration

The route prescribed for administering a medication depends on the properties and desired effect of the medication and the patient's physical and mental condition (Table 31-5). Work with the prescriber in determining the best route for a patient's medication.

Oral Routes. The oral route is the easiest and the most commonly used route. Medications are given by mouth and swallowed with fluid. Oral medications have a slower onset of action and a more prolonged effect than parenteral medications. Patients generally prefer the oral route.

Sublingual Administration. Some medications are readily absorbed after being placed under the tongue to dissolve (Fig. 31-3). A medication given by the **sublingual** route should not be swallowed because the medication does not have the desired effect. Nurses often give nitroglycerin by the sublingual route. Tell the patient not to drink anything until the medication is completely dissolved.

Building Competency in Patient-Centered Care Mr. Koop is recovering from abdominal surgery 2 days ago for removal of a tumor in his colon and is feeling progressively worse. His temperature was 37° C (98.6° F) 4 hours ago and is now 39.2° C (102.6° F). He is no longer able to tolerate oral fluids and states that he is nauseated. You check his order, which reads, "Acetaminophen 650 mg orally for temperature above 38.4° C (101.2° F)." On the basis of the assessment, you believe that, because Mr. Koop is nauseated, he will not be able to tolerate an oral dose of acetaminophen. Thus you decide that you need to call Mr. Koop's health care provider to see if the medication route can be changed to a rectal suppository. Using SBAR (Situation-Background-Assessment-Recommendation) as your guide, create a report that you will use when calling his health care provider.

Answers to questions can be found on the Evolve website.

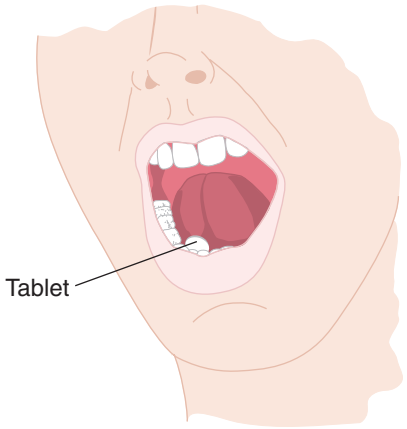

FIG. 31-3 Sublingual administration of a tablet.

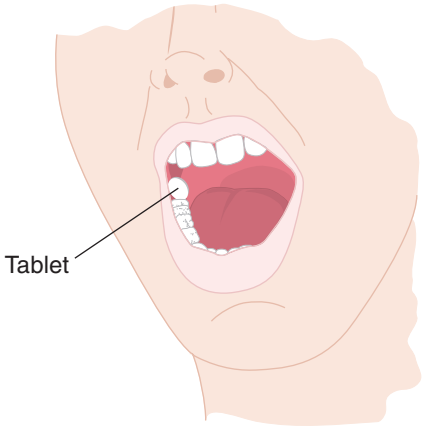

FIG. 31-4 Buccal administration of a tablet.

Buccal Administration. Administration of a medication by the **buccal** route involves placing the solid medication in the mouth against the mucous membranes of the cheek until it dissolves (Fig. 31-4). Teach patients to alternate cheeks with each subsequent dose to avoid mucosal irritation. Warn patients not to chew or swallow the medication or to take any liquids with it. A buccal medication acts locally on the mucosa or systemically as it is swallowed in a person's saliva.

Parenteral Routes. **Parenteral administration** involves injecting a medication into body tissues. The following are the four major sites of injection:

1. **Intradermal (ID):** Injection into the dermis just under the epidermis
2. **Subcutaneous:** Injection into tissues just below the dermis of the skin
3. **Intramuscular (IM):** Injection into a muscle
4. **Intravenous (IV):** Injection into a vein

Some medications are administered into body cavities other than the four types listed here. These additional routes include epidural, intrathecal, intraosseous, intraperitoneal, intrapleural, and intraarterial. Nurses usually are not responsible for the administration of medications through these advanced techniques. Whether or not you actually administer the medication, you remain responsible for monitoring the integrity of the medication delivery system, understanding the therapeutic value of the medication, and evaluating the patient's response to the therapy.

Epidural. Epidural medications are administered in the epidural space via a catheter, which is placed by a nurse anesthetist or an anesthesiologist. This route is used for the administration of regional analgesia for surgical procedures (see Chapter 43). Nurses who have advanced education in the epidural route can administer medications by continuous infusion or by a bolus dose.

Intrathecal. Physicians and specially educated nurses administer intrathecal medications through a catheter placed in the subarachnoid space or one of the ventricles of the brain. Intrathecal administration is often associated with long-term medication administration through surgically implanted catheters.

Intraosseous. This method of medication administration involves the infusion of medication directly into the bone marrow. It is most commonly used in infants and toddlers who have poor access to their intravascular space and when an emergency arises and IV access is impossible.

Intraperitoneal. Medications administered into the peritoneal cavity are absorbed into the circulation. Chemotherapeutic agents, insulin, and antibiotics are administered in this fashion.

Intrapleural. A syringe and needle or a chest tube is used to administer intrapleural medications directly into the pleural space. Chemotherapeutic agents are the most common medications administered via this method. Physicians also instill medications that help resolve persistent pleural effusion. This is called *pleurodesis,* which promotes adhesion between the visceral and parietal pleura.

Intraarterial. Intraarterial medications are administered directly into the arteries. Intraarterial infusions are common in patients who have arterial clots. The nurse manages a continuous infusion of clot-dissolving agents and carefully monitors the integrity of the infusion to prevent inadvertent disconnection of the system and subsequent bleeding.

Other methods of medication administration that are usually limited to physician administration are **intracardiac,** an injection of a medication directly into cardiac tissue, and **intraarticular,** an injection of a medication into a joint.

Topical Administration. Medications applied to the skin and mucous membranes generally have local effects. You apply topical medications to the skin by painting or spreading the medication over an area, applying moist dressings, soaking body parts in a solution, or giving medicated baths. Systemic effects often occur if a patient's skin is thin or broken down, the medication concentration is high, or contact with the skin is prolonged. A **transdermal disk** or patch (e.g., nitroglycerin, scopolamine, and estrogens) has systemic effects. The disk secures the medicated ointment to the skin. These topical applications are left in place for as little as 12 hours or as long as 7 days.

Nurses administer medications to mucous membranes in a variety of ways, including the following, by:

1. Directly applying a liquid or ointment (e.g., eyedrops, gargling, or swabbing the throat).
2. Inserting a medication into a body cavity (e.g., placing a suppository in rectum or vagina or inserting medicated packing into vagina).
3. Instilling fluid into a body cavity (e.g., eardrops, nose drops, or bladder and rectal **instillation** [fluid is retained]).
4. Irrigating a body cavity (e.g., flushing eye, ear, vagina, bladder, or rectum with medicated fluid [fluid is not retained]).
5. Spraying a medication into a body cavity (e.g., instillation into nose and throat).

Inhalation Route. The deeper passages of the respiratory tract provide a large surface area for medication absorption. Nurses

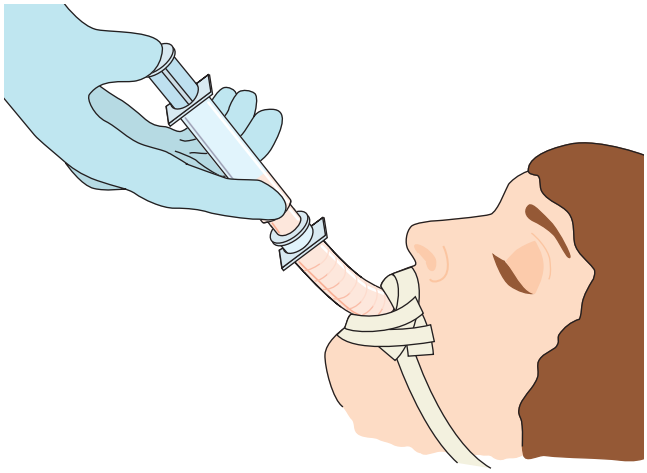

FIG. 31-5 Medication instilled through an endotracheal tube.

administer inhaled medications through the nasal and oral passages or endotracheal or tracheostomy tubes. Endotracheal tubes enter the patient's mouth and end in the trachea (Fig. 31-5), whereas tracheostomy tubes enter the trachea directly through an incision made in the neck. Inhaled medications are readily absorbed and work rapidly because of the rich vascular alveolar capillary network present in the pulmonary tissue. Many inhaled medications have local or systemic effects.

Intraocular Route. **Intraocular** medication delivery involves inserting a medication similar to a contact lens into the patient's eye. The eye medication disk has two soft outer layers that have medication enclosed in them. The nurse inserts the disk into the patient's eye, much like a contact lens, and it can remain there for up to 1 week.

Systems of Medication Measurement

The proper administration of a medication depends on your ability to compute medication doses accurately and measure medications correctly. Mistakes in calculating or measuring medications correctly often lead to fatal errors. As a nurse you are responsible for checking calculations carefully before giving a medication.

Medication therapy uses the metric, apothecary, and household systems of measurement. The apothecary system is used infrequently today. Although the U.S. Congress has not officially adopted the metric system, most health professionals in the United States use it. Health care providers usually write prescriptions to be self-administered in household measures for patients.

Metric System. As a decimal system, the **metric system** is the most logically organized. Metric units are easy to convert and compute through simple multiplication and division. Each basic unit of measurement is organized into units of 10. Multiplying or dividing by 10 forms secondary units. In multiplication the decimal point moves to the right; in division the decimal moves to the left. For example:

$$10 \text{ mg} \times 10 = 100 \text{ mg}$$

$$10 \text{ mg} \div 10 = 1 \text{ mg}$$

The basic units of measurement in the metric system are the meter (length), the liter (volume), and the gram (weight). For medication calculations only use the volume and weight units. In the metric system use lowercase or capital letters to designate basic units:

TABLE 31-6 Equivalents of Measurement

METRIC	APOTHECARY	HOUSEHOLD
1 mL	15-16 minims*	15 drops (gtt)
5 mL	1 dram*	1 teaspoon (tsp)
15 mL	4 drams*	1 tablespoon (tbsp)
30 mL	1 fluid ounce	2 tablespoons (tbsp)
240 mL	8 fluid ounces	1 cup (c)
480 mL (approximately 500 mL)	1 pint (pt)	1 pint (pt)
960 mL (approximately 1 L)	1 quart (qt)	1 quart (qt)
3840 mL (approximately 4 L)	1 gallon (gal)	1 gallon (gal)

*Minums and drams are no longer acceptable units of measure for medication administration although some medication cups and syringes still have them listed. Use mL for safe medication preparation (Morris, 2010).

Gram = g or Gm

Liter = l or L

Use lowercase letters for abbreviations for other units:

Milligram = mg

Milliliter = mL

A system of Latin prefixes designates subdivision of the basic units: *deci-* ($\frac{1}{10}$ or 0.1), *centi-* ($\frac{1}{100}$ or 0.01), and *milli-* ($\frac{1}{1000}$ or 0.001). Greek prefixes designate multiples of the basic units: *deka-* (10), *hecto-* (100), and *kilo-* (1000). When writing medication doses in metric units, prescribers and nurses use fractions or multiples of a unit. Convert fractions to decimals.

500 mg or 0.5 g, *not* $\frac{1}{2}$ g

10 mL or 0.01 L, *not* $\frac{1}{100}$ L

Many actual and potential medication errors happen with the use of fractions and decimal points. Follow practice standards when medications are ordered in fractions to prevent medication errors. For example, to make the decimal point more visible, a leading zero is *always* placed in front of a decimal (e.g., use 0.25 *not* .25). *Never* use a trailing zero (i.e., a zero after a decimal point) because, if a health care worker does not see the decimal point, the patient may receive 10 times more medication than that prescribed (e.g., use 5 *not* 5.0) (ISMP, 2010b; TJC, 2011).

Household Measurements. Household units of measure are familiar to most people. Their disadvantage is their inaccuracy. Household utensils such as teaspoons and cups vary in size. Scales to measure pints or quarts are not well calibrated. Household measures include drops, teaspoons, tablespoons, and cups for volume and pints and quarts for weight. The advantage of household measurements is their convenience and familiarity. When the accuracy of a medication dose is not critical (e.g., [OTC medications]), it is safe to use household measures. To calculate medications accurately, you need to know common equivalents of metric and household units (Table 31-6).

Solutions. The nurse uses solutions of various concentrations for injections, **irrigations,** and infusions. A **solution** is a given mass of solid substance dissolved in a known volume of fluid or a given

volume of liquid dissolved in a known volume of another fluid. When a solid is dissolved in a fluid, the concentration is in units of mass per units of volume (e.g., g/L, mg/mL). A concentration of a solution can also be expressed as a percentage. For example, a 10% solution is 10 g of solid dissolved in 100 mL of solution. A proportion also expresses concentrations. A $\frac{1}{1000}$ solution represents a solution containing 1 g of solid in 1000 mL of liquid or 1 mL of liquid mixed with 1000 mL of another liquid.

NURSING KNOWLEDGE BASE

The IOM (2003) published the book *To Err Is Human: Building a Safer Health System*. This book created a new national awareness of problems within the health care system. It estimated that up to 98,000 people die in any given year from medical errors that occur in hospitals. This means that more people die from medical errors than from motor vehicle accidents, breast cancer, acquired immunodeficiency syndrome (AIDS), and workplace injuries. Health care experts estimate that medication-related errors for hospitalized patients cost more than $3.5 billion annually (IOM, 2007).

Nurses play an important role in patient safety, especially in the area of medication administration. The safe administration of medications is also an important topic for current nursing researchers (Box 31-2). Nurses need to know how to calculate medication doses accurately and understand the different roles that members of the health care team play in prescribing and administering medications. All of the nurse's previous learning is important and is often applied to ensure safe medication administration.

BOX 31-2 EVIDENCE-BASED PRACTICE

Reducing Errors During Medication Administration

PICO Question: In hospitals does the use of bar-code scanning and an electronic medication administration record (eMAR) during medication administration decrease the incidence of medication errors made by nurses when compared with nurses who do not use bar-code scanning and eMAR?

Evidence Summary

Medication administration is a highly complex process. Errors often result from problems within one or more parts of the process. Many errors occur either when a medication is ordered or when it is administered. Research shows the combined use of bar-code technology and eMAR decreases most medication errors in various hospital settings (Foote and Coleman, 2008; Fowler, Sohler, and Zarillo, 2009; Green, 2008; Helmons, Wargel, and Daniels, 2009; Poon et al., 2010). However, sometimes these systems uncover increases in certain types of errors. For example, errors of omission (e.g., a patient not receiving a medication on time because he or she is off the nursing unit at a procedure) may become more apparent (Fowler, Sohler, and Zarillo, 2009; Helmons, Wargel, and Daniels, 2009).

Application to Nursing Practice

- The process of implementing bar-code and eMAR technology is complex and needs to be well planned and involve nursing staff to ensure successful implementation (Foote and Coleman, 2008).
- Even though the use of bar code scanning and eMAR reduces many errors, it does not eliminate all of them (Poon et al., 2010). Therefore nurses need to remain vigilant and consistently follow medication administration policies and protocols to ensure safe medication administration.
- Nurses need to analyze data collected from computerized systems about medication errors to identify ways to improve the medication administration process and enhance patient safety (Helmons, Wargel, and Daniels, 2009).

Clinical Calculations

To administer medications safely, you need to have an understanding of basic mathematics skills to calculate medication doses, mix solutions, and perform a variety of other activities. This is important because medications are not always dispensed in the unit of measure in which they are ordered. Medication companies package and bottle medications in standard dosages. For example, the patient's health care provider orders 20 mg of a medication that is available only in 40-mg vials. Nurses frequently convert available units of volume and weight to desired doses. Therefore be aware of equivalents in all major measurement systems. You use equivalents when performing other nursing actions such as when calculating patients' intake and output and IV flow rates.

Conversions Within One System. Converting measurements within one system is relatively easy; simply divide or multiply in the metric system. To change milligrams to grams, divide by 1000, moving the decimal 3 points to the left.

$$1000 \text{ mg} = 1 \text{ g}$$

$$350 \text{ mg} = 0.35 \text{ g}$$

To convert liters to milliliters, multiply by 1000 or move the decimal 3 points to the right.

$$1 \text{ L} = 1000 \text{ mL}$$

$$0.25 \text{ L} = 250 \text{ mL}$$

To convert units of measurement within the household system, consult an equivalent table. For example, when converting fluid ounces to quarts, you first need to know that 32 ounces is the equivalent of 1 quart. To convert 8 ounces to a quart measurement, divide 8 by 32 to get the equivalent, $\frac{1}{4}$ or 0.25 quart.

Conversion Between Systems. Nurses frequently determine the proper dose of a medication by converting weights or volumes from one system of measurement to another. Thus sometimes you convert metric units to equivalent household measures for use at home. To calculate medications it is necessary to work with units in the same measurement system. Tables of equivalent measurements are available in all health care institutions. The pharmacist is also a good resource.

Before converting, compare the measurement system available with that ordered. For example, the prescriber orders Robitussin 30 mL, but the patient only has tablespoons at home. To properly instruct the patient, you convert mL to tablespoons, which requires you to know the equivalent or refer to a table such as Table 31-6.

Dose Calculations. Methods used to calculate medication doses include the ratio and proportion method, the formula method, and dimensional analysis. Before completing any calculation, make a mental estimate of the approximate and reasonable dosage. If the estimate does not match the calculated solution, recheck the calculation before preparing and administering the medication. Many nursing students are anxious when calculating medication doses. To enhance accuracy and reduce anxiety, think critically about the processes used during the calculation and practice doing calculations until you feel confident about your mathematics skills (Walsh, 2008). In addition, choose the method of calculation with which you are most comfortable and use it consistently (Morris, 2010). Most health care agencies require a nurse to double-check calculations with another nurse before giving medications, especially when the risk for giving the wrong medication is high (e.g., heparin, insulin). *Always* have another nurse double-check your work if you are unsure about the answer

or if the answer to a medication calculation seems unreasonable or inappropriate.

The Ratio and Proportion Method. A ratio indicates the relationship between two numbers separated by a colon (:). The colon in the ratio indicates the need to use division. Think of a ratio as a fraction; the number to the left is the numerator, and the number to the right is the denominator. For example, the ratio 1:2 is the same as ½. Write a proportion in one of three ways:

Example 1: 1:2 = 4:8
Example 2: 1:2 :: 4:8
Example 3: 1/2 = 4/8

In a proportion the first and last numbers are called the *extremes*, and the second and third numbers are called the *means*. When multiplying the extremes, the answer is the same when multiplying the means. For example, in the previous proportions, multiplying the extremes ($1 \times 8 = 8$) is the same result as multiplying the means ($2 \times 4 = 8$). Because of this relationship, if you know three of the numbers in the proportion, calculating the unknown fourth number is easy. The numbers need to all be in the same unit and system of measurement. To solve a calculation using the ratio and proportion method, first estimate the answer in your mind. Then set up the proportion, labeling all the terms. Put the terms of the ratio in the same sequence (e.g., mg:mL = mg:mL). Cross multiply the means and the extremes and divide both sides by the number before the *x* to obtain the dosage. *Always* label the answer; if the answer is not close to the estimate, recheck the calculation.

Example: The prescriber orders 500 mg of amoxicillin to be administered in a gastric tube every 8 hours. The bottle of amoxicillin is labeled 400 mg/5 mL. Use the following steps to calculate how much amoxicillin to give:

1. **Estimate the answer:** The amount to be given is a little more than the amount that is provided in the solution; therefore the answer is a little more than 5 mL.
2. **Set up the proportion:**

$$\frac{400\ \text{mg}}{5\ \text{mL}} = \frac{500\ \text{mg}}{x\ \text{mL}}$$

3. **Cross multiply the means and the extremes:**

$$400x = 500 \times 5$$
$$400x = 2500$$

4. **Divide both sides by the number before *x*:**

$$\frac{400x}{400} = \frac{2500}{400}$$
$$x = \frac{2500}{400}$$
$$x = 6.25\ \text{mL}$$

5. **Compare the estimate in Step 1 with the answer in Step 4:** The answer (6.25 mL) is close to the estimated amount (a little more than 5 mL). Therefore the answer is correct; prepare and administer 6.25 mL in the patient's gastric tube.

The Formula Method. Using this method requires you to first memorize the formula. Estimate the answer and then place all the information from the medication order into the formula. Label all the parts of the formula and ensure that all measures in the formula are in the same units and system of measurement before calculating the dosage. If the measures are not in the same measurement system, convert the numbers to the same system before calculating the dose. Calculate and label the answer and compare the answer with the estimated answer. If the estimate is not similar to the answer, recheck the calculation. Use the following basic formula when using the formula method:

$$\frac{\text{Dose ordered}}{\text{Dose on hand}} \times \text{Amount on hand} = \text{Amount to administer}$$

The dose ordered is the amount of medication prescribed. The dose on hand is the dose (e.g., mg, units) of medication supplied by the pharmacy. The amount on hand is the basic unit or quantity of the medication that contains the dose on hand. For solid medications the amount on hand is often one capsule; the amount of liquid on hand is sometimes 1 mL or 1 L, depending on the container. For example, a liquid medication comes in the strength of 125 mg per 5 mL. In this case 125 mg is the dose on hand, and 5 mL is the amount on hand. The amount to administer is the actual amount of medication the nurse administers. Always express the amount to administer in the same unit as the amount on hand.

Example: The prescriber orders morphine sulfate 2 mg IV. The medication is available in a vial containing 10 mg/mL. The formula is applied as follows:

1. **Estimate the answer:** The medication is a liquid; thus the answer will be in milliliters (mL). The amount to be given is less than ½ of the dose; thus the answer will be less than ½ mL.
2. **Set up the formula:**

$$\frac{\text{Dose ordered}}{\text{Dose on hand}} \times \text{Amount on hand} = \text{Amount to administer}$$
$$\frac{2\ \text{mg}}{10\ \text{mg}} \times 1\ \text{mL} = \text{Amount to administer}$$

3. **Calculate the answer:**

$$\frac{2\ \text{mg}}{10\ \text{mg}} \times 1\ \text{mL} = 0.2\ \text{mL}$$

4. **Compare the estimate in Step 1 with the answer in Step 3:** The answer is less than ½ mL; thus it is close to the estimated answer. Prepare 0.2 mL of the medication in a syringe and administer it to the patient.

Dimensional Analysis. Dimensional analysis is the factor-label or the unit factor method. There is no need to memorize a formula since only one equation is needed and the same steps are used in solving every medication calculation. One research study shows that nursing students who use dimensional analysis often calculate medications more accurately than when they use the formula method (Greenfield, Whelan, and Cohn, 2006). Use the following steps to calculate medication doses by dimensional analysis:

1. Identify the unit of measure that you need to administer. For example, if you are giving a pill, you usually give a tablet or a capsule; for parenteral or liquid oral medications, the unit is milliliters.
2. Estimate the answer.
3. Place the name or appropriate abbreviation for *x* on the left side of the equation (e.g., *x* tab, *x* mL).
4. Place available information from the problem in a fraction format on the right side of the equation. Place the abbreviation or unit that matches what you are going to administer (determined in Step 1) in the numerator.

5. Look at the medication order and add other factors into the problem. Set up the numerator so it matches the unit in the previous denominator.
6. Cancel out like units of measurement on the right side of the equation. You should end up with only one unit left in the equation, and it should match the unit on the left side of the equation.
7. Reduce to the lowest terms if possible, and solve the problem or solve for *x*. Label your answer.
8. Compare your estimate from Step 1 with your answer in Step 2.

Example: The prescriber orders 0.45 g penicillin V potassium through a gastric tube. The bottle says: penicillin V potassium 125 mg/5 mL.

1. **Identify the unit of measure that you need to administer.** This medication is given in a gastric tube, which is a liquid medication; therefore the answer will be in milliliters (mL).
2. **Estimate the answer.** The medication order is more than three times but less than four times is the amount in the vial; thus the answer is more than 15 mL but less than 20 mL.
3. **Place the name or appropriate abbreviation for *x* on the left side of the equation.**

$$x\ \text{mL} =$$

4. **Place available information from the problem in a fraction format on the right side of the equation.** Since the medication will be administered in milliliters, place mL in the numerator.

$$x\ \text{mL} = \frac{5\ \text{mL}}{125\ \text{mg}}$$

5. **Look at the medication order and add other factors into the problem.** Set up the numerator so it matches the unit in the previous denominator. The order is for 0.45 g, and the medication is available in 125-mg bottles. Knowing that 1 g = 1000 mg, add this conversion to the calculation.

$$x\ \text{mL} = \frac{5\ \text{mL}}{125\ \text{mg}} \times \frac{1000\ \text{mg}}{1\ \text{g}} \times \frac{0.45\ \text{g}}{1}$$

6. **Cancel out like units of measurement on the right side of the equation.**

$$x\ \text{mL} = \frac{5\ \text{mL}}{125\ \cancel{\text{mg}}} \times \frac{1000\ \cancel{\text{mg}}}{1\ \cancel{\text{g}}} \times \frac{0.45\ \cancel{\text{g}}}{1}$$

7. **Reduce to the lowest terms if possible and solve the problem or solve for *x*.** Label your answer.

$$x = \frac{5 \times 1000 \times 0.45}{125}$$

$$x = \frac{2250}{125}$$

$$x = 18\ \text{mL}$$

8. **Compare the estimate from Step 2 with the answer in Step 7.** The calculated answer is 18 mL, which is between 15 mL and 20 mL. This matches the estimate made in Step 2. Prepare and administer 18 mL of medication as ordered.

Pediatric Doses. Current evidence shows that children are three times more at risk for experiencing a medication error than adults (TJC, 2008). Medication errors involving children frequently happen for the following reasons (Morris, 2010):

- Confusion between formulations for adults and children
- Availability of multiple pediatric concentrations of oral liquid medications
- Inaccurate preparation of medications that need to be diluted
- Similar packaging of medications and names of medications that look alike and sound alike
- Parents who do not understand how to correctly prepare and administer medications
- Errors in calculation and use of inaccurate measuring devices (e.g., household teaspoons and tablespoons) as opposed to devices made to measure small volume doses

Calculating children's medication doses requires caution (Hockenberry and Wilson, 2009). Even small errors or discrepancies in medication amounts can negatively affect a child's health (Morris, 2010). The child's age, weight, and maturity of body systems affect the ability to metabolize and excrete medications. Nurses sometimes have difficulties evaluating the child's response to a medication, especially when he or she cannot communicate verbally. For example, a side effect of vancomycin is ototoxicity. If a child cannot talk yet, it is challenging to assess for ototoxicity.

Use the following guidelines when calculating pediatric doses:

1. Most pediatric medications are ordered in milligrams per kilogram (mg/kg). Therefore ensure that the patient's weight is expressed in kilograms. Avoid converting the patient's weight whenever possible. If you have to convert pounds to kilograms, remember that 1 kg = 2.2 lb and convert the patient's weight before calculating the medication dosage.
2. Pediatric doses are usually a lot smaller than adult doses for the same medication. You frequently use micrograms and small syringes (e.g., tuberculin or 1 mL).
3. IM doses are very small and usually do not exceed 1 mL in small children or 0.5 mL in infants.
4. Subcutaneous dosages are also very small and do not usually exceed 0.5 mL.
5. Most medications are not rounded off to the nearest tenth. Instead they are rounded to the nearest thousandth.
6. Measure dosages that are less than 1 mL in syringes that are marked in tenths of a milliliter if the dosage calculation comes out even and does not need to be rounded. Use a tuberculin syringe for medication preparation when the medication needs to be rounded to the nearest thousandth.
7. Estimate the patient's dose before beginning the calculation; label and compare the answer with the estimate before preparing the medication.
8. To determine if a dose is safe before giving the medication, compare and evaluate the amount of medication ordered over 24 hours with the recommended dosage.

Different formulas and methods are used to calculate drug dosages in children. The two most common methods of calculating pediatric dosages are based on a child's weight or BSA. BSA is used in rare situations (e.g., determining chemotherapy doses). To estimate a child's BSA, use Mosteller's formula or the standard nomogram (e.g., the West nomogram). Refer to a pediatric or pharmacology resource and consult with the patient's health care provider or the pharmacist if you have to calculate a medication based on BSA.

Most of the time you calculate medications based on a child's weight. You can use the ratio and proportion method, the formula method, or dimensional analysis to calculate a pediatric dose using body weight. The example that follows explains how to use dimensional analysis to calculate pediatric doses. Refer to the previous sections on ratio and proportion and the formula method if you decide that they are easier for you to use.

Example: You receive an order to give ticarcillin/clavulanate 50 mg/kg q4h for a 5-year-old child who weighs 18 kg. The medication label says that there is 200 mg of ticarcillin/clavulanate in 1 mL of normal saline. How much ticarcillin/clavulanate do you give?

1. **Identify the unit of measure that you need to administer.** This medication is given IV piggyback, which is a parenteral medication. Therefore your answer will be in milliliters.
2. **Estimate the answer.** The medication is ordered 50 mg/kg. Round the child's weight up to 20 kg and multiply it by 50 mg to estimate the total amount of mg to be given. In your estimate the patient needs about 1000 mg. Because the medication comes in a vial of 200 mg in 1 mL and 1000 mg is 5 times larger than the dose of the medication and because you rounded the patient's weight up to 20 kg, you need to give a little less than 5 mL.
3. **Place the name or appropriate abbreviation for x on the left side of the equation.**

$$x\ \text{mL} =$$

4. **Place available information from the problem in a fraction format on the right side of the equation.** Set up the numerator so it matches the unit in the previous denominator: You are going to administer the medication in milliliters; therefore place the mL in the numerator.

$$x\ \text{mL} = \frac{1\ \text{mL}}{200\ \text{mg}}$$

5. **Look at the medication order and add other factors into the problem. Set up the numerator so that it matches the unit in the previous denominator.** You know that you need to give 50 mg/kg and that your patient weighs 18 kg.

$$x\ \text{mL} = \frac{1\ \text{mL}}{200\ \text{mg}} \times \frac{50\ \text{mg}}{1\ \text{kg}} \times \frac{18\ \text{kg}}{1}$$

6. **Cancel out like units of measurement on the right side of the equation.**

$$x\ \text{mL} = \frac{1\ \text{mL}}{200\ \cancel{\text{mg}}} \times \frac{50\ \cancel{\text{mg}}}{1\ \cancel{\text{kg}}} \times \frac{18\ \cancel{\text{kg}}}{1}$$

7. **Reduce to the lowest terms if possible and solve the problem or solve for *x*. Label your answer.**

$$x = \frac{50 \times 18}{200}$$
$$x = \frac{900}{200}$$
$$x = 4.5\ \text{mL}$$

8. **Compare the estimate from Step 2 with the answer in Step 7.** The answer is 4.5 mL, which is a little less than 5 mL. Since this is close to the estimate you made in Step 2, the calculation is correct, and you can continue with medication preparation at this time.

Prescriber's Role

The physician, nurse practitioner, or physician's assistant prescribes medications by writing an order on a form in the patient's medical record, in an order book, or on a legal prescription pad. Some prescribers use a desktop, laptop, or handheld electronic device to enter medication orders. Many hospitals are implementing computerized physician order entry (CPOE) to handle medication orders to decrease medication errors. In these systems the prescriber completes all computerized fields before the order for the medication is filled, thus avoiding incomplete or illegible orders.

Sometimes a prescriber orders a medication by talking directly to the nurse or by telephone. An order for a medication or medical treatment made over the telephone is called a telephone order. If the order is given verbally to the nurse, it is called a **verbal order.** When a verbal or telephone order is received, the nurse who took the order writes the complete order or enters it into a computer, reads it back, and receives confirmation from the prescriber to confirm accuracy. The nurse indicates the time and name of the prescriber who gave the order, signs it, and follows agency policy to indicate that it was read back. The prescriber countersigns the order at a later time, usually within 24 hours after giving it. Follow guidelines for taking verbal or telephone orders for medications safely (Box 31-3). Institutional policies vary regarding personnel who can take verbal or telephone orders. Nursing students cannot take them. They only give newly ordered medications after a registered nurse has written and verified the order.

Common abbreviations are often used when writing orders. Abbreviations indicate dosage frequencies or times, routes of administration, and special information for giving the medication (see Table 31-3). Medication errors frequently involve the use of abbreviations. Table 31-7 lists abbreviations that are associated with a high incidence of medication errors. Do ***not*** use these abbreviations when documenting medication orders or other information about medications (ISMP, 2010b; TJC, 2011b). Sometimes abbreviations used in different agencies vary. Check agency policy to determine which abbreviations are acceptable to use and their meaning.

Building Competency in Safety Your patient's health care provider has written the following orders. Which orders do you need to clarify before administering the medication? Provide rationale for your answers and rewrite the order so it follows the ISMP current medication order safety guidelines.

Lanoxin .25 mg QOD
Heparin 5,000 u SC twice a day
Aspirin 325 mg PO daily
Enalapril 10 mg PO twice a day
Lasix 40 mg IVP q day, hold for systolic blood pressure <100

Answers to questions can be found on the Evolve website.

Types of Orders in Acute Care Agencies

You must have a medication order before giving a medicine to a patient. Five common types of medication orders are based on the frequency and/or urgency of medication administration. Some conditions change the status of a patient's medication orders. For example, in some agencies the patient's preoperative medications are automatically discontinued, and the health care provider writes new medication orders after surgery (see Chapter 50). Agency policies that surround medication orders often vary. Nurses need to be aware of and follow these policies.

Standing Orders or Routine Medication Orders. A standing order is carried out until the prescriber cancels it by another order or a prescribed number of days elapse. A standing order often indicates a final date or number of treatments or doses. Many agencies have policies for automatically discontinuing standing orders. The following are examples of standing orders:

Tetracycline 500 mg PO q6h
Decadron 10 mg daily × 5 days

BOX 31-3 RECOMMENDATIONS TO REDUCE MEDICATION ERRORS ASSOCIATED WITH VERBAL MEDICATION ORDERS AND PRESCRIPTIONS (NCCMERP, 2006)*

Council Recommendations

Recommendations to Reduce Medication Errors Associated with Verbal Medication Orders and Prescriptions
Adopted February 20, 2001
Revised February 24, 2006

Preamble

Confusion over the similarity of drug names accounts for approximately 25% of all reports to the USP Medication Errors Reporting (MER) Program. To reduce confusion pertaining to verbal orders and to further support the Council's mission to minimize medication errors, the following recommendations have been developed.

In these recommendations verbal orders are prescriptions or medication orders that are communicated as oral, spoken communications between senders and receivers face to face, by telephone, or by other auditory device.

Recommendations

1. Verbal communication of prescription or medication orders should be limited to urgent situations where immediate written or electronic communication is not feasible.
2. Health care organizations† should establish policies and procedures that:
   - Describe limitations or prohibitions on use of verbal orders.
   - Provide a mechanism to ensure validity/authenticity of the prescriber.
   - List the elements required for inclusion in a complete verbal order.
   - Describe situations in which verbal orders may be used.
   - List and define the individuals who may send and receive verbal orders.
   - Provide guidelines for clear and effective communication of verbal orders.
3. Leaders of health care organizations should promote a culture in which it is acceptable, and strongly encouraged, for staff to question prescribers when there are any questions or disagreements about verbal orders. Questions about verbal orders should be resolved prior to the preparation, dispensing, or administration the medication.
4. Verbal orders for antineoplastic agents should ***NOT*** be permitted under any circumstances. These medications are not administered in emergency or urgent situations, and they have a narrow margin of safety.
5. Elements that should be included in a verbal order include:
   - Name of patient.
   - Age and weight of patient, when appropriate.
   - Drug name.
   - Dosage form (e.g., tablets, capsules, inhalants).
   - Exact strength or concentration.
   - Dose, frequency, and route.
   - Quantity and/or duration.
   - Purpose or indication (unless disclosure is considered inappropriate by the prescriber).
   - Specific instructions for use.
   - Name of prescriber and telephone number when appropriate.
   - Name of individual transmitting the order if different from the prescriber.
6. The content of verbal orders should be clearly communicated:
   - The name of the drug should be confirmed by any of the following:
     - Spelling
     - Providing both the brand and generic names of the medication
     - Providing the indication for use
   - In order to avoid confusion with spoken numbers, a dose such as 50 mg should be dictated as "fifty milligrams . . . five zero milligrams" to distinguish from "fifteen milligrams . . . one five milligrams."
   - In order to avoid confusion with drug name modifiers, such as prefixes and suffixes, additional spelling-assistance methods should be used (i.e., S as in Sam, X as in x-ray).
   - Instructions for use should be provided without abbreviations. For example, "1 tab tid" should be communicated as "Take/give one tablet three times daily."
   - Whenever possible, the receiver of the order should ***write*** down the complete order to enter it into a computer, then ***read*** it back, and receive confirmation from the individual who gave the order or test result.
7. All verbal orders should be reduced immediately to writing and signed by the individual receiving the order.
8. Verbal orders should be documented in the patient's medical record, reviewed, and countersigned by the prescriber as soon as possible.

†Health care organizations include community pharmacies, physicians' offices, hospitals, nursing homes, and home care agencies.

prn Orders. Sometimes the prescriber orders a medication to be given only when a patient requires it. This is a prn order. Use objective and subjective assessment and discretion in determining whether or not the patient needs the medication. An example of a prn order is:

Morphine sulfate 2 mg IV q2h prn for incisional pain

This order indicates that the patient needs to wait at least 2 hours between doses and can take the medication if experiencing pain at the incision. When administering medications, document the assessment findings that show why the patient needs the medication and the time of administration. Frequently evaluate the effectiveness of the medication and record findings in the appropriate record. Orders for prn medications that include a range (e.g., morphine sulfate IM 5-10 mg every 4-6 hours) are unclear and a source of medication errors. If a range order is written, ensure that the order follows agency policy for these types of orders. An example of a safer range order is to increase morphine dosage 50% to 100% if pain is moderate to severe.

Single (One-Time) Orders. Sometimes a prescriber orders a medication to be given only once at a specified time. This is common for preoperative medications or medications given before diagnostic examinations, for example:

Ativan 1 mg IV on call to MRI

STAT Orders. A STAT order signifies that a single dose of a medication is to be given immediately and only once. STAT orders are often written for emergencies when a patient's condition changes suddenly. For example:

Apresoline 10 mg IV STAT

Now Orders. A now order is more specific than a one-time order and is used when a patient needs a medication quickly but not right away, as in a STAT order. When receiving a now order,

TABLE 31-7 ISMP List of Error-Prone Abbreviations, Symbols, and Dose Designations

The abbreviations, symbols, and dose designations found in this table have been reported to ISMP through the USP-ISMP Medication Error Reporting Program as being frequently misinterpreted and involved in harmful medication errors. They should NEVER be used when communicating medical information. This includes internal communications, telephone/verbal prescriptions, computer-generated labels, labels for drug storage bins, medication administration records, as well as pharmacy and prescriber computer order entry screens. The Joint Commission (TJC) has established a National Patient Safety Goal that specifies that certain abbreviations must appear on the accredited organization's do-not-use list; we have highlighted these items with a double asterisk (**). However, we hope that you will consider others beyond the minimum TJC requirements. By using and promoting safe practices and educating one another about hazards, we can better protect our patients.

ABBREVIATIONS	INTENDED MEANING	MISINTERPRETATION	CORRECTION
µg	Microgram	Mistaken as "mg"	Use "mcg"
AD, AS, AU	Right ear, left ear, each ear	Mistaken as OD, OS, OU (right eye, left eye, each eye)	Use "right ear," "left ear," or "each ear"
BT	Bedtime	Mistaken as "BID" (twice daily)	Use "bedtime"
cc	Cubic centimeters	Mistaken as "u" (units)	Use "mL"
D/C	Discharge or discontinue	Premature discontinuation of medications if D/C (intended to mean "discharge") has been misinterpreted as "discontinued" when followed by a list of discharge medications	Use "discharge" and "discontinue"
IJ	Injection	Mistaken as "IV" or "intrajugular"	Use "injection"
IN	Intranasal	Mistaken as "IM" or "IV"	Use "intranasal" or "NAS"
HS	Half-strength	Mistaken as bedtime	Use "half-strength" or "bedtime"
hs	At bedtime, hours of sleep	Mistaken as half-strength	Use "bedtime" or "half-strength"
IU**	International unit	Mistaken as IV (intravenous) or 10 (ten)	Use "units"
o.d. or OD	Once daily	Mistaken as "right eye" (OD—oculus dexter), leading to oral liquid medications administered in the eye	Use "daily"
OJ	Orange juice	Mistaken as OD or OS (right or left eye); drugs meant to be diluted in orange juice may be given in the eye	Use "orange juice"
Per os	By mouth, orally	The "os" can be mistaken as "left eye" (OS—oculus sinister)	Use "PO," "by mouth," or "orally"
q.d. or QD**	Every day	Mistaken as q.i.d., especially if the period after the "q" or the tail of the "q" is misunderstood as an "I"	Use "daily"
qhs	Nightly at bedtime	Mistaken as "qhr" or every hour	Use "nightly"
qn	Nightly or at bedtime	Mistaken as "qh" (every hour)	Use "nightly" or "at bedtime"
q.o.d. or QOD**	Every other day	Mistaken as "q.d." (daily) or "q.i.d. (four times daily) if the "o" is poorly written	Use "every other day"
q1d	Daily	Mistaken as q.i.d. (four times daily)	Use "daily"
q6PM, etc.	Every evening at 6 PM	Mistaken as every 6 hours	Use "6 PM nightly" or "6 PM daily"
SC, SQ, sub q	Subcutaneous	SC mistaken as SL (sublingual); SQ mistaken as "5 every"; the "q" in "sub q" has been mistaken as "every" (e.g., a heparin dose ordered "sub q 2 hours before surgery" misunderstood as every 2 hours before surgery)	Use "subcut" or "subcutaneously"
ss	Sliding scale (insulin) or ½ (apothecary)	Mistaken as "55"	Spell out "sliding scale;" use "one-half" or "½"
SSRI	Sliding scale regular insulin	Mistaken as selective-serotonin reuptake inhibitor	Spell out "sliding scale (insulin)"
SSI	Sliding scale insulin	Mistaken as Strong Sol of Iodine (Lugol's)	

Continued

TABLE 31-7 **ISMP List of Error-Prone Abbreviations, Symbols, and Dose Designations—cont'd**

ABBREVIATIONS	INTENDED MEANING	MISINTERPRETATION	CORRECTION
i- /d	One daily	Mistaken as "tid"	Use "1 daily"
TIW or tiw	3 times a week	Mistaken as "3 times a day" or "twice in a week"	Use "3 times weekly"
U or u**	Unit	Mistaken as the number 0 or 4, causing a 10-fold overdose or greater (e.g., 4 U seen as "40" or 4 u seen as "44"); mistaken as "cc" so dose given in volume instead of units (e.g., 4 u seen as 4 cc)	Use "unit"
DOSE DESIGNATIONS AND OTHER INFORMATION	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
Trailing zero after decimal point (e.g., 1.0 mg)**	1 mg	Mistaken as 10 mg if the decimal point is not seen	Do not use trailing zeros for doses expressed in whole numbers
"Naked" decimal point (e.g., .5 mg)**	0.5 mg	Mistaken as 5 mg if the decimal point is not seen	Use zero before a decimal point when the dose is less than a whole unit
Drug name and dose run together (especially problematic for drug names that end in "l" such as Inderal40 mg; Tegretol300 mg)	Inderal 40 mg Tegretol 300 mg	Mistaken as Inderal 140 mg Mistaken as Tegretol 1300 mg	Place adequate space between the drug name, dose, and unit of measure
Numerical dose and unit of measure run together (e.g., 10mg, 100mL)	10 mg 100 mL	The "m" is sometimes mistaken as a zero or two zeros, risking a 10- to 100-fold overdose	Place adequate space between the dose and unit of measure
Abbreviations such as mg. or mL. with a period following the abbreviation	mg mL	The period is unnecessary and could be mistaken as the number 1 if written poorly	Use mg, mL, etc. without a terminal period
Large doses without properly placed commas (e.g., 100000 units; 1000000 units)	100,000 units 1,000,000 units	100000 has been mistaken as 10,000 or 1,000,000; 1000000 has been mistaken as 100,000	Use commas for dosing units at or above 1,000, or use words such as 100 "thousand" or 1 "million" to improve readability
DRUG NAME ABBREVIATIONS	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
ARA A	vidarabine	Mistaken as cytarabine (ARA C)	Use complete drug name
AZT	zidovudine (Retrovir)	Mistaken as azathioprine or aztreonam	Use complete drug name
CPZ	Compazine (prochlorperazine)	Mistaken as chlorpromazine	Use complete drug name
DPT	Demerol-Phenergan-Thorazine	Mistaken as diphtheria-pertussis-tetanus (vaccine)	Use complete drug name
DTO	Diluted tincture of opium, or deodorized tincture of opium (Paregoric)	Mistaken as tincture of opium	Use complete drug name
HCl	hydrochloric acid or hydrochloride	Mistaken as potassium chloride (The "H" is misinterpreted as "K")	Use complete drug name unless expressed as a salt of a drug
HCT	hydrocortisone	Mistaken as hydrochlorothiazide	Use complete drug name
HCTZ	hydrochlorothiazide	Mistaken as hydrocortisone (seen as HCT250 mg)	Use complete drug name
MgSO4**	magnesium sulfate	Mistaken as morphine sulphate	Use complete drug name
MS, MSO4**	morphine sulfate	Mistaken as magnesium sulphate	Use complete drug name
MTX	methotrexate	Mistaken as mitoxantrone	Use complete drug name
PCA	procainamide	Mistaken as patient-controlled analgesia	Use complete drug name
PTU	propylthiouracil	Mistaken as mercaptopurine	Use complete drug name
T3	Tylenol with codeine No. 3	Mistaken as liothyronine	Use complete drug name

TABLE 31-7 ISMP List of Error-Prone Abbreviations, Symbols, and Dose Designations—cont'd

DRUG NAME ABBREVIATIONS	INTENDED MEANING	MISINTERPRETATION	CORRECTION
TAC	triamcinolone	Mistaken as tetracaine, Adrenalin, cocaine	Use complete drug name
TNK	TNKase	Mistaken as "TPA"	Use complete drug name
ZnSO4	zinc sulfate	Mistaken as morphine sulphate	Use complete drug name
STEMMED DRUG NAMES	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
"Nitro" drip	nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name
"Norflox"	norfloxacin	Mistaken as Norflex	Use complete drug name
"IV Vanc"	intravenous vancomycin	Mistaken as Invanz	Use complete drug name
SYMBOLS	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
ʒ	Dram	Symbol for dram mistaken as "3"	Use the metric system
♍	Minim	Symbol for minim mistaken as "mL"	
×3d	For three days	Mistaken as "3 doses"	Use "for three days"
> and <	Greater than and less than	Mistaken as opposite of intended; mistakenly use incorrect symbol; "<10" mistaken as "40"	Use "greater than" or "less than"
/ (slash mark)	Separates two doses or indicates "per"	Mistaken as the number 1 (e.g., "25 units/10 units" misread as "25 units and 110" units)	Use "per" rather than a slash mark to separate doses
@	At	Mistaken as "2"	Use "at"
&	And	Mistaken as "2"	Use "and"
+	Plus or and	Mistaken as "4"	Use "and"
°	Hour	Mistaken as a zero (e.g., q2° seen as q20)	Use "hr," "h," or "hour"

the nurse has up to 90 minutes to administer the medication. Only administer now medications one time. For example:

Vancomycin 1 g IV piggyback now

Prescriptions. The prescriber writes **prescriptions** for patients who are to take medications outside the hospital. The prescription includes more detailed information than a regular order because the patient needs to understand how to take the medication and when to refill the prescription if necessary. Some agencies require prescribers to write prescriptions for controlled substances on a special prescription pad that is different (e.g., a different color) than the prescription pad used for other medications. Fig. 31-6 illustrates the parts of a prescription.

Pharmacist's Role

The pharmacist prepares and distributes prescribed medications. Pharmacists work with nurses, physicians, and other health care providers to evaluate the efficacy of patients' medications. They are responsible for filling prescriptions accurately and being sure that prescriptions are valid. Pharmacists in health care agencies rarely mix compounds or solutions, except in the case of IV solutions. Most medication companies deliver medications in a form ready for use. Dispensing the correct medication, in the proper dosage and amount, with an accurate label is the pharmacist's main task. He or she also provides information about medication side effects, toxicity, interactions, and incompatibilities.

Distribution Systems

Systems for storing and distributing medications vary. Pharmacists provide the medications, but nurses distribute them to patients. Institutions providing nursing care have a special area for stocking and dispensing medications. Special medication rooms, portable locked carts, computerized medication cabinets, and individual storage units next to patients' rooms are examples of storage areas used. Medication storage areas need to be locked when unattended.

Unit Dose. The unit-dose system uses carts containing a drawer with a 24-hour supply of medications for each patient. Each drawer is labeled with the name of the patient in his or her designated room. The unit dose is the ordered dose of medication that the patient receives at one time. Each tablet or capsule is wrapped in a foil or paper container. At a designated time each day the pharmacist or a pharmacy technician refills the drawers in the cart with a fresh supply. The cart also contains limited amounts of prn and stock medications for special situations. Controlled substances are not kept in the individual patient drawer. Instead they are kept

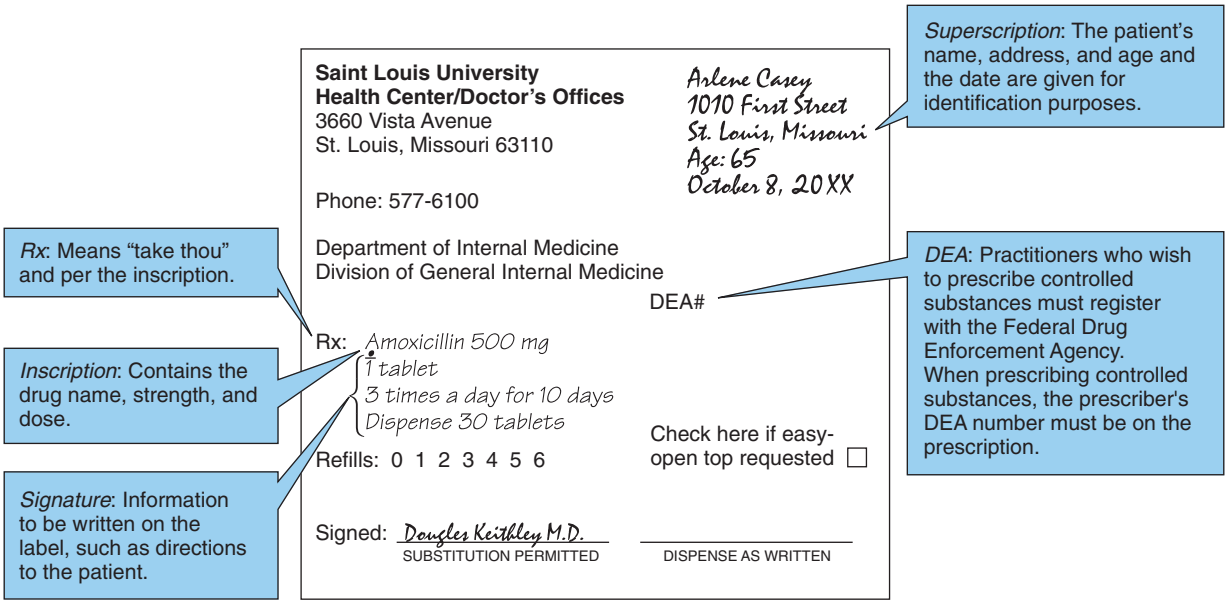

FIG. 31-6 Example of a medication prescription. (Courtesy Saint Louis University Medical Center, St Louis, Mo.)

FIG. 31-7 Automated medication dispensing system.

in a larger locked drawer to keep them secure. The unit-dose system reduces the number of medication errors and saves steps in dispensing medications.

Automated Medication Dispensing Systems. Automated medication dispensing systems (AMDSs) are used throughout the country (Fig. 31-7). The systems within an agency are networked with one another and with other agency computer systems (e.g., computerized medical record). AMDSs control the dispensing of all medications, including narcotics. Each nurse accesses the system by entering a security code. Some systems require bioidentification as well. In these systems you place your finger on a screen to access the computer. You select the patient's name and his or her drug profile before the AMDS dispenses a medication. In these systems you are allowed to select the desired medication, dosage, and route from a list displayed on the computer screen. The system causes the drawer containing medication to open, records it, and charges it to the patient. Systems that are connected to the patient's computerized medical record then record information about the medication (e.g., medication name, dose, time) and the nurse's name in the patient's medical record. Some systems require nurses to scan bar codes to identify the patient, the medication, and the nurse administering the medication before recording this information in the patient's computerized medical record. Agencies that implement AMDS with bar-code scanning often reduce the incidence of medication errors (see Box 31-2).

Nurse's Role

Administering medications to patients requires knowledge and a set of skills that are unique to a nurse. You first assess that the medication ordered is the correct medication. Do not assume that all medications that are in the patient's "drawer" or pillbox are to be given to him or her. Assess the patient's ability to self-administer medications, determine whether a patient should receive a medication at a given time, administer medications correctly, and closely monitor their effects. Patient and family education about proper medication administration and monitoring is an integral part of your role. Do not delegate any part of the medication administration process to nursing assistive personnel (NAP) and use the nursing process to integrate medication therapy into care.

Medication Errors

A **medication error** can cause or lead to inappropriate medication use or patient harm. Medication errors include inaccurate prescribing, administering the wrong medication, giving the medication using the wrong route or time interval, and administering extra doses or failing to administer a medication. Preventing medication errors is essential. The process of administering medications has many steps and involves many members of the health care team. Because nurses play an essential role in preparing and administering medications, they need to be vigilant in preventing errors (Box 31-4). Advances in technology have helped to decrease the occurrence of medication errors (Box 31-5).

Medication errors are related to practice patterns, health care product design, or procedures and systems such as product labeling

BOX 31-4 STEPS TO TAKE TO PREVENT MEDICATION ERRORS

- Prepare medications for one person at a time.
- Follow the six rights of medication administration.
- Be sure to read labels at least three times (comparing medication administration record [MAR] with label) before administering the medication.
- Use at least two patient identifiers and review the patient's allergies whenever administering a medication.
- Do not allow any other activity to interrupt administration of medication to a patient (e.g., phone call, pager, discussion with other staff).
- Double-check all calculations and other high-risk medication administration processes (e.g., patient-controlled analgesia) and verify with another nurse.
- Do not interpret illegible handwriting; clarify with prescriber.
- Question unusually large or small doses.
- Document all medications as soon as they are given.
- When you have made an error, reflect on what went wrong and ask how you could have prevented the error.
- Evaluate the context or situation in which a medication error occurred. This helps to determine if nurses have the necessary resources for safe medication administration.
- Attend in-service programs that focus on the medications commonly administered.
- Ensure that you are well rested when caring for patients. Nurses make more errors when they are fatigued.
- Involve and educate the patient when administering medications. Address patients' concerns about medications before administering them (e.g., concerns about their appearance or side effects).
- Follow established policies and procedures when using technology to administer medications (e.g., automated medication dispensing systems [AMDSs] and bar-code scanning). Medication errors occur when nurses "work around" the technology (e.g., override alerts without thinking about them).

Data from Koppel et al: Workarounds to barcode medication administration systems: their occurrences, causes, and threats to patient safety, *J Am Med Inform Assoc* 15(4):408, 2008; Lockley SW et al: Effects of health care provider work hours and sleep deprivation on safety and performance, *Joint Comm J Qual Patient Safety* 33(11):7, 2007; National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP): Reducing medication errors associated with at-risk behaviors, 2007, http://www.nccmerp.org/council/council2007-06-08.html.

BOX 31-5 INFORMATICS AND MEDICATION SAFETY

Many medication errors occur when the nurse incorrectly administers medications at the patient's bedside. The following innovations and advances in technology have helped reduce the number of medication errors in nursing practice:

- Networked computers allow all the patient's health care providers to see a current list of ordered and discontinued medications.
- Internet and intranet access allows nurses and other health care providers to access current information about medications (e.g., indications, desired effects, adverse effects) and specific agency policies that address medication administration (e.g., how fast to administer an intravenous [IV] push medication, how to administer medications through a nasogastric tube).
- In some agencies prescribers enter medication orders directly into a networked computer system or a personal handheld computer.
- Automated medication dispensing systems and electronic medication administration records (MARs) help with medication reconciliation, administration, and documentation.
- Bar-coding technology requires nurses to scan the medication, the patient's identification bracelet, and the nurse's identification badge before administering the medication, which helps ensure the six rights of medication administration.

Application to Nursing Practice

- Actively participate in selecting and evaluating advanced technologies and creating nursing policies and protocols used for medication administration.
- Always follow agency policies when administering medications.
- Implement agency policies when the technology cannot be used (e.g., during down time or power outages).
- Follow manufacturer guidelines for care of electronic equipment and report problems with technology immediately.

and distribution. When an error occurs, the patient's safety and well-being become the top priority. The nurse first assesses and examines the patient's condition and notifies the health care provider of the incident as soon as possible. Once the patient is stable, the nurse reports the incident to the appropriate person in the institution (e.g., manager or supervisor). The nurse is responsible for preparing a written occurrence or incident report that usually needs to be filed within 24 hours of the error. The report includes patient identification information; the location and time of the incident; an accurate, factual description of what occurred and what was done; and the signature of the nurse involved. The occurrence report is not a permanent part of the medical record and is not referred to anywhere in the record (see Chapters 23 and 26). This legally protects the nurse and institution. Agencies use occurrence reports to track incident patterns and initiate quality improvement programs as needed.

Report all medication errors, including those that do not cause obvious or immediate harm or near misses. It is important to feel comfortable in reporting an error and not fear repercussions from managerial staff. Even when a patient suffers no harm from a medication error, the institution can still learn why the mistake occurred and what can be done to avoid similar errors in the future.

Medication errors often happen when patients experience changes in the health care setting, level of care, or health care provider (e.g., goes to a health care provider's office, transfers from one patient care unit to another, is discharged from a health care setting). Reconciling the list of a patient's medications is essential to medication safety (TJC, 2011a). Nurses play an essential role in **medication reconciliation** (Box 31-6). Whenever a nurse admits a patient to a health care setting, he or she compares the medications that the patient took in the previous setting (e.g., home or another nursing unit) with his or her current medication orders (Mayhew, 2010). When the patient leaves that setting for another setting (e.g., skilled care facility or intensive care unit), the nurse communicates the patient's current medications with the health care providers in the new setting. The nurse also reconciles the patient's medications when he or she is discharged from an agency or is seen in an outpatient setting. Many agencies have computerized or written forms to facilitate the process of medication reconciliation. The process is challenging and takes a lot of time and concentration. Eliminate distractions and go slowly when reconciling patients' medications. Always clarify information when needed. Nurses need to consult with the patient, caregivers, family members, pharmacists, and other members of the health care team when reconciling medications.

BOX 31-6 PROCESS FOR MEDICATION RECONCILIATION

1. **Verify:** Obtain a comprehensive and current list of the patient's medications. Be sure to ask about vitamins, herbal and nutritional supplements, over-the-counter medications, insulin pens, transdermal patches, inhalers, and other medications that people do not typically consider to be medications (Razzi, 2009).
2. **Clarify:** Make sure that the list of medications, dosages, and frequencies is accurate; clarify the list with as many people as necessary (e.g., patient, caregiver, health care providers, pharmacists) to ensure accuracy.
3. **Reconcile:** Compare new medication orders with the current list; investigate any discrepancies with the patient's health care provider. Use computerized medical records and computerized prescriber order entry when possible to help with this process (Razzi, 2009).
4. **Transmit:** Communicate the updated and verified list to caregivers and the patient as appropriate. Teach patients to carry list of current medications and share with all health care providers (Razzi, 2009).

CRITICAL THINKING

Knowledge

You will use knowledge from many disciplines when administering medications to understand why a particular medication is prescribed for a patient and how the medication will alter the patient's physiology to have a therapeutic effect. For example, in physiology you learn that potassium is a major intracellular ion. When patients do not have enough potassium in their body (hypokalemia), they experience signs and symptoms such as muscle fatigue or weakness. In some cases severe hypokalemia is fatal as a result of associated cardiac dysrhythmias. Prescribed medications help to restore the patient's potassium level to normal, which then relieves the signs and symptoms of hypokalemia. In another example knowledge about child development indicates that children often associate medication administration with a negative experience. Use principles from child development to ensure that the child cooperates with the medication experience.

Nurses administer a variety of medications, and new medications are constantly approved. As a result, they do not always have knowledge about the medications they are asked to administer. Critical thinkers admit what they do not know and acquire the knowledge needed to safely administer unfamiliar medications. This means consulting more expert nurses, a pharmacist, the prescriber, or a medication book.

Experience

Nursing students have limited experience with medication administration as it applies to professional practice. Clinical experiences provide you with opportunities to use the nursing process as it applies to medication administration. As you gain experience in medication administration, your psychomotor skills ("the how-to") become more refined. However, psychomotor skills represent a small part of medication administration. Patient attitudes, knowledge, physical and mental status, and responses make medication administration a complex experience.

Attitudes

To administer medications safely, many critical thinking skills are essential. For example, be disciplined and take adequate time to prepare and administer medications. Take the time to read your patient's medical record before administering medications and carefully review his or her history, physical examination, and orders. Look up medications that you do not know in a medication reference and determine why each patient is taking each of his or her prescribed medications. Every step of safe medication administration requires a disciplined attitude and a comprehensive, systematic approach. Following the same procedure each time medications are administered ensures safe administration.

Responsibility and accountability are other critical thinking attitudes essential to safe medication administration. Accept full accountability and responsibility for all actions surrounding the administration of medications. Do not assume that a medication that is ordered for a patient is the correct medication or the correct dose. Be responsible for knowing that the medications and doses ordered are correct and appropriate. You are accountable if you give an ordered medication that is knowingly inappropriate for the patient. Therefore be familiar with each therapeutic effect, usual dosage, anticipated changes in laboratory data, and side effects of a drug. You are also responsible for ensuring that patients or caregivers who self-administer medications have been properly informed about all aspects of self-administration (TJC, 2010). If it is determined that a patient cannot safely self-administer medications, design interventions such as involving family caregivers to ensure safe self-administration of medications.

Standards

Standards are actions that ensure safe nursing practice. Standards for medication administration are set by individual health care agencies and the nursing profession. Agency policy usually sets limits on the nurse's ability to administer medications in certain units of the acute care setting. Sometimes nurses are limited by certain medication routes or dosages. Most institutions have nursing procedure manuals that contain policies that define the types of medications nurses can and cannot administer. The types and dosages of medications that nurses deliver often vary from unit to unit within the same facility. For example, phenytoin (Dilantin), a powerful medication for treating seizures, may be administered by mouth or IV push. In large dosages phenytoin affects heart rhythm. Therefore some agencies place limits on how much nurses can give to a patient on a nursing unit that does not have the ability to monitor the patient's heart rate and rhythm. Not all prescribers are aware of all of the limitations and sometimes prescribe medications that nurses cannot give in a particular health care setting. Recognize these limitations and inform the prescriber accordingly. Take appropriate actions to ensure that patients receive medications as prescribed and within the time prescribed in the appropriate environment.

Professional standards such as *Nursing: Scope and Standards of Practice* (American Nurses Association [ANA], 2010) (see Chapters 1 and 23) apply to the activity of medication administration. To prevent medication errors, follow the six rights of medication administration consistently every time you administer medications. Many medication errors can be linked, in some way, to an inconsistency in adhering to these six rights:

1. The right medication
2. The right dose
3. The right patient
4. The right route
5. The right time
6. The right documentation

Right Medication. A medication order is required for every medication that you administer to a patient. Sometimes prescribers

write orders by hand in the patient's medical record. However, many agencies use CPOE. CPOE allows prescribers to electronically order medications, eliminating the need for written orders and enhancing medication safety (Sowan et al., 2010). Regardless of how the nurse receives a medication order, he or she compares the prescriber's written orders with the medication administration record (MAR) or electronic medication administration record (eMAR) when it is initially ordered. Nurses verify medication information whenever new MARs are created or distributed or when patients transfer from one nursing unit or health care setting to another (TJC, 2011a).

Once you determine that information on the patient's MAR is accurate, use it to prepare and administer medications. When preparing medications from bottles or containers, compare the label of the medication container with the MAR three times: (1) before removing the container from the drawer or shelf, (2) as the amount of medication ordered is removed from the container, and (3) at the patient's bedside before administering the medication to the patient. Never prepare medications from unmarked containers or containers with illegible labels (TJC, 2010). With unit-dose prepackaged medications, check the label with the MAR when taking medications out of the medication dispensing system. Finally verify all medications at the patient's bedside with the patient's MAR and use at least two identifiers before giving the patient any medications (TJC, 2011a).

Patients who self-administer medications need to keep them in their original labeled containers, separate from other medications, to avoid confusion. Many hospitals request that all medication administration in the hospital setting be completed through nurses rather than letting patients self-administer to ensure that patients are not receiving double doses. Because the nurse who administers the medication is responsible for any errors related to it, nurses administer only the medications they prepare. You cannot delegate preparation of medication to another person and then administer the medication to the patient. If a patient questions the medication, do not ignore these concerns. An alert patient or a family caregiver familiar with a patient's medications knows whether a medication is different from those received before. In most cases the patient's medication order has changed; however, some patient questions reveal an error. When this occurs, withhold the medication and recheck it against the prescriber's orders. If a patient refuses a medication, discard it rather than returning it to the original container. Unit-dose medications can be saved if they are not opened. If a patient refuses narcotics, follow proper hospital procedure by having someone else witness the "wasted" medication.

Right Dose. The unit-dose system is designed to minimize errors. When preparing a medication from a larger volume or strength than needed or when the prescriber orders a system of measurement different from that which the pharmacy supplies, the chance of error increases. When performing medication calculations or conversions, have another qualified nurse check the calculated doses. After calculating doses, prepare the medication using standard measurement devices. Use graduated cups, syringes, and scaled droppers to measure medications accurately. At home have patients use kitchen measuring spoons rather than household teaspoons and tablespoons, which vary in volume.

Medication errors often occur when pills need to be split. To promote patient safety in inpatient settings, pharmacists split the medications, label and package them, and then send them to the nurse for administration. Because pill splitting is particularly problematic in the home care setting, the Institute for Safe Medication Practices (ISMP) (2006) developed suggestions to help with this process. Determine if the patient has the motor dexterity or visual acuity to split tablets. If at all possible, prescribers need to avoid ordering medications that require splitting.

Tablets are sometimes crushed and mixed with food. Be sure to completely clean a crushing device before crushing the tablet. Remnants of previously crushed medications increase the concentration of a medication or result in the patient receiving a portion of a medication that was not prescribed. Mix crushed medications with very small amounts of food or liquid (e.g., a single tablespoon). Do not use the patient's favorite foods or liquids because medications alter their taste and decrease the patient's desire for them. This is especially a concern for pediatric patients.

Not all medications are suitable for crushing. Some medications (e.g., extended-release capsules) have special coatings to prevent them from being absorbed too quickly. These medications should not be crushed. Refer to the "Do Not Crush List" (ISMP, 2010d, http://www.ismp.org/Tools/DoNotCrush.pdf) to ensure that a medication is safe to crush.

Right Patient. Medication errors often occur because one patient gets a drug intended for another patient. Therefore an important step in safe medication administration is being sure that you give the right medication to the right patient. It is difficult to remember every patient's name and face. Before administering a medication, use at least two patient identifiers (TJC, 2010). Acceptable patient identifiers include the patient's name, an identification number assigned by a health care agency, or a telephone number. Do not use the patient's room number as an identifier. To identify a patient correctly in an acute care setting, compare the patient identifiers on the MAR with the patient's identification bracelet while at the patient's bedside. If an identification bracelet becomes smudged or illegible or is missing, obtain a new one. In health care settings that are not acute care settings, TJC (2008) does not require the use of armbands for identification. However, nurses still need to use a system that verifies the patient's identification with at least two identifiers before administering medications.

Patients do not need to state their names and other identifiers when administering medications. Collect patient identifiers reliably when the patient is admitted to a health care setting. Once the identifiers are assigned to the patient (e.g., putting identifiers on an armband and placing the armband on the patient), the nurse uses the identifiers to match the patient with the MAR, which lists the correct medications. Asking patients to state their full names and identification information provides a third way to verify that the nurse is giving medications to the right patient.

In addition to using two identifiers, some agencies use a wireless bar-code scanner to help identify the right patient (Fig. 31-8). This system requires the nurse to scan a personal bar code that is commonly placed on the nurse's name tag first. Then he or she scans a bar code on the single-dose medication package. Finally the nurse scans the patient's armband. All this information is then stored in a computer for documentation purposes. This system helps eliminate medication errors because it provides another step to ensure that the right patient receives the right medication.

Right Route. Always consult the prescriber if an order does not designate a route of administration. Likewise, if the specified route is not the recommended route, alert the prescriber immediately. Recent evidence shows that medication errors involving the wrong route are common. For example, enteral and parenteral medications are at risk for confusion in the pediatric population because liquid medications are frequently given orally. When oral medications are prepared in parenteral syringes, there is a high risk for giving an oral medication through the parenteral route (ISMP,

FIG. 31-8 Nurse using bar-code scanner to identify patient during medication administration.

2010c; Paparella, 2008). The injection of a liquid designed for oral use produces local complications such as sterile abscess or fatal systemic effects. Prepare injections from preparations designed for parenteral use only. Medication companies label parenteral medications "for injectable use only." Label the syringe after preparing the medication and always use different syringes for enteral and parenteral medication administration (ISMP, 2010c). The enteral syringes are often a different color than the parenteral syringes and are clearly labeled for oral or enteral use. The syringe tips of enteral syringes are incompatible with parenteral medication administration systems. Needles do not attach to the syringes, and the syringes cannot be inserted into any type of IV line. In addition, be sure to remove any caps from the tip of an oral syringe before administering the medication. Failure to remove the cap can result in the patient aspirating it, thus blocking his or her trachea (Guenter, 2010; Paparella, 2008).

Right Time. In addition, you need to know why a medication is ordered for certain times of the day and whether you are able to alter the time schedule. For example, two medications are ordered, one q8h (every 8 hours) and the other 3 times a day. Both medications are scheduled for 3 times within a 24-hour period. The prescriber intends the q8h medication to be given around-the-clock to maintain therapeutic blood levels of the medication. In contrast, the nurse needs to give the 3-times-a-day medication during the waking hours. Each agency has a recommended time schedule for medications ordered at frequent intervals. You can alter these recommended times if necessary or appropriate.

The prescriber often gives specific instructions about when to administer a medication. A preoperative medication to be given "on call" means that the nurse gives the medication when the operating room staff members notify him or her that they are coming to get the patient for surgery. Give a medication ordered PC (after meals) within half an hour after a meal, when the patient has a full stomach. Give a STAT medication immediately.

Give priority to time-critical medications that must act and therefore be given at certain times. Hospitals designate which medications are time-critical and which are non–time-critical (CMS, 2011; ISMP, 2011). You administer time-critical medications within 30 minutes before or after their scheduled time. For example, give insulin (a time-critical medication) at a precise interval before a meal. Give antibiotics 30 minutes before or after they are scheduled, around-the-clock to maintain therapeutic blood levels. Give all routinely ordered non–time-critical medications within 1 to 2 hours before or after the scheduled time or per agency policy (CMS, 2011; ISMP, 2011).

Some medications require the nurse's clinical judgment in deciding the proper time for administration. Administer a prn sleeping medication when the patient is prepared for bed. In addition, use judgment when administering prn analgesics. For example, the nurse sometimes needs to obtain a STAT order from the prescriber if the patient requires a medication before the prn interval has elapsed. Nurses always document whenever they call the patient's health care provider to obtain a change in a medication order.

Before discharge from the hospital setting, evaluate a patient's need for home care, especially if he or she was admitted to the hospital because of a problem with medication self-administration. Patients often leave the hospital with a basic knowledge of their medications but are unable to remember or implement this knowledge once back home. Before patients are discharged from the hospital, evaluate whether the medications are adequate or prescribed at therapeutic levels for them.

At home some patients take several medications throughout the day. Help to plan schedules based on preferred medication intervals, the pharmacokinetics of the medications, and the patient's daily schedule. For patients who have difficulty remembering when to take medications, make a chart that lists the times to take each medication or prepare a special container to hold each timed dose.

Right Documentation. Nurses and other health care providers use accurate documentation to communicate with one another. Many medication errors result from inaccurate documentation. Therefore always document medications accurately at the time of administration and verify any inaccurate documentation before giving medications.

Before administering a medication, ensure that the MAR clearly reflects the patient's full name; the name of the ordered medication written out in full (no medication name abbreviations); the time the medication is to be administered; and the dosage, route, and frequency. Common problems with medication orders include incomplete information; inaccurate dosage form or strength; illegible order or signature; incorrect placement of decimals, leading to the wrong dosage; and nonstandard terminology. If there is any question about a medication order because it is incomplete, illegible, vague, or not understood, contact the prescribing health care provider before administering the medication. The prescribing health care provider is responsible to provide accurate, complete, and understandable medication orders. If health care providers are unable to do this, nurses implement agency policy (usually a "chain of command" policy) to determine who to contact until they resolve issues related to patients' medications. You are responsible to begin this chain of command to ensure that patients receive the correct medication. You are also responsible for documenting any preassessment data required of certain medications such as a blood pressure measurement for antihypertensive medications or laboratory values, as in the case of phenytoin, before giving the drug.

After administering a medication, indicate which medication was given on the patient's MAR per agency policy to verify that it was given as ordered. Record each medication on the patient's MAR as soon as you give medications to a patient. Inaccurate documentation such as failing to document giving a medication or documenting an incorrect dose leads to errors in subsequent decisions about patient care. For example, errors in documentation about insulin often result in negative patient outcomes. Consider the following

BOX 31-7 NURSES' SIX RIGHTS FOR SAFE MEDICATION ADMINISTRATION

1. The right to a complete and clearly written order
2. The right to have the correct drug route and dose dispensed
3. The right to have access to information
4. The right to have policies on medication administration
5. The right to administer medications safely and identify problems in the system
6. The right to stop, think, and be vigilant when administering medications

From Cook MC: Nurses' six rights for safe medication administration, *Mass Nurse* 69(6):8, 1999.

situation: a patient receives insulin before breakfast, but the nurse who gave the insulin forgot to document it. The nurse caring for the patient goes home, and the patient has a new nurse for the day. The new nurse notices that the insulin is not documented and assumes that the previous nurse did not give the insulin. Therefore the new nurse gives the patient another dose of insulin. Approximately 2 hours later, the patient experiences a low blood glucose level, which causes him or her to have seizures. Accurate documentation would have prevented this situation from happening.

Never document that you have given a medication until you have actually given it. The name of the medication, the dose, the time of administration, and the route all need to be documented on the MAR. Also document the site of any injections and the patient's responses to medications, either positive or negative. Nurses notify the patient's health care provider of any negative responses to medications and document the time, date, and name of the health care provider that was notified in the patient's medical record. The efforts you make in ensuring proper documentation help provide safe care (Box 31-7).

Maintaining Patients' Rights. In accordance with *The Patient Care Partnership* (American Hospital Association, 2003) and because of the potential risks related to medication administration, a patient has the following rights:

- To be informed of the name, purpose, action, and potential undesired effects of a medication
- To refuse a medication regardless of the consequences
- To have qualified nurses or physicians assess a medication history, including allergies and use of herbals
- To be properly advised of the experimental nature of medication therapy and give written consent for its use
- To receive labeled medications safely without discomfort in accordance with the six rights of medication administration
- To receive appropriate supportive therapy in relation to medication therapy
- To not receive unnecessary medications
- To be informed if medications are a part of a research study

Know these rights and handle all inquiries by patients and families courteously and professionally. Do not become defensive if a patient refuses medication therapy, recognizing that every person of consenting age has a right to refusal.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

BOX 31-8 NURSING ASSESSMENT QUESTIONS

- Which prescription and nonprescription medications and herbal and nutritional supplements do you take, when do you take them, and how do you take them? Do you have a list of medications from your pharmacy or health care provider's office?
- Why do you take the medications?
- Which side effects have you experienced?
- What have you been told to do if a side effect develops?
- Have you ever stopped taking your medications? If so, why?
- What do you do to help you remember to take your medications?
- Do you have any allergies to medications or foods? If so, describe what happens when you take the medication or eat the food.
- Describe your normal eating patterns. Which foods and at what times do you normally eat?
- How do your religious or cultural beliefs influence your beliefs about your medications?
- How do you pay for your medications? Do you sometimes have to stretch your budget to afford them or space them out to save money?
- What questions do you have about your medications?

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Use professional knowledge, skills, and attitudes to provide compassionate and coordinated care. This requires you to take the patient's preferences, values, and needs into consideration while determining his or her need for and potential response to medication therapy. Assess patients' experiences and encourage them to express their beliefs, feelings, and concerns about their medications. Putting patients in the center of their care helps you to see the situation through their eyes and contributes to safe medication administration. Begin your assessment by asking a variety of questions that help you better understand your patients' current medication management routine, the ability to afford medications, and beliefs and expectations about medications (Box 31-8).

History. Before administering medications, obtain or review the patient's medical history. A patient's medical history provides indications or contraindications for medication therapy. Disease or illness places patients at risk for adverse medication effects. For example, if a patient has a gastric ulcer, medications containing aspirin increase the likelihood of bleeding. Long-term health problems (e.g., diabetes or arthritis) require specific medications. This knowledge helps the nurse anticipate the type of medications that a patient requires. A patient's surgical history indicates use of medications. For example, after a thyroidectomy a patient requires thyroid hormone replacement.

Allergies. Inform the other members of the health care team if the patient has a history of allergies to medications and foods. Many medications have ingredients also found in food sources. For example, propofol (Diprivan), which is used for anesthesia and sedation, includes egg lecithin and soybean oil as inactive ingredients. Therefore patients who have an egg or soy allergy should not receive propofol (Skidmore-Roth, 2011). In some health care settings patients wear identification bands listing medication and food allergies. Ensuring that all allergies and the patient's reactions are noted on the patient's admission notes, medication records, and

history and physical examination facilitates communication of this essential information to members of the health care team.

Medications. Assess information about each medication that the patient takes, including length of time the medication has been taken, the current dosage, and whether or not the patient experiences side effects or has had adverse effects from the medication. In addition, review the action, purpose, normal dosage, routes, side effects, and nursing implications for administering and monitoring each medication. Often you need to consult several resources to gather necessary information. Pharmacology textbooks and handbooks; electronic medication manuals available on a computer, handheld computer, or AMDS; nursing journals; the *Physician's Desk Reference* (PDR); medication package inserts; and pharmacists are valuable resources. Nurses are responsible for knowing as much as possible about each medication given.

Diet History. A diet history reveals a patient's normal eating patterns and food preferences. An effective dosage schedule is planned around them. Teach the patient to avoid foods that interact with medications. In addition, some medications are more effective when taken with meals; teach patients about specific medications that must be taken with food.

Patient's Perceptual or Coordination Problems. A patient with perceptual fine-motor or coordination limitations has difficulty self-administering medication. For example, a patient who takes insulin to manage blood glucose and has arthritis has difficulty manipulating a syringe. Assess the patient's ability to prepare doses and take medications correctly. If the patient is unable to self-administer medications, assess if family or friends are available to assist or make a home care referral.

Patient's Current Condition. The ongoing physical or mental status of a patient affects whether a medication is given or how it is administered. *Assess a patient carefully before giving any medication.* For example, check the patient's blood pressure before giving an antihypertensive. A patient who is nauseated is probably unable to swallow a tablet. Notify the patient's health care provider if he or she is unable to take a medication. Assessment findings serve as a baseline in evaluating the effects of medication therapy.

Patient's Attitude About Medication Use. The patient's attitude about medications sometimes reveals a level of medication dependence or drug avoidance. Some patients do not express their feelings about taking a particular medication, particularly if dependence is a problem. Observe the patient's behavior for evidence of dependence or avoidance. Also be aware that his or her cultural beliefs about Western medicine sometimes interfere with medication compliance (Box 31-9; see Chapter 9).

Patient's Understanding of and Adherence to Medication Therapy. The patient's knowledge and understanding of medication therapy influence the willingness or ability to follow a medication regimen. If the patient has a history of poor adherence (e.g., frequently missed doses or failure to fill prescriptions), investigate if he or she can afford prescribed medications and review resources available for purchase of medications if indicated. Also determine if the patient understands the purpose of the medication, the importance of regular dosage schedules, proper administration methods, and the possible side effects. Without adequate knowledge and motivation, adherence to medication schedules is unlikely.

Patient's Learning Needs. Health-related information is difficult to understand because of the use of technical terminology. Serious errors can occur when patients do not understand information about their medications. Assess patients' health literacy regarding medication administration to determine their need for instruction (Cornett, 2009) (see Chapter 25). Consider patient responses to assessment questions that you ask about medications such as those listed in Box 31-8. When a patient is unable to answer questions about medications appropriately, assess him or her for challenges in health literacy.

BOX 31-9 CULTURAL ASPECTS OF CARE

Influences in Medication Administration

Health beliefs vary by culture and often influence how patients manage and respond to drug therapy. Significant differences in values, beliefs, and attitudes affect a patient's adherence to drug therapy. For example, cultures attach different symbolic meanings to medications and drug therapy. Herbal remedies and alternative therapies are common in various cultures and ethnic groups and interfere with prescribed medications. People from some cultures stop taking medications when their symptoms are resolved, even if the medications are still needed for management of a chronic illness (Krueger, 2009; Qureshi, 2010). In addition, health beliefs often differ markedly between health providers and patients, which further affects a patient's compliance with medical therapy (Krueger, 2009). Demographic changes in both age and race are factors that affect nursing practice in medication administration. In addition to the psychosocial aspect of medication therapy, pharmacological research has shown that different ethnic and racial groups experience differences in drug response, metabolism, and side effects.

Implications for Practice

- Assess cultural beliefs, attitudes, and values when administering and teaching patients about their medications.
- Resolve conflicts between medications and cultural beliefs to achieve optimal patient outcomes.
- Investigate if the patient practices any alternative therapies or is taking any herbal preparations.
- Consider cultural influences on drug response, metabolism, and side effects if a patient is not responding to drug therapy as expected. A change in the patient's medication is sometimes necessary.
- Assess food preferences that may interfere with patients' medication therapy (Giger and Davidhizar, 2008).

NURSING DIAGNOSIS

Assessment provides data about the patient's condition, ability to self-administer medications, and medication adherence, which determine actual or potential problems with medication therapy. Certain data are defining characteristics that, when clustered together, reveal nursing diagnoses. For example, *ineffective self-health management related to complexity of medical regimen* is indicated when patients do not respond as expected to their medications and admit to having difficulty in managing them. This list of nursing diagnoses may apply to patients during the administration of medications:

- Anxiety
- Ineffective health maintenance
- Readiness for enhanced immunization status
- Deficient knowledge (medications)
- Noncompliance (medications)
- Disturbed visual sensory perception
- Impaired swallowing
- Effective therapeutic regimen management

After selecting the diagnosis, identify the related factor, which drives the selection of nursing interventions. In the example of

ineffective self-health management, the related factor of inadequate resources versus lack of knowledge requires different interventions. If the patient's nursing diagnosis is related to inadequate finances, collaborate with family members, social workers, or community agencies to help him or her receive necessary medications. If the related factor is lack of knowledge, implement a teaching plan with appropriate follow-up.

PLANNING

Always organize your care activities to ensure the safe administration of medications. Hurrying to give patients medications leads to errors. It is important to minimize distractions or interruptions when preparing and administering medications (Brady, Malone, and Fleming, 2009).

Goals and Outcomes. Setting goals and related outcomes contributes to patient safety and allows for wise use of time during medication administration. For example, the nurse establishes the following goal and related outcomes for a patient with newly diagnosed type 2 diabetes:

Goal: The patient will safely administer all ordered medications before discharge.

Outcomes:

- The patient will verbalize understanding of desired and adverse effects of medications.
- The patient will state signs, symptoms, and treatment of hypoglycemia.
- The patient will be able to monitor blood glucose levels to determine if medication is appropriate to take or if a low blood glucose level should be treated.
- The patient will establish a daily routine that will coordinate timing of medication with mealtimes.

Setting Priorities. Prioritize care when administering medications. Use information gathered from the patient's assessment in determining which medications to give first and if it is appropriate to administer prn medications. For example, if a patient is in pain, it is important to provide pain medication as soon as possible. If the patient's blood pressure is elevated, administer the blood pressure medications before other medications. Nurses also prioritize when providing patient education about medications. Provide the most important information about the medications first. For example, hypoglycemia is a serious side effect of insulin. The patient taking insulin needs to be able to identify and treat hypoglycemia immediately; thus first teach him or her about the recognition and treatment of hypoglycemia before teaching about how to administer the injection.

Teamwork and Collaboration. Collaborate with a variety of health care providers when administering medications. First it is important to collaborate with the patient's family or friends whenever possible. Family members often reinforce the importance of medication regimens in the home setting. Nurses often collaborate with the prescriber, the pharmacist, and case managers to ensure that patients are able to afford their medications. On discharge ensure that patients know where and how to obtain medications. Be sure that patients are able to read medication labels and printed medication teaching sheets. Some patients also need to understand how to calculate dosages and prepare complex medication regimens. Collaborate with community resources (e.g., agency on aging, public health department, medical interpreters) when patients are illiterate or have difficulty understanding medication instructions (see Chapter 25).

IMPLEMENTATION

Health Promotion. In promoting or maintaining a patient's health, the nurse identifies factors that improve or diminish well-being. Health beliefs, personal motivations, socioeconomic factors, and habits (e.g., excessive alcohol intake) influence the patient's adherence with medications. Several nursing interventions promote adherence to the medication regimen and foster independence. Teach the patient and family about the benefit of a medication and the knowledge needed to take it correctly and integrate the patient's health beliefs and cultural practices into the treatment plan. Help the patient and family establish a medication routine that fits into the patient's normal schedule. Make referrals to community resources if the patient is unable to afford or cannot arrange transportation to obtain necessary medications.

Patient and Family Teaching. Patients may take medications incorrectly or not at all unless they are properly informed about them. Follow principles of patient education (see Chapter 25). Provide information about the purpose of medications and their actions and effects in a way that patients can understand. Many health care agencies offer easy-to-read teaching sheets about specific types of medications. Patients need to know how to take medications properly and the risks associated with failing to do so. For example, after receiving a prescription for an antibiotic, a patient needs to understand the importance of taking the full prescription. Failure to do this can lead to a worsening of the condition and the development of bacteria resistant to the medication.

Nurses teach patients how to correctly administer their medications. For example, teach a patient how to accurately measure a liquid medication. Provide special education to patients who depend on daily injections (Box 31-10). The patient learns to prepare and administer an injection correctly using aseptic technique. Teach family members or friends how to give injections in case the patient becomes ill or physically unable to handle a syringe. Provide specially designed equipment such as syringes with enlarged calibrated scales or medications with labels in Braille when patients have visual alterations.

Patients need to know the symptoms of medication side effects or toxicity. For example, patients taking anticoagulants learn to notify their health care providers immediately when signs of bleeding or bruising develop. Inform family members or friends of medication side effects such as changes in behavior because they are often the first persons to recognize such effects. Patients cope better with problems caused by medications if they understand how and when to act. All patients need to learn the basic guidelines for medication safety, which ensure the proper use and storage of medications in the home.

Acute Care. Patients are often hospitalized to receive expert nursing observation and documentation of responses to medications. When a nurse receives a medication order, several nursing interventions are essential for safe and effective medication administration.

Receiving, Transcribing, and Communicating Medication Orders. An order is required to administer any medication. Many health care agencies use CPOE. In these systems health care providers directly enter orders for their patients into the computer. Current evidence shows that CPOE helps to reduce medication errors and mortality rates (Longhurst et al., 2010). In the absence of CPOE, the health care provider handwrites orders onto an order sheet in the patient's chart. If orders are handwritten, be sure that medication names, dosages, and symbols are legible. Rewrite any unclear or illegible transcribed orders.

BOX 31-10 PATIENT TEACHING

Safe Insulin Administration

Objective

- Patient will correctly self-administer subcutaneous insulin.

Teaching Strategies

- Teach patient how to determine if insulin is expired.
- Instruct patient to keep medication in its original labeled container and refrigerated if needed.
- Demonstrate how to prepare a single insulin preparation.
- Assess visual acuity to ensure that patient is able to draw up the appropriate amount of insulin. Coach patient through the steps of administering subcutaneous insulin injection.
- Demonstrate how to rotate insulin injection sites.
- Help patient determine the amount of insulin required based on the results of home capillary glucose monitoring as ordered by the health care provider.
- Show patient how to keep a daily logbook for insulin injections, including results of home capillary glucose monitoring, type and amount of insulin given, expiration date on insulin vial, time of insulin injection, and injection site used.

Evaluation

- Ask patient to describe procedure used at home for determining the correct dose of insulin needed and injection site.
- Watch patient prepare insulin dose based on results of capillary glucose monitoring, select injection site, and self-administer injection.
- Review information recorded in patient logbook for completeness.
- If patient is unable to prepare the correct amount of insulin or self-administer safely, instruct a family caregiver and notify the health care provider.

BOX 31-11 COMPONENTS OF MEDICATION ORDERS

A medication order is incomplete unless it has the following parts:

Patient's full name: The patient's full name distinguishes the patient from other persons with the same last name. In the acute care setting patients are sometimes assigned special identification numbers (e.g., medical record number) to help distinguish patients with the same names. This number is often included on the order form.

Date and time that the order is written: The day, month, year, and time need to be included. Designating the time that an order is written helps clarify when certain orders are to start and stop. If an incident occurs involving a medication error, it is easier to document what happened when this information is available.

Medication name: The health care provider orders a medication by its generic or trade name. Correct spelling is essential in preventing confusion with medications with similar spelling.

Dose: The amount or strength of the medication is included.

Route of administration: The health care provider uses accepted abbreviations for medication routes. Accuracy is important to ensure that patients receive medications by the intended route.

Time and frequency of administration: The nurse needs to know what time and how frequently to administer medications. Orders for multiple doses establish a routine schedule for medication administration.

Signature of health care provider: The signature makes an order a legal request.

The process of verifying medical orders varies among health care agencies. Nurses follow agency policy and current national patient safety standards when receiving, transcribing, and communicating medication orders. *Nursing students are prohibited from receiving verbal and telephone orders.*

Medication orders need to contain all of the elements in Box 31-11. If the medication order is incomplete, inform the prescriber and ensure completeness before carrying it out. Nurses read back verbal or telephone orders to the prescriber to ensure that the correct order is obtained. The registered nurse follows institutional policy regarding receiving, recording, and transcribing verbal and telephone orders. Generally the prescriber must sign them within 24 hours.

Nurses and pharmacists check all medication orders for accuracy and thoroughness several times during the transcription process. They also take patients' current problems, treatments, laboratory values, and other prescribed medications into consideration to determine if the ordered medication is safe and appropriate. Once the nurse and pharmacist determine that a medication order is safe and appropriate, it is placed on the appropriate medication form, usually called the *MAR*. The MAR is either printed out on paper or is available electronically. An electronic version of the MAR is called an *eMAR*. Whether it is handwritten, printed out from a computer, or in an electronic version, it includes the patient's name, room, and bed number, medical record number, medical and food allergies, other patient identifiers (e.g., birth date); and medication name, dose, frequency, and route and time of administration. Each time a medication dose is prepared, the nurse refers to the MAR.

It is essential to verify the accuracy of every medication you give to your patients with the patients' orders. If the medication order is incomplete, incorrect, or inappropriate or if there is a discrepancy between the original order and the information on the MAR, consult with the prescriber. Do not give the medication until you are certain that you can follow the six rights of medication administration. When you give the wrong medication or an incorrect dose, *you* are legally responsible for the error.

Accurate Dose Calculation and Measurement. When measuring liquid medications, use standard measuring containers. The procedure for medication measurement is systematic to lessen the chance of error. Calculate each dose when preparing the medication, pay close attention to the process of calculation, and avoid interruptions from other people or nursing activities. Ask another nurse to double-check your calculations against the original medication order if you are *ever* in doubt about the accuracy of your calculation or if you are calculating a new or unusual dose.

Correct Administration. For safe administration follow the six rights of medication administration. Verify the patient's identity by using at least two patient identifiers (TJC, 2011a). In the acute care setting identifiers are usually on a patient's armband. Carefully compare the patient identifiers with the MAR to ensure that you are giving the medication to the right patient. When they are able, you can also ask patients to state their name as a third identifier. Use aseptic technique and proper procedures when handling and giving medications and perform necessary assessments (e.g., assess heart rate before giving antidysrhythmic medications) before administering a medication to a patient. Carefully monitor the patient's response to the medication, especially when he or she receives the first dose of a new medication.

Recording Medication Administration. Follow all agency policies when documenting medication administration. After administering a medication, record the name of the medication, dose, route, and exact time of administration immediately on the appropriate record form. Include the site of any injections per agency policy.

If a patient refuses a medication or is undergoing tests or procedures that result in a missed dose, explain the reason that the medication was not given in the nurses' notes. Some agencies require the nurse to circle the prescribed administration time on the medication record or to notify the health care provider when a patient misses a dose. Be aware of the effects that missing doses have on a patient (e.g., with hypertension or diabetes). Coordinating care with health care providers and other services when testing or diagnostic procedures are being completed helps to ensure patient safety and therapeutic control of the disease.

Restorative Care. Because of the numerous types of restorative care settings, medication administration activities vary. Patients with functional limitations often require a nurse to fully administer all medications. In the home care setting patients usually administer their own medications or receive assistance from family caregivers. Regardless of the type of medication activity, the nurse remains responsible for instructing patients and families in medication action, administration, and side effects. The nurse is also responsible for monitoring compliance with medication and determining the effectiveness of medications that have been prescribed.

Special Considerations for Administering Medications to Specific Age-Groups. A patient's developmental level is a factor for nurses to consider when administering medications. Knowledge of developmental needs helps you anticipate responses to medication therapy.

Infants and Children. Children vary in age; weight; surface area; and the ability to absorb, metabolize, and excrete medications. Children's doses are lower than those of adults; thus special caution is necessary when preparing medications for them. Medications are usually not prepared and packaged in standardized dose ranges for children. Preparing an ordered dose from an available amount requires careful calculation. In many pediatric settings the standard of practice is to have another nurse verify all pediatric dose calculations prior to administration.

All children require special psychological preparation before receiving medications. The child's parents are often valuable resources for determining the best way to give the child medication. Sometimes it is less traumatic for the child if a parent gives the medication and the nurse supervises. Supportive care is necessary if a child is expected to cooperate. Explain the procedure to a child, using words appropriate to his or her level of comprehension. Long explanations increase a child's anxiety, especially for painful procedures such as an injection. Involving the child in choices when possible usually results in greater success. For example, saying "It's time to take your tablet now. Do you want it with water or juice?" allows a child to make a choice. Do not give the child the option of not taking a medication. After giving a medication, praise him or her and even offer a simple reward such as a star or token. Tips for administering medication to children are in Box 31-12.

Older Adults. Older adults also require special consideration during medication administration (Box 31-13). In addition to physiological changes of aging (Fig. 31-9), behavioral and economic factors influence an older person's use of medications.

Polypharmacy. **Polypharmacy** happens when a patient takes two or more medications to treat the same illness, takes two or more medications from the same chemical class, uses two or more medications with the same or similar actions to treat several

BOX 31-12 TIPS FOR ADMINISTERING MEDICATIONS TO CHILDREN

Oral Medications

- Liquid forms are safer to swallow to avoid aspiration.
- Use droppers for administering liquids to infants; straws often help older children swallow pills.
- When mixing medications in other foods, use only a small amount. The child may refuse to take all of a larger mixture.
- Avoid mixing a medication with foods or liquids that the child is taking well because the child may in turn refuse them.
- A plastic, disposable oral syringe is the most accurate device for preparing liquid doses, especially those less than 10 mL. (Cups, teaspoons, and droppers are inaccurate.)
- When administering liquid medications, a spoon, plastic cup, or oral syringe (without needle) is useful.

Injections

- Use caution when selecting intramuscular (IM) injection sites. Infants and small children have underdeveloped muscles. Follow agency policy.
- Children are sometimes unpredictable and uncooperative. Make sure that someone (preferably another nurse) is available to restrain a child if needed. Have the parent act as a comforter, not restrainer, if restraint is necessary.
- Always awaken a sleeping child before giving an injection.
- Distracting the child with conversation, bubbles, or a toy reduces pain perception.
- If time allows, apply a lidocaine ointment to an injection site before the injection to reduce pain perception during the injection.

BOX 31-13 FOCUS ON OLDER ADULTS

Safety in Medication Administration

- Consult with prescriber to simplify the drug therapy plan whenever possible (Lehne, 2010).
- Keep instructions clear and simple and provide written material in large print (Lehne, 2010).
- Assess functional status to determine if patient will require assistance in taking medications (Ebersole et al., 2008).
- Provide memory aids (e.g., calendar, medication schedule) and written information about medications in print large enough for the patient to see (Ebersole et al., 2008).
- Some older adults have a greater sensitivity to drugs, especially those that act on the central nervous system. Therefore carefully monitor patients' responses to medications and anticipate dosage adjustments as needed (Ebersole et al., 2008).
- If patient has difficulty swallowing a capsule or tablet (Ebersole et al., 2008):
  - Ask the physician to substitute a liquid medication if possible.
  - Instruct patient to place medication on the front of the tongue and then swallow fluid to help wash it to the back of the throat; if patient continues to have problems, have him or her try taking medication with a small amount of semisolid food (e.g., applesauce).
- Teach alternatives to medications such as proper diet instead of vitamins and exercise instead of laxatives (Ebersole et al., 2008).
- Frequently review medication history, including over-the-counter medications (Ebersole et al., 2008).

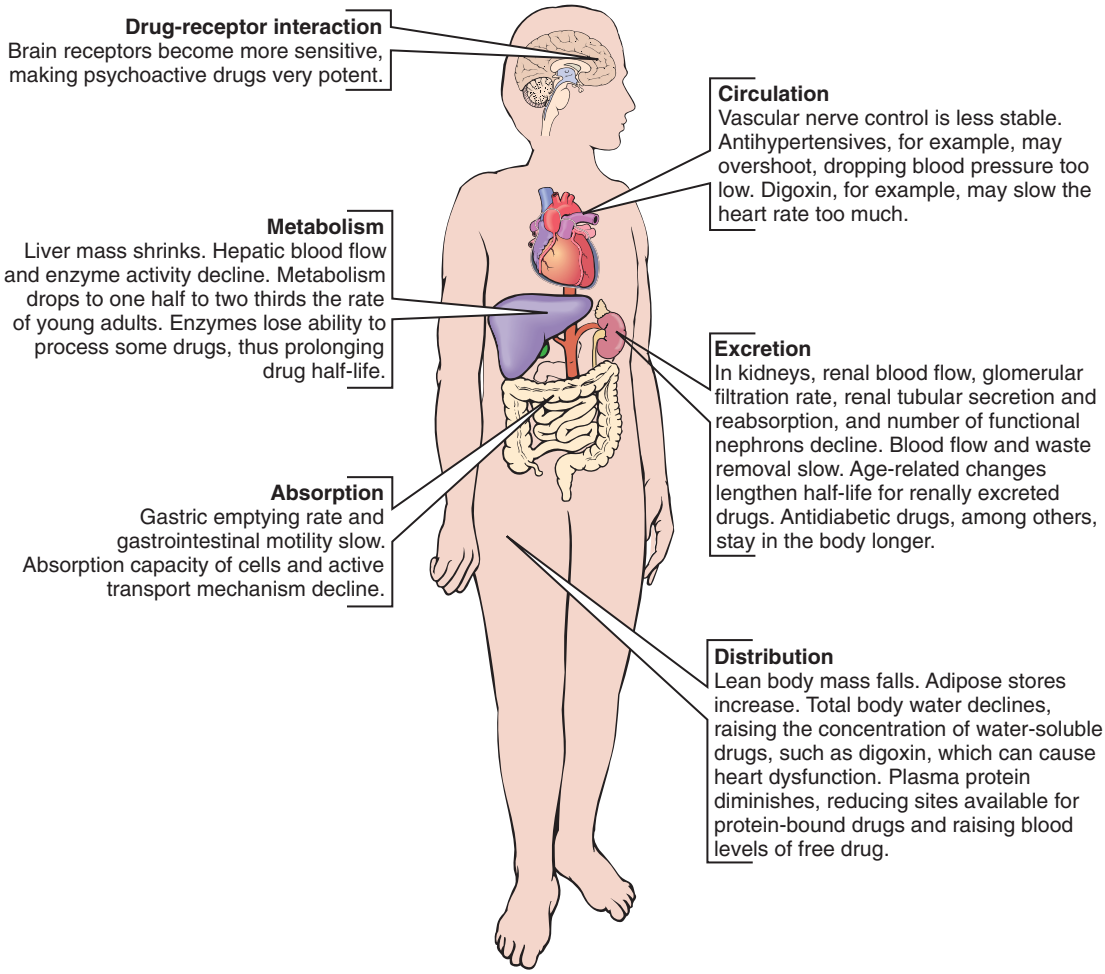

FIG. 31-9 Effects of aging on medication metabolism. (From Lewis SM et al: *Medical-surgical nursing,* ed 7, St Louis, 2007, Mosby.)

disorders simultaneously, or mixes nutritional supplements or herbal products with medications (Ebersole et al., 2008; Maggiore, Gross, and Hurria, 2010). Older adults also often experience polypharmacy when they seek relief from a variety of symptoms (e.g., pain, constipation, insomnia, and indigestion) by using OTC preparations. Sometimes polypharmacy is unavoidable. For example, some patients need to take more than one medication to control their high blood pressure. When the patient experiences polypharmacy, the risk of adverse reactions and medication interactions with other medications and food is increased.

Because many older adults suffer chronic health problems, polypharmacy is common. However, it is also becoming more common in children and patients with mental illnesses. Taking OTC medications frequently, lack of knowledge about medications, incorrect beliefs about medications, and visiting several health care providers to treat different illnesses increase the risk for polypharmacy. To minimize risks associated with polypharmacy, frequent communication among health care providers is essential to make sure that the patients' medication regimen is as simple as possible.

EVALUATION

Evaluation of medication administration is an essential role of professional nursing that requires assessment skills; critical thinking; analysis; and knowledge of medications, physiology, and pathophysiology. Nurses thoroughly and accurately gather data and complete a holistic evaluation of their patients. The goal of safe and effective medication administration involves the patient's response to therapy and ability to assume responsibility for self-care. When patients do not experience expected outcomes of medication therapy, investigate possible reasons and determine appropriate revisions to the patient's plan of care.

Through the Patient's Eyes. Evaluation is more effective when you value your patients' participation. Therefore partner with your patients and include them in the evaluation process. Ensure that they understand and are able to safely administer their medications. For example, if you are caring for a child who needs an inhaler, be sure to watch the patient use the inhaler. To determine if patients understand their medication schedules, ask them to explain when they take their medications and if they are able to take them as prescribed. When patients struggle with their medication schedule, determine barriers to medication adherence (e.g., cost, lack of knowledge) and remove these barriers if possible. Also remember that patients have different values and define health differently. These values and beliefs influence their perception of the effectiveness of their medications. Therefore ask patients to describe this effectiveness. Ask if they are satisfied with their medications and how they make them feel. Use patients' statements and

TABLE 31-8 Example Evaluation for Patient Goals

GOAL	EXPECTED OUTCOMES	EVALUATIVE MEASURE WITH EXAMPLE
Patient and family will understand medication therapy.	Patient and family will describe information about medication, dosage, schedule, purpose, and adverse effects.	*Written measurement:* Have patient write out medication schedule for a 24-hour period. *Oral questioning:* Ask patient to describe purpose, dosage, and adverse effects of each prescribed medication.
	Patient and family will identify situations that require medical intervention.	*Oral questioning:* Have family describe what to do when a patient has adverse effects from a medication.
	Patient and family demonstrate appropriate administration technique.	*Direct observation:* Have patient demonstrate filling of an insulin syringe and self-injection.
Patient will safely self-administer medications.	Patient follows prescribed treatment regimen.	*Anecdotal notes:* Have family keep log of patient's adherence to therapy for 1 week.
	Patient performs administration techniques correctly.	*Direct observation:* Observe patient instill eyedrops.
	Patient identifies available resources for obtaining necessary medication.	*Oral questioning:* Ask family to identify how to contact local pharmacy or community clinic for necessary medications.

responses to questions (e.g., "I feel less anxious now") when determining the effectiveness of medications. Including patients in the evaluation process empowers them and helps them become more actively involved in their care.

Patient Outcomes. A patient's clinical condition can change minute by minute. Use knowledge of the desired effect and common side effects of each medication to compare expected outcomes with actual findings. A change in a patient's condition is often physiologically related to health status or results from medications or both. Be alert for reactions in a patient taking several medications. Nurses use a variety of measures to evaluate patient responses to medications such as direct observation of physiological measures (e.g., blood pressure or laboratory values), behavioral responses (e.g., agitation), and rating scales (e.g., rating on a pain scale). The type of measurement used varies with the action being evaluated, the reading skill and knowledge level of the patient, and the patient's cognitive and psychomotor ability. The most common type of measurement that the nurse uses is a physiological measure. Examples of physiological measures are blood pressure, heart rate, and visual acuity. Nurses also use patient statements as evaluative measures. Table 31-8 contains examples of goals, expected outcomes, and corresponding evaluative measures.

BOX 31-14 PROTECTING THE PATIENT FROM ASPIRATION

- Assess patient's ability to swallow and cough and check for presence of gag reflex.
- Prepare oral medications in the form that is easiest to swallow.
- Allow patient to self-administer medications if possible.
- If patient has unilateral weakness, place the medication in the stronger side of the mouth.
- Administer pills one at a time, ensuring that each medication is properly swallowed before the next one is introduced.
- Thicken regular liquids or offer fruit nectars if patient cannot tolerate thin liquids.
- Avoid straws because they decrease the control patient has over volume intake, which increases the risk of aspiration.
- Have patient hold and drink from a cup if possible.
- Time medications to coincide with mealtimes or when patient is well rested and awake if possible.
- Administer medications using another route if risk of aspiration is severe.

MEDICATION ADMINISTRATION

A sound knowledge base is required for medications to be administered safely. Nurses need to be prepared to administer medications using a variety of routes. The following sections explain the steps involved in administering medications using various routes.

Oral Administration

The easiest and most desirable way to administer medications is by mouth (Skill 31-1 on pp. 612-615). Patients usually are able to ingest or self-administer oral medications with a minimum of problems. Food delays stomach emptying, which may decrease the therapeutic effects of oral medications. Therefore most oral medications reach their therapeutic action best if given 30 minutes to 1 hour before meals. In addition, some medications must be taken with food. Some situations contraindicate the patient's receiving medications by mouth (see Table 31-5). Many medications interact with nutritional and herbal supplements. You need to be knowledgeable about these interactions to determine the best time to give oral medications.

An important precaution to take when administering any oral preparation is to protect patients from aspiration. Aspiration occurs when food, fluid, or medication intended for GI administration inadvertently enters the respiratory tract. Protect the patient from aspiration by assessing his or her ability to swallow. Box 31-14 provides techniques that protect patients from aspirating. Proper positioning is essential in preventing aspiration. Position a patient in a seated position at a 90-degree angle when administering oral medications if not contraindicated by his or her condition. Usually having the patient slightly flex the head in a chin-down position reduces aspiration. Use a multidisciplinary approach (e.g., speech therapist, dietitian, and occupational therapist) with patients who have difficulty swallowing (Eisenstadt, 2010).

Special consideration is needed when administering medications to patients with enteral or small-bore feeding tubes (Box 31-15). Failing to follow current evidence-based recommendations from the American Society for Parenteral and Enteral Nutrition (ASPEN) can result in tube obstruction, reduced medication effectiveness, and increased risk of medication toxicity (Boullata, 2009). Before giving a medication by this route, verify that the location of

the tube (e.g., stomach or jejunum) is compatible with medication absorption. For example, iron dissolves in the stomach and is mostly absorbed in the duodenum. If iron is administered through a jejunal tube, it has poor bioavailability. Use liquid medications when possible. When liquid medications are not available, crush simple tablets or open gelatin capsules and dilute them in sterile water. Do not use tap water (Bankhead et al., 2009). Tap water often contains contaminants (e.g., pathogens, heavy metals) that can interact with a medication and affect its bioavailability (Boullata, 2009). Only use oral syringes when preparing medications for this route to prevent accidental parenteral administration. Flush tubes with at least 15 mL of sterile water before and after giving medications. When administering more than one medication at a time, give each separately and flush between medications with at least 15 mL of sterile water (Bankhead et al., 2009). Determine if medications need to be given on an empty stomach or if they are compatible with the patient's enteral feeding. If a medication needs to be given on an empty stomach or is not compatible with the feeding (e.g., phenytoin, carbamazepine [Tegretol], warfarin [Coumadin], fluoroquinolones, proton pump inhibitors), the feeding

Giving Medications Through an Enteral Tube (Nasogastric Tube, G-tube, J-Tube, or Small-Bore Feeding Tube)

Delegation Considerations

The skill of giving medications through an enteral tube cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:

- Potential side effects of medications and reporting their occurrence to the nurse.

Equipment

60-mL Oral syringe, gastric pH test strips (scale of 1.0 to 11.0 or greater), graduated container, sterile water, medication to be administered, pill crusher if medication in tablet form, medication administration record (MAR) (electronic or printed), clean gloves

1. Check accuracy and completeness of each MAR with prescriber's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any portion of printed MAR that is difficult to read.
2. Assess patient's knowledge about medication. Also assess medical history and for history or allergies to medications and foods. Make sure that patient's food and drug allergies are listed on the MAR and are prominently displayed on the patient's medical record per agency policy.
3. Avoid complicated medication regimens that frequently interrupt enteral feedings. Investigate and use alternative routes of medication administration if possible (e.g., intravenous, transdermal, rectal).
   a. Evaluate where medication is absorbed and ensure that point of absorption is not bypassed by feeding tube. For example, some medications (e.g., antacids) are absorbed in the stomach. If the patient's tube is placed in the intestines, these medications are not absorbed because the stomach is bypassed by the tube (Williams, 2008).
   b. Determine if medication interacts with enteral feeding. If interaction occurs, hold the feeding for at least 30 minutes before giving the medication (see agency policy or consult with pharmacist or drug reference).
4. Perform hand hygiene and prepare medication (see Skill 31-1, Steps 1a to 1g). Check label of medication with MAR two times for accuracy. *This is the first and second accuracy check.*
   a. Prepare medications in a liquid form (suspension, elixir, or solution) when possible to prevent tube obstruction (Bankhead et al., 2009).
   b. Before crushing tablets, be sure that they are crushable. Buccal, sublingual, enteric-coated or sustained-release medications cannot be crushed (Williams, 2008).
5. *Never* add medications directly to a tube feeding (Bankhead et al., 2009). Sometimes the tube feeding needs to be held. Verify this and the amount of time that you hold a feeding with agency policy, a pharmacist, or a medication reference before administering the medication to maximize the therapeutic effect of the medication (Bankhead et al., 2009; Williams, 2008).
6. Take medications to patient at correct time (see agency policy). Give time-critical, STAT, and single-order medications at the time ordered. Perform hand hygiene.
7. Identify the patient using at least two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.
8. Compare label of medications against MAR one more time at patient's bedside. *This is the third accuracy check.*
9. Explain procedure and medications to patient.
10. Grind simple compressed tablets to a fine powder. Open hard gelatin capsules and pour powder into a medication cup. Dissolve crushed tablets, contents of capsules, and powders in 15 to 30 mL of sterile water. Dissolve each medication separately (Bankhead et al., 2009).
11. Do not give whole or undissolved medications through the feeding tube (Williams, 2008).
12. Put on clean gloves. NOTE: If patient has a latex allergy, use latex-free gloves.
13. Stop feeding if applicable and verify placement of any feeding tube that enters the mouth or nose using pH testing (see Chapter 44).
14. Assess gastric residual (see Chapter 44).
15. Flush tube with at least 15 mL of sterile water.
16. Draw up medication in syringe. Do ***not*** mix medications together (Bankhead et al., 2009).
17. Connect syringe with medication to nasogastric tube, G-tube, J-tube, or small-bore feeding tube. Do not use pigtail vent.
18. Administer medication by either pushing the medication through the tube with the syringe or allowing it to flow into the body freely using gravity. Administer each medication separately. If resistance is felt when pushing medication through the tube, stop administration and contact the patient's health care provider.
19. Flush tube with at least 15 mL of sterile water between each medication (Bankhead et al., 2009).
20. After giving all the medications, flush tube with at least 15 mL of sterile water (Bankhead et al., 2009).
21. Restart tube feeding if appropriate; hold feeding for 30 minutes or longer if needed to avoid alterations in medication bioavailability (Bankhead et al., 2009).
22. Clean area and put supplies away. Remove gloves and perform hand hygiene.
23. Document administration of medications, dose, route, and time on MAR.
24. Evaluate patient's response to the medication at times that correspond with onset, peak and duration of the medication. If the desired effect is not achieved, a different medication or route of administration is probably indicated because of problems with the drug bioavailability when given the enteral route. If patient self-administers medications, evaluate his or her ability to give them and technique used. Provide and reinforce medication as needed.

needs to be held at least 30 minutes before or 30 minutes after medication administration (Boullata, 2009). Verify the time with a drug reference or consult with a pharmacist. Monitor the patient closely for adverse reactions. The risk for drug-drug interactions is high when two or more medications are given in this route because they can interact together as soon as they are administered.

Topical Medication Applications

Topical medications are medications that are applied locally, most often to intact skin. They come in many forms (see Table 31-1). They are also applied to mucous membranes.

Skin Applications. Because many locally applied medications such as lotions, pastes, and ointments create systemic and local effects, apply these medications using gloves and applicators. Use sterile technique if the patient has an open wound. Skin encrustation and dead tissues harbor microorganisms and block contact of medications with the tissues to be treated. Before applying medications, clean the skin thoroughly by washing the area gently with soap and water, soaking an involved site, or locally debriding tissue.

Apply each type of medication according to directions to ensure proper penetration and absorption. When applying ointments or pastes, spread the medication evenly over the involved surface and cover the area well without applying an overly thick layer. Prescribers sometimes order a gauze dressing to be applied over the medication to prevent soiling clothes and wiping away the medication. Lightly spread lotions and creams onto the surface of the skin; rubbing often causes irritation. Apply a liniment by rubbing it gently but firmly into the skin. Dust a powder lightly to cover the affected area with a thin layer.

Some topical medications are applied in the form of a transdermal patch that remains in place for an extended amount of time (e.g., 12 hours or 7 days). Before applying a new patch, remove the old one. Medication remains on the patch even after its recommended duration of use. Nurses and patients have inadvertently left old transdermal patches in place, resulting in the patient receiving an overdose of the medication. For example, patients who use fentanyl transdermal patches for pain management can experience respiratory depression, coma, and death when the patches are not removed. Many patches are clear, which makes them difficult to see. Therefore carefully assess the patient's skin and be sure to remove the existing patch before applying a new patch. Follow these guidelines to ensure safe administration of transdermal or topical medications (ISMP, 2007b):

- Document the location on the patient's body where the medication was placed on the MAR.
- When applying a transdermal patch, ask the patient if he or she has an existing patch.
- When taking a medication history or reconciling medications, specifically ask the patient if he or she takes any medications in the forms of patches, topical creams, or any route other than the oral route.
- If the dressing or patch is difficult to see (e.g., clear), apply a noticeable label to the patch.
- Document removal of the patch or medication on the MAR.

Nasal Instillation. Patients with nasal sinus alterations sometimes receive medications by spray, drops, or tampons (Box 31-16). The most commonly administered form of nasal instillation is decongestant spray or drops, used to relieve symptoms of sinus congestion and colds. Caution patients to avoid abuse of medications because overuse leads to a rebound effect in which the nasal congestion worsens. When excess decongestant solution is swallowed, serious systemic effects also develop, especially in children.

BOX 31-16 PROCEDURAL GUIDELINES

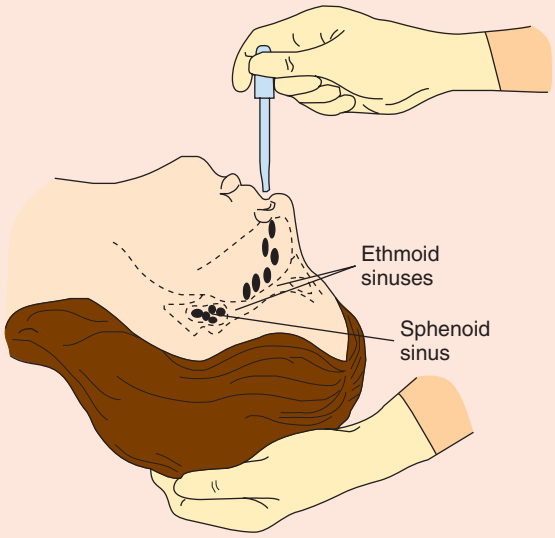
Administering Nasal Instillations

Delegation Considerations

The skill of administering nasal instillations cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:

- Potential side effects of medications and reporting their occurrence.

Equipment

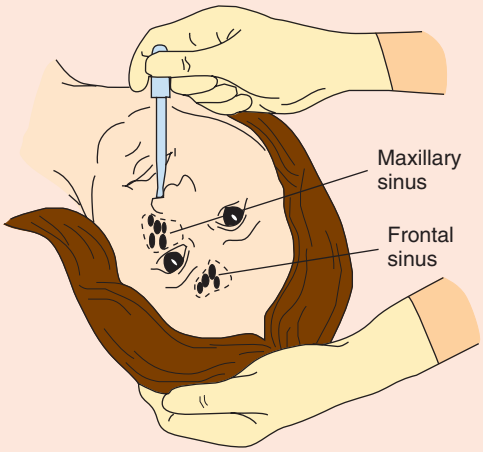


Prepared medication with clean dropper or spray container, facial tissue, small pillow (optional), washcloth (optional), clean gloves (if patient has extensive nasal drainage), medication administration record (MAR) (electronic or printed), penlight

1. Check accuracy and completeness of each MAR with prescriber's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any portion of printed MAR that is difficult to read.
2. Refer to the medical record to determine which sinus is affected if giving nasal drops.
3. Assess patient's medical history (e.g., history of hypertension, heart disease, diabetes mellitus, hyperthyroidism) and for history or allergies to medications and foods. Make sure that patient's food and drug allergies are listed on the MAR and prominently displayed on his or her medical record per agency policy.
4. Perform hand hygiene. Using a penlight, inspect condition of nose and sinuses. Palpate sinuses for tenderness (see Chapter 30).
5. Assess patient's knowledge regarding use of nasal instillation, technique for instillation, and willingness to learn self-administration.
6. Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
7. Perform hand hygiene and prepare medication (see Skill 31-1, Steps 1a to 1g). Compare medication label against MAR at least two times while preparing medication. *This is the first and second accuracy check.*
8. Take medication to patient at correct time (see agency policy). Perform hand hygiene.
9. Identify the patient using two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.
10. Compare names of medication on label with MAR one more time at patient's bedside. *This is the third accuracy check.*
11. Explain procedure to patient regarding positioning and sensations to expect such as burning or stinging of mucosa or choking sensation as medication trickles into throat.
12. Arrange supplies and medications at bedside. Apply clean gloves if patient has nasal drainage. NOTE: If patient has a latex allergy, use latex-free gloves.
13. Gently roll or shake container.
14. Instruct patient to clear or blow nose gently unless contraindicated (e.g., risk of increased intracranial pressure or nosebleeds).
15. *Administer nasal drops:*

Continued

BOX 31-16 PROCEDURAL GUIDELINES



***Administering Nasal Instillations*—cont'd**

STEP 15a(2) Position for instilling nose drops into ethmoid or sphenoid sinus.

- a. Help patient to supine position and position head properly.
  - (1) For access to posterior pharynx, tilt patient's head backward.
  - (2) For access to ethmoid or sphenoid sinus, tilt head back over edge of bed or place small pillow under patient's shoulder and tilt head back (see illustration).
  - (3) For access to frontal and maxillary sinus, tilt head back over edge of bed or pillow with head turned toward side to be treated (see illustration).
- b. Support patient's head with nondominant hand.
- c. Instruct patient to breathe through mouth.
- d. Hold dropper 1 cm (½ inch) above nares and instill prescribed number of drops toward midline of ethmoid bone.
- e. Have patient remain in supine position 5 minutes.
- f. Offer facial tissue to blot runny nose but caution patient against blowing nose for several minutes.

16. *Administer nasal spray:*
  - a. Help patient to supine position and position head slightly tilted forward.

STEP 15a(3) Position for instilling nose drops into frontal and maxillary sinus.

  - b. Help patient place spray nozzle into appropriate nares, pointing the nozzle to the side and away from the center of the nose.
  - c. Have patient spray medication into the nose while inhaling.
  - d. Help patient take nozzle out of nose and instruct him or her to breathe out through the mouth.
  - e. Offer facial tissue but caution patient against blowing nose for several minutes.
17. Assist patient to a comfortable position after medication is absorbed.
18. Dispose of soiled supplies in proper container and perform hand hygiene.
19. Document name of medication, dose, route, and time of administration on MAR.
20. Observe patient for onset of side effects 15 to 30 minutes after administration. Ask if he or she is able to breathe through nose after decongestant administration. It may be necessary to have patient occlude one nostril at a time and breathe deeply.
21. Evaluate patient's response to medications at times that correlate with the onset, peak, and duration of the medication. Evaluate patient for both desired effect and adverse effects. Reinspect condition of nasal passages between instillations.
22. Ask patient to review risks of overuse of decongestants and methods for administration.
23. Have patient demonstrate self-medication.

Saline drops are safer than nasal preparations that contain sympathomimetics (e.g., Afrin or Neo-Synephrine) as a decongestant for children.

It is easier to have the patient self-administer sprays because he or she is able to control the spray and inhale as it enters the nasal passages. For patients who use nasal sprays repeatedly, check the nares for irritation. Nasal drops are effective in treating sinus infections. Position patients to permit the medication to reach the affected sinus. Severe nosebleeds are usually treated with packing or nasal tampons, which are treated with epinephrine, to reduce blood flow. Usually a physician or advanced practice clinician places nasal tampons.

Eye Instillation. Common medications used by patients are eyedrops and ointments, including OTC preparations such as artificial tears and vasoconstrictors (e.g., Visine and Murine). Many patients, especially older adults, receive prescribed **ophthalmic** medications for eye conditions such as glaucoma or after cataract extraction. Age-related problems, including poor vision, hand tremors, and difficulty grasping or manipulating containers, affect the older adult's ability to self-administer eye medications. Instruct patients and family members about the proper techniques for administering them (Skill 31-2 on pp. 616-619). Determine the patient's and family's ability to self-administer through a return demonstration of the procedure. Showing patients each step of the procedure for instilling eyedrops can improve adherence. Follow these principles when administering eye medications:

- Avoid instilling any form of eye medications directly onto the cornea. The cornea of the eye has many pain fibers and thus is very sensitive to anything applied to it.
- Avoid touching the eyelids or other eye structures with eyedroppers or ointment tubes. The risk of transmitting infection from one eye to the other is high.
- Use eye medication only for the patient's affected eye.
- Never allow a patient to use another patient's eye medications.

BOX 31-17 PROCEDURAL GUIDELINES

Administering Ear Medications

Delegation Considerations

The skill of administering ear medications cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:

- Potential side effects and the need to report their occurrence.

Equipment

Medication administration record (MAR) (electronic or printed), clean gloves, and washcloth if patient has drainage from the ear; *for drops:* medication bottle with dropper, cotton-tipped applicator, cotton ball (optional); *for irrigation:* irrigating syringe, kidney-shaped basin, towel

1. Check accuracy and completeness of each MAR with prescriber's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any portion of printed MAR that is difficult to read.
2. Assess patient's medical history (e.g., history of dizziness, hearing loss) and allergies to medications, food, and latex.
3. Perform hand hygiene. Prepare medication (see Skill 31-1, Steps 1a to 1g). Check label of medication with MAR two times for accuracy. *This is the first and second accuracy check.*
4. Take medication to patient at correct time (see agency policy). Perform hand hygiene.
5. Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.
6. Compare names of medications on label with the MAR one more time at the patient's bedside. *This is the third accuracy check.* Hold medication container in hands for a few minutes to bring medication to body temperature.
7. Explain procedure to patient regarding positioning and sensations to expect such as hearing bubbling or feeling water in ear as medication trickles into ear.
8. Teach patient about medication.
9. Administer eardrops:
   a. Apply clean gloves and gently clean outer ear with washcloth if drainage is present. NOTE: If patient has a latex allergy, use latex-free gloves.
   b. Place patient in side-lying position (if not contraindicated by his or her condition) with ear to be treated facing up or have him or her sit in chair or at the bedside. If eardrops are a cloudy suspension, shake them for about 10 seconds.
   c. Straighten ear canal by pulling auricle down and back (children younger than 3 years) or upward and outward (children 4 years of age and older and adults).
   d. Instill prescribed drops holding dropper 1 cm (½ inch) above ear canal (see illustration).

STEP 9d Placing eardrop in ear.

   e. Ask patient to remain in side-lying position 2 to 3 minutes. Apply gentle massage or pressure to tragus of ear with finger unless contraindicated because of pain.
   f. If cotton ball is needed, place it into outermost part of canal. Do not press cotton deep into canal. Remove it after 15 minutes.
10. Clean the area and put supplies away.
11. Remove gloves and perform hand hygiene.
12. Document medication administration on MAR.
13. Evaluate patient's response to the medication at times that correspond with its onset, peak, and duration.

Intraocular Administration. The nurse administers some medications intraocularly (see Skill 31-2). Medications delivered this way resemble a contact lens. Place the medication into the conjunctival sac where it remains in place for up to 1 week. Medications such as pilocarpine are administered this way. Patients require teaching about monitoring for adverse reactions to the disk. They also need to know how to insert and remove the disk.

Ear Instillation. Internal ear structures are very sensitive to temperature extremes. Instill eardrops at room temperature to prevent vertigo, dizziness, or nausea. Although the structures of the outer ear are not sterile, sterile solutions are used in case the eardrum is ruptured. The entrance of nonsterile solutions into middle ear structures can result in infection. If a patient has ear drainage, be sure that the eardrum has not ruptured. Never occlude or block the ear canal with the dropper or irrigating syringe. Forcing medication into an occluded ear canal creates pressure that injures the eardrum. Box 31-17 provides guidelines for administering eardrops.

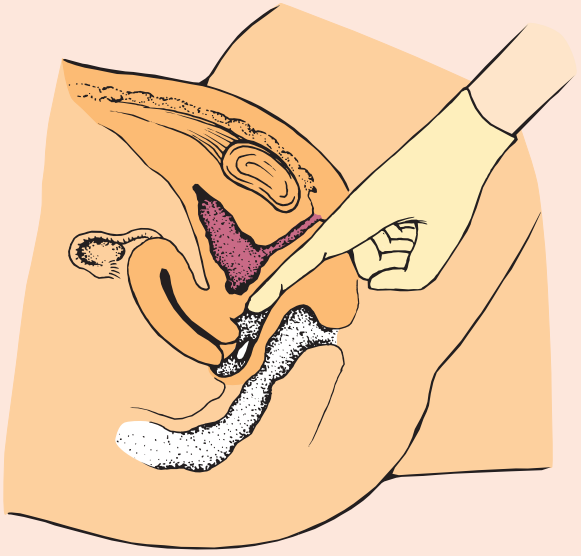
Vaginal Instillation. Vaginal medications are available as suppositories, foam, jellies, or creams. Solid, oval-shaped suppositories come individually packaged in foil wrappers and are sometimes stored in the refrigerator to prevent them from melting. After a suppository is inserted into the vaginal cavity, body temperature causes it to melt and be distributed and absorbed. Foam, jellies, and creams are administered with an applicator inserter (Box 31-18). Give a suppository with a gloved hand in accordance with standard precautions (see Chapter 28). Patients often prefer administering their own vaginal medications and need privacy. Because vaginal medications are often given to treat infection, discharge is usually foul smelling. Follow aseptic technique and offer the patient frequent opportunities to maintain perineal hygiene (see Chapter 39).

Rectal Instillation. Rectal suppositories are thinner and more bullet-shaped than vaginal suppositories. The rounded end prevents anal trauma during insertion. Rectal suppositories contain medications that exert local effects such as promoting defecation or systemic effects such as reducing nausea. Rectal suppositories are often stored in the refrigerator until administered. Sometimes it is necessary to clear the rectum with a small cleansing enema before inserting a suppository (Box 31-19).

BOX 31-18 PROCEDURAL GUIDELINES

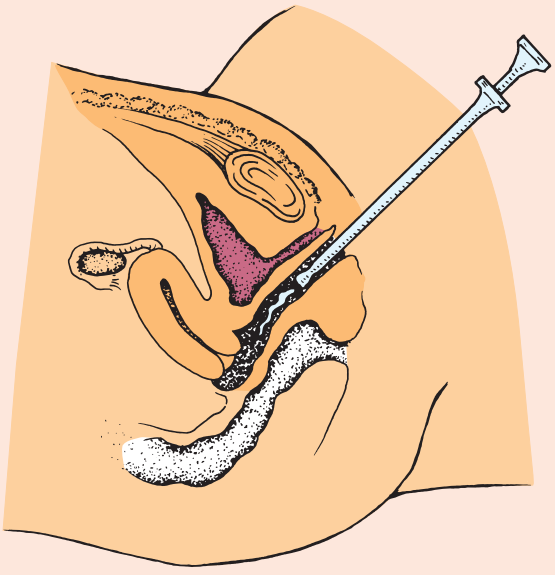
Administering Vaginal Medications

Delegation Considerations



The skill of administering vaginal medications cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Report new or increased vaginal discharge or bleeding and occurrence of potential side effects of medications.



Equipment

Vaginal cream, foam, jelly, or suppository with applicator (if required); clean gloves; towels and/or washcloth; perineal pad; drape or sheet; water-soluble lubricating jelly; medication administration record (MAR) (electronic or printed)

1. Check accuracy and completeness of each MAR with prescriber's medication order. Check patient's name and medication name, form (cream or suppository), dosage, and route and time of administration. Recopy or reprint any portion of printed MAR that is difficult to read.
2. Assess patient's medical history (e.g., history of vaginal drainage) and allergies to medications, food, and latex.
3. Perform hand hygiene. Prepare medication (see Skill 31-1, Steps 1a to 1g). Check name of medication on label with MAR two times for accuracy. *This is the first and second accuracy check.*
4. Take medication to patient at the correct time (see agency policy). Perform hand hygiene.
5. Identify patient using two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medical record.
6. Compare names of medication on label with the MAR one more time at patient's bedside. *This is the third accuracy check.*
7. Teach patient about the medication. Explain procedure regarding positioning and sensations to expect such as feelings of moisture or wetness in the vaginal area. Assess patient's ability to manipulate applicator or suppository and position self to insert medication. Be sure that patient understands the procedure if she plans to self-administer the medication.
8. Close room door or pull curtain to provide privacy.
9. Put on clean gloves. NOTE: If patient has a latex allergy, use latex-free gloves.
10. Be sure that lighting is adequate to visualize vaginal opening. Inspect condition of external genitalia and vaginal canal (see Chapter 30), noting appearance of any discharge. Clean area with towel or washcloth if necessary (see Chapter 39).
11. Help patient into dorsal recumbent position and keep abdomen and lower extremities draped.
12. Administer vaginal suppository:
    a. Remove suppository from foil wrapper and apply liberal amount of sterile, water-based lubricating jelly to the smooth or rounded end. Lubricate gloved index finger of dominant hand.
    b. With nondominant gloved hand expose vaginal orifice by gently retracting labial folds.
    c. With dominant gloved hand gently insert rounded end of suppository along posterior wall of vaginal canal entire length of finger (7.5 to 10 cm [3 to 4 inches]) to ensure equal distribution of medication along walls of vaginal cavity (see illustration).
    d. Withdraw finger and wipe away remaining lubricant from around orifice and labia.
13. Administer cream or foam:
    a. Fill cream or foam applicator following package directions.
    b. With nondominant gloved hand, expose vaginal orifice by gently retracting labial folds.
    c. With dominant gloved hand, insert applicator approximately 5 to 7.5 cm (2 to 3 inches). Push applicator plunger to deposit medication into vagina to allow equal distribution of medication (see illustration).

STEP 12c Insertion of suppository into vaginal canal.

STEP 13c Instillation of medication in vaginal canal.

    d. Withdraw applicator and place on paper towel. Wipe off residual cream from labia or vaginal orifice.
14. Dispose of supplies, remove gloves, and perform hand hygiene.
15. Instruct patient to remain on back for at least 10 minutes to allow medication to be distributed and absorbed evenly throughout vaginal cavity and not lost through orifice.
16. Document medication administration on MAR.
17. If using an applicator, wearing gloves, wash with soap and warm water, rinse, and store for future use.
18. Offer patient perineal pad when she resumes ambulation.
19. Evaluate patient's response to medication at times that correspond with the onset, peak, and duration of the medication. Inspect appearance of discharge of vaginal canal and condition of external genitalia between applications.

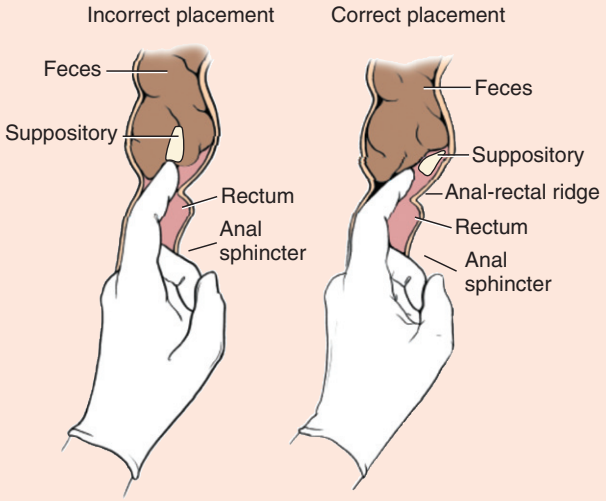
BOX 31-19 PROCEDURAL GUIDELINES

Administering Rectal Suppositories

Delegation Considerations

The skill of administering rectal suppositories cannot be delegated to nursing assistive personnel (NAP). Instruct NAP to:

- Expect and report fecal discharge or bowel movement.
- Report occurrence of potential side effects of medications.



Equipment

Rectal suppository, water-soluble lubricating jelly, clean gloves, drape or sheet, tissue, medication administration record (MAR) (electronic or printed)

1. Check accuracy and completeness of each MAR with prescriber's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any portion of printed MAR that is difficult to read.
2. Review medical history (e.g., hemorrhoids, anal fissures, rectal surgery, or bleeding) and allergies to medications, food, and latex.
3. Perform hand hygiene and prepare medication (see Skill 31-1, Steps 1a to 1g). Compare names of medication on label with the MAR two times for accuracy. *This is the first and second accuracy check.*
4. Take medication to patient at the correct time and perform hand hygiene.
5. Identify patient using two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medical record.
6. Compare names of medication on label with the MAR one more time at patient's bedside. *This is the third accuracy check.*
7. Teach patient about the medication. Explain procedure regarding positioning and sensations to expect such as feelings of needing to defecate. Be sure that patient understands the procedure if he or she is going to self-administer the medication.
8. Close room door or pull curtain to ensure privacy.
9. Put on clean gloves. NOTE: If patient has a latex allergy, use latex-free gloves.
10. Help patient to the Sims' position. Keep him or her draped with only anal area exposed.
11. Be sure that there is adequate lighting to visualize anus. Examine condition of anus externally and palpate rectal walls as needed (see Chapter 30). Dispose of gloves in proper receptacle if soiled.
12. Apply new pair of clean gloves (if previous gloves were soiled). NOTE: If patient has a latex allergy, use latex-free gloves.
13. Remove suppository from wrapper and lubricate rounded end (see illustration) with sterile water-soluble lubricating jelly. Lubricate index finger of dominant hand with a water-soluble lubricant.
14. Ask patient to take slow deep breaths through mouth and relax anal sphincter.
15. Retract buttocks with nondominant hand. Insert suppository gently through anus, past internal sphincter and against rectal wall, 10 cm (4 inches) in adults, 5 cm (2 inches) in children and infants (see illustration). Apply gentle pressure to hold buttocks together momentarily if needed to keep medication in place.

STEP 13 Remove suppository from wrapper.

STEP 15 Inserting rectal suppository. (From deWit S: *Fundamental concepts and skills for nursing,* ed 3, Philadelphia, 2009, Saunders.)

16. Withdraw finger and wipe anal area with tissue.
17. Dispose of supplies, remove gloves, and perform hand hygiene.
18. Ask patient to remain flat or on side for at least 5 minutes to prevent expulsion of suppository.
19. Place call light within patient's reach.
20. Document medication administration on MAR.
21. Observe for effects of suppository (e.g., bowel movement, relief of nausea) at times that correlate with the onset, peak, and duration of the medication.

Administering Medications by Inhalation

Medications administered with handheld inhalers are dispersed through an aerosol spray, mist, or powder that penetrates lung airways. The alveolar-capillary network absorbs medications rapidly.

Pressurized metered-dose inhalers (pMDIs), breath-actuated metered dose inhalers (BAIs), and dry powder inhalers (DPIs) deliver medications that produce local effects such as bronchodilation. Some medications create serious systemic side effects. pMDIs use a chemical propellant to push the medication out of the inhaler and require the patient to apply approximately 5 to 10 pounds of pressure to the top of the canister to administer the medication. Children or older adults with chronic respiratory diseases often use pMDIs. These two populations have diminished hand strength. Therefore it is essential to assess if patients in these groups have enough strength to use the pMDI.

BAIs release medication when a patient raises a lever and inhales. Release of the medication depends on the strength of the

patient's breath on inspiration and is a good choice for patients who have difficulty using pMDIs (Restrepo and Gardner, 2010).

DPIs hold dry powdered medication and create an aerosol when the patient inhales through a reservoir that contains a dose of the medication. Some DPIs are unit dosed. These inhalers require patients to load a single dose of medication into the inhaler with each use. Other DPIs hold enough medication to be used in 1 month. DPIs require less manual dexterity. Because the device is activated with the patient's breath, there is no need to coordinate puffs with inhalation. However, the medication inside the DPI can clump if the patient is in a humid climate, and some patients cannot inspire fast enough to administer the entire dose of the medication.

Patients who receive medications by inhalation frequently suffer chronic respiratory disease such as chronic asthma, emphysema, or bronchitis. Different respiratory problems require different inhaled medication. For example, patients with asthma usually receive antiinflammatory medications because asthma is primarily an inflammatory disease, whereas patients with chronic obstructive pulmonary disease (COPD) receive bronchodilators because they usually have problems with bronchoconstriction. Inhaled medications are also often described as "rescue" or "maintenance" medications. Rescue medications are short acting and taken for immediate relief of acute respiratory distress. Maintenance medications are used on a daily schedule to prevent acute respiratory distress. The effects of maintenance medications start within hours of administration and last for a longer period of time than rescue medications. Some inhalers contain combinations of rescue and maintenance medications. Because patients depend on inhaled medications for disease control and current evidence shows that many patients do not use their inhalers correctly, patients need to learn how to self-administer inhalers safely and effectively (Restrepo and Gardner, 2010) (Skill 31-3 on pp. 619-622).

Some patients use a spacer with the pMDI. The spacer is a 4- to 8-inch (10.16 to 20.32 cm) long tube that attaches to the pMDI and allows the particles of medication to slow down and break into smaller pieces, which improves drug absorption in the patient's airway. Spacers have a face mask for infants and children less than 4 years of age. They are especially helpful when the patient has difficulty coordinating the steps involved in self-administering inhaled medications. When patients do not use their inhalers and spacers correctly, they do not receive the full effect of the medication. Therefore patient education is essential. BAIs and DPIs do not use spacers.

One important aspect of patient teaching is to help the patient determine when the MDI, BAI, or DPI is empty and needs to be replaced. Floating the MDI in water to determine how much medication is left is no longer recommended because extra propellant causes the container to float even if no medication remains in the inhaler. Furthermore, non–ozone-depleting MDIs with hydrofluoroalkanes (HFAs) should never be immersed (Hess, 2008). Devices that count down the number of remaining doses are available for MDIs. Some DPIs have mechanisms that indicate how many doses are left. However, these mechanisms are not always accurate. Therefore, to calculate how long medication in an inhaler will last, divide the number of doses in the container by the number of doses the patient takes per day. For example, a patient is to take albuterol. The ordered dose is 2 puffs 4 times a day. The canister has a total of 200 puffs. Complete the following calculations to determine how long the MDI will last:

$$2 \text{ puffs} \times 4 \text{ times a day} = 8 \text{ puffs per day}$$

$$200 \text{ puffs} \div 8 \text{ puffs per day} = 25 \text{ days}$$

The canister in this example will last 25 days. To ensure that the patient does not run out of medication, teach him or her to refill it at least 7 to 10 days before it runs out.

BOX 31-20 PREVENTING INFECTION DURING AN INJECTION

- To prevent contamination of solution, draw medication from ampule quickly. Do not allow it to stand open.
- To prevent needle contamination, avoid letting needle touch contaminated surface (e.g., outer edges of ampule or vial, outer surface of needle cap, nurse's hands, countertop, table surface).
- To prevent syringe contamination, avoid touching length of plunger or inner part of barrel. Keep tip of syringe covered with cap or needle.
- To prepare skin, wash with soap and water if soiled with dirt, drainage, or feces and dry. Use friction and a circular motion while cleaning with an antiseptic swab. Swab from center of site and move outward in a 2-inch (5 cm) radius.

Administering Medications by Irrigations

Some medications irrigate or wash out a body cavity and are delivered through a stream of solution. Irrigations most commonly use sterile water, saline, or antiseptic solutions on the eye, ear, throat, vagina, and urinary tract. Use aseptic technique if there is a break in the skin or mucosa. Use clean technique when the cavity to be irrigated is not sterile, as in the case of the ear canal or vagina. Irrigations cleanse an area, instill a medication, or apply hot or cold to injured tissue (see Chapter 48).

Parenteral Administration of Medications

Parenteral administration of medications is the administration of medications by injection into body tissues. When medications are administered this way, it is an invasive procedure that is performed using aseptic techniques (Box 31-20). After a needle pierces the skin, there is risk of infection. Each type of injection requires certain skills to ensure that the medication reaches the proper location. The effects of a parenterally administered medication develop rapidly, depending on the rate of medication absorption. The nurse closely observes the patient's response.

Equipment. A variety of syringes and needles are available, each designed to deliver a certain volume of a medication to a specific type of tissue. Use nursing judgment when determining the syringe or needle that will be most effective.

Syringes. Syringes consist of a cylindrical barrel with a tip designed to fit the hub of a hypodermic needle and a close-fitting plunger. In general syringes are classified as being Luer-Lok or non–Luer-Lok. This nomenclature is based on the design of the tip of the syringe. Luer-Lok syringes have needles that are twisted onto the tip and lock themselves in place (Fig. 31-10, *A* and *B*). This design prevents the inadvertent removal of the needle. Non–Luer-Lok syringes (Fig. 31-10, C and *D*) have needles that slip onto the tip. Syringes have safety devices to prevent needlestick injury.

Syringes come in a number of sizes, from 0.5 to 60 mL. It is unusual to use a syringe larger than 5 mL for an injection. A 1- to 3-mL syringe is usually adequate for a subcutaneous or IM injection. A larger volume creates discomfort. Use larger syringes to administer certain IV medications and irrigate wounds or drainage tubes. Syringes often come prepackaged with a needle attached. However, you sometimes change a needle based on the route of administration and size of the patient.

FIG. 31-10 Types of syringes. **A,** 5-mL syringe. **B,** 3-mL syringe. **C,** Tuberculin syringe marked in 0.01 (hundredths) for doses less than 1 mL. **D,** Insulin syringe marked in units (50).

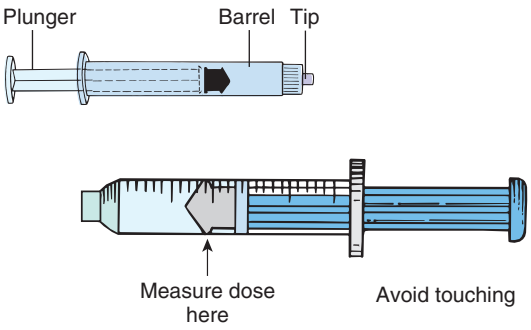


FIG. 31-11 Parts of a syringe.

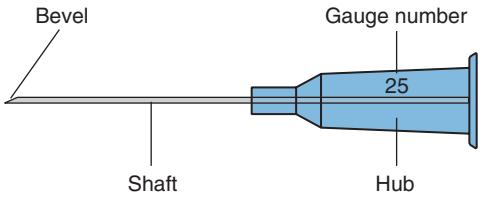

FIG. 31-12 Parts of the needle.

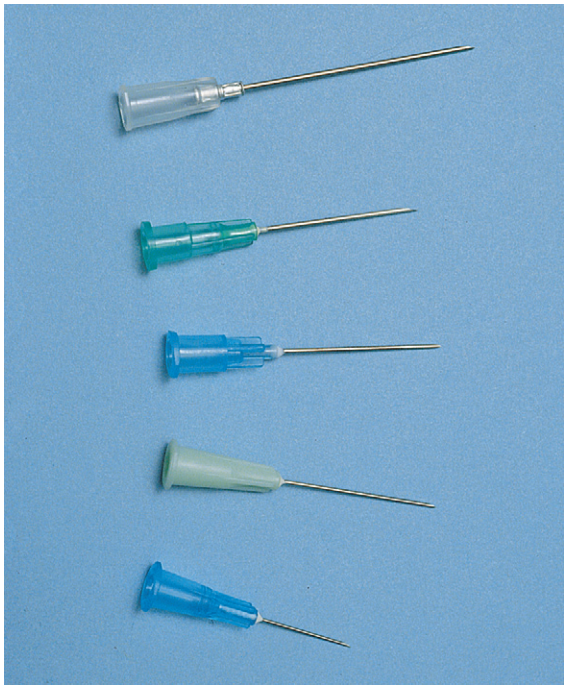

FIG. 31-13 Needles. Top to bottom: 19 gauge, 1½-inch length; 20 gauge, 1-inch length; 21 gauge, 1-inch length; 23 gauge, 1-inch length; and 25 gauge, ⅝-inch length.

The tuberculin syringe (Fig. 31-10, *C*) is calibrated in sixteenths of a minim and hundredths of a milliliter and has a capacity of 1 mL. Use a tuberculin syringe to prepare small amounts of medications (e.g., intradermal or subcutaneous injections). A tuberculin syringe is also useful when preparing small, precise doses for infants or young children.

Insulin syringes (Fig. 31-10, *D*) are available in sizes that hold 0.3 to 1 mL and are calibrated in units. Most insulin syringes are U-100s, designed to be used with U-100 strength insulin. Each milliliter of U-100 insulin contains 100 units of insulin.

Fill a syringe by pulling the plunger outward while the needle tip remains immersed in the prepared solution. Only touch the outside of the syringe barrel and the handle of the plunger to maintain sterility. Avoid letting any unsterile object touch the tip or inside of the barrel, the hub, the shaft of the plunger, or the needle (Fig. 31-11).

Needles. Some needles come packaged in individual sheaths to allow flexibility in choosing the right needle for a patient, whereas others are preattached to standard-size syringes. Most needles are made of stainless steel, and all are disposable. A needle has three parts: the hub, which fits onto the tip of a syringe; the shaft, which connects to the hub; and the bevel, or slanted tip (Fig. 31-12). The tip of a needle, or the bevel, is always slanted. The bevel creates a narrow slit when injected into tissue that quickly closes when the needle is removed to prevent leakage of medication, blood, or serum. Long beveled tips are sharper and narrower, minimizing discomfort when entering tissue used for subcutaneous or IM injections.

Most needles vary in length from ¼ to 3 inches (Fig. 31-13). Choose the needle length according to the patient's size and weight and the type of tissue into which the medication is to be injected. A child or slender adult generally requires a shorter needle. Use longer needles (1 to 1½ inches) for IM injections and a shorter needle (⅜ to ⅝ inch) for subcutaneous injections. As the needle gauge becomes smaller, the needle diameter becomes larger. The selection of a gauge depends on the viscosity of fluid to be injected or infused.

Disposable Injection Units. Disposable, single-dose, prefilled syringes are available for some medications. Be careful to check the medication and concentration because all prefilled syringes appear very similar. With these syringes you do not have to prepare

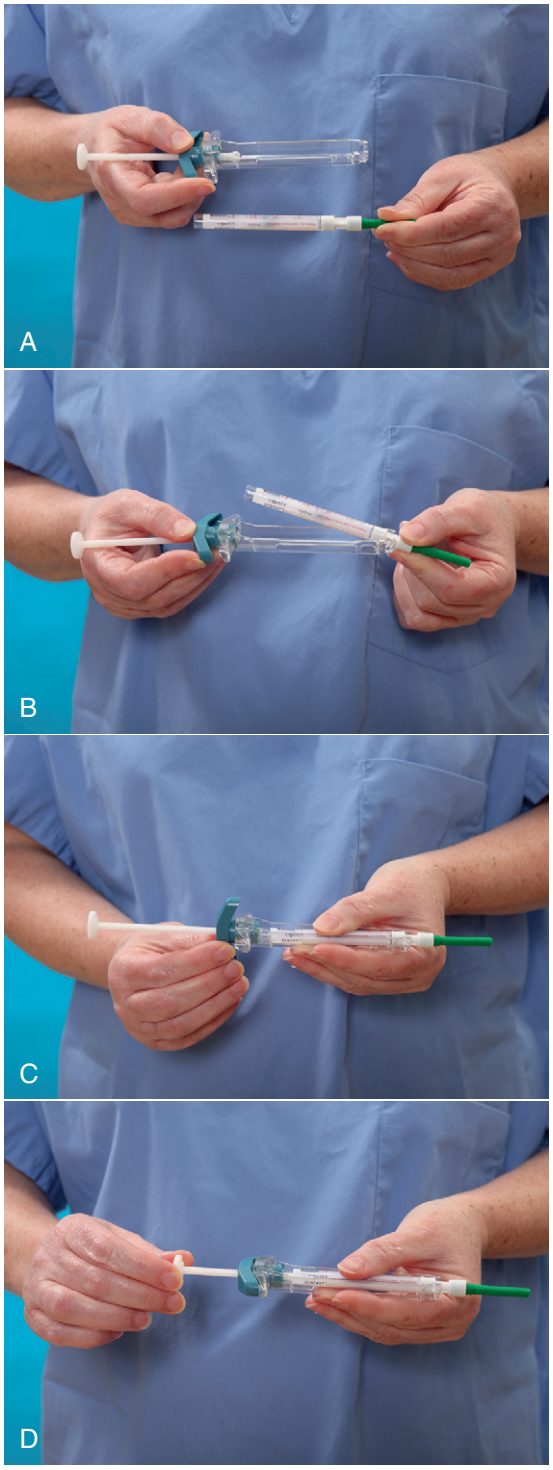

FIG. 31-14 **A,** Carpuject syringe and prefilled sterile cartridge with needle. **B,** Assembling the Carpuject. **C,** The cartridge slides into the syringe barrel. Turn and lock the syringe into the cartridge. **D,** Screw the plunger into the end of the cartridge. Expel excess medication to obtain accurate dose *(not pictured)*.

medication doses, except perhaps to expel portions of unneeded medications.

The Tubex and Carpuject injection systems include reusable plastic mechanisms that hold prefilled, disposable, sterile cartridge-needle units (Fig. 31-14). Load the cartridge Luer tip first into the

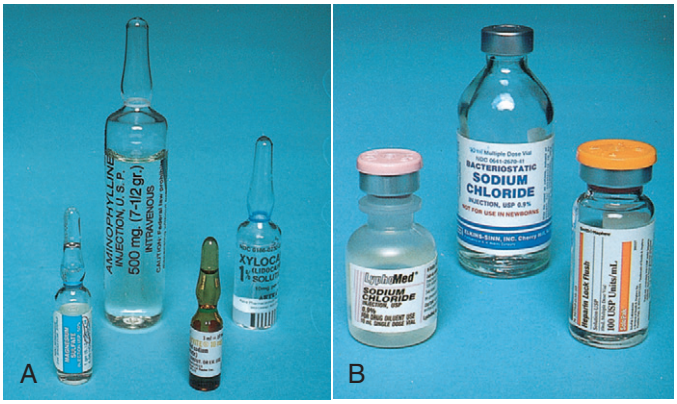

FIG. 31-15 **A,** Medication in ampules. **B,** Medication in vials.

plastic syringe holder, secure it (following package directions), and check for air bubbles in the syringe. Advance the plunger to expel air and excess medication as in a regular syringe. The glass cartridge can be used with needleless systems or safety needles. After giving the medication, safely dispose of the glass cartridge in a puncture-proof and leak-proof receptacle.

Preparing an Injection From an Ampule. Ampules contain single doses of medication in a liquid. Ampules are available in several sizes, from 1 mL to 10 mL or more (Fig. 31-15, *A*). An ampule is made of glass with a constricted neck that must be snapped off to allow access to the medication. A colored ring around the neck indicates where the ampule is prescored so you can break it easily. Carefully aspirate the medication into a syringe (Skill 31-4 on pp. 622-626) with a filter needle. The use of a filter needle prevents particulate matter such as small glass fragments from entering the syringe (Cocoman and Murray, 2008; Nicoll and Hesby, 2002). Replace the filter needle with an appropriate-size needle or a needleless access device before administering the injection.

Preparing an Injection From a Vial. A vial is a single-dose or multidose container with a rubber seal at the top (see Fig. 31-15, *B*). A metal cap protects the seal until it is ready for use. Vials contain liquid or dry forms of medications. Medications that are unstable in solution are packaged dry. The vial label specifies the solvent or diluent used to dissolve the medication and the amount of diluent needed to prepare a desired medication concentration. Normal saline and sterile distilled water are commonly used to dissolve medications.

Unlike the ampule, the vial is a closed system, and air needs to be injected into it to permit easy withdrawal of the solution. Failure to inject air when withdrawing creates a vacuum within the vial that makes withdrawal difficult. If concerned about drawing up parts of the rubber stopper or other particles into the syringe, use a filter needle when preparing medications from vials (Cocoman and Murray, 2008; Nicoll and Hesby, 2002). Some vials contain powder, which is mixed with a diluent during preparation and before injection (see Skill 31-4). After mixing multidose vials, make a label that includes the date and time of mixing and the concentration of medication per milliliter. Some multidose vials require refrigeration after the contents are reconstituted.

Mixing Medications. If two medications are compatible, it is possible to mix them in one injection if the total dose is within accepted limits so a patient does not have to receive more than one injection at a time. Most nursing units have charts that list common compatible medications. If there is any uncertainty about

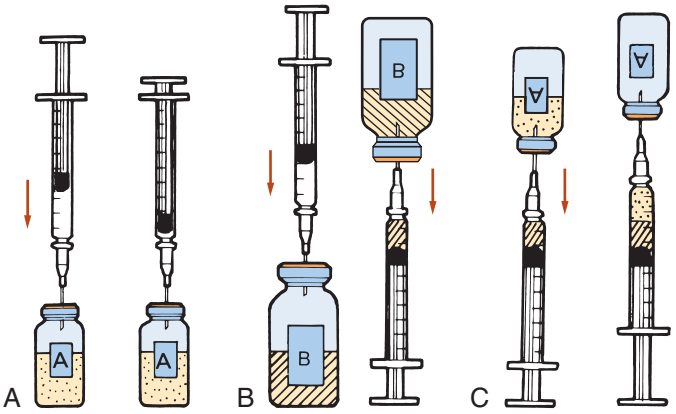

FIG. 31-16 **A,** Injecting air into vial A. **B,** Injecting air into vial B and withdrawing dose. **C,** Withdrawing medication from vial A; medications are now mixed.

medication compatibilities, consult a pharmacist or a medication reference.

Mixing Medications From a Vial and an Ampule. When mixing medication from both a vial and ampule, prepare medication from the vial first. Using the same syringe and filter needle, next withdraw medication from the ampule. Nurses prepare the combination in this order because it is not necessary to add air to withdraw medication from an ampule.

Mixing Medications From Two Vials. Apply these principles when mixing medications from two vials:

1. Do not contaminate one medication with another.
2. Ensure that the final dose is accurate.
3. Maintain aseptic technique.

Use only one syringe with a needle or needleless access device attached to mix medications from two vials (Fig. 31-16). Aspirate the volume of air equivalent to the dose of the first medication (vial A) (Fig. 31-16, *A*). Inject the air into vial A, making sure that the needle does not touch the solution. Withdraw the needle and aspirate air equivalent to the dose of the second medication (vial B). Inject the volume of air into vial B (Fig. 31-16, *B*). Immediately withdraw the medication from vial B into the syringe and insert the needle back into vial A, being careful not to push the plunger and expel the medication within the syringe into the vial. Withdraw the desired amount of medication from vial A into the syringe (Fig. 31-16, *C*). After withdrawing the necessary amount, withdraw the needle and apply a new safety needle or needleless access device suitable for injection.

Insulin Preparation. Insulin is the hormone used to treat diabetes. It is administered by injection because the GI tract breaks down and destroys an oral form of insulin. Most patients with diabetes who take insulin injections learn to administer their own injections. In the United States and Canada health care providers usually prescribe insulin in concentrations of 100 units per milliliter of solution. This is called *U-100 insulin*. Insulin is also commercially available in concentrations of 500 units per milliliter of solution; it is called *U-500 insulin*. U-500 insulin is 5 times as strong as U-100 insulin and is used only in rare cases when patients are very resistant to insulin (Davidson et al., 2010).

Use the correct syringe when preparing insulin. Use a 100-unit insulin syringe or an insulin pen to prepare U-100 insulin. Because there is no syringe currently designed to prepare U-500 insulin, many medication errors result with this kind of insulin. When ordering U-500 insulin, ensure that prescribers specify units and volume (e.g., 150 units, 0.3 mL of U-500 insulin) and use tuberculin syringes to draw up the doses. Verify dose with another nurse or pharmacist before administering it to the patient. Additional safety measures common with U-500 insulin include having the insulin listed as being concentrated in computerized medication dispensing systems, making prescribers and pharmacists verify that the patients is to receive U-500 insulin when it is ordered, and only stocking U-500 insulin on patient care units when it is ordered for a specific patient (ISMP, 2007a).

BOX 31-21 EXAMPLE OF CORRECTION INSULIN ORDER

Give regular insulin subcutaneously:
2 units for glucose 150 to 200 mg/dL
4 units for glucose 201 to 275 mg/dL
Call for glucose greater than 275 mg/dL

Clinical scenario: Before lunch patient's blood glucose level is 201. After referring to patient's correction insulin dose, the nurse administers 4 units of insulin to patient.

Insulin is classified by rate of action, including rapid, short, intermediate, and long acting. To provide safe and effective care, you need to know the onset, peak, and duration for each of your patients' ordered insulin doses. Refer to a medication reference or consult with a pharmacist if you are unsure of this information. Only regular insulin can be given intravenously. Orders for insulin injections attempt to imitate the normal pattern of a patient's insulin release from the pancreas. Some insulins come in a stable premixed solution (e.g., 70/30 insulin is 70% NPH [intermediate] and 30% regular), eliminating the need to mix the insulins in a syringe. Other patients use an insulin pen. The insulin pen provides multiple doses and allows the patient or nurse to dial in the dose, avoiding the need to use a syringe for insulin preparation. A patient with diabetes sometimes requires more than one type of insulin. For example, by receiving a short-acting (regular) and an intermediate-acting (NPH) insulin, a patient receives more sustained control of blood glucose levels over 24 hours.

Insulin is ordered by a specific dose at select times. Correction insulin, also known as sliding-scale insulin, provides a dose of insulin based on the patient's blood glucose level (Box 31-21). The term *correction insulin* is preferred because it indicates that small doses of rapid- or short-acting insulins are needed to correct a patient's elevated blood sugar. Reliance on correction insulin is unlikely to achieve long-term glucose control; therefore it should only be ordered on a temporary basis (ADA, 2010).

Before drawing up insulin doses, gently roll all cloudy insulin preparations between the palms of the hands to resuspend the insulin (ADA, 2004). Do not shake insulin vials; shaking causes bubbles to form. Bubbles take up space in the syringe and alter the dose.

If more than one type of insulin is required to manage the patient's diabetes, the nurse can mix two different types of insulin into one syringe *if* they are compatible (Box 31-22). If regular and intermediate-acting insulin is ordered, prepare the regular insulin first to prevent the regular insulin from becoming contaminated with the intermediate-acting insulin (ADA, 2004). Use the following principles when mixing insulins (ADA, 2004; Novo Nordisk, 2010):

- Patients whose blood glucose levels are well controlled on a mixed-insulin dose need to maintain their individual routine when preparing and administering their insulin.

BOX 31-22 PROCEDURAL GUIDELINES

Mixing Two Types of Insulin in One Syringe

Delegation Considerations

The skill of mixing two types of insulin in one syringe cannot be delegated to nursing assistive personnel (NAP).

Equipment

Insulin vials, insulin syringe, alcohol swabs, medication administration (MAR) (electronic or printed)

1. Check accuracy and completeness of each MAR with prescriber's medication order. Check patient's name and medication name, dosage, and route and time of administration.
2. Review medical history (e.g., type of diabetes, reason for elevated blood sugars) and allergies to medications, food, and latex.
3. Carefully verify insulin labels; compare labels against the MAR before preparing the dose to ensure that the correct type of insulin is prepared. *This is the first accuracy check.*
4. Perform hand hygiene.
5. If patient takes insulin that is cloudy, roll the bottle of insulin between the hands to resuspend the preparation.
6. Wipe off tops of both insulin vials with alcohol swabs.
7. Verify insulin dosages against MAR a second time. *This is the second accuracy check.*
8. If mixing rapid- or short-acting insulin with intermediate-acting insulin, take insulin syringe and aspirate volume of air equivalent to the dose of insulin to be withdrawn from intermediate-acting insulin first. If two intermediate-acting insulins are mixed, it makes no difference which vial you prepare first.
9. Insert needle and inject air into vial of intermediate-acting insulin. Do not let the tip of the needle touch the insulin.
10. Remove the syringe from the vial of intermediate-acting insulin without aspirating the insulin.
11. With the same syringe, inject air equal to the dose of insulin to be withdrawn into the vial of rapid- or short-acting insulin. Then withdraw the correct dose into the syringe.
12. Remove the syringe from the rapid- or short-acting insulin vial after carefully removing air bubbles in the syringe to ensure correct dose.
13. After verifying insulin dosages with MAR a third time, show insulin prepared in syringe to another nurse to verify that correct dosage of insulin was prepared. *This is the third accuracy check.* Determine which point on the syringe scale combined the units of insulin measured by adding the number of units of both insulins together (e.g., 3 units regular + 10 units NPH = 13 units total).
14. Place the needle of the syringe back into the vial of intermediate-acting insulin. Be careful not to push the plunger and inject insulin in syringe into the vial.
15. Invert vial and carefully withdraw the desired amount of insulin into the syringe.
16. Withdraw needle and check the fluid level in syringe. Keep needle of prepared syringe sheathed or capped until ready to administer medication. Show another nurse the syringe to verify that the correct dose was prepared.
17. Dispose of soiled supplies in proper receptacle. Place used vials in puncture-proof and leak-proof container and perform hand hygiene.
18. Because rapid- or short-acting insulin binds with intermediate-acting insulin, which reduces the action of the faster-acting insulin, administer mixture within 5 minutes of preparing it.

Modified from American Diabetes Association: Insulin administration: position statement, *Diabetes Care* 27(1S):S106, 2004.

- Do not mix insulin with any other medications or diluents unless approved by the prescriber.
- Never mix insulin glargine (Lantus) or insulin detemir (Levemir) with other types of insulin.
- Inject rapid-acting insulins mixed with NPH insulin within 15 minutes before a meal.
- Verify insulin doses with another nurse while preparing them if required by agency policy.

Administering Injections

Each injection route differs based on the type of tissues the medication enters. The characteristics of the tissues influence the rate of medication absorption and thus the onset of medication action. Before injecting a medication, know the volume of the medication to administer, the characteristics and viscosity of the medication, and the location of anatomical structures underlying injection sites (Skill 31-5 on pp. 626-631).

If a nurse does not administer injections correctly, negative patient outcomes result. Failure to select an injection site in relation to anatomical landmarks results in nerve or bone damage during needle insertion. Inability to maintain stability of the needle and syringe unit can result in pain and tissue damage. If you fail to aspirate the syringe before injecting an IM medication, the medication may accidentally be injected directly into an artery or vein. Injecting too large a volume of medication for the site selected causes extreme pain and results in local tissue damage.

Many patients, particularly children, fear injections. Patients with serious or chronic illness often are given several injections daily. Minimize the patient's discomfort in the following ways:

- Use a sharp-beveled needle in the smallest suitable length and gauge.
- Position the patient as comfortably as possible to reduce muscular tension.
- Select the proper injection site, using anatomical landmarks.
- Apply a vapocoolant spray (e.g., Fluori-Methane spray or ethyl chloride) or topical anesthetic (e.g., EMLA cream) to the injection site before giving the medication when possible.
- Divert the patient's attention from the injection through conversation using open-ended questioning.
- Insert the needle quickly and smoothly to minimize tissue pulling.
- Hold the syringe steady while the needle remains in tissues.
- Inject the medication slowly and steadily.

Subcutaneous Injections. Subcutaneous injections involve placing medications into the loose connective tissue under the dermis (see Skill 31-5). Because subcutaneous tissue is not as richly supplied with blood as the muscles, medication absorption is somewhat slower than with IM injections. However, medications are absorbed completely if the patient's circulatory status is normal. Because subcutaneous tissue contains pain receptors, the patient often experiences slight discomfort.

The best subcutaneous injection sites include the outer posterior aspect of the upper arms, the abdomen from below the costal margins to the iliac crests, and the anterior aspects of the thighs (Fig. 31-17). The site most frequently recommended for heparin injections is the abdomen (Fig. 31-18). Alternative subcutaneous sites for other medications include the scapular areas of the upper back and the upper ventral or dorsal gluteal areas. The injection site chosen needs to be free of skin lesions, bony prominences, and large underlying muscles or nerves.

The administration of low-molecular-weight heparin (LMWH) (e.g., enoxaparin) requires special considerations. When injecting the medication, use the right or left side of the abdomen at least 2 inches from the umbilicus (the patient's "love handles") and pinch the injection site as you insert the needle. Administer LMWH in its prefilled syringe with the attached needle and do not expel the air bubble in the syringe before giving the medication (Sanofi-Aventis, 2010).

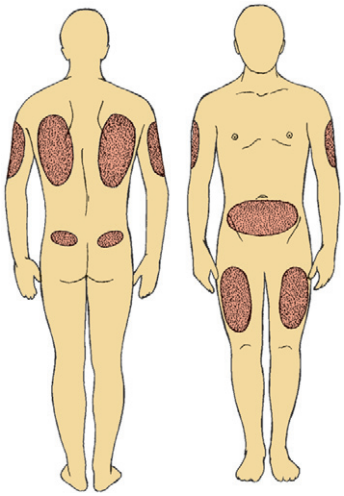

FIG. 31-17 Sites recommended for subcutaneous injections.

FIG. 31-18 Giving subcutaneous heparin in abdomen.

Use U-100 insulin syringes with preattached 25- to 31-gauge needles when giving U-100 insulin and 1-mL tuberculin syringes when giving U-500 insulin (ADA, n.d.; ISMP, 2002). Recommended sites for insulin injections include the upper arm and the anterior and lateral portions of the thigh, buttocks, and abdomen. Rotating injections within the same body part (intrasite rotation) provides more consistency in the absorption of the insulin. For example, if the patient receives the morning insulin in the right arm, give the next injection in a different place in the same arm. The injections are to be given at least an inch (2.5 cm) away from the previous site. No injection site should be used again for at least 1 month. The rate of insulin absorption varies based on the site; the abdomen has the quickest absorption, followed by the arms, thighs, and buttocks (ADA, 2004).

Only small volumes (0.5 to 1.5 mL) of water-soluble medications are given subcutaneously because the tissue is sensitive to irritating solutions and large volumes of medications. In children smaller volumes up to 0.5 mL are given (Hockenberry and Wilson, 2009). Collection of medications within the tissues causes sterile abscesses, which appear as hardened, painful lumps under the skin.

A patient's body weight indicates the depth of the subcutaneous layer. Therefore choose the needle length and angle of insertion based on the patient's weight and an estimation of the amount of subcutaneous tissue (Annersten and Willman, 2005). Generally a 25-gauge, ⅝-inch needle inserted at a 45-degree angle (Fig. 31-19) or a ½-inch needle inserted at a 90-degree angle deposits medications into the subcutaneous tissue of a normal-size patient. Some children require only a ½-inch needle. If the patient is obese, pinch the tissue and use a needle long enough to insert through fatty tissue at the base of the skinfold. Thin patients often do not have sufficient tissue for subcutaneous injections; the upper abdomen is usually the best site in this case. To ensure that a subcutaneous medication reaches the subcutaneous tissue, follow this rule: If you can grasp 2 inches (5 cm) of tissue, insert the needle at a 90-degree angle; if you can grasp 1 inch (2.5 cm) of tissue, insert the needle at a 45-degree angle (Rushing, 2004).

Intramuscular Injections. The IM route provides faster medication absorption than the subcutaneous route because of the greater vascularity of the muscle. However, IM injections are associated with many risks. Therefore, whenever administering a medication by the IM route, first verify that the injection is justified (Nicoll and Hesby, 2002; WHO, 2006). In many cases such as

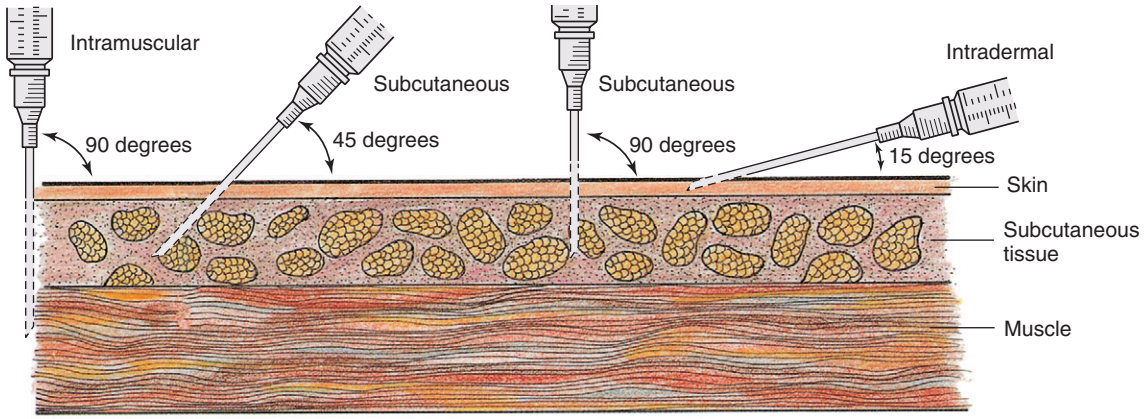

FIG. 31-19 Comparison of angles of insertion for intramuscular (90 degrees), subcutaneous (45 to 90 degrees), and intradermal (15 degrees) injections.

influenza and pneumonia shots, no alternative sites are available to give the medication.

Use a longer and heavier-gauge needle to pass through subcutaneous tissue and penetrate deep muscle tissue (see Skill 31-5). Weight and the amount of adipose tissue influence needle size selection. For example, a very obese patient often requires a needle 3 inches long, whereas a thin patient only requires a ½- to 1-inch needle (Koster et al., 2009; Zaybak et al., 2007). Because most agencies have needles that range in length from only ⅜ to 1½ inches, investigate different medication routes when IM injections are ordered for patients who are obese (TCHP Education Consortium, 2005).

The angle of insertion for an IM injection is 90 degrees (see Fig. 31-19). Muscle is less sensitive to irritating and viscous medications. A normal, well-developed adult patient tolerates 2 to 5 mL of medication into a larger muscle without severe muscle discomfort (Nicoll and Hesby, 2002; Prettyman, 2005). However, larger volumes of medication (4 to 5 mL) are unlikely to be absorbed properly. Children, older adults, and thin patients tolerate only 2 mL of an IM injection. Do not give more than 1 mL to small children and older infants, and do not give more than 0.5 mL to smaller infants (Hockenberry and Wilson, 2009).

Assess the muscle before giving an injection. Properly identify the site for the IM injection by palpating bony landmarks, and be aware of the potential complications associated with each site (Nicoll and Hesby, 2002). It needs to be free of tenderness. Repeated injections in the same muscle cause severe discomfort. With the patient relaxed, palpate the muscle to rule out any hardened lesions. Minimize discomfort during an injection by helping the patient assume a position that helps to reduce muscle strain. Other interventions such as distraction and applying pressure to the IM site decrease pain during an IM injection.

Sites. When selecting an IM site, consider the following: Is the area free of infection or necrosis? Are there local areas of bruising or abrasions? What is the location of underlying bones, nerves, and major blood vessels? What volume of medication is to be administered? Each site has different advantages and disadvantages.

Ventrogluteal. The ventrogluteal muscle involves the gluteus medius; it is situated deep and away from major nerves and blood vessels. This site is the preferred and safest site for all adults, children, and infants, especially for medications that have larger volumes and are more viscous and irritating (Hockenberry and Wilson, 2009; Nicoll and Hesby, 2002). The ventrogluteal site is recommended for volumes greater than 2 mL (Nicoll and Hesby, 2002). Research shows that injuries such as fibrosis, nerve damage, abscess, tissue necrosis, muscle contraction, gangrene, and pain are associated with all the common IM sites *except* the ventrogluteal site. Actually the only published case study of a complication at the ventrogluteal site reported a local reaction to the medication, which is not a complication associated with the site itself (Nicoll and Hesby, 2002).

Locate the ventrogluteal muscle by positioning the patient in a supine or lateral position. Flexing the knee and hip helps to relax this muscle. Place the palm of your hand over the greater trochanter of the patient's hip with the wrist perpendicular to the femur. Use the right hand for the left hip and use the left hand for the right hip. Point the thumb toward the patient's groin and the index finger toward the anterior superior iliac spine; extend the middle finger back along the iliac crest toward the buttock. The index finger, the middle finger, and the iliac crest form a V-shaped triangle; the injection site is the center of the triangle (Fig. 31-20, *A* to *C*).

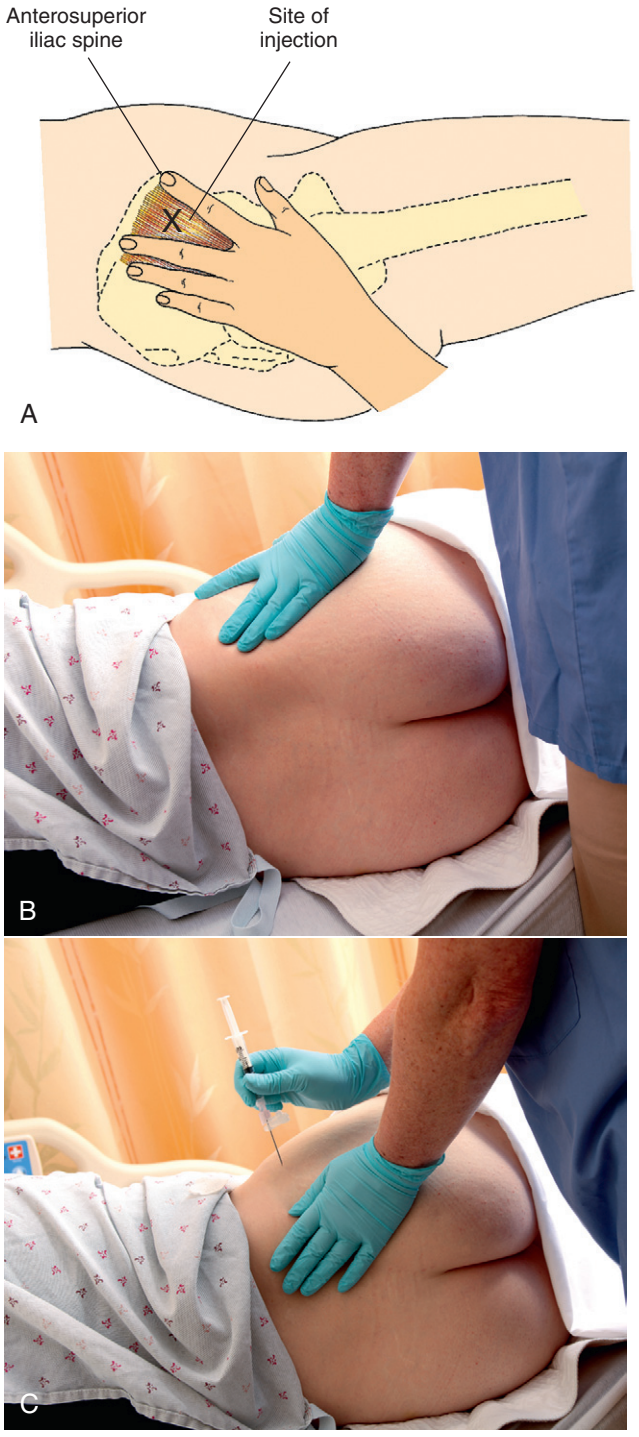

FIG. 31-20 **A,** Landmarks for ventrogluteal site. **B,** Locating ventrogluteal site in patient. **C,** Giving intramuscular injection in ventrogluteal muscle using the Z-track method.

Vastus Lateralis. The vastus lateralis muscle is another injection site for adults and children. The muscle is thick and well developed, is located on the anterior lateral aspect of the thigh, and extends in an adult from a hand breadth above the knee to a hand breadth below the greater trochanter of the femur (Fig. 31-21, *A* and *B*). Use the middle third of the muscle for injection. The width of the muscle usually extends from the midline of the thigh to the midline of the outer side of the thigh. With young children or

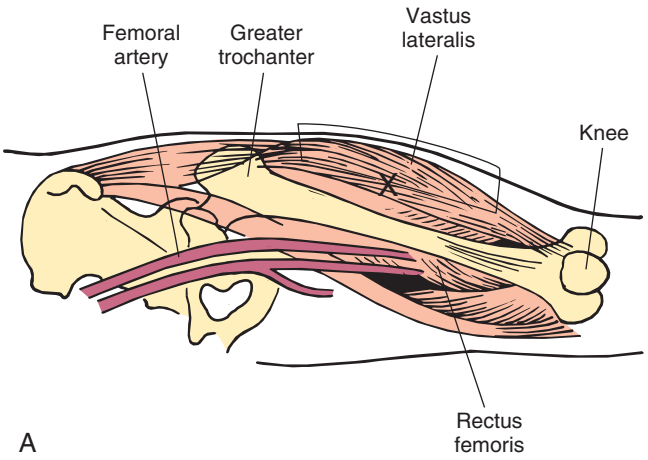

FIG. 31-21 **A,** Landmarks for vastus lateralis site. **B,** Giving intramuscular injection in vastus lateralis muscle.

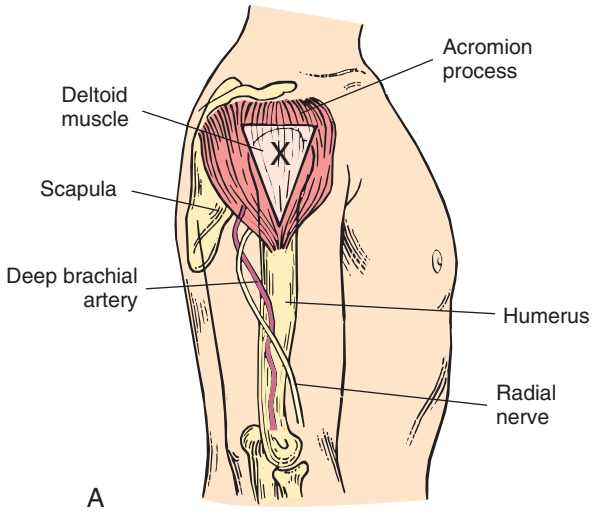

FIG. 31-22 **A,** Landmarks for deltoid site. **B,** Giving intramuscular injection in deltoid muscle.

cachectic patients, it helps to grasp the body of the muscle during injection to be sure that the medication is deposited in muscle tissue. To help relax the muscle, ask the patient to lie flat with the knee slightly flexed or in a sitting position. The vastus lateralis site is often used for infants, toddlers, and children receiving biologicals (e.g., immunoglobulins, vaccines, or toxoids) (Nicoll and Hesby, 2002).

Deltoid. Although the deltoid site is easily accessible, this muscle is not well developed in many adults. There is a potential for injury because the axillary, radial, brachial, and ulnar nerves, as well as the brachial artery, lie within the upper arm under the triceps and along the humerus. Use this site for small medication volumes (2 mL or less) (Nicoll and Hesby, 2002). Carefully assess the condition of the deltoid muscle, consult medication references for suitability of the medication, and carefully locate the injection site using anatomical landmarks (Fig 31-22, *A*). Use this site only for small medication volumes, when giving immunizations (e.g., hepatitis B, flu shots), or when other sites are inaccessible because of dressings or casts (Nicoll and Hesby, 2002). To locate the muscle, fully expose the patient's upper arm and shoulder. Do not roll up a tight-fitting sleeve. Have the patient relax the arm at the side and flex the elbow. The patient may sit, stand, or lie down (Fig. 31-22, *B*). Palpate the lower edge of the acromion process, which forms the base of a triangle in line with the midpoint of the lateral aspect of the upper arm. The injection site is in the center of the triangle, about 3 to 5 cm (1 to 2 inches) below the acromion process. You can also locate the site by placing four fingers across the deltoid muscle, with the top finger along the acromion process. The injection site is then three finger widths below the acromion process.

Use of the Z-Track Method in Intramuscular Injections. It is recommended that, when administering IM injections, the **Z-track method** be used to minimize local skin irritation by sealing the medication in muscle tissue (Nicoll and Hesby, 2002). To use the Z-track method, put a new needle on the syringe after preparing the medication so no solution remains on the outside needle shaft. Then select an IM site, preferably in a large, deep muscle such as the ventrogluteal muscle. Place the ulnar side of the nondominant hand just below the site and pull the overlying skin and subcutaneous tissues approximately 2.5 to 3.5 cm (1 to 1½ inches) laterally or downward (Nicoll and Hesby, 2002). Hold the skin in this position until you administer the injection. After preparing the site with an antiseptic swab, inject the needle deep into the muscle. Grasp the barrel of the syringe with the thumb and index finger of the nondominant hand and slowly inject the medication at a rate of 10 seconds per mL if there is no blood return on aspiration (Nicoll

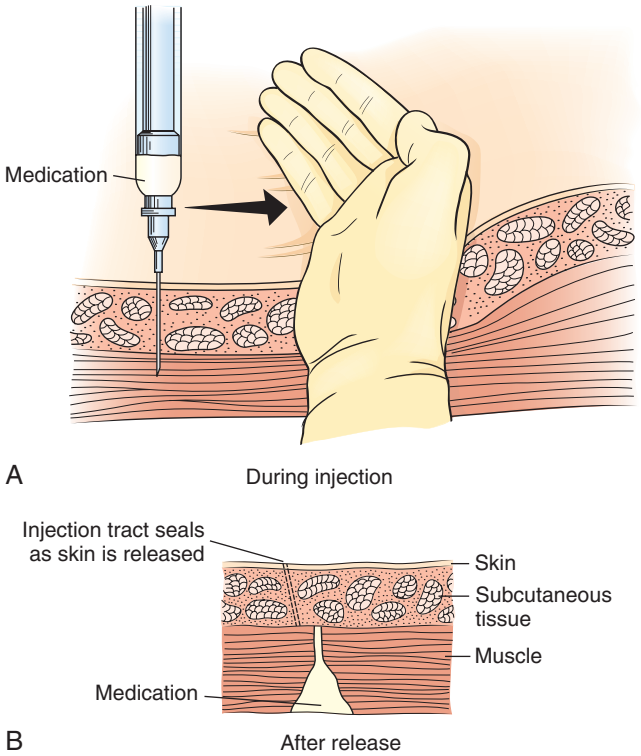

FIG. 31-23 **A,** Pulling on overlying skin during intramuscular injection moves tissue to prevent later tracking. **B,** Z-track method of injection prevents deposit of medication into sensitive tissue.

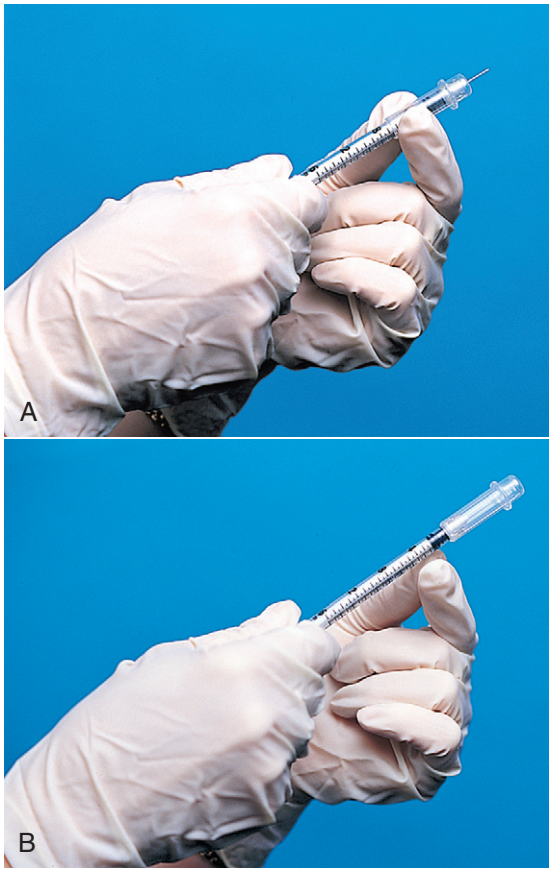

FIG. 31-24 Needle with plastic guard to prevent needlesticks. **A,** Position of guard before injection. **B,** After injection the guard locks in place, covering the needle.

and Hesby, 2002). The needle remains inserted for 10 seconds to allow the medication to disperse evenly rather than channeling back up the track of the needle (Nicoll and Hesby, 2002). Release the skin after withdrawing the needle. This leaves a zigzag path that seals the needle track where tissue planes slide across one another (Fig. 31-23, *A* and *B*). The medication cannot escape from the muscle tissue. Injections using this technique result in less discomfort and decrease the occurrence of lesions at the injection site (Nicoll and Hesby, 2002).

Intradermal Injections. Intradermal injections typically are used for skin testing (e.g., tuberculin screening and allergy tests). Because these medications are potent, they are injected into the dermis, where blood supply is reduced and medication absorption occurs slowly. Sometimes patients have a severe anaphylactic reaction if the medications enter the circulation too rapidly. Skin testing requires that the nurse be able to clearly see the injection sites for changes in color and tissue integrity. Intradermal sites need to be lightly pigmented, free of lesions, and relatively hairless. The inner forearm and upper back are ideal locations.

Use a tuberculin or small hypodermic syringe for skin testing. The angle of insertion for an intradermal injection is 5 to 15 degrees (see Fig. 31-19), and the bevel of the needle is pointed up. As you inject the medication, a small bleb resembling a mosquito bite appears on the surface of the skin. If a bleb does not appear or if the site bleeds after needle withdrawal, there is a good chance that the medication entered subcutaneous tissues. In this case test results will not be valid.

Safety in Administering Medications by Injection

Needleless Devices. Between 600,000 and 1 million accidental needlesticks and sharps injuries occur annually in health care settings (OSHA, 2009). Needlestick injuries commonly occur when health care workers recap needles, mishandle IV lines and needles, or leave needles at a patient's bedside. Exposure to bloodborne pathogens is one of the deadliest hazards to which nurses are exposed on a daily basis. Most needlestick injuries are preventable with the implementation of safe needle devices. The Needlestick Safety and Prevention Act mandates the use of special needle safety devices to reduce the frequency of needlestick injuries.

Safety syringes have a sheath or guard that covers a needle after it is withdrawn from the skin (Fig. 31-24, *A* and *B*). The needle is immediately covered, eliminating the chance for a needlestick injury. The syringe and sheath are disposed of together in a receptacle. Use needleless devices whenever possible to reduce the risk of needlestick and sharps injuries (OSHA, 2009). Always dispose of needles and other instruments considered sharps into clearly marked, appropriate containers (Fig. 31-25). Containers need to be puncture proof and leak proof. Never force a needle into a full needle disposal receptacle. Never place used needles and syringes in a wastebasket, in your pocket, on a patient's meal tray, or at the patient's bedside. Box 31-23 summarizes the recommendations for the prevention of needlestick injuries.

Intravenous Administration. The nurse administers medications intravenously by the following methods:

1. As mixtures within large volumes of IV fluids
2. By injection of a bolus or small volume of medication through an existing IV infusion line or intermittent venous access (heparin or saline lock)
3. By "piggyback" infusion of a solution containing the prescribed medication and a small volume of IV fluid through an existing IV line

FIG. 31-25 Sharps disposal using only one hand.

BOX 31-23 RECOMMENDATIONS FOR PREVENTION OF NEEDLESTICK INJURIES

- Avoid using needles when effective needleless systems or sharps with engineered sharps injury protection (SESIP) safety devices are available.
- Do not recap any needle.
- Plan safe handling and disposal of needles before beginning the procedure.
- Immediately dispose of needles, needleless systems, and SESIP into puncture-proof and leak-proof sharps disposal containers.
- Maintain a sharps injury log that includes the following: type and brand of device involved in the incident; location of the incident (e.g., department or work area); description of the incident; privacy of the employees who have had sharps injuries.

Data from Occupational Safety and Health Administration: Toxic and hazardous substances: bloodborne pathogens, *Fed Reg* CFR 29, part 1910.1030, April 3, 2006, http://www.osha.gov/SLTC/bloodbornepathogens/index.html. Accessed on September 18, 2011.

In all three methods the patient has either an existing IV infusion running continuously or an IV access site for intermittent infusions. In most agencies policies and procedures list persons who are able to give IV medications and the situations in which they may be given. These policies are based on the medication, capability, and availability of staff, and the type of monitoring equipment available.

Chapter 41 describes the technique for performing venipuncture and establishing continuous IV fluid infusions. Medication administration is only one reason for supplying IV fluids. IV fluid therapy is used primarily for fluid replacement in patients unable to take oral fluids and as a means of supplying electrolytes and nutrients.

When using any method of IV medication administration, observe patients closely for symptoms of adverse reactions. After a medication enters the bloodstream, it begins to act immediately, and there is no way to stop its action. Thus take special care to avoid errors in dose calculation and preparation. Carefully follow the six rights of safe medication administration, double-check medication calculations with another nurse, and know the desired action and side effects of every medication you give. If the medication has an antidote, make sure that it is available during administration. When administering potent medications, assess vital signs before, during, and after infusion.

Administering medications by the IV route has advantages. Often the nurse uses this route in emergencies when a fast-acting medication must be delivered quickly. The IV route is also best when it is necessary to give medications to establish constant therapeutic blood levels. Some medications are highly alkaline and irritating to muscle and subcutaneous tissue. These medications cause less discomfort when given intravenously. Because IV medications are immediately available to the bloodstream once they are administered, verify the prescribed rate of administration with a medication reference or a pharmacist before giving them to ensure that the medication is given safely over the appropriate amount of time. Patients experience severe adverse reactions if IV medications are administered too quickly.

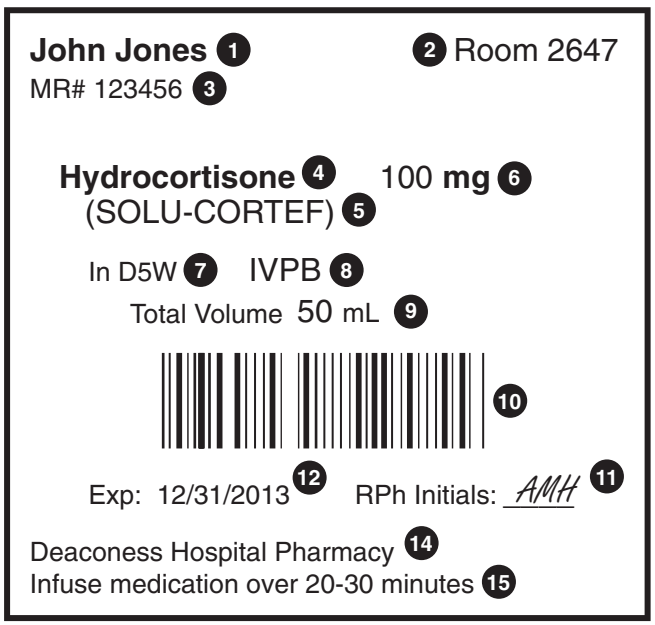
Large-Volume Infusions. Of the three methods of administering IV medications, mixing them in large volumes of fluids is the safest and easiest. Because the medication is not in a concentrated form, the risk of side effects or fatal reactions is minimal when infused over the prescribed time frame. Medications are diluted in large volumes (500 or 1000 mL) of compatible IV fluids such as normal saline or lactated Ringer's solution. Vitamins and potassium chloride are two types of medications commonly added to IV fluids. There is a danger with continuous infusion: if the IV fluid is infused too rapidly, the patient is at risk for medication overdose and circulatory fluid overload.

In the past nurses often mixed medications into IV fluids. However, standards developed by the U.S. Pharmacopeia and other health care professional organizations no longer support this practice on a routine basis (ASHP, n.d.b). Many patient safety risks such as incorrect calculation, nonaseptic preparation, and incorrect labeling occur when nurses have to prepare medications in IV containers on patient care units. Current best practices include use of IV medications that come in standardized concentrations and dosages; standardized procedures for ordering, preparing, and administering IV medications; and ready-to-administer doses when possible (ASHP, 2008). Nurses only mix medications into IV fluids in emergency situations. The nurse *never* prepares high-alert medications (e.g., heparin, dopamine, dobutamine, nitroglycerin, potassium, antibiotics, or magnesium) on a patient care unit. Check with a pharmacist before mixing a medication in an IV container. If the pharmacist confirms that you need to prepare the medication, ask another nurse to verify your medication calculations and have that nurse watch you during the entire procedure to ensure that you prepare the medication safely. First ensure that the IV fluid and medication are compatible. Then prepare the medication in a syringe (see Skill 31-4) using strict aseptic technique. Clean the injection port of the IV bag with an alcohol swab, remove the cap from the needle, and stick the needle into the IV fluid. Push the medication into the IV fluid and mix the solution by turning the IV bag gently end to end. Finally attach a medication label following ISMP safe label guidelines (2010e). Administer the medication to the patient at the prescribed rate (see Chapter 41). ***Do not*** add medications to IV bags that are already hanging because there is no way to tell the exact concentration of the medication. Add medications ***only*** to new IV bags.

When administering medications in large IV infusions, regulate the IV rate according to the health care provider's order. Monitor patients closely for adverse reactions to the medication and fluid volume overload. Also check the site frequently for infiltration and phlebitis (see Chapter 41).

Intravenous Bolus. An IV bolus involves introducing a concentrated dose of a medication directly into the systemic circulation (Skill 31-6 on pp. 631-635). Because a bolus requires only a small amount of fluid to deliver the medication, it is an advantage when the amount of fluid that the patient can take is restricted. The IV bolus, or "push," is the most dangerous method for administering medications because there is no time to correct errors. In addition, a bolus may cause direct irritation to the lining of blood vessels. Before administering a bolus confirm placement of the IV line. Never give a medication intravenously if the insertion site appears puffy or edematous or the IV fluid cannot flow at the proper rate. Accidental injection of a medication into the tissues around a vein causes pain, sloughing of tissues, and abscesses, depending on the composition of the medication.

Determine the rate of administration of an IV bolus medication by the amount of medication that can be given each minute. For example, if a patient is to receive 4 mL of a medication over 2 minutes, give 2 mL of the IV bolus medication every minute. Look up each medication to determine the recommended concentration and rate of administration. Consider the purpose for which an IV medication is prescribed and any potential adverse effects related to the rate or route of administration.



Volume-Controlled Infusions. Another way of administering IV medications is through small amounts (50 to 100 mL) of compatible IV fluids. The fluid is within a secondary fluid container separate from the primary fluid bag. The container connects directly to the primary IV line or to separate tubing that inserts into the primary line (Skill 31-7 on pp. 635-639). Three types of containers are volume-control administration sets (e.g., Volutrol or Pediatrol), piggyback sets, and mini-infusers. Using volume-controlled infusions has several advantages:

- It reduces risk of rapid-dose infusion by IV push. Medications are diluted and infused over longer time intervals (e.g., 30 to 60 minutes).
- It allows for administration of medications (e.g., antibiotics) that are stable for a limited time in solution.
- It allows for control of IV fluid intake.

Piggyback. A piggyback is a small (25 to 250 mL) IV bag or bottle connected to a short tubing line that connects to the *upper* Y-port of a primary infusion line or to an intermittent venous access (Fig. 31-26). The label on the medication follows the ISMP IV piggyback medication label format (2010e) (Fig. 31-27). The piggyback tubing is a microdrip or macrodrip system (see Chapter 41). The set is called a piggyback because the small bag or bottle is higher than the primary infusion bag or bottle. In the piggyback

14. Pharmacy information if required
15. Comments

FIG. 31-27 IV piggyback medication with label following ISMP safe-labeling guidelines.

setup the main line does not infuse when the piggybacked medication is infusing. The port of the primary IV line contains a back-check valve that automatically stops flow of the primary infusion once the piggyback infusion flows. After the piggyback solution infuses and the solution within the tubing falls below the level of the primary infusion drip chamber, the back-check valve opens, and the primary infusion again flows.

Volume-Control Administration. Volume-control administration (e.g., Buretrol) sets are small (150-mL) containers that attach just below the primary infusion bag or bottle. The set is attached and filled in a manner similar to that used with a regular IV infusion. Follow package directions for priming sets (see Chapter 41).

Mini-Infusion Pump. The mini-infusion pump is battery operated and allows medications to be given in very small amounts of fluid (5 to 60 mL) within controlled infusion times using standard syringes.

Intermittent Venous Access. An intermittent venous access (commonly called a *saline lock)* is an IV catheter capped off on the end with a small chamber covered by a rubber diaphragm or a specially designed cap. Special rubber-seal injection caps usually accept needle safety devices (see Chapter 41). Advantages to intermittent venous access include the following:

- Cost savings resulting from the omission of continuous IV therapy
- Effectiveness of nurse's time enhanced by eliminating constant monitoring of flow rates
- Increased mobility, safety, and comfort for the patient

Before administering an IV bolus or piggyback medication, assess the patency and placement of the IV site. After the medication has been administered through an intermittent venous access, the access must be flushed with a solution to keep it patent. Generally normal saline is an effective flush solution for peripheral catheters. Some agencies require the use of heparin. Nurses need to verify and follow institution policies regarding the care and maintenance of the IV site.

Administration of Intravenous Therapy in the Home. Sometimes patients are discharged from an acute care setting and continue to receive IV therapy in the home. Medications such as antibiotics, chemotherapy, total parenteral nutrition, analgesics, and blood transfusions are given in the home. Most patients who have home IV therapy have a central venous catheter inserted before discharge (see Chapter 41). In addition, patients who need to receive IV therapy in the home have home care nurses to assist with maintenance and monitoring.

Carefully assess patients and their families to determine their ability to manage this therapy at home. Begin instruction on IV care management while the patient is still in the hospital. Patients and families need to learn how to recognize problems and what to do when these problems occur. It is important for the family to recognize signs of infection and complications and know when to notify the home care nurse or health care provider when these occur. In addition, patients and their families need information regarding maintenance of IV administration equipment, including the infusion pump.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Be vigilant during the entire process of medication administration. Ensure that your patients receive the appropriate medications. Know why each medication is ordered for your patient. Understand what you need to do before, during, and after medication administration. Evaluate the effectiveness and assess for adverse effects after your patients take their medications.
- Take care of yourself. You think as clearly and critically as possible if you are healthy. Healthy behaviors such as getting adequate sleep, making healthy food choices, and relaxing pelvic floor muscles during stress are positive ways to help you better process information and make safe decisions during medication administration.
- Set up and prepare medications in distraction-free areas.
- Verify expiration date of medications during preparation. Do not administer expired medications.
- Identify each patient using at least two identifiers before administering medications.
- Clarify all unclear orders and ask for help whenever you are uncertain about a medication order or calculation. Consult with your peers, pharmacists, and other health care providers. Resolve all your concerns related to medication administration before preparing and giving medications.
- Use technology (e.g., bar-code scanning, electronic MARs) that is available to you when preparing and administering medications. Follow all policies related to the safe use of technology and do not use "work-arounds." Nurses who use "work-arounds" fail to follow agency protocols, policies, or procedures during medication administration in an attempt to administer medications to patients in a timelier manner. Failure to follow the standard of care greatly increases the risk for making a medication error, impairs patient safety, and places the nurse at risk for malpractice and disciplinary action (see Chapter 23).
- Educate patients about their medications during medication administration. Patients are often able to identify inappropriate medications. Answer all patient questions and resolve their concerns before giving medications. Include family caregivers in medication education when appropriate.
- In most circumstances you cannot delegate medication administration. Ensure that you follow standards set by your state Nurse Practice Act and guidelines established by the health care agency. Licensed practical nurses (LPNs) or licensed vocational nurses (LVNs) can usually administer medications given PO, subcutaneously, intramuscularly, and intradermally. In some cases they can give medications intravenously if they have had special training and if the medications are not high alert. Some states also allow certified medical assistants (CMAs) to administer some types of medications (e.g., PO medications) in some health care settings (e.g., long-term care facilities). The skills in this chapter assume that you are not in a setting where you can delegate medication administration to nursing assistive personnel (NAP). If you are practicing in a state and a health care setting that allow you to delegate medication administration, follow the guidelines for safe delegation (see Chapter 21), agency policies, and the standards outlined in the Nurse Practice Act in your state.

SKILL 31-1 ADMINISTERING ORAL MEDICATIONS

View Video!

Delegation Considerations

The skill of administering oral medications cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:

- Potential side effects of medications that you summarize, and reporting their occurrence.

Equipment

- Disposable medication cups
- Glass of water, juice, or preferred liquid
- Drinking straw
- Device for crushing or splitting tablets (optional)
- Clean gloves (if handling a medication)
- MAR (electronic or printed)

STEP	RATIONALE
ASSESSMENT	
1 Check accuracy and completeness of each medication administration record (MAR) with prescriber's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any portion of printed MAR that is difficult to read.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications. Illegible MARs are a source of medication errors (Poon et al., 2010).
2 Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.	Allows you to anticipate effects of drug and observe patient's response.
3 Assess for any contraindications to patient receiving oral medication, including being NPO, inability to swallow, nausea/vomiting, bowel inflammation or reduced peristalsis, recent gastrointestinal (GI) surgery, gastric suction, and decreased level of consciousness. Check patient's swallow, cough, and gag reflexes.	Alterations in GI function interfere with medication distribution, absorption, and excretion. Patients with GI suction do not receive benefit from oral medications because they are suctioned from the GI tract before they can be absorbed. Patients with impaired swallowing are at a risk for aspiration (Edmiaston et al., 2010).
CLINICAL DECISION: *If there are any contraindications to the patient receiving oral medications or if in doubt of the patient's ability to swallow oral medications, temporarily withhold medication and inform prescriber.*	
4 Assess patient's medical, medication, and diet history and history of allergies. List patient's food and drug allergies on *each* page of the MAR and prominently display it on the patient's medical record per agency policy. When patient has allergy, provide allergy bracelet.	Information reflects patient's need for and potential responses to medications. Information also indicates potential food and drug interactions. Communication of allergies is essential for safe, effective care.
5 Gather physical examination and laboratory data that influence medication administration (e.g., vital signs, renal and liver function, laboratory findings).	Data sometimes reveal need to hold medication or that medication is contraindicated. Poor liver and kidney function affects metabolism and excretion of medications (Lehne, 2010).
6 Assess patient's knowledge regarding health and medication use.	Determines patient's need for medication education and guidance needed to achieve drug adherence. Assessment often reveals problems such as medication tolerance, nonadherence, abuse, addiction, or dependence.
7 Assess patient's preferences for fluids. Maintain fluid restrictions when applicable. Determine if medication can be given with preferred fluid.	Fluids ease swallowing and facilitate absorption from the GI tract. They are necessary to maintain fluid restrictions. Some fluids interfere with absorption of medications.
PLANNING	
1 Collect appropriate equipment (e.g., disposable medication cup) and MAR.	Enhances time management and efficiency.
2 Plan preparation to avoid interruptions. Do not take phone calls or talk with others. Follow agency policy.	Interruption contributes to medication errors (Biron, Lavoie-Tremblay, and Loiselle, 2009).
IMPLEMENTATION	
1 Prepare medications:	
a. Perform hand hygiene.	Reduces transfer of microorganisms.
b. If using a medication cart, move it outside patient's room.	Organization of equipment saves time and reduces error.
c. Access automated dispensing system (ADS) or unlock medicine drawer or cart.	Medications are safeguarded when locked in cabinet, cart, or computerized medication dispensing system.
d. Prepare medication for *one patient at a time*. Follow the six rights of medication administration. Keep all pages of MARs for one patient together or look at only one patient's medication administration computer screen.	Preventing distractions limits preparation errors (Brady, Malone, and Fleming, 2009).
e. Select correct medication from stock supply, unit-dose drawer, or ADS. Compare name of medication on the label with MAR (see illustration). Exit ADS after removing drug(s).	Reading labels and comparing them with the transcribed order reduces error. *This is the first accuracy check.*
f. Check expiration date on each medication, one at a time. Return outdated drug to pharmacy.	

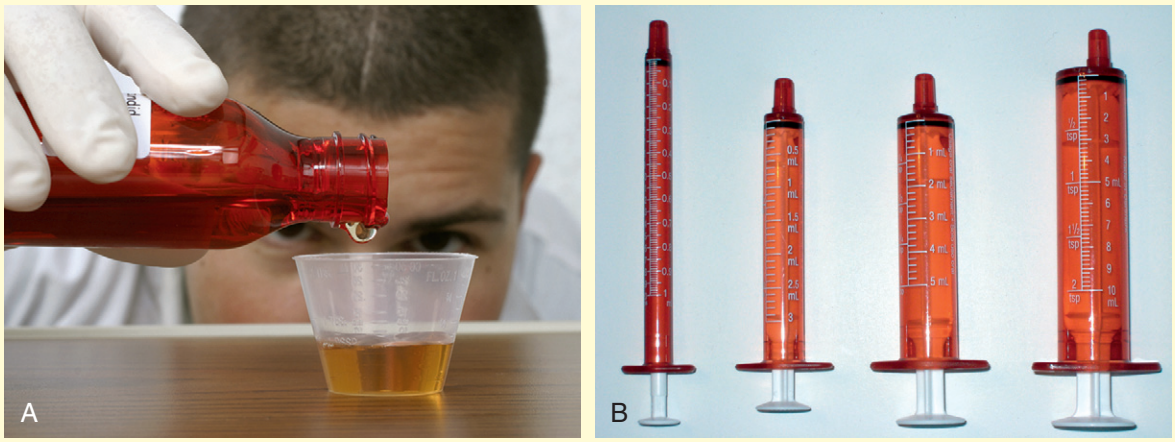
STEP	RATIONALE
g. Check or calculate medication dose as necessary. Double-check calculation. If needed, have another nurse verify calculations.	Double-checking reduces risk of error (Dickinson et al., 2010).
h. If preparing a controlled substance, check record for previous medication count and compare current count with supply available.	Controlled substance laws require nurses to carefully monitor and count dispensed narcotics.

CLINICAL DECISION: *Splitting tablets in half, even if they are prescored with a line down the middle, leads to medication errors. Medications need to be provided in the correct dose whenever possible. If a pill must be split within inpatient settings, the pharmacist splits the pill, repackages and labels it, and sends it to the nurse for administration. Nurses* ***should not*** *split pills (ISMP, 2006).*

i. Prepare solid forms of oral medications:	
(1) To prepare tablets or capsules from a floor stock bottle, pour required number into bottle cap and transfer medication to medication cup. Do not touch medication with fingers. Return extra tablets or capsules to bottle.	Avoids contamination of medications and avoids waste.
(2) To prepare unit-dose tablets or capsules, place packaged tablet or capsule directly into medicine cup. Do not remove wrapper (see illustration).	Wrapper maintains cleanliness of medications and allows you to identify medication name and dose at patient's bedside.
(3) When using a blister pack, "pop" medications through foil or paper backing into a medication cup.	Packs provide a 1-month supply, with each "blister" usually containing a single dose.
(4) Place all tablets or capsules for patient in one medicine cup, except for those requiring preadministration assessments (e.g., pulse rate or blood pressure); keep medications in their wrappers.	Keeping medications that require preadministration assessments separate from others makes it easier to withhold medications as necessary.
(5) If the patient has difficulty swallowing and liquid medications are not an option, use pill-crushing device (see illustration). Clean crushing device before using it. If a pill-crushing device is not available, place tablet between two medication cups and grind with a blunt instrument. Mix ground tablet in small amount (e.g., teaspoon) of soft food (custard or applesauce).	Large tablets are often difficult to swallow. Ground tablet mixed with palatable soft food is usually easier to swallow. Cleaning pill-crushing device ensures that contamination of medications does not occur.

STEP 1e The nurse verifies each medication with the medication administration record.

STEP 1i(2) Place tablet into medicine cup without removing wrapper.



STEP 1i(5) Pill-crushing device used to crush pills when necessary.

SKILL 31-1 ADMINISTERING ORAL MEDICATIONS—cont'd

STEP	RATIONALE

CLINICAL DECISION: *Not all medications can be crushed (e.g., capsules, enteric-coated drugs). Consult with pharmacist and/or the "Do Not Crush List" when in doubt (ISMP, 2010d).*

j. Prepare liquids:	
(1) Gently shake container. If medication is in a unit-dose container with correct amount to administer, no further preparation is necessary. If medication is in a multidose bottle, remove bottle cap from container and place cap upside down.	Shaking container ensures that medication is mixed before administration. Placing cap of bottle upside down prevents contamination of inside of cap.
(2) Hold multidose bottle with label against palm of hand while pouring.	Spilled liquid does not soil or fade label.
(3) Place medication cup at eye level on hard surface (e.g., countertop). Fill to desired level on scale (see illustration A). Make sure that scale is even with fluid level at its surface or base of meniscus, not edges. Draw up volumes of less than 10 mL in syringe designed for oral medication use without needle (see illustration B). *Do not* use parenteral syringe to draw up oral medications.	Ensures accuracy of measurement. Use of special oral syringe for oral medications prevents accidental parenteral administration of oral medication and is more accurate for small doses of medication (ISMP, 2010c).

STEP 1j(3) **A,** Pour desired volume of liquid so base of meniscus is level with line on scale. **B,** Use special oral medication syringes to prepare small amounts of liquid medications.

(4) Discard any excess liquid into sink or a place specially designated for wasting of medications. Wipe lip and neck of bottle with paper towel.	Prevents contamination of contents of bottle and prevents bottle cap from sticking.
(5) Administer liquid medication packaged in single-dose cup directly from the single-dose cup. Do not pour into medicine cup.	Avoids unnecessary manipulation of dose.
k. Before going to patient's room, compare patient's name and name of medication on label of prepared drugs with MAR.	Reading labels a second time reduces error. *This is the second accuracy check.*
l. Return stock containers or unused unit-dose medications to shelf or drawer and read label again.	Reading the label of medications in multiple-dose containers reduces administration errors.
m. Do not leave medications unattended.	Nurse is responsible for safekeeping of drugs.
2 Administer medications:	
a. Take medications to patient at correct time (see agency policy). Give time-critical, STAT, and single-order medications at time ordered. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers the patient needs, the prescribed medication, and the specific clinical indications (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
b. Identify patient using at least two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011a).

CLINICAL DECISION: *Replace patient identification bracelets that are missing, illegible, or faded.*

c. Compare names of medications on labels with MAR at patient's bedside.	Final check of medication labels against MAR at patient's bedside reduces medication administration errors. *This is the third check for accuracy.*
d. Explain purpose of each medication, its action, and possible adverse effects to patient. Allow patient to ask any questions about drugs.	Patient has right to be informed; questions often indicate need for teaching, nonadherence to therapy, or potential medication error.

STEP	RATIONALE
e. Perform necessary preadministration assessments (e.g., blood pressure, pulse).	Determines whether specific medications should be withheld at that time.
f. Assist patient to sitting or Fowler's position. Use side-lying position if sitting is contraindicated. Have patient stay in this position for 30 minutes after administration.	Sitting position prevents aspiration during swallowing (Eisenstadt, 2010; Palmer and Metheny, 2008).
g. Administer medications	
(1) For tablets: Some patients want to hold solid medications in hand or cup before placing in mouth. Offer water or juice to help patient swallow.	Patient becomes familiar with medications by seeing each drug. Choice of fluid can improve fluid intake.
(2) For sublingual-administered medications: Have patient place medication under tongue and allow it to dissolve completely (see Fig. 31-3, p. 572). Caution patient against swallowing tablet.	Medication is absorbed through blood vessels of undersurface of tongue. If swallowed, gastric juices destroy medication, or the liver detoxifies it so rapidly that therapeutic blood levels are not attained.
(3) For buccal medications: Have patient place medication in mouth against mucous membranes of the cheek until it dissolves (see Fig. 31-4, p. 572). Avoid administering liquids until buccal medication has dissolved.	Buccal medications act locally on mucosa or systemically as they are swallowed in saliva.
(4) For powdered medications: Mix with liquids at bedside and give to patient to drink.	When prepared in advance, powdered medications often thicken and even harden, making swallowing difficult.
(5) For crushed medications mixed in food: Give each medication separately in teaspoon of food.	Ensures that patient swallows all of medicine.
(6) Caution patient against chewing or swallowing lozenges.	Medication acts through slow absorption through oral mucosa, not gastric mucosa.
(7) Give effervescent powders and tablets immediately after dissolving.	Effervescence improves unpleasant taste and often relieves GI problems.
h. If patient is unable to hold medications, place medication cup to lips and gently introduce each drug into the mouth, one at a time. Do not rush.	Administering single tablet or capsule eases swallowing and decreases risk of aspiration.
CLINICAL DECISION: *If tablet or capsule falls to the floor, discard it and repeat preparation.*	
i. Stay until patient has completely swallowed each medication. Ask patient to open mouth if uncertain whether medication has been swallowed.	You are responsible for ensuring that patient receives ordered dosage. If left unattended, some patients do not take dose or save medications, causing risk to health.
j. For highly acidic medications (e.g., aspirin), offer patient nonfat snack (e.g., crackers) if not contraindicated by patient's condition.	Reduces gastric irritation.
k. Help patient return to comfortable position.	Maintains patient's comfort.
l. Dispose of soiled supplies and perform hand hygiene.	Reduces transmission of microorganisms.
m. Replenish stock such as cups and straws, return cart to medication room if used, and clean work area.	Clean and organized work space helps other staff complete duties efficiently.

EVALUATION

1 Evaluate patient's response to medications at times that correlate with onset, peak, and duration of the medication.	Evaluates therapeutic benefit of medication and detects onset of side effects or allergic reactions.
2 Ask patient or family member to identify medication name and explain purpose, action, dosage schedule, and potential side effects of drug.	Determines level of knowledge gained by patient and family.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient exhibits adverse effects (side effect, toxic effect, allergic reaction) such as urticaria, rash, wheezing.
- *Always* notify prescriber and pharmacy when patient exhibits adverse effects.
- Withhold further doses and add allergy information to patient's medical record.

2 Patient refuses medication.
- Explore reasons why patient does not want medication.
- Educate if misunderstandings of medication therapy are apparent.
- Do not force patient to take medication; patients have the right to refuse treatment. If patient continues to refuse medication despite educational attempts, record why the drug was withheld on patient's chart and notify prescriber.

RECORDING AND REPORTING

- Chart medication dose, route, time and date given on MAR immediately after administering.
- Record the reason that any drug is withheld and follow agency policy for proper recording.
- Record and report evaluation of medication effect to prescriber if required (e.g., report urine output following administration of diuretic if ordered by prescriber).

HOME CARE CONSIDERATIONS

- Instruct patients and family caregivers about all aspects of medication administration, including dosage, desired effect, when to take medications, proper storage of medications, anticipated side effects, and whether to take medication with or without food, to ensure safe medication administration at home.
- Evaluate patient's ability to safely self-administer medications. If unable to safely self-administer, attempt nursing interventions such as a chart or pillbox to assist in self-administration. If interventions fail and patient still is unable to administer medications safely, notify the prescriber.

SKILL 31-2 ADMINISTERING OPHTHALMIC MEDICATIONS

View Video!

Delegation Considerations

The skill of administering ophthalmic medications cannot be delegated to nursing assistive personnel (NAP). Instruct NAP about:

- Potential side effects of medications and to report their occurrence, including the potential for visual changes.

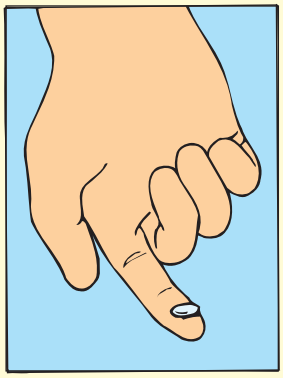
Equipment

- Medication bottle with sterile eyedropper or ointment tube or medicated intraocular disk
- Cotton ball or tissue
- Washbasin filled with warm water and washcloth if eyes have crust or drainage
- Eye patch and tape (optional)
- Clean gloves
- MAR

STEP	RATIONALE
ASSESSMENT	
1 Check accuracy and completeness of each medication administration record (MAR) with prescriber's medication order. Check patient's name and medication name and dosage (e.g., number of drops [if a liquid] and eye [right, left, or both eyes]), and route and time of administration. Recopy or reprint any portion of MAR that is difficult to read.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications. Illegible MARs are a source of medication errors (Poon et al., 2010).
2 Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.	Allows you to anticipate effects of drug and observe patient's response.
3 Assess condition of external eye structures (see Chapter 30). (You may also do this just before medication administration.)	Provides baseline to later determine if local response to medication occurs. Also indicates need to clean eye before medication application.
4 Assess patient's medical history, history of allergies (including latex), and medication history. If patient has latex allergy, use nonlatex gloves.	Factors in history influence how certain drugs act. Protects patient from risk of allergic medication response.
5 Determine whether patient has any symptoms of visual alterations.	Certain eye medications act to either lessen or increase these symptoms. Provides baseline assessment for recognizing change in patient's condition.
6 Assess patient's level of consciousness and ability to follow directions.	If patient becomes restless or combative during procedure, a greater risk of accidental eye injury exists.
7 Assess patient's knowledge regarding medication therapy and desire to self-administer medication.	Patient's level of understanding indicates need for health teaching. Motivation influences teaching approach.
8 Assess patient's ability to manipulate and hold dropper.	Reflects patient's ability to learn to self-administer medication.
PLANNING	
1 Collect appropriate equipment (e.g., tissue, clean gloves) and MAR.	Enhances time management and efficiency.
2 Plan preparation to avoid interruptions. Do not take phone calls. Follow agency policy.	Interruption contributes to medication errors (Biron, Lavoie-Tremblay, and Loiselle, 2009).
IMPLEMENTATION	
1 Perform hand hygiene and prepare medication (see Skill 31-1, Steps 1a to 1g). Be sure to check the label two times while preparing medication.	Hand hygiene reduces transmission of microorganisms. Ensures that patient receives correct medication. *This is the first and second accuracy check.*
2 Take medication to patient at correct time (see agency policy). Give time-critical, STAT, and single-order medications at time ordered. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers the patient needs, the prescribed medication, and the specific clinical indications (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3 Identify patient using at least two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011a).
4 Compare names of medications on labels with MAR at patient's bedside.	*Third check for accuracy ensures that right medication is administered.*
5 Explain procedure to patient; describe positioning and sensations to expect such as burning or eye irritation. Ask if patient has any questions.	Relieves anxiety about medication being instilled into eye.
6 Arrange supplies at bedside; apply clean gloves. If eyedrops are stored in refrigerator, allow them to come to room temperature before giving them.	Reduces transmission of microorganisms and follows standards to prevent accidental exposure to body fluids. Warming eyedrops reduces irritation to eye.

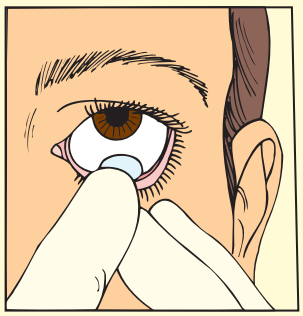
STEP	RATIONALE
7 Gently roll eyedrop container between your hands.	Ensures that medication is mixed before administration. Shaking bottle causes bubbles, which makes medication administration difficult.
8 Ask patient to lie supine or sit back in chair with head slightly hyperextended.	Position provides easy access to eye for medication instillation and minimizes drainage of medication through tear duct.
CLINICAL DECISION: *Do not hyperextend the neck of a patient with cervical spine injury.*	
9 If crusts or drainage is present along eyelid margins or inner canthus, gently wash away. Soak any crusts that are dried and difficult to remove by applying damp washcloth or cotton ball over eye for a few minutes. Always wipe clean from inner to outer canthus.	Crusts or drainage harbors microorganisms. Soaking allows easy removal and prevents pressure from being applied directly over eye. Cleaning from inner to outer canthus avoids entrance of microorganism into lacrimal duct.
10 Hold cotton ball or clean tissue in nondominant hand on patient's cheekbone just below lower eyelid.	Cotton or tissue absorbs medication that escapes eye.
11 With tissue or cotton resting below lower lid, gently press downward with thumb or forefinger against bony orbit.	Technique exposes lower conjunctival sac. Retraction against bony orbit prevents pressure and trauma to eyeball and fingers from touching eye.
12 Ask patient to look at ceiling.	Action retracts sensitive cornea up and away from conjunctival sac and reduces stimulation of blink reflex.
13 Instill ophthalmic drops:	
a. With dominant hand resting on patient's forehead, hold filled medication eyedropper or ophthalmic solution approximately 1 to 2 cm (½ to ¾ inches) above conjunctival sac (see illustration).	Helps prevent accidental contact of eyedropper with eye structures, thus reducing risk of injury to eye and transfer of infection to dropper. Ophthalmic medications are sterile.
b. Drop prescribed number of medication drops into conjunctival sac.	Conjunctival sac normally holds 1 or 2 drops. Provides even distribution of medication across eye.
c. If patient blinks or closes eye or if drops land on outer lid margins, repeat instillation.	Patient obtains therapeutic effect of drug only when drops enter conjunctival sac.
d. After instilling drops, ask patient to close eye gently.	Helps to distribute medication. Squinting or squeezing of eyelids forces medication from conjunctival sac (ASHP, n.d.a).
e. When administering medications that cause systemic effects, apply gentle pressure with your finger and clean tissue on the patient's nasolacrimal duct for 30 to 60 seconds.	Prevents overflow of medication into nasal and pharyngeal passages. Prevents absorption into systemic circulation (ASHP, n.d.a).
f. If patient receives more than one eye medication to the same eye at the same time, wait at least 5 minutes before administering the next medication and use a different cotton ball or tissue with each medication.	Avoids interaction between medications (ASHP, n.d.a).
14 Instill ophthalmic ointment:	
a. Holding ointment applicator above lower lid margin, apply thin stream of ointment evenly along inner edge of lower eyelid on conjunctiva (see illustration) from the inner canthus to outer canthus.	Distributes medication evenly across eye and lid margin.
b. Have patient close eye and rub lid lightly in circular motion with cotton ball if rubbing is not contraindicated.	Distributes medication evenly across eye and lid margin.

STEP 13a Hold eyedropper above conjunctival sac.



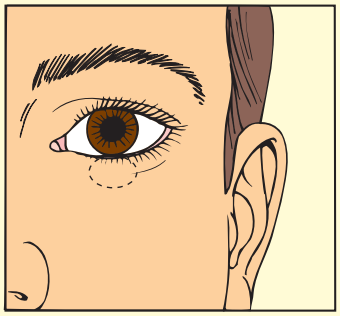
STEP 14a Apply ointment along lower eyelid.

SKILL 31-2 ADMINISTERING OPHTHALMIC MEDICATIONS—cont'd

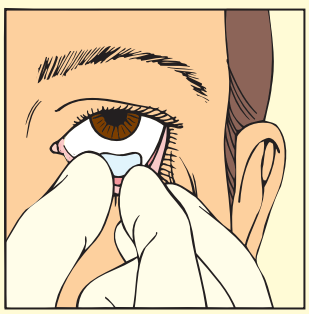


STEP	RATIONALE
15 Administer intraocular disk:	
a. Open package containing disk. Gently press fingertip against disk so it adheres to finger. Position convex side of disk on fingertip (see illustration).	Allows you to inspect disk for damage or deformity.
b. With other hand gently pull patient's lower eyelid away from the eye. Ask patient to look up.	Prepares conjunctival sac for receiving medicated disk.
c. Place disk in conjunctival sac so it floats on the sclera between the iris and lower eyelid (see illustration).	Ensures delivery of medication (Alvarez-Lorenzo et al., 2006).
d. Pull patient's lower eyelid out and over disk (see illustration). You should not be able to see the disk at this time. Repeat Step 15 if you can see the disk.	Ensures accurate medication delivery.
16 Removal of intraocular disk	
a. Perform hand hygiene and apply gloves.	Prevents transfer of microorganisms.
b. Explain procedure to patient.	Relieves anxiety about manipulation of disk in eye.
c. Gently pull on patient's lower eyelid using nondominant hand.	Exposes intraocular disk.
d. Using forefinger and thumb of opposite hand, pinch disk and lift it out of patient's eye (see illustration).	
17 If excess medication is on eyelid, gently wipe it from inner to outer canthus.	Promotes comfort and prevents trauma to eye (ASHP, n.d.a).
18 If patient had eye patch, apply clean one by placing it over affected eye so entire eye is covered. Tape securely without applying pressure to eye.	Clean eye patch reduces chance of infection.
19 Remove gloves, dispose of soiled supplies in proper receptacle, and perform hand hygiene.	Maintains neat environment at bedside and reduces transmission of microorganisms.

EVALUATION



1 Note patient's immediate response to instillation; ask if patient felt any discomfort.	Determines if procedure performed correctly and safely.
2 Observe response to medication by assessing visual changes and noting any side effects.	Evaluates effects of medication.
3 Ask patient to discuss purpose, action, side effects, and technique of administration of medication.	Determines patient's level of understanding.
4 Have patient demonstrate self-administration of next dose.	Provides feedback regarding competency with skill.



STEP 15a Gently position convex side of disk against fingertips.

STEP 15c Place disk in conjunctival sac between the iris and lower eyelid.

STEP 15d Gently pull lower eyelid over the disk.

STEP 16d Carefully pinch disk to remove it from patient's eye.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient cannot instill drops without supervision.
- Reinforce teaching and allow patient to self-administer drops as much as possible to enhance confidence.
- If patient cannot self-administer drops, teach family caregivers to instill them into patient's eye.

2 Patient displays signs of allergic reaction (e.g., tearing, reddened sclera) or systemic response (e.g., bradycardia) to medication.
- Hold medication and speak with prescriber.
- Follow institutional policy or guidelines for reporting adverse or allergic reaction to medications.
- Add information about allergy to medical record per agency policy.

RECORDING AND REPORTING

- Record medication, concentration, number of drops, time and date of administration, and eye (left, right, or both) that received medication on MAR.
- Record appearance of eye in nurses' notes.

HOME CARE CONSIDERATIONS

- Have patients with chronic health care problems consult with their health care provider before using over-the-counter eye medication.
- When using eyedrops at home, patients should not share medications with other family members because risk of infection transmission is high.

SKILL 31-3 USING METERED-DOSE OR DRY POWDER INHALERS

Delegation Considerations

The skill of administering metered-dose inhalers (MDIs) or dry powder inhalers (DPIs) and supervision of patients who self-administer them cannot be delegated to nursing assistive personnel (NAP). Instruct NAP about:

- Potential side effects of medications and changes in the patient's respiratory status (e.g., increased coughing) and reporting their occurrence.

Equipment

- MDI or DPI
- Spacer (optional with MDI)
- Facial tissues (optional)
- Washbasin or sink with warm water
- Paper towel
- MAR (electronic or printed)

STEP	RATIONALE
ASSESSMENT	
1 Check accuracy and completeness of each medication administration record (MAR) with prescriber's medication order. Check patient's name and medication name, dosage (e.g., number of puffs), route, and time for administration. Recopy or reprint any portion of MAR that is difficult to read.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications. Illegible MARs are a source of medication errors (Poon et al., 2010).
2 Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.	Allows you to anticipate effects of drug and observe patient's response.
3 Assess patient's medical history, history of allergies, and medication history.	Factors influence how drugs act. Reveals patient's risk for allergic response.
4 Assess patient's respiratory pattern and auscultate breath sounds.	Establishes baseline of airway status for comparison during and after treatment.
5 If previously instructed in self-administration, assess patient's ability to use inhaler (e.g., hold, manipulate, and depress canister; strength of inhalation).	Instruction sometimes only requires reinforcement of previous learning. Any impairment in ability to grasp container, breathe, or coordinate hand movement interferes with patient's ability to use MDI or DPI correctly.
6 Assess patient's *readiness* and *ability* to learn: patient asks questions about medication, disease, or complications; requests education in use of inhaler; is mentally alert, not fatigued or in pain, or in respiratory distress; and participates in own care.	Readiness affects patient's ability to understand explanations and actively participate in instruction. Mental or physical limitations affect patient's ability to learn and methods nurse uses for instruction (Bastable, 2008).
7 Assess patient's knowledge and understanding of disease and purpose and action of prescribed medications.	Knowledge of disease is essential for patient to realistically understand use of inhaler.
8 Determine medication schedule and number of inhalations prescribed for each dose.	Influences explanations nurse provides for use of inhaler.
PLANNING	
1 Collect appropriate equipment (e.g., spacer) and MAR.	Enhances time management and efficiency.
2 Provide adequate time for teaching session.	Prevents interruptions and enhances learning (Bastable, 2008).

SKILL 31-3 USING METERED-DOSE OR DRY POWDER INHALERS—cont'd

STEP	RATIONALE
IMPLEMENTATION	
1 Perform hand hygiene and prepare medication (see Skill 31-1, Steps 1a to 1g). Be sure to compare the label of the medication with the MAR two times while preparing the medication.	Following the same routine when preparing medications, eliminating distractions, and checking the label of the medication with transcribed order reduce error (Brady, Malone, and Fleming, 2009). *First and second check ensures that right medication is administered.*
2 Take medications to patient at correct time (see agency policy). Give time-critical, STAT, and single-order medications at time ordered. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers the patient needs, the prescribed medication, and the specific clinical indications (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3 Identify patient using at least two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011a).
4 Compare names of medications on labels with MAR at patient's bedside.	*Third check for accuracy ensures that right medication is administered.*
5 Instruct patient in comfortable environment by sitting in chair in hospital room or at kitchen table in home.	Patient is more likely to remain receptive of nurse's explanations if in a comfortable environment (Bastable, 2008).
6 Allow patient opportunity to manipulate inhaler, canister, and spacer device. Explain and demonstrate how canister fits into inhaler.	Patient needs to be familiar with how to use equipment.
CLINICAL DECISION: *If patient is using an MDI with or without a spacer and the inhaler is new or has not been used for several days, push a "test spray" into the air. You do not need to do this for a DPI.*	
7 Explain what metered dose is, and warn patient about overuse of inhaler, including medication side effects.	Patient must not administer excessive inhalations because of risk of serious side effects. If medication is given in recommended doses, side effects are uncommon.
8 Explain steps for administering squeeze-and-breathe MDI (demonstrate steps when possible): **a.** Insert MDI canister into the holder. **b.** Remove mouthpiece cover from inhaler.	Use of simple, step-by-step explanations allows patient to ask questions at any point during procedure (Bastable, 2008).
CLINICAL DECISION: *Clean dirt or foreign objects from mouthpiece before using inhaler to avoid inhalation of unwanted material.*	
c. Shake inhaler vigorously five or six times. Hold inhaler in dominant hand.	Ensures that fine particle are aerosolized.
d. Have patient sit up or stand and take a deep breath and exhale.	Empties lungs and prepares the patient's airway to receive the medication.
e. Instruct the patient to position the inhaler in one of two ways. **(1)** Close mouth around mouthpiece with opening toward back of throat (see illustration) and lips held tight around it. **(2)** Position mouthpiece 2 to 4 cm (1 to 2 inches) in front of the mouth (see illustration).	Proper positioning of inhaler is essential to administering medication correctly. Position directs aerosol toward airways.
f. With inhaler properly positioned, have patient hold it with thumb at mouthpiece and index and middle fingers at the top. This is called a *three-point* or *lateral hand position*.	MDIs work best when patients use a three-point or lateral hand position to activate canisters (Lilley et al., 2007).

STEP 8e(1) Patient opens lips and places inhaler in mouth with opening toward back of throat.

STEP 8e(2) Patient positions mouthpiece 1 to 2 inches away from mouth.

STEP	RATIONALE
g. Instruct patient to tilt head back slightly and inhale slowly and deeply through mouth for 3 to 5 seconds while depressing canister fully.	Distributes medication to airways during inhalation. Inhalation through mouth rather than nose draws medication more effectively into airways.
h. Have patient hold breath for about 10 seconds.	Allows tiny drops of aerosol spray to reach deeper branches of airways (MayoClinic.com, 2009b).
i. Remove MDI from mouth and exhale through pursed lips.	Keeps small airways open during exhalation.
9 Explain steps to administer MDI using a spacer such as an Aerochamber (demonstrate when possible):	Use of simple, step-by-step explanations allows patient to ask questions at any point during instruction.
a. Insert canister into holder. Remove mouthpiece cover from MDI and mouthpiece of spacer. Inspect spacer for foreign objects and ensure that valve is intact if spacer has one.	Inhaler fits into end of spacer.
b. Shake MDI inhaler vigorously five or six times.	Ensures that fine particles are aerosolized.
c. Insert MDI into end of spacer.	Spacer traps medication released from MDI; patient then inhales the drug from the device. These devices break up and slow down the medication particles, increasing the amount of medication that goes into the patient's lungs (MayoClinic.com, 2009a).
d. Instruct patient to place spacer mouthpiece into mouth and close lips. Do not insert beyond raised lip on mouthpiece. Avoid covering small exhalation slots with lips (see illustration).	Medication should not escape through the mouth.
e. Have patient breathe in and exhale completely and then breathe normally through spacer mouthpiece.	Empties lungs and prepares for medication.
f. Have patient depress medication canister, spraying one puff into spacer.	Emits spray that allows finer particles to be inhaled. Large droplets are retained in spacer.
g. Instruct patient to inhale deeply and slowly through mouth for 3 to 5 seconds.	Maximizes amount of medication that enters the lung.
h. Have patient hold breath for 10 seconds.	Ensures full medication distribution.
i. Remove MDI and spacer before exhaling.	Allows patient to exhale normally.
10 Explain steps to administer DPI or breath-activated MDI (demonstrate when possible):	
a. Remove cover from mouthpiece. **Do not shake** inhaler.	
b. Prepare medication as directed by manufacturer (e.g., hold inhaler upright and turn wheel to right and then to left until a click is heard, load medication pellet).	Primes inhaler, ensuring that medication is delivered to patient (MayoClinic.com, 2009a).
c. Exhale away from inhaler before inhalation.	Prevents loss of powder.
d. Position mouthpiece between lips (see illustration).	Prevents medication from escaping through mouth.
e. Inhale deeply and forcefully through mouth.	Creates aerosol.
f. Hold breath for 5 to 10 seconds.	Ensures full medication distribution.
11 Instruct patient to wait at least 20 to 30 seconds between inhalations of the same medication and 2 to 5 minutes between inhalations of different medications or as ordered by prescriber.	Medications must be inhaled sequentially. Always give bronchodilators before steroids. First inhalation opens airways. Second or third inhalation reduces inflammation and/or penetrates deeper airways.

CLINICAL DECISION: *If patient uses a corticosteroid, have him or her rinse mouth out with water or salt water or brush teeth after inhalation to reduce risk of fungal infection. Also teach patient to inspect oral cavity daily for redness, sores, or white patches. Report abnormal assessment findings to the patient's health care provider (MayoClinic.com, 2009a).*

STEP 9d Have patient place mouthpiece in mouth and close lips, being careful to keep exhalation slots exposed.

STEP 10d Have patient place mouthpiece of dry powdered inhaler between lips.

SKILL 31-3 USING METERED-DOSE OR DRY POWDER INHALERS—cont'd

STEP	RATIONALE
12 Instruct patient against repeating inhalations before next scheduled dose.	Medications are prescribed at intervals during day to provide constant drug levels and minimize side effects.
13 Explain that patient may feel gagging sensation in throat caused by droplets of medication on pharynx or tongue. Approximately 2 minutes after dose have patient rinse mouth out with warm water.	Results when inhalant is sprayed and inhaled incorrectly.
14 Instruct patient how to clean inhaler:	
a. Once a day remove canister from inhaler. Inhaler and cap need to be rinsed in warm running water. Inhaler needs to be completely dry before using.	Accumulation of spray around mouthpiece interferes with proper distribution during use.
b. Twice a week, the L-shaped plastic mouthpiece needs to be washed with mild dishwashing soap and warm water. Rinse and dry well before putting canister back inside mouthpiece.	Removes residual medication. Do not place inhalers holding cromolyn, nedocromil, or hydrofluoroalkanes (HFAs) in water.

EVALUATION

1 Ask if patient has any questions.	Clarifies misconceptions or misunderstanding.
2 Have patient explain and demonstrate steps in use of inhaler.	Return demonstration provides feedback for measuring patient's learning.
3 Ask patient to explain medication schedule, side effects, and when to call health care provider.	Improves likelihood of adherence to therapy.
4 Ask patient to calculate how many days the inhaler will last.	Helps patient determine when to reorder prescription.
5 Assess patient's respiratory status: ease of respirations, auscultation of lungs, and use of pulse oximetry (see Chapter 30).	Determines status of breathing pattern and adequacy of ventilation.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient needs a bronchodilator more than every 4 hours.
- Indicates respiratory problems; reassessment of type of medication and delivery methods is needed.
- Notify health care provider if respiratory status does not improve.

2 Patient experiences cardiac dysrhythmias, light-headedness, and/or syncope, especially if receiving beta-adrenergics.
- Withhold all further doses of medication.
- Consult with health care provider.

3 Patient is not able to self-administer medication properly.
- Explore alternative delivery routes or methods of medication administration.

4 Patient experiences paroxysms of coughing caused by irritation of posterior pharynx.
- Consult with health care provider to reassess type of medication or delivery method.

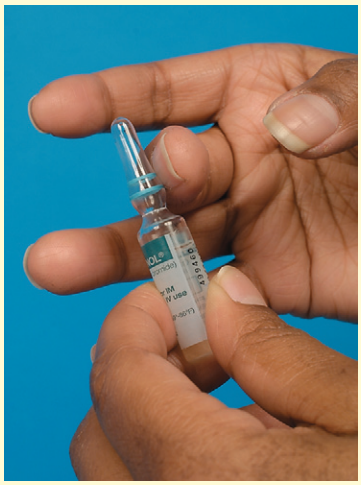
RECORDING AND REPORTING

- Document skills taught and patient's ability to perform skills.
- Record medication, time and date of administration, route, and number of puffs on the MAR.
- Document patient's response to medication in nurses' notes.
- Report any undesirable effects from medication.

HOME CARE CONSIDERATIONS

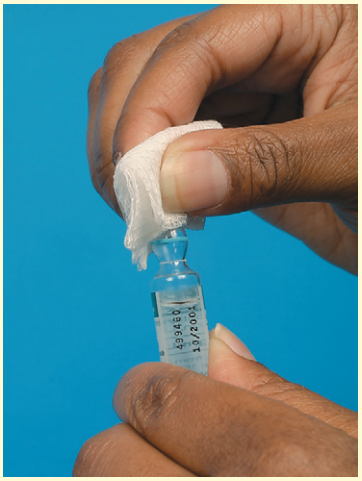
- Remind patients to carry their prescribed inhalers to use emergently in case of an acute asthma attack.

SKILL 31-4 PREPARING INJECTIONS



Delegation Considerations

The skill of preparing injections cannot be delegated to nursing assistive personnel (NAP).



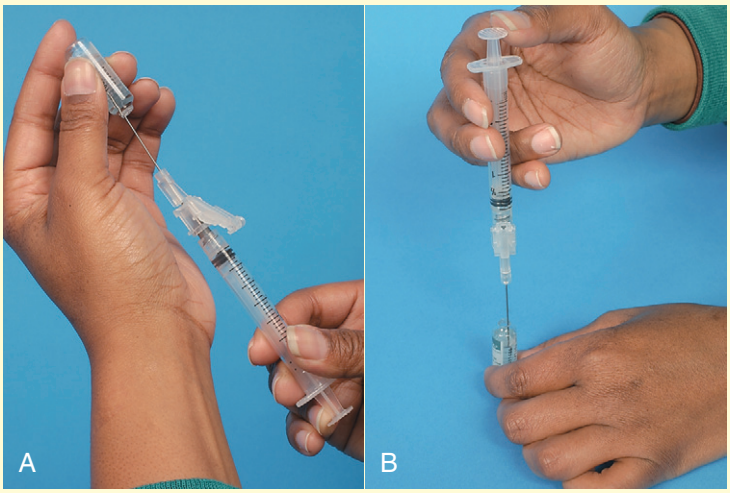
Equipment

- Small gauze pad or unopened alcohol swab
- MAR (electronic or printed)
- Medication in an ampule
  - Safety syringe, needle, and filter needle
- Medication in a vial
  - Safety syringe
  - Needles:
    - — Blunt tip vial access cannula (if needleless system used)
    - — Filter needle (if indicated)
    - — Needle for drawing up medication (if needed)
    - — Safety needle for injection
- Diluent (e.g., normal saline or sterile water) (if indicated)

STEP	RATIONALE
ASSESSMENT	
1 Check accuracy and completeness of each medication administration record (MAR) with prescriber's medication order. Check patient's name and medication name, dosage, and route and time for administration. Recopy or reprint any portion of MAR that is difficult to read.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications. Illegible MARs are a source of medication errors (Poon et al., 2010).
2 Review pertinent information related to medication, including action, purpose, dose and route, side effects, and nursing implications.	Allows nurse to administer medication properly and monitor patient's response.
3 Assess patient's body build, muscle size, and weight.	Determines type and size of syringe and needles for injection.
PLANNING	
1 Collect appropriate equipment (e.g., disposable medication cup) and MAR.	Enhances time management and efficiency.
2 Plan preparation to avoid interruptions. Do not take phone calls or talk with others. Follow agency policy.	Interruption contributes to medication errors (Biron, Lavoie-Tremblay, and Loiselle, 2009).
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Prepare medication (see Skill 31-1, Steps 1a to 1h). Be sure to check the label two times while preparing medication.	Following the same routine when preparing medications, eliminating distractions, and checking the label of the medication with transcribed order reduces error (Brady et al., 2009). *First and second check ensures that right medication is administered.*
a. Ampule preparation	
(1) Tap top of ampule lightly and quickly with finger until fluid moves from neck of ampule (see illustration).	Dislodges any fluid that collects above neck of ampule. All solution moves into lower chamber.
(2) Place small gauze pad or unopened alcohol swab just above neck of ampule (see illustration).	Placing pad around neck of ampule protects nurse's fingers from trauma as glass tip is broken off.
(3) Snap neck of ampule quickly and firmly away from hands (see illustration).	Protects nurse's fingers and face from shattering glass.
(4) Draw up medication quickly, using filter needle long enough to reach bottom of ampule.	System is open to airborne contaminants. Needle needs to be long enough to access medication for preparation. Filter needles filter out any fragments of glass (Nicoll and Hesby, 2002).
(5) Hold ampule upside down or set it on a flat surface with filter needle in center of ampule opening. Do not allow needle tip or shaft to touch rim of ampule.	Broken rim of ampule is considered contaminated. When ampule is inverted, solution comes out if needle tip or shaft touches rim of ampule.

STEP 2a(1) Tapping ampule moves fluid down neck.

STEP 2a(2) Gauze pad placed just above neck of ampule.

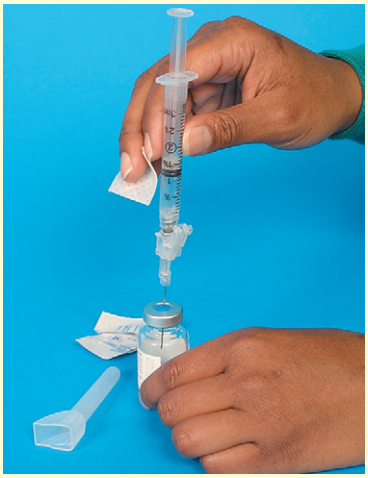


STEP 2a(3) Snapping neck away from hands.

SKILL 31-4 PREPARING INJECTIONS—cont'd

STEP	RATIONALE
(6) Aspirate medication into syringe by gently pulling back on plunger (see illustrations).	Withdrawal of plunger creates negative pressure within syringe barrel, which pulls fluid into syringe.
(7) Keep needle tip under surface of liquid. Tip ampule to bring all fluid within reach of needle.	Prevents aspiration of air bubbles.
(8) If air bubbles are aspirated, do not expel air into ampule.	Air pressure forces liquid out of ampule and medication is lost.
(9) To expel excess air bubbles, remove needle from ampule. Hold syringe with needle pointing up. Tap side of syringe to cause bubbles to rise toward needle. Draw back slightly on plunger and push plunger upward to eject air. Do not eject fluid.	Withdrawing plunger too far removes it from barrel. Holding syringe vertically allows fluid to settle in bottom of barrel. Pulling back on plunger allows fluid within needle to enter barrel so it is not expelled. Air at top of barrel and within needle is then expelled.
(10) If syringe contains excess fluid, use sink or other specially designated area for medication disposal. Hold syringe vertically with needle tip up and slanted slightly toward sink. Slowly eject excess fluid into sink. Recheck fluid level in syringe by holding it vertically.	Medication dose prepared accurately. Position of needle allows medication to be expelled without flowing down needle shaft. Rechecking fluid level ensures proper dose.
(11) Cover needle with its safety sheath or scoop needle to recap. Replace filter needle with safety needle or needleless access device for injection.	Prevents contamination of needle. Filter needles cannot be used for injection. Scooping technique prevents needlestick injury.
b. Vial containing a solution	
(1) Remove cap covering top of unused vial to expose sterile rubber seal, keeping rubber seal sterile. If a multidose vial has been used before, cap is already removed. Firmly and briskly wipe surface of rubber seal with alcohol swab and allow it to dry.	Vial comes packaged with seal that cannot be replaced after cap removal. Not all drug manufacturers guarantee that caps of unused vials are sterile. Therefore swab seals with alcohol before preparing medication. Allowing alcohol to dry prevents needle from being coated with alcohol and mixing with medication.
(2) Pick up syringe and remove needle cap or cap covering needleless vial access device (see illustration). Pull back on plunger to draw amount of air into syringe equal to volume of medication to be aspirated from vial.	Inject air first into vial to prevent buildup of negative pressure in vial when aspirating medication.

CLINICAL DECISION: *Some medications and agencies require use of a filter needle when preparing medications from a vial. See agency policy (Nicoll and Hesby, 2002). If using a filter needle to aspirate the medication, it is changed to a regular needle of suitable size to administer the medication.*



STEP 2a(6) **A,** Medication aspirated with ampule inverted. **B,** Medication aspirated with ampule on flat surface.

STEP 2b(2) Syringe with needleless adapter.

STEP	RATIONALE
(3) With vial on flat surface, insert tip of needle with beveled tip entering first or needleless access device through center of rubber seal (see illustration). Apply pressure to tip of needle during insertion.	Center of seal is thinner and easier to penetrate. Injecting beveled tip first and using firm pressure prevent coring of rubber seal, which could enter vial or needle.
(4) Inject air into the airspace of the vial, holding on to plunger. Hold plunger with firm pressure; air pressure within the vial sometimes forces the plunger backward.	Injecting air before aspirating fluid creates vacuum needed to get medication to flow into syringe. Injecting into airspace of vial prevents formation of bubbles and inaccuracy in dose.
(5) Invert vial while keeping firm hold on syringe and plunger (see illustration). Hold vial between thumb and middle fingers of nondominant hand. Grasp end of syringe barrel and plunger with thumb and forefinger of dominant hand to counteract pressure in vial.	Inverting vial allows fluid to settle in lower half of container. Position of hands prevents forceful movement of plunger and permits easy manipulation of syringe.
(6) Keep tip of needle below fluid level.	Prevents aspiration of air.
(7) Allow air pressure from vial to fill syringe gradually with medication. If necessary, pull back slightly on plunger to obtain correct amount of solution.	Positive pressure within vial forces fluid into syringe.
(8) When desired volume is obtained, position needle into airspace of vial; tap side of syringe barrel carefully to dislodge any air bubbles. Eject any air remaining at top of syringe into vial.	Forcefully striking barrel while needle is inserted in vial bends needle. Accumulation of air displaces medication and causes dose errors.
(9) Remove needle from vial by pulling back on barrel of syringe.	Accidentally pulling plunger rather than barrel causes plunger to separate from barrel, resulting in loss of medication.
(10) Hold syringe at eye level at 90-degree angle to ensure correct volume and absence of air bubbles. Remove any remaining air by tapping barrel to dislodge air bubbles (see illustration). Draw back slightly on plunger; push plunger upward to eject air. Do not eject fluid. Recheck volume of medication.	Holding syringe vertically allows fluid to settle in bottom of barrel. Pulling back on plunger allows fluid within needle to enter barrel so it is not expelled. Air at top of barrel and within needle is then expelled.

STEP 2b(3) Insert safety needle through center of vial diaphragm (with vial flat on table).

STEP 2b(5) Withdraw fluid with vial inverted.

STEP 2b(10) Hold syringe upright; tap barrel to dislodge air bubbles.

SKILL 31-4 PREPARING INJECTIONS—cont'd

STEP	RATIONALE
(11) If medication will be injected into patient's tissue, change needle to appropriate gauge and length according to route of medication.	Inserting needle through a rubber stopper dulls beveled tip. New needle is sharper. Because no fluid is along shaft, needle does not track medication through tissues.
(12) For multidose vial make label that includes date of mixing, concentration of medication per milliliter, and your initials.	Ensures that future doses will be prepared correctly. Some medications need to be discarded a certain number of days after mixing of vial.
c. Vial containing a powder (reconstituting medications)	
(1) Remove cap covering vial of powdered medication and cap covering vial of proper diluent. Firmly swab both seals with alcohol swab and allow to dry.	Not all drug manufacturers guarantee that caps of unused vials are sterile. Therefore seals must be swabbed with alcohol before preparing medication. Allowing alcohol to dry prevents needle from being coated with alcohol and mixing with medication.
(2) Draw up diluent into syringe following Steps 2b(2)-(10).	Prepares diluent for injection into vial containing powdered medication.
(3) Insert tip of safety needle or needleless access device through center of rubber seal of vial of powdered medication. Inject diluent into vial. Remove needle.	Diluent begins to dissolve and reconstitute medication.
(4) Mix medication thoroughly. Roll in palms. **Do not shake.**	Ensures proper dispersal of medication throughout solution. Shaking produces bubbles.
(5) Reconstituted medication in vial is ready to be drawn into new syringe. Read label carefully to determine dose after reconstitution.	Once diluent is added, concentration of medication (mg/mL) determines dose to be given. Read medication label carefully to avoid medication errors.
(6) Prepare medication in syringe following Steps 2b(2)-(12).	

CLINICAL DECISION: *Some agencies require prepared parenteral medications to be verified for accuracy by another nurse. Check policies before administering medication.*

3 Compare label of medication with MAR for the final time at the patient's bedside before administering medication.	*Third check for accuracy ensures that right medication is administered.*
4 Dispose of soiled supplies. Place broken ampule and/or used vials and used needle in puncture-proof and leak-proof container. Clean work area and perform hand hygiene.	Proper disposal of glass and needle prevents accidental injury to staff. Controls transmission of infection.

EVALUATION

1 Compare dose in syringe with desired dose.	Determines that dose is accurate.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Air bubbles remain in syringe.
- Expel air from syringe and add medication to syringe until correct dose is prepared.

2 Incorrect dose is prepared.
- Discard prepared dose and prepare corrected new dose.

SKILL 31-5 ADMINISTERING INJECTIONS

View Video!

Delegation Considerations

The skill of administering injections cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:
- Potential medication side effects and to report their occurrence along with any changes in a patient's vital signs or level of consciousness (e.g., sedation).

Equipment

- Proper size safety syringe and needle:
  - *Subcutaneous:* Syringe (1 to 3 mL) and needle (27 to 25 gauge, $\frac{3}{8}$ to $\frac{5}{8}$ inch)
  - *Subcutaneous U-100 insulin:* Insulin syringe (0.3, 0.5, or 1 mL) with preattached needle (28 to 31 gauge, $\frac{5}{16}$ to $\frac{1}{2}$ inch)
  - *Subcutaneous U-500 insulin:* 1-mL tuberculin syringe with needle (25 to 27 gauge, $\frac{1}{2}$ to $\frac{5}{8}$ inch)
  - *Intramuscular (IM):* Syringe 2 to 3 mL for adult, 0.5 to 1 mL for infants and small children
  - Needle, length corresponding to site of injection and age of patient. Refer to following guidelines; length needed may vary outside of these guidelines for patients who are smaller or larger than average.

Site	Child (Hockenberry and Wilson, 2009)	Adult (Nicoll and Hesby, 2002)
Ventrogluteal	$\frac{1}{2}$ to 1 inch	$1\frac{1}{2}$ inch
Vastus lateralis	$\frac{5}{8}$ to 1 inch	$\frac{5}{8}$ to 1 inch
Deltoid	$\frac{1}{2}$ to 1 inch	1 to $1\frac{1}{2}$ inch

Equipment—cont'd

- Needle gauge often depends on length of needle. Administer most biologicals and medications in aqueous solutions with 20- to 25-gauge needle. Use 18- to 25-gauge needles for medications in oil-based solutions (Nicoll and Hesby, 2002).
  - *Intradermal (ID):* 1-mL tuberculin syringe with needle (25 to 27 gauge, ½ to ⅝ inch)
- Small gauze pad
- Alcohol swab
- Vial or ampule of medication or skin test solution
- Clean gloves
- MAR (electronic or printed)

STEP	RATIONALE
ASSESSMENT	
1 Check accuracy and completeness of each medication administration record (MAR) with prescriber's medication order. Check patient's name and medication name, dosage, and route and time for administration. Recopy or reprint any portion of MAR that is difficult to read.	The order sheet is the most reliable source and only legal record of medications patient is to receive. Ensures that patient receives the correct medications. Illegible MARs are a source of medication errors (Poon et al., 2010).
2 Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, nursing implications.	Allows you to anticipate effects of drug and observe patient's response.
3 Assess patient's medical and medication history and history of allergies. Know his or her normal response to an allergy.	Reveals need for medication. Allows for early identification of patient risk for allergic response. May require different medication prescription. Do not administer medication to which patient is allergic.
4 Check date of expiration for medication.	Drug potency increases or decreases when outdated.
5 Observe verbal and nonverbal responses toward receiving injection.	Injections are often painful. Some patients have anxiety, which increases pain.
6 Assess for contraindications.	
a. **For subcutaneous injections**	
(1) Assess for factors such as circulatory shock or reduced local tissue perfusion. Assess adequacy of patient's adipose tissue.	Reduced tissue perfusion interferes with medication absorption and distribution. Physiological changes of aging or patient illness often influence the amount of subcutaneous tissue that a patient possesses. This influences methods for administering injections.
b. **For IM injections**	
(1) Assess for factors such as muscle atrophy, reduced blood flow, or circulatory shock.	Atrophied muscle absorbs medication poorly. Factors interfering with blood flow to muscles impair medication absorption.
7 Assess patient symptoms or condition for which medication has been prescribed.	Provides baseline to determine response to therapy.
CLINICAL DECISION: *Because of documented adverse effects of IM injections, other routes of medication administration are safer. Verify that IM injection is necessary and explore alternative medication routes if possible (Nicoll and Hesby, 2002; World Health Organization [WHO], 2006).*	
PLANNING	
1 Collect appropriate equipment (e.g., safety syringe, needles) and MAR.	Enhances time management and efficiency.
2 Plan preparation to avoid interruptions. Do not take phone calls or talk with others. Follow agency policy.	Interruption contributes to medication errors (Biron, Lavoie-Tremblay, and Loiselle, 2009).
IMPLEMENTATION	
1 Perform hand hygiene. Aseptically prepare correct medication dose from ampule or vial (see Skill 31-4). Check label of medication with MAR two times while preparing medication.	Ensures that medication is sterile. Preparation techniques differ for ampule and vial. *First and second checks ensure that right medication is administered.*
2 Take medication to patient at the correct time (see agency policy). Give time-critical, STAT, and single-order medications at time ordered. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers the patient needs, the prescribed medication, and the specific clinical indications (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3 Close room curtain or door.	Provides privacy.
4 Identify patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011a).
5 Compare name of medication on label with MAR one more time at patient's bedside.	Third check for accuracy ensures that right medication is administered.
6 Explain steps of procedure and tell patient that injection will cause a slight burning or sting.	Helps minimize patient's anxiety.

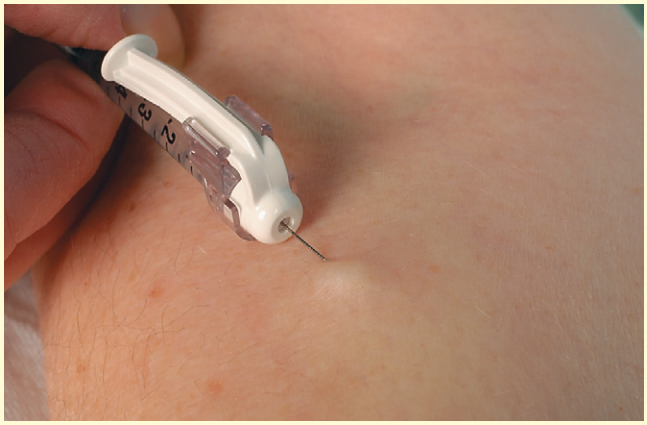
SKILL 31-5 ADMINISTERING INJECTIONS—cont'd

STEP	RATIONALE
7 Apply clean gloves. NOTE: If patient has latex allergy, use latex-free gloves.	Reduces transfer of microorganisms.
8 Keep sheet or gown draped over body parts not requiring exposure.	Respects dignity of patient while area to be injected is exposed.
9 Select appropriate injection site. Inspect skin surface over sites for bruises, inflammation, or edema.	Injection sites need to be free of abnormalities that interfere with medication absorption. Sites used repeatedly become hardened from lipohypertrophy (increased growth in fatty tissue). Do not use an area that is bruised or has signs associated with infection.
a. *Subcutaneous:* Palpate sites for masses or tenderness. Avoid these areas. For daily insulin, rotate site within anatomical area. Be sure that needle is correct size by grasping skinfold at site with thumb and forefinger. Measure fold from top to bottom. Needle should be one-half length.	Subcutaneous injections are sometimes mistakenly given in the muscle, especially in abdomen and thigh sites. Appropriate size of needle and angle of injection ensures that medication is injected in the subcutaneous tissue (Birkebaek et al., 2008).
b. *IM:* Note integrity and size of muscle and palpate for tenderness or hardness. Avoid these areas. If injections are given frequently, rotate sites. Use ventrogluteal site if possible.	The ventrogluteal site is the preferred site for adults. This site is also preferred for children who are receiving viscous or irritating solutions (Hockenberry and Wilson, 2009; Nicoll and Hesby, 2002).
c. *ID:* Note lesions or discolorations of skin. If possible, select site three to four finger widths below antecubital space and a hand width above wrist. If you cannot use forearm, inspect upper back. If necessary, use sites for subcutaneous injections.	An ID site needs to be clear so you can see results of skin test and interpret them correctly (CDC, 2010).
10 Help patient to comfortable position:	
a. *Subcutaneous:* Have patient relax arm, leg, or abdomen, depending on site chosen for injection.	Relaxation of site minimizes discomfort.
b. *IM:* Position patient depending on site chosen (e.g., sit or lie flat, on side, or prone).	Reduces strain on muscle and minimizes discomfort of injections.
c. *ID:* Have patient extend elbow and support it and forearm on flat surface.	Stabilizes injection site for easiest accessibility.
d. Have patient talk about subject of interest. Ask open-ended questions.	Distraction reduces anxiety.
CLINICAL DECISION: *Ensure that patient's position is not contraindicated by medical condition.*	
11 Relocate site using anatomical landmarks.	Injection into correct anatomical site prevents injury to nerves, bones, and blood vessels (Nicoll and Hesby, 2002).
12 Clean site with an antiseptic swab. Apply swab at center of site and rotate outward in circular direction for approximately 5 cm (2 inches) (see illustration).	Mechanical action of swab removes secretions containing microorganisms.
13 Hold swab or gauze between third and fourth fingers of nondominant hand.	Gauze or swab remains readily accessible when needle is withdrawn.
14 Remove needle cap or sheath from needle by pulling it straight off.	Preventing needle from touching sides of cap prevents contamination.
15 Hold syringe between thumb and forefinger of dominant hand.	
a. *Subcutaneous:* Hold as dart, palm down (see illustration).	Quick, smooth injection requires proper manipulation of syringe parts.
b. *IM:* Hold as dart, palm down.	
c. *ID:* Hold bevel of needle pointing up.	With bevel up, medication is less likely to be deposited into tissues below dermis.

STEP 12 Clean site with circular motion.

STEP 15a Hold syringe as if grasping a dart.

STEP	RATIONALE
16 Administer injection:	
a. Subcutaneous	
(1) For average-size patient, pinch skin with nondominant hand.	Pinching skin elevates subcutaneous tissue and desensitizes area.
(2) Inject needle quickly and firmly at 45- to 90-degree angle. Release skin. *Option:* Continue to pinch skin and release after injecting medications.	Quick, firm insertion minimizes discomfort. (Injecting medication into compressed tissue irritates nerve fibers.) Correct angle prevents accidental injection into muscle.
(3) For obese patient pinch skin at site and inject needle at 90-degree angle below tissue fold.	Obese patients have fatty layer of tissue above subcutaneous layer.
CLINICAL DECISION: *Piercing a blood vessel during a subcutaneous injection is very rare. Therefore aspiration is not necessary when administering subcutaneous injections.*	
(4) Inject medication slowly (see illustration).	Minimizes discomfort.



STEP 16a(4) Inject medication slowly.

b. Intramuscular	
(1) Position ulnar aspect of your nondominant hand just below site and pull skin approximately 2.5 to 3.5 cm (1.5 inches) down or laterally to administer in a Z-track. Hold position until medication is injected (see Fig. 31-23, p. 608). With dominant hand inject needle quickly at 90-degree angle into muscle.	Z-track creates zigzag path through tissues that seals needle track to avoid tracking of medication. Use Z-track for all IM injections (Nicoll and Hesby, 2002). A quick, dartlike injection reduces discomfort.
(2) *Option:* If patient's muscle mass is small, grasp body of muscle between thumb and fingers.	Ensures that medication reaches muscle mass (Hockenberry and Wilson, 2009).
(3) Insert needle into the muscle using a smooth, steady motion. After needle pierces skin, grasp lower end of syringe barrel with nondominant hand to stabilize syringe. Continue to hold skin tightly with nondominant hand. Move dominant hand to end of plunger. Do not move syringe.	A smooth, steady motion reduces pain at the moment of injection (Nicoll and Hesby, 2002). Smooth manipulation of syringe reduces discomfort from needle movement. Skin needs to remain pulled until after injecting medication to ensure Z-track administration.
(4) Pull back on plunger 5 to 10 seconds. If no blood appears, inject medicine slowly, at a rate of 1 mL/10 seconds.	This time is necessary to ensure that the needle in not in a low-flow blood vessel (Nicoll and Hesby, 2002). Aspiration of blood into syringe indicates intravenous (IV) placement of needle. Slow injection rate reduces pain and tissue trauma, and reduces chance of leakage of medication back through the needle track (Hockenberry and Wilson, 2009; Nicoll and Hesby, 2002).
CLINICAL DECISION: *If blood appears in syringe, remove needle and dispose of medication and syringe properly. Prepare another dose of medication for injection.*	
(5) Wait 10 seconds. Then smoothly and steadily withdraw needle and release skin.	Allows for medication to absorb into muscle before removing syringe rather than leaking back out through the track that the needle created (Nicoll and Hesby, 2002).
c. Intradermal	
(1) With nondominant hand stretch skin over site with forefinger or thumb.	Needle pierces tight skin more easily.
(2) With needle almost against patient's skin, insert it slowly with bevel up at a 5- to 15-degree angle until resistance is felt. Advance it through epidermis to approximately 3 mm ($\frac{1}{8}$ inch) below skin surface. You will see needle tip through skin.	Ensures that needle tip is in dermis. You obtain inaccurate results if you do not inject needle at correct angle and depth (CDC, 2010).

SKILL 31-5 ADMINISTERING INJECTIONS—cont'd

STEP	RATIONALE
(3) Inject medication slowly. Normally you feel resistance. If not, needle is too deep; remove and begin again. Nondominant hand can stabilize needle during the injection.	Slow injection minimizes discomfort at site. Dermal layer is tight and does not expand easily when solution is injected. Stabilizing needle prevents unnecessary movements and decreases patient discomfort.
(4) While injecting medication, notice that small bleb approximately 6 mm (¼ inch) in diameter (resembling mosquito bite) appears on surface of skin (see illustration). Instruct patient that this is a normal finding.	Bleb indicates that medication is deposited in dermis.

STEP 16c(4) Injection creates a small bleb.

17 Withdraw needle while applying alcohol swab or gauze gently over site.	Support of tissue around injection site minimizes discomfort during needle withdrawal. Dry gauze minimizes patient discomfort associated with alcohol on nonintact skin.
18 Apply gentle pressure. *Do not massage site.* Apply bandage if needed.	Massage causes underlying tissue damage. Massaging ID site disperses medication into underlying tissue layers and alters test results.
19 Help patient to comfortable position.	Gives patient sense of well-being.
20 Discard uncapped needle or needle enclosed in safety shield and attached syringe into puncture-proof and leak-proof receptacle.	Prevents injury to patient and health care personnel. Recapping needles increases risk of needlestick injury (OSHA, 2009).
21 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
22 Stay with patient and observe for allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction, which is a life-threatening emergency.

EVALUATION

1 Return to room and ask if patient feels any acute pain, burning, numbness, or tingling at injection site.	Continued discomfort often indicates injury to underlying bones or nerves.
2 Inspect site, noting any bruising or induration. Document bruising or induration if present. Notify health care provider and provide warm compress to site.	Bruising or induration indicates complication associated with injection.
3 Observe patient's response to medication at times that correlate with onset, peak, and duration of medication.	IM medications are rapidly absorbed. Adverse effects of parenteral medications develop rapidly. Nurse's observations determine efficacy of medication action.
4 Ask patient to explain purpose and effects of medication.	Evaluates patient's understanding of information taught.
5 *For ID injections:* Use skin pencil and draw circle around perimeter of injection site. Read site within appropriate amount of time, designated by type of medication or skin test administered.	Pencil mark makes site easy to find. Results of skin testing are read at various times, based on type of medication used or type of skin testing completed. Refer to manufacturer directions to determine when to read results of test.

CLINICAL DECISION: *Read tuberculin test at 48 to 72 hours. Induration (hard, dense, raised area) of skin around injection site indicates positive reaction, as follows:*

- *15 mm or more in patients with no known risk factors for tuberculosis (TB)*
- *10 mm or more in patients who are recent immigrants; injection drug users; residents and employees of high-risk settings; mycobacteriology laboratory personnel; patients with clinical conditions placing them at high risk; children less than 4 years of age; and infants, children, and adolescents exposed to high-risk adults*
- *5 mm or more in patients who are human immunodeficiency virus (HIV) positive, have fibrotic changes on chest x-ray film consistent with previous TB infection, have had organ transplants, or are immunosuppressed (CDC, 2010).*

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Raised, reddened, or hard zone (induration) forms around ID test site.
- Notify patient's health care provider.
- Document sensitivity to injected allergen or positive test if tuberculin skin testing was completed.

2 Hypertrophy of skin develops from repeated subcutaneous injections.
- Do not use this site for future injections.
- Instruct patient not to use site for 6 months.

3 Patient develops signs and symptoms of allergy or side effects.
- Follow agency policy or guidelines for appropriate response to adverse drug reactions.
- Notify patient's health care provider immediately.
- Add allergy information to patient's medical record.

4 Patient complains of localized pain, numbness, tingling, or burning at injection site, indicating possible injury to nerve or tissues.
- Assess injection site.
- Document findings.
- Notify patient's health care provider.

RECORDING AND REPORTING

- Chart medication dose, route, site, time, and date given on MAR immediately after giving medication per agency policy.
- Document if scheduled medication is withheld and record the reason per agency policy.
- Report any undesirable effects from medication to prescriber.
- Record patient's response to medications in nurses' notes and report to prescriber if required.

HOME CARE CONSIDERATIONS

- Assess patient's readiness to learn before instructing in self-injections. Some patients are hesitant to administer injections to themselves; thus relieve any anxiety before teaching this skill to a patient.
- Some patients prefer to reuse their syringes to save costs. This practice is safe and practical if the needle is not contaminated during the preparation and administration of the injection. Teach patients to immediately recap needles after use.
- Patients can often purchase or obtain sharps boxes for home use. If this is not possible, they can use a hard plastic bottle that they cannot see through (e.g., a fabric softener bottle or detergent bottle) to safely store syringes after use. Disposal of needles used in the home varies among communities. Check with local authorities to verify how to dispose of needles.

SKILL 31-6 ADMINISTERING MEDICATIONS BY INTRAVENOUS BOLUS

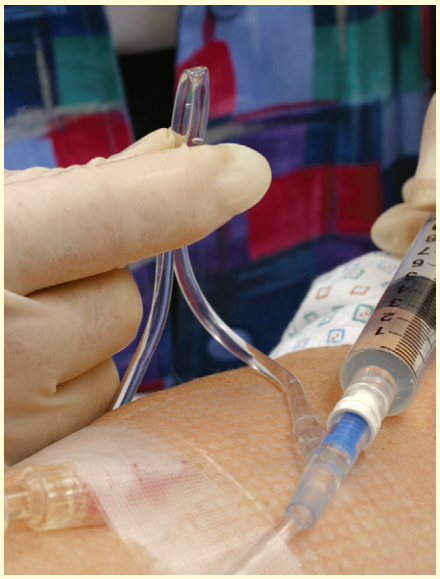
Delegation Considerations

The skill of administering medications by intravenous (IV) bolus cannot be delegated to nursing assistive personnel (NAP). Inform NAP about:
- Potential side effects of medications and need to report their occurrence.
- The need to report discomfort at infusion site as soon as possible.
- Obtaining any required vital signs and reporting these findings to the nurse.

Equipment

- Watch with second hand
- MAR (electronic or printed)
- Clean gloves
- Antiseptic swab
- Medication in vial or ampule
- Safety syringe for medication preparation
- Needleless device or sterile safety needle (21 to 25 gauge)
- IV lock: vial of appropriate flush solution (saline most common, heparinized flush is sometimes used; if using heparin, most common concentration is 10 to 100 units/mL; see agency policy)

STEP	RATIONALE
ASSESSMENT	
1 Check accuracy and completeness of each medication administration record (MAR) with prescriber's medication order. Check patient's name and medication name, dosage, route, and time for administration. Recopy or reprint any portion of MAR that is difficult to read.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications. Illegible MARs are a source of medication errors (Poon et al., 2010).

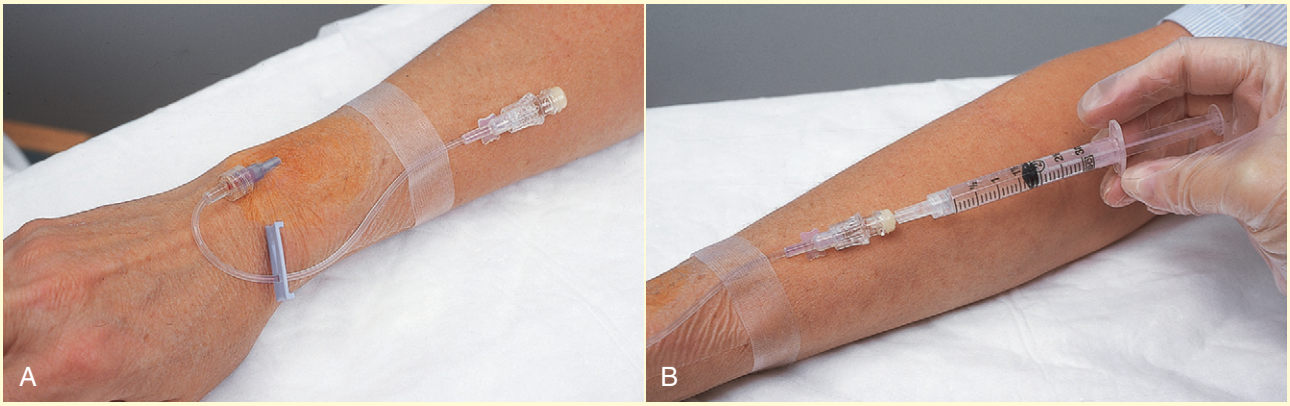


SKILL 31-6 ADMINISTERING MEDICATIONS BY INTRAVENOUS BOLUS—cont'd

STEP	RATIONALE
CLINICAL DECISION: *Some IV medications can only be pushed safely when a patient is being continuously monitored for dysrhythmias, blood pressure changes, or other adverse effects. Therefore some medications can only be pushed in specific areas within a health care agency. See agency policy for special monitoring requirements before giving medication (Lehne, 2010).*	
2 Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, how slowly to give medication, compatibility with IV fluids, and nursing implications.	Allows you to give medication safely and monitor patient's response to therapy (Lehne, 2010). Prevents incompatible drug reaction.
3 If pushing medication into an IV line, determine compatibility of medication with IV fluids and any additives within IV solution.	IV medications are not always compatible with IV solution and/or additives.
4 Perform hand hygiene. Assess IV or saline lock insertion site for signs of infiltration or phlebitis (see Chapter 41).	Confirming placement of IV catheter and integrity of surrounding tissue ensures that medication is administered safely. Do not administer medication if site is inflamed or edematous.
5 Check patient's medical history and history of drug or latex allergies.	IV bolus delivers medication rapidly. Allergic reactions can be fatal.
6 Assess patient's understanding of purpose of medication therapy.	Reveals need for patient education.
PLANNING	
1 Collect appropriate equipment (e.g., syringe, medication) and MAR.	Enhances time management and efficiency.
CLINICAL DECISION: *Some IV medications require dilution before administration. Verify with agency policy. If a small amount of medication is given (e.g., less than 1 mL), dilute medication in 5 to 10 mL of normal saline or sterile water so medication does not collect in "dead spaces" (e.g., Y-site injection port, IV cap) of the IV delivery system. Verify that medication can be diluted by consulting medication reference or checking with pharmacist first.*	
2 Plan preparation to avoid interruptions. Do not take phone calls or talk with others. Follow agency policy.	Interruption contributes to medication errors (Biron, Lavoie-Tremblay, and Loiselle, 2009).
IMPLEMENTATION	
1 Perform hand hygiene. Prepare ordered medication from vial or ampule using aseptic technique (see Skill 31-4). Check label of medication carefully with MAR two times.	Ensures that medication is sterile. Preparation techniques differ for ampule and vial. *First and second checks ensure that right medication is administered.*
2 Take medication to patient at correct time (see agency policy). Give time-critical, STAT, and single-order medications at time ordered. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers the patient needs, the prescribed medication, and the specific clinical indications (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3 Identify patient using at least two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011a).
4 Compare names of medications on labels with MAR one more time at patient's bedside.	*Third check for accuracy ensures that right medication is administered.*
5 Explain procedure to patient. Encourage patient to report symptoms of discomfort at IV site.	Keeps patient informed and ensures patient-centered care. Helps identify possible infiltration early.
6 Put on clean gloves. NOTE: If patient has latex allergy, use latex-free gloves.	Reduces transmission of microorganisms. During IV bolus administration there is a risk of blood exposure.
7 **IV push (existing line):**	
a. Select injection port of IV tubing closest to patient. Whenever possible, injection port should accept a needleless syringe. Use IV filter if required by medication reference or agency policy.	Follows provisions of the Needle Safety and Prevention Act of 2001 (OSHA, 2009).
CLINICAL DECISION: *Never administer IV medications through tubing that is infusing blood, blood products, or parenteral nutrition solutions.*	
b. Clean injection port with antiseptic swab. Allow to dry.	Prevents introduction of microorganisms during needle insertion.
c. Connect syringe to port of IV line. Insert needleless tip or small-gauge needle of syringe containing prepared drug through center of injection port (see illustration).	Prevents damage to diaphragm of port and subsequent leakage.

STEP	RATIONALE
d. Occlude IV line by pinching tubing just above injection port (see illustration). Pull back gently on syringe plunger to aspirate blood return.	Final check that medication is being delivered into bloodstream.
CLINICAL DECISION: *In some cases, especially with a smaller-gauge IV needle, blood return is not always aspirated, even if IV is patent. If IV site shows no signs of infiltration and IV fluid is infusing without difficulty, proceed with IV push.*	
e. Release tubing and inject medication within amount of time recommended by institutional policy, pharmacist, or medication reference manual. Use watch to time administration (see illustration). You can pinch the IV line while pushing medication and release when not pushing it. Allow IV fluids to infuse when not pushing medication.	Ensures safe medication infusion. Rapid injection of IV medication can be fatal (Lehne, 2010). Allowing IV fluids to infuse while pushing IV drug enables medications to be delivered to patient at prescribed rate.
CLINICAL DECISION: *When IV medication is incompatible with IV fluids, stop the IV fluids, clamp the IV line above the injection site, flush with 10 mL of normal saline or sterile water, give the IV bolus over the appropriate amount of time, flush with another 10 mL of normal saline or sterile water at the same rate as the medication was administered, and restart the IV fluids at the prescribed rate. If IV line that is currently hanging contains a medication (e.g., ranitidine), disconnect IV line and administer IV push as outlined in Step 8 to avoid giving a sudden bolus of the medication in existing IV line. Some IV medications and fluids cannot be stopped. Verify agency policy regarding temporarily stopping IV fluids or continuous IV medications. If unable to stop IV infusion, start a new IV site (see Chapter 41) and administer medication using the IV lock method.*	

STEP 7c Connecting syringe to IV line with blunt needleless cannula tip.



STEP 7d Intravenous line pinched above injection port to aspirate for blood return.

STEP 7e Using watch to time an IV push medication.

SKILL 31-6 ADMINISTERING MEDICATIONS BY INTRAVENOUS BOLUS—cont'd

STEP	RATIONALE
f. After injecting medication, release tubing, withdraw syringe, and recheck fluid infusion rate.	Injection of bolus alters rate of fluid infusion. Rapid fluid infusion causes circulatory overload.
8 IV push (IV lock)	
a. Prepare two syringes with 2 to 3 mL of normal saline (0.9%) in syringe.	
CLINICAL DECISION: *Current evidence reflects that saline flushes are effective in maintaining patency of IV lines and do not carry risk of thrombocytopenia associated with heparin flushes.*	
b. Administer medication:	
(1) Clean injection port of lock with antiseptic swab.	Prevents introduction of microorganisms during needle insertion.
(2) Insert syringe containing normal saline (0.9%) into injection port of IV lock (see illustration).	

STEP 8b(2) **A,** IV catheter with saline lock adapter. **B,** Syringe inserted into injection port.

(3) Pull back gently on syringe plunger and look for blood return.	Determines whether IV needle or catheter is positioned in vein.
CLINICAL DECISION: *At times a blood return is not aspirated even though lock is patent. If IV site does not show signs of infiltration and IV site flushes without difficulty, proceed with IV push.*	
(4) Flush IV lock with normal saline by pushing slowly on plunger.	Clears IV lock of blood.
CLINICAL DECISION: *Observe closely area of skin above IV catheter. Note any puffiness or swelling as IV lock is flushed, which indicates infiltration into vein, requiring removal of catheter.*	
(5) Remove saline flush syringe.	
(6) Clean injection port of lock with antiseptic swab.	Prevents transmission of infection.
(7) Insert syringe containing prepared medication into injection port of IV lock.	
(8) Inject medication within amount of time recommended by institutional policy, pharmacist, or medication reference manual. Use watch to time administration.	Rapid injection of IV medication can result in death. Following guidelines for IV push rates promotes patient safety (Lehne, 2010).
(9) After administering bolus, withdraw syringe.	
(10) Clean injection port of lock with antiseptic swab.	Prevents transmission of microorganisms.
(11) Flush injection port by attaching syringe with normal saline. Inject normal saline flush at same rate medication was delivered.	Irrigation with saline prevents occlusion of IV access device and ensures that all medication is delivered. Flushing IV site at same rate as medication ensures that any medication remaining within IV needle is delivered at correct rate.
9 Dispose of uncapped needles and syringes in puncture-proof and leak-proof container.	Reduces accidental needlesticks (OSHA, 2009).
10 Remove and dispose of gloves. Perform hand hygiene.	Reduces transmission of microorganisms.

STEP	RATIONALE
EVALUATION	
1 Observe patient closely for adverse reaction as drug is administered and for several minutes thereafter.	IV medications act rapidly.
2 Observe IV site during injection for sudden swelling.	Swelling indicates infiltration into tissues surrounding vein.
3 Assess patient's status after giving medication to evaluate its effectiveness.	IV bolus medications often cause rapid changes in patient's physiological status. Some medications require careful monitoring and possibly laboratory testing (e.g., vasopressors require monitoring of blood pressure and heart rate; dilantin requires laboratory studies to determine if it is in a therapeutic level).
4 Ask patient to explain purposes and side effects of medication.	Evaluates learning.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient develops adverse reaction to medication.
- Stop delivering medication immediately and follow institution policy or guidelines for appropriate response and reporting of adverse drug reactions.
- Add allergy information to patient's medical record.

2 IV site shows symptoms of infiltration or phlebitis (see Chapter 41).
- Stop infusing medication.
- Treat IV site as indicated by agency policy.
- Insert new IV site if continuing IV therapy.

3 Patient is unable to explain medication information.
- Patient requires reinstruction or is unable to learn at this time.

RECORDING AND REPORTING

- Record medication, dose, time and date, and route of administration.
- Report any adverse reactions immediately to health care provider. Patient's response may indicate need for additional medical therapy.
- Record patient's response to medication in nurses' notes.

SKILL 31-7 ADMINISTERING INTRAVENOUS MEDICATIONS BY PIGGYBACK, INTERMITTENT INTRAVENOUS INFUSION SETS, AND MINI-INFUSION PUMPS

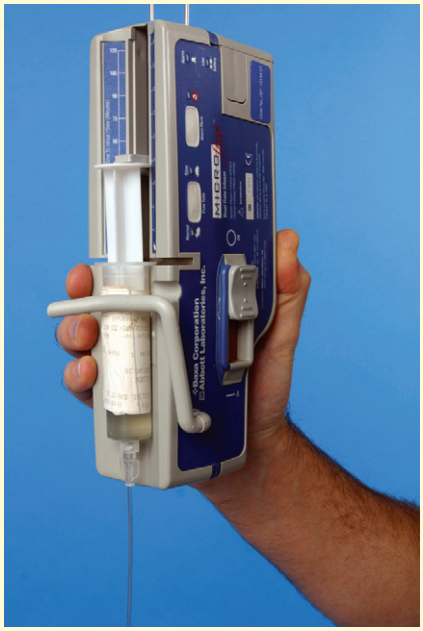
Delegation Considerations

The skill of administering intravenous (IV) medications by piggyback, intermittent IV infusion sets, and mini-infusion pumps cannot be delegated to nursing assistive personnel (NAP). Instruct NAP about:
- Potential side effects of medications and to report their occurrence to the nurse immediately.
- Reporting patient's verbalization of discomfort at infusion site.
- Reporting changes in patient's condition or vital signs.

Equipment

- Adhesive tape (optional)
- Antiseptic swab
- IV pole
- MAR (electronic or printed)
- Clean gloves
- Piggyback or mini-infusion pump
  - Medication prepared in 5- to 250-mL labeled infusion bag or syringe
  - Short microdrip, macrodrip or mini-infusion tubing set for piggyback with needleless system attachment
    - —Needleless device or stopcocks
    - —Mini-infusion pump if needed
- Volume-control administration set
  - Buretrol
  - Infusion tubing with needleless system attachment
  - Syringe (1 to 20 mL)
  - Vial or ampule of ordered medication

STEP	RATIONALE
ASSESSMENT	
1 Check accuracy and completeness of each medication administration record (MAR) with prescriber's medication order. Check patient's name and medication name, dosage, and route and time of administration. Recopy or reprint any portion of MAR that is difficult to read.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications. Illegible MARs are a source of medication errors (Poon et al., 2010).
2 Review patient's medical history and history of allergies.	Helps you anticipate therapeutic effect of medication. Intravenous bolus delivers medication rapidly. Allergic reactions can be fatal.

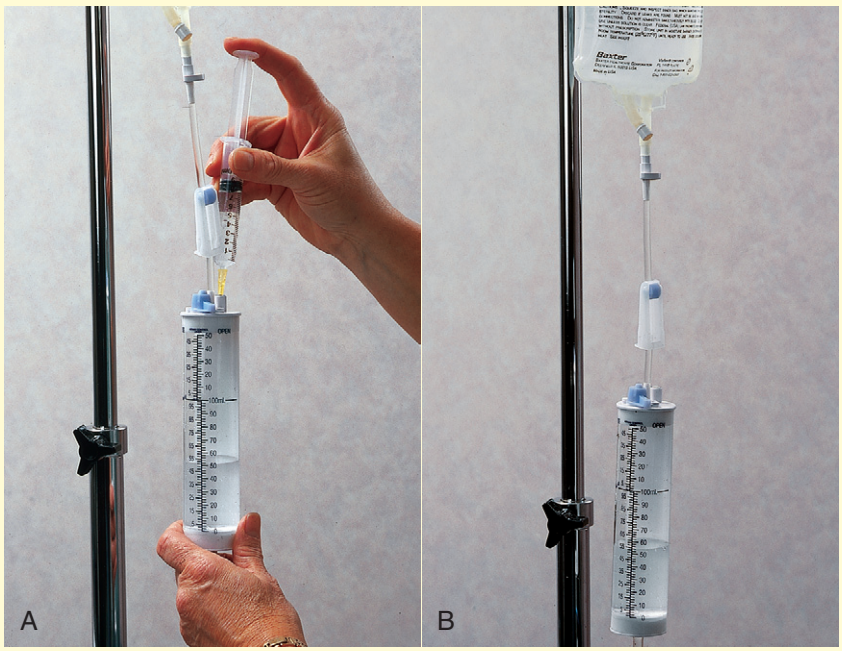


SKILL 31-7 ADMINISTERING INTRAVENOUS MEDICATIONS BY PIGGYBACK, INTERMITTENT INTRAVENOUS INFUSION SETS, AND MINI-INFUSION PUMPS—cont'd

STEP	RATIONALE
3 Review pertinent information related to medication: action, purpose, normal dose and route, side effects, time of onset and peak action, compatibility with existing IV fluids, and nursing implications.	Allows you to give medication safely and to monitor patient's response to therapy.
4 Assess patency of patient's existing IV infusion line by noting infusion rate of main IV line (see Chapter 41).	IV line must be patent, and fluids need to infuse easily for medication to reach venous circulation effectively.
CLINICAL DECISION: *If the patient's IV site is saline locked, clean the port with alcohol and assess the patency of the IV line by flushing it with 2 to 3 mL of sterile normal saline. Attach appropriate IV tubing to the saline lock and administer the medication via piggyback, tandem, mini-infusion, or volume-control administration set. When the infusion is completed, disconnect the tubing, clean the port with alcohol, and flush the IV line with 2 to 3 mL of sterile normal saline. Maintain sterility of IV tubing between intermittent infusions.*	
5 Perform hand hygiene. Assess IV insertion site for signs of infiltration or phlebitis: redness, pallor, swelling, and tenderness on palpation.	Confirmation of placement of IV needle or catheter and integrity of surrounding tissues ensures safe medication administration.
6 Assess patient's understanding of purpose of medication therapy.	Reveals need for education.
PLANNING	
1 Collect appropriate equipment (e.g., medication, tubing) and MAR.	Enhances time management and efficiency.
2 Plan preparation to avoid interruptions. Do not take phone calls or speak with others. Follow agency policy.	Interruption contributes to medication errors (Biron, Lavoie-Tremblay, and Loiselle, 2009).
IMPLEMENTATION	
1 Perform hand hygiene. Prepare medication from an ampule or vial (see Skill 31-4). Be sure to compare the label of the medication with the MAR two times while preparing the medication.	Ensures that medication is sterile. Preparation techniques differ for ampule and vial. *First and second checks ensure that right medication is administered.*
2 Take medication to patient at correct time (see agency policy). Give time-critical, STAT, and single-order medications at time ordered. Perform hand hygiene.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers the patient needs, the prescribed medication, and the specific clinical indications (CMS, 2011; ISMP, 2011). Hand hygiene decreases transfer of microorganisms.
3 Identify patient using at least two patient identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011a).
4 Explain purpose of medication and side effects to patient. Explain that you will give medication through existing IV line. Encourage patient to report symptoms of discomfort at site immediately.	
5 Compare names of medications on labels with MAR one more time at patient's bedside.	*Third check for accuracy ensures that right medication is administered.*
6 Put on clean gloves. NOTE: If patient has a latex allergy, use latex-free gloves.	Reduces transmission of microorganisms. During IV administration there is a risk of blood exposure.
7 Administer medications	
a. Piggyback infusion	
CLINICAL DECISION: *Never administer IV medications through tubing that is infusing blood, blood products, or parenteral nutrition solutions.*	
(1) Connect infusion tubing to medication bag (see Chapter 41). Allow solution to fill tubing by opening regulator flow clamp. Once tubing is full, close clamp and cap end of tubing.	Infusion tubing needs to be filled with solution and free of air bubbles to prevent air embolus.
(2) Hang piggyback medication bag above level of primary fluid bag (use hook to lower main bag) (see Fig. 31-26, p. 610).	Height of fluid bag affects rate of flow to patient.
(3) Connect tubing of piggyback infusion to appropriate connector on primary infusion line.	

STEP	RATIONALE
(a) *Needleless system:* Wipe off needleless port of main IV line and insert tip of piggyback infusion tubing (see illustration).	Use needleless connections to prevent accidental needlestick injuries (OSHA, 2009). Establishes route for IV medication to enter main IV line.
(b) *Stopcock:* Wipe off stopcock port with alcohol swab and connect tubing. Turn stopcock to open position.	Stopcock eliminates need for needle.
(4) Regulate flow rate of medication solution by adjusting regulator clamp or IV pump infusion rate (see Chapter 41). Infusion times vary. Refer to medication reference or agency policy for safe flow rate.	Provides slow, intermittent infusion of medication and maintains therapeutic blood levels.
(5) After medication has infused, check flow regulator on primary infusion. Primary infusion automatically begins to flow after piggyback solution is empty. If stopcock is used, turn it to off position.	Back-check valve on piggyback stops flow of the primary infusion until second medication infuses. Checking flow rate ensures proper administration of IV fluids.
(6) Regulate main infusion line to desired rate if necessary.	Infusion of piggyback sometimes interferes with main line infusion rate.
(7) Leave IV piggyback bag and tubing in place for future medication administration or discard in appropriate containers.	Establishment of secondary line produces route for microorganisms to enter main line. Repeated changes in tubing increase risk of infection transmission (see agency policy).
b. Mini-infusion administration	
(1) Connect prefilled syringe to mini-infusion tubing.	Special tubing designed to fit syringe delivers medication to main IV line.
(2) Carefully apply pressure to syringe plunger, allowing tubing to fill with medication.	Ensures that tubing is free of air bubbles to prevent air embolus.
(3) Place syringe into mini-infusion pump (follow product directions). Be sure that syringe is secured (see illustration).	
(4) Connect mini-infusion tubing to main IV line.	
(a) *Needleless system:* Wipe off needleless port and insert tip of mini-infusion tubing.	Needleless system reduces risk of needlestick injuries (OSHA, 2009).
(b) *Stopcock:* Wipe off stopcock port with alcohol swab and connect tubing. Turn stopcock to open position.	Stopcock reduces risk of needlestick injuries.
(5) Hang infusion pump with syringe on IV pole alongside main IV bag. Set pump to deliver medication within time recommended by institutional policy, pharmacist, or medication reference manual. Use alarm if medication is delivered into heparin/saline lock. Press button on pump to begin infusion.	Pump automatically delivers medication at safe, constant rate based on volume in syringe.
(6) After medication has infused, check flow rate on primary infusion. The infusion automatically begins to flow once the pump stops. Regulate main infusion line to desired rate as needed. (NOTE: If stopcock is used, turn off mini-infusion line.)	Maintains patency of primary IV line.

STEP 7a(3)(a) For needleless system insert tip of piggyback infusion tubing into port.



STEP 7b(3) Ensure that syringe is secure after placing it into mini-infusor pump.

SKILL 31-7 ADMINISTERING INTRAVENOUS MEDICATIONS BY PIGGYBACK, INTERMITTENT INTRAVENOUS INFUSION SETS, AND MINI-INFUSION PUMPS—cont'd

STEP	RATIONALE
c. Volume-control administration set (e.g., Buretrol)	
(1) Fill Buretrol with desired amount of fluid (50 to 100 mL) by opening clamp between Buretrol and main IV bag (see illustration).	Small volume of fluid dilutes IV medication and reduces risk of too-rapid infusion.
(2) Close clamp and check to be sure that clamp on air vent of Buretrol chamber is open.	Prevents additional leakage of fluid into Buretrol. Air vent allows fluid in Buretrol to exit at regulated rate.
(3) Clean injection port on top of Buretrol with antiseptic swab.	Prevents introduction of microorganisms during needle insertion.
(4) Remove needle cap or sheath, insert syringe needle through port, and inject medication (see illustrations). Gently rotate Buretrol between hands.	Rotating mixes medication with solution in Buretrol to ensure equal distribution.
(5) Regulate IV infusion rate to allow medication to infuse in time recommended by agency policy, a pharmacist, or a medication reference manual.	For optimal therapeutic effect, medication needs to infuse in prescribed time interval.
(6) Label Buretrol with name of medication, dosage, and total volume, including diluent and time of administration following ISMP (2010e) safe medication label format (see Fig. 31-27, p. 610).	Alerts nurses to medication being infused. Prevents other medications from being added to Buretrol.
(7) If patient is receiving a continuous IV infusion, check continuous infusion rate after Buretrol infusion is complete to ensure the appropriate rate of IV fluid administration.	Ensures appropriate fluid balance.
8 Dispose of uncapped needle or needle enclosed in safety shield and syringe in proper container.	Prevents accidental needlesticks (OSHA, 2009).
9 Discard supplies in appropriate container and perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 Assess patient's status after administering medication.	Evaluates effect of medication.
2 Observe patient for signs of adverse reactions.	IV medications act rapidly.
3 During infusion periodically check infusion rate and condition of IV site.	IV line needs to remain patent for proper medication administration. Development of infiltration necessitates discontinuing infusion.
4 Ask patient to explain purpose and side effects of medication.	Evaluates patient's understanding of instruction.

STEP 7c(1) Filling volume-control administration device.

STEP 7c(4) **A,** Medication injected into device**. B,** Prepared device.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient develops adverse drug reaction.
- Stop medication infusion immediately.
- Follow institutional policy or guidelines for appropriate response and reporting of adverse drug reactions.
- Document allergy in patient's medical record.

2 Medication does not infuse over desired period.
- Determine reason (e.g., improper calculation of flow rate, malpositioning of IV needle at insertion site, or infiltration).
- Take corrective action as indicated.

3 IV site shows signs of phlebitis or infiltration (see Chapter 41).
- See related interventions in Skill 31-6.

RECORDING AND REPORTING

- Record medication, dose, route, time and date administered on MAR.
- Record volume of fluid in medication bag or Buretrol on intake and output form.
- Report adverse reactions to patient's health care provider.

HOME CARE CONSIDERATIONS

- Teach patient and family caregiver to dispose of needles and contaminated equipment in puncture-proof containers (e.g., coffee can).
- Instruct family about community resources to obtain supplies.

KEY POINTS

- Learning medication classifications improves understanding of nursing implications for administering medications with similar characteristics.
- All controlled substances are handled according to strict procedures that account for each medication.
- The nurse applies understanding of the physiology of medication action when timing administration, selecting routes, initiating actions to promote medication efficacy, and observing responses to medications.
- The older adult's body undergoes structural and functional changes that alter medication actions and influence the manner in which nurses provide medication therapy.
- Verify medication calculations with another nurse to ensure accuracy.
- Medications given parenterally are absorbed more quickly than those administered by other routes.
- Each medication order needs to include the patient's name, order date, medication name, dosage, route, time of administration, drug indication, and prescriber's signature.
- A medication history reveals allergies, medications a patient is taking, and the patient's adherence to therapy.
- The six rights of medication administration contribute to accurate preparation and administration of medication doses.
- The six rights of medication administration are the right medication, right dose, right patient, right route, right time, and right documentation.
- Nurses need to avoid distractions and follow the same routine when preparing medications to reduce medication errors.
- Nurses administer only medications they prepare, and prepared medications are never left unattended.
- Document medications immediately after administration.
- A nurse uses clinical judgment in determining the best time to administer prn medications.
- The nurse reports a medication error immediately.
- When preparing medications, the nurse checks the medication container label against the MAR three times.
- The Z-track method for IM injections protects subcutaneous tissues from irritating parenteral fluids.
- Failure to select injection sites by anatomical landmarks leads to tissue, bone, or nerve damage.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Janice, a nursing student, is caring for Esteban, a 48-year-old Latino who had diabetes and hypertension. Esteban's health care provider writes a new medication order for furosemide 30 mg IVP STAT and then q8h.

1. What does Janice need to know about furosemide before administering it?
2. Three vials of furosemide arrive on the patient care unit. The labels on the vials say: "40 mg furosemide/4 mL." How much medication does Janice prepare in the syringe?
3. Janice collects the appropriate equipment to administer the medication, performs hand hygiene, prepares the medication in the syringe, and takes it to Esteban at the correct time. Which step does she need to take next in administering the medication?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse is having difficulty reading a physician's order for a medication. He or she knows that the physician is very busy and does not like to be called. What is the most appropriate next step for the nurse to take?
   1. Call a pharmacist to interpret the order
   2. Call the physician to have the order clarified
   3. Consult the unit manager to help interpret the order
   4. Ask the unit secretary to interpret the physician's handwriting

2. The patient has an order for 2 tablespoons of Milk of Magnesia. How much medication does the nurse give him or her?
   1. 2 mL
   2. 5 mL
   3. 16 mL
   4. 30 mL
3. A nurse is administering eardrops to an 8-year-old patient with an ear infection. How does the nurse pull the patient's ear when administering the medication?
   1. Outward
   2. Back
   3. Upward and back
   4. Upward and outward
4. A patient is to receive cephalexin (Keflex) 500 mg PO. The pharmacy has sent 250-mg tablets. How many tablets does the nurse administer?
   1. ½ tablet
   2. 1 tablet
   3. 1½ tablets
   4. 2 tablets
5. A nurse is administering medications to a 4-year-old patient. After he or she explains which medications are being given, the mother states, "I don't remember my child having that medication before." What is the nurse's next action?
   1. Give the medications
   2. Identify the patient using two patient identifiers
   3. Withhold the medications and verify the medication orders
   4. Provide medication education to the mother to help her better understand her child's medications
6. A patient is transitioning from the hospital to the home environment. A home care referral is obtained. What is a priority in relation to safe medication administration for the discharge nurse?
   1. Set up the follow-up appointments with the physician for the patient.
   2. Ensure that someone will provide housekeeping for the patient at home.
   3. Ensure that the home care agency is aware of medication and health teaching needs.
   4. Make sure that the patient's family knows how to safely bathe him or her and provide mouth care.
7. A nursing student takes a patient's antibiotic to his room. The patient asks the nursing student what it is and why he should take it. Which information does the nursing student include when replying to the patient?
   1. Only the patient's physician can give this information.
   2. The student provides the name of the medication and a description of its desired effect.
   3. Information about medications is confidential and cannot be shared.
   4. He has to speak with his assigned nurse about this.
8. The nurse is administering a sustained-release capsule to a new patient. The patient insists that he cannot swallow pills. What is the nurse's next best course of action?
   1. Ask the prescriber to change the order
   2. Crush the pill with a mortar and pestle
   3. Hide the capsule in a piece of solid food
   4. Open the capsule and sprinkle it over pudding
9. The nurse takes a medication to a patient, and the patient tells him or her to take it away because she is not going to take it. What is the nurse's next action?
   1. Ask the patient's reason for refusal
   2. Explain that she must take the medication
   3. Take the medication away and chart the patient's refusal
   4. Tell the patient that her physician knows what is best for her
10. The nurse receives an order to start giving a loop diuretic to a patient to help lower his or her blood pressure. The nurse determines the appropriate route for administering the diuretic according to:
    1. Hospital policy.
    2. The prescriber's orders.
    3. The type of medication ordered.
    4. The patient's size and muscle mass.
11. A patient is receiving an intravenous (IV) push medication. If the drug infiltrates into the outer tissues, the nurse:
    1. Continues to let the IV run.
    2. Applies a warm compress to the infiltrated site.
    3. Stops the administration of the medication and follows agency policy.
    4. Should not worry about this because vesicant filtration is not a problem.
12. If a patient who is receiving intravenous (IV) fluids develops tenderness, warmth, erythema, and pain at the site, the nurse suspects:
    1. Sepsis.
    2. Phlebitis.
    3. Infiltration.
    4. Fluid overload.
13. After seeing a patient, the physician gives a nursing student a verbal order for a new medication. The nursing student first needs to:
    1. Follow ISMP guidelines for safe medication abbreviations.
    2. Explain to the physician that the order needs to be given to a registered nurse.
    3. Write down the order on the patient's order sheet and read it back to the physician.
    4. Ensure that the six rights of medication administration are followed when giving the medication.
14. A nurse accidently gives a patient a medication at the wrong time. The nurse's first priority is to:
    1. Complete an occurrence report.
    2. Notify the health care provider.
    3. Inform the charge nurse of the error.
    4. Assess the patient for adverse effects.
15. A patient is taking albuterol through a pressurized metered-dose inhaler (pMDI) that contains a total of 200 puffs. The patient takes 2 puffs every 4 hours. How many days will the pMDI last?

    _____ days

Answers: **1.** 2; **2.** 4; **3.** 4; **4.** 4; **5.** 3; **6.** 3; **7.** 2; **8.** 1; **9.** 1; **10.** 2; **11.** 3; **12.** 2; **13.** 2; **14.** 4; **15.** 16.

CHAPTER

32

Complementary and Alternative Therapies

OBJECTIVES

- Differentiate between complementary and alternative therapies.
- Describe the clinical applications of relaxation therapies.
- Discuss the relaxation response and its effect on somatic ailments.
- Identify the principles and effectiveness of imagery, meditation, and breathwork.
- Describe the purpose and principles of biofeedback.
- Describe the methods of and the psychophysiological responses to therapeutic touch.
- Explain the scope of practice of chiropractic therapy.
- Discuss the principles and applications of acupuncture.
- Describe safe and unsafe herbal therapies.

The general health of North American people has steadily improved over the course of the last century as evidenced by lower mortality rates and increased life expectancies. Changes in science and medicine have provided the knowledge and technology to successfully alter the course of many illnesses. Despite the success of **allopathic medicine** (conventional western medicine), many conditions such as chronic back and neck pain, arthritis, gastrointestinal problems, allergies, headache, and anxiety are sometimes difficult to treat. As a result, more patients are exploring alternative methods to relieve their symptoms. Researchers estimate that up to 75% of patients seek care from their primary care practitioners for stress, pain, and health conditions for which there are no known causes or cures (Rakel and Faass, 2006). Although allopathic medicine is quite effective in treating numerous physical ailments (e.g., bacterial infections, structural abnormalities, and acute emergencies), it is generally less effective in decreasing stress-induced illnesses, managing chronic disease, caring for the emotional and spiritual needs of individuals, and improving quality of life and general well-being.

The number of patients seeking unconventional treatments has risen considerably over the past decade. The most recent comprehensive national survey estimates that between 38.3% and 62.1% of the U.S. population uses complementary and alternative medicine (CAM) (Barnes et al., 2008). In part this increase is caused by (1) a desire for less invasive, less toxic, "more natural" treatments; (2) lack of satisfaction with allopathic treatments; (3) an increasing desire by patients to take a more active role in their treatment process; (4) beliefs that a combination of treatments (allopathic and complementary) result in better overall results; (5) the increased number of research articles in journals such as *Journal of Alternative and Complementary Medicine* and the *Journal of Holistic Nursing;* and (6) beliefs and values that are consistent with an approach to health that incorporates the mind, body, and spirit or a holistic approach (Koithan, 2009).

COMPLEMENTARY AND ALTERNATIVE APPROACHES TO HEALTH

The National Institutes of Health/National Center for Complementary and Alternative Medicine (NIH/NCCAM, 2010b) defines CAM as "a group of diverse medical and health care systems, practices,

and products that are not presently considered to be part of conventional medicine." **Complementary therapies** are therapies used in addition to conventional treatment recommended by the person's health care provider. As the name implies, complementary therapies complement conventional treatments. Many of them such as therapeutic touch contain diagnostic and therapeutic methods that require special training. Others such as guided imagery and breathwork are easily learned and applied. Complementary therapies also include relaxation; exercise; massage; reflexology; prayer; biofeedback; hypnotherapy; creative therapies, including art, music, or dance therapy; meditation; chiropractic therapy; and herbs/supplements (Fontaine, 2005). Another term that is used to describe interventions used in this fashion, particularly by licensed health care providers, is *integrative therapies* (Kreitzer et al., 2009).

Alternative therapies may include the same interventions as complementary therapies; but they become the primary treatment, replacing allopathic medical care. For example, a person with chronic pain uses yoga to encourage flexibility and relaxation at the same time that nonsteroidal antiinflammatory or opioid medications are prescribed. Both sets of interventions are based on conventional pathophysiology and anatomy while acknowledging the mind-body connection that contributes to the physiological pain response. In this case yoga is used as a complementary intervention. However, another patient decides a meditative practice that includes yoga and other lifestyle changes is more helpful than an allopathic approach to chronic pain. This patient studies these practices more deeply, adhering to one of the many schools or traditions, and decides to use these practices as the primary approach to manage chronic pain. In this case yoga is an alternative treatment. Several therapies are always considered alternative because they are based on completely different philosophies and life systems than those used by allopathic medicine. These are identified by NIH/NCCAM as **whole medical systems** such as traditional Chinese medicine (TCM), Ayurveda, and various forms of traditional or folk medicine. Table 32-1 presents types of complementary and alternative therapies.

Because of the increased interest in complementary therapies, many institutions, including medical and nursing schools, have training programs that incorporate complementary and alternative therapy content into the curriculum. Some schools have **integrative health care programs** that allow health care consumers the opportunity to be treated by a team of providers consisting of both allopathic and complementary practitioners. More fully defined, **integrative health care** emphasizes the importance of the relationship between practitioner and patient; focuses on the whole person; is informed by evidence; and makes use of appropriate therapeutic approaches, health care professionals, and disciplines to achieve optimal health (Kreitzer et al., 2009).

Nurses have historically practiced in an integrative fashion; a review of nursing theory (see Chapter 4) reveals the values of holism, relational care, and informed practice. However, nursing has identified its practice as holistic rather than integrated. Holistic nursing regards and treats the mind-body-spirit of the patient. Nurses use holistic nursing interventions such as relaxation therapy, music therapy, touch therapies, and guided imagery. Such interventions affect the whole person (mind-body-spirit) and are effective, economical, noninvasive, nonpharmacological complements to medical care. Nurses use holistic interventions to augment standard treatments, replace interventions that are ineffective or debilitating, and promote or maintain health (Dossey and Keegan, 2009). The American Holistic Nurses Association maintains Standards of Holistic Nursing Practice, which defines and establishes the scope of holistic practice and describes the level of care expected from a holistic nurse (AHNA/ANA, 2007).

Increasing interest in CAM is evident in the increased number of publications on CAM topics in respected health care journals and the development of new journals that specifically focus on complementary and alternative therapies (e.g., *Evidence-Based Complementary and Alternative Medicine* and *Integrative Cancer Therapies*). The ongoing mission of the National Institutes of Health/National Center for Complementary and Alternative Medicine (NCCAM) supports the investigation of the benefits and safety of CAM interventions. Although the body of evidence about CAM is growing, limited data make it difficult to establish the specific benefits of complementary therapies. Reasons are varied but reflect the growing and developing nature of the science. Therefore nurses should weigh the risk and benefits of each intervention and consider the following when recommending complementary therapies: (1) the history of each therapy (many have been used by cultures for thousands of years to support health and ameliorate suffering); (2) nursing's history and experience with a particular therapy; (3) other forms of evidence reporting outcomes and safety data, including case study and qualitative research; and (4) the cultural influences and context for certain patient populations.

This chapter discusses several types of complementary and alternative therapies, including a description, the clinical applications, and the limitations of each therapy. The therapies are organized into two categories. The first are nursing-accessible therapies that you can begin to learn and apply in patient care. The second category includes training-specific therapies such as chiropractic therapy or acupressure that a nurse cannot perform without additional training and/or certification.

NURSING-ACCESSIBLE THERAPIES

Some complementary therapies and techniques are general in nature and use natural processes (e.g., breathing, thinking and concentration, presence, movement) to help people feel better and cope with both acute and chronic conditions (Box 32-1). You need to learn about these techniques and incorporate them as a part of your independent nursing practice with patients (AHNA/ANA, 2007). Assess your patients and obtain their permission before using complementary therapies. In addition, conduct ongoing outcomes assessment and evaluation of your patients' responses to the interventions. Sometimes changes to physician-prescribed therapies, such as medication doses, are needed when complementary therapies alter physiological responses and lead to therapeutic responses.

Complementary therapies teach individuals ways in which to change their behavior to alter physical responses to stress and improve symptoms such as muscle tension, gastrointestinal discomfort, pain, or sleep disturbances. Active involvement is a primary principle for these therapies; individuals achieve better responses if they commit to practice the techniques or exercises daily. Therefore to achieve effective outcomes, therapeutic strategies need to be matched with an individual's lifestyle, his or her beliefs and values, and his or her treatment preferences.

Relaxation Therapy

People face stressful situations in everyday life that evoke the **stress response** (see Chapter 37). The mind varies the biochemical functions of the major organ systems in response to feedback. Thoughts and feelings influence the production of chemicals (i.e., neurotransmitters, neurohormones, and peptides) that circulate throughout the body and convey messages via cells to various

TABLE 32-1 Complementary and Alternative Therapies

TYPES	DEFINITIONS
Biologically Based Therapies	
(Natural products)	
Dietary supplements	Defined by the Dietary Supplement Health and Education Act of 1994 and used to supplement dietary/nutritional intake by mouth; contain one or more dietary ingredients, including vitamins, minerals, herbs or other botanical products
Herbal medicines	Plant-based therapies used in whole systems of medicine or as individual preparations by allopathic providers and consumers for specific symptoms or issues
Macrobiotic diet	Predominantly a vegan diet (no animal products except fish); initially used in the management of a variety of cancers; emphasis placed on whole cereal grains, vegetables, and unprocessed foods
Mycotherapies	Fungi-based (mushroom) products
Orthomolecular medicine (megavitamin)	Increased intake of nutrients such as vitamin C and beta-carotene; treats cancer, schizophrenia, autism, and certain chronic diseases such as hypercholesterolemia and coronary artery disease
Probiotics	Live microorganisms (in most cases, bacteria) that are similar to beneficial microorganisms found in the human gastrointestinal system; also called *good bacteria*
The "Zone"	Dietary program that requires eating protein, carbohydrate, and fat in a 30:40:30 ratio: 30% of calories from protein, 40% from carbohydrate, and 30% from fat; used to balance insulin and other hormones for optimal health
Energy Therapies	
(Use or manipulation of energy fields)	
Healing touch	Biofield therapy; uses gentle touch directly on or close to body to influence and support the human energy system and bring balance to the whole body (physical, spiritual, emotional, and mental); a formal educational and certification system provides credentials for practitioners
Reiki therapy	Biofield therapy derived from ancient Buddhist rituals; practitioner places hands on or above a body area and transfers "universal life energy," providing strength, harmony, and balance to treat a patient's health disturbances
Therapeutic touch	Biofield therapy involving direction of a practitioner's balanced energies in an intentional manner toward those of a patient; practitioner's hands lay on or close to a patient's body
Magnet therapy	Bioelectromagnetic therapy; devices (magnets) applied to the body surface, producing a measurable magnetic field; used primarily to alleviate pain associated with musculoskeletal injuries or disorders
Manipulative and Body-Based Methods	
(Involve movement of body with focus on body structures and systems)	
Acupressure	Applying digital pressure in a specified way on designated points on the body to relieve pain, produce analgesia, or regulate a body function
Chiropractic medicine	Manipulating the spinal column; includes physiotherapy and diet therapy
Craniosacral therapy	Assessing the craniosacral motion for rate, amplitude, symmetry, and quality and attuning/aligning the spinal column, cerebrospinal fluid, and rhythmic processes releasing restrictions or abnormal barriers to motion
Massage therapy	Manipulating soft tissue through stroking, rubbing, or kneading to increase circulation, improve muscle tone, and provide relaxation
Simple touch	Touching the patient in appropriate and gentle ways to make connection, display acceptance, and give appreciation
Mind-Body Interventions	
(Honor connections between thoughts and physiological functioning using emotion to influence health and well-being)	
Acupuncture	Traditional Chinese method of producing analgesia or altering the function of a body system by inserting thin needles along a series of lines or channels, called *meridians;* direct needle manipulation of energetic meridians influences deeper internal organs by redirecting *qi*
Art therapy	Use of art to reconcile emotional conflicts, foster self-awareness, and express patients' unspoken and frequently unconscious concerns about their disease
Biofeedback	Process providing a person with visual or auditory information about autonomic physiological functions of the body such as muscle tension, skin temperature, and brain wave activity through the use of instruments
Breathwork	Using a variety of breathing patterns to relax, invigorate, or open emotional channels
Guided imagery	Concentrating on an image or series of images to treat pathological conditions
Healing intention (prayer)	Variety of techniques used in multiple cultures that incorporate caring, compassion, love, or empathy with the target of prayer
Meditation	Self-directed practice for relaxing the body and calming the mind using focused rhythmic breathing

Continued

TABLE 32-1 Complementary and Alternative Therapies—cont'd

TYPES	DEFINITIONS
Music therapy	Using music to address physical, psychological, cognitive, and social needs of individuals with disabilities and illnesses; improves physical movement and/or communication, develops emotional expression, evokes memories, and distracts people who are in pain
Psychotherapy	Treatment of emotional and mental disorders by psychological techniques
Tai chi	Incorporating breath, movement, and meditation to cleanse, strengthen, and circulate vital life energy and blood; stimulate the immune system and maintain external and internal balance
Yoga	Focuses on body musculature, posture, breathing mechanisms, and consciousness; goal is attainment of physical and mental well-being through mastery of body achieved through exercise, holding of postures, proper breathing, and meditation
Movement Therapies **(Eastern or Western approaches to promote well-being)**	
Dance therapy	Intimate and powerful medium because it is a direct expression of the mind and body; treats persons with social, emotional, cognitive, or physical problems
Feldenkrais method	Alternative therapy based on establishment of good self-image through awareness and correction of body movements; integrates the understanding of the physics of body movement patterns with an awareness of the way people learn to move, behave, and interact
Pilates	Method of body movement used to strengthen, lengthen, and improve the voluntary control of muscles and muscle groups, especially those used for posture and core strengthening; awareness of breathing and precise movements are integral components
Whole Medical Systems **(Complete systems of theory and practice that have evolved independently from or parallel to allopathic [conventional] medicine)**	
Ayurvedic medicine	One of the oldest systems of medicine practiced in India since the first century AD. Ancient Sanscrit books are considered the main texts on Ayurveda medicine—*Caraka Samhita* and *Sushruta Samhita*. There are eight branches of Ayurvedic medicine, including internal medicine; surgery; treatment of head and neck disease; gynecology, obstetrics, and pediatrics; toxicology; psychiatry; elder care and rejuvenation; and sexual vitality. Treatments balance the doshas using a combination of dietary and lifestyle changes, herbal remedies and purgatives, massage, meditation, and exercise.
Homeopathic medicine	Developed in Germany and practiced in the United States since the mid-1800s. It is a system of medical treatments based on the theory that certain diseases can be cured by giving small, highly diluted doses of substances that in a healthy person would produce symptoms like those of the disease. Prescribed substances called *remedies* are made from naturally occurring plant, animal, or mineral substances and are used to stimulate the vital force of the body so it can heal itself.
Latin American traditional healing	*Curanderismo* is a Latin American traditional healing system that includes a humoral model for classifying food, activity, drugs, and illnesses and a series of folk illnesses. The goal is to create a balance between the patient and his or her environment, thereby sustaining health.
Native American traditional healing	Tribal traditions are individualistic, but similarities across traditions include the use of sweating and purging, herbal remedies, and ceremonies in which a shaman (a spiritual healer) makes contact with spirits to ask their direction in bringing healing to people to promote wholeness and healing.
Naturopathic medicine	A system of therapeutics focused on treating the whole person and promoting health and well-being rather than an individual disease. Therapeutics include herbal medicine, nutritional supplementation, physical medicine, homeopathy, lifestyle counseling, and mind-body therapies with an orientation toward assisting the person's internal capacity for self-healing (vitalism).
Traditional Chinese medicine	An ancient healing tradition identified in the first century AD focused on balancing yin/yang energies. It is a set of systematic techniques and methods, including acupuncture, herbal medicines, massage, acupressure, moxibustion (use of heat from burning herbs), Qi gong (balancing energy flow through body movement), cupping, and massage. Fundamental concepts are from Taoism, Confucianism, and Buddhism.

systems within the body. The stress response is a good example of the way in which systems cooperate to protect an individual from harm. Physiologically the cascade of changes associated with the stress response causes increased heart and respiratory rates; tightened muscles; increased metabolic rate; and a general sense of foreboding, fear, nervousness, irritability, and negative mood. Other physiological responses include elevated blood pressure; dilated pupils; stronger cardiac contractions; and increased levels of blood glucose, serum cholesterol, circulating free fatty acids, and triglycerides. Although these responses prepare a person for short-term stress, the effects on the body of long-term stress sometimes include structural damage and chronic illness such as angina, tension headaches, cardiac arrhythmias, pain, ulcers, and atrophy of the immune system organs (Dossey and Keegan, 2009).

The **relaxation response** is the state of generalized decreased cognitive, physiological, and/or behavioral arousal. Relaxation also involves arousal reduction. The process of relaxation elongates the muscle fibers, reduces the neural impulses sent to the brain, and

BOX 32-1 EVIDENCE-BASED PRACTICE

Pain in Hospitalized Children

PICO Question: Do complementary therapies safely and effectively reduce pain and discomfort in hospitalized children?

Evidence Summary

Pain is a complex phenomenon for children, involving psychological, biological, and sociological factors. Hospitalization and pain are often linked in the minds of children. Despite advances in pediatric pain management, recent studies demonstrate that many children continue to have uncontrolled moderate-to-severe pain when they are in the hospital. Several systematic analyses focusing on the use of alternative therapies to control pain show that many complementary and nonpharmacological therapies, such as relaxation, distraction, focused breathing, imagery, art therapy and humor, are effective in reducing discomfort in children who are hospitalized (Chambers et al., 2009; Lasseter, 2006; Rheingans, 2007). Barriers to the use of alternative and complementary therapies included nurses' heavy workloads and the need for further education about how to use these techniques.

Application to Nursing Practice

- Children who are hospitalized often respond positively to complementary therapies, experience reduced pain, and need fewer medications to control their pain.
- Instructing parents on specific complimentary therapies used for their child's pain control (e.g., breathing techniques, art therapy) allows the parents to use these techniques.
- Nurses need to learn about and use complementary therapies such as breathing techniques and distraction to alleviate the pain associated with painful and stressful procedures, especially among children.

thus decreases the activity of the brain and other body systems. Decreased heart and respiratory rates, blood pressure, and oxygen consumption and increased alpha brain activity and peripheral skin temperature characterize the relaxation response. The relaxation response occurs through a variety of techniques that incorporate a repetitive mental focus and the adoption of a calm, peaceful attitude (Snyder and Lindquist, 2010).

Relaxation helps individuals develop cognitive skills to reduce the negative ways in which they respond to situations within their environment. Cognitive skills include the following:

- Focusing (the ability to identify, differentiate, maintain attention on, and return attention to simple stimuli for an extended period)
- Passivity (the ability to stop unnecessary goal-directed and analytic activity)
- Receptivity (the ability to tolerate and accept experiences that are uncertain, unfamiliar, or paradoxical).

The long-term goal of relaxation therapy is for people to continually monitor themselves for indicators of tension and consciously let go and release the tension contained in various body parts.

Progressive relaxation training teaches the individual how to effectively rest and reduces tension in the body. The person learns to detect subtle localized muscle tension sequentially, one muscle group at a time (e.g., the upper arm muscles, the forearm muscles). In doing so the individual learns to differentiate between high-intensity tension (strong fist clenching), very subtle tension, and relaxation (Dossey and Keegan, 2009). He or she practices this activity using different muscle groups. One active progressive relaxation technique involves the use of slow, deep abdominal breathing while tightening and relaxing an ordered succession of

FIG. 32-1 Yoga is a discipline that focuses on muscles, posture, breathing, and consciousness.

muscle groups, focusing on the associated bodily sensations while letting go of extraneous thoughts. When guiding a patient, you may decide to begin with the muscles in the face, followed by those in the arms, hands, abdomen, legs, and feet. Conversely you may also guide a patient to tense and relax muscles, beginning with the feet and working up the body.

The goal of **passive relaxation** is to still the mind and body intentionally without the need to tighten and relax any particular body part. One effective passive relaxation technique incorporates slow, abdominal breathing exercises while imagining warmth and relaxation flowing through specific body parts such as the lungs or hands. Passive relaxation is useful for persons for whom the effort and energy expenditure of active muscle contracting leads to discomfort or exhaustion.

Clinical Applications of Relaxation Therapy. Research shows relaxation techniques effectively lower blood pressure and heart rate, decrease muscle tension, improve well-being, and reduce symptom distress in persons experiencing a variety of situations (e.g., complications from medical treatments, chronic illness, or loss of a significant other) (Bloch et al., 2010; Kwekkeboom et al., 2008). Research also indicates that relaxation, alone or in combination with imagery, yoga (Fig. 32-1), and music, reduces pain and anxiety while improving well-being (Schmidt et al., 2008; Weeks and Nilsson, 2010). Other benefits of relaxation include the reduction of hypertension (Dickinson et al., 2008), depression (Jorm et al., 2008), and menopausal symptoms, including vasomotor responses, insomnia, mood, and musculoskeletal pain (Innes et al., 2010).

Relaxation enables individuals to exert control over their lives. Some experience a decreased feeling of helplessness and a more positive psychological state overall. Relaxation also reduces workplace stress on nursing units. For example, deep-breathing exercises, centering, and focusing attention often lead to improved staff satisfaction, staff relationships and communication, and workload perceptions (Clarke et al., 2009). Nursing units that incorporate relaxation activities into daily routines experience reduced turnover and improved patient satisfaction scores (Zborowsky and Kreitzer, 2009).

Limitations of Relaxation Therapy. During relaxation training individuals learn to differentiate between low and high levels of muscle tension. During the first months of training sessions, when the person is learning how to focus on body sensations and tensions, there are reports of increased sensitivity in detecting muscle tension. Usually these feelings are minor and resolve as the person continues with the training. However, be aware that on

occasion some relaxation techniques result in continued intensification of symptoms or the development of altogether new symptoms (Dossey and Keegan, 2009).

An important consideration when choosing any type of relaxation technique is the physiological and psychological status of the individual. Some patients with advanced disease such as cancer or acquired immunodeficiency syndrome (AIDS) seek relaxation training to reduce their stress response. However, techniques such as active progressive relaxation training require a moderate expenditure of energy, which often increases fatigue and limits an individual's ability to complete relaxation sessions and practice. Therefore active progressive relaxation is not appropriate for patients with advanced disease or those who have decreased energy reserves. Passive relaxation or guided imagery is more appropriate for these individuals.

Meditation and Breathing

Meditation is any activity that limits stimulus input by directing attention to a single unchanging or repetitive stimulus so the person is able to become more aware of self (Snyder and Lindquist, 2010). It is a general term for a wide range of practices that involve relaxing the body and stilling the mind. The root word, *meditari,* means to consider or pay attention to something. Although the meditation has its roots in eastern religious practices (Hindu, Buddhism, and Taoism), conventional health care practitioners began to recognize its healing potential in the early 1970s (Snyder and Lindquist, 2010). According to Benson (1975), the four components of meditation are (1) a quiet space, (2) a comfortable position, (3) a receptive attitude, and (4) a focus of attention. He described meditation as a process that anyone can use to calm down; cope with stress; and, for those with spiritual inclinations, feel one with God or the universe.

Meditation is different from relaxation; the purpose of meditation is to become "mindful," increasing our ability to live freely and escape destructive patterns of negativity. Meditation is self-directed; it does not necessarily require a teacher and can be learned from books or audiotapes (Kabat-Zinn, 2005). Most meditation techniques involve slow, relaxed, deep, abdominal breathing that evokes a restful state, lowers oxygen consumption, reduces respiratory and heart rates, and reduces anxiety (Chiesa and Serretti, 2010).

Clinical Applications of Meditation. Several recent studies support the clinical benefits of meditation. For example, meditation reduces overall systolic and diastolic blood pressures and significantly reduces hypertensive risk (Nidich et al., 2009). It also successfully reduces relapses in alcohol treatment programs (Garland et al., 2010). Patients with cancer who use mindfulness-based cognitive therapies often experience less depression, anxiety, and distress and report an improved quality of life (Foley et al., 2010). Patients suffering from posttraumatic stress disorders and chronic pain also benefit from mindfulness meditation (Kimbrough et al., 2010). In addition, meditation increases productivity, improves mood, increases sense of identity, and lowers irritability (Dossey and Keegan, 2009).

Considerations for the appropriateness of meditation include the person's degree of self-discipline; it requires ongoing practice to achieve lasting results. Most meditation activities are easy to learn and do not require memorization or particular procedures. Patients typically find mindfulness and meditation self-reinforcing. The peaceful, positive mental state is usually pleasurable and provides an incentive for individuals to continue meditating.

Limitations of Meditation. Although meditation contributes to improvement in a variety of physiological and psychological ailments, it is contraindicated for some people. For example, a person who has a strong fear of losing control will possibly perceive it as a form of mind control and thus will be resistant to learning the technique. Some individuals also become hypertensive during meditation and require a much shorter session than the average 15- to 20-minute session.

Meditation may also increase the effects of certain drugs. Therefore monitor individuals learning meditation closely for physiological changes with respect to their medications. Prolonged practice of meditation techniques sometimes reduces the need for antihypertensive, thyroid-regulating, and psychotropic medications (e.g., antidepressants and anti-anxiety agents). In these cases, adjustment of the medication is necessary.

Imagery

Imagery or visualization is a mind-body therapy that uses the conscious mind to create mental images to stimulate physical changes in the body, improve perceived well-being, and/or enhance self-awareness. Frequently imagery, combined with some form of relaxation training, facilitates the effect of the relaxation technique. Imagery is self-directed, in which individuals create their mental images, or guided, during which a practitioner leads an individual through a particular scenario (Dossey and Keegan, 2009). When guiding an imagery exercise, direct the patient to begin slow abdominal breathing while focusing on the rhythm of breathing. Then direct the patient to visualize a specific image such as ocean waves coming to shore with each inspiration and receding with each exhalation. Next instruct the patient to take notice of the smells, sounds, and temperatures that he or she is experiencing. As the imagery session progresses, instruct the patient to visualize warmth entering the body during inspiration and tension leaving the body during exhalation. Individualize imagery scenarios for each patient to ensure that the image does not evoke negative memories or feelings.

Imagery often evokes powerful psychophysiological responses such as alterations in gastric secretions, body chemistry, internal and superficial blood flow, wound healing, and heart rate/heart rate variability (Pincus and Sheikh, 2009). Although most imagery techniques involve visual images, they also include the auditory, proprioceptive, gustatory, and olfactory senses. An example of this involves visualizing a lemon being sliced in half and squeezing the lemon juice on the tongue. This visualization produces increased salivation as effectively as the actual event. People typically respond to their environment according to the way they perceive it and by their own visualizations and expectancies. Therefore you need to individualize imagery for each patient (Snyder and Lindquist, 2010).

Creative visualization is one form of self-directed imagery that is based on the principle of mind-body connectivity (i.e., every mental image leads to physical or emotional changes) (Gawain, 2008). Box 32-2 lists patient teaching strategies for creative visualization.

Clinical Applications of Imagery. Imagery has applications in a number of pediatric and adult patient populations. For example, it helps control or relieve pain, decrease nightmares, and improve sleep (Pincus and Sheikh, 2009). It also aids in the treatment of chronic conditions such as asthma, cancer, sickle cell anemia, migraines, autoimmune disorders, atrial fibrillation, functional urinary disorders, menstrual and premenstrual syndromes, gastrointestinal disorders such as irritable bowel syndrome and ulcerative colitis, and rheumatoid arthritis (Snyder and Lindquist, 2010).

BOX 32-2 PATIENT TEACHING

Creative Visualization

Objective

- The patient will demonstrate skills in creative visualization.

Teaching Strategies

- Set goals the patient can meet. Success achieves confidence and increased self-esteem.
- Create a clear image. Although it is sometimes difficult to develop a visual image, if the patient views the goals of the imagery with clear thoughts and in the present tense, the patient will be more successful in creating an effective image.
- Have the patient frequently visualize the image. Have him or her perform this visualization during relaxing states and throughout the day but particularly before bedtime or on wakening, when his or her mind usually is more relaxed.
- Have the patient repeat encouraging statements while focusing on the image. This alleviates any doubts about his or her ability to achieve established goals.

Evaluation

- Observe patient behaviors for presence of anxiety or increased discomfort.
- Ask patient to describe the helpfulness of the visualization experience.
- Have patient describe use of positive self-dialogue and images of desired health habits, feelings, and desires for healing.
- Ask how the patient is coping with daily stressors.

Limitations of Imagery. Imagery is a behavioral intervention that has relatively few side effects (Roffe, Schmidt, and Ernst, 2005). Yet increased anxiety and fear sometimes occur when imagery is used to treat posttraumatic stress disorders and social anxiety disorders (Cook et al., 2010). Some patients with chronic obstructive pulmonary disease (COPD) and asthma experience increased airway constriction when using guided imagery (Reed, 2007). Thus you need to closely monitor patients when beginning this therapy.

TRAINING-SPECIFIC THERAPIES

Training-specific therapies are CAM treatments that nurses administer only after completing a specific course of study and training. These therapies require postgraduate certificates or degrees indicating completion of additional education and training, national certification, or additional licensure beyond the registered nurse (RN) to practice and administer them. Several training-specific therapies (e.g., biofeedback and acupuncture) are very effective and often recommended by western health care practitioners (Trigkilidas, 2010; Wheat and Larkin, 2010). However, others (e.g., homeopathy and naturopathy) have not been adequately studied, and their effectiveness in many conditions has been questioned (Borelli and Ernst, 2010). Although many of these complementary therapies elicit positive effects, all therapies carry some risk, particularly when used in conjunction with conventional medical therapies. Therefore you need advanced knowledge to effectively talk about them with patients and provide education about their safe use.

Biofeedback

Biofeedback is a mind-body technique that uses instruments to teach self-regulation and voluntary self-control over specific physiological responses. Electronic or electromechanical instruments measure, process, and provide information to patients about their muscle tension, cardiac activity, respiratory rates, brain-wave patterns, and autonomic nervous system activity. This information, or feedback, is given in physical, physiological, auditory, and/or visual feedback signals that increase a person's awareness of internal processes that are linked to illness and distress. Biofeedback therapies are used to change thinking, emotions, and behaviors, which in turn support beneficial physiological changes, resulting in improved health and well-being. For example, patients connected to a biofeedback device sometimes hear a sound if their pulse rate or blood pressure increases out of their therapeutic zone. Practitioners then help patients interpret these sounds and use a variety of breathing, relaxation, and imaging exercises to gain voluntary control over their racing heart or their increasing systolic blood pressure (Applied Psychophysiology and Biofeedback Association, 2008).

Biofeedback is an effective addition to more traditional relaxation programs because it immediately demonstrates to patients their ability to control some physiological responses and the relationship among thoughts, feelings, and physiological responses. It helps individuals focus on and monitor specific body parts. Biofeedback helps patients control the physiological functions that are most difficult to control by providing immediate feedback about which stress relaxation behaviors work most effectively. Eventually patients notice positive physiological changes without the need for instrument feedback.

Clinical Applications of Biofeedback. Biofeedback in a variety of forms has application in numerous situations, with evidence supporting its effectiveness dating back to the 1980s. Recent systematic literature reviews suggest that it is helpful in stroke recovery, smoking cessation, attention deficit hyperactivity disorder (ADHD), epilepsy, headache disorders, and a variety of gastrointestinal and urinary tract disorders (Arns et al., 2009; Hollands et al., 2010). One of the most critical components of any behavioral program is adherence to the treatment regimen. Patients who are compliant have more positive results.

Limitations of Biofeedback. Although biofeedback produces effective outcomes in many patients, there are several precautions, particularly in those with psychological or neurological conditions. During biofeedback sessions repressed emotions or feelings for which coping is difficult sometimes surface. For this reason practitioners who offer biofeedback need to be trained in more traditional psychological methods or have qualified professionals available for referral. In addition, long-term use of biofeedback sometimes lowers blood pressure, heart rates, and other physiological parameters. As with other biobehavioral interventions, monitor patients closely to determine the need for medication adjustments.

Acupuncture

As a key component of TCM, **acupuncture** is one of the oldest practices in the world. In TCM, acupuncture is only one intervention used. When applied outside the whole system practice of TCM, acupuncture is viewed as a mind-body therapy and is called medical acupuncture. In the United States medical acupuncture is often provided as an individual treatment by conventionally trained physicians, nurses, chiropractors, dentists, and acupuncturists for many chronic conditions. Many states now have regulations and licensure requirements to practice as an acupuncturist.

Acupuncture regulates or realigns the **vital energy *(qi),*** which flows like a river through the body in channels that form a system of pathways called **meridians.** Twelve primary and eight secondary meridians are used by medical acupuncturists. An obstruction in

FIG. 32-2 Acupuncture accesses the *qi* through specific points along the energy meridians of the body.

FIG. 32-3 The practitioner intentionally directs interpersonal energy to facilitate the patient's healing process during a therapeutic touch session.

these channels blocks energy flow in other parts of the body. Acupuncturists insert needles in specific areas along the channels called **acupoints,** through which the *qi* can be influenced and flow reestablished (Fig. 32-2). Application of heat or weak electrical currents enhances the effects of the needles (Fontaine, 2005).

Clinical Applications of Acupuncture. Current evidence shows that acupuncture modifies the body's response to pain and how pain is processed by central neural pathways and cerebral function (NIH/NCCAM, 2010a). Acupuncture is effective for low back pain, myofascial pain (e.g., temporomandibular joint disorder and trigeminal neuralgia), simple and migraine headaches, osteoarthritis, plantar heel pain, and chronic shoulder pain (Lee et al., 2010; Molsberger et al., 2010). It is also used to treat other problems such as sinusitis, gastrointestinal disorders, chronic pruritus, perimenstrual symptoms, menopausal symptoms, clinical depression, smoking, and other addictions with varying effectiveness (Scheid et al., 2010).

Limitations of Acupuncture. Acupuncture is a safe therapy when the practitioner has the appropriate training and uses sterilized needles. Although needle complications occur, they are rare if the practitioner takes appropriate steps to ensure the safety of the equipment and the patient. Reported complications include infections resulting from inadequately sterilized needles or those that are left in place for an extended length of time, broken needles, puncture of an internal organ, bleeding, fainting, seizures, and posttreatment drowsiness.

Caution is necessary when using acupuncture with pregnant patients and those who have a history of seizures, are carriers of hepatitis, or are infected with human immunodeficiency virus (HIV). Treatment is contraindicated in persons who have bleeding disorders and skin infections. Further, semipermanent needles should not be used with patients who have valvular heart disease because of the increased risk of infection. Electroacupuncture is not recommended for persons with a pacemaker and those who have cardiac arrhythmias or epilepsy or are pregnant (Fontaine, 2005).

Therapeutic Touch

Therapeutic touch (TT), developed in the 1970s, is one of the "touch therapies" identified by NCCAM. It affects the energy fields that surround and penetrate the human body with the conscious intent to help or heal (Dossey and Keegan, 2009). Other touch therapies include acupressure, healing touch (HT), reiki, and the M technique. Blending ancient eastern traditions with modern nursing theory, TT uses the energy of the provider to positively influence the patient's energy field.

TT consists of placing the practitioner's open palms either on or close to the body of a person (Fig. 32-3). It occurs in five phases: centering, assessing, unruffling, treating, and evaluating. To begin the practitioner centers physically and psychologically, becoming fully present in the moment and quieting outside distractions. Then the practitioner scans the body of the patient with the palms (roughly 2 to 6 inches [5 to 15 cm] from the body) from head to toe. While assessing the energetic biofield of the patient, the practitioner focuses on the quality of the *qi,* identifying areas of accumulated energetic tensions, uneasiness, sluggishness, or congestion that manifest as sensations of congestion, pressure, warmth, coolness, blockage, pulling or drawing, or static or tingling. The practitioner then redirects these energetic patterns to harmonize distressed areas or to stimulate movement of *qi* in areas that are stuck and congested. Using long downward strokes over the energy fields of the body, the practitioner touches the body or maintains the hands in a position a few inches away from the body. The final phase consists of evaluating the patient, reassessing the energy field to ensure that energy is flowing freely, and determining additional outcomes and responses to the treatment (Krieger, 1975, 1979).

Clinical Applications of Therapeutic Touch. The evidence supporting the effectiveness of TT is inconclusive, although it may be effective in treating pain in adults and children, dementia, trauma, and anxiety during acute and chronic illnesses (Jain and Mills, 2010). Box 32-3 summarizes the importance of touch in older adults.

Limitations of Therapeutic Touch. Although the use of TT causes very few complications or side effects, it is contraindicated in certain patient populations. For example, people who are sensitive to human interaction and touch (e.g., those who have been physically abused or have psychiatric disorders) often misinterpret the intent of the treatment and feel threatened and anxious by it. Other patients, including pregnant women, neonates, patients with cardiovascular and neurological instabilities, or patients who are dying, sometimes are sensitive to energy repatterning. Sessions with these populations need to be time limited and particularly gentle (Snyder and Lindquist, 2010).

Chiropractic Therapy

Chiropractic therapy, a manipulative or body-based therapy, was developed in 1895 in Iowa. Chiropractors graduate from well-established postbaccalaureate educational programs similar to medical schools. The central belief of the chiropractic profession

BOX 32-3 FOCUS ON OLDER ADULTS

The Importance of Touch

- Touch is a primal need, as necessary as food, growth, or shelter. Touch is like a nutrient transmitted through the skin, and "skin hunger" is like a form of malnutrition that has reached epidemic proportions in the United States, especially among older adults (Fontaine, 2005).
- Older adults need touch as much as or more than any other age-group. However, the elderly often experience "skin hunger." Older adults often have fewer family members or friends to touch them at a time when simple touch may enhance communication, especially when other senses are reduced (Dossey and Keegan, 2009).
- Simple touch helps older adults feel more connected to and accepted by those around them and more in tune with their environment. Touch enhances self-esteem and sense of worth.
- Nurses who react adversely to skin changes caused by aging often find it difficult to touch older adults. This reluctance communicates a negative message to the older adult (Dossey and Keegan, 2009). Therefore be aware of your own reactions to touch when caring for older adults to ensure a therapeutic approach to patient-centered care.

is that body structure (primarily that of the spine and spinal cord) and the ability of the body to function normally are closely related. When the spine is misaligned, energy flow is impeded, and the innate healing abilities of the body are impaired. Chiropractic therapy aims to normalize the relationship between structure and function by a series of manipulations. Practitioners use their hands or a device to provide manipulation, which is the application of a controlled, sudden forceful movement to a joint, moving it beyond its passive range of motion. Often manipulations are combined with additional therapeutic modalities, including ice and heat, electrical stimulation, deep tissue massage, joint immobilization, lifestyle counseling, and medications.

Chiropractic care is a popular form of complementary therapy in the United States; 8.6% of the adult and 3% of the pediatric population visit chiropractors each year, representing almost 20 million health care visits (Barnes et al., 2008). Compared to other forms of complementary therapies, chiropractic care is often covered by insurance plans, including Medicare, Medicaid, state workers' compensation plans, health maintenance organizations (HMOs), and private insurance plans. Licensure is regulated by individual state governments, and scopes of practice and prescriptive authority vary from state to state.

Clinical Applications of Chiropractic Therapy. The basic goals of chiropractic therapy focus on restoring structural and functional imbalances. Chiropractors believe that structure and function coexist with one another and that alterations or distortions in structure ultimately lead to abnormalities in function. A major structural problem that chiropractors treat is vertebral (neck/back) subluxation with its accompanying symptom of pain.

Chiropractic therapy improves acute pain and disability in some patients. This therapy is also sometimes effective over longer periods to reduce pain caused by acute and subacute low back pain and joint pain caused by osteoarthritis (Walker et al., 2010). Chiropractic care may also enhance the effects of conventional treatments in pediatric asthma (Kaminskyj et al., 2010). Chiropractic interventions are also used to treat headaches, dysmenorrhea, vertigo, tinnitus, and visual disorders (Hawk et al., 2010).

Limitations of Chiropractic Therapy. Although chiropractic therapies are safe for a variety of conditions, chiropractors do not treat several diseases or conditions with manipulation. Bone and joint infections require pharmaceutical or surgical intervention because the structural integrity of the bone is compromised if excessive force is used. Other contraindications include acute myelopathy, fractures, dislocations, rheumatoid arthritis, and osteoporosis.

Some risks are associated with chiropractic therapy. A variety of injuries, ranging in severity from mild adverse responses (e.g., mild transient headache, increased pain and stiffness) to more serious injuries (e.g., vertebral artery dissection), sometimes happen (Ernst, 2007). Degree and risk of injury depend on the type of manipulation performed, location of the manipulation (cervical spine is more susceptible to serious injury), overall health of the patient, and expertise of the provider. When educating patients about chiropractic care, you need to include educational and licensure credentials of qualified chiropractors, typical treatments, and possible complications.

TABLE 32-2 Three Causes of Disease According to Traditional Chinese Medicine

CAUSE OF DISEASE	INFLUENCES
Internal causes	Internal causes originate in emotions and affect different organs: anger (liver), joy (heart), fear (kidney), grief/sadness (lung), pensiveness/worry (spleen), and shock (heart/kidney).
External causes	Six "evils" primarily linked to weather and climate (wind, cold, fire, damp, summer heat, and dryness) are manifested as linked patterns such as wind-cold, wind-heat, fire-toxin.
Nonexternal, noninternal causes	Additional causes of disharmony include congenital weak constitutions (birth defects), trauma, overexertion, excessive sexual activity, poor quality diet, and parasites and poisons.

Traditional Chinese Medicine

Traditional Chinese medicine (TCM) is a whole system of medicine that began as a primitive ethnic healing system approximately 3600 years ago. Chinese medicine views health as "life in balance," which manifests as lustrous hair, a radiant complexion, engaged interactions, a body that functions without limitations, and emotional balance. Health promotion encourages healthy diet, moderate regular exercise, regular meditation/introspection, healthy family and social relationships, and avoidance of environmental toxins such as cigarette smoke.

Several concepts and principles guide the TCM system of assessment, diagnosis, and intervention. The most important of these is the concept of **yin and yang,** which represent opposing yet complementary phenomena that exist in a state of dynamic equilibrium. Examples are night/day, hot/cold, and shady/sunny. Yin represents shade, cold, and inhibition; whereas yang represents fire, light, and excitement. Yin also represents the inner part of the body, specifically the viscera, liver, heart, spleen, lung, and kidney; whereas yang represents the outer part, specifically the bowels, stomach, and bladder. Harmony and balance in every aspect of life are the keys to health, including yin/yang balance. Practitioners believe that disease occurs when there is an imbalance in these two paired opposites (Maciocia, 1989). Imbalance occurs as excess or deficiencies in three areas: external, internal, or neither internal nor external (Table 32-2). It ultimately leads to disruption of vital energy,

qi, which then compromises the body-mind-spirit of the person, causing "*disease.*" Disruptions in *qi* along the meridians can be systematically evaluated and treated by TCM practitioners.

TCM is an individualized treatment system based on a very specific assessment process. Practitioners use four methods to evaluate a patient's condition: observing, hearing/smelling, asking/interviewing, and touching/palpating. In Chinese medicine outward manifestations reflect the internal environment. For example, the color, shape, and coating of the tongue reflect the general condition of the internal organs. The pulses provide information about the condition and balance of *qi,* blood, ying and yang, and internal organs. Therapeutic modalities include acupuncture, Chinese herbs, tui na massage, **moxibustion** (burning moxa, a cone or stick of dried herbs that have healing properties on or near the skin) **cupping** (placing a heated cup on the skin to create a slight suction), **tai chi** (originally a martial art that is now viewed as a moving meditation in which patients move their bodies slowly, gently, and with awareness while breathing deeply), ***qi gong*** (originally a martial art, now viewed as a series of carefully choreographed movements or gestures that are designed to promote and manipulate the flow of *qi* within the body), lifestyle modifications, and dietary changes.

Clinical Applications of Traditional Chinese Medicine. In spite of widespread use of TCM in Asia, evidence about its effectiveness is limited. Most research in this field focuses on the study of individual treatment components of TCM such as acupuncture and herbal therapies. However, some evidence shows that TCM is helpful in treating fibromyalgia (Cao et al., 2010) and in reducing pain and spasticity in children with cerebral palsy (Zhang et al., 2010).

Limitations of Traditional Chinese Medicine. TCM is not currently regulated in most states, although acupuncture is. The federal government recognizes the Accreditation Commission for Acupuncture and Oriental Medicine (ACAOM) as responsible for accrediting schools that teach acupuncture and TCM, and approximately one third of the states that license acupuncture require graduation from an ACAOM-accredited school. The National Certification Commission for Acupuncture and Oriental Medicine (NCCAOM) offers a certification examination for acupuncture and Chinese herbal and manipulative therapies. Refer patients requesting TCM to a qualified practitioner found at http://www.nccaom.org/find/index.html.

There is some concern about the safety of Chinese herbal treatments that are used in teas, remedies, and supplements. The U.S. Food and Drug Administration (FDA) does not regulate, inspect, or ensure that the ingredients of these herbs are safe and without toxins. Recent reports about these products suggest that many Chinese herbs are contaminated with drugs, toxins, or heavy metals or that many ingredients may not be clearly listed or labeled. Further, these herbs can be very powerful, interacting with drugs and causing serious complications. When assessing a person using TCM, you always need to ask about the full complement of therapies, including the types of herbs that the patient is using. Some patients consider these as teas or dietary additives, powders, or supplements and not as over-the-counter medications.

Natural Products and Herbal Therapies

Researchers estimate that approximately 25,000 plant species are used medicinally throughout the world. It is the oldest form of medicine known to man, and archeological evidence suggests that herbal remedies have been used for over 60,000 years. Herbal medicines are a prominent part of health care among indigenous populations worldwide. In addition, interest in countries in which health care is primarily conventional allopathic medicine is also increasing (Snyder and Lindquist, 2010).

Nonvitamin, nonmineral natural products are used by almost 20% of the U.S. population to prevent disease and illness and to promote health and well-being (Barnes et al., 2008). A natural product is a chemical compound or substance produced by a living organism and includes herbal medicines (also known as botanicals), dietary supplements, vitamins, minerals, mycotherapies (fungi-based products), essential oils (aromatherapy), and probiotics. Many are sold over the counter as dietary supplements. The most frequently used products are garlic, Echinacea, saw palmetto, ginkgo biloba, cranberry, soy, ginseng, black cohosh, St. John's wort, glucosamine, peppermint, fish oil/omega 3, soy, and milk thistle (Blumenthal et al., 2006).

Herbal medicines are not approved for use as drugs and are not regulated by the FDA. For this reason many are sold as foods or food supplements. The Dietary Supplement Health and Education Act (1994) allows companies to sell herbs as dietary supplements as long as there are no health claims written on their labels. Natural products in the United States are prepared primarily from plant materials. They are provided as tinctures or extracts, elixirs, syrups, capsules, pills, tablets, lozenges, powders, ointments or creams, drops, and suppositories.

Clinical Applications of Herbal Therapy. A number of herbs are safe and effective for a variety of conditions (Table 32-3). Nurses have used cranberry juice to treat urinary tract infections for decades. Research now supports the use of cranberry supplements to prevent urinary tract infections because cranberry molecules bind with the iron that bacteria need to grow and reproduce and substances in cranberry block adherence of bacteria to the walls of the bladder (Rossi et al., 2010). Chamomile is a plant substance that has been widely used in teas to promote sleep and relaxation and treat mild gastrointestinal disturbances and premenstrual symptoms. Clinical trials have recently found that chamomile may have modest benefits for people with mild-to-moderate generalized anxiety disorder (Amsterdam et al., 2009).

Limitations of Herbal Therapy. Simply because a product is "natural" does not make it "safe." Although herbal medicines provide beneficial effects for a variety of conditions, a number of problems exist. Because they are not regulated, concentrations of the active ingredients vary considerably. Contamination with other herbs or chemicals, including pesticides and heavy metals, is also problematic. Not all companies follow strict quality control and manufacturing guidelines that set standards for acceptable levels of pesticides, residual solvents, bacterial levels, and heavy metals. For this reason, teach patients to purchase herbal medicines only from reputable manufacturers. Labels on herbal products need to contain the scientific name of the botanical, the name and address of the actual manufacturer, a batch or lot number, the date of manufacture, and the expiration date. Using natural products that have been verified by the U.S. Pharmacopeia (USP) is another way to ensure product safety, quality, and purity. Look for the USP Verified Dietary Supplement mark on product labels when buying or recommending natural products.

Some herbs also contain toxic products that have been linked to cancer. Table 32-4 lists several unsafe herbs. Some herbal substances contain powerful chemicals. As with any other medication, examine herbs for interaction and compatibility with other prescribed or over-the-counter substances that are being used simultaneously.

TABLE 32-3 Safe or Effective Herbs Determined by Non-U.S. Regulatory Authorities

COMMON NAME AND USES	EFFECTS	POTENTIAL DRUG INTERACTIONS
Aloe		
Skin disorders, including inflammation and acute injuries (used topically)	Acceleration of wound healing	Furosemide (Lasix) and loop diuretics
GI ulcerations, including Crohn's disease and ulcerative colitis (taken orally)	Unknown mechanism, although there is a known laxative effect	May enhance the effects of laxatives when taken orally
Chamomile		
Inflammatory diseases of GI and upper respiratory tracts	Antiinflammatory	Drugs that cause drowsiness (alcohol, barbiturates, benzodiazepines, narcotics, antidepressants)
Generalized anxiety disorder	Calming agent	
Echinacea		
Upper respiratory tract infections	Stimulant of immune system	Antirejection and other drugs that weaken immune system May interact with antiretrovirals and other drugs used in the treatment of HIV/AIDS
Feverfew		
Wound healing	Antiinflammatory	Warfarin (Coumadin) and blood thinners
Arthritis	Inhibition of serotonin and prostaglandins	Aspirin and ibuprofen
Garlic		
Elevated cholesterol levels	Inhibition of platelet aggregation	Warfarin and blood thinners
Hypertension		Saquinavir (Fortovase) and other anti-HIV drugs
Ginger		
Nausea and vomiting	Antiemetic	Warfarin and blood thinners Aspirin and NSAIDs
Gingko biloba		
Alzheimer's disease and dementia	Memory improvement, although these effects are now in question given results in two recent clinical trials	Warfarin and anticoagulants Aspirin and NSAIDs
Ginseng		
Age-related diseases	Increased physical endurance, improved immune function	Warfarin and anticoagulants Aspirin and NSAIDs MAO inhibitors
Licorice		
GI disorders, including gastric ulcers and hepatitis C	Unknown	Corticosteroids and other immunosuppressive drugs Digoxin Antihypertensive drugs
Saw palmetto		
Benign prostatic hyperplasia	Prevention of conversion of testosterone to dihydrotestosterone (needed for prostate cell multiplication)	Finasteride (Propecia) and antiandrogen drugs
Chronic pelvic pain	Unknown mechanism	None known
Valerian		
Sleep disorders, mild anxiety and restlessness	Central nervous system depression	Barbiturates and other sleep medications Alcohol Antihistamines

Data from National Institutes of Health/National Center for Complementary and Alternative Medicine: *Herbs at a glance,* 2010, accessed September 10, 2010, from http://nccam.nih.gov/health/herbsataglance.htm.

AIDS, Acquired immunodeficiency disease; *GI,* gastrointestinal; *HIV,* human immunodeficiency virus; *MAO,* monoamine oxidase; *NSAIDs,* nonsteroidal antiinflammatory drugs.

TABLE 32-4 **Unsafe Herbs**

COMMON NAME	EFFECTS	COMMENTS
Calamus (Indian type most toxic)	Fever Digestive aid	Contains varying amounts of carcinogenic *cis*-isoasarone Documented cases of kidney damage and seizures with oral preparations
Chaparral	Anticancer Used for bronchitis in traditional healing systems (Native American and Hispanic folk medicine) Found in "natural" weight-loss products	No proven efficacy Induces severe liver toxicity in some cases Severe uterine contractions
Coltsfoot	Antitussive	Contains carcinogenic pyrrolizidine alkaloids Hepatotoxic
Comfrey	Wound healing and acute injuries Used for antiinflammatory effects in osteoarthritis and rheumatoid arthritis	Contains carcinogenic pyrrolizidine alkaloids May induce venoocclusive disease Hepatotoxic
Ephedra (ma huang)	Central nervous system stimulant Bronchodilator Cardiac stimulation Weight loss	Unsafe for people with hypertension, diabetes, or thyroid disease Avoid consumption with caffeine
Life root	Menstrual flow stimulant	Hepatotoxic
Pokeweed	Antirheumatic Anticancer	Do not use with children, but many websites state that it is safe with observation and monitoring and proper dosing; often used with folk remedies and in native American healing

NURSING ROLE IN COMPLEMENTARY AND ALTERNATIVE THERAPIES

The interest in complementary and alternative therapies continues to increase. Most people using and seeking information about these therapies are well educated and have a strong desire to actively participate in decision making about their health care. This increased interest comes not only from health care consumers but also from allopathic physicians who have increasing concerns that current conventional medicine is not meeting the needs of their patients. Many allopathic physicians do not refer their patients for complementary therapies because they are not familiar with them and have had little, if any, education and training about integrating these traditions with their practice. Many physicians have reservations about complementary therapies because they have not been tested appropriately in clinical trials in which other factors that influence the outcomes are strictly controlled.

In North America and Europe many professional groups are exploring the use of complementary and alternative therapies and facilitating and monitoring research in this area. Proposals put forth by several of the these groups include assessing the public use of complementary and alternative therapies, integrating CAM educational components in the curriculum for all health care programs, providing appropriate information to the public, and encouraging and facilitating communication between CAM and conventional care providers to improve public health and ensure the quality and safety of health care. For example, if health care providers want to recommend the best treatment option for each health condition, allopathic providers need to be aware of the evidence supporting complementary therapies and how to safely refer patients to complementary therapy providers. Contrastingly, complementary therapy providers need to participate in the research process, working with scientists to demonstrate the effectiveness of these therapies on patient outcomes within the more rigorous framework of western science. All providers, including nurses, need to encourage open, honest dialogue about the use of complementary and alternative therapies by patients and better understand the benefits of therapies that encourage active participation by their patients in preventing or managing illness rather than relying solely on surgery or drugs.

Integrative health care, a strategy that is gaining popularity, involves a multiple-practitioner group practice in which a patient seeks care simultaneously from more than one type of practitioner. Patients have the option to choose the type of practitioner that they believe is beneficial for their particular health problem. Patients who benefit from these groups are those who have chronic health problems that have historically been difficult to treat using traditional allopathic approaches such as fibromyalgia, chronic fatigue syndrome, or chronic pain syndromes. A multiple-practitioner group practice represents a pluralistic and truly complementary health care system in which both alternative and allopathic practitioners work side-by-side to improve the well-being of their patients. The integrative approach is consistent with the holistic approach that nurses learn to practice. Nurses have the potential for becoming essential participants in this type of health care philosophy. Many nurses already practice the use of touch, relaxation techniques, imagery, and breathwork. Familiarize yourself with the evidence in each modality that you incorporate into your practice. Know which patient is most likely to benefit from each therapy, which complications might occur, and which precautions are needed when using these therapies.

In addition, you need enough knowledge to discuss complementary and alternative therapies with patients and help them make health care decisions. Always ask patients directly about their use of complementary therapies, including self-care activities such as yoga, meditation, or dietary supplements. Be knowledgeable about the evidence for different complementary therapies so you can make appropriate recommendations about which therapies are possibly useful for patients. Know about the different credentialing processes and how to refer patients to competent providers. Understand thoroughly the potential benefits and risks so information is clearly and fully disclosed. Be knowledgeable so you can give advice to patients about when to seek conventional care and when it is safe to consider complementary care services. For example, if a patient complains of right lower abdominal pain, nausea, and vomiting, be suspicious of appendicitis and recommend assessment by an allopathic physician. However, if the patient has a chronic gastrointestinal disorder and has a diagnosis of irritable bowel syndrome, the patient may benefit from relaxation and herbal therapy. Be aware of the safety precautions for each complementary therapy and incorporate these in your teaching plans. Finally understand your state Nurse Practice Act with regard to complementary therapies and practice only within the scope of these laws.

Nurses work very closely with their patients and are in the unique position of becoming familiar with the patient's spiritual and cultural viewpoints. They are often able to determine which complementary therapies are more appropriately aligned with these beliefs and offer recommendations accordingly. Being knowledgeable about CAM therapies will help you provide accurate information to patients and other health care professionals.

KEY POINTS

- Integrative health care programs use a multidisciplinary (both allopathic and complementary) treatment approach that provides holistic care to patients.
- The stress response is an adaptive response that allows individuals to respond to stressful situations.
- A chronic stress response is often maladaptive, leading to chronic muscle tension, mood changes, and immune changes.
- Complementary therapies require commitment and regular involvement by the patient to be most effective and have prolonged beneficial outcomes.
- Choose complementary therapies appropriately according to the patient's functional status, belief or religious perspectives, access to health care, and insurance coverage.
- Medication doses need to be changed when complementary therapies significantly and consistently alter physiological responses.
- Complementary therapies accessible to nursing include relaxation, meditation and mindfulness techniques, and imagery. Evidence supports their use to decrease the effects of stress and improve overall patient well-being.
- Many complementary therapies require additional education and certification, including biofeedback, touch therapies (TT, Reiki, and HT), and acupuncture.
- Although increasing evidence supports the use of complementary therapies, many complementary and alternative therapies still lack a scientific basis but are effective based on observed positive outcomes in a number of patients.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Margaret Thompson is a 76-year-old Catholic woman who has been diagnosed with a slow-growing renal tumor. She is scheduled for surgery. You are responsible for the admission assessment and initial care for this patient. What assessment questions about complementary and alternative therapies are important to include during this preoperative period?
2. During the initial assessment Ms. Thompson asks many questions. "Is it cancer? Will the surgery result in a disability? What can I expect? Will I have to be in intensive care unit (ICU)?" You conclude that she is afraid of both the surgical procedure and the outcome. What types of specific nursing-accessible complementary therapies will you offer her during the preoperative period to reduce her anxiety and help her prepare for surgery?
3. In the days following surgery you are assigned to care for Ms. Thompson. Although physically she is recovering quite well from the procedure, you note that she is becoming more despondent and depressed. Preparing for discharge, what complementary and alternative medicine (CAM) therapies do you recommend to help her deal with her depression and cancer diagnosis?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. When planning patient education, it is important to remember that patients with which of the following often find relief in complementary therapies?
   1. Lupus and diabetes
   2. Ulcers and hepatitis
   3. Heart disease and pancreatitis
   4. Chronic back pain and arthritis
2. Which complementary therapies are most easily learned and applied by the nurse? (Select all that apply.)
   1. Massage therapy
   2. Traditional Chinese medicine
   3. Progressive relaxation
   4. Breathwork and imagery
   5. Therapeutic touch
3. Which statement best describes the evidence associated with complementary therapies as a whole?
   1. Many clinical trials in complementary therapies support their effectiveness in a wide range of clinical problems.
   2. It is difficult to find funding for studies about complementary therapies. Therefore we should not expect to find evidence supporting its use.
   3. The science supporting the effectiveness of complementary therapies is early in its development. Systematic reviews of the evidence often indicate beginning support for therapies, but there is a lack of strong evidence supporting their widespread use.
   4. Most of the research examining complementary and alternative therapies has found little evidence, suggesting that although people like them, they are not effective.
4. The nurse understands that providing holistic care includes treating which of the following?

1. Disease, spirit, and family interactions
2. Desires and emotions of the patient
3. Mind-body-spirit of the patient and their families
4. Muscles, nerves, and spine disorders

5. In addition to an adequate patient assessment, when the nurse uses one of the nursing-accessible complementary therapies, he or she must ensure that which of the following has occurred?
   1. The family has provided permission.
   2. The patient has provided permission and consent.
   3. The health care provider has given approval or provided orders for the therapy.
   4. He or she has documented that the patient has a complete understanding of complementary and alternative medicine.
6. Which role do patients have in complementary and alternative medicine therapy?
   1. Submissive to the practitioner
   2. Actively involved in the treatment
   3. An educator for other health care professionals
   4. A total believer in what is being taught
7. The nurse is caring for a patient experiencing a stress response. The nurse plans care with the knowledge that systems respond to stress in what manner?
   1. Always fail and cause illness and disease
   2. Cause structural damage to the body
   3. React the same way for all individuals
   4. Protect an individual from harm in the short term but cause negative responses over time
8. When meditation therapy is used, nurses need to monitor patients' medications carefully because meditation may augment the effects of certain drugs such as:
   1. Prednisone and antibiotics.
   2. Insulin and vitamins.
   3. Cough syrups and aspirin.
   4. Antihypertensive and thyroid-regulating medications.
9. A patient who has been using relaxation wants a better response. The nurse recommends the addition of biofeedback. What is the expected outcome related to using this additional modality?
   1. To eat less food
   2. To control diabetes
   3. To live longer with acquired immunodeficiency syndrome (AIDS)
   4. To learn how to control some autonomic nervous system responses
10. A patient asks a nurse about therapeutic touch (TT). Which of the following does the nurse include when providing patient education about TT? Therapeutic touch:
    1. Intentionally mobilizes energy to balance, harmonize, and repattern the recipient's biofield
    2. Intentionally heals specific diseases or corrects certain symptoms
    3. Is overwhelmingly effective in many conditions
    4. Is completely safe and does not warrant any special precautions
11. A nurse provides care for a diverse group of patients, including many immigrants. To better understand various types of health care, the nurse learns the traditional Chinese medicine system:
    1. Uses acupuncture as its primary intervention modality
    2. Uses many modalities that are based on the individual and include herbal therapies, moxibustion, and acupuncture
    3. Uses primarily herbal remedies (that are known to have high levels of lead products) and exercise
    4. Is the equivalent of medical acupuncture
12. The nurse is planning care for a group of patients who have requested the use of complementary health modalities. Which patient is not a good candidate for imagery?
    1. Pregnant patient
    2. Hypertensive patient
    3. Patient with posttraumatic stress disorder (PTSD)
    4. A pediatric patient
13. Several nurses on a busy unit are using relaxation strategies while at work. What is the desired workplace outcome from this intervention? (Select all that apply.)
    1. Improved health among the staff
    2. Increased patient safety
    3. Improved staff satisfaction
    4. Increased staff retention
    5. Fewer overtime assignments
14. The nurse is caring for a patient who uses several herbal preparations in addition to prescribed medications. What does the nurse need to understand about herbal preparations?
    1. They are regulated by the Food and Drug Administration (FDA); therefore patients and providers should feel confident that they are completely safe.
    2. They are natural products and therefore are safe as long as you use them cautiously and prudently for the conditions that are indicated.
    3. They are covered by insurance, including Medicare, Medicaid, and private payers.
    4. They should be treated as though they were "drugs" of sorts because many have active ingredients that can interact with other medications and change physiological responses.
15. The nurse manager of a community clinic arranges for staff in-services about various complementary therapies available in the community. What is the purpose of this training? (Select all that apply.)
    1. Nurses have a long history of providing some of these therapies and need to be knowledgeable about their positive outcomes.
    2. Nurses are often asked for recommendations and strategies that promote well-being and quality of life.
    3. Nurses play an essential role in patient education to provide information about the safe use of these healing strategies.
    4. Nurses appreciate the cultural aspects of care and recognize that many of these complementary strategies are part of a patient's life.
    5. Nurses play an essential role in the safe use of complementary therapies.
    6. Nurses learn how to provide all of the complementary modalities during their basic education.

CHAPTER

33

Self-Concept

OBJECTIVES

- Discuss factors that influence the components of self-concept.
- Identify stressors that affect self-concept and self-esteem.
- Describe the components of self-concept as related to psychosocial and cognitive developmental stages.
- Explore ways in which a nurse's self-concept and nursing actions affect a patient's self-concept and self-esteem.
- Discuss evidence-based practice applicable for identity confusion, disturbed body image, low self-esteem, and role conflict.
- Examine cultural considerations that affect self-concept.
- Apply the nursing process to promote a patient's self-concept.

KEY TERMS

Body image, p. 658
Identity, p. 660
Identity confusion, p. 662
Role ambiguity, p. 663
Role conflict, p. 663
Role overload, p. 663
Role performance, p. 661
Role strain, p. 663
Self-concept, p. 658
Self-esteem, p. 661
Sick role, p. 663

- Key Term Flashcards
- Content Updates

Self-concept is an individual's view of self. It is a subjective view and a complex mixture of unconscious and conscious thoughts, attitudes, and perceptions. Self-concept, or how a person *thinks* about oneself, directly affects self-esteem, or how one *feels* about oneself. Although these two terms are often used interchangeably, nurses need to differentiate the two so they correctly and completely assess patients and develop an individualized plan of care based on the patient's needs.

Nurses care for patients who face a variety of health problems that threaten their self-concept and self-esteem. The loss of bodily function, decline in activity tolerance, and difficulty in managing a chronic illness are examples of situations that change a patient's self-concept. As a nurse, you will help patients adjust to alterations in self-concept and support components of self-concept to promote successful coping and positive health outcomes.

SCIENTIFIC KNOWLEDGE BASE

The development and maintenance of self-concept and self-esteem begin at a young age and continue across the life span with a general tendency for boys to report higher self-esteem than girls. However, the exact amount of this gender difference and the way it varies across the life span remain unclear. Parents and other primary caregivers influence the development of a child's self-concept and self-esteem. In addition, individuals learn and internalize cultural influences on self-concept and self-esteem in childhood and adolescence (Guilamo-Ramos, 2009). There is a significant amount of emphasis on fostering a school-age child's self-concept. In general, young children tend to rate themselves higher than they rate other children, suggesting that their view of themselves is positively inflated. Adolescence is a particularly critical time when many variables, including school, family, and friends, affect self-concept and self-esteem (Martyn-Nemeth et al., 2009). The adolescent experience can adversely affect self-esteem, often more strongly for girls than for boys. For example, some adolescent girls are more sensitive about their appearance and how others view them. Thus it is important to assess changes in self-esteem among early, middle, and late adolescence because changes in self-concept occur over time (Fig. 33-1).

Job satisfaction and overall performance in adulthood are also linked to self-esteem. Sometimes when individuals lose a job, their sense of self diminishes, they lose motivation to be socially active, or they even become depressed. They lose their job identity, and this alters their self-perceptions. Establishing a stable sense of self that transcends relationships and situations is a developmental goal of adulthood.

Evidence suggests that sense of self is often negatively affected in older adulthood because of the intensity of emotional and physical changes associated with aging (Ebersole et al., 2008; Price, 2010). For example, when an older adult loses a partner or experiences a change in health, sometimes there is a change in social interaction or even self-care practices.

FIG. 33-1 Adolescents' participation in group activities can foster self-esteem. (From Hockenberry MJ, Wilson D: *Wong's essentials of pediatric nursing,* ed 8, St Louis, 2009, Mosby.)

Researchers also found ethnic and cultural differences in self-concept and self-esteem across the life span that impact health behaviors. In Latino youth, ethnic pride and self-esteem serve as protective factors against risk behaviors, including intentions to smoke cigarettes and to have sexual intercourse (Guilamo-Ramos, 2009). Cultural identity of older adults is one of the major elements of self-concept and a key aspect of self-esteem (Ebersole et al., 2008). Considering aging from a cultural perspective provides the context for providing the highest-quality nursing care. Sensitivity to factors that affect self-concept and self-esteem in diverse cultures is essential to ensure an individualized approach to health care.

How individuals view themselves and their perception of their health are closely related. Lower self-esteem is a risk factor that leaves one vulnerable to health problems, whereas higher self-esteem and strong social relationships support good health (Stinson et al., 2008). A patient's belief in personal health often enhances his or her self-concept. Statements such as "I can get through anything" or "I've never been sick a day in my life" indicate that a person's thoughts about personal health are positive. Illness, hospitalization, and surgery also affect self-concept. Chronic illness often affects the ability to provide financial support and maintain relationships, which then affects an individual's self-esteem and perceived roles within the family. Negative perceptions regarding health status are reflected in such statements as "It's not worth it anymore" or "I'm a burden to my family." Further, chronic illness affects identity and body image as reflected by verbalizations such as "I'll never get any better" or "I can't stand to look at myself anymore."

What individuals think and how they feel about themselves affect the way in which they care for themselves physically and emotionally and how they care for others. Further, a person's behaviors are generally consistent with both self-concept and self-esteem. Individuals who have a poor self-concept often do not feel in control of situations and worthy of care, which influences decisions regarding health care. Patients often have difficulty making even simple decisions, such as what to eat. Knowledge of variables that affect self-concept and self-esteem is critical to provide effective treatment.

BOX 33-1 SELF-CONCEPT: DEVELOPMENTAL TASKS

Trust versus Mistrust (Birth to 1 Year)
- Develops trust following consistency in caregiving and nurturing interactions
- Distinguishes self from environment

Autonomy versus Shame and Doubt (1 to 3 Years)
- Begins to communicate likes and dislikes
- Increasingly independent in thoughts and actions
- Appreciates body appearance and function (e.g., dressing, feeding, talking, and walking)

Initiative versus Guilt (3 to 6 Years)
- Identifies with a gender
- Enhances self-awareness
- Increases language skills, including identification of feelings

Industry versus Inferiority (6 to 12 Years)
- Incorporates feedback from peers and teachers
- Increases self-esteem with new skill mastery (e.g., reading, mathematics, sports, music)
- Aware of strengths and limitations

Identity versus Role Confusion (12 to 20 Years)
- Accepts body changes/maturation
- Examines attitudes, values, and beliefs; establishes goals for the future
- Feels positive about expanded sense of self

Intimacy versus Isolation (Mid-20s to Mid-40s)
- Has stable, positive feelings about self
- Experiences successful role transitions and increased responsibilities

Generativity versus Self-Absorption (Mid-40s to Mid-60s)
- Able to accept changes in appearance and physical endurance
- Reassesses life goals
- Shows contentment with aging

Ego Integrity versus Despair (Late 60s to Death)
- Feels positive about life and its meaning
- Interested in providing a legacy for the next generation

NURSING KNOWLEDGE BASE

In providing evidence-based practice to patients, incorporate professional nursing knowledge developed from the humanities, sciences, nursing research, and clinical practice. A broad knowledge base allows nurses to have a holistic view of patients, thus promoting quality patient care that best meets the self-concept needs of each patient and family. Understanding a patient's self-concept is a necessary part of all nursing care (Stuart, 2009).

Development of Self-Concept

The development of self-concept is a complex lifelong process that involves many factors. Erikson's psychosocial theory of development (1963) remains beneficial in understanding key tasks that individuals face at various stages of development. Each stage builds on the tasks of the previous stage. Successful mastery of each stage leads to a solid sense of self (Box 33-1).

Learn to recognize an individual's failure to achieve an age-appropriate developmental stage or his or her regression to an earlier stage in a period of crisis. This understanding allows you to individualize care and determine appropriate nursing interventions. Self-concept is always changing and is based on the following:

- Sense of competency
- Perceived reactions of others to one's body
- Ongoing perceptions and interpretations of the thoughts and feelings of others
- Personal and professional relationships
- Academic and employment-related identity
- Personality characteristics that affect self-expectations
- Perceptions of events that have an impact on the self
- Mastery of prior and new experiences
- Ethnic, cultural, racial, and spiritual identity

Self-esteem is usually highest in childhood, declines during adolescence, gradually rises throughout adulthood, and diminishes again in old age (Stuart, 2009). Although this pattern varies, in general it holds true across gender, socioeconomic status, and ethnicity. Children often report high self-esteem because their sense of self is inflated by a variety of extremely positive sources, and the subsequent decline is from time to time associated with a shift to more realistic information about the self.

Erikson's (1963) emphasis on the generativity stage (see Chapter 11) explains the rise in self-esteem and self-concept in adulthood. The individual focuses on being increasingly productive and creative at work, while at the same time promoting and guiding the next generation. Several individuals report a decline in self-esteem in later adulthood (Ebersole et al., 2008). Based on Erikson's stages of development, a decline in self-concept in later adulthood reflects a diminished need for self-promotion and a shift in self-concept to a more modest and balanced view of self. Identifying specific nursing interventions to address the unique needs of patients at various life stages is essential.

Components and Interrelated Terms of Self-Concept

A positive self-concept gives a sense of meaning, wholeness, and consistency to a person. A healthy self-concept has a high degree of stability, which generates positive feelings toward self. The components of self-concept are identity, body image, and role performance. Because how one thinks about oneself (self-concept) affects how one feels about oneself (self-esteem), both concepts need to be evaluated.

Identity. **Identity** involves the internal sense of individuality, wholeness, and consistency of a person over time and in different situations. It implies being distinct and separate from others. Being "oneself" or living an authentic life is the basis of true identity. Children learn culturally accepted values, behaviors, and roles through identification and modeling. They often gain an identity from self-observations and from what individuals tell them. An individual first identifies with parenting figures and later with other role models such as teachers or peers. To form an identity, the child must be able to bring together learned behaviors and expectations into a coherent, consistent, and unique whole (Erikson, 1963).

The achievement of identity is necessary for intimate relationships because individuals express identity in relationships with others (Stuart, 2009). Sexuality is a part of identity, and its focus differs across the life span. For example, as an adult ages, the focus shifts from procreation to companionship, physical and emotional intimacy, and pleasure-seeking (Ebersole et al., 2008). Gender identity is a person's private view of maleness or femaleness; gender role is the masculine or feminine behavior exhibited. This image and its meaning depend on culturally determined values (see Chapters 9 and 22).

BOX 33-2 CULTURAL ASPECTS OF CARE

Promoting Self-Concept and Self-Esteem in Culturally Diverse Patients

Racial and cultural identity is an important component of a person's self-concept and self-esteem. Early in growth and development an individual develops this identity within the context of family. As an individual grows, the cultural aspects of his or her self-concept are reinforced through social, family, or cultural experiences. In addition, a person's self-concept is strengthened or questioned through political, social, or cultural influences experienced in the home, school, and workplace environments. Positive or negative cultural role modeling, ethnic identity, and past experiences influence self-concept.

Implications for Practice

- Develop an open, nonrestrictive attitude for assessing and encouraging cultural practices to improve patients' self-concept.
- Understand that the relationship among self-esteem, stress, and social support can facilitate the development of nursing strategies to promote effective coping in ethnically diverse adolescents (Martyn-Nemeth et al., 2009).
- Ask patients what they think is important to help them feel better or gain a stronger sense of self.
- Encourage cultural identity and ethnic pride by individualizing self-care practices and offering treatment choices to meet patients' self-concept needs.
- Facilitate culturally sensitive health promotion activities that address at-risk behaviors identified through evidence-based practice (e.g., smoking, weight and shape issues, premature sexual experiences, excessive and violent video gaming (Guilamo-Ramos, 2009; Jackson et al., 2009).

Cultural differences in identity exist (Box 33-2). Racial or cultural identity develops from identification and socialization within an established group and through the experience of integrating the response of individuals outside the cultural or racial group into one's self-concept. Differences in ethnic identity (e.g., Mexican American or Cuban American) exist through identification with traditions, customs, and rituals within one's race/ethnic group (e.g., Hispanic/Latino). In general, the more a person identifies with social groups, the greater his or her self-esteem. In addition, when ethnic identity is central to self-concept and is positive, ethnic pride and self-esteem tend to be high (Guilamo-Ramos, 2009). An individual who experiences discrimination, prejudice, or environmental stressors such as low-income or high-crime neighborhoods often conceptualizes himself or herself differently than an individual who experiences better living conditions.

Body Image. **Body image** involves attitudes related to the body, including physical appearance, structure, or function. Feelings about body image include those related to sexuality, femininity and masculinity, youthfulness, health, and strength. These mental images are not always consistent with a person's actual physical structure or appearance. Some body image distortions have deep psychological origins, such as the eating disorder anorexia nervosa. Other alterations occur as a result of situational events, such as the loss or change in a body part. Be aware that most men and women experience some degree of dissatisfaction with their bodies, which affects body image and overall self-concept. Individuals often

FIG. 33-2 An individual's appearance influences self-concept. (From Sorrentino SA, Remmert LN: *Mosby's textbook for nursing assistants,* ed 8, St Louis, 2012, Mosby.)

exaggerate disturbances in body image when a change in health status occurs. The way others view a person's body and the feedback offered are also influential. For example, a controlling, violent husband tells his wife that she is ugly and that no one else would want her. Over the years of marriage she incorporates this devaluation into her self-concept.

Cognitive growth and physical development also affect body image. Normal developmental changes such as puberty and aging have a more apparent effect on body image than on other aspects of self-concept. Hormonal changes during adolescence and menopause influence body image. The development of secondary sex characteristics and the changes in body fat distribution have a tremendous impact on an adolescent's self-concept. Early maturation is associated with lower psychological well-being and lower enjoyment of physical activity, which in turn could negatively impact body image (Davison et al., 2007). For both male and female adolescents, negative body image is a risk factor for suicidal thoughts (Brausch and Muehlenkamp, 2007). A threat to body image and overall self-concept can affect adherence to recommended health regimens, including diet and taking medications as prescribed (Thomas, 2007). Changes associated with aging (e.g., wrinkles; graying hair; and decrease in visual acuity, hearing, and mobility) also affect body image in an older adult.

Cultural and societal attitudes and values influence body image. Culture and society dictate the accepted norms of body image and influence one's attitudes (Fig. 33-2). Racial and ethnic background plays an integral role in body satisfaction in adolescent girls and is reflected in differences in body satisfaction among groups. Further, body image is more favorable in cultures in which girls describe more reasonable views about physical appearance, report less social pressure for thinness, and have less tendency to base self-esteem on body image. Values such as ideal body weight and shape and attitudes toward piercing and tattoos are culturally based. American society emphasizes youth, beauty, and wholeness. Western cultures have been socialized to dread the normal aging process, whereas eastern cultures view aging very positively and respect older adults. Body image issues are often associated with impaired self-concept and self-esteem.

Role Performance. **Role performance** is the way in which individuals perceive their ability to carry out significant roles (e.g., parent, supervisor, or close friend). Normal changes associated with maturation result in changes in role performance. For example, when a man has a child, he becomes a father. The new role of father involves many changes in behavior if the man is going to be successful. Group interventions aimed at improving fathering experiences have led to significant improvements in the father's participation in the family, including role performance, involvement, communication, self-esteem, a sense of increased competence, and decreased stress in parenting (Gearing et al., 2008). Roles that individuals follow in given situations involve socialization, expectations, or standards of behavior. The patterns are stable and change only minimally during adulthood.

Ideal societal role behaviors are often hard to achieve in real life. Individuals have multiple roles and personal needs that sometimes conflict. Successful adults learn to distinguish between ideal role expectations and realistic possibilities. To function effectively in multiple roles, a person must know the expected behavior and values, desire to conform to them, and be able to meet the role requirements. Fulfillment of role expectations leads to an enhanced sense of self. Difficulty or failure in meeting role expectations leads to deficits and often contributes to decreased self-esteem or altered self-concept.

Self-Esteem. **Self-esteem** is an individual's overall feeling of self-worth or the emotional appraisal of self-concept. It is the most fundamental self-evaluation because it represents the overall judgment of personal worth or value. Self-esteem is positive when one feels capable, worthwhile, and competent (Rosenberg, 1965). A person's self-esteem is related to his or her evaluation of his or her effectiveness at school, within the family, and in social settings. The evaluation of others also is likely to have a profound influence on a person's self-esteem. For example, college athletes report greater levels of self-esteem and social connectedness and lower levels of depression than nonathletes. The positive influence of team support can protect college athletes from disturbances of self-esteem and depression symptoms (Armstrong and Oomen-Early, 2009).

Considering the relationship between a person's actual self-concept and his or her ideal self enhances understanding of that person's self-esteem. The ideal self consists of the aspirations, goals, values, and standards of behavior that a person considers ideal and strives to attain. In general, a person whose self-concept comes close to matching the ideal self has high self-esteem, whereas a person whose self-concept varies widely from the ideal self suffers from low self-esteem (Stuart, 2009). Once established, basic feelings about the self tend to be constant, even though a situational crisis can temporarily affect self-esteem.

Factors Influencing Self-Concept

A self-concept stressor is any real or perceived change that threatens identity, body image, or role performance (Fig. 33-3). An individual's perception of the stressor is the most important factor in determining his or her response. The ability to reestablish balance following a stressor is related to numerous factors, including the number of stressors, duration of the stressor, and health status (see Chapter 37). Stressors challenge a person's adaptive capacities. Changes that occur in physical, spiritual, emotional, sexual, familial, and sociocultural health affect self-concept. Being able to adapt to stressors is likely to lead to a positive sense of self, whereas failure to adapt often leads to a negative self-concept.

Any change in health is a stressor that potentially affects self-concept. A physical change in the body sometimes leads to an altered body image, affecting identity and self-esteem. Chronic illnesses often alter role performance, which change an individual's identity and self-esteem. Further, an essential process in the adjustment to loss is the development of a new self-concept. A loss of a partner can lead to a loss of identity and a lower self-esteem. Unlike

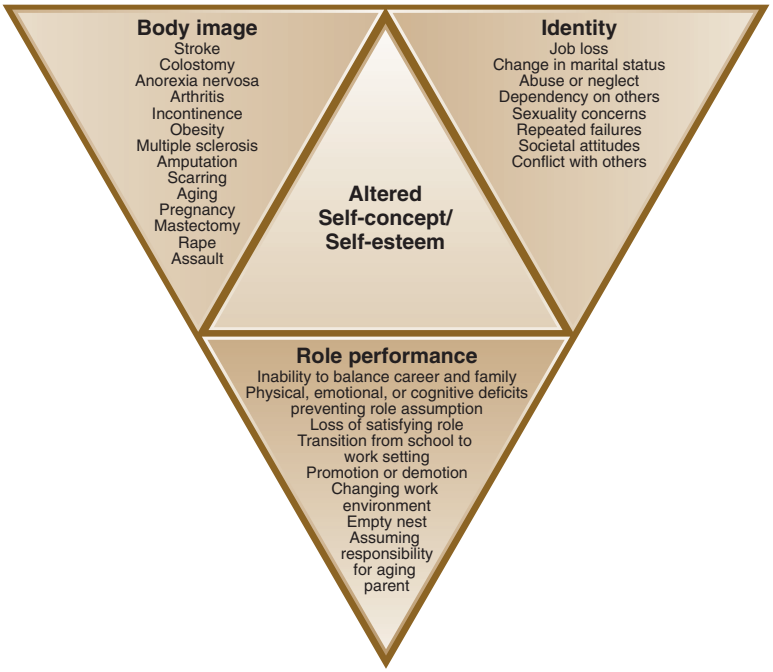

FIG. 33-3 Common stressors that influence self-concept.

the loss in self-esteem shown in vulnerable older adults, the resiliency demonstrated in some older adults may reflect more sophisticated cognitive strategies to manage losses.

The stressors created as a result of a crisis also affect a person's health. If the resulting identity confusion, disturbed body image, low self-esteem, or role conflict is not relieved, illness can result. For example, the diagnosis of cancer places additional demands on a person's established living pattern. It changes his or her appraisal of and satisfaction with the current level of physical, emotional, and social functioning. In this case assess self-esteem, effectiveness of coping strategies, and social support. During self-concept crises, supportive and educative resources are valuable in helping a person learn new ways of coping with and responding to the stressful event or situation to maintain or enhance self-concept.

Identity Stressors. Stressors affect an individual's identity throughout life, but individuals are particularly vulnerable during adolescence. Adolescents are trying to adjust to the physical, emotional, and mental changes of increasing maturity, which results in insecurity and anxiety. It is also a time when the adolescent is developing psychosocial competence, including coping strategies (see Chapter 37).

An adult generally has a more stable identity and thus a more firmly developed self-concept than an adolescent. Cultural and social stressors rather than personal stressors have more impact on an adult's identity. For example, an adult has to balance career and family or make choices regarding honoring religious traditions from one's family of origin. **Identity confusion** results when people do not maintain a clear, consistent, and continuous consciousness of personal identity. It occurs at any stage of life if a person is unable to adapt to identity stressors.

Body Image Stressors. A change in the appearance, structure, or function of a body part requires an adjustment in body image. An individual's perception of the change and the relative importance placed on body image affects the significance of a loss of function or change in appearance. For example, if a woman's body image incorporates reproductive organs as the ideal, a hysterectomy needed because of a diagnosis of uterine cancer is a significant alteration and can result in a perceived loss of femininity or wholeness. Changes in the appearance of the body such as an amputation, facial disfigurement, or scars from burns are obvious stressors affecting body image. Mastectomy and colostomy are surgical procedures that alter the appearance and function of the body, yet the changes are not apparent to others when the individual is dressed. Although potentially undetected by others, these bodily changes significantly impact the individual. Even some elective changes such as breast augmentation or reduction affect body image. Chronic illnesses such as heart and renal disease affect body image because the body no longer functions at an optimal level. The patient has to adjust to a decrease in activity tolerance that impacts his or her ability to perform normal activities of daily living. In addition, pregnancy, significant weight gain or loss, pharmacological management of illness, or radiation therapy changes body image. Negative body image often leads to adverse health outcomes.

The response of society to physical changes in an individual often depends on the conditions surrounding the alteration. Some social changes have allowed the public to respond more favorably to illness and altered body image. For example, the media frequently presents positive stories about persons adjusting in a healthy manner following serious disabilities (e.g., Christopher Reeve's spinal cord injury) or adapting to a debilitating illness (e.g., Michael J. Fox's Parkinson's disease). These stories change public awareness and the perception of what constitutes a disability and provide positive role models for individuals undergoing self-concept stressors and their families, friends, and society as a whole. In view of the growing epidemic of obesity in western cultures, parents and health care providers need to address weight management issues without causing further injury to body image. Providing a social environment that focuses on health and fitness rather than a drive for thinness for girls or muscularity for boys can

potentially increase adolescent satisfaction with their bodies (Brunet et al., 2010).

Role Performance Stressors. Throughout life a person undergoes numerous role changes. Situational transitions occur when parents, spouses, children, or close friends die or people move, marry, divorce, or change jobs. It is important to recognize that a shift along the continuum from illness to wellness is as stressful as a shift from wellness to illness. Any of these transitions may lead to role conflict, role ambiguity, role strain, or role overload.

Role conflict results when a person has to simultaneously assume two or more roles that are inconsistent, contradictory, or mutually exclusive. For example, when a middle-age woman with teenage children assumes responsibility for the care of her older parents, conflicts occur in relation to being both a parent to her children and the child of her parents. Negotiating a balance of time and energy between her children and parents creates role conflicts. The perceived importance of each conflicting role influences the degree of conflict experienced. The **sick role** involves the expectations of others and society regarding how an individual behaves when sick. Role conflict occurs when general societal expectations (take care of yourself, and you will get better) and the expectations of co-workers (need to get the job done) collide. The conflict of taking care of oneself while getting everything done is often a major challenge.

Role ambiguity involves unclear role expectations, which makes people unsure about what to do or how to do it, creating stress and confusion. Role ambiguity is common in the adolescent years. Parents, peers, and the media pressure adolescents to assume adultlike roles, yet many lack the resources to move beyond the role of a dependent child. Role ambiguity is also common in employment situations. In complex, rapidly changing, or highly specialized organizations, employees often become unsure about job expectations.

Role strain combines role conflict and role ambiguity. Some express role strain as a feeling of frustration when a person feels inadequate or unsuited to a role such as providing care for a family member with Alzheimer's disease.

Role overload involves having more roles or responsibilities within a role than are manageable. This is common in an individual who unsuccessfully attempts to meet the demands of work and family while carving out some personal time. Often during periods of illness or change, those involved either as the one who is ill or as a significant other find themselves in role overload.

Self-Esteem Stressors. Individuals with high self-esteem are generally more resilient and better able to cope with demands and stressors than those with low self-esteem. Low self-worth contributes to feeling unfulfilled and disconnected from others. Decreased self-worth can potentially result in depression and unremitting uneasiness or anxiety. Illness, surgery, or accidents that change life patterns also influence feelings of self-worth. Chronic illnesses such as diabetes, arthritis, and cardiac dysfunction require changes in accepted and long-assumed behavioral patterns. The more the chronic illness interferes with the ability to engage in activities contributing to feelings of worth or success, the more it affects self-esteem.

Self-esteem stressors vary with developmental stages. Perceived inability to meet parental expectations, harsh criticism, inconsistent discipline, and unresolved sibling rivalry reduce the level of self-worth of children. A developmental milestone such as pregnancy introduces unique self-concept stressors and has significant health care implications. For some economically disadvantaged youth, safe sex behaviors are not always valued, and pregnancy is an affirmation of ethnic identity. Low self-esteem during adolescence also has significant real-world consequences in adulthood, including poor health, criminal behavior, and limited economic prospects compared to adolescents with high self-esteem. Self-esteem and health behaviors are intertwined. Stressors affecting the self-esteem of an adult include failure in work and unsuccessful relationships. Self-concept stressors in older adults include health problems, declining socioeconomic status, spousal loss or bereavement, loss of social support, and decline in achievement experiences following retirement (Box 33-3).

BOX 33-3 FOCUS ON OLDER ADULTS

Enhancing Self-Concept in Older Adults

Self-concept is sometimes negatively affected in older adulthood because of a number of life changes. However, in some individuals, aging promotes improved coping strategies that protect against the declining feelings of self-esteem, despite the physical and emotional changes associated with aging (Ebersole et al., 2008). Gender differences in the last decades of life exist as men become more negative about appearance and function of their bodies than do women (Kaminski and Hayslip, 2006). Nursing interventions aimed at enhancing self-concept and self-esteem in older adults is essential, particularly during illness, injury, or disability.

Implications for Practice

- Clarify what the life changes mean and the effect on self-concept. Discuss health problems, declining socioeconomic status, spousal loss or bereavement, and loss of social support following retirement.
- Conduct supportive conversations to understand challenges to the patient's perceptions of body image adjustments as part of aging and changes associated with illness, injury, or disability (Price, 2010).
- Be alert to preoccupation with physical complaints. Assess complaints thoroughly and, if no physical explanation exists, encourage older adult to verbalize needs (fear, insecurity, loneliness) in a nonphysical way (Stuart, 2009).
- Identify positive and negative coping mechanisms. Support effective strategies.
- Encourage the use of storytelling and review of old photographs.
- Communicate that the older adult is worthwhile by actively listening to and accepting the person's feelings, being respectful, and praising healthy behaviors.
- Allow additional time to complete tasks. Reinforce the older adult's efforts at independence (Ebersole et al., 2008).

Building Competency in Safety You are caring for Paul Taylor, a 69-year-old man, who suffered a debilitating stroke. The stroke was unexpected and sudden. Mr. Taylor did not know that he had hypertension because he had not been getting annual checkups. His body image has dramatically changed from that of a man of strength to that of a helpless individual. Mr. Taylor worries about being a burden to his family. He and his wife, Meredith, are terrified. His self-concept has changed from that of a strong laborer, one who did his own plumbing and car repairs, to a man who must completely rely on others. Mr. Taylor's identity is not clear to him anymore. He has no clear role within the family, his body image has been drastically altered, his sexual health has suffered, and his self-esteem has never been lower. He says, "My family would be better off if I were dead." What is your priority nursing intervention to ensure Mr. Taylor's safety?

Answers to questions can be found on the Evolve website.

Family Effect on Self-Concept Development

The family plays a key role in creating and maintaining the self-concepts of its members. Children develop a basic sense of who they are from their family caregivers. A child also gains accepted norms for thinking, feeling, and behaving from family members. Sometimes well-meaning parents cultivate negative self-concepts in children. Some literature suggests that parents are the most important influences on a child's development, yet variations in parenting approach depend on the culture. Specifically a child's positive self-esteem and school achievement are fostered by parents who respond in a firm, consistent, and warm manner. High parental support and parental monitoring are related to greater self-esteem and lower risk behaviors. For example, in Mexican American adolescents perceived parental educational involvement combined with their perceived acculturation and self-esteem significantly affect their aspirations and achievement (Carranza et al., 2009). Parents who are harsh, inconsistent, or have low self-esteem themselves often behave in ways that foster negative self-concepts in their children. Positive communication and social support foster self-esteem and well-being in adolescence. To reverse a patient's negative self-concept, first assess the family's style of relating (see Chapter 10). Family and cultural factors sometimes influence negative health practices such as cigarette smoking (Box 33-4). Self-concept change demands an evidence-based practice approach supported by the entire health care team.

Nurse's Effect on Patient's Self-Concept

A nurse's acceptance of a patient with an altered self-concept promotes positive change. Often this simply involves sitting with a patient and forming a therapeutic relationship. When a patient's physical appearance has changed, it is likely that both the patient and the family look to nurses and observe their verbal and nonverbal responses and reactions to the changed appearance. You need to remain aware of your own feelings, ideas, values, expectations, and judgments. Self-awareness is critical in understanding and accepting others. Nurses need to assess and clarify the following self-concept issues about themselves:

- Thoughts and feelings about lifestyle, health, and illness
- Awareness of how their own nonverbal communication affects patients and families
- Personal values and expectations and how these affect patients
- Ability to convey a nonjudgmental attitude toward patients
- Preconceived attitudes toward cultural differences in self-concept and self-esteem

Some patients with a change in body appearance or function are extremely sensitive to the verbal and nonverbal responses of the health care team. A positive, matter-of-fact approach to care provides a model for the patient and family to follow. For example, when you observe a positive change in a patient's behavior, note it and allow the patient to establish its meaning. Nurses have a significant effect on patients by conveying genuine interest and acceptance. Including self-concept issues in the planning and delivery of care can positively influence patient outcomes. Building a trusting nurse-patient relationship that incorporates both the patient and family in the decision-making process enhances self-concept. Nurses individualize their approach by highlighting a patient's unique needs and incorporating alternative health care practices or methods of spiritual expression into the plan of care. It is important that health care providers understand the degree to which self-esteem and sexuality affect patient outcomes (Figueroa-Hass, 2007).

BOX 33-4 EVIDENCE-BASED PRACTICE

Self-Concept and the Impact of Body Image, Self-Esteem, and Stress on Adolescent Smoking Behaviors

PICO Question: How does self-concept influence smoking behaviors in adolescents?

Evidence Summary

The prevalence of tobacco use in the United States is highest between ages 18 and 24 (24%), with college students representing the highest portion of smokers (CDC, 2006). In 2009, 19% of high school students reported current cigarette use, while 9% of high school students reported current smokeless tobacco use (CDC, 2010). The prevalence of current cigarette use was higher among ninth-grade female than same-grade male students and higher among 12th-grade male than same-grade female students. Overall the prevalence of current cigarette use in both males and females was higher among white, followed by Hispanic, and then black students. Previous studies have shown that weight concerns, especially in women, motivate users to continue smoking and predict smoking relapse. Smokers were more likely to perceive higher amounts of stress and lower self-esteem (Croghan et al., 2006; Nelson and Gordon-Larsen, 2006). The majority of smokers, regardless of gender, consider tobacco use to be an important stress-management practice. Identifying risk and protective factors is important for smoking prevention programs (Greene and Banerjee, 2008). Enhancing opportunities to learn communication skills and engage in alternative behaviors, including physical activity, may reduce smoking as an adolescent risk behavior (Croghan et al., 2006; Nelson and Gordon-Larsen, 2006).

Application to Nursing Practice

- Smoking cessation efforts should include stress management and self-esteem and body image improvement (Croghan et al., 2006).
- A priority nursing action is the assessment of child and adolescent coping strategies. Appropriate techniques include effective communication, conflict resolution, and stress.
- Families, peers, teachers, and health care providers should instill students' ethnic pride, which promotes self-concept and the use of protective factors against risk behaviors, such as smoking (Guilamo-Ramos, 2009).
- Body-weight concerns and family, social environment, and behavioral factors are important issues to address during preadolescence and adolescence.
- Implement effective, healthy, and realistic weight management methods for adolescents. Techniques include promoting fun, family-oriented activities such as television viewing and gaming and eliminating dieting (Nelson and Gordon-Larsen, 2006).
- Identifying risk factors for early drug and alcohol use, including genetic predisposition, family environment, ethnic identity, and sedentary behaviors needs to be a priority for health care providers (Croghan et al., 2006; Guilamo-Ramos, 2009).

Your nursing care significantly affects a patient's body image. For example, the body image of a woman following a mastectomy is positively influenced by a nurse showing acceptance of the mastectomy scar. On the other hand, a nurse who has a shocked or disgusted facial expression contributes to the woman developing a negative body image. Patients closely watch the reactions of others to their wounds and scars, and it is very important to be aware of your responses toward the patient. Statements such as "This wound is healing nicely" or "This tissue looks healthy" are affirmations for the body image of the patient. Nonverbal behaviors convey the level of caring that exists for a patient and affect self-esteem. Anticipate personal reactions, acknowledge them, and focus on the patient

instead of the unpleasant task or situation. Nurses who put themselves in the patient's situation incorporate measures to ease embarrassment, frustration, anger, and denial.

Preventive measures, early identification, and appropriate treatment minimize the intensity of self-esteem stressors and the potential effects for a patient and his or her family. Learn to design specific self-concept interventions to fit a patient's profile of risk factors. It is essential to assess a patient's perception of a problem and work collaboratively to resolve self-concept issues. For example, incorporating self-esteem activities into regular school health and physical education curriculum can result in a positive change in students' physical self-esteem and family self-esteem (Lai et al., 2009). Interventions designed to promote active living and healthy eating may be beneficial for preventing childhood obesity, improving self-esteem, preventing chronic diseases, and improving mental health in adulthood (Wang et al., 2009).

Building Competency in Patient-Centered Care You are a third-year nursing student who feels insecure in the clinical setting. You hope that your clinical instructor won't ask you questions about your patient because you "forget" everything when your assigned faculty approaches; you feel embarrassed that you sometimes "hide" or "look busy" to avoid interacting with your instructor. You wonder, "How can I attend to my patient's self-concept and self-esteem issues when I can't even deal with my own?" What actions must you take to improve your self-esteem and self-concept as a student nurse?

Answers to questions can be found on the Evolve website.

CRITICAL THINKING

Successful critical thinking requires synthesis of knowledge, experience, information gathered from patients and families, critical thinking attitudes, and ethical and professional standards. Solid clinical judgment requires anticipating and securing the necessary information, analyzing the data, and making appropriate decisions regarding patient care.

In the case of self-concept, it is essential to integrate knowledge from nursing and other disciplines, including self-concept theory, communication principles, and a consideration of cultural and developmental factors. Previous experience in caring for patients with self-concept alterations helps to individualize care. Self-concept profoundly influences a person's response to illness. A critical thinking approach to care is essential.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. The nursing process is continuous until the patient's self-concept is improved, restored, or maintained.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. In assessing self-concept and self-esteem, first focus on each component of self-concept (identity, body image, and role performance). Assessment needs to include looking for the range of behaviors suggestive of an altered self-concept or self-esteem (Box 33-5), actual and potential self-concept stressors (see Fig. 33-3), and coping patterns. Gathering comprehensive assessment data requires the critical synthesis of information from multiple sources (Fig. 33-4). In addition to direct questioning (Box 33-6), nurses gather much of the data regarding self-concept through observation of the patient's nonverbal behavior and by paying attention to the content of the patient's conversations. Take note of the manner in which patients talk about the people in their lives because this provides clues to both stressful and supportive relationships and key roles the patient assumes. Using knowledge of developmental stages to determine which areas are likely to be important to the patient, inquire about these aspects of the person's life. For example, ask a 70-year-old patient about his life and what has been important to him. The individual's conversation likely provides data relating to role performance, identity, self-esteem, stressors, and coping patterns.

Through the Patient's Eyes. An important factor in assessing self-concept is the person's viewpoint of his or her health condition and its influence on self-concept. Give patients the opportunity to tell their stories of how they perceive their illness or condition affecting their identity, their image of themselves, and their ability to lead a normal lifestyle. Also assess patients' expectations of health care by asking them how interventions will make a difference. This is also an opportunity to discuss the patient's goals. For example, a nurse working with a patient who is experiencing anxiety related to an upcoming diagnostic study asks the patient

BOX 33-5 BEHAVIORS SUGGESTIVE OF ALTERED SELF-CONCEPT

- Avoidance of eye contact
- Slumped posture
- Unkempt appearance
- Overly apologetic
- Hesitant speech
- Overly critical or angry
- Frequent or inappropriate crying
- Negative self-evaluation
- Excessively dependent
- Hesitant to express views or opinions
- Lack of interest in what is happening
- Passive attitude
- Difficulty in making decisions

BOX 33-6 NURSING ASSESSMENT QUESTIONS

Nature of the Problem

- How would you describe yourself?
- What aspects of your appearance do you like?
- Tell me about the things you do that make you feel good about yourself.
- Tell me about your primary roles. How effective are you at carrying out each of these roles?

Onset and Duration

- When did you start to think or feel differently about yourself?
- How long have you struggled with _____ (specify identity, body image, role performance, or self-esteem)?
- Can you remember a time when you felt good about yourself?

Effect on Patient

- Tell me how your self-concept affects your ability to take care of yourself.
- What impact does your self-esteem have on relationships?
- How does your self-esteem affect other areas of your life?

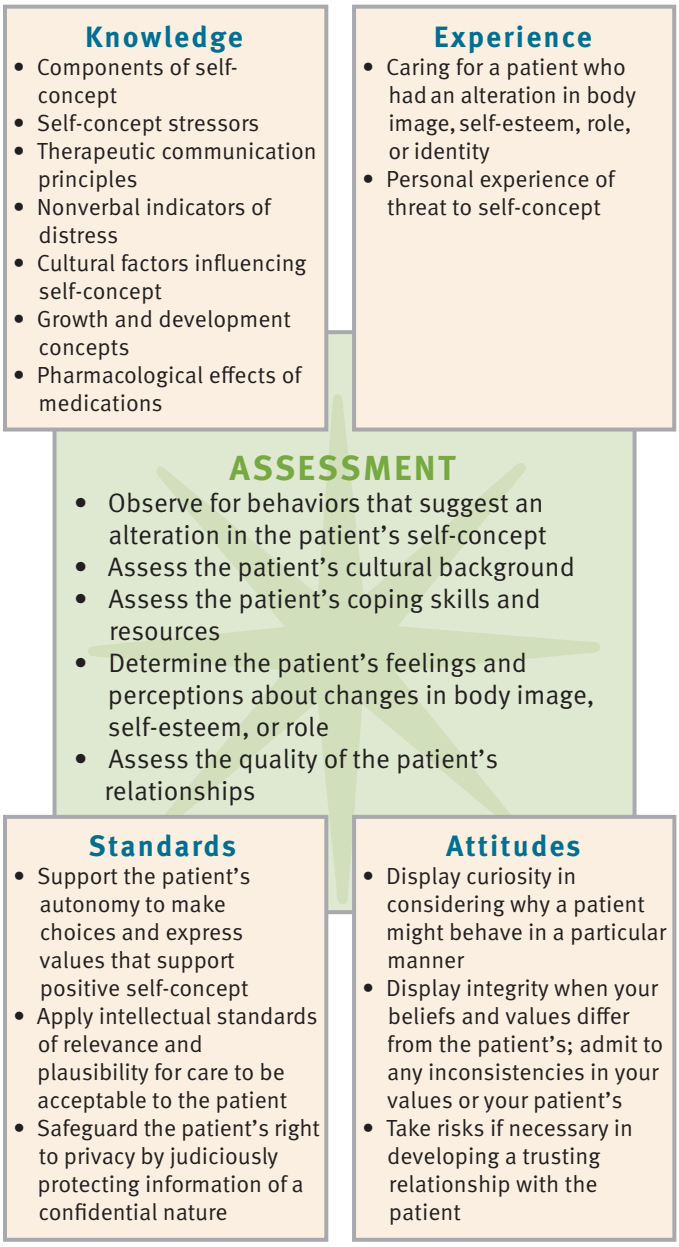

FIG. 33-4 Critical thinking model for self-concept assessment.

about his expectations of the relaxation exercise that they have been practicing together. The patient's response gives the nurse valuable information about the patient's beliefs and attitudes regarding the efficacy of the interventions and the potential need to modify the nursing approach.

Coping Behaviors. The nursing assessment also includes consideration of previous coping behaviors; the nature, number, and intensity of the stressors; and the patient's internal and external resources. Knowledge of how a patient has dealt with stressors in the past provides insight into his or her style of coping. Patients do not address all issues in the same way, but they often use a familiar coping pattern for newly encountered stressors. Identify previous coping strategies to determine whether these patterns have contributed to healthy functioning or created more problems. For example, the use of drugs or alcohol during times of stress often creates additional stressors (see Chapter 37).

BOX 33-7 NURSING DIAGNOSTIC PROCESS

Situational Low Self-Esteem

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Ask patient to explain thoughts and feelings about self.	Patient is tearful and reports negative thoughts about self. She reports not wanting to have any visitors.
Observe patient's behavior and ask family if she is experiencing emotional or behavior changes.	Spouse describes withdrawal and avoidance of intimacy. Spouse states that wife is unable to make decisions.
Determine if patient has had issues with self-esteem in the past and her plans to improve her self-esteem.	Patient denies any self-esteem issues since adolescence. She describes a willingness to bring her husband to a counselor to discuss ways that he can support her return to high self-esteem.

Significant Others. Exploring resources and strengths such as availability of significant others or prior use of community resources is important in formulating a realistic and effective plan of care. Valuable information comes from conversations with family and significant others. Significant others sometimes have insights into the person's way of dealing with stressors. They also have knowledge about what is important to the person's self-concept. The way in which a significant other talks about the patient and the significant other's nonverbal behaviors provide information about what kind of support is available for the patient.

NURSING DIAGNOSIS

Carefully consider the assessment data to identify a patient's actual or potential problem areas. Rely on knowledge and experience, apply appropriate professional standards, and look for clusters of defining characteristics that indicate a nursing diagnosis. Although there are four nursing diagnostic labels for altered self-concept, the following list (NANDA International, 2009) also provides examples of self-concept–related nursing diagnoses:

- Disturbed body image
- Caregiver role strain
- Disturbed personal identity
- Ineffective role performance
- Readiness for enhanced self-concept
- Chronic low self-esteem
- Situational low self-esteem
- Risk for situational low self-esteem

Making nursing diagnoses about self-concept is complex. Often isolated data are defining characteristics for more than one nursing diagnosis (Box 33-7). For example, a patient expresses feelings of uncertainty and inadequacy. These are defining characteristics for both *anxiety* and *situational low self-esteem.* Realizing that the patient is demonstrating defining characteristics of more than one nursing diagnosis guides you to gather specific data to validate and differentiate the underlying problem. To further assess the possibility of *anxiety* as the nursing diagnosis, consider whether the person has any of the following defining characteristics: Is the person experiencing increased muscle tension, shakiness, a sense of being "rattled," or restlessness? These symptoms suggest *anxiety* as the more appropriate diagnosis. On the other hand, if the person

expresses a predominantly negative self-appraisal, including inability to handle situations or events and difficulty making decisions, these characteristics suggest that *situational low self-esteem* is more appropriate. To further aid in differentiating between the two demonstrated diagnoses, information regarding recent events in the person's life and how the person has viewed himself or herself in the past provide insight into the most appropriate nursing diagnosis. As you gather additional data, usually the priority nursing diagnosis becomes evident.

To validate critical thinking regarding a nursing diagnosis, share observations with the patient and allow him or her to verify perceptions. This approach often results in the patient providing additional data, which further clarifies the situation. For example, "I noticed that you jumped when I touched your arm. Are you feeling uneasy today?" allows the patient to verify whether he or she is in fact anxious and describe his or her concerns.

PLANNING

During planning synthesize knowledge, experience, critical thinking attitudes, and standards (Fig. 33-5). Critical thinking ensures that a patient's plan of care integrates information known about the individual and key critical thinking elements (see the Nursing Care Plan). Professional standards are especially important to consider when developing a plan of care. These standards often establish ethical or evidence-based practice guidelines for selecting effective nursing interventions.

Another method to assist in planning care is a concept map. An example of an illustrative concept map (Fig. 33-6) shows the relationship of a primary health problem (postoperative bilateral radical mastectomy) and four nursing diagnoses and several interventions. The concept map shows how the nursing diagnoses are interrelated. It also assists in showing the interrelationships among nursing interventions. A single nursing intervention can be effective for more than one diagnosis.

Goals and Outcomes. Develop an individualized plan of care for each nursing diagnosis. Work collaboratively with the patient to set realistic expectations for care. Make sure that goals are individualized and realistic with measurable outcomes. In establishing goals, consult with the patient about whether they are achievable. Consultation with significant others, mental health clinicians, and community resources results in a more comprehensive and workable plan. When you set goals, consider the data necessary to demonstrate that the patient's problem would change if the nursing diagnosis were managed. The outcome criteria should reflect these changes. For example, a patient is diagnosed with *situational low self-esteem related to a recent job layoff.* Establish a goal: "Patient's self-esteem and self-concept will improve in 1 week." Examples of expected outcomes directed toward that goal include the following:

- The patient will discuss a minimum of three areas of her life where she is functioning well.
- The patient will be able to voice the recognition that losing her job is not reflective of her worth as a person.
- The patient will attend a support group for out-of-work professionals.

Setting Priorities. The care plan presents the goals, expected outcomes, and interventions for a patient with an alteration in self-concept. Interventions help the patient adapt to the stressors that led to the self-concept disturbance and support and reinforce the development of coping methods. Often a patient perceives a situation as overwhelming and feels hopeless about returning to the level of previous functioning. The patient often needs time to adapt to physical changes but can work toward progressive improvement in self-concept and self-esteem.

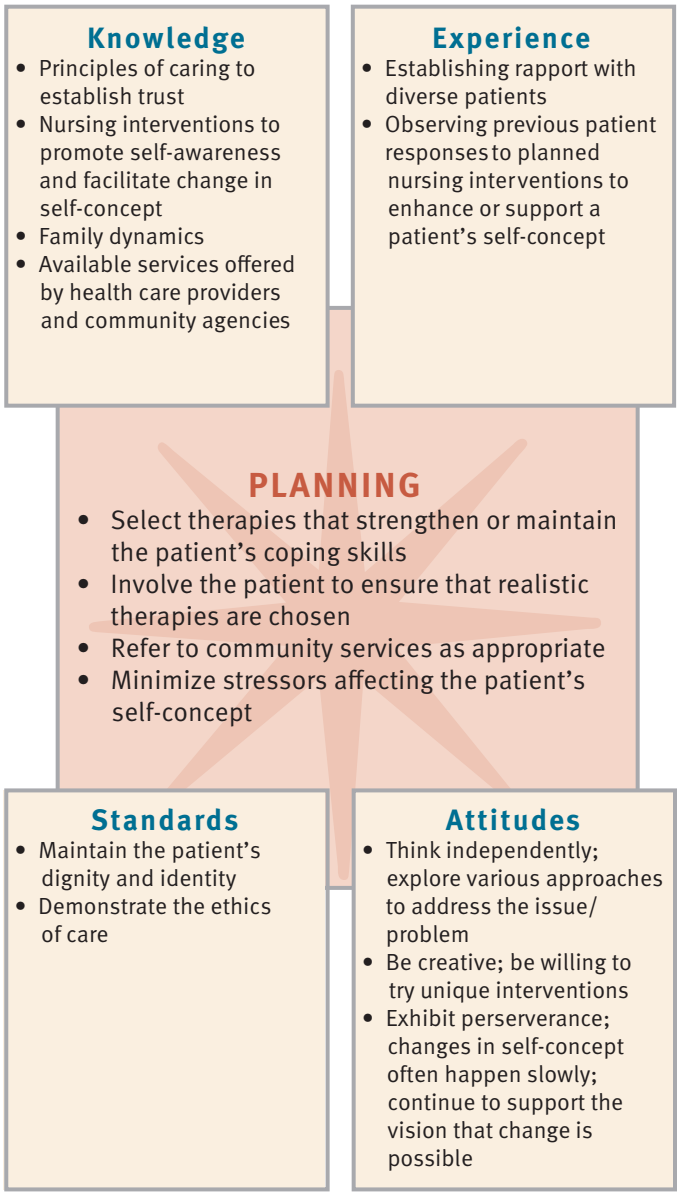

FIG. 33-5 Critical thinking model for self-concept planning.

Establishing priorities includes using therapeutic communication to address self-concept issues, which ensures that the patient's ability to address physical needs is maximized. Look for strengths in both the individual and the family and provide resources and education to turn limitations into strengths. Patient teaching creates understanding of the normalcy of certain situations (e.g., nature of a chronic disease, change in relationships, or effect of a loss). Often, once patients understand their situations, their sense of hopelessness and helplessness is lessened.

Teamwork and Collaboration. A patient's perceptions of significant others are important to incorporate into the plan of care. Individuals who have experienced deficits in self-concept before the current episode of treatment have often established a system of support that includes mental health clinicians, clergy, and other community resources. Before including family members,

NURSING CARE PLAN

Situational Low Self-Esteem

ASSESSMENT

Mrs. Johnson, a 45-year-old married woman who had a bilateral radical mastectomy resulting from malignant breast cancer, has been assigned to Susan Carr, nursing student. Susan completed Mrs. Johnson's physical assessment. She has been adequately medicated for pain. Ms. Carr sits down to discuss how the mastectomy has affected Mrs. Johnson's self-concept and self-esteem.

Assessment Activities	*Findings/Defining Characteristics**
Assess identity concerns (e.g., sexual role, femininity). Ask how the loss of breasts has affected her sense of self.	Mrs. Johnson **looks away, shakes her head,** and states, "**I feel like less of a woman.** My husband says I'm still attractive, but I don't believe him."
Observe Mrs. Johnson's mood and affect and her nonverbal communication and interactions with others.	Mrs. Johnson demonstrates **intermittent eye contact, frequent crying when alone, pulling hospital gown tightly across chest,** and **superficial conversations** with family members.
Assess Mrs. Johnson's involvement in self-care activities.	Mrs. Johnson is **unable to decide when to bathe, comb hair, or apply typical makeup.** Avoids looking in a mirror.
Offer opportunities to participate in treatment and provide supportive-educative nursing care.	**Mrs. Johnson avoids** looking at or touching her chest and **does not ask questions** about her condition.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Situational low self-esteem related to negative view of self

PLANNING

Goals	*Expected Outcomes (NOC)*†
Mrs. Johnson's perceived self-concept will improve in 1 week	**Self-Esteem** Mrs. Johnson will verbalize feelings of self-acceptance and self-worth within 4 days.
Mrs. Johnson will regain sense of her ability to achieve role performance before discharge.	Mrs. Johnson will demonstrate maintenance of basic grooming and hygiene needs within 2 days. **Role Performance** Mrs. Johnson will describe role changes associated with mastectomy and will verbalize commitment to accessing community resources by day of discharge. **Body Image** Mrs. Johnson will demonstrate adjustment to changes in body appearance within 1 week.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Self-Esteem Enhancement	
Use communication techniques to facilitate an environment and activities that will increase self-esteem.	A therapeutic nurse-patient relationship promotes positive patient outcome, including the patient's assuming responsibility for her own care (Stuart, 2009).
Monitor Mrs. Johnson's statements of self-worth.	Self-esteem and body image are strong predictors of depression (MacPhee and Andrews, 2006). The nurse must assess thoughts and feelings, including depression and risk for suicide, to ensure the patient's safety and make appropriate referrals (Folse and Hahn, 2009).
Encourage increased responsibility for self and assist patient with accepting dependence on others, as appropriate.	Promoting self-care enhances self-concept, including improving role performance (Stuart, 2009).
Role Enhancement	
Assist Mrs. Johnson with identifying specific role changes brought on by mastectomy.	Only after the problem is accurately defined can alternative choices be proposed (Stuart, 2009).
Body Image Enhancement	A threat to body image and overall self-concept often influences adherence to recommended health regimens (Thomas, 2007).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

NURSING CARE PLAN

***Situational Low Self-Esteem*—cont'd**

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Mrs. Johnson how effective she feels in her ability to identify and express feelings verbally and nonverbally.	Mrs. Johnson reports, "I've been able to talk with my husband, even about my concerns that he won't find me attractive anymore."	Improved verbal and nonverbal communication noted
Monitor changes in Mrs. Johnson's statements about herself.	Mrs. Johnson is making fewer negative comments and is evaluating body image more realistically but remains dissatisfied with appearance.	Small improvement in self-esteem; body image more realistic, but remains negative Discusses body image with husband and nursing student
Observe Mrs. Johnson's participation in self-care related to mastectomy.	Mrs. Johnson is more assertive in completing basic hygiene; has used a mirror to examine mastectomy scar.	Meeting self-care needs
Ask Mrs. Johnson to identify resources outside the hospital.	Mrs. Johnson has expressed interest in attending local breast cancer survivors' support group.	Scheduled to attend mastectomy support group 2 days after scheduled discharge

CONCEPT MAP

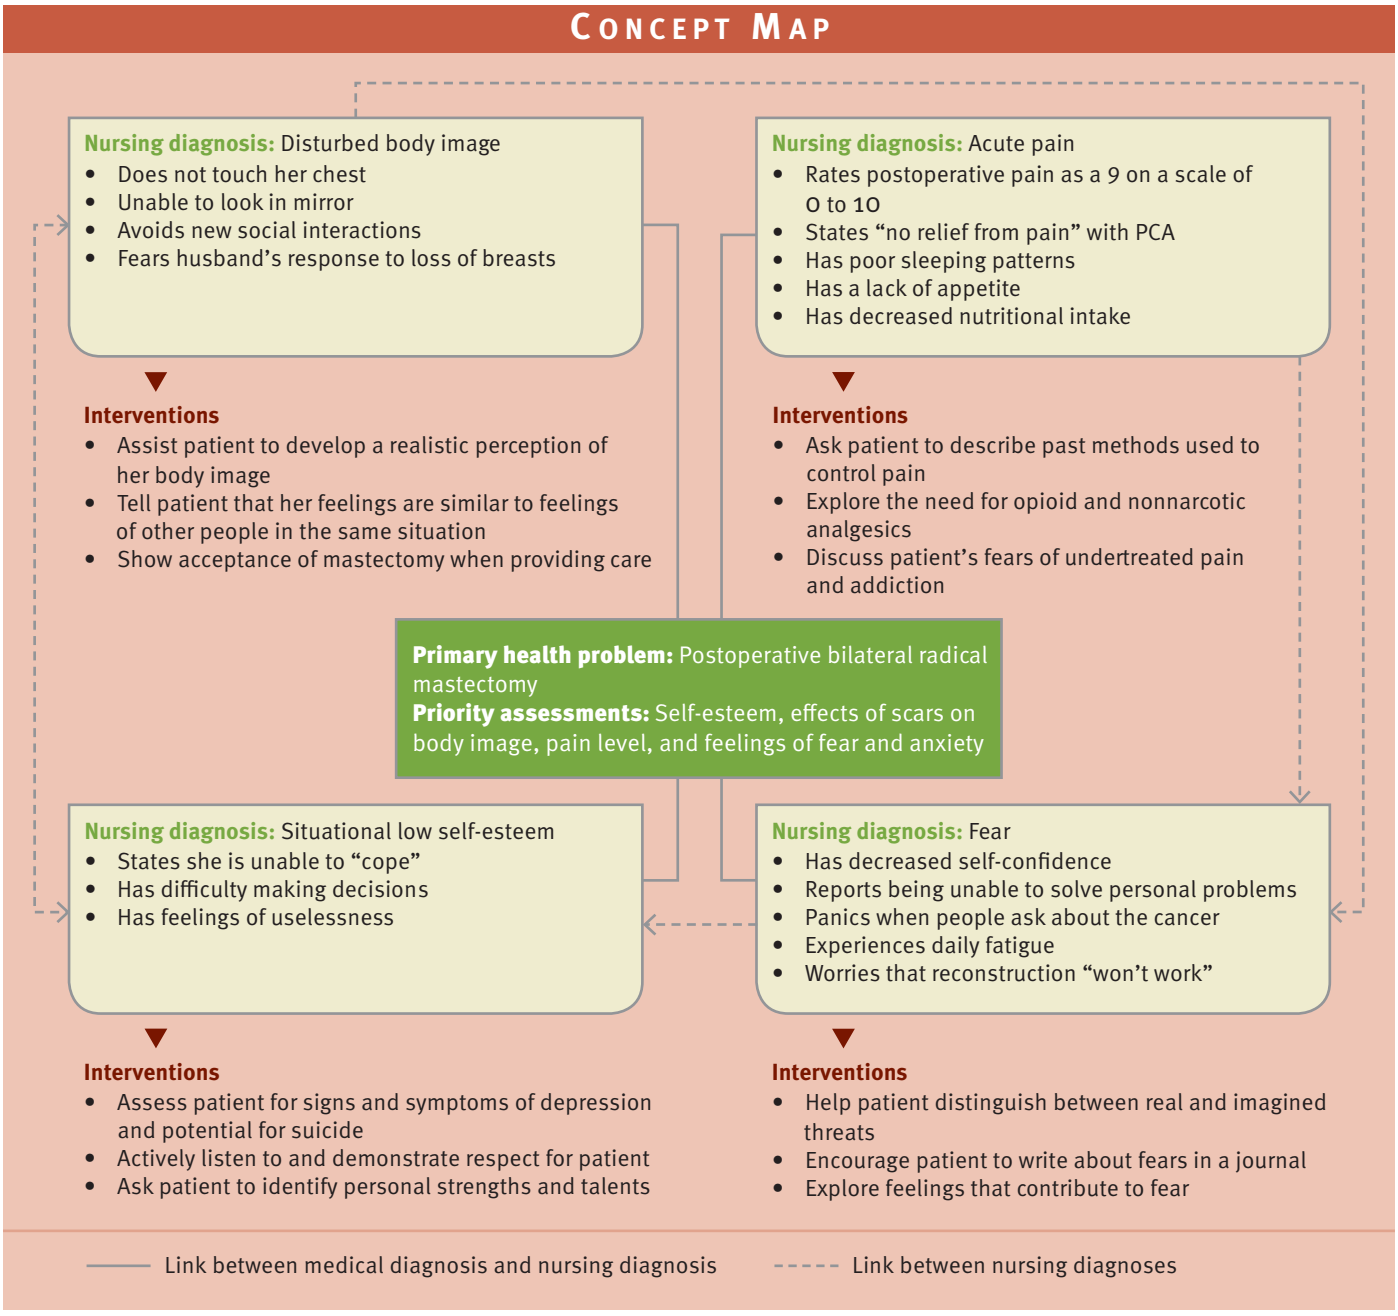

FIG. 33-6 Concept map for Mrs. Johnson. *PCA,* Patient-controlled analgesia.

consider the patient's desires for their involvement and cultural norms regarding who most frequently makes decisions in the family. Patients who are experiencing threats to or alterations in self-concept often benefit from collaboration with mental health and community resources to promote increased awareness. Additional resources include physical therapy, occupational therapy, behavioral health, social services, and pastoral care. Knowledge of available resources allows appropriate referrals.

IMPLEMENTATION

As with all the steps of the nursing process, a therapeutic nurse-patient relationship is central to the implementation phase. You develop the goals and outcome criteria and then consider nursing interventions for promoting a healthy self-concept and helping the patient move toward his or her goals. To develop effective nursing interventions, consider each nursing diagnosis and individualize interventions that address the diagnosis. Collaborating with members of the health care team maximizes the comprehensiveness of the approach to self-concept issues. Regardless of the health care setting, it is important to work with patients and their families or significant others to promote a healthy self-concept. For example, select nursing interventions that help patients regain or restore the elements that contribute to a strong and secure sense of self. The approaches chosen vary according to the level of care required.

Health Promotion. Work with patients to help them develop healthy lifestyle behaviors that contribute to a positive self-concept. Measures that support adaptation to stress such as proper nutrition, regular exercise within the patient's capabilities, adequate sleep and rest, and stress-reducing practices contribute to a healthy self-concept. Nurses are in a unique position to identify lifestyle practices that put a person's self-concept at risk or are suggestive of altered self-concepts. For example, a young teacher visits a clinic with complaints of being unable to sleep and experiencing anxiety attacks. In gathering the nursing history, lifestyle practices such as too little rest, a large number of life changes occurring simultaneously, and excessive use of alcohol emerge. These data, when taken together, are suggestive of actual or potential self-concept disturbances. Determine how the patient views the various lifestyle elements to facilitate his or her insight into behaviors and make referrals or provide needed health teaching.

Acute Care. In the acute care setting some patients experience potential threats to their self-concept because of the nature of the treatment and diagnostic procedures. Threats to a person's self-concept often result in anxiety and/or fear. As a nurse, you need to address the patient's numerous stressors, including fear of unknown diagnoses (prior to diagnostic tests), the need to modify lifestyle, and anticipated changes in functioning. In the acute care setting there is often more than one stressor, thus increasing the overall stress level for the patient and family.

Nurses in the acute care setting encounter patients who face the need to adapt to an altered body image as a result of surgery or other physical change. With shortened lengths of stay, addressing these needs is difficult to do while in an acute care setting; thus appropriate follow-up and referrals, including home care, are essential. Remain sensitive to the patient's level of acceptance of any changes. Forcing confrontation with a change before the patient is ready likely delays the person's acceptance. Signs that a person is receptive to accepting a change include asking questions related to how to manage a particular aspect of what has happened or looking at the changed body area. As the patient expresses readiness to integrate the body change into his or her self-concept, let him or her know about support groups that are available and offer to make the initial contact.

BOX 33-8 PATIENT TEACHING

Alterations in Self-Concept

Objective

- Situational low self-esteem will be reduced in the home care setting.

Teaching Strategies

- Encourage opportunities for patient to care for self (Stuart, 2009).
- Elicit patient's perceptions of strengths and weaknesses.
- Express verbally and behaviorally that patient is responsible for behavior.
- Identify relevant stressors with patient and ask for appraisal of them.
- Explore patient's adaptive and maladaptive coping responses to problems.
- Incorporate psychiatric co-morbidities (e.g., depression, somatoform disorders) and alterations to self-esteem and body image when planning treatment approaches (Sertoz et al., 2009).
- Collaboratively identify alternative solutions; encourage alternatives not previously tried.
- Continue to reinforce strengths and successes.

Evaluation

- Confirm perception and actual use of improved communication skills.
- Observe level of participation in decisions that affect care.
- Observe patient's establishment of a simple routine.
- Observe patient taking necessary action to change maladaptive coping responses and maintain adaptive ones (Stuart, 2009).
- Confirm with patient and family how to apply new coping resources to continued change.

Restorative and Continuing Care. Often in a home care environment a nurse has more of an opportunity to work with a patient to reach the goal of attaining a more positive self-concept. Interventions designed to help a patient reach the goal of adapting to changes in self-concept or attaining a positive self-concept are based on the premise that the patient first develops insight and self-awareness concerning problems and stressors and then acts to solve the problems and cope with the stressors. One way to achieve this is by reframing the patient's thoughts and feelings in a more positive way. Incorporate this approach into patient teaching for alterations in self-concept, including situational low self-esteem, that sometimes are present in the home care setting (Box 33-8).

Increase the patient's self-awareness by allowing him or her to openly explore thoughts and feelings. A priority nursing intervention is the expert use of therapeutic communication skills to clarify the expectations of a patient and family. Open exploration makes the situation less threatening for a patient and encourages behaviors that expand self-awareness. Accept the patient's thoughts and feelings nonjudgmentally, help the patient clarify interactions with others, and be empathic. Support self-expression and stress the patient's self-responsibility.

Help the patient define problems clearly and identify positive and negative coping mechanisms. Work closely with him or her to analyze adaptive and maladaptive responses, contrast different alternatives, devise a plan, and discuss outcomes. Collaborate with the patient to identify alternative solutions and develop realistic goals to facilitate real change and encourage further goal-setting behaviors. Design opportunities that result in success, reinforce the patient's skills and strengths, and help him or her find needed assistance. Encourage the patient to commit to decisions and

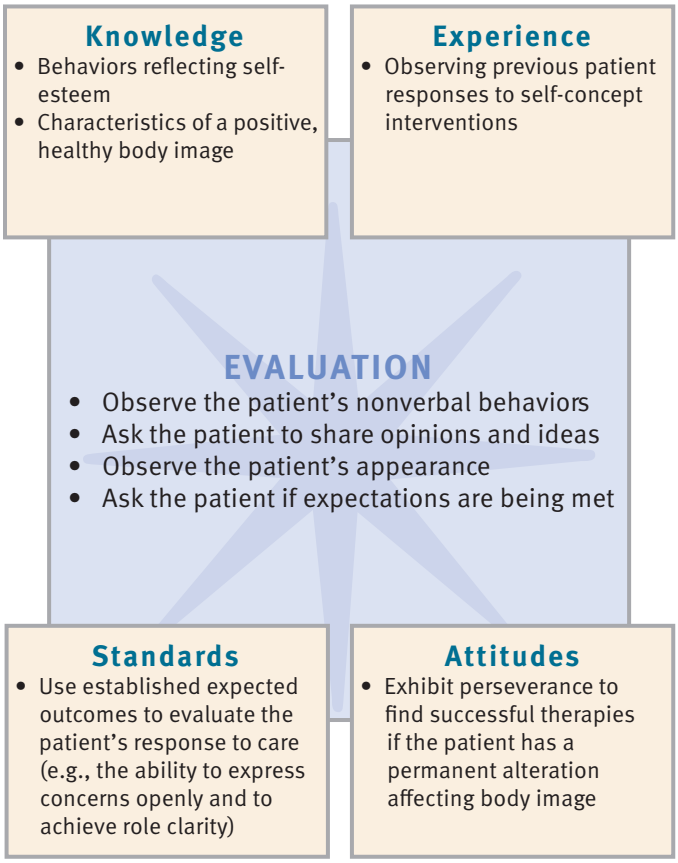

FIG. 33-7 Critical thinking model for self-concept evaluation.

actions to achieve goals by teaching him or her to move away from ineffective coping mechanisms and develop successful coping strategies. Supporting attempts that are helpful is essential because with each success a patient is able to make another attempt.

EVALUATION

Through the Patient's Eyes. Use critical thinking to evaluate the patient's perceived success in meeting each goal and the established expected outcomes (Fig. 33-7). Frequent evaluation of patient progress is necessary. Apply knowledge of behaviors and characteristics of a healthy self-concept when reviewing the actual behaviors that patients display. This determines whether outcomes have been met.

Patient Outcomes. Expected outcomes for a patient with a self-concept disturbance include nonverbal behaviors indicating a positive self-concept, statements of self-acceptance, and acceptance of change in appearance or function. Key indicators of a patient's self-concept are nonverbal behaviors. For example, a patient who has had difficulty making eye contact demonstrates a more positive self-concept by making more frequent eye contact during conversation. Social interaction, adequate self-care, acceptance of the use of prosthetic devices, and statements indicating understanding of teaching all indicate progress. Investing in satisfying activities, exerting choices in daily life, understanding own needs during transitions, and adapting to life circumstances are evidence of self-esteem and self-efficacy in older adults (Ebersole et al., 2008). A positive attitude toward rehabilitation and increased movement toward independence facilitate a return to preexisting roles at work or at home. Patterns of interacting also reflect changes in self-concept. For example, a patient who has been hesitant to express personal views more readily offers opinions and ideas as self-esteem increases.

The goals of care sometimes become unrealistic or inappropriate as a patient's condition changes. Revise the plan if needed, reflecting on successful experiences with other patients. Patient adaptation to major changes takes a year or longer, but the fact that this period is long does not suggest problems with adaptation. Look for signs that the patient has reduced some stressors and that some behaviors have become more adaptive. If initial outcomes regarding self-concept are not met, individualize the following questions:

- Tell me what you will do if you are not able to return to work (may substitute school or home) as planned.
- Who will you contact if you are not feeling any better about yourself in 2 weeks?
- What are you doing to actively promote improvement in your self-concept and self-esteem?
- How will you know that your self-concept and self-esteem are improving?

Changes in self-concept take time. Although change is often slow, care of a patient with a self-concept disturbance is rewarding.

KEY POINTS

- Self-concept is an integrated set of conscious and unconscious attitudes and perceptions about self.
- Components of self-concept are identity, body image, and role performance.
- Each developmental stage involves factors that are important to the development of a healthy, positive self-concept.
- Identity is particularly vulnerable during adolescence.
- Body image is the mental picture of one's body and is not necessarily consistent with a person's actual body structure or physical appearance.
- Body image stressors include changes in physical appearance, structure, or functioning caused by normal developmental changes or illness.
- Self-esteem stressors include developmental and relationship changes, illness, surgery, accidents, and the responses of other individuals to changes resulting from these events.
- Role stressors, including role conflict, role ambiguity, and role strain, originate in unclear or conflicting role expectations; the effects of illness often aggravate this.
- A nurse's self-concept and nursing actions have an effect on a patient's self-concept.
- Planning and implementing nursing interventions for self-concept disturbance involve expanding a patient's self-awareness, encouraging self-exploration, aiding in self-evaluation, helping formulate goals in regard to adaptation, and assisting a patient in achieving these goals.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. On the second postoperative day you enter the room and find Mrs. Johnson crying. She states that she has just gotten off the phone with her 23-year-old daughter and has agreed to care for her 3-month-old granddaughter while the daughter returns to work. You were informed in shift report that Mrs. Johnson had a restless night and has not taken pain medication since 2030.

You assess that she is in moderate pain, which you immediately treat with morphine. Within 40 minutes Mrs. Johnson reports that the morphine has decreased her pain rating from a 6 to a 3 on a scale of 0 to 10 but has left her somewhat drowsy. Mrs. Johnson has shared with you some of her concerns about whether or not she can actually provide child care for her granddaughter but states, "Maybe it will make me feel worthwhile and will take my mind off of how disgusting I look." She continues, "I just want to be normal again." How would you address her comment regarding "being normal again" and her lack of understanding of her physical condition, including pain management, increased fatigue, and limitations regarding lifting?

2. As a part of your home care experience, you are assigned to visit Mrs. Johnson who, in addition to caring for her infant granddaughter, is also caring for her mother, who is increasingly agitated and aggressive secondary to Alzheimer's disease. When you go to the home, you find Mrs. Johnson tearful. She says, "I can't do this anymore. She doesn't like anything I cook. She calls me two or three times during the night to sit with her; sometimes she doesn't even recognize me. The baby is constantly crying; I think she senses my stress. I feel so overwhelmed." What additional assessment data would be important to gather? What priority nursing diagnosis could be made for Mrs. Johnson?
3. You suspect that Mrs. Johnson's depressed mood and loss of interest in usual activities exceeds your previous diagnosis of situational low self-esteem. Describe which assessment data are needed to modify your plan of care. Identify your priority actions.

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Following a bilateral mastectomy, a 50-year-old patient refuses to eat, discourages visitors, and pays little attention to her appearance. One morning the nurse enters the room to see the patient with her hair combed and makeup applied. Which of the following is the best response from the nurse?
   1. "What's the special occasion?"
   2. "You must be feeling better today."
   3. "This is the first time I have seen you look this good."
   4. "I see that you've combed your hair and put on makeup."
2. A patient diagnosed with major depressive disorder has a nursing diagnosis of chronic low self-esteem related to negative view of self. Which of the following would be the most appropriate cognitive intervention by the nurse?
   1. Promote active socialization with other patients
   2. Role play to increase assertiveness skills
   3. Focus on identifying strengths and accomplishments
   4. Encourage journaling of underlying feelings
3. Several staff members complain about a patient's constant questions such as "Should I have a cup of coffee or a cup of tea?" and "Should I take a shower now or wait until later?" Which interpretation of the patient's behavior helps the nurses provide optimal care?
   1. Asking questions is attention-seeking behavior.
   2. Inability to make decisions reflects a self-concept issue.
   3. Dependence on staff must be stopped immediately.
   4. Indecisiveness is aimed at testing how the staff reacts.
4. A depressed patient is crying and verbalizes feelings of low self-esteem and self-worth such as "I'm such a failure … I can't do anything right." The best nursing response would be to:
   1. Remain with the patient until he or she stops crying.
   2. Tell the patient that is not true and that every person has a purpose in life.
   3. Review recent behaviors or accomplishments that demonstrate skill ability.
   4. Reassure the patient that you know how he is feeling and that things will get better.
5. An adult woman is recovering from a mastectomy for breast cancer and is frequently tearful when left alone. The nurse's approach should be based on an understanding of which of the following:
   1. Patients need support in dealing with the loss of a body part.
   2. The patient's family should take the lead role in providing support.
   3. The nurse should explain that breast tissue is not essential to life.
   4. The patient should focus on the cure of the cancer rather than loss of the breast.
6. When caring for an 87-year-old patient, the nurse needs to understand that which of the following most directly influences the patient's current self-concept:
   1. Attitude and behaviors of relatives providing care
   2. Caring behaviors of the nurse and health care team
   3. Level of education, economic status, and living conditions
   4. Adjustment to role change, loss of loved ones, and physical energy
7. A 20-year-old patient diagnosed with an eating disorder has a nursing diagnosis of situational low self-esteem. Which of the following nursing interventions would be best to address self-esteem?
   1. Offer independent decision-making opportunities
   2. Review previously successful coping strategies
   3. Provide a quiet environment with minimal stimuli
   4. Support a dependent role throughout treatment
8. The nurse asks the patient, "How do you feel about yourself?" The nurse is assessing the patient's:
   1. Identity.
   2. Self-esteem.
   3. Body image.
   4. Role performance.
9. The nurse can increase a patient's self-awareness through which of the following actions? (Select all that apply.)
   1. Helping the patient define her problems clearly
   2. Allowing the patient to openly explore thoughts and feelings
   3. Reframing the patient's thoughts and feelings in a more positive way
   4. Have family members assume more responsibility during times of stress
10. When developing an appropriate outcome for a 15-year-old girl, the nurse considers that a primary developmental task of adolescence is to:
    1. Form a sense of identity.
    2. Create intimate relationships.
    3. Separate from parents and live independently.
    4. Achieve positive self-esteem through experimentation.
11. An appropriate nursing diagnosis for an individual who experiences confusion in the mental picture of his physical appearance is:

1. Acute confusion.
2. Disturbed body image.
3. Chronic low self-esteem.
4. Situational low self-esteem.

12. In planning nursing care for an 85-year-old male, the most important basic need that must be met is:
    1. Assurance of sexual intimacy.
    2. Preservation of self-esteem.
    3. Expanded socialization.
    4. Increase in monthly income.
13. Based on knowledge of Erikson's stages of growth and development, the nurse plans her nursing care with the knowledge that old age is primarily focused on:
    1. Intimacy versus Isolation.
    2. Autonomy versus Shame and Doubt.
    3. Generativity versus Self-Absorption.
    4. Ego Integrity versus Despair.
14. The home health nurse is visiting a 90-year-old man who lives with his 89-year-old wife. He is legally blind and is 3 weeks' post right hip replacement. He ambulates with difficulty with a walker. He comments that he is saddened now that his wife has to do more for him and he is doing less for her. Which of the following is the priority nursing diagnosis?
    1. Self-care deficit, toileting
    2. Deficient knowledge regarding resources for the visually impaired
    3. Disturbed body image
    4. Risk for situational low self-esteem
15. Based on knowledge of the developmental tasks of Erikson's Industry versus Inferiority, the nurse emphasizes proper technique for use of an inhaler with a 10-year-old boy so he will:
    1. Increase his self-esteem with mastery of a new skill.
    2. Accept changes in his appearance and physical endurance.
    3. Experience success in role transitions and increased responsibilities.
    4. Appreciate his body appearance and function.

Answers: **1.** 4; **2.** 3; **3.** 2; **4.** 1; **5.** 1; **6.** 4; **7.** 1; **8.** 2; **9.** 1, 2, 3; **10.** 1; **11.** 2; **12.** 2; **13.** 4; **14.** 4; **15.** 1.

CHAPTER

34

Sexuality

OBJECTIVES

- Identify personal attitudes, beliefs, and biases related to sexuality.
- Discuss the nurse's role in maintaining or enhancing a patient's sexual health.
- Describe key concepts of sexual development across the life span.
- Identify causes of sexual dysfunction.
- Assess a patient's sexuality.
- Formulate appropriate nursing diagnoses for patients with alterations in sexuality.
- Identify patient risk factors in the area of sexual health.
- Identify and describe nursing interventions to promote sexual health.
- Evaluate patient outcomes related to sexual health needs.
- Identify other health care providers and community resources available to help patients resolve sexual concerns that are outside the nurse's level of expertise.
- Use critical thinking skills when helping patients meet their sexual needs.

Sexuality is part of a person's personality and is important for overall health. Even though discussion of sexual topics has increased over the years, many adults lack knowledge regarding **sexuality.** Although patients may be hesitant to bring up their concerns, they often share their feelings when the nurse addresses sexuality in a relaxed, matter-of-fact manner. To feel comfortable addressing sexuality, nurses need therapeutic communication skills and to be knowledgeable about sexual functioning, issues, and assessment. Many values and issues surround sexuality. Religious teachings, cultural influences on **gender roles,** beliefs about **sexual orientation,** and social and environmental climates influence the values systems for both patients and health care providers.

Sexuality has many definitions. Expression of an individual's sexuality is influenced by interaction among biological, sociological, psychological, spiritual, economic, political, religious, and cultural factors (Gorman and Sultan, 2008; World Health Organization [WHO], 2010). In addition, values, attitudes, behaviors, relationships with others, and the need to establish emotional closeness with others influence sexuality.

Sexuality differs from *sexual health*. According to WHO (2010), **sexual health** is "a state of physical, emotional, mental and social well-being in relation to sexuality; it is not merely the absence of disease, dysfunction or infirmity." People who are sexually healthy have a positive and respectful approach to sexuality and sexual relationships. They also have a potential for having pleasurable and safe sexual experiences that are free from coercion, discrimination, and violence.

SCIENTIFIC KNOWLEDGE BASE

Nurses help patients achieve sexual health by having a sound scientific knowledge base regarding sexuality. A basic understanding of sexual development, sexual orientation, **contraception,** abortion, and **sexually transmitted infections (STIs)** is necessary.

Sexual Development

Sexuality changes as a person grows and develops. Each stage of development brings changes in sexual functioning and the role of sexuality in relationships.

Infancy and Early Childhood. The first 3 years of life are crucial in the development of **gender identity** (Edelman and

Mandle, 2010). The child identifies with the parent of the same sex and develops a complementary relationship with the parent of the opposite sex. Children become aware of differences between the sexes, begin to perceive that they are either male or female, and interpret the behaviors of others as behavior appropriate for a female or a male.

School-Age Years. During the school years parents, educators, and peer groups serve as role models and teachers about how men and women act with and relate to one another. School-age children generally have questions regarding the physical and emotional aspects of sex. They need accurate information from home and school about changes in their bodies and emotions during this period and what to expect as they move into puberty (Edelman and Mandle, 2010). Knowledge about normal emotional and physical changes associated with puberty decreases anxiety as these changes begin to happen. Menstruation or nocturnal emission is sometimes frightening for uninformed children, and some view them as evidence of a dreadful disease.

Puberty/Adolescence. The emotional changes during puberty and adolescence are as dramatic as the physical ones. The adolescent functions within a powerful peer group, with the almost constant anxiety of "Am I normal?" and "Will I be accepted?" (Fig. 34-1). They face many decisions and need accurate information on topics such as body changes, sexual activity, emotional responses within intimate sexual relationships, STIs, contraception, and pregnancy.

In the United States approximately 46% of high school students report that they have had sexual intercourse at least one time and 14% of high school students had had four or more sexual partners (CDC, 2010a). One reason why adolescents are sexually active is because many believe that sexual intercourse helps them achieve goals of intimacy, relationships, and pleasure (Fantasia, 2009). A substantial number of sexually active teenagers do not protect themselves from pregnancy or STIs. The dynamics of sexual risk taking are not fully understood, but studies have found correlations among drug/alcohol use, sexual abuse, and unsafe sex (Elkington, Bauermeister, and Zimmerman, 2010; Fantasia, 2009). Adolescents tend to think that unwanted pregnancy, STIs, and other negative outcomes of sexual behavior are not likely to happen to them. Parents need to understand the importance of providing factual information, sharing their values, and promoting sound decision-making skills. They need to know that, even with the best guidance and information, adolescents make their own decisions and need to be held accountable for them.

FIG. 34-1 Adolescents function within a powerful network of peers as they explore their sexual identity. (© bikeriderlondon.)

Adolescence is often a time when individuals explore their primary sexual orientation (Bowder and Greenberg, 2010). They may identify with a sexual minority group such as **lesbian, gay, bisexual,** or **transgender** (LGBT) (Young-Bruehl, 2010). Adolescents often face significant stress related to these choices and benefit from education about sexuality issues (Doty et al., 2010). Support from peers, family, school counselors, clergy, nurses, and other health professionals is important during this time.

Building Competency in Patient-Centered Care A 15-year-old girl tells the nurse at a family planning clinic that she is sexually active but does not use birth control. She states that her boyfriend won't use condoms and she is concerned about pregnancy. In addition, she lives at home with her parents, and she doesn't want them to know that she is using contraception. What assessment and teaching strategies would you use to address these patient concerns?

Answers to questions can be found on the Evolve website.

Young Adulthood. Although young adults have matured physically, they continue to explore and mature emotionally in relationships. Intimacy and sexuality are issues for all young adults whether they are in a sexual relationship, choose to abstain from sex, remain single by choice, are homosexual, or are widowed. People are sexually healthy in numerous ways. Sexual activity is often defined as a basic need, and healthy sexual desire is channeled into forms of intimacy throughout a lifetime.

As sexually active adults develop intimate relationships, they learn techniques of stimulation that are satisfying to both themselves and their sexual partners. Some adults need permission or affirmation that alternative ways of sexual expression other than penile-vaginal intercourse are normal. Other individuals require significant education or therapy to achieve mutually satisfying sexual relationships.

Middle Adulthood. Changes in physical appearance in middle adulthood sometimes lead to concerns about sexual attractiveness. In addition, actual physical changes related to aging affect sexual functioning. Decreasing levels of estrogen in **perimenopausal** woman lead to diminished vaginal lubrication and decreased vaginal elasticity. Both of these changes often lead to **dyspareunia,** or the occurrence of pain during intercourse. Decreasing levels of estrogen may also result in a decreased desire for sexual activity. As men age, they are likely to experience changes such as an increase in the postejaculatory refractory period and delayed ejaculation. Anticipatory guidance regarding these normal changes, using vaginal lubrication, and creating time for caressing and tenderness ease concerns regarding sexual functioning. Some aging adults also need to adjust to the impact of chronic illness, medications, aches, pains, and other health concerns about sexuality.

Later in the adult years some individuals have to adjust to the social and emotional changes associated with children moving away from home. This results in either a time of renewed intimacy between partners or a time when formerly intimate partners realize that they no longer care for one another or have common interests. In either case, when children leave home, intimate relationships usually change.

Older Adulthood. Sexuality in older adults is an important aspect of health that is often overlooked by health care providers. Studies show a positive correlation between sexual activity and physical health in older adults (Lindau and Gavrilova, 2010; Lindau et al., 2007). Many studies suggest that older adults retain

BOX 34-1 FOCUS ON OLDER ADULTS

Sexuality in Older Adults

- Sexuality and continued interest in sex throughout middle and late life is usually associated with good physical health (Lindau and Gavrilova, 2010).
- Pathological problems with the aging sexual response are often related to illnesses and side effects from medications (Hillman, 2008).
- Older adults are often reluctant to discuss sexual problems with health care providers (Green and Kodish, 2009; Lindau et al., 2007).
- Older adults who live in assisted-living or extended care facilities lose their privacy and experience a decline in physical and cognitive abilities that affects their sexual expression (Frankowski and Clark, 2009).
- The number of older lesbian, gay, bisexual, and transgendered (LGBT) population is increasing as the general population ages (Fredriksen-Goldsen and Muraco, 2010)
- Many older adults are unfamiliar with the use of condoms and other health promotion activities (e.g., having protected sex with a limited number of sexual partners) related to prevention of sexually transmitted infection (Smith and Christakis, 2009).

an interest in sexual function and are sexually active. Other studies conclude that there is a decline of sexual interest and behavior among older adults, especially in women (Box 34-1). Factors that determine sexual activity in older adults include present health status, past and present life satisfaction, and the status of marital or intimate relationships. For example, many older women are widowed or divorced and lack available sexual partners, which accounts for their decline in sexual activity. Nurses working with older adults need to be aware of the sexuality of their patients, assess interest and functioning, and plan accordingly (Wallace, 2008). It is essential to maintain a nonjudgmental attitude and convey that sexual activity is normal in later years. Emphasize that sexual activity is not essential to maintaining quality of life, especially when patients have decided not to remain sexually active.

To be effective in promoting sexual health, nurses need to understand the normal sexual changes that occur as people age. The excitement phase prolongs in both men and women, and it usually takes longer for them to reach orgasm. The refractory time following orgasm is also longer. Both genders experience a reduced availability of sex hormones. Men often have erections that are less firm and shorter acting. Women usually do not have difficulty maintaining sexual function unless they have a medical condition that impairs their sexual activity. Typically the infrequency of sex in older women is related to the age, health, and sexual function of their partner. Women continue to experience changes related to menopause, and those with problems related to urinary incontinence often experience embarrassment during intercourse. Couples who have physically disabling conditions often need information about which positions are more comfortable when having sexual intercourse.

Sexual Orientation

Sexual orientation describes the predominant pattern of a person's sexual attraction over time. Many stereotypical myths remain about people who are LGBT. Current evidence indicates that they experience decreased access to health care and do not readily seek preventive care (Brown, 2009; Williamson, 2010). Nonjudgmental nurses who have a solid knowledge base help to discourage these myths and provide nursing care that includes attention to the person's sexual orientation.

Contraception

Numerous contraceptive options are available to sexually active couples today. They provide varying levels of protection against unwanted pregnancies. Some methods do not require a prescription, whereas others require a prescription or some other type of intervention from a health care provider. Methods that are effective for contraception do not always reduce the risk of STIs. For example, the pill and intrauterine device (IUD) are effective as birth control but not for protection from STIs. Effectiveness varies with each contraceptive method and the consistency of use. Unplanned pregnancies occur because contraceptives are not used, are used inconsistently, or are used improperly (Gabelnick et al., 2009).

Nonprescription Contraceptive Methods. Nonprescription methods for contraception include abstinence, barrier methods, and timing of intercourse with regard to the woman's ovulation cycle. Although abstinence from sexual intercourse is 100% effective, it is often difficult for both men and women to use consistently. Any act of unprotected intercourse potentially results in pregnancy and exposure to STIs.

Barrier methods include over-the-counter spermicidal products and condoms. Spermicidal products (e.g., creams, jellies, foams, and sponges) are put into the vagina before intercourse to create a spermicidal barrier between the uterus and ejaculated sperm. A **condom** is a thin rubber sheath that fits over the penis to prevent entrance of sperm into the vagina. A diaphragm is a barrier method, which must be used with a spermacide with each sexual encounter. Vaginal spermicides and condoms are most effective when instructions are followed carefully; their combined use is more effective in preventing pregnancy than the use of either one alone (Warner and Steiner, 2009).

Nonprescription methods of contraception based on the physiological changes of the menstrual cycle include the rhythm, basal body temperature, cervical mucus, and fertility-awareness methods. Couples who use these methods need to understand the reproductive cycle of the woman's body and the subtle signs and signals that her body gives during the cycle. To prevent pregnancy couples abstain from sexual intercourse during designated fertile periods.

Methods That Require a Health Care Provider's Intervention. Contraceptive methods that require the intervention of a health care provider include hormonal contraception, IUDs, the diaphragm, the cervical cap, and **sterilization.** Hormonal contraception is available in several forms: oral contraceptive pills, vaginal contraceptive rings, hormonal injections, subdermal implant, transdermal skin patches, and IUDs. Hormonal contraception alters the hormonal environment to prevent ovulation, thicken cervical mucus, and thin the lining of the uterus.

An IUD is a plastic device inserted by a health care provider into the uterus through the cervical opening. IUDs contain either copper or progesterone. The primary mechanism by which both types of IUDs prevent pregnancy is to stop the sperm from fertilizing an egg (Grimes, 2009; Murphy, 2011; Ortiz and Croxatto, 2007). The release of progesterone may also increase cervical mucus thickness and alter the lining of the uterus.

The **diaphragm** is a round, rubber dome that has a flexible spring around the edge. It is used with a contraceptive cream or jelly and is inserted in the vagina so it provides a contraceptive barrier over the cervical opening. The woman needs to be refitted after a significant change in weight (10-lb gain or loss) or pregnancy. The cervical cap functions like the diaphragm; however, it covers only the cervix. It may be left in place longer, and some perceive it as more comfortable than the diaphragm.

Sterilization is the most effective contraception method other than abstinence. Female sterilization, or **tubal ligation,** involves cutting, tying, or otherwise ligating the fallopian tubes. In male sterilization, or **vasectomy,** the vas deferens, which carries the sperm away from the testicles, is cut and tied. Both a tubal ligation and a vasectomy are usually considered permanent surgical procedures.

Sexually Transmitted Infections

The incidence of STIs continues to increase. About 19 million people in the United States are diagnosed with an STI each year; almost half of them are 15 to 24 years of age (CDC, 2009). The prevalence of STIs is a major health concern for several reasons. Black and Hispanic populations are diagnosed with STIs more frequently than whites, and women have more complications associated with STIs than men. In addition, social factors such as poverty, low literacy, discrimination, use of illegal drugs (e.g., crack cocaine, methamphetamine), incarceration, sexual abuse, and racial segregation contribute to racial disparities in the STI rates (Hogben and Leichliter, 2008). Treatment of STIs in America costs about $16 million annually (CDC, 2009). Commonly diagnosed STIs include syphilis, gonorrhea, chlamydia, trichomoniasis, and infection with the human papillomavirus (HPV) and herpes simplex virus (HSV) type II (genital warts and genital herpes, respectively).

As the name implies, STIs are transmitted from infected individuals to partners during intimate sexual contact. The site of transmission is usually genital, but sometimes it is oral-genital or anal-genital. People most likely to be infected share one key characteristic: unprotected sex with multiple partners. Gonorrhea, chlamydia, syphilis, and pelvic inflammatory disease (PID) are caused by bacteria and are usually curable with antibiotics. Patients need to take antibiotics for the full course of treatment. However, an emerging concern is that some of these bacterial infections (e.g., gonorrhea and syphilis) are now developing antibiotic-resistant strains. Infections such as genital herpes, HPV, and human immunodeficiency virus (HIV) are caused by viruses and cannot be cured.

A major problem in dealing with STIs is finding and treating the people who have them. Some people do not know that they are infected because symptoms are sometimes absent or go unnoticed (CDC, 2009). Common symptoms of an STI include discharge from the vagina, penis, or anus; pain during sex or when urinating; blisters or sores in the genital area; and fever (Marrazzo et al., 2009). Because sexual behavior often includes the whole body rather than just the genitalia, many parts of the body are potential sites for an STI. The ears, mouth, throat, tongue, nose, and eyelids are sometimes used for sexual pleasure. The perineum, anus, and rectum are also frequently included in sexual activity. Furthermore, any contact with another person's body fluids around the head or an open lesion on the skin, anus, or genitalia can transmit an STI.

Sometimes people do not seek treatment because they are embarrassed to discuss sexual symptoms or concerns. They are also often hesitant to talk about their sexual behavior if they believe that it is not "normal." Any sexual behavior that embarrasses the patient often hinders the detection of an STI. Develop communication skills and a nonjudgmental attitude to provide effective care for those diagnosed with one. Detect valuable clues about an STI by establishing trust, talking with patients, and asking questions in a caring manner. Assess attitudes toward sexuality and adjust the intervention to make it acceptable to the patient's sexual value system.

Human Immunodeficiency Virus Infection. HIV infection is sometimes spread through sexual contact. Although HIV is present in most body fluids, it is a bloodborne pathogen. Transmission occurs when there is an exchange of body fluid. Primary routes of transmission include contaminated intravenous (IV) needles, anal intercourse, vaginal intercourse, oral-genital sex, and transfusion of blood and blood products. Populations that are at risk for HIV include people who use illicit IV drugs and share needles, individuals with hemophilia, and people who have unprotected sexual contact.

The natural history of HIV is composed of three stages. The primary infection stage lasts for about a month after contracting the virus. During this time the person often experiences flulike symptoms. Then he or she enters the clinical latency phase; at this time there are no symptoms of infection. HIV antibodies appear in the blood about 6 weeks to 3 months after infection. If left untreated, people who are infected with HIV live about 10 years. The last stage, acquired immunodeficiency syndrome (AIDS), happens when the person begins to show symptoms of the disease. AIDS is a serious, debilitating, and eventually fatal disease. Highly active antiretroviral therapy (HAART) greatly increases the survival time of persons who live with HIV/AIDS (Marrazzo et al., 2009).

Human Papillomavirus Infection. HPV is the most common STI in the United States, with approximately 6 million new infections every year (CDC, 2010b). Most HPV infections are asymptomatic and self-limiting. However, certain types of HPV can cause cervical cancer in women and anogenital cancers and genital warts in both men and women (CDC, 2010b; Palefsky, 2010). HPV is spread through direct contact with warts, semen, and other body fluids from others who have the disease. The textured warts often have a cauliflower appearance and are most common on the penis and scrotum in men and the vagina and cervix in women. An HPV vaccine that protects both men and woman against the types of HPV that most commonly cause health concerns is available (CDC, 2010b).

Chlamydia. An infection of the bacteria *Chlamydia trachomatis* causes chlamydia. It is the most commonly reported bacterial STI in the United States, affecting about 2.8 million Americans each year (CDC, 2009). Chlamydia infects the genitourinary tract and rectum in adults, and it causes conjunctivitis and pneumonia in newborn babies. Transmission occurs when the person comes in contact with fluids from infected sites (e.g., cervix or urethra). It is a major health issue because, if it is not treated, it causes PID, ectopic pregnancy, **infertility,** and neonatal complications. The risk of infection is higher in people who are less than 25 years old and who do not consistently use barrier contraceptives. It is also common in people who have multiple sex partners and who are infected with other STIs (Marrazzo et al., 2009). Most chlamydia infections go undiagnosed and untreated because 75% of women and 50% of men experience no symptoms (Grimshaw-Mulcahy, 2008). Symptoms that women often experience include dysuria, urinary frequency, and purulent vaginal discharge. In men it usually infects the urethra and causes nongonococcal urethritis (NGU). Dysuria and urethral discharge are common symptoms of NGU (Marrazzo et al., 2009).

NURSING KNOWLEDGE BASE

Factors Influencing Sexuality

Use critical thinking skills and basic nursing knowledge when addressing patients' sexual health needs. Draw from the following areas of nursing knowledge: sociocultural dimensions of sexuality, decisional issues, and alterations in sexual health.

BOX 34-2 CULTURAL ASPECTS OF CARE

Latinos and HIV/AIDS Risk Factors

Latinos are less likely to use condoms, less likely to seek human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS) testing and have a higher incidence of HIV/AIDS than other ethnic groups in the United States. Latinos with HIV are diagnosed later in the disease process and often in the acute care setting with symptoms and complications associated with AIDS. Sociocultural factors such as gender roles, lack of knowledge, language, younger age at onset of sexual activity, and limited communication between parents and children about use of contraceptives contribute to this discrepancy (Wohl et al., 2009). Traditional Latino culture supports beliefs in abstinence until marriage, and many believe that teaching children about sex promotes sexual activity. Parents are not comfortable teaching their children, especially their daughters, about sex (Lescano et al., 2009).

Implications for Practice

- Direct interventions toward the family versus the individual since collectivism and family are fundamental to Latino culture.
- Whenever possible, first establish a strong therapeutic relationship with the patient and family before discussing sexual health.
- Design culturally sensitive and specific nursing interventions for Latino patients and families.
- Provide written and verbal information (in English and Spanish) about sex education, assertive communication, power in relationships, and negotiation skills.
- Encourage community resources such as churches and schools to improve sex education in Latino families and communities.
- Promote community and multimedia education campaigns in Spanish and English languages.
- Increase HIV testing offered at community and public clinics and consider combining HIV testing with other laboratories to promote acceptance by Latinos.

Sociocultural Dimensions of Sexuality

Cultural rules and norms regarding acceptable behavior within the culture influence sexuality. People assign different meanings to sexuality based on their culture, gender, education, socioeconomic status, and religion (Giger and Davidhizar, 2008; Stilos et al., 2008). Society plays a powerful role in shaping sexual values and attitudes and supporting specific expression of sexuality in its members.

Each cultural and social group has its own set of rules and norms that guide sexual behavior, sexual health, and the willingness to discuss this private part of life. For example, cultural norms influence how people find partners, whom they choose as partners, how they relate to one another, how often they have sex, and what they do when they have sex. Personal beliefs enable certain practices and prohibit others (Box 34-2).

Impact of Pregnancy and Menstruation on Sexuality. Sexual interest and activity of women and their partners vary during pregnancy and menstruation. Some cultures encourage sexual intercourse or male-female contact during menstruation and pregnancy, but other cultures strictly forbid it. For example, in the Hindu culture a woman avoids worship, cooking, and other members of the family during menstruation. Research has found no physiological contraindication to intercourse during menstruation or during most pregnancies. Female sexual interest tends to fluctuate during pregnancy, with increased interest during the second trimester and often decreased interest during the first and third trimesters. There is often a decrease in libido during the first trimester because of nausea, fatigue, and breast tenderness. During the second trimester blood flow to the pelvic area increases to supply the placenta, resulting in increased sexual enjoyment and libido. During the third trimester the increased abdominal size often makes finding a comfortable position difficult (Lowdermilk et al., 2010).

Discussing Sexual Issues. Sexuality is a significant part of each person's being, yet sexual assessment and interventions are not always included in health care (Lindau et al., 2007; Stilos et al., 2008). The area of sexuality is often emotionally charged for nurses and patients. Sometimes nurses avoid discussing sexual issues with patients because they lack information or have different values than their patients. Nurses who have difficulty discussing topics related to sexuality need to explore their discomfort and develop a plan to address it. If you are uncomfortable with topics related to sexuality, the patient is unlikely to share sexual concerns with you.

Decisional Issues

Individuals make many decisions about their sexuality. Some nurses help patients make decisions about contraception and abortion.

Contraception. Decisions patients make regarding contraception have far-reaching effects on their lives. Pregnancy, whether planned or unplanned, significantly affects the life of the mother and father and often their support network. Effects are physical, interpersonal, social, financial, and societal. The choice to use contraception is multifaceted and not completely understood. Factors that affect the effectiveness of contraception include the method of contraception, the couple's understanding of the contraceptive method, the consistency of use, and compliance with the requirements of the chosen method. Choice of contraception method varies in relation to the age, marital status, income, education, and previous pregnancies of the woman (Mosher and Jones, 2010).

Abortion. Half of all pregnancies in the United States are unplanned; the majority of unplanned pregnancies occur in teenagers, women over 40 years of age, and low-income nonwhite women (Paul and Stewart, 2009). Almost half of unintended pregnancies end in abortion (Mosher and Jones, 2010). Abortions have been performed since ancient times. The safety and availability of abortions in the United States improved after the 1973 Supreme Court decision *Roe v Wade,* which established the right of every woman to have an abortion. Abortions are safer and less costly when performed in the early weeks of pregnancy.

Abortion is a hotly debated issue. Women and their partners who face an unwanted pregnancy may consider it. If caring for a patient contemplating abortion, provide an environment in which the patient is able to discuss the issue openly, allowing exploration of various options with an unwanted pregnancy. Discuss religious, social, and personal issues in a nonjudgmental manner with patients. Reasons for choosing an abortion vary and include terminating an unwanted pregnancy or aborting a fetus known to have birth defects. When a woman chooses abortion as a way of dealing with an unwanted pregnancy, the woman and often her partner experience a sense of loss, grief, and/or guilt.

Be aware of personal values related to abortion. Nurses are entitled to their personal views and should not be forced to participate in counseling or procedures contrary to beliefs and values. It is essential to choose specialties or places of employment where personal values are not compromised and the care of a patient in need of health care is not jeopardized.

Prevention of Sexually Transmitted Infections. Abstinence is the only practice that is considered to be 100% effective

in preventing transmission of STIs. Responsible sexual behavior includes knowing one's sexual partner, being able to openly discuss sexual and drug-use history with the partner, not allowing drugs or alcohol to influence decision making, and using protective devices.

Alterations in Sexual Health

Infertility. Infertility is the inability to conceive after 1 year of unprotected intercourse. A couple who wants to conceive and cannot has special needs. Some experience a sense of failure and feel that their bodies are defective. Sometimes the desire to become pregnant grows until it permeates most waking moments. Some individuals become preoccupied with creating just the right circumstances for conception. With advances in reproductive technology, infertile couples face many choices that involve religious and ethical values and financial limitations.

Choices for the infertile couple include pursuit of adoption, medical assistance with fertilization, or adapting to the probability of remaining childless. Organizations such as RESOLVE: The National Organization of Infertility, a national support group for couples with infertility, or international adoption groups provide couples with support and offer referral sources.

Sexual Abuse. Sexual abuse is a widespread health problem. Abuse crosses all gender, socioeconomic, age, and ethnic groups. Most often it is at the hands of a former intimate partner or family member. Sexual abuse has far-ranging effects on physical and psychological functioning (Edelman and Mandle, 2010). Sometimes sexual abuse begins, continues, or even intensifies during pregnancy. Cues that raise a question of possible sexual abuse include extreme jealousy and refusal to leave a woman's presence. The overall appearance is sometimes that of a very concerned and caring husband or boyfriend, when the underlying reason for this behavior is very different.

When you recognize abuse, mobilize support for the victim and the family. All family members usually require therapy to promote healthy interactions and relationships. Rape victims often need to work through the crisis before feeling comfortable with intimate expressions of affection. The partner needs to know how to help and support the victim. Children who have been sexually molested need to understand that they are not at fault for the incident. The parents need to understand that their response is critical to how the child reacts and adapts. Nurses are in an ideal position to assess occurrences of sexual violence, help patients confront these stressors, and educate individuals regarding community services. Nurses must also report suspected abuse to the proper authorities.

Personal and Emotional Conflicts. Ideally sex is a natural, spontaneous act that passes easily through a number of recognizable physiological stages and ends in one or more orgasms. In reality this sequence of events is more the exception than the rule. Nurses meet patients who have problems with one or more of the stages of sexual activity, including the feeling of wanting sex, the physiological processes and emotions of having sex, and the feelings experienced after sex. For example, some women and men who are taking antidepressants report that their ability to reach orgasm is negatively affected.

Sexual Dysfunction. **Sexual dysfunction,** the absence of complete sexual functioning, is common. The incidence of sexual dysfunction in the general population is estimated to be as high as 40% in men and 45% in women (Gorman and Sultan, 2008; Murtagh, 2010; Shifren et al., 2008). It is more prevalent in men and women with poor emotional and physical health (Box 34-3). Sometimes the exact cause cannot be determined.

BOX 34-3 ILLNESSES AND MEDICATIONS THAT AFFECT SEXUAL FUNCTIONING OF MEN AND WOMEN

Illnesses
- Diabetes mellitus
- Cancer (e.g., prostate, breast, colon, ovarian, testicular, rectal)
- Neuropathy
- Spina bifida
- Spinal cord injury
- Unstable angina
- Uncontrolled hypertension
- Chronic obstructive pulmonary disease
- Human immunodeficiency virus (HIV) infection
- Substance abuse
- Depression

Medications
- Antihypertensives
- Antipsychotics
- Antidepressants
- Antianxiety
- Diuretics
- Oncological agents
- Recreational or illicit drugs

Data from Chapleau C et al: Antidepressant-induced sexual dysfunction, *Consultant* 50(7):282, 2010; Harzichristou DG et al: Recommendations for the clinical evaluation of men and women with sexual dysfunction, *J Sex Med* 7:337, 2010; Gorman LM and Sultan DF: The patient with sexual dysfunction. In Gorman L, editor: *Psychosocial nursing for general patient care,* ed 3, Philadelphia, 2008, FA Davis; Lilley LL et al: *Pharmacology and the nursing process,* ed 6, St Louis, 2011, Mosby.

Erectile dysfunction (ED) affects as many as 40% of men between 40 and 70 years of age in the United States and is often unreported (Green and Kodish, 2009; Hillman, 2008). It occurs more frequently in older men, but it occurs in younger men as well (Lindau et al., 2007). Risk factors are similar to those for heart disease (i.e., diabetes mellitus, hyperlipidemia, hypertension, hypothyroidism, chronic renal failure, smoking, obesity, alcohol abuse, and lack of exercise). The etiology of ED is often multifactorial. Neurogenic problems, medications, or endocrine or psychogenic factors can cause it. An age-related decrease in testosterone often results in decreased tone of the erectile tissues.

One of the most common problems affecting women of all ages is **hypoactive sexual desire disorder** (HSDD) (Kingsberg, 2011; West et al., 2008). Biological, organic, or psychosocial factors can contribute to the incidence of HSDD. Chronic medical conditions such as breast or gynecological cancers and hormonal fluctuations, pain, or depression and anxiety can contribute to a decreased interest in sexual intimacy.

CRITICAL THINKING

Successful critical thinking requires synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Nurses use clinical judgment to anticipate information needs, analyze assessment data, and make appropriate decisions regarding patient care. Fig. 34-2 shows how to use elements of critical thinking and patient assessment data to develop appropriate nursing diagnoses.

In the case of sexuality, integrate knowledge from nursing and other disciplines. Have a thorough understanding of safe sex practices and the risks and behaviors associated with sexual problems to anticipate how to assess a patient and interpret findings. Use previous experiences to provide care for patients with sexual issues in a more reflective and helpful way. Patients have different customs and values from those of the nurse. Professional standards require respect for each patient as an individual. Critical thinking attitudes

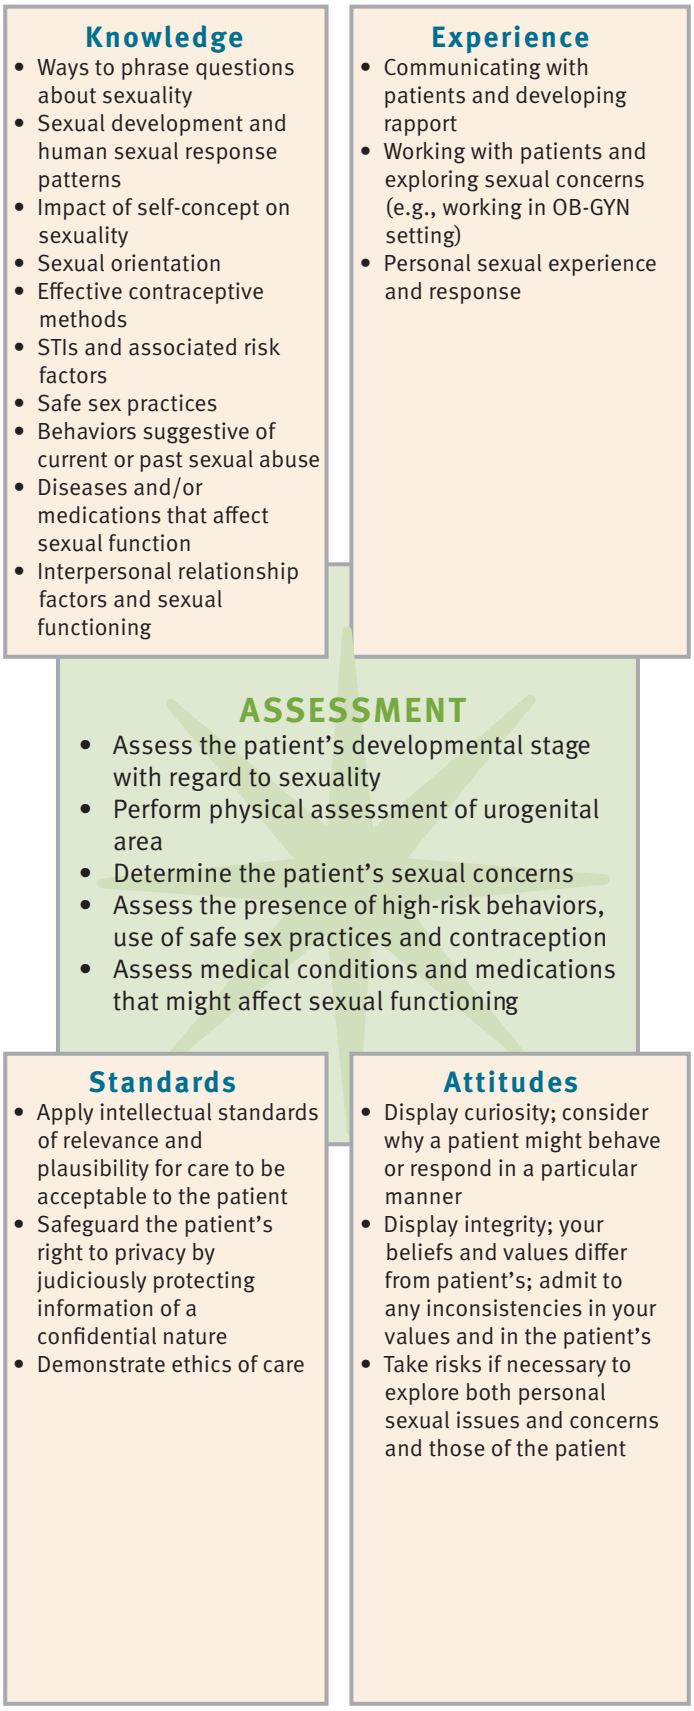

FIG. 34-2 Critical thinking model for sexuality assessment. *OB-GYN,* Obstetric-gynecological; *STI,* sexually transmitted infection.

such as integrity require you to recognize when personal opinions and values are in conflict with those of the patient and to consider how to proceed in a way that is mutually beneficial.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach to help you develop and implement an individualized plan of care. Assess all relevant factors, including physical, psychological, social, and cultural, to determine a patient's sexual well-being. The nursing role in addressing sexual concerns ranges from ongoing assessment to providing information, counseling, and referral. Keep in mind that nurses are not expected to have answers to all sexual issues and concerns identified.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. As in any patient assessment, it is important to understand the patient's expectations regarding care. Questions such as "What would you like to have happen in regard to your sexual health problems?" and "What initial steps might you take?" help the patient identify desired outcomes. It is important to set aside personal views and consider the patient's needs and preferences for care.

Factors Affecting Sexuality. In gathering a sexual history consider physical, functional, relationship, lifestyle, developmental, and self-esteem factors that influence sexual functioning. Sexual desire varies among individuals; some people want and enjoy sex every day, whereas others want sex only once a month, and still others have no sexual desire and are quite comfortable with that fact. Sexual desire becomes an issue if the person wants to satisfy sexual desire more often, if he or she believes that it is necessary to measure up to some cultural norm, or if there is a discrepancy between the sexual desires of the partners in a relationship.

Ask patients to describe factors that typically influence their sexual desire. Knowing the patients' medical history and probing for information is helpful. For example, minor illness, medications, and fatigue often decrease sexual desire. Lifestyle factors such as the use or abuse of alcohol, lack of sleep, lack of time, or the demands of caring for a new baby are other influencing factors. For example, working parents sometimes feel so overburdened that they perceive sexual advances from a partner as an additional demand on them. Confirm factors that potentially affect sexual desire and determine with the patient the extent to which sexual function is impaired.

Self-concept issues (see Chapter 33), including identity, body image, role performance, and self-esteem, affect a patient's sexuality. Consider how these factors relate to the patient's condition. For example, poor body image associated with chronic disease magnifies feelings of rejection. This often results in diminished or absent sexual desire. Problems with a person's self-esteem frequently lead to conflicts involving sexuality. Patients who experience negative feelings often suppress sexual feelings when they have not developed a healthy sense of a sexual self. Low sexual self-esteem negatively affects a person's self-concept.

Issues in a relationship often affect sexual desire. After the initial glow of a new relationship has faded, some couples find that they have major differences in their values or lifestyles. Ask couples to

TABLE 34-1 Signs and Symptoms That Indicate Possible Current Sexual Abuse or a History of Sexual Abuse

TYPES OF FINDINGS	SYMPTOMS OFTEN FOUND IN CHILDREN	SYMPTOMS OFTEN FOUND IN ADULTS
Injuries and/or physical signs	• Bruises, bleeding, soreness, or irritation of external genitalia, anus, mouth, or throat • Sexually transmitted infections • Recurrent urinary tract infections • Unintended pregnancy • Chronic pain • Difficulty walking or sitting • Unusual odor in genital area • Penile discharge • Torn, stained, or bloody underclothing	• Welts, bruising, swelling, scars, burns, or lacerations on arms, legs, breasts, or abdomen • Wounds that do not match the patient's "story" • Multiple bruises in various stages of healing • Vaginal or rectal bleeding • Fractures of face, nose, ribs, or arms • Trauma to labia, vagina, cervix, or anus • Vomiting or abdominal tenderness
Behavior, nonverbal and/or vague somatic complaints	• Physical aggression • Sexual acting out • Excessive masturbation • Expressions of low self-esteem • Poor school performance • Poor peer relationships • Sleep disturbances • Social withdrawal and excessive daydreaming • Running away from home • Substance abuse or suicide attempts	• Facial grimacing • Absence of facial response or flat affect • Anxiety • Depression • Panic attacks • Difficulty sleeping • Anorexia • Slow, unsteady gait

Data from Hockenberry MJ, Wilson D: *Wong's essentials of pediatric nursing,* ed 8, St Louis, 2009, Elsevier; Davidson MR, London ML, Ladewig PA: *Olds' Maternal-newborn nursing & women's health across the lifespan,* ed 8, Upper Saddle River, NJ, 2008, Pearson Prentice Hall; Ball JW, Bindler RC: *Pediatric nursing caring for children,* ed 4, Upper Saddle River, NJ, 2008, Pearson Prentice Hall.

BOX 34-4 PLISSIT ASSESSMENT OF SEXUALITY

Permission to discuss sexuality issues
Limited **I**nformation related to sexual health problems being experienced
Specific **S**uggestions—only when the nurse is clear about the problem
Intensive **T**herapy—referral to professional with advanced training if necessary

Modified from Annon JS: The PLISSIT model: a proposed conceptual scheme for the behavioral treatment of sexual problems, *J Sex Educ Ther* 2(2):1, 1976.

describe how close they feel to each other and how often they interact on an intimate level. Assess communication patterns between sexual partners to determine sexual satisfaction within a relationship.

Sexual Health History. Most patients want to know how medications, treatments, and surgical procedures influence their sexual relationship even though they often do not ask questions. With experience nurses recognize that most patients welcome the opportunity to talk about their sexuality, especially when they are experiencing difficulties. The PLISSIT assessment model helps nurses discuss sexuality with patients in a relaxed, matter-of-fact manner (Wallace, 2008) (Box 34-4).

Incorporate assessment questions related to sexuality in the nursing history (Box 34-5). Using an opening statement puts the patient at ease when introducing these questions (e.g., "Sex is an important part of life, and a person's health status often affects sexuality. Many people have questions and concerns about their sexual health. What questions or concerns do you have now?"). Use knowledge of developmental stages to determine which areas are likely to be important for the patient. For example, when gathering a sexual history from an older adult, it is important to keep in mind that some have difficulty discussing intimate details with health care providers.

BOX 34-5 NURSING ASSESSMENT QUESTIONS

- Are you sexually active?
- With whom do you have sex: men, women, or both?
- How many sexual partners do you have (or have you ever had)?
- How do you feel about the sexual aspects of your life?
- Have you noticed any changes in the way you feel about yourself?
- How has your illness, medication, or surgery affected your sex life?
- It is not unusual for people with your condition to be experiencing some sexual changes. Have you noticed any changes or do you have any concerns?
- Are you in a relationship in which someone is hurting you?
- Has anyone ever forced you to have sex against your will?
- Tell me what you know about safe sex practices, use of contraceptives, or prevention of sexually transmitted infections.

Nurses who conduct sexual assessments of children and adolescents face special challenges. Use language that is accurate and that the child or adolescent understands. Also promote normal development, avoid minimizing problems, and screen for sexual concerns while making the child or adolescent feel at ease. The sexual counseling of minors raises ethical and legal issues regarding the patient's rights to health care and education on the one hand and the parents' or guardian's right to supervise information on the other. Children and adolescents frequently respond when they know that having questions related to sexuality is normal. Being open, positive, and interested when introducing sexual questions is helpful.

In light of the prevalence of domestic violence and sexual abuse, questions relating to abusive relationships are important. Address these questions in private. Recognizing both subjective and objective signs and symptoms of abuse in children and adults aids in identification of this too-common problem (Table 34-1).

Some individuals are too embarrassed or do not know how to ask sexual questions directly. Look for clues that a person has questions. For example, a patient expresses concern about how his or her partner will respond now or makes a sexual comment or joke. Observing for and listening to concerns about sexuality take practice. With experience a nurse develops skill in clarifying and paraphrasing to help individuals express sexual concerns. By including sexuality in the nursing history, the nurse acknowledges that sexuality is an important component of health and creates an opportunity for the person to discuss sexual concerns.

Sexual Dysfunction. Many illnesses, injuries, medications, and aging changes have a negative effect on sexual health. Sexual dysfunction is either temporary or permanent. Apply knowledge about conditions that frequently cause sexual dysfunction while assessing a patient's risks (see Box 34-3). Awareness of the possible effects of physical problems, altered self-concept, medications, and the factors addressed thus far on sexual functioning helps in conducting a thorough assessment. Some patients bring up the topic of sexual dysfunction. Other times issues become evident as the patient answers other nursing history questions.

Physical Assessment. The physical examination is important in evaluating the cause of sexual concerns or problems and usually provides the best opportunity to teach an individual about sexuality. In examining a woman's breasts and the external and internal genitalia, a nurse has the opportunity to assess the woman's reaction, answer questions, and provide information about the examination of anatomical and physiological structures. For example, a nurse teaches a woman how to perform breast self-examination during physical assessment (see Chapter 30). During physical assessment of the genitalia, he or she teaches men how to perform testicular self-examination (see Chapter 30). Knowledge of normal scrotal anatomical structures helps men detect signs of testicular cancer. Instruct both men and women on signs and symptoms of STIs during the examination when patients' histories suggest risks for STIs.

NURSING DIAGNOSIS

After completing an assessment and applying critical thought to the diagnostic process, select diagnoses applicable to the patient's needs. Possible nursing diagnoses related to sexual functioning are listed here:

- Anxiety
- Ineffective coping
- Interrupted family processes
- Deficient knowledge (contraception/STIs)
- Sexual dysfunction
- Ineffective sexuality pattern
- Social isolation
- Risk for other-directed violence
- Risk for self-directed violence

Assessment data that signal a nursing diagnosis related to sexuality often include history of surgery of reproductive organs, changes in appearance or body image, a history of or current physical or sexual abuse, chronic illness, or developmental milestones such as puberty or menopause. To make a nursing diagnosis related to sexual dysfunction, consider anatomical, physiological, sociocultural, ethical, and situational issues thoroughly.

As with making any nursing diagnosis, clarify that the defining characteristics exist and that the patient perceives a problem or difficulty with regard to sexuality (Box 34-6). Determining the etiological or contributing factors helps in planning effectively and selecting the appropriate nursing interventions. For example, the nursing interventions appropriate for the nursing diagnosis of *sexual dysfunction* are different for different etiological factors. *Sexual dysfunction related to misinformation about the risk of sexually transmitted infections* requires counseling and education on how to maintain safe sexual practices. In contrast, patients who experience *sexual dysfunction related to physical abuse* need counseling and referral to community resources (e.g., crisis services and physical abuse support group).

BOX 34-6 NURSING DIAGNOSTIC PROCESS

Sexual Dysfunction

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Review medical and medication history	History of hypertension History of uncomplicated MI Takes propranolol (Inderal)
Have patient describe sexual problems	Less interested in having intercourse with wife since taking propranolol (Inderal) Rarely has sexual intercourse with wife Sometimes has trouble having an erection
Patient's fears and concerns	Fearful will have chest pain or another MI while having intercourse

PLANNING

Goals and Outcomes. Synthesize information from multiple resources to develop an individualized plan of care (Fig. 34-3). Critical thinking ensures that the patient's plan of care integrates all that a nurse knows about the individual and critical thinking elements as they pertain to sexuality. Professional standards are especially important to consider when developing a plan of care. Maintain a patient's dignity and identity at all times. For example, to convey respect for the patient's gender preferences, include a lesbian or gay partner in the plan to the degree that the patient wishes.

Develop an individualized plan of care for each nursing diagnosis (see the Nursing Care Plan). Set realistic goals and measurable outcomes with the patient. For example, a patient who has dyspareunia has a nursing diagnosis of *sexual dysfunction related to decreased sexual desire*. The nurse and patient develop a goal to report decreased anxiety and greater satisfaction with sexual activity within 1 month. Expected outcomes include that the patient will do the following:

- Consistently use a water-soluble lubricant before sexual intercourse within 1 week
- Discuss stressors that contribute to sexual dysfunction with partner within 2 weeks
- Identify alternative, satisfying, and acceptable sexual practices for self and partner within 4 weeks

A concept map is another method that is useful in organizing patient care (Fig. 34-4). The concept map shows the relationship of a medical diagnosis (decreased libido and depression) to the four nursing diagnoses identified from the patient assessment data. It also shows the links and relationship to the nursing diagnosis and interventions appropriate for each diagnosis. For example, *ineffective coping* affects and contributes to social isolation; and as long as the patient has ineffective coping, the social isolation continues or perhaps worsens.

NURSING CARE PLAN

Sexual Dysfunction

ASSESSMENT

Mr. Clements is a 65-year-old African American patient who had an uncomplicated myocardial infarction (MI) 3 days ago. He is stable and experienced no complications following his MI. He currently is on a cardiac telemetry nursing unit. According to Mr. Clements' medical record, he last visited his advanced practice nurse in the office 2 months ago and was diagnosed with hypertension. He was given a prescription for propranolol (Inderal). Mr. Clements is married and lives with his wife.

His blood pressure today is 122/82 mm Hg. Mr. Clements reports that he has been taking his medication regularly. The nurse knows that patients who have had MIs and are taking antihypertensive medications often experience sexual problems. When assessed by the nurse, Mrs. Clements expresses that she is still interested in having a sexual relationship with her spouse.

Assessment Activities	*Findings/Defining Characteristics**
Ask Mr. Clements if his interest in sex has changed since he started taking propranolol.	He responds that he has been **less interested in having sexual intercourse with his wife** since he started taking propranolol.
Ask Mr. Clements to compare his sexual relationship with his wife before and after taking propranolol.	He states they used to have intercourse 1 to 3 times per week, and since he started taking propranolol **they rarely have intercourse.**
Ask Mr. Clements if he has noticed any changes in his erect penis.	He states that he **sometimes has trouble having an erection.**
Ask Mr. Clements what concerns or fears he has about resuming his sexual relationship with his wife now that he has had an MI.	He states that **he is afraid that after discharge he will have chest pain or another heart attack if he has sexual intercourse** with his wife.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Sexual dysfunction related to altered body function (side effects of propranolol) and lack of knowledge.

PLANNING

Goal	*Expected Outcomes (NOC)*†
Patient will express satisfaction with sexual relationship with wife within 1 month.	**Sexual Functioning** Patient will express renewed sexual interest within 2 weeks. Patient will sustain arousal through orgasm within 3 weeks.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Sexual Counseling	
Establish trust and respect with Mr. Clements. Offer privacy during conversations.	Establishing trust and offering privacy express sense of caring, increasing likelihood of patient's ability to express concerns (Wallace, 2008). Advancing age and fear of embarrassment are major barriers to discussing erectile dysfunction (Green and Kodish, 2009).
Discuss possible effects of MI and propranolol on sexual functioning and when it is safe to resume sexual intercourse (within 7-10 days after an uncomplicated MI) (Steinke and Jaarsma, 2008).	Discussion enhances understanding about reasons for sexual difficulties and provides safe guidelines for resumption of sexual intercourse following MI (Adams and Holland, 2011).
Include Mrs. Clements in discussions about sexual issues as frequently as possible and when appropriate.	Including partner in the plan of care helps patients cope better with problems (Wallace, 2008).
Anxiety Reduction	
Encourage Mr. Clements to express fears about resuming sexual activity and assure him that others who have had MIs experience similar fears.	Knowing that feelings and fears are normal helps decrease anxiety and encourages return of sexual activity (Wallace, 2008).

‡Intervention classification labels from Bulechek GM, Butcher HK, Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Mr. Clements if he and his wife are satisfied with their sexual relationship during return office visit.	Mr. Clements reports that his interest in sex is back to normal and he is able to have an erection.	Mr. Clements reports sexual interest and function; he and his wife are satisfied with their relationship.

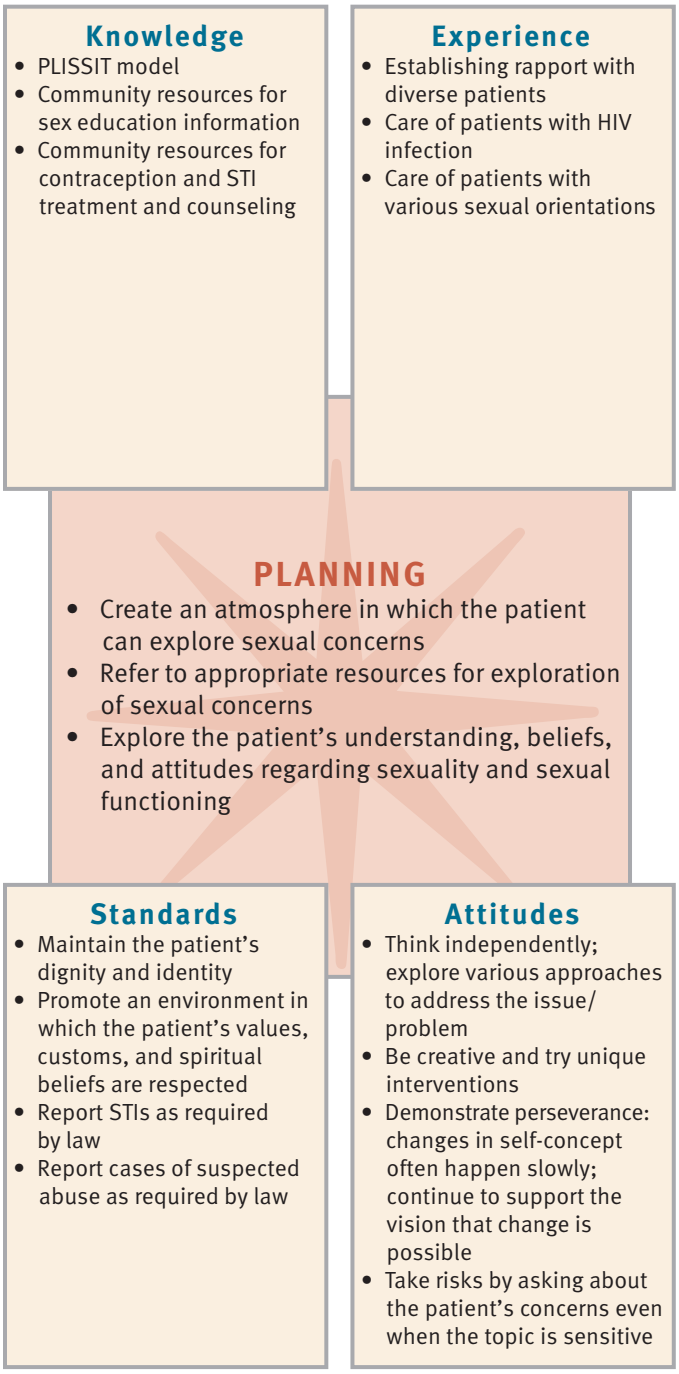

FIG. 34-3 Critical thinking model for sexuality planning. *HIV,* Human immunodeficiency virus; *STI,* sexually transmitted infection.

Setting Priorities. The care plan shows the goals, expected outcomes, and interventions for a patient experiencing sexual dysfunction. Nursing interventions for patients with sexual concerns focus on supporting the patient's need for intimacy and sexual activity. Patients often feel overwhelmed and hopeless about returning to the level of previous sexual functioning. They usually need time to adapt to physical and psychosocial changes that affect their sexuality and sexual health.

The priority in addressing needs related to sexuality includes establishing a therapeutic relationship so the patient feels comfortable in discussing issues related to sexuality. Look for strengths in both the patient and the family while providing education and access to resources to turn limitations into strengths. Patient teaching communicates the normalcy of feelings following certain situations (e.g., the diagnosis of a chronic illness or the loss of a body part). The nurse determines the patient's needs and plans accordingly.

The patient's current problems and needs help the nurse determine the priorities related to the patient's sexual health. Priorities for sexual health often include resuming sexual activities. For example, if the patient is recovering from a mastectomy and is having problems resuming an intimate relationship with her spouse because of problems related to body image, the nurse helps her adapt to and cope with the changes in her body image associated with the mastectomy. Once the patient's issues related to body image are resolved, she is able to restore intimacy with her spouse and address her sexual health needs.

Teamwork and Collaboration. Planning in the area of sexuality often includes collaboration with other health care providers and referrals to community resources (Box 34-7). Nurses generally raise awareness of sexual issues, help to clarifying concerns, and/or provide information. Nurses who have specialized education in sexual functioning and counseling provide more intensive sex therapy. It is necessary to understand the limits of your knowledge base and include other health care providers such as sex therapists, clinical psychologists, and social workers as appropriate to meet patients' needs for sexual health. For example, conflicts in marriage usually require intensive treatment with a mental health professional or certified sex therapist. For the woman who is currently in an abusive relationship, the nurse collaborates with special women's shelters that provide counseling and serve as a safe place for her while further plans are made.

BOX 34-7 EXAMPLES OF COMMUNITY RESOURCES RELATING TO SEXUALITY

- Planned Parenthood
- Health department (often for both family planning and sexually transmitted infections)
- Groups that provide education/services for those with particular conditions include the following:
  - American Diabetes Association
  - American Heart Association
  - Muscular Dystrophy Association
  - Muscular Sclerosis Society
- Sexual abuse support groups and hot lines
- Women's shelters (for those who have been physically and/or sexually abused)
- Resolve: The National Infertility Association (http://www.resolve.org)
- North America Menopause Society (http://www.menopause.org)

IMPLEMENTATION

As a nurse, promote sexual health as a component of overall wellness by identifying patients at increased risk (Box 34-8), providing appropriate information, helping individuals gain insight into their problems, and exploring methods to deal with them effectively.

Health Promotion. Helping patients maintain or gain sexual health involves consideration of factors that influence sexual satisfaction. Educate patients about sexual health, including measures for contraception, safe sex practices, and prevention of STIs.

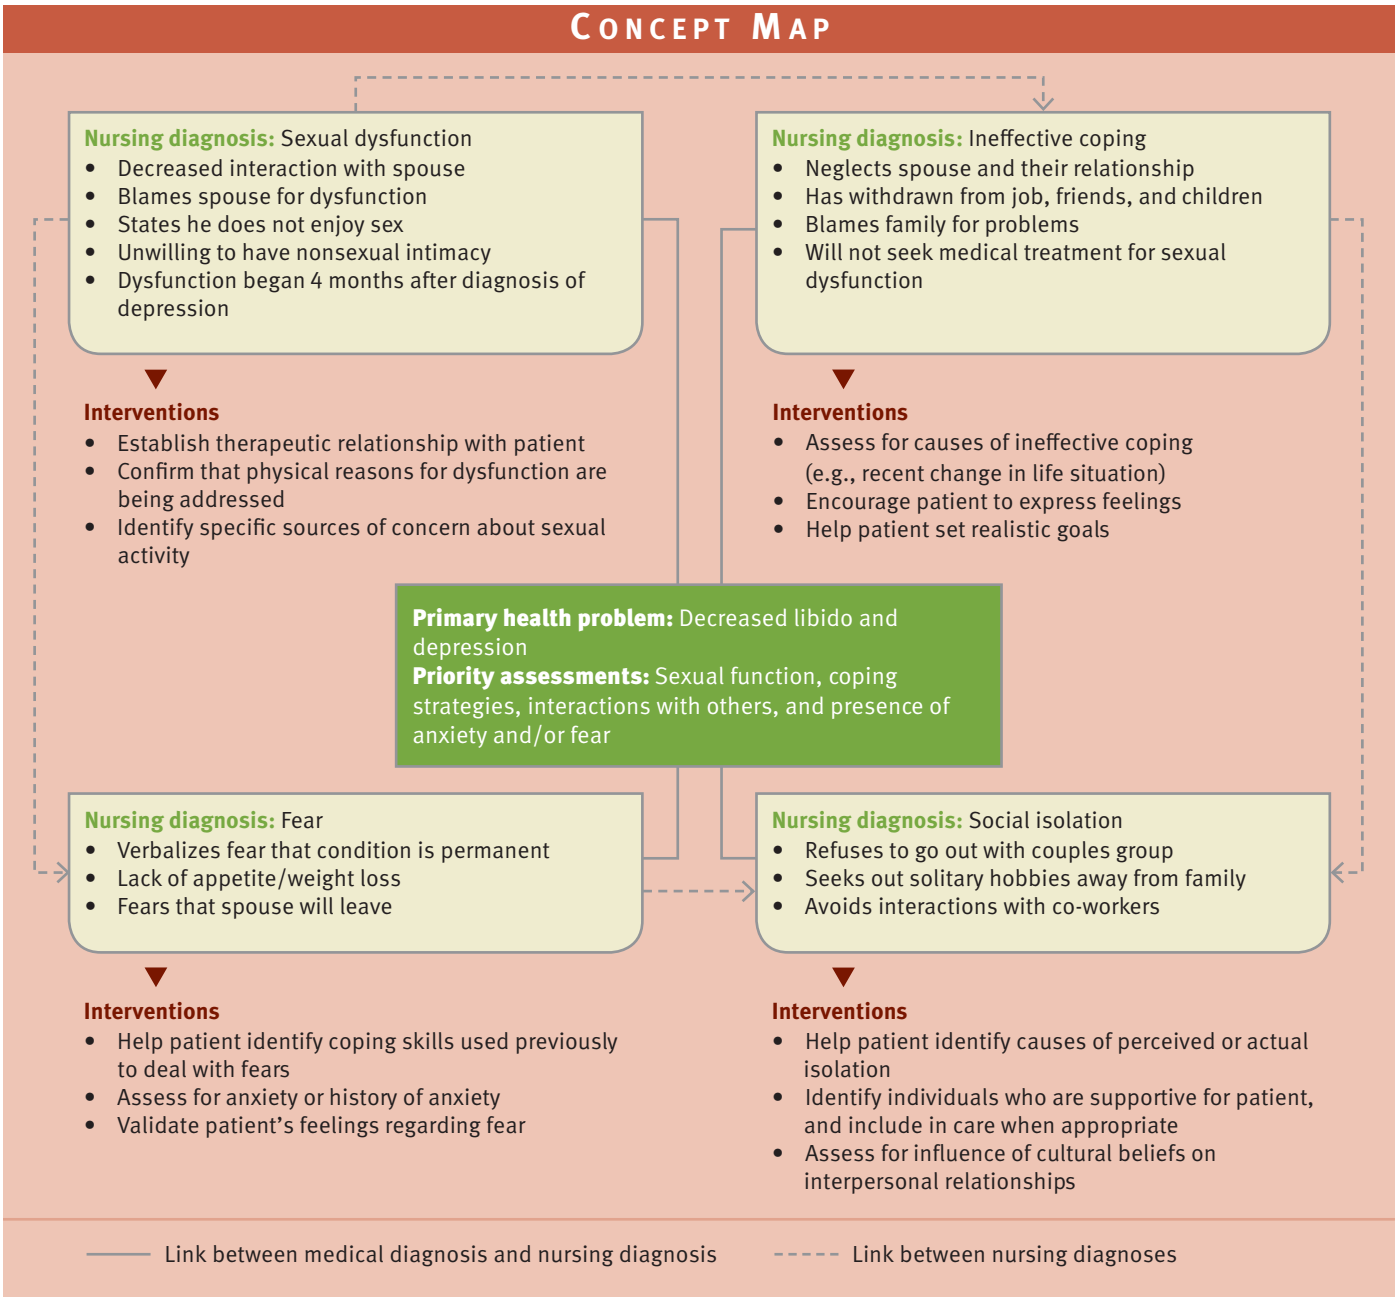

FIG. 34-4 Concept map for Mr. Clements.

Regular breast self-examinations, mammograms, and Papanicolaou (Pap) smears are important sexual health measures for women; testicular self-examinations are important for men. Offer the HPV vaccine to males and females who are between 9 and 26 years of age. The vaccine is safe for girls as young as 9 years old and is recommended for females ages 13 to 26 if they have not already completed the three required injections. Booster doses currently are not recommended. The vaccine is most effective if administered before sexual activity or exposure (CDC, 2010b; Palefsky, 2010).

Exploring an individual's values, discussing levels of satisfaction, and providing sex education require therapeutic communication skills. Structure the environment and timing to provide privacy, comfort, and uninterrupted time (Wallace, 2008). For example, when discussing methods of contraception with a woman, provide education in a private area with the patient fully dressed rather than in the examination room when the patient is only partially clothed.

Topics of education vary and often are related to the patient's developmental level. For example, a nurse talks to school-age children regarding the appearance of breast buds or pubic hair. When discussing sexual health with patients of childbearing age, always consider the patient's cultural and religious beliefs regarding contraception. The discussion includes the desire for children, usual sexual practices, and acceptable methods of contraception. Nurses review all methods of contraception to allow patients to make informed decisions.

Major developmental crises (e.g., puberty, **climacteric,** or menopause) prompt education about sexuality. Situational crises

BOX 34-8 EVIDENCE-BASED PRACTICE

Health Risk Behaviors Associated with Body Art

PICO Question: Do American college students who have body art participate in high-risk behaviors more frequently than college students without body art?

Evidence Summary

Body piercing and tattoos are becoming more prevalent and socially acceptable across all ages of society. They are associated with health risks ranging from local or systemic infection, even to death (Hayward and Tindale, 2008). Studies show that adolescents with multiple piercings are more predisposed to high-risk behaviors and confirm a positive correlation between the incidence of body art (tattoos, piercings) and deviance in college students (Koch et al., 2010; Rivardo and Keelan, 2010). Illegal deviant behaviors included in the study were regular marijuana use, occasional use of other illegal drugs, and a history of arrest for crimes. Legal deviant behaviors involved cheating on college assignments, multiple sex partners, and binge drinking. Individuals with four or more tattoos were 2 to 10 times more likely than those with no tattoos to report deviance. Participants reporting seven or more body piercings or piercings located in the nipples or genitals were 2 to 4 times more likely than those without intimate piercings to report regular marijuana use, occasional use of other illegal drugs, and a history of arrest for crimes. Students with higher occurrence of body art were also more likely to cheat on college assignments, binge drink, report sexual activity at a younger age, and have multiple sex partners.

Application to Nursing Practice

- Nurses need to be aware of health risks associated with piercing and tattoos.
- Individuals with multiple tattoos and piercings, especially intimate piercings, are often at increased risk for drug abuse and sexually transmitted infections.
- Routinely assess patients with body art for signs of local and systemic infection; educate about common symptoms they may experience.
- Provide education to patients with body art about safe sex practices, contraception, sexually transmitted infections, and the importance of related health screenings.

BOX 34-9 PATIENT TEACHING

Using a Condom Correctly

Objective

- Patient will verbalize correct use of a condom.

Teaching Strategies

- Develop a trusting relationship with patient.
- Explain to patient to always use a latex or rubber condom when having vaginal, oral, or anal sex and to store condoms in a cool, dry place away from sunlight.
- Encourage patient to read the label on the condom package to check the expiration date and ensure that the condom protects against sexually transmitted infections.
- Instruct patient to never reuse a condom or use a damaged condom.
- Explain how to correctly apply the condom (e.g., put it on as soon as the penis is hard and before vaginal, anal, or oral contact; gently squeeze any air out from the tip of the condom, leaving space for semen; unroll the condom to the base of the penis).
- Teach patient to pull out right after ejaculating and hold onto the condom when pulling out.
- Instruct patient to only use water-based lubricants (e.g., K-Y jelly) to prevent the condom from breaking; do not use petroleum jelly, massage oils, body lotions, or cooking oil.

Evaluation

- Ask patient to describe where condoms are stored.
- Ask patient questions that verify understanding of instruction (e.g., What would you do if you noticed that a condom you just opened had an open slit in it?).

such as a life change with pregnancy, illness, extreme financial stress, placement of a spouse in a nursing home, or loss and grief affect sexuality. Effects can last for days, months, or years and are often minimized when the individual is prepared for possible changes in sexual functioning.

Demonstrate recognition, acceptance, and respect for an older adult's sexuality by displaying a willingness to openly discuss sex and sexuality-related concerns. Strategies that enhance sexual functioning include the following (Kautz and Upadhyaya, 2010):

- Avoid alcohol and tobacco.
- Eat well-balanced meals.
- Plan sexual activity for times when the couple feels rested.
- Take pain medication if needed before sexual intercourse.
- Use pillows and alternate positioning to enhance comfort.
- Encourage touch, kissing, hugging, and other tactile stimulation.
- Communicate concerns and fears with partner and health care provider.

Individuals who have more than one sex partner or whose partner has other sexual experiences need to learn about safe sex practices. Provide information about STI symptoms and transmission, use of condoms, and risky sexual activities (e.g., trauma from penile-anal sex). To prevent HIV infection, teach patients to avoid having multiple sex partners and use condoms to reduce the risk of HIV/AIDS. Role play is useful in helping a person learn to say no or negotiate with a partner to use a condom (Box 34-9). Also teach patients to avoid the use of IV drugs. If people do use IV drugs, tell them to avoid sharing needles with others and to always use new needles. When discussing safe sex, consider patients' physical and emotional health.

Encourage patients to have regular health examinations to maintain sexual health. Often asymptomatic STIs are diagnosed during a physical examination with appropriate laboratory work. Annual health examinations provide an opportunity to discuss contraception and safe sex practices. However, some people do not routinely seek annual health examinations. Barriers to health screenings include cultural beliefs, low socioeconomic status, and low health literacy (Hogben and Leichliter, 2008; Shaw et al., 2009). Consider cultural implications as well. For example, Arab women frequently do not have breast examinations, mammograms, and cervical cancer screening because of religious and cultural beliefs about modesty (Cohen and Azaiza, 2010). Develop a therapeutic relationship with patients and provide culturally sensitive education that is written at an appropriate reading level (see Chapter 25). Encourage patients to find health care providers that they can trust and help patients who are uninsured or underinsured locate resources that can help them pay for important sexual health screenings (Hogben and Leichliter, 2008).

Acute Care. Illness and surgery create situational stressors that often affect a person's sexuality. During periods of illness individuals experience major physical changes, the effects of drugs or treatments, the emotional stress of a prognosis, concern about

future functioning, and separation from significant others. Never assume that sexual functioning is not a concern merely because of an individual's age or severity of prognosis. After identifying concerns, address them in the context of his or her value system.

When a patient identifies sexual concerns, initiate discussion and education appropriately. Help patients to anticipate how their illness or disease will change over time and the adjustments that will be necessary to achieve sexual fulfillment.

Restorative and Continuing Care. Frequently nurses establish relationships with couples that encourage honest and open discussions about sexual health during restorative or continuing care. Address needs by taking a sexual health history and implementing a basic model such as PLISSIT to provide options for patients (see Box 34-4). Assessment and management of sexual concerns are important when promoting sexual intimacy and providing closeness and closure between partners at the end of life.

In the home environment it is important to provide information on how an illness limits sexual activity and give ideas for adapting or facilitating sexual activity. Interventions range from giving permission for a partner to lie in bed and hold a patient to coordinating nursing care and medications to provide opportunity for privacy and intimacy. Often nurses help individuals create an environment that is comfortable for sexual activity in the home. This sometimes involves making recommendations for ways to arrange the bedroom to accommodate physical limitations. For example, some individuals who are in a wheelchair prefer being able to move the chair close to the side of the bed at an angle that allows for more ease in touching and caressing. Suggestions regarding how to accommodate barriers such as Foley catheters or drainage tubes contribute to sexual activity.

In the long-term care setting facilities need to make proper arrangements for privacy during residents' sexual experiences (Frankowski and Clark, 2009). The ideal situation is to set up a pleasant room that is used for a variety of activities that the resident is able to reserve for private visits with a spouse or partner. If this is not possible, make arrangements for the roommate of a patient to be somewhere else to allow a couple time alone. Never leave patients alone in a situation in which they can injure themselves.

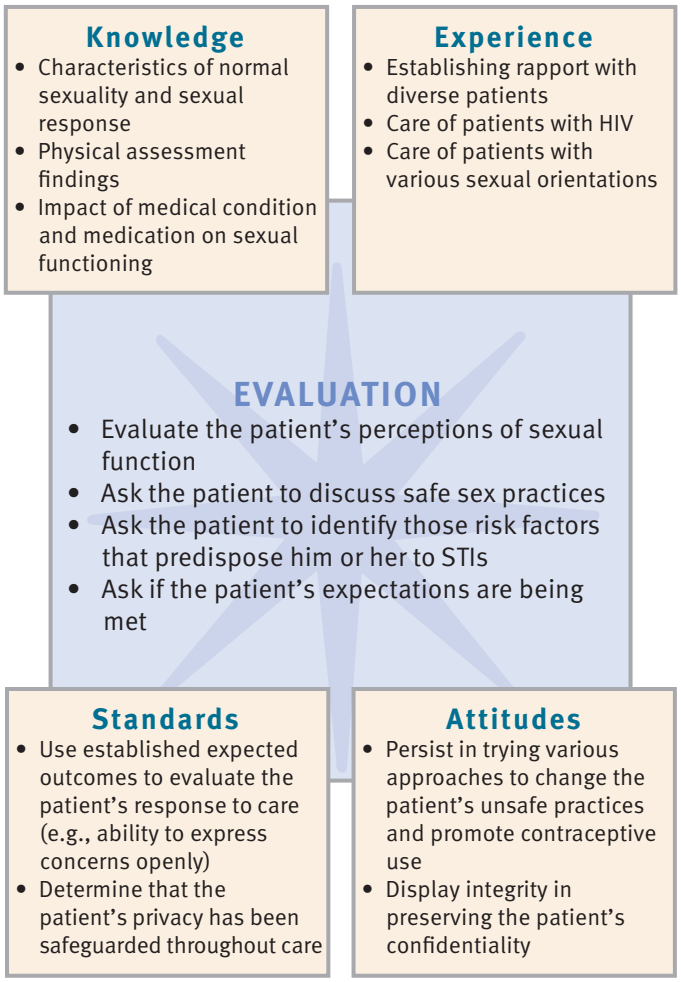

FIG. 34-5 Critical thinking model for sexuality evaluation. *HIV,* Human immunodeficiency virus; *STI,* sexually transmitted infection.

EVALUATION

Through the Patient's Eyes. Evaluate patient responses to nursing interventions to determine if goals and outcome criteria have been met (Fig. 34-5). Critical thinking ensures that the nurse applies what is known about sexuality and the patient's unique situation.

Have follow-up discussions with the patient or partner to determine whether goals and outcomes have been achieved. Sexuality is felt more than observed, and sexual expression requires an intimacy that is not amenable to observation. Therefore ask patients questions about risk factors, sexual concerns, and their level of satisfaction. Observe behavioral cues such as eye contact, posture, and extraneous hand movements that indicate comfort or suggest continued anxiety or concern as topics are addressed. Anticipate the need to modify expectations with the individual and partner when evaluating outcomes. Sometimes a nurse needs to establish more appropriate time frames in which to achieve the target goals. Ask patients to define what is acceptable and satisfying while considering the partner's level of sexual satisfaction.

Patient Outcomes. When outcomes are not met, begin to ask questions to determine appropriate changes in interventions. Examples of questions include the following:

- What other questions do you have about your sexual health?
- Did you experience less pain during sexual intercourse after taking your pain medication?
- Which positions did you find most comfortable when you had sexual intercourse? Which positions were most awkward?
- What barriers are preventing you from discussing your feelings and fears with your partner?

KEY POINTS

- Sexuality is related to all dimensions of health; therefore address sexual concerns or problems while providing routine nursing care.
- Sexuality is a part of each individual's identity and includes biological sex, gender identity, gender role, and sexual partner preference.
- Attitudes toward sexuality vary widely. Religious beliefs, values of society, the media, the family, and other factors all influence it.
- Nurses' attitudes toward sexuality vary and often differ from those of patients; be sensitive to patients' sexual preferences and needs.
- Sexual development begins in infancy and involves some level of sexual behavior or growth in all developmental stages.

- The physiological sexual response changes with aging, but aging does not lead to diminished sexuality.
- Sexual health contributes to an individual's sense of self-worth and positive interpersonal relationships.
- Sexual dysfunctions result from varied and complex etiologies.
- Interventions for sexual dysfunctions depend on the condition and the patient; they often include giving information, teaching specific exercises, improving communication between partners, and referral to a knowledgeable professional.
- Sexual biases, comfort with touching genitalia, desire for future fertility, financial status, ability to plan sexual contact, and ability to communicate with the sex partner all affect the choice and use of effective contraceptive methods.
- Include a brief review of sexuality whenever assessing a patient's level of wellness.
- Most nursing interventions that enhance sexual health require providing education.
- Evaluate outcomes of care by talking with patients regarding satisfaction with sexual functioning and through observations of nonverbal behaviors that suggest anxiety. Include the partner when appropriate.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Mr. Clements returns to see the advanced practice nurse (APN) in his cardiologist's office for a routine visit. During the visit the APN plans to assess Mr. Clements' sexuality. What can the APN do to help Mr. Clements feel comfortable in discussing his sexuality? Develop an opening statement that would be effective in decreasing his anxiety about discussing this private aspect of his life.
2. During the office visit Mr. and Mrs. Clements state that, although they are able to engage in sexual intercourse, it is taking both of them longer to reach orgasm. Explain why they are experiencing this change and describe at least three strategies that they could use to enhance their sexual functioning.
3. Mrs. Clements vocalizes concern about continuing sexual activity because Mr. Clements sometimes becomes short of breath during intercourse. She also says he seems to have less energy by the end of the day than before the MI. Using the PLISSIT model, give two examples of specific suggestions that the APN might give to the couple.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse is providing education on sexually transmitted infections (STIs) to a group of adolescents. The nurse knows that further teaching is needed when one of the adolescents states:
   1. "A vaccine is available to reduce infection from certain types of human papillomavirus."
   2. "I should be screened for an STI after I am with a new partner."
   3. "I know I'm not infected if I don't have any symptoms such as discharge or sores."
   4. "A viral infection such as herpes or human papillomavirus cannot be treated with antibiotics."
2. A 25-year-old patient is in the emergency department and states that she has had a cough and fever for the past 3 days. While performing a physical assessment, the nurse finds several bruises that are in various stages of healing and suspects that the patient possibly is a victim of sexual abuse. Which of the following is the nurse's first action?
   1. Refer the patient to a sexual counselor
   2. Tell the patient about the safe house for women
   3. Ask the patient to describe how she got the bruises
   4. Report the abuse immediately to the proper authorities
3. A 26-year-old married woman recently discovered that she is pregnant and is at her first prenatal visit. While assessing the patient, the woman's health nurse practitioner discovers that she has purulent vaginal discharge. The patient states, "It burns when I urinate, and I seem to have to go to the bathroom frequently." Based on these symptoms, the nurse practitioner determines that further follow-up is needed because the patient:
   1. Should be tested for human immunodeficiency virus (HIV).
   2. May have a sexually transmitted infection (STI) such as chlamydia.
   3. Is experiencing normal signs of pregnancy.
   4. Needs education on proper perineal hygiene.
4. A new graduate nurse is working in a rehabilitation center that specializes in the care of patients with spinal cord injuries (SCIs). The new graduate knows that sexual issues are common among patients with SCIs. Which of the following actions enhances the nurse's comfort in discussing sexual issues with the patients? (Select all that apply.)
   1. Clarifying personal values related to sexuality
   2. Role playing discussion of sexual concerns with another nurse
   3. Attending a conference to enhance knowledge about sexuality
   4. Avoiding a discussion of sexual concerns until after completing new nurse orientation
5. The nurse is gathering a sexual history from a 68-year-old man in a nursing home. It is important for the nurse to keep in mind that:
   1. Older adults are usually not part of a sexual minority group.
   2. Older adults sometimes do not reveal intimate details.
   3. Older men and women lose their interest in sex.
   4. Older adults in nursing homes do not usually participate in sexual activity.
6. Certain cultural groups in the United States are disproportionately affected by diseases such as human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS). The nurse understands that this is most likely caused by: (Select all that apply.)
   1. Expectations about behavior by men or women in the culture.
   2. Higher percentages of lesbian, gay, bisexual, or transgender individuals in the culture.
   3. Genetic predisposition to the disease in the culture
   4. Communication patterns and language practiced by the culture.
7. Since the majority of sexually transmitted infections (STIs) have few if any symptoms, it is important for the nurse to:
   1. Encourage regular screenings in all sexually active individuals.
   2. Provide information about contraception options.

3. Administer prescribed antibiotics for human papillomavirus (HPV) or genital herpes outbreaks.
4. Ask all patients if they are experiencing any symptoms.

8. Establishing trust and encouraging disclosure about sexuality are often facilitated if the nurse begins by asking the patient:
   1. How often he or she has sexual intercourse.
   2. To disrobe in preparation for the physical assessment.
   3. For permission to discuss sexual issues.
   4. For specific examples of sexual practices and problems.
9. A 15-year-old girl states that she is having unprotected intercourse with her boyfriend. She asks for more information about birth control methods. The nurse informs the patient that: (Select all that apply.)
   1. Condoms or diaphragms must be used with each sexual encounter.
   2. Hormonal methods offer little protection against sexually transmitted infections (STIs).
   3. Barrier methods offer some protection against STIs.
   4. Sterilization is an effective option that she should consider.
10. The nurse reviews the health history of a 24-year-old woman who indicates that she has had three new sexual partners since her previous examination 2 years ago. The nurse discusses the need for sexually transmitted infection (STI) screening with the patient even though she denies symptoms or discomfort. The nurse realizes that the most serious complication from untreated STIs in females is:
    1. Genital discharge and dyspareunia.
    2. Painful menstrual cycles.
    3. Infertility and pelvic inflammatory disease.
    4. Genital warts.
11. The nurse is providing education about condom use at a community clinic for older adults. Which of following statements demonstrates that the adults understand correct use of condoms? (Select all that apply.)
    1. "I can use any kind of lubricant such as lotions or baby oil."
    2. "Before using the condom, I should check the package for damage or expiration."
    3. "I need to use a condom to help reduce the risk of sexually transmitted infections."
    4. "A good place to store condoms is in the bathroom so they don't dry out."
12. Which of the following represents a nonjudgmental approach when gathering a sexual health history?
    1. How do you and your wife/husband feel about intimacy?
    2. Do you have sex with men, women, or both?
    3. Are you heterosexual or homosexual?
    4. What is your sexual orientation?
13. A 54-year-old male patient who is being seen for an annual physical tells the nurse that he is having difficulty sustaining an erection. The nurse reviews his health history and notes no current health problems except medical treatment for depression. The nurse understands that:
    1. A personal issue such as this is best addressed by the male physician during the examination.
    2. Erectile dysfunction affects most men over the age of 50.
    3. The patient needs to be screened for sexually transmitted infections (STIs).
    4. Antidepressant medication may be affecting his sexual functioning.
14. The nurse at a community health center is teaching a group of menopausal women about normal changes in the female sexual response that occur with aging. The nurse knows that the information is understood when one of the women states that:
    1. It's normal for me to take longer to reach an orgasm.
    2. I might experience chest pain or shortness of breath during intercourse.
    3. It's normal for me to lose interest in sexual relationships.
    4. I won't need to be concerned about contraception or sexually transmitted infections because of my age.
15. A school nurse is completing a health history on an adolescent female and notices several body piercings and tattoos. The student tells the nurse that she is planning to get more tattoos and piercings over the summer break. The nurse tells the student piercing and tattoos can:
    1. Prevent you from being involved in contact sports.
    2. Only create health problems if they are located in the nipples or genital area.
    3. Increase your risk for infection at the site and in the body.
    4. Be a safe and important way of establishing your personality.

Answers: **1.** 3; **2.** 2; **3.** 2; **4.** 1, 2, 3; **5.** 2; **6.** 1, 4; **7.** 1; **8.** 3; **9.** 2, 3; **10.** 3; **11.** 2, 3; **12.** 2; **13.** 4; **14.** 1; **15.** 3.

CHAPTER

35

Spiritual Health

OBJECTIVES

- Discuss the influence of spiritual practices on the health status of patients.
- Describe the relationship among faith, hope, and spiritual well-being.
- Compare and contrast the concepts of religion and spirituality.
- Perform an assessment of a patient's spirituality.
- Explain the importance of establishing a caring relationship with patients to gain spiritual insight.
- Discuss nursing interventions designed to promote spiritual health.
- Establish presence with patients.
- Evaluate how patients attain spiritual health.

The word *spirituality* derives from the Latin word *spiritus,* which refers to breath or wind. The spirit gives life to a person. It signifies whatever is at the center of all aspects of a person's life (Smith, 2008). Florence Nightingale believed that spirituality was a force that provided energy needed to promote a healthy hospital environment and that caring for a person's spiritual needs was just as essential as caring for his or her physical needs (Dolamo, 2010). Today **spirituality** is often defined as an awareness of one's inner self and a sense of connection to a higher being, nature, or some purpose greater than oneself (Smith, 2008; Vachon, Fillion, and Achille, 2009). A person's health depends on a balance of physical, psychological, sociological, cultural, developmental, and spiritual factors. Spirituality is important in helping individuals achieve the balance needed to maintain health and well-being and cope with illness. Research shows that spirituality positively affects and enhances health, quality of life, health promotion behaviors, and disease prevention activities (Jurkowski, Kurlanska, and Ramos, 2010; Lee, 2009).

Too often nurses and other health care providers fail to recognize the spiritual dimension of their patients because spirituality is not scientific enough, it has many definitions, and it is difficult to measure. In addition, some nurses and health care providers do not believe in God or an ultimate being, some are not comfortable with discussing the topic, and others claim that they do not have time to address spiritual needs (Tanyi, McKenzie, and Chapek, 2009). The concepts of spirituality and religion are often interchanged, but spirituality is a much broader and more unifying concept than religion (Vachon, Fillion, and Achille, 2009).

The human spirit is powerful, and spirituality has different meanings for different people (Pesut et al., 2008). Therefore nurses need to be aware of their own spirituality to provide appropriate and relevant spiritual care to others. They need to care for the whole person and accept a patient's beliefs and experiences when providing spiritual care (Ellis and Narayanasamy, 2009; Mueller, 2010). Being able to determine the importance that spirituality holds for patients depends on a nurse's ability to develop a caring relationship (see Chapter 7). Nursing care involves helping patients use their spiritual resources as they identify and explore what is meaningful in their lives and find ways to cope with the impact of illness and the ongoing stressors of life.

SCIENTIFIC KNOWLEDGE BASE

The relationship between spirituality and healing is not completely understood. However, the individual's intrinsic spirit seems to be an important factor in healing. Healing often takes place because of believing. Current evidence shows a link between mind, body, and spirit. An individual's beliefs and expectations often have effects on his or her physical and psychological well-being (Burris et al., 2009). Many of these effects are tied to hormonal and neurological function. For example, relaxation exercises and guided imagery improve immune function in certain situations (Lahmann

et al., 2010; Weigensberg et al., 2009) and reduce perceptions of pain and anxiety (Casida and Lemanski, 2010). Laughter raises pain thresholds, boosts the immune system, reduces stress and anxiety, relieves tension, and elevates mood (Harkins 2009; Swetz et al., 2009). A person's inner beliefs and convictions are powerful resources for healing. Nurses who support the spirituality of patients and their families are successful in helping patients achieve desirable health outcomes.

NURSING KNOWLEDGE BASE

Nursing research shows the association between spirituality and health. For example, Pierce et al. (2008) found that caregivers used spirituality to cope with the daily aspects of providing care to family members who have had strokes. Hollywell and Walker (2009) found that prayer often helps those who attend church or who are older, female, or less educated cope with chronic illnesses and maintain feelings of well-being. The increased interest in studying the relationship between spirituality and health has greatly contributed to nursing science.

Current Concepts in Spiritual Health

A variety of concepts describe spiritual health. To provide meaningful and supportive spiritual care, it is important to understand the concepts of spirituality, spiritual well-being, faith, religion, and hope. Each concept offers direction in understanding the views that individuals have of life and its value.

Spirituality. Spirituality is a complex concept that is unique to each individual; it depends on a person's culture, development, life experiences, beliefs, and ideas about life (McSherry, 2007). Furthermore, spirituality is an inherent human characteristic that exists in all people, regardless of their religious beliefs. It gives individuals the *energy* needed to discover themselves, cope with difficult situations, and maintain health (Villagomeza, 2006). Energy generated by spirituality helps patients feel well and guides choices made throughout life. Spirituality enables a person to love, have faith and hope, seek meaning in life, and nurture relationships with others. Because it is subjective, multidimensional, and personal, researchers and scholars cannot agree on a universal definition of spirituality (Tanyi, McKenzie, and Chapek, 2009). However, five distinct but overlapping constructs are frequently found in definitions of spirituality (Fig. 35-1).

Self-transcendence is a sense of authentically connecting to one's inner self (Vachon, Fillion, and Achille, 2009), whereas **transcendence** is the belief that a force outside of and greater than the person exists beyond the material world (Bailey et al., 2009). Individuals usually see this force as positive, and it allows people to have new experiences and develop new perspectives that are beyond ordinary physical boundaries. Examples of transcendent moments include the feeling of awe when holding a new baby or looking at a beautiful sunset. Spirituality offers a sense of **connectedness** intrapersonally (connected within oneself), interpersonally (connected with others and the environment), and transpersonally (connected with the unseen, God, or a higher power). Through connectedness patients are able to move beyond the stressors of everyday life and find comfort, faith, hope, peace, and empowerment (Nelson-Becker, Nakashima, and Canda, 2007). *Faith* allows people to have firm beliefs despite lack of physical evidence. It enables them to believe in and establish transpersonal connections. Although many people associate faith with religious beliefs, it exists without religious beliefs (Villagomeza, 2006). *Hope* has several meanings that vary on the basis of how it is being experienced; it usually refers to an energizing source that has an orientation to future goals and outcomes (Phillips-Salimi et al., 2007; Vachon, Fillion, and Achille, 2009).

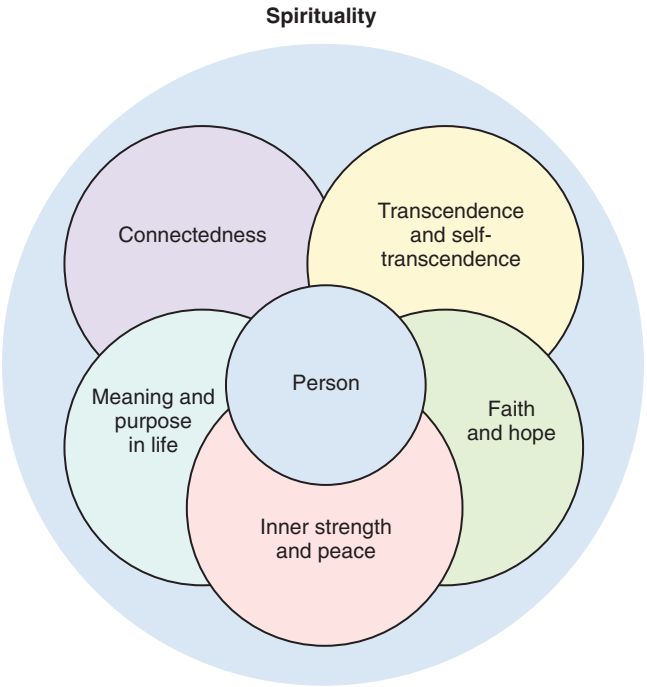

FIG. 35-1 The concept of spirituality has five distinct but overlapping constructs.

Spirituality gives people the ability to find a dynamic and creative sense of *inner strength* that is often used when making difficult decisions. Inner strength is a source of energy that instills hope, provides motivation, and promotes a positive outlook on life (Lundman et al., 2010). *Inner peace* fosters calm, positive, and peaceful feelings despite life experiences of chaos, fear, and uncertainty. These feelings help people feel comforted even in times of great distress (Hanson et al., 2008). Spirituality also helps people find *meaning and purpose in life* in both positive and negative life events (Bailey et al., 2009; Vachon, Fillion, and Achille, 2009).

Some people do not believe in the existence of God **(atheist)** or they believe that there is no known ultimate reality **(agnostic).** This does not mean that spirituality is not an important concept for the atheist or agnostic (Smith-Stoner, 2007). Atheists search for meaning in life through their work and their relationships with others. Agnostics discover meaning in what they do or how they live because they find no ultimate meaning for the way things are. They believe that people bring meaning to what they do.

Spirituality is an integrating theme. A person's concept of spirituality begins in childhood and continues to grow throughout adulthood (Narayanasamy et al., 2004; Smith and McSherry, 2004). It represents the totality of one's being, serving as the overriding perspective that unifies the various aspects of an individual. It spreads through all dimensions of a person's life, whether or not the person acknowledges or develops it.

Spiritual Well-Being. The concept of **spiritual well-being** is often described as having two dimensions. The vertical dimension supports the transcendent relationship between a person and God or some other higher power. The horizontal dimension describes positive relationships and connections that people have with others (Gray, 2006; Smith, 2006). Spiritual well-being has a positive effect on health. Those who experience spiritual well-being feel connected to others and are able to find meaning or purpose in their

lives. Spiritual well-being leads to spiritual health. Those who are spiritually healthy experience joy, are able to forgive themselves and others, accept hardship and mortality, report an enhanced quality of life, and have a positive sense of physical and emotional well-being (Whelan-Gales et al., 2009; Yampolsky et al., 2008).

Faith. In addition to being a part of the definition of spirituality, the concept of **faith** has other common definitions. Faith is a cultural or institutional religion such as Judaism, Buddhism, Islam, or Christianity. It is also a relationship with a divinity, higher power, authority, or spirit that incorporates a reasoning faith (belief) and a trusting faith (action). Reasoning faith provides confidence in something for which there is no proof. It is an acceptance of what reasoning cannot explain. Sometimes faith involves a belief in a higher power, spirit guide, God, or Allah. Faith is also the manner in which a person chooses to live. It gives purpose and meaning to an individual's life, allowing for action. Many times patients who are ill have a positive outlook on life and continue to pursue daily activities rather than resign themselves to the symptoms of the disease. Their faith often becomes stronger because they view their illness as an opportunity for personal growth (Alcorn et al., 2010; Ford et al., 2010).

Religion. Religion is associated with the "state of doing," or a specific system of practices associated with a particular denomination, sect, or form of worship. Religion refers to the system of organized beliefs and worship that a person practices to outwardly express spirituality. Many people practice a faith or belief in the doctrines and expressions of a specific religion or sect such as the Lutheran church or Orthodox Judaism. People from different religions view spirituality differently. For example, a Buddhist believes in Four Noble Truths: life is suffering; suffering is caused by clinging; suffering can be eliminated by eliminating clinging; and to eliminate clinging and suffering, one follows an eightfold path. The path includes right understanding, intention, speech, action, livelihood, effort, mindfulness, and concentration. It promotes wisdom, moral behavior, and meditation (Wilkins, Mailoo, and Kularatne, 2010). A Buddhist turns inward, valuing self-control, whereas a Christian looks to the love of God to provide enlightenment and direction in life.

When providing spiritual care to a patient, it is important to understand the differences between religion and spirituality. Many people tend to use the terms *spirituality* and *religion* interchangeably. Although closely associated, these terms are not synonymous. Religious practices encompass spirituality, but spirituality does not need to include religious practice. Religious care helps patients maintain their faithfulness to their belief systems and worship practices. Spiritual care helps people identify meaning and purpose in life, look beyond the present, and maintain personal relationships and a relationship with a higher being or life force.

Hope. Spirituality and faith bring **hope.** When a person has the attitude of something to live for and look forward to, hope is present. It is a multidimensional concept that provides comfort while people endure life-threatening situations, hardships, and other personal challenges. It is closely associated with faith and is energizing, giving individuals a motivation to achieve and the resources to use toward that achievement. People express hope in all aspects of their lives to help them deal with life stressors. Hope is a valuable personal resource whenever someone is facing a loss (see Chapter 36) or a difficult challenge (Duggleby, Cooper, and Penz, 2009).

Spiritual Health

People gain spiritual health by finding a balance between their values, goals, and beliefs and their relationships within themselves and others. Throughout life a person often grows more spiritual, becoming increasingly aware of the meaning, purpose, and values of life. In times of stress, illness, loss, or recovery, a person often uses previous ways of responding or adjusting to a situation. Often these coping styles lie within the person's spiritual beliefs.

Spiritual beliefs change as patients grow and develop. Spirituality begins as children learn about themselves and their relationships with others. Nurses who understand a child's spiritual beliefs are able to care for and comfort the child (Mueller, 2010). As children mature into adulthood, they experience spiritual growth by entering into lifelong relationships. An ability to care meaningfully for others and self is evidence of a healthy spirituality.

Beliefs among older people vary based on many factors such as gender, past experience, religion, economic status, and ethnic background. Healthy spirituality in older adults is one that gives peace and acceptance of the self. It is often based on a lifelong relationship with a Supreme Being. Illness and loss sometimes threaten and challenge the spiritual developmental process. Older adults often express their spirituality by turning to important relationships and giving of themselves to others (Edelman and Mandle, 2010).

Factors Influencing Spirituality

When illness, loss, grief, or a major life change occurs, either people use spiritual resources to help them cope or spiritual needs and concerns develop. **Spiritual distress** is the "impaired ability to experience and integrate meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater than oneself" (NANDA International, 2011). Spiritual distress causes a person to feel doubt, loss of faith, and a sense of being alone or abandoned. Individuals often question their spiritual values, raising questions about their way of life, purpose for living, and source of meaning. Spiritual distress also occurs when there is conflict between a person's beliefs and prescribed health regimens or the inability to practice usual rituals.

Acute Illness. Sudden, unexpected illness frequently creates significant spiritual distress. For example, both the 50-year-old patient who has a heart attack and the 20-year-old patient who is in a motor vehicle accident face crises that threaten their spiritual health. The illness or injury creates an unanticipated scramble to integrate and cope with new realities (e.g., disability). People often look for ways to remain faithful to their beliefs and value systems. Some pray, attend religious services more often, or spend time reflecting on the positive aspects of their lives. Often conflicts develop around a person's beliefs and the meaning of life. Anger is common; and patients sometimes express it against God, their families, themselves, or the nurse. The strength of a patient's spirituality influences how he or she copes with sudden illness and how quickly he or she moves to recovery. Nurses use knowledge of a person's spiritual well-being and implement spiritual interventions to maximize inner peace and healing (Yeager et al., 2010).

Chronic Illness. Many chronic illnesses threaten the person's independence, causing fear, anxiety, and spiritual distress. Dependence on others for routine self-care needs often creates feelings of powerlessness. Powerlessness and the loss of a sense of purpose in life impair the ability to cope with alterations in functioning. Spirituality significantly helps patients and their family caregivers adapt to the changes that result from chronic illness (Box 35-1). Successful adaptation often provides spiritual growth. Patients who have a sense of spiritual well-being, feel connected with a higher power and others, and are able to find meaning and purpose in life are better able to cope with and accept their chronic illness (Daaleman and Dobbs, 2010; Ebadi et al., 2009).

BOX 35-1 EVIDENCE-BASED PRACTICE

Spirituality and Caregiver Well-Being

PICO Question: What is the effect of spirituality on the well-being of adults who care for family members with chronic illnesses?

Evidence Summary

The CDC (2010) estimates that 133 million Americans have at least one chronic illness. Most people with chronic illnesses live and are cared for at home. Family caregivers of individuals with chronic illnesses often experience stress, depression, burden, and changes to their physical health (Herrera et al., 2009; Sanders et al., 2008). As the population continues to age, the number of family caregivers will continue to climb (Choi, Tirrito, and Mills, 2008). Therefore it is essential to explore ways to enhance their well-being.

Research supports a positive correlation between spirituality and family caregiver well-being. Church-based emotional support, faith in God or a higher being, and prayer help to reduce caregiver burden and stressors, especially in culturally diverse populations (Sanders et al., 2008; Strudwick and Morris, 2010). Family caregivers who are able to attend religious services and receive support from members of their congregation experience less mental distress and caregiver burden (Herrera et al., 2009). Spirituality helps caregivers find meaning during times of hardship, which enhances life satisfaction (Roscoe, 2009). Family caregivers who interpret their caregiving experience positively experience less depression and better health (Roscoe, 2009). However, caregivers still often experience grief and loss and have to work hard to obtain support from different health care agencies (Sanders et al., 2008; Strudwick and Morris, 2010). Frequently assessing family caregiver needs and providing spiritual care enhance the caregiving experience.

Application to Nursing Practice

- Use assessment data about the spirituality and spiritual behaviors or practices from caregivers of family members with chronic illnesses to identify areas of strength and support.
- When appropriate, encourage family caregivers to participate in spiritual behaviors or practices and encourage members from the caregivers' congregations to visit to enhance social support and reduce caregiver burden.
- Consider cultural differences and explore personal preferences when determining nursing interventions to enhance spiritual well-being.
- Inform caregivers of spiritual resources available in the community (e.g., parish nurses, community- or faith-based support groups, clergy, social services).
- Arrange for respite care to allow caregivers to attend religious services if desired to enhance social support and reduce caregiver burden.

Terminal Illness. Terminal illness commonly causes fears of physical pain, isolation, the unknown, and dying. It creates an uncertainty about what death means, making patients susceptible to spiritual distress. However, some patients have a spiritual sense of peace that enables them to face death without fear. Spirituality helps these patients find peace in themselves and their death. Individuals experiencing a terminal illness often find themselves reviewing their life and questioning its meaning. Common questions they ask include "Why is this happening to me?" or "What have I done?" Terminal illness often affects family and friends just as much as the patient. It causes members of the family to ask important questions about its meaning and how it will affect their relationship with the patient (see Chapter 36). In addition to managing patients' physical and psychosocial symptoms experienced at the end of life, empower them to have a greater sense of control over their disease, regardless of whether they receive care in a hospital or at home. Providing holistic care is essential because dying is a part of life that encompasses the patient's physical, social, psychological, and spiritual health (Wasserman, 2008).

Near-Death Experience. Some nurses care for patients who have had a near-death experience (NDE). An NDE is a psychological phenomenon of people who either have been close to clinical death or have recovered after being declared dead. It is not associated with a mental disorder. Persons who experience an NDE often tell the same story of feeling themselves rising above their bodies and watching caregivers initiate lifesaving measures. Most individuals describe passing through a tunnel to a bright light, encountering people who had preceded them in death, and feeling an inner tranquility and peace. Instead of moving toward the light, they learn that it is not time for them to die, and they return to life (Rominger, 2010).

Patients who have an NDE are often reluctant to discuss it, thinking that others will not understand. However, individuals experiencing an NDE who discuss it with family or caregivers find acceptance and meaning from this powerful experience. They are often no longer afraid of death. After a patient has survived an NDE, it is important to remain open and give him or her a chance to explore what happened. Provide support if the patient decides to share the experience with significant others (Duffy, 2007).

CRITICAL THINKING

The helping role is important in nursing practice (Benner, 1984). Patients look to nurses for help that is different than the help they seek from other health care professionals. Expert nurses acquire the ability to anticipate personal issues affecting patients and their spiritual well-being. Critical thinking, knowledge, and skills help nurses enhance patients' spiritual well-being and health. While using the nursing process, apply knowledge, experience, attitudes, and standards in providing appropriate spiritual care (Fig. 35-2). Nurses who are comfortable with their own spirituality often are more likely to care for their patients' spiritual needs. Nurses who foster their own personal, emotional, and spiritual health become resources for their patients and use their own spirituality as a tool when caring for themselves and their patients (Chism and Magnan, 2009; Ellis and Narayanasamy, 2009).

Taking a faith history reveals patient's beliefs about life, health, and a Supreme Being. Knowing patients' cultural preferences provides additional insight into their spiritual practices. Applying knowledge of spiritual concepts, principles of caring (see Chapter 7), and therapeutic communication skills (see Chapter 24) helps nurses readily recognize and understand patients' spiritual needs. Convey caring and openness to successfully promote honest discussion about patients' spiritual beliefs.

A sound understanding of ethics and values (see Chapter 22) is essential when providing spiritual care. A person's values or beliefs about the worth of a given idea, attitude, or custom are linked to his or her spiritual well-being. Application of ethical principles ensures respect for a patient's spiritual and religious convictions.

Personal experience in caring for patients in spiritual distress is valuable when helping patients select coping options. You need to determine if your spirituality is beneficial in assisting patients. Nurses who sense a personal faith and hope regarding life are usually better able to help their patients. Previous personal and professional experiences with dying patients, patients with chronic disease, or those who have experienced significant losses provide lessons in how to help patients face difficult challenges and how to offer support to family and friends.

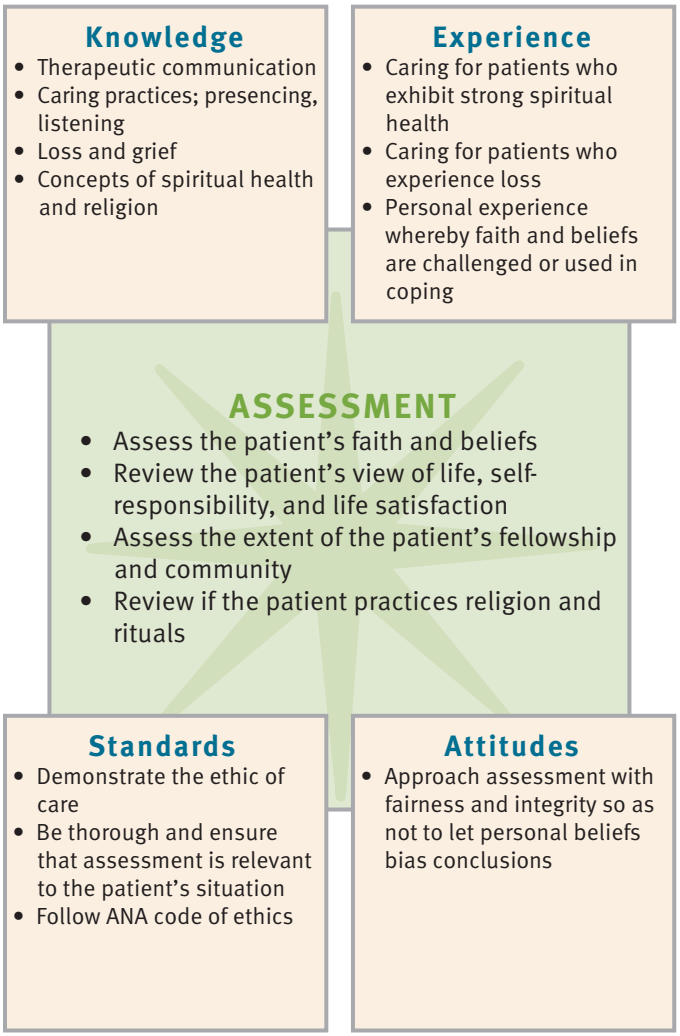

FIG. 35-2 Critical thinking model for spiritual health assessment. *ANA,* American Nurses Association.

Because each person has a unique spirituality, you need to know your own beliefs so you are able to care for each patient without bias (Tiew and Creedy, 2010). Use critical thinking when assessing each patient's reaction to illness and loss and when determining if spiritual intervention is necessary. Humility is essential, especially when caring for patients from diverse cultural and/or religious backgrounds. Recognize personal limitations in knowledge about patients' spiritual beliefs and religious practices. Effective nurses show genuine concern as they assess their patients' beliefs and determine how spirituality influences their patients' health. You demonstrate integrity by refraining from voicing your opinions about religion or spirituality when your beliefs conflict with those of your patients.

The application of intellectual standards helps you make accurate clinical decisions and helps patients find meaningful and logical ways to acquire spiritual healing. Critical thinking ensures that you obtain significant and relevant information when making decisions about patients' spiritual needs. The nature of a person's spirituality is complex and highly individualized. Therefore avoid making assumptions about his or her religion and beliefs. Significance and relevance are standards of critical thinking that ensure that you explore the issues that are most meaningful to patients and most likely to affect spiritual well-being.

In setting standards for quality health care, The Joint Commission (2010) requires health care organizations to assess patients' denomination, beliefs, and spiritual practices and acknowledge their rights to spiritual care. Health care organizations also need to provide for patients' spiritual needs through pastoral care or others who are certified, ordained, or lay individuals.

The American Nurses Association Code of Ethics for Nurses (Fowler, 2010) requires nurses to practice nursing with compassion and respect for the inherent dignity, worth, and uniqueness of each patient despite socioeconomic status, personal characteristics, or type of health problem. It is essential to promote an environment that respects patients' values, customs, and spiritual beliefs. Routinely implementing nursing interventions such as prayer or meditation is coercive and/or unethical. Therefore determine which interventions are compatible with the patient's beliefs and values before selecting them. An ethic of caring (see Chapter 22) provides a framework for decision making and places the nurse as the patient's advocate.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to use to develop and implement an individualized plan of care. The core of nursing includes a commitment to caring and respect for an individual's uniqueness. Application of the nursing process from the perspective of a patient's spiritual needs is not simple. It goes beyond assessing his or her religious practices. Understanding a patient's spirituality and then appropriately identifying the level of support and resources needed require a compassionate perspective. Remove any personal biases or misconceptions from patient assessments and be willing to share and discover another person's meaning and purpose in life, illness, and health. Love, trust, hope, forgiveness, meaning, and community are universal spiritual needs. Learning to share these needs helps you find a way to give patients spiritual care and support. Patients bring certain spiritual resources that help them assume healthier lives, recover from illness, or face impending death. Supporting and recognizing the positive side of a patient's spirituality goes a long way toward delivering effective, individualized nursing care.

ASSESSMENT

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Because spirituality is deeply subjective, it means different things to different people (Bailey et al., 2009).

Through the Patient's Eyes. It is essential to take the time to assess the patient's viewpoints and establish a trusting relationship with him or her. Focus nursing assessment on aspects of spirituality that life experiences and events most likely influence. As you and your patients reach a point of learning together, spiritual caring occurs.

Spiritual assessment is therapeutic because it expresses a level of caring and support. It is also a fundamental part of the nursing assessment. Because completing a spiritual assessment takes time, conduct an ongoing assessment over the course of the patient's stay in the health care setting if possible. Establish trust and rapport and make the opportunity to conduct meaningful discussions with patients a priority.

BOX 35-2 NURSING ASSESSMENT QUESTIONS

Spirituality and Spiritual Health
- What gives you energy during difficult times?
- Which aspects of your spirituality have been most helpful to you?
- Which aspects of your spirituality would you like to discuss?

Faith, Belief, Fellowship, and Community
- To what or whom do you look as a source of strength, hope, or faith in times of difficulty?
- How does your faith help you cope?
- Do you use prayer?
- What can I do to support your religious beliefs or faith commitment?
- What gives your life meaning?

Life and Self-Responsibility
- How do you feel about the changes this illness has caused?
- How do these changes affect what you now need to do?

Life Satisfaction
- How happy or satisfied are you with your life?
- What accomplishments help you feel satisfied with your life?

Connectedness
- What feelings do you have after you pray?
- Who do you feel is the most important person in your life?

Vocation
- How has your illness affected the way you live your life spiritually at home or where you work?
- In what way has your illness affected your ability to express what is important in life to you?

You can assess a patient's spiritual health in several different ways. One way is to ask direct questions (Box 35-2). This approach requires you to feel comfortable asking others about their spirituality. Several assessment tools are available to help nurses clarify values and assess spirituality. For example, the spiritual well-being (SWB) scale has 20 items that assess the individual's view of life and relationship with a higher power (Gray, 2006). The B-E-L-I-E-F assessment tool helps nurses evaluate a child's and family's spiritual and religious needs (McEvoy, 2003). The acronym stands for the following:

B—Belief system
E—Ethics or values
L—Lifestyle
I—Involvement in a spiritual community
E—Education
F—Future events

Effective spiritual assessment tools such as the SWB and B-E-L-I-E-F help nurses remember important areas to assess. A patient's response to items on assessment tools often indicates areas that need further investigation. For example, if after using an assessment tool, a nurse finds that a patient has difficulty accepting change, the nurse needs to spend time understanding how the patient is accepting and managing the new illness. Whether you use an assessment tool or direct an assessment with questions that are based on principles of spirituality, it is important not to impose your personal value systems on the patient. This is particularly true when the patient's values and beliefs are similar to those of your own because it then becomes very easy to make false assumptions. When nurses understand the overall approach to spiritual assessment, they are able to enter into thoughtful discussions with their patients, gain a greater awareness of the personal resources that patients bring to a situation, and incorporate the resources into an effective plan of care.

Faith/Belief. Assess the source of authority and guidance that patients use in life to choose and act on their beliefs. Determine if the patient has a religious source of guidance that conflicts with medical treatment plans and affects the option that nurses and other health care providers are able to offer patients. For example, if a patient is a Jehovah's Witness, blood products are not an acceptable form of treatment. Christian Scientists often refuse any medical intervention, believing that their faith heals them. It is also important to understand a patient's philosophy of life. Assessment data reveal the basis of the patient's belief system regarding meaning and purpose in life and the patient's spiritual focus. This information often reflects the impact that illness, loss, or disability has on the person's life. Considerable religious diversity exists in the United States. A patient's religious faith and practices, views about health, and the response to illness often influence how nurses provide support (Table 35-1).

Life and Self-Responsibility. Spiritual well-being includes life and self-responsibility. Individuals who accept change in life, make decisions about their lives, and are able to forgive others in times of difficulty have a higher level of spiritual well-being. During illness patients often are unable to accept limitations or do not know how to regain a functional and meaningful life. Their sense of helplessness reflects spiritual distress. However, patients often use their spiritual well-being as a resource as they adapt to changes and seek solutions to deal with limitations. Assess the extent to which a patient understands the limitations or threats posed by an illness and the manner in which he or she chooses to adjust to them.

Connectedness. People who are connected to themselves, others, nature, and God or another Supreme Being cope with the stress brought on by crisis and chronic illness. Patients remain connected with God by praying (Fig. 35-3). Prayer is personal communication with one's god. It provides a sense of hope, strength, security, and well-being; and it is a part of faith (Hollywell and Walker, 2009; Krause and Bastida, 2009). Help patients become or remain connected by respecting each patient's unique sense of spirituality. Assess whether the patient loses the ability to express a sense of relatedness to something greater than the self.

Life Satisfaction. Spiritual well-being is tied to a person's satisfaction with life and what he or she has accomplished (Katerndahl, 2008). Assessing a person's satisfaction with life often provides insight to appropriate nursing care. When people are satisfied with life, more energy is available to deal with new difficulties and resolve problems.

Culture. Spirituality is a personal experience within a cultural context. It is important to know a patient's culture of origin and assess his or her values (Tiew and Creedy, 2010). It is common in many cultures for individuals to believe that they have led a worthwhile and purposeful life. Remaining connected with their cultural heritage often helps patients define their place in the world and express their spirituality. Asking them about their faith and belief systems is a good beginning for understanding the relationship between culture and spirituality (Box 35-3).

Fellowship and Community. Fellowship is a type of relationship that an individual has with other persons (e.g., family, close friends, fellow members of a church, or neighbors). Explore the extent and nature of the patient's support networks. It is unwise

TABLE 35-1 **Religious Beliefs About Health**

RELIGIOUS OR CULTURAL GROUP	HEALTH CARE BELIEFS	RESPONSE TO ILLNESS	IMPLICATIONS FOR HEALTH AND NURSING
Hinduism	Accepts modern medical science	Past sins cause illness. Prolonging life is discouraged.	Allow time for prayer and purity rituals. Allow use of amulets, rituals, and symbols.
Sikhism	Accepts modern medical science	Females are to be examined by females. Removing undergarments causes great distress.	Provide time for devotional prayer. Allow use of religious symbols.
Buddhism	Accepts modern medical science	Followers sometimes refuse treatment on Holy Days. Nonhuman spirits invading the body cause illness. Sometimes followers want a Buddhist priest. They usually accept death as last stage of life and usually permit withdrawal of life support. Followers do not practice euthanasia. They often do not take time off from work or family responsibilities when sick.	Health is an important part of life. Good health is maintained by caring for self and others. Medications are not always accepted because of belief that chemical substances in the body are harmful.
Islam	Must be able to practice the Five Pillars of Islam Sometimes has a fatalistic view of health	Muslims use faith healing. Family members are a comfort. Group prayer is strengthening. They often permit withdrawal of life support. They do not practice euthanasia. They believe that time of death is predetermined and cannot be changed. They maintain a sense of hope and often avoid discussions of death.	Women prefer female health care providers. During month of Ramadan Muslims do not eat until after the sun goes down. Health and spirituality are connected. Family and friends visit during time of illness. They usually do not consider organ transplantation or donation and postmortem examinations.
Judaism	Believes in the sanctity of life Balance between God and medicine Observance of the Sabbath important Treatments sometimes refused on the Sabbath	Visiting the sick is an obligation. There is an obligation to seek care, exercise, sleep, eat well, and avoid drug and alcohol abuse. Euthanasia is forbidden. Life support is discouraged.	Jews believe that it is important to stay healthy. They expect the nurse to provide competent health care. Allow patients to express their feelings. Allow family to stay with dying patient.
Christianity	Accepts modern medical science Complementary or alternative medicine often followed (see Chapter 32)	Followers use prayer, faith healing. They appreciate visits from clergy. Some use laying on of hands. Holy Communion is sometimes practiced. Anointing of the sick is given when patient is ill or near death (Catholic).	Christians are usually in favor of organ donation. Health is important to maintain. Allow time for patients to pray by themselves, with family or friends.
Navajos	Concepts of health have a fundamental place in their concept of humans and their place in the universe	Blessingway is a practice that attempts to remove ill health by means of stories, songs, rituals, prayers, symbols, and sand paintings.	Navajos prefer holistic approach to health care. They often are not on time for appointments. Promote physical, mental, spiritual, and social health of persons, families, and communities. Allow family members to visit. Provide teaching about wellness, not disease prevention, when possible.
Appalachians	External locus of control Nature controls life and health Accept folk healers Good Christian members of community are called as servants to minister to disabled	They dislike hospitals. They tend not to follow medical regimens but expect to be helped directly when seeking episodic treatment.	They become anxious in unfamiliar settings. Encourage communication with family and friends when ill.

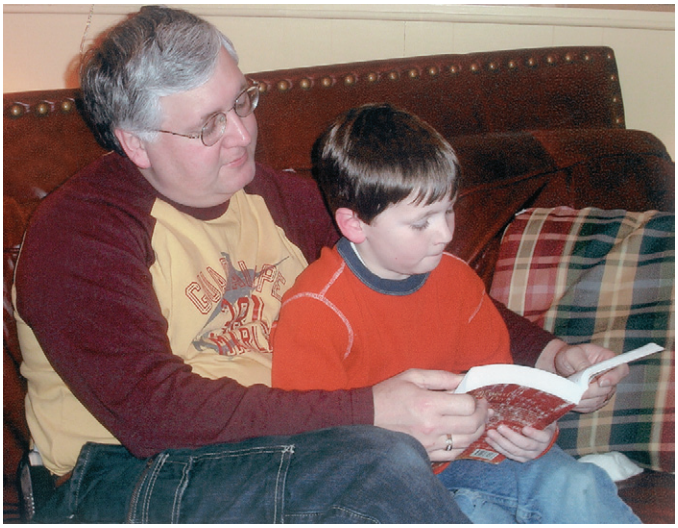

FIG. 35-3 Praying or reading a bible together enhances the connectedness between parents and their children.

BOX 35-3 CULTURAL ASPECTS OF CARE

Spirituality and Culture

Spirituality and spiritual health vary among cultures. Therefore nurses need to assess how their patients' culture affects spirituality. For example, spiritual aspects of life are frequently important to Latinos. *Personalismo* is a cultural value that indicates warmth, closeness, and empathy in relationships with other people and a universal being. *Familismo*, another Latino cultural value, indicates commitment and loyalty to immediate and extended family (Campesino et al., 2009). For African Americans spirituality is associated with guidance, coping, strength, and peace. It is often a catalyst for recovery, and community- and faith-based programs are effective in promoting health (Gallia and Pines, 2009). Although people who practice Buddhism believe that suffering is a part of life, they try to avoid it when possible (Wilkins, Mailoo, and Kularatne, 2010). At the end of life they prepare for "a good death," which requires quiet time for meditation and prayer.

Implications for Practice

- Explore the spirituality of patients from different cultures by assessing the meaning of health and how patients achieve balance, stability, peace, or comfort in their lives.
- Offer a universal and holistic approach to assessing patients' needs by demonstrating caring and using therapeutic communication techniques.
- Promote an environment during assessment that respects human rights, values, customs, and spiritual beliefs.
- Include appropriate pastoral care professionals in the assessment process.
- Avoid use of language that alienates or discriminates among different religions.

to assume that a given network offers the kind of support that a patient desires. For example, calling the patient's clergy to request a visit is inappropriate if the patient finds little fellowship with that individual.

Ritual and Practice. Assessing the use of rituals and practices helps nurses understand a patient's spirituality. Rituals include participation in worship, prayer, sacraments (e.g., baptism, Holy Eucharist), fasting, singing, meditating, scripture reading, and making offerings or sacrifices. Different religions have different rituals for life events. For example, Buddhists practice baptism later in life and find burial or cremation acceptable at death. Muslims wash the body of a dead family member and wrap it in white cloth with the head turned toward the right shoulder. Orthodox and Conservative Jews circumcise their newborn sons 8 days after birth. Determine whether illness or hospitalization has interrupted a patient's usual rituals or practices. A ritual often provides the patient with structure and support during difficult times. If rituals are important to the patient, use them as part of nursing intervention.

Vocation. Individuals express their spirituality on a daily basis in life routines, work, play, and relationships. Spirituality is often a part of a person's identity and vocation in life. Determine if illness or hospitalization alters the ability to express some aspect of spirituality as it relates to the person's work or daily activities. Expression of spirituality is highly individual and includes showing an appreciation for life in the variety of things people do, living in the moment and not worrying about tomorrow, appreciating nature, expressing love toward others, and being productive. When illness or loss prevents patients from expressing their spirituality, understand the psychological, social, and spiritual implications and provide appropriate guidance and support.

Building Competency in Patient-Centered Care You are caring for Grace, a 52-year-old who experienced multiple fractures following a motor vehicle crash. Grace is experiencing difficulties with mobility and she is not going to be able to go back to work for at least 6 months. She is currently having extensive rehabilitation to help her complete activities of daily living. When you walk into Grace's room, she will not look at you. You can tell that she has been crying. She has a flat affect and states, "I just don't know why God did this to me. How am I going to go on from here?"

Identify at least three questions you will ask Grace to assess her spiritual well-being and plan effective, evidence-based care.

Answers to questions can be found on the Evolve website.

NURSING DIAGNOSIS

A spiritual assessment allows a nurse to learn a great deal about the patient and the extent that spirituality plays in his or her life. Exploring the patient's spirituality sometimes reveals responses to health problems that require nursing intervention or the existence of a strong set of resources that allow the patient to cope effectively. Analyze data to find patterns of defining characteristics and select appropriate nursing diagnoses (Box 35-4). In identifying diagnoses, recognize the significance that spirituality has for all types of health problems. Be sure that each diagnosis has an accurate related factor to guide the selection of individualized, purposeful, and goal-directed interventions. Potential nursing diagnoses for spiritual health include the following:

- Anxiety
- Ineffective coping
- Fear
- Complicated grieving
- Hopelessness
- Powerlessness
- Readiness for enhanced spiritual well-being
- Spiritual distress
- Risk for spiritual distress

Three nursing diagnoses accepted by NANDA International (2011) pertain specifically to spirituality. *Readiness for enhanced spiritual*

BOX 35-4 NURSING DIAGNOSTIC PROCESS

Readiness for Enhanced Spiritual Well-Being

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Ask patient to describe personal source of faith and hope.	Patient expresses an inner strength and source of guidance.
Have patient describe level of satisfaction with life.	Life has purpose and meaning; patient finds satisfaction while providing community service as a volunteer.
Determine who provides the greatest source of strength and support to the patient during times of difficulty.	Patient pursues interactions with friends and family.

well-being is based on defining characteristics that show a person's ability to experience and integrate meaning and purpose in life through connectedness with self and others. A patient with this nursing diagnosis has potential resources on which to draw when faced with illness or a threat to well-being. If the patient does not know how to engage personal resources to cope with health problems, offer support in exploring options.

The nursing diagnoses of *spiritual distress* and *risk for spiritual distress* create different clinical pictures. Defining characteristics from a nurse's assessment reveal patterns that reflect a person's actual or potential dispiritedness (e.g., expressing lack of hope, meaning, or purpose in life; anger toward God; or verbalizing conflicts about personal beliefs). Patients likely to be at risk for spiritual distress include those who have poor relationships, have experienced a recent loss, or are suffering some form of mental or physical illness.

Accurate selection of diagnoses requires critical thinking. Review all concrete data (e.g., religious rituals and sources of fellowship), your assessment of previous patient experiences, your own spirituality, and your appraisal of the patient's spiritual well-being. Validate and clarify defining characteristics with the patient before making a diagnosis and plan of care. Commonly patients have multiple nursing diagnoses.

PLANNING

During the planning step of the nursing process, develop a plan of care for each of the patient's nursing diagnoses. Critical thinking at this step is important because you reflect on previous experiences and apply knowledge and critical thinking attitudes and standards in selecting the most appropriate nursing interventions (Fig. 35-4). Prior experience with other patients is valuable when selecting interventions to support spiritual well-being. Integrate assessment data with knowledge about resources and therapies available for spiritual care to develop an individualized plan of care (see the Nursing Care Plan). Match the patient's needs with evidence-based interventions that are supported and recommended in the clinical and research literature. Use a concept map (Fig. 35-5) to organize patient care and show how the patient's medical diagnosis, assessment data, and nursing diagnoses are interrelated.

Confidence, an important critical thinking attitude, builds trust, enabling you and a patient to enter into a healing relationship together. Attempting to meet or support patients' spiritual needs is not simple; frequently you need additional resources. For example,

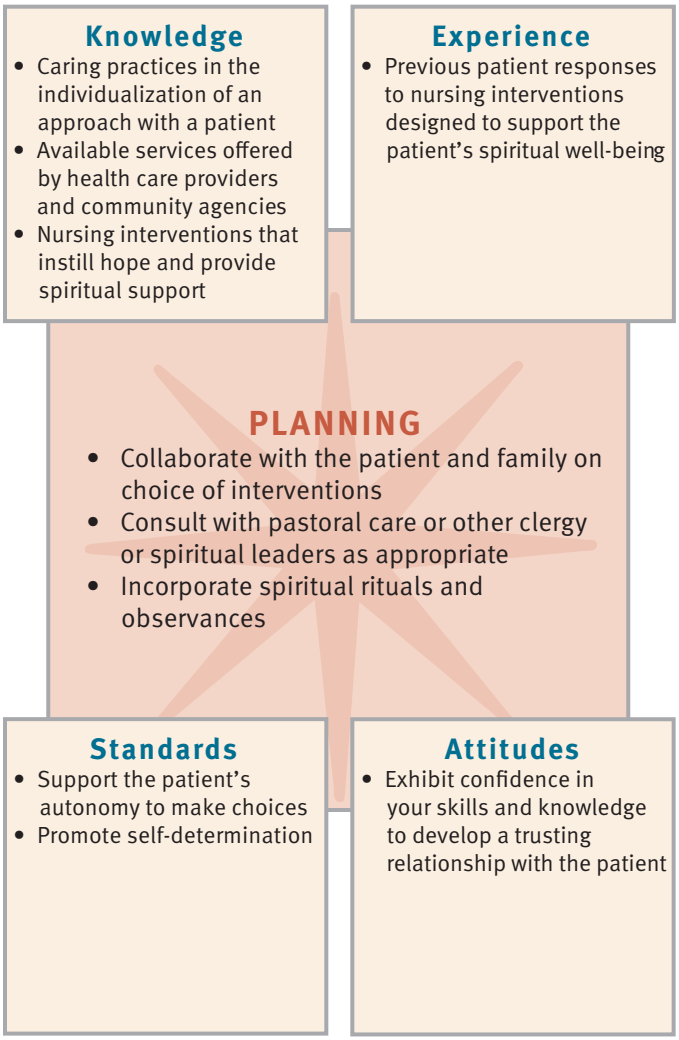

FIG. 35-4 Critical thinking model for spiritual health planning.

sometimes a nurse's skills in helping patients interpret and understand the meaning of illness and loss are limited. Because spiritual care is so personal, standards of autonomy and self-determination are critical in supporting the patient's decisions about the plan of care.

Goals and Outcomes. A spiritual care plan includes realistic and individualized goals along with relevant outcomes. It is important to collaborate closely with patients when setting goals and choosing related interventions. Setting realistic goals requires you to know a patient well. When spiritual care requires helping patients adjust to loss or stressful life situations, goals are long term. However, short-term outcomes such as renewing participation in religious practices help the patient progressively reach a more spiritually healthy situation. In establishing a plan of care, an example of a goal and associated outcomes follows:

The patient will improve personal harmony and connections with members of his or her support system.

- The patient will express an acceptance of illness.
- The patient will report the ability to rely on family members for support.
- The patient will initiate social interactions with family and friends.

Setting Priorities. Spiritual care is very personalized. Your relationship with a patient allows you to understand the patient's

NURSING CARE PLAN

Spiritual Distress

ASSESSMENT

Jose Gomez is a 24-year-old Latino who has recently been diagnosed with human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS). The clinic nurse, Leah, has been talking with Jose during his last three visits. During clinic visits Jose expresses a fear of dying. His partner, Will, visits Jose at home periodically, but he has been visiting much less often than before the diagnosis. Jose states that he "used to go to a Catholic church" when he was younger and explains that he currently has a poor relationship with his mother and his brother. The nurse practitioner recently told Jose that he is in the end stage of his illness and suggested that he consider hospice care. Leah now talks with Jose in a private conference area.

Assessment Activities	*Findings/Defining Characteristics**
Ask Jose how his illness affects his source of strength or hope.	Jose responds, "**How can God do this to me?** There are moments when I just **feel so angry**. What is going to happen to me?"
Ask Jose who provides the greatest source of support to him in his life.	He begins to cry and admits, "**I feel so alone. Will has not been there** when I need him."
Ask Jose how his illness affected his faith and beliefs.	Jose responds, "My church does not accept homosexuality, so **I don't feel like I fit in** there. I have always had faith in God."

***Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Spiritual distress related to terminal illness.

PLANNING

Goals	*Expected Outcomes (NOC)†*
Jose will maintain feelings of control as he approaches the end of his life.	**Dignified Life Closure** Jose will share feelings about dying in 1 week. Jose will initiate contact and begin to heal relationships with his family within 3 weeks.
Jose will establish connections with self, significant others, and God.	**Spiritual Health** Jose will visit with Will in the next 2 weeks to share his thoughts, feelings, and beliefs. Jose will identify and participate in spiritual activities in 1 month.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Spiritual Growth Facilitation	
Ask Jose to identify activities that will help heal his body, mind, and spirit.	Spirituality and religious activities often help men who are HIV positive cope with their illness (Hampton, Halkitis, and Mattis, 2010).
Encourage Jose to pray; offer to pray with him.	People who are Latino sometimes pray more frequently than they attend church; prayer often provides spiritual strength (Campesino et al., 2009).
Spiritual Support	
Use therapeutic communication to establish trust and a caring presence.	Providing spiritual care requires caring, compassion, and respect (Tiew and Creedy, 2010).
Encourage Jose to renew his relationships with Will, his mother, and his brother.	The Latino cultural values of *personalismo* and *simpático* (close, personal relationships with others) enhance connection with God (Campesino et al., 2009).
Teach Jose methods of relaxation, meditation, and guided imagery.	Relaxation methods such as relaxation, meditation, and guided imagery help promote quality of life and enhance serenity and dignity in Latino patients who are dying (Elias, Giglio, and Pimenta, 2008) and in patients with HIV (Horowitz, 2010).

‡Intervention classification labels from Bulechek GM, Butcher HK, Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

priorities. When establishing a mutually agreed-on plan with the patient, he or she is able to identify what is most important. Spiritual priorities do not need to be sacrificed for physical care priorities. For example, when a patient is in acute distress, focus care to provide the patient a sense of control. When a patient is terminally ill, spiritual care often is the most important nursing intervention.

Teamwork and Collaboration. If the patient participates in a formal religion, involve members of the clergy or members of the church, temple, mosque, or synagogue in the plan of care. In a

NURSING CARE PLAN

***Spiritual Distress*—cont'd**

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Jose how he currently feels about having end-stage AIDS.	"I am not quite as frightened as I was a few weeks ago."	Jose reports an improved outlook. Expect continued fears about dying.
Ask Jose about his relationships with Will, his mother, and his brother.	"It meant a great deal to tell Will and my family how I feel. They did not know how to help me. We now talk on the phone almost every day."	Jose successfully increased connection with significant others.
Ask Jose which spiritual activities he finds helpful.	"I have been praying and have been using the breathing techniques you taught me every day. They have helped me feel better about myself and my situation. I don't feel so angry anymore."	Prayer and relaxation activities have enhanced positive feelings about self and reduced feelings of anger.

CONCEPT MAP

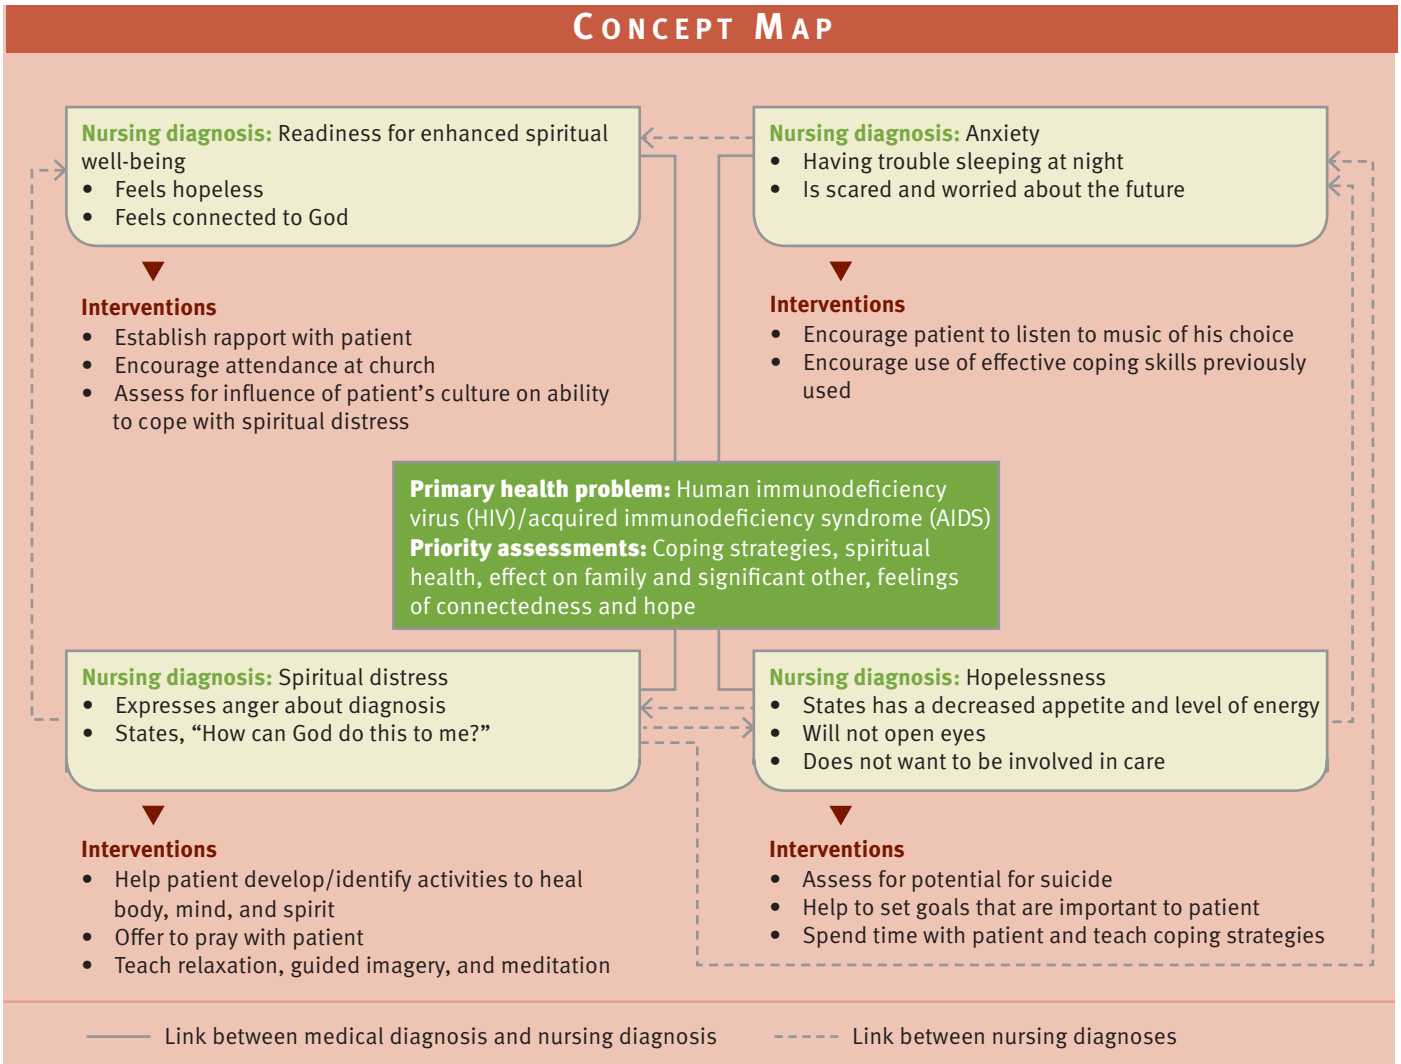

FIG. 35-5 Concept map for Jose Gomez.

hospital setting the pastoral-care department is a valuable resource. These professionals provide insight about how and when to best support patients and their families. In addition, significant others such as spouses, siblings, parents, and friends need to be involved in the patient's care as appropriate. This means that the nurse learns from the assessment which individuals or groups have formed a relationship with the patient. These individuals sometimes become involved in all levels of the nurse's plan. They often assist in giving physical care, providing emotional comfort, and sharing spiritual support.

IMPLEMENTATION

Establish caring relationships with patients to discover their beliefs about the meaning of illness or loss and the effect they have on the meaning and purpose of life. Achieving this level of understanding with patients enables you to deliver care in a sensitive, creative, and appropriate manner.

Health Promotion. Spiritual care needs to be a central theme in promoting an individual's overall well-being (Lopez et al., 2009). Spirituality is one personal resource that affects the balance between health and illness. In settings where health promotion activities occur, patients often need information, counseling, and guidance to make the necessary choices to remain healthy.

Establishing Presence. Nurses contribute to a sense of well-being and provide hope for recovery when they spend time with their patients (Tiew and Creedy, 2010). Behaviors that establish the nurse's presence include paying attention, answering questions, listening, and having a positive and encouraging (but realistic) attitude. Establishing presence is part of the art of nursing. It is not simply being in the same room with a patient while performing procedures or sharing technical information with him or her. Presence involves "being with" a patient versus "doing for" a patient (Benner, 1984). It involves offering closeness with the patient physically, psychologically, and spiritually (see Chapter 7).

When health promotion is the focus of care, a nurse's presence gives patients the confidence needed to remain healthy. Demonstrate a caring presence by listening to patients' concerns and willingly involving family in discussions about the patients' health. Show self-confidence when providing health instruction and support patients as they make decisions about their health. The patient who seeks health care is often fearful of experiencing an illness that threatens loss of control and looks for someone to offer competent direction. Encouraging words of support and a calm, decisive approach establish a presence that builds trust and well-being.

Supporting a Healing Relationship. Learn to look beyond isolated patient problems and recognize the broader picture of a patient's holistic needs. For example, do not just look at a patient's back pain as a problem to solve with quick remedies; rather look at how the pain influences the patient's ability to function and achieve goals established in life. A **holistic** view enables you to establish a helping role and a healing relationship. Three factors are evident when a healing relationship develops between nurse and patient:

1. Mobilizing hope for the nurse and patient
2. Finding an interpretation or understanding of the illness, pain, anxiety, or other stressful emotion that is acceptable to the patient
3. Helping the patient use social, emotional, and spiritual resources (Benner, 1984)

Mobilizing the patient's hope is central to a healing relationship. Hope motivates people with strategies to face challenges in life (Duggleby, Cooper, and Penz, 2009). Help patients find things for which to hope. For example, a patient newly diagnosed with diabetes wants to learn how to manage the disease to continue a productive and satisfying way of life. An adult daughter who has decided to become caregiver to her older adult parent hopes to be able to protect the parent from injury or worsening disability. Hope helps a patient work toward recovery. To help patients achieve hope, work together to find an explanation of the situation that is acceptable to the patient. Help the patient realistically exercise hope by supporting a positive attitude toward life or a desire to be informed and make decisions.

To further support a healing relationship, remain aware of the patient's spiritual resources and needs. It is always important for patients to be able to express and exercise their beliefs and find spiritual comfort. When life stressors or illness create confusion or uncertainty, recognize the possible effect on a patient's well-being. How does the nurse use and strengthen spiritual resources? Begin by encouraging a patient to discuss the effect that illness has had on personal beliefs and faith, thus giving the chance to clarify any misconceptions or inaccuracies in information. Having a clear sense of what illness will be like for an individual helps the person to apply all resources toward recovery.

Acute Care. Within acute care settings patients experience multiple stressors that threaten their sense of control. Ongoing assessment of spiritual needs is essential because the patient's needs often change rapidly (Smith, 2006). Support and enhancement of a patient's spiritual well-being are challenges when the focus of health care seems to be on treatment and cure rather than care (Tiew and Creedy, 2010). To overcome these challenges display a soothing presence and supportive touch when providing nursing care. The artful use of hands, encouraging words of support, promotion of connectedness, and a calm and decisive approach establish a presence that builds trust.

Support Systems. Use of support systems is important in any health care setting. They provide patients with the greatest sense of well-being during hospitalization and serve as a human link connecting the patient, the nurse, and the patient's lifestyle before an illness. Part of the patient's caregiving environment is the regular presence of supportive family and friends. Provide privacy during visits and plan care with the patient and the patient's support network to promote the interpersonal bonding that is needed for recovery. The support system is a source of faith and hope and an important resource in conducting meaningful religious rituals.

When patients look to family and friends for support, encourage them to visit the patient regularly. Help family members feel comfortable in the health care setting and use their support and presence to promote the patient's healing. For example, including family members in prayer is a thoughtful gesture if it is appropriate to the patient's religion and if family members are comfortable participating. Having the family bring meaningful religious symbols to the patient's bedside offers significant spiritual support.

Other important resources to patients are spiritual advisors and members of the clergy. Many hospitals have pastoral-care departments. Pastoral-care professionals have expertise in understanding how an illness influences a person's beliefs and how the beliefs of the person influence illness and recovery. Ask if patients desire to have a member of the clergy visit during their hospitalization. When requested by patients or families, keep clergy informed of any physical, psychosocial, or spiritual concerns affecting the patient. Show respect for patients' spiritual values and needs by allowing time for pastoral-care members to provide spiritual care and facilitating the administration of sacraments, rites, and rituals.

Diet Therapies. Food and nutrition are important aspects of patient care and often an important component of some religious observances (Table 35-2). Food and the rituals surrounding the preparation and serving of food are sometimes important to a person's spirituality. Consult with a dietitian to integrate patients' dietary preferences into daily care. In the event that a hospital or other health care agency cannot prepare food in the preferred way, ask the family to bring meals that fit into dietary restrictions posed by the patient's condition.

Supporting Rituals. Nurses provide spiritual care by supporting patients' participation in spiritual rituals and activities. Plan care

TABLE 35-2 Religious Dietary Regulations Affecting Health Care

RELIGION	DIETARY PRACTICES
Hinduism	Some sects are vegetarians. The belief is not to kill *any* living creature.
Buddhism	Some are vegetarians and do not use alcohol. Many fast on Holy Days.
Islam	Consumption of pork and alcohol is prohibited. Followers fast during the month of Ramadan.
Judaism	Some observe the kosher dietary restrictions (e.g., avoid pork and shellfish, do not prepare and eat milk and meat at the same time).
Christianity	Some Baptists, Evangelicals, and Pentecostals discourage the use of alcohol and caffeine. Some Roman Catholics fast on Ash Wednesday and Good Friday. Some do not eat meat on Fridays during Lent.
Jehovah's Witnesses	Members avoid food prepared with or containing blood.
Mormonism	Members abstain from alcohol and caffeine.
Russian Orthodox Church	Followers observe fast days and a "no meat" rule on Wednesdays and Fridays. During Lent all animal products, including dairy products and butter, are forbidden.
Native Americans	Individual tribal beliefs influence food practices.

to allow time for religious readings, spiritual visitations, or attendance at religious services. Allow family members to plan a prayer session or an organized reading of scriptures on a regular basis. Make arrangements with pastoral-care staff for the patient and family to participate in religious practices (e.g., receiving sacraments). Clergy often visit people who are unable to attend religious services. Taped meditations, classical or religious music, and televised religious services provide other effective options. The nurse respects icons, medals, prayer rugs, or crosses that patients bring to a health setting and ensures they are not accidentally lost, damaged, or misplaced. Supporting spiritual rituals is especially important for older adults (Box 35-5).

Restorative and Continuing Care. For patients who are recovering from a long-term illness or disability or who suffer chronic or terminal disease, spiritual care becomes especially important. Many of the nursing interventions applicable in health promotion and acute care apply to this level of health care as well.

Prayer. Prayer offers an opportunity to renew personal faith and belief in a higher being in a specific, focused way that is either highly ritualized and formal or quite spontaneous and informal. It is an effective coping resource for physical and psychological symptoms (Hollywell and Walker, 2009). Patients pray in private or pursue opportunities for group prayer with family, friends, or clergy. Nurses are supportive of prayer by giving patients privacy, suggesting prayer when they know that patients use it as a coping resource, and participating in prayer with patients. If prayer is not suitable for a patient, alternatives include listening to music or reading a book, poetry, or other inspirational texts selected by the patient.

Meditation. Meditation effectively creates a relaxation response that reduces daily stress. It reduces blood pressure, reduces stress and pain, and enhances the function of the immune system (Horowitz, 2009). Nurses often use guided imagery to help patients learn meditation (see Chapter 32). When patients use meditation in conjunction with their spiritual beliefs, they often report an increased spirituality that they commonly describe as experiencing the presence of a power, force, or energy or what was perceived as God (Box 35-6).

Supporting Grief Work. Patients who experience terminal illness or who have suffered permanent loss in body function because of a disabling disease or injury require the nurse's support in grieving

BOX 35-5 FOCUS ON OLDER ADULTS

Spirituality and Spiritual Health

- There is an association between an older adult's spirituality and his or her ability to adjust or cope with illness (Ebersole et al., 2008).
- Religious activities and spiritual experiences are very common among older adults. Those who experience spiritual well-being have strong social support and better physical and psychological health (Stranahan, 2008).
- Respecting privacy and dignity is an essential part of nursing care, especially when meeting spiritual needs of the older adult (Ellis and Narayanasamy, 2009).
- Many patients use a variety of strategies such as spiritual rituals, exercise, and complementary medicine to cope with pain and chronic illness. Including religious activities and meditation positively enhances coping and feelings of peace (Narayansamy, 2007).
- Feelings of connectedness are important for the older adult (Anderberg and Berglund, 2010). Enhance connectedness by helping older patients find meaning and purpose in life, listening actively to concerns, and being present.
- Beliefs in the afterlife increase as adults grow older. Make visits from clergy, social workers, lawyers, and financial advisors available so patients feel as though they have completed all unfinished business. Leaving a legacy to loved ones prepares the older adult to leave the world with a sense of meaning (Ebersole et al., 2008). Legacies include oral histories, works of art, publications, photographs, or other objects of significance.
- Older-adult caregivers often use their spirituality and spiritual behaviors or practices to help them deal with crisis and conflict (Strudwick, 2010).

BOX 35-6 PATIENT TEACHING

Meditation Techniques

Objective

- The patient will verbalize feelings of relaxation and self-transcendence after meditation.

Teaching Strategies

- Provide patient a brief description of information and a printed teaching guide that describes how to meditate.
- Help patient identify a quiet room in the home that has minimal interruptions.
- Explain that peaceful music or the quiet whirring of a fan blocks out distractions.
- Teach steps of meditation—sit in a comfortable position with the back straight; breathe slowly; and focus on a sound, prayer, or image.
- Encourage patient to meditate for 10 to 20 minutes twice a day.
- Answer questions and reinforce information as needed.

Evaluation

- Have patient describe feelings following meditation.

over and coping with their loss. Chapter 36 summarizes interventions to use in grief work. Your ability to enter into a therapeutic and spiritual relationship with patients supports them during times of grief.

EVALUATION

Through the Patient's Eyes. The evaluation of a patient's spiritual care requires you to think critically in determining if efforts at restoring or maintaining the patient's spiritual health were successful (Fig. 35-6). Include the patient in your evaluation of care. Outcomes established during the planning phase serve as the standards to evaluate the patient's progress. Ask him or her if you and the health care team met their expectations and if there is anything else you can do to enhance their spiritual well-being. In addition, evaluate ethical concerns that arise in the course of the patient's spiritual care and support. Apply critical thinking attitudes and use therapeutic communication techniques to ensure sound nursing judgments.

Patient Outcomes. Attaining spiritual health is a lifelong goal. In evaluating outcomes, compare the patient's level of spiritual health with the behaviors and perceptions noted in the nursing assessment. Evaluation data related to spiritual health are usually subjective. For example, if a nurse's assessment finds the patient losing hope, the follow-up evaluation involves asking the patient if feelings of hope have been restored. Include family and friends when gathering evaluative information. Successful outcomes reveal the patient developing an increased or restored sense of connectedness with family; maintaining, renewing, or reforming a sense of purpose in life; and for some a confidence and trust in a Supreme Being or power. When outcomes are not met, ask questions to determine appropriate continuing care. Examples of questions to ask include the following:

- Do you feel the need to forgive someone or to be forgiven by someone?
- What spiritual activities such as prayer or meditation were helpful in the past?
- Would you like for me to ask a friend, family member, or someone from pastoral care to talk with you?
- What can I do to help you feel more at peace?
- Sometimes people need to give themselves permission to feel hope when they experience difficult events. What can you do to allow yourself to feel hope again?

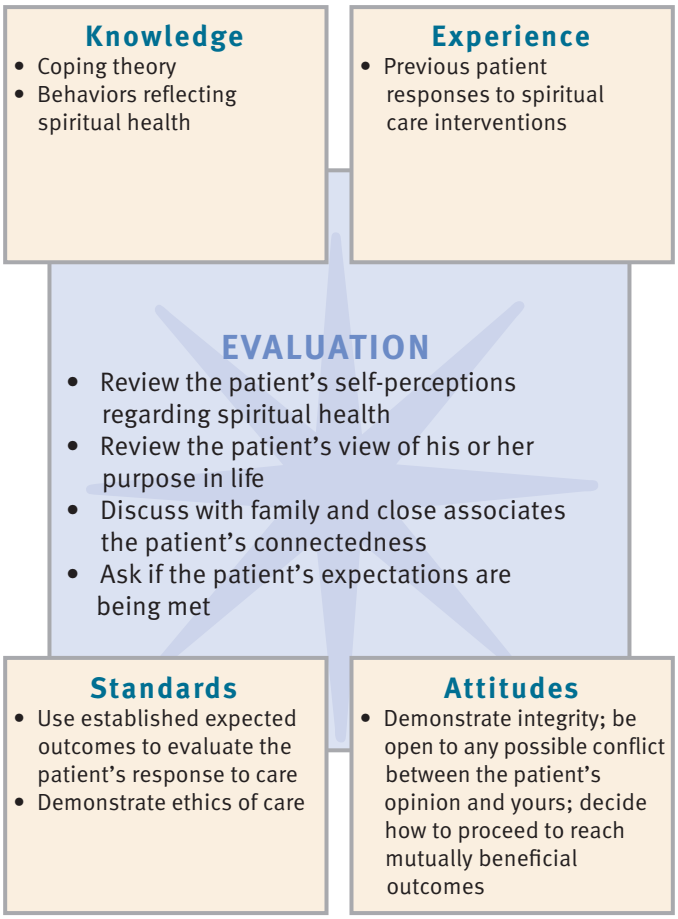

FIG. 35-6 Critical thinking model for spiritual health evaluation.

KEY POINTS

- Attending to a patient's spirituality ensures a holistic focus to nursing practice.
- Beneficial health outcomes occur when individuals are able to exercise their spiritual beliefs.
- Frequently spirituality and religion are interchanged, but spirituality is a much broader and more unifying concept than religion.
- Spirituality is highly personal and unique to each individual.
- Faith and hope are closely linked to a person's spiritual well-being, providing an inner strength for dealing with illness and disability.
- When patients experience acute or chronic illness or a terminal disease, spiritual resources either help them move to recovery, or spiritual distress develops.
- A spiritual assessment is most successful when the nurse applies knowledge that is relevant to therapeutic communication, principles of loss and grief, and knowledge of caring practices.
- The personal nature of spirituality requires open communication and the establishment of trust between nurse and patient.
- Nurses need to determine if a patient's religious beliefs conflict with medical treatment.
- An important part of spiritual assessment is learning who makes up the patient's community of faith.
- Establishing presence involves giving attention, answering questions, having an encouraging attitude, and expressing a sense of trust.
- Connectedness and fellowship with other persons are a source of hope for a patient.
- Part of a patient's caregiving environment is the regular presence of family, friends, and spiritual advisors.
- Prayer is an effective coping resource for physical and psychological symptoms.
- When evaluating spiritual care, successful outcomes reveal the patient developing an increased or restored sense of connectedness with family and maintaining, renewing, or reforming a sense of purpose in life.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Jose continues to regularly visit the human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) clinic. The nurse wants to incorporate a spiritual assessment
