Antidiarrheal Agents. For patients with diarrhea, frequent passage of liquid stools becomes a problem. Many patients use over-the-counter agents such as Imodium to relieve common diarrhea. However, the most effective antidiarrheal agents are prescriptive opiates such as codeine phosphate, opium tincture (Paregoric), and diphenoxylate (Lomotil). Antidiarrheal opiate agents decrease intestinal muscle tone to slow passage of feces. Opiates inhibit peristaltic waves that move feces forward, but they also increase segmental contractions that mix intestinal contents. As a result, the intestinal walls absorb more water. Use antidiarrheal agents with caution because opiates are habit forming. Patients with diarrhea lasting more than 2 days need a stool culture and evaluation of diet and fluid intake for intolerances of food and fluids (e.g., excessive use of fruits, lactose).

Enemas. An enema is the instillation of a solution into the rectum and sigmoid colon. The primary reason for an enema is to promote defecation by stimulating peristalsis. The volume of fluid instilled breaks up the fecal mass, stretches the rectal wall, and initiates the defecation reflex. Enemas are also a vehicle for medications that exert a local effect on rectal mucosa. The most common use for an enema is temporary relief of constipation. Other indications include removing impacted feces, emptying the bowel before diagnostic tests or surgery, and beginning a program of bowel training.

Cleansing Enemas. Cleansing enemas promote the complete evacuation of feces from the colon. They act by stimulating peristalsis through the infusion of a large volume of solution or through local irritation of the mucosa of the colon. They include tap water, normal saline, soapsuds solution, and low-volume hypertonic saline. Each solution has a different osmotic effect, influencing the movement of fluids between the colon and interstitial spaces beyond the intestinal wall. Infants and children receive only normal saline because they are at risk for fluid imbalance.

Tap Water. Tap water is hypotonic and exerts an osmotic pressure lower than fluid in interstitial spaces. After infusion into the colon, tap water escapes from the bowel lumen into interstitial spaces. The net movement of water is low. The infused volume stimulates defecation before large amounts of water leave the bowel. Do not repeat tap-water enemas because water toxicity or circulatory overload develops if the body absorbs large amounts of water.

Normal Saline. Physiologically normal saline is the safest solution to use because it exerts the same osmotic pressure as fluids in interstitial spaces surrounding the bowel. The volume of infused saline stimulates peristalsis. Giving saline enemas does not create the danger of excess fluid absorption.

Hypertonic Solutions. Hypertonic solutions infused into the bowel exert osmotic pressure that pulls fluids out of interstitial spaces. The colon fills with fluid, and the resultant distention promotes defecation. Patients unable to tolerate large volumes of fluid benefit most from this type of enema, which is by design low volume. This type of enema is contraindicated for patients who are dehydrated and young infants. A hypertonic solution of 120 to 180 mL (4 to 6 oz) is usually effective. The commercially prepared Fleet enema is the most common.

Soapsuds. You add soapsuds to tap water or saline to create the effect of intestinal irritation to stimulate peristalsis. Use only pure castile soap that comes in a liquid form included in most soapsuds enema kits. Use soapsuds enemas with caution in pregnant women and older adults because they cause electrolyte imbalance or damage to the intestinal mucosa.

The health care provider sometimes orders a high or low cleansing enema. The terms *high* and *low* refer to the height from which, and hence the pressure with which, the fluid is delivered. High enemas cleanse the entire colon. After the enema is infused, ask the patient to turn from the left lateral to the dorsal recumbent, over to the right lateral position. The position change ensures that fluid reaches the large intestine. A low enema cleanses only the rectum and sigmoid colon.

Oil Retention. Oil-retention enemas lubricate the rectum and colon. The feces absorb the oil and become softer and easier to pass. To enhance action of the oil, the patient retains the enema for several hours if possible.

Other Types of Enemas. Carminative enemas provide relief from gaseous distention. They improve the ability to pass flatus. An example of a carminative enema is MGW solution, which contains 30 mL of magnesium, 60 mL of glycerin, and 90 mL of water.

Medicated enemas contain drugs. An example is sodium polystyrene sulfonate (Kayexalate), used to treat patients with dangerously high serum potassium levels. This drug contains a resin that exchanges sodium ions for potassium ions in the large intestine. Another medicated enema is neomycin solution, an antibiotic used to reduce bacteria in the colon before bowel surgery.

Enema Administration. Enemas are available in commercially packaged, disposable units or with reusable equipment prepared before use. Sterile technique is unnecessary because the colon normally contains bacteria. However, wear gloves to prevent the transmission of fecal microorganisms.

Explain the procedure, including the position to assume, precautions to take to avoid discomfort, and length of time necessary to retain the solution before defecation. If the patient needs to take the enema at home, explain the procedure to a family member.

Often the health care provider orders "enemas until clear." This means that the enema is repeated until the patient passes fluid that is clear and contains no fecal material. It is often necessary to give as many as three enemas, but caution the patient against using more than three. Excess enema use seriously depletes fluids and electrolytes. If the enema fails to return a clear solution after three times (check agency policy) or if the patient seems to not be tolerating the rigors of repeated enemas, notify the health care provider.

Giving an enema to a patient who is unable to contract the external sphincter poses difficulties. Give the enema with the patient positioned on the bedpan. Giving the enema with the patient sitting on the toilet is unsafe because the curved rectal tubing scrapes the rectal wall. Skill 46-1 on pp. 1112-1115 outlines the steps for an enema administration.

Digital Removal of Stool. For a patient with an impaction, the fecal mass is sometimes too large to pass voluntarily. If enemas fail, break up the fecal mass with the fingers and remove it in sections. Digital removal is a last resort in the management of severe constipation and practiced when all other methods have failed. The procedure is very uncomfortable for the patient. Excess rectal manipulation causes irritation to the mucosa; bleeding; and stimulation of the vagus nerve, which results in a reflex slowing of the heart rate. Because of the potential complications of the procedure, a health care provider's order is necessary to remove a fecal impaction (Kyle, 2007c) (Box 46-8).

BOX 46-8 PROCEDURAL GUIDELINES

Digital Removal of Stool

Delegation Considerations

The skill of digital removal of stool cannot be delegated to nursing assistive personnel (NAP).

Equipment

Clean gloves, stethoscope, water-soluble anesthetic lubricant (check agency policy on type of lubricant), towel, washcloth, soap and water, and bedpan

1. Patient identification. Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record (TJC, 2011).
2. Explain the purpose of the procedure and ways patient can assist.
3. Verify medical history of impaction and patient's last bowel movement.
4. Observe for abdominal distention and auscultate abdomen.
5. Obtain baseline vital signs before the procedure.
6. Position patient on the left side with knees flexed and back toward you (Steggall, 2008).
7. Pull curtains around bed. Drape the trunk and lower extremities with a bath blanket and place a waterproof pad under the buttocks. Place a bedpan next to the patient.
8. Apply gloves and lubricate the index and middle fingers of your dominant hand with anesthetic lubricating jelly (Steggall, 2008).
9. Instruct patient to take slow deep breaths, gently and gradually insert the gloved index finger, and feel the anal sphincter relax around the finger. Then insert middle finger into the rectum and advance the finger slowly along the rectal wall toward the umbilicus (Kyle, 2007c; Steggall, 2008).
10. Gently loosen the fecal mass by moving fingers in a scissors motions to fragment fecal mass. Work the finger into the hardened mass.
11. Work the feces downward toward the end of the rectum. Remove small pieces at a time and discard into bedpan.
12. Periodically assess patient's vital signs and look for signs of fatigue.

CLINICAL DECISION: Stop the procedure if the heart rate drops significantly or the rhythm changes.

13. Continue to remove feces and allow patient to rest at intervals (Chien and Bradway, 2010).
14. After completion wash and dry the buttocks and anal area.
15. Remove bedpan and dispose of feces. Remove gloves by turning them inside out and discard.
16. Assist patient to toilet or clean bedpan if urge to defecate develops.
17. Perform hand hygiene.
18. Assess patient's vital signs and determine level of comfort. Auscultate bowel sounds and gently palpate abdomen.
19. Observe for rectal bleeding, diarrhea, changes from baseline vital signs, and increasing pain or abdominal distention.
20. Record results of removal of impaction by describing fecal characteristics.

Inserting and Maintaining a Nasogastric Tube. A patient's condition or situation sometimes requires special interventions to decompress the GI tract. Such conditions include surgery (see Chapter 50), infections of the GI tract, trauma to the GI tract, and conditions in which peristalsis is absent.

A nasogastric (NG) tube is a pliable hollow tube that is inserted through the patient's nasopharynx into the stomach. NG intubation has several purposes (Table 46-6). There are two main categories of NG tubes: Fine- or small-bore tubes and large-bore tubes.

TABLE 46-6 Purposes of Nasogastric Intubation

PURPOSE	DESCRIPTION	TYPE OF TUBE
Decompression	Removal of secretions and gaseous substances from gastrointestinal (GI) tract; prevention or relief of abdominal distention (Lewis et al., 2011)	Salem sump, Levin, Miller-Abbott
Enteral feeding (see Chapter 44)	Instillation of liquid nutritional supplements or feedings into stomach for patients unable to swallow fluid (Lewis et al., 2011)	Duo, Dobhoff, Levin
Compression	Internal application of pressure by means of inflated balloon to prevent internal esophageal or GI hemorrhage (Lewis et al., 2011)	Sengstaken-Blakemore
Lavage	Irrigation of stomach in cases of active bleeding, poisoning, or gastric dilation (Lewis et al., 2011)	Levin, Ewald, Salem sump

Large-bore tubes, 12-Fr and above, are usually used for gastric decompression or removal of gastric secretions. Small-bore tubes are frequently used for medication administration and enteral feedings (see Chapter 44 for enteral feedings). The Levin and Salem sump tubes are the most common for stomach decompression. The Levin tube is a single-lumen tube with holes near the tip. You connect it to a drainage bag or to an intermittent suction device to drain stomach secretions.

The Salem sump tube is preferable for stomach decompression. The tube has two lumina: one for removal of gastric contents and one to provide an air vent. A blue "pigtail" is the air vent that connects with the second lumen. When the main lumen of the sump tube is connected to suction, the air vent permits free, continuous drainage of secretions. Never clamp off the air vent, connect it to suction, or use it for irrigation.

NG tube insertion does not require sterile technique. Simply use clean technique. The procedure is uncomfortable. The patient experiences a burning sensation as the tube passes through the sensitive nasal mucosa. When it reaches the back of the pharynx, the patient sometimes begins to gag. Help him or her relax to make tube insertion easier. Some institutions allow you to use Xylocaine jelly when inserting the tube because it increases patient comfort during the procedure (Skill 46-2 on pp. 1115-1120).

One of the greatest problems in caring for a patient with an NG tube is maintaining comfort. Because the tube constantly irritates the nasal mucosa, you assess the condition of the patient's nares and mucosa for inflammation and excoriation. The tape or fixation device used to anchor the tube often becomes soiled. Change it every day to lessen irritation. Frequent lubrication of the nares also minimizes excoriation. With one nares occluded, the patient breathes through the mouth. Frequent mouth care (at least every 2 hours) helps minimize dehydration. A glass of cool water for rinsing is useful, but the patient who is allowed nothing by mouth (NPO) should not swallow the water. The patient frequently complains of a sore throat. An ice bag applied externally to the throat helps. If ordered by the health care provider, the patient gargles with topical Xylocaine jelly and/or uses lozenges to minimize the irritation.

After you insert the tube, you need to maintain its patency. Sometimes the tip of the tubing rests against the stomach wall, or the tube becomes blocked with thick secretions. Therefore regular irrigation is necessary. Flushing the tube with normal saline by way of a catheter-tipped syringe clears blockages in the tube. If an NG tube continues to drain improperly after irrigation, reposition it by advancing or withdrawing it slightly. Any change in tube position requires you to verify its placement in the patient's GI tract.

The NG tube sometimes causes distention. Its presence causes many patients to swallow large volumes of air. Channels of gastric secretions also form along the walls of the stomach and bypass the suction holes. Turning the patient regularly helps to collapse the channels and promotes emptying of stomach contents (Durston, 2009).

Continuing and Restorative Care. Regular elimination patterns need to begin for a patient to recover and return home or to an extended care facility. When patients have a colostomy, they need to learn to care for the ostomy. Other patients require bowel retraining. It is important to remember that you initiate ostomy care and bowel retraining in acute care settings. However, because these are long-term care needs, teaching is usually completed in restorative care settings. Evidence-based interventions reduce the risk of stoma problems in the older adult population over time (Box 46-9).

Care of Ostomies. Patients with temporary or permanent bowel diversions have unique elimination needs. An individual with an ostomy wears a pouch or appliance to collect **effluent,** stool discharged from the stoma (Dorman, 2009). The patient needs to use meticulous skin care to prevent liquid stool from irritating the skin around the stoma.

Irrigating a Colostomy. Although this practice is not as common as it once was, some patients irrigate their left-sided colostomies to regulate colon emptying. Other patients do not want to spend the additional 60 to 90 minutes in the bathroom every day; thus they empty their pouch as necessary (Dorman, 2009). Only colostomies can be irrigated.

Never use an enema set to irrigate a colostomy. Instead you use specific equipment, which includes a special cone-tipped irrigator to prevent bowel penetration and backflow of the irrigating solution (Fig. 46-19). Help patients to schedule irrigations at times that fit within their daily routine. Before irrigating the stoma, patients usually sit on the toilet and place an irrigating sleeve over the stoma. The end of this sleeve extends into the bowl of the commode. The health care provider orders the amount and type of irrigation solution. For adults the amount typically ranges from 500 to 700 mL of tap water. The patient instills the solution slowly through the lubricated cone tip. Irrigation usually takes 5 to 10 minutes. The patient then removes the cone tip and waits 30 to 45 minutes for the solution and feces to drain out of the irrigation sleeve. Once the drainage stops, the patient applies a stoma cap or a pouch.

Pouching Ostomies. An ostomy requires a pouch to collect fecal material. An effective pouching system protects the skin, contains fecal material, remains odor free, and is comfortable and inconspicuous. A person wearing a pouch needs to feel secure enough to participate in any activity (Deitz, 2010b).

Many pouching systems are available. To ensure that a pouch fits well and meets the patient's needs, consider the location of the ostomy, type and size of the stoma, type and amount of ostomy drainage, size and contour of the abdomen, condition of the skin around the stoma, physical activities of the patient, patient's personal preference, age and dexterity, and cost of equipment. A **wound ostomy continence nurse (WOCN)** is a nurse specially educated to care for ostomy patients; the WOCN collaborates with staff nurses to be sure that the patient uses the correct pouching system, especially when the patient is ill or is experiencing health changes or problems with the ostomy. For example, you initiate a referral to a WOCN when planning the care of a patient who has a high-output ostomy that requires a pouch modification.

BOX 46-9 EVIDENCE-BASED PRACTICE

Recognition of Skin Problems

PICO Question: In patients with ostomies, what is the effect of patient education and knowledge on the prevention of skin breakdown around the ostomy?

Evidence Summary

Patients with an ostomy are at risk for development of peristomal skin problems. Maintenance of healthy peristomal skin, with the skin around the stoma being clean, dry, and intact is a priority following ostomy surgery (Williams et al., 2010). Persons with an ileostomy experience the highest incidence of skin problems, whereas persons with a colostomy have a lower incidence of skin problems (Herlufsen et al., 2006). The most common cause of peristomal skin disorders is effluent, which causes skin irritation, ulceration, or erosion. Reasons for effluent leakage include poor-fitting stoma appliances, poor adhesive adherence, peristomal hernia, and surgical complications (Williams et al., 2010).With shorter postoperative hospital stays, it is challenging for nurses to provide the extensive patient education on pouching systems, ostomy care, and problem-solving techniques needed to prevent peristomal skin problems (Ratliff, Scarano, and Donovan, 2005). Patients often failed to recognize early signs of skin irritation and did not report a skin problem (Herlufsen et al., 2006; Thompson et al., 2011). This lack of knowledge resulted in patients delaying to seek health care to treat the skin problem (Herlufsen et al., 2006). Patient education is an important factor in preventing complications following ostomy surgery. Nurses need to provide education to patients before discharge and follow up with patients after discharge to prevent peristomal skin problems.

Implications for Practice

- Evaluate patient's knowledge and ability to assess skin disorders for early recognition and treatment of skin disorders.
- Provide patient education on signs and symptoms of skin disorders to ensure early identification of skin problems (Herlufsen et al., 2006; Williams et al., 2010).
- Work with the patient to find the simplest ostomy appliance possible with minimal or no accessories (William et al., 2010).
- Refer patients to an ostomy specialist if assistance is needed to manage the ostomy (Thompson et al., 2011).

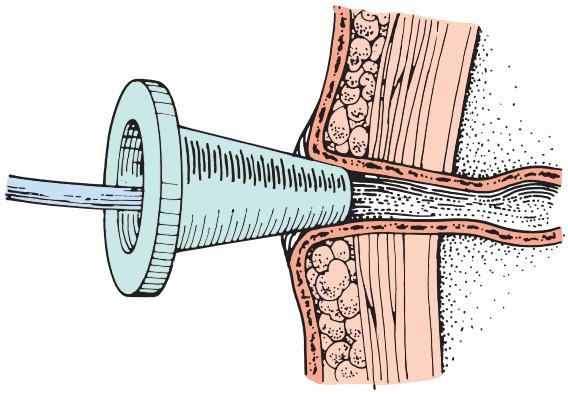

FIG. 46-19 Ostomy irrigation cone inserted into stoma.

A pouching system consists of a pouch and skin barrier. Some pouching systems such as Squibb-ConvaTec, Hollister, Coloplast, and Smith & Nephew are attached to the patient's skin from the adhesive surface of the product; whereas other pouching systems such as VIP are nonadhesive. Pouches come in one- and two-piece systems that are disposable or reusable. Some pouches have the opening precut by the manufacturer; others require the stoma opening to be custom cut to the patient's specific stoma size.

Skin barriers include wafers, pastes, powders, and liquid film applied to the skin around the stoma (Hoeflok et al., 2009). Some wafer skin barriers are permanently attached to the ostomy pouch. These are called *one-piece pouch systems*. With a two-piece system, the patient detaches the pouch from the skin barrier for emptying or changing. This allows the skin barrier to remain around the patient's stoma for several days, thus minimizing the chance of skin damage from too-frequent removal of the skin barrier from the peristomal skin. When using a two-piece pouching system, it is important to remember that the skin barrier and pouch need to be the corresponding size and from the same manufacturer. A pouch from one manufacturer does not fit correctly on a skin barrier from another manufacturer. Be sure to use an ostomy pouch made for collecting fecal matter (colostomy or ileostomy) and not one for collecting urine (urostomy).

Assess the stoma color. A normal stoma is bright pink or brick red. Notify the health care provider if the stoma is blue, brown, or black, which indicates circulation problems to the stoma (WOCN et al., 2010). You need to measure the stoma size carefully when selecting and cutting out the opening on the wafer skin barrier. Too tight of an opening constricts the stoma and causes irritation and necrosis. Subtle stoma changes occur over time. Encourage patients to visit their enterostomal nurse at least annually to ensure proper pouching and fit (see Box 46-9). A good skin barrier protects the skin, prevents irritation from repeated removal of the pouch, and is comfortable for the patient to wear (see Fig. 46-21 in Skill 46-3). Skill 46-3 on p. 1121-1124 describes steps for applying a pouching system.

Patients with new stomas often feel vulnerable when they leave the hospital. To provide a smooth transition from hospital to home, offer help for the patient and family caregivers (Richbourg et al., 2007). Effective patient teaching helps patients with a new ostomy transition smoothly to home (Dixon, 2007) (Box 46-10).

Nutritional Considerations for Patients with Ostomies. Nutritional therapy is important for patients with ostomies. During the first weeks after surgery many health care providers recommend low-fiber diets, particularly for patients with ileostomies, because the small bowel requires time to adapt to the diversion. Low-fiber foods include bread, noodles, rice, cream cheese, eggs (not fried), strained fruit juices, lean meats, fish, and poultry. As ostomies heal, patients are able to eat almost any food. High-fiber foods such as fresh fruits and vegetables help ensure a more solid stool. Patients need to avoid blockages of the bowel. The surgical construction of the stoma affects the likelihood of blockage.

A patient with an ileostomy needs to eat slowly and chew food completely. Drinking 10 to 12 glasses of water daily (unless contraindicated) also prevents blockage. High-fiber foods that cause problems include stringy meats, mushrooms, popcorn, fruits such as cherries, and some seafood such as shrimp and crab. Patients with ostomies often benefit from avoiding foods that cause gas and odor, including broccoli, cauliflower, dried beans, and Brussels sprouts.

Bowel Training. The patient with incontinence is unable to maintain bowel control. A **bowel training** program helps some patients defecate normally, especially those who still have some neuromuscular control.

BOX 46-10 PATIENT TEACHING

Teaching the Patient How to Provide Ostomy Care

Objective

- Patient/caregiver will demonstrate how to change an ostomy pouch.

Teaching Strategies

- Provide a comprehensive list of the products needed to care for the ostomy (Durston, 2009; Rust, 2007).
- Provide patient/caregiver with supplies to last 1 to 2 weeks and the contact number and location of nearest medical supply store (Dorman, 2009).
- Show patient/caregiver the step-by-step approach for changing an ostomy pouch (Deitz, 2010b; Durston, 2009).
- Provide at least one opportunity for patient/caregiver to change the ostomy pouch while patient is in the hospital.
- Arrange visits from a community stoma care nurse or home care nurse and provide contact numbers (Deitz, 2010b; Pearson, 2010).
- Provide detailed discharge instructions for skin care, clothing, driving, lifting, resuming exercise, and when to contact the health care provider (Dixon, 2007).

Evaluation

- Observe patient/caregiver change ostomy pouch.
- Ask patient/caregiver to state signs of stoma irritation and how to relieve it.
- Ask patient/caregiver to describe expected output from stoma and when to call the health care provider.

The training program involves setting up a daily routine. By attempting to defecate at the same time each day and using measures that promote defecation, the patient gains control of bowel reflexes (Mengel, 2009). The program requires time, patience, and consistency. The health care provider determines the patient's physical readiness and ability to benefit from bowel training. A successful program includes the following:

- Assessing the normal elimination pattern and recording times when the patient is incontinent
- Incorporating principles of gerontological nursing when providing bowel retraining programs for the older adult (Box 46-11)
- Choosing a time in the patient's pattern to initiate defecation-control measures
- Giving stool softeners orally every day or a cathartic suppository at least half an hour before the selected defecation time (lower colon needs to be free of stool so suppository contacts intestinal mucosa)
- Offering a hot drink (hot tea) or fruit juice (prune juice) (or whatever fluids normally stimulate peristalsis for the patient) before the defecation time
- Helping the patient to the toilet at the designated time
- Avoiding medications such as opioids that increase constipation
- Providing privacy and setting a time limit for defecation (15 to 20 minutes)
- Instructing the patient to lean forward at the hips while sitting on the toilet, apply manual pressure with the hands over the abdomen, and bear down but not strain to stimulate colon emptying
- Not criticizing or conveying frustration if the patient is unable to defecate

BOX 46-11 FOCUS ON OLDER ADULTS

Bowel Retraining

- Constipation is common in older patients (Gray-Vickrey, 2010).
- Coarse bran rather than refined fiber is more effective in increasing stool weight (Holman et al., 2008).
- A minimum of 1500 mL of fluid per day reduces the risk of constipation, with increased fluid needs during summer months and for those on diuretics with stable cardiovascular status (Holman et al., 2008; JBI, 2008).
- If holding a drinking cup is a problem, consider using a lighter plastic cup and filling half full, refilling frequently.
- Fruit juices increase fiber content and intake.
- Encourage regular exercise. Maintaining an erect posture in an immobile patient reduces the risk of constipation (Holman et al., 2008; JBI, 2008).
- Patients need to feel at ease during elimination. Lack of privacy leads the patient to ignore the urge to defecate (Pegram et al., 2008).
- Review all medications with the health care provider to provide substitute medications that are less likely to cause constipation whenever possible (Chien and Bradway, 2010).
- Behavioral interventions such as habit training provide relief of constipation. Have patients sit on the toilet about 30 minutes after a meal, whether or not they feel the urge to defecate (Chien and Bradway, 2010).

- Maintaining normal exercise within the patient's physical ability

Maintenance of Proper Fluid and Food Intake. In choosing a diet for promoting normal elimination, consider the frequency of defecation, characteristics of feces, and types of foods that impair or promote defecation. The patient with frequent constipation or impaction requires an increased intake of high-fiber foods and more fluids. However, he or she needs to realize that diet therapy provides only long-term relief of elimination problems and does not give immediate relief from problems such as constipation.

When diarrhea is a problem, recommend foods with low-fiber content and discourage foods that typically cause gastric upset or abdominal cramping. Diarrhea caused by illness is sometimes debilitating. If the patient cannot tolerate foods or liquids orally, intravenous therapy (with potassium supplements) is necessary. The patient returns to a normal diet slowly, often beginning with fluids. Excessively hot or cold fluids stimulate peristalsis, causing abdominal cramps and further diarrhea. As tolerance to liquids improves, the patient eats solid foods.

Promotion of Regular Exercise. A daily exercise program helps prevent elimination problems. Walking, riding a stationary bicycle, or swimming stimulates peristalsis. Patients who are sedentary at work are most in need of regular exercise.

For a patient temporarily immobilized, attempt ambulation as soon as possible. If the condition permits, help the patient walk to a chair on the evening of the day of surgery. Have him or her walk farther each day.

Some patients have difficulty passing stool because of weak abdominal and pelvic floor muscles. Exercises help patients who are confined to bed use a bedpan. The patient practices the exercises as follows:

- Lie supine; tighten the abdominal muscles as though pushing them to the floor. Hold the muscles tight to the count of three; relax. Repeat 5 to 10 times as tolerated.
- Flex and contract the thigh muscles by raising one knee slowly toward the chest. Repeat for each leg at least 5 times and increase frequency as tolerated.

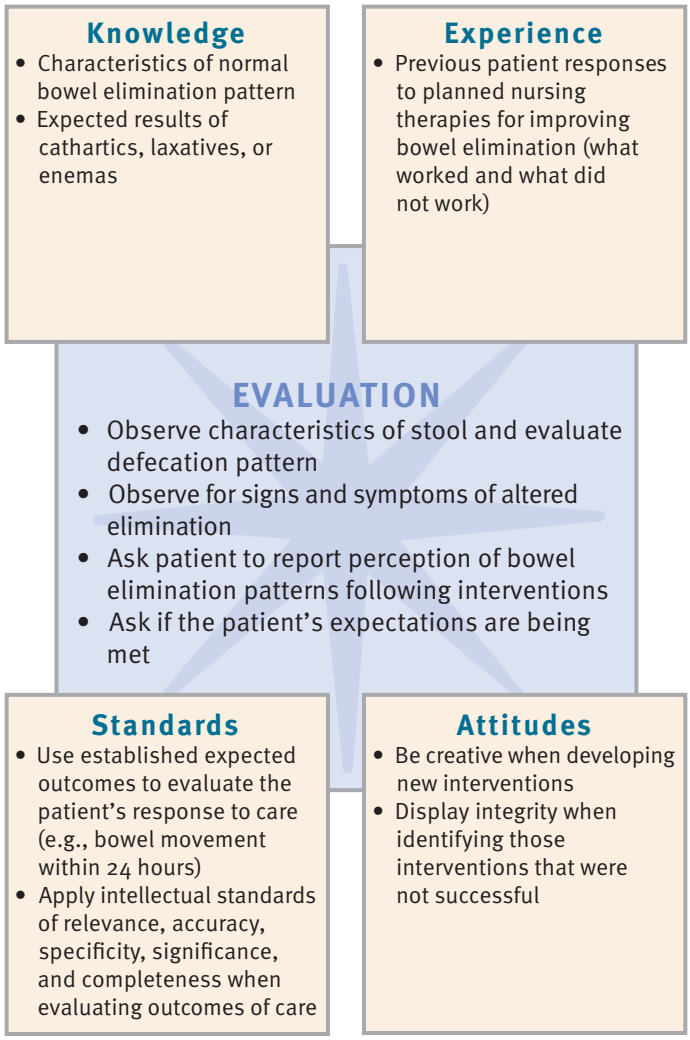

FIG. 46-20 Critical thinking model for elimination evaluation.

Hemorrhoids. Pain results when hemorrhoid tissues are irritated directly. The primary goal for the patient with hemorrhoids is to have soft-formed, painless bowel movements. Proper diet, fluids, and regular exercise improve the likelihood of stools being soft. If the patient becomes constipated, passage of hard stools causes bleeding and irritation. An ice pack or a warm sitz bath (see Chapter 48) provides temporary relief of swollen hemorrhoids.

Maintenance of Skin Integrity. The patient with diarrhea or fecal incontinence is at risk for skin breakdown when fecal contents remain on the skin. The same problem exists for the patient with an ostomy that drains liquid stool. Liquid stool is usually acidic and contains digestive enzymes. Irritation from repeated wiping with toilet tissue aggravates skin breakdown. Bathing the skin after soiling helps, but sometimes it results in more breakdown unless the patient dries the skin thoroughly.

When caring for a patient who is debilitated, incontinent, and unable to ask for assistance, check often for defecation. You can protect the anal areas with petrolatum, zinc oxide, or another ointment that holds moisture in the skin, preventing drying and cracking. Yeast infections of the skin often develop easily. Several powdered antifungal agents are effective against yeast. Do not use baby powder or cornstarch because they have no medical properties, often cake on the skin, are difficult to remove, and enhance fungal infections of the skin.

EVALUATION

Through the Patient's Eyes. The effectiveness of care depends on success in meeting the expected outcomes of self-care. Optimally the patient will be able to have regular, pain-free defecation of soft-formed stools. The patient is the only one who is able to determine if the bowel elimination problems have been relieved and which therapies were the most effective (Fig. 46-20).

Patient Outcomes. If the nurse establishes a therapeutic relationship with the patient, the patient feels comfortable in discussing the intimate details often associated with bowel elimination. Patients are not embarrassed as nurses help them with elimination needs. Patients relate feelings of comfort and freedom from pain as elimination needs are met within the limits of their condition and treatment. Evaluate a patient's level of knowledge regarding establishing a normal elimination pattern, caring for an ostomy, and promoting skin integrity. Also determine the extent to which the patient accomplishes normal defection. Ask the patient to describe changes in diet, fluid intake, and activity to promote bowel health. You ask the following questions when a patient's outcomes are not met:

- Do you use medications such as laxatives or enemas to help you defecate?
- What barriers are preventing you from eating a diet high in fiber and participating in regular exercise?
- How much fluid do you drink in a typical day? What types of fluids do you normally drink?
- What challenges do you encounter when you change your ostomy pouch?

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized, patient care.

- Instruct patients who self-administer enemas to use the side-lying position. Tell them not to self-administer an enema while sitting on the toilet because this position results in curved rectal tubing, causing friction that wears down the rectal wall.
- If a patient has cardiac disease or is taking cardiac or hypertensive medication, obtain pulse rate because manipulation of rectal tissue stimulates the vagus nerve and sometimes causes a sudden decline in pulse rate, which increases the patient's risk of fainting while on the bedpan, bedside commode, or toilet.

SKILL 46-1 ADMINISTERING A CLEANSING ENEMA

View Video!

Delegation Considerations

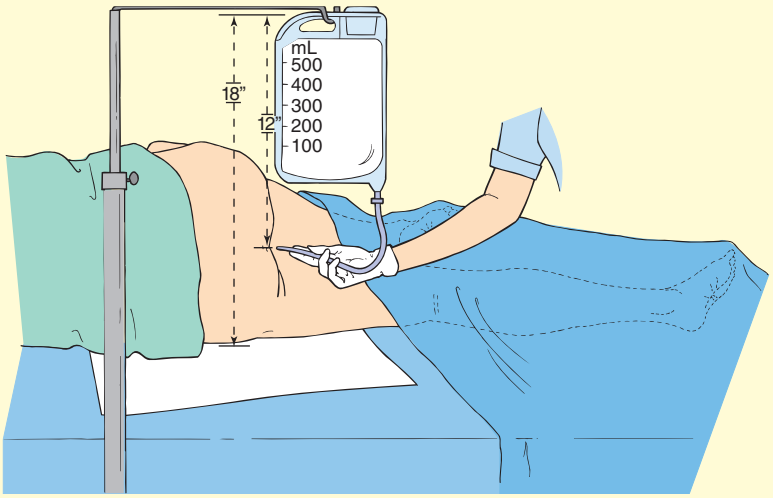
The skill of administering an enema can be delegated to nursing assistive personnel (NAP). However, the nurse must first assess the patient for specific considerations such as need for alternative positioning, comfort, and stable vital signs before the procedure. Instruct NAP about:

- Proper way to position patients who have mobility restrictions such as patients with arthritis or severe fatigue.
- How to position patients who also have therapeutic equipment present such as drains, intravenous (IV) catheters, or traction.
- Specific signs and symptoms of patient's intolerance to the procedure and when to stop it such as abdominal pain more than a pressure sensation, abdominal cramping, abdominal distention, or rectal bleeding.

Equipment

- Clean gloves
- Water-soluble lubricant
- Waterproof, absorbent pads
- Bath blanket
- Toilet tissue
- Bedpan, bedside commode, or access to toilet
- Washbasin, washcloths, towel, and soap
- IV pole
- Enema kit with
  - Enema container
  - Tubing and clamp (if not already attached to container)
  - Appropriate-size rectal tube
    - *Adult:* 22- to 30-Fr
    - *Child:* 12- to 18-Fr
  - Correct volume of warmed solution:
    - *Adult:* 750 to 1000 mL
    - *Child:*
      - 150 to 250 mL, infant
      - 250 to 350 mL, toddler
      - 300 to 500 mL, school-age child
      - 500 to 750 mL, adolescent

or



- Prepackaged enema container with rectal tip

STEP	RATIONALE
ASSESSMENT	
1 Assess status of patient: last bowel movement, normal bowel patterns, hemorrhoids, mobility, external sphincter control, and abdominal pain.	Determines factors indicating need for enema and influencing type of enema used.
2 Assess for presence of increased intracranial pressure, glaucoma, or recent rectal or prostate surgery.	Conditions contraindicate use of enemas (Pegram et al., 2008).
3 Check patient's medical record to clarify rationale for the enema.	Determines purpose of enema administration: preparation for special procedure or relief of constipation.

STEP	RATIONALE
4 Review health care provider's order for enema.	Order by health care provider is required. Determines number and type of enema to give.
5 Identify patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
6 Inspect for abdominal distention and auscultate for bowel sounds.	Establishes baseline for determining effectiveness of enema.
PLANNING	
1 Explain purpose of enema and determine patient's level of understanding.	Allows time to plan for appropriate teaching measures.
2 Collect appropriate equipment and arrange at beside.	Ensures smooth procedure.
IMPLEMENTATION	
1 Assemble enema bag with appropriate solution and rectal tube.	
2 Perform hand hygiene and apply gloves.	Reduces transmission of microorganisms.
3 Provide privacy by closing curtains around bed or closing door.	Reduces embarrassment for patient.
4 Raise bed to appropriate working height and raise side rail on patient's left.	Promotes good body mechanics and patient safety.
5 Assist patient into left side-lying (Sims') position with right knee flexed. You can also place children in dorsal recumbent position.	Allows enema solution to flow downward by gravity along natural curve of sigmoid colon and rectum, thus improving retention of solution.
CLINICAL DECISION: *If patient is suspected of having poor sphincter control, position on bedpan. Patient will have difficulty retaining enema solution. Do not administer enema with patient sitting on toilet.*	
6 Place waterproof pad under hips and buttocks.	Prevents soiling of linen.
7 Cover patient with bath blanket, exposing only rectal area and clearly visualizing anus.	Provides warmth, reduces exposure of body parts, and allows patient to feel more relaxed and comfortable.
8 Place bedpan or commode in easily accessible position. If patient is expelling contents in toilet, ensure that toilet is free. (If patient is getting up to bathroom to expel enema, place his or her slippers and bathrobe in easily accessible position.)	Used in case patient is unable to retain enema solution.
9 Administer enema:	
a. Enema bag	
(1) Add warmed solution to enema bag: warm tap water as it flows from faucet; place saline container in basin of hot water before adding saline to enema bag; check temperature of solution by pouring small amount over inner wrist.	Hot water burns intestinal mucosa. Cold water causes abdominal cramping and is difficult to retain (Holman et al., 2008).
(2) Raise container, release clamp, and allow solution to flow long enough to fill tubing.	Procedure removes air from tubing.
(3) Reclamp tubing.	Reclamping prevents further loss of solution.
(4) Lubricate 6 to 8 cm (2½ to 3 inches) of tip of rectal tube with water-soluble lubricating jelly.	Lubricating allows smooth insertion of rectal tube without risk of irritation or trauma to mucosa.
(5) Gently separate buttocks and locate anus. Instruct patient to relax by breathing out slowly through mouth. Then touch patient's skin next to anus with tip of rectal tube.	Breathing out and touching skin with tube promotes relaxation of external anal sphincter.
(6) Insert end of tubing of enema bag slowly by pointing tip in direction of patient's umbilicus (see illustration). Length of insertion varies: *Adult:* 7.5-10 cm (3-4 inches) *Adolescent:* 7.5-10 cm (3-4 inches) *Child:* 5-7.5 cm (2-3 inches) *Infant:* 2.5-3.75 cm (1-1½ inches)	Careful insertion prevents trauma to rectal mucosa from accidental lodging of tube against rectal wall. Insertion beyond proper limit causes bowel perforation (Pegram et al., 2008).
(7) Hold tubing in rectum constantly until end of fluid instillation.	Bowel contraction causes expulsion of rectal tube.
(8) Open regulating clamp and allow solution to enter slowly with container at patient's hip level.	Rapid instillation stimulates evacuation of rectal tube.
(9) Raise height of enema container slowly to appropriate level above anus: 30-45 cm (12-18 inches) for high enema, 30 cm (12 inches) for regular enema, 7.5 cm (3 inches) for low enema. Instillation time varies with volume of solution you administer.	Proper height allows for continuous, slow instillation of solution. Raising container too high causes rapid instillation and possible painful distention of colon (Pegram et al., 2008). High pressure causes rupture of bowel in infant.
(10) Lower container to decrease flow of solution or clamp tubing if patient experiences cramping or if fluid escapes around rectal tube.	Temporary cessation of instillation prevents cramping, which prevents patient from retaining all fluid, altering effectiveness of enema.
(11) Clamp tubing after all solution is instilled.	Clamping prevents air from entering rectum.

SKILL 46-1 ADMINISTERING A CLEANSING ENEMA—cont'd

STEP	RATIONALE

STEP 9a(6) Insertion of enema tube into rectum.

CLINICAL DECISION: *If pain occurs or resistance is felt at any time during procedure, stop and confer with physician. Do not force the tube.*

b. Prepackaged disposable container	
(1) Remove plastic cap from rectal tip. Tip is already lubricated, but you can apply more jelly as needed.	Lubrication provides for smooth insertion of rectal tube without causing rectal irritation or trauma.
(2) Gently separate buttocks and locate rectum. Instruct patient to relax by breathing out slowly through mouth.	Breathing out promotes relaxation of external rectal sphincter.
(3) Insert tip of bottle gently into rectum: *Adult:* 7.5-10 cm (3-4 inches) *Adolescent:* 7.5-10 cm (3-4 inches) *Child:* 5-7.5 cm (2-3 inches) *Infant:* 2.5-3.75 cm (1-1½ inches)	Gentle insertion prevents trauma to rectal mucosa.
(4) Squeeze bottle until all of solution has entered rectum and colon. Instruct patient to retain solution until urge to defecate occurs, usually 2 to 5 minutes.	Hypertonic solutions require only small volumes to stimulate defecation. Transient hyperphosphatemia correlates with retention greater than 15 minutes (Jacobson et al., 2010).
10 Place layers of toilet tissue around tube at anus and gently withdraw rectal tube.	Provides patient's comfort and cleanliness.
11 Explain to patient that feeling of distention is normal. Ask patient to retain solution as long as possible while lying quietly in bed. (For infant or young child, gently hold buttocks together for a few minutes.)	Solution distends bowel. Length of retention varies with type of enema and patient's ability to contract rectal sphincter. Longer retention promotes more effective stimulation of peristalsis and defecation (Kyle, 2007b).
12 Discard enema container and tubing in proper receptacle or rinse out thoroughly with warm soap and water if reusing container.	Reduces transmission and growth of microorganisms.
13 Assist patient to bathroom or help to position on bedpan.	Normal squatting position promotes defecation.
14 Assist patient as needed with washing anal area with warm soap and water (if administering perineal care, use gloves).	Fecal contents irritate skin. Hygiene promotes patient's comfort.
15 Remove and discard gloves and perform hand hygiene.	Good hygiene reduces transmission of microorganisms.

EVALUATION

1 Evaluate color, consistency, and amount of stool; odor; and fluid passed.	Determines efficacy of enema.
2 Observe abdomen for distention.	Determines if distention is relieved.
3 Ask patient about cramping or discomfort.	Provides information about patient's level of comfort.

CLINICAL DECISION: *When enemas are ordered "until clear," observe contents of solution passed. Return is "clear" when no solid fecal material exists, but the solution sometimes remains discolored.*

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Abdomen becomes rigid and distended.
- Stop enema if you are instilling fluid.
- Notify health care provider and obtain vital signs.

2 Abdominal pain or cramping develops.
- Decrease height of enema bag and slow rate of instillation.
- Have patient take slow, deep breaths in through nose and out through mouth.

3 Bleeding occurs.
- Stop enema administration.
- Notify health care provider.
- Obtain vital signs and assess abdomen and rectum.

RECORDING AND REPORTING

- Record type and volume of enema given and characteristics of results.
- Report failure of patient to defecate to health care provider.

HOME CARE CONSIDERATIONS

- For patients who require enemas for bowel preparation at home, instruct family not to exceed recommended fluid volume levels or number of enemas. Instruct family about need for slow administration of warmed fluid.
- Instruct family about the negative side effects of tap water enemas.

SKILL 46-2 INSERTING AND MAINTAINING A NASOGASTRIC TUBE FOR GASTRIC DECOMPRESSION

Delegation Considerations

The skill of inserting and maintaining a nasogastric (NG) tube cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP to:
- Measure and record the drainage.
- Provide oral and nasal hygiene.
- Perform selected comfort measures such as positioning, offering ice chips if allowed.
- Correctly anchor NG tube to patient's gown after changing gown or repositioning patient.

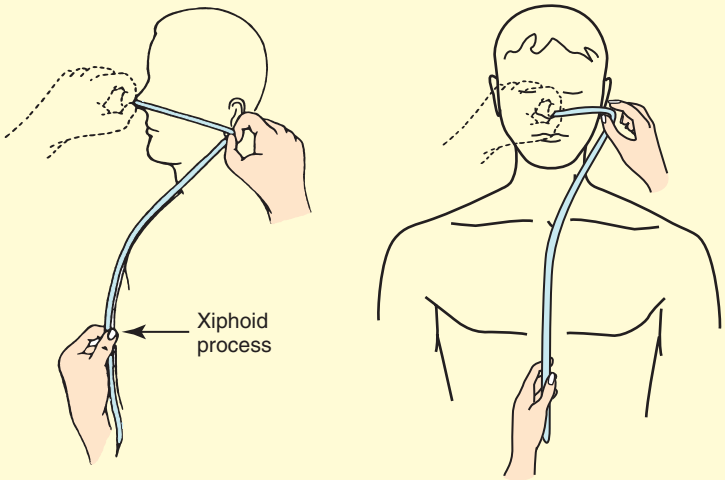
Equipment

- Inserting large-bore tube
  - 14- or 16-Fr NG tube (smaller lumens are not used for decompression in adults because the tube must be able to remove thick secretions)
  - Water-soluble lubricating jelly
  - Clean gloves
  - pH test strips (measure gastric aspirate acidity)
  - Tongue blade
  - Flashlight
  - Emesis basin
  - Asepto bulb or catheter-tipped syringe
  - Normal saline
  - 2.5 cm (1 inch)–wide hypoallergenic tape or commercial fixation device
  - Tincture of benzoin (optional)
  - Safety pin and rubber band
  - Clamp of suction machine and pressure gauge if wall suction is used
  - Towel, facial tissues
  - Glass of water with straw
- Irrigating NG tube
  - Asepto bulb or catheter-tipped syringe
  - Normal saline and basin
  - Clean gloves
- Discontinuing NG tube
  - Towel, facial tissue
  - Clean gloves
  - Soap and water

STEP	RATIONALE
ASSESSMENT	
1 Perform hand hygiene.	Good hygiene reduces transmission of organisms.
2 Inspect condition of patient's nasal and oral cavity.	Baseline condition of nasal and oral cavity determines need for special nursing measures for oral hygiene after tube placement.
3 Ask if patient has had history of nasal surgery and note if deviated nasal septum is present.	You insert tube into **uninvolved** nasal passage. Procedure is often contraindicated if surgery is recent.

SKILL 46-2 INSERTING AND MAINTAINING A NASOGASTRIC TUBE FOR GASTRIC DECOMPRESSION—cont'd

STEP	RATIONALE
4 Auscultate for bowel sounds. Palpate patient's abdomen for distention, pain, and rigidity.	Baseline determination of level of abdominal distention later serves as comparison once tube is inserted. In presence of diminished or absent bowel sounds, auscultate each quadrant for 5 minutes (Seidel et al., 2011).
5 Assess patient's level of consciousness and ability to follow instructions.	Assessment determines patient's ability to assist in procedure.



CLINICAL DECISION: *If patient is confused, disoriented, or unable to follow commands, obtain assistance from another staff member to insert the tube.*

PLANNING

1 Identify patient using two identifiers (e.g., Name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Explain procedure.	Explanation gains patient's cooperation and lessens possibility that patient will remove tube.
3 Determine if patient had an NG tube insertion in the past and, if so, which naris was used.	Previous experience complements explanations and helps you determine which naris to use.
4 Check medical record for health care provider's order; type of NG tube to be placed; and whether tube is to be attached to suction, gravity, or feeding solution.	Procedure requires health care provider's order. Adequate decompression depends on NG suction.
5 Prepare equipment at bedside. Cut a piece of tape about 10 cm (4 inches) long and split one end in half to form a V or have NG tube fixator device available.	Ensures well-organized procedure. Tape or fixator device is used to hold tube in place after insertion.

IMPLEMENTATION

1 Position patient in high-Fowler's position with pillows behind head and shoulders. Raise bed to horizontal level comfortable for nurse.	Promotes patient's ability to swallow during procedure. Positioning of bed prevents strain on nurse.
2 Have patient blow nose. Place bath towel over his or her chest; give him or her facial tissues. Place emesis basin within reach.	Removes existing nasal secretions. Prevents soiling of patient's gown. Tube insertion through nasal passages sometimes causes tearing and coughing with increased salivation.
3 Pull curtain around bed or close room door.	Provides privacy.
4 Stand on patient's right side if right-handed, left side if left-handed.	Allows easiest manipulation of tubing.
5 Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
6 Instruct patient to relax and breathe normally while occluding one naris. Repeat this action for other naris. Select nostril with greater airflow.	Tube passes more easily through naris that is more patent. Ensures that tube insertion does not obstruct nasal airflow.
7 Measure distance to insert tube: **a.** *Traditional method:* Measure distance from tip of nose to earlobe to xiphoid process (see illustrations) **b.** *Hanson method:* Mark 50-cm (20-inch) point on tube and measure traditionally. Tube insertion is at midway point between 50 cm (20 inches) and traditional mark.	Approximates distance from naris to stomach. Distance varies with each patient (Durston, 2009).

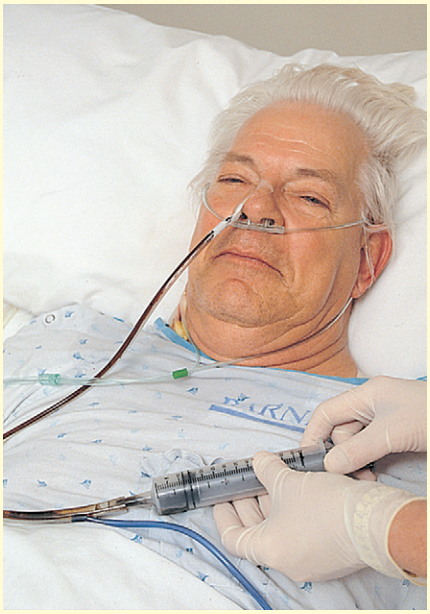
STEP 7a Technique for measuring distance to insert nasogastric tube.

STEP	RATIONALE
8 Mark length of tube to be inserted by placing small piece of tape so it can easily be removed.	Marks amount of tube to be inserted from nares to stomach (Durston, 2009).
9 Curve 10 to 15 cm (4 to 6 inches) of end of tube tightly around index finger and release.	Curving tube tip aids insertion and decreases tube stiffness.
10 Lubricate 7.5 to 10 cm (3 to 4 inches) of end of tube with water-soluble lubricating jelly.	Minimizes friction against nasal mucosa and aids insertion of tube. Water-soluble lubricant is less toxic than oil-based if aspirated.
11 Initially instruct patient to extend neck back against pillow (see illustration); insert tube gently and slowly through naris, aiming end of tube downward.	Facilitates initial passage of tube through naris and maintains clear airway for open naris.

STEP 11 Insert nasogastric tube with curved end pointing downward.

12 Continue to pass tube along floor of nasal passage, aiming downward toward patient's ear. If resistance is met, apply gentle downward pressure to advance tube. (Do not force past resistance.)	Minimizes discomfort of tube rubbing against upper nasal turbinates. Resistance is caused by posterior nasopharynx. Downward pressure helps tube curl around corner of nasopharynx.
13 If you meet resistance, try to rotate tube and see if it advances. If still resistant, withdraw tube, allow patient to rest, relubricate tube, and insert into other naris.	Forcing against resistance causes trauma to mucosa (Durai et al., 2009). Helps relieve patient's anxiety.

CLINICAL DECISION: *If unable to insert tube in either naris, stop procedure and notify health care provider.*

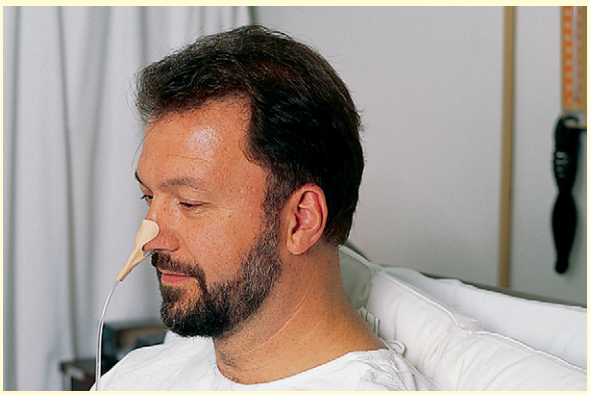


14 Continue inserting tube until just past nasopharynx by gently rotating it toward opposite nostril and passing it just above oropharynx.	Helps prevent coiling of tube in oropharynx.
a. Stop tube advancement and allow patient to relax, and provide tissues.	Relieves patient's anxiety; tearing is natural response to mucosal irritation, and excessive salivation often occurs because of oral stimulation.
b. Explain to patient that next step requires that he or she swallow. Give patient glass of water unless contraindicated.	Sipping water aids passage of NG tube into esophagus.
15 With tube just above oropharynx, instruct patient to flex head forward, take a small sip of water, and swallow. Advance tube 2.5 to 5 cm (1 to 2 inches) with each swallow of water. If patient is not allowed fluids, instruct to dry swallow or suck air through straw.	Flexed position closes off upper airway to trachea and opens esophagus. Swallowing closes epiglottis over trachea and helps move the tube into the esophagus. Swallowing water reduces gagging or choking. Suction removes water from stomach once it is connected.
16 If patient begins to cough, gag, or choke, withdraw tube slightly (do not remove it) and stop tube advancement. Instruct patient to breathe easily and take sips of water.	Sometimes tube accidentally enters larynx and produces coughing; withdrawal of tube reduces risk of laryngeal entry (Durai et al., 2009). Swallowing water eases gagging. Give water cautiously to reduce risk of aspiration.

CLINICAL DECISION: *If vomiting occurs, help patient clear airway; use oral suctioning if needed. Do not proceed until airway is cleared.*

17 If patient continues to gag and cough or complains that tube feels as though it is coiling in back of throat, check back of oropharynx with tongue blade. If tube has coiled, withdraw it until tip is back in oropharynx. Reinsert with patient swallowing.	When tube coils around itself in back of throat, it stimulates gag reflex (Durai et al., 2009).
18 After patient relaxes, continue to advance tube with swallowing until tape or mark is reached. Temporarily anchor tube to patient's cheek with piece of tape until tube placement is verified.	Tip of tube needs to be well within stomach for adequate decompression. Anchor tube before verifying placement.

SKILL 46-2 INSERTING AND MAINTAINING A NASOGASTRIC TUBE FOR GASTRIC DECOMPRESSION—cont'd



STEP	RATIONALE
19 Verify tube placement. Check agency policy for preferred methods for checking NG tube placement.	
a. Inspect posterior pharynx for presence of coiled tube.	Tube is pliable and can coil up in back of pharynx instead of advancing into esophagus (Durai et al., 2009).
b. Attach Asepto or catheter-tipped syringe to end of tube and aspirate gently back on syringe to obtain gastric contents, observing color (see illustration).	Gastric contents are usually cloudy and green but may be off-white, tan, bloody, or brown in color. Aspiration of contents provides means to measure fluid pH and thus determine tube tip placement in gastrointestinal tract (Durai et al., 2009). Other common aspirate colors include the following: duodenal placement (yellow or bile stained), esophagus (may or may not have saliva-appearing aspirate).
c. Measure pH of aspirate with color-coded pH paper with range of whole numbers from 1.0 to 11.0 or greater (see illustration).	Gastric aspirates have decidedly acidic pH values, preferably 5.5 or less, compared with intestinal aspirates, which are usually 6.0 or greater, or respiratory secretions, which are usually alkaline at 7.0 or greater (Durston, 2009). Use only gastric (Gastrocult) pH test and not Hemoccult test.
d. Have ordered x-ray film examination performed of chest/abdomen.	X-ray film is best verification of initial placement of tube (Durai et al., 2009).
e. If tube is not in stomach, advance another 2.5-5 cm (1-2 inches) and repeat Steps 19a-e to check tube position.	Tube must be in stomach to provide decompression.
20 Anchoring tube:	
a. After tube is properly inserted and positioned, either clamp end or connect it to drainage bag or suction source.	Drainage bag is used for gravity drainage. Intermittent low suction is most effective for decompression. Patient going to operating room or for diagnostic test often has tube clamped.
b. Tape tube to nose; avoid putting pressure on nares.	Prevents tissue necrosis. Tape anchors tube securely.
(1) Apply small amount of tincture of benzoin to lower end of nose and allow to dry *(optional).*	Benzoin prevents loosening of tape if patient perspires.
(2) Apply tape to nose, leaving split ends free. Be sure that top end of tape over nose is secure.	
(3) Carefully wrap two split ends of tape around tube (see illustration).	
(4) *Alternative:* Apply tube fixation device using shaped adhesive patch (see illustration).	
c. Fasten end of NG tube to patient's gown by looping rubber band around tube in slipknot. Pin rubber band to gown (provides slack for movement).	Reduces pressure on nares if tube moves.

STEP 19b Aspiration of gastric contents.

STEP 19c Checking pH of gastric aspirate.

STEP	RATIONALE
 **STEP 20b(3)** Tape is crossed over and around nasogastric tube.	 **STEP 20b(4)** Patient with tube fixation device.
21 Unless health care provider orders otherwise, elevate head of bed 30 degrees.	Helps prevent esophageal reflux and minimizes irritation of tube against posterior pharynx (Durai et al., 2009).
22 Once placement is confirmed:	
a. Place red mark on tube to indicate where it exits nose.	The mark or tube length is to be used as a guide to indicate whether displacement may have occurred.
b. Measure tube length from nares to connector as an alternate method.	
c. Document tube length in patient record.	
23 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
24 Tube irrigation:	
a. Perform hand hygiene and apply gloves.	Reduces transmission of microorganisms.
b. Check for tube placement in stomach (see Step 19). Reconnect NG tube to connecting tube.	Prevents accidental entrance of irrigating solution into lungs (Durai et al., 2009).
c. Draw up 30 mL of normal saline into Asepto or catheter-tipped syringe.	Use of saline minimizes loss of electrolytes from stomach fluids.
d. Clamp NG tube. Disconnect from connection tubing and lay end of connection tubing on towel.	Reduces soiling of patient's gown and bed linen.
e. Insert tip of irrigating syringe into end of NG tube. Remove clamp. Hold syringe with tip pointed at floor and inject saline slowly and evenly. Do not force solution.	Position of syringe prevents introduction of air into vent tubing, which could cause gastric distention. Solution introduced under pressure causes gastric trauma. Do not introduce saline through blue "pigtail" air vent of Salem sump tube.
f. If resistance occurs, check for kinks in tubing. Turn patient onto left side. Report repeated resistance to health care provider.	Tip of tube is possibly against stomach lining. Repositioning on left side helps to dislodge tube away from stomach lining. Buildup of secretions causes distention.
g. After instilling saline, immediately aspirate or pull back slowly on syringe to withdraw fluid. If amount aspirated is greater than amount instilled, record difference as output. If amount aspirated is less than amount instilled, record difference as intake.	Irrigation clears tubing; thus stomach remains empty. Fluid remaining in stomach is measured as intake.
h. Reconnect NG tube to drainage or suction. (If solution does not return, repeat irrigation.)	Reestablishes drainage collection; you repeat irrigation or repositioning of tube until NG tube drains properly.
i. Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 Determine amount and character of contents draining from NG tube. Ask if patient feels nauseated.	Determines if tube is decompressing stomach of contents.
2 After palpating patient's abdomen, note any distention, pain, and rigidity and auscultate for presence of bowel sounds. Turn off suction while auscultating.	Determines success of abdominal decompression and return of peristalsis. The sound of suction apparatus is transmitted to abdomen and misinterpreted as bowel sounds.
3 Evaluate condition of nares and nose.	Evaluates onset of skin and tissue irritation.
4 Observe position of tubing.	Determines if tension is being applied to nasal structures.
5 Ask if patient feels sore throat or irritation in pharynx.	Evaluates level of patient's discomfort.
DISCONTINUATION OF NASOGASTRIC TUBE	
ASSESSMENT	
1 Auscultate for presence of bowel sounds.	Serves as baseline for when tube is removed.

SKILL 46-2 INSERTING AND MAINTAINING A NASOGASTRIC TUBE FOR GASTRIC DECOMPRESSION—cont'd

STEP	RATIONALE
PLANNING	
1 Verify order to discontinue NG tube.	Health care provider's order required for procedure.
2 Identify patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
3 Explain procedure to patient and reassure that removal is less distressing than insertion.	Minimizes anxiety and increases patient cooperation.
IMPLEMENTATION	
1 Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
2 Turn off suction and disconnect NG tube from drainage bag or suction. Remove tape or fixation device from bridge of nose and unpin tube from gown.	Have tube free of all connections before removal.
3 Stand on patient's right side if right-handed, left side if left-handed.	Allows easiest manipulation of tube.
4 Hand patient facial tissue; place clean towel across chest. Instruct patient to take and hold deep breath.	Patient sometimes needs to blow nose after removal of tube. Towel prevents gown from getting soiled. Airway is temporarily obstructed during tube removal.
5 Clamp or kink tubing securely and pull tube out steadily and smoothly into towel held in other hand while patient holds breath.	Clamping prevents tube contents from draining into oropharynx. Reduces trauma to mucosa and minimizes patient's discomfort. Towel covers tube, which is usually an unpleasant sight. Holding breath prevents aspiration.
6 Clean nares and provide mouth care.	Promotes comfort.
7 Dispose of tube and drainage equipment into proper container.	Reduces transmission of microorganisms.
8 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 After tube removal, auscultate patient's bowel sounds and periodically check for abdominal distention.	Confirms that peristalsis has returned.
2 Measure amount of drainage in container and note character of content.	Provides accurate measure of fluid output.
3 Explain procedure for drinking fluids if not contraindicated.	Requires health care provider's order. Once fluids are allowed, the order usually begins with small amount of ice chips; amount increases as patient is able to tolerate more.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient's abdomen becomes distended and/or painful.
- Assess patency of tube and irrigate as needed.
- Verify that suction is on as ordered.

2 Patient complains of sore throat from dry, irritated mucous membranes.
- Increase frequency of oral hygiene.
- Ask health care provider if patient can suck on ice chips or throat lozenges.

3 Patient develops irritation of skin around nares.
- Provide skin care to nares and retape so tube does not press against nares.
- Consider switching tube to other naris.

4 Patient develops signs of pulmonary aspiration: fever, shortness of breath, pulmonary congestion.
- Perform respiratory assessment.
- Notify health care provider; expect order for chest x-ray.

RECORDING AND REPORTING

- Record in nurses' notes time, type, and size of NG tube inserted, patient's tolerance of procedure, confirmation of placement, character of gastric contents, pH value, whether tube is clamped or connected to drainage device, and amount of suction applied.
- Record in nurses' notes and/or flow sheet placement checks and amount and character of contents draining from NG tube every shift, unless ordered more often by health care provider.
- Record in nurse's notes time and date that NG tube was removed, patient's tolerance of procedure, and his or her status following procedure.

SKILL 46-3 POUCHING AN OSTOMY

View Video!

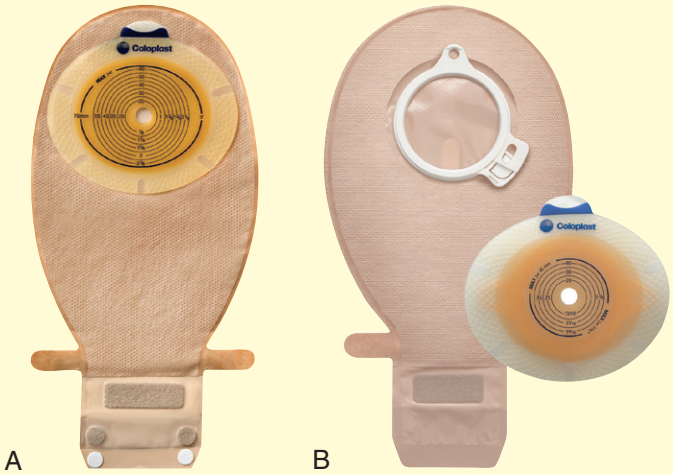
Delegation Considerations

The skill of pouching a newly established ostomy cannot be delegated to nursing assistive personnel (NAP). Pouching an established ostomy can be delegated. Inform NAP about:

- Appropriate pouch and skin barrier.
- The signs of stoma and peristomal skin changes to report to a registered professional nurse.
- Monitoring and reporting characteristics and volume of ostomy output and reporting changes in volume and/or consistency for further assessment.
- Special equipment needed to complete the procedure.

Equipment

- Clear drainable colostomy/ileostomy pouch in correct size for two-piece system or custom cut-to-fit one-piece type with attached skin barrier (Fig. 46-21, *A* and *B*)
- Pouch closure device as needed
- Ostomy measuring guide
- Adhesive remover (optional)
- Clean gloves
- Washcloths
- Towel or disposable waterproof barrier
- Basin with warm tap water
- Scissors/pen
- Skin barrier if not attached to pouching system
- Stoma paste or Stomahesive (optional)
- Tape or ostomy belt (optional)
- Stethoscope



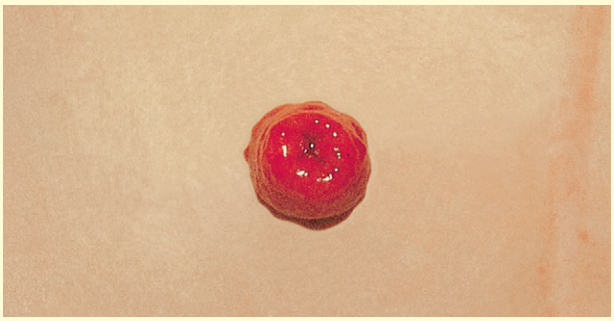


FIG. 46-21 Ostomy pouches and skin barriers. **A,** SenSura® one-piece pouch with Velcro closure. **B,** SenSura® two-piece pouching system with separate skin barrier and attachable pouch. (NOTE: Skin barriers would need to be custom cut according to stoma size.) (Courtesy Coloplast, Minneapolis, Minn)

STEP	RATIONALE
ASSESSMENT	
1 Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
2 Auscultate for bowel sounds.	Documents presence of peristalsis.
3 Observe skin barrier and pouch for leakage and length of time in place. NOTE: Depending on type of pouching system used (such as with an opaque pouch), remove the pouch to fully observe the stoma. Clear pouches permit viewing of stoma without their removal.	Indicates need for different type of pouch or sealant. Routine observation allows for early detection of potential problems (Dorman, 2009). Leaking often indicates need for different pouch or sealant (Hoeflok et al., 2009). Intact skin barriers with no evidence of leakage do not need to be changed daily and remain in place for 5 to 7 days (Durston, 2009; Richbourg et al., 2008).
4 Observe stoma for color, swelling, trauma, and healing; it is normally moist and reddish-pink. Assess type of stoma. Stoma is flush with skin or budlike protrusion on abdomen (see illustration for a normal bud stoma).	Healthy stomas are pink to brick red in color (WOCN et al., 2010). Notify health care provider immediately if color is blue, brown, or black in color.
5 Observe effluent from stoma and keep record of intake and output. Ask patient about skin tenderness.	Effluent from stoma is caustic; and, if it comes in contact with sensitive peristomal skin, risk of skin breakdown increases (Erwin-Toth et al., 2010).
6 Observe abdominal incision (if present).	Relationship of abdominal incision to stoma determines proper placement of pouch. Presence of pressure areas from pouching system requires a different system (WOCN et al., 2010).
7 Check existing bag for gas accumulation.	If excessive gas accumulation is present, determine need for patient to switch to pouch with vent or filter (WOCN et al., 2010).

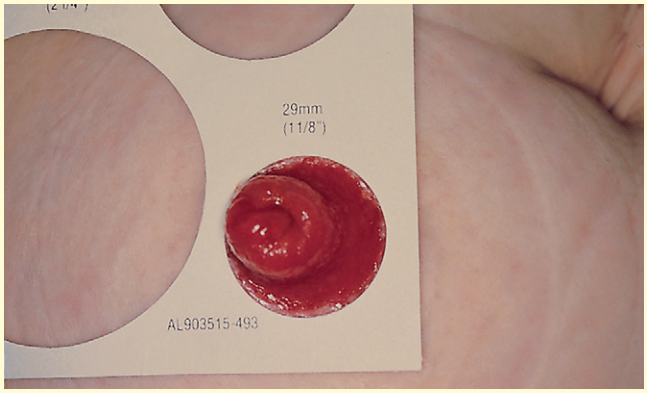
SKILL 46-3 POUCHING AN OSTOMY—cont'd

STEP	RATIONALE

STEP 4 Bud stoma. (Permission to use and/or reproduce this copyrighted photo has been granted by the owner, Hollister Inc.)

8 Assess abdomen for best type of pouching system to use. Consider the following: **a.** Contour and peristomal plane **b.** Presence of scars, incisions **c.** Location and type of stoma **d.** Patient's self-care ability	Determines pouching system selection and need for other equipment. For a stoma to have an adequate seal with an ostomy appliance, it needs to be placed within abdominal rectus muscle, away from abdominal creases and folds, away from bony understructures, and surrounded by at least 5 cm (2 inches) of smooth surface on all sides (Rust, 2007). Patients who have difficulty using their hands or limited vision find a one-piece system or a precut pouch and skin barrier more desirable to use (Pearson, 2010). Patients who have mobility problems or spinal cord injuries benefit by using equipment that has a longer pouch, which is easier to empty independently when sitting. For patients who prefer being able to keep the skin barrier in place for several days and change just the pouch, the two-piece system is desirable.

CLINICAL DECISION: *Because of stoma and abdominal characteristics, some patients need their ostomy pouching system to curve outward to avoid leakage (Deitz and Gates, 2010a).*



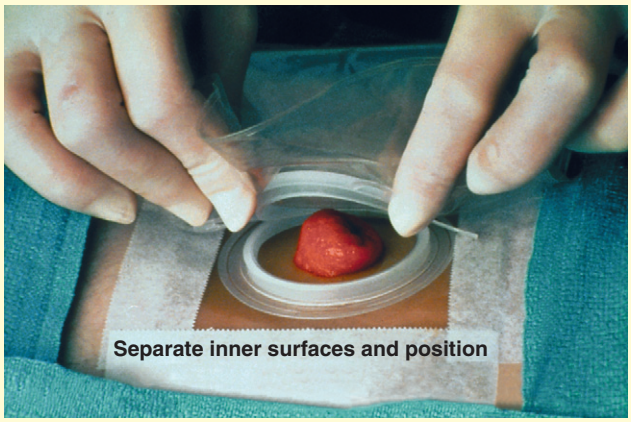
PLANNING

1 Identify patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Explain procedure to patient; encourage patient's interaction and questions.	Lessens patient's anxiety and promotes participation.
3 Assemble equipment and close room curtains or door.	Optimizes use of time; provides privacy.

IMPLEMENTATION

1 Position patient either standing or supine and drape, leaving area around stoma exposed. If seated, position patient either on or in front of toilet.	With patient supine there are fewer skin wrinkles, which allows for ease of application of pouching system; maintains patient dignity.
2 Perform hand hygiene and apply gloves.	Reduces transmission of microorganisms.
3 Place towel or disposable waterproof barrier under patient.	Protects bed linen.
4 Gently cleanse peristomal skin with warm water using gauze pads or clean washcloth; do not scrub skin; dry completely by patting with gauze or towel.	Avoid use of soap because it leaves residue on skin that interferes with pouch adhesion. Skin needs to be dry for skin barrier and pouch to adhere. Moisture increases risk for fungal infections. Do not be alarmed if blood appears on gauze pad. Stomas sometimes ooze blood as result of cleansing. Surface of stoma is highly vascular mucous membrane. Bleeding into pouch is abnormal (WOCN et al., 2010).
5 Use adhesive remover to rid remaining portions of skin barrier.	Improper removal of barrier irritates skin, causes skin tears, and results in poor adherence of new pouch (Dorman, 2009; Szymanski et al., 2010).
6 Measure stoma for correct size of pouching system needed using manufacturer measuring guide (see illustration).	Ensures accuracy in determining correct pouch size needed. New stomas shrink up to 6-8 weeks (Deitz, 2010b).
7 Select appropriate pouch based on patient assessment. With custom cut-to-fit pouch, use ostomy guide to cut opening on pouch 0.15 to 0.3 cm ($\frac{1}{16}$ to $\frac{1}{8}$ inch) larger than stoma before removing backing. Prepare pouch by removing backing from barrier and adhesive. With ileostomy, apply thin circle of barrier paste around opening in pouch; allow to dry (see illustration).	Determines correct size equipment. Too large an opening permits fecal drainage to ooze from under appliance, causing skin irritation. Too small an opening causes appliance to cut into stoma (WOCN et al., 2010).

STEP	RATIONALE



STEP 6 Measuring a stoma.

STEP 7 Preparing ostomy pouch.

STEP 9a(2) Applying one-piece pouch. (Courtesy ConvaTec, Princeton, NJ.)

STEP 9b(1) Application of barrier-paste flange. (Courtesy ConvaTec, Princeton, NJ.)

CLINICAL DECISION: *If patient has a large volume of liquid stool from an ileostomy, consider using a "high-output" pouch that contains the volume of effluent and reduces the frequency of pouch emptying.*

8 Apply skin barrier and pouch. If creases next to stoma occur, use barrier paste to fill in; let dry 1-2 minutes.	Barrier paste increases adherence of pouch to skin or fills in irregularities (Erwin-Toth et al., 2010).
9 When applying skin barrier to stoma that is close to patient's abdominal incision, trim skin barrier to fit.	Allows for better fit.
a. For one-piece pouching system	
(1) Use skin sealant wipes on skin directly under adhesive skin barrier or pouch; allow to dry. Press adhesive backing of pouch and/or skin barrier smoothly against skin, starting from bottom and working up and around sides.	Ensures smooth, wrinkle-free seal. Be careful of irritated or open areas because skin sealants often contain alcohol (WOCN et al., 2010).
(2) Hold pouch by barrier, center over stoma, and press down gently on barrier; bottom of pouch points toward patient's knees (see illustration).	Different position of pouch is sometimes necessary to allow better gravity flow. For example, patient confined to bed needs to have pouch positioned horizontally over side of abdomen.
(3) Maintain gentle finger pressure 1-2 minutes around barrier.	Gentle pressure and body heat assist in adhesion.
b. For two-piece pouching system	
(1) Apply barrier-paste flange (barrier with adhesive) as in previous steps for one-piece system. Then snap on pouch and maintain finger pressure (see illustration).	Creates wrinkle-free, secure seal; decreases irritation from adhesive on skin. Some two-piece pouching systems have snapping or clicking sound that occurs when attaching pouch to skin barrier.
c. For both pouching systems, gently tug on pouch in downward direction.	Determines that pouch is securely attached.

SKILL 46-3 POUCHING AN OSTOMY—cont'd

STEP	RATIONALE
10 Gently press on pectin or karaya flange to facilitate adhesion.	Skin barriers add to security of keeping pouch system securely attached.
11 Although many ostomy pouches are odor proof, explain to patient not to use "home remedies" to control ostomy odor, which will possibly harm stoma. Do not make pinhole in pouch to relieve odor.	Causes damage to pouch and defeats purpose of odor-proof pouch. **Never add aspirin to ostomy pouch** since it causes stoma bleeding. Making pinhole to remove flatus allows effluent to leak.
12 Fold bottom of drainable open-ended pouches up once. Close using clamp or manufacturer device.	Maintains secure seal to prevent leakage.
13 Properly dispose of old pouch and soiled equipment. Some patients ask to spray air freshener.	Lessens room odor.
14 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
15 Change one- or two-piece pouch every 3-7 days unless leaking. Pouch remains in place for tub bath or shower. After bath pat adhesive dry.	Avoid unnecessary trauma to skin from too-frequent bag changes. Drying ensures adhesion of pouch.

EVALUATION

1 Ask if patient feels discomfort around stoma.	Determines presence of skin irritation.
2 Note appearance of stoma, peristomal skin, and existing incision (if present) while removing pouch and cleansing skin. Observe condition of skin barrier and adhesive. Inspect edges of pouch for "tracking" of effluent under edges.	Determines condition of tissues and progress of healing. Determines presence of leaks.
3 Auscultate bowel sounds and observe characteristics of stool.	Determines status of peristalsis and bowel elimination.
4 Observe patient's nonverbal behaviors while applying the pouch. Ask if patient has any questions about pouching.	Indicates emotional response to stoma and readiness for teaching. Determines level of understanding of procedure.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient experiences damage to peristomal skin.
- Assess for and report to health care provider for treatment:
  - Mechanical damage caused by inappropriate skin care, incorrect tape removal.
  - Chemical damage caused by waste coming into contact with peristomal skin or skin reaction to adhesive.
  - Damage caused by a fungal infection (candidiasis), usually caused by persistent moisture on peristomal skin.

2 Stoma becomes necrotic as manifested by purple or black color, dry instead of moist, failure to bleed, or sloughing tissue.
- Assess circulation to stoma and observe for excessive edema or tension on bowel suture line (if present).
- Immediately report this finding to the health care provider.

3 Patient refuses to view stoma or participate in care.
- Allow patient to express feelings.
- Provide information to patient and family about ostomy support groups and ostomy care nurses in the community.

RECORDING AND REPORTING

- Record type of pouch, skin barrier applied, and time; amount and appearance of stool, texture, condition of peristomal skin, and sutures. Record patient teaching.
- Report any of the following to the nurse and/or health care provider:
  - Abnormal appearance of stoma (e.g., bleeding, ulcerations, blue or black in color), suture line, peristomal skin, character of output, absence of bowel sounds
  - No flatus in 24 to 36 hours and no stool by third day
- Document abdominal distention and excessive tenderness, nature of bowel sounds.
- Record patient's level of participation and need for teaching.

HOME CARE CONSIDERATIONS

- Evaluate patient's home toileting facilities. This includes presence of adequate toileting facilities, flushable toilet, and number and location of toilets.
- Caution the patient that most ostomy pouches and barriers cannot be flushed down the toilet; they clog the system. Dispose of used ostomy pouch according to local sanitation regulations.

KEY POINTS

- Mechanical breakdown of food elements, gastrointestinal motility, and selective absorption and secretion of substances by the large intestine influence the character of feces.
- Food high in fiber content and an increased fluid intake keep feces soft.
- Ongoing use of cathartics, laxatives, and enemas affects and delays normal defecation reflexes.
- Vagal stimulation, which slows the heart rate, occurs during straining while defecating, taking rectal temperatures, enemas, and digital removal of impacted stool.
- The greatest danger from diarrhea is development of fluid and electrolyte imbalance.
- The location of an ostomy influences consistency of the stool.
- Focus assessment of elimination patterns on bowel habits, factors that normally influence defecation, recent changes in elimination, and a physical examination.

- Indirect and direct visualization of the lower GI tract requires cleansing of the bowel before the procedure.
- Consider frequency of defecation, fecal characteristics, and effect of foods on GI function when selecting a diet promoting normal elimination.
- Proper positioning on a bedpan allows the patient to assume a position similar to squatting without experiencing muscle strain.
- NG intubation decompresses the gastric contents by removing secretions and gaseous products from the GI tract.
- The purposes of gastric decompression are to keep the GI tract free of secretions, reduce nausea and gas, and decrease the risk of vomiting and aspiration.
- Proper selection and use of an ostomy pouching system is necessary to prevent damage to the skin around the stoma.
- Dangers during digital removal of stool include traumatizing the rectal mucosa and promoting vagal stimulation.
- Skin breakdown occurs after repeated exposure to liquid stool.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

A few days after Javier, the home care nurse, visited Larry in his home, Larry became nauseous, bloated, and had abdominal pain. He took an over-the-counter laxative and went to bed. Around 2:00 AM Larry woke with severe abdominal pain. He noticed that his belly was larger than normal, hard, and painful to touch. He felt if he could have a bowel movement, he would feel better. Once Larry was in the bathroom, he began to vomit and passed out from the abdominal pain. His mother heard him and ran to his side, finding him unconscious. She called for an ambulance.

1. Larry arrives in the emergency department of the hospital with vomiting and severe abdominal pain. Which nursing assessment questions does the nurse ask?
2. The nurse receives an order to insert a nasogastric (NG) tube. Once the NG is in place, how does the nurse determine if it is indeed in the stomach?
3. Which additional diagnostic test does the emergency department nurse anticipate that Larry would have?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. During the nursing assessment a patient reveals that he has diarrhea and cramping every time he has ice cream. He attributes this to the cold nature of the food. However, the nurse begins to suspect that these symptoms are associated with:
   1. Food allergy.
   2. Irritable bowel.
   3. Lactose intolerance.
   4. Increased peristalsis.
2. When assessing a 55-year-old patient who is in the clinic for a routine physical, the nurse instructs the patient about the need to obtain a stool specimen for guaiac fecal occult blood testing (gFOBT):
   1. If patient reports rectal bleeding.
   2. When there is a family history of polyps.
   3. As part of a routine examination for colon cancer.
   4. If a palpable mass is detected on digital examination.
3. Which of the following medications listed in a patient's medication history possibly causes gastrointestinal bleeding? (Select all that apply.)
   1. Aspirin
   2. Cathartics
   3. Antidiarrheal opiate agents
   4. Nonsteroidal antiinflammatory drugs (NSAIDs)
4. Nurses discourage patients from straining on defecation primarily because it causes: (Select all that apply.)
   1. Pain.
   2. Impaction.
   3. Hemorrhoids.
   4. Dysrhythmias.
5. A cleansing enema is ordered for a 55-year-old patient before intestinal surgery. The nurse understands that the maximum amount of fluid given is:
   1. 150 to 200 mL.
   2. 200 to 400 mL.
   3. 400 to 750 mL.
   4. 750 to 1000 mL.
6. A patient starts to experience pain while receiving an enema. The nurse notes blood in the return fluid and rectal bleeding. What action does the nurse take first?
   1. Administers pain medication
   2. Slows down the rate of instillation
   3. Tells the patient to breathe slowly and relax
   4. Stops the instillation and obtains vital signs
7. Number the steps to irrigating a nasogastric tube (NG) in correct order:
   1. Slowly aspirate the syringe.
   2. Reconnect the NG tube to suction.
   3. Clamp and disconnect the NG tube.
   4. Perform hand hygiene and apply clean gloves.
   5. Insert tip of syringe into NG tube and slowly inject 30 mL saline.
8. List the correct order in which to apply an ostomy pouch:
   1. Remove the used pouch and skin barrier.
   2. Perform hand hygiene and apply clean gloves.
   3. Assess the stoma for color, swelling, and healing.
   4. Gently cleanse the peristomal skin with warm tap water.
   5. Apply nonallergenic tape around the pectin skin barrier.
   6. Cut an opening on the pouch 0.15-0.3 cm ($\frac{1}{16}$ to $\frac{1}{8}$ inch) larger than the stoma.
   7. Press the adhesive backing of the pouch smoothly against the skin.
9. A patient is admitted for lower gastrointestinal (GI) bleeding. What color of stool does the nurse anticipate the patient to have?
   1. Red
   2. Black
   3. Green
   4. Orange
10. The nurse is caring for a patient with a colostomy. Which intervention is most important?
    1. Cleansing the stoma with hot water
    2. Inserting a deodorant tablet in the stoma bag
    3. Selecting a bag with an appropriate-size stoma opening
    4. Wearing sterile gloves while caring for the stoma
11. The nurse understands that, when comparing nasogastric tubes used for gastric decompression, a Salem sump is specifically designed to:
    1. Minimize the risk of a bowel obstruction.
    2. Ensure drainage of the intestines.

3. Prevent gastric mucosal damage.
4. Promote resting the gut.

12. Before collecting a stool sample for occult blood, the nurse instructs the nursing assistive personnel to:
    1. Ask the patient to void.
    2. Wash the patient's perineum.
    3. Secure a sterile, specimen container.
    4. Plan to collect the first specimen of the day.
13. The nurse is taking a health history of a newly admitted patient with a diagnosis Rule/out bowel obstruction. Which of the following is the priority question to ask the patient?
    1. Describe your bowel movements.
    2. How often do you have a bowel movement?
    3. When was the last time you moved your bowels?
    4. Do you routinely use stool softeners, laxatives, or enemas?
14. The nurse is caring for a 78-year-old man with diarrhea. Of the following problems, which is the most important to consider?
    1. Malnutrition
    2. Dehydration
    3. Skin breakdown
    4. Incontinence
15. The nurse recognizes which patient needs to use a fracture pan for a bowel movement?
    1. The patient who is obese
    2. The patient experiencing confusion
    3. The patient on bed rest
    4. A patient recovering from hip surgery

CHAPTER

47

Mobility and Immobility

OBJECTIVES

- Describe the functions of the musculoskeletal (skeleton, skeletal muscles) and nervous systems in the regulation of movement.
- Discuss physiological and pathological influences on body alignment and joint mobility.
- Identify changes in physiological and psychosocial function associated with mobility and immobility.
- Assess for correct and impaired body alignment and mobility.
- Formulate appropriate nursing diagnoses for impaired body alignment and mobility.
- Develop individualized nursing care plans for patients with impaired body alignment and mobility.
- Discuss the importance of no-lift policies for the patient and health care provider.
- Describe equipment needed for safe patient handling and movement.
- Discuss the impact of national patient safety resources, initiatives, and regulations in relation to patient handling and movement.
- Compare and contrast active and passive range-of-motion exercises.
- Evaluate the nursing plan for maintaining body alignment and mobility.

People use **mobility** for many purposes (e.g., expression of emotions or satisfaction of basic needs with nonverbal gestures). It is also used to show self-defense, perform activities of daily living (ADLs), and participate in recreational activities. Many functions of the body depend on mobility. Intact musculoskeletal and nervous systems are necessary for optimal physical mobility and functioning.

Clinical nursing practice related to mobility and immobility requires the incorporation of scientific and nursing knowledge and skills to provide competent care. Knowing the movements and functions of muscles in maintaining posture and movement and implementing evidence-based knowledge about safe patient handling are essential to protecting the safety of both the patient and the nurse.

SCIENTIFIC KNOWLEDGE BASE

Nature of Movement

Movement is a complex process that requires coordination between the musculoskeletal and nervous systems. **Body mechanics** is a term used to describe the coordinated efforts of the musculoskeletal and nervous systems. Although nurses need to understand the physics surrounding body mechanics, lifting techniques historically used in nursing practice that emphasize body mechanics often cause debilitating injuries to nursing and other health care staff (de Castro et al., 2006). Today nurses use information about body

alignment, balance, gravity, and friction when implementing nursing interventions such as positioning patients, determining the risk of patient falls, and selecting the safest way to move or transfer patients.

Alignment and Balance. The terms *body alignment* and *posture* are similar and refer to the positioning of the joints, tendons, ligaments, and muscles while standing, sitting, and lying. **Body alignment** means that the individual's center of gravity is stable. Correct body alignment reduces strain on musculoskeletal structures, aids in maintaining adequate muscle tone, promotes comfort, and contributes to balance and conservation of energy. Without balance control the center of gravity is displaced, thus creating a risk for falls and subsequent injuries. Balance is enhanced by keeping the center of gravity of the body low with a wide base of support and maintaining correct body posture.

Individuals require balance for maintaining a static position (e.g., sitting) and moving (e.g., walking). Disease, injury, pain, physical development (e.g., age), and life changes (e.g., pregnancy) compromise the ability to remain balanced. Medications that cause dizziness and prolonged immobility also affect balance. Impaired balance is a major threat to physical safety and contributes to a fear of falling and self-imposed restrictions on activity.

Gravity and Friction. Weight is the force exerted on a body by gravity. The force of weight is always directed downward, which is why an unbalanced object falls. Unsteady patients fall if their center of gravity becomes unbalanced because of the gravitational pull on their weight.

To lift safely the lifter has to overcome the weight of the object and know its center of gravity. In symmetrical inanimate objects the center of gravity is at the exact center of the object. However, people are not geometrically perfect; their centers of gravity are usually at 55% to 57% of standing height and are in the midline, which is why only using principles of body mechanics in lifting patients often leads to injury of the nurse or health care professional.

Friction is a force that occurs in a direction to oppose movement. The greater the surface area of the object that is moved, the greater the friction. A larger object produces greater resistance to movement. In addition, the force exerted against the skin while the skin remains stationary and the bony structures move is called **shear.** Unfortunately a common example is when the head of the bed is elevated beyond 60 degrees and gravity pulls the bony skeleton toward the foot of the bed while the skin remains against the sheets. The blood vessels in the underlying tissue are stretched and damaged, resulting in impeded blood flow to the deep tissues. Ultimately pressure ulcers often develop within the undermined tissue; the surface tissue appears less affected. To decrease surface area and reduce friction when patients are unable to assist with moving up in bed, nurses use an ergonomic assistive device such as a full body sling. This sling mechanically lifts the patient off the surface of the bed, thereby preventing friction, tearing, or shearing his or her delicate skin, and protects the nurse and other staff from injury (Nelson et al., 2009).

Physiology and Regulation of Movement

Skeletal System. The skeleton provides attachments for muscles and ligaments and the leverage necessary for movement. Thus the skeleton is the supporting framework of the body and is made up of four types of bones: long, short, flat, and irregular. Long bones contribute to height (e.g., the femur, fibula, and tibia in the leg) and length (e.g., the phalanges of the fingers and toes). Short bones (e.g., the carpal bones in the foot and the patella in the knee) occur in clusters and, when combined with ligaments and cartilage, permit movement of the extremities. Flat bones (e.g., some bones in the skull and the ribs in the thorax) provide structural contour. Irregular bones make up the vertebral column and some bones of the skull such as the mandible.

Bones are further characterized by firmness, rigidity, and elasticity. Firmness results from inorganic salts such as calcium and phosphate that are in the bone matrix. It is related to the rigidity of the bone, which is necessary to keep long bones straight and enables bones to withstand weight bearing. In addition, bones have a degree of elasticity and skeletal flexibility that change with age. For example, the newborn has a large amount of cartilage and is highly flexible but is unable to support weight. The toddler's bones are more pliable than those of an older person and are better able to withstand falls. Older adults, especially women, are more susceptible to bone loss (resorption) and osteoporosis, which increase the risk of fractures.

The skeletal system has several functions. It protects vital organs (e.g., the skull around the brain and the ribs around the heart and lungs) and aids in calcium regulation. Bones store calcium and release it into the circulation as needed. Patients with decreased calcium regulation and metabolism are at risk for developing osteoporosis and **pathological fractures** (fractures caused by weakened bone tissue). In addition, the internal structure of long bones contains bone marrow, participates in red blood cell (RBC) production, and acts as a reservoir for blood. Patients with altered bone marrow function or diminished RBC production fatigue easily because of reduced hemoglobin and oxygen-carrying ability. This fatigue decreases their mobility and increases the risk for falling.

Joints. Joints are the connections between bones. Each joint is classified according to its structure and degree of mobility. There are four classifications of joints: synostotic, cartilaginous, fibrous, and synovial.

The synostotic joint refers to bones jointed by bones. No movement is associated with this type of joint, and the bony tissue that forms between the bones provides strength and stability. The classic example of this type of joint is the skull, where fusion of the joint occurs later in life (Fig. 47-1, *A*).

In the cartilaginous joint, or synchondrosis joint, cartilage unites bony components. This type of joint allows for bone growth while providing stability. When bone growth is complete, the joints ossify. The first sternocostal joint is an example of a synchondrosis joint (Fig. 47-1, *B*).

The fibrous joint, or syndesmosis joint, is a joint in which a ligament or membrane unites two bony surfaces. The fibers of ligaments are flexible and stretch, permitting a limited amount of movement. The paired bones of the lower leg (tibia and fibula) are syndesmotic joints (Huether and McCance, 2008) (Fig. 47-1, *C*).

The synovial joint, or true joint, is a freely movable joint in which contiguous bony surfaces are covered by articular cartilage and connected by ligaments lined with a synovial membrane. Joining of the humeral radius and ulna by cartilage and ligaments forms a pivotal joint (Fig. 47-1, *D*). Other types of synovial joints are the ball-and-socket joints such as the hip joint and the hinge joints such as the interphalangeal joints of the fingers.

Ligaments. Ligaments are white, shiny, flexible bands of fibrous tissue binding joints together and connecting bones and cartilages. Ligaments are elastic and aid joint flexibility and support (Fig. 47-2). In addition, some ligaments have a protective function. For example, ligaments between the vertebral bodies and the ligamentum flavum prevent damage to the spinal cord during movement of the back.

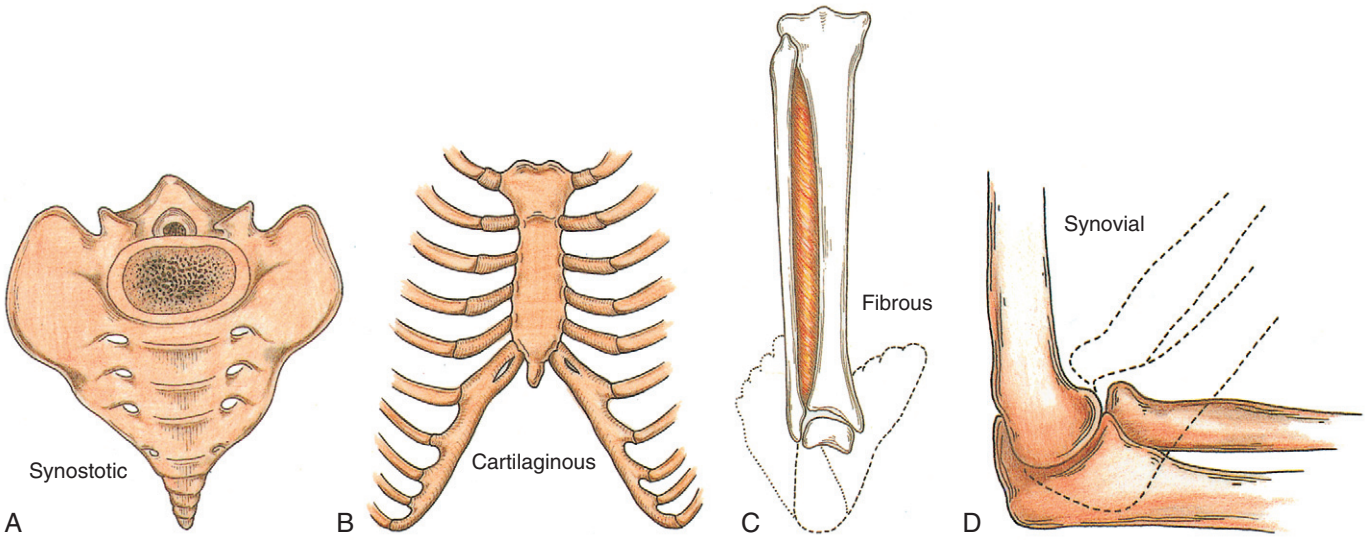

FIG. 47-1 Joint types. **A,** Synostotic. **B,** Cartilaginous. **C,** Fibrous. **D,** Synovial.

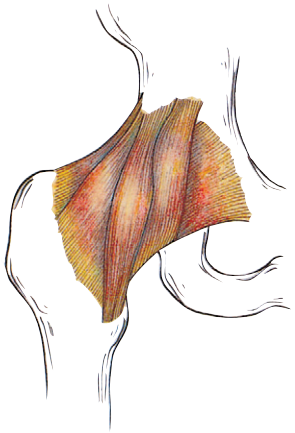

FIG. 47-2 Ligaments of hip joint.

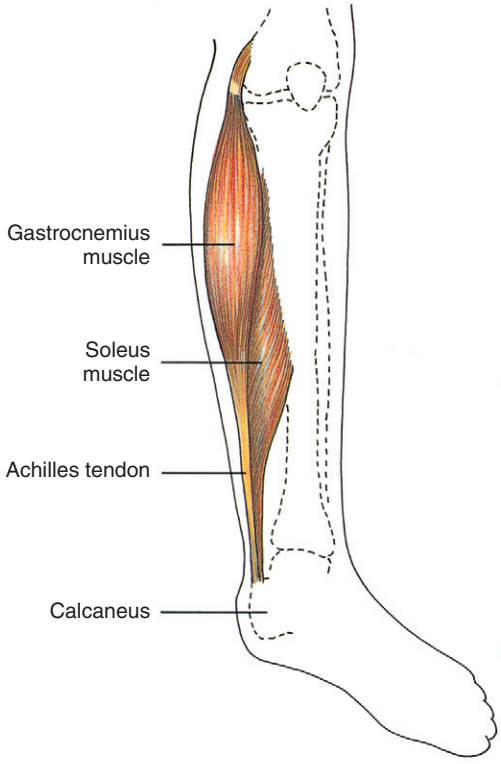

FIG. 47-3 Tendons and muscles of lower leg.

Tendons. Tendons are white, glistening, fibrous bands of tissue that connect muscle to bone. They are strong, flexible, and inelastic; and they occur in various lengths and thicknesses. The Achilles tendon (tendo calcaneus) is the thickest and strongest tendon in the body. It begins near the midposterior of the leg and attaches the gastrocnemius and soleus muscles in the calf to the calcaneal bone in the back of the foot (Fig. 47-3).

Cartilage. Cartilage is nonvascular (without blood vessels) supporting connective tissue located chiefly in the joints and thorax, trachea, larynx, nose, and ear. The fetus has a large amount of temporary cartilage, which is replaced by bone developed during infancy. Permanent cartilage is **unossified** (not hardened), except in advanced age and diseases such as osteoarthritis.

Joints, ligaments, tendons, and cartilage facilitate strength and flexibility of the skeleton. Strength enables the skeletal system to support the body. A person's flexibility is demonstrated through range of motion (ROM). However, strength and flexibility do not result entirely from these four structures. Adequate skeletal muscle is also necessary.

Skeletal Muscle. Movement of bones and joints involves active processes that are carefully integrated to achieve coordination. Skeletal muscles, because of their ability to contract and relax, are the working elements of movement. Anatomical structure and attachment to the skeleton enhance contractile elements of the skeletal muscle.

Muscles are made of fibers that contract when stimulated by an electrochemical impulse that travels from the nerve to the muscle across the neuromuscular junction. The electrochemical impulse causes the filaments (predominantly protein molecules of myosin and actin) within the fiber to slide past one another, with the filaments changing length.

Muscle contractions are categorized by functional purpose: moving, resisting, or stabilizing body parts. In **concentric tension**

increased muscle contraction causes muscle shortening, resulting in movement such as when a patient uses an overhead trapeze to pull up in bed. **Eccentric tension** helps control the speed and direction of movement. For example, when using an overhead trapeze, the patient slowly lowers himself to the bed. The lowering is controlled when the antagonistic muscles lengthen. Concentric and eccentric muscle actions are necessary for active movement and therefore are referred to as dynamic or **isotonic contraction. Isometric contraction** (static contraction) causes an increase in muscle tension or muscle work but no shortening or active movement of the muscle (e.g., instructing the patient to tighten and relax a muscle group, as in quadriceps set exercises or pelvic floor exercises). Voluntary movement is a combination of isotonic and isometric contractions.

Although isometric contractions do not result in muscle shortening, energy expenditure increases. This type of muscle work is comparable to having a car in neutral with the driver continually depressing the accelerator and racing the engine. The driver is not going anywhere but expends a large amount of energy. It is important to understand the energy expenditure (increased respiratory rate and increased work on the heart) associated with isometric exercises because the exercises are sometimes contraindicated in certain patients' illnesses (e.g., myocardial infarction or chronic obstructive pulmonary disease).

Muscle Movement and Posture. Muscles that attach to bones of leverage provide necessary strength to move an object. **Leverage** is an inducing or compelling force and occurs when specific bones such as the humerus, ulna, and radius and the associated joint such as the elbow act together as a lever. Force is applied to one end of the bone to lift a weight as another point rotates the bone in the opposite direction.

Muscles associated primarily with maintaining posture are short and featherlike in appearance because they converge obliquely at a common tendon. Muscles of the lower extremities, trunk, neck, and back are concerned primarily with **posture** (the position of the body in relation to the surrounding space). These muscle groups work together to stabilize and support body weight, and they allow an individual to maintain a sitting or standing posture.

Muscle Regulation of Posture and Movement. Posture and movement depend on the skeleton and the shape and development of skeletal muscles. They also contribute to musculoskeletal function and often reflect personality, discomfort, and mood. For example, a person with a dramatic personality gestures with the hands, a person who is fatigued or depressed may slouch, and a person with abdominal pain may curl into a fetal-like position.

Coordination and regulation of different muscle groups depend on muscle tone and activity of antagonistic, synergistic, and antigravity muscles (see Chapter 38). **Muscle tone,** or tonus, is the normal state of balanced muscle tension. The body achieves tension by alternating contraction and relaxation without active movement of neighboring fibers of a specific muscle group. Muscle tone helps maintain functional positions such as sitting or standing without excess muscle fatigue and is maintained through continual use of muscles. ADLs require muscle action and help maintain muscle tone. When a patient is immobile or on prolonged bed rest, activity level, activity tolerance, and muscle tone decrease.

Nervous System. The nervous system regulates movement and posture. The precentral gyrus, or motor strip, is the major voluntary motor area and is in the cerebral cortex. A majority of motor fibers descend from the motor strip and cross at the level of the medulla. Thus the motor fibers from the right motor strip initiate voluntary movement for the left side of the body, and motor fibers from the left motor strip initiate voluntary movement for the right side of the body.

During voluntary movement impulses descend from the motor strip to the spinal cord. An impulse exits the spinal cord through efferent motor nerves and travels through the nerves. Through a complex process neurotransmitters, or chemicals such as acetylcholine, transfer electric impulses from the nerve across the neuromuscular junction to the muscle. The neurotransmitter reaches a muscle and stimulates it, causing movement. Movement is impaired by disorders that alter neurotransmitter production, transfer of impulses from the nerve to the muscle, or activation of muscle activity. Parkinsonism is an example of such a disorder (see Chapter 38).

Pathological Influences on Mobility

Many pathological conditions affect mobility. Although a complete description of each is beyond the scope of this chapter, an overview of four pathological influences are presented.

Postural Abnormalities. Congenital or acquired postural abnormalities affect the efficiency of the musculoskeletal system and body alignment, balance, and appearance. During assessment observe body alignment and ROM (see Chapter 38). Postural abnormalities can cause pain, impair alignment or mobility, or both. Knowledge about the characteristics, causes, and treatment of common postural abnormalities is necessary for lifting, transfer, and positioning (Table 47-1). Some postural abnormalities limit ROM. Nurses intervene to maintain maximum ROM in unaffected joints and then design interventions to strengthen affected muscles and joints, improve the patient's posture, and adequately use affected and unaffected muscle groups. Referral to and/or collaboration with a physical therapist enhances the nurse's interventions for a patient with a postural abnormality.

Muscle Abnormalities. Injury and disease lead to numerous alterations in musculoskeletal function. For example, the muscular dystrophies are a group of familial disorders that cause degeneration of skeletal muscle fibers. They are the most prevalent of the muscle diseases in childhood. Patients with muscular dystrophy experience progressive, symmetrical weakness and wasting of skeletal muscle groups, with increasing disability and deformity (McCance and Huether, 2009).

Damage to the Central Nervous System. Damage to any component of the central nervous system that regulates voluntary movement results in impaired body alignment, balance, and mobility. Trauma from a head injury, ischemia from a stroke or brain attack (cerebrovascular accident [CVA]), or bacterial infection such as meningitis can damage the cerebellum or the motor strip in the cerebral cortex. Damage to the cerebellum causes problems with balance, and motor impairment is directly related to the amount of destruction of the motor strip. For example, a person with a right-sided cerebral hemorrhage with necrosis has destruction of the right motor strip that results in left-sided hemiplegia. Trauma to the spinal cord also impairs mobility. For example, a complete transection of the spinal cord results in a bilateral loss of voluntary motor control below the level of the trauma because motor fibers are cut.

Direct Trauma to the Musculoskeletal System. Direct trauma to the musculoskeletal system results in bruises, contusions, sprains, and fractures. A fracture is a disruption of bone tissue continuity. Fractures most commonly result from direct external trauma, but they also occur as a consequence of some deformity of the bone (e.g., pathological fractures of osteoporosis, Paget's disease, or osteogenesis imperfecta). Young children are usually able to form new bone more easily than adults and, as a result, have

TABLE 47-1 Postural Abnormalities

ABNORMALITY	DESCRIPTION	CAUSE	POSSIBLE TREATMENTS*
Torticollis	Inclining of head to affected side, in which sternocleidomastoid muscle is contracted	Congenital or acquired condition	Surgery, heat, support, or immobilization, depending on cause and severity, gentle ROM
Lordosis	Exaggeration of anterior convex curve of lumbar spine	Congenital condition Temporary condition (e.g., pregnancy)	Spine-stretching exercises (based on cause)
Kyphosis	Increased convexity in curvature of thoracic spine	Congenital condition Rickets, osteoporosis Tuberculosis of spine	Spine-stretching exercises, sleeping without pillows, using bed board, bracing, spinal fusion (based on cause and severity)
Scoliosis	Lateral "S"- or "C"-shaped spinal column with vertebral rotation, unequal heights of hips and shoulders	Sometimes a consequence of numerous congenital, connective tissue and neuromuscular disorders	Approximately half of children with scoliosis require surgery Nonsurgical treatment is with braces and exercises
Congenital hip dysplasia	Hip instability with limited abduction of hips and occasionally adduction contractures (head of femur does not articulate with acetabulum because of abnormal shallowness of acetabulum)	Congenital condition (more common with breech deliveries)	Maintenance of continuous abduction of thigh so head of femur presses into center of acetabulum Abduction splints, casting, surgery
Knock-knee (genu valgum)	Legs curved inward so knees come together as person walks	Congenital condition Rickets	Knee braces, surgery if not corrected by growth
Bowlegs (genu varum)	One or both legs bent outward at knee, which is normal until 2 to 3 years of age	Congenital condition Rickets	Slowing rate of curving if not corrected by growth With rickets, increase of vitamin D, calcium, and phosphorus intake to normal ranges
Clubfoot	*95%:* Medial deviation and plantar flexion of foot (equinovarus) *5%*: Lateral deviation and dorsiflexion (calcaneovalgus)	Congenital condition	Casts, splints such as Denis Browne splint, and surgery (based on degree and rigidity of deformity)
Footdrop	Inability to dorsiflex and invert foot because of peroneal nerve damage	Congenital condition Trauma Improper position of immobilized patient	None (cannot be corrected) Prevention through physical therapy Bracing with ankle-foot orthotic (AFO)
Pigeon toes	Internal rotation of forefoot or entire foot, common in infants	Congenital condition Habit	Growth, wearing reversed shoes

Data from McCance K, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2009, Mosby.
ROM, Range of motion.
*Severity of condition and cause dictate treatment, which is individualized to the patient's needs.

few complications after a fracture. Treatment often includes positioning the fractured bone in proper alignment and immobilizing it to promote healing and restore function. Even this temporary immobilization results in some **muscle atrophy,** loss of muscle tone, and joint stiffness.

NURSING KNOWLEDGE BASE

Fully understanding movement and mobility requires more than an overview of movement and the physiology and regulation of movement by the musculoskeletal and nervous systems. You need to know how to apply these scientific principles in the clinical setting to determine the safest way to move patients and to understand the effect of immobility on the physiological, psychosocial, and developmental aspects of patient care.

Safe Patient Handling

Nurses are exposed to the hazards related to lifting and transferring patients in many settings such as inpatient nursing units, long-term care facilities, and the operating room (de Castro et al., 2006). Manually lifting and transferring patients contributes to the high incidence of work-related musculoskeletal problems and back injuries in nurses and other health care staff (Nelson and Baptiste, 2006). Current evidence shows that many nurses frequently transfer to different positions and leave the profession because of work-related injuries (de Castro et al., 2006). Implementing evidence-based interventions and programs (e.g., lift teams) reduces the number of work-related injuries, which improves the health of the nurse and reduces indirect costs to the health care agency (e.g., workers' compensation and replacing injured workers).

Today many states have laws that mandate safe patient handling in health care agencies. Health care agencies are implementing comprehensive safe patient–handling programs in all parts of the United States. Comprehensive safe patient–handling programs include the following elements: an ergonomics assessment protocol for health care environments, patient assessment criteria, algorithms for patient handling and movement, special equipment kept in convenient locations to help transfer patients, back injury resource nurses, an "after-action review" that allows the health care

team to apply knowledge about moving patients safely in different settings, and a no-lift policy (Nelson, 2006).

Factors Influencing Mobility-Immobility

To determine how to move patients safely, assess their ability to move. Mobility refers to a person's ability to move about freely, and **immobility** refers to the inability to do so. Some patients can be mobile or immobile, whereas others experience varying degrees of partial immobility. Think of mobility as a continuum, with mobility on one end, immobility on the other, and varying degrees of partial immobility between the end points. Some patients move back and forth between mobility and immobility, but for others immobility is absolute and continues indefinitely. The terms *bed rest* and *impaired physical mobility* are used frequently when discussing patients on the mobility-immobility continuum.

Bed rest is an intervention that restricts patients to bed for therapeutic reasons. Nurses and health care providers most often prescribe this intervention. Bed rest has many different interpretations among health care professionals. Patients with a wide variety of conditions are placed on bed rest. The duration of bed rest depends on the illness or injury and the patient's prior state of health.

The effects of muscular deconditioning associated with lack of physical activity are often apparent in a matter of days. This cluster of symptoms is often referred to as the "hazards of immobility." The individual of average weight and height without a chronic illness on bed rest loses muscle strength from baseline levels at a rate of 3% a day. Immobility also is associated with cardiovascular, skeletal, and other organ changes. The term *disuse atrophy* describes the tendency of cells and tissue to reduce in size and function in response to prolonged inactivity resulting from bed rest, trauma, casting, or local nerve damage (McCance and Huether, 2009).

Periods of immobility or prolonged bed rest cause major physiological, psychological, and social effects. These effects are gradual or immediate and vary from patient to patient. The greater the extent and the longer the duration of immobility, the more pronounced the consequences. The patient with complete mobility restrictions is continually at risk for the hazards of immobility.

Systemic Effects. All body systems work more efficiently with some form of movement. Exercise has positive outcomes for all major systems of the body. When there is an alteration in mobility, each body system is at risk for impairment. The severity of the impairment depends on the patient's overall health, degree and length of immobility, and age. For example, older adults with chronic illnesses develop pronounced effects of immobility more quickly than do younger patients with the same immobility problem.

Metabolic Changes. Changes in mobility alter endocrine metabolism, calcium resorption, and functioning of the gastrointestinal system. The endocrine system, made up of hormone-secreting glands, maintains and regulates vital functions such as (1) response to stress and injury; (2) growth and development; (3) reproduction; (4) maintenance of the internal environment; and (5) energy production, use, and storage.

When injury or stress occurs, the endocrine system triggers a series of responses aimed at maintaining blood pressure and preserving life. It is important in maintaining homeostasis. Tissues and cells live in an internal environment that the endocrine system helps regulate through maintenance of sodium, potassium, water, and acid-base balance. It also regulates energy metabolism. Thyroid hormone increases the basal metabolic rate (BMR), and energy becomes available to cells through the integrated action of gastrointestinal and pancreatic hormones (McCance and Huether, 2009).

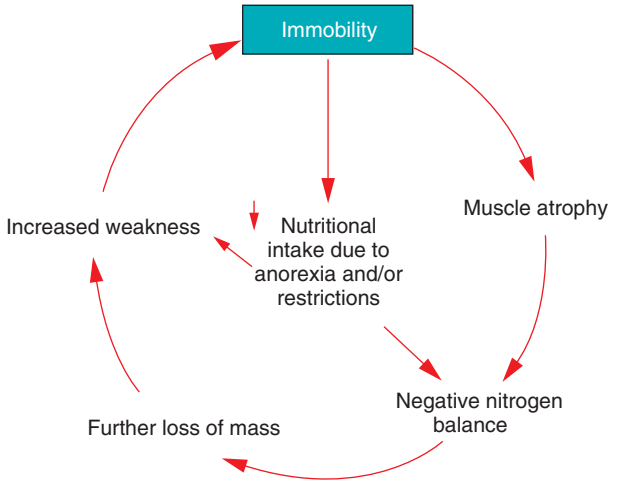

FIG. 47-4 Factors contributing to negative nitrogen balance associated with immobility. (From Gröer MW, Shekleton ME: *Basic pathophysiology: a holistic approach,* ed 3, St Louis, 1989, Mosby.)

Immobility disrupts normal metabolic functioning: decreasing the metabolic rate; altering the metabolism of carbohydrates, fats, and proteins; causing fluid, electrolyte, and calcium imbalances; and causing gastrointestinal disturbances such as decreased appetite and slowing of peristalsis. However, in the presence of an infectious process, immobilized patients often have an increased BMR as a result of fever or wound healing because these increase cellular oxygen requirements (Huether and McCance, 2008).

A deficiency in calories and protein is characteristic of patients with a decreased appetite secondary to immobility. The body is constantly synthesizing proteins and breaking them down into amino acids to form other proteins (see Chapter 41). When the patient is immobile, his or her body often excretes more nitrogen (the end product of amino acid breakdown) than it ingests in proteins, resulting in **negative nitrogen balance** (Fig. 47-4). Weight loss, decreased muscle mass, and weakness result from tissue catabolism (tissue breakdown) (McCance and Huether, 2009).

Another metabolic change associated with immobility is calcium resorption (loss) from bones. Immobility causes the release of calcium into the circulation. Normally the kidneys excrete the excess calcium. However, if the kidneys are unable to respond appropriately, hypercalcemia results. Pathological fractures occur if calcium resorption continues as the patient remains on bed rest or continues to be immobile (Huether and McCance, 2008).

Impairments of gastrointestinal functioning caused by decreased mobility vary. Difficulty in passing stools (constipation) is a common symptom, although pseudodiarrhea often results from a fecal impaction (accumulation of hardened feces). Be aware that this finding is not normal diarrhea, but rather liquid stool passing around the area of impaction (see Chapter 46). Left untreated, fecal impaction results in a mechanical bowel obstruction that partially or completely occludes the intestinal lumen, blocking normal propulsion of liquid and gas. The resulting fluid in the intestine produces distention and increases intraluminal pressure. Over time intestinal function becomes depressed, dehydration occurs, absorption ceases, and fluid and electrolyte disturbances worsen.

Respiratory Changes. Regular aerobic exercise enhances respiratory functioning. Lack of movement and exercise places patients at

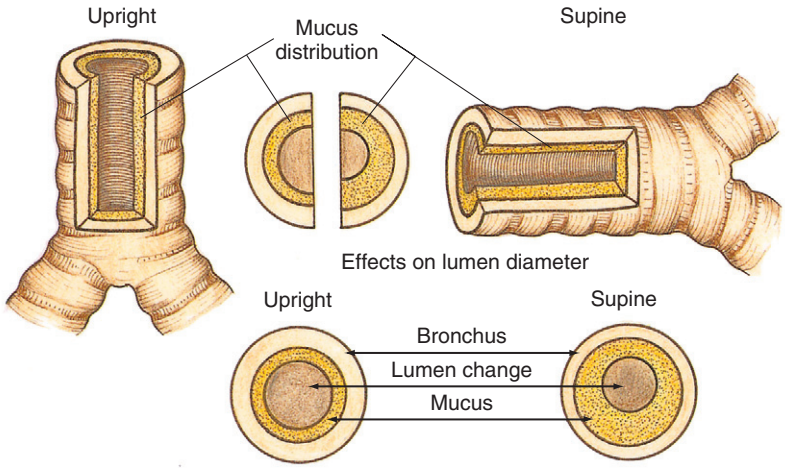

FIG. 47-5 Effect of recumbency and gravity on distribution of respiratory tract and diameter of bronchiolar lumen. (From Gröer MW, Shekleton ME: *Basic pathophysiology: a holistic approach,* ed 3, St Louis, 1989, Mosby.)

higher risk for respiratory complications. Patients who are immobile are at high risk for developing pulmonary complications. The most common respiratory complications are **atelectasis** (collapse of alveoli) and **hypostatic pneumonia** (inflammation of the lung from stasis or pooling of secretions). Both decreased oxygenation and prolonged recovery add to the patient's discomfort (Lewis et al., 2011). In atelectasis secretions block a bronchiole or a bronchus; and the distal lung tissue (alveoli) collapses as the existing air is absorbed, producing hypoventilation. The site of the blockage affects the severity of atelectasis. Sometimes an entire lung lobe or a whole lung collapses. At some point in the development of these complications, there is a proportional decline in the patient's ability to cough productively. Ultimately the distribution of mucus in the bronchi increases, particularly when the patient is in the supine, prone, or lateral position (Fig. 47-5). Mucus accumulates in the dependent regions of the airways (Fig. 47-6). Hypostatic pneumonia frequently results because mucus is an excellent place for bacteria to grow.

Cardiovascular Changes. Immobilization also affects the cardiovascular system. The three major changes are orthostatic hypotension, increased cardiac workload, and thrombus formation.

Orthostatic hypotension is an increase in heart rate of more than 15% and a drop of 15 mm Hg or more in systolic blood pressure or a drop of 10 mm Hg or more in diastolic blood pressure when the patient changes from the supine to standing position (Huether and McCance, 2008). In the immobilized patient decreased circulating fluid volume, pooling of blood in the lower extremities, and decreased autonomic response occur. These are especially evident in the older adult.

As the workload of the heart increases, so does its oxygen consumption. Therefore the heart works harder and less efficiently during periods of prolonged rest. As immobilization increases, cardiac output falls, further decreasing cardiac efficiency and increasing workload.

Patients who are immobile are also at risk for thrombus formation. A **thrombus** is an accumulation of platelets, fibrin, clotting factors, and the cellular elements of the blood attached to the interior wall of a vein or artery, which sometimes occludes the lumen of the vessel (Fig. 47-7). Three factors contribute to venous thrombus formation: (1) damage to the vessel wall (e.g., injury during surgical procedures), (2) alterations of blood flow (e.g., slow blood

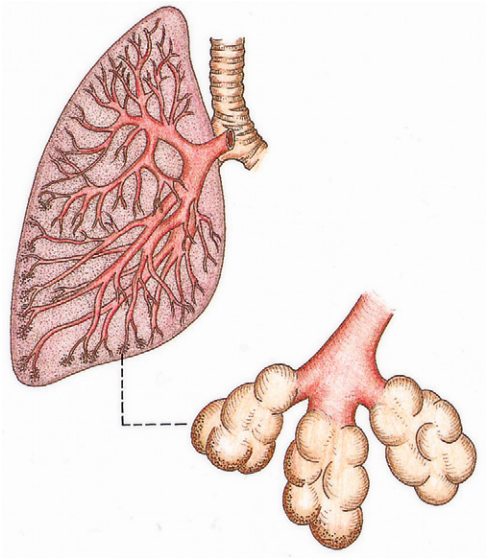

FIG. 47-6 Pooling of secretions in dependent regions of lungs in supine position.

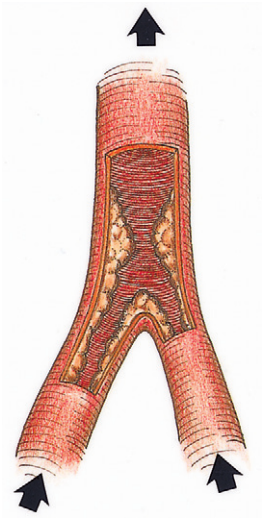

FIG. 47-7 Thrombus formation in a vessel.

flow in calf veins associated with bed rest), and (3) alterations in blood constituents (e.g., a change in clotting factors or increased platelet activity). These three factors are often referred to as *Virchow's triad* (Huether and McCance, 2008).

Musculoskeletal Changes. The effects of immobility on the musculoskeletal system include permanent or temporary impairment or permanent disability. Restricted mobility sometimes results in loss of endurance, strength, and muscle mass and decreased stability and balance. Other effects of restricted mobility affecting the skeletal system are impaired calcium metabolism and joint mobility.

Muscle Effects. Because of protein breakdown, the patient loses lean body mass. The reduced muscle mass is unable to sustain activity without increased fatigue. If immobility continues and the patient does not exercise, there is further loss of muscle mass. Muscle weakness always occurs with immobility, and prolonged immobility often leads to disuse atrophy. Muscle atrophy is a widely observed response to illness, decreased ADLs, and immobilization. Loss of endurance, decreased muscle mass and strength, and joint instability (see Skeletal Effects) put patients at risk for falls (see Chapter 38).

Skeletal Effects. Immobilization causes two skeletal changes: impaired calcium metabolism and joint abnormalities. Because immobilization results in bone resorption, the bone tissue is less dense or atrophied, and **disuse osteoporosis** results. When disuse osteoporosis occurs, the patient is at risk for pathological fractures.

Osteoporosis is a major health concern in this country. The first Surgeon General's report on the topic of bone health stated that one in two Americans over 50 years of age will be at risk for fractures related to osteoporosis by the year 2020. Furthermore, the National Osteoporosis Foundation (2010) reports that 44 million Americans (55% of those over the age of 50) either have osteoporosis or are at risk for developing it. Approximately 80% of people who have osteoporosis are female. Although primary osteoporosis is different in origin from the osteoporosis that results from immobility, it is imperative for nurses to recognize that immobilized patients are at high risk for accelerated bone loss if they have primary osteoporosis.

Immobility can lead to joint contractures. A **joint contracture** is an abnormal and possibly permanent condition characterized by fixation of the joint. It is important to note that flexor muscles for joints are stronger than extensor muscles and therefore contribute to the formation of contractures. Disuse, atrophy, and shortening of the muscle fibers cause joint contractures. When a contracture occurs, the joint cannot achieve full ROM. Contractures sometimes leave a joint or joints in a nonfunctional position, as seen in patients who are permanently curled in a fetal position. Early prevention of contractures is essential; they can begin to form after only 8 hours of immobility in the older adult (Fletcher, 2005).

One common and debilitating contracture is footdrop (Fig. 47-8). When **footdrop** occurs, the foot is permanently fixed in plantar flexion. Ambulation is difficult with the foot in this position because the patient cannot dorsiflex the foot. The patient with footdrop is unable to lift the toes off the ground. Patients who have suffered CVAs or brain attacks with resulting right- or left-sided paralysis (hemiplegia) are at risk for footdrop.

Urinary Elimination Changes. Immobility alters the patient's urinary elimination. In the upright position urine flows out of the renal pelvis and into the ureters and bladder because of gravitational forces. When the patient is recumbent or flat, the kidneys and ureters move toward a more level plane. Urine formed by the kidney needs to enter the bladder unaided by gravity. Because the peristaltic contractions of the ureters are insufficient to overcome gravity, the renal pelvis fills before urine enters the ureters (Fig. 47-9). This condition is called **urinary stasis** and increases the risk of urinary tract infection and renal calculi (see Chapter 45). **Renal calculi** are calcium stones that lodge in the renal pelvis or pass through the ureters. Immobilized patients are at risk for calculi because they frequently have hypercalcemia.

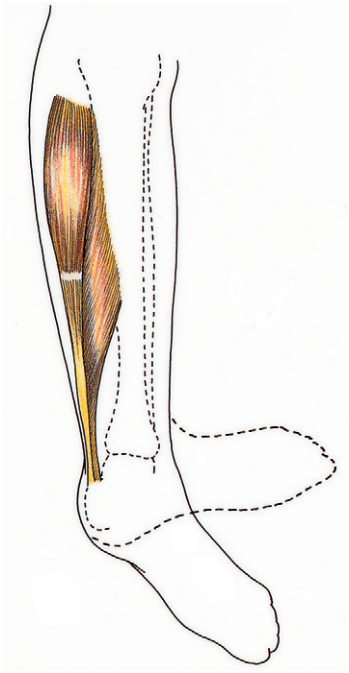

FIG. 47-8 Footdrop. Ankle is fixed in plantar flexion. Normally ankle is able to flex *(dotted line),* which eases walking.

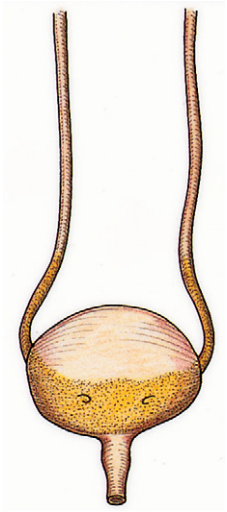

FIG. 47-9 Stasis of urine with reflux to ureters.

As the period of immobility continues, fluid intake often diminishes. When combined with other problems such as fever, the risk for dehydration increases. As a result, urinary output declines on or about the fifth or sixth day after immobilization, and the urine becomes concentrated. This concentrated urine increases the risk for calculi formation and infection. Inappropriate perineal care after bowel movements, particularly in women, increases the risk

of urinary tract contamination by *Escherichia coli* bacteria. Another cause of urinary tract infections in immobilized patients is the use of an indwelling urinary catheter.

Integumentary Changes. The changes in metabolism that accompany immobility add to the harmful effect of pressure on the skin in the immobilized patient. This makes immobility a major risk factor for pressure ulcers. Any break in the integrity of the skin is difficult to heal. Preventing a pressure ulcer is much less expensive than treating one; therefore preventive nursing interventions are imperative (WOCN, 2009).

A **pressure ulcer** is an impairment of the skin as a result of prolonged ischemia (decreased blood supply) in tissues (see Chapter 48). The ulcer is characterized initially by inflammation and usually forms over a bony prominence. Ischemia develops when the pressure on the skin is greater than the pressure inside the small peripheral blood vessels supplying blood to the skin.

Tissue metabolism depends on the supply of oxygen and nutrients to and the elimination of metabolic wastes from the blood. Pressure affects cellular metabolism by decreasing or totally eliminating tissue circulation. When a patient lies in bed or sits in a chair, the weight of the body is on bony prominences. The longer the pressure is applied, the longer the period of ischemia and therefore the greater the risk of skin breakdown. The older adult is especially at risk. For example, an older adult who is immobilized on a backboard following a trauma can develop skin breakdown within 3 hours (Fletcher, 2005).

Psychosocial Effects. Immobilization often leads to emotional and behavioral responses, sensory alterations, and changes in coping. When normal, healthy young men who were part of a National Aeronautics and Space Administration (NASA) study were on bed rest for several weeks, they exhibited signs of sensory deprivation: altered sleep patterns and significant increases in anxiety, hostility, and depression (Fletcher, 2005). Every patient responds to immobility differently.

Patients with restricted mobility may have some depression. Depression is an affective disorder characterized by exaggerated feelings of sadness, melancholy, dejection, worthlessness, emptiness, and hopelessness out of proportion to reality. It results from worrying about present and future levels of health, finances, and family needs. Because immobilization removes the patient from a daily routine, he or she has more time to worry about disability. Worrying quickly increases the patient's depression, causing withdrawal. Withdrawn patients often do not want to participate in their own care.

Developmental Changes

Developmental changes tend to be associated with immobility in the very young and older adults. The immobilized young or middle-age adult who has been healthy experiences few, if any, developmental changes. However, there are exceptions. For example, a mother with complications following birth has to go onto bed rest and as a result cannot interact with her newborn as expected.

Infants, Toddlers, and Preschoolers. The newborn infant's spine is flexed and lacks the anteroposterior curves of the adult (see Chapter 12). As the baby grows, musculoskeletal development permits support of weight for standing and walking. Posture is awkward because the head and upper trunk are carried forward. Because body weight is not distributed evenly along a line of gravity, posture is off balance, and falls occur often. The infant, toddler, or preschooler is usually immobilized because of trauma or the need to correct a congenital skeletal abnormality. Prolonged immobilization delays the child's gross motor skills, intellectual development, or musculoskeletal development.

Adolescents. The adolescent stage usually begins with a tremendous increase in growth (see Chapter 12). Growth is frequently uneven. Prolonged immobilization alters adolescent growth patterns. In addition, adolescents who experience immobility often are behind peers in gaining independence and accomplishing certain skills such as obtaining a driver's license. Social isolation is a concern for this age-group when immobilization occurs.

Adults. An adult who has correct posture and body alignment feels good, looks good, and generally appears self-confident. The healthy adult also has the necessary musculoskeletal development and coordination to carry out ADLs (see Chapter 13). When periods of prolonged immobility occur, all physiological systems are at risk. In addition, the role of the adult often changes with regard to the family or social structure. Some adults lose their jobs, which affects their self-concept (see Chapter 33).

Older Adults. A progressive loss of total bone mass occurs with the older adult. Some of the possible causes of this loss include decreased physical activity, hormonal changes, and bone resorption. The effect of bone loss is weaker bones. Older adults often walk more slowly, take smaller steps, and appear less coordinated. Prescribed medications alter their sense of balance or affect their blood pressure when they change position too quickly, increasing their risk for falls and injuries (see Chapter 14). The outcomes of a fall include not only possible injury but also hospitalization, loss of independence, psychological effects, and quite possibly death (Yeom et al., 2009).

Older adults often experience functional status changes secondary to hospitalization and altered mobility status (Box 47-1). Immobilization of older adults increases their physical dependence on others and accelerates functional losses. Immobilization of some older adults results from a degenerative disease, neurological trauma, or chronic illness. In others it occurs gradually and progressively, and in others—especially those who have had a stroke—immobilization is sudden. When providing nursing care for an older adult, encourage the patient to perform as many self-care activities as possible, thereby maintaining the highest level of mobility. Sometimes nurses inadvertently contribute to a patient's immobility by providing unnecessary help with activities such as bathing and transferring.

BOX 47-1 FOCUS ON OLDER ADULTS

Problems of Nutrition As They Relate to Hospitalized Immobile Older Adults

For many older adults, admission to the hospital often results in functional decline despite the treatment for which they were admitted. Some older adults have problems related to mobility and quickly regress to a dependent state. But keeping in mind their nutritional needs and status is extremely important.

Usual aging is associated with decreased muscle strength and aerobic capacity. This becomes exacerbated when the nutritional state is not assessed properly.

- A nutritional assessment needs to be included in the plan of care for the older adult experiencing immobility.
- Anorexia and insufficient assistance with eating lead to malnutrition, which contributes to the known problems associated with immobility.
- There is a direct relationship between the success of older adults' rehabilitation and their nutritional status.

CRITICAL THINKING

Critical thinking requires the combination of knowledge, experiences, patient data, critical thinking attitudes, and intellectual and professional standards. The needs of the immobile patient are multiple and complex. After conducting a thorough assessment, the nurse identifies appropriate nursing diagnoses and implements effective nursing care.

To understand the impact of immobility on the patient and family, integrate knowledge from nursing and other disciplines, previous experiences, and information gathered from patients. In addition, the use of critical thinking attitudes is necessary when designing a plan of care for successful interventions related to immobility. Professional standards such as those developed by the Agency for Healthcare Research and Quality (AHRQ, 2009) and the Wound, Ostomy and Continence Nurses Society (WOCN, 2009) and intellectual standards such as accuracy provide valuable guides for mobility management (Fig. 47-10). In addition, many agencies have standards for practice related to transferring patients and fall and pressure ulcer prevention.

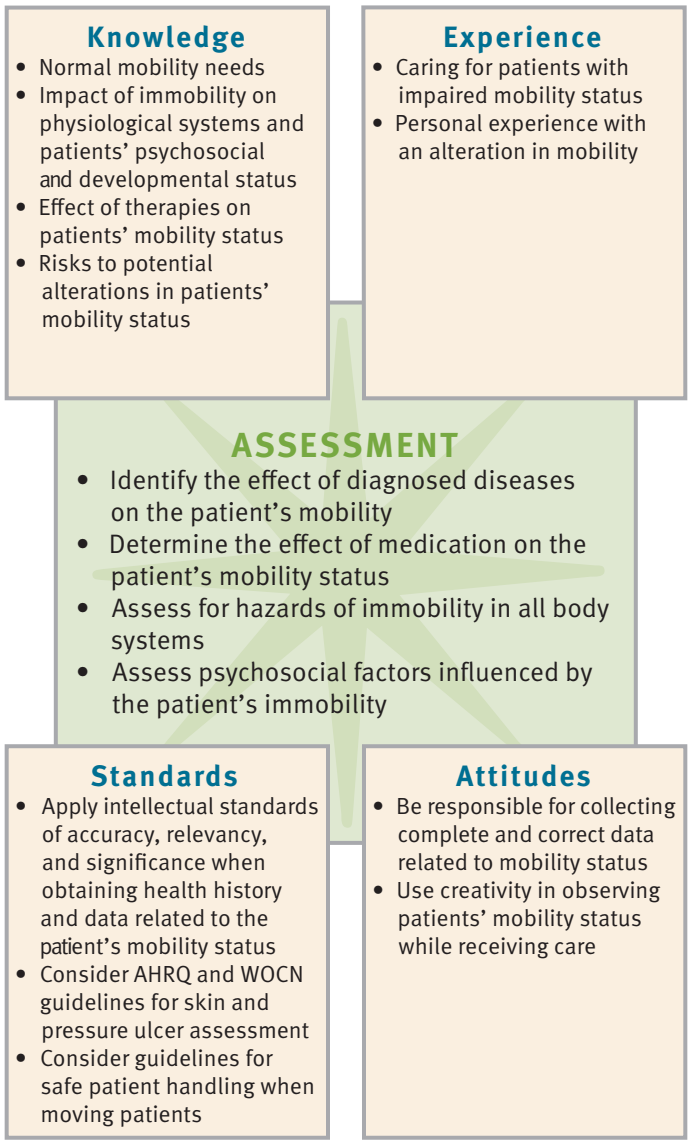

FIG. 47-10 Critical thinking model for immobility assessment. *AHRQ,* Agency for Healthcare Research and Quality; *WOCN,* Wound, Ostomy and Continence Nurses Society.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop an individualized plan of care. Patients with preexisting mobility impairments and those who are at risk for immobility will *greatly benefit* from your application of the nursing process and the use of your critical thinking skills to design a care plan that improves the patient's functional status, promotes self-care, maintains psychological well-being, and reduces the hazards of immobility.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Nursing assessment of the patient includes aspects of both mobility and immobility.

Through the Patient's Eyes. Usually the nurse assesses for and asks questions about the patient's degree of both mobility and immobility during physical examination (Box 47-2). Keep in mind that the patient is a full partner in providing information and designing the plan of care. You convey respect for the patient's preferences, values, and needs when implementing the nursing process and designing a plan of care with the patient (Cromwell and Berg, 2006).

Mobility. Assessment of patient mobility focuses on ROM, gait, exercise and activity tolerance, and body alignment. When unsure of the patient's abilities, begin assessment of mobility with the patient in the most supportive position and move to higher levels according to his or her tolerance. Generally the assessment of movement starts while the patient is lying and proceeds to assessing sitting positions in bed, transfers to chair, and finally walking. This helps to protect the patient's safety.

Range of Motion. **Range of motion (ROM)** is the maximum amount of movement available at a joint in one of the three planes

BOX 47-2 NURSING ASSESSMENT QUESTIONS

Mobility
- Describe any changes you've noticed in your ability to walk and take care of yourself on a daily basis.
- Have you experienced any stiffness, swelling, pain, or difficulty with moving? If so, describe how you felt.
- Have you noticed any shortness of breath?

Immobility
- Describe your normal daily activity. Has this changed recently?
- How have your appetite and diet changed since you've had problems moving around?
- Describe what you eat in a normal day.
- Does your day seem very long?
- Are you sleeping well at night?
- Have you noticed any places on your skin that are reddened or have any open sores?
- Describe any changes you've noticed in urinating and/or in having bowel movements.

of the body: sagittal, transverse, or frontal (Fig. 47-11). The sagittal plane is a line that passes through the body from front to back, dividing it into a left and right side. The frontal plane passes through the body from side to side and divides it into front and back. The transverse plane is a horizontal line that divides the body into upper and lower portions.

Ligaments, muscles, and the nature of the joint limit joint mobility in each of the planes. However, some joint movements are specific to each plane. In the sagittal plane movements are flexion and extension (e.g., fingers and elbows), dorsiflexion and plantar flexion (feet), and extension (e.g., hip). In the frontal plane movements are abduction and adduction (e.g., arms and legs) and eversion and inversion (feet). In the transverse plane movements are pronation and supination (hands) and internal and external rotation (hips).

When assessing ROM, ask questions about and physically examine the patient for stiffness, swelling, pain, limited movement, and unequal movement. Chapter 30 describes specific techniques for measuring the degrees of motion in a joint. Assessment of ROM is important as a baseline measure to compare and evaluate whether loss in joint mobility has occurred. Patients whose mobility is restricted require ROM exercises to reduce the hazards of immobility. Therefore assess the type of ROM exercise that a patient is able to perform. ROM exercises are active (the patient moves all joints through their ROM unassisted), passive (the patient is unable to move independently, and the nurse moves each joint through its ROM), or somewhere in between (Table 47-2). For example,

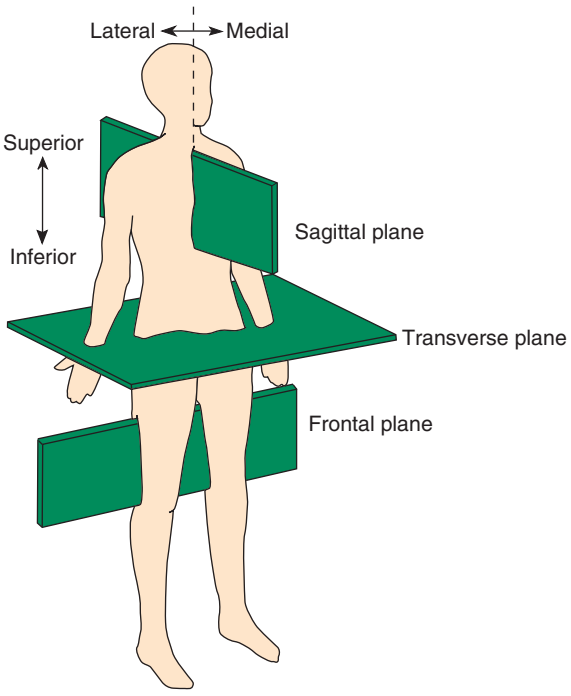

FIG. 47-11 Planes of body.

TABLE 47-2 Range-of-Motion Exercises

BODY PART	TYPE OF JOINT	TYPE OF MOVEMENT	RANGE (DEGREES)	PRIMARY MUSCLES
Neck, cervical spine	Pivotal	*Flexion:* Bring chin to rest on chest.	45	Sternocleidomastoid
		Extension: Return head to erect position.	45	Trapezius
		Hyperextension: Bend head back as far as possible.	10	Trapezius
		Lateral flexion: Tilt head as far as possible toward each shoulder.	40-45	Sternocleidomastoid
		Rotation: Turn head as far as possible in circular movement.	180	Sternocleidomastoid, trapezius
Shoulder	Ball and socket	*Flexion:* Raise arm from side position forward to position above head.	180 45-60	Coracobrachialis, biceps brachii, deltoid, pectoralis major
		Extension: Return arm to position at side of body.	180	Latissimus dorsi, teres major, triceps brachii
		Hyperextension: Move arm behind body, keeping elbow straight.	45-60	Latissimus dorsi, teres major, deltoid
		Abduction: Raise arm to side to position above head with palm away from head.	180	Deltoid, supraspinatus
		Adduction: Lower arm sideways and across body as far as possible.	320	Pectoralis major
		Internal rotation: With elbow flexed, rotate shoulder by moving arm until thumb is turned inward and toward back.	90	Pectoralis major, latissimus dorsi, teres major, subscapularis
		External rotation: With elbow flexed, move arm until thumb is upward and lateral to head.	90	Infraspinatus, teres major, deltoid
		Circumduction: Move arm in full circle (Circumduction is combination of all movements of ball-and-socket joint.)	360	Deltoid, coracobrachialis, latissimus dorsi, teres major
Elbow	Hinge	*Flexion:* Bend elbow so lower arm moves toward its shoulder joint and hand is level with shoulder.	150	Biceps brachii, brachialis, brachioradialis
		Extension: Straighten elbow by lowering hand.	150	Triceps brachii
Forearm	Pivotal	*Supination:* Turn lower arm and hand so palm is up.	70-90	Supinator, biceps brachii
		Pronation: Turn lower arm so palm is down.	70-90	Pronator teres, pronator quadratus

Continued

TABLE 47-2 **Range-of-Motion Exercises—cont'd**

BODY PART	TYPE OF JOINT	TYPE OF MOVEMENT	RANGE (DEGREES)	PRIMARY MUSCLES
Wrist	Condyloid	*Flexion:* Move palm toward inner aspect of forearm.	80-90	Flexor carpi ulnaris, flexor carpi radialis
		Extension: Move fingers and hand posterior to midline.	80-90	Extensor carpi radialis brevis, extensor carpi radialis longus, extensor carpi ulnaris
		Hyperextension: Bring dorsal surface of hand back as far as possible.	80-90	Extensor carpi radialis brevis, extensor carpi radialis longus, extensor carpi ulnaris
		Abduction: Place hand with palm down and extend wrist laterally toward fifth finger.	Up to 30	Flexor carpi radialis, extensor carpi radialis brevis, extensor carpi radialis longus
		Adduction: Place hand with palm down and extend wrist medially toward thumb.	30-50	Flexor carpi ulnaris, extensor carpi ulnaris
Fingers	Condyloid hinge	*Flexion:* Make fist.	90	Lumbricales, interosseus volaris, interosseus dorsalis
		Extension: Straighten fingers.	90	Extensor digiti quinti proprius, extensor digitorum communis, extensor indicis proprius
		Hyperextension: Bend fingers back as far as possible.	30-60	
		Abduction: Spread fingers apart.	30	Interosseus dorsalis
		Adduction: Bring fingers together.	30	Interosseus volaris
Thumb	Saddle	*Flexion:* Move thumb across palmar surface of hand.	90	Flexor pollicis brevis
		Extension: Move thumb straight away from hand.	90	Extensor pollicis longus, extensor pollicis brevis
		Abduction: Extend thumb laterally (usually done when placing fingers in abduction and adduction).	30	Abductor pollicis brevis
		Adduction: Move thumb back toward hand.	30	Adductor pollicis obliquus, adductor pollicis transversus
		Opposition: Touch thumb to each finger of same hand.		Opponens pollicis, opponens digiti minimi
Hip	Ball and socket	*Flexion:* Move leg forward and up.	90-120	Psoas major, iliacus, sartorius
		Extension: Move back beside other leg.	90-120	Gluteus maximus, semitendinosus, semimembranosus
		Hyperextension: Move leg behind body.	30-50	Gluteus maximus, semitendinosus, semimembranosus
		Abduction: Move leg laterally away from body.	30-50	Gluteus medius, gluteus minimus
		Adduction: Move leg back toward medial position and beyond if possible.	30-50	Adductor longus, adductor brevis, adductor magnus
		Internal rotation: Turn foot and leg toward other leg.	90	Gluteus medius, gluteus minimus, tensor fasciae latae
		External rotation: Turn foot and leg away from other leg.	90	Obturatorius internus, obturatorius externus
		Circumduction: Move leg in circle.		Psoas major, gluteus maximus, gluteus medius, adductor magnus
Knee	Hinge	*Flexion:* Bring heel back toward back of thigh.	120-130	Biceps femoris, semitendinosus, semimembranosus, sartorius
		Extension: Return leg to floor.	120-130	Rectus femoris, vastus lateralis, vastus medialis, vastus intermedius
Ankle	Hinge	*Dorsal flexion:* Move foot so toes are pointed upward.	20-30	Tibialis anterior
		Plantar flexion: Move foot so toes are pointed downward.	45-50	Gastrocnemius, soleus
Foot	Gliding	*Inversion:* Turn sole of foot medially.	10 or less	Tibialis anterior, tibialis posterior
		Eversion: Turn sole of foot laterally.	10 or less	Peroneus longus, peroneus brevis
Toes	Condyloid	*Flexion:* Curl toes downward.	30-60	Flexor digitorum, lumbricalis pedis, flexor hallucis brevis
		Extension: Straighten toes.	30-60	Extensor digitorum longus, extensor digitorum brevis, extensor hallucis longus
		Abduction: Spread toes apart.	15 or less	Abductor hallucis, interosseus dorsalis
		Adduction: Bring toes together.	15 or less	Adductor hallucis, interosseus plantaris

provide support for a weak patient while the patient performs most of the movement. Some patients are able to move some joints actively, whereas the nurse passively moves others. First consider the medical plan of care and if active ROM exercises are appropriate; then assess the patient's ability to engage in active ROM exercises and the need for assistance, teaching, or reinforcement. In general, exercises need to be as active as health and mobility allow. Contractures develop in joints not moved periodically through their full ROM. Assessment data from patients with limited joint movements vary based on the area affected.

Neck. A flexion contracture of the neck is a serious disability because the patient's neck is permanently flexed with the chin close to or actually touching the chest. Assessment reveals altered body alignment, changes in the visual field, and decreased level of independent functioning.

Shoulder. One feature of the shoulder that sets it apart from other joints in the body is that the strongest muscle controlling it, the deltoid, is in complete elongation in the normal position. No other muscle exerts its full strength when in complete elongation. Patients with limited movement in the shoulder have difficulty moving their arms.

Elbow. The elbow functions optimally at an angle of approximately 90 degrees. An elbow fixed in full extension is disabling and limits the patient's independence.

Forearm. Most functions of the hand are best carried out with the forearm in moderate pronation. When the forearm is fixed in a position of full supination, the patient's use of the hand is limited.

Wrist. The primary function of the wrist is to place the hand in slight dorsiflexion, the position of functioning. When the wrist is fixed in even a slightly flexed position, the grasp is weakened.

Fingers and Thumb. The ROM in the fingers and thumb enables the patient to perform ADLs and activities requiring fine-motor skills such as carpentry, needlework, drawing, and painting. The functional position of the fingers and thumb is slight flexion of the thumb in opposition to the fingers.

Hip. Because the lower extremities are concerned chiefly with locomotion and weight bearing, stability of the hip joint is more important than its mobility. For example, if one hip has no mobility but is fixed in a neutral position and fully extended, it is possible to walk without a significant limp. However, contractures often fix the hip in positions of deformity. Excessive abduction makes the affected leg appear too short, whereas excessive adduction makes it appear too long. In either case the patient has limited locomotion and walks with an obvious limp. Internal and external rotation contractures cause an abnormal and unbalanced gait.

Knee. A primary function of the knee is stability, which is achieved by ROM, ligaments, and muscles. However, the knees cannot remain stable under weight-bearing conditions unless there is adequate quadriceps power to maintain the knee in full extension. An immobile knee joint results in serious disability. The degree of disability depends on the position in which the knee is stiffened. If it is fixed in full extension, the person needs to sit with the leg out in front. When the knee is flexed, the person limps while walking. The greater the flexion, the greater is the limp.

Ankle and Foot. Without full ROM of the ankle, gait deviations occur. If the joint is not stable, the person falls. When the person relaxes as in sleep or coma, the foot relaxes and assumes a position of plantar flexion. As a result, it becomes fixed in plantar flexion (footdrop), which impairs the ability to walk.

Toes. Excessive flexion of the toes results in clawing. When this is a permanent deformity, the foot is unable to rest flat on the floor, and the patient is unable to walk properly. Flexion contractures are the most common foot deformity associated with reduced joint mobility.

Gait. The term **gait** describes a particular manner or style of walking. The gait cycle begins with the heel strike of one leg and continues to the heel strike of the other leg. Assessing a patient's gait allows you to draw conclusions about balance, posture, safety, and ability to walk without assistance. The mechanics of human gait involve coordination of the skeletal, neurological, and muscular systems of the human body.

Exercise and Activity Tolerance. **Exercise** is physical activity for conditioning the body, improving health, and maintaining fitness. Nurses use it as therapy to correct a deformity or restore the overall body to a maximal state of health. When a person exercises, physiological changes occur in body systems (see Chapter 38).

Assessment of the patient's energy level includes the physiological effects of exercise and activity tolerance. **Activity tolerance** is the type and amount of exercise or work that a person is able to perform. Assessment of activity tolerance is necessary when planning activity such as walking, ROM exercises, or ADLs. Activity tolerance assessment includes data from physiological, emotional, and developmental domains (see Chapter 38). This assessment is applicable in all clinical settings.

As activity begins, monitor patients for symptoms such as dyspnea, fatigue, chest pain, and/or a change in vital signs. The weak or debilitated patient is unable to sustain even slight changes in activity because of the increased demand for energy. Seemingly simple tasks such as eating and moving in bed often result in extreme fatigue. When the patient experiences decreased activity tolerance, carefully assess how much time he or she needs to recover. Decreasing recovery time indicates improving activity tolerance.

People who are depressed, worried, or anxious are frequently unable to tolerate exercise. Depressed patients tend to withdraw rather than participate. Patients who worry or are frequently anxious expend a tremendous amount of mental energy and often report feeling fatigued. Because of this, they also experience physical and emotional exhaustion.

Developmental changes also affect activity tolerance. As the infant enters the toddler stage, the activity level increases, and the need for sleep declines. The child entering preschool or primary grades expends mental energy in learning and often requires more rest after school or before strenuous play. The adolescent going through puberty requires more rest because much body energy is expended for growth and hormone changes (see Chapter 42).

Changes still occur through the adult years, but many of them are related to work and lifestyle choices. Pregnancy causes fluctuations in a woman's energy tolerance, especially during the first and third trimesters, when she experiences increased fatigue. Hormonal changes and fetal development use body energy, and the woman is sometimes unable or unmotivated to carry out physical activities. During the last trimester fetal development consumes a great deal of the mother's energy; and the size and location of the fetus limit the ability to take a deep breath, resulting in less oxygen being available for physical activities.

As the person grows older, activity tolerance changes. Muscle mass is reduced, and posture and bone composition change. Changes in the cardiorespiratory system such as decreased maximum heart rate and lung compliance, which affect the intensity of exercise, often occur. As age progresses, some older individuals still exercise but do so at a reduced intensity. The more inactive a patient is, the more pronounced are these activity changes.

Body Alignment. Perform assessment of body alignment with the patient standing, sitting, or lying down. This assessment has the following objectives:

- Determining normal physiological changes in body alignment resulting from growth and development for each patient
- Identifying deviations in body alignment caused by incorrect posture
- Providing opportunities for patients to observe their posture
- Identifying learning needs of patients for maintaining correct body alignment
- Identifying trauma, muscle damage, or nerve dysfunction
- Obtaining information concerning other factors that contribute to incorrect alignment such as fatigue, malnutrition, and psychological problems

The first step in assessing body alignment is to put patients at ease so they do not assume unnatural or rigid positions. When assessing the body alignment of an immobilized or unconscious patient, remove pillows and positioning supports from the bed and place the patient in the supine position.

Standing. Characteristics of correct body alignment for the standing patient include the following:

1. The head is erect and midline.
2. When observed posteriorly, the shoulders and hips are straight and parallel.
3. When observed posteriorly, the vertebral column is straight.
4. When observed laterally, the head is erect, and the spinal curves are aligned in a reversed S pattern. The cervical vertebrae are anteriorly convex, the thoracic vertebrae are posteriorly convex, and the lumbar vertebrae are anteriorly convex.
5. When observed laterally, the abdomen is comfortably tucked in, and the knees and ankles are slightly flexed. The person appears comfortable and does not seem conscious of the flexion of knees or ankles.
6. The arms hang comfortably at the sides.
7. The feet are slightly apart to achieve a base of support, and the toes are pointed forward.
8. When viewing the patient from behind, the center of gravity is in the midline, and the line of gravity is from the middle of the forehead to a midpoint between the feet. Laterally the line of gravity runs vertically from the middle of the skull to the posterior third of the foot (Fig. 47-12).

Sitting. Characteristics of correct alignment of the sitting patient include the following:

1. The head is erect, and the neck and vertebral column are in straight alignment.
2. The body weight is distributed evenly on the buttocks and thighs.
3. The thighs are parallel and in a horizontal plane.
4. Both feet are supported on the floor (Fig. 47-13), and the ankles are flexed comfortably. With patients of short stature, use a footstool to ensure that ankles are flexed comfortably.
5. A 2.5- to 5-cm (1- to 2-inch) space is maintained between the edge of the seat and the popliteal space on the posterior surface of the knee. This space ensures that there is no pressure on the popliteal artery or nerve to decrease circulation or impair nerve function.
6. The patient's forearms are supported on the armrest, in the lap, or on a table in front of the chair.

It is particularly important to assess alignment when sitting if the patient has muscle weakness, muscle paralysis, or nerve damage.

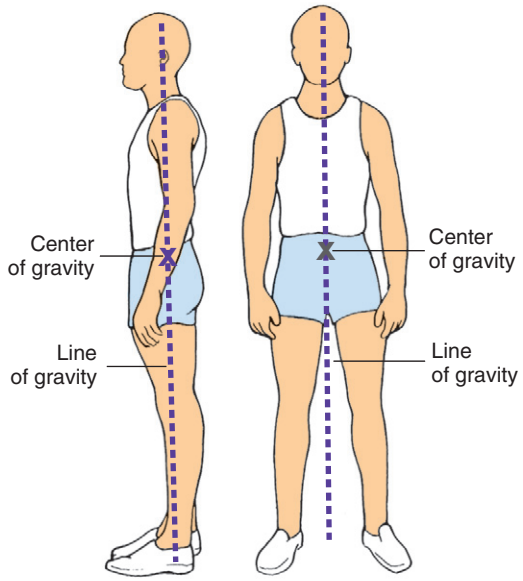

FIG. 47-12 Correct body alignment when standing.

FIG. 47-13 Correct body alignment when sitting.

Patients who have these problems have diminished sensation in the affected area and are unable to perceive pressure or decreased circulation. Proper alignment while sitting reduces the risk of musculoskeletal system damage in such a patient. The patient with severe respiratory disease sometimes assumes a posture of leaning on the table in front of the chair in an attempt to breathe more easily. This is called *orthopnea.*

Lying. People who are conscious have voluntary muscle control and normal perception of pressure. As a result, they usually assume a position of comfort when lying down. Because their ROM, sensation, and circulation are within normal limits, they change positions when they perceive muscle strain and decreased circulation.

Assess body alignment for a patient who is immobilized or bedridden with the patient in the lateral position. Remove all positioning supports from the bed except for the pillow under the head and support the body with an adequate mattress (Fig. 47-14). This

TABLE 47-3 Assessment of the Physiological Hazards of Immobility

SYSTEM	ASSESSMENT TECHNIQUES	ABNORMAL FINDINGS
Metabolic	Inspection	Slowed wound healing, abnormal laboratory data
	Inspection	Muscle atrophy
	Anthropometric measurements (mid-upper arm circumference, triceps skinfold measurement)	Decreased amount of subcutaneous fat
	Palpation	Generalized edema
Respiratory	Inspection	Asymmetrical chest wall movement, dyspnea, increased respiratory rate
	Auscultation	Crackles, wheezes
Cardiovascular	Auscultation	Orthostatic hypotension
	Auscultation, palpation	Increased heart rate, third heart sound, weak peripheral pulses, peripheral edema
Musculoskeletal	Inspection, palpation	Decreased range of motion, erythema, increased diameter in calf or thigh
	Palpation	Joint contracture
	Inspection	Activity intolerance, muscle atrophy, joint contracture
Skin	Inspection, palpation	Break in skin integrity
Elimination	Inspection	Decreased urine output, cloudy or concentrated urine, decreased frequency of bowel movements
	Palpation	Distended bladder and abdomen
	Auscultation	Decreased bowel sounds

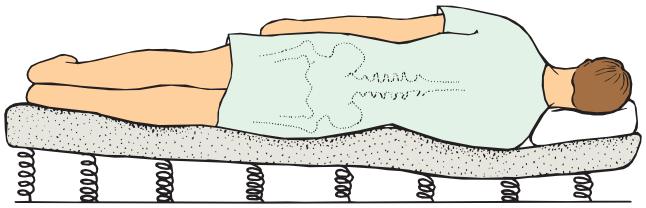

FIG. 47-14 Correct body alignment when lying down.

position allows for full view of the spine and back and helps provide other baseline body alignment data such as whether the patient is able to remain positioned without aid. The vertebrae are aligned, and the position does not cause discomfort. Patients with impaired mobility (e.g., traction or arthritis), decreased sensation (e.g., hemiparesis following a CVA), impaired circulation (e.g., diabetes), and lack of voluntary muscle control (e.g., spinal cord injury) are at risk for damage when lying down.

Immobility. Assess the patient for hazards of immobility by performing a head-to-toe physical assessment (see Chapter 30). In addition, focus on certain physiological areas and the patient's psychosocial and developmental dimensions. Table 47-3 summarizes how to assess for the physiological hazards of immobility.

Metabolic System. When assessing metabolic functioning, use **anthropometric measurements** (measures of height, weight, and skinfold thickness) to evaluate muscle atrophy (see Chapter 30). In addition, analyze intake and output records for fluid balance. Does intake equal output? Intake and output measurements help the nurse determine whether a fluid imbalance exists (see Chapter 41). Dehydration and edema increase the rate of skin breakdown in a patient who is immobilized. Monitoring laboratory data such as levels of electrolytes, serum protein (albumin and total protein), and blood urea nitrogen (BUN) aid the nurse in determining metabolic functioning.

Monitoring food intake and elimination patterns and assessing wound healing help to determine altered gastrointestinal functioning and potential metabolic problems. If the patient has a wound, the rate of healing indicates how well nutrients are delivered to tissues. Normal progression of healing indicates that metabolic needs of injured tissues are being met. Anorexia commonly occurs in patients who are immobilized. Assess the patient's food intake before the meal tray is removed to determine the amount eaten. Assess his or her dietary patterns and food preferences at the onset of immobilization to help prevent nutritional imbalances (see Chapter 44).

Respiratory System. Perform a respiratory assessment at least every 2 hours for patients with restricted activity. Inspect chest wall movements during the full inspiratory-expiratory cycle. If a patient has an atelectatic area, chest movement is often asymmetrical. Auscultate the entire lung region to identify diminished breath sounds, crackles, or wheezes. Focus auscultation on the dependent lung fields because pulmonary secretions tend to collect in these lower regions.

Cardiovascular System. Cardiovascular nursing assessment of the patient who is immobilized includes blood pressure monitoring, evaluation of apical and peripheral pulses, and observation for signs of venous stasis (e.g., edema and delayed wound healing).

Although not all patients experience orthostatic hypotension, nurses monitor their vital signs during the first few attempts at sitting or standing (see Chapter 29). Move the patient gradually during position changes and monitor him or her closely for dizziness while assessing orthostatic blood pressures. The longer the period of immobility, the greater is the risk of hypotension when the patient stands (Huether and McCance, 2008).

Also assess apical and peripheral pulses (see Chapter 30). Recumbent positions increase cardiac workload and result in an increased pulse rate. In some patients, particularly older adults, the heart does not tolerate the increased workload, and a form of cardiac failure develops. A third heart sound, heard at the apex, is an early indication of congestive heart failure. Monitoring peripheral pulses allows the nurse to evaluate the ability of the heart to pump blood. Immediately document and report the absence of a peripheral pulse in the lower extremities to the patient's health care provider, especially if the pulse was present previously.

Edema sometimes develops in patients who have had injury or whose heart is unable to handle the increased workload of bed rest. Because edema moves to dependent body regions, assessment of the patient experiencing immobility includes the sacrum, legs, and feet. If the heart is unable to tolerate the increased workload, peripheral body regions such as the hands, feet, nose, and earlobes are colder than central body regions. To assess for a deep vein thrombosis (DVT), remove the patient's elastic stockings and/or sequential compression devices (SCDs) every 8 hours (or according to agency policy) and observe the calves for redness, warmth, and tenderness. Homans' sign, or calf pain on dorsiflexion of the foot, is contraindicated in patients when a DVT is suspected. It is no longer a reliable indicator in assessing for DVT, and it is present in other conditions (see Chapter 30).

Measure bilateral calf circumference and record it daily as an alternative assessment for DVT. To do this, mark a point on each calf 10 cm (3.9 inches) down from the midpatella. Measure the circumference each day using the mark for placement of the tape measure. Unilateral increases in calf circumference are an early indication of thrombosis. Because DVTs also occur in the thigh, take thigh measurements daily if the patient is prone to thrombosis. A dislodged venous thrombus, called an **embolus,** can travel through the circulatory system to the lungs and impair circulation and oxygenation, resulting in tachycardia and shortness of breath. Venous emboli that travel to the lungs are sometimes life threatening. More than 90% of all pulmonary emboli begin in the deep veins of the lower extremities (Huether and McCance, 2008).

Musculoskeletal System. Major musculoskeletal abnormalities to identify during nursing assessment include decreased muscle tone and strength, loss of muscle mass, and contractures. The anthropometric measurements described previously indicate losses in muscle tone and muscle mass.

Early assessment of ROM is important because it establishes a baseline against which later measurements can be compared to evaluate whether a loss in joint mobility has occurred. Measure ROM with a goniometer (see Fig. 38-9). Physical assessment cannot identify disuse osteoporosis. However, patients on prolonged bed rest, postmenopausal women, patients taking steroids, and people with increased serum and urine calcium levels have a greater risk for bone demineralization. Consider the risk of disuse osteoporosis when planning nursing interventions. Although some falls result in injury, others occur because of pathological fractures secondary to osteoporosis.

Integumentary System. Continually assess the patient's skin for breakdown and color changes such as pallor or redness. Consistently use a standardized tool such as the Braden Scale. This identifies patients with a high risk for impaired skin integrity or early changes in the condition of patients' skin. Early identification allows for early intervention. Observe the skin often during routine care (e.g., when the patient is turned, during hygiene measures, and when providing for elimination needs). At a minimum, skin assessment occurs every 2 hours (see Chapter 48).

Elimination System. Evaluate the patient's elimination status on each shift and total intake and output every 24 hours. Compare the amounts over time. Determine that the patient is receiving the correct amount and type of fluids orally or parenterally (see Chapters 41 and 45). Inadequate intake and output or fluid and electrolyte imbalances increase the risk for renal system impairment, ranging from recurrent infections to kidney failure. Dehydration also increases the risk for skin breakdown, thrombus formation, respiratory infections, and constipation.

Assessment of elimination status includes the adequacy of dietary choices, bowel sounds, and the frequency and consistency of bowel movements (see Chapter 46). Accurate assessment enables the nurse to intervene before constipation and fecal impaction occur.

Psychosocial Assessment. Many alterations in physiological, sociocultural, and developmental functioning are related to immobility. Often these problems are interrelated, and it is imperative that nursing care focuses on all dimensions. Often the focus of immobility is on the easily visible physical problems such as skin impairment, but do not overlook its psychosocial and developmental aspects.

Abrupt changes in personality often have a physiological cause such as surgery, a medication reaction, a pulmonary embolus, or an acute infection. For example, the primary symptom of compromised older patients with an acute urinary tract infection or fever is confusion. Identifying confusion is an important component of the nurse's assessment. Acute confusion in older adults is not normal; a thorough nursing assessment is the priority (Ebersole et al., 2008).

Common reactions to immobilization include boredom and feelings of isolation, depression, and anger. Observe for changes in a patient's emotional status and listen carefully to family if they report emotional changes. Examples of change that indicate psychosocial concerns are a cooperative patient who becomes less cooperative or an independent patient who asks for more help than is necessary. The nurse investigates reasons for such alterations. Identifying how the patient usually copes with loss is vital (see Chapters 35 and 36). A change in mobility status, whether permanent or not, causes a grief reaction. Families are a key resource for information about behavior changes.

Identify and correct unexplained changes in the sleep-wake cycle. Nurses prevent or minimize most stimuli that interrupt the sleep-wake cycle (e.g., nursing activities, a noisy environment, or discomfort). However, some medications such as analgesics, sleeping pills, or cardiovascular drugs also cause sleep disturbances (see Chapter 42).

Because psychosocial changes usually occur gradually, observe the patient's behavior on a daily basis. If behavioral changes occur, determine the cause(s) and evaluate the changes. Identifying the cause helps you to design appropriate nursing interventions.

Developmental Assessment. Include a developmental assessment of patients who are immobilized. When caring for a young child, determine whether he or she is able to meet developmental tasks and is progressing normally. The child's development sometimes regresses or slows because he or she is immobilized. Design nursing interventions that maintain normal development, provide physical and psychosocial stimuli after identifying a child's developmental needs, and assure the parents that developmental delays are usually temporary.

Immobilization of a family member changes family functioning. The family's response to this change often leads to problems, stress, and anxieties. Children, when seeing parents who are immobile, sometimes have difficulty understanding what is occurring and difficulty coping.

Immobility has a significant effect on the older adult's levels of health, independence, and functional status. Nursing assessment enables the nurse to determine the patient's ability to meet needs independently and adapt developmental changes such as declining physical functioning and altered family and peer relationships. A decline in developmental functioning needs prompt investigation to determine why the change occurred and interventions that can

return the patient to an optimal level of functioning as soon as possible. Activities that reduce immobility and promote participation in ADLs are vital to preventing functional decline (Kawamoto et al., 2006). Assessment also includes the patient's home and community to identify factors that are risks to his or her mobility and safety (see Chapter 38).

Building Competency in Patient-Centered Care You are caring for Mr. Jason Glynn, 91 years old, in the emergency department (ED). He lives with his wife Eileen of 63 years. Both are competent, active in their community, and not dependent on their two grown children. He was brought to the ED after falling from a ladder while cleaning leaves from the gutters of their home. He has an open fracture of the tibia and fibula of his right leg. He rated his pain as 9 on a scale of 0 to 10 and cannot remember his last tetanus injection. He is scheduled for surgery, an open reduction and internal fixation using plates and screws as soon as the operating room (OR) team is ready. Which assessments must you perform, and what are your priority actions for Mr. Glynn at this time?

Answers to questions can be found on the Evolve website.

NURSING DIAGNOSIS

A patient who is experiencing an alteration in mobility often has one or more nursing diagnoses. The two diagnoses most directly related to mobility problems are *impaired physical mobility* and *risk for disuse syndrome.* The diagnosis of *impaired physical mobility* applies to the patient who has some limitation but is not completely immobile. The diagnosis of *risk for disuse syndrome* applies to the patient who is immobile and at risk for multisystem problems because of inactivity. Beyond these diagnoses, the list of potential diagnoses is extensive, because immobility affects multiple body systems. Other possible nursing diagnoses include the following:

- Ineffective airway clearance
- Ineffective coping
- Risk for injury
- Risk for impaired skin integrity
- Insomnia
- Social isolation

Assessment reveals clusters of data that indicate whether a patient is at risk or if an actual problem exists. The clusters of data include defining characteristics that support the diagnostic label and probable cause of the diagnosis. Locating the probable cause of the diagnosis (based on assessment data) is important to planning patient-centered goals and subsequent nursing interventions that will best help the patient.

Impaired physical mobility related to reluctance to initiate movement requires slightly different interventions than impaired physical mobility related to pain in the left shoulder. Thus it is critical that nursing assessment activities identify and cluster defining characteristics that ultimately support the nursing diagnosis selected (Box 47-3). The diagnosis related to reluctance to initiate movement requires interventions aimed at keeping the patient as mobile as possible and encouraging him or her to perform self-care and ROM. The diagnosis related to pain requires the nurse to assist the patient with comfort measures so he or she is then willing and more able to move. In both situations the nurse explains how activity enhances healthy body functioning.

Often the physiological dimension is the major focus of nursing care for patients with impaired mobility. Thus the psychosocial and developmental dimensions are neglected. Yet all dimensions are important to health. During immobilization some patients experience decreased social interaction and stimuli. These patients frequently use the nurse's call bell to request minor physical attention when their real need is greater socialization. Nursing diagnoses for health needs in developmental areas reflect changes from the patient's normal activities. Immobility leads to a developmental crisis if the patient is unable to resolve problems and continue to mature.

Immobility also leads to multiple complications (e.g., renal calculi, DVT, pulmonary emboli, or pneumonia). If these conditions develop, collaborate with the health care provider or nurse practitioner for prescribed therapy to intervene. Be alert for and prevent these potential complications when possible.

BOX 47-3 NURSING DIAGNOSTIC PROCESS

Impaired Physical Mobility Related to Left Hip/Leg Pain

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Measure ROM during exercise of extremities.	Patient has limited ROM in left hip/leg.
Observe patient attempt to move her left leg.	Patient has impaired movement attempting to move her left hip and leg.
Ask patient about perception of pain.	Patient complains of sharp pain in hip and leg when she tries to move it.
Ask patient about endurance and activity tolerance.	Patient reports no muscle strength in left leg. "I can't move it by myself."

ROM, Range of motion.

PLANNING

During planning the nurse synthesizes information from resources such as knowledge of the role of respiratory and physical therapy, standards such as skin care guidelines from the Agency for Healthcare Research and Quality (AHRQ) and Wound, Ostomy and Continence Nurses Society (WOCN), protocols for patients at risk for falls, attitudes such as creativity and perseverance, and past experiences with immobilized patients (Fig. 47-15). Critical thinking ensures that the patient's plan of care integrates all that you know about the individual and key critical thinking elements. Professional standards are especially important to consider when you develop a plan of care. These standards often establish scientifically proven guidelines for selecting effective nursing interventions. Finally, as stated earlier, the patient is a full partner in designing the plan of care, and this input must be reflected when establishing the goals and outcomes.

Goals and Outcomes. Develop an individualized plan of care for each nursing diagnosis (see the Nursing Care Plan). Set realistic expectations for care and include the patient and family when possible. Set goals that are individualized, realistic, and measurable. The goals focus on preventing problems or risks to body alignment and mobility.

Develop goals and expected outcomes to assist the patient in achieving his or her highest level of mobility and reducing the hazards of immobility. For example, a patient who has left-sided paralysis following a stroke has two long-term goals. The first, directed toward improved mobility, is "Patient uses walker to ambulate safely in the home." A parallel goal directed toward the

NURSING CARE PLAN

Impaired Physical Mobility

ASSESSMENT

Ms. Carmella Cavallo, a 97-year-old patient, is admitted to a skilled care unit for rehabilitation 10 days after the surgical procedure of fixation of a fractured left hip. She has a history of smoking but stopped 40 years ago. She has no cardiac problems and no hypertension. She experiences "aches" and "stiffness" in her knees but usually says that she "has no pain" when asked. The three small incisions are clean, dry, and intact. Staples were removed yesterday.

Assessment Activities	*Findings/Defining Characteristics**
Ask Ms. Cavallo to rate her pain on a scale of 0 to 10.	She **rates her pain as a 2** on a scale of 0 to 10 at rest, but it **increases to an 8** with any movement of her left leg.
Assess Ms. Cavallo's ability to transfer.	She is **not able to transfer even** with help from chair to bed.
Ask Ms. Cavallo how her surgery has affected her mobility.	She responds that she wants to get out of bed but, when she moves her left leg, her nonverbal signs indicate that she is in severe pain. She says that it is a "sharp, stabbing pain."

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Impaired physical mobility related to musculoskeletal impairment from surgery and pain with movement

PLANNING

Goals	*Expected Outcomes*†
Ms. Cavallo will be able to transfer with assistive device by discharge.	**Body Positioning: Self-Initiated** Ms. Cavallo will be able to move from her bed to her chair and back again using her walker and assist ×1 within 5 days. Ms. Cavallo will be able to transfer from her chair to her bedside commode using her walker within 5 days.
Ms. Cavallo will walk 100 feet using her walker by discharge.	**Ambulation** Ms. Cavallo will walk to her door and around her room with her walker within 10 days. Ms. Cavallo will walk 100 feet at a slow pace using her walker 3 times a day in 14 days and will increase the distance that she walks by 100 feet every day after that.

†Nursing outcomes classification from Moorhead S et al., editors: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS‡	RATIONALE
Exercise Therapy: Ambulation	
Consult with physical therapist on selection of transfer technique.	Ensures safe transfer technique with less risk of patient injury.
Instruct Ms. Cavallo on safe transfer and ambulation techniques in an environment with few distractions. Provide written materials that reinforce verbal instructions.	Providing instruction in a quiet environment and giving written instructions in large, easy-to-read print enhances learning in the older patient (Mamaril, 2006).
Establish realistic increments for transferring and increasing distance for ambulation.	Gradually increasing physical activity and setting realistic goals for ambulation encourages activity in older adults (Yen, 2005).
Pain Management	
Administer pain medication based on your assessment of Ms. Cavallo's needs and on a schedule rather than prn if patient exhibits signs of being in pain but does not request pain medication and dose is not relieving her pain.	Obtain order to adjust (increase or decrease dose) based on her report of pain severity or her ability to perform activities of daily living (ADLs) (Pasero and McCaffery, 2007).
Observe for overt and covert signs of pain when she is moving or attempting to implement plan from physical therapy (PT) and have prn dose of pain medication ordered if additional pain medication is needed for PT activities.	It is important for you to have "as needed" dose of pain medication for patient in case requires a supplemental dose (APS, 2008).

‡Intervention classification labels from Bulecheck GM, Butcher HK, Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Ms. Cavallo if her mobility has improved after therapy. Observe her transfer from bed to chair.	Ms. Cavallo is able to transfer from bed to chair using her walker and stand-by assistance of nurse.	Ms. Cavallo has achieved goal of transferring with walker and assistance.
Assess Ms. Cavallo as she walks in the hall; measure how far she walks.	Ms. Cavallo is able to walk 200 feet in the hall with her walker.	Activity level is improving. Continue interventions and continue to encourage ambulation.

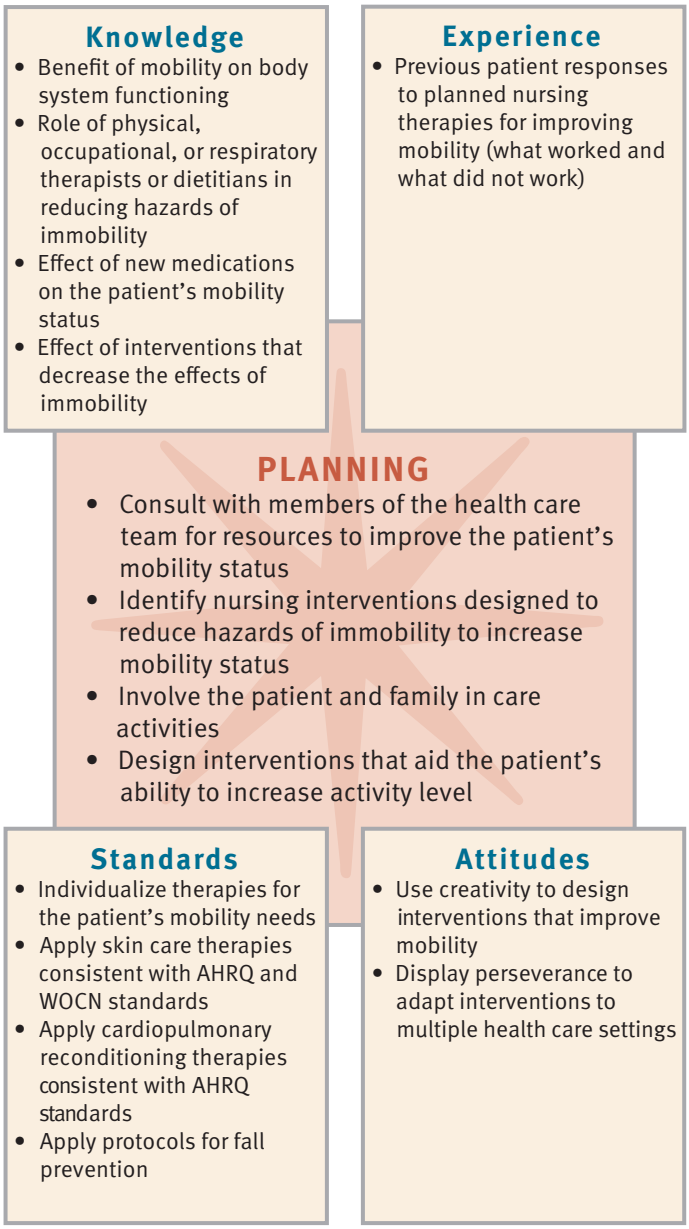

FIG. 47-15 Critical thinking model for immobility planning. *AHRQ,* Agency for Healthcare Research and Quality; *WOCN,* Wound, Ostomy and Continence Nurses Society.

hazards of immobility is "Patient's skin remains intact." Both of these goals are essential to restoring maximal mobility for this patient. Because there is impaired sensation, both the patient and caregivers need to be aware of the patient's need to have the skin free of pressure. Expected outcomes for the second goal include the following:

- Patient's skin color and temperature return to normal baseline within 20 minutes of position change.
- Patient changes position at least every 2 hours.

Setting Priorities. The effect that problems have on the patient's mental and physical health determines the immediacy of any problem. Set priorities when planning care to ensure that immediate needs are met first. This is particularly important when patients have multiple diagnoses (Fig. 47-16). Plan therapies according to severity of risks to the patient; and individualize the plan according to the patient's developmental stage, level of health, and lifestyle.

It is especially important in priority setting to make sure that you do not overlook potential complications. Many times actual problems such as pressure ulcers and disuse syndrome are addressed only after they develop. Therefore monitor the patient often, reinforcing prevention techniques to both the patient and other caregivers and supervising nursing assistive personnel in carrying out activities aimed at preventing complications of impaired mobility.

Teamwork and Collaboration. Care of the patient experiencing alterations in mobility requires a team approach. Nurses often delegate some interventions to nursing assistive personnel. Nursing assistive personnel can encourage the patient to do leg exercises, use the incentive spirometer, and cough and deep breathe (see Chapter 40). They can turn and position patients and apply elastic stockings. They can also help the nurse measure leg circumferences and height and weight.

Collaborate with other health care team members such as physical or occupational therapists when it is essential to consider mobility needs. Understanding the need for and having open communications with other members of the interdisciplinary care team results in better patient outcomes and hopefully prevents the hazards of immobility. It is through these collaborative efforts and teamwork that patients benefit most. For example, physical therapists are a resource for planning ROM or strengthening exercises, and occupational therapists are a resource for planning ADLs that patients need to modify or relearn. Wound care specialists and respiratory therapists are often involved in patient care, especially with patients who are experiencing complications related to their immobility. Consult a registered dietitian when the patient is experiencing nutritional problems; and refer him or her to a mental health advanced practice nurse, licensed social worker, or psychologist to assist with coping or other psychosocial issues.

Discharge planning begins when a patient enters the health care system. In anticipation of the patient's discharge from an institution, make appropriate referrals or consult a case manager or a discharge planner to ensure that the patient's needs are met at home. Consider the patient's home environment when planning therapies to maintain or improve body alignment and mobility. Referrals to home care or outpatient therapy are often needed.

IMPLEMENTATION

Health Promotion. Health promotion activities include a variety of interventions such as education, prevention, and early detection. Examples of health promotion activities that address mobility and immobility include prevention of work-related injury, fall-prevention measures, exercise, and early detection of scoliosis.

Prevention of Work-Related Musculoskeletal Injuries. The rate of work-related injuries in health care settings has increased in recent years. In 2006 there were 4.4 cases per 100 full-time workers who experienced occupational injury and illness compared with 5 cases per 100 for private industry overall. The rate for nursing homes was 10.1 per 100 workers (USDL, 2007). Most these injuries occurred as a result of overexertion, which resulted in back injuries and other musculoskeletal problems. Back injuries are often the direct result of improper lifting and bending. The most common back injury is strain on the lumbar muscle group, which includes the muscles around the lumbar vertebrae. Injury to these areas affects the ability to bend forward, backward, and from side to side and limits the ability to rotate the hips and lower back. Research has demonstrated that ergonomic programs in health care facilities

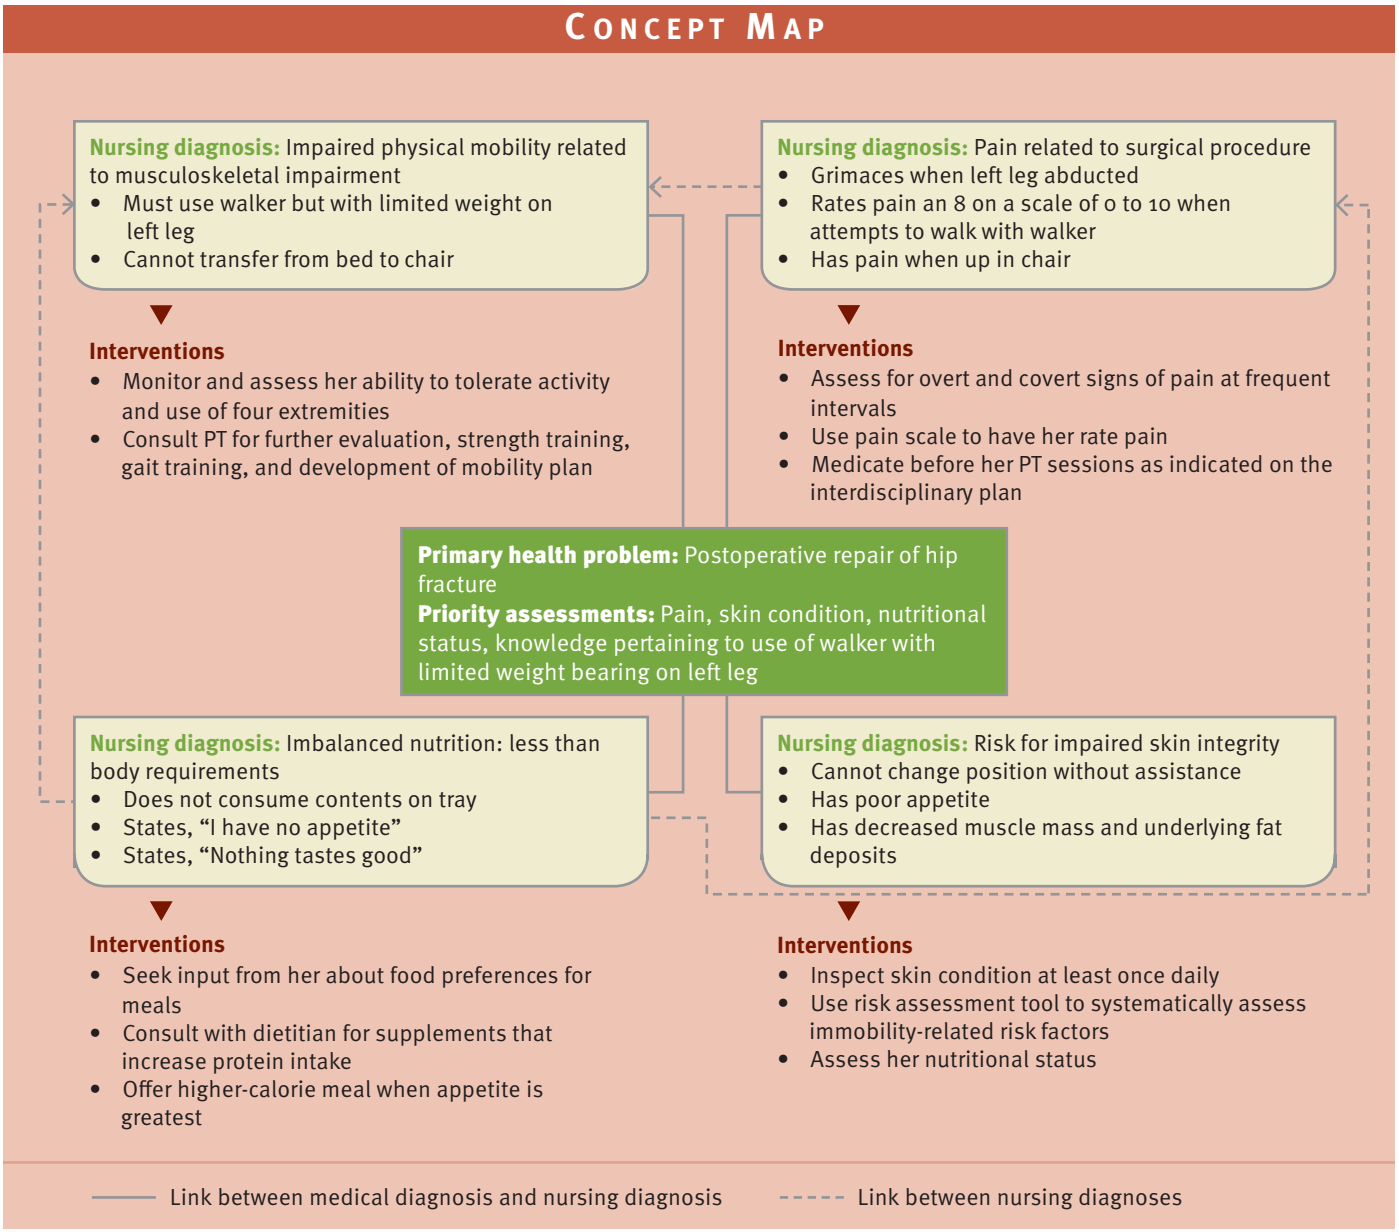

FIG. 47-16 Concept map for Ms. Cavallo. *PT,* Physical therapy.

reduce costs, injuries to employees, and missed work days. Matz (2007) noted that patient quality of care is *best* when staff are healthy and they are not experiencing any pain or discomfort.

Nurses and other health care staff are especially at risk for injury to lumbar muscles when lifting, transferring, or positioning immobilized patients. Therefore be aware of agency policies and protocols that protect staff and patients from injury. When lifting, assess the weight you will lift and determine the assistance you will need. Current evidence supports that using mechanical or other ergonomic assistive devices is the safest way to reposition and lift patients who are unable to do these activities themselves (Box 47-4). Many agencies have developed special patient lift teams and have instituted a no-lift policy.

Musculoskeletal injuries among health care workers are not only related to lifting and transferring patients. Nurses spend time in many activities bending and twisting, which also cause injury. Examples of such activities include lifting objects; pushing beds; and bathing, feeding, dressing, and undressing patients (Nelson et al., 2009). Therefore, in addition to knowing how to move patients safely, nurses also need to apply concepts related to body mechanics in the workplace. Before beginning a task, know your individual capabilities for activities such as lifting and moving objects. If providing care (e.g., bathing) to a patient, consider his or her condition and whether or not he or she can assist you. When you cannot safely complete a task (e.g., moving a bed from one room to another), assess the number of people you will need to help you and do not start until the task can be completed safely to prevent injury to you, the other members of the health care team, and the patient. Follow these steps to prevent injury:

1. Keep the weight to be lifted as close to the body as possible; this action places the object in the same plane as the lifter and close to the center of gravity for balance.

BOX 47-4 EVIDENCE-BASED PRACTICE

Reporting Staff Injuries to Reduce Future Injuries and Establish Safe Patient–Handling Policies for ALL Patients

PICO Question: Can the use of the E-OSHA 300 log metric be as effective for health care providers' reporting of injuries acquired while caring for obese patients as those reported while caring for nonobese patients to reduce future injuries to staff?

Evidence Summary

Even though evidence exists that body mechanics do not prevent injuries (Nelson and Baptiste, 2006) and nurses are beginning to report injuries associated with lifting and moving patients in their agencies, there must be a metric to standardize the reporting of these injuries (Randall et al., 2009). Added to the necessity for standardization is the number of individuals who are undergoing bariatric surgery. The evidence collected by the research indicated that the E-OSHA 300 log would provide the data needed to monitor the injuries in a systematic fashion and thereby heighten the awareness of the risks involved in manually handling bariatric patients.

Application to Nursing Practice

- Health care agencies need to provide devices to reduce the risk of injury associated with handling *all* patients (Wanless and Page, 2009).
- Nurses *must stop* using the traditional manual methods when transferring obese patients.
- Use assistive devices according to the assessment performed.
- *Report all injuries* using the E-OSHA 300 log metric for consistency.

E-OSHA, Expanded occupational safety and health administration.

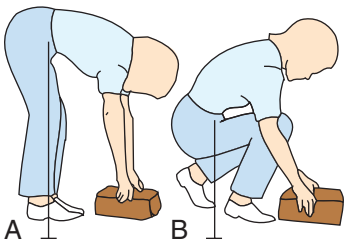

FIG. 47-17 Incorrect **(A)** and correct **(B)** body position for lifting.

2. Bend at the knees; this helps to maintain the center of gravity and uses the stronger leg muscles to do the lifting (Fig. 47-17).
3. Tighten abdominal muscles and tuck the pelvis; this provides balance and helps protect the back.
4. Maintain the trunk erect and knees bent so multiple muscle groups work together in a coordinated manner (see Chapter 38); do not allow the trunk to twist.

Exercise. Although many diseases and physical problems cause or contribute to immobility, it is important to remember that exercise programs enhance feelings of well-being and improve endurance, strength, and health. Exercise reduces the risk of many health problems such as cardiovascular disease, diabetes, and osteoporosis. Help the chronically ill overcome barriers to physical activity. For example, if a patient has a below-the-knee amputation, suggest activities such as lifting soup cans, which capitalize on the patient's strengths and abilities. Encourage hospitalized patients to perform stretching, ROM exercises, and light walking within the limits of their condition (see Chapter 38).

BOX 47-5 CULTURAL ASPECTS OF CARE

Mobility Related to Individuals and Their Cultural Influences

Many activities are specifically linked to culture such as time orientation, health care practices, health promotion, nutrition, religion, family systems, and death. Less attention has been given to the impact of culture on mobility. However, cultural influences have an important role in exercise and physical activity.

Culture influences preferences for activity and exercise. Certain cultures discourage involvement in organized recreational physical activities such as basketball, running, and aerobics. Ethnic dancing is an effective activity that is acceptable in Korean countries. Other cultures emphasize exercise in terms of activities of daily living such as walking, gardening, and prayer/meditation. As an example, people from Bangladesh often view prayer as a structured form of exercise, whereas many Muslims value participation in community activities and consider walking to the mosque a part of their weekly exercise regimen.

A sedentary lifestyle puts a patient at risk for being overweight. Children from many cultures who live in the United States are becoming more sedentary. The number of obese children is especially increasing in Hispanic and Native American populations. One researcher found that older Hispanic women only participated in exercise classes that were required when they were in school. They believed that doing housework and caring for their families met their exercise needs.

Implications for Practice

- Evaluate patterns of daily living and culturally prescribed activities before suggesting specific forms of exercise to patients.
- Help patients plan physical activities that are culturally acceptable.
- Exercise programs need to be flexible and accommodate family and community responsibilities of the culture.
- Encourage culturally specific and individually tailored interventions to facilitate commitment to exercise.
- Educate patients of all ages on the importance of exercise in preserving health and correct any misconceptions.

Nurses contribute to promoting health for many patients by encouraging or starting managed exercise programs. Exercise is a key prescription for health promotion of all patients, regardless of their age. In older adults routine exercise or activity helps maintain ROM and functional mobility and improves balance (Ebersole et al., 2008). Take cultural preferences into consideration when helping patients design exercise plans (Box 47-5).

Bone Health in Patients with Osteoporosis. Patients at risk for or diagnosed with osteoporosis have special health promotion needs. Encourage patients at risk to be screened for osteoporosis and assess their diets for calcium and vitamin D intake. Patients who have lactose intolerance need dietary teaching about alternative sources of calcium.

For patients diagnosed with osteoporosis, early evaluation, consultation, and referral with health care providers, dietitians, and physical therapists are important interventions, especially when they become immobilized. The goal of the patient with osteoporosis is to maintain independence with ADLs. Assistive ambulatory devices, adaptive clothing, and safety bars help the patient maintain independence. Patient teaching needs to focus on limiting the severity of the disease through diet and activity (Box 47-6).

Acute Care. Patients in acute care settings who experience altered physical mobility usually have some problems associated

BOX 47-6 PATIENT TEACHING

Teaching Patients with Osteoporosis

Objective

- Patient will verbalize strategies to prevent or limit the severity of osteoporosis.

Teaching Strategies

- Instruct patient and/or caregiver about common risk factors and how to modify lifestyle (e.g., smoking, caffeine, alcohol, hormone replacement as recommended by health care provider).
- Teach patient and/or caregiver the current recommended dietary allowances for calcium and review foods high in calcium (e.g., milk fortified with vitamin D, leafy green vegetables, yogurt, and cheese).
- Instruct patients and/or caregiver in appropriate types of weight-bearing exercises as recommended by health care provider or physical therapist to prevent injury or fractures.
- Teach patient and/or caregiver about safety, fall prevention, and strategies to create a safe home environment (e.g., remove scatter rugs; ensure that hallways, steps, and rooms are well lit).
- Instruct patient and/or caregiver in self-administration of prescribed medication used to treat osteoporosis.
- Promote positive self-image in patient by providing realistic yet optimistic and positive feedback about changes in appearance and mobility.

Evaluation

- Patient and/or caregiver can verbalize *three lifestyle modifications* such as stopping smoking, reducing caffeine or alcohol intake, or increasing dietary calcium.
- Patient and/or caregiver can verbalize *at least four* foods high in calcium and vitamin D.
- Patient and/or caregiver can *demonstrate appropriate weight-bearing exercises* and plan times for exercise.
- Patient and/or caregiver verbalize *three safety strategies* that they can implement at home to prevent falls.
- Patient and/or caregiver verbalize *specific knowledge* about osteoporosis medications.
- Patient and/or caregiver express positive but realistic feedback regarding effects of disease.

with the hazards of immobility such as impaired respiratory status, orthostatic hypotension, and impaired skin integrity. Therefore design nursing interventions to reduce the impact of immobility on body systems and prepare the patient for the restorative phase of care.

Metabolic System. Because the body needs protein to repair injured tissue and rebuild depleted protein stores, give the immobilized patient a high-protein, high-calorie diet. A high-calorie intake provides sufficient fuel to meet metabolic needs and replace subcutaneous tissue. Also ensure that the patient is taking vitamin B and C supplements when necessary. Supplementation with vitamin C is needed for skin integrity and wound healing; vitamin B complex assists in energy metabolism.

If the patient is unable to eat, nutrition must be provided parenterally or enterally. Total parenteral nutrition refers to delivery of nutritional supplements through a central or peripheral intravenous catheter. Enteral feedings include delivery through a nasogastric, gastrostomy, or jejunostomy tube of high-protein, high-calorie solutions with complete requirements of vitamins, minerals, and electrolytes (see Chapter 44).

Respiratory System. Nursing interventions that support the respiratory system are important. Patients need to frequently reexpand their lungs to maintain their elastic recoil property. In addition, secretions accumulate in the dependent areas of the lungs. Often patients with restricted mobility experience weakness; and, as this progresses, the cough reflex gradually becomes inefficient. All of these factors put the patient at risk of developing pneumonia. The stasis of secretions in the lungs is life threatening for an immobilized patient.

A variety of nursing interventions are available to expand the lungs, dislodge and mobilize stagnant secretions, and clear the lungs. All of these interventions help reduce the risk of pneumonia. Prevention begins with assessment. Assess the patient's respiratory status per agency policy. Assessment findings that indicate pneumonia include productive cough with greenish-yellow sputum; fever; pain on breathing; and crackles, wheezes, and dyspnea. It is essential to implement pulmonary interventions in all patients, even those who do not have pneumonia.

Encourage the patient to deep breathe and cough every 1 to 2 hours. Teach alert patients to deep breathe or yawn every hour or to use an incentive spirometer. Instruct the patient to take in three deep breaths and cough with the third exhalation.

Chest physiotherapy (CPT) (percussion and positioning) is another effective method for preventing pneumonia and keeping the airway clear. CPT helps the patient drain secretions from specific segments of the bronchi and lungs into the trachea so he or she is able to cough and expel them. Respiratory assessment findings identify areas of the lungs requiring CPT (see Chapter 40).

Ensure that patients who are immobile take an adequate fluid intake. Unless there is a medical contraindication, an adult needs to drink at least 1100 to 1400 ml of noncaffeinated fluids daily. This helps keep mucociliary clearance normal. Expect pulmonary secretions to be removed easily with coughing and appear thin, watery, and clear. Without adequate hydration, pulmonary secretions become thick and tenacious and difficult to remove. Offering fluids on a regularly timed schedule also helps with bowel and urine elimination and aids in maintaining circulation and skin integrity.

Cardiovascular System. The effects of bed rest or immobilization on the cardiovascular system include orthostatic hypotension, increased cardiac workload, and thrombus formation. Design nursing therapies to minimize or prevent these alterations.

Reducing Orthostatic Hypotension. When patients who are on bed rest or are immobile move to a sitting or standing position, they often experience orthostatic hypotension. They have an increased pulse rate, a decreased pulse pressure, and a drop in blood pressure. If symptoms become severe enough, the patient can faint (Huether and McCance, 2008). To prevent injury, nurses implement interventions that reduce or eliminate the effects of orthostatic hypotension. Mobilize the patient as soon as the physical condition allows, even if this only involves dangling at the bedside or moving to a chair. This activity maintains muscle tone and increases venous return. Isometric exercises (i.e., activities that involve muscle tension without muscle shortening) have no beneficial effect on preventing orthostatic hypotension, but they improve activity tolerance. When getting an immobile patient up for the first time, assess the situation using a safe patient–handling algorithm (see Fig. 47-21) (Nelson, 2006). This is a precautionary step that protects the nurse and patient from injury and also allows the patient to do as much of the transfer as possible.

Reducing Cardiac Workload. The nurse designs interventions to reduce cardiac workload, which is increased by immobility. A

primary intervention is to discourage the patient from using the Valsalva maneuver. The patient holds his or her breath when using this maneuver, such as while straining during defecation or moving up in bed. This increases intrathoracic pressure, which in turn decreases venous return and cardiac output. When the strain is released, venous return and cardiac output immediately increase, and systolic blood pressure and pulse pressure rise. These pressure changes produce a reflex bradycardia and possible decrease in blood pressure that can result in sudden cardiac death in patients with heart disease. Teach the patient to breathe out while moving side-to-side or up in bed.

Preventing Thrombus Formation. The most cost-effective way to address DVT is through an aggressive program of prophylaxis. It begins with identification of patients at risk and continues throughout their immobilization. This is clearly a collaborative role between nurses and health care providers. Use the nursing assessment to identify risk factors. Many interventions reduce the risk of thrombus formation in the immobilized patient. Leg, foot, and ankle exercises; regularly providing fluids; position changes; and patient teaching need to begin when the patient becomes immobile (see Chapter 50).

Common dosage for heparin therapy for DVT prophylaxis is 5000 units given subcutaneously 2 hours before surgery and repeated every 8 to 12 hours until the patient is fully mobile or discharged. Heparin is an anticoagulant, and it suppresses clot formation. Common dosage of enoxaparin (Lovenox) (a low-molecular-weight heparin) in the prophylaxis of DVTs is 30 to 40 mg subcutaneously 2 hours before surgery and continued every 8 to 12 hours throughout the postoperative period. Because bleeding is a potential side effect of these medications, continually assess the patient for signs of bleeding such as hematuria, bruising, coffee ground–like vomitus or GI aspirate, guaiac-positive stools, and bleeding gums.

SCDs and intermittent pneumatic compression (IPC) consist of sleeves or stockings made of fabric or plastic that are wrapped around the leg and secured with Velcro (Box 47-7). Once they are applied, connect the sleeves to a pump that alternately inflates and deflates the stocking around the leg. A typical cycle is inflation for 10 to 15 seconds and deflation for 45 to 60 seconds. Inflation pressures average 40 mm Hg. Use of SCD/IPC on the legs decreases venous stasis by increasing venous return through the deep veins of the legs. For optimal results begin use of SCD/IPC as soon as possible and maintain it until the patient becomes fully ambulatory.

Elastic stockings (sometimes called *antiembolitic stockings)* also aid in maintaining external pressure on the muscles of the lower extremities and thus promote venous return (Box 47-8). To obtain the correct size, measure the patient's calf, thigh, and leg length accurately. When considering applying graded compression stockings, first assess the patient's suitability for wearing them. Do not apply them if he or she has a local condition affecting the leg (e.g., any skin lesion, gangrenous condition, or recent vein ligation) because application compromises circulation. Apply them properly and remove them at least once per shift. Be sure to assess circulation at the toes to ensure that the stockings are not too tight.

Proper positioning reduces the patient's risk of thrombus formation because compression of the leg veins is minimized. Therefore, when positioning patients, use caution to prevent pressure on the posterior knee and deep veins in the lower extremities. Teach patients to avoid the following: crossing the legs, sitting for prolonged periods of time, wearing clothing that constricts the legs or waist, and massaging the legs. Report suspected DVT immediately to the patient's health care provider. Elevate the leg but avoid pressure on the thrombus. Instruct the family, patient, and all health care personnel not to massage the area because of the danger of dislodging the thrombus.

FIG. 47-18 Continuous passive range-of-motion machine.

ROM exercises reduce the risk of contractures and aid in preventing thrombi. Activity causes contraction of the skeletal muscles, which in turn exerts pressure on the veins to promote venous return, thereby reducing venous stasis. Specific exercises that help prevent thrombophlebitis are ankle pumps, foot circles, and knee flexion. Ankle pumps, sometimes called *calf pumps,* include alternating plantar flexion and dorsiflexion. Foot circles require the patient to rotate the ankle. Encourage patients to make the letters of the alphabet with their feet every 1 to 2 hours. Knee flexion involves alternately extending and flexing the knee. These exercises are sometimes referred to as *antiembolic exercises* and need to be done hourly while awake.

Musculoskeletal System. Exercises to prevent excessive muscle atrophy and joint contractures help maintain musculoskeletal function. If the patient is unable to move part or all of the body, perform passive ROM exercises for all immobilized joints while bathing the patient and at least 2 or 3 more times a day. If one extremity is paralyzed, teach the patient to put each joint independently through its ROM. Patients on bed rest need to have active ROM exercises incorporated into their daily schedules. Teach patients to integrate exercises during ADLs.

Some orthopedic conditions require more frequent passive ROM exercises to restore the function of the injured joint after surgery. Patients with such conditions need to use automatic equipment (continuous passive motion [CPM]) for passive ROM exercises) (Fig. 47-18). The CPM machine moves an extremity to a prescribed angle for a prescribed period. Researchers are currently investigating new uses for CPM. In one study patients who had a CVA and received CPM therapy to their affected shoulder had better joint stability than patients who received traditional ROM exercises (Lynch et al., 2005).

Integumentary System. The major risk to the skin from restricted mobility is the formation of pressure ulcers. Early identification of high-risk patients helps prevent pressure ulcers (see Chapter 48). Interventions aimed at prevention include positioning, skin care, and the use of therapeutic devices to relieve pressure. Change the immobilized patient's position according to his or her activity level, perceptual ability, treatment protocols, and daily routines. Although turning every 1 to 2 hours is recommended for preventing ulcers,

BOX 47-7 PROCEDURAL GUIDELINES

Applying Sequential Compression Devices

Delegation Considerations

The skill of applying sequential compression devices (SCDs) can be delegated to NAP. The nurse is responsible for assessing circulation in the extremities. Instruct NAP to notify nurse:

- If patient complains of pain in leg.
- If discoloration develops in extremities.

Equipment

Sequential compression device (SCD) insufflator with air hoses attached, adjustable Velcro compression stockings/SCD sleeve, hygiene supplies

1. Assess patient for need for sequential compression stockings. In some agencies an order is required. Perform hand hygiene.
2. Obtain baseline assessment data about status of circulation, pulse, and skin integrity of patient's lower extremities before initiating sequential compression stockings.
3. Identify patient using two identifiers (i.e., name and birth date or name and account number, according to agency policy). Ask patient to state name.
4. Perform hand hygiene. Provide hygiene to patient's lower extremities as needed.
5. Assemble and prepare equipment.
6. Arrange SCD sleeve under patient's leg according to leg position indicated on inner lining of sleeve (see illustration).
   a. Back of patient's ankle should line up with ankle on inner lining of sleeve.
   b. Position back of the knee with popliteal opening (see illustration).
7. Wrap SCD sleeve securely around patient's leg.
8. Verify fit of SCD sleeves by placing two fingers between patient's leg and sleeve (see illustration).
9. Attach connector of SCD sleeve to plug on mechanical unit. Arrow on compressor lines up with arrow on plug from mechanical unit (see illustration).
10. Turn mechanical unit on. Green light indicates that unit is functioning.
11. Observe functioning of unit for one complete cycle.
12. Reposition patient for comfort and perform hand hygiene.
13. Remove compression stockings at least once per shift.
14. Monitor skin integrity and circulation to patient's lower extremities as ordered or as recommended by SCD manufacturer.

STEP 6 Correct leg position on inner lining.

STEP 6b Position back of patient's knee with popliteal opening.

STEP 8 Check fit of SCD sleeve.

STEP 9 Align arrows when connecting to mechanical unit.

it is sometimes necessary to use devices for relieving pressure. Usually the time that a patient sits uninterrupted in a chair is limited to 1 hour. This interval is shortened in patients who are at very high risk for skin breakdown. Reposition patients frequently because uninterrupted pressure causes skin breakdown. Teach patients to shift their weight every 15 minutes. Chair-bound patients need to have a device for the chair that reduces pressure (AHRQ, 2010).

Elimination System. The nursing interventions for maintaining optimal urinary functioning are directed at keeping the patient well hydrated and preventing urinary stasis, calculi, and infections without causing bladder distention. Adequate hydration (e.g., at

BOX 47-8 PROCEDURAL GUIDELINES

Applying Antiembolitic Elastic Stockings

Delegation Considerations

The nurse can delegate the skill of applying antiembolitic elastic stockings to nursing assistive personnel (NAP). Before delegation instruct the NAP to inform the nurse:

- If patient complains of leg pain or leg swelling.
- If patient has any skin irritation.

Also instruct the NAP to direct the patient:

- To avoid activities that promote venous stasis (e.g., crossing legs, wearing garters).
- To elevate legs while sitting and before applying stockings to improve venous return.
- Not to massage legs.
- To avoid wrinkles in stocking.

Equipment

Tape measure, elastic support stockings, hygiene supplies

1. Identify patient using two identifiers (i.e., name and birth date or name and account number, according to agency policy). Assess patient for risk factors in Virchow's triad:
   a. *Hypercoagulability:* All patients with clotting disorders, fever, dehydration, pregnancy, and first 6 weeks after delivery if the woman was confined to bed and used oral contraceptive (especially if patient smokes)
   b. *Venous wall abnormalities:* Local trauma, orthopedic surgeries, major abdominal surgery, varicose veins, atherosclerosis
   c. *Blood stasis:* Immobility, obesity, pregnancy
2. Observe for signs, symptoms, and condition of patient skin that contraindicate use of antiembolitic elastic stockings. Signs and symptoms include:
   a. Dermatitis or open skin lesion.
   b. Recent skin graft.
   c. Decreased circulation in lower extremities as evidenced by cyanotic, cool extremities, gangrenous conditions affecting lower limb(s).
3. Assess and document condition of patient's skin and circulation to leg and foot (i.e., presence of popliteal and pedal pulses, edema, and discoloration of skin; temperature; lesions; or abrasions).
4. Obtain physician's or health care provider's order.
5. Assess patient's or caregiver's understanding of application of antiembolitic elastic stockings.

CLINICAL DECISION: Clinical signs of thrombophlebitis vary according to the size and location of the thrombus. Signs and symptoms of superficial thrombosis include palpable veins and surrounding areas being tender to the touch, reddened, and warm. Temperature elevation and edema may or may not be present. Signs and symptoms of deep vein thrombosis (DVT) include swollen extremity; pain; warm, cyanotic skin; and temperature elevation. However, up to 80% of patients are asymptomatic. Homans' sign (pain in the calf on dorsiflexion of the foot) is no longer considered reliable. Less than 20% of patients have a positive Homans' sign (Black and Hawks, 2009).

6. Use tape measure to measure patient's legs to determine proper stocking size.
7. Explain procedure and reasons for applying stockings.
8. Perform hand hygiene. Provide hygiene to patient's lower extremities as needed.
9. Position patient in supine position.
10. Apply elastic stockings:
    a. Turn elastic stocking inside out up to heel. Place one hand into stocking, holding heel. Pull top of stocking with other hand inside out over foot of stocking
    b. Place patient's toes into foot of elastic stocking, making sure that stocking is smooth (see illustration).
    c. Slide remaining portion of stocking over patient's foot, being sure that toes are covered. Make sure that foot fits into toe and heel position of stocking (see illustration).
    d. Slide top of stocking up over patient's calf until stocking is completely extended. Be sure that stocking is smooth and that no ridges or wrinkles are present, particularly behind knee (see illustration).
    e. Instruct patient not to roll stockings partially down.
11. Reposition patient for comfort and perform hand hygiene.
12. Remove stockings at least once per shift.
13. Inspect stockings for wrinkles or constriction.
14. Inspect elastic stockings to determine that there are no wrinkles, rolls, or binding.
15. Observe circulatory status of lower extremities. Observe color, temperature, and condition of skin. Palpate pedal pulses.
16. Observe patient's response to wearing antiembolitic elastic stockings.
17. Observe patient or caregiver applying stockings.

STEP 10b Place toes into foot of stocking.

STEP 10c Slide heel of stocking over foot.

STEP 10d Slide stocking up leg until completely extended.

least 1100 to 1400 mL of noncaffeinated fluids daily) helps prevent renal calculi and urinary tract infections. The well-hydrated patient needs to void large amounts of dilute urine that is approximately equal to fluid intake. Also record the frequency and consistency of bowel movements. Provide a diet rich in fluids, fruits, vegetables, and fiber to facilitate normal peristalsis. If a patient is unable to maintain regular bowel patterns, stool softeners, cathartics, or enemas are sometimes necessary. If the patient is incontinent, modify the care plan to include toileting aids and a hygiene schedule so the increased urinary output does not cause skin breakdown.

Psychosocial Changes. Use assessment data to identify effects of prolonged immobilization. People who have a tendency toward depression or mood swings are at greater risk for developing psychosocial effects during bed rest or immobilization. Many nursing interventions meet the patient's psychosocial needs. Anticipate changes in the patient's psychosocial status and provide routine and informal socialization. Observe the patient's ability to cope with restricted mobility. In institutional health care settings do not schedule nursing care activities between 10:00 PM and 7:00 AM to minimize sleep interruptions. For example, the nurse administers medications and assesses vital signs when the patient is turned or receives special skin care. If the nursing care plan is not improving coping patterns, consult a clinical nurse specialist, counselor, social worker, spiritual adviser, or other health care professional. Incorporate their recommendations into the care plan.

Nurses provide stimuli to maintain a patient's orientation. Plan nursing activities so the patient is able to talk and interact with staff. If possible, place him or her in a room with others who are mobile and interactive. If a private room is required, ask staff members to visit throughout the shift to provide meaningful interaction. A daily newspaper helps the patient keep track of events and time. Bedside conversations at appropriate moments familiarize him or her with nursing activities, meals, and visiting hours. Books help occupy the patient when he or she is alone. The patient can participate in craft activities. Radio, television, and videotapes provide stimulation and help pass the time.

Involve patients in their care whenever possible. For example, encourage the patient to determine when the bed should be made. Some patients rest better during the night when fresh sheets are put on in the evening rather than in the morning. The patient needs to provide as much self-care as possible. Keep hygiene and grooming articles within easy reach. Encourage patients to wear their glasses or artificial teeth and shave or apply makeup. People use these activities to maintain their body image, thus improving their outlook.

Developmental Changes. Ideally immobilized patients continue normal development. Nursing interventions can help. Nursing care needs to provide mental and physical stimulation, particularly for a young child. Incorporate play activities into the care plan. For example, completing puzzles helps a child to develop fine-motor skills, and reading helps him or her to develop cognitively. Encourage parents to stay with a child who is hospitalized. Place a child who is immobilized with children of the same age who are not immobilized unless a contagious disease is present. Allow the child to participate in nursing interventions such as dressing changes, cast care, and care of traction. The nurse needs to recognize significant changes from normal behavioral patterns and consult with a pediatric clinical nurse specialist, counselor, or other health care professional.

Restricted mobility of older patients presents unique nursing problems. Older patients who are frail or have chronic illnesses are often at increased risk for the psychosocial hazards of immobility. Maintaining a calendar and clock with a large dial, conversing about current events and family members, and encouraging visits from significant others reduce the risk of social isolation. Spending time in the room talking and listening to the patient also helps reduce the risk of social isolation.

Nurses need to encourage older immobilized patients to perform as many ADLs as independently as possible. Patients need to continue to perform personal grooming if they did so before their mobility was restricted. This type of activity preserves the patient's dignity and gives him or her a sense of accomplishment.

Positioning Techniques. Patients with impaired nervous, skeletal, or muscular system functioning and increased weakness and fatigability often require help from the nurse to attain proper body alignment while in bed or sitting. Several positioning devices are available for maintaining good body alignment for patients. Pillows are positioning aids and are sometimes readily available. Before using a pillow, determine whether it is the proper size. A thick pillow under the patient's head increases cervical flexion. A thin pillow under body prominences does not protect skin and tissue from damage caused by pressure. When additional pillows are unavailable or if they are an improper size, use folded sheets, blankets, or towels as positioning aids.

Apply positioning boots to prevent footdrop by maintaining the feet in dorsiflexion. Ankle-foot orthotic (AFO) devices also help maintain dorsiflexion. Patients who wear positioning boots or AFOs need to have these removed periodically (e.g., 2 hours on, 2 hours off).

A **trochanter roll** prevents external rotation of the hips when the patient is in a supine position. To form a trochanter roll, fold a cotton bath blanket lengthwise to a width that extends from the greater trochanter of the femur to the lower border of the popliteal space (Fig. 47-19). Place the blanket under the buttocks and roll it counterclockwise until the thigh is in neutral position or inward rotation. When the hip is aligned correctly, the patella faces directly upward. Use sandbags in place of or in addition to trochanter rolls. Sandbags are sand-filled plastic tubes or bags that are shaped to body contours. Hand rolls maintain the thumb in slight adduction and in opposition to the fingers, which maintain a functional

FIG. 47-19 Trochanter roll.

position. Evaluate the hand roll to make sure that the hand is indeed in a functional position. Hand rolls are most often used with patients whose arms are paralyzed or who are unconscious. Do not use rolled washcloths as hand rolls because they do not keep the thumb well abducted, especially in patients who have a spastic paralysis. Hand-wrist splints are individually molded for the patient to maintain proper alignment of the thumb (slight adduction) and wrist (slight dorsiflexion). Use splints only on the patient for whom they were made and follow the splint schedule (e.g., wear for 2 hours, remove for 2 hours).

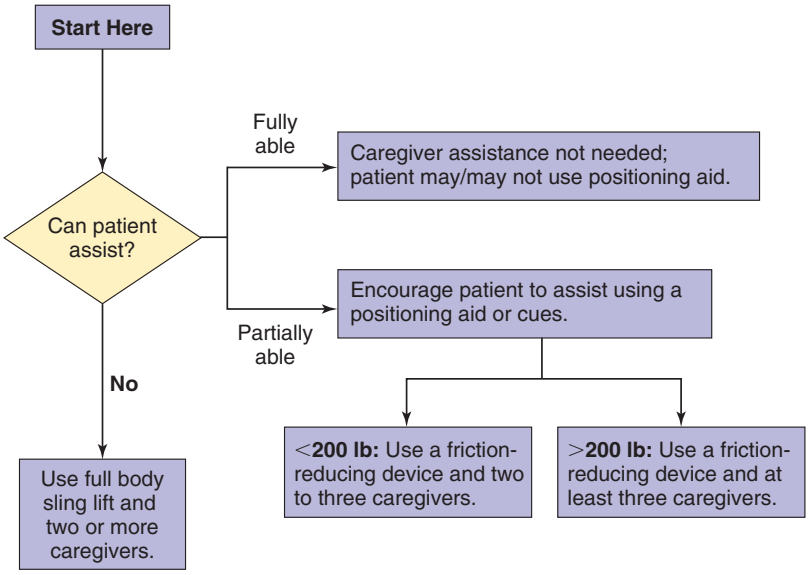
The **trapeze bar** is a triangular device that hangs down from a securely fastened overhead bar that is attached to the bed frame. It allows the patient to pull with the upper extremities to raise the trunk off the bed, assist in transfer from bed to wheelchair, or perform upper-arm exercises (Fig. 47-20). It increases independence, maintains upper body strength, and decreases the shearing action from sliding across or up and down in bed.

Although each procedure for positioning has specific guidelines, the nurse follows some universal steps for patients who require positioning assistance (Skill 47-1 on pp. 1159-1166). Following the guidelines reduces the risk of injury to the musculoskeletal system when the patient is sitting or lying. When joints are unsupported, their alignment is impaired. Likewise, if joints are not positioned in a slightly flexed position, their mobility is decreased. During positioning also assess for pressure points (see Fig. 48-9). When actual or potential pressure areas exist, nursing interventions involve removal of the pressure, thus decreasing the risk for development of pressure ulcers and further trauma to the musculoskeletal system. In these patients use the 30-degree lateral position.

Supported Fowler's Position. In the supported Fowler's position, the head of the bed is elevated 45 to 60 degrees, and the patient's knees are slightly elevated without pressure to restrict circulation in the lower legs. The patient's illness and overall condition influence the angle of head and knee elevation and the length of time that the patient needs to remain in the supported Fowler's position. Supports need to permit flexion of the hips and knees and proper alignment of the normal curves in the cervical, thoracic, and lumbar vertebrae. The following are common trouble areas for the patient in the supported Fowler's position:

- Increased cervical flexion because the pillow at the head is too thick and the head thrusts forward
- Extension of the knees, allowing the patient to slide to the foot of the bed
- Pressure on the posterior aspect of the knees, decreasing circulation to the feet
- External rotation of the hips
- Arms hanging unsupported at the patient's sides
- Unsupported feet or pressure on the heels
- Unprotected pressure points at the sacrum and heels
- Increased shearing force on the back and heels when the head of the bed is raised greater than 60 degrees

FIG. 47-20 Patient using trapeze bar.



Supine Position. Patients in the supine position rest on their backs. In the supine position the relationship of body parts is essentially the same as in good standing alignment except that the body is in the horizontal plane. Use pillows, trochanter rolls, and hand rolls or arm splints to increase comfort and reduce injury to the skin or musculoskeletal system. The mattress needs to be firm enough to support the cervical, thoracic, and lumbar vertebrae. Shoulders are supported, and the elbows are slightly flexed to control shoulder rotation. A foot support prevents footdrop and maintains proper alignment. The following are some common trouble areas for patients in the supine position:

- Pillow at the head that is too thick, increasing cervical flexion
- Head flat on the mattress
- Shoulders unsupported and internally rotated
- Elbows extended
- Thumb not in opposition to the fingers
- Hips externally rotated
- Unsupported feet
- Unprotected pressure points at the occipital region of the head, vertebrae, coccyx, elbows, and heels

Prone Position. The patient in the prone position lies face or chest down. Often his or her head is turned to the side; but, if a pillow is under the head, it needs to be thin enough to prevent cervical flexion or extension and maintain alignment of the lumbar spine. Placing a pillow under the lower leg permits dorsiflexion of the ankles and some knee flexion, which promote relaxation. If a pillow is unavailable, the ankles need to be in dorsiflexion over the end of the mattress. Although the prone position is seldom used in practice, consider this as an alternative, especially in patients who normally sleep in this position. The prone position also may have some benefits in patients with acute respiratory distress syndrome and acute lung injury (Marklew, 2006). Specialty beds that safely position acutely ill patients in the prone position are available. Assess for and correct any of the following potential trouble points with patients in the prone position:

- Neck hyperextension
- Hyperextension of the lumbar spine
- Plantar flexion of the ankles
- Unprotected pressure points at the chin, elbows, female breasts, hips, knees, and toes

Side-Lying Position. In the side-lying (or lateral) position the patient rests on the side with the major portion of body weight on the dependent hip and shoulder. A 30-degree lateral position is recommended for patients at risk for pressure ulcers (see Chapter 48) (AHRQ, 2010). Trunk alignment needs to be the same as in

- This is not a one-person task: DO NOT PULL FROM HEAD OF BED.
- When pulling a patient up in bed, the bed should be flat or in a Trendelenburg position (when tolerated) to aid in gravity, with the side rail down.
- For patients with stage III or IV pressure ulcers, care should be taken to avoid shearing force.
- The height of the bed should be appropriate for staff safety (at the elbows).
- If the patient can assist when repositioning "up in bed," ask the patient to flex the knees and push on the count of three.
- During any patient-handling task, if the caregiver is required to lift more than 35 lb of a patient's weight, then the patient should be considered to be fully dependent and assistive devices should be used.

FIG. 47-21 Algorithm used to reposition patient in bed. (From Nelson A: *Safe patient handling and movement algorithms,* 2006, VISN8 Patient Safety Center, http://www.visn8.med.va.gov/patientsafetycenter/SafePtHandling/default.asp.)

standing. The patient needs to maintain the structural curves of the spine, the head needs to be supported in line with the midline of the trunk, and rotation of the spine needs to be avoided. The following trouble points are common in the side-lying position:

- Lateral flexion of the neck
- Spinal curves out of normal alignment
- Shoulder and hip joints internally rotated, adducted, or unsupported
- Lack of foot support
- Lack of protection for pressure points at the ear, shoulder, anterior iliac spine, trochanter, and ankles
- Excessive lateral flexion of the spine if the patient has large hips and a pillow is not placed superior to the hips at the waist

Sims' Position. Sims' position differs from the side-lying position in the distribution of the patient's weight. In Sims' position the patient places the weight on the anterior ileum, humerus, and clavicle. Trouble points common in Sims' position include the following:

- Lateral flexion of the neck
- Internal rotation, adduction, or lack of support to the shoulders and hips
- Lack of foot support
- Lack of protection for pressure points at the ileum, humerus, clavicle, knees, and ankles

Transfer Techniques. Nurses often provide care for immobilized patients whose position must be changed, who must be moved up in bed, or who must be transferred from a bed to a chair or from a bed to a stretcher. As noted earlier, body mechanics alone do not protect the nurse from injury to the musculoskeletal system when moving, lifting, or transferring patients. Although nurses use many transfer techniques, knowledge of ergonomics and safe patient handling is crucial in maintaining caregiver and patient safety.

Assess every situation that involves patient handling and movement to minimize risk of injury. After completing the assessment, nurses use an algorithm (Fig. 47-21) to guide decisions about safe patient handling (Nelson et al., 2009). Use the patient's strength when lifting, transferring, or moving when possible. Involving the patient has the added bonus of increasing participation in self-care, thus promoting a sense of accomplishment. In addition to handling patients safely, nurses need to assume an active role in their workplaces to ensure that a culture of safety exists and that appropriate patient-handling equipment is readily available (Waters et al., 2007).

Moving Patients. A safe transfer is the first priority. Patients require various levels of assistance to move up in bed, move to the side-lying position, or sit up at the side of the bed. For example, a young, healthy woman may need support as she sits at the side of the bed for the first time after childbirth, whereas an older man may need help from two or more nurses to do the same task 1 to 2 days after surgery.

Always ask the patient to help to the fullest extent possible. To determine what the patient is able to do alone and how many people are needed to help move him or her in bed, assess him or

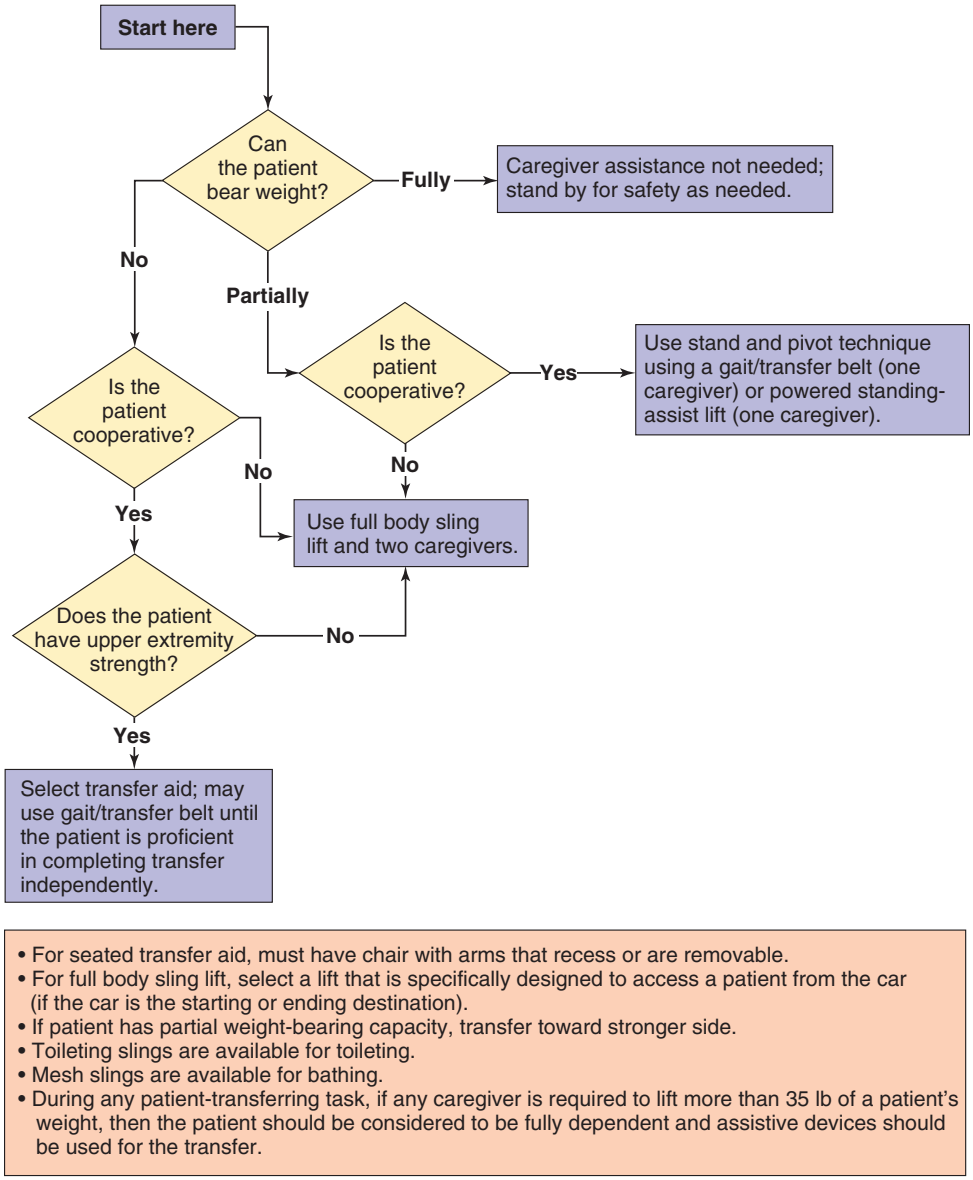


FIG. 47-22 Algorithm used to transfer patient to and from bed to chair, chair to toilet, chair to chair, or car to chair. (From Nelson A: *Safe patient handling and movement algorithms,* 2006, VISN8 Patient Safety Center, http://www.visn8.med.va.gov/patientsafetycenter/SafePtHandling/default.asp.)

her to determine whether the illness contradicts exertion (e.g., cardiovascular disease). Next, determine whether the patient comprehends what is expected. For example, a patient recently medicated for postoperative pain is too lethargic to understand instructions; thus to ensure safety, two nurses are necessary to move him or her. Then determine his or her comfort level. It is important to evaluate your personal strength and knowledge of the procedure. Finally determine whether the patient is too heavy or immobile for you to move alone (Nelson et al., 2009). Through assessment tools and patient movement algorithms, you determine the safest method by which to move the patient. Skill 47-1 and Skill 47-2 on pp. 1159-1173 describe the steps commonly used in moving patients in bed and transferring them to a sitting position at the side of the bed.

Transferring a Patient from a Bed to a Chair. Refer to an algorithm when transferring a patient from a bed to a chair (Fig. 47-22). Before beginning, move obstacles out of the way to prepare the environment and ensure that enough help is available. If a caregiver needs to lift more than 35 pounds, use assistive devices for the transfer (Fig. 47-23). Explain the procedure to the patient before the transfer. Place the chair next to the bed.

Next determine if the patient can bear weight. If the patient can bear weight fully, stand near him or her during the transfer as needed for safety reasons. If he or she can only partially bear weight and is cooperative, the transfer requires one caregiver. The nurse either stands and pivots the patient into the chair using a gait or transfer belt or uses a powered standing-assist lift. Two caregivers and a full body sling are needed for transferring uncooperative patients who can bear partial weight and for patients who cannot bear weight and are either uncooperative or do not have upper body strength. A seated transfer aid such as a friction-reducing lateral-assist device is used with or without a gait belt for patients

FIG. 47-23 **A1,** Ensure that safety straps are secured appropriately when using motorized lift to help patient move to standing position. **A2,** Patient grasps handles as nurse enables motorized lift. **A3,** Patient is in standing position with feet on floor and is ready to ambulate to chair with nurses' help. **B1,** When patient is unable to walk, secure safety straps and use platform of motorized lift. **B2,** Patient is in upright position. **B3,** Position patient in front of chair. **B4,** Explain to patient need to hold on to handles as motorized lift begins to lower patient into chair. **B5,** Guide patient into chair.

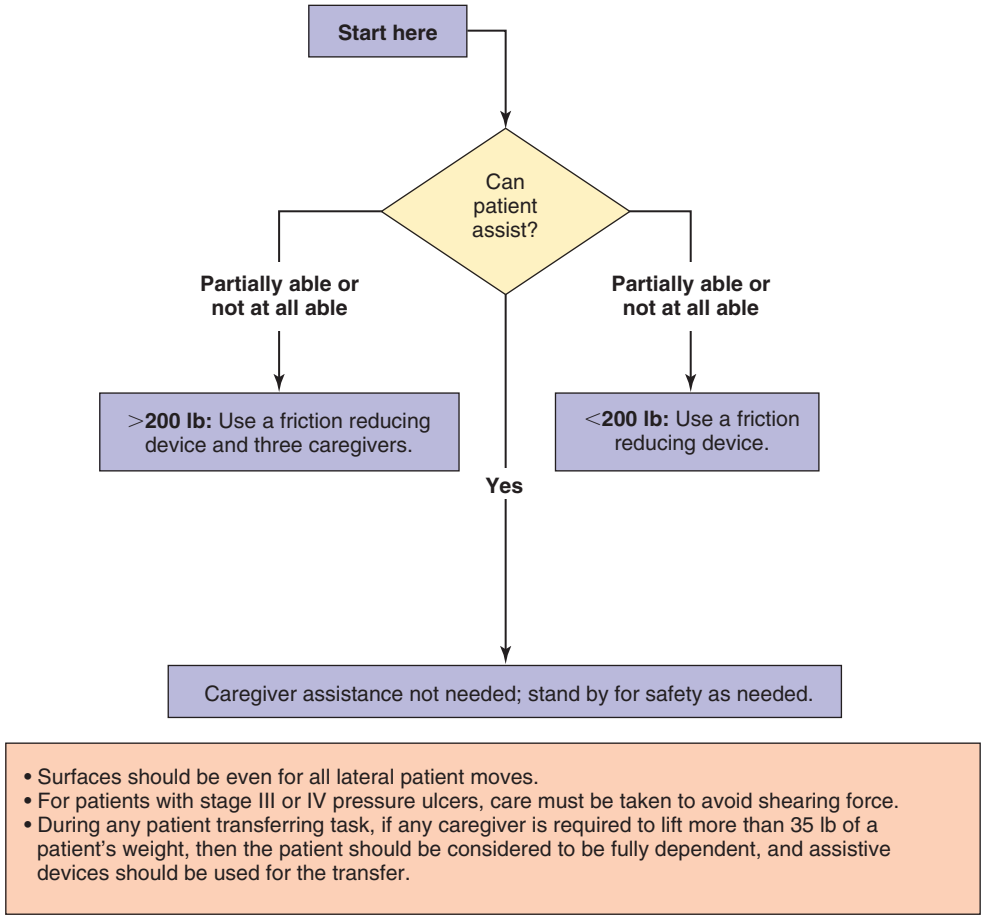

FIG. 47-24 Algorithm used to complete lateral transfer to and from bed to stretcher, trolley. (From Nelson A: *Safe patient handling and movement algorithms,* 2006, VISN8 Patient Safety Center, http://www.visn8.med.va.gov/patientsafetycenter/SafePtHandling/default.asp.)

who cannot bear weight but who are cooperative and have sufficient upper body strength to complete the transfer. If a seated transfer aid is used, the chair needs to have arms that are able to be removed or moved out of the way. Transfer patients who have partial weight bearing toward their stronger side (Baptiste et al., 2006; Nelson et al., 2009).

Transferring a Patient from a Bed to a Stretcher. To transfer a patient from a bed to a stretcher, first consult an appropriate algorithm (Fig. 47-24). Determine if the patient is able to assist in the procedure. Patients who receive opioid pain medications often need additional assistance during the transfer because they may be unable to assist or may have difficulty understanding the caregiver's directions.

Allow patients who can complete the transfer independently to move to the stretcher on their own and stand by to ensure a safe transfer. Determine the patient's weight if he or she can assist partially or cannot assist at all. Use a friction-reducing device for patients who weigh less than 200 pounds. If the patient weighs 200 pounds or more, use a friction-reducing device and three caregivers. Before moving the patient, place the stretcher and the bed side by side to allow him or her to transfer quickly and easily using the friction-reducing device.

Use caution when the patient has or is suspected of having spinal cord trauma. If you have to move the patient, place a transfer board under him or her to maintain spinal alignment before transferring to a stretcher. Prepare the patient for the transfer and ask for help when possible (e.g., by folding the arms over the chest). Make sure that the environment is free from obstacles and remove unnecessary equipment from the bed.

Restorative and Continuing Care. The goal of restorative care for the patient who is immobile is to maximize functional mobility and independence and reduce residual functional deficits such as impaired gait and decreased endurance. The focus in restorative care is not only on ADLs that relate to physical self-care but also on **instrumental activities of daily living (IADLs).** IADLs are activities that are necessary to be independent in society beyond eating, grooming, transferring, and toileting and include such skills as shopping, preparing meals, banking, and taking medications.

The nurse uses many of the same interventions as described in the health promotion and acute care sections, but the emphasis is on working collaboratively with patients and their significant others and with other health care professionals to facilitate the patient's return to maximal functional ability in both ADLs and IADLs.

Intensive specialized therapy such as occupational or physical therapy is common. If the patient is in an institution, he or she likely goes to the therapy department 2 to 3 times a day. The nurse's role is to work collaboratively with these professionals and reinforce exercises and teaching. For example, after a stroke or brain attack, a patient likely receives gait training from a physical therapist; speech rehabilitation from a speech therapist; and help from an occupational therapist for ADLs such as dressing, bathing and

toileting, or household chores. The therapy is not always able to restore total functional health, but it often helps the patient adapt to the mobility limitations or complications. Equipment frequently used to help patients adapt to mobility limitations includes walkers, canes, wheelchairs, and assistive devices such as toilet seat extenders, reaching sticks, special silverware, and clothing with Velcro closures.

Range-of-Motion Exercises. To ensure adequate joint mobility, teach the patient about ROM exercises. Walking also increases joint mobility. Patients with restricted mobility are unable to perform some or all ROM exercises independently. Provide ROM exercises to maintain maximum joint mobility. To ensure that patients routinely receive ROM exercises, schedule them at specific times, perhaps with another nursing activity such as during the patient's bath. This enables the nurse to systematically reassess mobility while improving the patient's ROM. In addition, bathing usually requires that extremities and joints are put through complete ROM.

Passive ROM exercises begin as soon as the patient's ability to move the extremity or joint is lost. Carry out movements slowly and smoothly, just to the point of resistance; ROM should not cause pain. Never force a joint beyond its capacity. Each movement needs to be repeated 5 times during the session.

When performing passive ROM exercises, stand at the side of the bed closest to the joint being exercised. Perform passive ROM exercises using a head-to-toe sequence and moving from larger to smaller joints. If an extremity is to be moved or lifted, place a cupped hand under the joint to support it, support the joint by holding the adjacent distal and proximal areas (Fig. 47-25), or support the joint with one hand and cradle the distal portion of the extremity with the remaining arm (Fig. 47-26). See Table 47-2 for detailed ROM for each joint. Appropriate ROM exercises are based on the patient and the affected joint.

Walking. When a patient has a limited ability to walk, assess his or her activity tolerance, tolerance to the upright position (orthostatic hypotension), strength, presence of pain, coordination, and balance to determine the amount of assistance needed. Explain how far the patient should try to walk, who is going to help, when the walk will take place, and why walking is important. In addition, determine with the patient how much independence he or she can assume.

Check the environment to be sure that there are no obstacles in the patient's path. Clear chairs, over-bed tables, and wheelchairs out of the way so the patient has ample room to walk safely. Before starting, establish rest points in case activity tolerance is less than estimated or the patient becomes dizzy. For example, place a chair in the hall for the patient to rest if needed. A nurse who does not have a lot of strength and who is unable to ambulate a patient alone needs to request help and ensure that the patient has an assistive device such as a walker (see Chapter 38). A nurse stands on either side of the patient, and each holds one side of the gait belt.

Provide support at the waist by using a **gait belt** so the patient's center of gravity remains midline. While walking, the patient should not lean to one side because this alters the center of gravity, distorts balance, and increases the risk of falling. Return a patient who at any point appears unsteady or complains of dizziness to a nearby bed or chair. If the patient faints or begins to fall, assume a wide base of support with one foot in front of the other, thus supporting the body weight. Then gently lower the patient to the floor, protecting the head. Although lowering a patient to the floor is not difficult, the nursing student needs to practice this technique with a friend or classmate before attempting it in a clinical setting.

FIG. 47-25 Supporting joint by holding distal and proximal areas adjacent to joint.

FIG. 47-26 Cradling distal portion of extremity.

Patients with **hemiplegia** (one-sided paralysis) or **hemiparesis** (one-sided weakness) often need assistance with walking. When an assistive device is used, stand on the patient's affected side and support him or her with a gait belt. Providing support by holding the patient's arm is incorrect because the nurse cannot easily support the patient's weight to lower him or her to the floor if he or she faints or falls. In addition, if the patient falls with the nurse holding an arm, a shoulder joint may be dislocated.

EVALUATION

Through the Patient's Eyes. Just as it was important to include the patient during the assessment and planning phase of the care plan, it is essential to have the patient's evaluation of the plan of care. Were the goals met, or is more work required? You must now determine with the patient and others involved with care if the

goals or outcomes established with and for the patient have indeed been met; what still needs to be achieved from the patient's perspective; and the construction of a new plan of care. In other words, how have the patient's expectations changed and in what ways?

Patient Outcomes. From your perspective as the nurse, you are to evaluate outcomes and response to nursing care and compare the patient's actual outcomes with the outcomes selected during planning such as his or her ability to maintain or improve body alignment, joint mobility, walking, moving, or transferring. Evaluate the effectiveness of specific interventions designed to promote body alignment, improve mobility, and protect the patient from the hazards of immobility. Evaluate the patient's and family's understanding of all teaching provided as well (Fig. 47-27). The continuous nature of evaluation allows you to determine whether new or revised therapies are required and if new nursing diagnoses have developed.

When outcomes are not met, consider asking the following questions:

- Are there ways we can assist you to increase your activity?
- Which activities are you having trouble completing right now?
- How do you feel about not being able to dress yourself and make your own meals?
- Which exercises do you find most helpful?
- What goals for your activity would you like to set now?

Once these questions have been asked and you have addressed the limited mobility and its associated problems through the patient's eyes, you are prepared to adjust the plan of care to address the remaining clinical problems that your patient is experiencing related to immobility.

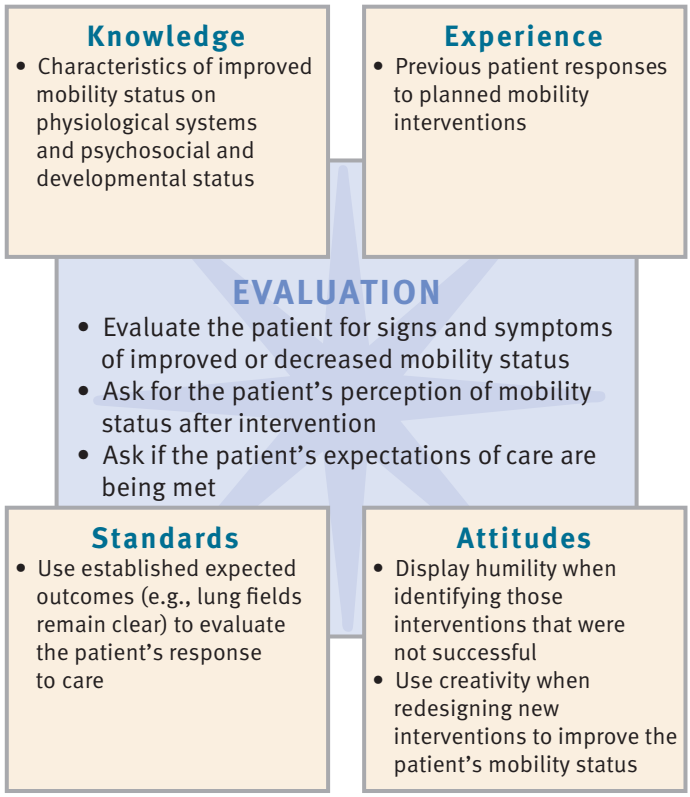

FIG. 47-27 Critical thinking model for immobility evaluation.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, access and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient-centered care.

- Mentally review the transfer steps before beginning the procedure, this ensures both the patient's and your safety.
- Assess the patient's mobility and strength to determine the assistance that he or she is able to offer during transfer. Stand on patient's weak side when assisting (Pierson and Fairchild, 2008).
- Determine the amount and type of assistance required for safe positioning and transfer, including the type of transfer equipment and the number of personnel to safely transfer and prevent harm to patient and health care providers.
- Raise the side rail on the side of the bed opposite of where you are standing to prevent the patient from falling out of bed on that side.
- Arrange equipment (e.g., intravenous lines, feeding tube, Foley catheter) so it does not interfere with the positioning or transfer process.
- Evaluate the patient for correct body alignment and pressure risks after the transfer.
- Make sure that all personnel understand how equipment functions before it is used.
- Educate patients about how equipment functions to reduce their anxiety and enlist their cooperation.

Delegation Considerations

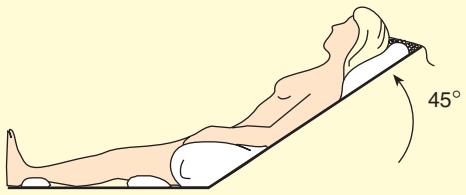
The skill of moving and positioning patients in bed can be delegated to nursing assistive personnel (NAP). The nurse is responsible for assessing the patient's level of comfort and for any hazards of immobility. Instruct NAP about:

- Any limitations affecting movement and positioning.
- Scheduled times to reposition patient through the shift.
- When to request assistance (e.g., when the patient is unable to assist the nurse, has a lot of equipment, or is confused.

Equipment

- Pillows
- Therapeutic boots, splints, ankle support devices if needed
- Trochanter roll
- Sandbag
- Hand rolls
- Side rails
- Appropriate safe patient–handling assistive device

SKILL 47-1 MOVING AND POSITIONING PATIENTS IN BED—cont'd



STEP	RATIONALE
ASSESSMENT	
1 Assess patient's body alignment and comfort level while he or she is lying down.	Provides baseline data for later comparisons. Determines ways to improve position and alignment.
2 Assess for risk factors that contribute to complications of immobility:	Increased risk factors require more frequent repositioning.
a. Paralysis, hemiparesis resulting from a cerebrovascular accident (CVA); decreased sensation	Paralysis impairs movement; muscle tone changes; sensation is often affected. Because of difficulty in moving and poor awareness of involved body part, patient is unable to protect and position body part for self (Lewis et al., 2011).
b. Impaired mobility from traction, arthritis, or other contributing disease processes	Traction or arthritic changes of affected extremity result in decreased range of motion (ROM).
c. Impaired circulation	Decreased circulation predisposes patient to pressure ulcers.
d. *Age:* Very young, older adults	Premature and young infants require frequent turning because their skin is fragile. Normal physiological changes associated with aging predispose older adults to greater risks for developing complications of immobility (Butler, 2006; Ebersole et al., 2008).
e. Level of consciousness and mental status.	Comatose or semicomatose patients are unable to verbalize areas of skin pressure, increasing the risk for skin breakdown.
3 Assess patient's physical ability to help with moving and positioning:	Enables nurse to use patient's mobility, coordination, and strength; determines need for additional help. Ensures patient's and nurse's safety (Nelson et al., 2009).
a. Age	Some older adults move more slowly with less strength.
b. Level of consciousness and mental status	Determines need for special aids or devices. Patients with altered levels of consciousness do not always understand instructions and are often unable to help.
c. Disease process	Cardiopulmonary disease requires patient to have head of bed elevated.
d. Strength, coordination	Determines amount of assistance provided by patient during position change.
e. ROM	Limited ROM contraindicates certain positions.
4 Assess patient's height, weight, and body shape.	Devices used for safe patient handling have different weight restrictions; bariatric patients require special beds, lifts, wheelchairs, and toileting and bathing equipment (Nelson et al., 2009).
5 Assess health care provider's orders. Clarify whether any positions are contraindicated because of patient's condition (e.g., spinal cord injury; respiratory difficulties; certain neurological conditions; presence of incisions, drains, and tubing).	Placing patient in an inappropriate position causes injury.
6 Assess for presence of tubes, incisions, and equipment (e.g., traction).	Alters positioning procedure and affects patient's ability to independently change positions.
7 Assess condition of patient's skin.	Provides baseline to determine effects of positioning.
8 Assess ability and motivation of patient, family members, and primary caregiver to participate in moving and positioning patient in bed in anticipation of discharge to home.	Determines ability of patient and caregivers to help with positioning.
PLANNING	
1 Collect appropriate equipment. Get extra help as needed. Close door to room or close bedside curtains.	Having appropriate number of people to position patient prevents patient and nurse injury. Provides for patient privacy.
2 Perform hand hygiene.	Reduces transfer of microorganisms.
3 Verify patient's identity by using at least two patient identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record. Explain procedure.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011). Improves patient safety. In most acute care settings you use the patient's name and identification number on armband and medical record to identify patients. Decreases anxiety and increases patient cooperation.
4 Raise level of bed to comfortable working height. Remove all pillows and devices used for positioning.	Raises work toward nurse's center of gravity. Reduces any interference during positioning.
IMPLEMENTATION	
1 Position patient flat in bed if tolerated. Keep patient aligned.	Repositioning from flat position decreases friction and possible shear on patient's skin.

CLINICAL DECISION: *Before flattening bed, account for all tubing, drains, and equipment to prevent dislodgement or tipping if caught in mattress or bed frame as bed is lowered.*

STEP	RATIONALE
a. Moving patient up in bed (two nurses):	This is not a one-person task. Helping a patient move up in bed without help from other co-workers or without the aid of an assistive device (i.e., friction-reducing pad) is not recommended or considered safe for the patient or nurse (ANA, 2011; CDC, 2009). If the patient is unable to fully assist, then refer to Step 1b.
(1) Remove pillow from under head and shoulders and place it at head of bed.	Prevents striking patient's head against head of bed.
(2) Face head of bed.	Facing direction of movement prevents twisting your body while moving patient.
(3) Each nurse places one arm under patient's head and shoulders and one arm under patient's thighs.	Provides support across length of patient's body.
(4) *Alternate position if patient can assist:* Position one nurse at patient's upper body. Nurse's arm nearest head of bed is under patient's head and opposite shoulder. Position other nurse at patient's lower back and torso.	Prevents trauma to patient's musculoskeletal system by supporting shoulder and hip joints and evenly distributing weight.
(5) Place feet apart, with foot nearest head of bed in front of other foot (forward-backward stance)	Wide base of support increases balance. Stance enables nurse to shift weight as patient moves up in bed, thereby reducing friction, and enables patient to use long muscles for movement.
(6) Before moving patient, instruct him or her to flex knees with feet flat on bed.	Decreases friction and enables patient to use leg muscles during movement.
(7) Also instruct patient to flex neck, tilting chin toward chest.	Prevents hypertension of neck when moving patient up in bed.
(8) Have patient help moving by pushing with feet on bed surface.	Reduces friction. Increases patient mobility. Decreases workload.
(9) Flex your knees and hips, bringing forearms closer to level of bed.	Increases balance and strength by bringing center of gravity of nurse closer to patient. Uses thighs instead of back muscles.
(10) Instruct patient on count of 3 to push heels and elevate trunk while breathing out, thus moving toward head of bed.	Prepares patient for move. Reinforces assistance in moving up in bed. Increases patient cooperation. Breathing out avoids patient performing Valsalva.
(11) On count of 3, rock and shift weight from front to back leg. At the same time patient pushes with heels and elevates trunk.	Rocking enables nurse to improve balance and overcome inertia. Shifting weight counteracts patient's weight and reduces force needed to move load. Patient's assistance reduces friction and workload for nurse.
b. Moving immobile patient up in bed with drawsheet (two nurses):	

CLINICAL DECISION: *Use safe nursing judgment by increasing number of nurses or NAP when moving a larger patient up in bed. If in doubt, acquire more help.*

(1) Place drawsheet under patient by turning from side to side. Extend sheet from shoulder to thighs. Return patient to supine position.	Supports patient's body weight and reduces friction during movement.
(2) Position one nurse at each side of patient's hips.	Distributes weight equally between nurses.
(3) Grasp drawsheet firmly near patient.	
(4) Place feet apart, with foot nearest head of bed in front of other, flex your knees and hips, on count of 3 shift weight from front to back leg, and move patient and drawsheet to desired position in bed.	Rocking enables nurse to improve balance and overcome inertia. Shifting weight counteracts patient's weight and reduces force needed to move load.
c. Positioning patient in supported Fowler's position (see illustration):	

STEP 1c Supported Fowler's position.

(1) Elevate head of bed 45 to 60 degrees.	Increases comfort, improves ventilation, and increases patient's opportunity to socialize or relax.
(2) Rest head against mattress or on small pillow.	Prevents flexion contractures of cervical vertebrae.
(3) Use pillows to support arms and hands if patient does not have voluntary control or use of hands and arms.	Prevents shoulder dislocation from effect of downward pull of unsupported arms, promotes circulation by preventing venous pooling, and prevents flexion contractures of arms and wrists.
(4) Position pillow at lower back.	Supports lumbar vertebrae and decreases flexion of vertebrae.
(5) Place small pillow under thigh.	Prevents hyperextension of knee and occlusion of popliteal artery caused by pressure from body weight.
(6) Elevate patient's heel in heel boots or other heel pressure-relief devices.	Heel pressure-relief devices are more effective than pillows for consistently reducing pressure from the mattress on the heels. When pillows are used, they must be repositioned each time the patient moves (Walsh and Plonczynski, 2007).

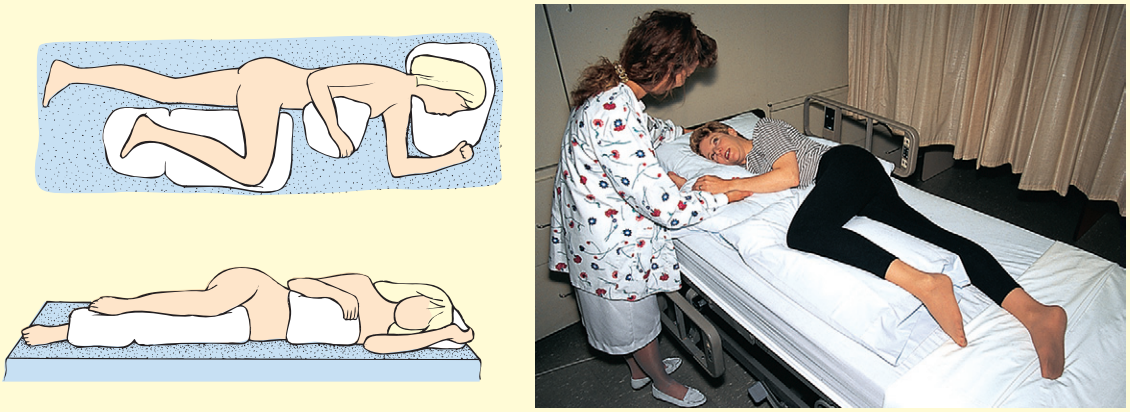
SKILL 47-1 MOVING AND POSITIONING PATIENTS IN BED—cont'd

STEP	RATIONALE
CLINICAL DECISION: *To keep feet in proper alignment and prevent footdrop, use foot support devices such as ankle or foot boots. In addition, a foot cradle is often used for patients with poor peripheral circulation as a means of reducing pressure on the tips of patient's toes (check agency policy).*	
d. Positioning hemiplegic patient in supported Fowler's position:	
(1) Elevate head of bed 45 to 60 degrees.	Increases comfort, improves ventilation, and increases patient's opportunity to relax.
(2) Position patient in sitting position as straight as possible.	Counteracts tendency to slump toward affected side. Improves ventilation and cardiac output; decreases intracranial pressure. Improves patient's ability to swallow and helps to prevent aspiration of food, liquids, and gastric secretions (Glenn-Molali, 2008).
(3) Position head on small pillow with chin slightly forward. If patient is totally unable to control head movement, avoid hyperextension of neck.	Prevents hyperextension of neck. Too many pillows under head cause or worsen neck flexion contracture.
CLINICAL DECISION: *If the patient has a paralyzed extremity, provide support for involved arm and hand on over-bed table in front of patient. Place arm away from patient's side and support elbow with pillow.* • *Position flaccid hand in normal resting position with wrist slightly extended, arches of hand maintained, and fingers partially flexed; use section of rubber ball cut in half; clasp patient's hands together.* • *Position spastic hand with wrist in neutral position or slightly extended; extend fingers with palm down or leave them in relaxed position palm up. At times it is difficult to position spastic hands without the use of specially made splints for the patient.*	
(4) Flex knees and hips by using pillow or folded blanket under knees.	Ensures proper alignment. Flexion prevents prolonged hyperextension, which possibly impairs joint mobility.
(5) Place trochanter rolls along side of patient's legs.	Reduces external rotation of hip.
(6) Support feet in dorsiflexion with foot support such as ankle or foot boots (check agency policy).	Prevents footdrop by placing ankle in neutral dorsiflexion. Stimulation of ball of foot by firm surface has tendency to increase muscle tone in patient with extensor spasticity of lower extremity.
e. Positioning patient in supine position:	
(1) Be sure that patient is comfortable on back with head of bed flat.	Some patients' physical conditions do not tolerate supine position.
(2) Place small rolled towel under lumbar area of back.	Provides support for lumbar spine.
(3) Place pillow under upper shoulders, neck, or head.	Maintains correct alignment and prevents flexion contractures of cervical vertebrae.
(4) Place trochanter rolls or sandbags parallel to lateral surface of patient's thighs if patient is immobile.	Reduces external rotation of hip.
(5) Position patient's heels in heel boots or other heel pressure-relief device (check agency policy).	Heel pressure-relief devices are more effective than pillows for consistently reducing pressure from the mattress on the heels.
(6) If needed, support feet in dorsiflexion with foot support such as ankle or foot boots (check agency policy).	Prevents footdrop by placing ankle in neutral dorsiflexion. Stimulation of ball of foot by firm surface has tendency to increase muscle tone in patient with extensor spasticity of lower extremity.
(7) Place pillows under pronated forearms, keeping upper arms parallel to patient's body (see illustrations).	Reduces internal rotation of shoulder and prevents extension of elbows. Maintains correct body alignment.

STEP 1e(7) Supine position with supporting pillows.

(8) Place firm hand rolls in patient's hands. Consider physical therapy referral for use of hand splints.	Reduces extension of fingers and abduction of thumb. Maintains thumb slightly adducted and in opposition to fingers.

STEP	RATIONALE
f. Positioning hemiplegic patient in supine position:	
(1) Be sure that patient is comfortable on back with head of bed flat.	Some patients' physical conditions do not tolerate supine position.
(2) Place folded towel or small pillow under shoulder of affected side.	Decreases possibility of pain, joint contracture, and subluxation. Maintains mobility in muscles around shoulder to permit normal movement patterns.
(3) Keep affected arm away from body with elbow extended and palm up. (Alternate position is to place arm out to side, with elbow bent and hand toward head of bed.)	Maintains mobility in arm, joints, and shoulder to permit normal movement patterns. (Alternate position counteracts limitation of ability of arm to rotate outward at shoulder [external rotation]. Need external rotation to raise arm overhead without pain.)
CLINICAL DECISION: *Position affected hand in one of the recommended positions for flaccid or spastic hand.*	
(4) Place folded towel under hip of involved side.	Diminishes effect of spasticity in entire leg by controlling hip position.
(5) Flex affected knee 30 degrees by supporting it on pillow or folded blanket.	Slight flexion breaks up abnormal extension pattern of leg. Extensor spasticity is most severe when patient is supine.
(6) Support patient's heel in heel boots or other heel pressure-relief device (check agency policy).	Prevents footdrop by placing ankle in neutral dorsiflexion. Stimulation of ball of foot by firm surface has tendency to increase muscle tone in patient with extensor spasticity of lower extremity.
g. Positioning patient in prone position:	
(1) With patient supine, place arm on side to be turned alongside the body. Roll patient over the arm positioned close to the body, with elbow straight and hand under hip. Position on abdomen in center of bed.	Positions patient correctly to maintain alignment.
(2) Turn patient's head to one side and support head with small pillow (see illustration).	Reduces flexion or hyperextension of cervical vertebrae.



STEP 1g(2) Prone position with supporting pillows.

(3) Place small pillow under patient's abdomen below level of diaphragm.	Reduces pressure on breasts of some female patients and decreases hyperextension of lumbar vertebrae and strain on lower back.
(4) Support arms in flexed position level at shoulders.	Maintains proper body alignment. Support reduces risk of joint dislocation.
(5) Support lower legs with pillows to elevate toes.	Prevents footdrop. Reduces external rotation of hips. Eliminates mattress pressure on toes.
h. Positioning hemiplegic patient in prone position:	
CLINICAL DECISION: *Increase frequency of positioning if pressure areas begin to appear; joint mobility becomes impaired or worsened, or patient demonstrates signs of discomfort. Consult with physical and occupational therapists as needed.*	
(1) Move patient toward unaffected side, with patient remaining supine.	Creates room for proper patient alignment in center of bed when patient rolls onto abdomen.
(2) Place pillow on patient's abdomen.	Prevents sagging of abdomen when patient rolls over; decreases hyperextension of lumbar vertebrae and strain on lower back.
(3) Roll patient onto affected side.	
(4) Roll patient onto abdomen by positioning involved arm close to patient's body, with elbow straight and hand under hip. Roll patient carefully over arm.	Prevents injury to affected side.
(5) Turn head toward involved side.	Promotes development of neck and trunk extension, which is necessary for standing and walking.
(6) Position involved arm out to side, with elbow bent, hand toward head of bed, and fingers extended (if possible).	Counteracts limitation of ability of arm to rotate outward at shoulder (external rotation). External rotation needs to be present to raise arm over head without pain.

SKILL 47-1 MOVING AND POSITIONING PATIENTS IN BED—cont'd

STEP	RATIONALE
(7) Flex knees slightly by placing pillow under legs from knees to ankles.	Flexion prevents prolonged hyperextension, which impairs joint mobility.
(8) Support feet with foot-support devices (e.g., ankle or foot boots) (check agency policy).	Maintains feet in dorsiflexion.
i. Positioning patient in 30-degree lateral (side-lying) position (see illustrations):	
(1) Patient lies supine with head of bed as low as he or she tolerates.	Provides position of comfort for patient and removes pressure from bony prominences on back and buttocks.
(2) Position patient to side of bed. Then move to opposite side of bed toward which patient is to be turned. Use friction-reducing device or mechanical lift per manufacturer guidelines if patient cannot help with moving.	Provides room for patient to turn to side. Use of safe patient–handling equipment reduces workload of caregivers and enhances safety (deCastro et al., 2006).
(3) Prepare to turn patient onto side. Flex his or her knee that is not next to mattress. Place one hand on patient's hip and one hand on patient's shoulder.	Positioning sets up leverage for easy turning.
(4) Roll patient onto side toward nurse.	Decreases trauma to tissues. In addition, patient is positioned so leverage on hip makes turning easy.
(5) Place pillow under patient's head and neck.	Maintains alignment. Reduces lateral neck flexion. Decreases strain on sternocleidomastoid muscle.
(6) Place hands under patient's dependent shoulder and bring shoulder blade forward.	Prevents patient's weight from resting directly on shoulder joint.
(7) Position both arms in slightly flexed position. Support upper arm with pillow level with shoulder; other arm, by mattress.	Decreases internal rotation and adduction of shoulder. Supports both arms in slightly flexed position. Improves ventilation because chest is able to expand.
(8) Place hands under dependent hip and bring hip slightly forward so angle from hip to mattress is approximately 30 degrees	The 30-degree lateral position reduces pressure on trochanter.
(9) Place tuck-back pillow behind patient's back. (Make by folding pillow lengthwise. Smooth area slightly tucked under patient's back.)	Provides support to maintain patient on side.
(10) Place pillow under semiflexed upper leg level at hip from groin to foot.	Maintains leg in correct alignment. Prevents pressure on bony prominence.
(11) Support feet with foot-support devices (e.g., ankle or foot boots (check agency policy).	Maintains dorsiflexion of feet. Prevents footdrop.
j. Positioning patient in Sims' (semiprone) position (see illustration):	
(1) Be sure that patient is comfortable in supine position.	Provides for proper body alignment while patient is lying down.
(2) Position patient in side-lying position, lying partially on abdomen, with dependent arm straight along his or her body.	Facilitates turning onto side. Avoids injury to arm; semiprone position places less pressure on abdomen.

STEP 1i Side-lying position with pillows in place.

STEP 1j Sims' (semiprone) position with pillows in place.

STEP	RATIONALE
(3) Carefully lift patient's dependent shoulder and bring arm back behind him or her.	
(4) Place small pillow under patient's head.	Patient is rolled only partially on abdomen.
(5) Place pillow under flexed upper arm, supporting arm level with shoulder.	Maintains proper alignment and prevents lateral neck flexion. Prevents internal rotation of shoulder.
(6) Place pillow under flexed upper leg, supporting leg level with hip.	Prevents internal rotation of hip and adduction of leg. Flexion prevents hyperextension of leg. Reduces mattress pressure on knees and ankles.
(7) Support feet with foot-support devices such as ankle or foot boots (check agency policy).	Maintains feet in dorsiflexion. Prevents footdrop.
k. Logrolling patient (three nurses):	
CLINICAL DECISION: *Supervise and aid personnel when there is a health care provider's order to* ***logroll*** *a patient. Patients who have suffered from spinal cord injury or are recovering from neck, back, or spinal surgery often need to keep the spinal column in straight alignment to prevent further injury.*	
(1) Place pillow between patient's knees.	Prevents tension on spinal column and adduction of hip.
(2) Cross patient's arms on chest.	Prevents injury to arms.
(3) Position two nurses or other staff members on side of bed to which patient will be turned. Position third nurse or staff member on other side of bed (see illustration). If needed, four nurses are used; fourth nurse stands on same side as third nurse.	Distributes weight equally between nurses.
(4) Fanfold or roll drawsheet along side of the patient.	Provides strong handles to grip the drawsheet or pull sheet without slipping.
(5) Move patient as one unit in a smooth, continuous motion on the count of three (see illustration).	This maintains proper alignment by moving all body parts at the same time, preventing tension or twisting of the spinal column.
(6) Nurse on opposite side of bed places pillows along length of patient (see illustration).	Pillows keep patient aligned.
(7) Gently lean patient as a unit back toward pillows for support (see illustration).	Ensures continued straight alignment of spinal column, preventing injury.
2 Perform hand hygiene.	Reduces transmission of microorganisms.

STEP 1k(3) Position nurses on each side of patient.

STEP 1k(5) Move patient as a unit, maintaining proper alignment.

STEP 1k(6) Place pillows along patient's back for support.

STEP 1k(7) Gently lean patient as a unit against pillows.

SKILL 47-1 MOVING AND POSITIONING PATIENTS IN BED—cont'd

STEP	RATIONALE
EVALUATION	
1 Evaluate patient's body alignment, position, and level of comfort.	Determines effectiveness of positioning. Add or remove supports (e.g., pillows, bath blankets) to promote comfort and correct body alignment.
2 Measure ROM.	Determines if joint contracture is developing.
3 Observe for areas of erythema or breakdown involving skin.	Indicates complications of immobility or improper positioning of body part. Determines if need exists for increasing frequency of repositioning patient.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Joint contractures develop or worsen.
- Consult physical and/or occupational therapy.
- Ensure that activity and ROM orders are implemented consistently.

2 Skin shows areas of erythema and breakdown.
- Increase frequency of turning and repositioning; place turning schedule above patient's bed.
- Consult skin care team.
- Implement other activities per agency skin care policy or protocol (e.g., assess more frequently, consult dietitian, place patient on pressure-relieving mattress).

3 Patient avoids moving.
- Administer pain medications as ordered by a health care provider to ensure patient's comfort before moving if he or she is in pain and allow pain medication to take effect before proceeding.
- Provide patient education about benefits of moving.

RECORDING AND REPORTING

- Document repositioning or turn and observations during procedure (e.g., condition of skin, joint movement, patient's ability to assist with positioning) in nurses' notes.
- Report observations at change of shift.

HOME CARE CONSIDERATIONS

- Teach family how to use safe patient–handling equipment if necessary.
- Teach patient and family about the signs of skin breakdown and the importance of safety during positioning for patients with decreased sensation.

SKILL 47-2 USING SAFE AND EFFECTIVE TRANSFER TECHNIQUES

View Video!

Delegation Considerations

The skill of effective transfer techniques can be delegated to nursing assistive personnel (NAP). Patients who are transferred for the first time after prolonged bed rest, extensive surgery, critical illness, or spinal cord trauma usually require supervision by the nurse. Instruct NAP about:
- Seeking assistance when moving or lifting a patient (e.g., when the patient is overweight or confused).
- Patient limitations (e.g., changes in blood pressure, mobility restrictions) that affect safe transfer techniques

Equipment

- Transfer belt, sling, or lapboard (as needed)
- Nonskid shoes, bath blankets, and pillows
- *Wheelchair:* Position chair at 45-degree angle to bed, lock brakes, remove footrests, lock bed brakes.
- *Stretcher:* Position next to bed, lock brakes on stretcher, lock brakes on bed.
- *Mechanical lift:* Use frame, canvas strips or chains, and hammock or canvas strips.

STEP	RATIONALE
ASSESSMENT	
1 Assess physiological capacity to transfer:	Provides information relative to patient's abilities, physical status, ability to comprehend, and number of individuals needed to provide safe transferring.
a. Muscle strength (legs and upper arms)	Immobile patients have decreased muscle strength, tone, and mass. Affects ability to bear weight or raise body.
b. Joint mobility (range of motion [ROM]) and contracture formation	Immobility or inflammatory processes (e.g., arthritis) sometimes lead to contracture formation and impaired joint mobility.

STEP	RATIONALE
c. Paralysis or paresis (spastic or flaccid)	Patient with central nervous system damage often has bilateral paralysis (requiring transfer by swivel bar, sliding bar, or mechanical lift) or unilateral paralysis, which requires belt transfer to "best" side. Weakness (paresis) requires stabilization of knee while transferring. Flaccid arm needs to be supported with sling during transfer.
d. Risk for orthostatic (postural) hypotension (e.g., previously on bed rest, first time arising from supine position following surgical procedure, history of dizziness when arising)	Determines risk of fainting or falling during transfer. Immobilized patients have decreased ability for autonomic nervous system to equalize blood supply, resulting in drop of 20 mm Hg or more in blood pressure when rising from sitting position (Jarvis, 2008; Monahan et al., 2007).
e. Activity tolerance	Determines ability of patient to assist with transfer.
f. Level of comfort	Pain reduces patient's motivation and ability to be mobile. Pain relief before transfer enhances patient participation.
g. Vital signs	Vital sign changes such as increased pulse and respiration indicate activity intolerance (see Chapter 29).
2 Assess patient's sensory status:	Determine influence of sensory loss on ability to make transfer. Visual field loss decreases patient's ability to see in direction of transfer. Peripheral sensation loss decreases proprioception. Patients with visual and hearing losses need transfer techniques adapted to deficits. Patients with a cerebrovascular accident (CVA) sometimes lose area of visual field, which profoundly affects vision and perception.
a. Adequacy of central and peripheral vision	
b. Adequacy of hearing	
c. Loss of peripheral sensation	
CLINICAL DECISION: *Patients with hemiplegia also often "neglect" one side of the body (inattention to or unawareness of one side of body or environment), which distorts perception of the visual field. If patient experiences neglect of one side, instruct him or her to scan all visual fields when transferring.*	
3 Assess patient's cognitive status.	Determines patient's ability to follow directions and learn transfer techniques.
CLINICAL DECISION: *Patients with head trauma or CVA have perceptual cognition deficits that create safety risks. If patient has difficulty comprehending, simplify instructions and maintain consistency.*	
4 Assess patient's level of motivation:	Altered psychological states reduce patient's desire to engage in activity.
a. Patient's eagerness versus unwillingness to be mobile	
b. Whether patient avoids activity and offers excuses	
5 Assess previous mode of transfer (if applicable).	Determines mode of transfer and assistance required to provide continuity.
6 Assess patient's specific risk of falling or being injured when transferred (e.g., neuromuscular deficits, motor weakness, calcium loss from bones, cognitive and visual dysfunction, altered balance).	Certain conditions increase risk of falling or potential injury.
7 Assess special transfer equipment needed for home setting. Assess home environment for hazards.	Prior teaching of family and support persons, assessing home for safety risks and functionality, and providing applicable aids greatly enhance transfer ability at home.
PLANNING	
1 Gather appropriate equipment.	
2 Determine number of people needed to assist with transfer. Do not start procedure until all caregivers are available.	Ensures safe patient transfer.
3 Perform hand hygiene. Verify that bed brakes are locked.	Reduces transmission of microorganisms. Promotes patient and caregiver safety.
4 Explain procedure to patient.	Increases patient participation.
IMPLEMENTATION	
1 Transfer patient	
a. Assisting cooperative patient to sitting position in bed:	

SKILL 47-2 USING SAFE AND EFFECTIVE TRANSFER TECHNIQUES—cont'd

STEP	RATIONALE
CLINICAL DECISION: *Careful assessment of your patient's ability to assist in the following position technique is extremely important. Consider the use of a mechanical lift. Your role in assisting your patient to a sitting position is a guide and instruction. If patient can bear weight and move to a sitting position independently, allow him or her to do so and offer assistance (Nelson and Baptiste, 2006).*	
(1) Raise bed to waist level. Place patient in supine position.	Enables nurse to assess patient's body alignment continually.
(2) Face head of bed at a 45-degree angle and remove pillows.	Proper positioning reduces twisting of your body when moving patient. Pillows cause interference when patient is sitting up in bed.
(3) Place feet in wide base of support, with foot closer to bed in front of other foot.	Improves balance and allows transfer of body weight as you move patient to sitting position.
(4) Place hand nearer head of bed under patient's shoulders, supporting his or her head and cervical vertebrae.	Maintains alignment of head and cervical vertebrae and allows for even lifting of patient's upper trunk.
(5) Place other hand on bed surface.	Provides support and balance.
(6) Raise patient to sitting position by shifting weight from front to back leg.	Improves balance, overcomes inertia, and transfers weight in direction in which you move patient.
(7) Push against bed using arm that is placed on bed surface.	Divides activity between arms and legs and protects back from strain. By bracing one hand against mattress and pushing against it as you lift patient, you transfer weight away from your back muscles through your arm onto the mattress.
b. Assisting cooperative patient who can partially bear weight to sitting position on side of bed:	
(1) With bed flat and waist high, turn patient to side, using assistance of another caregiver if necessary. Patient needs to face nurse on side of bed that patient will be sitting (see illustration).	Decreases amount of work needed by nurse and patient.
(2) Raise head of bed 30 degrees.	Facilitates raising patient to sitting position and protects him or her from falling.
(3) Stand opposite patient's hips. Turn diagonally so you face patient and far corner of head of bed.	Places your center of gravity nearer patient. Reduces twisting of your body because you are facing direction of movement.
(4) Place feet apart with foot closest to bed in front of other foot (see illustration).	Increases balance and allows transfer of body weight as you move patient to a sitting position.
(5) Place arm nearer head of bed under patient's shoulders, supporting head and cervical vertebrae.	Maintains alignment of head and cervical vertebrae and allows for even lifting of patient's trunk.

STEP 1b(1) Side-lying position.

STEP 1b(4) Proper foot placement.

STEP	RATIONALE
 **STEP 1b(6)** Nurse places arm over patient's thighs.	 **STEP 1b(7)** Nurse shifts weight to rear leg and elevates patient.
(6) Place other arm over patient's thighs (see illustration).	Supports hip and prevents patient from falling backward during procedure.
(7) Move patient's lower legs and feet over side of bed. Pivot toward rear leg, allowing patient's upper legs to swing downward. At same time shift weight to back leg and elevate patient (see illustration).	Decreases friction and resistance. Weight of patient's legs when off bed allows gravity to lower legs, and weight of legs assists in pulling upper body in sitting position.
c. Transferring cooperative patient who is partially weight bearing from bed to chair:	
CLINICAL DECISION: *Allow patient to transfer independently if able to fully bear weight. Stand by as needed to promote safe transfer (Nelson et al., 2009).*	
(1) Assist patient to sitting position on side of bed (see Step 1b). Have chair placed next to bed at a 45-degree angle on patient's strong side. Allow patient to sit on side of bed (dangling) for a few minutes before transferring. Ask if patient feels dizzy. Do not leave unattended while dangling.	Positions chair within easy access for transfer. Placing chair on patient's stronger side allows patient to help with transferring. Dangling helps equilibrate blood pressure, reducing risk for dizziness or fainting when standing.
(2) Apply transfer belt or other transfer aids.	Transfer belt maintains stability of patient during transfer and reduces risk for falling (Nelson et al., 2009). Patient's arm needs to be in sling if flaccid paralysis is present.
(3) Ensure that patient has stable nonskid shoes. Weight-bearing or strong leg is forward, with weak foot back.	Nonskid soles decrease risk of slipping during transfer. Always have patient wear shoes during transfer; bare feet increase risk of falls. Patient stands on stronger, or weight-bearing, leg.
(4) Spread feet apart.	Ensures balance with wide base of support.
(5) Flex hips and knees, aligning knees with patient's knees (see illustration).	Flexing knees and hips lowers center of gravity to object to be raised; aligning knees with those of patient allows for stabilization of knees when patient stands.
(6) Grasp transfer belt from underneath along patient's sides.	Provides movement of patient at center of gravity. Never lift patients with upper-extremity paralysis or paresis by or under arms (Nelson et al., 2009).
CLINICAL DECISION: *Use a transfer belt or walking belt with handles in place of the under-axilla technique. The under-axilla technique is physically stressful for nurses and uncomfortable for patients (Owens et al., 1999).*	
(7) Rock patient up to standing position on count of 3 while straightening hips and legs and keeping knees slightly flexed (see illustration). Unless contraindicated, instruct patient to use hands to push up if applicable.	Rocking motion gives patient's body momentum and requires less muscular effort to lift patient.
(8) Maintain stability of patient's weak or paralyzed leg with knee.	Often patient maintains ability to stand on paralyzed or weak limb with support of knee to stabilize (Pierson and Fairchild, 2008).
(9) Pivot on foot farther from chair.	Maintains support of patient while allowing adequate space for patient to move.
(10) Instruct patient to use armrests on chair for support and ease into chair (see illustration).	Increases patient stability.
(11) Flex hips and knees while lowering patient into chair (see illustration).	Prevents injury to nurse from poor body mechanics.

SKILL 47-2 USING SAFE AND EFFECTIVE TRANSFER TECHNIQUES—cont'd

STEP	RATIONALE

STEP 1c(5) Nurse flexes hips and knees, aligning knees with patient's knees.

STEP 1c(7) Nurse rocks patient to standing position.

STEP 1c(10) Patient uses armrests for support.

STEP 1c(11) Nurse eases patient into chair.

(12) Assess patient for proper alignment for sitting position. Provide support for paralyzed extremities. Lapboard or sling supports flaccid arm. Stabilize leg with bath blanket or pillow.	Prevent injury to patient from poor body alignment.
(13) Praise patient's progress, effort, or performance.	Continued support and encouragement provide incentive for patient perseverance.
d. Using mechanical lift and full body sling to transfer uncooperative patient who can bear partial weight or patient who cannot bear weight and is either uncooperative or does not have upper body strength to move from bed to chair:	
(1) Position lift properly at bedside.	Ensures safe elevation of patient off bed. (Before using lift, be thoroughly familiar with its operation.)
(2) Position chair near bed and allow adequate space to maneuver lift.	Prepares environment for safe use of lift and subsequent transfer.

STEP	RATIONALE
(3) Raise bed to high position with mattress flat. Lower side rail.	Maintains nurses' alignment during transfer.
(4) Keep side rail up on the side opposite from you.	Maintains patient safety.
(5) Roll patient away from you.	Positions patient for use of lift sling.
(6) Place sling under patient. Place lower edge under patient's knees (wide piece) and upper edge under patient's shoulders (narrow piece).	Allows positioning of patient on mechanical/hydraulic sling. Places sling under patient's center of gravity and greatest portion of body weight.
(7) Roll patient to opposite side and pull body sling through.	Completes positioning of patient on mechanical/hydraulic sling.
(8) Roll patient supine onto canvas seat.	Sling needs to extend from shoulders to knees (hammock) to support patient's body weight equally.
(9) Remove patient's glasses if appropriate.	Swivel bar is close to patient's head and can break eyeglasses.
(10) If using a transportable Hoyer lift, place horseshoe-shaped base of lift under side of bed (on side with chair).	Positions lift efficiently and promotes smooth transfer.
(11) Lower upper horizontal bar to sling level following manufacturer directions. Some lifts require valve to be locked.	Positions lift close to patient. Locking valve prevents injury to patient.
(12) Attach hooks on strap to holes in sling. Short straps hook to top holes of sling; longer straps hook to bottom of sling.	Secures hydraulic lift to sling.
(13) Elevate head of bed.	Positions patient in sitting position.
(14) Fold patient's arms over chest.	Prevents injury to paralyzed arms.
(15) Use lift to raise patient off bed (see illustration).	Moves patient off bed.
(16) Use steering handle to pull lift from bed and maneuver to chair.	Moves patient from bed to chair.
(17) Move lift to chair.	Positions lift in front of chair.
(18) Position patient and lower slowly into chair following manufacturer guidelines (see illustration).	Safely guides patient into back of chair as seat descends.
(19) Remove straps and mechanical/hydraulic lift.	Prevents damage to skin and underlying tissues from canvas or hooks.
(20) Check patient's sitting alignment and correct if necessary.	Prevents injury from poor posture.
e. Transferring patient from bed to stretcher (bed at stretcher level):	
(1) Raise bed to height of stretcher.	Bed and stretcher need to be at same level to allow patient to slide from bed to stretcher.
(2) Lower head of bed as much as patient can tolerate. Cross patient's arms on chest. Ensure that bed brakes are locked.	Prevents injury to arms during transfer.
(3) Lower side rails. Two caregivers stand on the side where the stretcher will be; third caregiver stands on other side.	Minimizes caregivers' stretching. Prevents patient from falling out of bed and promotes safety.
(4) Two caregivers help patient roll onto side toward them (use of drawsheet is optional) with smooth, continuous motion.	Positions patient for placing friction-reducing lateral transfer device.
(5) Place slide board under drawsheet or follow manufacturer guidelines (see illustrations). Gently roll patient back onto slide board.	Patient needs to be placed on transfer device properly to allow safe transfer.
(6) Align stretcher along side of bed. Lock wheels of stretcher once it is in place. Instruct patient not to move.	Positions stretcher in correct position for transfer and prevents patient from falling out of bed.
(7) All three caregivers place feet widely apart with one slightly in front of the other and grasp friction-reducing device.	Prepares for transfer. Wide base of support allows nurse to shift weight and minimizes back strain.
(8) On count of three, two caregivers pull drawsheet or patient from bed onto stretcher while third person holds slide board in place. Using friction-reducing device, shift weight from front to back foot (see illustration). Position patient in center of stretcher.	Transfers patient smoothly and efficiently to the stretcher.

STEP 1d(15) Use mechanical lift to raise patient off bed.

STEP 1d(18) Use mechanical lift to lower patient into chair.

SKILL 47-2 USING SAFE AND EFFECTIVE TRANSFER TECHNIQUES—cont'd

STEP	RATIONALE

STEP 1e(5) **A,** Two caregivers position sliding board under patient. **B,** Two caregivers place air-assisted device under patient. **C,** Patient rolls to opposite side while other caregiver unrolls air-assisted device. **D,** Secure safety straps.

STEP 1e(8) **A,** Transfer of patient from bed to stretcher using sliding board. **B,** Inflating air-assisted transfer device. **C,** Transfer of patient using air-assisted transfer device.

(9)	Put up side rail of stretcher on side where caregivers are, roll stretcher away from side of bed, and put side rail up on that side.	Side rails prevent patient from falling off stretcher.
(10)	Cover patient with sheet or blanket.	Promotes comfort and preserves patient dignity.
(11)	Perform hand hygiene.	Reduces transmission of microorganisms.
(12)	Following transfer, evaluate patient's body alignment.	Prompt identification of poor alignment reduces risks to patient's skin and musculoskeletal systems.
2	Perform hand hygiene.	Reduces transmission of microorganisms.

STEP	RATIONALE
EVALUATION	
1 Evaluate vital signs. Ask if patient feels fatigued.	Evaluates patient's response to postural changes and activity.
2 Observe for correct body alignment and presence of pressure points on skin.	Minimizes risk for immobility complications.
3 Ask if patient experienced pain during transfer.	Determines need for additional pain control or alteration of technique of transferring.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient sustains injury on transfer.
- Evaluate incident that caused injury (e.g., assessment inadequate, change in patient status, improper use of equipment).
- Complete occurrence report according to institution policy.

2 Patient's level of weakness does not permit active transfer.
- Obtain assistance from additional nursing personnel.
- Increase bed activity and exercise to heighten tolerance.

3 Patient continues to bear weight on non–weight-bearing limb.
- Reinforce information about weight-bearing status.

4 Patient transfers well on some occasions, poorly on others.
- Assess patient for factors that affect ability to transfer (e.g., pain, fatigue, confusion) before transfer.
- Allow for a rest period before transferring, medicate for pain if indicated, or reorient patient.

RECORDING AND REPORTING

- Record procedure, including pertinent observations: weakness, ability to follow directions, weight-bearing ability, balance, ability to pivot, number of personnel needed to assist, and amount of assistance (muscle strength) required in nurses' notes.
- Report any unusual occurrence to nurse in charge. Report transfer ability and assistance needed to next shift or other caregivers. Report progress or transfer difficulties to rehabilitation staff (physical therapist or occupational therapist).

HOME CARE CONSIDERATIONS

- Teach family members about safe patient handling and how to use equipment properly. Observe return demonstration of use of equipment.
- Ensure that families have access to appropriate equipment (e.g., transfer belts, mechanical lifts) at home to assist in safe transfer techniques.

KEY POINTS

- Body mechanics are the coordinated efforts of the musculoskeletal and nervous systems as the person moves, lifts, bends, stands, sits, lies down, and completes daily activities.
- Use findings from evidence-based nursing research about safe patient handling to prevent injuries to nurses and patients when moving and transferring.
- Coordination and regulation of muscle groups depend on muscle tone; activity of antagonistic, synergistic, and antigravity muscles; and neural input to muscles.
- Body alignment is the condition of joints, tendons, ligaments, and muscles in various body positions.
- Balance occurs when there is a wide base of support, the center of gravity falls within the base of support, and a vertical line falls from the center of gravity through the base of support.
- Developmental stages influence body alignment and mobility; the greatest impact of physiological changes on the musculoskeletal system is observed in children and older adults.
- The risk of disabilities related to immobilization depends on the extent and duration of immobilization and the patient's overall level of health.
- Immobility presents hazards in the physiological, psychological, and developmental dimensions.
- The nursing process and critical thinking assist in providing care for patients who are experiencing or are at risk for the adverse effects of impaired body alignment and immobility.
- Patients with impaired body alignment require nursing care to maintain correct positioning such as the supported Fowler's, supine, prone, side-lying, and Sims' positions.
- Patient movement algorithms serve as assessment tools and guide safe patient handling and movement.
- Appropriate friction-reducing assistive devices and mechanical lifts need to be used for patient transfers when applicable.
- No-lift policies benefit all members of the health care system: patients, nurses, and administration.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Ms. Cavallo, 97 years of age, has been a resident at the rehabilitation unit for 6 weeks. She has been receiving rehabilitation therapy following the repair of her fractured left hip. The nursing assistive personnel (NAP) tells you that Ms. Cavallo has not been finishing her meals over the past 2 days because of poor appetite. As you enter her room today, she states, "Go away. I'm tired of all of this, and I just want to stay in bed today." You explore why she feels this way. You discover that she is unsure how to use her walker and feels safer in bed. She states, "I'm still afraid that I'm going to fall because I keep forgetting how to use my walker, and I can't fall if I stay in bed, right?"

1. On the basis of these data, you develop a nursing diagnosis of *deficient knowledge* (use of walker and effects of immobility) *related to lack of recall*. Identify one goal, two expected

outcomes, and three related nursing interventions with rationales that will help her meet the identified goal and outcomes.
2. You finish teaching Ms. Cavallo about the hazards of immobility, and you begin your morning assessment. As you are assessing her skin, you notice that she has a 2-cm (0.79-inch) reddened area on her coccyx. The skin in this area is intact, and you find no other reddened areas anywhere else.
   a. How would you document this finding?
   b. Which risk factors contribute to this finding?
3. You convince Ms. Cavallo to get out of bed and sit in her chair for 30 minutes. Describe the decision-making process you use to determine the safest way to transfer her. Include essential assessment data that you need before transferring her into her chair.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. An older adult has limited mobility as a result of a surgical repair of a fracture hip. During assessment you note that the patient cannot tolerate lying flat. Which of the following assessment data support a possible pulmonary problem related to impaired mobility? (Select all that apply.)
   1. B/P = 128/84
   2. Respirations 26 per minute on room air
   3. HR 114
   4. Crackles heard on auscultation
   5. Pain reported as 3 on scale of 0 to 10 after medication
2. A patient has her call bell on and looks frightened when you enter the room. She has been on bed rest for 3 days following a fractured femur. She says, "It hurts when I try to breathe, and I can't catch my breath." Your first action is to:
   1. Call the health care provider to report this change in condition.
   2. Give the patient a paper bag to breathe into to decrease her anxiety.
   3. Assess her vital signs, perform a respiratory assessment, and be prepared to start oxygen.
   4. Explain that this is normal after such trauma and administer the ordered pain medication.
3. The nurse puts elastic stockings on a patient following major abdominal surgery. The nurse teaches the patient that the stockings are used after a surgical procedure to:
   1. Prevent varicose veins.
   2. Prevent muscular atrophy.
   3. Ensure joint mobility and prevent contractures.
   4. Promote venous return to the heart.
4. A nurse is teaching a community group about ways to minimize the risk of developing osteoporosis. Which of the following statements made by a woman in the audience reflects a need for further education?
   1. "I usually go swimming with my family at the YMCA 3 times a week."
   2. "I need to ask my doctor if I should have a bone mineral density check this year."
   3. "If I don't drink milk at dinner, I'll eat broccoli or cabbage to get the calcium that I need in my diet."
   4. "I'll check the label of my multivitamin. If it has calcium, I can save money by not taking another pill."
5. The patient at greatest risk for developing multiple adverse effects of immobility is a:
   1. 1-year-old child with a hernia repair.
   2. 80-year-old woman who has suffered a hemorrhagic cerebrovascular accident (CVA).
   3. 51-year-old woman following a thyroidectomy.
   4. 38-year-old woman undergoing a hysterectomy.
6. An older adult who was in a car accident and fractured his femur has been immobilized for 5 days. Which nursing diagnosis is related to patient safety when the nurse assists this patient out of bed for the first time?
   1. Chronic pain
   2. Impaired skin integrity
   3. Risk for ineffective cerebral tissue perfusion
   4. Risk for activity intolerance
7. A patient had a left-sided cerebrovascular accident 3 days ago and is receiving 5000 units of heparin subcutaneously every 12 hours to prevent thrombophlebitis. The patient is receiving enteral feedings through a small-bore nasogastric (NG) tube because of dysphagia. Which of the following symptoms requires the nurse to call the health care provider immediately?
   1. Pale yellow urine
   2. Unilateral neglect
   3. Slight movement noted on the R side
   4. Coffee ground–like aspirate from the feeding tube
8. A home care nurse is preparing the home for a patient who is discharged to home following a left-sided stroke. The patient is cooperative and can ambulate with a quad-cane. Which of the following must be corrected or removed for the patient's safety? (Select all that apply.)
   1. The rubber mat in the walk-in shower
   2. The three-legged stool on wheels in the kitchen
   3. The braided throw rugs in the entry hallway and between the bedroom and bathroom
   4. The night-lights in the hallways, bedroom, and bathroom
   5. The cordless phone next to the patient's bed
9. The nurse is caring for a patient whose calcium intake must increase because of high risk factors for osteoporosis. The nurse would recommend which of the following menus?
   1. Cream of broccoli soup with whole wheat crackers and tapioca for dessert
   2. Hamburger on soft roll with a side salad and an apple for dessert
   3. Low-fat turkey chili with sour cream and fresh pears for dessert
   4. Chicken salad on toast with tomato and lettuce and honey bun for dessert
10. Before transferring a patient from the bed to a stretcher, which assessment data does the nurse need to gather? (Select all that apply.)
    1. Patient's weight
    2. Patient's level of cooperation
    3. Patient's ability to assist
    4. Presence of medical equipment
    5. 24-hour calorie intake
11. A patient of any age can develop a contracture of a joint when:
    1. The adductors muscles are weakened as a result of immobility.
    2. The muscle fibers become shortened because of disuse.
    3. The calcium-to-phosphorus ratio becomes disrupted.
    4. There is a deficiency in vitamin D.

12. Immobilized patients are at risk for impaired skin integrity. Which of the following interventions would reduce this risk? (Select all that apply.)
    1. Repositioning patient every 1 to 2 hours while awake
    2. Using an objective, valid scale to assess patient's risk for pressure ulcer development
    3. Using a device to relieve pressure when patient is seated in chair
    4. Teaching patient how to shift weight at regular intervals while sitting in a chair
    5. A good rule is: the higher the risk for skin breakdown, the shorter the interval between position changes
13. Which of the following indicates that additional assistance is needed to transfer the patient from the bed to the stretcher?
    1. The patient is 5 feet 6 inches and weighs 120 lbs.
    2. The patient speaks and understands English.
    3. The patient received an injection of morphine 30 minutes ago for pain.
    4. You feel comfortable handling a patient of his size and with his level of cooperation.
14. A patient with left-sided weakness asks his nurse, "Why are you walking on my left side? I can hold on to you better with my right hand." What would be your best therapeutic response?
    1. "Walking on your left side lets me use my right hand to hold on to your arm. In case you start to fall, I can still hold you."
    2. " Would you like me to walk on your right side so you feel more secure?"
    3. "Either side is appropriate, but I prefer the left side. If you like, I can have another nurse walk with you who will hold you on the right side."
    4. "By walking on your left side I can support you and help keep you from injury if you should start to fall. By holding your waist I would protect your shoulder if you should start to fall or faint.
15. Which is an outcome for a patient diagnosed with osteoporosis?
    1. Maintain serum level of calcium.
    2. Maintain independence with activities of daily living (ADLs).
    3. Reduce supplemental sources of vitamin D.
    4. Reverse bone loss through dietary manipulation.

Answers: **1.** 2, 3, 4; **2.** 3; **3.** 4; **4.** 4; **5.** 2; **6.** 4; **7.** 4; **8.** 2, 3; **9.** 1; **10.** 1, 2, 3, 4; **11.** 2; **12.** 2, 3, 4, 5; **13.** 3; **14.** 4; **15.** 2.

CHAPTER

48

Skin Integrity and Wound Care

OBJECTIVES

- Discuss the risk factors that contribute to pressure ulcer formation.
- Describe the pressure ulcer staging system.
- Discuss the normal process of wound healing.
- Describe the differences of wound healing by primary and secondary intention.
- Describe complications of wound healing.
- Explain the factors that impede or promote wound healing.
- Describe the differences between nursing care of acute and chronic wounds.
- Complete an assessment for a patient with impaired skin integrity.
- List nursing diagnoses associated with impaired skin integrity.
- Develop a nursing care plan for a patient with impaired skin integrity.
- List appropriate nursing interventions for a patient with impaired skin integrity.
- State evaluation criteria for a patient with impaired skin integrity.

Skin, the largest organ in the body, constitutes 15% of the total adult body weight (Wysocki, 2012). It is a protective barrier against disease-causing organisms and a sensory organ for pain, temperature, and touch; and it synthesizes vitamin D. Injury to the skin poses risks to safety and triggers a complex healing response. A nurse's most important responsibilities include assessing and monitoring skin integrity; identifying problems; and planning, implementing, and evaluating interventions to maintain skin integrity. Once a wound occurs, it is critical to know the process of normal wound healing to identify the appropriate nursing interventions.

SCIENTIFIC KNOWLEDGE BASE

Skin

The skin has two layers: the epidermis and the dermis (Fig. 48-1). They are separated by a membrane, often referred to as the *dermal-epidermal junction*. The epidermis, or the top layer, has several layers. The stratum corneum is the thin, outermost layer of the epidermis. It consists of flattened, dead, keratinized cells. The cells originate from the innermost epidermal layer, commonly called the *basal layer*. Cells in the basal layer divide, proliferate, and migrate toward the epidermal surface. After they reach the stratum corneum, they flatten and die. This constant movement ensures replacement of surface cells sloughed during normal desquamation or shedding. The thin stratum corneum protects underlying cells and tissues from dehydration and prevents entrance of certain chemical agents. The stratum corneum allows evaporation of water from the skin and permits absorption of certain topical medications.

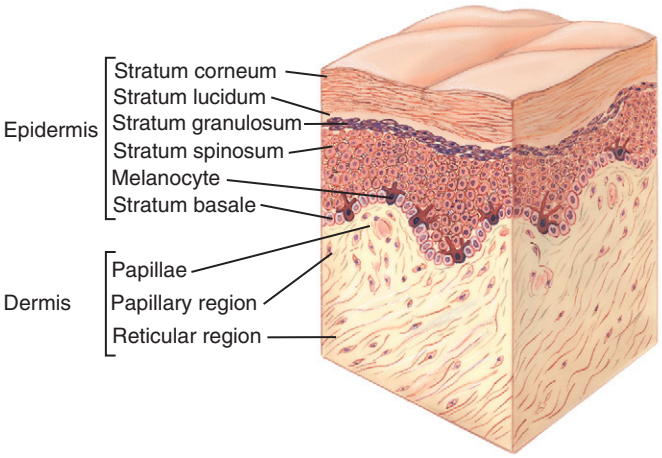

FIG. 48-1 Layers of skin. (From Applegate E: *The anatomy and physiology learning system*, ed 3, St Louis, 2006, Saunders.)

FIG. 48-2 Pressure ulcer with tissue necrosis.

BOX 48-1 FOCUS ON OLDER ADULTS

Skin-Associated Issues

- Age-related changes such as reduced skin elasticity, decreased collagen, and thinning of underlying muscle and tissues cause the older adult's skin to be easily torn in response to mechanical trauma, especially shearing forces (Wysocki, 2012).
- Concomitant medical conditions and polypharmacy, which are common in the older adult, are factors that interfere with wound healing.
- The attachment between the epidermis and dermis becomes flattened in older adults, allowing the skin to be easily torn in response to mechanical trauma (e.g., tape removal).
- Aging causes a diminished inflammatory response, resulting in slow epithelialization and wound healing (Doughty and Sparks-Defriese, 2012).
- The hypodermis decreases in size with age. Older patients have little subcutaneous padding over bony prominences; thus they are more prone to skin breakdown (Wysocki, 2012).
- An identified risk factor for the development of pressure ulcers is malnutrition (Posthauer and Thomas, 2008).

The dermis, the inner layer of the skin, provides tensile strength, mechanical support, and protection to the underlying muscles, bones, and organs. It differs from the epidermis in that it contains mostly connective tissue and few skin cells. **Collagen** (a tough, fibrous protein), blood vessels, and nerves are found in the dermal layer. Fibroblasts, which are responsible for collagen formation, are the only distinctive cell type within the dermis.

Understanding skin structure helps you maintain skin integrity and promote wound healing. Intact skin protects the patient from chemical and mechanical injury. When the skin is injured, the epidermis functions to resurface the wound and restore the barrier against invading organisms while the dermis responds to restore the structural integrity (collagen) and the physical properties of the skin. The normal aging process alters skin characteristics and makes skin more vulnerable to damage. Box 48-1 provides a summary of the changes in aging skin.

Pressure Ulcers

Pressure ulcer, pressure sore, decubitus ulcer, and *bedsore* are terms used to describe impaired skin integrity related to unrelieved, prolonged pressure. The most current terminology is **pressure ulcer** (Fig. 48-2), which is consistent with the recommendations of the pressure ulcer guidelines written by the Wound, Ostomy and Continence Nurses Society (WOCN, 2010). A pressure ulcer is localized injury to the skin and other underlying tissue, usually over a body prominence, as a result of pressure or pressure in combination with shear and/or friction. A number of contributing factors are also associated with pressure ulcers; the significance of these factors is yet to be elucidated (EPUAP and NPUAP, 2009). Any patient experiencing decreased mobility, decreased sensory perception, fecal or urinary incontinence, and/or poor nutrition is at risk for pressure ulcer development.

Many factors contribute to the formation of a pressure ulcer. Pressure is the major cause. Tissues receive oxygen and nutrients and eliminate metabolic wastes via the blood. Any factor that interferes with blood flow in turn interferes with cellular metabolism and the function or life of the cells. Prolonged, intense pressure affects cellular metabolism by decreasing or obliterating blood flow, resulting in tissue ischemia and ultimately tissue death.

Pathogenesis of Pressure Ulcers. Pressure is the major element in the cause of pressure ulcers. Three pressure-related factors contribute to pressure ulcer development: (1) pressure intensity, (2) pressure duration, and (3) tissue tolerance.

Pressure Intensity. A classic research study identified capillary closing pressure as the minimal amount of pressure required to collapse a capillary (e.g., when the pressure exceeds the normal capillary pressure range of 15 to 32 mm Hg) (Burton and Yamada, 1951). Therefore, if the pressure applied over a capillary exceeds the normal capillary pressure and the vessel is occluded for a prolonged period of time, **tissue ischemia** can occur. If the patient has reduced sensation and cannot respond to the discomfort of the ischemia, tissue ischemia and tissue death result.

The clinical presentation of obstructed blood flow occurs when evaluating areas of pressure. After a period of tissue ischemia, if the pressure is relieved and the blood flow returns, the skin turns red. The effect of this redness is vasodilation (blood vessel expansion), called *hyperemia* (redness). Evaluate an area of hyperemia by pressing a finger over the affected area. If it blanches (turns lighter in color) and the erythema returns when you remove your finger, the hyperemia is transient and is an attempt to overcome the ischemic episode, thus called *blanching hyperemia* (Pieper, 2012). However, if the erythematous area does not blanch (nonblanching erythema) when you apply pressure, deep tissue damage is probable.

Blanching occurs when the normal red tones of the light-skinned patient are absent. It does not occur in patients with darkly

BOX 48-2 CHARACTERISTICS OF DARK SKIN WITH IMPAIRED INTEGRITY

Color
- Color remains unchanged when pressure is applied.
- If patient previously has a pressure ulcer, that area of skin may be lighter than original color.

Temperature
- Circumscribed area of intact skin may be warm to touch. As tissue changes color, intact skin feels cool to touch.
- Inflammation is detected by making comparisons to surrounding skin.

Appearance
- Edema may occur with induration and appear taut and shiny.
- Localized area of skin may be purple/blue or violet instead of red.

Adapted from Nix DP: Skin and wound inspection and assessment. In Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts*, ed 4, St Louis, 2012, Mosby.

pigmented skin. The Task Force on the Implications for Darkly Pigmented Intact Skin in the Prediction and Prevention of Pressure Ulcers (Bennett, 1995) defined darkly pigmented skin as skin that "remains unchanged (does not blanch) when pressure is applied over a bony prominence, irrespective of the patient's race or ethnicity." Characteristics of intact dark skin that alert nurses to the potential for pressure ulcers are in Box 48-2.

Pressure Duration. Low pressure over a prolonged period and high-intensity pressure over a short period are two concerns related to duration of pressure. Both types of pressure cause tissue damage. Extended pressure occludes blood flow and nutrients and contributes to cell death (Pieper, 2012). Clinical implications of pressure duration include evaluating the amount of pressure (checking skin for reactive hyperemia) and determining the amount of time that a patient tolerates pressure (checking to be sure after relieving pressure that the affected area blanches).

Tissue Tolerance. The ability of tissue to endure pressure depends on the integrity of the tissue and the supporting structures. The extrinsic factors of shear, friction, and moisture affect the ability of the skin to tolerate pressure: the greater the degree to which the factors of shear, friction, and moisture are present, the more susceptible the skin will be to damage from pressure. The second factor related to tissue tolerance is the ability of the underlying skin structures (blood vessels, collagen) to assist in redistributing pressure. Systemic factors such as poor nutrition, increased aging, hydration status, and low blood pressure affect the tolerance of the tissue to externally applied pressure.

Risk Factors for Pressure Ulcer Development. A variety of factors predispose a patient to pressure ulcer formation. These factors are often directly related to disease such as decreased level of consciousness, the presence of a cast, or secondary to an illness (e.g., decreased sensation following a cerebrovascular accident).

Impaired Sensory Perception. Patients with altered sensory perception for pain and pressure are more at risk for impaired skin integrity than those with normal sensation. Patients with impaired sensory perception of pain and pressure are unable to feel when a portion of their body undergoes increased, prolonged pressure or pain. Thus the patient who can't feel or sense that there is pain or pressure is at risk for the development of pressure ulcers.

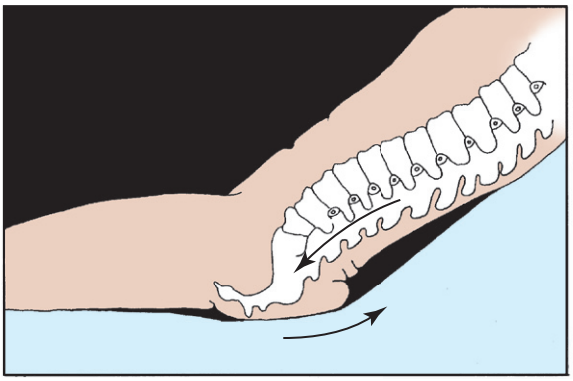

FIG. 48-3 Shear exerted in sacral area.

Impaired Mobility. Patients unable to independently change positions are at risk for pressure ulcer development. For example, patients with spinal cord injuries have decreased or absent motor and sensory impairment and are unable to reposition off bony prominences.

Alteration in Level of Consciousness. Patients who are confused or disoriented and those who have expressive aphasia or other inability to verbalize or changing levels of consciousness are unable to protect themselves from pressure ulcer development. Patients who are confused or disoriented are sometimes able to feel pressure but are not always able to understand how to relieve it or communicate their discomfort. Patients in a coma cannot perceive pressure and are unable to move voluntarily to relieve pressure.

Shear. Shear force is the sliding movement of skin and subcutaneous tissue while the underlying muscle and bone are stationary (Bryant, 2012). For example, shear force occurs when the head of the bed is elevated and the sliding of the skeleton starts but the skin is fixed because of friction with the bed (Fig. 48-3). It also occurs when transferring a patient from bed to stretcher and the patient's skin is pulled across the bed. When shear is present, the skin and subcutaneous layers adhere to the surface of the bed, and the layers of muscle and the bones slide in the direction of body movement. The underlying tissue capillaries are stretched and angulated by the shear force. As a result, necrosis occurs deep within the tissue layers. The tissue damage occurs deep in the tissues, causing undermining of the dermis.

Friction. The force of two surfaces moving across one another such as the mechanical force exerted when skin is dragged across a coarse surface such as bed linens is called **friction** (WOCN, 2010). Unlike shear injuries, friction injuries affect the epidermis or top layer of the skin. The denuded skin appears red and painful and is sometimes referred to as a "sheet burn." A friction injury occurs in patients who are restless, in those who have uncontrollable movements such as spastic conditions, and in those whose skin is dragged rather than lifted from the bed surface during position changes.

Moisture. The presence and duration of moisture on the skin increases the risk of ulcer formation. Moisture reduces the resistance of the skin to other physical factors such as pressure and/or shear force. Prolonged moisture softens skin, making it more susceptible to damage. Immobilized patients who are unable to perform their own hygiene needs depend on the nurse to keep the skin dry and intact. Skin moisture originates from wound drainage, excessive perspiration, and fecal or urinary incontinence.

Classification of Pressure Ulcers

You need to assess pressure ulcers at regular intervals using systematic parameters to evaluate wound healing, plan appropriate interventions, and evaluate progress. Assessment includes depth of tissue involvement (staging), type and approximate percentage of tissue in wound bed, wound dimensions, exudate description, and condition of surrounding skin.

One method for assessment of a pressure ulcer is the use of a staging system. Staging systems for pressure ulcers are based on describing the depth of tissue destroyed. Accurate staging requires knowledge of the skin layers. A major drawback of a staging system is that you cannot stage an ulcer covered with necrotic tissue because the necrotic tissue is covering the depth of the ulcer. The necrotic tissue must be debrided or removed to expose the wound base to allow for assessment.

Pressure ulcer staging describes the pressure ulcer depth at the point of assessment. Thus, once you have staged the pressure ulcer, this stage endures even as it heals. Pressure ulcers do not progress from a stage III to a stage I; rather, a stage III ulcer demonstrating signs of healing is described as a healing stage III pressure ulcer (Pieper, 2012). The EPUAP and NPUAP have developed clinical practice guidelines for pressure ulcers and have advanced the following classification/staging system (EPUAP and NPUAP, 2009):

Stage I: Nonblanchable Redness of Intact Skin. Intact skin presents with nonblanchable erythema of a localized area usually over a bony prominence. Discoloration of the skin, warmth, edema, hardness, or pain may also be present. Darkly pigmented skin may not have visible blanching.

Further description: The area may be painful, firm, soft, warmer, or cooler than adjacent tissue. Stage I may be difficult to detect in individuals with dark skin tones. It may indicate "at-risk" persons (Fig. 48-4, *A*).

Stage II: Partial-thickness Skin Loss or Blister. A partial-thickness loss of dermis presents as a shallow open ulcer with a red-pink wound bed without slough. It may also present as an intact or open/ruptured serum-filled or serosangineous filled blister.

Further description: Stage II presents as a shiny or dry shallow ulcer without slough or bruising. This stage should not be used to describe skin tears, tape burns, incontinence-associated dermatitis, maceration, or excoriation (Fig. 48-4, *B*).

Stage III: Full-thickness Skin Loss (Fat Visible). A stage III ulcer is a full-thickness tissue loss. Subcutaneous fat may be visible; but bone, tendon, or muscle is *not* exposed. Some slough may be present. It *may* include undermining and tunneling.

Further description: The depth of a stage III pressure ulcer varies by anatomical location. The bridge of the nose, ear, occiput, and malleolus do not have (adipose) subcutaneous tissue; and stage III ulcers can be shallow. In contrast, areas of significant adiposity can develop extremely deep stage III pressure ulcers. Bone/tendon is not visible or directly palpable (Fig. 48-4, *C*).

Stage IV: Full-thickness Tissue Loss (Muscle/Bone Visible). A stage IV ulcer is a full-thickness tissue loss with exposed bone, tendon, or muscle. Slough or eschar may be present. It often includes undermining and tunneling.

Further description: The depth of a stage IV pressure ulcer varies by anatomical location. The bridge of the nose, ear, occiput, and malleolus do not have (adipose) subcutaneous tissue; and these ulcers can be shallow. Stage IV ulcers can extend into muscle and/or supporting structures (e.g., fascia, tendon, or joint capsule), making osteomyelitis or osteitis likely to occur. Exposed bone/muscle is visible or directly palpable (Fig. 48-4, *D*).

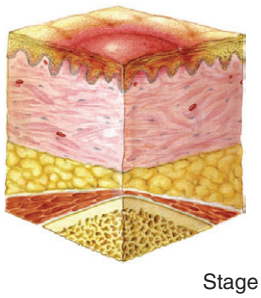
Unstageable/Unclassified: Full-thickness Skin or Tissue Loss—Depth Unknown. The EPUAP and the NPUAP (2009) developed a definition for an ulcer in which the base of the wound cannot be visualized and a definition of tissue injury in which the depth of injury is unknown. An unstageable ulcer is a full-thickness tissue loss in which actual depth of the ulcer is completely obscured by slough (yellow, tan, gray, green, or brown) and/or eschar (tan, brown, or black) in the wound bed (Fig. 48-4, *E*).

Further description: Until enough slough and/or eschar are removed to expose the base of the wound, the true depth cannot be determined; but it is either a stage III or IV. Stable (dry, adherent, intact without erythema or fluctuance) eschar on the heels serves as "the natural (biological) cover of the body" and should not be removed.

Suspected Deep-Tissue Injury—Depth Unknown. Suspected deep-tissue injury is a purple or maroon localized area of discolored intact skin or blood-filled blister caused by damage of underlying soft tissue from pressure and/or shear (Fig. 48-4, *F*).

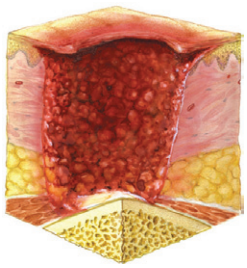
Further description: The area may be preceded by tissue that is painful, firm, mushy, boggy, warmer, or cooler than adjacent tissue. Deep-tissue injury may be difficult to detect in individuals with dark skin tones. Evolution may include a thin blister over a dark wound bed. The wound may further evolve and become covered by thin eschar. Evolution may be rapid, exposing additional layers of tissue even with treatment.

In addition, Bennett (1995) suggests that, when assessing patients with darkly pigmented skin, proper lighting is important to accurately assess the skin (see Box 48-2). Either natural light or a halogen light is recommended. This prevents the blue tones that fluorescent light sources produce on darkly pigmented skin, which interferes with accurate assessment. Additional aspects of assessing dark skin are in Box 48-3.



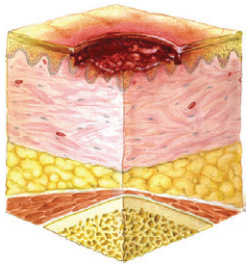
BOX 48-3 CULTURAL ASPECTS OF CARE

Skin Color Impact



Detecting cyanosis and other changes in skin color in patients is an important clinical skill. However, this detection becomes a challenge in dark-skinned patients (Nix, 2012; Rajendran et al, 2006). There are concerns about the inability of practitioners to describe accurately early pressure ulcer or pressure injury in people with darkly pigmented skin (Henderson et al., 1997). Cyanosis is "a slightly bluish-grayish slatelike or dark purple discoloration of the skin caused by the presence of at least 5 g of reduced hemoglobin in arterial blood." Color differentiation of cyanosis varies according to skin pigmentation. In dark-skinned patients, you need to know the individual's baseline skin tone. You should not confuse the normal hyperpigmentation of Mongolian spots that are seen on the sacrum of African, Native American, and Asian patients with cyanosis. Observe the patient's skin in nonglare daylight. The Gaskin's Nursing Assessment of Skin Color (GNASC) is a useful tool for assessment for identifying changes in skin color that increase the patient's risk for pressure ulcers (Gaskin, 1986).

Implications for Practice



- It is difficult but possible to detect cyanosis in the dark-skinned patient.
- Be aware of situations that produce changes in skin tone such as inadequate lighting.
- Examine body sites with the least melanin such as under the arm for underlying color identification.
- Evaluate pigmented skin for color-specific changes in skin tone.

You need to assess the type of tissue in the wound base; this information is used to plan appropriate interventions. The assessment of tissue type includes the amount (percentage) and appearance (color) of viable and nonviable tissue. **Granulation tissue** is red, moist tissue composed of new blood vessels, the presence of which indicates progression toward healing. Soft yellow or white tissue is characteristic of **slough** (stringy substance attached to wound bed), and it must be removed by a skilled clinician before the wound is able to heal. Black or brown necrotic tissue is **eschar,** which also needs to be removed before healing can proceed.

The measurement of the size of the wound provides overall changes in size, which is an indicator for wound healing progress (Nix, 2012). Use disposable wound-measuring devices to obtain measurement of width and length. Select a uniform, consistent

TABLE 48-1 Wound Classification

DESCRIPTION	CAUSES	IMPLICATIONS FOR HEALING
Onset and Duration		
Acute		
Wound that proceeds through an orderly and timely reparative process that results in sustained restoration of anatomical and functional integrity	Trauma, a surgical incision	Wounds are usually easily cleaned and repaired. Wound edges are clean and intact.
Chronic		
Wound that fails to proceed through an orderly and timely process to produce anatomical and functional integrity	Vascular compromise, chronic inflammation, or repetitive insults to tissue (Doughty and Sparks-Defriese, 2012)	Continued exposure to insult impedes wound healing.
Healing Process		
Primary Intention		
Wound that is closed	Surgical incision, wound that is sutured or stapled	Healing occurs by epithelialization; heals quickly with minimal scar formation.
Secondary Intention		
Wound edges not approximated	Pressure ulcers, surgical wounds that have tissue loss	Wound heals by granulation tissue formation, wound contraction, and epithelialization.
Tertiary Intention		
Wound left open for several days, then wound edges are approximated (see Fig. 48-4,*C*)	Wounds that are contaminated and require observation for signs of inflammation	Closure of wound is delayed until risk of infection is resolved (Doughty and Sparks-Defriese, 2012).

method for measuring wound length and width to facilitate meaningful comparisons of wound measurements across time (EPUAP and NPUAP, 2009). Measure depth by using a cotton-tipped applicator in the wound bed.

Wound **exudate** should describe the amount, color, consistency, and odor of wound drainage and is part of the wound assessment. Excessive exudate indicates the presence of infection. Finally, assess the condition of the skin surrounding the wound for redness, warmth, maceration, or edema (swelling). The presence of any of these factors on the skin surrounding the wound indicates wound deterioration.

The skin around the wound (periwound) should be assessed. Examine the periwound area for redness, warmth, and signs of maceration and palpate the area for signs of pain or induration.

Wound Classifications

A **wound** is a disruption of the integrity and function of tissues in the body (Baharestani, 2008). It is imperative for the nurse to know that *all wounds are not created equal.* Understanding the etiology of a wound is important because the treatment for it varies, depending on the underlying disease process.

There are many ways to classify wounds. Wound classification systems describe the status of skin integrity, cause of the wound, severity or extent of tissue injury or damage, cleanliness of the wound (Table 48-1), or descriptive qualities of the wound tissue such as color (Fig. 48-5). Wound classifications enable a nurse to understand the risks associated with a wound and implications for healing.

Process of Wound Healing. Wound healing involves integrated physiological processes. The tissue layers involved and their capacity for regeneration determine the mechanism for repair for any wound (Doughty and Sparks-Defriese, 2012).

There are two types of wounds: those with loss of tissue and those without. A clean surgical incision is an example of a wound with little tissue loss. The surgical incision heals by **primary intention** (Fig. 48-6, *A*). The skin edges are **approximated,** or closed, and the risk of infection is low. Healing occurs quickly, with minimal scar formation, as long as infection and secondary breakdown are prevented (Doughty and Sparks-Defriese, 2012). In contrast, a wound involving loss of tissue such as a burn, pressure ulcer, or severe laceration heals by **secondary intention.** The wound is left open until it becomes filled by scar tissue. It takes longer for a wound to heal by secondary intention; thus the chance of infection is greater. If scarring from secondary intention is severe, loss of tissue function is often permanent (Fig. 48-6, *B*).

Wound Repair. Partial-thickness wounds are shallow wounds involving loss of the epidermis (top layer) and possibly partial loss of the dermis. These wounds heal by regeneration because epidermis regenerates. An example of this is the repair of a clean surgical wound or an abrasion. Full-thickness wounds extending into the dermis (involving both layers of tissue) heal by scar formation because deeper structures do not regenerate. Pressure ulcers are an example of full-thickness wounds.

Partial-Thickness Wound Repair. Three components are involved in the healing process of a partial-thickness wound: inflammatory response, epithelial proliferation (reproduction) and migration, and reestablishment of the epidermal layers.

Tissue trauma causes the *inflammatory response,* which in turn causes redness and swelling to the area with a moderate amount of serous exudate. This response is generally limited to the first 24 hours after wounding. The epithelial cells begin to regenerate, providing new cells to replace the lost cells. The *epithelial proliferation and migration* start at both the wound edges and the epidermal cells lining the epidermal appendages, allowing for quick resurfacing. Epithelial cells begin to migrate across the wound bed soon after the wound occurs. A wound left open to air can resurface within 6 to 7 days, whereas one that is kept moist can resurface in 4 days. The difference in the healing rate is related to the fact that

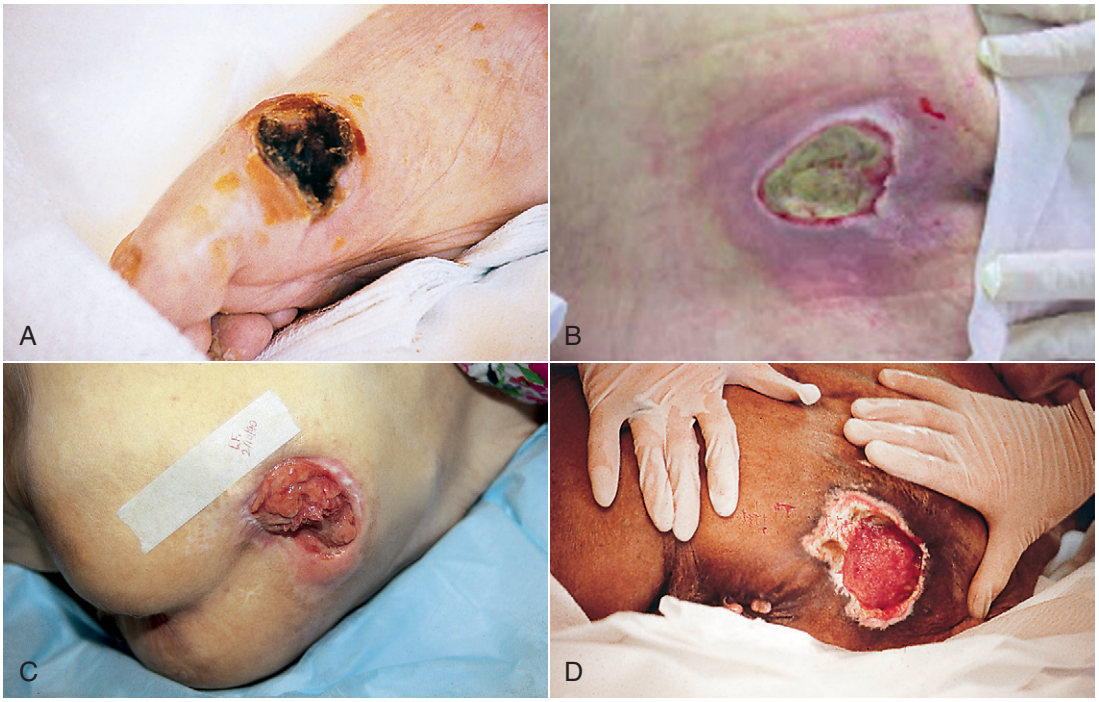

FIG. 48-5 Wounds classified by color assessment. **A,** Black wound. **B,** Yellow wound. **C,** Red wound. **D,** Mixed-color wound. (**A** and **D,** Courtesy Scott Health Care—A Molnlyche Company, Philadelphia, Pa; **B** and **C** from Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts,* ed 4, St Louis, 2012, Mosby.)

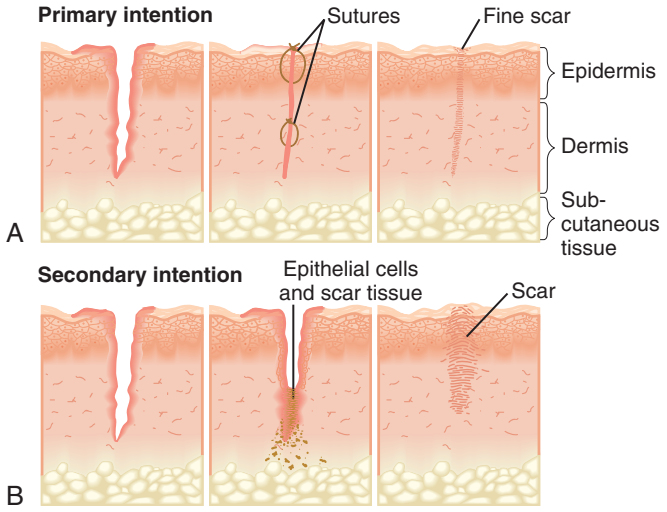

FIG. 48-6 **A,** Wound healing by primary intention such as a surgical incision. Wound healing edges are pulled together and approximated with sutures or staples, and healing occurs by connective tissue deposition. **B,** Wound healing by secondary intention. Wound edges are not approximated, and healing occurs by granulation tissue formation and contraction of the wound edges. (From Black JM, Hawks JH: *Medical-surgical nursing: clinical management for positive outcomes,* ed 8, St Louis, 2009, Mosby.)

epidermal cells only migrate across a moist surface. In a dry wound the cells migrate down into a moist level before migration can occur (Doughty and Sparks-Defriese, 2012). New epithelium is only a few cells thick and must undergo *reestablishment of the epidermal layers.* The cells slowly reestablish normal thickness and appear as dry, pink tissue.

Full-Thickness Wound Repair. The four phases involved in the healing process of a full-thickness wound are hemostasis, inflammatory, proliferative, and remodeling.

Hemostasis. A series of events designed to control blood loss, establish bacterial control, and seal the defect occurs when there is an injury. During **hemostasis** injured blood vessels constrict, and platelets gather to stop bleeding. Clots form a **fibrin** matrix that later provides a framework for cellular repair.

Inflammatory Phase. In the inflammatory stage damaged tissue and mast cells secrete histamine, resulting in vasodilation of surrounding capillaries and exudation of serum and white blood cells into damaged tissues. This results in localized redness, edema, warmth, and throbbing. The inflammatory response is beneficial, and there is no value in attempting to cool the area or reduce the swelling unless the swelling occurs within a closed compartment (e.g., ankle or neck).

Leukocytes (white blood cells) reach the wound within a few hours. The primary-acting white blood cell is the neutrophil, which begins to ingest bacteria and small debris. The second important leukocyte is the monocyte, which transforms into macrophages. The macrophages are the "garbage cells" that clean a wound of bacteria, dead cells, and debris by phagocytosis. Macrophages continue the process of clearing the wound of debris and release growth factors that attract fibroblasts, the cells that synthesize collagen (connective tissue). Collagen appears as early as the second day and is the main component of scar tissue.

In a clean wound the inflammatory phase establishes a clean wound bed. The inflammatory phase is prolonged if too little inflammation occurs, as in a debilitating disease such as cancer or after administration of steroids. Too much inflammation also prolongs healing because arriving cells compete for available nutrients. An example is a wound infection in which the increased metabolic

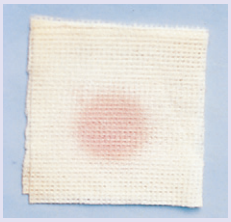
energy requirements present in an infected wound compete for the available calorie intake.

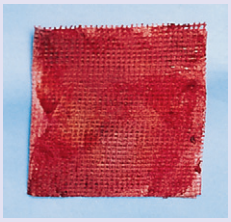
Proliferative Phase. With the appearance of new blood vessels as reconstruction progresses, the proliferative phase begins and lasts from 3 to 24 days. The main activities during this phase are the filling of the wound with granulation tissue, contraction of the wound, and the resurfacing of the wound by **epithelialization.** Fibroblasts are present in this phase and are the cells that synthesize collagen, providing the matrix for granulation. Collagen mixes with the granulation tissue, and this matrix supports the reepithelialization. Collagen provides strength and structural integrity to a wound. During this period the wound contracts to reduce the area that requires healing. Finally the epithelial cells migrate from the wound edges to resurface. In a clean wound the proliferative phase accomplishes the following: the vascular bed is reestablished (granulation tissue), the area is filled with replacement tissue (collagen, contraction, and granulation tissue), and the surface is repaired (epithelialization). Impairment of healing during this stage usually results from systemic factors such as age, anemia, hypoproteinemia, and zinc deficiency.

Remodeling. Maturation, the final stage of healing, sometimes takes place for more than a year, depending on the depth and extent of the wound. The collagen scar continues to reorganize and gain strength for several months. However, a healed wound usually does not have the tensile strength of the tissue it replaces. Collagen fibers undergo remodeling or reorganization before assuming their normal appearance. Usually scar tissue contains fewer pigmented cells (melanocytes) and has a lighter color than normal skin. In dark-skinned individuals the scar tissue may be more highly pigmented than surrounding skin.

Complications of Wound Healing

Hemorrhage. **Hemorrhage,** or bleeding from a wound site, is normal during and immediately after initial trauma. Hemostasis occurs within several minutes unless large blood vessels are involved or the patient has poor clotting function. Hemorrhage occurring after hemostasis indicates a slipped surgical suture, a dislodged clot, infection, or erosion of a blood vessel by a foreign object (e.g., a drain). Hemorrhage occurs externally or internally. For example, if a surgical suture slips from a blood vessel, bleeding occurs internally within the tissues, and there are no visible signs of blood unless a surgical drain is present. A surgical drain may be inserted into tissues beneath a wound to remove fluid that collects in underlying tissues.





You detect internal bleeding by looking for distention or swelling of the affected body part, a change in the type and amount of drainage from a surgical drain, or signs of hypovolemic shock. A **hematoma** is a localized collection of blood underneath the tissues. It appears as a swelling, change in color, sensation, or warmth or mass that often takes on a bluish discoloration. A hematoma near a major artery or vein is dangerous because pressure from the expanding hematoma obstructs blood flow.

External hemorrhaging is obvious. The nurse observes dressings covering the wound for bloody drainage. If bleeding is extensive, the dressing soon becomes saturated, and frequently blood drains from under the dressing and pools beneath the patient. Observe all wounds closely, particularly surgical wounds, in which the risk of hemorrhage is great during the first 24 to 48 hours after surgery or injury.

Infection. Wound infection is the second most common health care–associated infection (nosocomial) (see Chapter 28). According to the Centers for Disease Control and Prevention (CDC) (2001), a wound is infected if purulent material drains from it, even if a culture is not taken or has negative results. A sample of drainage from an infected wound does not always reveal bacteria because of poor culture technique or administration of antibiotics. Positive culture findings do not always indicate an infection because many wounds contain colonies of noninfective resident bacteria. In fact, all chronic dermal wounds are considered contaminated with bacteria. What differentiates contaminated wounds from infected wounds is the amount of bacteria present. It is generally agreed that wounds with more than 100,000 (10^5) organisms per gram of tissue are infected (Stotts, 2012b). The chances of wound infection are greater when the wound contains dead or necrotic tissue, there are foreign bodies in or near the wound, and the blood supply and local tissue defenses are reduced. Bacterial wound infection inhibits wound healing.

Some contaminated or traumatic wounds show signs of infection early, within 2 to 3 days. A surgical wound infection usually does not develop until the fourth or fifth postoperative day. The patient has a fever, tenderness and pain at the wound site, and an elevated white blood cell count. The edges of the wound appear inflamed. If drainage is present, it is odorous and **purulent,** which causes a yellow, green, or brown color, depending on the causative organism (Table 48-2).

TABLE 48-2 Types of Wound Drainage

TYPE	APPEARANCE
Serous	Clear, watery plasma
	
Purulent	Thick, yellow, green, tan, or brown
	
Serosanguineous	Pale, pink, watery; mixture of clear and red fluid
	
Sanguineous	Bright red; indicates active bleeding
	

Dehiscence. When a wound fails to heal properly, the layers of skin and tissue separate. This most commonly occurs before collagen formation (3 to 11 days after injury). **Dehiscence** is the partial or total separation of wound layers. A patient who is at risk for poor wound healing (e.g., poor nutritional status, infection, or obesity) is at risk for dehiscence. However, obese patients have a higher risk because of the constant strain placed on their wounds and the poor healing qualities of fat tissue (Camden, 2012). Dehiscence frequently involves abdominal surgical wounds and occurs after a sudden strain such as coughing, vomiting, or sitting up in bed. Patients often report feeling as though something has given way. When there is an increase in serosanguineous drainage from a wound, be alert for the potential for dehiscence. A strategy to prevent dehiscence is to place a folded thin blanket or pillow over an abdominal wound when the patient is coughing. This provides a splint to the area, supporting the healing tissue when coughing increases the intraabdominal pressure.

Evisceration. With total separation of wound layers, **evisceration** (protrusion of visceral organs through a wound opening) occurs. The condition is an emergency that requires surgical repair. When evisceration occurs, the nurse places sterile towels soaked in sterile saline over the extruding tissues to reduce chances of bacterial invasion and drying of the tissues. If the organs protrude through the wound, blood supply to the tissues is compromised. The presence of an evisceration is a surgical emergency. Immediately contact the surgical team, do not allow the patient anything by mouth (NPO), observe him or her for signs and symptoms of shock, and prepare him or her for emergency surgery.

NURSING KNOWLEDGE BASE

Prediction and Prevention of Pressure Ulcers

A major aspect of nursing care is the maintenance of skin integrity. Consistent, planned skin care interventions are critical to ensuring high-quality care. Nurses constantly observe their patients' skin for breaks or impaired skin integrity. Impaired skin integrity occurs from prolonged pressure, irritation of the skin, and/or immobility, leading to the development of pressure ulcers. A pressure ulcer is a localized injury to the skin and/or underlying tissue, usually over a bony prominence, as a result of pressure or pressure in combination with shear and/or friction (EPUAP and NPUAP, 2009).

Risk Assessment. Several instruments are available for assessing patients who are at risk for developing a pressure ulcer. By identifying at-risk patients, you are able to put interventions into place for the at-risk patient and spare patients with little risk for pressure ulcer development the unnecessary and sometimes costly preventive treatment. Prevention and treatment of pressure ulcers are major nursing priorities. The incidence of pressure ulcers in a facility or agency is an important indicator of quality of care. Evidence exists that a program of prevention guided by risk assessment simultaneously reduces the institutional incidence of pressure ulcers by as much as 60% and brings down the costs of prevention at the same time (Braden, 2001). Several risk-assessment scales (Bergstrom et al., 1987; Norton et al., 1962) developed by nurses enable systematic risk assessment of patients. The Braden Scale, a widely used risk-assessment tool, is in the WOCN guidelines (2010) as being a valid tool to use for pressure ulcer risk assessment. The Braden Scale (Table 48-3) was developed based on risk factors in a nursing home population (Bergstrom et al., 1987) and is composed of six subscales: sensory perception, moisture, activity, mobility, nutrition, and friction/shear. The total score ranges from 6 to 23; a lower total score indicates a higher risk for pressure ulcer development (Braden and Bergstrom, 1989). The cutoff score for onset of pressure ulcer risk with the Braden Scale in the general adult population is 18 (Ayello and Braden, 2002). It is highly reliable when used to identify patients at greatest risk for pressure ulcers (Bergstrom et al., 1987; Braden and Bergstrom, 1994). The Braden Scale is the most commonly used assessment scale for pressure ulcer risk.

Prevention. Preventing pressure ulcers is a priority in caring for patients and is not limited to patients with restrictions in mobility. Impaired skin integrity is not usually a problem in healthy, immobilized individuals but is a serious and potentially devastating problem in ill or debilitated patients (WOCN, 2010).

Economic Consequences of Pressure Ulcers. Pressure ulcers are a continual problem in acute and restorative care settings. For adult patients with pressure ulcers, 56.5% were 65 years and older (WOCN, 2010). Paralysis and spinal cord injury are common preexisting conditions among younger adults with primary diagnosis of pressure ulcers. Older adults admitted to acute and long-term facilities are a vulnerable population. Among persons admitted to long-term care, 10.3% to 18.4% had one or more pressure ulcers on admission (Baumgarten et al., 2003; Siem et al., 2003).

When a pressure ulcer occurs, the length of stay in a hospital and the overall cost of health care increase. The actual cost of treatment is difficult to estimate. About 1.6 million patients each year in acute care settings develop pressure ulcers, representing a cost of $11 to $17.2 billion to the U.S. health care system (Pieper, 2012). Adult inpatient hospital stays with a diagnosis of pressure ulcers totaled $11 billion in 2006 (WOCN, 2010). Although it is difficult to get a handle on the exact numbers of pressure ulcers, the number of patients with pressure ulcers, and the cost, the occurrence of pressure ulcers is costly to patients in terms of disability, pain, and suffering and in the costs to institutions and third-party payers. The Centers for Medicare and Medicaid Services (CMS) implemented a policy effective October 1, 2008 whereby hospitals no longer receive additional reimbursement for care related to eight conditions, including stage III and IV pressure ulcers that occur during the hospitalization. This policy was put in place to provide additional incentives for hospitals to improve quality of care. Using guidelines such as the WOCN Guidelines (WOCN, 2010) helps reduce or eliminate the occurrence of pressure ulcers and prevent the expense that will not be reimbursed.

Factors Influencing Pressure Ulcer Formation and Wound Healing

Impaired skin integrity resulting in pressure ulcers is primarily the result of pressure. However, additional factors, including shear force, friction, moisture, nutrition, tissue perfusion, infection, and age, increase the patient's risk for pressure ulcer development and poor wound healing.

Nutrition. For patients weakened or debilitated by illness, nutritional therapy is especially important. A patient who has undergone surgery (see Chapter 50) and is well nourished still requires at least 1500 kcal/day for nutritional maintenance. Alternatives such as enteral feedings (see Chapter 44) and parenteral nutrition (see Chapter 41) are available for patients unable to maintain normal food intake.

Normal wound healing requires proper nutrition (Table 48-4). Deficiencies in any of the nutrients result in impaired or delayed healing (Stotts, 2012a). Physiological processes of wound healing depend on the availability of protein, vitamins (especially A and C), and the trace minerals zinc and copper. Collagen is a protein formed from amino acids acquired by fibroblasts from protein

TABLE 48-3 Braden Scale for Predicting Pressure Ulcer Risk

Patient's Name _____ Evaluator's Name _____ Date of Assessment _____

Sensory Perception				
Ability to respond meaningfully to pressure-related discomfort	1. Completely limited Unresponsive (does not moan, flinch, or grasp) to painful stimuli caused by diminished level of consciousness or sedation OR Limited ability to feel pain over most of body surface	2. Very limited Responds only to painful stimuli Cannot communicate discomfort except by moaning or restlessness OR Has sensory impairment that limits ability to feel pain or discomfort over ½ of body	3. Slightly limited Responds to verbal commands but cannot always communicate discomfort or need to be turned OR Has some sensory impairment that limits ability to feel pain or discomfort in one or two extremities	4. No impairment Responds to verbal commands Has no sensory deficit that would limit ability to feel or voice pain or discomfort
Moisture				
Degree to which skin is exposed to moisture	1. Constantly moist Skin kept moist almost constantly by perspiration, urine, etc. Dampness detected every time patient is moved or turned	2. Moist Skin often, but not always, moist Necessary to change linen at least once a shift	3. Occasionally moist Skin occasionally moist, requiring an extra linen change approximately once a day	4. Rarely moist Skin usually dry Required linen changing only at routine intervals
Activity				
Degree of physical activity	1. Bedfast Confined to bed	2. Chairfast Ability to walk severely limited or nonexistent Cannot bear own weight and/or must be assisted into chair or wheelchair	3. Walks occasionally Walks occasionally during day but for very short distances, with or without assistance Spends majority of each shift in bed or chair	4. Walks frequently Walks outside room at least twice a day and inside room at least once every 2 hours during waking hours
Mobility				
Ability to change and control body position	1. Completely immobile Does not make even slight changes in body or extremity position without assistance	2. Very limited Makes occasional slight changes in body or extremity position but unable to make frequent or significant changes independently	3. Slightly limited Makes frequent, although slight, changes in body or extremity position independently	4. No limitations Makes major and frequent changes in position without assistance
Nutrition				
Usual food intake pattern	1. Very poor Never eats a complete meal; rarely eats more than ⅓ of any food offered; eats 2 servings or less of protein (meat or dairy products) per day Takes fluids poorly; does not take a liquid dietary supplement OR Is NPO and/or maintained on clear liquids or IVs for more than 5 days	2. Probably inadequate Rarely eats a complete meal and generally eats only about ½ of any food offered Protein intake includes only 3 servings of meat or dairy products per day; occasionally takes a dietary supplement OR Receives less than optimum amount of liquid diet or tube feeding	3. Adequate Eats over half of most meals; eats a total of four servings of protein (meat, dairy products) each day Occasionally refuses a meal but usually takes a supplement if offered OR Is on tube feeding or total parenteral nutrition regimen that probably meets most of nutritional needs	4. Excellent Eats most of every meal; never refuses a meal; usually eats a total of four or more servings of meat and dairy products Occasionally eats between meals Does not require supplementation
Friction and Shear				
	1. Problem Requires moderate-to-maximum assistance in moving; complete lifting without sliding against sheets impossible Frequently slides down in bed or chair, requiring frequent repositioning with maximum assistance Spasticity, contractures, or agitation leads to almost constant friction	2. Potential problem Moves feebly or requires minimum assistance; during a move skin probably slides to some extent against sheets, chair, restraints, or other devices Maintains relatively good position in chair or bed most of the time but occasionally slides down	3. No apparent problem Moves in bed and in chair independently and has sufficient muscle strength to lift up completely during move Maintains good position in bed or chair at all times	TOTAL SCORE

TABLE 48-4 Role of Selected Nutrients in Wound Healing

NUTRIENT	ROLE IN HEALING	RECOMMENDATIONS	SOURCES
Calories	Fuel for cell energy "Protein protection"	35-40 kcal/kg/day or enough to maintain positive nitrogen balance	
Protein	Fibroplasia, angiogenesis, collagen formation and wound remodeling, immune function	1-1.5 g/kg/day or enough to maintain positive nitrogen balance	Poultry, fish, eggs, beef
Vitamin C (ascorbic acid)	Collagen synthesis, capillary wall integrity, fibroblast function, immunological function, antioxidant	100-1000 mg/day Need long time to develop clinical scurvy from vitamin C deficiency Low toxicity	Citrus fruits, tomatoes, potatoes, fortified fruit juices
Vitamin A	Epithelialization, wound closure, inflammatory response, angiogenesis, collagen formation Can reverse steroid effects on skin and delayed healing	1600-2000 retinol equivalents per day Supplement if deficient 20,000 units × 10 days	Green leafy vegetables (spinach), broccoli, carrots, sweet potatoes, liver
Vitamin E	No known role in wound healing, antioxidant	None	Fish, oysters, liver, dark meat, eggs, legumes
Zinc	Collagen formation, protein synthesis, cell membrane and host defenses	15-30 mg Correct deficiencies No improvement in wound healing with supplementation unless zinc deficient Use with caution—large doses can be toxic May inhibit copper metabolism and impair immune function	Vegetables, meats, legumes
Fluid	Essential fluid environment for all cell function	30-35 mL/kg/day Increase by another 10-15 mL/kg if patient is on an air-fluidized bed	Use noncaffeine, nonalcoholic fluids without sugar Water is best—6-8 glasses/day

Modified from Ayello EA et al.: Nutritional aspects of wound healing, *Home Healthc Nurse* 17(11):719, 1999; and Stotts NA: Nutritional assessment and support. In Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts,* ed 4, St Louis, 2012a, Mosby.

ingested in food. Vitamin C is necessary for synthesis of collagen. Vitamin A reduces the negative effects of steroids on wound healing. Trace elements are also necessary; (i.e., zinc for epithelialization and collagen synthesis and copper for collagen fiber linking).

Calories provide the energy source needed to support the cellular activity of wound healing. Protein needs especially are increased and are essential for tissue repair and growth. A balanced intake of various nutrients (i.e., protein, fat, carbohydrates, vitamins, and minerals) is critical to support wound healing.

Serum proteins are biochemical indicators of malnutrition (Stotts, 2012a). Serum albumin is probably the most frequently measured of these laboratory parameters. Albumin alone is not sensitive to rapid changes in nutritional status. Transferrin also evaluates protein status, but alone it does not determine malnutrition. The best measure of nutritional status is prealbumin, because it reflects not only what the patient has ingested but also what the body has absorbed, digested, and metabolized (Stotts, 2012a).

Tissue Perfusion. Oxygen fuels the cellular functions essential to the healing process; therefore the ability to perfuse the tissues with adequate amounts of oxygenated blood is critical to wound healing (Doughty and Sparks-Defriese, 2012). Patients with peripheral vascular disease are at risk for poor tissue perfusion because of poor circulation. Oxygen requirements depend on the phase of wound healing (e.g., chronic tissue hypoxia is associated with impaired collagen synthesis and reduced tissue resistance to infection).

Infection. Wound infection prolongs the inflammatory phase; delays collagen synthesis; prevents epithelialization; and increases the production of proinflammatory cytokines, which leads to additional tissue destruction (Stotts, 2012b). Indications that a wound infection is present include the presence of purulent drainage; change in odor, volume, or character of wound drainage; redness in the surrounding tissue; fever; or pain.

Age. Increased age affects all phases of wound healing. A decrease in the functioning of the macrophage leads to a delayed inflammatory response, delayed collagen synthesis, and slower epithelialization.

Psychosocial Impact of Wounds. The psychosocial impact of wounds on the physiological process of healing is unknown. The patient's psychological response to any wound is part of the nurse's assessment. Body image changes often impose a great stress on the patient's adaptive mechanisms. They also influence self-concept (see Chapter 33) and sexuality (see Chapter 34). Make sure that the patient's personal and social resources for adaptation are a part of the assessment. Factors that affect the patient's perception of the wound include the presence of scars, drains (drains are often necessary for weeks or even months after certain procedures), odor from drainage, and temporary or permanent prosthetic devices.

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require the nurse to anticipate the information necessary, analyze the data, and make decisions regarding patient care.

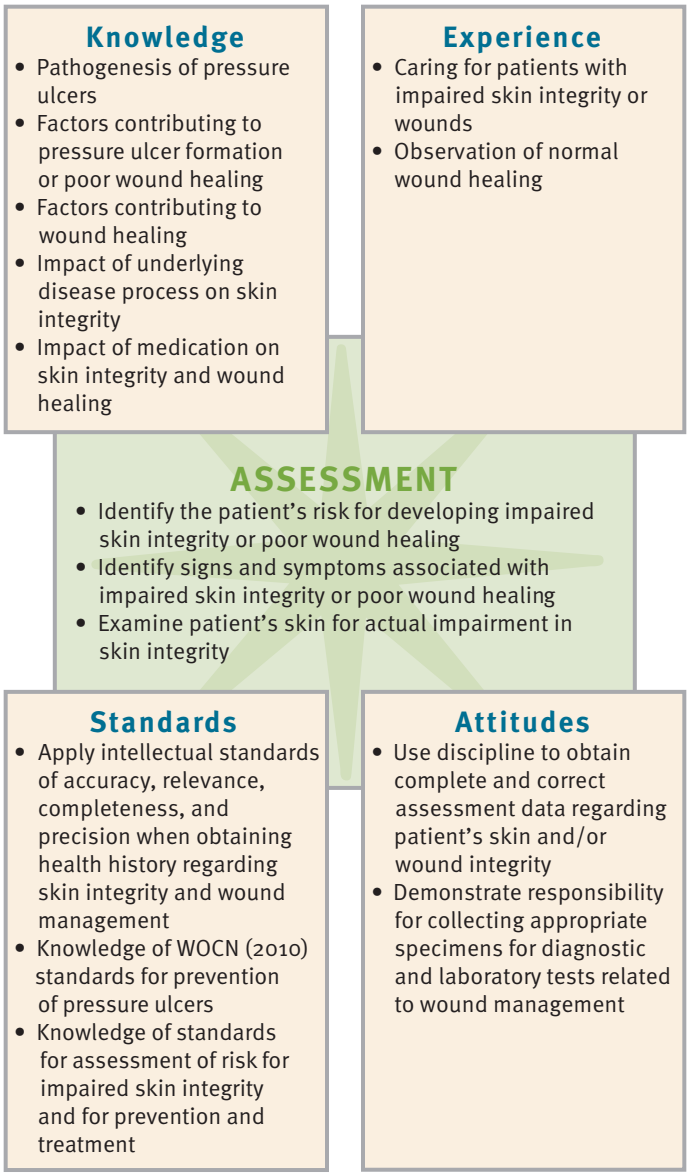

FIG. 48-7 Critical thinking model for skin integrity and wound care assessment. *WOCN,* Wound, Ostomy, and Continence Nurses Society.

Critical thinking is always changing. During assessment (Fig. 48-7) consider all elements that build toward making appropriate nursing diagnoses.

When caring for patients who have impaired skin integrity and chronic wounds, integrate knowledge from nursing and other disciplines, previous experiences, and information gathered from patients to understand the risk to skin integrity and wound healing. Knowledge of normal musculoskeletal physiology, the pathogenesis of pressure ulcers, normal wound healing, and the pathophysiology of underlying diseases enables you to have a scientific basis for care. The WOCN (2010) has guidelines for assessment of risk for impaired skin integrity, prevention measures, interventions to promote wound healing, and other standards of practice, which you should use in planning care. Past experience with patients at risk for impaired skin integrity or patients with wounds increases the experiential knowledge base helping you to identify interventions. Finally you need to be disciplined during assessment to obtain comprehensive and correct assessment data. You also need to be creative. Because chronic wounds are difficult to heal, be diligent in evaluating nursing interventions and determining which interventions are effective and which need modification.

BOX 48-4 NURSING ASSESSMENT QUESTIONS

Skin Integrity

Sensation
- Do you have decreased feeling in your extremities or any other region?
- Are you sensitive to heat or cold?

Mobility
- Do you have any physical limitations, injury, or paralysis that limits your mobility?
- Can you change your position easily?
- Is movement painful?

Continence
- Do you have any problems with involuntary loss of urine or stool?
- What assistance do you need using the toilet?
- How often do you need to use the toilet? During the day? During the night?

Presence of Wound
- What caused the wound?
- When did the wound occur? What is its location and dimensions?
- When did you receive a tetanus shot?
- What has happened to this wound since it occurred? What were the changes and what caused them?
- Which treatments, activities, or care have slowed or helped the wound-healing process? Are there special needs for this wound to heal?
- Are there associated symptoms such as pain or itching with the wound? How are they being managed, and are the interventions effective?
- What is the goal for the patient, wound, and healing?

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Baseline and continual assessment data provide critical information about a patient's skin integrity and the increased risk for pressure ulcer development. Focusing on specific elements such as a patient's level of sensation, movement, and continence status helps guide the skin assessment (Box 48-4).

Through the Patient's Eyes. When patients have an acute surgical or traumatic wound, the wound sometimes heals promptly and without complications. However, when pressure ulcers or chronic wounds are present, the course of treatment is lengthy and costly. Because the patient and family need to be involved with wound care management, it is important to know the patient's expectations. A patient who has realistic goals and is informed about the length of time for wound healing is more likely to adhere to the specific therapies designed to promote healing and prevent

BOX 48-5 PROCEDURAL GUIDELINES

Skin Assessment

Delegation Considerations

The skill of skin assessment for skin integrity or the presence of skin breakdown cannot be delegated to nursing assistive personnel (NAP). Direct/inform/instruct the NAP to report:

- Any changes in the patient's skin to the nurse immediately.
- Patient's exposure to body fluids (e.g., urine, feces, wound drainage, gastric secretions).

Equipment

Skin assessment documentation record (check agency policy)

1. Observe pressure points. Compression of these areas for prolonged periods of time by bony prominences or external sources causes tissue ischemia and cell death (WOCN, 2010).
   a. Bony prominences—heels, ankles, knees, hips, sacral area, ischial area, spinal area, shoulders, and elbows (see Fig. 48-9)
   b. Cast edges; areas next to nasogastric tubes, drainage tubes, or oxygen tubing
2. When you find reddened areas, gently press the area with a gloved finger to assess the ability of the tissue to blanch. If the area does not blanch, suspect tissue injury.
3. Check perineal area for signs of reddened, irritated skin. Perineal skin is at high risk for skin breakdown in the patient with fecal and/or urinary incontinence.
4. Observe underlying skin areas where tape, tubing, casts, or splints are in contact with skin.
5. Note previous areas of skin breakdown, check for any breaks in skin integrity, or note nonblanching erythema in this area. Areas of previous skin breakdown do not heal to the same strength as intact noninjured skin; therefore these areas are at higher risk for skin breakdown.
6. Determine if potential or actual skin breakdown is present and institute appropriate preventive or treatment protocols.
7. Record findings and the preventive or treatment protocols initiated per agency policy.

further skin breakdown. Therefore it is important to assess the patient's perception of what is occurring with the wound healing interventions. The health care professional wants to determine the patient's and family's understanding of wound assessment; wound interventions; and supportive interventions such as positioning, nutrition, and ambulation.

Skin. A nurse continually assesses the skin for signs of ulcer development (Box 48-5). The neurologically impaired patient; the chronically ill patient in long-term care; the patient with diminished mental status; and the intensive care unit (ICU), oncology, hospice, or orthopedic patient have increased potential for developing pressure ulcers.

Assessment for tissue pressure damage includes visual and tactile inspection of the skin. Perform baseline assessment to determine a patient's normal skin characteristics and any actual or potential areas of breakdown. You need to individualize assessment characteristics of a patient's skin, depending on his or her skin tone (Bennett, 1995; Henderson et al., 1997). Accurate assessment of patients with darker skin pigmentation is an essential skill for all health care providers (Nix, 2012). Assessment characteristics of darkly pigmented skin are in Boxes 48-2 and 48-3.

Pay particular attention to areas located over bony prominences or under casts, traction, splints, braces, collars, or other orthopedic devices. The frequency of pressure checks depends on the schedule

FIG. 48-8 Formation of pressure ulcer on heel resulting from external pressure from mattress of bed. (Courtesy Janice Colwell, RN, MS, CWOCN, FAAN, Clinical Nurse Specialist, University of Chicago Medical Center.)

of appliance application and the response of the skin to the external pressure (Fig. 48-8).

When you note hyperemia, document the location, size, and color and reassess the area after 1 hour. When you suspect **abnormal reactive hyperemia,** outline the affected area with a marker to make reassessment easier. These signs are early indicators of impaired skin integrity, but damage to the underlying tissue is sometimes more progressive. Tactile assessment enables you to use palpation to acquire further data about **induration** and the damage to the skin and underlying tissues.

Gently palpate the reddened tissue, observing for blanching with return to normal skin tones in patients with light-toned skin. In addition, palpate for induration, noting the size in millimeters or centimeters of the induration around the injured area and changes in temperature of the surrounding skin and tissues.

Use visual and tactile inspection over the body areas most frequently at risk for pressure ulcer development (Fig. 48-9). For example, when a patient lies in bed or sits in a chair, he or she places body weight heavily on certain bony prominences. Body surfaces subjected to the greatest weight or pressure are at greatest risk for pressure ulcer formation.

Pressure Ulcers. Pressure ulcers have multiple etiological factors. Assessment for pressure ulcer risk includes using an appropriate predictive measure and assessing a patient's mobility, nutrition, presence of body fluids, and comfort level (Skill 48-1 on pp. 1213-1215).

Predictive Measures. On admission to acute care and rehabilitation hospitals, nursing homes, home care programs, and other health care facilities, assess individuals for risk of pressure ulcer development (WOCN, 2010). Perform pressure ulcer risk assessment systematically (WOCN, 2010). Use an assessment tool such as the Braden scale (see Table 48-3). The interpretation of the meaning of the total numerical scores differs with each risk-assessment scale. Lower numerical scores on the Braden scale indicate that a patient is at high risk for skin breakdown. A benefit of the predictive instruments is to increase a nurse's early detection of patients at greatest risk for ulcer development. Once you identify these patients, institute the appropriate interventions to maintain skin integrity and implement prevention strategies (WOCN, 2010). Perform reassessment for pressure ulcer risk on a scheduled basis.

Mobility. Assessment includes documenting the level of mobility and the potential effects of impaired mobility on skin integrity.

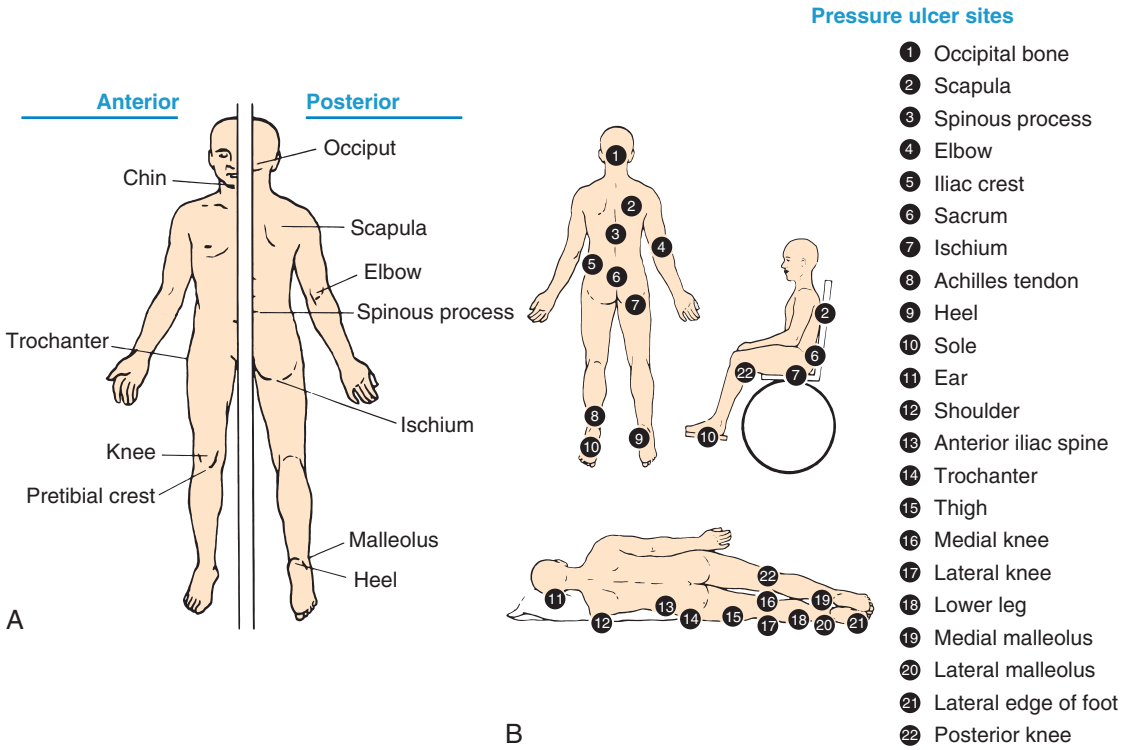

FIG. 48-9 A, Bony prominences most frequently underlying pressure ulcer. **B,** Pressure ulcer sites. (Modified from Trelease CC: Developing standards for wound care, *Ostomy Wound Manage* 20:46, 1988.)

Documenting assessment of mobility also includes obtaining data regarding the quality of muscle tone and strength. For example, determine whether the patient is able to lift weight off of the sacral area and roll the body to a side-lying position. Some patients have adequate range of motion to move independently into a more protective position. Finally note the patient's activity tolerance (see Chapter 38).

You must assess mobility as part of baseline data. If a patient has some degree of mobility independence, reinforce the frequency of position changes and measures to relieve pressure. The frequency of position changes is based on ongoing skin assessment; revise it as data change. Be meticulous when assessing pressure sites.

Nutritional Status. An assessment of patients' nutritional status is an integral part of the initial assessment data for patients at risk for impaired skin integrity and wounds (Stotts, 2012a). Malnutrition is a risk factor for pressure ulcer development (Posthauer and Thomas, 2008). A loss of 5% of usual weight, weight less than 90% of ideal body weight, and a decrease of 10 pounds in a brief period are all signs of actual or potential nutritional problems (Stotts, 2012a).

Body Fluids. Continual exposure of the skin to body fluids increases a patient's risk for skin breakdown and pressure ulcer formation (Box 48-6). Some body fluids such as saliva and serosanguineous drainage are not as caustic to the skin, and the risk of skin breakdown from exposure to these fluids is low. However, exposure to urine, bile, stool, ascitic fluid, and purulent wound exudates carries a moderate risk for skin breakdown, especially in patients who have other risk factors such as chronic illness or poor nutrition. Finally exposure to gastric and pancreatic drainage has the highest risk for skin breakdown. Again, it is important to prevent and reduce the patient's exposure to body fluids; and, when exposure occurs, you need to provide meticulous hygiene and skin care.

BOX 48-6 RISK FOR SKIN BREAKDOWN FROM BODY FLUIDS

Low Risk
- Saliva
- Serosanguineous drainage

Moderate Risk
- Bile
- Stool
- Urine
- Ascitic fluid
- Purulent exudate

High Risk
- Gastric drainage
- Pancreatic drainage

Pain. Until recently there has been little research about pain and pressure ulcers. The WOCN (2010) has recommended the assessment and management of pain be included in the care of patients with pressure ulcers (Dallam et al., 2008). Maintaining adequate pain control and patient comfort increases the patient's willingness and ability to increase mobility, which in turn reduces pressure ulcer risk.

Wounds. A nurse often assesses wounds under two conditions: at the time of injury before treatment and after therapy, when the wound is relatively stable. Each condition requires him or her to make different observations and take different actions. Regardless of the setting, it is important that you initially

obtain information regarding the cause and history of the wound (see Box 48-4).

Emergency Setting. You see wounds in any setting, including clinics, emergency departments, youth camps, or your own backyard. The type of wound determines the criteria for inspection. For example, you do not need to inspect for signs of internal bleeding after an abrasion, but you should inspect in the event of a puncture wound.

When you judge a patient's condition to be stable because of the presence of spontaneous breathing, a clear airway, and a strong carotid pulse (see Chapters 30 and 40), inspect the wound for bleeding. An **abrasion** is superficial with little bleeding and is considered a partial-thickness wound. The wound often appears "weepy" because of plasma leakage from damaged capillaries. A **laceration** sometimes bleeds more profusely, depending on the depth and location of the wound. For example, minor scalp lacerations tend to bleed profusely because of the rich blood supply to the scalp. Lacerations greater than 5 cm (2 inches) long or 2.5 cm (1 inch) deep cause serious bleeding. **Puncture** wounds bleed in relation to the depth and size of the wound (e.g., a nail puncture does not cause as much bleeding as a knife wound). The primary dangers of puncture wounds are internal bleeding and infection.

Inspect the wound for foreign bodies or contaminant material. Most traumatic wounds are dirty. Soil, broken glass, shreds of cloth, and foreign substances clinging to penetrating objects sometimes become embedded in the wound.

The size of the wound is the next step in assessment. A deep laceration requires suturing. A large, open wound may expose bone or tissue that needs to be protected.

When the injury is a result of trauma from a dirty penetrating object, determine when the patient last received a tetanus toxoid injection. Tetanus bacteria reside in soil and in the gut of humans and animals. A tetanus antitoxin injection is necessary if the patient has not had one within 5 years.

Stable Setting. When a patient's condition is stabilized (e.g., after surgery or treatment), assess the wound to determine progress toward healing. If the wound is covered by a dressing and the health care provider has not ordered it changed, do not directly inspect it unless you suspect serious complications. In such a situation inspect only the dressing and any external drains. If the health care provider prefers to change the dressing, he or she assesses the wound at least daily. When removing dressings, take care to avoid accidental removal or displacement of underlying drains. Because removal of dressings can be painful, consider giving an analgesic at least 30 minutes before exposing a wound.

Wound Appearance. Observe whether wound edges are closed. A surgical incision healing by primary intention should have clean, well-approximated edges. Crusts often form along the wound edges from exudate. A puncture wound is usually a small, circular wound with the edges coming together toward the center. If a wound is open, the edges are separated, and you inspect the condition of tissue at the wound base. Also look for complications such as dehiscence and evisceration. The outer edges of a wound normally appear inflamed for the first 2 to 3 days, but this slowly disappears. Within 7 to 10 days a normally healing wound resurfaces with epithelial cells, and edges close. Table 48-5 lists assessment characteristics for abnormal wound healing in primary and secondary wounds. If infection develops, the area directly surrounding the wound becomes brightly inflamed and swollen.

Skin discoloration usually results from bruising of interstitial tissues or hematoma formation. Blood collecting beneath the skin first takes on a bluish or purplish appearance. Gradually, as the clotted blood is broken down, shades of brown and yellow appear.

TABLE 48-5 Assessment of Abnormal Healing in Primary and Secondary Intention Wounds

PRIMARY INTENTION WOUNDS	SECONDARY INTENTION WOUNDS
Incision line poorly approximated	Pale or fragile granulation tissue, granulation tissue bed excessively dry or moist
Drainage present more than 3 days after closure	Purulent exudate present
Inflammation increased in first 3-5 days after injury	Necrotic or slough tissue present in wound base
No epithelialization of wound edges by day 4	Epithelialization not continuous
No healing ridge by day 9	Fruity, earthy, or putrid odor present Presence of fistula(s), tunneling, undermining

Modified from Stotts NA, Cavanaugh CE: Assessing the patient with a wound, *Home Healthc Nurse* 17(1):27, 1999.

Character of Wound Drainage. Note the amount, color, odor, and consistency of drainage. The amount of drainage depends on the location and extent of the wound. For example, drainage is minimal after a simple appendectomy. In contrast, it is moderate for 1 to 2 days after drainage of a large abscess. When you need an accurate measurement of the amount of drainage within a dressing, weigh the dressing and compare it with the weight of the same dressing when clean and dry. The general rule is that 1 g of drainage equals 1 mL of volume of drainage. Another method of quantifying wound drainage is to chart the number of dressings used and the frequency of change. An increase or decrease in the number or frequency of dressings indicates a relative increase or decrease in wound drainage. The color and consistency of drainage vary, depending on the components. Types of drainage include the following: **serous, sanguineous, serosanguineous,** and purulent (see Table 48-2). If the drainage has a pungent or strong odor, you should suspect an infection. Describe the appearance of the wound according to characteristics observed. An example of accurate recording follows:

Abdominal incision is 5 cm in length in RLQ; edges well approximated without inflammation or exudate. 1.2-cm diameter circle of serous drainage present on one 4 × 4 gauze changed every 8 hours.

Drains. The health care provider inserts a drain into or near a surgical wound if there is a large amount of drainage. Some drains are sutured in place. Exercise caution when changing the dressing around drains that are not sutured in place to prevent accidental removal. A Penrose drain lies under a dressing; at the time of placement a pin or clip is placed through the drain to prevent it from slipping farther into a wound (Fig. 48-10). It is usually the health care provider's responsibility to pull or advance the drain as drainage decreases to permit healing deep within the drain site.

Assess the number of drains, drain placement, character of drainage, and condition of collecting equipment. Observe the security of the drain and its location with respect to the wound. Next note the character of drainage. If there is a collecting device, measure the drainage volume. Because a drainage system needs to be patent, look for drainage flow through and around the tubing.

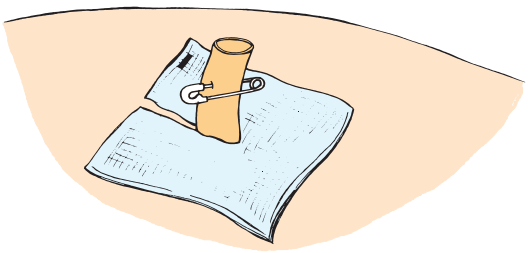

FIG. 48-10 Penrose drain.

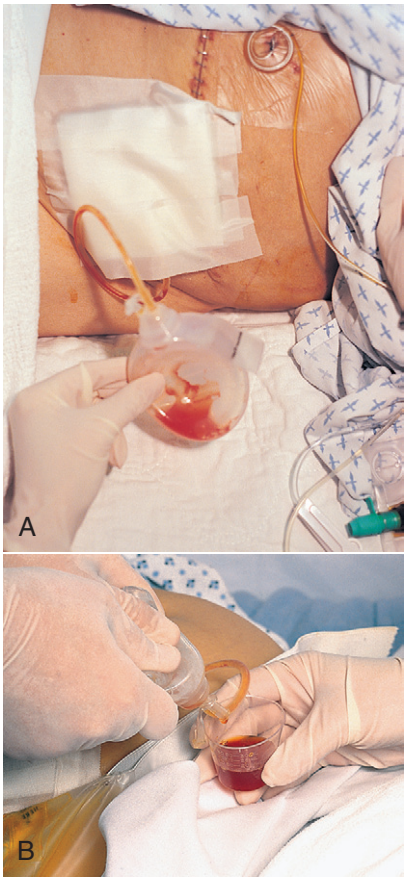

FIG. 48-11 Jackson-Pratt drainage device. **A,** Drainage tubes and reservoir. **B,** Emptying drainage reservoir.

A sudden decrease in drainage through the tubing may indicate a blocked drain, and you need to notify the health care provider. When a drain is connected to suction, assess the system to be sure that the pressure ordered is being exerted. Evacuator units such as a Hemovac or Jackson-Pratt (Fig. 48-11) exert a constant low pressure as long as the suction device (bladder or container) is fully compressed. These types of drainage devices are often referred to as *self-suction*. When the evacuator device is unable to maintain a vacuum on its own, notify the surgeon, who then orders a secondary vacuum system (such as wall suction). If fluid accumulates within the tissues, wound healing does not progress at an optimal rate, and this increases the risk of infection.

Wound Closures. Surgical wounds are closed with staples, sutures, or wound closures. A frequent skin closure is the stainless-steel staple. The staple provides more strength than nylon or silk sutures and tends to cause less irritation to tissue. Look for irritation around staple or suture sites and note whether closures are intact. Normally for the first 2 to 3 days after surgery the skin around sutures or staples is edematous. Continued swelling may indicate that the closures are too tight. The skin can be cut by overly tight suture material, leading to wound separation. Early suture removal reduces formation of defects along the suture line and minimizes chances of unattractive scar formation.

Dermabond is a tissue adhesive that forms a strong bond across apposed wound edges, allowing normal healing to occur below. It can be used to replace small sutures for incisional repair. A vial containing the Dermabond solution is used to apply the product to approximated tissue. The wound edges are held together until the solution dries, providing an adhesive closure. Although generally used for small superficial lacerations, some surgeons use it on larger wounds where subcutaneous sutures are needed (Bruns and Worthington, 2000).

Palpation of Wound. When inspecting a wound, observe swelling or separation of wound edges. While wearing gloves, lightly press the wound edges, detecting localized areas of tenderness or drainage collection. If pressure causes fluid to be expressed, note the character of the drainage. The patient is normally sensitive to palpation of wound edges. Extreme tenderness indicates infection.

Wound Cultures. If you detect purulent or suspicious-looking drainage, obtaining a specimen of the drainage for culture may be necessary (see Chapter 28). Never collect a wound culture sample from old drainage. Resident colonies of bacteria from the skin grow within exudate and are not always the true causative organisms of a wound infection. Clean a wound first with normal saline to remove skin flora. Aerobic organisms grow in superficial wounds exposed to the air, and anaerobic organisms tend to grow within body cavities. Use a different method of specimen collection for each type of organism per agency policy (Box 48-7).

Gram stains of drainage are often performed as well. This test allows the health care provider to order appropriate treatment earlier than when only cultures are done. No additional specimens are usually required. The microbiology laboratory needs only to be notified to perform the additional test.

The gold standard of wound culture is tissue biopsy. A health care provider or wound care specialist with special training obtains the biopsy (Stotts, 2012b).

NURSING DIAGNOSIS

Assessment reveals clusters of data to indicate whether an actual or a risk for *impaired skin integrity* exists. In addition, the assessment data will provide information on the related factor. For example, a postoperative patient has purulent drainage from a surgical wound and reports tenderness around the area of the wound. These data support a nursing diagnosis of *impaired skin integrity related to infection* (Box 48-8). After completing an assessment of a patient's wound, the nurse identifies nursing diagnoses that direct supportive and preventive care. Multiple nursing diagnoses are associated with impaired skin integrity and wounds:

- Risk for infection
- Imbalanced nutrition: less than body requirements
- Acute or chronic pain
- Impaired physical mobility
- Impaired skin integrity
- Risk for impaired skin integrity
- Ineffective peripheral tissue perfusion
- Impaired tissue integrity

BOX 48-7 RECOMMENDATIONS FOR STANDARDIZED TECHNIQUES FOR WOUND CULTURES*

Needle Aspiration Procedure

- Clean intact skin with a disinfectant solution. Allow to dry.
- Use a 10-mL disposable syringe with a 22-gauge needle, pulling 0.5 mL of air into the syringe.
- Insert the needle through intact skin next to the wound; withdraw plunger and apply suction to the 10-mL mark.
- Move the needle back and forward at different angles for two to four explorations.
- Remove the needle, expel the excess air, and cap and prepare the syringe for the laboratory (Stotts, 2012b).

Quantitative Swab Procedure

- Clean the wound surface with a nonantiseptic solution.
- Use a sterile swab from a culturette tube (Fig. 48-12).
- Moisten the swab with normal saline.
- Rotate the swab in 1 cm^2 (0.4 in^2) of clean tissue in the open wound. Apply pressure to the swab to elicit tissue fluid (Stotts, 2012b). Insert the tip of the swab into the appropriate sterile container, label, and transport to the laboratory.

Modified from Stotts NA: Wound infection: diagnosis and management. In Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts,* ed 4, St Louis, 2012, Mosby.
*Check agency policy to determine need to obtain health care provider order.

BOX 48-8 NURSING DIAGNOSTIC PROCESS

Impaired Skin Integrity Related to Infection

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Inspect surface of skin.	Presence of wound, break in skin integrity Yellow, foul-smelling drainage from wound Edges of wound red and warm, not approximated
Inspect wound for signs of healing.	Brown-red or beige drainage 5 days after surgery Edges of wound not approximated
Obtain patient's temperature, heart rate, white blood cell count, and serum albumin level	Patient febrile, heart rate 125 beats/min, leukocyte (white blood cell) count 12,000/mm^3, serum albumin less than 3.5 g/100 mL

Some patients are at risk for poor wound healing because of previously defined factors that impair healing. Thus, even though the patient's wound appears normal, the nurse identifies nursing diagnoses such as *impaired nutrition* or *ineffective peripheral tissue perfusion* that direct nursing care toward support of wound repair.

The nature of a wound can cause problems unrelated to wound healing. Alteration in comfort and impaired mobility are problems that have implications for the patient's eventual recovery. For example, a large abdominal incision causes enough pain to interfere with the patient's ability to turn in bed effectively.

PLANNING

After identifying nursing diagnoses, develop a plan of care for a patient who has actual or is at risk for *impaired skin integrity*. During planning synthesize information from multiple resources (Fig. 48-13). Critical thinking ensures that a patient's plan of care integrates all that you know about the individual and key critical thinking elements. Professional standards are especially important to consider when you develop a plan of care.

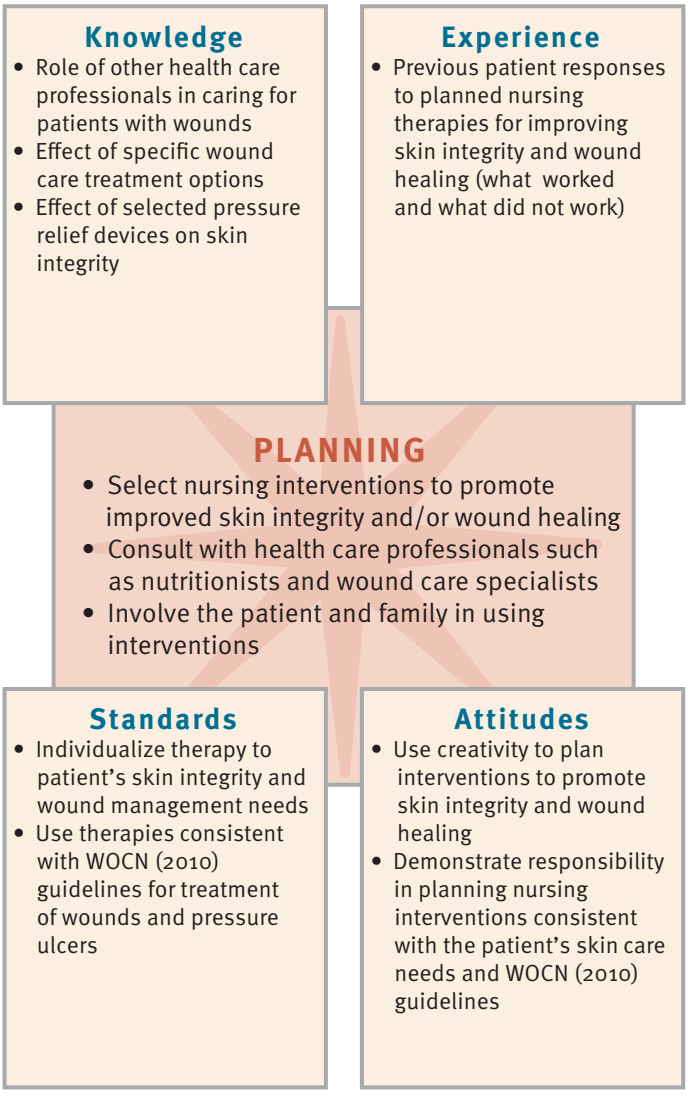

FIG. 48-13 Critical thinking model for skin integrity and wound care planning. *WOCN,* Wound, Ostomy, and Continence Nurses Society.

Patients who have large, chronic wounds or infected wounds have multiple nursing care needs. A concept map helps to individualize care for a patient who has multiple health problems and related nursing diagnoses (Fig. 48-14). This map helps you use critical thinking skills to organize complex patient assessment data into related nursing diagnoses with the patient's chief medical diagnosis. As you identify linkages between the nursing diagnoses and the chief medical diagnosis, the concept map also links potential interventions that apply to the patient's health care needs.

Goals and Outcomes. Nursing care is based on a patient's identified needs and priorities. You establish goals and expected outcomes, and from the goals you plan interventions according to the risk for pressure ulcers or the type and severity of the wound and the presence of any complications such as infection, poor nutrition, peripheral vascular diseases, or immunosuppression that can affect wound healing (see the Nursing Care Plan). A goal frequently identified when working with a patient with a wound is to see wound improvement within a 2-week period. The outcomes of this goal can include the following:

- Higher percentage of granulation tissue in the wound base
- No further skin breakdown in any body location
- An increase in the caloric intake by 10%

These outcomes are reasonable if the overall goal for the patient is to heal the wound. Plan therapies according to the severity and type of wound and the presence of any complicating conditions (e.g.,

NURSING CARE PLAN

Impaired Skin Integrity

ASSESSMENT

Mrs. Stein, who is 76 years of age, is 7 days postoperative for a total hip replacement. She developed redness and oozing of foul-smelling tan-colored drainage from the hip incision on postoperative day 4. Significant medical history includes arthritis and mild hypertension. Because of surgical pain at the incision site, she did not easily transfer from her bed to the chair. Now on day 7 she notes some pain at the incision and complains of a painful, burning sensation in the sacral region. She is continent of urine and stool but continues to "scoot" over to the side of the bed when preparing for bed-to-chair transfers.

Assessment Activities	*Findings/Defining Characteristics**
Obtain an oral temperature.	Patient has **elevated temperature** and is diaphoretic.
Ask Mrs. Stein how the surgical site limits her mobility.	She relates that her hip always aches and the pain increases on movement. She tells you that she prefers to keep the hip immobile to keep the pain level down. Position of comfort is supine, and Mrs. Stein resists position changes.
Perform a total body skin assessment, paying special attention to the surgical incision and sacral area.	Open areas: sacrum and left hip incision.
Sacral area.	Patient has **reactive hyperemia** around the open sacral area; this **area does not blanch on palpation.** There is a **partial-thickness ulcer directly over the sacral area.**
Left hip, surgical incision.	**Small openings** between staples oozing tan foul-smelling fluid. Periwound area red and warm.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Impaired skin integrity related to pressure and friction on sacral bony prominence and infection of original wound

PLANNING

Goals	*Expected Outcomes (NOC)†*
	Tissue Integrity: Skin
Injury to Mrs. Stein's skin and underlying tissue resulting from pressure and friction on bony prominence will be reduced within 2 to 4 weeks.	Mrs. Stein will have intact skin integrity in the area of nonblanching erythema. Mrs. Stein's sacral ulcer will show signs of healing. Mrs. Stein will maintain intact skin over other pressure points.
Red area around hip wound and tan-colored drainage will be absent within 5 days.	Left hip wound demonstrates signs of healing.
	Immobility Consequences: Physiological
Mrs. Stein's ability to tolerate position changes and correctly change positions will improve within 2 to 4 weeks.	Reactive hyperemia will be within normal limits at all pressure points. Reactive hyperemia in sacral region will have a decrease in nonblanchable pressure areas.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

Continued

NURSING CARE PLAN

***Impaired Skin Integrity*—cont'd**

INTERVENTIONS (NIC)‡	RATIONALE
Pressure Management	
Reposition Mrs. Stein every 90 minutes. Offer pain medication as needed. When Mrs. Stein transfers from bed to chair, remind her not to slide over sheets but to pick up pelvis and relocate from one position to another. Be careful not to slide Mrs. Stein on sheets.	Repositioning removes pressure and allows normal hyperemic response. Frequency of turning is based on initial and ongoing assessment (Bryant and Nix, 2012). Sliding patient's skin on sheets causes friction and deteriorates involved area.
Elevate head of bed no more than 30 degrees.	The higher the head of the bed is elevated, the more likely it is that shearing forces are present, adding to pain and deterioration of the skin loss in the sacral area (WOCN, 2010).
Pressure Ulcer Care	
Keep skin dry and clean; avoid rubbing area.	Moisture softens skin and causes a break in skin integrity. Rubbing an area of nonblanching erythema causes further tissue damage (WOCN, 2010).
Use moisture barrier ointment over the ulcer at least 3 times a day to decrease friction and provide moisture to the open tissue.	An ointment covers the area, providing base of ulcer with moisture, which encourages healing. Ointment prevents sheets from rubbing on area, thus decreasing the friction.
Surgical Wound Care	
Irrigate wound with saline solution twice per day per wound care provider's order.	Cleans wound and surrounding area of wound debris and exudate.
Apply dressing (i.e., gauze moistened with antibiotic solution twice a day after irrigation) according to wound care provider's order.	Provides appropriate topical therapy to wound, placing wound in best environment for healing.
At frequent intervals evaluate patient's pain level and offer pain medication as indicated by assessment.	Provides patient with pain reduction/relief, allowing for greater mobility and comfort.

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Findings*	*Achievement of Outcome*
Perform daily total body skin and wound assessments. Chart results.	No new skin breakdown noted.	No other areas of pain or discomfort are reported.
	Decreased redness at the sacral area.	Decreased pain at sacral site is reported.
	Presence of reepithelialization in sacral area.	Ulcer in sacral area is healed.
	Reduction in hip wound, periwound redness, and amount of wound drainage.	Surgical incision is no longer open; no drainage and no periwound redness.
Palpate reddened area around sacrum.	Sacral area begins to show signs of normal reactive hyperemia blanching following palpation.	Sacral region is improving; no break in epidermis.
	Other pressure points have normal reactive hyperemia and blanching.	Other pressure points remain intact.

infection, poor nutrition, immunosuppression, and diabetes) that affect wound healing. Other goals of care for patients with wounds include the following: promoting wound hemostasis, preventing infection, promoting wound healing, maintaining skin integrity, gaining comfort, and promoting health.

Setting Priorities. You establish nursing care priorities in wound care based on the comprehensive patient assessment and goals and established outcomes. These priorities also depend on whether the patient's condition is stable or emergent. An acute wound needs immediate intervention; whereas in the presence of a chronic, stable wound the patient's hygiene is more important. When there is a risk for pressure ulcer development, preventive interventions such as skin care practices, elimination of shear, and positioning are high priorities. Promotion of wound healing is a major nursing priority; and the type of wound care administered depends on the type, size, and location of the wound and overall treatment goals.

Other patient factors to consider when establishing priorities include patient preferences, daily activities, and family factors. These factors are important regardless of the setting for health care. The priorities of care may not vary from outpatient, home, acute care, or restorative care settings.

Teamwork and Collaboration. With early discharge from health care settings, it is important to consider a patient's plan for discharge. Anticipating the patient's discharge wound care needs and related equipment and resources such as referral to a home care agency or outpatient wound care clinic helps to improve not only wound healing but also the patient's level of independence. Patients and their families often need to continue the objectives of wound management after discharge (Box 48-9). You need to consider the ability of the caregiver and the amount of time needed to change a particular dressing when selecting a dressing for the patient to use after discharge. For example, in the home setting some caregivers choose more expensive dressing materials

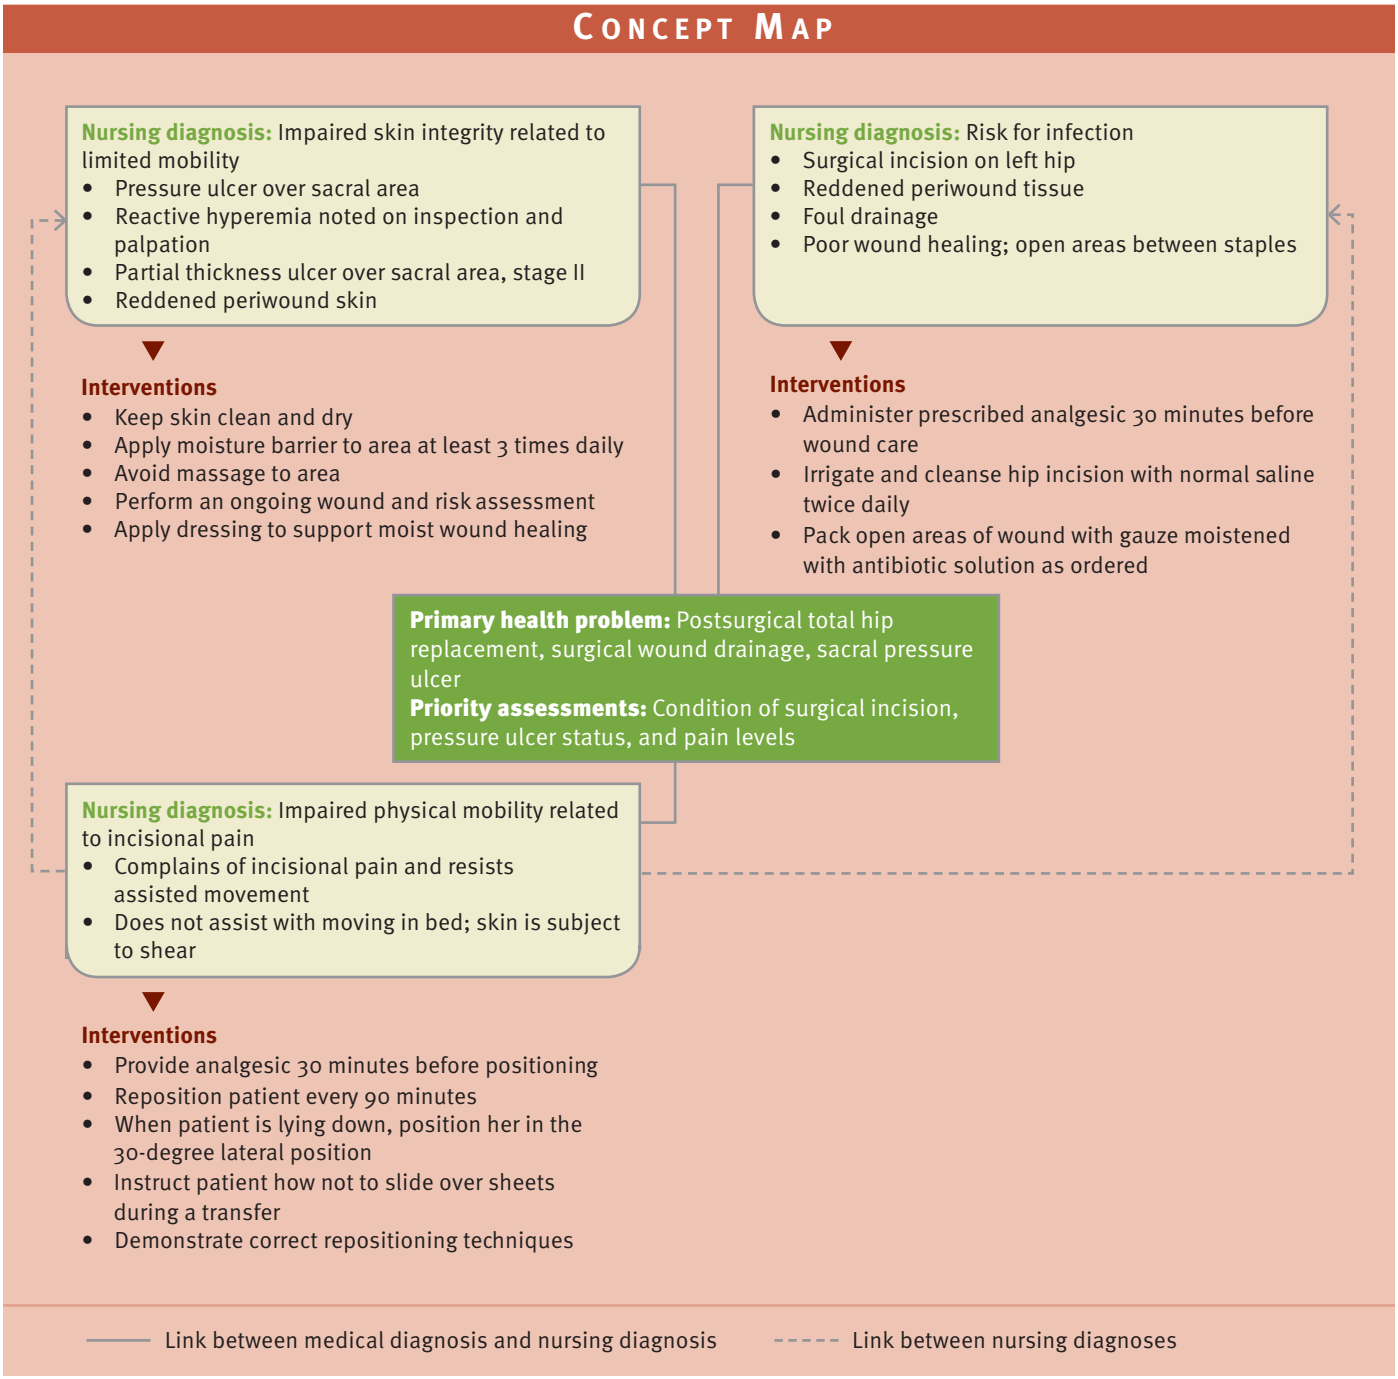

FIG. 48-14 Concept map for Mrs. Stein.

to reduce the frequency of dressing changes. The nurse and patient work together to establish ways of maintaining patient involvement in nursing care and promoting wound healing, whether the patient is in the hospital or home.

IMPLEMENTATION

Health Promotion. Perhaps the most effective intervention for problems with skin integrity and wound care is prevention. Prompt identification of high-risk patients and their risk factors helps to prevent pressure ulcers.

Prevention of Pressure Ulcers. When a patient is immobile, the major risk to the skin is the formation of pressure ulcers. Nursing interventions focus on prevention. The first step in prevention is to assess the patient's risk factors for pressure ulcer development (Table 48-6). Plan on reducing or eliminating the identified risk factors.

Early identification of patients at risk and their risk factors helps you prevent pressure ulcers. Prevention minimizes the impact that risk factors or contributing factors have on pressure ulcer development. Three major areas of nursing interventions for prevention of pressure ulcers are: (1) skin care and management of

BOX 48-9 HOME CARE RECOMMENDATIONS

Ulcer/Wound Assessment

Assessment and documentation of a pressure ulcer need to occur at least weekly, unless there is evidence of deterioration, in which case the nurse needs to reassess both the pressure ulcer and the patient's overall management immediately. In the home setting this requires the assistance of the patient and family because weekly assessment is not always feasible.

Psychosocial Assessment and Management

- Assess the patient's resources (e.g., availability and skill of caregivers, finances, equipment). A successful treatment program requires adequate caregiver and equipment resources.
- Evaluate caregivers for their ability to comprehend and implement the treatment requirements.
- Evaluate caregivers for their level of strength and endurance.
- Consider economic factors because they often limit the supply and availability of equipment and opportunities to relieve caregivers.
- Use an approach that focuses on the psychosocial and physical factors affecting wound care

Ulcer Care Dressings

- Consider caregiver time when selecting a dressing.
- In the home setting some caregivers choose dressing materials manufactured to reduce the frequency of dressing changes.

Infection Control

- Clean dressings are most commonly used in the home setting.
- Clean dressings, as opposed to sterile ones, are recommended for home use until research demonstrates otherwise. This recommendation is in keeping with principles regarding nosocomial infections and with past success of clean urinary catheterization in the home setting, and it takes into account the expense of sterile dressings and the dexterity required for application. The caregiver can use the "no-touch" technique for dressing changes. This technique is a method of changing surface dressings without touching the wound or the surface of any dressing that might be in contact with the wound. Adherent dressings should be grasped by the corner and removed slowly, whereas gauze dressings can be pinched in the center and lifted off.
- Contaminated dressings in the home should be disposed of in a manner consistent with local regulations. The Environmental Protection Agency recommends placing soiled dressings in securely fastened plastic bags before adding them to other household trash. However, local regulations vary, and home care agencies and patients need to follow procedures that are consistent with local laws.

Modified from Agency for Health Care Policy and Research, Panel for the Treatment of Pressure Ulcers in Adults: *Treatment of pressure ulcers,* Clinical Practice Guideline No. 15, AHCPR Pub No. 95-0653, Rockville, Md, 1994, Agency for Health Care Policy and Research, Public Health Service, US Department of Health and Human Services.

TABLE 48-6 A Quick Guide to Pressure Ulcer Prevention

RISK FACTOR	NURSING INTERVENTIONS
Decreased sensory perception	Assess pressure points for signs of nonblanching reactive hyperemia. Provide pressure-redistribution surface.
Moisture	Assess need for incontinence management. Following each incontinent episode, clean area with no-rinse perineal cleaner and protect skin with moisture-barrier ointment.
Friction and shear	Reposition patient using drawsheet and lifting off surface. Provide trapeze to facilitate movement. Position patient at a 30-degree lateral turn and limit head elevation to 30 degrees.
Decreased activity/ mobility	Establish and post individualized turning schedule.
Poor nutrition	Provide adequate nutritional and fluid intake; assist with intake as necessary. Consult dietitian for nutritional evaluation.

incontinence; (2) mechanical loading and support devices, which include proper positioning and the use of therapeutic surfaces; and (3) education (WOCN, 2010).

Topical Skin Care and Incontinence Management. You need to perform frequent skin assessment (see Box 48-5) at a minimum on a once-a-day basis. However, high-risk patients have more frequent skin assessments such as every shift. In addition, ensure that the patient's skin is clean and dry.

When you clean the skin, avoid soap and hot water. Use cleaners with nonionic surfactants that are gentle to the skin (WOCN, 2010). Many types of products are available for skin care, and you need to match their use to the specific needs of the patient. After you clean the skin and make sure that it is completely dry, apply moisturizer to keep the epidermis well lubricated but not oversaturated.

Make an effort to control, contain, or correct incontinence, perspiration, or wound drainage. Patients who have fecal incontinence and who are also receiving enteral tube feeding provide a management challenge. When patients have an incontinent episode, gently clean the area, dry, and apply a thick layer of moisture barrier to the exposed areas. A moisture barrier protects the skin from excessive moisture and bacteria found in the urine or stool.

It is helpful to use the expertise of an advanced practice nurse with a focus on wound care or management of incontinence while caring for at-risk patients. Methods for controlling or containing incontinence vary. You can treat urinary incontinence with behavioral techniques, medication, and surgery. Behavioral techniques help patients learn ways to control their bladder and sphincter muscles. Two examples are bladder and habit training, which is also called *timed voiding*.

Consider using absorbent pads and garments only after trying these measures. Although controversial, absorbent products such as absorptive underpads and garments are sometimes part of the treatment plan for an incontinent patient. Use only products that wick moisture away from the patient's skin (WOCN, 2010).

Positioning. Positioning interventions reduce pressure and **shearing force** to the skin. Elevating the head of the bed to 30 degrees or less decreases the chance of pressure ulcer development from shearing forces (WOCN, 2010). Change the immobilized patient's position according to activity level, perceptual ability, and daily routines (Brienza et al., 2008). A standard turning interval of 1½ to 2 hours does not always prevent pressure ulcer development. Patients need repositioning on a schedule of at least every 2 hours if allowed by their overall condition. When repositioning, use positioning devices to protect bony prominences (WOCN, 2010). The WOCN guidelines (2010) recommend a 30-degree lateral position (Fig. 48-15), which should prevent positioning directly over the

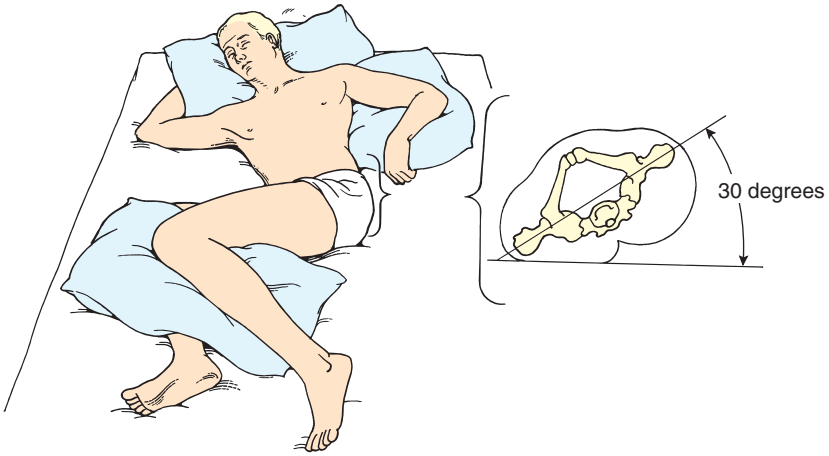

FIG. 48-15 Thirty-degree lateral position at which pressure points are avoided. (Adapted from Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts,* ed 4, St Louis, 2012, Mosby.)

Building Competency in Safety Ms. Willet, a 79-year-old Indian woman, is approximately 300 lb and her height is 5'1". She has recently undergone a left knee replacement and has an immobilizer on her left knee. The immobilizer makes it difficult for her to assist in movement. There is an order to reposition her every 2 hours as her condition warrants. She is unable to effectively assist in repositioning. What should your considerations be in planning her repositioning schedule?

Answers to questions can be found on the Evolve website.

BOX 48-10 PATIENT TEACHING

Pressure-Redistribution Surfaces

Objective

- Patient and family will describe understanding of the purposes and basic operations of the pressure-redistribution surface.

Teaching Strategies

- Explain the reasons for the pressure-redistribution surface.
- Explain proper body mechanics while using the pressure-redistribution surface.
- Educate in the use and care of the pressure-redistribution surface (WOCN, 2010).
- Explain additional pressure-redistribution measures.

Evaluation

- Patient and family will state basic purposes for the pressure-redistribution surface.
- Patient and family will be able to describe the function of the pressure-redistribution surface.
- Patient and family will be able to demonstrate proper use of the pressure-redistribution surface.

bony prominence. To prevent shear and friction injuries, use a transfer device to lift rather than drag the patient when changing positions (see Chapter 47).

Some patients are able to sit in a chair. Make sure to limit the total amount of time they sit to 2 hours or less. In the sitting position the pressure on the ischial tuberosities is greater than in the supine position. In addition, teach a mobile patient at risk for skin breakdown in a sitting position to shift weight every 15 minutes (WOCN, 2010). Shifting weight provides short-term relief on the ischial tuberosities. Also have him or her sit on foam, gel, or an air cushion to redistribute weight away from the ischial areas. Rigid and donut-shaped cushions are contraindicated because they reduce blood supply to the area, resulting in wider areas of ischemia (WOCN, 2010).

After repositioning the patient, reassess the skin. Identifying characteristics that indicate early signs of tissue ischemia in darkly pigmented skin are in Boxes 48-2 and 48-3. For patients with light-toned skin, observe for **normal reactive hyperemia** and blanching. Never massage the reddened areas. Massaging reddened areas increases breaks in the capillaries in the underlying tissues and the risk of injury to underlying tissue and pressure ulcer formation (WOCN, 2010).

Support Surfaces (Therapeutic Beds and Mattresses). A support surface is a specialized device for pressure redistribution designed for management of tissue loads, microclimate, and/or other therapeutic functions (i.e., mattresses, integrated bed system, mattress replacement, overlay or seat cushion, or seat cushion overlay) (EPUAP and NPUAP, 2009). A variety of support surfaces, including specialty v and mattresses, reduce the hazards of immobility to the skin and musculoskeletal system. However, none eliminates the need for meticulous nursing care. No single device eliminates the effects of pressure on the skin.

When selecting support surfaces, incorporate the patient's needs. Knowledge about support surface characteristics (Table 48-7) assists you in clinical decision making. In selecting a support surface, know the patient's risks and the purpose for the support surface; a flow chart is often helpful (Fig. 48-16). Teach patients and families the reason for and proper use of the beds or mattresses (Box 48-10). Some common errors with support surfaces are placing the wrong side of the support surface toward the patient, not plugging powered support surfaces into the electrical source,

TABLE 48-7 Support Surfaces

CATEGORIES AND DEFINITIONS	MECHANISM OF ACTION	INDICATIONS	EXAMPLES OF MANUFACTURERS' AND PRODUCT NAMES
Low-Air-Loss			
Available as a mattress placed directly on the existing bed frame or an overlay placed directly on top of an existing surface	Pressure redistribution Provides a flow of air to assist in managing the heat and humidity of the skin	Prevention or treatment of skin breakdown	Hill Rom/Flexicair Eclipse, Kinetic Concepts, Inc/First Step Select The ROHO Group/Select Air Mattress
Nonpowered			
Any support surface not requiring or using external sources of energy for operation *Examples:* Foam, interconnected air-filled cells	Pressure redistribution Air moves to and from cells as body position changes	Prevention or treatment of skin breakdown	ROHO/ Dry Flotation Mattress, Gaymar Industries/Sof-Care
Air-Fluidized Beds			
Surfaces that change load distribution properties when powered and when patient is in contact with the surface	Provides pressure redistribution via a fluidlike medium created by forcing air through beads as characterized by immersion and envelopment	Prevention or treatment of skin breakdown May also be used to protect newly flapped or grafted surgical sites and for patients with excessive moisture	Kinetic Concepts, Inc/FluidAir Elite, Hill Rom/Clinitron
Lateral Rotation			
Provides passive motion to promote mobilization of respiratory secretions and provides low-air-loss therapy	A feature of a support surface that provides rotation about a longitudinal axis as characterized by degree of patient turn, duration, and frequency	Treatment and prevention of pulmonary complications associated with immobility	Hill Rom/V-Cue Dynamic Air Therapy, Kinetic Concepts, Inc/ TriaDyne

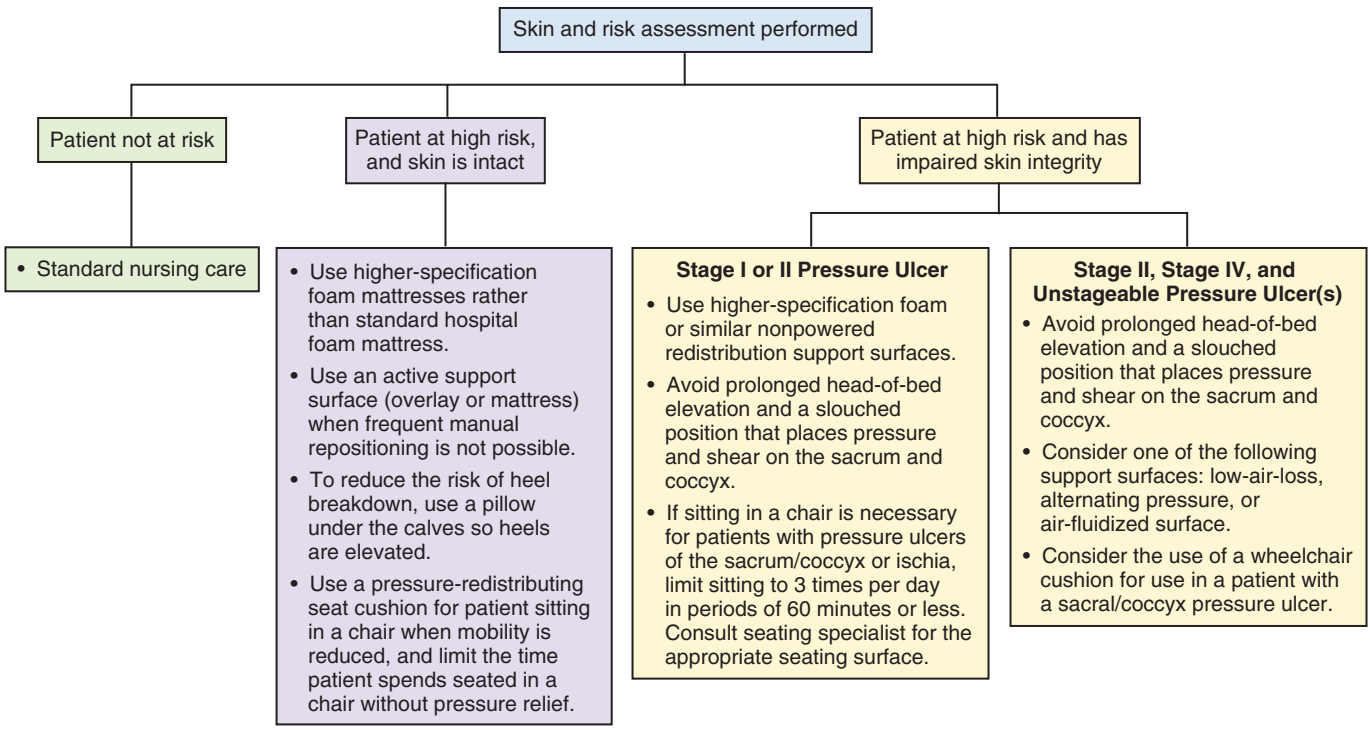

FIG. 48-16 Considerations for choosing the appropriate support surface. (Modified from WOCN: *Guideline for prevention and management of pressure ulcers,* 2010, Mt Laurel, NJ; and National Pressure Ulcer Advisory Panel (NPUAP) and European Pressure Ulcer Advisory Panel (EPUAP): *International guideline for prevention and treatment of pressure ulcers,* Washington DC, 2009, National Pressure Ulcer Advisory Panel.)

not turning on the power source for powered support surfaces, failing to place hand between the metal bed frame and the mattress to determine if patient sinks to the point of touching the bed frame for some support surfaces, and improperly inflating some support surfaces. When used correctly, these support services help reduce pressure ulcers in patients at risk.

Acute Care

Management of Pressure Ulcers. Treatment of patients with pressure ulcers requires a holistic approach that uses the expertise of several multidisciplinary health care professionals (WOCN, 2010). In addition to the nurse, the health care provider, the wound care nurse specialist, physical therapist, occupational therapist, nutritionist, and pharmacist are involved. Aspects of pressure ulcer treatment include local care of the wound and supportive measures such as adequate nutrients and redistribution of pressure (Skill 48-2 on pp. 1215-1217).

When treating a pressure ulcer, reassess the wound for location, stage, size, tissue type and amount, exudate, and surrounding skin condition (Nix, 2012). Acute wounds require close monitoring (every 8 hours). Sometimes chronic wound assessment occurs less frequently. Depending on the topical management system, evaluate the wound with every dressing change, usually not more than 1 time per day.

The use and documentation of a systematic approach to monitor progress of an actual pressure ulcer leads to better decision making and optimum outcomes (Nix, 2012). Several healing and documentation tools are available to document wound assessments over time. Using a tool helps link assessment to outcomes so an evaluation of the plan of care follows objective criteria (Nix, 2012). For example, the Bates-Jensen Wound Assessment Tool (Harris et al., 2010) addresses 15 wound characteristics. You score individual items and calculate the sum total, providing an overall indication of wound status. The scoring assists in evaluating whether the goals of the wound management are effective.

Wound Management. Maintenance of a physiological local wound environment is the goal of effective wound management (Rolstad, Bryant, and Nix, 2012). To maintain a healthy wound environment, you need to address the following principles: prevent and manage infection, clean the wound, remove nonviable tissue, manage exudate, maintain the wound in a moist environment, and protect the wound.

A wound does not move through the phases of healing if it is infected. Preventing wound infection includes cleaning and removing nonviable tissue. Clean pressure ulcers only with noncytotoxic wound cleaners such as normal saline or commercial wound cleaners. Noncytotoxic cleaners do not damage or kill fibroblasts and healing tissue (Rolstad, Bryant, and Nix, 2012). Some commonly used cytotoxic solutions are Dakin's solution (sodium hypochlorite solution), acetic acid, povidone-iodine, and hydrogen peroxide. These **are not** used in clean, granulating wounds.

Irrigation is a common method of delivering a wound-cleaning solution to the wound. Studies have shown that there is an optimal effective range of irrigation pressures that ensures adequate removal of bacteria (Gardner and Frantz, 2008). One method to ensure an irrigation pressure within the correct range is to use a 19-gauge needle or an angiocatheter and a 35-mL syringe that delivers saline to a pressure ulcer at 8 psi (Fig. 48-17).

FIG. 48-17 Wound irrigation.

Debridement is the removal of nonviable, necrotic tissue. Removal of necrotic tissue is necessary to rid the wound of a source of infection, enable visualization of the wound bed, and provide a clean base necessary for healing.

The method of debridement depends on which is most appropriate to the patient's condition and care goals (WOCN, 2010). It is important to remember that during the debridement process some normal wound observations to make include an increase in wound exudate, odor, and size. You need to assess and prevent or effectively manage pain that occurs with debridement (WOCN, 2010).

Methods of debridement include mechanical, autolytic, chemical, and sharp/surgical. One method of mechanical debridement is the use of wet-to-dry saline gauze dressings. Place moistened gauze into the wound and allow the dressing to dry thoroughly before "pulling" the gauze that has adhered to the tissue out of the pressure ulcer. This is a nonselective method of debridement because devitalized and viable tissues are both removed; thus it is not used routinely. Never use this method in a clean, granulating wound. Other methods of mechanical debridement are wound irrigation (high-pressure irrigation and pulsatile high-pressure lavage) and whirlpool treatments (Ramundo, 2012).

Autolytic debridement uses synthetic dressings over a wound to allow the eschar to be self-digested by the action of enzymes that are present in wound fluids. You accomplish this by using dressings that support moisture at the wound surface. If the wound base is dry, use a dressing that adds moisture; if there is excessive exudate, use a dressing that absorbs the excessive moisture while maintaining moisture at the wound bed. Some examples of these dressings are transparent film and hydrocolloid dressings.

You can accomplish chemical debridement with the use of a topical enzyme preparation, Dakin's solution, or sterile maggots. Topical enzymes induce changes in the substrate resulting in the breakdown of necrotic tissue (Ramundo, 2012). Depending on the type of enzyme used, the preparation either digests or dissolves the tissue. These preparations require a health care provider's order. Dakin's solution breaks down and loosens dead tissue in a wound. Apply the solution to gauze and apply to the wound. Sterile maggots are used in a wound because it is thought that they ingest the dead tissue.

Surgical debridement is the removal of devitalized tissue by using a scalpel, scissors, or other sharp instrument. Health care providers and in some states trained advanced practice nurses perform surgical debridement of an ulcer or wound. Nurses should check the Nurse Practice Act for their state to see if surgical debridement is a nursing function. It is the quickest method of debridement. It is usually indicated when the patient has signs of cellulitis or sepsis.

A moist environment supports the movement of epithelial cells and facilitates wound closure. A wound that has excessive exudate

(drainage) provides an environment that supports bacterial growth, macerates the periwound skin, and slows the healing process. If excessive wound exudate is present, evaluate the volume, consistency, and odor of the drainage to determine if signs and symptoms of infection are present.

Remember, the wound will not heal unless the contributory factors are controlled or eliminated. Therefore it is critically important for you to address the causative factors (e.g., shear, friction, pressure, and moisture), or it is unlikely that the wound will heal despite topical therapy (Rolstad, Bryant, and Nix, 2012).

The treatment plan needs to be altered as a wound heals. For example, a transparent film dressing is used initially to autolytically debride (liquefy the tissue using body moisture) a necrotic wound. Once the wound is cleaned of necrotic tissue, discontinue the transparent film dressing; and, based on the wound base characteristics, choose a new dressing. A wound with excessive drainage requires a dressing with a high absorptive capacity. Continued reassessment is key to supporting the wound as it moves through the phases of wound healing.

Education. Education of the patient and caregivers is an important nursing function (Rolstad, Bryant, and Nix, 2012). A variety of educational tools, including videotapes and written materials, are available for you to use when teaching patients and caregivers/family to prevent and treat pressure ulcers and care for wounds. The Agency for Health Care Policy and Research (AHCPR, 1992a, 1994) has booklets on pressure ulcer prevention and treatment that are helpful when teaching patients and their caregivers/family. They are available in English and Spanish. Individualize your teaching for each patient, especially older patients.

Understanding and assessing the experience of the patient and support person are also important dimensions in the treatment of people with pressure ulcers (WOCN, 2010). Clinicians are only just now exploring through research the caregiver's perspective of the concerns and issues faced by frail older spouses caring for their loved ones with pressure ulcers. You need to plan interventions to meet the identified psychosocial needs of patients and their support persons (WOCN, 2010).

Nutritional Status. Nutritional assessment and support of the patient with a wound is based on the appreciation that nutrition is fundamental to normal cellular integrity and tissue repair (Stotts, 2012a). Early intervention is necessary to correct inadequate nutrition and support healing. The Joint Commission (2008) recommends nutritional assessment within 24 hours of admission. Reassessments reflect changes in status and effects of interventions (Stotts, 2012a). Box 48-11 defines parameters for clinically significant malnutrition (AHCPR, 1994). Assess the patient's mouth and skin for signs of nutritional deficiencies (see Chapter 44). Give vitamin and mineral supplements if you suspect or know of any deficiencies.

Protein Status. Patients with pressure ulcers who are underweight or losing weight need enhanced caloric and protein supplementation (WOCN, 2010). A patient can lose as much as 50 g of protein per day from an open, weeping pressure ulcer. Although the recommended intake of protein for adults is 0.8 g/kg/day, a higher intake of protein up to 1.8 g/kg/day is necessary for healing. Increased protein intake helps rebuild epidermal tissue. Increased caloric intake helps replace subcutaneous tissue. Vitamin C promotes collagen synthesis, capillary wall integrity, fibroblast function, and immunological function.

Hemoglobin. A low hemoglobin level decreases delivery of oxygen to the tissues and leads to further ischemia. When possible, maintain hemoglobin at 12 g/100 mL.

BOX 48-11 RECOMMENDATIONS FOR NUTRITIONAL ASSESSMENT AND MANAGEMENT OF PRESSURE ULCERS

Assessment of Clinically Significant Malnutrition

- Screen and assess the nutritional status of the patient with a pressure ulcer on admission and with each condition change.
- Assess weight status to determine weight history and significant loss from usual weight (≥5% change in 30 days or ≥10% in 180 days).

Interventions

- Refer patients with pressure ulcers to the dietitian for early intervention for nutritional problems.
- Provide 30-35 calories/kg body weight for individuals under stress with a pressure ulcer.
- Consider nutritional support when oral intake is inadequate.
- Encourage consumption of a balanced diet that includes good sources of vitamins and minerals.

Modified from European Pressure Ulcer Advisory Panel and National Pressure Ulcer Advisory Panel: *Treatment of pressure ulcers: quick reference guide,* Washington, DC, 2009, National Pressure Ulcer Advisory Panel.

First Aid for Wounds. In an emergency setting use first aid measures for wound care. Under stable conditions a variety of interventions ensure wound healing. When a patient suffers a traumatic wound, first aid interventions include stabilizing cardiopulmonary function (see Chapter 40), promoting hemostasis, cleaning the wound, and protecting it from further injury.

Hemostasis. After assessing the type and extent of the wound, control bleeding by applying direct pressure on it with a sterile or clean dressing such as a washcloth. After bleeding subsides, an adhesive bandage or gauze dressing taped over the laceration allows skin edges to close and a blood clot to form. If a dressing becomes saturated with blood, add another layer of dressing, continue to apply pressure, and elevate the affected part. Avoid further disruption of skin layers. Serious lacerations need to be sutured by a health care provider. Pressure dressings used during the first 24 to 48 hours after trauma help maintain hemostasis.

Normally allow a puncture wound to bleed to remove dirt and other contaminants such as saliva from a dog bite. When a penetrating object such as a knife blade is present, *do not remove the object.* The presence of the object provides pressure and controls some bleeding. Removal causes massive, uncontrolled bleeding. Except for skull injuries, apply pressure around the penetrating object but not on it and transport the patient to an emergency facility.

Cleaning. The process of cleaning a wound involves selecting an appropriate cleaning solution and using a mechanical means of delivering that solution without causing injury to the healing wound tissue (WOCN, 2010). Gently cleaning a wound removes contaminants that serve as sources of infection. However, vigorous cleaning using a method with too much mechanical force causes bleeding or further injury. For abrasions, minor lacerations, and small puncture wounds, first rinse the wound with normal saline and lightly cover the area with a dressing. When a laceration is bleeding profusely, only brush away surface contaminants and concentrate on hemostasis until the patient can be cared for in a clinic or hospital.

According to the WOCN guidelines (2010), normal saline is the preferred cleaning agent. It is physiologically neutral and does not harm tissue. Gentle cleaning with normal saline and the

application of moist saline dressings are often used in healing wounds. Use saline to maintain the moist surface needed to promote the development and migration of epithelial tissue. Wet-to-dry saline dressings are only for debriding wounds. Never use them in a clean, granulating wound.

Protection. Regardless of whether bleeding has stopped, protect a wound from further injury by applying sterile or clean dressings and immobilizing the body part. A light dressing applied over minor wounds prevents entrance of microorganisms.

Dressings. The more extensive the wound, the larger the dressing required. In the home a clean towel or diaper is often the best secondary dressing. A bulky dressing applied with pressure minimizes movement of underlying tissues and helps immobilize the entire body part. A bandage or cloth wrapped around a penetrating object should immobilize it adequately.

Alternative dressings are available to cover and protect certain types of wounds such as large wounds, wounds with drainage tubes or suction catheters in the wound, and wounds that need frequent changing because of excessive drainage. Pouches or special wound collection systems cover these wounds and collect their drainage. Some of these devices have a plastic door on the front of the wound pouch, allowing you to change the packing without removing the pouch from the skin.

The use of dressings requires an understanding of wound healing. A variety of dressing materials are commercially available. The correct dressing selection facilitates wound healing (Rolstad, Bryant, and Nix, 2012). The dressing type depends on the assessment of the wound and the phase of wound healing. When you identify the objectives for the wound care, the dressing choice becomes clear. A wound that requires infection management requires a different set of dressings than one requiring the removal of nonviable tissue.

For surgical wounds that heal by primary intention, it is common to remove dressings as soon as drainage stops. In contrast, when dressing a wound healing by secondary intention, the dressing material becomes a means for providing moisture to the wound or assisting in debridement.

Purposes of Dressings. A dressing serves several purposes:

- Protects a wound from microorganism contamination
- Aids in hemostasis
- Promotes healing by absorbing drainage and debriding a wound
- Supports or splints the wound site
- Protects patients from seeing the wound (if perceived as unpleasant)
- Promotes thermal insulation of the wound surface
- Provides a moist environment

When the skin is broken, a dressing helps reduce exposure to microorganisms. However, when drainage is minimal, the healing process forms a natural fibrin seal that eliminates the need for a dressing. Wounds with extensive tissue loss always need a dressing.

Pressure dressings promote hemostasis. Applied with elastic bandages, a pressure dressing exerts localized downward pressure over an actual or potential bleeding site. A pressure dressing eliminates dead space in underlying tissues so wound healing progresses normally. Check pressure dressings to be sure that they do not interfere with circulation to a body part. Assess skin color, pulses in distal extremities, the patient's comfort, and changes in sensation. Pressure dressings are not removed routinely.

A primary function of a dressing on a healing wound is to absorb drainage. Most surgical gauze dressings have three layers: a contact or primary layer, an absorbent layer, and an outer protective or secondary layer. The contact dressing covers the incision and part of the adjacent skin. Fibrin, blood products, and debris adhere to its surface. A problem occurs if the wound drainage dries, causing the dressing to stick to the suture line. Improperly removing the dressing causes disruption of the healing epidermal surface. If the dressing is sticking to the surgical incision, lightly moisten it with saline solution. This causes the dressing to become saturated, loosening it from the incisional area and preventing trauma to the incisional area during removal.

The dressing technique varies, depending on the goal of the treatment plan for the wound. For example, if the goal is to maintain a moist environment for a clean granulating wound, it is important to not let the saline-moistened gauze dressing dry and stick to it. This is in direct contrast to the dressing technique that you use if the goal of care is to mechanically debride the wound using a saline wet-to-dry dressing. When wounds such as a necrotic wound require debriding, use a wet-to-dry dressing technique. Place the moist dressing (contact dressing) into the wound and allow it to dry. The contact dressing debrides necrotic tissue and debris. In this case the contact dressing is allowed to dry so it sticks to underlying tissue, and debridement occurs during removal.

Dressings applied to a draining wound require frequent changing to prevent microorganism growth and skin breakdown. Bacteria grow readily in the dark, warm, moist environment under a dressing. Skin surfaces become macerated and irritated. Minimize periwound skin breakdown by keeping the skin clean and dry and reducing the use of tape.

The absorbent dressing layer serves as a reservoir for additional secretions. The wicking action of woven gauze dressings pulls excess drainage into the dressing and away from the wound. The final outer layer of a dressing helps prevent bacteria and other external contaminants from reaching the wound surface. Usually the outer dressing is made of a thicker dressing material. Apply adhesives to this layer to secure the dressings.

A dressing needs to support a moist wound environment if the wound is healing by secondary intention. A moist wound base facilitates the movement of epithelialization, thus allowing the wound to resurface as quickly as possible.

Types of Dressings. Dressings vary by type of material and mode of application (wet or dry) (Skill 48-3 on pp. 1218-1221). They need to be easy to apply, comfortable, and made of materials that promote wound healing. The WOCN guidelines (2010) are helpful when selecting dressings based on the goal of wound treatment (Box 48-12). To avoid causing damage to the periwound skin, it is important that the dressing technique that you use to treat pressure ulcers and other wounds is not excessively moist (Box 48-13).

Most pressure ulcers require dressings. The type of dressing is usually based on the stage of the pressure ulcer, the type of tissue in the wound, and the function of the dressing (Table 48-8). Before placing a dressing on a pressure ulcer, it is important to know the stage of the pressure ulcer; have done a thorough assessment of it; and understand the goal of the treatment, the mechanism of action of the dressing, and principles of wound care.

Gauze sponges are the oldest and most common dressing. They are absorbent and are especially useful in wounds to wick away the wound exudate. Gauze is available in different textures and various lengths and sizes; the 4×4 is the most common size. Gauze can be saturated with solutions and used to clean and pack a wound. When used to pack a wound, the gauze is saturated with the solution (usually normal saline), wrung out, unfolded, and lightly packed into the wound. The purpose of this type of dressing is to

BOX 48-12 DRESSING CONSIDERATIONS

- Clean the wound and periwound area at each dressing change, minimizing trauma to the wound (WOCN, 2010).
- Use a dressing that continuously provides a moist environment.
- Perform wound care using topical dressings as determined by a thorough assessment. No specific studies have proven an optimal dressing type for pressure ulcers (WOCN, 2010).
- Choose a dressing that keeps the surrounding intact (periulcer) skin dry while keeping the ulcer bed moist.
- Choose a dressing that controls exudate but does not desiccate the ulcer bed.
- The type of dressing may change over time as the pressure ulcer heals or deteriorates. The wound should be monitored at every dressing change and regularly assessed to determine whether modifications in the dressing type are needed (WOCN, 2010).
- Consider caregiver time, ease of use, availability, and cost when selecting a dressing.

BOX 48-13 EVIDENCE-BASED PRACTICE

Moisture-Associated Skin Damage

PICO Question: Which interventions can be used to prevent moisture-associated skin damage that can occur around a wound in a patient?

Evidence Summary

Appropriate wound management to support healing is critical for patients with pressure ulcers and other chronic wounds. Advances in wound healing document the benefit of a moist wound environment and the accepted practice of moist wound healing. But when moisture is present in excess and allowed to sit on the periwound skin, it leads to damaging maceration (Woo, Ayello, and Sibald, 2009). Maceration is defined as a softening of tissues by soaking until connective fibers can be teased apart (Gray and Weir, 2007). This condition is classified as moisture-associated skin damage. Interventions that focus on preventive steps include use of a dressing that absorbs excessive moisture while maintaining a moist wound bed (Gray and Weir, 2007), selection of the right dressing and size to absorb the wound exudate, the appropriate frequency of dressing change (Woo, Ayello, and Sibald, 2009), and use of a skin protectant to the periwound skin.

Application to Nursing Practice

- Use of a skin protectant (no-sting film barrier, petrolatum-based or zinc-based protectant) helps to prevent periwound skin maceration.
- Dressing selection needs to be individualized to the type of wound and wound-healing goals.
- Frequency of dressing change should not exceed manufacturer-recommended "wear time" (Woo, Ayello, and Sibald, 2009).
- Assess the effectiveness of the absorbent capacity of the dressing and make changes based on the amount of wound drainage.

provide moisture to the wound yet to allow wound drainage to be wicked into the gauze pad. Unfolding the dressing allows easier wicking action.

Use nonadherent gauze dressings such as Telfa over clean wounds with little or no drainage. Telfa gauze has a shiny, nonadherent surface that does not stick to incisions or wound openings but allows drainage to pass through to the gauze topper.

Another type of dressing is a self-adhesive, transparent film. This type of dressing traps moisture over the wound, providing a moist environment (Fig. 48-18). The transparent film dressing is ideal for small superficial wounds such as partial-thickness wounds or to protect high-risk skin. Use a film dressing as a secondary dressing and for autolytic debridement of small wounds. It has the following advantages:

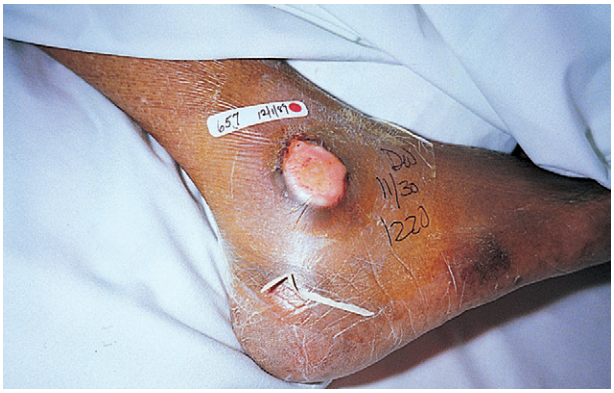

FIG. 48-18 Transparent film dressing.

- Adheres to undamaged skin
- Serves as a barrier to external fluids and bacteria but still allows the wound surface to "breathe" because oxygen passes through the transparent dressing
- Promotes a moist environment that speeds epithelial cell growth
- Can be removed without damaging underlying tissues
- Permits viewing a wound
- Does not require a secondary dressing

Hydrocolloid dressings are dressings with complex formulations of colloids, elastomeric, and adhesive components. They are adhesive and occlusive. The wound contact layer of this dressing forms a gel as fluid is absorbed and maintains a moist healing environment. Hydrocolloids support healing in clean granulating wounds and autolytically debride necrotic wounds; they are available in a variety of sizes and shapes. This type of dressing has the following functions:

- Absorbs drainage through the use of exudate absorbers in the dressing
- Maintains wound moisture
- Slowly liquefies necrotic debris
- Is impermeable to bacteria and other contaminants
- Is self-adhesive and molds well
- Acts as a preventive dressing for high-risk friction areas
- May be left in place for 3 to 5 days, minimizing skin trauma and disruption of healing

This type of dressing is most useful on shallow to moderately deep dermal ulcers. Hydrocolloid dressings cannot absorb the amount of drainage from heavily draining wounds, and some are contraindicated for use in full-thickness and infected wounds. Some hydrocolloids leave a residue in the wound bed that is easy to confuse with purulent drainage.

Hydrogel dressings are gauze or sheet dressings impregnated with water- or glycerin-based amorphous gel. This type of dressing hydrates wounds and absorbs some smaller amounts of exudate. Hydrogel dressings are for partial-thickness and full-thickness wounds, deep wounds with some exudate, necrotic wounds, burns, and radiation-damaged skin. They are very useful in painful wounds because they are very soothing to the patient and do not adhere to the wound bed and thus cause little trauma during removal. A disadvantage is that some hydrogels require a secondary

TABLE 48-8 Dressings by Pressure Ulcer Stage

PRESSURE ULCER STAGE	PRESSURE ULCER STATUS	DRESSING	COMMENTS*	EXPECTED CHANGE	ADJUVANTS
I	Intact	None	Allows visual assessment	Resolves slowly without epidermal loss over 7-14 days	Turning schedule Support hydration Nutritional support
		Transparent dressing	Protects from shear Not to be used in presence of excessive moisture		
		Hydrocolloid	Does not always allow visual assessment		Pressure-redistribution surface or chair cushion
II	Clean	Composite film	Limits shear	Heals through reepithelialization	Turning schedule Support hydration Nutritional support
		Hydrocolloid	Change when seal of dressing breaks; maximal wear time 7 days		Manage incontinence
		Hydrogel	Provides a moist environment		
III	Clean	Hydrocolloid	Must change when seal of dressing breaks; maximal wear time 7 days	Heals through granulation and reepithelialization	See previous stages; evaluate pressure-redistribution needs
		Hydrogel covered with foam dressing	Applied over wound to protect and absorb moisture		
		Calcium alginate	Used with significant exudate; must cover with secondary dressing		
		Gauze	Used with normal saline or other prescribed solution; must unfold to make contact with wound		
		Growth factors	Used with gauze per manufacturer instructions		.
IV	Clean	Hydrogel covered with foam dressing	Applied over wound to protect and absorb moisture	Heals through granulation and reepithelialization	Surgical consultation often necessary for closure (see stages I, II, and III)
		Calcium alginate	Used with significant exudate; must cover with secondary dressing		
		Gauze	Used with normal saline or other prescribed solution; must unfold to make contact with wound; fill all dead space with gauze		
		Growth factors	Used with gauze		
Unstageable	Wound covered with eschar	Adherent film	Facilitates softening of eschar	Eschar lifts at edges as debridement progresses	See previous stages; surgical consultation sometimes considered for debridement
		Gauze plus ordered solution	Delivers solution and wicks wound drainage and softens eschar	Eschar softens	
		Enzymes	Facilitate debridement	Eschar softens	
		None	If eschar is dry and intact, no dressing used, allowing eschar to act as physiological cover; may be indicated for treatment of heel eschar		

*As with all occlusive dressings, wound should *not* be clinically infected.

dressing and you must take care to prevent periwound maceration. Hydrogels come in a sheet dressing or a tube; thus you are able to squirt the gel directly into the wound base.

Hydrogel has the following advantages:

- Is soothing and can reduce wound pain
- Provides a moist environment
- Debrides necrotic tissue (by softening the necrotic tissue)
- Does not adhere to the wound base and is easy to remove

Many other types of dressings are available. Foam and alginate dressings are for wounds with large amounts of exudate and those that need packing. Foam dressings are also used around drainage tubes to absorb drainage. Calcium alginate dressings are

manufactured from seaweed and come in sheet and rope form. The alginate forms a soft gel when it comes in contact with wound fluid. These highly absorbent dressings are for wounds with an excessive amount of drainage and do not cause trauma when removed from the wound. *Do not use these in dry wounds, and they require a secondary dressing.* Several manufacturers produce composite dressings, which combine two different dressing types into one dressing. Research is ongoing regarding which type of dressing is best for which type of wound.

Changing Dressings. To prepare for changing a dressing, you need to know the type of dressing, the presence of underlying drains or tubing, and the type of supplies needed for wound care. Poor preparation causes a break in aseptic technique (see Chapter 28) or accidental dislodging of a drain. Your judgment in modifying a dressing change procedure is important during wound care, particularly if the character of a wound changes. Notifying the health care provider of any change is essential.

Sometimes (e.g., with chronic nonsurgical wounds) the nurse uses a clean technique for a dressing change. The clean technique refers to the fact that the nurse maintains medical versus sterile asepsis (Chapter 28). He or she wears clean gloves, but the dressing materials are in sterile packages and are carefully placed over the wound. Deep wounds that require irrigation are usually irrigated with a sterile solution. A complete patient and wound history is essential in determining when a clean dressing technique is appropriate. For example, chronic pressure ulcer wounds use a clean technique. On the other hand, a fresh surgical wound requires sterile technique so as not to introduce microorganisms into a healing wound.

The health care provider's order for changing a dressing indicates the dressing type, the frequency of changing, and any solutions or ointments to be applied to the wound. An order to "reinforce dressing prn" (add dressings without removing the original one) is common right after surgery, when the health care provider does not want accidental disruption of the suture line or bleeding. The medical or operating room record usually indicates whether drains are present and from what body cavity they drain. After the first dressing change, describe the location of drains and the type of dressing materials and solutions to use in the patient's care plan. Follow these guidelines during a dressing change procedure:

- Assessing the skin beneath the tape
- Performing thorough hand hygiene before and after wound care
- Wearing sterile gloves before directly touching an open or fresh wound (see Chapter 28)
- Removing or changing dressings over closed wounds when they become wet or if the patient has signs or symptoms of infection and as ordered

To prepare a patient for a dressing change, do the following:

- Evaluate patient's pain and, if indicated, administer required analgesics so peak effects occur during the dressing change
- Describe steps of the procedure to lessen patient anxiety
- Gather all supplies required for the dressing change
- Recognize normal signs of healing
- Answer questions about the procedure or the wound

Often it is necessary to teach patients how to change dressings in preparation for home care. In this situation, demonstrate dressing changes to the patient and family and then provide an opportunity for them to practice. Usually wound healing has progressed to the point that risks of complications such as dehiscence or evisceration are minimal. The patient needs to be able to change a dressing independently or with assistance from a family member before discharge. Contaminated dressings in the home should be disposed of in a manner consistent with local regulations. Skill 48-3 outlines the steps for changing dry and moist dressings.

FIG. 48-19 V.A.C. unit. *V.A.C.*, Vacuum-assisted closure. (Courtesy Kinetic Concepts, Inc [KCI], San Antonio, Tex.)

Packing a Wound. The first step in packing a wound is to assess its size, depth, and shape. These characteristics are important in determining the size and type of dressing used to pack a wound. The dressing needs to be flexible and in contact with the entire wound surface. Make sure that the type of material used to pack the wound is appropriate. Many new dressing materials such as alginates are also used for packing. If gauze is the appropriate dressing material, saturate it with the ordered solution, wring out, unfold, and lightly pack into the wound. The entire wound surface needs to be in contact with part of the moist gauze dressing (see Skill 48-3).

It is important to remember not to pack the wound too tightly. Overpacking causes pressure on the tissue in the wound bed. Pack the wound only until the packing material reaches the surface of the wound; there should never be so much packing material that it extends higher than the wound surface. Packing that overlaps onto the wound edges causes maceration of the tissue surrounding the wound.

A treatment modality for wounds is negative-pressure wound therapy (NPWT) or vacuum-assisted closure (one brand name is V.A.C.). NPWT is the application of subatmospheric (negative) pressure of a wound through suction to facilitate healing and collect wound fluid (Netsch, 2012). The **vacuum-assisted closure (V.A.C.)** (Fig. 48-19) is a device that assists in wound closure by applying localized negative pressure to draw the edges of a wound together (Fig. 48-20, *A* and *B*). NPWT supports wound healing by edema reduction and fluid removal, macro deformation and wound contraction, and micro deformation and mechanical stretch perfusion. Secondary effects include angiogenesis, granulation tissue formation, and reduction in bacterial bioburden (Netsch, 2012) (Fig. 48-21). There have been modifications to the V.A.C. The V.A.C. Instill allows intermittent instillation of fluids into the wound, especially those wounds not responding to traditional NPWT (Jerome, 2007).

NPWT is used for treating acute and chronic wounds (Skill 48-4 on pp. 1221-1224). The schedule for changing NPWT dressings varies, depending on the type of wound and amount of drainage. Wear time for the dressing is anywhere from 24 hours to 5 days. As the wound heals, granulation tissue lines its surface. The wound has a stippled or granulated appearance. The surface area sometimes increases or decreases, depending on wound location and the amount of drainage removed by the NPWT system. NPWT is also used to enhance the take of split-thickness skin grafts. It is placed

BOX 48-14 MAINTAINING AN AIRTIGHT SEAL

To avoid wound desiccation, the wound needs to stay sealed once therapy is initiated. Problem seal areas include wounds around joints and near the sacrum. The following points assist in maintaining an airtight seal:

- Clip hair around wound.
- Cut transparent film to extend 3 to 5 cm (1.2 to 2 in) beyond wound parameter.
- Avoid wrinkles in transparent film.
- Patch leaks with transparent film.
- Use multiple small strips of transparent film to hold dressing in place before covering it with large piece of transparent film.
- Avoid adhesive remover because it leaves a residue that hinders film adherence.

From Chua PC et al: Vacuum-assisted wound closure, *Am J Nurs* 100(12):45, 2000.

over the graft intraoperatively, decreasing the ability of the graft to shift and evacuating fluids that build up under it (Netsch, 2012; Xie et al., 2010). An airtight seal must be maintained (Box 48-14).

Securing Dressings. Use tape, ties, or a secondary dressing and cloth binders to secure a dressing over a wound site. The choice of anchoring depends on the wound size and location, the presence of drainage, the frequency of dressing changes, and the patient's level of activity.

Most often strips of tape are used to secure dressings if the patient is not allergic to it. Nonallergenic paper and plastic tapes minimize skin reactions. Common adhesive tape adheres well to the surface of the skin, whereas elastic adhesive tape compresses closely around pressure bandages and permits more movement of a body part. Skin sensitive to adhesive tape becomes severely inflamed and denuded and in some cases even sloughs when the tape is removed. It is important to assess skin under tape at each dressing change.

Tape is available in various widths such as 1.3, 2.5, 5 and 7.5 cm (½, 1, 2, and 3 inches). Choose the size that sufficiently secures the dressing. For example, a large abdominal wound dressing needs to remain secure over a large area despite frequent stress from movement, respiratory effort, and possibly abdominal distention. Strips of 7.5-cm (3-inch) adhesive better stabilize such a large dressing so it does not continually slip off. When applying tape, ensure that it adheres to several inches of skin on both sides of the dressing and that it is placed across the middle of the dressing. When securing the dressing, press the tape gently, making sure to exert pressure away from the wound. This way, tension occurs in both directions away from the wound, minimizing skin distortion and irritation. Never apply tape over irritated or broken skin. Protect irritated skin by using a solid skin barrier and applying the tape over the barrier.

To remove tape safely, loosen the ends and gently pull the outer end parallel with the skin surface toward the wound. Apply light traction to the skin away from the wound as the tape is loosened and removed. The traction minimizes pulling of the skin. Adhesive remover also loosens the tape from the skin. If tape covers an area of hair growth, the patient experiences less discomfort if you pull it in the direction of the hair growth.

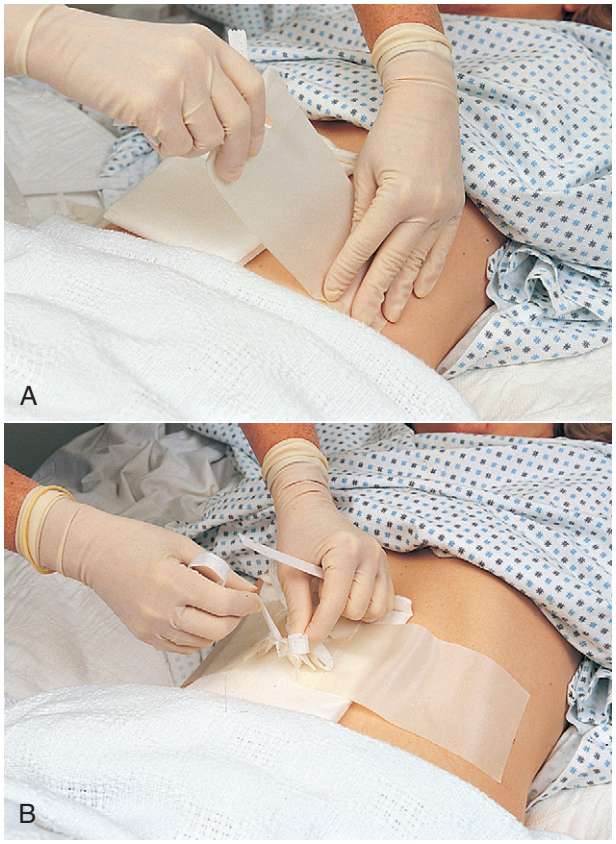

FIG. 48-22 Montgomery ties. **A,** Each tie is placed at side of dressing. **B,** Securing ties encloses dressing.

To avoid repeated removal of tape from sensitive skin, secure dressings with pairs of reusable Montgomery ties (Fig. 48-22). Each section consists of a long strip; half contains an adhesive backing to apply to the skin, and the other half folds back and contains a cloth tie or a safety pin/rubber band combination that you fasten across a dressing and untie at dressing changes. A large, bulky dressing often requires two or more sets of Montgomery ties. Another method to protect the surrounding skin on wounds that need frequent dressing changes is to place strips of hydrocolloid dressings on either side of the wound edges, cover the wound with a dressing, and apply the tape to the dressing. To provide even support to a wound and immobilize a body part, apply elastic gauze or cloth bandages and binders over a dressing.

Comfort Measures. A wound is often painful, depending on the extent of tissue injury. Use several techniques to minimize discomfort during wound care. Carefully removing tape, gently cleaning wound edges, and carefully manipulating dressings and drains minimize stress on sensitive tissues. Careful turning and positioning also reduce strain on a wound. Administering analgesic medications 30 to 60 minutes before dressing changes (depending on the time of peak action of a drug) also reduces discomfort.

Cleaning Skin and Drain Sites. Although a moderate amount of wound exudate promotes epithelial cell growth, some health care providers order cleaning a wound or drain site if a dressing does not absorb drainage properly or if an open drain deposits drainage onto the skin. Wound cleaning requires good hand hygiene and aseptic techniques (see Chapter 28). You sometimes use irrigation to remove debris from a wound.

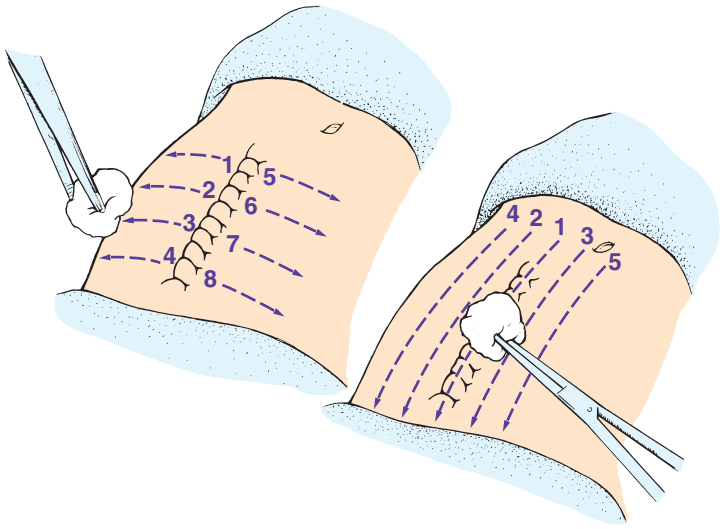

FIG. 48-23 Methods for cleaning a wound site.

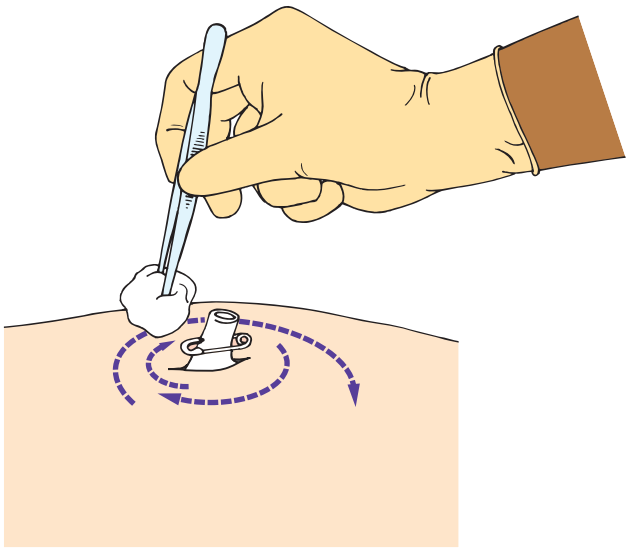

FIG. 48-24 Cleaning a drain site.

Basic Skin Cleaning. Clean surgical or traumatic wounds by applying noncytotoxic solutions with sterile gauze or by irrigation. The following three principles are important when cleaning an incision or the area surrounding a drain:

1. Clean in a direction from the least contaminated area such as from the wound or incision to the surrounding skin (Fig. 48-23) or from an isolated drain site to the surrounding skin (Fig. 48-24).
2. Use gentle friction when applying solutions locally to the skin.
3. When irrigating, allow the solution to flow from the least to most contaminated area (see Skill 48-5).

After applying a solution to sterile gauze, clean away from the wound. Never use the same piece of gauze to clean across an incision or wound twice.

Drain sites are a source of contamination because moist drainage harbors microorganisms. If a wound has a dry incisional area

FIG. 48-25 Incision closed with metal staples.

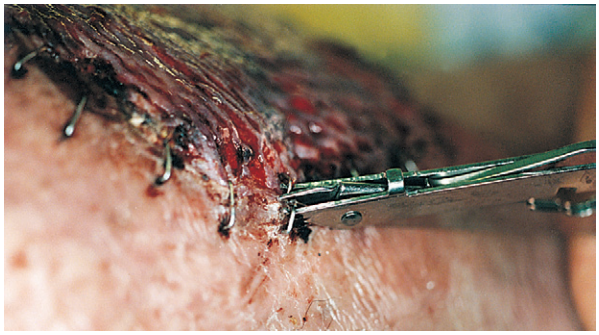

FIG. 48-26 Staple remover.

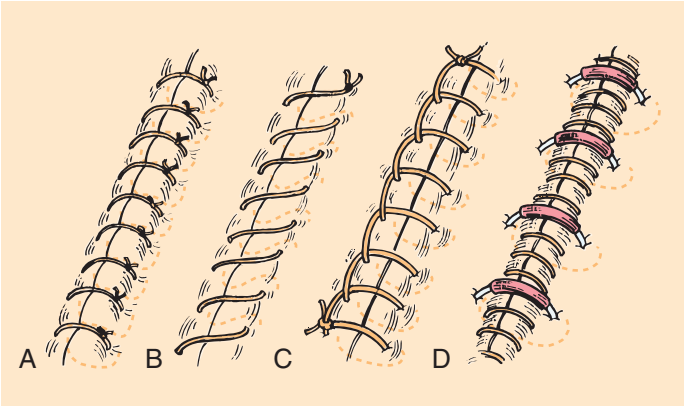

FIG. 48-27 Examples of suturing methods. **A,** Intermittent. **B,** Continuous. **C,** Blanket continuous. **D,** Retention.

and a moist drain site, cleaning moves from the incisional area toward the drain. Use two separate swabs or gauze pads, one to clean from the top of the incision toward the drain and one to clean from the bottom of the incision toward the drain. To clean the area of an isolated drain site, clean around the drain, moving in circular rotations outward from a point closest to the drain. In this situation the skin near the site is more contaminated than the site itself. To clean circular wounds, use the same technique as in cleaning around a drain.

Irrigation. Irrigation is a special way of cleaning wounds. Use an irrigating syringe to flush the area with a constant low-pressure flow of solution. The gentle washing action of the irrigation cleans a wound of exudate and debris. Irrigation is particularly useful for open, deep wounds; wounds involving an inaccessible body part such as the ear canal; or when cleaning sensitive body parts such as the conjunctival lining of the eye.

Wound Irrigations. Irrigation of an open wound requires sterile technique. Use a 35-mL syringe with a 19-gauge needle (Rolstad, Bryant, and Nix, 2012) to deliver the solution. This irrigation system has a safe pressure and does not damage healing wound tissue. It is important to never occlude a wound opening with a syringe because this results in the introduction of irrigating fluid into a closed space. The pressure of the fluid causes tissue damage and discomfort. Always irrigate a wound with the syringe tip over but not in the drainage site. Make sure that fluid flows directly into the wound and not over a contaminated area before entering the wound. Skill 48-5 on pp. 1224-1226 lists steps for wound irrigation.

Suture Care. A surgeon closes a wound by bringing the wound edges as close together as possible to reduce scar formation. Proper wound closure involves minimal trauma and tension to tissues with control of bleeding.

Sutures are threads or metal used to sew body tissues together (Fig. 48-25). The patient's history of wound healing, the site of surgery, the tissues involved, and the purpose of the sutures determine the suture material used. For example, if the patient has had repeated surgery for an abdominal hernia, the health care provider can choose wire sutures to provide greater strength for wound closure. In contrast, a small laceration of the face calls for the use of very fine Dacron (polyester) sutures to minimize scar formation.

Sutures are available in a variety of materials, including silk, steel, cotton, linen, wire, nylon, and Dacron. They come with or without sharp surgical needles attached. Steel staples are a common type of outer skin closure that causes less trauma to tissues than sutures while providing extra strength.

Sutures are placed within tissue layers in deep wounds and superficially as the final means for wound closure. Deep sutures are usually composed of an absorbable material that disappears over time. Sutures are foreign bodies and thus are capable of causing local inflammation. The surgeon tries to minimize tissue injury by using the finest suture possible and the smallest number necessary.

Policies vary within institutions as to who is able to remove sutures. If it is appropriate that the nurse remove them, a health care provider's order is required. An order for suture removal is not written until the health care provider believes that the wound has closed (usually in 7 days). Special scissors with curved cutting tips or special staple removers slide under the skin closures for suture removal (Fig. 48-26). The health care provider usually specifies the number of sutures or staples to remove. If the suture line appears to be healing in certain locations better than in others, some health care providers choose to have only some sutures removed (e.g., every other one).

To remove staples, insert the tips of the staple remover under each wire staple. While slowly closing the ends of the staple remover together, squeeze the center of the staple with the tips, freeing it from the skin (see Fig. 48-26).

To remove sutures, first check the type of suturing used (Fig. 48-27). With intermittent suturing the surgeon ties each individual suture made in the skin. Continuous suturing, as the name implies, is a series of sutures with only two knots, one at the beginning and

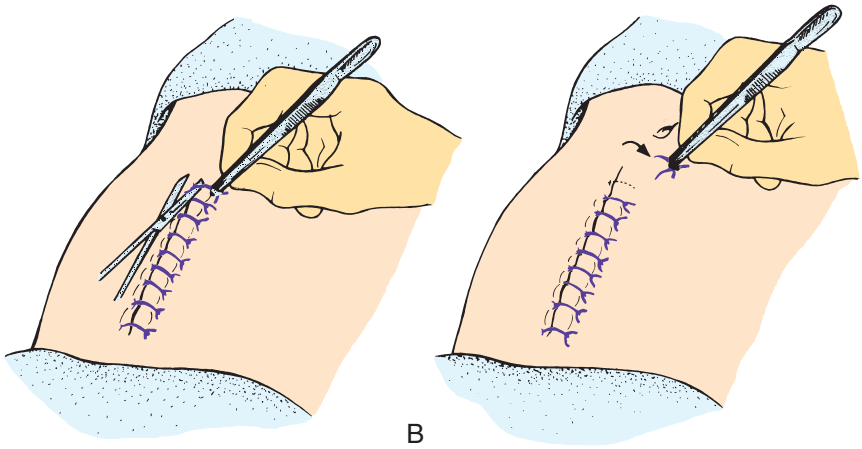

FIG. 48-28 Removal of intermittent suture. **A,** Cut suture as close to skin as possible, away from knot. **B,** Remove suture and never pull contaminated stitch through tissues.

one at the end of the suture line. Retention sutures are placed more deeply than skin sutures, and nurses may or may not remove them, depending on agency policy. The manner in which the suture crosses and penetrates the skin determines the method for removal. *Never pull the visible portion of a suture through underlying tissue.* Sutures on the surface of the skin harbor microorganisms and debris. The portion of the suture beneath the skin is sterile. Pulling the contaminated portion of the suture through tissues can lead to infection. Clip suture materials as close to the skin edge on one side as possible and pull the suture through from the other side (Fig. 48-28).

Drainage Evacuation. When drainage interferes with healing, evacuation is achieved by using either a drain alone or a drainage tube with continuous suction. You may apply special skin barriers, including hydrocolloid dressings similar to those used with ostomies (see Chapter 46), around drain sites. The skin barriers are soft material applied to the skin with adhesive. Drainage flows on the barrier but not directly on the skin. **Drainage evacuators** (Fig. 48-29) are convenient portable units that connect to tubular drains lying within a wound bed and exert a safe, constant, low-pressure vacuum to remove and collect drainage. Ensure that suction is exerted and that connection points between the evacuator and tubing are intact. The evacuator collects drainage. Assess for volume and character every shift and as needed. When the evacuator fills, measure output by emptying the contents into a graduated cylinder and immediately reset the evacuator to apply suction.

Bandages and Binders. A simple gauze dressing is often not enough to immobilize or provide support to a wound. Binders and bandages applied over or around dressings provide extra protection and therapeutic benefits by the following:

1. Creating pressure over a body part (e.g., an elastic pressure bandage applied over an arterial puncture site)
2. Immobilizing a body part (e.g., an elastic bandage applied around a sprained ankle)
3. Supporting a wound (e.g., an abdominal binder applied over a large abdominal incision and dressing)
4. Reducing or preventing edema (e.g., a pressure bandage applied to the lower leg)
5. Securing a splint (e.g., a bandage applied around hand splints for correction of deformities)
6. Securing dressings (e.g., elastic webbing applied around leg dressings after a vein stripping)

FIG. 48-29 Setting suction on drainage evacuator. *1,* With drainage port open, raise level on diaphragm. *2,* Push straight down on lever to lower diaphragm. *3,* Closure of port prevents escape of air and creates vacuum pressure.

Bandages are available in rolls of various widths and materials, including gauze, elasticized knit, elastic webbing, flannel, and muslin. Gauze bandages are lightweight and inexpensive, mold easily around contours of the body, and permit air circulation to prevent skin maceration. Elastic bandages conform well to body parts but are also for exerting pressure.

Binders are bandages that are made of large pieces of material to fit a specific body part. Most binders are made of elastic or cotton. An abdominal binder and a breast binder are examples.

Principles for Applying Bandages and Binders. Correctly applied bandages and binders do not cause injury to underlying and nearby body parts or create discomfort for the patient. For example, a chest binder should not be so tight as to restrict chest wall expansion. Before applying a bandage or binder, the nurse's responsibilities include the following:

- Inspecting the skin for abrasions, edema, discoloration, or exposed wound edges
- Covering exposed wounds or open abrasions with a sterile dressing
- Assessing the condition of underlying dressings and changing if soiled

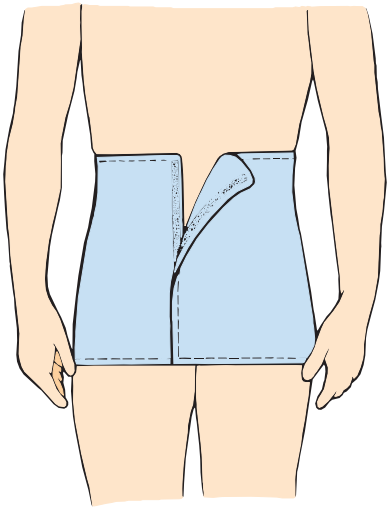

FIG. 48-30 Securing an abdominal binder with Velcro.

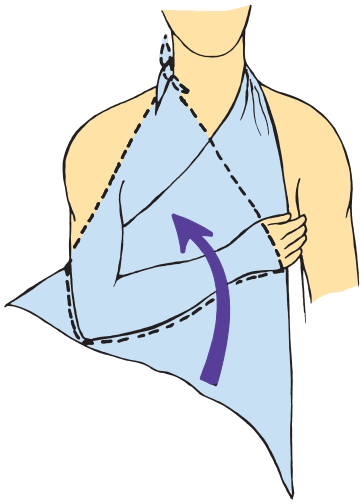

FIG. 48-31 Application of sling.

- Assessing the skin of underlying areas that will be distal to the bandage for signs of circulatory impairment (coolness, pallor or cyanosis, diminished or absent pulses, swelling, numbness, and tingling) to provide a means for comparing changes in circulation after bandage application

After applying a bandage, the nurse assesses, documents, and immediately reports changes in circulation, skin integrity, comfort level, and body function (e.g., ventilation or movement). The nurse who applies a bandage loosens or readjusts it as necessary. He or she needs a health care provider's order before loosening or removing a bandage applied by a health care provider. The nurse explains to the patient that any bandage or binder feels relatively firm or tight. Carefully assess a bandage to be sure that it is applied properly and providing therapeutic benefit and replace any soiled bandages.

Binder Application. Binders are especially designed for the body part to be supported. The most common type of binder is the abdominal binder (Skill 48-6 on pp. 1226-1228). Well-fitting bras are now replacing breast binders. Both provide support after breast surgery or exert pressure to reduce lactation in a woman after childbirth.

Abdominal Binders. An abdominal binder supports large abdominal incisions that are vulnerable to tension or stress as the patient moves or coughs (Fig. 48-30). Secure an abdominal binder with safety pins, Velcro strips, or metal stays.

Slings. Slings support arms with muscular sprains or fractures. A commercially manufactured sling consists of a long sleeve that extends above the elbow with a strap that fits around the neck. In the home patients can use a large triangular piece of cloth. The patient sits or lies supine during sling application (Fig. 48-31). Instruct him or her to bend the affected arm, bringing the forearm straight across the chest. The open sling fits under the patient's arm and over the chest, with the base of the triangle under the wrist and the point of the triangle at his or her elbow. One end of the sling fits around the back of the patient's neck. Bring the other end up and over the affected arm while supporting the extremity. Tie the two ends at the side of the neck so the knot does not press against the cervical spine. Fold the loose material at the elbow evenly around the elbow and pin. Always support the lower arm and hand at a level above the elbow to prevent the formation of dependent edema.

Bandage Application. Rolls of bandage secure or support dressings over irregularly shaped body parts. Each roll has a free outer end and a terminal end at the center of the roll. The rolled portion of the bandage is its body, and its outer surface is placed against the patient's skin or dressing. Skill 48-7 on pp. 1228-1229 describes the steps for applying an elastic bandage. Use a variety of bandage turns, depending on the body part to be bandaged.

Heat and Cold Therapy

Assessment for Temperature Tolerance. Before applying heat or cold therapies, assess the patient's physical condition for signs of potential intolerance to heat and cold. First observe the area to be treated. Assess the skin, looking for any open areas such as alterations in skin integrity (e.g., abrasions, open wounds, edema, bruising, bleeding, or localized areas of inflammation) that increase the patient's risk of injury. Because the health care provider commonly orders heat and cold applications for traumatized areas, the baseline skin assessment provides a guide for evaluating skin changes that can occur during therapy. Include in your assessment the neurological system for sensation (to understand if the patient senses extremes of cold or heat) and the patient's mental status to be sure that he or she can correctly communicate any issues with the hot or cold therapy.

Assessment includes identification of conditions that contraindicate heat or cold therapy. Do not cover an active area of bleeding with a warm application because bleeding will continue. Warm applications are contraindicated when the patient has an acute, localized inflammation such as appendicitis because the heat causes the appendix to rupture. If a patient has cardiovascular problems, it is unwise to apply heat to large portions of the body because the resulting massive vasodilation disrupts blood supply to vital organs.

Cold is contraindicated if the site of injury is already edematous. It further retards circulation to the area and prevents absorption of the interstitial fluid. If the patient has impaired circulation (e.g., arteriosclerosis), it further reduces blood supply to the affected area. Cold therapy is also contraindicated in the presence of neuropathy, because the patient is unable to perceive temperature change and damage resulting from temperature extremes. One other contraindication for cold therapy is shivering. Cold applications sometimes intensify shivering and dangerously increase body temperature.

Assess the patient's response to stimuli. Sensation to light touch, pinprick, and mild temperature variations (see Chapter 30) reveals the ability of the patient to recognize when heat or cold becomes excessive. If a patient has peripheral vascular disease, pay particular attention to the integrity of extremities. For example, if the health care provider's order is to apply a cold compress to a lower extremity, assess circulation to the leg by assessing for capillary refill; observing skin color; and palpating skin temperatures, distal pulses, and edematous areas. If signs of circulatory inadequacy are present, it is important for you to question the order.

Level of consciousness influences the ability to perceive heat, cold, and pain. If a patient is confused or unresponsive, the nurse needs to make frequent observations of skin integrity after therapy begins.

Also assess the condition of equipment being used. Check electrical equipment for cracked cords, frayed wires, damaged insulation, and exposed heating components. Make sure that equipment containing circulating fluids does not have leaks. Check equipment for evenness of temperature distribution.

Local application of heat and cold to an injured body part is sometimes therapeutic. However, before using these therapies, you need to understand normal body responses to local temperature variations, assess the integrity of the body part, determine the patient's ability to sense temperature variations, and ensure proper operation of equipment. You are legally responsible for safe administration of heat and cold applications.

Bodily Responses to Heat and Cold. Exposure to heat and cold causes systemic and local responses. Systemic responses occur through heat-loss mechanisms (sweating and vasodilation) or mechanisms promoting heat conservation (vasoconstriction and piloerection) and heat production (shivering) (see Chapter 30). Local responses to heat and cold occur through stimulation of temperature-sensitive nerve endings within the skin. This stimulation sends impulses from the periphery to the hypothalamus, which becomes aware of local temperature sensations and triggers adaptive responses for maintenance of normal body temperature. If alterations occur along temperature sensation pathways, the reception and eventual perception of stimuli are altered.

The body is able to tolerate wide variations in temperature. The normal temperature of the surface of the skin is 34° C (93.2° F), but temperature receptors usually adapt quickly to local temperatures between 15° and 45° C (59° and 113° F). Pain develops when local temperatures exceed this range. Excessive heat causes a burning sensation. Cold produces a numbing sensation before pain.

The adaptive ability of the body creates the major problem in protecting patients from injury resulting from temperature extremes. A person initially feels an extreme change in temperature but within a short time hardly notices it. This is dangerous because a person insensitive to heat and cold extremes can suffer serious tissue injury. You need to recognize patients most at risk for injuries from heat and cold applications (Table 48-9).

Local Effects of Heat and Cold. Heat and cold stimuli create different physiological responses. The choice of heat or cold therapy depends on local responses desired for wound healing (Table 48-10).

Effects of Heat Application. Heat generally is quite therapeutic, improving blood flow to an injured part. However, if heat is applied for 1 hour or more, the body reduces blood flow by a reflex vasoconstriction to control heat loss from the area. Periodic removal and reapplication of local heat restores vasodilation. Continuous exposure to heat damages epithelial cells, causing redness, localized tenderness, and even blistering.

TABLE 48-9 Conditions That Increase Risk of Injury from Heat and Cold Application

CONDITION	RISK FACTORS
Very young or older patients	Thinner skin layers in children increase risk of burns. Older patients have reduced sensitivity to pain.
Open wounds, broken skin, stomas	Subcutaneous and visceral tissues are more sensitive to temperature variations. They also contain no temperature and fewer pain receptors.
Areas of edema or scar formation	Reduced sensation to temperature stimuli occurs because of thickening of skin layers from fluid buildup or scar formation.
Peripheral vascular disease (e.g., diabetes, arteriosclerosis)	Body extremities are less sensitive to temperature and pain stimuli because of circulatory impairment and local tissue injury. Cold application further compromises blood flow.
Confusion or unconsciousness	Perception of sensory or painful stimuli is reduced.
Spinal cord injury	Alterations in nerve pathways prevent reception of sensory or painful stimuli.
Abscessed tooth or appendix	Infection is highly localized. Application of heat causes rupture with spread of microorganisms systemically.

Effects of Cold Application. The application of cold initially diminishes swelling and pain. Prolonged exposure of the skin to cold results in a reflex vasodilation. The inability of the cells to receive adequate blood flow and nutrients results in tissue ischemia. The skin initially takes on a reddened appearance, followed by a bluish-purple mottling, with numbness and a burning type of pain. Skin tissues freeze from exposure to extreme cold.

Factors Influencing Heat and Cold Tolerance. The response of the body to heat and cold therapies depends on the following factors:

- A person is better able to tolerate short exposure to temperature extremes than prolonged exposure.
- Exposed skin layers and certain areas of the skin (e.g., the neck, inner aspect of the wrist and forearm, and perineal region) are more sensitive to temperature variations. The foot and palm of the hand are less sensitive.
- The body responds best to minor temperature adjustments. If a body part is cool and a hot stimulus touches the skin, the response is greater than if the skin were already warm.
- A person has less tolerance to temperature changes to which a large area of the body is exposed.
- Tolerance to temperature variations changes with age. Patients who are very young or old are most sensitive to heat and cold.
- If a patient's physical condition reduces the reception or perception of sensory stimuli, tolerance to temperature extremes is high, but the risk of injury is also high.
- Uneven temperature distribution suggests that the equipment is functioning improperly.

Application of Heat and Cold Therapies. A prerequisite to using any heat or cold application is a health care provider's order, which includes the body site to be treated and the type, frequency, and duration of application (Box 48-15). Consult agency procedure manual for correct temperatures to use.

TABLE 48-10 Therapeutic Effects of Heat and Cold Applications

PHYSIOLOGICAL RESPONSE	THERAPEUTIC BENEFIT	EXAMPLES OF CONDITIONS TREATED
Heat		
Vasodilation	Improves blood flow to injured body part; promotes delivery of nutrients and removal of wastes; lessens venous congestion in injured tissues	Open wounds, rectal surgery, episiotomy, painful hemorrhoids, muscle tension, vaginal inflammation, wound debridement
Reduced blood viscosity	Improves delivery of leukocytes and antibiotics to wound site	
Reduced muscle tension	Promotes muscle relaxation and reduces pain from spasm or stiffness	
Increased tissue metabolism	Increases blood flow; provides local warmth	
Increased capillary permeability	Promotes movement of waste products and nutrients	
Cold		
Vasoconstriction	Reduces blood flow to injured body part, preventing edema formation; reduces inflammation	Direct trauma (sprains, strains, fractures, muscle spasms), superficial laceration or puncture wound, minor burn, suspected malignancy in area of injury or pain, injections, arthritis and joint trauma
Local anesthesia	Reduces localized pain	
Reduced cell metabolism	Reduces oxygen needs of tissues	
Increased blood viscosity	Promotes blood coagulation at injury site	
Decreased muscle tension	Relieves pain	

BOX 48-15 SAFETY SUGGESTIONS FOR APPLYING HEAT OR COLD THERAPY

- *Do* explain to patient sensations to be felt during the procedure.
- *Do* instruct patient to report changes in sensation or discomfort immediately.
- *Do* provide a timer, clock, or watch so patient can help the nurse time the application.
- *Do* keep the call light within patient's reach.
- *Do* refer to the policy and procedure manual of the institution for safe temperatures.
- *Do not* allow patient to adjust temperature settings.
- *Do not* allow patient to move an application or place hands on the wound site.
- *Do not* place patient in a position that prevents movement away from the temperature source.
- *Do not* leave unattended a patient who is unable to sense temperature changes or move from the temperature source.

BOX 48-16 CHOICE OF DRY OR MOIST APPLICATIONS

Advantages

Moist Applications

- Moist application reduces drying of skin and softens wound exudate.
- Moist compresses conform well to most body areas.
- Moist heat penetrates deeply into tissue layers.
- Warm moist heat does not promote sweating and insensible fluid loss.

Dry Applications

- Dry heat has less risk of burns to skin than moist applications.
- Dry application does not cause skin maceration.
- Dry heat retains temperature longer because evaporation does not occur.

Disadvantages

Moist Applications

- Prolonged exposure causes maceration of skin.
- Moist heat cools rapidly because of moisture evaporation.
- Moist heat creates greater risk for burns to skin because moisture conducts heat.

Dry Applications

- Dry heat increases body fluid loss through sweating.
- Dry applications do not penetrate deep into tissues.
- Dry heat causes increased drying of skin.

Choice of Moist or Dry. You can administer heat and cold applications in dry or moist forms. The type of wound or injury, the location of the body part, and the presence of drainage or inflammation are factors to consider in selecting dry or moist applications. Box 48-16 summarizes advantages and disadvantages of both.

Warm, Moist Compresses. Warm, moist compresses improve circulation, relieve edema, and promote consolidation of purulent drainage. A compress is a piece of gauze dressing moistened in a prescribed warmed solution. A pack is a larger cloth or dressing applied to a larger body area.

Heat from warm compresses dissipates quickly. To maintain a constant temperature, you need to change the compress often or apply a waterproof heating pad over it. Because moisture conducts heat, the temperature setting of any device should be lower for a moist compress than for a dry application. You can also use a layer of plastic wrap or a dry towel to insulate the compress and retain heat. Moist heat promotes vasodilation and evaporation of heat from the surface of the skin. For this reason a patient can feel chilly. Always try to control drafts within the room and keep the patient covered with a blanket or robe.

Warm Soaks. Immersion of a body part in a warmed solution promotes circulation, lessens edema, increases muscle relaxation, and provides a means to apply medicated solution. Sometimes a soak is also accompanied by wrapping the body part in dressings and saturating them with the warmed solution.

Position the patient comfortably, place waterproof pads under the area to be treated, and heat the solution to about 40.5° to 43° C (105° to 110° F). After immersing the body part, cover the container and extremity with a towel to reduce heat loss. It is usually necessary to remove the cooled solution and add heated solution after about 10 minutes. The challenge is to keep the solution at a constant temperature. Never add a hotter solution while

the body part remains immersed. After any soak dry the body part thoroughly to prevent maceration.

Sitz Baths. The patient who has had rectal surgery, an episiotomy during childbirth, painful hemorrhoids, or vaginal inflammation benefits from a sitz bath, a bath in which only the pelvic area is immersed in warm or, in some situations, cool fluid. The patient sits in a special tub or chair or a basin that fits on the toilet seat so the legs and feet remain out of the water. Immersing the entire body causes widespread vasodilation and nullifies the effect of local heat application to the pelvic area.

The desired temperature for a sitz bath depends on whether the purpose is to promote relaxation or to clean a wound. It is often necessary to add warm or cool water during the procedure, which normally lasts 20 minutes, to maintain a constant temperature. Agency procedure manuals recommend safe water temperatures. A disposable sitz basin contains an attachment resembling an enema bag that allows gradual introduction of additional water.

Prevent overexposure of the patient by draping bath blankets around his or her shoulders and thighs and controlling drafts. The patient should be able to sit in the basin or tub with feet flat on the floor and without pressure on the sacrum or thighs. Because exposure of a large portion of the body to heat causes extensive vasodilation, assess the pulse and facial color and ask whether the patient feels light-headed or nauseated.

Commercial Hot Packs. Commercially prepared disposable hot packs apply warm, dry heat to an injured area. The chemicals mix and release heat when you strike, knead, or squeeze the pack. Package directions recommend the time for heat application.

Cold, Moist, and Dry Compresses. The procedure for applying cold, moist compresses is the same as that for warm compresses. Apply cold compresses for 20 minutes at a temperature of 15° C (59° F) to relieve inflammation and swelling. You can use clean or sterile compresses.

Commercially prepared cold packs that are similar to the disposable hot packs for dry applications are available. They come in various shapes and sizes to fit different body parts. When using cold compresses, observe for adverse reactions such as burning or numbness, mottling of the skin, redness, extreme paleness, and a bluish skin discoloration.

Cold Soaks. The procedure for preparing cold soaks and immersing a body part is the same as for warm soaks. The desired temperature for a 20-minute cold soak is 15° C (59° F). Control drafts and use outer coverings to protect the patient from chilling. It is often necessary to add cold water during the procedure to maintain a constant temperature.

Ice Bags or Collars. For a patient who has a muscle sprain, localized hemorrhage, or hematoma or who has undergone dental surgery, an ice bag is ideal to prevent edema formation, control bleeding, and anesthetize the body part. Proper use of the bag requires the following steps:

1. Fill the bag with water, secure the cap, invert to check for leaks, and pour out the water.
2. Fill the bag two-thirds full with crushed ice so you are able to easily mold it over a body part.
3. Release any air from the bag by squeezing its sides before securing the cap because excess air interferes with conduction of cold.
4. Wipe off excess moisture.
5. Cover the bag with a flannel cover, towel, or pillowcase.
6. Apply the bag to the injury site for 30 minutes; you can reapply the bag in an hour.

EVALUATION

You evaluate nursing interventions for reducing and treating pressure ulcers by determining the patient's response to nursing therapies and whether he or she achieved each goal. To evaluate outcomes and responses to care, you measure the effectiveness of interventions. The optimal outcomes are to prevent injury to the skin and tissues, reduce injury to the skin and underlying tissues, and possible wound healing with restoration of skin integrity.

Through the Patient's Eyes. It is important to include the patient and caregiver in the evaluation process. Determine what they know about the formation of impaired skin integrity, determine how the patient and caregiver feel about the presence of the wound and the need for wound care, and develop a plan of care to provide education and support. Chronic wounds such as pressure ulcers take time to heal, and it is likely that the patient will be in the home setting with the pressure ulcer.

Patient Outcomes. Because each patient has different risk factors for impaired skin integrity, you need to individualize nursing interventions. Patients with minimal mobility impairments or relatively stable health status need only a few measures. You evaluate nursing interventions for reducing and treating pressure ulcers by determining the patient's response to nursing therapies and whether he or she achieved each goal (Fig. 48-32).

Patients with impaired skin integrity need evaluation on an ongoing basis for factors that contribute to skin breakdown. This includes a comprehensive skin assessment and a wound assessment

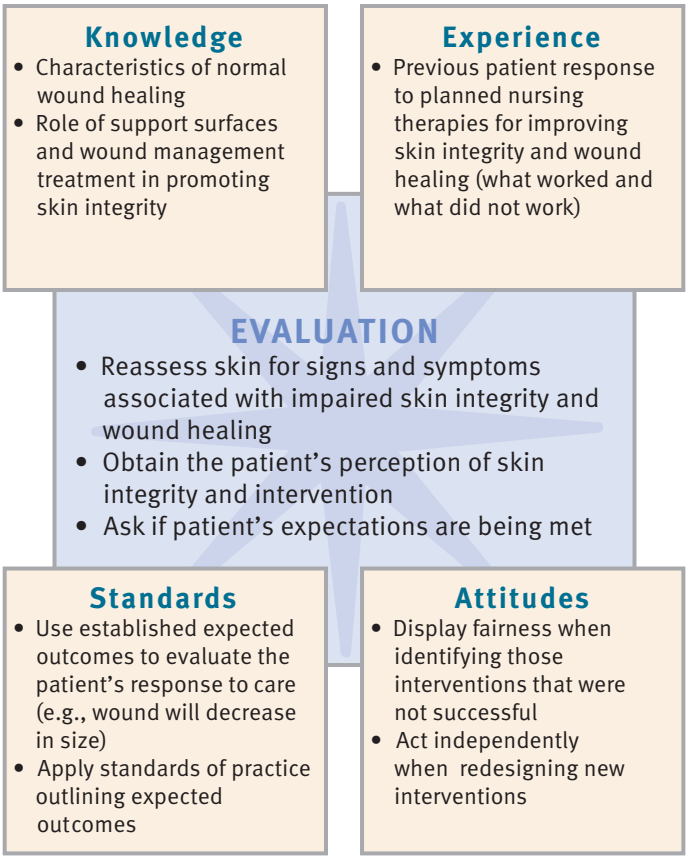

FIG. 48-32 Critical thinking model for skin integrity and wound care evaluation.

using a validated risk-assessment tool. Assessment provides the foundation for the plan of care, and evaluation is critical for monitoring the effectiveness of the plan (Nix, 2012).

If the identified outcomes are not met for a patient with impaired skin integrity, questions to ask include the following:

- Was the etiology of the skin impairment addressed? Were the pressure, friction, shear, and moisture components identified; and did the plan of care decrease the contribution of each of these components?
- Was wound healing supported by providing the wound base with a moist protected environment?
- Were issues such as nutrition assessed and a plan of care developed that provided the patient with the calories to support healing?

Finally, evaluate the need for additional referrals to other experts in wound care and pressure ulcers, such as nurses certified in wound care. Care of patients with a pressure ulcer or wound requires a multidisciplinary team approach.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient-centered care:

- Position patient in a manner that the side rails on the bed are in an upright position to prevent him or her from rolling over the side of the bed.
- When changing wound dressings, keep a plastic bag within reach to discard dressings and prevent cross-contamination. Keep extra gloves within reach to allow a change of gloves if the gloves become soiled.
- If irrigating a wound, use goggles for protection from splashing.
- When applying an elastic bandage, check the extremity where the bandage is applied for temperature or sensation changes.

SKILL 48-1 ASSESSMENT FOR RISK FOR PRESSURE ULCER DEVELOPMENT

View Video!

Delegation Considerations

The skill of assessing patients for risk of pressure ulcers cannot be delegated to nursing assistive personnel (NAP). Direct/inform/instruct the NAP to:

- Report any changes to the patient's skin such as redness, blistering, abrasion, or cuts to the nurse for further nursing assessment.
- Keep the patient's skin dry and provide hygiene following incontinence of urine or stool or exposure to other body fluids.
- Reposition the patient according to the frequency established on the nursing care plan or agency policy.
- Avoid trauma to the patient's skin from tape, pressure, friction, or shear.

Equipment

- Risk assessment tool, Braden Scale
- Documentation record

STEP	RATIONALE
ASSESSMENT	
1 Identify at-risk individuals needing prevention and specific factors placing them at risk.	Determines factors that increase patient's risk for developing pressure ulcers (Braden, 2001).
a. Use validated risk assessment tool such as the Braden Scale.	Ensures consistent, reliable, comparable assessments (WOCN, 2010).
b. Assess patient and obtain risk score on admission to acute care, rehabilitation hospitals, nursing homes, home care programs, and other health care facilities.	Provides baseline assessment.
2 Determine patient's ability to respond meaningfully to pressure-related discomfort (sensory perception).	Patient with complete or partial limited ability to respond to pressure-related discomfort cannot communicate discomfort, has a limitation in ability to feel pain, and thus is at risk for developing pressure ulcers.
3 Apply clean gloves and conduct a systematic skin assessment over bony prominences.	Bony prominences are at high risk of skin breakdown because of high pressures exerted on these areas when patient is immobile. A finding of redness or impairment in skin integrity necessitates planning appropriate interventions.
a. Observe for at-risk areas for skin breakdown, including back of head, shoulders, ribs, hips, sacral region, ischium, inner and outer knees, inner and outer ankles, heels and feet (see Fig. 48-9).	
4 Assess the following potential sites for skin breakdown:	
a. Ears and nares	Cartilage that nasal cannulas or tubing compresses develops pressure necrosis.
b. Lips	Oral airway and endotracheal tubes exert pressure if left in place for prolonged time periods.
c. Tube sites (e.g., gastrostomy or nasogastric tubes, Foley catheters, Jackson-Pratt drains)	Tubes exert pressure if taped snugly against skin or if there is stress at insertion site. If moisture is present around tube insertion sites, leakage of bodily fluids compromises skin integrity.
d. Orthopedic and positioning devices (e.g., casts, braces, cervical collar)	Improperly fitted or applied devices have potential to cause pressure on adjacent skin and underlying tissue.

SKILL 48-1 ASSESSMENT FOR RISK FOR PRESSURE ULCER DEVELOPMENT—cont'd

STEP	RATIONALE
5 Assess all skin surfaces for the following:	
a. Absence of superficial skin layers	Damage of superficial skin layers indicates injury from friction or moisture. The area is moist and sore to the touch.
b. Blisters	Suggests skin damage from friction and/or inappropriate tape removal. Blisters occur when top layer of skin is pulled or rubbed, separating epidermis from dermis.
c. Any loss of epidermis and dermis	Indicates damage to skin. Determine cause of this damage and begin interventions to prevent further damage.
6 Assess degree to which patient's skin is exposed to moisture. Remove gloves and perform hand hygiene.	Exposure to excessive moisture increases risk for skin breakdown (Bryant, 2012).
7 Evaluate patient's activity level.	Patient who is bedfast or chairfast or only walks occasionally is at risk for developing pressure areas because of the degree of physical inactivity (WOCN, 2010).
a. Determine patient's ability to change and control body position (mobility).	Potential for friction and shear increases when patient is completely dependent on others for position change.
b. Determine patient's preferred positions.	Weight of body is on certain bony prominences, and patient resists repositioning off these areas.
8 Assess patient's usual food intake pattern (nutrition).	Patient who rarely or never eats a complete meal is at risk for pressure ulcer formation.
a. Review weight pattern, calorie intake, and nutritional laboratory values (see Box 48-11).	Decreased nutrition status is linked with pressure ulcer formation and poor wound healing (WOCN, 2010).
b. Complete fluid intake assessment.	Fluid imbalance, either dehydration or edema, increases patient's risk for pressure ulcers (Stotts, 2012a).
9 Assess presence of friction and/or shear.	Patient who has a problem moving, requires maximum assistance in moving, or slides against sheets when moved is at an increased risk of skin damage (Bryant, 2012).
PLANNING	
1 Explain procedure to patient.	Promotes patient cooperation and reduces anxiety.
IMPLEMENTATION	
1 Note the score on the risk assessment scale. (NOTE: Numerical values in Steps a through f refer to the Braden Scale.)	The documentation provides a baseline for comparison of increased or decreased risk for development of pressure ulcers and allows planning of interventions.
a. As the Braden Scale scores become lower, predicted risk becomes higher.	*Scores:* 15 to 18, at risk 13 to 14, moderate risk 10 to 12, high risk 9 or below, very high risk
b. Link risk assessment to preventive protocols. Perform hand hygiene and apply gloves.	Protocols target problem areas to assist in prevention of skin breakdown.
(1) Institute at-risk interventions (score of 15 to 18). Consider instituting frequent turning, protecting patient's heels, using a pressure-redistribution surface, and managing moisture.	Decreases risk of skin breakdown.
(2) Institute moderate-risk interventions (score of 13 to 14). Consider protocol of frequent turning; protecting patient's heels; providing pressure-redistribution surface; providing foam wedges for 30-degree lateral positioning; and managing moisture, shear, and friction.	Decreases pressure on bony prominences and reduces the increased risk of skin breakdown.
(3) Institute high-risk interventions (score of 10 to 12). Consider a protocol that increases the frequency of turning; supplements turning with small shifts in position; facilitates maximal remobilization; protects the patient's heels; provides pressure-redistribution surface; provides foam wedges for 30-degree lateral positioning; and manages moisture, friction, and shear. If needed, institute nutritional interventions to reduce risk of pressure ulcer development.	Addresses factors that contribute to skin breakdown and plans for interventions to address causative factors (Bryant, 2012). Nutrition therapy promotes skin healing.
(4) Institute very high–risk interventions (score of 9 or below). Consider protocol that incorporates points for high-risk patients plus uses pressure-redistribution surface if patient has intractable pain or severe pain exacerbated by turning.	Plans interventions to decrease the effects of immobility, decreased sensory perception, moisture, friction, shear, decreased activity, and nutritional issues in a high-risk individual.

STEP	RATIONALE
2 When you note reddened area, check for the following:	
a. Skin discoloration (e.g., redness in light-tone skin; purplish or bluish in darkly pigmented skin) (see Box 48-3)	May indicate that tissue was under pressure.
b. Blanchable erythema	Indicates pressure damage that will resolve. If redness lightens under application of pressure, make sure that vessels are intact and that there is no tissue damage present.
c. Nonblanchable erythema	Indicates potential damage to blood vessels and tissue damage. Once blood vessels are damaged, red area will not lighten in color because tissue and blood vessels are inflamed. Position patient off area.
d. Pallor or mottling	Persistent hypoxia in tissues alters circulation, and pallor or mottling may occur.
3 Remove gloves and perform hand hygiene. Reposition patient.	Reduces transmission of infection.
4 Educate patient and family regarding pressure ulcer risk and prevention.	Helps patients and family understand interventions designed to reduce pressure ulcer risk.

EVALUATION

1 Observe patient's skin daily, especially areas at risk (check agency policy).	Determines over time patient's response to risk-redistribution interventions.
2 Observe tolerance of patient for positioning.	Frequent change in position further reduces patient's risk for pressure ulcer development.
3 Compare current risk assessment with previous scores.	Documents effectiveness of interventions and assists in providing individualized plan of care.
4 Evaluate food intake and nutrition laboratory values.	Determines success of nutritional supplements in improving nutritional status.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Skin does not blanch when firmly pressed, has purple discoloration, or has significant color change.
- Reassess frequency of turning schedule.
- Implement agency skin care protocols.
- Consider use of pressure-redistribution surface to reduce pressure ulcer risk.

RECORDING AND REPORTING

- Record patient's risk score.
- Record appearance of skin under pressure.
- Describe position, turning intervals, pressure-redistribution devices, and other prevention strategies.
- Report any need for additional consultations for the high-risk patient.

HOME CARE CONSIDERATIONS

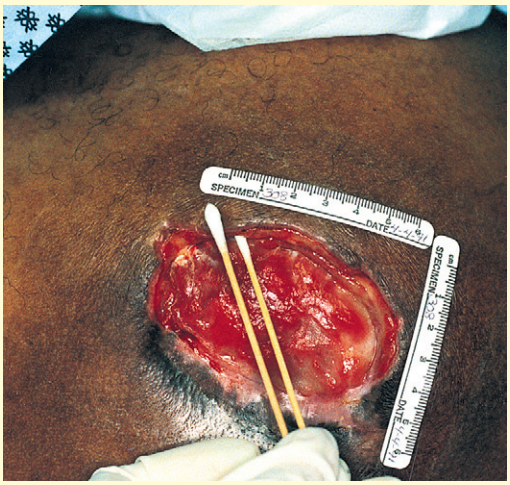
- Instruct family caregiver in use of the 30-degree lateral position. This position prolongs the time between position changes, resulting in fewer sleep interruptions for patient and caregiver.
- Individualize pressure-redistribution maneuvers for patient needs and home environment. Provide family with resources for hospital equipment.

SKILL 48-2 TREATING PRESSURE ULCERS

View Video!

Delegation Considerations

The skill of treating pressure ulcers cannot be delegated to nursing assistive personnel (NAP). In some practice settings you can delegate *nonsterile* dressing application for chronic, established wounds when a nurse has evaluated and designated the protocol. The *assessment* of the wound remains within the scope of the nurse even if the dressing change is delegated. Direct/inform/instruct the NAP to:
- Report changes in skin integrity to the nurse immediately.
- Report pain, fever, or wound drainage to the nurse immediately.
- Report any potential contamination to existing dressing (e.g., patient incontinence or other bodily fluids, dressing becomes dislodged).



Equipment

- Clean gloves
- Plastic bag for dressing disposal
- Measuring device
- Cotton-tipped applicators
- Topical cleaning agent
- Dressing of choice (see Table 48-8)
- Hypoallergenic tape (if needed)
- Documentation record
- Scale for assessing wound healing
- Sterile gloves (check agency policy)

STEP	RATIONALE
ASSESSMENT	
1 Identify patient using two identifiers. (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).

SKILL 48-2 TREATING PRESSURE ULCERS—cont'd

STEP	RATIONALE
2 Assess patient's level of comfort using a scale of 0 to 10 and determine need for pain medication.	Patients tolerate dressing change procedure better if pain is controlled.
3 Determine if patient has allergies to topical agents.	Topical agents cause localized skin reactions.
4 Review order for topical agent or dressing and location.	Ensures that you administer proper medication and treatment.
5 Close room door or bedside curtains. Position patient to allow dressing removal. Describe to patient what will be done.	Provides privacy and ensures that area is accessible for dressing change. Decreases patient's anxiety.
6 Perform hand hygiene and apply clean gloves. Remove dressing and place in plastic bag.	Reduces transmission of microorganisms and prevents accidental exposure to body fluids.
7 Assess pressure ulcer(s). All pressure ulcers need individual assessments.	Consistent assessment provides the basis for evaluating wound progress (Nix, 2012).
a. Note color, type, and percentage of tissue type present in wound base.	Tissue type assists in choice of dressing.
b. Measure width and length of ulcer(s). Determine width by measuring dimension from left to right and length from top to bottom (see illustration).	Ulcer size changes as healing progresses; therefore the longest and widest areas of the wound change over time. Measuring the width and length by measuring consistent areas provides a consistent measurement (Nix, 2012).

STEP 7b Measuring wound width, length, and undermining.

c. Measure depth of pressure ulcer with sterile cotton-tipped applicator or other device that allows measurement of wound depth.	Depth measure is important for determining wound volume. Although surface area adequately represents tissue loss in stage II ulcers, volume more adequately represents tissue loss in stage III and IV wounds.
d. Measure depth of undermining using a cotton-tipped applicator and gently probing under skin edges (see illustration for step 7b).	Undermining represents the loss of the underlying tissue (subcutaneous and muscle) to greater extent than skin. Undermining indicates progressive tissue loss and needs to be accommodated with an appropriate dressing.
8 Assess periwound skin; check for maceration, redness, denuded area.	Deterioration of skin around wound indicates infection, excessive wound exudate, or skin stripping from adhesive removal.

PLANNING

1 Explain procedure to patient and family.	Preparatory explanations relieve anxiety, correct any misconceptions about ulcer and its treatment, and offer opportunity for patient and family education.
2 Prepare the following necessary equipment and supplies:	
a. Washbasin, warm water, soap, washcloth, and bath towel	
b. Normal saline or other wound-cleaning agent in sterile solution container	Ulcer surface must be cleaned before application of topical agents and new dressing.

CLINICAL DECISION: *Use only noncytotoxic agents to clean ulcers.*

c. Prescribed topical agent (e.g., enzymatic agents, topical antibiotic). Follow manufacturer instruction on package insert carefully.	Enzymes debride dead tissue to clean ulcer surface. Topical antibiotics are used to decrease bioburden of wound and should be considered for use if no healing is noted after 2 to 4 weeks of optimal care (WOCN, 2010).

CLINICAL DECISION: *If using enzymatic debriding agent, do not use wound-cleaning agents with metals.*

STEP	RATIONALE
d. Select appropriate dressing and tape based on pressure ulcer characteristics, purpose for which dressing is intended, and patient care setting (see Table 48-8).	Dressing should maintain a moist environment for wound while keeping surrounding skin dry.
3 Position patient to allow dressing removal and position plastic bag for dressing disposal.	Area should be accessible for dressing change. Proper disposal of old dressing promotes proper handling of contaminated waste.
IMPLEMENTATION	
1 Close room door or bedside curtains. Perform hand hygiene and apply clean gloves. Open sterile packages and topical solution containers as necessary.	Maintains privacy and provides organized access to supplies.
2 Remove bed linen and patient's gown as necessary to expose ulcer and surrounding skin. Keep remaining parts covered.	Prevents unnecessary exposure.
3 Clean ulcer thoroughly with normal saline or cleaning agent. Clean with irrigating syringe for deep ulcers.	Removes wound debris.
4 Remove gloves, perform hand hygiene, and apply clean or sterile gloves.	Aseptic technique must be maintained during cleaning and all phases of pressure ulcer treatment. Check agency policy regarding use of clean or sterile gloves.
5 Apply topical agents as prescribed:	
a. **Debriding enzymes**	
(1) Apply thin, even layer of ointment over necrotic areas of ulcer only. Do not apply enzyme to surrounding skin. Check manufacturer direction for frequency of application.	Thin layer absorbs and acts more effectively than thick layer. Excess medication irritates surrounding skin (Rolstad, Bryant, and Nix, 2012). Some enzymes cause burning, paresthesia, and dermatitis to surrounding skin.
(2) Apply gauze dressing directly over ulcer.	Protects wound and keeps enzymes in place. Prevents bacteria from entering wound.
(3) Tape securely in place.	Keeps dressing in place.
b. **Hydrogel**	
(1) Cover surface of ulcer with hydrogel using applicator or gloved hand.	Provides maintenance of moist wound environment.
(2) Apply dry gauze, hydrocolloid, or transparent film dressing over wound and adhere to intact skin.	Covers wound base, maintaining hydrogel wound interface.
c. **Calcium alginate**	
(1) Pack wound with alginate using applicator or gloved hand.	Provides maintenance of wound moisture while absorbing excess drainage.
(2) Apply dry gauze or foam over alginate. Tape in place.	Holds alginate against wound surface.
6 Reposition patient comfortably off pressure area and other pressure points.	Reduces pressure on existing wound and decreases pressure on at-risk areas.
7 Remove gloves and dispose of soiled supplies. Perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 Evaluate pressure ulcer at each dressing change or sooner if wound or patient's condition deteriorates (Nix, 2012). Use agency tool for wound assessment.	Not all patients with wounds demonstrate quick wound healing because of other health care issues. Wound evaluation provides a report of wound healing progress or lack of it.
2 Compare wound findings to identified plan of care; if wound is not progressing toward healing as indicated by an increase in size, increased presence of pain, foul-smelling drainage, or increase in devitalized tissue, discuss findings with health care team.	Ensures that an appropriate plan for wound care is in place.

CLINICAL DECISION: *A clean pressure ulcer should show evidence of some healing within 2 to 4 weeks. Do not use the pressure ulcer staging system to measure healing. System measures depth of wound, not healing (WOCN, 2010).*

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Skin surrounding ulcer becomes macerated.
- Reduce exposure of surrounding skin to topical agents and moisture.
- Consider the use of a liquid skin barrier on periwound skin.

2 Ulcer becomes deeper with increased drainage.
- Notify health care provider about possible change in pressure ulcer status.
- Obtain necessary wound cultures.
- Obtain additional consults (e.g., wound care specialist).

RECORDING AND REPORTING

- Complete wound documentation required for one of the wound assessment instruments per agency protocol.
- Record appearance of ulcer; describe type of topical agent, dressing applied, and patient response.
- Report any deterioration in ulcer appearance to nurse in charge or health care provider.

HOME CARE CONSIDERATIONS

- Patients need to dispose of contaminated dressings in the home in a manner consistent with local regulations.
- Discuss need for home pressure-redistribution surface or bed.

SKILL 48-3 APPLYING DRY AND MOIST DRESSINGS

Delegation Considerations

The skill of applying dry and moist dressings to the new acute wound cannot be delegated to nursing assistive personnel (NAP). In some settings aspects of wound care such as changing dressings using *clean* technique for chronic wounds are delegated. The *assessment* of the wound remains within the scope of the nurse even if the dressing change is delegated. Direct the NAP to:

- Report pain, fever, bleeding, or wound drainage to the nurse immediately.
- Report any potential contamination to existing dressing (e.g., patient incontinence or other bodily fluids, dressing becomes dislodged).

Equipment

- Sterile gloves
- Variety of gauze dressings and pads
- Irrigation kit
- Cleaning solution
- Sterile solution
- Clean, disposable gloves
- Tape, ties, or bandage as needed
- Waterproof pad and bag
- Extra gauze dressings, or topper dressing (ABD pads)
- Montgomery ties; elastic net
- Option: Mask or eyewear for risk of splashing

STEP	RATIONALE
ASSESSMENT	
1 Identify patient using two identifiers. (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Perform hand hygiene. Review medical record for information about size and location of wound.	Reduces transmission of microorganisms. Helps to plan for proper type and amount of supplies needed. Alerts you when assistance is needed to hold dressings in place.
3 Assess patient's level of comfort using a scale of 0 to 10.	Removal of dry dressing is painful; some patients require pain medication.
4 Review orders for dressing change procedure.	Indicates type of dressing or applications to use.
5 Assess patient's and family's knowledge of purpose and steps of dressing change.	Determine specific areas for patient and family teaching.
6 Assess for risk of delayed or poor wound healing (e.g., age, obesity, diabetes, peripheral vascular diseases, poor nutritional status, steroid medications, stress, immunosuppression medications, and radiation therapy).	
PLANNING	
1 Explain procedure to patient and instruct him or her not to touch wound area or sterile supplies.	Decreases anxiety. Sudden, unexpected movement on patient's part results in contamination of wound and supplies.
2 Position patient comfortably and drape with bath blanket to expose only wound site.	Provides access to wound yet minimizes unnecessary exposure.
3 Plan dressing change 30 to 60 minutes following administration of analgesia.	Allows for peak action of medication so patient has optimal level of comfort during dressing change. Patients tolerate dressing changes when their pain is controlled.
IMPLEMENTATION	
1 Close room door or pull bedside curtains. Perform hand hygiene and apply gown, goggles, and mask when risk for spray exists.	Provides privacy and reduces transmission of microorganisms.
2 Position patient comfortably and drape only to expose wound site.	Draping provides access to wound while minimizing unnecessary exposure.
3 Place disposable bag within reach of work area. Fold top of bag to make cuff (see illustration).	Ensures easy disposal of soiled dressings. Prevents soiling of outer surface of bag.
4 *Remove tape:* Pull parallel to skin toward dressing; remove remaining adhesive from skin.	Pulling tape toward dressing reduces stress on suture line or wound edges.
5 With gloved hand carefully remove gauze dressings one layer at a time, taking care not to dislodge drains or tubes.	Removal of one layer at a time reduces chance of accidental removal of underlying drains.
a. If dressing sticks on a wet-to-dry dressing, do not moisten it; instead gently free it and alert patient of potential discomfort.	Wet-to-dry dressing should debride wound (Ramundo, 2012). Do not wet dressing to remove it. It is supposed to be dry so it removes necrotic tissue from wound.
b. If dressing sticks on dry dressing, moisten with saline and then remove.	Prevents tearing of wound edges.
CLINICAL DECISION: *Never use a wet-to-dry dressing in a clean granulating wound. Use only for debridement (Ramundo, 2012).*	
6 Observe wound for color, edema, drains, and exudates and amount of drainage on dresssing.	Provides estimate of drainage amount and assessment of condition of wound.
7 Fold dressings with drainage contained inside and remove gloves inside out. With small dressings remove gloves inside out over dressing (see illustration). Dispose of gloves and soiled dressings in disposable bag. Perform hand hygiene.	Reduces transmission of microorganisms. Prevents contact of hands with material on gloves.

STEP	RATIONALE

STEP 3 Disposable waterproof bag placed near dressing site.

STEP 7 Removal of disposable gloves over contaminated dressing.

8 Open sterile dressing tray or individually wrapped sterile supplies. Place on bedside table.
Sterile dressings remain sterile while on or within sterile surface. Preparation of supplies prevents break in technique during dressing change.

9 Clean wound with solution. Clean from least-contaminated area, which is the incision or center of wound, to most-contaminated area, which is outside of incision and surrounding skin. Dry area.
Prevents contamination of previously cleaned area.

10 If ordered, clean or irrigate wound:
- **a.** Pour ordered solution into sterile irrigation container.
- **b.** Apply clean gloves and protective eyewear. Place waterproof pad under patient. Using syringe, gently allow solution to flow over wound. (Some commercial cleaners come in a spray bottle. Spray wound to loosen debris.)
- **c.** Continue until irrigation flow is clear.
- **d.** Dry surrounding skin using gauze pads.
- **e.** Measure wound.

Removes drainage containing microorganisms.

Measurement of wound size with each dressing change provides data about progression of wound healing.

11 Apply dressing:
- **a. Dry dressing**
  - **(1)** Apply clean or sterile gloves. Check agency policy.
  - **(2)** Inspect wound for appearance, drains, drainage, and integrity.
  - **(3)** Apply sterile, loose woven gauze dry dressing, covering wound.
  - **(4)** Apply topper dressing if indicated.

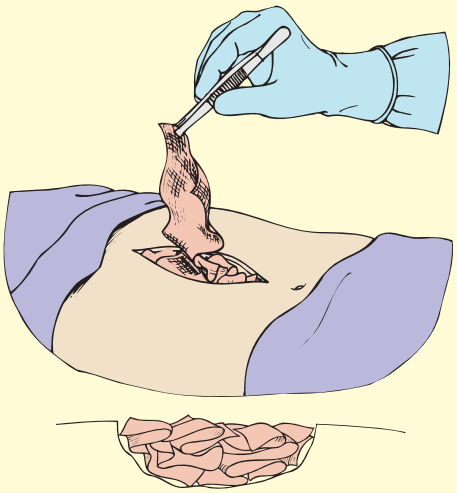
Some agencies or condition of wounds requires sterile gloves. Allows handling of sterile supplies without contamination.
Indicates status of wound healing.
Protects wound from external environment.
Topper dressing (e.g., ABD) prevents strike-through of wound drainage and provides a surface to tape the dressing in place.

- **b. Moist dressing**
  - **(1)** Apply sterile gloves (see agency policy).
  - **(2)** Assess appearance of surrounding skin (see illustration).

Allows handling of sterile supplies without contamination.
Surrounding skin assessment provides an evaluation of wound management.

SKILL 48-3 APPLYING DRY AND MOIST DRESSINGS—cont'd

STEP	RATIONALE
(3) Moisten gauze with prescribed solution. Gently wring out excess solution. Unfold.	Gauze needs to be moist to allow for absorption of wound debris.
(4) Apply gauze as single layer directly onto wound surface (see illustration). If wound is deep, gently pack dressing into wound base by hand or forceps until all wound surfaces are in contact with gauze. If tunneling is present, use cotton-tipped applicator to place gauze into tunneled area. Be sure that gauze does not touch surrounding skin.	Inner gauze needs to be moist, not dripping wet, to absorb drainage and adhere to debris. Excessively moist dressings result in moisture-associated skin damage (maceration) in periwound skin (Gray and Weir, 2007). Wound needs to be loosely packed to facilitate wicking of drainage into absorbent outer layer of dressing.
(5) Cover with sterile dry gauze and topper dressing.	Topper dressing prevents strike-through of wound drainage and provides surface to tape dressing in place.
12 Secure dressing.	
a. *Tape:* Apply nonallergenic tape to secure dressing in place.	Goal for securing a dressing is to keep dressing in place and intact without causing damage to underlying and surrounding skin.
b. Montgomery ties (see Fig. 48-22)	
(1) Expose adhesive surface of tape on end of each tie.	
(2) Place ties on opposite sides of dressing.	
(3) Place adhesive directly on skin or use skin barrier.	A solid skin barrier protects intact skin from stretch and tension of adhesive tape.
(4) Secure dressing by lacing ties across it.	
c. For dressings on an extremity, secure dressing with rolled gauze or elastic net (see illustration).	Prevents slipping of dressing.



STEP 11b(2) Exposure of wound facilitates assessment of wound and surrounding skin.

STEP 12c Elastic net securing lower-extremity dressing.

STEP 11b(4) Packing wound with single layer of gauze.

STEP	RATIONALE
12 Remove gloves and dispose of in bag. Remove any mask or eyewear.	Reduces transmission of infection.
13 Write date and time dressing applied on tape in ink (not marker).	
14 Assist patient to comfortable position.	Improves patient comfort.
15 Dispose of supplies and perform hand hygiene.	Reduces transmission of infection.

EVALUATION

1 Inspect condition of wound and any drainage.	Determines rate of healing.
2 Ask patient to rate level of pain during and after procedure.	Pain is early indicator of wound complications or result of dressing material pulling underlying tissue.
3 Inspect condition of dressing and note any observable drainage every shift.	Determines status of wound drainage.
4 Ask patient to describe techniques of dressing change.	Documents patient learning.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Wound appears inflamed, tender, with or without drainage.
- Monitor patient for signs of infection (e.g., increased temperature, white blood cell count).
- Obtain wound culture per order.
- Notify health care provider.

2 Wound drainage increases.
- Increase frequency of dressing changes.
- Notify health care provider, who may consider drain placement to facilitate wound drainage.

3 Wound bleeds during dressing change.
- Observe color. If drainage is bright red and excessive, you need to apply pressure.
- Inspect along dressing and underneath patient to determine amount of bleeding.
- Obtain vital signs as needed.
- Notify health care provider.

4 Patient reports a sensation that "something has given way under the dressing."
- Observe wound for increased drainage or separation of sutures.
- Protect wound. Cover with sterile moist dressing.
- Instruct patient to lie still and place on NPO status.
- Notify health care provider.

RECORDING AND REPORTING

- Report brisk, bright red bleeding, or evidence of wound dehiscence or evisceration to health care provider immediately.
- Report wound and periwound tissue appearance, color, tissue type, presence and characteristics of exudate, type and amount of dressings used, and tolerance of patient to procedure.
- Record patient's level of comfort.

HOME CARE CONSIDERATIONS

- More expensive specialty dressings are sometimes used because they decrease the frequency of dressing changes.
- Clean dressings may also be used in the home setting.
- Patients need to dispose of contaminated dressings in the home in a manner consistent with local regulations.

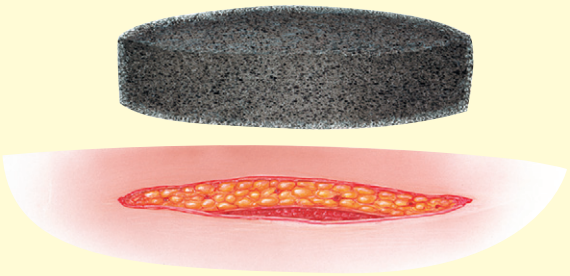
SKILL 48-4 IMPLEMENTATION OF NEGATIVE-PRESSURE WOUND THERAPY

Delegation Considerations

The assessment for and placement of negative-pressure wound therapy (NPWT) cannot be delegated to nursing assistive personnel (NAP). Direct the NAP to:
- Report to the nurse any change in patient's temperature, level of comfort.
- Change in the pressure in the NPWT unit.
- Any change in the integrity of the dressing.

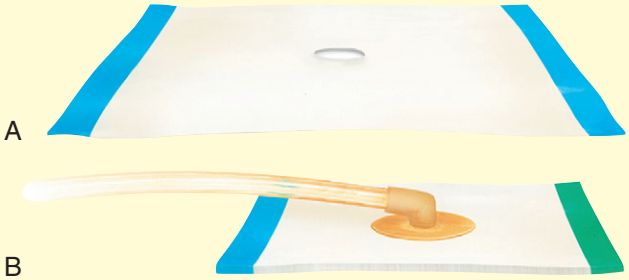
Equipment

- NPWT unit (For this skill the vacuum-assisted closure (V.A.C.) unit is used for illustration; several other systems are available, and their application may be slightly different; refer to manufacturer directions.) (requires health care provider order) (see Fig. 48-19)
- Foam dressing and transparent dressing
- Tubing for connection between NPWT unit and dressing
- Gloves, clean and sterile
- Scissors (sterile)
- Skin preparation/skin barrier
- Moist washcloth
- Plastic trash bag
- Linen bag
- Stethoscope
- Protective gown, mask, goggles if risk of splashing wound drainage
- Gauze squares



SKILL 48-4 IMPLEMENTATION OF NEGATIVE-PRESSURE WOUND THERAPY—cont'd

STEP	RATIONALE
ASSESSMENT	
1 Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Assess location, appearance, and size of wound to be dressed (see Skill 48-2).	Allows you to gather information regarding status of wound healing, presence of complications, and type of supplies and assistance needed to apply the NPWT dressing.
3 Review health care provider's orders for frequency of dressing change, type of foam to use, and amount of negative pressure to be used.	Health care provider orders frequency of dressing changes and special instructions.
4 Assess patient's level of comfort using a scale of 0 to 10.	Patient who is comfortable during procedure is less likely to move suddenly, causing wound or supply contamination.
5 Assess patient's and family member's knowledge of purpose of dressing.	Identifies patient's learning needs. Prepares patient and family if dressing needs to be changed at home.
PLANNING	
1 Explain to patient what the dressing change involves.	Provides patient with rationale for dressing change and reduces fears. Maintaining patient comfort assists in completing skill smoothly.
2 Administer ordered analgesic 30 minutes before dressing change.	Provides time for pain medication to have optimal effect to reduce or relieve patient's pain at wound site.
3 Perform hand hygiene. Assemble supplies.	Reduces transmission of microorganisms. Organizes procedure.
IMPLEMENTATION	
1 Close room door or cubicle curtains.	Provides privacy.
2 Position patient comfortably and drape to expose only wound site. Instruct patient not to touch wound or sterile supplies.	Draping provides access to wound while minimizing unnecessary exposure.
3 Place disposable waterproof bag within reach of work area with top folded to make a cuff.	Facilitates safe disposal of soiled dressings.
4 Apply clean gloves. If there is a risk for splash or spray, apply protective gown, goggles, and mask.	Reduces exposure to infectious microorganisms.
5 Keep system in "de vac" mode for 30 to 60 minutes before changing dressing.	Found to loosen foam dressing for easier, less painful removal.
6 When NPWT is in place, push therapy on/off button.	
a. Keeping tube connectors with NPWT unit; disconnect tubes from one another to drain fluids into canister.	Deactivates therapy and allows for proper drainage of fluid in drainage tubing.
b. Before lowering, tighten clamp on canister tube.	
7 Gently stretch transparent film horizontally and slowly pull away from skin.	Reduces stress on suture line or wound edges, irritation, and discomfort.
8 Remove old dressing, observing appearance and drainage on dressing. Use caution to avoid tension on any drains that are present. Discard dressing and remove gloves. Perform hand hygiene.	Determines dressings needed for replacement. Avoids accidental removal of drains because they are sometimes sutured in place.
9 Apply sterile or clean gloves (see agency policy). Irrigate wound with normal saline or other solution ordered by health care provider. Blot with gauze to dry.	Irrigation removes wound debris.
CLINICAL DECISION: *When drainage looks purulent, amount or color changes, or it has a foul odor, obtain wound cultures even when they are not ordered for that particular dressing change (Chua et al., 2000; Jerome, 2007).*	
10 Measure wound as ordered: at baseline, first dressing change, weekly; discharge from therapy. Remove and discard gloves. Perform hand hygiene.	Objectively documents wound healing process in response to NPWT (Nix, 2012).
11 Depending on type of wound, apply new sterile or clean gloves.	Fresh sterile wounds require sterile gloves. Chronic wounds may require clean technique. Never wear same gloves worn to remove old dressing or irrigate wound because cross-contamination may occur.
12 Apply skin protectant/barrier film to skin around wound.	Maintains air-tight seal needed for NPWT and protects periwound skin from maceration.
13 Prepare wound edges with skin preparation to enhance seal and protect the periwound tissue.	Promotes adherence of dressing to site.
14 Prepare foam dressing.	
a. Select appropriate foam.	Black, polyurethane (PU) foam has larger pores and is most effective in stimulating granulation tissue and **wound contraction.** White, polyvinyl alcohol (PVA) soft foam is denser with smaller pores and is used when growth of granulation tissue needs to be restricted (KCI, 2007; Netsch, 2012).



STEP	RATIONALE
b. Using sterile scissors, cut foam to exact wound size with foam height extending ½ inch above skin surface. Dressing must fit size and shape of wound, including tunnels and undermined areas.	Foam will contract to level of skin.

CLINICAL DECISION: *Some patients experience more pain with the black foam because of excessive wound contraction. For this reason they often need to be switched to the PVA soft foam.*

15 Gently place foam in wound; be sure that foam is in contact with entire wound base, margins, and tunneled and undermined areas (see illustration).	Maintains negative pressure to entire wound.
16 Apply wrinkle-free transparent dressing over foam and 3 to 5 cm (1.2 to 2 inches) of surrounding healthy skin. Secure tubing to unit (see illustration).	Ensures that wound is properly covered and helps achieve negative-pressure seal (see Box 48-14). Connects negative pressure from the NPWT unit to wound foam.
17 Secure tubing to transparent film, aligning drainage holes to ensure an occlusive seal. Do not apply tension to drape and tubing.	Excessive tension compresses foam dressing and impedes wound healing. It also produces shear force on periwound area (KCI, 2007).
18 Secure tubing several centimeters away from the dressing.	Prevents pull on primary dressing, which causes leaks in negative-pressure system (Chua et al., 2000; KCI, 2007).
19 Once you have completely covered the wound (see illustration), connect tubing from dressing to tubing from canister and NPWT unit.	Intermittent or continuous negative pressure can be administered at 50 to 175 mm Hg, according to health care provider's order and patient comfort. The average is 125 mm Hg (Netsch, 2012).
a. Remove canister from sterile packaging and push into unit until you hear a click. NOTE: An alarm sounds if canister is not engaged properly.	
b. Connect dressing tubing to canister tubing. Make sure that both clamps are open.	
c. Place unit on level surface or hang from foot of bed. NOTE: The unit alarms and deactivates therapy if it is tilted beyond 45 degrees.	
d. Press in green-lit power button and set pressure as ordered.	
20 Discard old dressing materials; remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
21 Inspect NPWT system to verify that negative pressure is achieved.	Negative pressure is achieved when there is an airtight seal.
a. Verify that display screen reads THERAPY ON.	
b. Be sure that clamps are open and tubing is patent.	
c. Identify air leaks by listening with stethoscope or moving hand around edges of wound while applying light pressure.	
d. If leak is present, use strips of transparent film to patch areas around edges of wound.	

STEP 15 Dressing application. Properly sized foam to cover wound.

STEP 16 **A,** Wrinkle-free transparent dressing applied over foam. **B,** Secure tubing to foam and transparent dressing. (Courtesy Kinetic Concepts, Inc [KCI], San Antonio, Tex.)

STEP 19 Foam, transparent dressing, and tubing secured over existing wound. (Courtesy Kinetic Concepts, Inc [KCI], San Antonio, Tex.)

SKILL 48-4 IMPLEMENTATION OF NEGATIVE-PRESSURE WOUND THERAPY—cont'd

STEP	RATIONALE
EVALUATION	
1 Inspect condition of wound on an ongoing basis; note drainage and odor.	Determines status of wound healing.
2 Ask patient to rate pain using a scale of 0 to 10.	Determines patient's level of comfort following procedure.
3 Compare wound with baseline wound assessment.	Provides objective documentation of wound healing.
4 Verify airtight dressing seal and proper negative pressure.	To achieve prescribed vacuum level, wound must be covered with airtight seal. This airtight seal and negative pressure promote wound drainage, circulation, and healing.
5 Measure wound drainage in canister on regular basis per agency policy.	Monitors fluid balance and wound drainage.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Wound appears inflamed and tender, drainage has increased, and an odor is present.
- Notify health care provider.
- Obtain wound culture per order.
- Increase frequency of dressing changes.

2 Patient reports increase in pain.
- If using black foam, switch to the PVA foam product.
- Patient sometimes needs more analgesic support when NPWT is initiated.
- Reduce negative pressure.

3 Negative pressure seal has broken.
- *Take preventive measures:* Shave hair around wound, avoid wrinkles in transparent dressing, and avoid use of adhesive remover because it leaves residue that hinders film adherence.
- Reinforce with transparent dressing strips.

RECORDING AND REPORTING

- Record appearance of wound, color, characteristics of any drainage, and presence of wound healing augmentation.
- Record pressure setting of NPWT.
- Record date and time of dressing change.
- Report brisk, bright bleeding; evidence of poor wound healing; and possible wound infection.

HOME CARE CONSIDERATIONS

- Patients can use NPWT in the home safely. Some patients need clinic visits or home care nursing visits to monitor wound healing.
- Provide resources to patient for supplies for NPWT.
- Instruct family and caregiver regarding proper disposal of contaminated product.

SKILL 48-5 PERFORMING WOUND IRRIGATION

View Video!

Delegation Considerations

The skill of wound irrigation cannot be delegated to nursing assistive personnel. In the case of a chronic wound, you can delegate cleaning using *clean* technique. Assessment of any wound, care of acute new wounds, and evaluation of wound irrigation are responsibilities of the nurse and are never delegated. Direct the NAP to:
- Report any change in wound appearance or increased wound drainage to the nurse.
- Use proper clean technique to avoid cross-contamination from irrigation syringes and equipment.

Equipment

- Irrigant/cleaning solution (volume 1.2 to 2 times the estimated wound volume)
- Irrigation delivery system, depending on amount of pressure desired:
- Sterile irrigation 35-mL syringe with sterile soft angio catheter or 19-gauge needle (Rolstad, Bryant, and Nix, 2012)
- Clean gloves and sterile gloves (check agency policy)
- Waterproof underpad, if needed
- Gauze dressing supplies
- Disposable waterproof bag
- Gown, goggles, or mask, if risk of spray

STEP	RATIONALE
ASSESSMENT	
1 Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Assess patient's level of pain. Administer prescribed analgesic 30 to 45 minutes before starting wound irrigation procedure.	Discomfort is related directly to wound or indirectly to muscle tension or immobility. Increased comfort level permits patient to move more easily and be positioned to facilitate wound irrigation.
3 Review medical record for health care provider's prescription for irrigation of open wound and type of solution to be used.	Open wound irrigation requires medical order, including type of solution to use.

STEP	RATIONALE
4 Assess medical record for signs and symptoms related to patient's open wound.	Data provide a baseline to indicate change in condition of wound (Nix, 2012).
a. Extent of impairment of skin integrity, including size of wound (Measure length, width, and depth. Wounds should be measured in centimeters and in the following order: length, width, and depth.)	Assesses volume of irrigation solution needed. Data also used as baseline to indicate change in condition of wound.
b. Drainage from wound (amount and color) (Amount can be measured by part of dressing saturated or in terms of quantity [e.g., scant, moderate, copious].)	Expect amount to decrease as healing takes place. Serous drainage is clear like plasma; sanguineous or bright red drainage indicates fresh bleeding; serosanguineous drainage is pink; purulent drainage is thick and yellow, pale green, or white.
c. Odor (must state whether or not there is odor)	Strong odor indicates infectious process.
d. Wound color	Color represents a balance between necrotic tissue and new scar tissue. Proper selection of wound products based on the color of the wound facilitates removal of necrotic tissue and promotes new tissue growth (Rolstad, Bryant, and Nix, 2007).
e. Consistency of drainage	Type and color of drainage depend on moisture of wound and type of organisms present.
f. Culture reports	Chronic wounds heal by secondary intention, and they are often colonized with bacteria.
g. Condition of dressing: Dry and clean; evidence of bleeding, profuse drainage	Provides an initial assessment of present wound drainage.
PLANNING	
1 Explain procedure of wound irrigation and cleaning.	Information reduces patient's anxiety.
2 Administer prescribed analgesic 30 to 60 minutes before starting wound irrigation procedure.	Promotes pain control and permits patient to move more easily and be positioned to facilitate wound irrigation.
3 Position patient.	
a. Position comfortably so wound is vertical to collection basin, which permits gravitational flow of irrigating solution through wound and into collection receptacle.	Directing solution from top to bottom of wound and from clean to contaminated area reduces spread of infection. Position patient during planning stage, keeping in mind the bed surfaces needed for later preparation of equipment.
b. Place container of irrigant/cleaning solution in basin of hot water to warm solution to body temperature.	Warmed solution increases comfort and reduces vascular constriction response in tissues.
c. Place padding or extra towel in bed.	Protects bedding.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Form cuff on waterproof bag and place it near bed.	Cuffing helps to maintain large opening, thereby permitting placement of contaminated dressing without touching refuse bag itself.
3 Close room door or bed curtains.	Maintains privacy.
4 Apply gown, mask, or goggles if needed.	Protects nurse from splashes or sprays of blood and body fluids.
5 Apply clean gloves and remove soiled dressing and discard in waterproof bag. Discard gloves and perform hand hygiene.	Reduces transmission of microorganisms.
6 Prepare equipment; open sterile supplies.	
7 Put on clean or sterile gloves (check agency policy).	
8 To irrigate wound with wide opening:	
a. Fill 35-mL syringe with irrigation solution.	Flushing wound helps remove debris and facilitates healing by secondary intention.
b. Attach 19-gauge needle or angio catheter (see Fig. 48-17).	Provides ideal pressure for cleaning and removing debris (Gardner and Frantz, 2008).
c. Hold syringe tip 2.5 cm (1 inch) above upper end of wound and over area being cleaned.	Prevents syringe contamination. Careful placement of syringe prevents unsafe pressure of flowing solution.
d. Using continuous pressure, flush wound; repeat Steps 8a, b, and c until solution draining into basin is clear.	Clear solution indicates that you have removed all debris.
9 To irrigate deep wound with very small opening:	
a. Attach soft angio catheter to filled irrigating syringe.	Catheter permits direct flow of irrigant into wound. Expect wound to take longer to empty when opening is small.
b. Lubricate tip of catheter with irrigating solution; then gently insert it into wound and pull out about 1 cm (½ inch).	Removes tip from fragile inner wall of wound.
c. Using slow, continuous pressure, flush wound. **CAUTION:** Splashing sometimes occurs during this step.	Cleans all wound surfaces.
d. Pinch off catheter just below syringe while keeping catheter in place.	Avoids contamination of sterile solution.
e. Remove and refill syringe. Reconnect to catheter and repeat until solution draining into basin is clear.	

SKILL 48-5 PERFORMING WOUND IRRIGATION—cont'd

STEP	RATIONALE
CLINICAL DECISION: *Pulsatile high-pressure lavage may be the irrigation of choice for necrotic wounds. The amount of irrigant depends on the size of the wound. Pressure settings on the device should remain between 8 and 15 psi. Do not use pulsatile high-pressure lavage on exposed blood vessels, muscle, tendon, and bone. This type of irrigation should not be used with graft sites and should be used with caution in patients receiving anticoagulant therapy (Ramundo, 2012).*	
10 Obtain cultures, if needed, after cleaning with nonbacteriostatic saline.	The type of wound culture obtained depends on the resources available in the facility. The three most common types of wound specimens are wound tissue, needle aspirated wound fluid, and swabs (Gardner and Frantz, 2008).
CLINICAL DECISION: *Consider culturing a wound if it has a foul, purulent odor; inflammation surrounds the wound; a nondraining wound begins to drain; or patient is febrile.*	
11 Assess type of tissue in wound bed and periwound skin.	Identifies wound-healing progress and determines type of wound cleaning needed; determines if wound has increased in size.
12 Dry wound edges with gauze.	Prevents maceration of surrounding tissue caused by excess moisture.
13 Apply appropriate dressing (see Skills 48-2 and 48-3).	Maintains protective barrier and healing environment for wound.
14 Remove gloves and, if worn, mask, goggles, and gown.	Prevents transfer of microorganisms.
15 Dispose of equipment and soiled supplies. Perform hand hygiene.	Reduces transmission of microorganisms.
16 Assist patient to comfortable position.	
EVALUATION	
1 Inspect dressing periodically.	Determines patient's response to wound irrigation and need to modify plan of care.
2 Determine patient's level of pain.	Patient's pain should not increase as a result of wound irrigation.
3 Observe for presence of retained irrigant.	Retained irrigant is medium for bacterial growth and subsequent infection.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Wound does not appear to heal.
- Obtain wound culture per order.
- Notify health care provider, who may change dressing and or irrigation frequency.

2 Wound drainage increases.
- Apply more absorbent gauze.
- Increase the frequency of irrigation.

RECORDING AND REPORTING

- Record wound irrigation, patient response, and appearance of wound on progress notes.
- Immediately report any evidence of fresh bleeding, sharp increase in pain, retention of irrigant, or signs of shock to attending health care provider.

HOME CARE CONSIDERATIONS

- Teach patient and caregiver how to make normal saline, especially if cost is an issue. You make normal saline by using 8 tsp of salt in 1 gallon of distilled water (Fellows and Cresodina, 2006).

SKILL 48-6 APPLYING AN ABDOMINAL BINDER

Delegation Considerations

The skill of applying an abdominal binder can be delegated to nursing assistive personnel (NAP). The nurse is responsible for wound assessment; the evaluation of wound care interventions and assessment of the patient's ability to breathe deeply, cough effectively, and move independently; and assessment of skin for irritation/abrasion, of incision/wound and dressing, and of comfort level before a binder or sling is applied for the first time. Direct the NAP to:
- Immediately notify the nurse of any change in patient's respiratory status.
- Report any increase in wound drainage to the nurse.
- Report any changes in skin integrity under or adjacent to the binder to the nurse.
- Remove the binder at prescribed intervals.

Equipment

- Gloves if wound drainage is present
- Abdominal binder:
  - Correct size cloth/elastic straight binder
  - Safety pins (unless Velcro closure or metal fasteners are attached): six to eight safety pins are usually adequate for abdominal binders

STEP	RATIONALE
ASSESSMENT	
1 Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Observe patient with need for support of abdomen. Observe ability to breathe deeply and cough effectively.	Baseline assessment determines patient's ability to breathe and cough. Impaired ventilation of lung leads to alveolar atelectasis and inadequate arterial oxygenation.
3 Review medical record if medical order for binder is required and reasons for application.	Application of supportive binders is based on nursing judgment. In some situations health care provider input is required.
4 Inspect skin for actual or potential alterations in integrity. Observe for irritation, abrasion, skin surfaces that rub against one another, or allergic response to adhesive tape used to secure dressing.	Actual impairments in skin integrity sometimes worsen with application of binder. Binders sometimes cause pressure and excoriation.
5 Inspect any surgical dressing.	Dressing replacement or reinforcement precedes application of any binder.
6 Assess patient's comfort level, using analog scale of 0 to 10 (see Chapter 43) and noting any objective signs and symptoms.	Data determines effectiveness of binder placement.
7 Gather necessary data for sizing appropriate binder.	Ensures proper fit of binder.
PLANNING	
1 Explain procedure to patient and family.	Promotes patient's understanding and reduces anxiety.
2 Demonstrate skill to patient or family caregiver.	Reduces anxiety and ensures continuity of care after discharge.
3 Help patient to a comfortable position.	
4 Close room door or bedside curtains.	Provides privacy.
IMPLEMENTATION	
1 Perform hand hygiene and apply gloves (if likely to contact wound drainage).	Reduces transmission of microorganisms.
2 Apply abdominal binder.	
a. Position patient in supine position with head slightly elevated and knees slightly flexed.	Minimizes muscular tension on abdominal organs.
b. Fanfold far side of binder toward midline of binder.	Reduces time patient remains in uncomfortable position.
c. Instruct and help patient to roll onto side away from you and toward raised side rail while firmly supporting abdominal incision and dressing with hands.	Reduces pain and discomfort.
d. Place fan-folded ends of binder under patient.	Permits placement and centering of binder with minimal discomfort.
e. Instruct or assist patient in rolling back over folded ends.	
f. Unfold and stretch ends out smoothly on far side of bed.	Maintains skin integrity and comfort.
g. Instruct patient to roll back into supine position.	Facilitates chest expansion and adequate wound support when binder is closed.
h. Adjust binder so supine patient is centered over it, using symphysis pubis and costal margins as lower and upper landmarks.	Centers support from binder over abdominal structures, which reduces incidence of decreased lung expansion.
CLINICAL DECISION: *Cover any exposed areas of an incision or wound with sterile dressing.*	
i. Close binder. Pull one end of binder over center of patient's abdomen. While maintaining tension on that end of binder, pull opposite end over center and secure with Velcro closure tabs, metal fasteners, or horizontally placed safety pins (see Fig. 48-30).	Provides continuous wound support and comfort.
j. Adjust binder as necessary.	Promotes comfort and chest expansion.
k. Remove and dispose of gloves. Perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 Observe site for skin integrity, circulation, and characteristics of wound. (Periodically remove binder and surgical dressing to assess wound characteristics.)	Determines that binder has not resulted in complication to skin, wound, or underlying organs.
2 Evaluate comfort level of patient, using analog scale of 0 to 10 and noting any objective signs and symptoms.	Binders should not increase discomfort.
3 Evaluate patient's ability to ventilate properly, including deep breathing and coughing.	Identifies any impaired ventilation and potential pulmonary complications.
4 Identify patient's need for help with activities such as hair combing, dressing, and ambulating.	Mobility of upper extremities is often limited, depending on severity and location of incision.

SKILL 48-6 APPLYING AN ABDOMINAL BINDER—cont'd

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient's pain increases.
- Remove binder and assess wound.
- Reapply binder using less pressure.

2 Patient's respiratory rate decreases.
- Remove binder.
- Encourage patient to cough and deep breathe.
- Reapply binder using less pressure.

3 Patient develops impaired skin integrity under binder.
- Remove binder.
- Initiate skin care measure to heal affected site.

RECORDING AND REPORTING

- Report any skin irritation to nurse at between-shift report.
- Record application of binder, condition of skin, circulation, integrity of dressing, and patient's comfort level.

HOME CARE CONSIDERATIONS

- Abdominal binders are washable and placed over a line to dry.
- Instruct caregiver to avoid excessive pressure with binder application.

SKILL 48-7 APPLYING AN ELASTIC BANDAGE

Delegation Considerations

The skill of applying an elastic bandage can be delegated to nursing assistive personnel (NAP). The nurse is responsible for wound assessment and the evaluation of the wound. In addition, the nurse is responsible for assessing for adequate circulation to the extremity distal to the elastic bandage. Direct the NAP to:
- Report any restrictions that the patient has (e.g., unable to independently raise leg or roll over).
- Report any change in the skin color of the patient's injured extremity.
- Report any increases in patient's pain.

Equipment

- Correct width and number of bandages
- Safety pins, clips, or adhesive tape
- Clean gloves if wound drainage is present

STEP	RATIONALE
ASSESSMENT	
1 Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Review medical record for specific orders related to application of elastic bandage. Note area to be covered, type of bandage required, frequency of change, and previous response to treatment.	Specific orders sometimes direct procedure, including factors such as extent of application (e.g., toe to knee, toe to groin) and duration of treatment.
3 Perform hand hygiene and apply gloves if needed. Inspect skin for alterations in integrity as indicated by abrasions, discoloration, chafing, or edema. (Look carefully at bony prominences.)	Altered skin integrity contraindicates the use of elastic bandages.
4 Inspect surgical dressing if present. Remove gloves and perform hand hygiene.	Surgical dressing replacement or reinforcement precedes application of any bandage. Reduces transmission of microorganisms.
5 Observe adequacy of circulation (distal to bandage) by noting surface temperature, skin color, and sensation in body parts to be wrapped.	Comparison of area before and after application of bandage is necessary to ensure continued adequate circulation. Impairment of circulation can result in coolness to touch when compared with opposite side of body, cyanosis, pallor of skin, diminished or absent pulses, edema or localized pooling, and numbness or tingling of part.
6 Assess patient's and family caregiver's present knowledge and level of skill if bandaging will be continued at home.	Ensures that planning and teaching are individualized.

STEP	RATIONALE
PLANNING	
1 Explain each step of procedure to patient.	Increased knowledge promotes cooperation and reduces anxiety.
2 Demonstrate skill to patient and family caregiver.	Helps to ensure continuity of care after discharge.
CLINICAL DECISION: *Apply bandages to lower extremities before patient sits or stands. Elevate dependent extremities for 20 minutes before bandage application to enhance venous return.*	
IMPLEMENTATION	
1 Close room door or curtains.	Maintains patient's comfort and dignity.
2 Help patient assume comfortable, anatomically correct position.	Maintains alignment. Prevents musculoskeletal deformity.
3 Perform hand hygiene and apply gloves if drainage is present.	Reduces transmission of microorganisms.
4 Hold roll of elastic bandage in dominant hand and use other hand to lightly hold beginning of bandage at distal body part. Continue transferring roll to dominant hand as bandage is wrapped.	Maintains appropriate and consistent bandage tension.
CLINICAL DECISION: *Toes or fingertips need to be visible for follow-up circulatory assessment.*	
5 Apply bandage from distal point toward proximal boundary using variety of turns to cover various shapes of body parts. A spiral dressing is often used to cover cylindrical body parts such as wrist or upper arms. To apply bandage in an ascending motion, overlapping previous bandage by one-half to two-thirds width of bandage. Use figure-eight dressing to cover joint because snug fit provides excellent immobilization. *To apply:* Overlap turns, alternately ascending and descending over bandaged part; each turn crossing previous one to form figure eight.	Bandage is applied in manner that conforms evenly to body part and promotes venous return.
6 Unroll and very slightly stretch bandage.	Maintains uniform bandage tension.
7 Overlap turns by one-half to two-thirds width of bandage roll.	Prevents uneven bandage tension and circulatory impairment.
8 Secure first bandage with clip or tape before applying additional rolls.	
9 Apply additional rolls without leaving any skin surface uncovered. Secure last bandage applied.	Prevents wrinkling or loose ends.
10 Remove gloves if worn and perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 Assess distal circulation when bandage application is complete and at least twice during 8-hour period.	Early detection and management of circulatory impairment ensures healthy neurovascular status.
a. Observe skin color for pallor or cyanosis.	
b. Palpate skin for warmth.	
c. Palpate pulses and compare bilaterally.	
d. Ask if patient is aware of pain, numbness, tingling, or other discomfort.	Neurovascular changes indicate impaired venous return.
e. Observe mobility of extremity.	Determines if bandage is too tight, which restricts movement, or if joint immobility is attained.
2 Have patient demonstrate bandage application.	Return demonstration evaluates learning.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Impaired circulation distal to elastic bandage
- Release bandage.
- Palpate extremity and assess pulse, temperature, and capillary refill.
- Reapply dressing with less pressure.

2 Break in skin under elastic bandage
- Remove bandage.
- Reapply bandage over different area of skin with less pressure.

3 Patient unable to perform dressing change
- Reinstruct patient or family caregiver on bandage application.
- Observe patient or family caregiver apply bandage.

RECORDING AND REPORTING

- Document condition of wound, integrity of dressing, application of bandage, circulation, and patient's comfort level.
- Report any changes in neurological or circulatory status to nurse in charge or health care provider.

HOME CARE CONSIDERATIONS

- Instruct patient or caregiver not to make bandages too tight, which interferes with circulation.
- Elastic bandages that reduce swelling are best applied to the feet and ankles in the morning, before getting out of bed.
- Always remove an elastic bandage daily and inspect skin beneath it.

KEY POINTS

- Pressure ulcers contribute to patient discomfort and decreased functional status, increased length of stay in acute and extended care settings, and increased cost of care.
- Wound assessment scales help measure improvement of a healing pressure ulcer; do not use the staging system for this purpose.
- Evaluate all patients on an ongoing basis for risk factors that contribute to development of impaired skin integrity.
- Alterations in mobility, sensory perception, level of consciousness, and nutrition and the presence of moisture increase the risk for pressure ulcer development.
- The risk of impaired skin integrity related to immobilization depends on the extent and duration of immobilization.
- Pressure, shearing force, and friction are contributing factors to the development of pressure ulcers.
- When the external pressure against the skin is greater than the pressure needed to keep the capillary open, blood flow decreases to the adjacent tissues.
- Meticulous ongoing assessment of the skin and identification of risk factors are important in decreasing the opportunity for pressure ulcer development.
- Preventive skin care is aimed at controlling external pressure on bony prominences and keeping the skin clean, well lubricated and hydrated, and free of excess moisture.
- Proper positioning reduces the effects of pressure and guards against the shearing force.
- Therapeutic beds and mattresses redistribute the effects of pressure; however, base selection on assessment data to identify the best bed for individual needs.
- Cleaning and topical agents used to treat pressure ulcers vary according to the stage of the pressure ulcer and condition of the wound bed. Assessment of the ulcer enables the nurse to select proper skin care agents.
- Direct nutritional interventions at improving wound healing through increasing protein and calorie levels.
- Wound assessment requires a description of the appearance of the wound base, size, presence of exudate, and the periwound skin condition.
- When tissue loss is extensive, a wound heals by secondary intention.
- The chances of wound infection are greater when the wound contains dead or necrotic tissue, when foreign bodies lie on or near the wound, and when the blood supply and tissue defenses are reduced.
- The principles of wound first aid include control of bleeding, cleaning, and protection.
- The layers of a dry dressing absorb drainage and prevent entrance of bacteria.
- A moist environment supports wound healing.
- The wet-to-dry dressing mechanically removes dead tissue and wound exudate to debride the wound.
- When cleaning wounds or drain sites, clean from the least to most contaminated area, away from wound edges.
- Apply a bandage or binder in a manner that does not impair circulation or irritate the skin.
- An acute sprain, closed fracture, or bruise responds best to cold applications.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Because of the foul-smelling tan-colored drainage from Mrs. Stein's hip incision, the staples were removed by the health care provider, and an order was written for moist saline gauze dressing to the area 3 times a day. When the dressing is removed, which factors are critical to assess?
2. A head-to-toe skin assessment is done per institutional policy on a daily basis. At the most recent assessment of Mrs. Stein's skin, redness was noted over the sacral area; on direct examination a small area of denuded tissue was noted. The area was assessed and was found to have minimal depth and a red, moist base. How would you describe the impairment in skin integrity in your charting?
3. What will you include in your plan of care for Mrs. Stein to address the impairment in skin integrity in the sacral area?
4. Mrs. Stein will be discharged tomorrow. Which issues must be assessed regarding her care before discharge? Describe why these issues are of importance.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. When repositioning an immobile patient, the nurse notices redness over a bony prominence. What is indicated when a reddened area blanches on fingertip touch?
   1. A local skin infection requiring antibiotics
   2. Sensitive skin that requires special bed linen
   3. A stage III pressure ulcer needing the appropriate dressing
   4. Blanching hyperemia, indicating the attempt by the body to overcome the ischemic episode.
2. Which type of pressure ulcer is noted to have intact skin and may include changes in one or more of the following: skin temperature (warmth or coolness), tissue consistency (firm or soft), and/or pain?
   1. Stage I
   2. Stage II
   3. Stage III
   4. Stage IV
3. When obtaining a wound culture to determine the presence of a wound infection, from where should the specimen be taken?
   1. Necrotic tissue
   2. Wound drainage
   3. Drainage on the dressing
   4. Wound after it has first been cleaned with normal saline
4. After surgery the patient with a closed abdominal wound reports a sudden "pop" after coughing. When the nurse examines the surgical wound site, the sutures are open, and pieces of small bowel are noted at the bottom of the now-opened wound. Which corrective intervention should the nurse do first?
   1. Allow the area to be exposed to air until all drainage has stopped
   2. Place several cold packs over the area, protecting the skin around the wound

3. Cover the area with sterile, saline-soaked towels and immediately notify the surgical team; this is likely to indicate a wound evisceration
4. Cover the area with sterile gauze, place a tight binder over it, and ask the patient to remain in bed for 30 minutes because this is a minor opening in the surgical wound and should reseal quickly

5. Which description best fits that of serous drainage from a wound?
   1. Fresh bleeding
   2. Thick and yellow
   3. Clear, watery plasma
   4. Beige to brown and foul smelling
6. For a patient who has a muscle sprain, localized hemorrhage, or hematoma, which wound care product helps prevent edema formation, control bleeding, and anesthetize the body part?
   1. Binder
   2. Ice bag
   3. Elastic bandage
   4. Absorptive diaper
7. Which skin care measures are used to manage a patient who is experiencing fecal and urinary incontinence?
   1. Keeping the buttocks exposed to air at all times
   2. Using a large absorbent diaper, changing when saturated
   3. Using an incontinence cleaner, followed by application of a moisture-barrier ointment
   4. Frequent cleaning, applying an ointment, and covering the areas with a thick absorbent towel
8. Which of the following describes a hydrocolloid dressing?
   1. A seaweed derivative that is highly absorptive
   2. Premoistened gauze placed over a granulating wound
   3. A debriding enzyme that is used to remove necrotic tissue
   4. A dressing that forms a gel that interacts with the wound surface
9. Which of the following is an indication for a binder to be placed around a surgical patient with a new abdominal wound?
   1. Collection of wound drainage
   2. Reduction of abdominal swelling
   3. Reduction of stress on the abdominal incision
   4. Stimulation of peristalsis (return of bowel function) from direct pressure
10. When is an application of a warm compress indicated? (Select all that apply.)
    1. To relieve edema
    2. For a patient who is shivering
    3. To improve blood flow to an injured part
    4. To protect bony prominences from pressure ulcers
11. What is the removal of devitalized tissue from a wound called?
    1. Debridement
    2. Pressure reduction
    3. Negative pressure wound therapy
    4. Sanitization
12. Name the three important dimensions to consistently measure to determine wound healing.
13. What does the Braden Scale evaluate?
    1. Skin integrity at bony prominences, including any wounds
    2. Risk factors that place the patient at risk for skin breakdown
    3. The amount of repositioning that the patient can tolerate
    4. The factors that place the patient at risk for poor healing
14. On assessing your patient's sacral pressure ulcer, you note that the tissue over the sacrum is dark, hard, and adherent to the wound edge. What is the correct stage for this patient's pressure ulcer?
    1. Stage II
    2. Stage IV
    3. Unstageable
    4. Suspected deep tissue damage
15. Name one intervention and the rationalization to use that intervention to reduce the likelihood of a shear injury to a patient.

CHAPTER

49

Sensory Alterations

OBJECTIVES

- Differentiate among the processes of reception, perception, and reaction to sensory stimuli.
- Discuss the relationship of sensory function to an individual's level of wellness.
- Discuss common causes and effects of sensory alterations.
- Discuss common sensory changes that normally occur with aging.
- Identify factors to assess in determining a patient's sensory status.
- Identify nursing diagnoses relevant to patients with sensory alterations.
- Develop a plan of care for patients with sensory deficits.
- List interventions for preventing sensory deprivation and controlling sensory overload.
- Describe conditions in a health care agency or patient's home that you can modify to promote meaningful sensory stimulation.
- Discuss ways to maintain a safe environment for patients with sensory deficits.

Imagine the world without sight, hearing, or the ability to feel objects or sense aromas around you. Human beings rely on a variety of sensory stimuli to give meaning and order to events occurring in their environment. The senses form the perceptual base of our world. Stimulation comes from many sources in and outside the body, particularly through the senses of sight (visual), hearing **(auditory),** touch **(tactile),** smell **(olfactory),** and taste **(gustatory).** The body also has a **kinesthetic** sense that enables a person to be aware of the position and movement of body parts without seeing them. **Stereognosis** is a sense that allows a person to recognize the size, shape, and texture of an object. The ability to speak is not a sense but it is similar in that some patients lose the ability to interact meaningfully with other human beings. Meaningful stimuli allow a person to learn about the environment and are necessary for healthy functioning and normal development. When sensory function is altered, a person's ability to relate to and function within the environment changes drastically.

Many patients seeking health care have preexisting sensory alterations. Others develop them as a result of medical treatment (e.g., hearing loss from antibiotic use or hearing or visual loss from brain tumor removal) or hospitalization. The health care environment is a place of unfamiliar sights, sounds, and smells and minimal contact with family and friends. If patients feel depersonalized and are unable to receive meaningful stimuli, serious sensory alterations sometimes develop.

As a nurse, you meet the needs of patients with existing sensory alterations and recognize patients most at risk for developing sensory problems. You also help patients who have partial or complete loss of a major sense to find alternate ways to function safely within their environment.

SCIENTIFIC KNOWLEDGE BASE

Normal Sensation

Normally the nervous system continually receives thousands of bits of information from sensory nerve organs, relays the information through appropriate channels, and integrates the information into a meaningful response. Sensory stimuli reach the sensory organs to elicit an immediate reaction or present information to the brain to be stored for future use. The nervous system must be intact for sensory stimuli to reach appropriate brain centers and for an individual to perceive the sensation. After interpreting the significance

TABLE 49-1 Normal Hearing and Vision

FUNCTION	ANATOMY AND PHYSIOLOGY
Ear	
Transmits to the brain an accurate pattern of all sounds received from the environment, the relative intensity of these sounds, and the direction from which they originate	Two ears provide stereophonic hearing to judge sound direction. The external ear canal shelters the eardrum and maintains relatively constant temperature and humidity to maintain elasticity. The middle ear is an air-containing space between the eardrum and oval window. It contains three small bones (ossicles). The eardrum and ossicles transfer sound to the fluid-filled inner ear. Movement of the stapes in the oval window creates vibrations in the fluid that bathes the membranous labyrinth, which contains the end organs of hearing and balance. The union of the vestibular (balance) and cochlear (hearing) portions of the labyrinth explains the combination of hearing and balance symptoms that occur with inner ear disorders. Vibration of the eardrum transmits through the bony ossicles. Vibrations at the oval window transmit in perilymph within the inner ear to stimulate hair cells that send impulses along the eighth cranial nerve to the brain.
Eye	
Transmits to the brain an accurate pattern of light that is reflected from solid objects in the environment and becomes transformed into color and hue	Light rays enter the convex cornea and begin to converge. Fine adjustment of light rays occurs as they pass through the pupil and lens. Change in the shape of the lens focuses light on the retina. The retina has a pigmented layer of cells to enhance visual acuity. The sensory retina contains the rods and cones (i.e., photoreceptor cells sensitive to stimulation from light). Photoreceptor cells send electrical potentials by way of the optic nerve to the brain.

of a sensation, the person is then able to react to the stimulus. Table 49-1 summarizes normal hearing and vision.

Reception, perception, and reaction are the three components of any sensory experience (see Chapter 43). Reception begins with stimulation of a nerve cell called a *receptor,* which is usually for only one type of stimulus such as light, touch, or sound. In the case of special senses, the receptors are grouped close together or located in specialized organs such as the taste buds of the tongue or the retina of the eye. When a nerve impulse is created, it travels along pathways to the spinal cord or directly to the brain. For example, sound waves stimulate hair cell receptors within the organ of Corti in the ear, which causes impulses to travel along the eighth cranial nerve to the acoustic area of the temporal lobe. Sensory nerve pathways usually cross over to send stimuli to opposite sides of the brain.

The actual perception or awareness of unique sensations depends on the receiving region of the cerebral cortex, where specialized brain cells interpret the quality and nature of sensory stimuli. When a person becomes conscious of a stimulus and receives the information, perception takes place. Perception includes integration and interpretation of stimuli based on the person's experiences. A person's level of consciousness influences perception and interpretation of stimuli. Any factors lowering consciousness impair sensory perception. If sensation is incomplete such as blurred vision or if past experience is inadequate for understanding stimuli such as pain, the person can react inappropriately to the sensory stimulus.

It is impossible to react to all stimuli entering the nervous system. The brain prevents sensory bombardment by discarding or storing sensory information. A person usually reacts to stimuli that are most meaningful or significant at the time. However, after continued reception of the same stimulus, a person stops responding, and the sensory experience goes unnoticed. For example, a person concentrating on reading a good book is not aware of background music. This adaptability phenomenon occurs with most sensory stimuli except for those of pain.

The balance between sensory stimuli entering the brain and those actually reaching a person's conscious awareness maintains a person's well-being. If an individual attempts to react to every stimulus within the environment or if the variety and quality of stimuli are insufficient, sensory alterations occur.

Sensory Alterations

The most common types of sensory alterations are sensory deficits, sensory deprivation, and sensory overload. When a patient suffers from more than one sensory alteration, the ability to function and relate effectively within the environment is seriously impaired.

Sensory Deficits. A deficit in the normal function of sensory reception and perception is a **sensory deficit.** A person loses a sense of self with impaired senses. Initially he or she withdraws by avoiding communication or socialization with others in an attempt to cope with the sensory loss. It becomes difficult for the person to interact safely with the environment until he or she learns new skills. When a deficit develops gradually or when considerable time has passed since the onset of an acute sensory loss, a person learns to rely on unaffected senses. Some senses may even become more acute to compensate for an alteration. For example, a blind patient develops an acute sense of hearing to compensate for visual loss.

Patients with sensory deficits often change behavior in adaptive or maladaptive ways. For example, a patient with a hearing impairment turns the unaffected ear toward the speaker to hear better, whereas another patient avoids people because he or she is embarrassed about not being able to understand what other people say. Box 49-1 summarizes common sensory deficits and their influence on those affected.

Sensory Deprivation. The reticular activating system in the brainstem mediates all sensory stimuli to the cerebral cortex; thus patients are able to receive stimuli even while sleeping deeply. Sensory stimulation must be of sufficient quality and quantity to maintain a person's awareness. Three types of **sensory deprivation** are reduced sensory input (sensory deficit from visual or hearing loss), the elimination of patterns or meaning from input (e.g., exposure to strange environments), and restrictive environments (e.g., bed rest) that produce monotony and boredom (Ebersole et al., 2008).

BOX 49-1 COMMON SENSORY DEFICITS

Visual Deficits

Presbyopia: A gradual decline in the ability of the lens to accommodate or focus on close objects. Individual is unable to see near objects clearly.

Cataract: Cloudy or opaque areas in part of the lens or the entire lens that interfere with passage of light through the lens, causing problems with glare and blurred vision. Cataracts usually develop gradually, without pain, redness, or tearing in the eye.

Dry eyes: Result when tear glands produce too few tears, resulting in itching, burning, or even reduced vision.

Glaucoma: A slowly progressive increase in intraocular pressure that, if left untreated, causes progressive pressure against the optic nerve, resulting in peripheral visual loss, decreased visual acuity with difficulty adapting to darkness, and a halo effect around lights.

Diabetic retinopathy: Pathological changes occur in the blood vessels of the retina, resulting in decreased vision or vision loss caused by hemorrhage and macular edema.

Macular degeneration: Condition in which the macula (specialized portion of the retina responsible for central vision) loses its ability to function efficiently. First signs include blurring of reading matter, distortion or loss of central vision, and distortion of vertical lines.

Hearing Deficits

Presbycusis: A common progressive hearing disorder in older adults.

Cerumen accumulation: Buildup of earwax in the external auditory canal. Cerumen becomes hard and collects in the canal and causes conduction deafness.

Balance Deficit

Dizziness and disequilibrium: Common condition in older adulthood, usually resulting from vestibular dysfunction. Frequently a change in position of the head precipitates an episode of vertigo or disequilibrium.

Taste Deficit

Xerostomia: Decrease in salivary production that leads to thicker mucus and a dry mouth. Often interferes with the ability to eat and leads to appetite and nutritional problems.

Neurological Deficits

Peripheral neuropathy: Disorder of the peripheral nervous system, characterized by symptoms that include numbness and tingling of the affected area and stumbling gait.

Stroke: Cerebrovascular accident caused by clot, hemorrhage, or emboli disrupting blood flow to the brain. Creates altered proprioception with marked incoordination and imbalance. Loss of sensation and motor function in extremities controlled by the affected area of the brain also occurs. A stroke affecting the left hemisphere of the brain results in symptoms on the right side such as difficulty with speech. A stroke on the right hemisphere has symptoms on the left side, which includes visual spatial alterations such as loss of half of a visual field or inattention and neglect, especially to the left side.

BOX 49-2 EFFECTS OF SENSORY DEPRIVATION

Cognitive

- Reduced capacity to learn
- Inability to think or problem solve
- Poor task performance
- Disorientation
- Bizarre thinking
- Increased need for socialization, altered mechanisms of attention

Affective

- Boredom
- Restlessness
- Increased anxiety
- Emotional lability
- Panic
- Increased need for physical stimulation

Perceptual

- Changes in visual/motor coordination
- Reduced color perception
- Less tactile accuracy
- Changes in ability to perceive size and shape
- Changes in spatial and time judgment

Modified from Ebersole P et al.: *Toward healthy aging: human needs and nursing response,* ed 7, St Louis, 2008, Mosby.

There are many effects of sensory deprivation (Box 49-2). In adults the symptoms are similar to psychological illness, confusion, symptoms of severe electrolyte imbalance, or the influence of psychotropic drugs. Therefore always be aware of a patient's existing sensory function and the quality of stimuli within the environment.

Sensory Overload. When a person receives multiple sensory stimuli and cannot perceptually disregard or selectively ignore some stimuli, **sensory overload** occurs. Excessive sensory stimulation prevents the brain from responding appropriately to or ignoring certain stimuli. Because of the multitude of stimuli leading to overload, a person no longer perceives the environment in a way that makes sense. Overload prevents meaningful response by the brain; the patient's thoughts race, attention scatters in many directions, and anxiety and restlessness occur. As a result, overload causes a state similar to that produced by sensory deprivation. However, in contrast to deprivation, overload is individualized. The amount of stimuli necessary for healthy function varies with each individual. People are often subject to environmental overload more at one time than another. A person's tolerance to sensory overload varies with level of fatigue, attitude, and emotional and physical well-being.

The acutely ill patient easily experiences sensory overload. The patient in constant pain or who undergoes frequent monitoring of vital signs is at risk. Multiple stimuli combine to cause overload even if the nurse offers a comforting word or provides a gentle back rub. Some patients do not benefit from nursing intervention because their attention and energy are focused on more stressful stimuli. Another example is a patient who is hospitalized in an intensive care unit (ICU), where the activity is constant. Lights are always on. Patients can hear sounds from monitoring equipment, staff conversations, equipment alarms, and the activities of people entering the unit. Even at night an ICU is very noisy.

It is easy to confuse the behavioral changes associated with sensory overload with mood swings or simple disorientation. Look for symptoms such as racing thoughts, scattered attention, restlessness, and anxiety. Patients in ICUs sometimes resort to constantly fingering tubes and dressings. Constant reorientation and control of excessive stimuli become an important part of a patient's care.

NURSING KNOWLEDGE BASE

Factors Influencing Sensory Function

Many factors influence the capacity to receive or perceive stimuli. All are conditions or situations that you manage when delivering care.

Age. Infants and children are at risk for visual and hearing impairment because of a number of genetic, prenatal, and postnatal conditions. A concern with high-risk neonates is that early, intense visual and auditory stimulation can adversely affect visual and auditory pathways and alter the developmental course of other sensory organs (Hockenberry and Wilson, 2011). Visual changes during adulthood include presbyopia and the need for glasses for reading. These changes usually occur from ages 40 to 50. In addition, the cornea, which assists with light refraction to the retina, becomes flatter and thicker. These aging changes lead to astigmatism. Pigment is lost from the iris, and collagen fibers build up in the anterior chamber, which increases the risk of glaucoma by decreasing the resorption of intraocular fluid. Other normal visual changes associated with aging include reduced visual fields, increased glare sensitivity, impaired night vision, reduced depth perception, and reduced color discrimination.

Hearing changes begin at the age of 30. Changes associated with aging include decreased hearing acuity, speech intelligibility, and pitch discrimination. Low-pitched sounds are easiest to hear, but it is difficult to hear conversation over background noise. It is also difficult to discriminate the consonants *(z, t, f, g)* and high-frequency sounds *(s, sh, ph, k)*. Vowels that have a low pitch are easiest to hear. Speech sounds are distorted, and there is a delayed reception and reaction to speech. A concern with normal age-related sensory changes is that older adults with a deficit are sometimes inappropriately diagnosed with dementia (Ebersole et al., 2008).

Gustatory and olfactory changes begin around age 50 and include a decrease in the number of taste buds and sensory cells in the nasal lining. Reduced taste discrimination and sensitivity to odors are common.

Proprioceptive changes common after age 60 include increased difficulty with balance, spatial orientation, and coordination. Older adults cannot avoid obstacles as quickly, and the automatic response to protect and brace oneself when falling is slower. Older adults experience tactile changes, including declining sensitivity to pain, pressure, and temperature secondary to peripheral vascular disease and neuropathies.

Meaningful Stimuli. Meaningful stimuli reduce the incidence of sensory deprivation. In the home meaningful stimuli include pets, music, television, pictures of family members, and a calendar and clock. The same stimuli need to be present in health care settings. Note whether patients have roommates or visitors. The presence of others offers positive stimulation. However, a roommate who constantly watches television, persistently tries to talk, or continuously keeps lights on contributes to sensory overload. The presence or absence of meaningful stimuli influences alertness and the ability to participate in care.

Amount of Stimuli. Excessive stimuli in an environment causes sensory overload. The frequency of observations and procedures performed in an acute health care setting are often stressful. If a patient is in pain or restricted by a cast or traction, overstimulation frequently is a problem. In addition, a room that is near repetitive or loud noises (e.g., an elevator, stairwell, or nurses' station) contributes to sensory overload.

Social Interaction. The amount and quality of social contact with supportive family members and significant others influence sensory function. The absence of visitors during hospitalization or residency in an extended care facility influences the degree of isolation a patient feels. This is a common problem in hospital intensive care settings, where visitation is often restricted. The ability to discuss concerns with loved ones is an important coping mechanism for most people. Therefore the absence of meaningful conversation results in feelings of isolation, loneliness, anxiety, and depression for a patient. Often this is not apparent until behavioral changes occur.

Environmental Factors. A person's occupation places him or her at risk for hearing, visual, and peripheral nerve alterations. Individuals who have occupations involving exposure to high noise levels (e.g., factory or airport workers) are at risk for noise-induced hearing loss and need to be screened for hearing impairments. Hazardous noise is common in work settings and recreational activities. Noisy recreational activities that weaken hearing ability include target shooting and hunting, woodworking, and listening to loud music. Individuals who have occupations involving risk of exposure to chemicals or flying objects (e.g., welders) are at risk for eye injuries and need to be screened for visual impairments. Sports activities and consumer fireworks also place individuals at risk for visual alterations. Occupations that involve repetitive wrist or finger movements (e.g., heavy assembly line work) cause pressure on the median nerve, resulting in carpal tunnel syndrome. Carpal tunnel syndrome alters tactile sensation and is one of the most common industrial or work-related injuries. Patients at risk for carpal tunnel need to be carefully assessed for numbness, tingling, weakness, and pain.

A hospitalized patient is sometimes at risk for sensory alterations as a result of exposure to environmental stimuli or a change in sensory input. Patients who are immobilized by bed rest or who have a chronic disability are unable to experience all of the normal sensations of free movement. Another group at risk includes patients isolated in a health care setting or at home because of conditions such as active tuberculosis (see Chapter 28). These patients stay in private rooms and are often unable to enjoy normal interactions with visitors.

Cultural Factors. Certain sensory alterations occur more commonly in select ethnic groups. Analysis of data from the African Descent and Glaucoma Evaluation study (ADAGES) showed that people of African ethnicity perform significantly worse than people of European descent on tests of visual function (Racette et al., 2010). Cultural disparities in vision impairment are significant, in part because visual impairment may be indirectly associated with an increased risk of suicide through poor self-rated health (Lam et al., 2008). Box 49-3 summarizes additional sensory alterations that are associated with a patient's cultural heritage.

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge and information gathered from patients, experience, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the information necessary, analyze the data, and make decisions regarding patient care. Patients' conditions are always changing. During assessment (Fig. 49-1) consider all critical thinking elements that help you make appropriate nursing diagnoses. In the case of sensory alterations, integrate knowledge of the pathophysiology of sensory deficits, factors that affect sensory function, and therapeutic communication principles. This knowledge enables you to conduct appropriate

BOX 49-3 CULTURAL ASPECTS OF CARE

Disparities in Sensory Alteration

Studies indicate that differences in sensory impairments exist among ethnic groups. Non-Hispanic white and Mexican-American people have a higher prevalence of hearing problems than non-Hispanic black people (Dillon et al., 2010). Latinos have higher rates of developing visual impairment, blindness, diabetic eye disease, and cataracts than non-Hispanic whites (National Eye Institute, 2010a). Whites have a higher incidence of age-related macular degeneration than people of African descent (National Eye Institute, 2010b).

Although early diagnosis and treatment may slow the progression of sensory impairments, patients do not always volunteer information about impairments. They often focus on other symptoms or medical conditions, or they do not think that their primary care physician is the right person to talk to (Rosenberg and Sperazza, 2008).

Implications for Practice

- Encourage patients to discuss sensory impairments by asking a few simple but focused questions.
- Enhance your knowledge of the services available to patients with sensory impairments and educate patients about the organizations that exist to provide assistance.
- Facilitate access to services to promote the early detection and treatment of sensory impairments.
- Identify the patient's preferred method of communication—use an interpreter service if needed.
- Ensure that health information is available in the appropriate language and format (e.g., large print).

assessments, anticipate what to recognize when a patient describes a sensory problem, and make judgments of any abnormalities. For example, knowing the typical symptoms caused by a cataract helps you recognize the pattern of visual changes that a patient with cataracts reports.

Previous experiences in caring for patients with sensory deficits enable nurses to recognize limitations in function in each new patient and how they affect the patient's ability to carry out daily activities. For example, after caring for a patient with a hearing impairment, you are able to conduct a more effective assessment of the next patient by using approaches that promote the patient's ability to hear your questions.

When critical thinking attitudes and standards are applied during assessment, they ensure a thorough and accurate database from which to make decisions. For example, perseverance is necessary to learn details about how visual changes influence a patient's ability to socialize. Evidence-based standards of care and practice such as those from the American Academy of Ophthalmology and the American Speech-Language-Hearing Association provide criteria for screening sensory problems and establishing standards for competent, safe, effective care and practice. Use critical thinking to conduct a thorough assessment and then plan, implement, and evaluate care that enables the patient to function safely and effectively (Box 49-4).

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care for your patients.

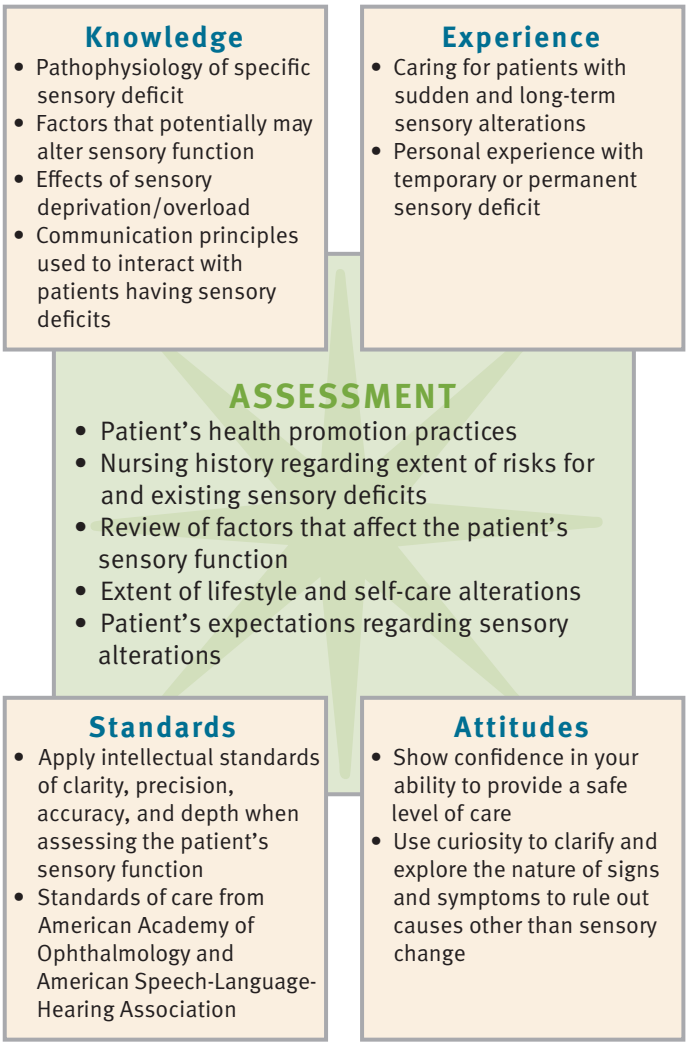

FIG. 49-1 Critical thinking model for sensory alterations assessment.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. When conducting an assessment, value the patient as a full partner in planning, implementing, and evaluating care. Patients are often hesitant to admit sensory losses. Therefore start gathering information by establishing a therapeutic rapport with the patient. Elicit his or her values, preferences, and expectations with regard to his or her sensory impairment. Many patients have a definite plan as to how they want their care delivered. Some patients expect caregivers to recognize and appropriately manage and adjust their environment to meet their sensory needs. This includes helping the patient learn and adapt to a changed lifestyle based on the specific sensory impairment. Determine from the patient which interventions have been helpful in the past in the management of limitations. Assess the patient's expertise with his or her own health and symptoms. Always remember that patients with sensory alterations have strengthened their other senses and expect caregivers to anticipate their needs (e.g., for safety and security).

BOX 49-4 EVIDENCE-BASED PRACTICE

Consequences of Waiting for Cataract Surgery

PICO Question: Are adult patients who wait 6 months or longer for cataract surgery at increased risk for negative outcomes compared to patients who wait less than 6 months?

Evidence Summary

Cataracts are a major disease affecting vision. With appropriate evaluation this disease is readily diagnosed and treated. The high levels of efficacy and minimal complications associated with cataract surgery have led to a high demand for this procedure. Current literature shows that vision impairment is associated with impaired activities of daily living, social isolation, and decreased function (Lam et al., 2008). Thus the development of evidence-based benchmarks for medically acceptable wait times has significant implications.

Outcomes associated with wait times of less than 6 weeks are better than those associated with wait times more than 6 months. Patients who wait more than 6 months to have cataract surgery typically experience more vision loss, a reduced quality of life, and an increased rate of falls compared with patients who wait less than 6 weeks (Hodge et al., 2007).

Application to Nursing Practice

- Facilitate the prompt referral of patients with cataracts to an ophthalmologist.
- Before surgery provide all relevant information to patients about what happens before, during, and after surgery (Wasfi and Abd-Elsayed, 2008).
- Ensure that all patients receive written information to minimize anxiety (Wasfi and Abd-Elsayed, 2008).
- Encourage patients to access support from others with visual impairments.
- During the wait period help to identify creative strategies to promote self-care.

BOX 49-5 NURSING ASSESSMENT QUESTIONS

Nature of the Problem

- What type of problem are you having with your vision/hearing?
- What have you tried to correct the vision/hearing difficulty?
- Do you use any devices to improve your vision/hearing?

Signs and Symptoms

- Ask a patient with visual alterations: Do you require books with large print or on audiotape? Are you able to prepare a meal or write a check?
- Ask a patient with hearing alterations: What types of sounds or tones do you have difficulty hearing? Do people tell you that they have to "shout" for you to hear them? Do you have a ringing, crackling, or buzzing in your ears?
- Is there pain: sharp, dull, burning, itching?
- Have you noticed any redness, swelling, or drainage? Any signs of infection?

Onset and Duration

- When did you notice the problem? How long has this problem lasted?
- Does it come and go, or is it constant?

Predisposing Factors

- Do you work or participate in any activities that have the potential for vision/hearing injury? If so, how do you protect your hearing and vision?
- Do you have a family history of cataracts, glaucoma, macular degeneration, or hearing loss?
- When was your last vision/hearing examination?

Effect on Patient

- What effect has your vision/hearing problem had on your work, family, or social life?
- Have changes in your vision/hearing affected your feelings of independence?
- How does your vision/hearing problem make you feel about yourself?
- Do you have problems with routine care of glasses, contact lenses, or hearing aids?

When assessing a patient with or at risk for sensory alteration, first consider the pathophysiology of existing deficits and the factors influencing sensory function to anticipate how to approach his or her assessment. For example, if a patient has a hearing disorder, adjust your communication style and focus the assessment on relevant criteria related to hearing deficits. Collect a history that also assesses the patient's current sensory status and the degree to which a sensory deficit affects the patient's lifestyle, psychosocial adjustment, developmental status, self-care ability, health promotion habits, and safety. Also focus the assessment on the quality and quantity of stimuli within the patient's environment.

Persons at Risk. Older adults are a high-risk group because of normal physiological changes involving sensory organs. However, be careful not to automatically assume that a patient's sensory problem is related to advancing age. For example, adult sensorineural hearing loss is often caused by exposure to excess and prolonged noise or metabolic, vascular, and other systemic alterations. Some patients benefit from a referral to an audiologist or **otolaryngologist** if assessment reveals serious hearing problems.

Other individuals at risk for sensory alterations include those living in a confined environment such as a nursing home. Although most quality nursing homes or centers offer meaningful stimulation through group activities, environmental design, and mealtime gatherings, there are exceptions. The individual who is confined to a wheelchair, suffers from poor hearing and/or vision, has decreased energy, and avoids contact with others is at significant risk for sensory deprivation. If the environment creates monotony, the individual is less able to learn and think. Patients who are acutely ill are also at risk because of an unfamiliar and unresponsive environment. This does not mean that all hospitalized patients have sensory alterations. However, you need to carefully assess patients subjected to continued sensory stimulation (e.g., ICU settings, long-term hospitalization, or multiple therapies). Assess the patient's environment within both the health care setting and the home, looking for factors that pose risks or need adjustment to provide safety and more stimulation.

Sensory Alterations History. The nursing history includes assessment of the nature and characteristics of sensory alterations or any problem related to an alteration (Box 49-5). When taking the history, consider the ethnic or cultural background of the patient because certain alterations are higher in some cultural groups.

During the history it is useful to assess the patient's self-rating for a sensory deficit by asking, "Rate your hearing as excellent, good, fair, poor, or bad." Then, based on the patient's self-rating, explore his or her perception of a sensory loss more fully. This provides an in-depth look at how the sensory loss influences the patient's quality of life. In the case of hearing problems, a screening tool such as the Hearing Handicap Inventory for the Elderly

TABLE 49-2 Assessment of Sensory Function

ASSESSMENT ACTIVITIES	BEHAVIOR INDICATING DEFICIT (CHILDREN)	BEHAVIOR INDICATING DEFICIT (ADULTS)
Vision		
Ask patient to read newspaper, magazine, or lettering on menu. Ask patient to identify colors on color chart or crayons. Observe patients performing ADLs.	Self-stimulation, including eye rubbing, body rocking, sniffing or smelling, arm twirling; hitching (using legs to propel while in sitting position) instead of crawling	Poor coordination, squinting, underreaching or overreaching for objects, persistent repositioning of objects, impaired night vision, accidental falls
Hearing		
Assess patient's hearing acuity (see Chapter 30) using spoken word and tuning fork tests. Assess for history of tinnitus. Observe patient conversing with others. Inspect ear canal for hardened cerumen. Observe patient behaviors in a group.	Frightened when unfamiliar people approach, no reflex or purposeful response to sounds, failure to be awakened by loud noise, slow or absent development of speech, greater response to movement than to sound, avoidance of social interaction with other children	Blank looks, decreased attention span, lack of reaction to loud noises, increased volume of speech, positioning of head toward sound, smiling and nodding of head in approval when someone speaks, use of other means of communication such as lip-reading or writing, complaints of ringing in ears
Touch		
Check patient's ability to discriminate between sharp and dull stimuli. Assess whether patient is able to distinguish objects (coin or safety pin) in the hand with eyes closed. Ask whether patient feels unusual sensations.	Inability to perform developmental tasks related to grasping objects or drawing, repeated injury from handling of harmful objects (e.g., hot stove, sharp knife)	Clumsiness, overreaction or underreaction to painful stimulus, failure to respond when touched, avoidance of touch, sensation of pins and needles, numbness Unable to identify object placed in hand
Smell		
Have patient close eyes and identify several nonirritating odors (e.g., coffee, vanilla).	Difficult to assess until child is 6 or 7 years old, difficulty discriminating noxious odors	Failure to react to noxious or strong odor, increased body odor, decreased sensitivity to odors
Taste		
Ask patient to sample and distinguish different tastes (e.g., lemon, sugar, salt). (Have patient drink or sip water and wait 1 minute between each taste.)	Inability to tell whether food is salty or sweet, possible ingestion of strange-tasting things	Change in appetite, excessive use of seasoning and sugar, complaints about taste of food, weight change

ADLs, Activities of daily living.

(HHIE-S) effectively identifies patients needing audiological intervention. The HHIE-S is a 5-minute, 10-item questionnaire that assesses how the individual perceives the social and emotional effects of hearing loss. The higher the HHIE-S score, the greater the handicapping effect of a hearing impairment.

A nursing history also reveals any recent changes in a patient's behavior. Frequently friends or family are the best resources for this information. Ask the family the following questions:

- Has your family member shown any recent mood swings (e.g., outbursts of anger, nervousness, fear, or irritability)?
- Have you noticed the family member avoiding social activities?

Mental Status. Assessment of mental status is valuable when you suspect sensory deprivation or overload. Observation of a patient during history taking, during the physical examination (see Chapter 30), and while providing nursing care offers valuable data about key patient behaviors and his or her mental status. Observe the patient's physical appearance and behavior, measure cognitive ability, and assess his or her emotional status. The Mini-Mental State Examination (MMSE) is a tool you can use to measure disorientation, change in problem-solving abilities, and altered conceptualization and abstract thinking (see Chapter 30). For example, a patient with severe sensory deprivation is not always able to carry on a conversation, remain attentive, or display recent or past memory. An important step toward preventing cognition-related disability is education by nurses about disease process, available services, and assistive devices.

Physical Assessment. To identify sensory deficits and their severity, use physical assessment techniques to assess vision, hearing, olfaction, taste, and the ability to discriminate light touch, temperature, pain, and position (see Chapter 30). Table 49-2 summarizes specific assessment techniques for identifying sensory deficits. You gather more accurate data if the examination room is private, quiet, and comfortable for the patient. In addition, rely on personal observation to detect sensory alterations. Patients with a hearing impairment may seem inattentive to others, respond with inappropriate anger when spoken to, believe people are talking about them, answer questions inappropriately, have trouble following clear directions, and have monotonous voice quality and speak unusually loud or soft.

Ability to Perform Self-Care. Assess patients' functional abilities in their home environment or health care setting, including the ability to perform feeding, dressing, grooming, and toileting activities. For example, assess whether a patient with altered vision is able to find items on a meal tray and read directions on a prescription. Also determine a patient's ability to perform instrumental activities of daily living (IADLs), such as reading bills and writing checks, differentiating money denominations, and driving a vehicle at night. If a patient seems to have a sensory deficit, does he or she show concern for grooming? Does a patient's loss of balance prevent rising from a toilet seat safely? Can a patient recovering from a stroke manipulate buttons or zippers for dressing? If a sensory alteration impairs a patient's functional ability, providing resources within the home is a necessary part of discharge

planning. Your findings may indicate the need for an occupational therapy consult.

Health Promotion Habits. Assess the daily routines that patients follow to maintain sensory function. What type of eye and ear care is a part of the patient's daily hygiene? For individuals who participate in sports (e.g., racquetball) or recreational activities (e.g., motorcycle riding) or who work in a setting where ear or eye injury is a possibility (e.g., chemical exposure, welding, glass or stone polishing, or constant exposure to loud noise), determine if they wear safety glasses or hearing protective devices (HPDs). Do patients who use assistive devices such as eyeglasses, contact lenses, or hearing aids know how to provide daily care (see Chapter 39)? Do patients use the devices, and are they in proper working order?

It is also important to assess a patient's adherence with routine health screening. When was the last time the patient had an eye examination or hearing evaluation? For adults routine screening of visual and hearing function is imperative to detect problems early. This is especially true in the case of glaucoma, which, if undetected, leads to permanent visual loss. Recommended screening guidelines usually occur on the basis of age. When a patient begins to show a hearing deficit, incorporate routine screening in regular examinations.

Environmental Hazards. Patients with sensory alterations are at risk for injury if their living environments are unsafe. For example, a patient with reduced vision cannot see potential hazards clearly. A patient with proprioceptive problems loses balance easily. A patient with reduced sensation cannot perceive hot versus cold temperatures. The condition of the home, the rooms, and the front and back entrances are often problematic to the patient with sensory alterations. Assess the patient's home for common hazards, including the following:

- Uneven, cracked walkways leading to front/back door
- Extension and phone cords in the main route of walking traffic
- Loose area rugs and runners placed over carpeting
- Bathrooms without shower or tub grab bars
- Water faucets unmarked to designate hot and cold
- Unlit stairways, lack of handrails

In the hospital environment caregivers often forget to rearrange furniture and equipment to keep paths from the bed and chair to the bathroom and entrance clear. It is helpful to walk into a patient's room and look for safety hazards:

- Is the call light within easy, safe reach?
- Are intravenous (IV) poles on wheels and easy to move?
- Are suction machines, IV pumps, or drainage bags positioned so a patient can rise from a bed or chair easily?

An additional problem faced by patients who are visually impaired is the inability to read medication labels and syringe markings. Ask the patient to read a label to determine if he or she is able to read the dosage and frequency. If a patient has a hearing impairment, check to see whether the sounds of a doorbell, telephone, smoke alarm, and alarm clock are easy to discriminate.

Communication Methods. To understand the nature of a communication problem, you need to know whether a patient has trouble speaking, understanding, naming, reading, or writing. Patients with existing sensory deficits often develop alternate ways of communicating. To interact with the patient and promote interaction with others, understand his or her method of communication (Fig. 49-2). Vision becomes almost a primary sense for people with hearing impairments.

FIG. 49-2 Nurse sits at eye level so patient with hearing impairment can communicate.

Patients with visual impairments are unable to observe facial expressions and other nonverbal behaviors to clarify the content of spoken communication. Instead they rely on voice tones and inflections to detect the emotional tone of communication. Some patients with visual deficits learn to read Braille. Patients with **aphasia** have varied degrees of inability to speak, interpret, or understand language. **Expressive aphasia,** a motor type of aphasia, is the inability to name common objects or express simple ideas in words or writing. For example, a patient understands a question but is unable to express an answer. Sensory or **receptive aphasia** is the inability to understand written or spoken language. A patient is able to express words but is unable to understand questions or comments of others. Global aphasia is the inability to understand language or communicate orally.

The temporary or permanent loss of the ability to speak is extremely traumatic to an individual. Assess a patient's alternate communication method and whether it causes anxiety. Patients who have undergone laryngectomies often write notes, use communication boards or laptop computers, speak with mechanical vibrators, or use esophageal speech. Patients with endotracheal or tracheostomy tubes have a temporary loss of speech. Most use a notepad to write their questions and requests. However, some patients become incapacitated and unable to write messages. Determine whether the patient has developed a sign-language system or symbols to communicate needs.

Social Support. Assess if a patient lives alone and whether family or friends frequently visit. It is important to assess the patient's social skills and level of satisfaction with the support given by family and friends. Is the patient satisfied with the support available? Is he or she able to solve problems with family members? Is there a family caregiver who offers support when the patient requires assistance as a result of a sensory loss? The long-term effects of sensory alterations influence family dynamics and a patient's willingness to remain active in society.

Use of Assistive Devices. Assess the use of assistive devices (e.g., use of a hearing aid or glasses) and the sensory effects for the patient. This includes learning how often the patient uses the devices daily, the patient's or family caregiver's method of cleaning, and the patient's knowledge of what to do when a problem develops. When you identify that the patient has an assistive device, it is important to remember that, just because the individual has the assistive device, it does not mean that it works or that the patient uses it or benefits from it.

BOX 49-6 NURSING DIAGNOSTIC PROCESS

Risk for Injury

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Assess patient's visual acuity.	Has reduced ability to see objects clearly; needs brighter light to read; has trouble distinguishing edges of stairs
Visit home setting and inspect for hazards that pose risks to patient.	Lighting in rooms, hallways, and stairwells very dim; carpet in living room old, edges curled up; steps leading up to front entrance of home
Review medical record from clinic visit.	Diagnosis of cataracts in both eyes

Other Factors Affecting Perception. Factors other than sensory deprivation or overload cause impaired perception (e.g., medications or pain). Assess the patient's medication history, which includes prescribed and over-the-counter medications and herbal products. Also gather information regarding the frequency, dose, method of administration, and last time these medications were taken. Some antibiotics (e.g., streptomycin, gentamicin, and tobramycin) are **ototoxic** and permanently damage the auditory nerve, whereas chloramphenicol sometimes irritates the optic nerve. Opioid analgesics, sedatives, and antidepressant medications often alter the perception of stimuli. Conduct a thorough pain assessment (see Chapter 43) when you suspect that pain is causing perceptual problems.

NURSING DIAGNOSIS

After assessment review all available data and look critically for patterns and trends suggestive of a health problem relating to sensory alterations (Box 49-6). Validate findings to ensure accuracy of the diagnosis. Determine the factor that likely causes the patient's health problem. The etiology or related factor of a nursing diagnosis is a condition that nursing interventions can affect. The etiology needs to be accurate; otherwise nursing therapies are ineffective.

Some patients have health care problems for which sensory alteration is the etiology, such as with the diagnosis of *risk for injury.* You select nursing diagnoses by recognizing the way that sensory alterations affect a patient's ability to function (e.g., *self-care deficit).* In addition, most patients present themselves to health care professionals with multiple diagnoses (Fig. 49-3). In the example of the concept map, a patient with a cataract has the nursing diagnoses of *risk for injury, anxiety, fear,* and *risk for falls.* The sensory alteration caused by the cataract is an etiology for both risk for injury and risk for falls. Furthermore, fear occurs as a response to a perceived risk of falling. You need to recognize patterns of data that reveal health problems created by the patient's sensory alteration. Examples of nursing diagnoses that apply to patients with sensory alterations include the following:

- Risk-prone health behavior
- Impaired verbal communication
- Risk for injury
- Impaired physical mobility
- Bathing self-care deficit
- Dressing self-care deficit
- Toileting self-care deficit
- Situational low self-esteem
- Risk for falls
- Social isolation

PLANNING

During planning synthesize information from multiple resources (Fig. 49-4). Reflect on knowledge gained from the assessment and knowledge of how sensory deficits affect normal functioning. In this way you are able to recognize the extent of the patient's deficit and know the type of interventions most likely to be helpful. Also consider the role that health professionals play in planning care and the available community resources that will be useful. Previous experience in caring for patients with sensory alterations is invaluable.

When applying critical thinking to planning care, professional standards are particularly useful. These standards recommend evidence-based interventions for the patient's condition. For example, patients who have visual deficits and are hospitalized are often placed on a fall-prevention protocol that incorporates research-based precautions to ensure patient safety.

Goals and Outcomes. During planning develop an individualized plan of care for each nursing diagnosis (see the Nursing Care Plan). Partner with the patient to develop a realistic plan that incorporates what you know about his or her sensory problems and the extent to which he or she can maintain or improve sensory function. Goals and outcomes need to be realistic and measurable. An example of a goal of care for a patient with an actual or potential sensory alteration is "The patient will achieve improvement in hearing acuity within 2 weeks." Associated outcomes for this goal include the following:

- The patient and family will report using communication techniques to send and receive messages within 2 days.
- The patient will successfully demonstrate correct technique for cleaning a hearing aid within 1 week.
- The patient will self-report improved hearing acuity.

Setting Priorities. You consider the type and extent of sensory alteration affecting a patient when determining priorities of care. For example, a patient who enters the emergency department after experiencing eye trauma has priorities of reducing anxiety and preventing further injury to the eye. In contrast, a patient who is being discharged from an outpatient surgery department following cataract removal has the priority of learning about self-care restrictions. Safety is always a top priority. The patient also helps prioritize aspects of care. For example, a patient wishes to learn ways to communicate more effectively or participate in favorite hobbies given his or her limitation.

Some sensory alterations are short term (e.g., a patient experiencing sensory overload in an ICU). Thus appropriate interventions are likely to be temporary (e.g., frequent reorientation or introduction of pleasant stimuli such as a back rub). Some sensory alterations such as permanent visual loss require long-term goals of care for patients to adapt. Patients who have sensory alterations at the time of entering a health care setting are usually most informed about how to adapt interventions to their lifestyles. For example, allow patients who are blind to control whatever parts of their care they can. Sometimes it becomes necessary for the patient to make major changes in self-care activities,

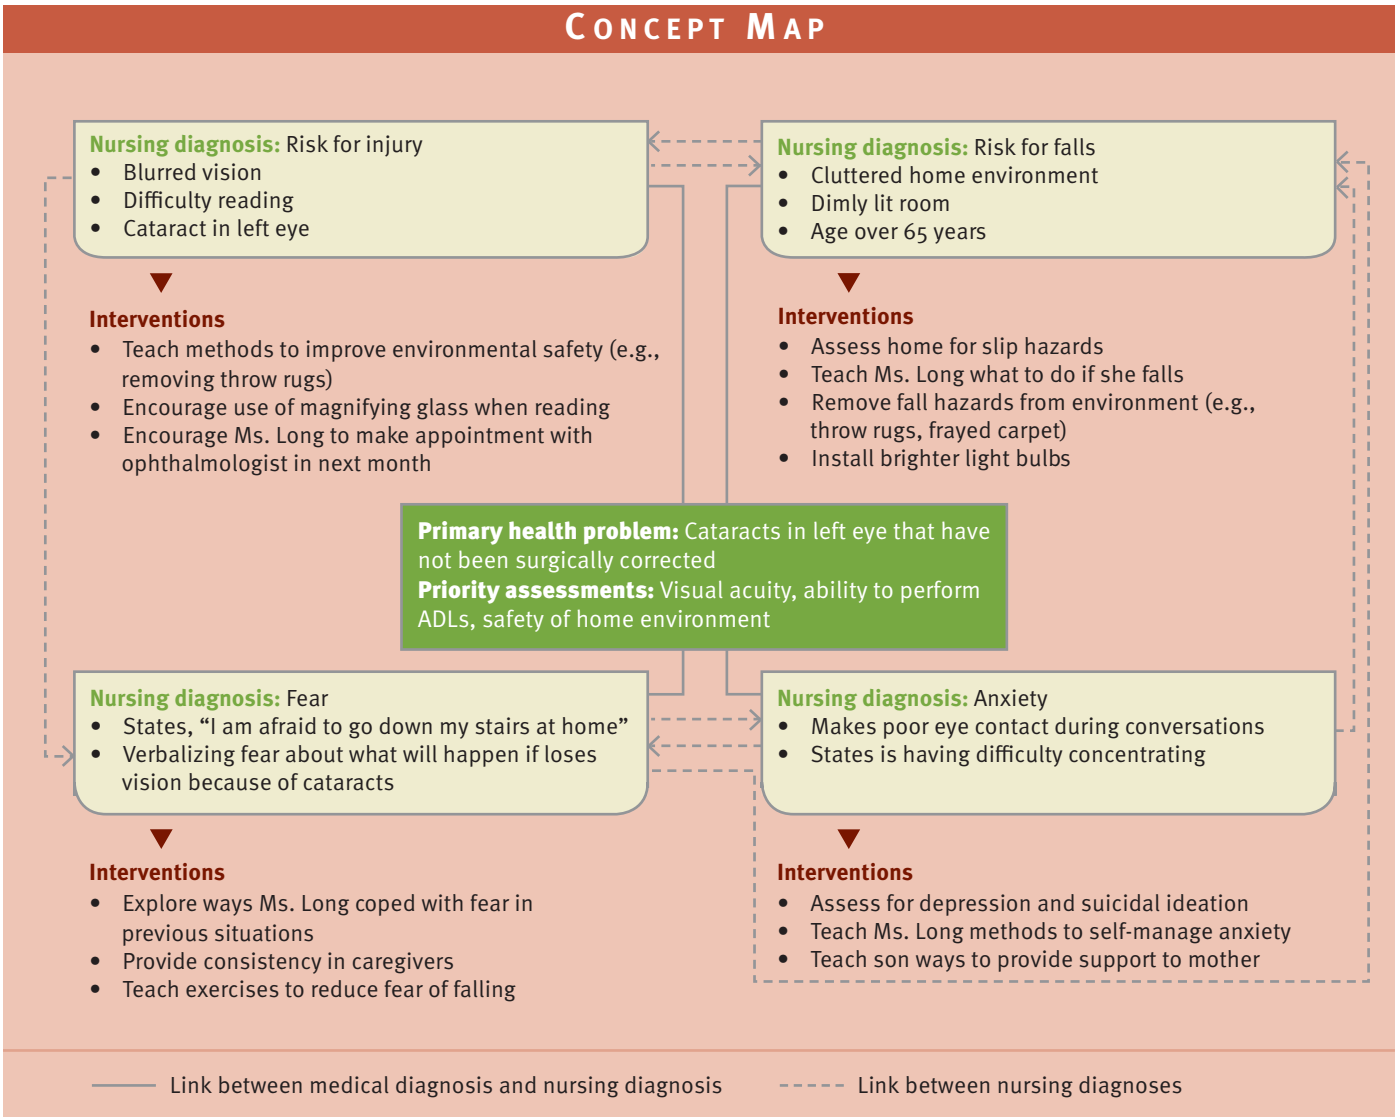

FIG. 49-3 Concept map for Ms. Long.

communication, and socialization to ensure safe and effective nursing care.

Teamwork and Collaboration. When developing a plan of care, consider all resources available to patients. The family plays a key role in providing meaningful stimulation and learning ways to help the patient adjust to any limitations. Engaging the family or designated surrogate is a fundamental skill of patient-centered care (Cronenwett et al., 2007). You also frequently refer patients to other health care professionals. For example, early referrals to occupational or speech therapists speeds a patient's recovery. If a patient has a major loss of sensory function and is also unable to manage medical needs such as medication self-administration or dressing changes, referral to home care is an option. Valuing intraprofessional and interprofessional collaboration is an essential nurse competency and plays a role in quality patient care (Cronenwett et al., 2007). Numerous community-based resources (e.g., local chapter of the Society for the Blind and Visually Impaired and the Area Agency on Aging) are also available. Try to arrange a volunteer to visit a patient or have printed materials made available that describe ways to cope with sensory problems.

IMPLEMENTATION

Nursing interventions involve the patient and family so the patient is able to maintain a safe, pleasant, and stimulating sensory environment. The most effective interventions enable a patient with sensory alterations to function safely with existing deficits and continue a normal lifestyle. Patients can learn to adjust to sensory impairments at any age with the proper support and resources. Use measures to maintain a patient's sensory function at the highest level possible.

Health Promotion. Good sensory function begins with prevention. When a patient seeks health care, provide education about interventions that reduce the risk for sensory losses. Also recommend relevant visual and hearing guidelines.

Screening. An estimated 80 million people have potentially blinding eye diseases (National Eye Institute, 2010c). Preventable blindness is a worldwide health issue that begins with children and requires appropriate screening. Four recommended interventions are (1) screening for rubella, syphilis, chlamydia, and gonorrhea in women who are considering pregnancy; (2) advocating adequate

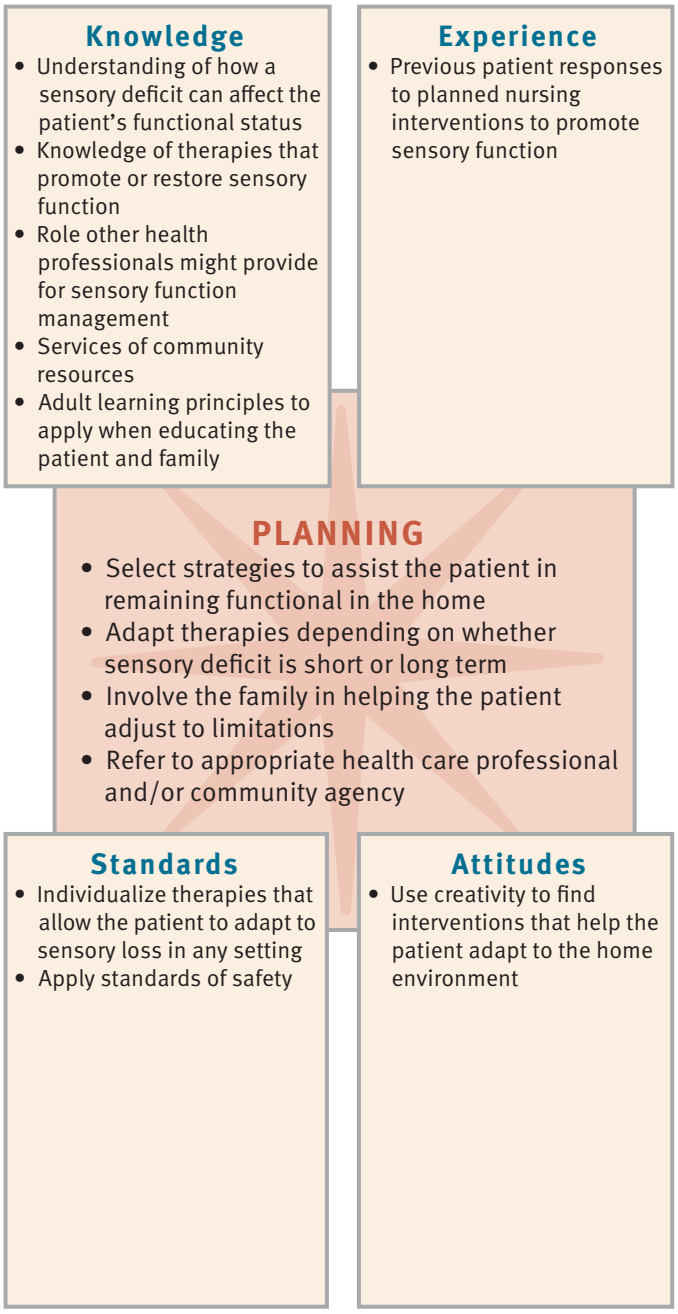

FIG. 49-4 Critical thinking model for sensory alterations planning.

prenatal care to prevent premature birth (with the danger of exposure of the infant to excessive oxygen); (3) administering eye prophylaxis in the form of erythromycin ointment approximately 1 hour after an infant's birth; and (4) periodic screening of all children, especially newborns through preschoolers, for congenital blindness and visual impairment caused by refractive errors and **strabismus** (Hockenberry and Wilson, 2011).

Visual impairments are common during childhood. The most common visual problem is a **refractive error** such as nearsightedness. The nurse's role is one of detection, education, and referral. Parents need to know the signs of visual impairment (e.g., failure to react to light and reduced eye contact from the infant). Instruct parents to report these signs to their health care provider immediately. Vision screening of school-age children and adolescents helps detect problems early. The school nurse is usually responsible for vision testing.

In the United States glaucoma is the second leading cause of blindness in the general population and the primary cause of blindness in African Americans. If left undetected and untreated, it leads to permanent visual loss. The American Academy of Ophthalmology (2010) recommends a regular medical eye examination with measurement of intraocular pressure every 2 years for those over 40 years old. Examinations need to occur every 1 to 2 years if there is a family history of glaucoma or if the patient is of African ancestry, has had a serious eye injury in the past, is taking steroid medications, or is over 65 years of age.

Hearing impairment is one of the most common disabilities in the United States. An estimated 37 million people in the United States are deaf or hard of hearing (CDC, 2008). Children at risk include those with a family history of childhood hearing impairment, perinatal infection (rubella, herpes, or cytomegalovirus), low birth weight, chronic ear infection, and Down syndrome. Advise pregnant women of the importance of early prenatal care, avoidance of ototoxic drugs, and testing for syphilis or rubella.

Children with chronic middle ear infections, a common cause of impaired hearing, need to receive periodic auditory testing. Warn parents of the risks and to seek medical care when the child has symptoms of earache or respiratory infection.

Because aging is associated with degenerative changes in the ear, patients need to have hearing screenings at least every decade through age 50 and every 3 years thereafter (American Speech-Language-Hearing Association, 2011). Once a patient reports a hearing loss, regular testing also becomes necessary. In addition, a patient who works or lives in a high–noise level environment requires an annual screening. Occupational health nurses play a key role in the assessment of the auditory system and the initiation of prompt referrals. The early identification and treatment of problems help older adults be more active and healthy.

Preventive Safety. Trauma is a common cause of blindness in children. Penetrating injury from propulsive objects such as firecrackers or slingshots or from penetrating wounds from sticks, scissors, or toy weapons are just a few examples. Parents and children require counseling on ways to avoid eye trauma such as avoiding use of toys with long, pointed projections and instructing children not to walk or run while carrying pointed objects. Instruct patients that they can find safety equipment in most sports shops and large department stores.

Adults are at risk for eye injury while playing sports and working in jobs involving exposure to chemicals or flying objects. The Occupational Safety and Health Administration (OSHA, 2010) has guidelines for workplace safety. Employers are required to have eye wash stations and to have employees wear eye goggles and/or use equipment such as HPDs to reduce the risk of injury. *Healthy People 2020* (USDHHS, 2009) identifies goals that include reducing new cases of work-related, noise-induced hearing loss. Occupational health nurses reinforce the use of protective devices. In addition, nurses need to routinely assess patients for noise exposure and participate in providing hearing conservation classes for teachers, students, and patients.

Another means of prevention involves regular immunization of children against diseases capable of causing hearing loss (e.g., rubella, mumps, and measles). Nurses who work in health care providers' offices, schools, and community clinics instruct patients

NURSING CARE PLAN

Risk for Injury

ASSESSMENT

Ms. Judy Long is a 70-year-old retired widow who resides in a two-story home with her son. She tells the community health nurse that she is having increased difficulty with night driving and blurry vision. She enjoys reading and sewing; however, her reduced vision limits her ability to participate in these activities. Ms. Long reports that her vision is blurred even with glasses and she is afraid that she will fall. Ms. Long visited an ophthalmologist 1 year ago, but didn't follow up with the recommended treatment.

Assessment Activities	*Findings/Defining Characteristics**
Ask Ms. Long to describe her vision changes.	Ms. Long states, "My left eye seems to have a film over it that makes my **vision blurred.** I am having **difficulty reading.** I also have **difficulty with night driving."**
Ask Ms. Long to describe life changes that have occurred since the change in vision.	Ms. Long states, "I've lost my independence because I can no longer drive at night. **I'm hesitant to use the stairs at home because I can't judge steps clearly**."
Assess Ms. Long's visual acuity.	Ms. Long can't read the Snellen chart with the left eye.
Ask Ms. Long the results of the visit to the ophthalmologist.	Ms. Long states, "I was told I had a **cataract of the left eye,** and surgery was recommended."
Conduct a home hazard assessment.	There is **clutter in the home, dim lighting,** and **stairs without handrails.**

***Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Risk for injury

PLANNING

Goal	*Expected Outcomes (NOC)†*
	Safe Home Environment
Ms. Long will maintain independence in a safe home environment.	Ms. Long and her son will make recommended changes to home environment within 4 weeks.
	Ms. Long will report an increased sense of home safety and independence within 4 weeks.

†Outcome classification labels from Moorhead S et al.: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Environmental Management	
Teach Ms. Long and her son methods to improve environmental safety such as installing handrails along stairs, securing carpeting, removing throw rugs, and painting stairs.	A decrease in visual acuity and depth perception places a patient at risk for falls in the presence of environmental hazards (Ebersole et al., 2008). Environmental safety modifications reduce injury.
Teach Ms. Long to use a light over the shoulder for reading and sewing.	Good lighting and an adjustable lamp reduce glare (Rosenberg and Sperazza, 2008).
Explain use of a pocket magnifier and offer list of locations where Ms. Long can purchase one.	Magnifier enlarges visual images when reading or doing close work (Ebersole et al., 2008).
Have Ms. Long make appointment with ophthalmologist within the next 4 weeks.	Older adults need a routine eye examination annually or as recommended (Ebersole et al., 2008).
Emotional Support	
Encourage Ms. Long to express feelings regarding loss of vision and lifestyle changes.	Visual impairment often leads to functional disabilities that have adverse effects on quality of life (Hodge et al., 2007).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Ms. Long to describe the changes made in the home to reduce environmental hazards.	Ms. Long responds that she has removed the clutter and placed handrails at the entryway. She has also placed lighting behind her chair, and there are 100-watt lights in the living room.	Ms. Long reports feeling safer walking the stairs and moving about in her home. The home hazards have been reduced.
As Ms. Long uses a magnifier, have her read a medication label.	Ms. Long is able to read name of medication and dosage correctly.	Visual acuity has not been further compromised.
Ask Ms. Long if she is able to maintain a degree of independence with the environmental and lifestyle modifications.	Ms. Long states, "I'm more independent at home, and until surgery I don't mind having someone drive for me."	Ms. Long has attained some degree of independence.

BOX 49-7 PATIENT TEACHING

Troubleshooting Hearing Aid Malfunction

Objective

- Patient and family member will identify source of malfunction in hearing aid.

Teaching Strategies

- Show patient and family member locations on hearing aid device where damage (e.g., cracks, fraying) is likely to occur: ear mold or case, earphone, dials, cord, and connection plugs.
- Demonstrate battery replacement: Have extra set of unused batteries available.
- Review method to check volume: Turn dial to maximum gain and check. Is voice clear?
- Consult manufacturer directions for specific care measures for cleaning battery case and ear mold.
- Review factors to report to hearing aid laboratory: static, distortion of sound, poor volume quality.

Evaluation

- Have patient and family member describe types of common malfunctions with hearing aid.
- Have patient and family demonstrate battery removal and cleaning.

about the importance of early and timely immunization. In all populations use caution when administering ototoxic drugs.

Use of Assistive Devices. Patients who wear corrective contact lenses, eyeglasses, or hearing aids need to make sure that they are clean, accessible, and functional (see Chapter 39). It is helpful to have a family member or friend who also knows how to care for and clean an assistive aid (Box 49-7). A contact lens wearer must frequently clean lenses (see Chapter 39) and use the appropriate solutions for cleaning and disinfection. Contact lens wearers are subject to serious eye infections caused by infrequent lens disinfection, contamination of lens storage cases or contact lens solutions, and use of homemade saline. Swimming while wearing lenses also creates a serious risk of infection. Reinforce proper lens care in any health maintenance discussion.

Older adults are often reluctant to use hearing aids. Reasons cited most often include cost, appearance, insufficient knowledge about hearing aids, amplification of competing noise, and unrealistic expectations. Neuromuscular changes in the older adult such as stiff fingers, enlarged joints, and decreased sensory perception also make the handling and care of a hearing aid difficult. Fortunately today there are a wide variety of aids that not only enhance a person's hearing but also are cosmetically acceptable and useful for persons with manual dexterity issues. Chapter 39 summarizes the types of hearing aids available and tips for proper care and use.

Acknowledging a need to improve hearing is a person's first step. Give patients useful information on the benefits of hearing aid use. A person who understands the need for good hearing will likely be influenced to wear hearing aids. It is also important to have a significant other available to assist with hearing aid adjustment. Federal regulations require medical clearance from a health care provider before an individual can purchase a hearing aid. Hearing aids are contraindicated for the following conditions: visible congenital or traumatic deformity of the ear, active drainage in the last 90 days, sudden or progressive hearing loss within the last 90 days, acute or chronic dizziness, unilateral sudden hearing loss within the last 90 days, visible cerumen accumulation or a foreign body in the ear canal, pain or discomfort in the ear, or an audiometric air-bone gap of 15 decibels or greater. A nursing assessment detects the first seven of these conditions during a physical examination. Refer the patient to an otolaryngologist for further counseling (Ebersole et al., 2008).

Promoting Meaningful Stimulation. Life becomes more enriching and satisfying when meaningful and pleasant stimuli exist within the environment. You can help patients adjust to their environment in many ways so it becomes more stimulating. You do this best by considering the normal physiological changes that accompany sensory deficits.

Vision. As a result of the normal changes of aging, the pupil's ability to adjust to light diminishes; thus older adults are often very sensitive to glare. Suggest the use of yellow or amber lenses and shades or blinds on windows to minimize glare. Wearing sunglasses outside obviously reduces the glare of direct sunlight. Other interventions to enhance vision for patients with visual impairment include warm incandescent lighting and colors with sharp contrast and intensity.

The ability to read is important. Therefore allow patients to use their glasses whenever possible (e.g., during procedures and instruction). Some patients with reduced visual acuity need more than corrective lenses. A pocket magnifier helps a patient read most printed material. Telescopic lens eyeglasses are smaller, easier to focus, and have a greater range. Books and other publications are also available in larger print. If a patient has a legal or other important document that he or she wishes to read, standard copying machines have enlarging capabilities. Closed-circuit television magnifying units enlarge written characters up to 45 times (Ebersole et al., 2008).

With aging a person experiences a change in color perception. Perception of the colors blue, violet, and green usually declines. Brighter colors such as red, orange, and yellow are easier to see. Offer suggestions of ways to decorate a room and paint hallways or stairwells so the patient is able to differentiate surfaces and objects in a room.

Hearing. To maximize residual hearing function, work closely with the patient to suggest ways to modify the environment. Patients can amplify the sound of telephones and televisions. An innovative way to enrich the lives of the hearing impaired is recorded music. Some patients with severe hearing loss are able to hear music recorded in the low-frequency sound cycles.

One way to help an individual with a hearing loss is to ensure that the problem is not impacted cerumen. With aging, cerumen thickens and builds up in the ear canal. Excessive cerumen occluding the ear canal causes **conductive hearing loss.** Instilling a softening agent such as 0.5 to 1 mL of warm mineral oil into the ear canal followed by irrigation of a solution of 3% hydrogen peroxide in a quart of warmed water removes cerumen and significantly improves the patient's hearing ability (Ebersole et al., 2008).

Taste and Smell. Promote the sense of taste by using measures to enhance remaining taste perception. Good oral hygiene keeps the taste buds well hydrated. Well seasoned, differently textured food eaten separately heightens taste perception. Flavored vinegar or lemon juice adds tartness to food. Always ask the patient which foods are most appealing. Improving taste perception improves food intake and appetite as well.

Stimulation of the sense of smell with aromas such as brewed coffee, cooked garlic, and baked bread heightens taste sensation. The patient needs to avoid blending or mixing foods because these actions make it difficult to identify tastes. Older persons need to

chew food thoroughly to allow more food to contact remaining taste buds.

Improve smell by strengthening pleasant olfactory stimulation. Make a patient's environment more pleasant with smells such as cologne, mild room deodorizers, fragrant flowers, and sachets. Consult with patients to find out which scents they can tolerate. The removal of unpleasant odors (e.g., bedpans or soiled dressings) also improves the quality of a patient's environment.

Touch. Patients with reduced tactile sensation usually have the impairment over a limited portion of their bodies. Providing touch therapy stimulates existing function. If a patient is willing to be touched, hair brushing and combing, a back rub, and touching the arms or shoulders are ways of increasing tactile contact. When sensation is reduced, a firm pressure is often necessary for a patient to feel a nurse's hand. Turning and repositioning also improves the quality of tactile sensation.

If a patient is overly sensitive to tactile stimuli **(hyperesthesia),** minimize irritating stimuli. Keeping bed linens loose to minimize direct contact with a patient and protecting the skin from exposure to irritants are helpful measures. Physical therapists can recommend special wrist splints for patients to wear to dorsiflex their wrists and relieve nerve pressure when they have numbness and tingling or pain in the hands, as with carpal tunnel syndrome. For patients who use computers, special keyboards and wrist pads are available to decrease the pressure on the median nerve, aid in pain relief, and promote healing.

Establishing Safe Environments. When sensory function becomes impaired, individuals become less secure within their home and workplace. Security is necessary for a person to feel independent. Make recommendations for improving safety within a patient's living environment without restricting independence. During a home visit or while completing an examination in the clinic, offer several useful suggestions for home safety. The nature of the actual or potential sensory loss determines the safety precautions taken.

Adaptations for Visual Loss. When a patient experiences a decrease in visual acuity, peripheral vision, adaptation to the dark, or depth perception, safety is a concern. With reduced peripheral vision a patient cannot see panoramically because the outer visual field is less discrete. With reduced depth perception a person is unable to judge how far away objects are located. This is a special danger when he or she walks down stairs or over uneven surfaces.

Driving is a particular safety hazard for older adults with visual alterations. Reduced peripheral vision prevents a driver from seeing a car in an adjacent lane. A sensitivity to glare creates a problem for driving at night with headlights. Vision is a primary consideration for safety, but there are other factors as well. In the case of older adults, decreased reaction time, reduced hearing, and decreased strength in the legs and arms further compromise driving skills. Some safety tips to share with those who continue to drive include the following: drive in familiar areas, do not drive during rush hour, avoid interstate highways for local drives, drive defensively, use rear-view and side-view mirrors when changing lanes, avoid driving at dusk or night, go slow but not too slow, keep the car in good working condition, and carry a preprogrammed cellular phone.

The presence of visual alterations makes it difficult for a person to conduct normal activities of living within the home. Because of reduced depth perception, patients can trip on throw rugs, runners, or the edge of stairs. Teach patients and family members to keep all flooring in good repair and advise them to use low-pile carpeting. Thresholds between rooms need to be level with the floor. Recommend the removal of clutter to ensure clear pathways for walking and arrangement of furniture so a patient can move about easily without fear of tripping or running into objects. Suggest that stairwells have a securely fastened banister or handrail extending the full length of the stairs.

Front and back entrances to the home, work areas, and stairwells need to be properly lighted. Light fixtures need high-wattage bulbs with wider illumination. A light switch should be located at the top and bottom of stairwells. It is also important to be sure that lighting on the stairs does not cast shadows. Have a family member paint the edge of steps so the patient can clearly see each step, especially the first and last. When possible have patients replace steps inside and outside the home with ramps.

An added consideration is to administer eye medications safely (see Chapter 31). Patients need to closely adhere to regular medication schedules for conditions such as glaucoma. Labels on medication containers need to be in large print. Make sure that a friend or spouse is familiar with dosage schedules in case a patient is unable to self-administer a medication. Patients with visual impairments often have difficulty manipulating eyedroppers.

Adaptations for Reduced Hearing. Patients hear important environmental sounds (e.g., doorbells and alarm clocks) best if they are amplified or changed to a lower-pitched, buzzerlike sound. Lamps designed to turn on in response to sounds such as doorbells, burglar alarms, smoke detectors, and babies crying are also available. Family members and anyone who calls the patient regularly need to learn to let the phone ring for a longer period. Amplified receivers for telephones and telephone communications devices (TCDs) are available that use a computer and printer to transfer words over the telephone for the hearing impaired. Both sender and receiver need to have the special device to complete a call.

Adaptations for Reduced Olfaction. The patient with a reduced sensitivity to odors is often unable to smell leaking gas, a smoldering cigarette, fire, or spoiled food. Advise patients to use smoke detectors and take precautions such as checking ashtrays or placing cigarette butts in water. In addition, teach patients to check food package dates, inspect the appearance of food, and keep leftovers in labeled containers with the preparation date. Pilot gas flames need to be checked visually.

Adaptations for Reduced Tactile Sensation. When patients have reduced sensation in their extremities, they are at risk for injury from exposure to temperature extremes. Always caution these patients on the use of water bottles or heating pads (see Chapter 48). The temperature setting on the home water heater should be no higher than 48.8° C (120° F). If a patient also has a visual impairment, it is important to be sure that water faucets are clearly marked "hot" and "cold," or use color codes (i.e., red for hot and blue for cold).

Communication. A sensory deficit often causes a person to feel isolated because of an inability to communicate with others. It is important for individuals to be able to interact with people around them. The nature of the sensory loss influences the methods and styles of communication that nurses use during interactions with patients (Box 49-8). You also teach communication methods to family members and significant others. For patients with visual deficits or blindness, speak normally, not from a distance, and be sure to have sufficient lighting.

The patient with a hearing impairment is often able to speak normally. To more clearly hear what a person communicates, family and friends need to learn to move away from background noise, rephrase rather than repeat sentences, be positive, and have

BOX 49-8 COMMUNICATION METHODS

Patients with Aphasia

- Listen to the patient and wait for him or her to communicate.
- Do not shout or speak loudly (hearing loss is not the problem).
- If the patient has problems with comprehension, use simple, short questions and facial gestures to give additional clues.
- Speak of things familiar and of interest to the patient.
- If the patient has problems speaking, ask questions that require simple yes or no answers or blinking of the eyes. Offer pictures or a communication board so the patient can point.
- Give the patient time to understand; be calm and patient; do not pressure or tire him or her.
- Avoid patronizing and childish phrases.

Patients with an Artificial Airway

- Use pictures, objects, or word cards so the patient can point.
- Offer a pad and pencil or Magic Slate for the patient to write messages.
- Do not shout or speak loudly.
- Give the patient time to write messages because patients fatigue easily.
- Provide an artificial voice box (vibrator) for the patient with a laryngectomy to use to speak.

Patients with Hearing Impairment

- Get the patient's attention. Do not startle him or her when entering the room. Do not approach a patient from behind. Be sure that he or she knows that you wish to speak.
- Face the patient and stand or sit on the same level. Be sure that your face and lips are illuminated to promote lip-reading. Keep hands away from mouth.
- Be sure that patients keep eyeglasses clean so they are able to see your gestures and face.
- If the patient wears a hearing aid, make sure that it is in place and working.
- Speak slowly and articulate clearly. Older adults often take longer to process verbal messages.
- Use a normal tone of voice and inflections of speech. Do not speak with something in your mouth.
- When you are not understood, rephrase rather than repeat the conversation.
- Use visible expressions. Speak with your hands, your face, and your eyes.
- Do not shout. Loud sounds are usually higher pitched and often impede hearing by accentuating vowel sounds and concealing consonants. If you need to raise your voice, speak in lower tones.
- Talk toward the patient's best or normal ear.
- Use written information to enhance the spoken word.
- Do not restrict the hands of a patient who is deaf. Never have intravenous lines in both of the patient's hands if the preferred method of communication is sign language.
- Avoid eating, chewing, or smoking while speaking.
- Avoid speaking from another room or while walking away.

patience. In a group setting it is better to form a semicircle in front of the patient so he or she can see who is speaking next; this helps foster group involvement. On the other hand, some patients who are deaf have serious speech alterations. Some use sign language or lip reading, wear special hearing aids, write with a pad and pencil, or learn to use a computer for communication. Special communication boards that contain common terms (e.g., *pain, bathroom, dizzy*, or *walk*) help patients express their needs.

Patient education is one aspect of communication. Teaching booklets are available in large print for patients with visual loss. The patient who is blind often requires more frequent and detailed verbal descriptions of information. This is particularly true if there are no instructional booklets written in Braille. Patients with visual impairments can also learn by listening to audiotapes or the sound portion of a televised teaching session. Patients with hearing impairments often benefit from written instructional materials and visual teaching aids (e.g., posters and graphs). Demonstrations by the nurse are very useful. Hospitals are required to make professional interpreters available to read sign language for patients who are deaf.

Acute Care. When patients enter acute care settings for therapeutic management of sensory deficits or as a result of traumatic injury, use different approaches to maximize sensory function existing at the time. Safety is an obvious priority until the patient's sensory status is either stabilized or improved. For example, patients with sensory deficits have a high risk for falls in the acute care environment. It is very important to know the extent of any existing sensory impairment before the acute episode of illness so you are able to reinforce what the patient already knows about self-care or plan for more instruction before and following discharge.

Orientation to the Environment. The patient with recent sensory impairment requires a complete orientation to the immediate environment. Provide reorientation to the institutional environment by ensuring that name tags on uniforms are visible, addressing the patient by name, explaining where the patient is (especially if patients are transported to different areas for treatment), and using conversational cues to time or location. Reduce the tendency for patients to become confused by offering short and simple, repeated explanations and reassurance. Encourage family members and visitors to help orient patients to the hospital surroundings.

Patients with serious visual impairment need to feel comfortable in knowing the boundaries of the immediate environment. Normally we see physical boundaries within a room. Patients who are blind or severely visually impaired often touch the boundaries or objects to gain a sense of their surroundings. The patient needs to walk through a room and feel the walls to establish a sense of direction. Help patients by explaining objects within the hospital room, such as furniture or equipment. It takes time for a patient to absorb room arrangement. He or she often needs to reorient again as you explain the location of key items (e.g., call light, telephone, and chair). Remember to approach the patient from the front to avoid startling him or her.

It is important to keep all objects in the same position and place. After an object is moved even a short distance, it no longer exists for a person who is blind. Simply moving a chair creates a safety hazard. Ask the patient if any item needs to be rearranged to make ambulation easier. Clear traffic patterns to the bathroom. Give the patient extra time to perform tasks. He or she needs a detailed description of how to perform an activity and moves slowly to remain safe.

Patients confined to bed are at risk for sensory deprivation. Normally movement gives an awareness of self through vestibular and tactile stimulation. Movement patterns influence sensory perception. The limited movement of bed rest changes how a person interprets the environment; surroundings seem different, and objects seem to assume shapes different from normal. A person who is on bed rest requires routine stimulation through range-of-motion exercises, positioning, and participation in self-care activities (as appropriate). Comfort measures such as washing the face and hands and providing back rubs improve the quality of stimulation and lessen the chance of sensory deprivation. Planning time to talk with patients is also essential. Explain unfamiliar

environmental noises and sensations. A calm, unhurried approach gives you quality time to help reorient and familiarize the patient with care activities. The patient who is well enough to read will benefit from a variety of reading material.

Communication. The most common language disorder following a stroke is aphasia. Depending on the type of aphasia, the inability to communicate is often frustrating and frightening (see Box 49-8). Initially you need to establish very basic communication and recognize that it does not indicate intellectual impairment or degeneration of personality. Explain situations and treatments that are pertinent to the patient because he or she is able to understand the speaker's words. Because a stroke often causes partial or complete paralysis of one side of a patient's body, the patient needs special assistive devices. A variety of communication boards for different levels of disability are available. Sensitive pressure switches activated by the touch of an ear, nose, or chin control electronic communication boards (Ebersole et al., 2008). Make referrals to speech therapists to develop appropriate rehabilitation plans.

In acute care hospitals or long-term care facilities, nurses often care for patients with artificial airways (such as an endotracheal tube) (see Chapter 40). The placement of an endotracheal tube prevents a patient from speaking. In this case the nurse uses special communication methods to facilitate his or her ability to express needs. The patient is sometimes completely alert and able to hear and see the nurse normally. Giving patients time to convey any needs or requests is very important. Use creative communication techniques (e.g., a communication board or laptop computer) to foster and strengthen a patient's interactions with health care personnel, family, and friends.

Controlling Sensory Stimuli. Patients need time for rest and freedom from stress caused by frequent monitoring and repeated tests. Reduce sensory overload by organizing the patient's plan of care. Combining activities such as dressing changes, bathing, and vital sign measurement in one visit prevents him or her from becoming overly fatigued. The patient also needs scheduled time for rest and quiet. Planning for rest periods often requires cooperation from family, visitors, and health care colleagues. Coordination with laboratory and radiology departments minimizes the number of interruptions for procedures. A creative solution to decrease excessive environmental stimuli that prevents restful, healing sleep is to institute "quiet time" in ICUs. Quiet time means dimming the lights throughout the unit, closing the shades, and shutting the doors. Data collected from one hospital that implemented "quiet time" demonstrated significantly lower noise levels and light levels during day-shift quiet time. Patients were also more likely to sleep during daytime quiet hours (Dennis et al., 2010).

Building Competency in Evidence-Based Practice You are the nurse manager of a busy medical intensive care unit (ICU). The administrators of the hospital have reported that patients in the ICU are dissatisfied with noise levels impacting their rest and sleep. They have asked you to determine if implementation of quiet time will have a positive impact on sleep and patient satisfaction. Develop a PICO question (see Chapter 5) that answers the question, and identify each part of the PICO question.

Answers to questions can be found on the Evolve website.

When patients experience sensory overload or deprivation, their behavior is often difficult for family or friends to accept. Encourage the family not to argue with or contradict the patient but to calmly explain location, identity, and time of day. Engaging the patient in a normal discussion about familiar topics assists in reorientation. Anticipating patient needs such as voiding helps reduce uncomfortable stimuli.

FIG. 49-5 Nurse assists in ambulation of patient with visual impairment. (From Sorrentino SA, Remmert LN: *Mosby's textbook for nursing assistants,* ed 8, St Louis, 2012, Mosby.)

Try to control extraneous noise in and around a patient's room. It is often necessary to ask a roommate to lower the volume on a television or to move the patient to a quieter room. Keep equipment noise to a minimum. Turn off bedside equipment not in use such as suction and oxygen equipment. Avoid making abrupt loud noises such as dropping objects or causing the over-bed table to suddenly adjust to the lowest level. Nursing staff also need to control laughter or conversation at the nurses' station. Allow patients to close their room doors.

When the patient leaves an acute care setting for the home environment, communicate with colleagues in the home care setting about the patient's existing sensory deficits and the interventions that helped the patient adapt to sensory problems. You achieve continuity of care when the patient only has to make minimal changes in the home setting.

Safety Measures. The patient with recent visual impairment often requires help with walking. The presence of an eye patch, frequently instilled eyedrops, and the swelling of eyelid structures following surgery are just a few factors that cause a patient to need more assistance than usual. A sighted guide gives confidence to patients with visual impairments and ensures safe mobility. Ebersole et al. (2008) list three suggestions for a sighted guide:

1. Ask the patient if he or she wants a "sighted guide." If assistance is accepted, offer an elbow or arm. Instruct the patient to grasp your arm just above the elbow (Fig. 49-5). If necessary, physically help the person by guiding his or her hand to your arm or elbow.
2. Go one-half step ahead and slightly to the side of the person. The shoulder of the person needs to be directly behind your shoulder. If the person is frail, place the hand on your forearm.
3. Relax and walk at a comfortable pace. Warn the patient when you approach doorways or narrow spaces.

While walking with the patient, describe the surroundings and ensure that obstacles have been removed. Never leave a patient with a visual impairment standing alone in an unfamiliar area. It is important to teach family members techniques for assisting with ambulation. Nursing staff also need to ensure that the patient knows where the call light is before leaving the patient alone. Place necessary objects in front of the patient to prevent falls caused by reaching over the bedside. Appropriate use of side rails is also an option (see Chapter 38).

Nurses often rely on patients in health care settings to report unusual sounds such as a suction apparatus running improperly or an IV pump alarm. However, the patient with a hearing loss does not always hear these sounds and thus requires more frequent visits by nurses. The patient also benefits from learning to use vision to discover sources of danger. It is wise to note on the intercom system at the nurse's station and in the medical record if the patient is deaf and/or blind. A patient lacking the ability to speak cannot call out for assistance. Patients need to have message boards and call lights close at hand.

Patients with reduced tactile sensation risk injury when their conditions confine them to bed because they are unable to sense pressure on bony prominences or the need to change position. These patients rely on nurses for timely repositioning, moving tubes or devices on which the patient is lying, and turning to avoid skin breakdown. When a patient is less able to sense temperature variations, use extra caution in applying heat and cold therapies (see Chapter 48) and preparing bathwater. Check the condition of the patient's skin frequently.

Restorative and Continuing Care

Maintaining Healthy Lifestyles. After a patient has experienced a sensory loss, it becomes important to understand the implications of the loss and make adjustments needed to continue a normal lifestyle. Sensory impairments need not prevent a person from leading an active, rewarding life. Many of the interventions applicable to health promotion such as adapting the home environment are useful after a patient leaves an acute care setting.

Understanding Sensory Loss. Patients who have experienced a recent sensory loss need to understand how to adapt so their living environments are safe and appropriately stimulating. All family members need to understand the way that a patient's sensory impairment affects normal daily activities. Family and friends are more supportive when they understand sensory deficits and factors that worsen or lessen sensory problems. For example, family and friends need to learn how to communicate with someone who has a hearing loss. Community resources are available to provide information to assist patients with personal management needs. The American Foundation for the Blind, American Red Cross, and National Association for Speech and Hearing offer resource materials and product information.

Socialization. The ability to communicate is gratifying. It tests a person's intellect, opens opportunities, and allows him or her to exchange the feelings that he or she has about others. When sensory alterations hinder interactions, a person feels ineffective and loses self-esteem. When patients feel socially unaccepted, they perceive sensory losses as seriously impairing their quality of life.

Interacting with others becomes a burden for many patients with sensory alterations. They lose the motivation to engage in social situations, resulting in a deep sense of loneliness. Use therapies to reduce loneliness, particularly in older adults (Box 49-9). These principles support the *Healthy People 2020* objective to increase the proportion of adults with disabilities reporting sufficient emotional support. In addition, family members need to learn to focus on a person's ability to interact rather than on his or her disability. For example, do not assume that a person who is hard of hearing does not wish to speak. A person who is blind can still enjoy a walk through a park with a companion describing the sights around them.

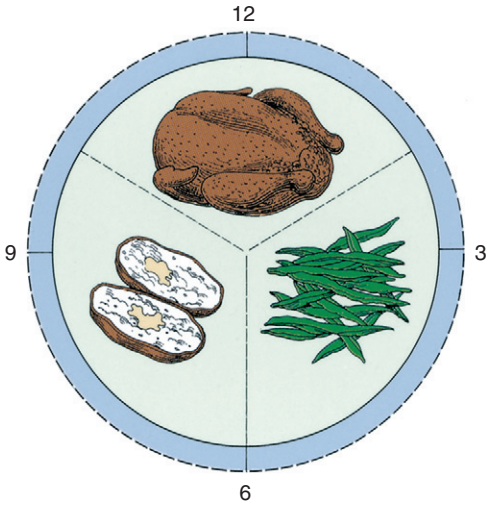

FIG. 49-6 Location of food using clock as frame of reference.

BOX 49-9 FOCUS ON OLDER ADULTS

Principles for Reducing Loneliness

- Spend time with a person in silence or conversation.
- When it is culturally appropriate, use physical contact—holding a hand, embracing a shoulder—to convey caring.
- Recommend alterations in living arrangements if physical isolation is a factor.
- Help older adults keep contact with people important to them.
- Provide information about support groups or groups that provide assistive services.
- Arrange for security escort services as needed.
- Introduce the idea of bringing a companion such as a pet into the home when appropriate
- Link a person with organizations attuned to the social needs of older adults.

Promoting Self-Care. The ability to perform self-care is essential for self-esteem. Frequently family members and nurses believe that persons with sensory impairments require assistance, when in fact they are able to help themselves. To help with meals, arrange food on the plate and condiments, salad, or drinks according to numbers on the face of a clock (Fig. 49-6). It is easy for the patient to become oriented to the items after the nurse or family member explains the location of each item.

Help patients reach toilet facilities safely. Safety bars need to be installed near the toilet. It is often helpful to have the bar a different color than the wall for easier visibility. Never place towels on a safety bar because they interfere with a person's grasp. Toilet paper needs to be within easy reach. Sharply contrasting colors within the room helps the partially sighted and promotes functional independence. General principles for promoting self-care in older adults also include using warm incandescent lighting and controlling glare by using shades and blinds (Ebersole et al., 2008).

If the sense of touch is diminished, the patient can dress more easily with zippers or Velcro strips, pullover sweaters or blouses,

and elasticized waists. If a patient has partial paralysis and reduced sensation, the patient dresses the affected side first. Encourage family members responsible for selecting clothing for patients with visual impairments to follow the patient's preferences. Any sensory impairment has a significant influence on body image, and it is important for the patient to feel well groomed and attractive. Some patients need assistance with basic grooming such as brushing, combing, and shampooing hair. Others need assistance with medication administration, clothing identification, and learning to manage routine procedures such as blood pressure and glucose monitoring. An assortment of low-vision devices is now available. It is important for you to make appropriate referrals to allow the patient to maintain a maximum degree of independence.

Patients with proprioceptive problems often lose their balance easily. Make sure that bathrooms have nonskid surfaces in the tub and shower. Install grab bars either vertically or horizontally in tubs and showers, depending on how the patient is able to grasp or hold onto the bar. Instruct family members to supervise ambulation and sitting, make frequent checks to prevent falls, and caution the patient against leaning forward.

EVALUATION

Through the Patient's Eyes. It is important to evaluate whether care measures maintain or improve a patient's ability to interact and function within the environment. The patient is the source for evaluating outcomes. He or she is the only one who knows if sensory abilities are improved and which specific interventions or therapies are most successful in facilitating a change in his or her performance (Fig. 49-7). Collaborate with family members to determine if the patient's ability to function within the home has improved.

If you have successfully developed a good relationship with a patient, notice that subtle behaviors often indicate the level of his or her satisfaction. You may notice that the patient responds appropriately, such as by smiling. However, it is important for you to ask the patient if his or her sensory needs have been met. For example, ask, "Have we done all we can do to help improve your ability to hear?" If the patient's expectations have not been met, ask the patient, "How can the health care team better meet your needs?" Working closely with the patient and family enables you to redefine expectations that can be realistically met within the limits of the patient's condition and therapies. You have been effective when the patient's goals and expectations have been met.

Patient Outcomes. To evaluate the effectiveness of specific nursing interventions, use critical thinking and make comparisons with baseline sensory assessment data to evaluate if sensory alterations have changed. It is your responsibility to determine if expected outcomes have been met. For example, use evaluative data to determine whether care measures improve or at least maintain a patient's ability to interact and function within the environment. The nature of a patient's sensory alterations influences how you evaluate the outcome of care. When caring for a patient with a hearing deficit, use proper communication techniques and then evaluate whether he or she has gained the ability to hear or interact more effectively. When expected outcomes have not been achieved, there is a need to change interventions or alter the patient's environment. If outcomes are not met, it is important to ask questions such as "How are you feeling emotionally?" "Do you feel that you are at risk for injury?"

If you have directed nursing care at improving or maintaining sensory acuity, evaluate the integrity of the sensory organs and the patient's ability to perceive stimuli. Evaluate interventions designed to relieve problems associated with sensory alterations on the basis of the patient's ability to function normally without injury. When you directly or indirectly (through education) alter a patient's environment, evaluate by observing whether the patient makes environmental changes. When designing patient teaching to improve sensory function, it is important to determine whether the patient is following recommended therapies and meeting mutually set goals. Asking the patient to explain or demonstrate self-care skills is an effective evaluative measure. It is often necessary to reinforce previous instruction if learning has not taken place. If outcomes are not met, these are examples of questions to ask:

- "How often do you wear your hearing aids/corrective lenses?"
- "Are you able to participate in a small group discussion?"
- "Are you able to read the newspaper without squinting?"

The results of your evaluation will determine whether to continue the existing plan of care, make modifications, or end the use of select interventions.

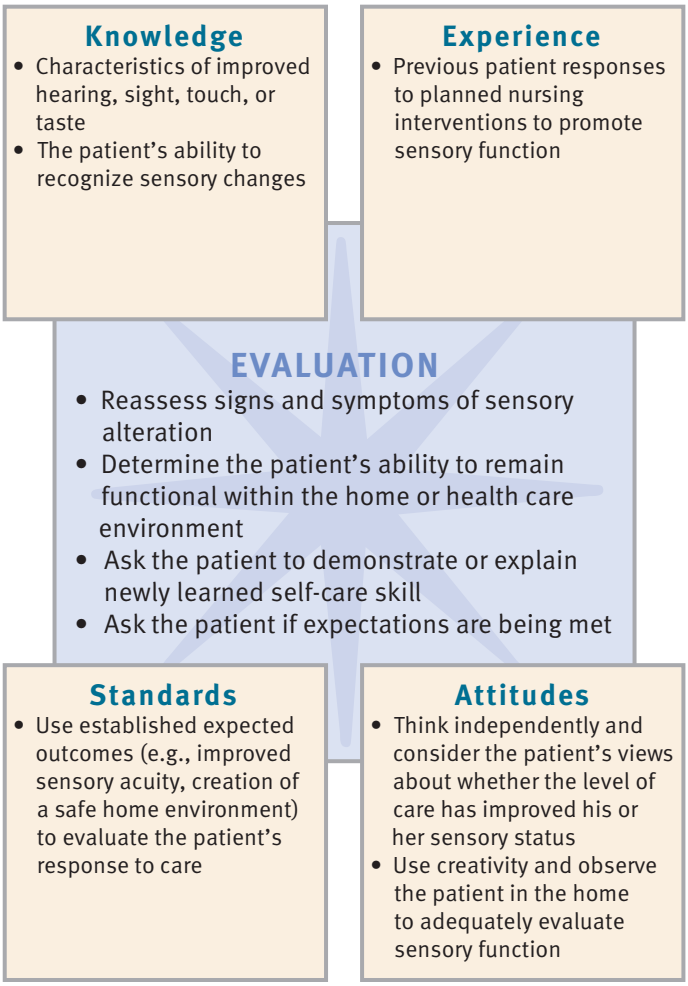

FIG. 49-7 Critical thinking model for sensory alterations evaluation.

KEY POINTS

- Sensory reception involves the stimulation of sensory nerve fibers and the transmission of impulses to higher centers within the brain.

- When sensory function is impaired, the sense of self is impaired and affects one's ability to socialize.
- Sensory deprivation results from an inadequate quality or quantity of sensory stimuli.
- Aging results in a gradual decline of acuity in all senses.
- Patients who are older, immobilized, or confined in isolated environments are at risk for sensory alterations.
- Assessment of a patient's health promotion habits reveals risks for sensory impairment.
- Patients often do not admit to a sensory loss.
- An assessment of hazards in the environment requires the nurse to tour living areas in the home and look for conditions that increase the chances of injury such as falls.
- The plan of care for patients with sensory alterations needs to include participation by family members. The extent of support from family members and significant others influences the quality of sensory experiences.
- Patients with sensory deficits often develop alternate ways of communicating that rely on other senses.
- Care of patients at risk for sensory deprivation includes introducing meaningful and pleasant stimuli for all senses.
- To prevent sensory overload, control stimuli and orient the patient to the environment.
- Patients with artificial airways are able to communicate effectively with communication boards, laptop computers, and written messages.

CRITICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

One month has passed since Ms. Long made an informed decision to have cataract surgery. After surgery she reported improved vision and ability to participate in activities of daily living. Today the community health nurse visits, and Ms. Long reports shortness of breath with activity. After the nurse consults with Ms. Long's health care provider, Ms. Long is admitted to the emergency department with a diagnosis of heart failure exacerbation.

1. Three days after being admitted to the hospital, Ms. Long reports less shortness of breath; however, she is restless and fatigued. She is on a cardiac monitor and continues to receive oxygen. The staff nurse reports that Ms. Long has slept very little since her admission. Her semiprivate room is directly across from a busy central nurses' station, and she frequently calls out for assistance. Identify the sensory alteration Ms. Long is experiencing and identify three strategies that will ensure that she gets enough sleep.
2. Ms. Long was released from the hospital in good health 1 week after admission. Following the recommendation of her health care provider, she regularly attends a heart failure support group. She has asked you to speak with the group regarding age-related visual changes and signs and symptoms that may indicate problems. What information will you share with them to promote healthy vision?
3. Ms. Long is worried about how to communicate with her sister who had a stroke and developed aphasia. What would you teach her to help her communicate more effectively with her sister?

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A patient has been on contact isolation for 4 days because of a gastrointestinal infection. He has had few visitors and few opportunities to leave his room. His ambulation is also still limited. Nursing measures to reduce sensory deprivation include: (Select all that apply.)
   1. Arranging for him to have a roommate.
   2. Turning off the lights and closing the room drapes.
   3. Arranging for peacefulness and frequent rest periods.
   4. Helping him to a chair or bringing a flower into the room.
   5. Sitting down, speaking, touching, and listening to his feelings and perceptions.
2. The home care nurse is instructing a nursing assistant about interventions to facilitate location of items for patients with vision impairment. Which strategy is not effective in enhancing a patient's impaired vision?
   1. Use of fluorescent lighting
   2. Use of warm incandescent lighting
   3. Use of colors with sharp contrast and intensity
   4. Use of yellow or amber lenses to decrease glare
3. A 72-year-old patient with bilateral hearing loss wears a hearing aid in her left ear. Which of the following approaches best facilitate communication with her?
   1. Speak directly into the patient's left ear.
   2. Approach the patient from behind and speak frequently.
   3. Face the patient when speaking; speak slower and in a normal volume.
   4. Face the patient when speaking; use a louder than normal tone of voice.
4. The nurse is caring for an older patient with glaucoma. When developing a discharge plan, which of the priority interventions enables the patient to function safely with existing deficits and continue a normal lifestyle?
   1. Encourage the patient's family to visit him or her once a month.
   2. Suggest to the patient that he or she consider moving to a long-term care facility.
   3. Say nothing because it is most appropriate that the patient identify personal interventions to compensate for a sensory alteration.
   4. Work closely with the patient to identify ways to modify his or her home environment and refer to appropriate community-based resources.
5. A 74-year-old patient who has returned to the nursing home following surgical removal of bilateral cataracts reports feeling a little uncertain about walking by herself. Which of the following approaches do you use to assist her with ambulation?
   1. Walk one-half step behind and slightly to her side.
   2. Have her grasp your arm just above the elbow and walk at a comfortable pace, warning her when you approach obstacles.
   3. Allow her to stand alone in unfamiliar areas to encourage confidence building.
   4. If she requires assistance, place your hand around her waist.
6. Because hearing impairment is one of the most common disabilities among children, a health promotion intervention is to teach parents and children to:
   1. Avoid activities in which there may be crowds.
   2. Delay childhood immunizations until hearing can be verified.

3. Prophylactically administer antibiotics to reduce the incidence of infections.
4. Take precautions when involved in activities associated with high-intensity noises.

7. The nurse is conducting discharge teaching for a patient with diminished tactile sensation. Which of the following statements by the patient would indicate that additional teaching is needed?
   1. "I am at risk for injury from temperature extremes."
   2. "I may be able to dress more easily with zippers or pullover sweaters."
   3. "A home care referral may help me achieve a maximum degree of independence."
   4. "I have right-sided partial paralysis and reduced sensation, so I should dress the left side of my body first."
8. The nurse completes an assessment of a 67-year-old female patient who comes to the clinic for the first time. During the examination the patient's temperature is 99.6° F (37.6° C), heart rate 80 beats/min, respiratory rate 18 breaths/min, and blood pressure 142/84 mm Hg. She is not attentive as the nurse asks questions. At one point, she shouts answers to questions about her diet. However, as the nurse speaks, the patient consistently smiles and nods in agreement. The nurse's assessment indicates:
   1. A visual deficit.
   2. Patient is normal.
   3. A hearing deficit.
   4. Sensory overload.
9. When communicating with a patient who has expressive aphasia, the highest priority for the nurse is:
   1. To ask open-ended questions.
   2. To understand that the patient will be uncooperative.
   3. To coach the patient to respond.
   4. To offer pictures or a communication board so the patient can point.
10. A patient with a history of a hearing deficit comes to the medical clinic for a routine checkup. His wife died 2 years ago, and he admits to feeling lonely much of the time. Interventions the nurse uses to reduce loneliness include: (Select all that apply.)
    1. Reassuring the patient that loneliness is a normal part of aging.
    2. Providing information about local social groups in the patient's neighborhood.
    3. Maintaining distance while talking to avoid overstimulating the patient.
    4. Recommending that the patient consider making living arrangements that will put him closer to family or friends.
11. A nurse is performing an assessment on a patient admitted to the emergency department with eye trauma. The nurse's priority interventions include which of the following? (Select all that apply.)
    1. Conducting a home safety assessment and identifying hazards in the patient's living environment
    2. Reinforcing eye safety at work and in activities that place the patient at risk for eye injury
    3. Placing necessary objects such as the call light and water in front of the patient to prevent falls due to reaching
    4. Orienting the patient to the environment to reduce anxiety and prevent further injury to the eye
12. Which patient is most likely to experience sensory deprivation?
    1. A 79-year-old visually impaired resident of a nursing home who enjoys taking part in different hobbies and activities
    2. A 14-year-old girl isolated in the hospital because of severe immune system suppression
    3. A hearing-impaired 66-year-old woman who lives in an assisted-living facility
    4. A 9-year-old boy who is deaf and uses sign language to communicate with his friends, family, and teachers
13. The medical record of an older adult reveals a stroke affecting the right hemisphere of the brain. Which of these assessment findings should the nurse expect to find? (Select all that apply.)
    1. Visual spatial alterations such as loss of half of a visual field
    2. Loss of sensation and motor function on the right side of the body
    3. Inattention and neglect, especially to the left side
    4. Cloudy or opaque areas in part of the lens or the entire lens
14. A nurse is performing a home care assessment on a patient with a hearing impairment. The patient reports, "I think my hearing aid is broken. I can't hear anything." Which of the following teaching strategies should not be implemented?
    1. Demonstrating hearing aid battery replacement
    2. Reviewing method to check volume on hearing aid
    3. Discussing measures for cleaning battery
    4. Turning dial to minimum setting and, in a louder-than-normal voice, asking the patient, "Is this voice clear?"
15. When assessing a 45-year-old patient's sensory status, which of the following assessment findings does the nurse consider a normal part of aging?
    1. Presbyopia and the need for glasses for reading
    2. Reduced sensitivity to odors
    3. Impaired balance and coordination
    4. Reduced taste discrimination

Answers: **1.** 4, 5; **2.** 1; **3.** 3; **4.** 4; **5.** 2; **6.** 4; **7.** 4; **8.** 3; **9.** 4; **10.** 2, 4; **11.** 3, 4; **12.** 2; **13.** 1, 3; **14.** 4; **15.** 1.

CHAPTER

50

Care of Surgical Patients

OBJECTIVES

- Explain the concept of perioperative nursing care.
- Differentiate among classifications of surgery and types of anesthesia.
- Describe the assessment data to collect for a surgical patient.
- Demonstrate postoperative exercises: diaphragmatic breathing, coughing, incentive spirometer use, turning, and leg exercises.
- Design a preoperative teaching plan.
- Prepare a patient for surgery.
- Explain the nurse's role in the operating room.
- Describe the rationale for nursing interventions designed to prevent postoperative complications.
- Explain the differences and similarities in caring for ambulatory versus inpatient surgical patients.

Perioperative nursing care is nursing care given before (preoperative), during (intraoperative), and after (postoperative) surgery. It takes place in hospitals, surgical centers attached to hospitals, freestanding surgical centers, or health care providers' offices. Perioperative nursing is a fast-paced, changing, and challenging field. It is based on the nurse's understanding of several important principles, including:

- High-quality and patient safety–focused care.
- Multidisciplinary teamwork.
- Effective therapeutic communication and collaboration with the patient, the patient's family, and the surgical team.
- Effective and efficient assessment and intervention in all phases of surgery.
- Advocacy for the patient and the patient's family.
- Understanding of cost containment.

When you work in a perioperative setting, you need to practice strict surgical asepsis, thoroughly document care, and emphasize patient safety in all phases of care. Effective teaching and discharge planning prevent or minimize complications and ensure quality outcomes. The nursing process provides a basis for perioperative nursing, with the nurse individualizing strategies throughout the perioperative period so the patient has a smooth course from admission into the health care system through convalescence. Continuity of care is stressed in the perioperative model.

Care of the patient having surgery has shifted from hospital-based to home-based convalescence, with responsibility shifting to the patient and/or family. As the length of hospital stay decreases, the educational needs of the patient undergoing a surgical procedure increase. Patients return home with complex medical/surgical conditions that require both education and follow-up. Proper patient education is essential to ensuring positive surgical outcomes.

HISTORY OF SURGICAL NURSING

The discipline of surgery progressed as a science in the twentieth century to give physicians the means to treat conditions that were difficult or impossible to manage with medicine alone. In 1956 the

Association of Operating Room Nurses (AORN) was formed to gain knowledge of surgical principles and explore methods to improve nursing care of surgical patients. The organization is now known as the **Association of periOperative Registered Nurses;** however, AORN is still its acronym. AORN is the driving force for the practice of perioperative nursing and has developed standards of nursing practice that outline the scope of responsibility of the perioperative nurse. It was the first nursing organization to develop structure, process, and outcome standards as defined by the American Nurses Association (ANA). Current standards of perioperative professional practice include a patient-centered model of care with focus on (1) clinical practice, (2) professional practice, (3) administrative practice, (4) patient outcomes, and (5) quality improvement (AORN, 2011).

Ambulatory Surgery

During the 1970s the advent of **ambulatory surgery** centers (ASCs), also referred to as *outpatient surgery, short-stay surgery,* or *same-day surgery*, changed the perioperative process. Centers providing these services are hospital-based or freestanding surgical centers. Starting in 1982 Medicare began paying for surgeries performed in ASCs, and now over half of all elective surgical procedures occur on an outpatient basis. This increase is the result of payer changes and advances in medical technology. These procedures include ophthalmic, gastroenterological, gynecological, eye-ear-nose-throat, orthopedic, cosmetic/restorative, and general (Ambulatory Surgery Center Association, 2010). Many patients are discharged the day of surgery following reversal of the anesthetic agent. One-day surgery, in which the patient is admitted the day of surgery and observed overnight (23-hour admission), also occurs.

There are benefits for the patient who has ambulatory surgery. Anesthetic drugs that metabolize rapidly with few aftereffects allow shorter operative times and faster recovery time. Ambulatory surgery also offers cost savings by eliminating the need for hospital stays, thus reducing the possibility of acquiring health care–associated infections (HAIs). For example, many abdominal procedures such as gallbladder removal **(cholecystectomy)** are now performed using **laparoscopic** procedures. Laparoscopic surgery involves the use of minimally invasive techniques with small incisions and cameras or scopes for performance of the surgery as opposed to a large incision required for an open surgery. Because of the small incision, a laparoscopic cholecystectomy involves only a few hours to a 24-hour hospital stay and a recovery period of a week. By contrast, an open cholecystectomy involves a larger abdominal incision with a hospitalization of 1 to 3 days and up to a 4-week recovery period. Advances in medical technology have made laparoscopic procedures more commonplace and less risky. Thus many surgeons use them instead of traditional surgical procedures, thereby decreasing the length of surgery, hospitalization, and associated costs.

SCIENTIFIC KNOWLEDGE BASE

Classification of Surgery

The types of surgical procedures are classified according to seriousness, urgency, and purpose (Table 50-1). Some procedures fall into more than one classification. For example, surgical removal of a disfiguring scar is minor in seriousness, elective in urgency, and reconstructive in purpose. Frequently the classes overlap. An urgent procedure is also major in seriousness. Sometimes the same operation is performed for different reasons on different patients. For example, a gastrectomy may be performed as an emergency procedure to resect a bleeding ulcer or as an urgent procedure to remove a cancerous growth. The classification indicates the level of care a patient requires. The American Society of Anesthesiologists (ASA) assigns classification based on a patient's physiological condition independent of the proposed surgical procedure (Table 50-2). Anesthesia always involves risks even in healthy patients, but certain patients are at higher risk, including those who are volume depleted or who have poor cardiac function (Rothrock, 2007). ASA physical status classes 1 and 2 and also stable class 3 are now acceptable for ambulatory surgery. Classes 4 and 5 require inpatient surgery.

NURSING KNOWLEDGE BASE

Nurses made significant contributions demonstrating the benefit of preoperative education and preparation on positive patient outcomes following surgery. Structured preoperative teaching includes the AORN (2011) standards to prevent pulmonary and circulatory complications. Educating a patient before surgery can lead to increased patient satisfaction and decreased anxiety (Rosen, 2008).

Significant evidence-based knowledge is also available for proper wound care interventions. Nursing research contributes to our knowledge of the characteristics of wound healing and the types of applications most likely to be beneficial after surgery. Chapter 48 describes in detail a variety of interventions used to treat wounds, including surgical wounds.

Within the operating room (OR) setting, nursing knowledge improves the standards for infection control and patient safety. Evidence-based practice changes within the OR improve the quality of care for surgical patients and ultimately patient outcomes.

CRITICAL THINKING

Successful critical thinking synthesizes knowledge, information gathered from patients, previous experience, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the necessary information, analyze the data, and make decisions about patient care. A patient's condition is always changing. During assessment (Fig. 50-1) consider all of the elements that build toward making appropriate nursing diagnoses.

When caring for the perioperative patient, integrate knowledge from anatomy and physiology, pathophysiology, and the surgical stress response, along with previous experiences in caring for surgical patients. Apply this knowledge using a patient-centered care approach to making clinical decisions. The use of critical thinking attitudes ensures that a plan of care is comprehensive and incorporates evidence-based principles for successful perioperative care (e.g., airway management, infection control, pain management, and discharge planning). The use of professional standards developed by the Agency for Health Care Research and Quality (AHRQ) (http://www.ahrq.gov), AORN (http://www.aorn.org), the **American Society of PeriAnesthesia Nurses (ASPAN)** (http://www.aspan.org), and the **American Society of Anesthesiologists (ASA)** (http://www.asahq.org) provides valuable guidelines for perioperative management and evaluation of process and outcomes. Always review these guidelines within the context of new emerging evidence-based practice, agency policies, and the scope of practice of the state in which you practice.

TABLE 50-1 Classification of Surgical Procedures

TYPE	DESCRIPTION	EXAMPLE
Seriousness		
Major	Involves extensive reconstruction or alteration in body parts; poses great risks to well-being	Coronary artery bypass, colon resection, removal of larynx, resection of lung lobe
Minor	Involves minimal alteration in body parts; often designed to correct deformities; involves minimal risks compared with major procedures	Cataract extraction, facial plastic surgery, tooth extraction
Urgency		
Elective	Performed on basis of patient's choice; is not essential and is not always necessary for health	Bunionectomy, facial plastic surgery, hernia repair, breast reconstruction
Urgent	Necessary for patient's health; often prevents additional problems from developing (e.g., tissue destruction or impaired organ function); not necessarily emergency	Excision of cancerous tumor, removal of gallbladder for stones, vascular repair for obstructed artery (e.g., coronary artery bypass)
Emergency	Must be done immediately to save life or preserve function of body part	Repair of perforated appendix or traumatic amputation, control of internal hemorrhaging
Purpose		
Diagnostic	Surgical exploration that allows health care providers to confirm diagnosis; often involves removal of tissue for further diagnostic testing	Exploratory laparotomy (incision into peritoneal cavity to inspect abdominal organs), breast mass biopsy
Ablative	Excision or removal of diseased body part	Amputation, removal of appendix, cholecystectomy
Palliative	Relieves or reduces intensity of disease symptoms; does not produce cure	Colostomy, debridement of necrotic tissue, resection of nerve roots
Reconstructive/ restorative	Restores function or appearance to traumatized or malfunctioning tissues	Internal fixation of fractures, scar revision
Procurement for transplant	Removal of organs and/or tissues from a person pronounced brain dead for transplantation into another person	Kidney, heart, or liver transplant
Constructive	Restores function lost or reduced as result of congenital anomalies	Repair of cleft palate, closure of atrial septal defect in heart
Cosmetic	Performed to improve personal appearance	Blepharoplasty for eyelid deformities; rhinoplasty to reshape nose

TABLE 50-2 Physical Status (PS) Classification of the American Society of Anesthesiologists

CLASS	DESCRIPTION	CHARACTERISTICS
P1	A normal healthy patient	No physiological, biological, organic disturbance
P2	A patient with mild systemic disease	Cardiovascular (CV) disease with minimal restriction on activity
P3	A patient with severe systemic disease	Hypertension (HTN), obesity, diabetes mellitus (DM)
P4	A patient with severe systemic disease that is a constant threat to life	CV or pulmonary disease that limits activity, severe diabetes with systemic complications, history of myocardial infarction (MI), angina pectoris, or poorly controlled HTN
P5	A **moribund** patient who is not expected to survive without the operation	Severe cardiac, pulmonary, renal, hepatic, or endocrine dysfunction
P6	A patient declared brain dead whose organs are being removed for donor purpose	Patients may have a wide variety of dysfunctions that are being managed to optimize blood flow to the heart and organs (e.g., aggressive fluid replacement and blood pressure medications)

Modified from Physical Status (PS) Classification. Reprinted with permission of the American Society of Anesthesiologists, 520 N. Northwest Highway, Park Ridge, Illinois, 60068-2573, http://www.asahq.org/clinical/physicalstatus.htm, 2010.

PREOPERATIVE SURGICAL PHASE

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

Patients having surgery enter the health care setting in different stages of health. A patient may enter the hospital or ambulatory surgical center on a predetermined day feeling relatively healthy and prepared to face elective surgery. In contrast, a person in a motor vehicle crash may face emergency surgery with no time to prepare. The ability to establish rapport and maintain a professional relationship with the patient is an essential component of

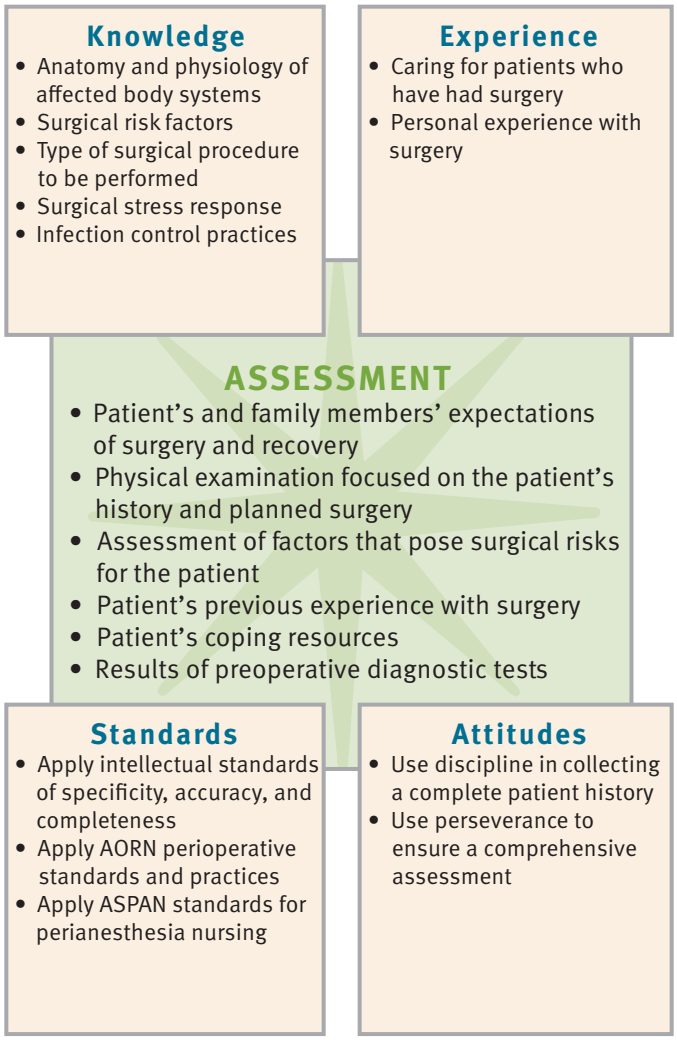

FIG. 50-1 Critical thinking model for surgical patient assessment. *AORN,* Association of periOperative Registered Nurses; *ASPAN,* American Society of PeriAnesthesia Nurses.

the preoperative phase. You must do this quickly, with compassion and effectiveness.

The patient meets many health care personnel, including surgeons, nurse anesthetists, anesthesiologists, surgical technologists, and nurses. All play a role in the patient's care and recovery. Family members attempt to provide support through their presence but face many of the same stressors as the patient. You need to effectively communicate with the patient and family because the nurse-patient relationship is the foundation of care (see Chapter 24). Assess the patient's physical, emotional, and spiritual well-being and cultural heritage; recognize the degree of surgical risk; coordinate diagnostic tests; identify nursing diagnoses and nursing interventions; and establish outcomes in collaboration with the patient and the patient's family. Communicate pertinent data and the plan of care to the surgical team members.

ASSESSMENT

A thorough patient assessment and critical analysis of findings ensure that you make patient-centered clinical decisions required for safe nursing care. The aim of the preoperative assessment is to identify the patient's normal preoperative function to recognize, prevent, and minimize possible postoperative complications. Ambulatory and same-day surgical programs offer challenges in gathering a complete assessment in a short time. A multidisciplinary team approach is essential. Patients are admitted only hours before surgery; thus it is important for you to organize and verify data obtained before surgery and implement a perioperative plan of care. This occurs both in ASCs and with patients who require a hospital stay.

Most assessments begin before admission for surgery—in the health care provider's office, preadmission clinic, or anesthesia clinic or by telephone. Some patients answer a self-report inventory. Other times a health care provider performs a physical examination or orders laboratory tests. Before surgery nurses begin teaching, answer questions, and begin paperwork. This streamlines the care required by the patient on the day of surgery.

So as not to waste time duplicating information from the preoperative examination, focus on key measurements for all body systems to ensure that no one overlooked any obvious problems. Also make sure that the patient understands any previous education. Even though the surgeon screens the patient before scheduling surgery, preoperative assessment occasionally reveals an abnormality that delays or cancels surgery. For example, consider an infection in a patient with a cough and low-grade fever on admission and notify the surgeon immediately.

Through the Patient's Eyes. Individualize each plan of care to be patient centered, including the patient's expectations of surgery and the road to recovery. Does the patient expect full pain relief or simply to have his or her pain reduced? Does the patient expect to be independent immediately after surgery, or does he or she expect to be fully dependent on the nurse or family? These are only a few of the questions that you need to ask to establish a plan of care that matches the patient's needs and expectations. It is important to consider the patient's values as they relate to the nature of surgery. Also be sure to incorporate any of his or her previous experiences with surgery (e.g., pain, ability to advance through postoperative exercises, experience with diet) so your current assessment is accurate and relevant. Findings often reveal patient preferences to postoperative care allowing for a more individualized care approach.

Nursing History. Conduct an initial interview to collect a patient history similar to that described in Chapter 30. If a patient is unable to relate all of the necessary information, rely on family members as resources.

Medical History. A review of the patient's medical history includes past illnesses and surgeries and the primary reason for seeking medical care. The patient's current medical record and medical records from past hospitalizations are excellent sources of data. Preexisting illnesses influence patients' abilities to tolerate surgery and nurses' choices of therapies to help them reach full recovery (Table 50-3). The history of previous surgery influences the level of physical care required after an upcoming surgical procedure. Screen patients scheduled for ambulatory surgery for medical conditions that increase the risk for complications during or after surgery. For example, a patient who has a history of heart failure may experience a further decline in cardiac function during and after surgery. The patient with heart failure in the preoperative period may require beta-blocker medications, intravenous (IV) fluids infused at a slower rate, or administration of a diuretic after blood transfusions. Box 50-1 highlights an example of a focused assessment for a patient with a cardiac history.

Risk Factors. Various conditions and factors increase a person's risk in surgery. Knowledge of risk factors enables you to take necessary precautions in planning care.

Age. Very young and older adults are at risk for complications because of immature or declining physiological status. Mortality rates are higher in very young and very old surgical patients. During surgery nurses and health care providers are especially concerned with maintaining an infant's normal body temperature. The infant has an underdeveloped shivering reflex, and often wide temperature variations occur. Anesthesia adds to the risk because anesthetics often cause vasodilation and heat loss.

During surgery an infant has difficulty maintaining a normal circulatory blood volume. He or she has considerably less total blood volume than an older child or adult. Even a small amount of blood loss is serious. A reduced circulatory volume makes it difficult for the infant to respond to increased oxygen demands during surgery. In addition, the infant is highly susceptible to complications associated with dehydration. However, if blood or fluids are replaced too quickly, overhydration may occur. Other unique

TABLE 50-3 Medical Conditions That Increase Risks of Surgery

TYPE OF CONDITION	REASON FOR RISK
Bleeding disorders (thrombocytopenia, hemophilia)	Increase risk of hemorrhage during and after surgery.
Diabetes mellitus	Increases susceptibility to infection and impairs wound healing from altered glucose metabolism and associated circulatory impairment. Stress of surgery often results in hyperglycemia (Lewis et al., 2011).
Heart disease (recent myocardial infarction, dysrhythmias, heart failure) and peripheral vascular disease	Stress of surgery causes increased demands on myocardium to maintain cardiac output. General anesthetic agents depress cardiac function.
Obstructive sleep apnea	Administration of opioids increases risk of airway obstruction after surgery. Patients desaturate as revealed by drop in oxygen saturation by pulse oximetry.
Upper respiratory infection	Increases risk of respiratory complications during anesthesia (e.g., pneumonia and spasm of laryngeal muscles).
Liver disease	Alters metabolism and elimination of drugs administered during surgery and impairs wound healing and clotting time because of alterations in protein metabolism.
Fever	Predisposes patient to fluid and electrolyte imbalances and may indicate underlying infection.
Chronic respiratory disease (emphysema, bronchitis, asthma)	Reduces patient's means to compensate for acid-base alterations (see Chapter 41). Anesthetic agents reduce respiratory function, increasing risk for severe hypoventilation.
Immunological disorders (leukemia, acquired immunodeficiency syndrome [AIDS], bone marrow depression, and use of chemotherapeutic drugs or immunosuppressive agents)	Increases risk of infection and delayed wound healing after surgery.
Abuse of street drugs	People abusing drugs sometimes have underlying disease (human immunodeficiency virus [HIV], hepatitis) that affects healing.
Chronic pain	Regular use of pain medications often results in higher tolerance. Increased doses of analgesics are sometimes necessary to achieve postoperative pain control.

BOX 50-1 NURSING ASSESSMENT QUESTIONS: CARDIAC HISTORY

Nature of the Problem
- Do you have a history of heart attack, heart failure, angina (chest pain), irregular heartbeat, or valve disease?
- Which medications are you taking?
- Are you taking any vitamins or other supplements?
- Have you had any recent medical testing or procedures on your heart (e.g., cardiac catheterization or echocardiogram)?

Signs and Symptoms
- Are you having any chest pain?
- How do you sleep at night (position, use of pillows, awakened with chest pain)?
- Do your feet swell?
- Are you short of breath or having any difficulty breathing?

Onset and Duration
- How often do you have chest pain, when does it start, how long does it last, what alleviates it?
- When do your feet swell (all the time, end of the day, only after a busy day)?
- When do you become short of breath?

Severity
- On a scale of 0 to 10 (with 0 being no pain and 10 the worst pain), what number do you give your chest pain?
- Describe your usual activity level. Can you climb stairs; can you do housework?
- Do you exercise regularly? What exercise?

Self-Management and Culture
- Have you changed your activity level, sleep amount, diet, or fluid intake recently?
- Are you taking any herbal or over-the-counter medications?

Through the Patient's Eyes
- How are you feeling about your upcoming surgery? Has it affected your symptoms?
- Are you having any additional stress currently?

aspects of a child's surgical care include airway management, management of temperature alterations, and treatment of emergence delirium or delayed emergence from anesthesia.

With advancing age patients have less physical capacity to adapt to the stress of surgery because of deterioration in certain body functions. Perioperative registered nurses (RNs) should recognize the physiological, cognitive/psychological, and sociological changes associated with aging and understand that age alone puts older adults at risk for surgical complications (AORN, 2010). Despite the risk, the majority of patients undergoing surgery are older adults. Table 50-4 summarizes physiological factors that place older patients at risk during surgery.

Nutrition. Before surgery assess if the patient is on a therapeutic diet and if there are any factors influencing food intake such as ability to chew and swallow and the presence of regurgitation after meals. This affects your choice of postoperative foods and liquids. In addition, normal tissue repair and resistance to infection depend on adequate nutrients. Surgery intensifies this need. After surgery a patient requires at least 1500 kcal/day to maintain energy reserves. Increased protein, vitamins A and C, and zinc facilitate wound healing (see Chapters 44 and 48). A patient who is malnourished is prone to poor tolerance to anesthesia, negative nitrogen balance from lack of protein, delayed blood-clotting mechanisms, infection, and poor wound healing. Assess the patient's weight and height to determine body mass index. Many hospitalized patients display some degree of malnutrition. If a patient has elective surgery, attempt to correct nutritional imbalances before surgery. However, if a patient who is malnourished must undergo an emergency procedure, efforts to restore nutrients occur after surgery.

Obesity. Obesity increases surgical risk by reducing ventilatory and cardiac function. Obstructive sleep apnea, hypertension, coronary artery disease, diabetes mellitus, and heart failure are

TABLE 50-4 Physiological Factors That Place the Older Adult at Risk During Surgery

ALTERATIONS	RISKS	NURSING IMPLICATIONS
Cardiovascular System		
Degenerative change in myocardium and valves	Decreased cardiac reserve puts older adults at risk for decreased cardiac output, especially during times of stress (AORN, 2010)	Assess baseline vital signs for tachycardia, fatigue, and arrhythmias (AORN, 2010).
Rigidity of arterial walls and reduction in sympathetic and parasympathetic innervation to the heart	Alterations predispose patient to postoperative hemorrhage and rise in systolic and diastolic blood pressure	Maintain adequate fluid balance to minimize stress to the heart. Ensure that blood pressure level is adequate to meet circulatory demands.
Increase in calcium and cholesterol deposits within small arteries; thickened arterial walls	Predispose patient to clot formation in lower extremities	Instruct patient in techniques of leg exercises and proper turning. Apply elastic stockings or intermittent pneumatic compression (IPC) devices. Administer anticoagulants as ordered by health care provider. Provide education regarding effects, side effects, and dietary considerations.
Integumentary System		
Decreased subcutaneous tissue and increased fragility of skin	Prone to pressure ulcers and skin tears	Assess skin every 4 hours; pad all bony prominences during surgery. Turn or reposition at least every 2 hours.
Pulmonary System		
Decreased respiratory muscle strength and cough reflex (AORN, 2010)	Increased risk for atelectasis	Instruct patient in proper technique for coughing, deep breathing, and use of spirometer. Ensure adequate pain control to allow for participation in exercises.
Reduced range of movement in diaphragm	Residual capacity (volume of air is left in lung after normal breath) increased, reducing amount of new air brought into lungs with each inspiration	When possible, have patient ambulate and sit in chair frequently.
Stiffened lung tissue and enlarged air spaces	Blood oxygenation reduced	Obtain baseline oxygen saturation; measure throughout perioperative period.
Gastrointestinal System		
Gastric emptying delayed	Increases the risk for reflux and indigestion (AORN, 2010)	Position patient with head of bed elevated at least 45 degrees. Reduce size of meals in accordance with ordered diet.
Renal System		
Decreased renal function, with reduced blood flow to kidneys	Increased risk of shock when blood loss occurs; increased risk for fluid and electrolyte imbalance (AORN, 2010)	For patients hospitalized before surgery, determine baseline urinary output for 24 hours.
Reduced glomerular filtration rate and excretory times	Limits ability to eliminate drugs or toxic substances	Assess for adverse response to drugs.
Decreased bladder capacity	Increases the risk for urgency, incontinence, and urinary tract infections (AORN, 2010) (Sensation of need to void often does not occur until bladder is filled)	Instruct patient to notify nurse immediately when sensation of bladder fullness develops. Keep call light and bedpan within easy reach. Toilet every 2 hours or more frequently if indicated.

Continued

TABLE 50-4 **Physiological Factors That Place the Older Adult at Risk During Surgery—cont'd**

ALTERATIONS	RISKS	NURSING IMPLICATIONS
Neurological System		
Sensory losses, including reduced tactile sense and increased pain tolerance	Decreased ability to respond to early warning signs of surgical complications	Inspect bony prominences for signs of pressure that patient is unable to sense. Orient patient to surrounding environment. Observe for nonverbal signs of pain.
Blunted febrile response during infection (AORN, 2010)	Increased risk of undiagnosed infection	Ensure careful, close monitoring of patient temperature; provide warm blankets; monitor heart function; warm intravenous fluids (AORN, 2010).
Decreased reaction time	Confusion and delirium after anesthesia; increased risk for falls	Allow adequate time to respond, process information, and perform tasks. Perform fall risk screening and institute fall precautions. Screen for delirium with validated tools. Orient frequently to reality and surroundings.
Metabolic System		
Lower basal metabolic rate	Reduced total oxygen consumption	Ensure adequate nutritional intake when diet is resumed but avoid intake of excess calories.
Reduced number of red blood cells and hemoglobin levels	Reduced ability to carry adequate oxygen to tissues	Administer necessary blood products. Monitor blood test results and oxygen saturation.
Change in total amounts of body potassium and water volume	Greater risk for fluid or electrolyte imbalance	Monitor electrolyte levels and supplement as necessary. Provide cardiac monitoring (telemetry) as needed.

common in the **bariatric** (obese) population. Embolus, **atelectasis,** and pneumonia are common postoperative complications in the patient who is obese. He or she often has difficulty resuming normal physical activity after surgery and is susceptible to poor wound healing and wound infection because of the structure of fatty tissue, which contains a poor blood supply. This slows delivery of essential nutrients, antibodies, and enzymes needed for wound healing (see Chapter 48). It is often difficult to close the surgical wound of a patient who is obese because of the thick adipose layer; thus he or she is at risk for dehiscence (opening of the suture line) and evisceration (abdominal contents protruding through surgical incision).

Obstructive Sleep Apnea. **Obstructive sleep apnea (OSA)** is a syndrome of periodic, partial, or complete obstruction of the upper airway during sleep. Patients with diagnosed OSA have an increased incidence of postoperative complications, the most frequent being oxygen desaturation (Liao et al., 2009). Assess for a history of diagnosed OSA and use of continuous positive airway pressure (CPAP), noninvasive positive-pressure ventilation (NIPPV), or apnea monitoring. Instruct patients who use CPAP or NIPPV to bring their machine to the hospital or surgery center. Many patients with OSA are undiagnosed; thus it is becoming standard practice to assess for risk of OSA before surgery. It is necessary to ask the patient and sleep partner about symptoms of OSA such as snoring, apnea during sleep, frequent arousals during sleep, morning headaches, daytime somnolence, and chronic fatigue (ASA, 2006; Seet and Chung, 2010).

Immunocompromise. Patients with conditions that alter immune function are more at risk for developing infection after surgery. Examples include patients with cancer, bone marrow alterations, and those who undergo radiation therapy. Radiation is sometimes given before surgery to reduce the size of a cancerous tumor so it can be removed surgically. It has some unavoidable effects on normal tissue such as excess thinning of skin layers, destruction of collagen, and impaired vascularization of tissue. Ideally the surgeon waits to perform surgery 4 to 6 weeks after completion of radiation treatments. Otherwise the patient may face serious wound-healing problems. In addition, the use of chemotherapeutic drugs for cancer treatment, immunosuppressive medications for preventing rejection after organ transplantation, and steroids for treating a variety of inflammatory or autoimmune conditions increases the risk for infection.

Fluid and Electrolyte Imbalance. The body responds to surgery as a form of trauma. Severe protein breakdown causes a negative nitrogen balance (see Chapter 44) and hyperglycemia. Both of these effects decrease tissue healing and increase the risk of infection. As a result of the adrenocortical stress response, the body retains sodium and water and loses potassium within the first 2 to 5 days after surgery. The severity of the stress response influences the degree of fluid and electrolyte imbalance. Extensive surgery results in a greater stress response. A patient who is hypovolemic or who has serious preoperative electrolyte alterations is at significant risk during and after surgery. For example, an excess or depletion of potassium increases the chance of dysrhythmias during or after surgery. If the patient has preexisting diabetes mellitus or renal, gastrointestinal (GI), or cardiovascular abnormalities, the risk of fluid and electrolyte alterations is even greater.

Pregnancy. The perioperative plan of care addresses not one, but two patients: the mother and the developing fetus. The pregnant patient has surgery only on an emergent or urgent basis. Because all of the mother's major systems are affected during pregnancy, the risk for intraoperative complications is increased. General anesthesia is administered with caution because of the increased risk of fetal death and preterm labor. Psychological assessment of mother and family is essential.

Perceptions and Knowledge Regarding Surgery. A patient's past experience with surgery influences physical and psychological responses to a procedure. Assess the patient's previous experiences with surgery as a foundation for anticipating his or her needs, providing teaching, addressing fears, and clarifying

concerns. Ask the patient to discuss the previous type of surgery, level of discomfort, extent of disability, and overall level of care required. Address any complications that the patient experienced. It is also important to assess patients for motion sickness and nausea and vomiting during previous surgeries since these factors increase the risk for aspiration (McCaffrey, 2007). Prior anesthesia records are a useful source of information if previous problems occurred.

The surgical experience affects the family unit as a whole. Therefore prepare both the patient and the family for the surgical experience. Understanding of a patient's and family's knowledge, expectations, and perceptions allows you to plan teaching and provide individualized emotional support measures.

Each patient fears surgery. Some fears are the result of past hospital experiences, warnings from friends and family, or lack of knowledge. Assess the patient's understanding of the planned surgery, its implications, and planned postoperative activities. Ask questions such as "Tell me what you think will happen before and after surgery" or "Explain what you know about surgery." Nurses face ethical dilemmas when patients are misinformed or unaware of the reason for surgery. Confer with the surgeon if the patient has an inaccurate perception or knowledge of the surgical procedure before the patient is sent to the surgical suite. Also determine whether the health care provider explained routine preoperative and postoperative procedures and assess the patient's readiness and willingness to learn. When a patient is well prepared and knows what to expect, reinforce his or her knowledge.

Medication History. Presence of preexisting co-morbid conditions such as hypertension, renal or heart disease, respiratory disorders, and diabetes increases a patient's surgical risk. If a patient regularly uses prescription or over-the-counter medications, the surgeon or anesthesia provider may temporarily discontinue the drugs before surgery or adjust the dosages. Certain medications pose greater risks for surgical complications (Table 50-5). Instruct patients to ask the health care provider if they need to take usual medications the morning of surgery. Also ask them if they take any herbal preparations because many patients do not view herbs as medications and often omit them from their medication history (see Chapter 32). Certain herbs interfere with the action of other medications (consult the pharmacist). For hospitalized patients prescription drugs taken before surgery are automatically discontinued after surgery unless the health care provider reorders them. The use of a medication reconciliation process (see Chapter 31) is common practice to ensure that at the time of a patient's admission a complete list of the medications the patient is taking at home is created and documented. The patient and, as needed, the family needs to be involved to be sure that there is an accurate and current medication list for the patient (TJC, 2011).

Allergies. Assess for patients' allergies to drugs during the perioperative period. Also assess for latex, food, and contact allergies (e.g., to tape, ointments, or solutions). A wide variety of equipment and materials used in the OR contains latex; thus assessment is critical. Patients most at risk for a latex allergy include people with genetic predisposition to latex allergy, children with spina bifida, patients with urogenital abnormalities or spinal cord injury (because of a long history of urinary catheter use), patients with a history of multiple surgeries, health care professionals, and workers who manufacture rubber products. Patients with an allergy to certain foods such as bananas, chestnuts, kiwi fruit, avocadoes, and tomatoes have shown a cross-sensitivity to latex (Sussman and Gold, 2010). Surgical centers provide latex-free environments for patients with known latex allergies.

TABLE 50-5 Drugs with Special Implications for the Surgical Patient

DRUG CLASS	EFFECTS DURING SURGERY
Antibiotics	Potentiate (enhance action of) anesthetic agents. If taken within 2 weeks before surgery, aminoglycosides (gentamicin, neomycin, tobramycin) may cause mild respiratory depression from depressed neuromuscular transmission.
Antidysrhythmics	Medications (e.g., beta blockers) can reduce cardiac contractility and impair cardiac conduction during anesthesia.
Anticoagulants	Medications such as warfarin (Coumadin) or aspirin alter normal clotting factors and thus increase risk of hemorrhaging. Discontinue at least 48 hours before surgery.
Anticonvulsants	Long-term use of certain anticonvulsants (e.g., phenytoin [Dilantin] and phenobarbital) alters metabolism of anesthetic agents.
Antihypertensives	Medications such as beta blockers and calcium channel blockers interact with anesthetic agents to cause bradycardia, hypotension, and impaired circulation. They inhibit synthesis and storage of norepinephrine in sympathetic nerve endings.
Corticosteroids	With prolonged use corticosteroids such as prednisone cause adrenal atrophy, which reduces the ability of the body to withstand stress. Before and during surgery, dosages are often temporarily increased.
Insulin	Patients' need for insulin changes after surgery. Stress response and intravenous (IV) administration of glucose solutions often increase dosage requirements after surgery. Decreased nutritional intake often decreases dosage requirements.
Diuretics	Diuretics such as furosemide (Lasix) potentiate electrolyte imbalances (particularly potassium) after surgery.
Nonsteroidal anti-inflammatory drugs (NSAIDs)	NSAIDs (e.g., ibuprofen) inhibit platelet aggregation and prolong bleeding time, increasing susceptibility to postoperative bleeding.
Herbal therapies: ginger, gingko, ginseng	These herbal therapies have the ability to affect platelet activity and increase susceptibility to postoperative bleeding. Ginseng is reported to increase hypoglycemia with insulin therapy.

Some patients are too young or have not had any exposure to drugs; thus they do not know if they have allergies. The type of allergic response is very important to assess. Allergies are not the same as unpleasant side effects. For example, codeine may cause nausea (a side effect) or hypotension and confusion (an allergy). When asking a patient about allergies, realize that the term *allergy* is confusing for some patients. Asking a patient if he or she has ever "had a problem with a medication or substance" is a helpful approach to questioning. Ensure that you list the patient's allergies appropriately in his or her chart and/or the hospital computer system and any other places designated by institutional policy such as an allergy band.

Smoking Habits. The patient who smokes is at greater risk for postoperative pulmonary complications than a patient who does not (Smetana, 2009). The chronic smoker already has an increased amount and thickness of mucus secretions in the lungs. General anesthetics increase airway irritation and stimulate pulmonary secretions, which the airways retain as a result of reduction in ciliary activity during anesthesia. After surgery the patient who smokes has greater difficulty clearing the airways of mucus secretions and needs to know the importance of postoperative deep breathing and coughing (see Chapter 40).

Alcohol Ingestion and Substance Use and Abuse. Habitual use of alcohol and illegal drugs predisposes the patient to adverse reactions to anesthetic agents. Some patients experience a cross-tolerance to anesthetic agents, necessitating higher-than-normal doses. In addition, the health care provider may need to increase postoperative dosages of analgesics. Patients with a history of excessive alcohol ingestion are often malnourished, which delays wound healing. These patients are also at risk for liver disease, portal hypertension, and esophageal varices (predisposing the patient to bleeding disorders). The patient who habitually uses alcohol and is required to remain in the hospital longer than 24 hours is also at risk for acute alcohol withdrawal and its more severe form, delirium tremens (DTs).

Support Sources. Because a patient's family does not always consist of blood relations, always assess who comprises family and their level of support. The patient usually cannot immediately assume the same level of physical activity enjoyed before surgery. With ambulatory surgery patients and families assume responsibility for postoperative care. The family is an important resource for the patient with physical limitations and provides the emotional support needed to motivate him or her to return to a previous state of health. Sometimes a family member remembers preoperative and postoperative teaching better than the patient. With older adults having ambulatory surgery, it is important to establish before surgery that the patient will receive a postdischarge phone call as a check on recovery progress. Because some older adults are unable to hear or reach a phone after surgery, identify if a family member will be staying with the patient to answer the phone. Another option is an arrangement for the family member to call the surgery center the next day to ensure proper follow-up (Mamaril, 2006).

Ask if family members or friends are able to provide support. Some patients want someone else present when you provide instructions or explanations. Encourage family presence when feasible, especially for patients in the ambulatory setting. Often a family member becomes the patient's coach, offering valuable support during the postoperative period when the patient's participation in care is vital.

Occupation. Surgery often results in physical changes and limits that prevent a person from returning to work or lengthen recovery time before work can be resumed. Assess the patient's occupational history to anticipate the possible effects of surgery on recovery, return to work, and eventual work performance. Explain any restrictions such as lifting, use of the extremities, or climbing stairs before a patient returns to work. When a patient is unable to return to a job, refer him or her to a social worker and/or occupational therapist for job-training programs or to help him or her seek economic assistance.

Preoperative Pain Assessment. Surgical manipulation of tissues, treatments, and positioning on the OR table contribute to postoperative pain. Before surgery conduct a comprehensive pain assessment, including the patient's and family's expectations for pain management following surgery. Ask patients to describe their perceived tolerance to pain, past experiences, and prior successful interventions used. Teaching patients how to score their pain before surgery allows for more effective self-report of pain after surgery (Bond et al., 2005). Use a pain instrument to rate the presence and severity of pain before surgery (see Chapter 43). Frequent pain assessments are necessary to alert nurses to treat the pain and assess the adequacy (outcome) of pain interventions.

Review of Emotional Health. Surgery is psychologically stressful. Patients are often anxious about the surgery and its implications and believe that they are powerless over their situation. Family members may perceive the patient's surgery as a disruption of their lifestyle. Hospitalization and the recovery period at home are sometimes lengthy. The family is usually concerned about the patient returning to a normal, productive life. When the patient has chronic illness, the family is either fearful that surgery will result in further disability or hopeful that it will improve their lifestyle. To understand the impact of surgery on a patient's and family's emotional health, assess the patient's feelings about surgery, self-concept, body image, and coping resources.

It is difficult to assess a patient's feelings thoroughly when ambulatory surgery is scheduled because you have less time to establish a relationship with him or her. You can address these concerns initially with the patient during a home visit or on the telephone before surgery. In a hospital room choose a time for discussion after completing admitting procedures or diagnostic tests. Explain that it is normal to have fears and concerns. For example, patients often have a fear of being "put to sleep" under anesthesia because it causes loss of control. A patient's ability to share feelings partially depends on your willingness to listen, be supportive, and clarify misconceptions. Assure patients of their right to ask questions and seek information.

Self-Concept. Patients with a positive self-concept are more likely to approach surgical experiences appropriately. Assess self-concept by asking patients to identify personal strengths and weaknesses (see Chapter 33). Patients who are quick to criticize or scorn their own personal characteristics may have little self-regard or may be testing your opinion of their character. Poor self-concept hinders the ability to adapt to the stress of surgery and aggravates feelings of guilt or inadequacy.

Body Image. Surgical removal of any diseased body part often leaves permanent disfigurement, alteration in body function, or concern over mutilation. Loss of certain body functions (e.g., with a colostomy or amputation) may compound a patient's fears. Assess for body image alterations that patients perceive will result from surgery. Individuals respond differently, depending on their culture, age, experience in seeing others with alterations, and their own self-concept and self-esteem (see Chapter 33).

Often surgery changes the physical or psychological aspects of patients' sexuality. Excision of breast tissue, an ostomy, hysterectomy, or removal of the prostate gland affects patients' perceptions of their sexuality. Surgery such as hernia repair or cataract extraction forces patients to temporarily refrain from sexual intercourse until they return to normal physical activity. Encourage patients to express concerns about their sexuality. The patient facing even temporary sexual dysfunction requires understanding and support. Hold discussions about the patient's sexuality with his or her sexual partner so the partner gains a shared understanding of how to cope with limitations in sexual function (see Chapter 34).

Coping Resources. Assessment of feelings and self-concept reveals whether the patient is able to cope with the stress of surgery. The physiological effects of stress are well documented. Activation

of the endocrine system results in the release of hormones and catecholamines, which increases blood pressure, heart rate, and respiration. Platelet aggregation also occurs, along with many other physiological responses. Be aware of these responses and assist with stress management (see Chapter 37).

Ask the patient about past stress management techniques and behaviors that helped resolve any tension or nervousness. When reviewing the patient's coping resources, ask him or her about specific family members and friends who may provide support. Once identified, include these individuals in any patient teaching and interventions to manage stress and anxiety.

Culture and Religion. Culture is a system of beliefs and values developed over time and passed on through many generations. Patients come from diverse cultural, ethnic, and religious backgrounds, which affect the way each patient perceives and reacts to the surgical experience. An important aspect of patient-centered care is to identify a family's and patient's expectations for relief of pain, discomfort, and suffering (Cronenwett et al., 2007). If you do not acknowledge and plan for cultural, ethnic, and religious differences in the perioperative plan of care, you may not achieve desired surgical outcomes (Box 50-2). The acquisition of knowledge about a patient's cultural and ethnic heritage helps you care for the perioperative patient. Although it is important to recognize and plan for differences based on culture, it is also necessary to recognize that members of the same culture are individuals and do not always hold these shared beliefs.

Physical Examination. Conduct a partial or complete physical examination, depending on the amount of time available and the patient's preoperative condition. Chapter 30 describes physical assessment techniques. Assessment focuses on findings from the patient's medical history and on body systems that the surgery is likely to affect. The nursing assessment complements the surgeon's and anesthesia provider's physical examination (Bray, 2006).

General Survey. Observe the patient's general appearance. Gestures and body movements may reflect weakness caused by illness. Assess the patient for a malnourished appearance. Height, body weight, and history of recent weight loss are important indicators of nutritional status.

Preoperative vital signs, including blood pressure while sitting and standing, and pulse oximetry provide important baseline data with which to compare alterations that occur during and after surgery. Some institutions request that you obtain blood pressure in both arms for comparison. Anxiety and fear commonly cause elevations in heart rate and blood pressure. Preoperative assessment of vital signs is also important to rule out fluid and electrolyte abnormalities (see Chapter 41).

An elevated temperature before surgery is a cause for concern. If the patient has an underlying infection, the surgeon may choose to postpone surgery until the infection has been treated. An elevated body temperature increases the risk of fluid and electrolyte imbalance after surgery. Notify the surgeon immediately if the patient has an elevated temperature.

Head and Neck. The condition of oral mucous membranes is one indicator of the level of hydration. Inspect the area between the gums and cheek, the soft palate, and the nasal sinuses. Sinus drainage indicates respiratory or sinus infection. During the examination of the oral mucosa, identify any loose or capped teeth because they can become dislodged during endotracheal intubation. Note the presence of dentures, prosthetic devices, or piercings so they can be removed before surgery, especially if the patient receives general anesthesia.

Integument. Carefully inspect the skin, especially over bony prominences such as the heels, elbows, sacrum, back of head, and scapula. During surgery patients often lie in a fixed position for several hours, making them at increased risk for pressure ulcers (see Chapter 48) (Walton-Geer, 2009). Chronic use of steroids also increases a patient's susceptibility to skin tears. The overall condition of the skin reveals the patient's level of hydration. An older adult is at high risk for alteration in skin integrity from positioning (pressure forces) and sliding on the OR table (shearing forces).

Thorax and Lungs. Assessment of the patient's breathing pattern and chest excursion measures ventilatory capacity. A decline in ventilatory function places the patient at risk for respiratory complications. Auscultation of breath sounds indicates whether the patient has pulmonary congestion or narrowing of airways. Existing atelectasis or moisture in the airways is aggravated during surgery. Serious pulmonary congestion usually results in postponement of the surgery. Certain anesthetics cause laryngeal muscle spasm. If you auscultate wheezing in the airways before surgery, the patient is at risk for further airway narrowing during surgery and after extubation (removal of the endotracheal tube); therefore notify health care providers of these findings.

Heart and Vascular System. Assess the character of the apical pulse and listen to heart sounds. Assess peripheral pulses, capillary refill, and the color and temperature of extremities. If peripheral pulses are not palpable, use a Doppler instrument for assessment of their presence. Acceptable capillary refill occurs in less than 2 seconds. Measurement of capillary refill and assessment of peripheral pulses are particularly important for the patient having vascular surgery or for a patient who has casts or constricting bandages applied to the extremities after surgery (see Chapter 30).

BOX 50-2 CULTURAL ASPECTS OF CARE

Providing Culturally Sensitive Care for the Patient Having Surgery

Patients' culture, religious group, and country of origin influence their health care beliefs. Your approach to perioperative care should respect patients' cultural values and incorporate them to improve adherence to the care plan (Galanti, 2008). The use of a wide variety of resources within a health care agency, in the literature, and from the Internet helps nurses provide culturally sensitive care.

Implications for Practice

- Preoperative assessment needs to include a cultural assessment with questions such as primary language spoken, feelings regarding surgery and pain, pain management, expectations, support system, and feelings toward self-care with postoperative implications (e.g., Does patient relate to concept of pain? Does patient have feelings about gender of caregiver? Does patient follow custom of giving family members control over decisions? Does patient have religious convictions that affect perioperative care such as opposition to the administration of blood products?).
- Be sensitive about when and who to use as professional interpreters to communicate with non–English-speaking patients because some patients may have difficulty sharing personal health information with people who are younger or of a specific gender.
- Use materials and teaching techniques that are culturally relevant and language appropriate to communicate and assess the non–English-speaking patient regarding factors such as pain, general comfort, temperature, and need to void.
- Provide preoperative and postoperative educational materials in a variety of languages.

TABLE 50-6 Diagnostic Screening for Surgical Patients

MEASUREMENT AND NORMAL VALUES	INTERPRETATION
Complete blood count (CBC) *RBC: Men:* 4.7-6.1 million/mm^3 *Women:* 4.2-5.4 million/mm^3 *Hgb: Men:* 14-18 g/100 mL *Women:* 12-16 g/100 mL *Hct: Men:* 42%-52%; *Women:* 37%-47% *WBC: Adults and children >2 yr:* 5000-10,000/mm^3	Peripheral venous sample of blood may reveal infection, low blood volume, and potential for oxygenation problems. Surgeon may order blood replacement.
Serum electrolytes *Sodium (Na^+):* 136-145 mEq/L (135-145 mmol/L) *Potassium (K^+):* 3.5-5 mEq/L (3.5-5 mmol/L) *Chloride (Cl^-):* 95-105 mEq/L (95-105 mmol/L) *Bicarbonate (HCO_3^-):* 22-26 mEq/L (arterial); 24-30 mEq/L (venous)	Peripheral venous sample of blood may reveal significant fluid and electrolyte imbalances before surgery. Attention is given to Na^+, K^+, and Cl^- levels. IV fluid replacement may be indicated before surgery.
Coagulation studies *PT:* 11-12.5 seconds *INR:* 0.76-1.27 *APTT:* 30-40 seconds *Platelets:* 150,000-400,000/mm^3	PT, INR, APTT, and platelet counts reveal clotting ability of blood and patients at risk for bleeding tendencies and thrombus formation.
Serum creatinine *Men:* 0.6-1.2 mg/100 mL *Women:* 0.5-1.1 mg/100 mL	Ability of kidneys to excrete creatinine, by-product of muscle metabolism, indicates renal function. Elevated level can indicate renal failure.
BUN 10-20 mg/100 mL	Ability of kidneys to excrete urea and nitrogen indicates renal function. BUN becomes elevated if patient is dehydrated. Preoperative IV fluid replacement is often necessary.
Glucose *Fasting:* 70-105 mg/100 mL	Fingerstick or peripheral blood sample. Patients often require treatment of low or high levels before and after surgery.

Modified from Pagana KD, Pagana TJ: *Mosby's diagnostic and laboratory test reference,* ed 10, St Louis, 2011, Mosby.
APTT, Activated partial thromboplastin time; *BUN,* blood urea nitrogen; *Hct,* hematocrit; *Hgb,* hemoglobin; *INR,* international normalized ratio; *IV,* intravenous; *PT,* prothrombin time; *RBC,* red blood cell; *WBC,* white blood cell.

Abdomen. Assess the abdomen for size, shape, symmetry, and presence of distention. Ask how often the patient has regular bowel movements and inquire about the color and consistency of stools. Auscultate bowel sounds.

Neurological Status. Preoperative assessment of neurological status is important for all patients receiving general anesthesia. The baseline neurological status assists with the assessment of ascent from anesthesia. Observe the patient's level of orientation, alertness, mood, and ease of speech, noting whether he or she answers questions appropriately and is able to recall recent and past events. A patient who will have surgery for neurological disease (e.g., brain tumor or aneurysm) sometimes demonstrates an impaired level of consciousness or altered behavior. If the patient is scheduled for spinal anesthesia, preoperative assessment of gross motor function and strength is important. Spinal anesthesia causes temporary paralysis of the lower extremities (see Chapter 43). Be aware of a patient entering surgery with weakness or impaired mobility of the lower extremities and communicate this to the perioperative team so care providers do not become alarmed when full motor function does not return as the spinal anesthetic wears off.

Diagnostic Screening. Patients have a variety of preoperative tests and procedures to confirm or rule out preexisting alterations requiring surgery or that will affect recovery. Usually patients scheduled for ambulatory surgery have tests done several days before surgery. Testing done the day of surgery is usually limited to tests such as glucose monitoring for the patient with diabetes. You need to be familiar with the tests, their purposes, and how to monitor results.

The patient's medical history, physical assessment findings, and surgical procedure determine the type of tests ordered. For example, a type and cross-match are indicated before surgery for procedures in which blood loss is expected (e.g., hip and knee replacements) in case the patient needs a blood transfusion during surgery. The surgeon designates the number of blood units to have available during surgery. Table 50-6 gives the purpose and normal values for common blood tests. If diagnostic tests reveal severe problems, the surgeon will probably cancel surgery until the cause of the problem is identified or the condition stabilizes. You are responsible for preparing patients for diagnostic studies and coordinating completion of the tests. Review diagnostic results as they become available, alert health care providers to findings, and assist with planning appropriate therapy.

If a patient is over the age of 40 or has heart disease, the health care provider often orders a chest x-ray film examination or an electrocardiogram (ECG). The chest x-ray film is an examination of the condition of the heart and lungs. An ECG measures the electrical activity of the heart to determine whether the heart rate, rhythm, and other factors are normal. Pulmonary function testing and occasionally arterial blood gas analysis are conducted on patients with preexisting lung disease. Blood glucose levels are measured before surgery when patients have diabetes.

Autologous infusions are an option for some patients who choose to donate their own blood before surgery to reduce the risk of transfusion-related infections and transfusion reactions (see Chapter 41). The patient makes the donation several weeks before the scheduled surgery. The patient who self-donates sometimes has

BOX 50-3 NURSING DIAGNOSTIC PROCESS

Fear Related to Knowledge Deficit and Previous Surgical Experience

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Ask patient to describe previous surgical experiences.	Apprehension over anesthesia and postoperative pain
Ask patient about preoperative education/preparation before admission.	Fear of the unknown, of having complications Unaware of preoperative testing
Observe patient's nonverbal behavior.	Increased tension
Assess vital signs.	Increased heart rate, increased blood pressure

a lower hemoglobin and hematocrit level on the day of surgery. Autotransfusion via a cell-saver device during surgery is possible if health care providers are anticipating large blood loss (e.g., open-heart surgery). Although the cell saver is expensive, it returns washed red blood cells to the patient and decreases the risk of transfusion reactions and blood-related infections by using the patient's own blood (Rothrock, 2007).

NURSING DIAGNOSIS

Cluster patterns of defining characteristics are gathered during the assessment to identify nursing diagnoses for the surgical patient (Box 50-3). The patient with preexisting health problems is likely to have a variety of risk diagnoses. For example, a patient with preexisting bronchitis who has abnormal breath sounds and a productive cough is at risk for *ineffective airway clearance.* The nature of the surgery and assessment of the patient's health status provide defining characteristics and risk factors for a number of nursing diagnoses. For example, because a patient will have a surgical incision and an IV infusion, there is a risk for developing infection at the surgical site or in the bloodstream (sepsis). A diagnosis of *risk for infection* requires your attention from admission through recovery.

The related factors for each diagnosis establish directions for nursing care that is provided during one or all surgical phases. For example, the diagnosis of *ineffective airway clearance related to abdominal pain* requires different interventions than the diagnosis *ineffective airway clearance related to excess mucus.* Preoperative nursing diagnoses allow you to take precautions and actions so care provided during the intraoperative and postoperative phases is consistent with the patient's needs.

Nursing diagnoses made before surgery also focus on the potential risks that a patient may face after surgery. Preventive care is essential so you can manage the surgical patient effectively. The following are some common nursing diagnoses relevant to the patient having surgery:

- Ineffective airway clearance
- Anxiety
- Fear
- Risk for deficient fluid volume
- Risk for perioperative positioning injury
- Deficient knowledge (specify)
- Impaired physical mobility
- Nausea
- Acute pain
- Delayed surgical recovery

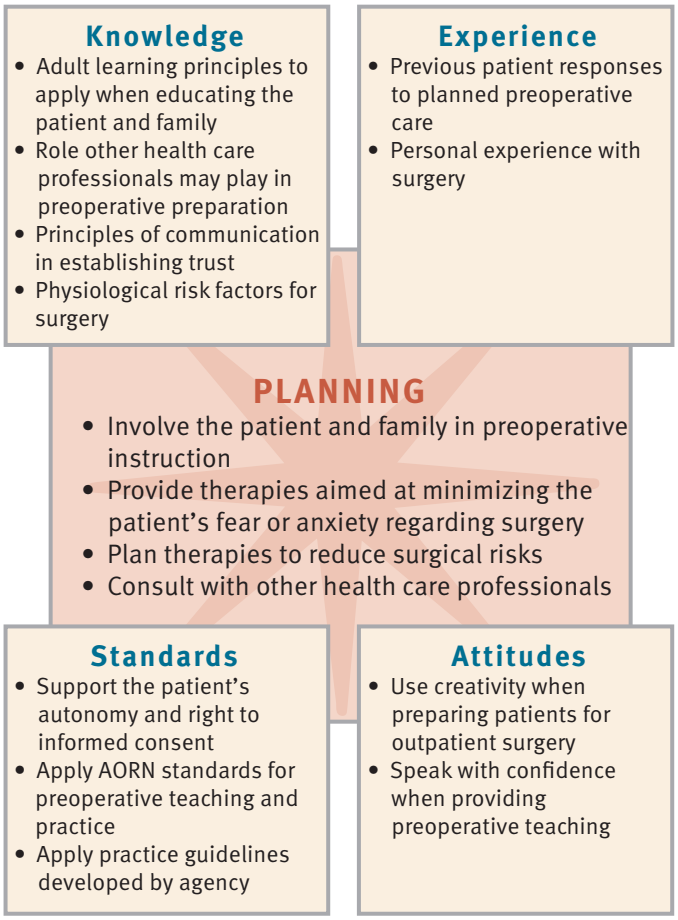

FIG. 50-2 Critical thinking model for surgical patient planning. *AORN,* Association of periOperative Registered Nurses.

PLANNING

During planning synthesize information to establish a plan of care based on the patient's nursing diagnoses (see the Nursing Care Plan). Apply critical thinking in your selection of nursing interventions (Fig. 50-2). For example, apply knowledge pertaining to adult learning principles, standards for preoperative education (AORN, 2011), and the patient's unique learning needs to formulate a well-designed **preoperative teaching plan** for the diagnosis of *deficient knowledge.* Critical thinking ensures that the patient's plan of care integrates knowledge, previous experiences, critical thinking attitudes, and established standards of practice. Previous experience in caring for surgical patients helps you anticipate how to approach patient care (e.g., complications to prevent and anticipate and methods to reduce anxiety). Professional standards are especially important to consider when selecting interventions for the plan of care. These standards often establish scientifically proven guidelines for preferred nursing interventions.

Successful planning requires involving the surgical patient and family to set realistic expectations for care. Early involvement of the patient when developing the surgical care plan minimizes surgical risks and postoperative complications. A patient informed about the surgical experience is less likely to be fearful and is able to participate in the postoperative recovery phase so expected

NURSING CARE PLAN

Deficient Knowledge Regarding Preoperative and Postoperative Care Requirements Related to Lack of Exposure to Information

ASSESSMENT

Mrs. Campana is an 80-year-old patient scheduled to be admitted in 5 days for elective bowel resection. You are the nurse in the ambulatory surgery center (ASC) preoperative testing area, assigned to prepare Mrs. Campana for surgery. During your initial discussion with Mrs. Campana, you assess that she is alert and oriented. She states she has severely reduced visual acuity but is able to hear your questions clearly. She has had previous surgery, but that was 10 years ago. She lives alone and has a daughter who is coming in town the day of surgery and will stay with her 2 weeks after surgery.

Assessment Activities	*Findings/Defining Characteristics**
Ask Mrs. Campana what she has been told by her surgeon regarding her surgery.	She states that her surgeon explained the procedure with a drawing of the bowel and the location of the part to be removed **but has not described the care she will receive afterward.**
Ask Mrs. Campana what she understands about preoperative preparation and what to expect after surgery.	She verbalizes understanding of medicines to take the morning of surgery, her diet before surgery and when to stop eating, and who to call for questions. **She is unable to explain what to expect after surgery.**
Assess Mrs. Campana's concerns about surgery.	**She appears slightly anxious. She states, "I'm afraid I'll die during my surgery. I don't know what to expect."**

***Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Deficient knowledge regarding preoperative and postoperative care requirements related to lack of exposure to information

PLANNING

Goals	*Expected Outcomes (NOC)*†
	Knowledge: Treatment Procedures
Mrs. Campana will express understanding of the postoperative routines of surgical care by the day of surgery.	Mrs. Campana will describe the importance of postoperative exercises by the morning of surgery. Mrs. Campana will describe the schedule for activity and diet management following surgery by the first postoperative evening.
Mrs. Campana will participate actively in postoperative recovery activities by postoperative day 1.	Mrs. Campana will successfully perform postoperative exercises (turning, coughing, deep breathing [TCDB], diaphragmatic breathing [DB], incentive spirometry [IS], and leg exercises) on the evening of surgery.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡ *Preoperative Teaching*	RATIONALE
Before admission to the hospital, provide Mrs. Campana with audiotape program that explains preoperative and postoperative routines. Supply instruction booklet designed for patients with visual impairments. Make a follow-up call 24 hours before surgery to patient encouraging them to ask questions and voice concerns.	Preadmission education often results in less teaching time and better performance of exercises on admission. Education has a beneficial effect in reducing postoperative anxiety (American College of Surgeons, 2006).
On admission to hospital, demonstrate to Mrs. Campana and daughter how to perform postoperative exercises and how to get out of bed with assistance.	Demonstration is an effective method to reinforce instruction.
Coach Mrs. Campana during a return demonstration of postoperative exercises before surgery.	Learning occurs when a patient is actively involved in an education session (Edelman and Mandle, 2009). Evaluates learning and provides opportunity to reinforce instruction.
Correct any unrealistic expectations Mrs. Campana or daughter have regarding surgery.	Unrealistic expectations, when unmet, contribute to patient's anxiety. Psychological preparation for surgery reduces anxiety (American College of Surgeons, 2006).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Mrs. Campana to describe activity and diet therapies to expect following surgery.	She is able to verbalize progressive diet from NPO to full liquids but is not sure how quickly she will be expected to ambulate. She states that the booklet and audiotape were both helpful.	Mrs. Campana requires additional discussion of activity and long-term diet plan.

NURSING CARE PLAN

***Deficient Knowledge Regarding Preoperative and Postoperative Care Requirements Related to Lack of Exposure to Information*—cont'd**

EVALUATION—cont'd

Observe Mrs. Campana's demonstration of postoperative exercises.	She correctly demonstrates leg exercises and TCDB but is having difficulty with IS use.	Mrs. Campana demonstrates most postoperative exercises but needs further teaching and practice on IS use.
Explore with Mrs. Campana and daughter if they have any remaining fears or concerns.	Both Mrs. Campana and her daughter deny any fears or concerns at the present time.	Informational and psychological needs of Mrs. Campana and her daughter have been met.

outcomes are met. Establish diagnosis, interventions, and outcomes to ensure recovery or maintenance of the preoperative state.

Goals and Outcomes. Base the goals and outcomes of care on the individualized nursing diagnoses. Review and modify the plan during the intraoperative and postoperative periods. Outcomes established for each goal of care provide measurable behavioral evidence to gauge the patient's progress toward meeting stated goals. As an example, the goal "Patient is able to perform postoperative exercises during postoperative recovery" is measured through the following expected outcomes:

- Patient performs deep-breathing and coughing exercises on awakening from anesthesia.
- Patient performs postoperative leg exercises and early ambulation 24 hours after surgery.
- Patient verbalizes rationale for early ambulation 24 hours after surgery.

Setting Priorities. Use clinical judgment to prioritize nursing diagnoses and interventions based on the unique needs of each patient. Patients requiring emergent surgery often experience changes in their physiological status that require you to reprioritize quickly. For example, if a patient's blood pressure begins to drop; hemodynamic stabilization becomes a priority over education and stress management. Ensure that the approach to each patient is thorough and reflects an understanding of the implications of the patient's age, physical and psychological health, educational level, cultural and religious practices, and stated and/or written wishes concerning advance medical directives.

Teamwork and Collaboration. For patients having ambulatory surgery and those admitted the day of their scheduled surgery, the health care team must collaborate to ensure continuity of care. Preoperative planning ideally occurs days before admission to the hospital or surgical center. The collaboration between the health care provider's office and the surgical center is crucial to preparing the patient for the procedure. Preoperative instruction gives the patient time to think about the surgical experience, make necessary physical preparations (e.g., altering diet or discontinuing medication use), and ask questions about postoperative procedures. The patient having ambulatory surgery usually returns home on the day of surgery. Thus well-planned preoperative care ensures that he or she is well informed and able to be an active participant during recovery. The family or spouse also plays an active supportive role for the patient.

IMPLEMENTATION

Preoperative nursing interventions provide the patient with a complete understanding of the surgery and anticipated postoperative activities and prepare him or her physically and psychologically for surgical intervention.

Informed Consent. Surgery cannot be legally or ethically performed until a patient understands the need for a procedure, the steps involved, risks, expected results, and alternative treatments. Chapter 23 discusses in detail the nurse's responsibilities for **informed consent.** It is the surgeon's responsibility to explain the procedure and obtain the informed consent. After the patient completes the consent form, place it in the medical record. The record goes to the OR with the patient.

Health Promotion. Health promotion activities during the preoperative phase focus on health maintenance, prevention of complications, and anticipation of continued care needed after surgery.

Preoperative Teaching. Patient education is an important aspect of the patient's surgical experience (see Chapter 25). Provided in a systematic and structured format with teaching and learning principles, preoperative teaching regarding a patient's expected postoperative course has a positive influence on the patient's recovery (Kruzik, 2009). Preadmission nurses call patients up to 1 week before surgery to clarify questions and reinforce explanations. Preoperative information and instructions are delivered by telephone calls, mailings from the health care provider's office or hospital, printed preoperative teaching guidelines and checklists, or the use of videotapes or websites. The American College of Surgeons developed a patient education website titled *Partners in Surgical Care,* which provides a supplement to the surgeon's teaching (American College of Surgeons, 2006). Education throughout the perioperative period is essential. The Joanna Briggs Institute (2000) highlights the importance of preoperative teaching for knowledge acquisition and skill performance. It is ideal to attempt perioperative education before admission, during the hospital stay, and after discharge. Including family members in perioperative preparation is advisable. Often a family member is the coach for postoperative exercises when the patient returns from surgery. The family often has better retention of preoperative teaching and will be with the patient and able to help them in their recovery. If anxious relatives do not understand routine postoperative events, it is likely that their anxiety heightens the patient's fears and concerns. Perioperative preparation of family members before surgery lessens anxiety and misunderstanding.

Provide patients with information about sensations typically experienced after surgery. Preparatory information helps them anticipate the steps of a procedure and thus form realistic images of the surgical experience. For example, in the OR the anesthesia provider applies ointment to patients' eyes to prevent corneal

damage. Warning patients about sensations of blurred vision reduces their anxiety on awakening from surgery. Other sensations to describe include the expected pain at the surgical site, the tightness of dressings, dryness of the mouth, and the sensation of a sore throat resulting from an endotracheal tube.

Anxiety and fear are barriers to learning, and both emotions heighten as surgery approaches. If the patient is capable of and receptive to learning, present information in a logical sequence, beginning with preoperative events and advancing to intraoperative and postoperative routines. The AORN (2011) has the following standards to demonstrate patient understanding of the surgical experience.

Patient Cites Reasons for Preoperative Instructions and Exercises. When given a rationale for preoperative and postoperative procedures, the patient is better prepared to participate in care. Most preoperative teaching programs include explanation and demonstration of postoperative exercises: diaphragmatic breathing, incentive spirometry, coughing, turning, and leg exercises. These exercises help to prevent postoperative complications (Skill 50-1 on pp. 1287-1292). In addition, if the patient needs graded compression or elastic stockings or intermittent pneumatic compression (IPC) devices, teach about the purposes and the specific nursing care associated with the device (see Chapter 47).

After you explain each exercise, demonstrate it for the patient. Guide him or her through each exercise. For example, assess whether the patient is sitting properly and help him or her place the hands in the proper position during breathing. Allow the patient time for independent practice and return later to evaluate effectiveness before surgery.

Patient States Time of Surgery. Tell the patient and family the approximate time that surgery will begin and when they should arrive at the hospital or ASC. The surgeon informs the patient and family of the anticipated length of surgery. Unanticipated delays occur for many reasons. Make the family aware that delays occur for various reasons and do not necessarily indicate a problem.

Patient States Postoperative Unit and Location of Family During Surgery and Recovery. The unit to which the patient is admitted before surgery is often different from the postoperative unit. The family needs to know where the patient will be after surgery. Also explain where the family can wait and where the surgeon will attempt to find family members after surgery. Many institutions have implemented programs in which the circulating nurse gives periodic reports to the family in the waiting room for surgeries that are expected to be prolonged. If the patient will be taken to a special unit, it helps to orient the patient and family members to the environment of the unit before surgery.

Patient Discusses Anticipated Postoperative Monitoring and Therapies. The patient and family need to know about postoperative events. If they understand the frequency of postoperative vital sign monitoring before surgery occurs, they are less apprehensive when nurses measure vital signs. Also explain whether the patient is likely to have IV lines, monitoring lines, dressings, or drainage tubes or will require ventilator support.

Patient Describes Surgical Procedures and Postoperative Treatment. After the surgeon explains the basic purpose of a surgical procedure, some patients ask you additional questions to clarify information. First clarify with the patient what was discussed with the surgeon. When the patient has little or no understanding about the surgery, notify the surgeon that the patient requires further explanation. You can augment the surgeon's explanations.

Patient Describes Postoperative Activity Resumption. The type of surgery that patients undergo determines how quickly they can resume normal physical activity and regular eating habits. Explain that it is normal to progress gradually in activity and eating. If the patient tolerates activity and diet well, activity levels progress more quickly.

Patient Verbalizes Pain-Relief Measures. Pain is one of the surgical patient's most common fears. The family is also concerned for the patient's comfort. Pain after surgery is expected. Inform the patient and family of interventions available for pain relief (e.g., analgesics, positioning, splinting, and relaxation exercises) (see Chapter 43). The patient needs to know the schedule for analgesic drugs, the route of administration, and their effects.

Some patients avoid taking pain-relief drugs after surgery for fear of becoming dependent on them. Encourage the patient to use analgesics as ordered because, unless the pain is controlled, it is difficult for the patient to participate in postoperative therapy. Encourage the patient to take pain medications at the ordered intervals. Pain relief has been shown to be more effective when analgesics are given around-the-clock (ATC) rather than as needed (prn) (Paice et al., 2005), especially if pain is expected throughout the day. However, prn administration of analgesics after surgery is still very common. Closely assess the patient's pain level, tolerance to activity, and response to pain-relieving interventions. When pain is not regularly addressed, it becomes excruciating, and an analgesic often does not provide relief at the dose ordered. Teach patients who will have patient-controlled analgesia (PCA) how to push the button, the need to push the button when beginning to feel discomfort, and that use of the PCA does not cause overmedication (see Chapter 43). Also explain to the patient the length of time that it takes for the drug to begin working. Information from preoperative pain assessment is helpful when teaching about pain-relief measures (such as positioning and splinting).

Patient Expresses Feelings Regarding Surgery. Some patients feel like part of an assembly line before surgery. Frequent visits by staff, diagnostic testing, and physical preparation for surgery consume time; and the patient has few opportunities to reflect on the experience. Recognize the patient as a unique individual. The patient and family need time to express feelings about surgery and ask questions. The patient's level of anxiety influences the frequency of discussions. While delivering routine care, encourage expression of concerns, be patient and listen attentively. The family may wish to discuss concerns without the patient present so their fears do not frighten the patient and vice versa. Establishing a trusting and therapeutic relationship with the patient and family allows this to happen.

Acute Care. Acute care activities in the preoperative phase focus on the physical preparation of the patient for surgery.

Physical Preparation. The degree of preoperative physical preparation depends on the patient's health status, the planned surgery, and the surgeon's preferences. A seriously ill patient receives more supportive care in the form of medications, IV fluid therapy, and monitoring than the patient facing a minor elective procedure.

Maintaining Normal Fluid and Electrolyte Balance. The surgical patient is vulnerable to fluid and electrolyte imbalances as a result of the stress of surgery, inadequate preoperative intake, and the potential for excessive fluid losses during surgery (see Chapter 41). The American Society of Anesthesiologists Practice Guidelines for Preoperative Fasting (ASA, 2011) reviewed the current fasting practices for elective procedures requiring general anesthesia, regional anesthesia, or sedation. They recommend fasting before nonemergent procedures for the following time periods: do not take clear liquids for 2 hours; do not take breast milk for 4 hours;

and do not take formula, solids, and nonhuman milk for 6 hours. For fatty, fried, and meat sources the recommended fast is for 8 hours. A patient who is at home the evening before surgery needs to understand the importance of the specific fasting period ordered by the health care provider.

Agencies vary regarding these fasting guidelines. One difficulty is that often surgical cases begin before the time they are originally scheduled. When a patient is admitted NPO, remove fluids and solid foods from the patient's bedside and post a sign over the bed to alert hospital personnel and family members about fasting restrictions. Some patients take specific medications (e.g., anticoagulants, cardiovascular medications, anticonvulsants, and antibiotics) with a sip of water as ordered by their health care providers. Although the concept of preoperative fasting has changed over the past 10 years, studies and a systematic review demonstrate that the guidelines are not fully implemented and multidisciplinary improvement processes are necessary (Brady, Kinn, and Stuart, 2003).

Allow patients time to rinse their mouths with water or mouthwash and brush their teeth immediately before surgery as long as they do not swallow water. Notify the surgeon and anesthesia provider if the patient eats or drinks during the fasting period.

During surgery normal mechanisms for controlling fluid and electrolyte balance, including respiration, digestion, circulation, and elimination, are disturbed. Extensive losses of blood and other body fluids sometimes occur. The surgical stress response aggravates any fluid and electrolyte imbalance. Before the day of surgery patients are usually encouraged to eat foods high in protein with sufficient carbohydrates, fat, and vitamins. If a patient cannot eat because of GI alterations or impairments in consciousness, you will probably start an IV route for fluid replacement. The health care provider assesses serum electrolyte levels to determine the type of IV fluids and electrolyte additives to administer during surgery. Patients with severe nutritional imbalances sometimes require supplements with concentrated protein and glucose such as total parenteral nutrition (see Chapter 44).

Reducing Risk of Surgical Site Infection. A surgical site infection is one of the National Quality Forum (NQF)–endorsed patient safety measures that hospitals are encouraged to report (NQF, 2010). As of 2008 the Centers for Medicare and Medicaid Services (2010) no longer pays a higher reimbursement for hospitalizations complicated by certain types of surgical wound infections (e.g., mediastinitis after heart surgery, select orthopedic procedures, and certain bariatric procedures for obesity) if they were not present on admission. Thus there is great emphasis within hospitals for preventing the occurrence of surgical site infections.

The risk of developing a surgical site infection is determined by the amount and type of microorganisms contaminating a wound, susceptibility of the host, and the condition of the surgical wound itself. All three factors interact to cause infection. Antibiotics may be ordered in the preoperative period. A reduction in wound infection rates occurs when an antibiotic is administered 30 to 60 minutes before the surgical incision (Weber et al., 2008). The surgeon orders a specific time before surgery for the oral antibiotic to be taken or an IV antibiotic to be administered.

The skin is a favorite site for microorganisms to grow and multiply. Without proper skin preparation, the risk of postoperative wound infection is high. Many surgeons have patients bathe or shower the evening before surgery. Some health care providers ask patients to bathe or shower more than once, whereas others may have patients use an antibacterial soap to clean the proposed operative site. Depending on the surgical procedure, some patients shower the morning of surgery. If the surgical procedure involves the head, neck, or upper chest area, the patient may also be required to shampoo the hair. Cleaning and trimming fingernails and toenails is sometimes necessary.

The need for hair removal depends on the amount of hair, location of the incision, and surgical procedure planned (AORN, 2011). Hair removal can damage and cause breaks in the patient's skin, which allows for the entry of microorganisms. If required, perform hair removal, preferably with a clipper or shaver, as close to the time of surgery as possible. Short hospital stays reduce the chance of a health care–associated infection (HAI). Patients can also acquire respiratory, urinary tract, and wound infections during hospitalization. One advantage to having ambulatory surgical procedures is that the patient usually returns home after surgery.

Preventing Bowel and Bladder Incontinence. Some patients receive a bowel preparation (e.g., a cathartic or enema) if the surgery involves the lower GI system or lower abdominal organs. Manipulation of portions of the GI tract during surgery results in absence of peristalsis for 24 hours and sometimes longer. Enemas and cathartics such as polyethylene glycol electrolyte solution (GoLytely) clean the GI tract to prevent intraoperative incontinence and postoperative constipation. An empty bowel reduces risk of injury to the intestines and minimizes contamination of the operative wound if a portion of the bowel is incised or opened accidentally or if colon surgery is planned. The surgeon's order reads "give enemas until clear." This means that you administer enemas until the enema return contains no solid fecal material (see Chapter 46). Too many enemas given over a short time can cause serious fluid and electrolyte imbalances (Chapter 41). Most agencies limit the number of enemas (usually three) that a nurse may administer successively. Verify a patient's potassium level following bowel preparation.

Promoting Rest and Comfort. Rest is essential for normal healing. Anxiety about the impending surgery can easily interfere with a patient's ability to relax or sleep. The underlying condition requiring surgery is often painful, further impairing rest. Attempt to make the patient's environment quiet and comfortable. The health care provider may order a sedative-hypnotic or anxiolytic agent for the night before surgery. Sedative-hypnotics (e.g., temazepam [Restoril]) affect and promote sleep. Anxiolytic agents (e.g., alprazolam [Xanax]) act on the cerebral cortex and limbic system to relieve anxiety.

Preparation on the Day of Surgery. Complete several routine procedures before releasing patients for surgery.

Hygiene. Basic hygiene measures provide additional comfort before surgery. If the hospitalized patient is unwilling to take a complete bath, a partial bath is refreshing and removes irritating secretions or drainage from the skin. Because the patient cannot wear personal nightwear to the OR because it is restrictive and is a flammable hazard, provide a clean hospital gown. When the patient is NPO for the last several hours, his or her mouth is often very dry. Offer the patient mouthwash and toothpaste, again cautioning the patient not to swallow water.

Hair and Cosmetics. During surgery with the patient under general anesthesia, his or her head is positioned to introduce an endotracheal tube into the airway (see Chapter 40). This procedure may involve manipulation of the patient's hair and scalp. To avoid injury ask the patient to remove hairpins or clips before leaving for surgery. Electrocautery is frequently used during surgery. Hairpins and clips can become an exit source for the electricity and cause burns. Remove hairpieces or wigs as well. The patient applies a disposable hat before entering the OR.

During and after surgery the anesthesia provider and nurse assess skin and mucous membranes to determine the patient's level of oxygenation and circulation. Therefore remove all makeup (i.e., lipstick, powder, blush, nail polish) to expose normal skin and nail coloring. Pulse oximetry records accurate measurements through most nail polish colors, but removal is still considered good practice. Also remove contact lenses, false eyelashes, and eye makeup. Give the patient's glasses to the family immediately before the patient leaves for the OR. Document this per agency policy.

Removal of Prostheses. It is easy for any type of prosthetic device to become lost or damaged during surgery. The patient needs to remove all prostheses, including partial or complete dentures, artificial limbs, artificial eyes, and hearing aids. If a patient has a brace or splint, check with the health care provider to determine whether it should remain with him or her.

For many patients it is embarrassing to remove dentures, wigs, or other devices that enhance personal appearance. Always offer privacy as the patient removes personal items. Patients are sometimes allowed to keep these until they reach the preoperative area. Place dentures in special containers, labeled with the patient's name and other identification required by the agency, for safekeeping to prevent loss or breakage. In many agencies you document an inventory of all prosthetic devices or personal items and have them locked away. It is also common practice for nurses to give prostheses to family members or to keep the devices at the patient's bedside. Document these actions in the nursing notes, surgical checklist, or per agency policy.

Safeguarding Valuables. If a patient has valuables, give them to family members or secure them for safekeeping. Many hospitals require patients to sign a release to free the institution of responsibility for lost valuables. Valuables are usually stored and locked in a designated location. Often patients are reluctant to remove wedding rings or religious medals. A wedding band can be taped in place, but this is not the preferred practice. If there is a risk that the patient will experience swelling of the hand or fingers (mastectomy, hand surgery, fluid shifts), remove the band. Many hospitals allow patients to pin religious medals to their gowns, although the risk of loss increases. Remove other metal items such as piercings to reduce risk of burns. Document the location of valuables per hospital policy.

Preparing the Bowel and Bladder. Instruct the patient to void just before leaving for the OR and before giving preoperative medications. An empty bladder reduces discomfort during the procedure and reduces the risk of incontinence during surgery. If the patient is unable to void, record this information on the preoperative checklist. A straight urinary catheterization (Chapter 45) may be necessary if a bladder scan reveals large bladder volume, or an indwelling urinary catheter may be placed if the surgery is long or the incision is in the lower abdomen.

Vital Signs. Measure a final preoperative set of vital signs. The anesthesia provider uses these values as a baseline for intraoperative vital signs. If preoperative vital signs are abnormal, surgery may need to be postponed. Notify the surgeon of any abnormalities before sending the patient to surgery.

Documentation. Before the patient goes to the OR, check the contents of the medical record to be sure that pertinent laboratory results are present. Check consent forms for accuracy. A preoperative checklist is a useful tool for ensuring patient safety and completing nursing interventions. Check the nurses' notes to be sure that documentation of care is current. This is especially important if the hospitalized patient experienced unpredicted problems the night before surgery. Send a current medication administration record to the operating room.

Other Procedures. If an IV infusion is not started on the hospital unit, one will be placed in the preoperative holding area. An IV line is essential for establishing a route to deliver medications and fluids during surgery. Some patients need a nasogastric (NG) tube inserted before surgery, but this often occurs in the OR (see Chapter 46).

Administering Preoperative Medications. The advent of ambulatory surgery has reduced the use of preoperative medications. However, the anesthesia provider or surgeon sometimes orders preanesthetic drugs ("on-call medications," "preops") to reduce the patient's anxiety, the amount of general anesthesia required, the risk of nausea and vomiting and resultant aspiration, and respiratory tract secretions. Provide all nursing care measures (e.g., assistance to bathroom) before giving the patient preoperative medications. The patient must sign the consent form before you administer the medications. Because the drugs cause sedation, do not allow the patient to leave the bed or stretcher until surgical personnel arrive to transport him or her to the OR. Warn the patient to expect drowsiness and a dry mouth.

Eliminating Wrong Site and Wrong Procedure Surgery. Because of errors made in the past with patients undergoing the wrong surgery or having surgery performed on the wrong site, The Joint Commission (TJC) instituted Universal Protocol guidelines for preventing such mishaps. The Universal Protocol is now part of TJC ongoing National Patient Safety Goals (TJC, 2011). Implement this protocol whenever an invasive surgical procedure is to be performed no matter the location (e.g., hospital, ASC, or health care provider office). The three principles of the protocol include the following: (1) a preoperative verification that ensures that all relevant documents (e.g., consent forms, allergies, medical history, physical assessment findings) and results of laboratory tests and diagnostic studies are available before the start of the procedure and that the type of surgery scheduled is consistent with the patient's expectations; (2) marking the operative site with indelible ink to mark left and right distinction, multiple structures (e.g., fingers), and levels of the spine; and (3) a "time out" just before starting the procedure for final verification of the correct patient, procedure, site, and any implants (TJC, 2011). All members of the surgical/procedure team perform the time out. This protocol includes active patient or a legally designated representative involvement in the entire process. If the patient refuses a mark, note this on the procedure checklist and notify the surgeon.

Building Competency in Safety You are the nurse in the preoperative holding area and are preparing the patient for the operating room. You completed all preliminary procedures, storing valuables, checking the preoperative checklist, and assisting the patient to the bathroom. You are preparing to perform the Universal Protocol with patient verification. When is the right time to administer the preoperative sedative?

Answers to questions can be found on the Evolve website.

EVALUATION

The admitting nurse and the nurse in the preoperative area evaluate initial patient outcomes (Fig. 50-3). Although limited time is available to evaluate outcomes before surgery, compare the patient's current status with expected outcomes to determine whether new or revised interventions and/or nursing diagnoses need to be implemented.

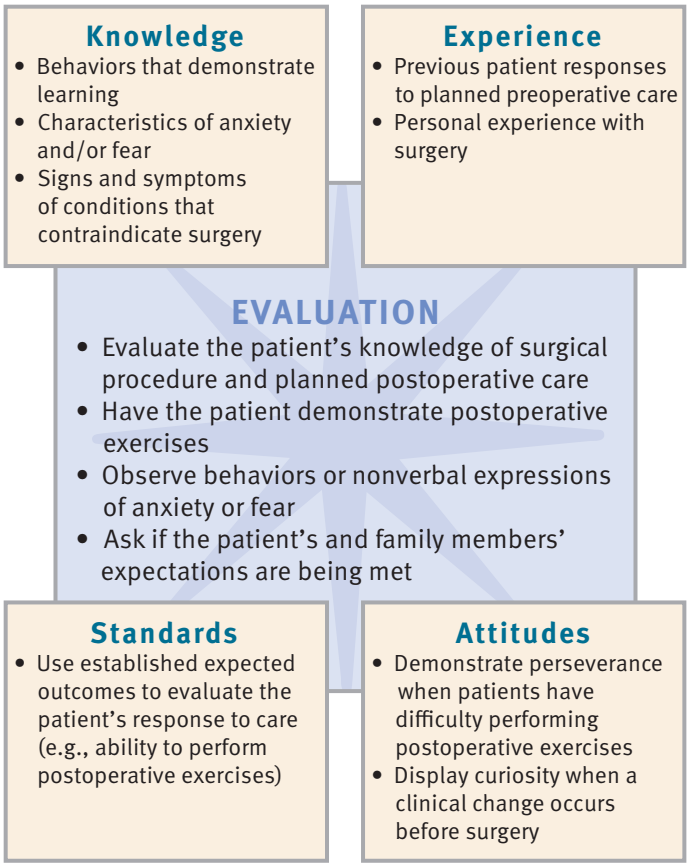

FIG. 50-3 Critical thinking model for surgical patient evaluation.

Through the Patient's Eyes. Evaluate whether the patient's expectations were met with respect to surgical preparation. For example, ask patients if they require additional information, if they desire to have their family members more involved, and if they have any unidentified needs. During evaluation, include a discussion of any misunderstandings so patient concerns can be clarified. When patients have expectations about pain control, this is a good time to reinforce how it will be managed after surgery.

Patient Outcomes. You are able to evaluate the patient's response to interventions designed for preoperative nursing diagnoses such as *deficient knowledge*. For example, ask the patient to describe the reason for postoperative exercises and the type of care activities to expect when the patient returns from surgery. Be thorough in your evaluation to determine if further instruction is needed after surgery. Interventions continue during and after surgery; thus the evaluation of many goals and outcomes does not occur until after surgery.

TRANSPORT TO THE OPERATING ROOM

Personnel in the OR notify the nursing unit or ambulatory surgery area when it is time for surgery. In many hospitals a nursing orderly or transporter brings a stretcher for transporting the patient. The transporter checks the patient's identification bracelet for two identifiers (name, birth date, or hospital number) (refer to institutional or agency policy) against the patient's medical record to be sure that the right person is going to surgery. Because some patients receive preoperative sedatives, the nurses and transporter help the patient transfer from bed to stretcher to prevent falls. The ambulatory surgery patient ambulates to the OR if able and not medicated. Provide the family an opportunity to visit before the patient is transported to the OR. Direct the family to a waiting area. In some hospitals the family is allowed to wait with the patient in the OR holding area until he or she is transported into the OR.

INTRAOPERATIVE SURGICAL PHASE

Care of the patient during surgery requires careful preparation and knowledge of the events that occur during the surgical procedure. The nurse usually functions in one of two roles: circulating nurse or scrub nurse. The **circulating nurse** must be an RN. His or her responsibilities include reviewing the preoperative assessment, establishing and implementing the intraoperative plan of care, evaluating the care, and providing for continuity of care after surgery. The circulating nurse assists with procedures such as endotracheal intubation and blood administration as needed. In addition, this nurse positions the patient, monitors sterile technique and a safe OR environment, assists the surgeon and surgical team by operating nonsterile equipment, provides additional supplies, verifies sponge and instrument counts, and maintains accurate and complete written records.

The **scrub nurse** is an RN, a licensed practical nurse, or a surgical technologist. This individual maintains a sterile field during the surgical procedure, assists with applying sterile drapes, hands instruments and other sterile supplies to surgeons, and counts the sponges and instruments.

PREOPERATIVE (HOLDING) AREA

In most hospitals the patient enters a holding area, also known as the preanesthesia care unit or presurgical care unit (PSCU), outside the OR. In the PSCU the nurse explains the steps for preparing the patient for surgery, reviews the preoperative checklist, assesses the patient's readiness both physically and emotionally, and reinforces teaching. Nurses in the PSCU are members of the OR staff and wear surgical scrub suits, hats, and footwear in accordance with infection control policies. In some ambulatory surgical settings a perioperative primary nurse admits the patient, circulates for the operative procedure, and manages the patient's recovery and discharge.

In the PSCU the nurse or anesthesia provider inserts an IV catheter into the arm to establish a route for fluid replacement and IV drugs if not placed previously. A large-bore (18-gauge) IV catheter ensures easy infusion of fluids and blood products if necessary. The nurse monitors vital signs, including pulse oximetry. The anesthesia provider usually performs a patient assessment at this time.

Because of the preoperative medications, the patient begins to feel drowsy. The temperature in the PSCU and adjacent OR suites is usually cool. Offer the patient an extra blanket. Conscious sedation starts at this time. The patient's stay in the PSCU is usually brief.

ADMISSION TO THE OPERATING ROOM

The OR staff transfer the patient to the OR room via a stretcher. The patient is usually still awake and notices nurses and health care providers wearing complete surgical masks, gowns, and eyewear. The staff carefully transfer the patient to the OR table, being sure that the stretcher and table are locked in place. After the patient is on the table, fasten a safety strap around him or her. Support the patient by explaining procedures and encouraging him or her to

ask questions. Sights and sounds in the surgical suite are sometimes frightening to patients.

NURSING PROCESS

ASSESSMENT

Thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. For example, typically the nurse in the OR focuses on skin integrity and mobility, identifying any problems that predispose the patient to injury if he or she is not positioned on the OR table correctly. Because patients are not able to speak for themselves while under general anesthesia, this assessment in the OR is very important for their safety. Review the preoperative care plan to establish or revise the intraoperative care plan. Observe the patient's psychological comfort during this assessment as well.

NURSING DIAGNOSIS

Review preoperative nursing diagnoses and modify them to individualize the care plan in the OR. The following are some common nursing diagnoses relevant to the patient intraoperatively:

- Ineffective airway clearance
- Risk for deficient fluid volume
- Risk for perioperative positioning injury
- Risk for impaired skin integrity

PLANNING

Goals and Outcomes. Patient-centered goals and outcomes of preoperative nursing diagnoses extend into the intraoperative phase. For example, a goal for the nursing diagnosis of *risk for impaired skin integrity* is "Skin will remain free of injury through surgical procedure." Expected outcomes for this goal include:

- Patient will have intact skin and show no signs of redness at end of surgery.
- Patient will be free of burns from the grounding pad at end of surgery.

Setting Priorities. The OR nurse uses judgment to provide a safe operative experience for the patient. Providing an aseptic environment and proper use of equipment and instruments are top priorities. If an unsafe practice is occurring, the circulating nurse is integral to ensuring the safety of the patient and operative personnel.

Teamwork and Collaboration. For optimal patient safety the preoperative health care team communicates important assessment findings to the surgical team to ensure a smooth transition in care. For example, alerting the operative team of a latex allergy or risk factors for complications during surgery requires collaboration and timely communication among all team members.

IMPLEMENTATION

A primary focus of intraoperative care is to prevent injury and complications related to anesthesia, surgery, positioning, and equipment use. The perioperative nurse is an advocate for the patient during surgery and protects his or her dignity and rights at all times.

Acute Care

Physical Preparation. After safely securing the patient on the OR table, apply monitoring devices to him or her. Patients receiving general and regional anesthesia undergo continuous electrocardiogram (ECG) and pulse oximetry monitoring. For ECG, place electrodes on the chest and extremities to record electrical activity of the heart. A monitor in the OR displays this activity. Pulse oximetry monitors oxygen saturation. Apply an electrical cautery grounding pad to the skin so cauterizing instruments can be used safely. Apply **graded compression stockings** (e.g., elastic stockings) or IPC stockings intraoperatively (especially for long cases) or after surgery according to agency policy (see Chapter 47). Document compression device application, capillary refill, and patient tolerance to procedures. For limb surgeries assess peripheral pulses distal to the operative site. Measure temperature continuously via bladder, esophageal, or rectal probes.

Latex Sensitivity/Allergy. As the incidence and prevalence of **latex sensitivity** and allergy increase, the need for recognition of potential sources of latex is extremely critical. Federal regulations enacted in September 1998 mandate that all medical supplies contain a label notifying the consumer of the latex content. The OR and postanesthesia care unit (PACU) have many products that contain latex (e.g., gloves, IV tubing, syringes, and rubber stoppers on bottles and vials). It is also present in common objects such as adhesive tape, disposable electrodes, endotracheal tube cuffs, protective sheets, and ventilator equipment. Signs and symptoms of a latex reaction include local effects ranging from urticaria and flat or raised red patches to vesicular, scaling, or bleeding eruptions. Acute dermatitis is sometimes present. Rhinitis and/or rhinorrhea are other common reactions to mild and severe latex allergy. Immediate hypersensitivity reactions are life threatening, with the patient exhibiting focal or generalized urticaria and edema, bronchospasm, and mucus hypersecretion, all of which can compromise respiratory status. Vasodilation compounded by increased capillary permeability can lead to circulatory collapse and eventual death. Because the patient is draped during surgery, blocking visualization of the skin, investigate any unexplained acute deterioration in a previously healthy patient for possible latex allergy.

The AORN (2011) has a guideline for safe and competent care of the patient identified as being at risk for latex allergy. A latex allergy cart needs to be available at all times. All of the contents must be latex free. The American Association of Nurse Anesthetists (AANA) recommends that the patient with a latex allergy be scheduled as the first case of the day in the operating room. The room needs to be cleaned thoroughly, including all equipment, and all unnecessary items removed. The patient can then be safely accommodated by using appropriate latex-free items during the perioperative period and recovery. Box 50-4 lists latex precautions.

Introduction of Anesthesia. Patients undergoing surgical procedures receive one of four types of anesthesia: general, regional, local, or conscious sedation.

General Anesthesia. Modern anesthetic agents are much easier to reverse and allow the patient to recover with fewer negative effects. **General anesthesia** results in an immobile, quiet patient who does not recall the surgical procedure. The patient's amnesia acts as a protective measure from the unpleasant events of the procedure. An anesthesia provider gives general anesthetics by IV infusion and inhalation routes through the three phases of anesthesia: induction, maintenance, and emergence. Surgery requiring general anesthesia involves major procedures with extensive tissue manipulation.

Induction includes the administration of anesthetic agents and endotracheal intubation. The maintenance phase includes positioning the patient, preparing the skin for incision, and the surgical procedure itself. Appropriate levels of anesthesia are maintained during this phase. During emergence anesthetics are decreased, and

BOX 50-4 LATEX AVOIDANCE PRECAUTIONS

1. By touching any latex object, health care workers can transmit the allergen by hand to patients. Caution should be taken to keep the powder from the gloves away from patients because the powder acts as a carrier for the latex protein. Do not snap gloves on and off.
2. Identify latex-sensitive patients. The operating room (OR) should be labeled latex free to avoid having personnel bring rubber products (e.g., wristbands, chart labels) into the room.
3. Develop programs to educate health care workers in the care of latex-sensitive patients. Develop educational programs for patients and their families in the care and precautions that should be taken to prevent latex exposure.

Recommendations for Patient Care (Patients with Latex Allergy or Latex Risk)

The Operating Room

- Notify the OR of potential latex-allergic patients.
- Schedule latex-allergic and/or latex-risk patients as the first case(s) in the morning. This ensures that any latex dust (from the previous day) has been removed by ventilation of the room overnight.
- Remove all latex products from the OR.
- Bring a latex-free cart (if available) into the room.
- Use a latex-free reservoir bag, airways and endotracheal tubes, and laryngeal mask airways.
- Use a nonlatex breathing circuit with plastic mask and bag.
- Place all monitoring devices, cords/tubes (oximeter, blood pressure, electrocardiograph wires) in stockinet and secure with tape to prevent direct skin contact. Items sterilized in ethylene oxide must be rinsed before use. Residual ethylene oxide reacts and can cause an allergic response in a latex-allergic patient.

Intravenous Line Preparation

- Use intravenous (IV) tubing without latex ports; use stopcocks if available.
- If unable to obtain IV tubing without latex ports, cover latex ports with tape.
- Cover all rubber injection ports on IV bags with tape and label as follows: *Do not inject or withdraw fluid through the latex port. NOTE: Pulmonary artery catheters (especially the balloon), central venous catheters, and arterial lines may all contain latex components.*

Operating Room Patient Care

- Use nonlatex gloves. (*Use caution:* Not all substitutes are equally impermeable to bloodborne pathogens; care and investigation should be taken in the selection of substitute gloves.)
- Use nonlatex tourniquets or nonlatex examination gloves or polyvinyl chloride tubing.
- Draw medication directly from opened multidose vials (remove stoppers) if medications are not available in ampules.
- Draw up medications immediately before the beginning of the case or before administration. The rubber allergen could leach out of the plunger of the syringe, causing a reaction. The intensity of this reaction appears to increase over time.
- Use latex-free or glass syringes.
- Use stopcocks to inject drugs rather than latex ports.
- Notify pharmacy and central supply that the patient for whom you are caring is latex sensitive so these departments can use appropriate procedure when preparing medications and instruments. Also notify radiology, respiratory therapy, housekeeping, food service, and postoperative care units so the appropriate precautions can be made to protect the patient.
- Place clear and readily visible signs on the doors of the OR to inform all who enter that the patient has a latex allergy.

Modified from *Perioperative Standards and Recommended Practices: AORN latex guideline,* Denver, 2011, AORN.

the patient begins to awaken. Because of the short half-life of today's medications, emergence often occurs in the OR. The duration of anesthesia depends on the length of surgery. The greatest risks from general anesthesia are the side effects of anesthetic agents, including cardiovascular depression or irritability, respiratory depression, and liver and kidney damage.

Regional Anesthesia. Induction of **regional anesthesia** results in loss of sensation in an area of the body. The method of induction such as spinal, epidural, or a peripheral nerve block influences the portion of sensory pathways that are anesthetized. No loss of consciousness occurs with regional anesthesia, but the patient is often sedated. The anesthesia provider gives regional anesthetics by infiltration and local application.

Risks are involved with infiltrative anesthetics, particularly in the case of spinal anesthesia. Because the level of anesthesia can rise, which means that the anesthetic agent moves upward in the spinal cord, this can affect breathing. This migration of anesthetic depends on the drug type and amount and patient position. If the level of anesthesia rises, respiratory paralysis can develop, requiring resuscitation. Elevation of the upper body prevents respiratory paralysis. Some patients have a sudden fall in blood pressure, which results from extensive vasodilation caused by the anesthetic block to sympathetic vasomotor nerves and pain and motor nerve fibers. The patient requires careful monitoring during and immediately after surgery.

Because the patient is responsive and capable of breathing voluntarily, it is unnecessary for the anesthesia provider to use an endotracheal tube. OR personnel often gain a false sense of security because of the patient's relative alertness. Remember that burns and other trauma can occur on the anesthetized part of the body without the patient being aware of the injury. It is necessary to frequently observe the position of extremities and the condition of the skin.

Local Anesthesia. **Local anesthesia** involves loss of sensation at the desired site (e.g., a skin growth or the cornea of the eye). The anesthetic agent (e.g., lidocaine [Xylocaine]) inhibits nerve conduction until the drug diffuses into the circulation. It is injected locally or applied topically. The patient experiences a loss in pain and touch sensation and motor and autonomic activities (e.g., bladder emptying). Local anesthesia is common for minor procedures performed in ambulatory surgery.

Conscious Sedation. **Conscious sedation** is routinely used for procedures that do not require complete anesthesia but rather a depressed level of consciousness. A patient under conscious sedation must independently maintain a patent airway and adequate ventilation and be able to respond appropriately to verbal stimuli or light tactile stimulation (Rothrock, 2007). Short-acting IV sedatives such as midazolam (Versed) are given.

Advantages of conscious sedation include adequate sedation, reduction of fear and anxiety, amnesia, relief of pain and noxious stimuli, mood alteration, elevation of pain threshold, enhanced patient cooperation, stable vital signs, and rapid recovery. A variety of therapeutic procedures is appropriate for conscious sedation. Nurses assisting with the administration of local anesthesia and

conscious sedation need to demonstrate competency in the care of these patients. Knowledge of anatomy, physiology, cardiac dysrhythmias, procedural complications, and pharmacological principles related to the administration of individual agents is essential. You also need to assess, diagnose, and intervene in the event of untoward reactions and demonstrate skill in airway management and oxygen delivery. Resuscitation equipment must be readily available when using local anesthesia or conscious sedation (AORN, 2011).

Positioning the Patient for Surgery. During general anesthesia the nursing personnel and surgeon often do not position the patient until the stage of complete relaxation. The surgical approach usually determines the choice of position. Ideally the patient's position provides good access to the operative site, sustains adequate circulatory and respiratory function, and ensures the patient's safety and skin integrity. It should not impair neuromuscular structures.

An alert person maintains normal range of joint motion by pain and pressure receptors. If a joint is extended too far, pain stimuli provide a warning that muscle and joint strain is too great. In a patient who is anesthetized, normal defense mechanisms cannot guard against joint damage, muscle stretch, and strain. The muscles are so relaxed that it is relatively easy to place the patient in a position the individual normally could not assume while awake. He or she often remains in a given position for several hours. Although it may be necessary to place a patient in an unusual position, try to maintain correct alignment and protect him or her from pressure, abrasion, and other injuries. Special mattresses, use of foam padding, and attachments to the OR table provide protection to extremities and bony prominences. Positioning should not impede normal movement of the diaphragm or interfere with circulation to body parts. If restraints are necessary, pad the skin to prevent trauma.

Documentation of Intraoperative Care. Throughout the surgical procedure, keep an accurate record of patient care activities and procedures performed by OR personnel. Documentation of intraoperative care provides useful data for the patient's postoperative period.

EVALUATION

The circulating nurse conducts an ongoing evaluation to ensure that interventions such as patient position are implemented correctly during the intraoperative phase of surgery.

Through the Patient's Eyes. While a patient is undergoing surgery, it is important to keep the family informed. Hospitals vary on their policies for when and how often families are given an update of the patient's condition. Families expect an estimate of when surgery begins and the length of time it will likely last. When you give an update to a family member, ask if he or she has further questions or concerns.

Patient Outcomes. Evaluate the patient's ongoing clinical status. Continuously monitor vital signs and intake and output (I&O). Measure the patient's body temperature during and at completion of the surgery, with the goal of keeping the patient normothermic. Inspect the skin under the grounding pad and at areas where positioning exerts pressure.

POSTOPERATIVE SURGICAL PHASE

After surgery a patient's care is often complex as a result of physiological changes. The type of anesthesia, nature of surgery, and the patient's previous condition determine the phases of recovery that he or she undergoes and the length of time spent in convalescence on an acute care nursing unit. Typically at the end of surgery the anesthesia provider and the circulating nurse accompany the patient to the PACU and provide a report to the nursing staff.

Patients who undergo general anesthesia are more likely to face complications than those who have only local anesthesia or conscious sedation. The patient who requires general anesthesia usually has extensive surgery and requires close monitoring in the PACU for phase I recovery. This lasts for a few hours. Ultimately the patient returns to the acute care unit for postoperative convalescence, which may last overnight or for several days. In contrast, an ambulatory surgical patient who has had local anesthesia with no sedation or conscious sedation most often only undergoes phase II recovery for a brief time (i.e., 1 to 2 hours). In phase II recovery nursing staff prepare the patient for care in the home or extended care setting (AORN, 2011).

IMMEDIATE POSTOPERATIVE RECOVERY (PHASE I)

Before the patient arrives in the PACU, a PACU nurse obtains data from the surgical team in the OR regarding the patient's general status and need for special equipment and nursing care. Careful planning allows the nursing staff to consider placement of patients in the PACU. For example, patients who undergo spinal anesthesia are aware of their surroundings and benefit from being in a quieter part of the PACU, away from patients needing frequent monitoring. The patient with a serious infection such as tuberculosis is isolated from other patients. Use standard precautions for infection control (see Chapter 28) for all patients.

When the patient is admitted to phase I recovery, personnel notify the nurses on the acute care nursing unit of his or her arrival. This allows the nursing staff to inform family members. Family members usually remain in the designated waiting area so they can be found when the surgeon arrives to explain the patient's condition. *It is the surgeon's responsibility to describe the patient's status, the results of surgery, and any complications that occurred.* You are a valuable resource to the family if complications have arisen in the operative phase and clarifying explanations are necessary.

When the patient enters the PACU, the nurse and members of the surgical team discuss his or her status. A standardized approach or tool for "hand-off" communications assists in providing accurate information about a patient's care, treatment and services, current condition, and any recent or anticipated changes (AORN, 2011; Manser et al., 2010). The hand-off is interactive, multidisciplinary, and done at the patient's bedside, allowing for a communication exchange that gives caregivers the chance to dialogue and ask questions (AORN, 2011). The surgical team's report includes a review of anesthetic agents administered so the PACU nurse is able to anticipate how quickly a patient should regain consciousness and analgesic needs. For example, a report on IV fluids or blood products administered during surgery from the anesthesia provider or perfusionist alerts the nurse to the patient's fluid and electrolyte balance. The surgeon often reports special concerns (e.g., whether the patient is at risk for hemorrhaging or infection). The OR nurse or anesthesia provider discusses whether there were complications during surgery such as excessive blood loss or cardiac irregularities. He or she also reports intraoperative patient positioning and condition of the skin. Frequently this report takes place while PACU nurses are admitting the patient. The PACU nurse attaches the patient to monitoring equipment such as the noninvasive blood pressure monitor, ECG monitor, and pulse oximeter. Patients often receive some form of oxygen in this immediate recovery period.

BOX 50-5 POSTANESTHESIA CARE ASSESSMENT

Parameters to Assess

- Vital signs
- Respiratory adequacy
- Postoperative cardiac status
- Peripheral circulation
- Postoperative neurological status
- Level of consciousness, alertness, lucidity
- Orientation
- Intravenous patency
- Pain level
- Motor abilities
- Return of sensory and motor control
- Skin integrity
- Temperature regulation
- Positioning
- Surgical wound condition
- Presence of nausea and vomiting

Adapted from Association of periOperative Registered Nurses: *Perioperative standards and recommended practices for inpatient and ambulatory settings,* Denver, 2011, AORN.

TABLE 50-7 Modified Aldrete Score

CRITERIA	SCORE
Activity	
Able to move four extremities voluntarily or on command	2
Able to move two extremities voluntarily or on command	1
Unable to move extremities voluntarily or on command	0
Respiratory	
Able to breathe deeply and cough freely	2
Dyspnea or limited breathing	1
Apneic	0
Circulation	
BP 20% of preanesthetic level	2
BP 20%-49% of preanesthetic level	1
BP 50% of preanesthetic level	0
Consciousness	
Fully awake	2
Arousable on calling	1
Not responding	0
Oxygen (O_2) Saturation	
Able to maintain O_2 saturation >92% on room air	2
Needs O_2 inhalation to maintain O_2 saturation >92%	1
O_2 saturation <90% even with O_2 supplement	0
TOTALS: Possible score range 0-10	

Modified from Aldrete JA: Modifications to the post anesthesia score for use in ambulatory surgery, *J Perianesth Nurs* 13(3):148, 1998; and Aldrete JA, Kroulik D: A post-anesthetic recovery score, *Anesth Analg* 49:924, 1970.
BP, Blood pressure.

After receiving hand-off communication from the OR, the PACU nurse conducts a complete systems assessment during the first few minutes of PACU care (AORN, 2011) (Box 50-5). Assessments are performed at least every 15 minutes or more frequently, depending on the patient's condition and unit policy. This assessment usually continues until discharge from the PACU. Perform assessments quickly and thoroughly and target them to the patient's unique needs and type of surgery. In the PACU, nursing interventions focus on monitoring and maintaining airway, respiratory, circulatory, and neurological status and managing pain.

Evaluate a patient's status and eventual readiness for discharge from the PACU on the basis of vital sign stability compared with the preoperative data. Other outcomes for discharge include body temperature control, good ventilatory function and oxygenation status, orientation to surroundings, absence of complications, minimal pain and nausea, controlled wound drainage, adequate urine output, and fluid and electrolyte balance. Patients with more extensive surgery requiring anesthesia of longer duration usually recover more slowly. The Aldrete score is an objective scoring system that helps identify when patients are ready for discharge (Aldrete and Kroulik, 1970). The Aldrete score or the **postanesthesia recovery score (PARS)** is the most widely used scoring tool (Table 50-7). The criteria are assessed on admission; at 5, 15, 30, 45, and 60 minutes; and on discharge from the PACU. The patient must receive a composite score of 8 to 10 before discharge from the PACU (Aldrete, 1998). If the patient's condition is still poor after 2 to 3 hours, the stay lengthens, or the surgeon transfers the patient to an intensive care unit (ICU).

When the patient is discharged from the PACU, another hand-off communication occurs between the PACU nurse and the nurse on the acute nursing unit at the patient's bedside. The nurses verify the patient's identification using two identifiers and the type of surgery performed. The hand-off includes review of vital signs, the type of surgery and anesthesia performed; blood loss; level of consciousness; general physical condition; and presence of IV lines, drainage tubes, and dressings. The PACU nurse's report helps the nurse on the acute nursing unit anticipate special patient needs and obtain necessary equipment. It is important to have uninterrupted time to review the recent pertinent events and ask questions. It is also important at this time for patient's family members to be informed as soon as possible of the patient's transfer plan (AORN, 2011).

The OR staff transport the patient on a stretcher to the nursing unit. Staff members from the unit assist in safely transferring the patient to a bed (see Chapter 38). If the PACU nurse is helping to transport the patient, he or she shows the acute care nurse the recovery room record and reviews the patient's condition and course of care. The PACU nurse also reviews the surgeon's orders that require attention. *Before the PACU nurse leaves the acute care area, the staff nurse assuming care for the patient takes a complete set of vital signs to compare with PACU findings.* Minor vital sign variations normally occur after transporting the patient.

RECOVERY IN AMBULATORY SURGERY (PHASE II)

The thoroughness and extent of postoperative recovery depends on the ambulatory patient's condition, type of surgery, and anesthesia. In some cases the patient goes through both phase I (PACU) and phase II recovery. Assess and care for patients in need of close monitoring in the same fashion as inpatients in phase I. Using the PARS, a score of 8 to 10 determines discharge from the PACU. After patients stabilize and no longer require close monitoring, transfer them to phase II recovery. With new anesthetic agents and techniques, known as *fast-track anesthesia,* patients experience a more rapid awakening in the OR and a quicker recovery (Kranke et al., 2008). Therefore many ambulatory surgery patients are able to bypass phase I.

Phase II recovery consists of a room equipped with medical recliner chairs, side tables, and foot rests. Kitchen facilities for preparing light snacks and beverages are usually located in the area,

TABLE 50-8 Expanded Postanesthetic Recovery Score for Ambulatory Patients Assessed at 0, 5, 10, 15, 30, 45, and 60 minutes

INDICES	TASK	SCORE
Activity	Able to move four extremities voluntarily or on command	2
	Able to move two extremities voluntarily or on command	1
	Unable to move extremities voluntarily or on command	0
Respiration	Able to breathe deeply and cough freely	2
	Dyspnea, limited breathing, or tachypnea	1
	Apneic or on mechanical ventilator	0
Circulation	BP 20% of preanesthetic level	2
	BP 20%-49% of preanesthetic level	1
	BP 50% of preanesthetic level	0
Consciousness	Fully awake	2
	Arousable on calling	1
	Not responding	0
O_2 saturation	Able to maintain O_2 saturation >92% on room air	2
	Needs O_2 inhalation to maintain O_2 saturation >92%	1
	O_2 saturation <90% even with O_2 supplement	0
Dressing	Dry and clean	2
	Wet but marked and not increasing	1
	Growing area of wetness	0
Pain	Pain free	2
	Mild pain handled by oral medication	1
	Severe pain requiring parenteral medication	0
Ambulation	Able to stand up and walk straight*	2
	Vertigo when erect	1
	Dizziness when supine	0
Fasting-feeding	Able to drink fluids	2
	Nauseated	1
	Nausea and vomiting	0
Urine output	Has voided	2
	Unable to void but comfortable	1
	Unable to void and uncomfortable	0
TOTALS	**Possible score range 0-20**	

Modified from Aldrete JA: Modifications to the post anesthesia score for use in ambulatory surgery, *J Perianesth Nurs* 13(3):148, 1998; and Aldrete JA, Kroulik D: A post-anesthetic recovery score, *Anesth Analg* 49:924, 1970.
NOTE: Total score must be at least 18 for patient to be discharged to home; lower score allowed if patient unable to walk or move extremities before surgery.
BP, Blood pressure; *O_2,* oxygen.
*May be substituted by Romberg's test, or picking up 12 paper clips in one hand.

along with bathrooms. Aldrete (1998) has added five more areas of functional assessment for the ambulatory surgery patient, which constitute the **postanesthesia recovery score for ambulatory patients (PARSAP)** (Table 50-8). The PARSAP is performed at the same time intervals as the PARS. The phase II environment promotes the patient's and family's comfort and well-being until discharge. Monitor patients but not at the same intensity as during phase I. In phase II recovery initiate postoperative teaching with patients and family members (Box 50-6).

BOX 50-6 PATIENT TEACHING

Postoperative Instructions for an Ambulatory Surgical Patient

Objective
- Patient will describe signs and symptoms of postoperative problems to report to health care provider.

Teaching Strategies
- Give instruction sheet with contact information, including health care provider's telephone number, surgery center's number, and follow-up appointment date and time. Allow patient and family to ask questions.
- Explain to family member the signs and symptoms of infection for which to observe.
- Explain name, dose, schedule, and purpose of medications and possible side effects. Provide drug information leaflets.
- Explain activity restrictions, diet progression, wound care guidelines, and the signs of any associated problems. Provide instruction sheet with clear, focused explanations.

Evaluation
- Have patient explain when and how to call health care provider with problems.
- Have patient recite date for follow-up appointment.
- Have patient and family member describe signs and symptoms of infection.
- Have patient verbalize name of drug, dose, when to take, and common side effects.
- Have patient demonstrate proper activity/movement and wound care.

Patients are discharged to home following ambulatory surgery when they meet certain criteria. When you are using the PARSAP, the patient must achieve a score of 18 or higher before being discharged. An exception is allowed if the patient was unable to walk or use extremities before surgery (Aldrete, 1998). Patients with known OSA or at high risk are not discharged from the recovery area to home until they are no longer at risk for postoperative respiratory depression, which may require a longer stay (ASA, 2006). Postoperative nausea and vomiting sometimes occur once the patient is home, even if the symptoms were not present in the surgery center. Options for therapy include the prophylactic use of the drug ondansetron (Zofran) (an orally disintegrating tablet), transcutaneous accupoint electrical stimulation, or a transdermal scopolamine patch (McCaffrey, 2007).

Review written postoperative instructions and prescriptions with the patient and family before releasing the patient and ensure that they verbalize understanding of these instructions. Always discharge the patient to a responsible adult.

POSTOPERATIVE CONVALESCENCE

Inpatients remain in the PACU until their condition stabilizes; they then return to the postoperative nursing unit. Nursing care focuses on returning the patient to a relatively functional level of wellness as soon as possible. The speed of convalescence depends on the type or extent of surgery, risk factors, pain management, and postoperative complications.

NURSING PROCESS

Once a surgical patient is transferred to an acute care nursing unit, ongoing postoperative care is essential to support recovery. Apply the nursing process and use a critical thinking approach in your care of patients.

ASSESSMENT

To assess a patient's postoperative condition, apply critical thinking while relying on information from the preoperative nursing assessment, knowledge regarding the surgical procedure performed, and events occurring during surgery. Critically analyze findings to detect any changes and make clinical decisions about the patient's care. A variation from the patient's norm may indicate the onset of surgically related complications.

Before the patient arrives on the nursing unit, prepare the bed and room for his or her return if he or she is returning to the same nursing unit. You are better prepared to care for the patient after surgery if the room is readied before the patient's return. A postoperative bedside unit should include the following:

1. Sphygmomanometer and/or automated noninvasive blood pressure monitor, stethoscope, and thermometer
2. Emesis basin
3. Clean gown
4. Washcloth, towel, and facial tissues
5. IV pole and infusion pump (if needed)
6. Suction equipment (if needed)
7. Oxygen equipment and oximetry monitor (if needed)
8. Extra pillows for positioning the patient comfortably
9. Bed pads to protect bed linen from drainage
10. Bed raised to stretcher height with bed linens pulled back and furniture moved to accommodate the stretcher and equipment (such as IV lines)

When the patient arrives on the acute care unit, monitor vital signs according to institution policy. Generally he or she is monitored every 15 minutes twice, every 30 minutes twice, hourly for 2 hours, and then every 4 hours or per orders. As the patient's condition stabilizes, he or she usually is monitored once a shift until discharge. Always base the frequency of assessment on the patient's current condition. *Do not assume that further monitoring is unnecessary if the patient appears normal during the initial assessment.* A patient's condition can change rapidly, especially during the postoperative period.

Thoroughly document the assessment, including vital signs, level of consciousness, airway status, condition of dressings and drains, comfort level, IV fluid status, and urinary output measurements. Enter patient data into the medical record on flow sheets, a computerized patient record, or written progress notes. The initial findings provide a baseline for comparing postoperative changes.

Through the Patient's Eyes. When a patient initially returns to the acute care nursing unit, the family and patient have expectations of the patient receiving prompt and attentive care. There is also the expectation that a nurse will explain the patient's immediate status and the plan of care for the next few hours. Seeing the patient return from surgery is a relief in many ways; but, if the patient has had complications or is not responding well, anxiety can easily return. As the patient stabilizes it is important to assess the patient's and family's expectations for recovery and the patient's convalescence once he or she returns home. What do they expect from staff during convalescence? Have you reviewed their expectations for the control of pain and other symptoms? Are family members prepared to assume care at discharge? Make the patient and family partners in your assessment so you can gather information necessary to develop a relevant plan of care. For example, determine the patient's and family's values and beliefs as they pertain to the meaning of the surgical condition and how it will affect the patient's ability to reassume his or her role in the family.

Airway and Respiration. Certain anesthetic agents cause respiratory depression. Thus be alert for shallow, slow breathing and a weak cough. Assess airway patency, respiratory rate, rhythm, depth of ventilation, symmetry of chest wall movement, breath sounds, and color of mucous membranes. If breathing is unusually shallow, place your hand near the patient's nose or mouth to feel exhaled air. Normal pulse oximetry values range between 92% and 100% saturation. Postoperative confusion is frequently secondary to hypoxia, especially in older adults.

An oral or nasal airway (see Chapter 40) may be inserted in the OR or PACU after removal of the endotracheal tube. It maintains a patent airway until patients can protect their airway. As patients awaken, they spit out the airway, or the nurse asks them to spit it out. The ability to do so signifies the return of a normal gag reflex.

One of your greatest concerns is airway obstruction. A number of factors contribute to obstruction, including history of OSA; weak pharyngeal/laryngeal muscle tone from anesthetics; secretions in the pharynx, bronchial tree, or trachea; and laryngeal or subglottic edema. In the postanesthetic patient the tongue causes the majority of airway obstructions. Ongoing assessment of airway patency is crucial. Patients remain in a side-lying position until airways are clear. Continue to assess respiratory status and breath sounds. Older patients, smokers, and patients with a history of respiratory disease are prone to developing complications such as atelectasis or pneumonia. Patients with OSA are often required to have continuous pulse oximetry while receiving IV opioids to detect oxygen desaturation quickly. Also assess the patient for any signs of shortness of breath or difficulty with endurance.

Circulation. The patient is at risk for cardiovascular complications resulting from actual or potential blood loss from the surgical site, side effects of anesthesia, electrolyte imbalances, and depression of normal circulatory-regulating mechanisms and ischemia. Careful assessment of heart rate and rhythm, along with blood pressure, reveals the patient's cardiovascular status. Compare preoperative vital signs with postoperative values. If the patient's blood pressure drops progressively with each check or if the heart rate changes or becomes irregular, notify the health care provider. A rhythm strip of the heart is obtained after surgery, compared with preoperative ECG tracings, and placed in the chart.

Assess circulatory perfusion by noting capillary refill, pulses, and the color and temperature of the nail beds and skin. If the patient has had vascular surgery or has casts or constricting devices that may impair circulation, assess peripheral pulses and capillary refill distal to the site of surgery. For example, after surgery to the femoral artery, assess posterior tibial and dorsalis pedis pulses. In addition, compare pulses in the affected extremity with those in the nonaffected extremity.

A common early circulatory problem is bleeding or hemorrhage. Blood loss may occur externally through a drain or incision or internally. Either type of hemorrhage results in a fall in blood pressure; elevated heart and respiratory rates; thready pulse; cool, clammy, pale skin; and restlessness. Notify the surgeon if these changes occur. Maintain IV fluid infusion. Monitor the patient's vital signs every 15 minutes or more frequently until the patient's condition stabilizes. Continue oxygen therapy. The surgeon may

consider medications or volume replacement and order blood counts and coagulation studies.

Temperature Control. The OR and recovery room environments are extremely cool. The patient's anesthetically depressed level of body function results in a lowering of metabolism and fall in body temperature. When patients begin to awaken more fully, they complain of feeling cold and uncomfortable. Older adults and pediatric patients are at higher risk for developing problems associated with hypothermia. The use of forced-air warming units in the PACU is helpful in increasing patient comfort and rewarming the patient.

In rare instances a genetic disorder known as **malignant hyperthermia,** a life-threatening complication of anesthesia, develops. Malignant hyperthermia causes hypercarbia (elevated carbon dioxide), tachypnea, tachycardia, premature ventricular contractions (PVCs), unstable blood pressure, cyanosis, skin mottling, and muscular rigidity. Despite the name, an elevated temperature occurs late. The increased expired carbon dioxide is one of the first signs. Although it often occurs during the induction phase of anesthesia, symptoms can occur after surgery or with repeated exposures to anesthesia (Rothrock, 2007). Without prompt detection and treatment, it is potentially fatal.

Monitor temperature closely in the acute care area. Because an elevated temperature may be the first indication of an infection, assess the patient for a potential source of infection, including the IV site (if present), the surgical incision/wound, and the respiratory and urinary tracts. Notify the health care provider because further evaluation is often necessary.

Fluid and Electrolyte Balance. Because of the surgical patient's risk for fluid and electrolyte abnormalities, assess the hydration status and monitor for signs of electrolyte alterations (see Chapter 41). Monitor and compare laboratory values with the patient's baseline. An important responsibility of the nurse is maintaining patency of IV infusions. The patient's only source of fluid intake immediately after surgery is through IV catheters. Inspect the patient's catheter insertion site to ensure that the catheter is properly positioned within a vein, fluid flows freely, and the site is free of phlebitis or infiltration. Accurate recording of I&O assesses renal and circulatory function. Measure all sources of output, including urine, surgically placed drains, gastric drainage, and wound drainage; note any insensible loss from diaphoresis. Assess daily weight for the first several days after surgery and compare with the preoperative weight. If the patient has a known cardiac history such as heart failure, continue daily weights. It is important to use a consistent scale, amount of clothing, and time of day to obtain accurate weight measurement.

Neurological Functions. In the PACU the patient is often drowsy. As anesthetic agents begin to metabolize, his or her reflexes return, muscle strength is regained, and a normal level of orientation returns. Continue monitoring neurological status on the nursing unit. Ensure that the patient is oriented to self and the hospital and responds to questions appropriately. Assess pupil and gag reflexes, hand grips, and movement of extremities (see Chapter 30). If a patient had surgery involving a portion of the neurological system, conduct a more thorough neurological assessment. For example, if the patient had low back surgery, assess leg movement, sensation, and strength.

Patients with regional anesthesia begin to experience a return in motor function before tactile sensation returns. Check the patient's sensation to touch (see Chapter 30). Knowing where regional anesthesia was introduced helps you check the distribution of the spinal nerves affected. Typically assess sensation by touching the patient bilaterally in the same area (e.g., lower arm on both sides or leg on both sides) and note where the patient feels touch. Test the sense of touch using hand pressure or a gentle pinch of the skin. Extremity strength assessment continues to be important if spinal or epidural anesthesia has been given. However, patients remain in the PACU until sensation and voluntary movement of the lower extremities are reestablished.

Skin Integrity and Condition of the Wound. During recovery and acute postoperative care, assess the condition of the skin, noting pressure areas, rashes, petechiae, abrasions, or burns. A rash often indicates a drug sensitivity or allergy. Abrasions or petechiae may result from a clotting disorder or inappropriate positioning or restraining that injures skin layers. Burns may indicate that an electrical cautery grounding pad was incorrectly placed on the patient's skin. Use an occurrence or adverse event report to document burns or serious injury to the skin according to agency policy (see Chapter 23). Note if the patient is complaining of any burning or pain in the eye that could indicate a corneal abrasion.

After surgery most surgical wounds have dressings that protect the wound site and collect drainage. Observe the amount, color, odor, and consistency of drainage on dressings. It is most common to see serosanguineous drainage immediately after surgery. Estimate the amount of drainage by noting the number of saturated gauze sponges. If drainage appears on the outer surface of a dressing, another way of assessing it is marking the outer perimeter of the drainage with tape or marking it and dating with the time noted. This way you can easily note if drainage is increasing (see Chapter 48). However, this is not the most accurate measure of volume of fluid lost. Reinforce the dressing as needed and call the surgeon if wound drainage is leaking through the dressing.

Many surgeons prefer to change surgical dressings the first time so they can inspect the incisional area. You have the opportunity on the acute care nursing unit to view and thoroughly assess and document the status of the incision/wound at the time of this initial dressing change. Assess if wound edges are approximated and whether there is presence of bleeding or drainage. It is also important to assess the patient's mobility level. If he or she is unable or unwilling to turn, pressure ulcer development is a concern. Institute the use of the Braden scale or another assessment tool to determine the patient's risk of developing pressure ulcers. Institute preventive measures such as a turning schedule and pressure-reduction devices (see Chapter 48).

Metabolism. Researchers have studied glucose control in the postoperative period over the past decade. Normoglycemia or glucose level less than 150 mg/dL in postsurgical patients, while being careful to avoid hypoglycemia, is now recommended as an evidenced-based practice (Lipshutz and Gropper, 2009). Nurses should monitor patient blood glucose levels routinely based on surgeon order or hospital policy.

Genitourinary Function. Depending on the surgery, some patients do not regain voluntary control over urinary function for 6 to 8 hours after anesthesia. An epidural or spinal anesthetic often prevents the patient from feeling bladder fullness. Palpate the lower abdomen just above the symphysis pubis for bladder distention. Another option is to use a bladder scan to assess bladder volume. If the patient has a urinary catheter, there should be a continuous flow of urine of 30 to 50 mL/hr in adults. Observe the color and odor of urine. Surgery involving portions of the urinary tract normally causes bloody urine for at least 12 to 24 hours, depending on the type of surgery.

Gastrointestinal Function. Anesthetics slow GI motility and often cause nausea. Normally during the immediate recovery

phase, faint or absent bowel sounds are auscultated in all four quadrants. Inspect the abdomen for distention that may be caused by accumulation of gas. In a patient who has had abdominal surgery, distention develops if internal bleeding occurs; however, this is a late sign of bleeding. Distention also occurs in the patient who develops a **paralytic ileus** (a nonmechanical obstruction caused by lack of intestinal peristalsis) from handling of the bowel in surgery.

In acute care closely monitor the patient's initial oral intake for potential aspiration or the presence of nausea and vomiting. Madsen et al. (2005) implemented a postoperative evidence-based practice project for assessment of bowel function return in patients having abdominal surgery. They found that assessing for the return of flatus and the first postoperative bowel movement as signs of returning bowel function were superior to bowel sound auscultation assessment. Other guidelines may be needed for other types of surgery. If an NG tube is in place, assess the patency of the tube (see Chapter 46) and the color and amount of gastric drainage.

Comfort. As patients awaken from general anesthesia, the sensation of pain becomes prominent. They perceive pain before regaining full consciousness. Acute incisional pain causes them to become restless and may be responsible for temporary changes in vital signs. It is difficult for patients to begin coughing and deep-breathing exercises when they experience pain. The patient who had regional or local anesthesia usually does not experience pain initially because the incisional area is still anesthetized. Ongoing assessment of the patient's discomfort and evaluation of pain-relief therapies are essential throughout the postoperative course. Pain scales are effective for assessing postoperative pain, evaluating the response to analgesics, and objectively documenting pain severity (see Chapter 43). Using preoperative pain assessments as a baseline, evaluate the effectiveness of interventions throughout the patient's recovery.

NURSING DIAGNOSIS

Determine the status of preoperative nursing diagnoses by clustering new postoperative assessment data. Then either revise or resolve preoperative diagnoses and identify relevant new diagnoses after surgery. A previously defined diagnosis such as *impaired skin integrity* may continue as a postoperative problem, particularly if your assessment reveals continued risks such as reduced mobility or excess diaphoresis. It is common to identify new nursing diagnoses after surgery because of the risks or problems associated with surgery. Also consider the assessed needs of a patient's family when you identify nursing diagnoses. In the formulation of nursing diagnoses, be accurate in identifying the related factor. For example, *impaired physical mobility related to reduced lower extremity strength* compared with *impaired physical mobility related to exercise intolerance* requires different nursing interventions. Potential nursing diagnoses for the postoperative patient include the following:

- Ineffective airway clearance
- Anxiety
- Fear
- Risk for infection
- Deficient knowledge (specify)
- Impaired physical mobility
- Nausea
- Acute pain
- Delayed surgical recovery

PLANNING

During the convalescent phase use current physical assessment data and analysis of the preoperative nursing history to plan the patient's care. The surgeon's postoperative orders and surgical team's report of the patient's operative condition also provide valuable data. Typical postoperative orders include:

- Frequency of vital sign monitoring and special assessments.
- Types of IV fluids and rates of infusion.
- Postoperative medications (especially those for pain and nausea).
- Resumption of preoperative medications as condition allows (some oral medications are converted to the IV route with appropriate dose adjustment).
- Fluids and food allowed by mouth.
- Level of activity that the patient is allowed to resume.
- Position that the patient is to maintain while in bed.
- I&O and daily weights.
- Laboratory tests and x-ray film studies.
- Special directions (e.g., surgical drains to suction, tube irrigations, dressing changes).

Goals and Outcomes. Review nursing diagnoses when establishing goals, expected outcomes, and interventions for the individual patient. Measurable outcomes provide specific guidelines for determining a patent's progress toward recovery from surgery. For example, a patient recovering from hip replacement surgery with the diagnosis of *impaired physical mobility related to pain and lower-extremity weakness* has specific outcomes selected that include targeted ambulation (e.g., steps to take and distance down hallway), pain relief, and improved range of joint movement. After meeting each outcome, the patient ultimately achieves the goal of independent ambulation at a preoperative level or better. At times goals and outcomes must extend from the convalescence period into the home setting. Also consider all goals of care established during the preoperative surgical phase that are still relevant. For example, a goal for the diagnosis of *risk for infection* would be "Patient remains free of infection after surgery." Expected outcomes for this goal would include:

- Patient's incision remains closed and intact.
- Patient's incision remains free of infectious drainage.
- Patient remains afebrile.

Setting Priorities. During the convalescent phase of recovery from general anesthesia, priorities for the first 24 hours continue to include maintenance of respiratory, circulatory, and neurological status and pain control. In addition, most surgeons are aggressive in increasing the patient's activity as soon as possible. As the patient progresses, focus priorities on advancement of patient activity (e.g., mobility, diet tolerance) to return the patient to preoperative functioning or better. The patient generally has multiple nursing diagnoses (Fig. 50-4). Reestablish priorities, often quickly, as the status of the patient's health problems change.

Teamwork and Collaboration. During recovery collaborate on the plan of care with respiratory therapy, physical therapy, occupational therapy, dietary, social work, home care, and others. Include family members as much as possible, especially if they will be assuming care responsibilities in the home. The goal of an interdisciplinary approach to care is to help the patient return to the best possible level of functioning with a smooth transition to home, rehabilitation, or long-term care. Acute care settings often have a nurse or social worker in a case manager role to coordinate interdisciplinary care so the most appropriate resources are available to patients.

IMPLEMENTATION

Acute Care. Primary causes for postoperative complications include impaired healing of the surgical wound, the effects of prolonged immobilization during surgery and convalescence, and the influence of anesthesia and analgesics. If a patient has surgical risks before surgery (e.g., increased age [Box 50-7], history of smoking, history of diabetes), the likelihood of complications is greater. Direct your postoperative nursing interventions at preventing complications so the patient returns to the highest level of functioning possible. Failure of the patient to become actively involved in recovery adds to the risk of complications (Table 50-9). Virtually any body system can be affected. Consider the interrelationship of all systems and therapies provided.

Maintaining Respiratory Function. To prevent respiratory complications begin pulmonary interventions early. The benefits of thorough preoperative teaching are reached when patients are able to participate actively in postoperative exercises. When patients awaken from anesthesia, help them maintain a patent airway. Position the patient on one side with the face downward and the neck slightly extended to facilitate a forward movement of the tongue and the flow of mucus secretions out of the mouth. A small folded towel supports the head. Another positioning technique to promote a patent airway involves elevating the head of the bed slightly and extending the patient's neck slightly, with the head turned to the side. In the PACU you sometimes need to perform a jaw thrust maneuver and/or chin lift continuously to maintain the patient's airway. Never position the patient with arms over or across the chest because this reduces maximum chest expansion.

Place patients with known OSA or at risk for OSA in the lateral, prone, or upright position throughout the perioperative period, never the supine position (ASA, 2006). Suction artificial airways and the oral cavity for mucus secretions (see Chapter 40). Avoid continually eliciting the gag reflex, which might cause vomiting.

BOX 50-7 FOCUS ON OLDER ADULTS

The Older-Adult Surgical Patient: Concerns and Nursing Interventions

- Age alone is no longer a factor for determining the benefit that an individual can achieve from a surgical procedure. Consequently nurses are caring for many more surgical patients of advanced age and are required to know the age-related factors that affect a surgical procedure (Eliopoulos, 2005; Turrentine et al., 2006).
- A smaller margin of physiological reserve makes the older adult less able to compensate during the perioperative period for changes that occur as a result of infection, hemorrhage, alterations in blood pressure, and fluid/electrolyte abnormalities. Ongoing, focused assessments are necessary.
- Older patients are at greater risk for postoperative delirium associated with an acute onset. Reduced level of consciousness, reduced ability to maintain attention, perceptual disturbances, and memory impairment characterize the typical presentation (Meiner, 2011).
- Implement individualized measures to help the older-adult surgical patient achieve rest, sleep, and orientation in the postoperative period to reduce the risk of delirium development.
- Altered and unexpected drug responses are often related to different pharmacokinetics in the older adult. Thus the nurse caring for the perioperative older patient needs to be alert to the possibility of a high risk for adverse medication events with the administration of anesthetic agents and postoperative analgesics, especially narcotics (Meiner, 2011). "Start low and go slow" is the guiding principle when medicating older adults because of their slow drug-clearance capability.

Data from Eliopoulos C: *Gerontologic nursing,* ed 6, Philadelphia, 2006, Lippincott; and Meiner SE: *Gerontologic nursing,* ed 4, St Louis, 2011, Mosby.

Before you remove an artificial airway (or the patient removes it), suction the back of the airway so secretions are not retained.

The following measures promote expansion of the lungs:

- Encourage diaphragmatic breathing exercises every hour while patients are awake.
- Administer CPAP or NIPPV to patients who use this modality at home (ASA, 2006).
- Instruct patients to use an incentive spirometer for maximum inspiration. The patient should try to reach the inspiratory target volume achieved before surgery on the spirometer.
- Encourage early ambulation. Walking causes patients to assume a position that does not restrict chest wall expansion and stimulates an increased respiratory rate.
- Help patients who are restricted to bed to turn on their side every 1 to 2 hours while awake and to sit when possible.
- Keep the patient comfortable. A patient who is comfortable is able to participate in deep breathing and coughing. Administer analgesics on time so pain does not become severe.

The following measures promote removal of pulmonary secretions if they are present:

- Encourage coughing exercises every 1 to 2 hours while patients are awake and maintain pain control to promote a deep, productive cough. *For patients who have had eye, intracranial, or spinal surgery, coughing may be contraindicated because of the potential increase in intraocular or intracranial pressure.*

TABLE 50-9 Postoperative Complications

COMPLICATION	CAUSE
Respiratory System	
Atelectasis: Collapse of alveoli with retained mucus secretions. Signs and symptoms include elevated respiratory rate, dyspnea, fever, crackles auscultated over involved lobes of lungs, and productive cough.	Inadequate lung expansion. Anesthesia, analgesia, and immobilized position prevent full lung expansion. There is greater risk in patients with upper abdominal surgery who have pain during inspiration and repress deep breathing.
Pneumonia: Inflammation of alveoli. It may involve one or several lobes of lung. Development in lower dependent lobes of lung is common in immobilized surgical patient. Signs and symptoms include fever, chills, productive cough, chest pain, purulent mucus, and dyspnea.	Poor lung expansion with retained secretions or aspirated secretions. Common resident bacterium in respiratory tract is *Diplococcus pneumoniae,* which causes most cases of pneumonia.
Hypoxemia: Inadequate concentration of oxygen in arterial blood. Signs and symptoms include restlessness, confusion, dyspnea, high or low blood pressure, tachycardia or bradycardia, diaphoresis, and cyanosis.	Anesthetics and analgesics depress respirations. Increased retention of mucus with impaired ventilation occurs because of pain or poor positioning. Patients with OSA are at increased risk for hypoxemia.
Pulmonary embolism: Embolus blocking pulmonary arterial blood flow to one or more lobes of lung. Signs and symptoms include dyspnea, sudden chest pain, cyanosis, tachycardia, and drop in blood pressure.	Same factors lead to formation of thrombus or embolus. Immobilized surgical patient with preexisting circulatory or coagulation disorders is at risk.
Circulatory System	
Hemorrhage: Loss of large amount of blood externally or internally in short period of time. Signs and symptoms include hypotension, weak and rapid pulse, cool and clammy skin, rapid breathing, restlessness, and reduced urine output.	Slipping of suture or dislodged clot at incisional site. Patients with coagulation disorders are at greater risk.
Hypovolemic shock: Inadequate perfusion of tissues and cells from loss of circulatory fluid volume. Signs and symptoms are same as for hemorrhage.	In surgical patient hemorrhage usually causes hypovolemic shock.
Thrombophlebitis: Inflammation of vein often accompanied by clot formation. Veins in legs are most commonly affected. Signs and symptoms include swelling and inflammation of involved site and aching or cramping pain. Vein feels hard, cordlike, and sensitive to touch.	Prolonged sitting or immobilization aggravates venous stasis. Trauma to vessel wall and hypercoagulability of blood increase risk of vessel inflammation.

Continued

TABLE 50-9 **Postoperative Complications—cont'd**

COMPLICATION	CAUSE
Circulatory System—cont'd	
Thrombus: Formation of clot attached to interior wall of a vein or artery, which can occlude the vessel lumen. Symptoms include localized tenderness along distribution of the venous system, swollen calf or thigh, calf swelling >3 cm (1.2 in) compared to asymptomatic leg, pitting edema in symptomatic leg, and decrease in pulse below location of thrombus (if arterial).	Venous stasis (see discussion of thrombophlebitis) and vessel trauma. Venous injury is common after surgery of hips and legs, abdomen, pelvis, and major vessels. Patients with pelvic and abdominal cancer or traumatic injuries to the pelvis or lower extremities are at high risk for thrombus formation.
Embolus: Piece of thrombus that has dislodged and circulates in bloodstream until it lodges in another vessel (commonly lungs, heart, brain, or mesentery).	Thrombi form from increased coagulability of blood (e.g., polycythemia and use of birth control pills containing estrogen).
Gastrointestinal System	
Paralytic ileus: Nonmechanical obstruction of the bowel caused by physiological, neurogenic, or chemical imbalance associated with decreased peristalsis. Common in initial hours after abdominal surgery.	Handling of intestines during surgery leads to loss of peristalsis for a few hours to several days.
Abdominal distention: Retention of air within intestines and abdominal cavity during gastrointestinal surgery. Signs and symptoms include increased abdominal girth, patient complaints of fullness, and "gas pains."	Slowed peristalsis from anesthesia, bowel manipulation, or immobilization. During laparoscopic surgeries influx of air for procedure causes distention and pain up to shoulders.
Nausea and vomiting: Symptoms of improper gastric emptying or chemical stimulation of vomiting center. Patient complains of gagging or feeling full or sick to stomach.	Abdominal distention, fear, severe pain, medications, eating or drinking before peristalsis returns, and initiation of gag reflex.
Genitourinary System	
Urinary retention: Involuntary accumulation of urine in bladder as result of loss of muscle tone. Signs and symptoms include inability to void, restlessness, and bladder distention. It appears 6-8 hours after surgery.	Effects of anesthesia and narcotic analgesics. Local manipulation of tissues surrounding bladder and edema interfere with bladder tone. Poor positioning of patient impairs voiding reflexes.
Urinary tract infection: An infection of the urinary tract as a result of bacterial or yeast contamination. Signs and symptoms include dysuria, itching, abdominal pain, possible fever, cloudy urine, presence of WBCs and leukocyte esterase positive on urinalysis.	Most frequently a result of catheterization of the bladder.
Integumentary System	
Wound infection: An invasion of deep or superficial wound tissues by pathogenic microorganisms; signs and symptoms include warm, red, and tender skin around incision; fever and chills; purulent material exiting from drains or from separated wound edges. Infection usually appears 3-6 days after surgery.	Infection is caused by poor aseptic technique or contaminated wound or surgical site before surgical exploration. For example, with a bowel perforation the patient is at increased risk for a wound infection because of bacterial contamination from the large intestine.
Wound dehiscence: Separation of wound edges at suture line. Signs and symptoms include increased drainage and appearance of underlying tissues. This usually occurs 6-8 days after surgery.	Malnutrition, obesity, preoperative radiation to surgical site, old age, poor circulation to tissues, and unusual strain on suture line from coughing or positioning cause dehiscence.
Wound evisceration: Protrusion of internal organs and tissues through incision. Incidence usually occurs 6-8 days after surgery.	See discussion of wound dehiscence. Patient with dehiscence is at risk for developing evisceration.
Skin breakdown: Result of pressure or shearing forces. Surgical patients are at increased risk if alterations in nutrition and circulation are present, resulting in edema and delayed healing.	Prolonged periods on the OR table and in the bed after surgery lead to pressure breakdown. Skin breakdown results from shearing during positioning on the OR table and improperly pulling patient up in bed.
Nervous System	
Intractable pain: Pain that is not amenable to analgesics and pain-alleviating interventions.	Intractable pain may be related to the wound or dressing, anxiety, or positioning.
Malignant hyperthermia: Severe hypermetabolic state and rigidity of the skeletal muscles caused by an increase in intracellular calcium ion concentration.	Rare genetic condition triggered with exposure to inhaled anesthetic agents and the depolarizing muscle relaxant succinylcholine.

OR, Operating room; *OSA,* obstructive sleep apnea; *WBCs,* white blood cells.

- Provide oral hygiene to facilitate expectoration of mucus. The oral mucosa becomes dry when patients are NPO or placed on limited fluid intake.
- Initiate orotracheal or nasotracheal suction for patients who are too weak or unable to cough (see Chapter 40).
- Administer oxygen as ordered and monitor oxygen saturation with a pulse oximeter. Continue monitoring oxygen saturations after discharge from the PACU for patients at risk for respiratory compromise from OSA (ASA, 2006). Administer oxygen to patients at risk for or diagnosed with OSA until they are able to maintain their baseline oxygen saturation while breathing room air.

Preventing Circulatory Complications. Measures for preventing circulatory complications avert venous stasis and thrombus formation (Box 50-8). Some patients are at greater risk of venous stasis because of the nature of their surgery or medical history. The following measures promote normal venous return and circulatory blood flow:

- Encourage patients to perform leg exercises at least every hour while awake. Exercise may be contraindicated in an

BOX 50-8 EVIDENCE-BASED PRACTICE

Prevention of Venous Thromboembolism in the Postsurgical Patient

PICO Question: Is mechanical prophylaxis compared with pharmacological prophylaxis the best method to prevent a venous thromboembolism (VTE) in the postsurgical patient?

Evidence Summary

According to the American College of Chest Physicians (ACCP) (Geerts et al, 2008), VTE is a high-risk concern for almost all hospitalized patients and a significant cause of increased hospital morbidity and mortality. It is the second most common complication in patients discharged from acute care hospitals in the United States. Patients have been identified as having higher risk for development of VTE based on varying factors. These risks have been stratified based on surgical procedure (minor, major), age (<40, 40-60, >60) and the presence of risk factors such as cancer or previous VTE (Geerts et al., 2004). Many screening tools are available to perform formal risk assessments on patients, but compliance is often low. Most centers use a simplified risk assessment to determine the method of thromboprophylaxis that increases compliance with prevention strategies.

Mechanical and pharmacological types of prophylaxis are available. Mechanical prevention includes early ambulation, graded compression stockings, intermittent pneumatic compression devices, or venous foot pumps. Mechanical methods are recommended for patients at high risk of bleeding and also in conjunction with pharmacological prevention for high-risk populations. Pharmacological prevention includes administration of low-molecular-weight heparin (LMWH), low-dose unfractionated heparin (LDUH) or fondaparinux (Arixtra). Aspirin alone should not be used for the prevention of VTE. When using LMWH, LDUH or fondaparinux, the target international normalized ratio (INR) should be 2.5 with a range of 2-3, and dosing should be based on renal function and manufacturer recommendations. Certain surgical procedures are associated with increased VTE risk. Patients who have sustained major trauma or spinal cord injury or are undergoing hip or knee arthroplasty or hip fracture surgery are deemed high risk (40%-80%) for VTE. Patients at moderate risk (10%-40% risk) are bed-bound medical patients and patients undergoing most general gynecological and urological surgical procedures. Low-risk patients (<10% risk) include minor surgery on physically mobile patients and active medical patients. Based on the risk of VTE and bleeding, a regimen of either mechanical prophylaxis alone or combined with pharmacological prophylaxis is recommended. Refer to the *ACCP Prevention of VTE Evidence-Based Clinical Practice Guidelines* (Geerts et al., 2008) for more detailed information. General recommendations based on risk are as follows:

- Low risk—Early ambulation, no specific thromboprophylaxis
- Moderate risk—LMWH, LDUH or fondaparinux with mechanical prophylaxis
- High risk—LMWH, fondaparinux, or vitamin K antagonist for prolonged therapy, with an INR goal of 2-3 with mechanical prophylaxis

Application to Nursing Practice

- Level of risk of VTE determines method of prophylaxis prescribed for postsurgical patients.
- Screening methods should be simple and formally applied on all patients.
- Early ambulation and the use of mechanical prophylaxis are recommended in all postsurgical patients.
- Pharmacological prophylaxis should be dosed according to manufacturer suggested dosing guidelines or for a target INR of 2-3. Check all orders carefully.

extremity with a vascular repair or realignment of fractured bones and torn cartilage.

- Apply graded compression stockings or IPC devices as ordered by the health care provider (see Chapter 47). Remove the stockings at least once per shift. Perform a thorough reassessment of the skin of the lower extremities at this time.
- Encourage early ambulation. Most patients ambulate the evening of surgery, depending on the severity of the surgery and their condition. The degree of activity allowed progresses as the patient's condition improves. Encourage ambulation even if a patient has an epidural catheter or PCA device. Before ambulation assess the patient's vital signs. Abnormalities such as hypotension or certain arrhythmias may contraindicate ambulation. If vital signs are at baseline, first help the patient sit on the side of the bed. Patient complaints of dizziness are a sign of postural hypotension. A recheck of blood pressure determines whether ambulation is safe. Assist with ambulation by standing on the patient's strong side and making sure that the patient is able to walk steadily. The first few times out of bed, patients may be able to walk only a few feet. This usually improves each time. Evaluate tolerance to activity by periodically assessing the pulse rate as the patient ambulates and note the rhythm and increase in rate. Know the patient's maximum heart rate achieved during maximum exercise. One simple method to calculate a predicted maximum heart rate is by using this formula (Cleveland Clinic, 2011):

220 – Patient's age = Predicted maximum heart rate

Example: A 60-year-old's predicted maximum heart rate is 160 beats/min. However, remember that a patient's acute surgical condition may not allow him or her to reach this rate. Confer with the patient's surgeon or physical therapist about a safe heart rate target. Always ask patients how they feel during exercise and whether they note chest pain or shortness of breath.

- Avoid positioning patients in a manner that interrupts blood flow to extremities. While in bed, patients should not have pillows or rolled blankets placed under the knees. Compression of the popliteal vessels can cause thrombi. When patients sit in chairs, elevate their legs on footstools. Never allow a patient to sit with one leg crossed over the other.
- Administer anticoagulant drugs as ordered. Patients at greatest risk for thrombus formation often receive prophylactic doses of anticoagulants such as heparin. Patients may also receive aspirin, warfarin (Coumadin), or enoxaparin (Lovenox) for anticoagulation.
- Promote adequate fluid intake orally or intravenously. Adequate hydration prevents concentrated accumulation of formed blood elements such as platelets and red blood cells. When the plasma volume is low, these elements gather and form small clots within blood vessels.

Achieving Rest and Comfort. Pain control is a priority to facilitate a surgical patient's recovery. For example, advances have been made in the use of multimodal analgesia, which combines different drug classes delivered through various routes, including use of local anesthetics alone or in combination with other nerve blocks or techniques such as PCA. The goal is to enhance the efficacy of pain

control while minimizing side effects of each modality (Costantini et al., 2011).

A patient's pain increases following surgery as the effects of anesthesia diminish. The patient becomes more aware of the surroundings and more perceptive of discomfort. The incisional area is only one source of pain. Irritation from drainage tubes, tight dressings, or casts and the muscular strains caused from positioning on the OR table also cause discomfort.

It is common to administer opioid analgesics (e.g., morphine or fentanyl) immediately after surgery. Initial analgesic doses are usually given by IV infusion in the PACU and titrated to patient comfort. After an anesthetized patient is awake and aware, PCA may be used. This is given by IV infusion, subcutaneous infusion, or an epidural catheter. The PCA system allows patients to administer their own IV analgesics from a specially prepared pump (see Chapter 43). If patients gain a sense of control over their pain, they usually have fewer postoperative problems. Many patients receive regional analgesia such as epidural analgesia continuously throughout the recovery period. Research has shown that epidural PCA provided pain relief and outcomes similar to IV patient-controlled morphine in cardiac surgery patients (Hansdottir et al., 2006). Similarly, Gupta et al. (2006) compared epidural analgesia with patient-controlled IV morphine in patients following radical retropubic prostatectomy and found pain scores to be lower in patients who received epidural analgesia. Epidural techniques are especially useful in patients with OSA who are at increased risk of airway compromise and postoperative complications with the use of systemic opioids after surgery (see Chapter 43). Nonsteroidal antiinflammatory agents are another alternative to systemic opioids in patients with OSA (ASA, 2006). You care for patients with a variety of pain-control techniques. Educate the patient and family regarding the technique and expected response.

If the patient has PCA and is trying to use it more frequently than the amount programmed, contact the health care provider to determine if it is appropriate to increase the amount of medication the patient is able to receive. The PCA provides a useful monitor of the effectiveness of pain medication. As oral intake is tolerated, facilitate changing the patient's pain medication from IV or epidural to oral administration. Do not overlook the importance of nonpharmacological interventions. Assess which care routines contribute to pain and use nonpharmacological measures to treat them. An example is to lower the head of the bed and use a pillow for incisional splinting while turning a patient with recent abdominal surgery. Use other methods of promoting pain relief such as positioning, back rubs, distraction, or imagery. Pain slows recovery. The patient becomes reluctant to cough, breathe deeply, turn, ambulate, or perform necessary exercises. Remember, *do not assume that the patient's pain is incisional.* When the patient without PCA or epidural analgesic asks for pain medication, determine the location, intensity, and character of the pain. Provide analgesics as often as allowed, around the clock the first 24 to 48 hours after surgery to improve pain control. If pain medications are not relieving discomfort, notify the health care provider for additional orders. Recognizing potential complications of analgesics and what to do if they occur is also an important role for the postoperative nurse.

Temperature Regulation. Temperature regulation is important after surgery. Patients are often cool after surgery; the PACU nurse provides warmed blankets immediately. If the temperature is 35.6° C (96° F) or below, use forced air or a convective warming device. Increasing body warmth causes the patient's metabolism to rise and circulatory and respiratory functions to improve.

Shivering is not always a sign of hypothermia but rather a side effect of certain anesthetic agents. Clonidine (Catapres) in small increments can decrease shivering as prescribed by the health care provider. Deep breathing and coughing are performed to help to expel retained anesthetic gases.

Malignant hyperthermia is a potentially lethal condition that can occur in patients receiving various inhaled anesthetic agents and succinylcholine. Suspect this when there is unexpected tachycardia and tachypnea; elevated carbon dioxide levels; jaw muscle rigidity; body rigidity of limbs, abdomen, and chest; or hyperkalemia. Temperature elevation is a late sign (Malignant Hyperthermia Association of the United States, 2010). When malignant hyperthermia develops, immediately administer dantrolene sodium ordered by the health care provider.

Surgical patients are at risk for infection for various reasons. If a patient becomes febrile, be aggressive in providing routine postoperative nursing interventions. For example, deep breathing and coughing, early ambulation, prompt removal of indwelling urinary and IV catheters, and aseptic care of the surgical wound decrease the risk of postoperative infections. Obtain wound and or blood cultures from patients suspected of having infections.

Maintaining Neurological Function. Orientation to the environment is important in maintaining the patient's mental status. Reorient the patient, explain that surgery is completed, and describe procedures and nursing measures. The patient who was properly prepared before surgery is less likely to be anxious during the postoperative period. Report any change in level of consciousness to health care providers.

Maintaining Fluid and Electrolyte Balance. An important nursing responsibility is maintaining patency of IV infusions in the postoperative period. The patient's only source of fluid intake immediately after surgery is through IV catheters. The health care provider orders a prescribed rate for each infusion. As the patient begins to take and tolerate oral fluids, the IV rate is decreased. When an ambulatory surgical patient awakens and is able to tolerate fluids by mouth without GI upset, the health care provider orders removal of the IV catheter. When acute care patients no longer need a continuous IV infusion, the IV line may be saline locked to preserve the site for antibiotics or other use (see Chapter 41). Some patients also receive blood products after surgery, depending on blood loss during surgery.

Promoting Normal Bowel Elimination and Adequate Nutrition. Normally a patient who has had general anesthesia does not receive fluids to drink in the PACU because of bowel sluggishness, the risk of nausea and vomiting, and grogginess from general anesthesia. To minimize nausea, avoid suddenly moving the patient. For patients at high risk for the development of nausea and vomiting or those who must not vomit (e.g., eye surgery), a combination of antiemetics is often more effective than a single agent (McCaffrey, 2007). If the patient has an NG tube, keep it patent by irrigating it as ordered (see Chapter 46). Occlusion of an NG tube results in accumulation of gastric contents within the stomach.

The patient likely begins taking ice chips or sips of fluids when arriving on the acute care unit. If these are tolerated, a clear liquid meal is usually ordered. Interventions for preventing GI complications promote return of normal elimination and faster return of normal nutritional intake. It takes several days for a patient who has had surgery on GI structures (e.g., a colon resection) to resume a normal diet. Normal peristalsis often does not return for 2 to 3 days. In contrast, the patient whose GI tract is unaffected directly by surgery can resume dietary intake after recovering from the

effects of anesthesia. The following measures promote return of normal elimination:

- Advance a patient's dietary intake gradually. For the first few hours after surgery he or she receives only IV fluids. Research has shown that the return of flatus and the first postoperative bowel movement are reliable in determining when to begin a normal diet in patients who have undergone abdominal surgery (Madsen, 2005). However, the evidence is limited to one study, and most surgeons rely on the return of flatus or bowel sounds to order a normal diet. Patients usually receive a normal diet the first evening after surgery unless they have undergone surgery on GI structures. Implement diet intake while judging the patient's response. For example, provide clear liquids such as water, apple juice, broth, or tea after nausea subsides. Overloading with large amounts of fluids leads to distention and vomiting. If the patient tolerates liquids without nausea, advance the diet as ordered. Patients who have had abdominal surgery are usually NPO the first 24 to 48 hours. As flatus and peristalsis return, provide clear liquids, followed by full liquids, a light diet of solid foods, and finally a patient's usual diet. Encourage intake of foods high in protein and vitamin C.
- Promote ambulation and exercise. Physical activity stimulates a return of peristalsis. The patient who suffers abdominal distention and "gas pain" may obtain relief while walking.
- Maintain an adequate fluid intake. Fluids keep fecal material soft for easy passage. Fruit juices and warm liquids are especially effective.
- Promote adequate food intake by stimulating the patient's appetite.
- Remove sources of noxious odors and provide small servings of nonspicy foods.
- Assist the patient to a comfortable position during mealtime. Have the patient sit, if possible, to minimize pressure on the abdomen.
- Provide desired servings of food. For example, some patients are more willing to face the first meal when servings are not large.
- Provide frequent oral hygiene. Adequate hydration and cleaning of the oral cavity eliminate dryness and bad tastes.
- Administer fiber supplements, stool softeners, and rectal suppositories as ordered. If constipation or distention develops, the health care provider orders cathartics or enemas to stimulate peristalsis.
- Provide meals when the patient is rested and free from pain. Often a patient loses interest in eating if mealtime has been preceded by exhausting activities such as ambulation, coughing and deep-breathing exercises or extensive dressing changes. When a patient has pain, the associated nausea often causes a loss of appetite.

Promoting Urinary Elimination. The depressant effects of anesthetics and analgesics impair the sensation of bladder fullness. If bladder tone is reduced, the patient has difficulty starting urination. However, patients need to void within 8 to 12 hours after surgery. Because a full bladder is painful and often causes restlessness in recovery, it often becomes necessary to insert a straight catheter. If the patient has an indwelling urinary catheter, the goal is to remove it as soon as possible because of the high risk for the development of an HAI (bladder or urinary tract). To help reduce and eliminate HAIs, evidence-based protocols are often enacted to ensure prompt removal of urinary catheters (Willson et al., 2009).

Patients who undergo surgery of the urinary system frequently have an indwelling urinary catheter inserted to maintain free urinary flow until voluntary control of urination returns. The following measures promote normal urinary elimination (see Chapter 45):

- Check the patient frequently for the need to void. A surgical patient restricted to bed needs assistance in handling and using a bedpan or urinal. Often the patient acquires a sudden feeling of bladder fullness and urgency to void and needs help quickly.
- Assess for bladder distention. If a patient does not void within 8 hours of surgery or bladder distention is present, it may be necessary to insert a straight urinary catheter. A health care provider's order is needed. Continued difficulty in voiding may require an indwelling catheter, although the risk for a urinary tract infection increases. Although the evidence is inconclusive, some centers advocate the use of bladder ultrasound to assess bladder volume and assist in the decision to place a urinary catheter.
- Monitor I&O. If a patient has an indwelling catheter, expect an output of about 30 to 50 mL/hr. Another way to gauge adequacy of output is by determining the patient's weight. An accepted level of urinary output is at least 1 mL/kg/hr for adults. For example, a 132-pound woman (60 kg) would be expected to produce 60 mL of urine hourly. If the urine is dark, concentrated, and low in volume, notify a health care provider. Patients easily become dehydrated as a result of fluid loss from surgical wounds. Measure I&O for several days after surgery until the patient achieves normal fluid intake and urinary output.

Promoting Wound Healing. A surgical wound undergoes considerable stress during convalescence. The stresses of inadequate nutrition, impaired circulation, and metabolic alterations increase the risk for delayed healing (see Chapter 48). A wound also undergoes considerable physical stress. Strain on sutures from coughing, vomiting, distention, and movement of body parts can disrupt the wound layers. Protect the wound and promote healing. A critical time for wound healing is 24 to 72 hours after surgery, after which a seal is established. If a wound becomes infected, it usually occurs 3 to 6 days after surgery. A clean surgical wound usually does not regain strength against normal stress for 15 to 20 days after surgery. Use aseptic technique during dressing changes and wound care (see Chapter 48). Keep surgical drains patent so accumulated secretions can escape from the wound bed. Ongoing observation of the wound identifies early signs and symptoms of infection.

Maintaining/Enhancing Self-Concept. The appearance of wounds, bulky dressings, and extruding drains and tubes threatens a patient's self-concept. The effects of surgery such as disfiguring scars often create permanent changes in a patient's body image. If surgery leads to impairment in body function, the patient's role within the family can change significantly. Observe patients for behaviors reflecting alterations in self-concept. Some patients show revulsion toward their appearance by refusing to look at incisions, carefully covering dressings with bed clothes, or refusing to get out of bed because of tubes and devices. The fear of not being able to return to a functional family role causes some patients to avoid participating in the plan of care.

The family becomes an important part of the efforts to improve the patient's self-concept. Explain the patient's appearance to the family and ways to avoid nonverbal expressions of revulsion or surprise. Encourage the family to accept the patient's needs and support his or her independence. If the condition is permanent,

the family learns to help the patient through the grieving process so he or she reaches a stage of acceptance. The following measures help to maintain the patient's self-concept:

- Provide privacy during dressing changes or inspection of the wound. Keep room curtains closed around the bed and drape the patient to expose only the dressing or incisional area.
- Maintain the patient's hygiene. Wound drainage and antiseptic solutions from the surgical skin preparation dry on the surface of the skin and cause irritation. A complete bath the first day after surgery renews the patient. When the gown becomes soiled by wound drainage, offer a clean gown and washcloth. Keep the patient's hair neatly combed and offer frequent oral hygiene. Room deodorizers are useful if the odor from drainage seems particularly troublesome to the patient and family.
- Prevent drainage devices from overflowing. You usually measure contents of drainage collection devices every 8 hours for output recording. The patient sometimes becomes preoccupied with observing the gradual collection of drainage, and some drainage devices leak contents if they become too full. Empty the devices periodically to prevent accidental spills and hampering of the patient's movement.
- Maintain a pleasant environment. Being in pleasant, comfortable surroundings heightens self-concept. Store or remove unused supplies. Keep the patient's bedside orderly and clean.
- Offer opportunities for the patient to discuss feelings about appearance. A patient who avoids looking at an incision may need to discuss fears or concerns. A patient having surgery for the first time is often more anxious than one who has had multiple surgeries. When the patient chooses to look at an incision for the first time, make sure that the area is clean. Eventually he or she will be able to care for the incision site by applying simple dressings or bathing the affected area.
- Provide the family with opportunities to discuss ways to promote the patient's self-concept. Encouraging independence is sometimes difficult for a family member who has a strong desire to help the patient in any way. By knowing about the appearance of a wound or incision, family members can be supportive during dressing changes. The topic or tone of a conversation helps family members distract a patient from dwelling on fears and concerns. Family members do not need to avoid discussing the future. However, they need help to know when it is appropriate to discuss future plans. Then the patient and family can work together to discuss realistic plans for the patient's return home.

Restorative and Continuing Care. In the postoperative period the nurse, patient, and family work to prepare the patient for discharge. Patients often have to continue wound care, follow activity or diet restrictions, continue medication therapy, and observe for signs and symptoms of complications on returning home. Education regarding these activities is specific to the type of surgery and is an ongoing process throughout hospitalization. Pieper et al. (2006) in a study of bariatric surgery patients found that the five most frequently mentioned postdischarge concerns were bowel function, wound pain, looking for wound complications, wound infection, and activity limitations. The higher the amount of perceived information received about incision care, the higher was the patient's knowledge rating. With ambulatory surgery patients, focused education within the limited time frame is essential. Including the family or support system provides a resource for the patient once home (see Box 50-6). With both ambulatory and hospitalized surgical patients, provide a wide variety of written educational materials. For example, offer materials with more pictures and illustrations for patients who do not speak English or have limited reading ability. Ensure that all materials are sensitive to various cultures and religions. Patients receive a copy of signed discharge instructions, and one copy remains in the medical record.

Some patients need home care assistance in the postoperative period after discharge. For example, nurses make referrals to home care for skilled nursing requirements when patients need wound care, ongoing IV therapy, or drain management. In addition, patients who are more physically dependent may require assistance from nursing assistive personnel to provide bathing and hygiene needs. The case coordinator or social worker at the hospital helps with discharge coordination. Encourage patients to show their discharge instructions to any home care provider.

Other patients, especially older adults, sometimes require discharge to a skilled nursing facility after their hospital recovery. During their convalescence in the skilled facility, patients work to gain mobility and recovery of their independent living skills. In addition, nurses provide wound care. A case coordinator or social worker works with the patient, family, and nurse to coordinate transfer to the skilled nursing facility.

EVALUATION

Through the Patient's Eyes. Addressing the ongoing concerns of patients and family members is an important part of evaluation after surgery. Evaluate patients' perceptions of the timeliness of response to their needs such as scheduled times for pain medication and prompt answering of a call light since these factors often influence patient satisfaction This is the opportunity to ask specific questions that address patient expectations and perceptions. For example, "Are you satisfied with the way we are managing your pain?" "Do you feel you have learned enough to be able to follow your diet at home?" "Are you having any ongoing issues, questions, or concerns that we can address for you at this time?" It is important to resolve any concerns or issues that the patient and family have before discharge.

Patient Outcomes. Evaluate the effectiveness of your care on the basis of the patient-centered expected outcomes established after surgery for each nursing diagnosis. Consult with the patient and family to gather evaluation data and remember that evaluation is ongoing. If a patient fails to progress as expected, revise his or her care plan based on evaluation findings and the patient's needs.

Make sure to evaluate for pain relief, using a pain scale. Determine the efficacy of both pharmacological and nonpharmacological measures. Use appropriate evaluative measures; inspect the condition of a wound, measure the distance or number of times that a patient is able to ambulate, and monitor the amount of fluid and food intake.

Part of your evaluation is determining the extent to which the patient and a family caregiver learn self-care measures. Have the patient and caregiver discuss the instructions you have provided so you know that they have the knowledge needed for the patient to return to as healthy and functional a state as possible. If the patient must perform any skill at home such as a dressing change or exercise, evaluate through return demonstration.

A phone call 24 hours after discharge to the patient's home is also helpful for evaluation. At this point the progress of recovery and asking if complications have developed can be addressed. This also is an opportunity to evaluate the patient's understanding of restrictions, wound care, medications, and necessary follow-up.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skill in this chapter, remember the following points to ensure safe, individualized patient-centered care:

- Coughing and deep breathing may be contraindicated after brain, spinal, head, neck, or eye surgery.
- Bariatric patients may have more improved lung function and vital capacity in the reverse Trendelenburg's position.
- Report any signs of venous thromboembolism such as leg swelling, pain, or redness to the medical team immediately.

SKILL 50-1 DEMONSTRATING POSTOPERATIVE EXERCISES

View Video!

Delegation Considerations

The skill of teaching postoperative exercises cannot be delegated. Nursing assistive personnel (NAP) reinforce and assist patients in performing postoperative exercises. Direct the NAP to:

- Encourage patients to practice exercises regularly following instruction.
- Inform the nurse if patient is unwilling to perform these exercises.

Equipment

- Pillow or wrapped blanket (used to splint surgical incision during coughing)
- Incentive spirometer
- Positive expiratory pressure device

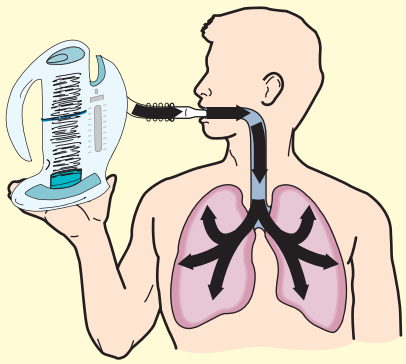
STEP	RATIONALE
ASSESSMENT	
1 Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Assess patient's risk for postoperative respiratory complications. Review medical history to identify presence of chronic pulmonary conditions (e.g., emphysema, asthma), any condition that affects chest wall movement, history of smoking, and presence of reduced hemoglobin.	General anesthesia predisposes patient to respiratory problems because lungs do not fully inflate during surgery, cough reflex is suppressed, and mucus collects within airway passages. After surgery patient may have reduced lung volume and require greater efforts to cough and deep breathe; inadequate lung expansion can lead to atelectasis and pneumonia. Previous chronic lung conditions increase patients' risk for developing respiratory complications (Kaw and Stoller, 2008). Smoking damages ciliary clearance and increases mucus. Reduced hemoglobin leads to inadequate oxygenation.
3 Auscultate lungs.	Establishes baseline for postoperative comparison.
4 Assess patient's ability to cough and deep breathe by having him or her take deep breath and observe movement of shoulders, abdomen, and chest wall. Observe chest excursion during deep breath. Ask patient to cough after taking deep breath.	Reveals maximum potential for chest expansion and ability to cough forcefully; serves as baseline to measure ability to perform exercises after surgery.
5 Assess patient's risk for postoperative venous stasis and thrombus formation (e.g., older patients, primary admitting diagnosis [e.g., trauma, orthopedic fracture, burn], patient's medical history [e.g., active cancer, atrial fibrillation, stroke, dehydration, previous clots], immobilized patients, women over 35 years who smoke and are taking oral contraceptives, position to assume on operating room table) (AORN, 2011).	Venous stasis, hypercoagulability, and vein trauma exist simultaneously for thrombus formation to occur (Geerts et al., 2008, Lewis et al., 2011). After general anesthesia, circulation slows; and when rate of blood flow slows, there is greater tendency for clot formation. Immobilization results in decreased muscular contraction in lower extremities, which promotes venous stasis. Manipulation and positioning during surgery sometimes cause trauma to leg veins.
6 Observe calves for redness, warmth, and tenderness, swollen calf or thigh, calf swelling more than 3 cm (1.2 inches) compared with asymptomatic leg, pitting edema in symptomatic leg, and collateral superficial veins. Compare legs for bilateral equality (Lewis et al., 2011), localized tenderness along distribution of venous system, swollen calf or thigh, calf swelling more than 3 cm (1.2 inches) compared with asymptomatic leg, pitting edema in symptomatic leg, and collateral superficial veins.	Signs of phlebitis and thrombus formation.

CLINICAL DECISION: *If any of the signs of thrombus formation is present, notify the health care provider immediately and do not manipulate extremity further. Surgery will usually be postponed. Graduated compression stockings, intermittent pneumatic compression stockings, and/or coagulation may be ordered.*

7 Assess patient's ability to move independently while in bed.	Determines existence of any mobility restrictions.
8 Assess patient's willingness and capability to learn exercises: note attention span, anxiety, level of consciousness, language level. Also assess family members' willingness to learn and support patient after surgery.	Determines ability of patient to learn exercises successfully. Prepares family member to be able to encourage or coach patient in performing exercises after surgery.
9 Assess patient's medical orders before and after surgery.	Some patients require adaptations to performing exercises. In some cases certain exercises may be contraindicated.

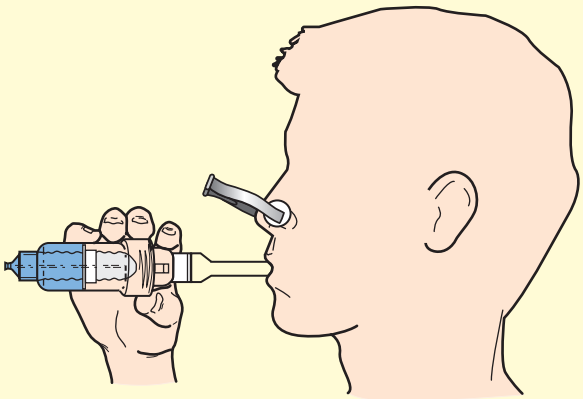
SKILL 50-1 DEMONSTRATING POSTOPERATIVE EXERCISES—cont'd

STEP	RATIONALE
PLANNING	
1 Explain postoperative exercises to patient and family caregiver, including importance to recovery and physiological benefits.	Information allows patient to understand significance of exercises and can motivate learning. People tend to learn new skills when they know their benefits.
2 Plan exercises when patient is not in pain.	Decreased pain enhances patient's ability to practice exercises.
3 Prepare the room.	Makes environment conducive to learning.
IMPLEMENTATION	
1 Demonstrate exercises	
a. Diaphragmatic breathing	
(1) Assist patient to comfortable semi-Fowler's position or sitting on side of bed or in chair or standing position.	Upright position facilitates diaphragmatic excursion.
(2) Stand or sit facing patient.	Allows patient to observe breathing exercise.
(3) Instruct patient to place palms of hands across from each other, down and along lower borders of anterior rib cage. Place tips of fingers lightly together (see illustration). Demonstrate for patient.	Position of hands allows patient to feel movement of chest and abdomen as diaphragm descends and lungs expand.



STEP 1a(3) Deep-breathing exercise—placement of hands on upper abdomen during inhalation.

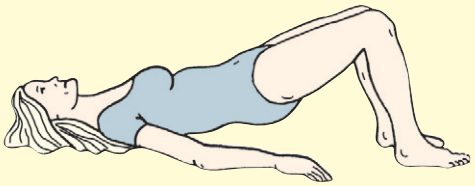
(4) Show patient how to take slow, deep breaths, inhaling through nose and pushing abdomen against hands. Have him or her feel middle fingers separate during inhalation. Explain that patient will feel normal downward movement of diaphragm while inhaling and that abdominal organs descend and chest wall expands. Demonstrate again.	Taking slow, deep breaths prevents panting or hyperventilation. Inhaling through nose warms, humidifies, and filters air. Diaphragmatic breathing allows air to pass by, partially obstructing mucus plug, increasing force to expel mucus. Explanation and demonstration focus on normal ventilatory movement of chest wall. Patient learns how diaphragmatic breathing feels.
(5) Instruct patient to avoid using chest and shoulders while inhaling.	Using auxiliary chest and shoulder muscles during breathing wastes energy and does not promote full lung expansion.
(6) Have patient hold slow, deep breath for count of three and then slowly exhale through mouth as if blowing out a candle (through pursed lips). Tell patient that middle fingertips will touch as chest wall contracts during exhalation.	Pursed-lip exhalation allows for gradual expulsion of all air.
(7) Repeat complete breathing exercise 3 to 5 times.	Allows patient to observe slow, rhythmic breathing pattern. Repetition of exercise reinforces learning.
(8) Have patient practice exercise. Instruct him or her to take 10 slow, deep breaths every hour while awake during postoperative period.	Regular deep breathing prevents postoperative complications of atelectasis.
b. Incentive spirometry	
(1) Perform hand hygiene.	Reduces transmission of microorganisms.
(2) Instruct patient to assume semi-Fowler's or high-Fowler's position.	Promotes optimal lung expansion during respiratory maneuver.
(3) For the bariatric patient, consider the reverse Trendelenburg's position.	Bariatric patients are often able to move their diaphragm better in the reverse Trendelenburg's position than in a Fowler's position.



STEP	RATIONALE
(4) Either set or indicate to patient on the incentive spirometer (IS) device scale the volume level to be attained with each breath (a targeted tidal volume). Use manufacturer guidelines to set the volume.	Establishes goal of volume level necessary for adequate lung expansion. Package insert helps determine target based on patient height and age (Pruitt, 2006).
(5) Explain to patient how to place mouthpiece of IS so lips completely cover mouthpiece (see illustration). Have patient demonstrate until position is correct.	Demonstration is reliable technique for teaching psychomotor skill and enables patient to ask questions.
(6) Instruct patient to inhale slowly and maintain constant flow through unit, attempting to reach goal volume. When patient reaches maximal inspiration, have him or her hold breath for 3 to 5 seconds (see illustration) and exhale slowly (Pruitt, 2006). Ensure that number of breaths does not exceed 10 to 12 per minute.	Maintains maximal inspiration and reduces risk of progressive collapse of individual alveoli. Slow breath (less than 12 breaths/min) prevents or minimizes pain from sudden pressure changes in chest.
(7) Instruct patient to breathe normally for short period between each of the 10 breaths on IS.	Prevents hyperventilation and fatigue.
(8) Have patient repeat breaths until goals are achieved.	Ensures correct use of IS.
(9) Have patient end with two coughs after end of 10 IS breaths hourly while awake.	Cough assists with lung secretion mobilization (Pruitt, 2006).
(10) Perform hand hygiene.	Reduces transmission of microorganisms.
c. Positive expiratory pressure therapy and "huff" coughing	
(1) Perform hand hygiene.	Reduces transmission of microorganisms.
(2) Set positive expiratory pressure (PEP) device for setting ordered.	Higher settings require more ventilatory effort.
(3) Instruct patient to assume semi-Fowler's or high-Fowler's position and place nose clip on patient's nose (see illustration).	Promotes optimum lung expansion, enabling patient to expectorate mucus. Clip prevents release of air through nose.
(4) Instruct patient to place lips around mouthpiece or demonstrate placement. Instruct patient to take a full breath and exhale 2 or 3 times longer than inhalation. Repeat pattern for 10 to 20 breaths.	Ensures that patient does all breathing through mouth and uses the device properly.

STEP 1b(5) Patient demonstrating incentive spirometry.

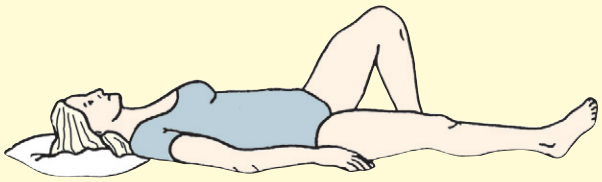
STEP 1b(6) Diagram of use of incentive spirometer.



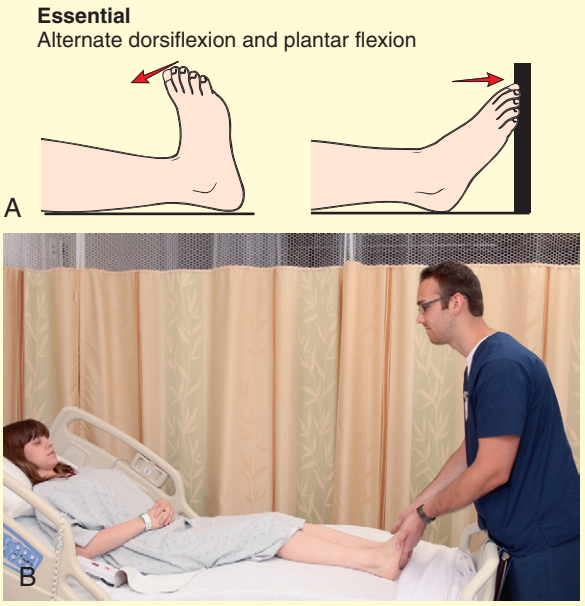
STEP 1c(3) Diagram of use of positive expiratory pressure device.

SKILL 50-1 DEMONSTRATING POSTOPERATIVE EXERCISES—cont'd

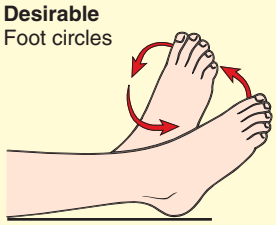
STEP	RATIONALE
(5) Have patient remove device from mouth; take a slow, deep breath; and hold for 3 seconds.	Promotes lung expansion before coughing.
(6) Have patient exhale in quick, short, forced "huffs."	"Huff" coughing or forced expiratory technique promotes bronchial hygiene by increasing expectoration of secretions (Fink, 2007).
d. Controlled coughing	
(1) Explain importance of maintaining upright semi-Fowler's or sitting position.	Position facilitates diaphragm excursion and enhances thorax expansion.
(2) If surgical incision will be either abdominal or thoracic, teach patient to place pillow or bath blanket over incisional area and place hands over pillow to splint incision. During breathing and coughing exercises, have patient press gently against incisional area for splinting or support (see illustration).	Surgical incision cuts through muscles, tissues, and nerve endings. Deep breathing and coughing place additional stress on suture line and cause discomfort. Splinting incision with hands or pillow provides firm support and reduces pulling.
(3) Demonstrate coughing. Instruct patient to take two slow, deep breaths, inhaling through nose and exhaling through mouth.	Deep breaths expand lungs fully so air moves behind mucus and facilitates effects of coughing.
(4) Instruct and show how to inhale deeply a third time and hold breath to count of three. Cough fully for two or three consecutive coughs without inhaling between coughs. (Tell patient to push all air out of lungs.)	Consecutive coughs help remove mucus more effectively and completely than one forceful cough.
CLINICAL DECISION: *Coughing is often contraindicated after brain, spinal, head, neck, or eye surgery because of potential increase in intracranial or intraocular pressure.*	
(5) Caution patient against just clearing throat instead of coughing. Explain that coughing does not cause injury to incision when done correctly.	Clearing throat does not remove mucus from deeper airways. Postoperative incisional pain makes it harder for patient to cough effectively.
(6) Have patient practice coughing exercises, splinting imaginary incision. Instruct patient to cough 2 to 3 times every 2 hours while awake.	Stresses value of deep coughing with splinting to effectively expectorate mucus with less discomfort.
(7) Instruct patient to look at sputum each time for consistency, odor, amount, and color changes and what to report to nurse.	Sputum characteristics indicate presence of pulmonary complication such as pneumonia.
e. Turning (example shows turning to right side)	
(1) Instruct patient to assume supine position and move to side of bed if permitted by surgery. Instruct patient to move by bending knees and pressing heels against mattress to raise and move buttocks (see illustration). Top side rails on both sides of bed should be in up position.	Positioning begins on side of bed so turning to other side does not cause patient to roll toward edge of bed. Buttocks lift prevents shearing force from body movement against sheets.



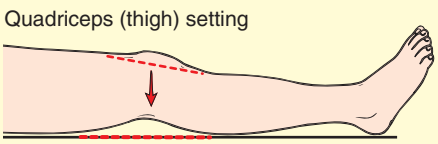
STEP 1d(2) Techniques for splinting incision. (From Lewis S et al: *Medical-surgical nursing: assessment and management of clinical problems,* ed 8, St Louis, 2011, Mosby.)



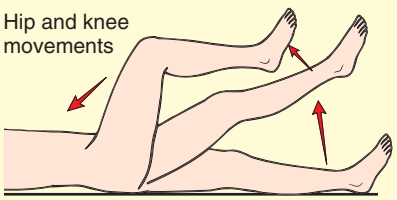
STEP 1e(1) Buttocks lift for moving to side of bed. (From Lowdermilk D, Perry SE: *Maternity and women's health care,* ed 9, St Louis, 2007, Mosby.)



STEP	RATIONALE
(2) Instruct patient to place right hand over incisional area to splint it *(optional)*	Supports and minimizes pulling on suture line during turning.
(3) Instruct patient to keep right leg straight and flex left knee up (see illustration). If back or vascular surgery was performed, patient needs to logroll (see Chapter 47) or requires assistance with turning.	Straight leg stabilizes patient's position. Flexed left leg shifts weight for easier turning.
(4) Have patient grab right side rail with left hand, pull toward right, and roll onto right side.	Pulling toward side rail reduces effort needed for turning.
(5) Instruct patient to turn every 2 hours while awake. Often patients require assistance with turning after surgery.	Reduces risk of vascular and pulmonary complications.
f. Leg exercises	
(1) Have patient assume supine position in bed. Guide through leg exercises by helping him or her perform passive range-of-motion exercises while simultaneously explaining exercise.	Provides normal anatomical position of lower extremities. Depending on surgical procedure and patient status, some of these leg exercises may be contraindicated.
(2) Rotate each ankle in complete circle. Instruct patient to draw imaginary circles with big toe (see illustration). Repeat 5 times.	Leg exercises maintain joint mobility and promote venous return to prevent thrombi.
(3) Alternate dorsiflexion and plantar flexion of both feet. Direct patient to feel calf muscles contract and relax alternately (see illustrations *A* and *B*). Repeat 5 times.	Stretches and contracts gastrocnemius muscles.
(4) Perform quadriceps setting by tightening thigh and bringing knee down toward mattress, then relaxing (see illustration). Repeat 5 times.	Contracts muscles of upper legs, maintains knee mobility, and enhances venous return.
(5) Have patient alternately raise each leg straight up from bed surface, keeping legs straight; have patient bend leg at hip and knee (see illustration). Repeat 5 times.	Promotes contraction and relaxation of quadriceps muscles.



STEP 1e(3) Leg position for turning. (From Lowdermilk D, Perry SE: *Maternity and women's health care,* ed 9, St Louis, 2007, Mosby.)



STEP 1f(3) **A,** Alternate dorsiflexion and plantar flexion. **B,** Patient pushes feet to perform plantar flexion. (**A** From Lewis S et al: *Medical-surgical nursing: assessment and management of clinical problems,* ed 7, St Louis, 2007, Mosby).

STEP 1f(2) Foot circles. (From Lewis S et al: *Medical-surgical nursing: assessment and management of clinical problems,* ed 7, St Louis, 2007, Mosby.)

STEP 1f(4) Quadriceps (thigh) setting. (From Lewis S et al: *Medical-surgical nursing: assessment and management of clinical problems,* ed 7, St Louis, 2007, Mosby).

STEP 1f(5) Hip and knee movements. (From Lewis S et al: *Medical-surgical nursing: assessment and management of clinical problems,* ed 7, St Louis, 2007, Mosby).

SKILL 50-1 DEMONSTRATING POSTOPERATIVE EXERCISES—cont'd

STEP	RATIONALE
2 Have patient continue to practice exercises before surgery at least every 2 hours while awake. Teach him or her how to coordinate turning and leg exercises with diaphragmatic breathing, IS, and coughing exercises.	Repetition of exercise sequence reinforces learning. Establishes routine for exercises that develops habit for performance. Sequence of exercises is leg exercises, turning, breathing, and coughing.
EVALUATION	
1 Observe patient perform all five exercises (only IS or PEP, not both) independently.	Provides opportunity for practice and return demonstration. Ensures that patient has learned correct technique.
2 Observe family member coach patient through steps of exercise.	Determines if family member can assist in a positive, appropriate way.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient is unable to perform exercises correctly before surgery.
- Assess for the presence of anxiety, pain, and fatigue.
- Teach patient stress reduction techniques and/or pain management strategies.
- Repeat teaching using more demonstration or redemonstration at time when family or friends are present.

2 Patient is unwilling to perform exercises after surgery because of incisional pain of thorax or abdomen (deep breathing, coughing, and turning) or because of surgery involving lower abdomen, groin, buttocks, or legs (leg exercises, turning).
- Instruct patient to ask for pain medication 30 minutes before performing postoperative exercise or to use patient-controlled analgesia (PCA) immediately before exercising.
- Report to surgeon or pain team inadequate pain relief and need to change analgesic or increase dose.

RECORDING AND REPORTING

- Record exercises demonstrated and whether patient is able to perform them independently.
- Report any problems patient has in completing exercises to nurse assigned to patient on next shift for follow-up.

HOME CARE CONSIDERATIONS

- Incorporate teaching of family members to help patient implement postoperative exercises at home.

KEY POINTS

- Surgery is classified by level of severity, urgency, and purpose.
- The preoperative period may be several days or only a few hours long, with some patients assessed in the health care provider's office, preadmission clinic, or anesthesia clinic or by telephone.
- Preoperative assessment of vital signs and physical findings provides an important baseline with which to compare postoperative assessment data.
- Nursing diagnoses for a surgical patient apply to nursing care during one or all phases of surgery.
- Primary responsibility for informed consent rests with the patient's surgeon.
- Structured preoperative teaching positively influences a patient's postoperative recovery.
- The explanation of all preoperative and postoperative routines and demonstration of postoperative exercises are basic to preoperative teaching.
- In ambulatory surgery nurses use the limited time available to educate patients, assess their health status, and prepare them for surgery.
- A routine preoperative safety checklist is a guide for final preparation of the patient before surgery.
- Nurses' responsibilities within the operating room focus on protecting the patient from potential harm.
- All medications taken before surgery are automatically discontinued after surgery unless a health care provider reorders the drugs.
- Family members are important in assisting patients with any physical limitations and providing emotional support during postoperative recovery.
- Care of the postoperative patient centers on the body systems that anesthesia, immobilization, and surgical trauma most likely affect.
- Accurate pain assessment and intervention are necessary for healing.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Campana has just been transported to your surgical nursing division from the PACU. She underwent a right colectomy (right-sided large bowel resection) for removal of a tumor. Her vital signs were stable in the postanesthesia care unit (PACU), and her temperature was 36.8° C (98° F). She has an intravenous (IV) line in her right arm, a Foley catheter, a nasogastric (NG) tube, and oxygen at 4 L/min per nasal cannula. She received 10 mg of morphine sulfate intravenously in the PACU and now has morphine patient-controlled analgesia (PCA) with a demand dose of 1 mg every 10 minutes connected to her IV line. When you assess her, she is slow to respond to your verbal questions.

1. Why may Mrs. Campana be slow to respond?
2. In a postoperative patient with decreased responsiveness such as Mrs. Campana, on which key assessments should you focus immediately?

3. Mrs. Campana's daughter enters the room and is very concerned about her mother's slowness to awaken. What do you tell her?

Evolve Answers to Clinical Application Questions can be found on the Evolve website.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Obesity places patients at an increased surgical risk because of which of the following factors? (Select all that apply.)
   1. Risk for bleeding is increased.
   2. Ventilatory capacity is reduced.
   3. Fatty tissue has a poor blood supply.
   4. Metabolic demands are increased.
2. The primary reason that family members should be included when the nurse teaches the patient preoperative exercises is so they can:
   1. Coach and encourage the patient after surgery.
   2. Demonstrate to the patient at home.
   3. Relieve the nurse by getting the patient to do the exercises every 2 hours.
   4. Practice with the patient while he or she is waiting to be taken to the operating room.
3. In the postanesthesia care unit (PACU) the nurse notes that the patient is having difficulty breathing and suspects an upper airway obstruction. The nurse would first:
   1. Suction the pharynx and bronchial tree.
   2. Give oxygen through a mask at 4 L/min.
   3. Ask the patient to use an incentive spirometer.
   4. Position the patient on one side with the face down and the neck slightly extended so the tongue falls forward.
4. Because an older adult is at increased risk for respiratory complications after surgery, the nurse should:
   1. Withhold pain medications and ambulate the patient every 2 hours.
   2. Monitor fluid and electrolyte status every shift and vital signs with temperature every 4 hours.
   3. Orient the patient to the surrounding environment frequently and ambulate the patient every 2 hours.
   4. Encourage the patient to turn, deep breathe, and cough frequently and ensure adequate pain control.
5. You are caring for a patient after surgery who underwent a liver resection. His prothrombin time (PT) or an activated partial thromboplastin time (APTT) is greater than normal. He has low blood pressure; tachycardia; thready pulse; and cool, clammy, pale skin, and he is restless. You assess his surgical wound, and the dressing is saturated with blood. Which immediate interventions should you perform? (Select all that apply.)
   1. Notify the surgeon.
   2. Maintain intravenous (IV) fluid infusion and prepare to give volume replacement.
   3. Monitor the patient's vital signs every 15 minutes or more frequently until his condition stabilizes.
   4. Wean oxygen therapy.
   5. Provide comfort through bathing.
6. You are a nurse in the postanesthesia care unit (PACU), and you note that your patient has a heart rate of 130 beats/min and a respiratory rate of 32 breaths/min; you also assess jaw muscle rigidity and rigidity of limbs, abdomen, and chest. What do you suspect, and which intervention is indicated?
   1. *Infection:* Notify surgeon and anticipate administration of antibiotics.
   2. *Pneumonia:* Listen to breath sounds, notify surgeon, and anticipate order for chest radiography.
   3. *Hypertension:* Check blood pressure, notify surgeon, and anticipate administration of antihypertensives.
   4. *Malignant hyperthermia:* Notify surgeon/anesthesia provider immediately, prepare to administer dantrolene sodium (Dantrium), and monitor vital signs frequently.
7. After a surgical patient has been given preoperative sedatives, which safety precaution should a nurse take?
   1. Reinforce to the patient to remain in bed or on the stretcher
   2. Raise the side rails and keep the bed or stretcher in the high position
   3. Determine if the patient has any allergies to latex
   4. Obtain informed consent immediately after sedative administration
8. The operating room (OR) and postanesthesia care unit (PACU) are high-risk environments for patients with a latex allergy. Which safety measures to prevent a latex reaction should the nurse implement? (Select all that apply.)
   1. Screening patients about food allergies known to have a cross-reactivity to latex such as kiwis and bananas
   2. Having a latex allergy cart available at all times
   3. Communicating with the operating room (OR) team as soon as 24 to 48 hours in advance of the surgery when a latex-sensitive patient is identified
   4. Scheduling the latex-sensitive patient for the last operative case of the day
9. A nurse is recovering a patient who received conscious sedation for cosmetic surgery. Which of the following is an advantage that conscious sedation has over general anesthesia?
   1. Loss of sensation at the surgical site
   2. Reduction of fear and anxiety and need for assistance with airway patency and ventilation
   3. Amnesia and relief of pain
   4. Monitoring in phase I recovery
10. You have been given the following postoperative patients to care for on your shift. Based on the information provided, which patient should you see first?
    1. A 75-year-old following hip replacement surgery who is complaining of moderate pain in the surgical site, with a heart rate of 92
    2. A 57-year-old following hip replacement 6 hours earlier who is receiving intravenous patient-controlled analgesia (PCA) with a history of OSA. The pulse oximeter has been alarming and reading 85%
    3. A 36-year-old following bladder neck suspension who is 30 minutes late to receive her postoperative dose of antibiotic
    4. A 48-year-old following total knee replacement who needs help repositioning in bed
11. Hand-off communications that occur between the postanesthesia care unit (PACU) nurse and the nurse on the postoperative nursing unit should be done when a patient returns to the nursing unit. Select appropriate components of a safe and effective hand-off. (Select all that apply.)
    1. Vital signs, the type of anesthesia provided, blood loss, and level of consciousness
    2. Uninterrupted time to review the recent pertinent events and ask questions

3. Verification of the patient using one identifier and the type of surgery performed
4. Review of pertinent events occurring in the operating room (OR) while at the nurses' station

12. A nurse is working in the preoperative holding area and is assigned to care for a patient who is having a prosthetic aortic valve placed. The nurse inserts an intravenous (IV) line and obtains vital signs. The patient has a temperature of 39° C (102° F), heart rate of 120, blood pressure (BP) of 84/50, and an elevated white blood cell (WBC) count. The nurse immediately notifies the surgeon of the patient's vital signs because:
    1. They need to get the patient into the operating room (OR) quickly to start the surgery because of the low blood pressure.
    2. The surgery may need to be delayed to check the patient's WBC count and investigate the source of fever before surgery.
    3. The nurse anticipates the need for a fluid bolus to increase the patient's BP.
    4. The nurse anticipates an order for a sedative to help calm the patient and decrease the heart rate.
13. A nurse is working in an ambulatory care setting and is ready to discharge a patient who is wheelchair dependent. The patient underwent dilation of an esophageal stricture. Her postanesthesia recovery score for ambulatory patients (PARSAP) score is 16. Her family is ready to go and eager to make the long road trip home. In determining if it is safe for the patient to be discharged at this time, the nurse should decide the following:
    1. The PARSAP score must be 18 or higher before being discharged.
    2. The patient's family is capable to care for her, and she understands her discharge instructions; thus the nurse proceeds with discharge.
    3. Since the patient hasn't been drinking much, the nurse is not concerned that she is unable to void and proceeds with discharge.
    4. Since the patient was admitted to the surgical center in a wheelchair, she can be discharged with a lower PARSAP score.
14. A patient is admitted through the emergency department for multisystem trauma following a motorcycle crash with multiple orthopedic injuries. He goes to surgery for repair of fractures. He is postoperative day 3 from an open reduction internal fixation of bilateral femur fractures and external fixator to his unstable pelvic fracture. Interventions that are necessary for prevention of venous thromboembolism in this high-risk postsurgical patient include: (Select all that apply.)
    1. Intermittent pneumatic compression stockings.
    2. Vitamin K therapy.
    3. Subcutaneous heparin or enoxaparin (Lovenox).
    4. Continuous heparin drip with a goal of an international normalized ratio (INR) 5 times higher than baseline.
15. You are caring for a 65-year-old patient 2 days after surgery and helping him walk down the hallway. The surgeon has ordered exercise as tolerated. Your assessment indicates that the patient's heart rate at baseline is 88. After walking approximately 30 yards down the hallway, the heart rate is 110. What should be your next action?
    1. Stop exercise immediately and have him sit in a nearby chair.
    2. Ask him how he feels; determine if there is any discomfort or shortness of breath; and, if not, continue exercise.
    3. Tell him that he needs to walk further to reach a heart rate of 120.
    4. Have him walk slower; he has reached his maximum.

Answers: **1.** 2, 3; **2.** 1; **3.** 4; **4.** 4; **5.** 1, 2, 3; **6.** 4; **7.** 1; **8.** 1, 2, 3; **9.** 3; **10.** 2; **11.** 1, 2; **12.** 2; **13.** 4; **14.** 1, 3; **15.** 2.

GLOSSARY

A

abduction Movement of a limb away from the body.

abrasion Scraping or rubbing away of epidermis; may result in localized bleeding and later weeping of serous fluid.

absorption Passage of drug molecules into the blood. Factors influencing drug absorption include route of administration, ability of the drug to dissolve, and conditions at the site of absorption.

acceptance Fifth stage of Kübler-Ross's stages of grief and dying. An individual comes to terms with a loss rather than submitting to resignation and hopelessness.

accessory muscles Muscles in the thoracic cage that assist with respiration.

accommodation Process of responding to the environment through new activity, thinking, and changing the existing schema or developing a new schema to deal with the new information. For example, a toddler whose parent consistently corrects him when he calls a horse a "doggie" accommodates and forms a new schema for horses.

accountability State of being answerable for one's actions—a nurse answers to himself or herself, the patient, the profession, the employing institution such as a hospital, and society for the effectiveness of nursing care performed.

accreditation Process whereby a professional association or nongovernmental agency grants recognition to a school or institution for demonstrated ability to meet predetermined criteria.

acculturation Process of adapting to and adopting a new culture.

acne Inflammatory, papulopustular skin eruption, usually occurring on the face, neck, shoulders, and upper back.

acromegaly Chronic metabolic condition caused by overproduction of growth hormone and characterized by gradual, marked enlargement and elongation of bones of the face, jaw, and extremities.

active listening Listening attentively with the whole person—mind, body, and spirit. It includes listening for main and supportive ideas; acknowledging and responding; giving appropriate feedback; and paying attention to the other person's total communication, including the content, intent, and feelings expressed.

active range-of-motion (ROM) exercise Exercise to the joint by the patient while doing activities of daily living or during joint assessment.

active strategies of health promotion Activities that depend on the patient's motivation to adopt a specific health program.

active transport Movement of materials across the cell membrane by means of chemical activity that allows the cell to admit larger molecules than would otherwise be possible.

activities of daily living (ADLs) Activities usually performed in the course of a normal day in the patient's life such as eating, dressing, bathing, brushing the teeth, or grooming.

activity tolerance Kind or amount of exercise or work that a person is able to perform.

actual loss Loss of an object, person, body part or function, or emotion that is overt and easily identifiable.

actual nursing diagnosis Judgment that is clinically validated by the presence of major defining characteristics.

acuity recording Mechanism by which entries describing patient care activities are made over a 24-hour period. The activities are then translated into a rating score, or acuity score, that allows for a comparison of patients who vary by severity of illness.

acute care Pattern of health care in which a patient is treated for an acute episode of illness, for the sequelae of an accident or other trauma, or during recovery from surgery.

acute illness Illness characterized by symptoms that are of relatively short duration, are usually severe, and affect the functioning of the patient in all dimensions.

adduction Movement of a limb toward the body.

adolescence Period in development between the onset of puberty and adulthood. It usually begins between 11 and 13 years of age.

adult day care centers Facility for the supervised care of older adults; provides activities such as meals and socialization during specified day hours.

advanced practice registered nurse (APRN) Generally the most independently functioning nurse. An APRN has a master's degree in nursing, advanced education in pathophysiology, pharmacology, and physical assessment; and certification and expertise in a specialized area of practice.

advanced sleep phase syndrome Common in older adults; a disturbance in sleep manifested by early waking in the morning with an inability to get back to sleep. It is thought that this syndrome is caused by advancing of the circadian rhythm of the body.

adventitious sounds Abnormal lung sounds heard with auscultation.

adverse effect Harmful or unintended effect of a medication, diagnostic test, or therapeutic intervention.

adverse reaction Any harmful, unintended effect of a medication, diagnostic test, or therapeutic intervention.

advocacy Process whereby a nurse objectively provides patients with the information they need to make decisions and supports the patients in whatever decisions they make.

afebrile Without fever.

affective learning Acquisition of behaviors involved in expressing feelings about attitudes, appreciation, and values.

afterload Resistance to left ventricular ejection; the work the heart must overcome to fully eject blood from the left ventricle.

age-related macular degeneration Progressive disorder in which the macula (the specialized portion of the retina responsible for central vision) degenerates as a result of aging and loses its ability to function efficiently. First signs include blurring of reading matter, distortion or loss of central vision, sensitivity to glare, and distortion of objects.

agnostic Individual who believes that any ultimate reality is unknown or unknowable.

airborne precautions Safeguards designed to reduce the risk of transmission of infectious agents through the air that a person breathes.

alarm reaction Mobilization of the defense mechanisms of the body and mind to cope with a stressor; the initial stage of the general adaptation syndrome.

aldosterone Mineralocorticoid steroid hormone produced by the adrenal cortex with action in the renal tubule to regulate sodium and potassium balance in the blood.

allergic reactions Unfavorable physiological response to an allergen to which a person has previously been exposed and has developed antibodies.

alopecia Partial or complete loss of hair; baldness.

Alzheimer's disease Disease of the brain parenchyma that causes a gradual and progressive decline in cognitive functioning.

AMBULARM Device used for the patient who climbs out of bed unassisted and is in danger of falling. This device is worn on the leg and signals when the leg is in a dependent position such as over the side rail or on the floor.

amino acid Organic compound of one or more basic groups and one or more carboxyl groups. Amino acids are the building blocks that construct proteins and the end products of protein digestion.

anabolism Constructive metabolism characterized by conversion of simple substances into more complex compounds of living matter.

analgesic Relieving pain; drug that relieves pain.

analogies Resemblances made between things otherwise unlike.

anaphylactic reactions Hypersensitive condition induced by contact with certain antigens.

aneurysm Localized dilations of the wall of a blood vessel; usually caused by atherosclerosis, hypertension, or a congenital weakness in a vessel wall.

anger Second stage of Kübler-Ross's stages of grief and dying. During this stage an individual resists loss by expressing extreme displeasure, indignation, or hostility.

angiotensin Polypeptide occurring in the blood, causing vasoconstriction, increased blood pressure, and the release of aldosterone from the adrenal cortex.

anion gap Difference between the concentrations of serum cations and anions; determined by measuring the concentrations of sodium cations and chloride and bicarbonate anions.

anions Negatively charged electrolytes.

anthropometric measurements Body measures of height, weight, and skinfolds to evaluate muscle atrophy.

anthropometry Measurement of various body parts to determine nutritional and caloric status, muscular development, brain growth, and other parameters.

antibodies Immunoglobulins essential to the immune system that are produced by lymphoid tissue in response to bacteria, viruses, or other antigens.

anticipatory grief Grief response in which the person begins the grieving process before an actual loss.

antidiuretic hormone (ADH) Hormone that decreases the production of urine by increasing the resorption of water by the renal tubules. ADH is secreted by cells of the hypothalamus and stored in the posterior lobe of the pituitary gland.

antiembolic stockings Elasticized stockings that prevent formation of emboli and thrombi, especially after surgery or during bed rest.

antigen Substance, usually a protein, that causes the formation of an antibody and reacts specifically with that antibody.

antipyretic Substance or procedure that reduces fever.

anxiolytics Drugs used primarily to treat episodes of anxiety.

aphasia Abnormal neurological condition in which language function is defective or absent; related to injury to speech center in cerebral cortex, causing receptive or expressive aphasia.

apical pulse Heartbeat as listened to with the bell or diaphragm of a stethoscope placed on the apex of the heart.

apnea Absence of respirations for a period of time.

apothecary system System of measurement. The basic unit of weight is a grain. Weights derived from the grain are the gram, ounce, and pound. The basic measure for fluid is the minim. The fluidram, fluid ounce, pint, quart, and gallon are measures derived from the minim.

approximate To come close together, as in the edges of a wound.

arcus senilis Opaque ring, gray to white in color, that surrounds the periphery of the cornea. The condition is caused by deposits of fat granules in the cornea. Occurs primarily in older adults.

asepsis Absence of germs or microorganisms.

aseptic technique Any health care procedure in which added precautions are used to prevent contamination of a person, object, or area by microorganisms.

assault Unlawful threat to bring about harmful or offensive contact with another.

assertive communication Type of communication based on a philosophy of protecting individual rights and responsibilities. It includes the ability to be self-directive in acting to accomplish goals and advocate for others.

assessment First step of the nursing process. Activities required in the first step are data collection, validation, sorting, and documentation. The purpose is to gather information for health problem identification.

assimilation To become absorbed into another culture and adopt its characteristics.

assisted living Residential living facilities in which each resident has his or her own room and shares dining and social activity areas.

associative play Form of play in which a group of children participates in similar or identical activities without formal organization, direction, interaction, or goals.

atelectasis Collapse of alveoli, preventing the normal respiratory exchange of oxygen and carbon dioxide.

atheist Individual who does not believe in the existence of God.

atherosclerosis Common arterial disorder characterized by yellowish plaques of cholesterol, lipids, and cellular debris in the inner layers of the walls of the large- and medium-size arteries.

atrioventricular (AV) node Part of the cardiac conduction system located on the floor of the right atrium; receives electrical impulses from the atrium and transmits them to the bundle of His.

atrophied Wasted or reduced size or physiological activity of a part of the body caused by disease or other influences.

attachment Initial psychosocial relationship that develops between parents and the neonate.

attentional set Internal state of the learner that allows focusing and comprehension.

auditory Related to or experienced through hearing.

auscultation Method of physical examination; listening to the sounds produced by the body, usually with a stethoscope.

auscultatory gap Disappearance of sound when obtaining a blood pressure; typically occurs between the first and second Korotkoff sounds.

authority Right to act in areas in which an individual has been given and accepts responsibility.

autologous transfusion Procedure in which blood is removed from a donor and stored for a variable period before it is returned to the donor's own circulation.

autonomy Ability or tendency to function independently.

B

back-channeling Active listening technique that prompts a respondent to continue telling a story or describing a situation. Involves use of phrases such as "Go on," "Uh huh," and "Tell me more."

bacteriuria Presence of bacteria in the urine.

balance Position in which the person's center of gravity is correctly positioned so falling does not occur.

bandages Available in rolls of various widths and materials, including gauze, elasticized knit, elastic webbing, flannel, and muslin. Gauze bandages are lightweight and inexpensive, mold easily around contours of the body, and permit air circulation to underlying skin to prevent maceration. Elastic bandages conform well to body parts but can also be used to exert pressure over a body part.

bargaining Third stage of Kübler-Ross's stages of grief and dying. A person postpones the reality of a loss by attempting to make deals in a subtle or overt manner with others or with a higher being.

baridi Condition among the Bena people of Tanzania attributed to disrespectful behavior within the family or transgression of cultural taboos. The person experiences physical and psychological symptoms and is usually treated by a traditional healer, who has the person make a public admission or an apology or who treats the person with herbal remedies.

basal cell carcinoma Malignant epithelial cell tumor that begins as a papule and enlarges peripherally, developing a central crater that erodes, crusts, and bleeds. Metastasis is rare.

basal metabolic rate (BMR) Amount of energy used in a unit of time by a fasting, resting subject to maintain vital functions.

battery Legal term for touching another's body without consent.

bed boards Boards placed under the mattress of a bed that provide extra support to the mattress surface.

bed rest Placement of the patient in bed for therapeutic reasons for a prescribed period.

benchmarking Identifying best practices and comparing them to current organizational practices to improve performance. This process helps to support the claims of quality care delivery by the institution.

beneficence Doing good or actively promoting doing good; one of the four principles of the ethical theory of deontology.

benign breast disease (fibrocystic) Benign condition characterized by lumpy, painful breasts and sometimes nipple discharge. Symptoms are more apparent before the menstrual period. Known to be a risk factor for breast cancer.

bereavement Response to loss through death; a subjective experience that a person suffers after losing a person with whom there has been a significant relationship.

biases and prejudices Beliefs and attitudes associating negative permanent characteristics to people who are perceived as different from oneself.

bi-level positive airway pressure (BiPAP) Ventilatory support used to treat patients with obstructive sleep apnea, patients with congestive heart failure, and preterm infants with underdeveloped lungs.

bilineally Kinship that extends to both the mother's and father's sides of the family.

binders Bandages made of large pieces of material to fit specific body parts.

bioethics Branch of ethics within the field of health care.

biological clock Cyclical nature of body function. Functions controlled from within the

body are synchronized with environmental factors; same meaning as biorhythm.

biological half-life Time it takes for the body to lower the amount of unchanged medication by half.

biotransformation Chemical changes that a substance undergoes in the body such as by the action of enzymes.

blanchable hyperemia Redness of the skin caused by dilation of the superficial capillaries. When pressure is applied to the skin, the area blanches, or turns a lighter color.

body image Peoples' subjective concept of their physical appearance.

body mechanics Coordinated efforts of the musculoskeletal and nervous systems to maintain proper balance, posture, and body alignment.

bone resorption Destruction of bone cells and release of calcium into the blood.

borborygmi Audible abdominal sounds produced by hyperactive intestinal peristalsis.

botanica Place that sells religious and herbal remedies.

bradycardia Slower-than-normal heart rate; heart contracts fewer than 60 times/min.

bradypnea Abnormally slow rate of breathing.

bronchospasm Excessive and prolonged contraction of the smooth muscle of the bronchi and bronchioles, resulting in an acute narrowing and obstruction of the respiratory airway.

bruit Abnormal sound or murmur heard while auscultating an organ, gland, or artery.

buccal Of or pertaining to the inside of the cheek or the gum next to the cheek.

buccal cavity Consists of the lips surrounding the opening of the mouth, the cheeks running along the side walls of the cavity, the tongue and its muscles, and the hard and soft palate.

buffer Substance or group of substances that can absorb or release hydrogen ions to correct an acid-base imbalance.

bundle of His Part of the cardiac conduction system that arises from the distal portion of the atrioventricular (AV) node and extends across the AV groove to the top of the intraventricular septum, where it divides into right and left bundle branches.

C

cachexia Malnutrition marked by weakness and emaciation, usually associated with severe illness.

capitation Payment mechanism in which a provider (e.g., health care network) receives a fixed amount of payment per enrollee.

carbohydrates Dietary classification of foods comprising sugars, starches, cellulose, and gum.

carbon monoxide Colorless, odorless, poisonous gas produced by the combustion of carbon or organic fuels.

cardiac index Adequacy of the cardiac output for an individual. It takes into account the body surface area (BSA) of the patient.

cardiac output (CO) Volume of blood expelled by the ventricles of the heart, equal to the amount of blood ejected at each beat multiplied by the number of beats in the period of time used for computation (usually 1 minute).

cardiopulmonary rehabilitation Actively assisting the patient with achieving and maintaining an optimal level of health through controlled physical exercise, nutrition counseling, relaxation and stress management techniques, prescribed medications and oxygen, and compliance.

cardiopulmonary resuscitation (CPR) Basic emergency procedures for life support consisting of artificial respiration and manual external cardiac massage.

care To feel concern for or interest in one who has sorrow or difficulties.

caring Universal phenomenon that influences the way we think, feel, and behave in relation to one another.

carriers People or animals who harbor and spread an organism that causes disease in others but do not become ill themselves.

case management Organized system for delivering health care to an individual patient or group of patients across an episode of illness and/or a continuum of care; includes assessment and development of a plan of care, coordination of all services, referral, and follow-up; usually assigned to one professional.

case management plan Multidisciplinary model for documenting patient care that usually includes plans for problems, key interventions, and expected outcomes for patients with a specific disease or condition.

catabolism Breakdown of body tissue into simpler substances.

cataplexy Condition characterized by sudden muscular weakness and loss of muscle tone.

cataracts Abnormal progressive condition of the lens of the eye characterized by loss of transparency.

cathartics Drugs that act to promote bowel evacuation.

catheterization Introduction of a catheter into a body cavity or organ to inject or remove fluid.

cations Positively charged electrolytes.

center of gravity Midpoint or center of the weight of a body or object.

centigrade Denotes temperature scale in which 0° is the freezing point of water and 100° is the boiling point of water at sea level; also called Celsius.

cerumen Yellowish or brownish waxy secretion produced by sweat glands in the external ear.

chancres Skin lesions or venereal sores (usually primary syphilis) that begin at the site of infection as papules and develop into red, bloodless, painless ulcers with a scooped-out appearance.

change-of-shift report Report that occurs between two scheduled nursing work shifts. Nurses communicate information about their assigned patients to nurses working on the next shift of duty.

channel Method used in the teaching-learning process to present content: visual, auditory, taste, smell. In the communication process a method used to transmit a message: visual, auditory, touch.

charting by exception (CBE) Charting methodology in which data are entered only when there is an exception from that which is normal or expected; reduces time spent documenting in charting. It is a shorthand method for documenting normal findings and routine care.

chest percussion Striking the chest wall with a cupped hand to promote mobilization and drainage of pulmonary secretions.

chest physiotherapy (CPT) Group of therapies used to mobilize pulmonary secretions for expectoration.

chest tube Catheter inserted through the thorax into the chest cavity for removing air or fluid; used after chest or heart surgery or pneumothorax.

Cheyne-Stokes respiration Occurs when there is decreased blood flow or injury to the brainstem.

chronic illness Illness that persists over a long time and affects physical, emotional, intellectual, social, and spiritual functioning.

circadian rhythm Repetition of certain physiological phenomena within a 24-hour cycle.

circulating nurse Assistant to the scrub nurse and surgeon whose role is to provide necessary supplies; dispose of soiled instruments and supplies; and keep an accurate count of instruments, needles, and sponges used.

civil law Statutes concerned with protecting a person's rights.

climacteric Physiological, developmental change that occurs in the male reproductive system between the ages of 45 and 60.

clinical criteria Objective or subjective signs and symptoms, clusters of signs and symptoms, or risk factors.

clinical decision making Problem-solving approach that nurses use to define patient problems and select appropriate treatment.

clinical-decision support systems Computerized programs used within the health care setting to support decision-making.

closed-ended question Form of question that limits a respondent's answer to one or two words.

clubbing Bulging of the tissues at the nail base caused by insufficient oxygenation at the periphery, resulting from conditions such as chronic emphysema and congenital heart disease.

code of ethics Formal statement that delineates a profession's guidelines for ethical behavior. A code of ethics sets standards or expectations for the professional to achieve.

cognitive learning Acquisition of intellectual skills that encompass behaviors such as thinking, understanding, and evaluating.

collaborative interventions Therapies that require the knowledge, skill, and expertise of multiple health care professionals.

collaborative problem Physiological complication that requires the nurse to use nursing- and health care provider–prescribed interventions to maximize patient outcomes.

colloid osmotic pressure Abnormal condition of the kidney caused by the pressure of concentrations of large particles such as protein molecules that will pass through a membrane.

colon Portion of the large intestine from the cecum to the rectum.

colonization Presence and multiplication of microorganisms without tissue invasion or damage.

comforting Acts toward another individual that display both an emotional and physical calm. The use of touch, establishing presence, the therapeutic use of silence, and the skillful and gentle performance of a procedure are examples of comforting nursing measures.

common law One source for law that is created by judicial decisions as opposed to those created by legislative bodies (statutory law).

communicable disease Any disease that can be transmitted from one person or animal to another by direct or indirect contact or by vectors.

communication Ongoing, dynamic series of events that involves the transmission of meaning from sender to receiver.

community health nursing Nursing approach that combines knowledge from the public health sciences with professional nursing theories to safeguard and improve the health of populations in the community.

community-based nursing Acute and chronic care of individuals and families to strengthen their capacity for self-care and promote independence in decision making.

competence Specific range of skills necessary to perform a task.

complete bed bath Bath in which the entire body of a patient is washed in bed.

compress Soft pad of gauze or cloth used to apply heat, cold, or medications to the surface of a body part.

computer-based patient record Comprehensive computerized system used by all health care practitioners to permanently store information pertaining to a patient's health status, clinical problems, and functional abilities.

concentration Relative content of a component within a substance or solution.

concentration gradient Gradient that exists across a membrane, separating a high concentration of a particular ion from a low concentration of the same ion.

concept map Care-planning tool that assists in critical thinking and forming associations between a patient's nursing diagnoses and interventions.

confianza Trust.

confidentiality Act of keeping information private or secret; in health care the nurse only shares information about a patient with other nurses or health care providers who need to know private information about a patient to provide care for him or her; information can only be shared with the patient's consent.

conjunctivitis Highly contagious eye infection. The crusty drainage that collects on eyelid margins can easily spread from one eye to the other.

connectedness Having close spiritual relationships with oneself, others, and God or another spiritual being.

connotative meaning Shade or interpretation of the meaning of a word influenced by the thoughts, feelings, or ideas that people have about the word.

conscious sedation Administration of central nervous system–depressant drugs and/or analgesics to provide analgesia, relieve anxiety, and/or provide amnesia during surgical, diagnostic, or interventional procedures.

constipation Condition characterized by difficulty in passing stool or an infrequent passage of hard stool.

consultation Process in which the help of a specialist is sought to identify ways to handle problems in patient management or in planning and implementing programs.

contact precautions Safeguards designed to reduce the risk of transmission of epidemiologically important microorganisms by direct or indirect contact.

continent urinary diversion (CUR) Surgical diversion of the drainage of urine from a diseased or dysfunctional bladder. Patient uses a catheter to drain the pouch.

continuous positive airway pressure (CPAP) Ventilatory support used to treat patients with obstructive sleep apnea, patients with congestive heart failure, and preterm infants with under developed lungs.

convalescence Period of recovery after an illness, injury, or surgery.

coping Making an effort to manage psychological stress.

core temperature Temperature of deep structures of the body.

cough Sudden, audible expulsion of air from the lungs. The person breathes in, the glottis is partially closed, and the accessory muscles of expiration contract to expel the air forcibly.

counseling Problem-solving method used to help patients recognize and manage stress and enhance interpersonal relationships. It helps patients examine alternatives and decide which choices are most helpful and appropriate.

crackles Fine bubbling sounds heard on auscultation of the lung; produced by air entering distal airways and alveoli, which contain serous secretions.

crime Act that violates a law and that may include criminal intent.

criminal law Concerned with acts that threaten society but may involve only an individual.

crisis Transition for better or worse in the course of a disease, usually indicated by a marked change in the intensity of signs and symptoms.

crisis intervention Use of therapeutic techniques directed toward helping a patient resolve a particular and immediate problem.

critical pathways Tools used in managed care that incorporate the treatment interventions of caregivers from all disciplines who normally care for a patient. Designed for a specific care type, a pathway is used to manage the care of a patient throughout a projected length of stay.

critical period of development Specific phase or period when the presence of a function or reasoning has its greatest effect on a specific aspect of development.

critical thinking Active, purposeful, organized, cognitive process used to carefully examine one's thinking and the thinking of other individuals.

crutch gait Gait achieved by a person using crutches.

cue Information that a nurse acquires through hearing, visual observations, touch, and smell.

cultural and linguistic competence Set of congruent behaviors, attitudes, and policies that come together in a system or agency or among professionals that enables effective work in cross-cultural situations.

cultural assessment Systematic and comprehensive examination of the cultural care values, beliefs, and practices of individuals, families, and communities.

cultural awareness Gaining in-depth awareness of one's own background, stereotypes, biases, prejudices, and assumptions about other people.

cultural care accommodation or negotiation Adapting or negotiating with the patient/families to achieve beneficial or satisfying health outcomes.

cultural care preservation or maintenance Retaining and/or preserving relevant care values so patients are able to maintain their well-being, recover from illness, or face handicaps and/or death.

cultural care repatterning or restructuring Reordering, changing, or greatly modifying a patient's/family's customs for a new, different, and beneficial health care pattern.

cultural competence Process in which the health care professional continually strives to achieve the ability and availability to work effectively with individuals, families, and communities.

cultural encounters Engaging in cross-cultural interactions; refining intercultural communication skills; gaining in-depth understanding of others and avoiding stereotypes; and managing cultural conflict.

cultural imposition Using one's own values and customs as an absolute guide in interpreting behaviors.

cultural knowledge Obtaining knowledge of other cultures; gaining sensitivity to, respect for, and appreciation of differences.

cultural pain Feeling that a patient has after a health care worker disregards the patient's valued way of life.

cultural skills Communication, cultural assessment, and culturally competent care.

culturally congruent care Care that fits people's valued life patterns and sets of meanings generated from the people themselves. Sometimes this differs from the professionals' perspective on care.

culturally ignorant or blind Uneducated about other cultures.

culture Integrated patterns of human behavior that include the language, thoughts, communications, actions, customs, beliefs, values, and institutions of racial, ethnic, religious, or social groups.

culture care theory Leininger's theory that emphasizes culturally congruent care.

culture-bound syndromes Illnesses restricted to a particular culture or group because of its psychosocial characteristics.

culturological nursing assessment Systematic and comprehensive examination of the cultural care values, beliefs, and practices of individuals, families, and communities.

cutaneous stimulation Stimulation of a person's skin to prevent or reduce pain perception. A massage, warm bath, hot and cold therapies, and transcutaneous electrical nerve stimulation are some ways to reduce pain perception.

cyanosis Bluish discoloration of the skin and mucous membranes caused by an excess of deoxygenated hemoglobin in the blood or a structural defect in the hemoglobin molecule.

D

DAR (data, action, patient response) Format used in focus charting for recording patient information.

data analysis Logical examination of and professional judgment about patient assessment data; used in the diagnostic process to derive a nursing diagnosis.

data cluster Set of signs or symptoms that are grouped together in logical order.

database Store or bank of information, especially in a form that can be processed by computer.

debridement Removal of dead tissue from a wound.

decentralized management Organizational philosophy that brings decisions down to the level of the staff. Individuals best informed about a problem or issue participate in the decision-making process.

decision making Process involving critical appraisal of information that results from recognizing a problem and ends with generating, testing, and evaluating a conclusion. Comes at the end of critical thinking.

defecation Passage of feces from the digestive tract through the rectum.

defendant Individual or organization against whom legal charges are brought in a court of law.

defining characteristics Related signs and symptoms or clusters of data that support the nursing diagnosis.

dehiscence Separation of the edges of a wound, revealing underlying tissues.

dehydration Excessive loss of water from the body tissues accompanied by a disturbance of body electrolytes.

delegation Process of assigning another member of the health care team to be responsible for aspects of patient care (e.g., assigning nurse assistants to bathe a patient).

delirium Acute state of confusion that is potentially reversible and often has a physical cause.

dementia Generalized impairment of intellectual functioning that interferes with social and occupational functioning.

denial Unconscious refusal to admit an unacceptable idea.

denotative meaning Meaning of a word shared by individuals who use a common language. The word *baseball* has the same meaning for all individuals who speak English, but the word *code* primarily denotes cardiac arrest to health care providers.

dental caries Abnormal destructive condition in a tooth caused by a complex interaction of food, especially starches and sugars, with bacteria that form dental plaque.

deontology Traditional theory of ethics that proposes to define actions as right or wrong based on the characteristics of fidelity to promises, truthfulness, and justice. The conventional use of ethical terms such as *justice, autonomy, beneficence,* and *nonmaleficence* constitutes the practice of deontology.

depression (1) Reduction in happiness and well-being that contributes to physical and social limitations and complicates the treatment of concomitant medical conditions. It is usually reversible with treatment. (2) Fourth stage of Kübler-Ross's stages of grief and dying. In this stage the person realizes the full impact and significance of the loss.

dermis Sensitive vascular layer of the skin directly below the epidermis; composed of collagenous and elastic fibrous connective tissues that give the dermis strength and elasticity.

determinants of health Many variables that influence the health status of individuals or communities.

detoxify To remove the toxic quality of a substance. The liver acts to detoxify chemicals in drug compounds.

development Qualitative or observable aspects of the progressive changes that one makes in adapting to the environment.

developmental crises Crises associated with normal and expected phases of growth and development (e.g., the response to menopause); same as maturational crises.

diabetic retinopathy Disorder of retinal blood vessels. Pathological changes secondary to increased pressure in the blood vessels of the retina result in decreased vision or vision loss caused by hemorrhage and macular edema.

diagnosis-related group (DRG) Group of patients classified to establish a mechanism for health care reimbursement based on length of stay. Classification is based on the following variables: primary and secondary diagnosis, co-morbidities, primary and secondary procedures, and age.

diagnostic process Mental steps (data clustering and analysis, problem identification) that follow assessment and lead directly to the formulation of a diagnosis.

diagnostic reasoning Process that enables an observer to assign meaning to and classify phenomena in clinical situations by integrating observations and critical thinking.

diaphoresis Secretion of sweat, especially profuse secretion associated with an elevated body temperature, physical exertion, or emotional stress.

diaphragmatic breathing Respiration in which the abdomen moves out while the diaphragm descends on inspiration.

diarrhea Increase in the number of stools and the passage of liquid, unformed feces.

diastolic Pertaining to diastole, or the blood pressure at the instant of maximum cardiac relaxation.

dietary reference intake (DRI) Information on each vitamin or mineral to reflect a range of minimum-to-maximum amounts that avert deficiency or toxicity.

diffusion Movement of molecules from an area of high concentration to one of lower concentration.

digestion Breakdown of nutrients by chewing, churning, mixing with fluid, and chemical reactions.

direct care interventions Treatments performed through interaction with the patient. For example, a patient may require medication administration, insertion of an intravenous infusion, or counseling during a time of grief.

discharge planning Activities directed toward identifying future proposed therapy and the need for additional resources before and after returning home.

discrimination Prejudicial outlook, action, or treatment.

disease Malfunctioning or maladaptation of biological or psychological processes.

disinfection Process of destroying all pathogenic organisms except spores.

disorganization and despair One of Bowlby's four phases of mourning in which an individual endlessly examines how and why the loss occurred.

distress Damaging stress; one of the two types of stress identified by Selye.

disuse osteoporosis Reductions in skeletal mass routinely accompanying immobility or paralysis.

diuresis Increased rate of formation and excretion of urine.

documentation Written entry into the patient's medical record of all pertinent information about him or her. These entries validate the patient's problems and care and exist as a legal record.

dominant culture Customs, values, beliefs, traditions, and social and religious views held by a group of people that prevail over another secondary culture.

dorsiflexion Flexion toward the back.

drainage evacuators Convenient portable units that connect to tubular drains lying within a wound bed and exert a safe, constant, low-pressure vacuum to remove and collect drainage.

droplet precautions Safeguards designed to reduce the risk of droplet transmission of infectious agents.

dysmenorrhea Painful menstruation.

dysphagia Difficulty swallowing; commonly associated with obstructive or motor disorders of the esophagus.

dyspnea Sensation of shortness of breath.

dysrhythmia Deviation from the normal pattern of the heartbeat.

dysuria Painful urination resulting from bacterial infection of the bladder and obstructive conditions of the urethra.

E

ecchymosis Discoloration of the skin or bruise caused by leakage of blood into subcutaneous tissues as a result of trauma to underlying tissues.

ectropion Eversion of the eyelid that exposes the conjunctival membrane and part of the eyeball.

edema Abnormal accumulation of fluid in interstitial spaces of tissues.

egocentric Developmental characteristic wherein a toddler is only able to assume the view of his or her own activities and needs.

electrocardiogram (ECG) Graphic record of the electrical activity of the myocardium.

electrolyte Element or compound that, when melted or dissolved in water or other solvent, dissociates into ions and can carry an electrical current.

electronic health record An electronic record of patient health information generated whenever a patient accesses medical care in any health care delivery setting.

electronic infusion device Piece of medical equipment that delivers intravenous fluids at a prescribed rate through an intravenous catheter.

electronic medical record Part of the electronic health record that contains patient data gathered in a health care setting at a specific time and place.

embolism Abnormal condition in which a blood clot (embolus) travels through the bloodstream and becomes lodged in a blood vessel.

emic worldview Insider or native perspective.

empathy Understanding and acceptance of a person's feelings and the ability to sense the person's private world.

empowered Gave legal authority to or enabled an individual or group; promoted self-actualization of an individual or group.

endogenous infections Infections produced within a cell or organism.

endorphins Hormones that act on the mind such as morphine and opiates and produce a sense of well-being and reducing pain.

endotracheal tube Short-term artificial airways to administer mechanical ventilation, relieve upper airway obstruction, protect against aspiration, or clear secretions.

enema Procedure involving introduction of a solution into the rectum for cleansing or therapeutic purposes.

enteral nutrition (EN) Provision of nutrients through the gastrointestinal tract when the patient cannot ingest, chew, or swallow food but can digest and absorb nutrients.

entropion Condition in which the eyelid turns inward toward the eye.

environment All of the many factors (e.g., physical and psychological) that influence or affect the life and survival of a person.

epidermis Outer layer of the skin that has several thin layers in different stages of maturation; shields and protects the underlying tissues from water loss, mechanical or chemical injury, and penetration by disease-causing microorganisms.

epidural infusion Type of nerve block anesthesia in which an anesthetic is intermittently or continuously injected into the lumbosacral region of the spinal cord.

erythema Redness or inflammation of the skin or mucous membranes that is a result of dilation and congestion of superficial capillaries; sunburn is an example.

eschar Thick layer of dead, dry tissue that covers a pressure ulcer or thermal burn. It may be allowed to be sloughed off naturally, or it may need to be surgically removed.

ethical dilemma Dilemma existing when the right thing to do is not clear. Resolution requires the negotiation of differing values among those involved in the dilemma.

ethical principles Set of guidelines for the expectations a profession and the standards of behavior for its members.

ethics Principles or standards that govern proper conduct.

ethics of care Delivery of health care based on ethical principles and standards of care.

ethnicity Shared identity related to social and cultural heritage such as values, language, geographical space, and racial characteristics.

ethnocentrism Tendency to hold one's own way of life as superior to that of others.

ethnohistory Significant historical experiences of a particular group.

etic worldview Outsider's perspective.

etiology Study of all factors that may be involved in the development of a disease.

eupnea Normal respirations that are quiet, effortless, and rhythmical.

eustress Stress that protects health; one of the two types of stress identified by Selye.

evaluation Determination of the extent to which established patient goals have been achieved.

evidence-based knowledge Knowledge that is derived from the integration of best research, clinical expertise, and patient values.

evidence-based practice Use of current best evidence from nursing research, clinical expertise, practice trends, and patient preferences to guide nursing decisions about care provided to patients.

evisceration Protrusion of visceral organs through a surgical wound.

exacerbations Increases in the gravity of a disease or disorder as marked by greater intensity in signs or symptoms.

excessive daytime sleepiness Extreme fatigue felt during the day. Signs of this include falling asleep at inappropriate times such as while eating, talking, or driving. May indicate a sleep disorder.

excoriation Injury to the surface of the skin caused by abrasion.

exhaustion stage Phase that occurs when the body can no longer resist the stress (i.e., when the energy necessary to maintain adaptation is depleted).

exogenous infection Infection originating outside an organ or part.

exostosis Abnormal benign growth on the surface of a bone.

expected outcomes Expected conditions of a patient at the end of therapy or a disease process, including the degree of wellness and the need for continuing care, medications, support, counseling, or education.

extended care facility Institution devoted to providing medical, nursing, or custodial care for an individual over a prolonged period such as during the course of a chronic disease or the rehabilitation phase after an acute illness.

extension Movement by certain joints that increases the angle between two adjoining bones.

extracellular fluid (ECF) Portion of body fluids composed of the interstitial fluid and blood plasma.

exudate Fluid, cells, or other substances that have been discharged from cells or blood vessels slowly through small pores or breaks in cell membranes.

F

face-saving Way of speaking or acting that preserves dignity.

Fahrenheit Denotes temperature scale in which 32° is the freezing point of water and 212° is the boiling point of water at sea level.

faith Set of beliefs and a way of relating to self, others, and a Supreme Being.

fajita Cotton binder used on a newborn's abdomen among Hispanics and Filipinos to prevent gas and umbilical hernia.

family Group of interacting individuals composing a basic unit of society.

family as context Nursing perspective in which the family is viewed as a unit of interacting members having attributes, functions, and goals separate from those of the individual family members.

family caregiving A family process that occurs in response to an illness and encompasses multiple cognitive, behavioral, and interpersonal processes.

family diversity Unique needs and characteristics of each member in a family.

family durability System of support for a family that includes immediate and extended family members.

family forms Patterns of people considered by family members to be included in the family.

family functioning Processes families use to achieve their goals.

family hardiness Internal strengths and durability of the family unit; characterized by a sense of control over the outcome of life events and hardships, a view of change as beneficial and growth-producing, and an active rather than passive orientation in responding to stressful life events.

family health Determined by the effectiveness of the family's structure, the processes that the

family uses to meet its goals, and internal and external forces.

family as patient Nursing approach that takes into consideration the effect of one intervention on all members of a family.

family resiliency Family's ability to cope with expected and unexpected stressors.

family structure Based on organization (i.e., ongoing membership) of the family and the pattern of relationships.

farmacia Place to obtain prescribed medications.

febrile Pertaining to or characterized by an elevated body temperature.

fecal impaction Accumulation of hardened fecal material in the rectum or sigmoid colon.

fecal incontinence Inability to control passage of feces and gas from the anus.

fecal occult blood test (FOBT) Measures microscopic amounts of blood in the feces.

feces Waste or excrement from the gastrointestinal tract.

feedback Process in which the output of a given system is returned to the system.

felony Crime of a serious nature that carries a penalty of imprisonment or death.

feminist ethics Ethical approach that focuses on relationships of those involved in an ethical dilemma rather than traditional abstract principles of deontology.

fever Elevation in the hypothalamic set point so body temperature is regulated at a higher level.

fictive Nonblood kin; considered family in some collective cultures.

fidelity Agreement to keep a promise.

fight-or-flight response Total physiological response to stress that occurs during the alarm reaction stage of the general adaptation syndrome. Massive changes in all body systems prepare a human being to choose to flee or remain and fight the stressor.

filtration Straining of fluid through a membrane.

fistula Abnormal passage from an internal organ to the surface of the body or between two internal organs.

flashback Recollection so strong that the individual thinks that he or she is actually experiencing the trauma again or seeing it unfold before his or her eyes.

flatus Intestinal gas.

flora Microorganisms that live on or within a body to compete with disease-producing microorganisms and provide a natural immunity against certain infections.

flow sheets Documents on which frequent observations or specific measurements are recorded.

Fluid volume deficit (FVD) Fluid and electrolyte disorder caused by failure of bodily homeostatic mechanisms to regulate the retention and excretion of body fluids. The condition is characterized by decreased output of urine, high specific gravity of urine, output of urine that is greater than the intake of fluid in the body, hemoconcentration, and increased serum levels of sodium.

fluid volume excess (FVE) Fluid and electrolyte disorder characterized by an increase in fluid retention and edema, resulting from failure of bodily homeostatic mechanisms to regulate the retention and excretion of body fluids.

focus charting Charting methodology for structuring progress notes according to the focus of the note (e.g., symptoms and nursing diagnosis). Each note includes data, actions, and patient response.

focused cultural assessment Method of evaluating a patient's ethnohistory, biocultural history, social organization, and religious and spiritual beliefs to find issues that are most relevant to the problem at hand.

food poisoning Toxic processes resulting from the ingestion of a food contaminated by toxic substances or bacteria-containing toxins.

food security All members of a household have access to sufficient, safe, nutritious food to maintain a healthy lifestyle.

foot boots Soft, foot-shaped devices designed to reduce the risk of footdrop by maintaining the foot in dorsiflexion.

footdrop Abnormal neuromuscular condition of the lower leg and foot characterized by an inability to dorsiflex, or evert, the foot.

friction Effects of rubbing or the resistance that a moving body meets from the surface on which it moves; a force that occurs in a direction to oppose movement.

functional health illiteracy Inability of an individual to obtain, interpret, and understand basic information about health.

functional health patterns Method for organizing assessment data based on the level of patient function in specific areas (e.g., mobility).

functional nursing Method of patient care delivery in which each staff member is assigned a task that is completed for all patients on the unit.

future orientation Time dimension emphasized by dominant American culture. It is characterized by direct communication and is focused on task achievement, whereas past orientation communication is circular and indirect and is focused on group harmony.

G

gait Manner or style of walking, including rhythm, cadence, and speed.

gastrostomy feeding tube Insertion of a feeding tube through a stoma into the stomach to provide enteral nutrition.

general adaptation syndrome (GAS) Generalized defense response of the body to stress; consists of three stages: alarm, resistance, and exhaustion.

general anesthesia Intravenous or inhaled medications that cause the patient to lose all sensation and consciousness.

genomics Describes the study of all the genes in a person and interactions of those genes with one another and with that person's environment.

geriatrics Branch of health care dealing with the physiology and psychology of aging and the diagnosis and treatment of diseases affecting older adults.

gerontology Study of all aspects of the aging process and its consequences.

gingivae Gums of the mouth; mucous membrane with supporting fibrous tissue that overlies the crowns of unerupted teeth and encircles the necks of teeth that have erupted.

glaucoma Abnormal condition of elevated pressure within an eye caused by obstruction of the outflow of aqueous humor. If untreated, it often results in peripheral visual loss, decreased visual acuity with difficulty adapting to darkness, and a halo effect around lights.

globalization Worldwide scope or application.

glomerulus Cluster or collection of capillary vessels within the kidney involved in the initial formation of urine.

gluconeogenesis Formation of glucose or glycogen from substances that are not carbohydrates such as protein or lipid.

glucose Primary fuel for the body; needed to carry out major physiological functions.

glycogen Polysaccharide that is the major carbohydrate stored in animal cells.

glycogenesis Process for storing glucose in the form of glycogen in the liver.

goals Desired results of nursing actions set realistically by the nurse and patient as part of the planning stage of the nursing process.

Good Samaritan laws Legislation enacted in some states to protect health care professionals from liability in rendering emergency aid unless there is proven willful wrong or gross negligence.

graduated measuring container Receptacle for volume measurement.

granny midwives Amateur health practitioners that assist in labor and delivery.

granulation tissue Soft, pink, fleshy projections of tissue that form during the healing process in a wound not healing by primary intention.

graphic record Charting mechanism that allows for the recording of vital signs and weight in such a manner that caregivers can quickly note changes in the patient's status.

grief Form of sorrow involving the person's thoughts, feelings, and behaviors that occurs as a response to an actual or perceived loss.

grieving process Sequence of affective, cognitive, and physiological states through which the person responds to and finally accepts an irretrievable loss.

grounded Connection between the electric circuit and the ground, which becomes part of the circuit.

growth Measurable or quantitative aspect of an individual's increase in physical dimensions as a result of an increase in number of cells. Indicators of growth include changes in height, weight, and sexual characteristics.

guided imagery Method of pain control in which the patient creates a mental image,

concentrates on that image, and gradually becomes less aware of pain.

gustatory Pertaining to the sense of taste.

H

halal Foods permissible for Muslims to eat.

hand rolls Rolls of cloth that keep the thumb slightly adducted and in opposition to the fingers.

hand-wrist splints Splints individually molded for the patient to maintain proper alignment of the thumb, slight adduction of the wrist, and slight dorsiflexion.

haram Foods prohibited by Muslim religious standards.

health Dynamic state in which individuals adapt to their internal and external environments so there is a state of physical, emotional, intellectual, social, and spiritual well-being.

health belief model Conceptual framework that describes a person's health behavior as an expression of his or her health beliefs.

health beliefs Patient's personal beliefs about levels of wellness that can motivate or impede participation in changing risk factors, participating in care, and selecting care options.

health care–acquired infection Infection that was not present or incubating at the time of admission to a health care setting.

health care problems Any conditions or dysfunctions that the patient experiences as a result of illness or treatment of an illness.

health informatics Application of computer and information science in all basic and applied biomedical sciences to facilitate the acquisition, processing, interpretation, optimal use, and communication of health-related data.

health literacy Patients' reading and mathematics skills, comprehension, ability to make health-related decisions, and successful functioning as a consumer of health care.

health promotion Activities such as routine exercise and good nutrition that help patients maintain or enhance their present level of health and reduce their risk of developing certain diseases.

health promotion model Defines health as a positive, dynamic state, not merely the absence of disease. The health promotion model emphasizes well-being, personal fulfillment, and self-actualization rather than reaction to the threat of illness.

health status Description of health of an individual or community.

heat exhaustion Abnormal condition caused by depletion of body fluid and electrolytes resulting from exposure to intense heat or the inability to acclimatize to heat.

heat stroke Continued exposure to extreme heat that raises the core body temperature to 40.5° C (105° F) or higher.

hematemesis Vomiting of blood, indicating upper gastrointestinal bleeding.

hematoma Collection of blood trapped in the tissues of the skin or an organ.

hematuria Abnormal presence of blood in the urine.

hemolysis Breakdown of red blood cells and release of hemoglobin that may occur after administration of hypotonic intravenous solutions, causing swelling and rupture of erythrocytes.

hemoptysis Coughing up blood from the respiratory tract.

hemorrhoids Permanent dilation and engorgement of veins within the lining of the rectum.

hemostasis Termination of bleeding by mechanical or chemical means or the coagulation process of the body.

hemothorax Accumulation of blood and fluid in the pleural cavity between the parietal and visceral pleurae.

hernia Protrusion of an organ through an abnormal opening in the muscle wall of the cavity that surrounds it.

hilots Amateur health practitioners that assist in labor and delivery among Filipinos.

holistic Of or pertaining to the whole; considering all factors.

holistic health Comprehensive view of the person as a biopsychosocial and spiritual being.

home care Health service provided in the patient's place of residence to promote, maintain, or restore health or minimize the effects of illness and disability.

homeostasis State of relative constancy in the internal environment of the body; maintained naturally by physiological adaptive mechanisms.

hope Confident but uncertain expectation of achieving a future goal.

hospice System of family-centered care designed to help terminally ill people be comfortable and maintain a satisfactory lifestyle throughout the terminal phase of their illness.

Hoyer lift Mechanical device that uses a canvas sling to easily lift dependent patients for transfer.

humidification Process of adding water to gas.

humor Coping strategy based on an individual's cognitive appraisal of a stimulus that results in behavior such as smiling, laughing, or feelings of amusement that lessen emotional distress.

hydrocephalus Abnormal accumulation of cerebrospinal fluid in the ventricles of the brain.

hydrostatic pressure Pressure caused by a liquid.

hyperactive/overactive bladder Common bladder complaint that occurs more frequently with aging and includes the symptoms of urgency, frequency, nocturia, and urge incontinence.

hypercalcemia Greater-than-normal amount of calcium in the blood.

hypercapnia Greater-than-normal amounts of carbon dioxide in the blood; also called hypercarbia.

hyperextension Position of maximal extension of a joint.

hyperglycemia Elevated serum glucose levels.

hypertension Disorder characterized by an elevated blood pressure persistently exceeding 120/80 mm Hg.

hyperthermia Situation in which body temperature exceeds the set point.

hypertonic Situation in which one solution has a greater concentration of solute than another; therefore the first solution exerts greater osmotic pressure.

hypertonicity Excessive tension of the arterial walls or muscles.

hyperventilation Respiratory rate in excess of that required to maintain normal carbon dioxide levels in the body tissues.

hypnotics Class of drug that causes insensibility to pain and induces sleep.

hypostatic pneumonia Pneumonia that results from fluid accumulation as a result of inactivity.

hypotension Abnormal lowering of blood pressure that is inadequate for normal perfusion and oxygenation of tissues.

hypothermia Abnormal lowering of body temperature below 35° C, or 95° F, usually caused by prolonged exposure to cold.

hypotonic Situation in which one solution has a smaller concentration of solute than another; therefore the first solution exerts less osmotic pressure.

hypotonicity Reduced tension of the arterial walls or muscles.

hypoventilation Respiratory rate insufficient to prevent carbon dioxide retention.

hypovolemia Abnormally low circulating blood volume.

hypoxemia Arterial blood oxygen level less than 60 mm Hg; low oxygen level in the blood.

hypoxia Inadequate cellular oxygenation that may result from a deficiency in the delivery or use of oxygen at the cellular level.

I

identity Component of self-concept characterized by one's persisting consciousness of being oneself, separate and distinct from others.

idiosyncratic reaction Individual sensitivity to effects of a drug caused by inherited or other bodily constitution factors.

illness (1) Abnormal process in which any aspect of a person's functioning is diminished or impaired compared with his or her previous condition. (2) The personal, interpersonal, and cultural reaction to disease.

illness behavior Ways in which people monitor their bodies, define and interpret their symptoms, take remedial actions, and use the health care system.

illness prevention Health education programs or activities directed toward protecting patients from threats or potential threats to health and minimizing risk factors.

imam Muslim priest.

immobility Inability to move about freely; caused by any condition in which movement is impaired or therapeutically restricted.

immunity Quality of being insusceptible to or unaffected by a particular disease or condition.

immunization Process by which resistance to an infectious disease is induced or augmented.

implementation Initiation and completion of the nursing actions necessary to help the patient achieve health care goals.

impression management Ability to interpret others' behavior within their own context of meanings and behave in a culturally congruent way to achieve desired outcomes of communication.

incentive spirometry Method of encouraging voluntary deep breathing by providing visual feedback to patients of the inspiratory volume they have achieved.

incident rates Rate of new cases of a disease in a specified population over a defined period of time.

incident report Confidential document that describes any patient accident while the person is on the premises of a health care agency. (See occurrence report.)

independent practice association (IPA) Managed care organization that contracts with physicians or health care providers who usually are members of groups and whose practices include fee-for-service and capitated patients.

indirect care interventions Treatments performed away from the patient but on behalf of the patient or group of patients.

induration Hardening of a tissue, particularly the skin, because of edema or inflammation.

infection Invasion of the body by pathogenic microorganisms that reproduce and multiply.

inference (1) Judgment or interpretation of informational cues. (2) Taking one proposition as a given and guessing that another proposition follows.

infiltration Dislodging an intravenous catheter or needle from a vein into the subcutaneous space.

inflammation Protective response of body tissues to irritation or injury.

informed consent Process of obtaining permission from a patient to perform a specific test or procedure after describing all risks, side effects, and benefits.

infusion pump Device that delivers a measured amount of fluid over a period of time.

infusions Introduction of fluid into the vein, giving intravenous fluid over time.

inhalation Method of medication delivery through the patient's respiratory tract. The respiratory tract provides a large surface area for drug absorption. Inhalation can be through the nasal or oral route.

injections Parenteral administration of medication; four major sites of injection: subcutaneous, intramuscular, intravenous, and intradermal.

insensible water loss Water loss that is continuous and not perceived by the person.

insomnia Condition characterized by chronic inability to sleep or remain asleep through the night.

inspection Method of physical examination by which the patient is visually systematically examined for appearance, structure, function, and behavior.

instillation To cause to enter drop by drop or very slowly.

institutional ethics committee Interdisciplinary committee that discusses and processes ethical dilemmas that arise within a health care institution.

instrumental activities of daily living (IADLs) Activities necessary for independence in society beyond eating, grooming, transferring, and toileting; include such skills as shopping, preparing meals, banking, and taking medications.

integrated delivery network (IDN) Set of providers and services organized to deliver a coordinated continuum of care to the population of patients served at a capitated cost.

interpersonal communication Exchange of information between two persons or among persons in a small group.

interstitial fluid Fluid that fills the spaces between most of the cells of the body and provides a substantial portion of the liquid environment of the body.

interview Organized, systematic conversation with the patient designed to obtain pertinent health-related subjective information.

intracellular fluid Liquid within the cell membrane.

intradermal (ID) Injection given between layers of the skin into the dermis. Injections are given at a 5- to 15-degree angle.

intramuscular (IM) Injections given into muscle tissue. The intramuscular route provides a fast rate of absorption that is related to the greater vascularity of the muscle. Injections are given at a 90-degree angle.

intraocular Method of medication delivery that involves inserting a medication disk similar to a contact lens into the patient's eye.

intrapersonal communication Communication that occurs within an individual (i.e., people "talk with themselves" silently or form an idea in their own mind).

intravascular fluid Fluid circulating within blood vessels of the body.

intravenous Injection directly into the bloodstream. Action of the drug begins immediately when given intravenously.

intravenous fat emulsions Soybean- or safflower oil–based solutions that are isotonic and may be infused with amino acid and dextrose solution through a central or peripheral line.

intubation Insertion of a breathing tube through the mouth or nose into the trachea to ensure a patent airway.

intuition Inner sensing that something is so.

irrigation Process of washing out a body cavity or wounded area with a stream of fluid.

ischemia Decreased blood supply to a body part such as skin tissue or to an organ such as the heart.

isolation Separation of a seriously ill patient from others to prevent the spread of an infection or protect the patient from irritating environmental factors.

isometric exercises Activities that involve muscle tension without muscle shortening, do not have any beneficial effect on preventing orthostatic hypotension, but may improve activity tolerance.

isotonic Situation in which two solutions have the same concentration of solute; therefore both solutions exert the same osmotic pressure.

J

jaundice Yellow discoloration of the skin, mucous membranes, and sclera caused by greater-than-normal amounts of bilirubin in the blood.

jejunostomy tube Hollow tube inserted into the jejunum through the abdominal wall for administration of liquefied foods to patients who have a high risk of aspiration.

joint contracture Abnormality that may result in permanent condition of a joint; is characterized by flexion and fixation; and is caused by disuse, atrophy, and shortening of muscle fibers and surrounding joint tissues.

joints Connections between bones; classified according to structure and degree of mobility.

judgment Ability to form an opinion or draw sound conclusions.

justice Ethical standard of fairness.

K

Kardex Trade name for card-filing system that allows quick reference to the particular need of the patient for certain aspects of nursing care.

karma Asian Indian belief that attributes mental illness to past deeds in one's previous life.

Korotkoff sound Sound heard during the taking of blood pressure using a sphygmomanometer and stethoscope.

Kussmaul respiration Increase in both rate and depth of respirations.

kyphosis Exaggeration of the posterior curvature of the thoracic spine.

L

la cuarantena Period of rest and restricted physical activity after childbirth that usually lasts 40 days.

la dieta Diet.

laceration Torn, jagged wound.

language Code that conveys specific meaning as words are combined.

laryngospasm Sudden uncontrolled contraction of the laryngeal muscles, which in turn decreases airway size.

law Rule, standard, or principle that states a fact or relationship between factors.

laxatives Drugs that act to promote bowel evacuation.

learning Acquisition of new knowledge and skills as a result of reinforcement, practice, and experience.

learning objective Written statement that describes the behavior that a teacher expects from an individual after a learning activity.

left-sided heart failure Abnormal condition characterized by impaired functioning of the left ventricle caused by elevated pressures and pulmonary congestion.

leukoplakia Thick, white patches observed on oral mucous membranes.

licensed practical nurse (LPN) Also known as the licensed vocational nurse (LVN) or in Canada, registered nurse's assistant (RNA); trained in basic nursing skills and the provision of direct patient care.

licensed vocational nurse (LVN) The LVN is the same as a licensed practical nurse (LPN), an individual trained in the United States in basic nursing techniques and direct patient care who practices under the supervision of a registered nurse. The LVN is licensed by a board after completing what is usually a 12-month educational program and passing a licensure examination. In Canada an LVN is called a certified nursing assistant.

lipids Compounds that are insoluble in water but soluble in organic solvents.

lipogenesis Process during which fatty acids are synthesized.

living wills Instruments by which a dying person makes wishes known.

local anesthesia Loss of sensation at the desired site of action.

logroll Maneuver used to turn a reclining patient from one side to the other or completely over without moving the spinal column out of alignment.

lordosis Increased lumbar curvature.

M

maceration Softening and breaking down of skin from prolonged exposure to moisture.

mal de ojo Evil eye.

malignant hyperthermia Autosomal-dominant trait characterized by often fatal hyperthermia in affected people exposed to certain anesthetic agents.

malpractice Injurious or unprofessional actions that harm another.

malpractice insurance Type of insurance to protect the health care professional. In case of a malpractice claim, the insurance pays the award to the plaintiff.

managed care Health care system in which there is administrative control over primary health care services. Redundant facilities and services are eliminated, and costs are reduced. Preventive care and health education are emphasized.

Maslow's hierarchy of needs Model developed by Abram Maslow that is used to explain human motivation.

matrilineal Kinship that is limited to only the mother's side.

maturation Genetically determined biological plan for growth and development. Physical growth and motor development are a function of maturation.

maturational loss Loss, usually of an aspect of self, resulting from the normal changes of growth and development.

Medicaid State medical assistance to people with low incomes, based on Title XIX of the Social Security Act. States receive matching federal funds to provide medical care and services to people meeting categorical and income requirements.

medical asepsis Procedures used to reduce the number of microorganisms and prevent their spread.

medical diagnosis Formal statement of the disease entity or illness made by the physician or health care provider.

medical record Patient's chart; a legal document.

Medicare Federally funded national health insurance program in the United States for people over 65 years of age. The program is administered in two parts. Part A provides basic protection against costs of medical, surgical, and psychiatric hospital care. Part B is a voluntary medical insurance program financed in part from federal funds and in part from premiums contributed by people enrolled in the program.

medication abuse Maladaptive pattern of recurrent medication use.

medication allergy Adverse reaction such as rash, chills, or gastrointestinal disturbances to a medication. Once a drug allergy occurs, the patient can no longer receive that particular medication.

medication dependence Maladaptive pattern of medication use in the following patterns: using excessive amounts of the medication, increased activities directed toward obtaining the medication, or withdrawal from professional or recreational activities.

medication error Any event that could cause or lead to a patient's receiving inappropriate drug therapy or failing to receive appropriate drug therapy.

medication interaction Response that occurs when one drug modifies the action of another drug. The interaction can potentiate or diminish the actions of another drug; or it may alter the way a drug is metabolized, absorbed, or excreted.

melanoma Group of malignant neoplasms, primarily of the skin, that are composed of melanocytes. Common in fair-skinned people having light-colored eyes and those who have been sunburned.

melena Abnormal black, sticky stool containing digested blood that is indicative of gastrointestinal bleeding.

menarche Onset of a girl's first menstruation.

Ménière's disease Chronic disease of the inner ear characterized by recurrent episodes of vertigo; progressive sensorineural hearing loss, which may be bilateral; and tinnitus.

menopause Physiological cessation of ovulation and menstruation that typically occurs during middle adulthood in women.

message Information sent or expressed by sender in the communication process.

metabolic acidosis Abnormal condition of high hydrogen ion concentration in the extracellular fluid caused by either a primary increase in hydrogen ions or a decrease in bicarbonate.

metabolic alkalosis Abnormal condition characterized by the significant loss of acid from the body or increased levels of bicarbonate.

metabolism Aggregate of all chemical processes that take place in living organisms and result in growth, generation of energy, elimination of wastes, and other functions concerned with the distribution of nutrients in the blood after digestion.

metacommunication Dependent not only on what is said but also on the relationship to the other person involved in the interaction. It is a message that conveys the sender's attitude toward self and the message and the attitudes, feelings, and intentions toward the listener.

metastasize Spread of tumor cells to distant parts of the body from a primary site (e.g., lung, breast, or bowel).

metered-dose inhaler (MDI) Device designed to deliver a measured dose of an inhalation drug.

metric system Logically organized decimal system of measurement; metric units can easily be converted and computed through simple multiplication and division. Each basic unit of measurement is organized into units of 10.

microorganisms Microscopic entities such as bacteria, viruses, and fungi that are capable of carrying on living processes.

micturition Urination; act of passing or expelling urine voluntarily through the urethra.

milliequivalent per liter (mEq/L) Number of grams of a specific electrolyte dissolved in 1 L of plasma.

mind mapping Graphic approach to represent the connections between concepts and ideas (e.g., nursing diagnoses) that are related to a central subject (e.g., the patient's health problems).

minerals Inorganic elements essential to the body because of their role as catalysts in biochemical reactions.

minimum data set (MDS) Required by the Omnibus Budget Reconciliation Act of 1987, the MDS is a uniform data set established by the Department of Health and Human Services. It serves as the framework for any state-specified assessment instruments used to develop a written and comprehensive plan of care for newly admitted residents of nursing facilities.

misdemeanor Lesser crime than a felony; the penalty is usually a fine or imprisonment for less than 1 year.

mobility Person's ability to move about freely.

moderate sedation/analgesia/conscious sedation Administration of central nervous system depressant drugs and/or analgesics to provide analgesia, relieve anxiety, and/or provide amnesia during surgical, diagnostic, or interventional procedures. Routinely used for diagnostic or therapeutic procedures that do not require complete anesthesia but simply a decreased level of consciousness.

monosaturated fatty acid Fatty acid in which some of the carbon atoms in the hydrocarbon chain are joined by double or triple bonds. Monounsaturated fatty acids have only one double or triple bond per molecule and are found as components of fats in such foods as fowls, almonds, pecans, cashew nuts, peanuts, and olive oil.

morals Personal conviction that something is absolutely right or wrong in all situations.

motivation Internal impulse that causes a person to take action.

mourning Process of grieving.

murmurs Blowing or whooshing sounds created by changes in blood flow through the heart or abnormalities in valve closure.

muscle tone Normal state of balanced muscle tension.

myocardial contractility Measure of stretch of the cardiac muscle fiber. It can also affect stroke volume and cardiac output. Poor contraction decreases the amount of blood ejected by the ventricles during each contraction.

myocardial infarction Necrosis of a portion of cardiac muscle caused by obstruction in a coronary artery.

myocardial ischemia Condition that results when the supply of blood to the myocardium from the coronary arteries is insufficient to meet the oxygen demands of the organ.

N

NANDA International North American Nursing Diagnosis Association organized in 1973. It formally identifies, develops, and classifies nursing diagnoses.

narcolepsy Syndrome involving sudden sleep attacks that a person cannot inhibit. Uncontrollable desire to sleep may occur several times during a day.

nasogastric (NG) tube Tube passed into the stomach through the nose to empty the stomach of its contents or deliver medication and/or nourishment.

nebulization Process of adding moisture to inspired air by the adding water droplets.

necessary losses Losses that every person experiences.

necrotic Of or pertaining to the death of tissue in response to disease or injury.

negative health behaviors Practices actually or potentially harmful to health such as smoking, drug or alcohol abuse, poor diet, and refusal to take necessary medications.

negative nitrogen balance Condition occurring when the body excretes more nitrogen than it takes in.

negligence Careless act of omission or commission that results in injury to another.

neonate Stage of life from birth to 1 month of age.

nephrons Structural and functional units of the kidney containing renal glomeruli and tubules.

neurotransmitter Chemical that transfers the electrical impulse from the nerve fiber to the muscle fiber.

nociceptors Somatic and visceral free nerve endings of thinly myelinated and unmyelinated fibers. They usually react to tissue injury but may also be excited by endogenous chemical substances.

nocturia Urination at night; can be a symptom of renal disease or may occur in persons who drink excessive amounts of fluids before bedtime.

nonblanchable hyperemia Redness of the skin caused by dilation of the superficial capillaries. The redness persists when pressure is applied to the area, indicating tissue damage.

noninvasive positive-pressure ventilation (NPPV) Used to prevent using invasive artificial airways (endotracheal [ET] tube or tracheostomy) in patients with acute respiratory failure, cardiogenic pulmonary edema, or exacerbation of chronic obstructive pulmonary disease. It has also been used following extubation of an ET tube.

nonmaleficence Fundamental ethical agreement to do no harm. Closely related to the ethical standard of beneficence.

nonrapid eye movement (NREM) sleep Sleep that occurs during the first four stages of normal sleep.

nonshivering thermogenesis Occurs primarily in neonates. Because neonates cannot shiver, a limited amount of vascular brown adipose tissue present at birth can be metabolized for heat production.

nonverbal communication Communication using expressions, gestures, body posture, and positioning rather than words.

normal sinus rhythm (NSR) The wave pattern on an electrocardiogram that indicates normal conduction of an electrical impulse through the myocardium.

numbing One of Bowlby's four phases of mourning. It is characterized by the lack of feeling or feeling stunned by the loss; may last a few days or many weeks.

Nurse Practice Acts Statutes enacted by the legislature of any of the states or the appropriate officers of the districts or possessions that describe and define the scope of nursing practice.

nurse-initiated interventions Response of the nurse to the patient's health care needs and nursing diagnoses. This type of intervention is an autonomous action based on scientific rationale that is executed to benefit the patient in a predicted way related to the nursing diagnosis and patient-centered goals.

nursing diagnosis Formal statement of an actual or potential health problem that nurses can legally and independently treat; the second step of the nursing process, during which the patient's actual and potential unhealthy responses to an illness or condition are identified.

nursing health history Data collected about a patient's present level of wellness, changes in life patterns, sociocultural role, and mental and emotional reactions to illness.

nursing intervention Any treatment based on clinical judgment and knowledge that a nurse performs to enhance patient outcomes.

nursing process Systematic problem-solving method by which nurses individualize care for each patient. The five steps of the nursing process are assessment, diagnosis, planning, implementation, and evaluation.

nursing-sensitive outcomes Outcomes that are within the scope of nursing practice; consequences or effects of nursing interventions that result in changes in the patient's symptoms, functional status, safety, psychological distress, or costs.

nurturant Behavior that involves caring for or fostering the well-being of another individual.

nutrients Foods that contain elements necessary for body function, including water, carbohydrates, proteins, fats, vitamins, and minerals.

O

obesity Abnormal increase in the proportion of fat cells, mainly in the viscera and subcutaneous tissues of the body.

objective data Information that can be observed by others; free of feelings, perceptions, prejudices.

occurrence report Confidential document that describes any patient accident while the person is on the premises of a health care agency. (See incident report.)

olfactory Pertaining to the sense of smell.

oncotic pressure Total influence of the protein on the osmotic activity of plasma fluid.

Open-ended question Form of question that prompts a respondent to answer in more than one or two words.

operating bed Table for surgery.

operating room (1) Room in a health care facility in which surgical procedures requiring anesthesia are performed. (2) Informal: a suite of rooms or an area in a health care facility in which patients are prepared for surgery, undergo surgical procedures, and recover from the anesthetic procedures required for the surgery.

ophthalmic Drugs given into the eye in the form of either eye drops or ointments.

ophthalmoscope Instrument used to illuminate the structures of the eye to examine the fundus, which includes the retina, choroid, optic nerve disc, macula, fovea centralis, and retinal vessels.

opioid Drug substance derived from opium or produced synthetically that alters perception of pain and that, with repeated use, may result in physical and psychological dependence (narcotic).

oral hygiene Condition or practice of maintaining the tissues and structures of the mouth.

orthopnea Abnormal condition in which a person must sit or stand to breathe comfortably.

orthostatic hypotension Abnormally low blood pressure occurring when a person stands.

osmolality Concentration or osmotic pressure of a solution expressed in osmoles or milliosmoles per kilogram of water.

osmolarity Osmotic pressure of a solution expressed in osmoles or milliosmoles per kilogram of the solution.

osmoreceptors Neurons in the hypothalamus that are sensitive to the fluid concentration in the blood plasma and regulate the secretion of antidiuretic hormone.

osmosis Movement of a pure solvent through a semipermeable membrane from a solution with a lower solute concentration to one with a higher solute concentration.

osmotic pressure Drawing power for water, which depends on the number of molecules in the solution.

osteoporosis Disorder characterized by abnormal rarefaction of bone, occurring most frequently in postmenopausal women, sedentary or immobilized individuals, and patients on long-term steroid therapy.

ostomy Surgical procedure in which an opening is made into the abdominal wall to allow the passage of intestinal contents from the bowel (colostomy) or urine from the bladder (urostomy).

otoscope Instrument with a special ear speculum used to examine the deeper structures of the external and middle ear.

ototoxic Having a harmful effect on the eighth cranial (auditory) nerve or the organs of hearing and balance.

outcome Condition of a patient at the end of treatment, including the degree of wellness and the need for continuing care, medication, support, counseling, or education.

outliers Patients with extended lengths of stay beyond allowable inpatient days or costs.

outpatient Patient who has not been admitted to a hospital but receives treatments in a clinic or facility associated with the hospital.

oxygen saturation Amount of hemoglobin fully saturated with oxygen, given as a percent value.

oxygen therapy Procedure in which oxygen is administered to a patient to relieve or prevent hypoxia.

P

pain Subjective, unpleasant sensation caused by noxious stimulation of sensory nerve endings.

palliative care Level of care that is designed to relieve or reduce intensity of uncomfortable symptoms but not to produce a cure. Palliative care relies on comfort measures and use of alternative therapies to help individuals become more at peace during end of life.

pallor Unnatural paleness or absence of color in the skin.

palpation Method of physical examination whereby the fingers or hands of the examiner are applied to the patient's body to feel body parts underlying the skin.

palpitations Bounding or racing of the heart associated with normal emotions or a heart disorder.

Papanicolaou (Pap) smear Painless screening test for cervical cancer. Specimens are taken of squamous and columnar cells of the cervix.

parallel play Form of play among a group of children, primarily toddlers, in which each one engages in an independent activity that is similar to but not influenced by or shared with the others.

paralytic ileus Usually temporary paralysis of intestinal wall that may occur after abdominal surgery or peritoneal injury and that causes cessation of peristalsis; leads to abdominal distention and symptoms of obstruction.

parenteral administration Giving medication by a route other than the gastrointestinal tract.

parenteral nutrition (PN) Administration of a nutritional solution into the vascular system.

parteras Lay midwives.

partial bed bath Bath in which body parts that might cause the patient discomfort if left unbathed (i.e., face, hands, axillary areas, back, and perineum) are washed in bed.

passive range-of-motion (PROM) exercises Range of movement through which a joint is moved with assistance.

passive strategies of health promotion Activities that involve the patient as the recipient of actions by health care professionals.

pathogenicity Ability of a pathogenic agent to produce a disease.

pathogens Microorganisms capable of producing disease.

pathological fractures Fractures resulting from weakened bone tissue; frequently caused by osteoporosis or neoplasms.

patient-centered care Concept to improve work efficiency by changing the way that patient care is delivered.

patient-controlled analgesia (PCA) Drug delivery system that allows patients to self-administer analgesic medications on demand.

patrilineal, patrilineally Kinship that is limited to only the father's side.

pay for performance Quality improvement program that rewards excellence through financial incentives to motivate change to achieve measurable improvements and improve patient care quality and safety.

perceived loss Loss that is less obvious to the individual experiencing it. Although easily overlooked or misunderstood, a perceived loss results in the same grief process as an actual loss.

perception Peoples' mental image or concept of elements in their environment, including information gained through the senses.

percussion Method of physical examination whereby the location, size, and density of a body part is determined by the tone obtained from the striking of short, sharp taps of the fingers.

perfusion (1) Passage of a fluid through a specific organ or an area of the body. (2) Therapeutic measure whereby a drug intended for an isolated part of the body is introduced via the bloodstream. (3) Relates to the ability of the cardiovascular system to pump oxygenated blood to the tissues and return deoxygenated blood to the lungs.

perineal care Procedure prescribed for cleaning the genital and anal areas as part of the daily bath or after various obstetrical and gynecological procedures.

perioperative nursing Refers to the role of the operating room nurse during the preoperative, intraoperative, and postoperative phases of surgery.

peripherally inserted central catheter (PICC) Alternative intravenous access when the patient requires intermediate-length venous access greater than 7 days to 3 months. Intravenous access is achieved by inserting a catheter into a central vein by way of a peripheral vein.

peristalsis Rhythmical contractions of the intestine that propel gastric contents through the length of the gastrointestinal tract.

peritonitis Inflammation of the peritoneum produced by bacteria or irritating substances introduced into the abdominal cavity by a penetrating wound or perforation of an organ in the gastrointestinal or reproductive tract.

PERRLA Acronym for "pupils equal, round, reactive to light, accommodation"; the acronym is recorded in the physical examination if eye and pupil assessments are normal.

personalismo Personalistic.

petechiae Tiny purple or red spots that appear on skin as minute hemorrhages within dermal layers.

pharmacokinetics Study of how drugs enter the body, reach their site of action, are metabolized, and exit from the body.

phlebitis Inflammation of a vein.

physician-initiated interventions Based on the physician's response to a medical diagnosis, the nurse responds to his or her written orders.

PIE note Problem-oriented medical record; the four interdisciplinary sections are the database, problem list, care plan, and progress notes.

placebos Dosage form that contains no pharmacologically active ingredients but may relieve pain through psychological effects.

plaintiff Individual who files formal charges against an individual or organization for a legal offense.

planning Process of designing interventions to achieve the goals and outcomes of health care delivery.

plantar flexion Toe-down motion of the foot at the ankle.

pleural friction rub Adventitious lung sound caused by inflamed parietal and visceral pleura rubbing together on inspiration.

pneumothorax Collection of air or gas in the pleural space.

point of maximal impulse (PMI) Point where the heartbeat can most easily be palpated through the chest wall. This is usually the fourth intercostal space at the midclavicular line.

point of view Way of looking at issues that reflects an individual's culture and societal influences.

poison Any substance that impairs health or destroys life when ingested, inhaled, or absorbed by the body in relatively small amounts.

poison control center One of a network of facilities that provides information regarding all aspects of poisoning or intoxication, maintains records of their occurrence, and refers patients to treatment centers.

polypharmacy Use of a number of different drugs by a patient who may have one or several health problems.

polyunsaturated fatty acid Fatty acid that has two or more carbon double bonds.

population Collection of individuals who have in common one or more personal or environmental characteristics.

positive health behaviors Activities related to maintaining, attaining, or regaining good health and preventing illness. Common positive health behaviors include immunizations, proper sleep patterns, adequate exercise, and nutrition.

postanesthesia care unit (PACU) Area adjoining the operating room to which surgical patients are taken while still under anesthesia.

postmortem care Care of a patient's body after death.

postural drainage Use of positioning along with percussion and vibration to drain secretions from specific segments of the lungs and bronchi into the trachea.

postural hypotension Abnormally low blood pressure occurring when an individual assumes the standing posture; also called orthostatic hypotension.

posture Position of the body in relation to the surrounding space.

power of attorney for health care Person designated by the patient to make health care decisions for the patient if the patient becomes unable to make his or her own decisions.

preadolescence Transitional developmental stage that occurs between childhood and adolescence.

preanesthesia care unit Area outside the operating room where preoperative preparations are completed.

preload Volume of blood in the ventricles at the end of diastole, immediately before ventricular contraction.

preoperative teaching Instruction regarding a patient's anticipated surgery and recovery that is given before surgery. Instruction includes, but is not limited to, dietary and activity restrictions, anticipated assessment activities, postoperative procedures, and pain-relief measures.

presbycusis Hearing loss associated with aging. It usually involves both a loss of hearing sensitivity and a reduction in the clarity of speech.

presbyopia Gradual decline in ability of the lens to accommodate or focus on close objects; reduces ability to see near objects clearly. This condition commonly develops with advancing age.

prescriptions Written directions for a therapeutic agent (e.g., medication, drugs).

presence Deep physical, psychological, and spiritual connection or engagement between a nurse and patient.

present time orientation Time dimension that focuses on what is happening here and now. Communication patterns are circular, and this time orientation is in conflict with the dominant organizational norm in health care that emphasizes punctuality and adherence to appointments.

pressure ulcer Inflammation, sore, or ulcer in the skin over a bony prominence.

presurgical care unit (PSCU) Area outside the operating room where preoperative preparations are completed.

preventive nursing actions Nursing actions directed toward preventing illness and promoting health to avoid the need for primary, secondary, or tertiary health care.

primary appraisal Evaluating an event for its personal meaning related to stress.

primary care First contact in a given episode of illness that leads to a decision regarding a course of action to resolve the health problem.

primary health care Combination of primary and public health care that is accessible to individuals and families in a community and provided at an affordable cost.

primary intention Primary union of the edges of a wound, progressing to complete scar formation without granulation.

primary nursing Method of nursing practice in which the patient's care is managed for the duration by one nurse who directs and coordinates other nurses and health care personnel. When on duty, the primary nurse cares for the patient directly.

primary prevention First contact in a given episode of illness that leads to a decision regarding a course of action to prevent worsening of the health problem.

problem identification One of the steps of the diagnostic process in which the patient's health care problem is recognized as a result of data analysis based on professional knowledge and experience.

problem solving Methodical, systematic approach to explore conditions and develop solutions, including analysis of data, determination of causative factors, and selection of appropriate actions to reverse or eliminate the problem.

problem-oriented medical record (POMR) Method of recording data about the health status of a patient that fosters a collaborative problem-solving approach by all members of the health care team.

productive cough Sudden expulsion of air from the lungs that effectively removes sputum from the respiratory tract and helps clear the airways.

professional standards review organization (PSRO) Focuses on evaluation of nursing care provided in a health care setting. The quality, effectiveness, and appropriateness of nursing care for the patient are the focus of evaluation.

prone Position of the patient lying face down.

proprioception Ability of the body to sense its position and movement in space.

prospective payment system (PPS) Payment mechanism for reimbursing hospitals for inpatient health care services in which a predetermined rate is set for treatment of specific illnesses.

prostaglandins Potent hormonelike substances that act in exceedingly low doses on target organs. They can be used to treat asthma and gastric hyperacidity.

proteins Any of a large group of naturally occurring, complex, organic nitrogenous compounds. Each is composed of large combinations of amino acids containing the elements carbon; hydrogen; nitrogen; oxygen; usually sulfur; and occasionally phosphorus, iron, iodine, or other essential constituents of living cells. Protein is the major source of building material for muscles, blood, skin, hair, nails, and the internal organs.

proteinuria Presence in the urine of abnormally large quantities of protein, usually albumin. Persistent proteinuria is usually a sign of renal disease or renal complications of another disease, hypertension, or heart failure.

protocol Written and approved plan specifying the procedures to be followed during an assessment or in providing treatment.

pruritus Symptom of itching; an uncomfortable sensation leading to the urge to scratch.

psychomotor learning Acquisition of ability to perform motor skills.

ptosis Abnormal condition of one or both upper eyelids in which the eyelid droops; caused by weakness of the levator muscle or paralysis of the third cranial nerve.

puberty Developmental period of emotional and physical changes, including the development of secondary sex characteristics and the onset of menstruation and ejaculation.

public health nursing Nursing specialty that requires the nurse to care for the needs of populations or groups.

public communication Interaction of one individual with large groups of people.

pulmonary hygiene More frequent turning, deep breathing, coughing, use of incentive spirometry, and chest physical therapy (PT) if ordered.

pulse deficit Condition that exists when the radial pulse is less than the ventricular rate as auscultated at the apex or seen on an electrocardiogram. The condition indicates a lack of peripheral perfusion for some of the heart contractions.

pulse pressure Difference between the systolic and diastolic pressures, normally 30 to 40 mm Hg.

Purkinje network Complex network of muscle fibers that spread through the right and left ventricles of the heart and carry the impulses that contract those chambers almost simultaneously.

pursed-lip breathing Deep inspiration followed by prolonged expiration through pursed lips.

pyrexia Abnormal elevation of the temperature of the body above 37° C (98.6° F) because of disease; same as fever.

pyrogens Substances that cause a rise in body temperature, as in the case of bacterial toxins.

Q

QSEN The Quality and Safety in the Education of Nurses (QSEN) initiative is the commitment of nursing to the competencies outlined in the Institute of Medicine report related to nursing education. QSEN encompasses six competencies: patient-centered care, teamwork, collaboration, evidence-based practice, quality improvement, and safety.

quality improvement Monitoring and evaluation of processes and outcomes in health care or any other business to identify opportunities for improvement.

quality indicator Quantitative measure of an important aspect of care that determines whether quality of service conforms to requirements or standards of care.

R

race Common biological characteristics shared by a group of people.

Ramadan Religious observance held during the ninth month of the Islamic calendar year. It involves fasting from sunrise to sunset.

range of motion (ROM) Range of movement of a joint from maximum extension to maximum flexion as measured in degrees of a circle.

rapid eye movement (REM) sleep Stage of sleep in which dreaming and rapid eye movements are prominent; important for mental restoration.

reaction Component of the pain experience that may include both physiological responses such as in the general adaptation syndrome and behavioral responses.

reality orientation Therapeutic modality for restoring an individual's sense of the present.

receiver Person to whom message is sent during the communication process.

reception Neurophysiological components of the pain experience in which nervous system receptors receive painful stimuli and transmit them through peripheral nerves to the spinal cord and brain.

record Written form of communication that permanently documents information relevant to health care management.

recovery Period of time immediately following surgery when the patient is closely observed for effects of anesthesia, changes in vital signs, and bleeding. The area is usually in the postanesthesia care unit.

referent Factor that motivates a person to communicate with another individual.

reflection Process of thinking back or recalling an event to discover the meaning and purpose of that event. Useful in critical thinking.

refractive error Defect in the ability of the lens of the eye to focus light such as occurs in nearsightedness and farsightedness.

regional anesthesia Loss of sensation in an area of the body supplied by sensory nerve pathways.

registered nurse (RN) In the United States a nurse who has completed a course of study at a state-approved, accredited school of nursing and has passed the National Council Licensure Examination (NCLEX-RN).

regression Return to an earlier developmental stage or behavior.

regulatory agencies Local, state, provincial, or national agencies that inspect and certify health care agencies as meeting specified standards. These agencies can also determine the amount of reimbursement for health care delivered.

rehabilitation Restoration of an individual to normal or near-normal function after a physical or mental illness, injury, or chemical addiction.

reinforcement Provision of a contingent response to a learner's behavior that increases the probability of recurrence of the behavior.

related factor Any condition or event that accompanies or is linked with the patient's health care problem.

relaxation Act of being relaxed or less tense.

reminiscence Recalling the past to assign new meaning to past experiences.

remissions Partial or complete disappearances of the clinical and subjective characteristics of chronic or malignant disease; remission may be spontaneous or the result of therapy.

renal calculi Calcium stones in the renal pelvis.

renin Proteolytic enzyme produced by and stored in the juxtaglomerular apparatus that surrounds each arteriole as it enters a glomerulus. The enzyme affects the blood pressure by catalyzing the change of angiotensinogen to angiotensin, a strong repressor.

reorganization Last phase of Bowlby's phases of mourning. During this phase, which sometimes requires a year or more, the person begins to accept unaccustomed roles, acquire new skills, and build new relationships.

reports Transfer of information from the nurses on one shift to the nurses on the following shift. Report may also be given by one of the members of the nursing team to another health care provider (e.g., a physician or therapist).

reservoir Place where microorganisms survive, multiply, and await transfer to a susceptible host.

residual urine Volume of urine remaining in the bladder after a normal voiding; the bladder normally is almost completely empty after micturition.

resistance stage Third stage of the stress response, when the person attempts to adapt to the stressor. The body stabilizes; hormone levels stabilize; and heart rate, blood pressure, and cardiac output return to normal.

resource utilization group (RUG) Method of classification for health care reimbursement for long-term care facilities.

respeto Respectful.

respiration Exchange of oxygen and carbon dioxide during cellular metabolism.

respiratory acidosis Abnormal condition characterized by increased arterial carbon dioxide concentration, excess carbonic acid, and increased hydrogen ion concentration.

respiratory alkalosis Abnormal condition characterized by decreased arterial carbon dioxide concentration and hydrogen ion concentration.

respite care Short-term health services to dependent older adults either in their home or in an institutional setting.

responsibility Carrying out duties associated with a particular role.

restorative care Health care settings and services in which patients who are recovering from illness or disability receive rehabilitation and supportive care.

restraint Device to aid in the immobilization of a patient or patient's extremity.

return demonstration Demonstration after the patient has first observed the teacher and then practiced the skill in mock or real situations.

rhonchi Abnormal lung sound auscultated when the patient's airways are obstructed with thick secretions.

right-sided heart failure Abnormal condition that results from impaired functioning of the right ventricle; characterized by venous congestion in the systemic circulation.

risk factor Any internal or external variable that makes a person or group more vulnerable to illness or an unhealthy event.

risk management Function of hospital or other health facility administration that is directed toward identification, evaluation, and correction of potential risks that could lead to injury of patients, staff members, or visitors and result in property loss or damage.

risk nursing diagnosis Describes human responses to health conditions/life processes that may develop in a vulnerable individual, family, or community.

role performance Way in which a person views his or her ability to carry out significant roles.

root cause analysis Process of data collection and analysis that aids in finding the real cause of the problem and working on dealing with it rather than just dealing with its effects.

S

Sabbath From sundown on Friday to sundown on Saturday, this religious observance is a day of rest and worship for Jews and some Christian sects.

sandbags Sand-filled plastic tubes that can be shaped to body contours. They can immobilize an extremity or maintain body alignment.

saturated fatty acid Fatty acid in which each carbon in the chain has an attached hydrogen atom.

scientific method Codified sequence of steps used in the formulation, testing, evaluation, and reporting of scientific ideas.

scientific rationale Reason why a specific nursing action was chosen based on supporting literature.

scoliosis Lateral spinal curvature.

scrub nurse Registered nurse or operating room technician who assists surgeons during operations.

secondary appraisal Evaluating one's possible coping strategies when confronted with a stressor.

secondary intention Wound closure in which the edges are separated; granulation tissue develops to fill the gap; and, finally, epithelium grows in over the granulation, producing a larger scar than results with primary intention.

secondary prevention Level of preventive medicine that focuses on early diagnosis, use of referral services, and rapid initiation of treatment to stop the progress of disease processes.

sedatives Medications that produce a calming effect by decreasing functional activity, diminishing irritability, and allaying excitement.

segmentation Alternating contraction and relaxation of gastrointestinal mucosa.

self-concept Complex, dynamic integration of conscious and unconscious feelings, attitudes, and perceptions about one's identity, physical being, worth, and roles; how a person perceives and defines self.

self-esteem Feeling of self-worth characterized by feelings of achievement, adequacy, self-confidence, and usefulness.

self-transcendence Sense of authentically connecting to one's inner self.

sender Person who initiates interpersonal communication by conveying a message.

sensible water loss Loss of fluid from the body through the secretory activity of the sweat glands and the exhalation of humidified air from the lungs.

sensory deficits Defects in the function of one or more of the senses, resulting in visual, auditory, or olfactory impairments.

sensory deprivation State in which stimulation to one or more of the senses is lacking, resulting in impaired sensory perception.

sensory overload State in which stimulation to one or more of the senses is so excessive that the brain disregards or does not meaningfully respond to stimuli.

sequential compression stockings Plastic stockings attached to an air pump that inflates and deflates the stockings, applying intermittent pressure sequentially from the ankle to the knee.

serum half-life Time needed for excretion processes to lower the serum drug concentration by half.

sexual dysfunction Inability or difficulty in sexual functioning caused by physiological or psychological factors or both.

sexual orientation Clear, persistent erotic preference for a person of one sex or the other.

sexuality "A function of the total personality . . . concerned with the biological, psychological, sociological, spiritual and culture variables of life . . ." (Sex Information and Education Council of the United States, 1980).

sexually transmitted infection Infectious process spread through sexual contact, including oral, genital, or anal sexual activity.

shear Force exerted against the skin while the skin remains stationary and the bony structures move.

side effect Any reaction or consequence that results from medication or therapy.

side rails Bars positioned along the sides of the length of the bed or stretcher to reduce the patient's risk of falling.

simpatia Friendly.

sinoatrial (SA) node Called the *pacemaker of the heart* because the origin of the normal heartbeat begins at the SA node. The SA node is in the right atrium next to the entrance of the superior vena cava.

situational crisis Unexpected crisis that arises suddenly in response to an external event or a conflict concerning a specific circumstance.

situational loss Loss of a person, thing, or quality resulting from a change in a life situation, including changes related to illness, body image, environment, and death.

sitz bath Bath in which only the hips or buttocks are immersed in fluid.

skilled nursing facility Institution or part of an institution that meets criteria for accreditation established by the sections of the Social Security Act that determine the basis for Medicaid and Medicare reimbursement for skilled nursing care, including rehabilitation and various medical and nursing procedures.

sleep State marked by reduced consciousness, diminished activity of the skeletal muscles, and depressed metabolism.

sleep apnea Cessation of breathing for a time during sleep.

sleep deprivation Condition resulting from a decrease in the amount, quality, and consistency of sleep.

SOAP note Progress note that focuses on a single patient problem and includes subjective and objective data, analysis, and planning; most often used in the problem-oriented medical record (POMR).

socializing Interacting with friends or other people; communicating with others to form relationships and help people feel relaxed.

solute Substance dissolved in a solution.

solution Mixture of one or more substances dissolved in another substance. The molecules of each of the substances disperse homogeneously and do not change chemically. A solution may be a liquid, gas, or solid.

solvent Any liquid in which another substance can be dissolved.

source record Organization of a patient's chart so each discipline (e.g., nursing, medicine, social work, or respiratory therapy) has a separate section in which to record data. Unlike POMR, the information is not organized by patient problems. The advantage of a source record is that caregivers can easily locate the proper section of the record in which to make entries.

sphygmomanometer Device for measuring the arterial blood pressure that consists of an arm or leg cuff with an air bladder connected to a tube, a bulb for pumping air into the bladder, and a gauge for indicating the amount of air pressure being exerted against the artery.

spiritual distress State of being out of harmony with a system of beliefs, a Supreme Being, or God.

spiritual well-being Individual's spirituality that enables a person to love, have faith and hope, seek meaning in life, and nurture relationships with others.

spirituality Spiritual dimension of a person, including the relationship with humanity, nature, and a supreme being.

standard of care Minimum level of care accepted to ensure high-quality care to patients. Standards of care define the types of therapies typically administered to patients with defined problems or needs.

standard precautions Guidelines recommended by the Centers for Disease Control and Prevention (CDC) to reduce risk of transmission of bloodborne and other pathogens in hospitals.

standardized care plans Written care plans used for groups of patients who have similar health care problems.

standing order Written and approved documents containing rules, policies, procedures, regulations, and orders for the conduct of patient care in various stipulated clinical settings.

statutory law Of or related to laws enacted by a legislative branch of the government.

stenosis Abnormal condition characterized by the constriction or narrowing of an opening or passageway in a body structure.

stereotypes Generalizations that are made about individuals without further assessment.

sterilization (1) Rendering a person unable to produce children; accomplished by surgical, chemical, or other means. (2) A technique for destroying microorganisms using heat, water, chemicals, or gases.

stoma Artificially created opening between a body cavity and the surface of the body (e.g., a colostomy formed from a portion of the colon pulled through the abdominal wall).

stress Physiological or psychological tension that threatens homeostasis or a person's psychological equilibrium.

stressor Any event, situation, or other stimulus encountered in a person's external or internal environment that necessitates change or adaptation by the person.

striae Streaks or linear scars that result from rapid development of tension in the skin.

stroke volume (SV) Amount of blood ejected by the ventricles with each contraction. It can be affected by the amount of blood in the left ventricle at the end of diastole (preload), the resistance to left ventricular ejection (afterload), and myocardial contractility.

subacute care Level of medical specialty care provided to patients who need a greater intensity of care than that provided in a skilled nursing facility but who do not require acute care.

subcultures Various ethnic, religious, and other groups with distinct characteristics from the dominant culture.

subcutaneous (sub-Q) Injection given into the connective tissue under the dermis. The subcutaneous tissue absorbs drugs more slowly than those injected into muscle. Injections are usually given at a 45-degree angle.

subjective data Information gathered from patient statements; the patient's feelings and perceptions. Not verifiable by another except by inference.

sublingual Route of medication administration in which the medication is placed underneath the patient's tongue.

Sunrise Model A model developed by Leininger that aids the health care practitioner in designing care decisions and actions in a culturally congruent fashion.

supine Position of the patient in which the patient is resting on his or her back.

suprainfection Secondary infection usually caused by an opportunistic pathogen.

suprapubic catheter Catheter surgically inserted through abdomen into bladder.

surfactant Chemical produced in the lungs to maintain the surface tension of the alveoli and keep them from collapsing.

surgical asepsis Procedures used to eliminate any microorganisms from an area. Also called *sterile technique*.

sympathy Concern, sorrow, or pity felt by the nurse for the patient. Sympathy is a subjective look at another person's world that prevents a clear perspective of all sides of the issues confronting that person.

synapse Region surrounding the point of contact between two neurons or between a neuron and an effector organ.

syncope Brief lapse in consciousness caused by transient cerebral hypoxia.

synergistic effect Effect resulting from two drugs acting synergistically. The effect of the two drugs combined is greater than the effect that would be expected if the individual effects of the two drugs acting alone were added together.

systolic Pertaining to or resulting from ventricular contraction.

T

tachycardia Rapid regular heart rate ranging between 100 and 150 beats/min.

tachypnea Abnormally rapid rate of breathing.

tactile Relating to the sense of touch.

tactile fremitus Tremulous vibration of the chest wall during breathing that is palpable on physical examination.

teaching Implementation method used to present correct principles, procedures, and techniques of health care; to inform patients about their health status; and to refer patients and family to appropriate health or social resources in the community.

team nursing Decentralized system in which the care of a patient is distributed among the members of a team. The charge nurse delegates authority to a team leader, who must be a professional nurse.

teratogens Chemical or physiological agents that may produce adverse effects in the embryo or fetus.

tertiary prevention Activities directed toward rehabilitation rather than diagnosis and treatment.

therapeutic communication Process in which the nurse consciously influences a patient or helps the patient to a better understanding through verbal and/or nonverbal communication.

therapeutic effect Desired benefit of a medication, treatment, or procedure.

thermoregulation Internal control of body temperature.

threshold Point at which a person first perceives a painful stimulus as being painful.

thrill Continuous palpable sensation like the purring of a cat.

thrombus Accumulation of platelets, fibrin, clotting factors, and the cellular elements of the blood attached to the interior wall of a vein or artery, sometimes occluding the lumen of the vessel.

tinnitus Ringing heard in one or both ears.

tissue ischemia Point at which tissues receive insufficient oxygen and perfusion.

tolerance Point at which a person is not willing to accept pain of greater severity or duration.

tort Act that causes injury for which the injured party can bring civil action.

total patient care Nursing delivery of care model originally developed during Florence Nightingale's time. In the model a registered nurse (RN) is responsible for all aspects of care for one or more patients. The RN works directly with the patient, family, physician or health care provider, and health care team members. The model typically has a shift-based focus.

touch To come in contact with another person, often conveying caring, emotional support, encouragement, or tenderness.

toxic effect Effect of a medication that results in an adverse response.

tracheostomy Procedure whereby a surgical incision is made into the trachea and a short artificial airway (a tracheostomy tube) is inserted.

transcendence The belief that there is a force outside of and greater than the person that exists beyond the material world.

transcultural Concept of care extending across cultures that distinguishes nursing from other health disciplines.

transcultural nursing Distinct discipline developed by Leininger that focuses on the comparative study of cultures to understand similarities and differences among groups of people.

transcutaneous electrical nerve stimulation (TENS) Technique in which a battery-powered device blocks pain impulses from reaching the spinal cord by delivering weak electrical impulses directly to the surface of the skin.

transdermal disk Medication delivery device in which the medication is saturated on a waferlike disk, which is affixed to the patient's skin. This method ensures that the patient receives a continuous level of medication.

transfer report Verbal exchange of information between caregivers when a patient is moved from one nursing unit or health care setting to another. The report includes information necessary to maintain a consistent level of care from one setting to another.

transfusion reaction Systemic response by the body to the administration of blood incompatible with that of the recipient.

trapeze bar Metal triangular-shaped bar that can be suspended over a patient's bed from an overhanging frame; permits patients to move up and down in bed while in traction or some other encumbrance.

trimester Referring to one of the three phases of pregnancy.

trochanter roll Rolled towel support placed against the hips and upper leg to prevent external rotation of the legs.

trough The lowest serum concentration of a medication before the next medication dose is administered.

turgor Normal resiliency of the skin caused by the outward pressure of the cells and interstitial fluid.

U

unsaturated fatty acid Fatty acid in which an unequal number of hydrogen atoms are attached and the carbon atoms attach to one another with a double bond.

ureterostomy Diversion of urine away from a diseased or defective bladder through an artificial opening in the skin.

urge incontinence A type of urinary incontinence that results from sudden, involuntary contraction of the muscles of the urinary bladder, resulting in an urge to urinate.

urinal Receptacle for collecting urine.

urinary diversion Surgical diversion of the drainage of urine such as a ureterostomy.

urinary incontinence Inability to control urination.

urinary reflux Abnormal, backward flow of urine.

urinary retention Retention of urine in the bladder; condition frequently caused by a temporary loss of muscle function.

urine hat Receptacle for collecting urine that fits toilet.

urometer Device for measuring frequent and small amounts of urine from an indwelling urinary catheter system.

urosepsis Organisms in the bloodstream.

utilitarianism Ethic that proposes that the value of something is determined by its usefulness. The greatest good for the greatest number of people constitutes the guiding principle for action in a utilitarian model of ethics.

utilization review (UR) committees Physician-supervised committees to review admissions, diagnostic testing, and treatments provided by physicians or health care providers to patients.

V

validation Act of confirming, verifying, or corroborating the accuracy of assessment data or the appropriateness of the care plan.

Valsalva maneuver Any forced expiratory effort against a closed airway such as when an individual holds his or her breath and tightens his or her muscles in a concerted, strenuous effort to move a heavy object or change positions in bed.

value Personal belief about the worth of a given idea or behavior.

valvular heart disease Acquired or congenital disorder of a cardiac valve characterized by stenosis and obstructed blood flow or valvular degeneration and regurgitation of blood.

variances Unexpected event that occurs during patient care and that is different from CareMap predictions. Variances or exceptions are interventions or outcomes that are not achieved as anticipated. Variance may be positive or negative.

variant Differing from a set standard.

vascular access devices Catheters, cannulas, or infusion ports designed for long-term, repeated access to the vascular system.

vasoconstriction Narrowing of the lumen of any blood vessel, especially the arterioles and the veins in the blood reservoirs of the skin and abdominal viscera.

vasodilation Increase in the diameter of a blood vessel caused by inhibition of its vasoconstrictor nerves or stimulation of dilator nerves.

venipuncture Technique in which a vein is punctured transcutaneously by a sharp rigid stylet (e.g., a butterfly needle), a cannula (e.g., an angiocatheter that contains a flexible plastic catheter), or a needle attached to a syringe.

ventilation Respiratory process by which gases are moved into and out of the lungs.

verbal communication Sending of messages from one individual to another or to a group of individuals through the spoken word.

vertigo Sensation of dizziness or spinning.

vibration Fine, shaking pressure applied by hands to the chest wall only during exhalation.

virulence Ability of an organism to rapidly produce disease.

visual Related to or experienced through vision.

vital signs Temperature, pulse, respirations, and blood pressure.

vitamins Organic compounds essential in small quantities for normal physiological and metabolic functioning of the body. With few exceptions, vitamins cannot be synthesized by the body and must be obtained from the diet or dietary supplements.

voiding Process of urinating.

vulnerable populations Collection of individuals who are more likely to develop health problems as a result of excess risks, limits in access to health care services, or being dependent on others for care.

W

wellness Dynamic state of health in which an individual progresses toward a higher level of functioning, achieving an optimum balance between internal and external environments.

wellness education Activities that teach people how to care for themselves in a healthy manner.

wellness nursing diagnosis Clinical judgment about an individual, group, or community in transition from a specific level of wellness to a higher level of wellness.

wheezes, wheezing Adventitious lung sounds caused by a severely narrowed bronchus.

work redesign Formal process used to analyze the work of a certain work group and change the actual structure of the jobs performed.

worldview Cognitive stance or perspective about phenomena characteristic of a particular cultural group.

wound culture Specimen collected from a wound to determine the specific organism that is causing an infectious process.

Y

yearning and searching Second phase of Bowlby's phases of mourning. It is characterized by emotional outbursts of tearful sobbing and acute distress.

Z

Z-track injection Technique for injecting irritating preparations into muscle without tracking residual medication through sensitive tissues.

Nursing Care Plans

Anxiety, 246
Deficient Knowledge: Surgical Procedure, 339
Risk for Falls, 376
Risk for Infection, 408
Elevated Body Temperature, 451
Sexual Dysfunction, 683
Spiritual Distress, 700
Hopelessness, 717
Caregiver Role Strain, 739
Activity Intolerance, 755
Impaired Oral Mucous Membrane, 781
Ineffective Airway Clearance, 838
Deficient Fluid Volume, 901
Insomnia, 951
Acute Pain, 976
Imbalanced Nutrition: Less Than Body Requirements, 1013
Stress Urinary Incontinence, 1057
Constipation, 1103
Impaired Physical Mobility, 1144
Impaired Skin Integrity, 1193
Risk for Injury, 1244
Deficient Knowledge Regarding Preoperative and Postoperative Care Requirements Related to Lack of Exposure to Information, 1266

Procedural Guidelines

Box 28-12 Caring for a Patient on Isolation Precautions, 417
Box 28-13 Applying a Surgical Type of Mask, 419
Box 29-6 Measurement of Temporal Artery Temperature, 449
Box 29-11 Palpating Systolic Blood Pressure, 463
Box 29-12 Electronic Blood Pressure Measurement, 464
Box 31-15 Giving Medications Through an Enteral Tube (Nasogastric Tube, G-tube, J-Tube, or Small-Bore Feeding Tube), 594
Box 31-16 Administering Nasal Instillations, 595
Box 31-17 Administering Ear Medications, 597
Box 31-18 Administering Vaginal Medications, 598
Box 31-19 Administering Rectal Suppositories, 599
Box 31-22 Mixing Two Types of Insulin in One Syringe, 604
Box 36-11 Care of the Body After Death, 726
Box 38-8 Helping Patients to Exercise, 757
Box 39-10 Care of Dentures, 787
Box 39-11 Shampooing Hair of Patient Who Is Bed-Bound, 789
Box 39-14 Making an Unoccupied Bed, 795
Box 40-9 Closed (In-Line) Suction Catheter, 847
Box 43-11 Massage, 980
Box 44-13 Obtaining Gastrointestinal Aspirate for pH Measurement, Large-Bore, and Small-Bore Feeding Tubes: Intermittent and Continuous Feeding, 1020
Box 45-11 Applying a Condom Catheter, 1065
Box 46-4 Performing a Guaiac Fecal Occult Blood Test, 1099
Box 46-8 Digital Removal of Stool, 1108
Box 47-7 Applying Sequential Compression Devices, 1150
Box 47-8 Applying Antiembolitic Elastic Stockings, 1151
Box 48-5 Skin Assessment, 1188

Skills

Administering a Cleansing Enema (Skill 46-1), 1112
Administering Enteral Feedings via Nasoenteric, Gastrostomy, or Jejunostomy Tubes (Skill 44-3), 1031
Administering Injections (Skill 31-5), 626
Administering Intravenous Medications by Piggyback, Intermittent Intravenous Infusion Sets, and Mini-Infusion Pumps (Skill 31-7), 635
Administering Medications by Intravenous Bolus (Skill 31-6), 631
Administering Ophthalmic Medications (Skill 31-2), 616
Administering Oral Medications (Skill 31-1), 612
Applying a Nasal Cannula or Oxygen Mask (Skill 40-4), 873
Applying a Sterile Gown and Performing Closed Gloving (Skill 28-4), 434
Applying an Abdominal Binder (Skill 48-6), 1226
Applying an Elastic Bandage (Skill 48-7), 1228
Applying Dry and Moist Dressings (Skill 48-3), 1218
Applying Restraints (Skill 27-1), 388
Aspiration Precautions (Skill 44-1), 1026
Assessing Respirations (Skill 29-3), 476
Assessing the Radial and Apical Pulses (Skill 29-2), 472
Assessment for Risk for Pressure Ulcer Development (Skill 48-1), 1213
Bathing and Perineal Care (Skill 39-1), 797
Blood Glucose Monitoring (Skill 44-4), 1035
Care of an Artificial Airway (Skill 40-2), 861
Care of Patients with Chest Tubes (Skill 40-3), 869
Changing a Peripheral Intravenous Dressing (Skill 41-4), 934
Closed Catheter Irrigation (Skill 45-4), 1081
Collecting Midstream (Clean-Voided) Urine Specimen (Skill 45-1), 1068
Demonstrating Postoperative Exercises (Skill 50-1), 1287
Hand Hygiene (Skill 28-1), 425
Implementation of Negative-Pressure Wound Therapy (Skill 48-4), 1221
Indwelling Catheter Care (Skill 45-3), 1079
Initiating Intravenous Therapy (Skill 41-1), 916
Inserting a Small-Bore Nasoenteric Tube for Enteral Feedings (Skill 44-2), 1028
Inserting a Straight or Indwelling Catheter (Skill 45-2), 1071
Inserting and Maintaining a Nasogastric Tube for Gastric Decompression (Skill 46-2), 1115
Maintenance of Intravenous System (Skill 41-3), 929
Making an Occupied Bed (Skill 39-5), 813
Measuring Blood Pressure (Skill 29-5), 480
Measuring Body Temperature (Skill 29-1), 467
Measuring Oxygen Saturation (Pulse Oximetry) (Skill 29-4), 478
Moving and Positioning Patients in Bed (Skill 47-1), 1159
Open Gloving (Skill 28-5), 436
Patient-Controlled Analgesia (Skill 43-1), 990
Performing Mouth Care for an Unconscious or Debilitated Patient (Skill 39-4), 811
Performing Nail and Foot Care (Skill 39-2), 805
Performing Wound Irrigation (Skill 48-5), 1224
Pouching an Ostomy (Skill 46-3), 1121
Preparation of Sterile Field (Skill 28-2), 427
Preparing Injections (Skill 31-4), 622
Providing Oral Hygiene (Skill 39-3), 808
Regulating Intravenous Flow Rate (Skill 41-2), 925
Seizure Precautions (Skill 27-2), 392
Suctioning (Skill 40-1), 855
Surgical Hand Asepsis (Skill 28-3), 431
Treating Pressure Ulcers (Skill 48-2), 1215
Using Home Oxygen Equipment (Skill 40-5), 875
Using Metered-Dose or Dry Powder Inhalers (Skill 31-3), 619
Using Safe and Effective Transfer Techniques (Skill 47-2), 1166
