2. Turn the patient from side to side on a regular schedule to relieve pressure areas and help clear lungs by mobilizing secretions; turning also provides kinesthetic (sensation of movement), proprioceptive (awareness of position), and vestibular (equilibrium) stimulation.
3. Reposition carefully after turning to prevent ischemia and shearing over pressure areas.
4. Position extremities in functional position, and monitor the skin underneath splints/orthosis to prevent skin breakdown and pressure neuropathies.
5. Perform range-of-motion (ROM) exercises of extremities at least four times daily; contracture deformities develop early in unconscious patients.

Maintaining Corneal Integrity

1. Protect the eyes from corneal irritation as the cornea functions as a shield. If the eyes remain open for long periods, corneal drying, irritation, and ulceration are likely to result.
2. Make sure the patient's eye is not rubbing against bedding if blinking and corneal reflexes are absent.
3. Inspect the condition of the eyes with a penlight.
4. Ensure that contact lenses have been removed.
5. Irrigate eyes with sterile saline or prescribed solution to remove discharge and debris.
6. Instill prescribed ophthalmic ointment in each eye to prevent glazing and corneal ulceration.
7. Apply eye patches, when indicated, ensuring that eyes remain closed under patch.

Reducing Fever

1. Look for possible sites of infections (respiratory, CNS, urinary tract, wound) when fever is present in an unconscious patient.
2. Monitor temperature frequently or continuously.
3. Control persistent elevations of temperature. Fever increases metabolic demands of the brain, decreases

circulation and oxygenation, and results in cerebral deterioration.

a. Monitor core temperature continuously and treat hyperthermia promptly. Hyperthermia increases the brain's metabolic rate and increases the risk of secondary injury. A body core temperature is 4 to 5 degrees lower than brain temperature.
b. Maintain a cool ambient temperature. Anticipate potential for overcooling and make environmental adjustments accordingly (eg, operating room environment).
c. Minimize excess covering on bed.
d. Administer prescribed antipyretics.
e. Use cool-water sponging and an electric fan blowing over the patient to increase surface cooling for hyperthermia resistant to antipyretics.
f. Use an external cooling device to maintain normothermia, but avoid rapid overcooling. Intravascular cooling devices may also be used.

Promoting Urinary Elimination

1. An indwelling or external urethral catheter may be used for short-term management.
2. Use intermittent bladder catheterization for distention as soon as possible to minimize risk of infection. Palpate over the patient's bladder at intervals or use a bladder scan to detect urine retention and an overdistended bladder.
3. Monitor for fever and cloudy urine.
4. Initiate a bladder-training program as soon as consciousness is regained.

Promoting Bowel Function

1. Auscultate for bowel sounds; palpate lower abdomen for distention.
2. Observe for constipation due to immobility and lack of dietary fiber. Stool softener or laxative, scheduled or as needed, may be prescribed to promote bowel elimination. The goal is bowel movement every other day.
3. Monitor for diarrhea resulting from infection, antibiotics, enteric feedings, hyperosmolar fluids, and fecal impaction.
    a. Perform a rectal examination if fecal impaction is suspected.
    b. Use fecal collection bags and provide meticulous skin care if the patient has fecal incontinence.

Family Education and Support

1. Develop a supportive and trusting relationship with the family or significant other.
2. Provide information and frequent updates on the patient's condition and progress.
3. Involve them in routine care and teach procedures that they can perform at home.
4. Demonstrate and teach methods of sensory stimulation to be used frequently.
    a. Use physical touch and reassuring voice.
    b. Talk to the patient in a meaningful way even when the patient does not seem to respond. Assume the

patient is able to hear even if unresponsive.

c. Orient the patient periodically to person, time, and place.

5. Demonstrate and teach methods frequently used to manage restlessness/agitation.
   a. Eliminate distractions.
   b. Reduce environmental stimuli (turn off television and radio, close door).
   c. Use one-to-one communication.
   d. Talk slowly and simplify information without talking down to the person.
6. Teach the family to recognize and report unusual restlessness, which could indicate cerebral hypoxia, metabolic imbalance, or pain.
7. Enlist the help of the social worker, home health agency, or other resources to assist family with such issues as financial concerns, guardianship, need for additional follow-up care (rehabilitation, long-term care facility), need for medical equipment in home, and/or respite care.

Evaluation: Expected Outcomes

- Neurologic status remains at baseline or improved.
- Maintains clear airway; coughs up secretions.
- Absence of signs of dehydration.
- Intact, pink mucous membranes.
- No skin breakdown or erythema.
- Absence of trauma to cornea.
- Core temperature within normal limits.
- Absence of urinary tract infection (UTI); maintenance of normal bladder emptying.
- Bowel movement on regular basis in response to bowel regimen.

Nursing Management of the Patient with Increased Intracranial Pressure

Intracranial pressure (ICP) is the pressure exerted by the contents inside the cranial vault—the brain tissue (gray and white matter), CSF, and the blood volume. A pressure reading at or greater than 20 mm Hg is defined as increased ICP.

EVIDENCE BASE American Association of Neuroscience Nurses. (2016). *AANN core curriculum for neuroscience nursing* (6th ed.). Glenview, IL: Author.

Pathophysiology and Etiology

1. ICP is composed of the following components and volume ratio: brain tissue, 80%; CSF, 10%; blood volume, 10%.
2. The Monro-Kellie doctrine states that the intracranial vault is a closed structure with a fixed intracranial volume. The intracranial contents must be kept in equilibrium and the ratio between volume and pressure must remain constant. Any increase in the volume of one component must be accompanied by a reciprocal decrease in one of the other components. When this volume–pressure relationship becomes unbalanced, ICP increases.
3. The brain attempts to compensate for rises in ICP by:
   a. Displacement/shunting of CSF from the intracranial compartment to the lumbar subarachnoid space (SAS). Normally, about 500 mL of CSF are produced and absorbed in 24 hours. About 125 to 150 mL circulates throughout the ventricular system and the SAS in the following ratio: 25 mL in the ventricles, 90 mL in the lumbar SAS, and 35 mL in the cisterns and surrounding SAS.
   b. Increased CSF absorption.
   c. Decreased cerebral blood volume by displacement of cerebral venous blood into the venous sinuses. Compensatory measures are finite. Increased ICP will ultimately occur if the volume of the intracranial mass exceeds the volume compensated.
4. Intracranial compliance is "tightness" of the brain. Compliance is the relationship between intracranial volume and ICP. It is a nonlinear relationship; as ICP increases, compliance decreases. With functional compensatory mechanisms, an increase in volume causes a small, transient increase in ICP. As compliance decreases, small increases in volume result in moderate increases in pressure. When compensatory mechanisms are exhausted, very slight increases in volume will produce large increases in pressure. The patient's response to changes in ICP will depend on where the patient is on the volume–pressure curve.
5. Factors that influence the ability of the body to achieve this steady state include the following:
   a. Systemic BP.
   b. Ventilation and oxygenation.

c. Metabolic rate and oxygen consumption (fever, shivering, physical activity).
d. Regional cerebral vasospasm.
e. Oxygen saturation and hematocrit.

6. Inability to maintain a steady state results in increased ICP. Traumatic brain injury (TBI), cerebral edema, intracerebral hemorrhage, ischemic stroke, abscess and infection, lesions, intracranial surgery, and radiation therapy can be potential etiologies of increased ICP.
7. Increased ICP constitutes an emergency and requires prompt treatment. ICP can be monitored by means of an intraventricular catheter, a subarachnoid screw or bolt, or an epidural pressure recording device.
8. Alterations or compromise in cerebral blood flow can be measured noninvasively by a TCD study. Increased velocities indicate vasospasm, diminished velocities indicate low blood flow, and absent velocities are consistent with no flow or brain death.

Nursing Assessment

Change in LOC

Caused by increased ICP. Assess for the following:

1. Change in LOC (awareness): drowsiness, lethargy.
2. Early behavioral changes: restlessness, irritability, confusion, and apathy.
3. Falling score on the GCS (see page 354).
   a. Change in orientation: disorientation to time, place, or person.
   b. Difficulty or inability to follow commands.
   c. Difficulty or inability in verbalization or in responsiveness to auditory stimuli.
   d. Change in response to painful stimuli (eg, purposeful to inappropriate or absent responses).
   e. Posturing (abnormal flexion or extension).

Changes in Vital Signs

Caused by pressure on brain stem. Assess for the following:

1. Rising BP or widening pulse pressure (the difference between systolic and diastolic BP). This may be followed by hypotension and labile vital signs, indicating further brain stem compromise.
2. Pulse changes with bradycardia changing to tachycardia as ICP rises.
3. Respiratory irregularities: tachypnea (early sign of increased ICP); slowing of rate with lengthening periods of apnea; Cheyne-Stokes (rhythmic pattern of increasing and decreasing depth of respirations with periods of apnea) or Kussmaul (paroxysms of difficult breathing) breathing; central neurogenic hyperventilation (prolonged, deep breathing); apneustic (sustained inspiratory effort) breathing; and ataxic (incoordinated and spasmodic) breathing.
4. Hyperthermia followed by hypothermia.

KEY DECISION POINT Watch for Cushing triad—bradycardia, hypertension (with widening pulse pressure), and irregular respirations; this is classic symptomatology related to uncompensated increased ICP and is considered a neurologic medical emergency. Alert health care provider and prepare for therapeutic intervention.

NURSING ALERT Respiratory irregularities may not be apparent if the patient is mechanically ventilated.

Pupillary Changes

1. Caused by increased pressure on optic and oculomotor nerves. Fundoscopic exam may reveal changes.
2. Inspect the pupils with a penlight to evaluate size, configuration, and reaction to light.
3. Compare both eyes for similarities or differences, particularly pupillary changes related to location and progression of brain stem herniation.
    a. Midbrain involvement—fixed and dilated.
    b. Pontine involvement—pinpoint pupils.
    c. Uncal herniation.
        i. Unilaterally dilating pupil ipsilateral to lesion.
        ii. Anisocoria (unequal) with sluggish light reaction in dilated pupil.
        iii. If treatment is delayed or unsuccessful, contralateral pupil becomes dilated and fixed to light.
        iv. When herniation of the brain stem occurs, both pupils assume midposition and remain fixed to light.
    d. Central transtentorial herniation.
        i. Pupils are small bilaterally (1 to 3 mm).
        ii. Reaction to light is brisk but with small range of constriction.
        iii. If treatment is delayed or unsuccessful, small pupils dilate moderately (3 to 5 mm) and fix irregularly at midposition.
        iv. When herniation of the brain stem occurs, both pupils dilate widely and remain fixed to light.
4. Pupillometer can be used to measure pupillary size and reactivity, detecting subtle change by utilizing infrared light.

Extraocular Movements

1. Evaluate gaze to determine if it is conjugate (paired, working together) or dysconjugate (eye deviates or movement is asymmetric).
2. Evaluate movement of eyes.

a. Inability to abduct or adduct: deviation of one or both eyes.
b. Alteration in vision (eg, blurred vision, diplopia, field cut).
c. Spontaneous roving, random eye movements.
d. Nystagmus on horizontal/vertical gaze.

3. Oculocephalic reflex (doll's eyes): brisk turning of the head left, right, up, or down with observation of eye movements in response to the stimulus. Tests brain stem pathways between CNs III, IV, VI, and VIII. This should not be performed on patients with suspected cervical spine injury, patients in a cervical collar, or patients with known cervical spine injuries unless part of the brain death examination.
4. Oculovestibular reflex (cold calorics): 30 to 60 mL of ice water instilled into the ear with the head of the bed elevated to 30 degrees. Tests brain stem pathways between CNs III, IV, VI, and VIII. Response preserved longer than the doll's eyes maneuver. Performed by health care provider as part of brain death examination.

Other Changes

Be alert for the following:

1. Headache increasing in intensity and aggravated by movement and straining.
2. Vomiting recurrent with little or no nausea, especially in early morning; may be projectile.
3. Papilledema from optic nerve compression.
4. Subtle changes, such as restlessness, headache, forced breathing, purposeless movements, and mental cloudiness.
5. Motor and sensory dysfunctions (proximal muscle weakness, presence of pronator drift).
6. Contralateral hemiparesis progressing to complete hemiplegia.
7. Speech impairment (expressive, receptive, or global aphasia) when dominant hemisphere involved.
8. Seizure activity: focal or generalized.
9. Decreased brain stem function (CN deficits, such as loss of corneal reflex, gag reflex, and ability to swallow).
10. Pathologic reflexes: Babinski, grasp, chewing, sucking.

Nursing Diagnosis

- Decreased Intracranial Adaptive Capacity.

Nursing Interventions

Decreasing ICP

NURSING ALERT Increased ICP is a true life-threatening medical emergency that requires immediate recognition and prompt therapeutic intervention.

---

1. Establish and maintain airway, breathing, and circulation.
2. Promote normal P_{CO_2}. Hyperventilation is not recommended for prophylactic treatment of increased ICP as cerebral circulation is reduced by 50% the first 24 hours after injury. Hyperventilation causes cerebral vasoconstriction and decreases cerebral blood flow to decrease ICP; this can potentiate secondary injury to the brain. Hyperventilation should be used only after all other treatment options have been exhausted or in an acute crisis.
3. Avoid hypoxia. Decreased P_{O_2} (less than 60 mm Hg) causes cerebral vasodilation, thus increasing ICP.
4. Maintain cerebral perfusion pressure (CPP) greater than 50 mm Hg. CPP is determined by subtracting the ICP from the MAP: CPP = MAP – ICP.
5. Administer mannitol (0.25 to 1 g/kg), an osmotic diuretic, if ordered. Osmotic diuretics act by establishing an osmotic gradient across the blood–brain barrier that depletes the intracellular and extracellular fluid volume within the brain and throughout the body. Mannitol will be ineffective if the blood–brain barrier is not intact.
6. Administer hypertonic saline (2% or 3%), if ordered. It creates an osmotic gradient that pulls extra fluid from the brain with an intact blood–brain barrier, lowers ICP, improves cerebral blood flow by reducing viscosity, and improves oxygen carrying capacity. Saline (23.4%) is used as a bolus to treat acute increases in ICP in conjunction with or in place of mannitol; requires central access for administration and should be given over 5 minutes.
7. Insert an indwelling urinary catheter for management of diuresis.
8. Administer corticosteroids, such as dexamethasone, as ordered, to reduce vasogenic edema associated with brain tumors. Corticosteroids are not recommended in the treatment of cytoxic (intracellular) cerebral edema related to trauma or stroke.
9. Maintain balanced fluids and electrolytes. Watch for increased or decreased serum sodium due to the following conditions that may occur with increased ICP.
    a. Diabetes insipidus (DI) results from the absence of antidiuretic hormone (ADH); this is reflected by increased urine output with elevation of serum osmolarity and sodium.
    b. The syndrome of inappropriate antidiuretic hormone (SIADH) results from the secretion of ADH in the absence of changes in serum osmolality. This is a hypervolemic state reflected by decreased urine output with decreased serum sodium and increased free water.
    c. Cerebral salt wasting is associated with abnormal release of aldosterone resulting in increased elimination of sodium and decreased interstitial volume (hypovolemic state) (see Table 15-4).
10. Monitor effects of anesthetic agents, such as propofol, and sedatives, such as midazolam or dexmedetomidine hydrochloride, which may be given to prevent sudden changes in ICP due to coughing, straining, or “fighting” the ventilator. Short-acting medications are preferred to allow for intermittent neurologic assessment.
11. High-dose barbiturates, such as pentobarbital, may be used in patients with refractory increased ICP. (*Note*: Prophylactic use is not recommended. It is utilized when all other treatments have failed.) Dosing: 10 mg/kg over 30 minutes; then 5 mg/kg every hour for 3 hours followed by maintenance dose of 1

mg/kg/hr. (Goal serum barbiturate level of 3 to 4 mg/dL.)

a. High-dose barbiturates induce a comatose state and suppress brain metabolism, which, in turn, reduces cerebral blood flow and ICP. Only pupillary response is assessed.
b. Be alert to the high level of nursing support required. All responses to environmental and noxious stimuli (suctioning, turning) are abolished as well as all protective reflexes.
c. Cough or gag reflex will be absent and the patient will be unable to protect the airway, increasing susceptibility to pneumonia.
d. Monitor ICP, arterial pressure, and serum barbiturate levels, as indicated. Perform continuous EEG monitoring to document burst suppression (suppression of cortical activity) and ensure adequate dosing of barbiturates, if used.
e. Monitor temperature because barbiturate coma causes hypothermia.
f. Diminished GI motility and high risk for ileus.

12. Maintain normothermia and treat fever aggressively. Fever increases cerebral blood flow and cerebral blood volume; acute increases in ICP occur with fever spikes. Cerebral temperature is 4 to 5 degrees higher then body core temperature; therefore, small increases in body core temperature can create drastic increases in the core temperature of the brain. Infection is a common complication of ICP, and in the presence of fever, an infectious workup should be completed.
13. Avoid positions or activities that may increase ICP. Keep head in alignment with shoulders; neck flexion or rotation increases ICP by impeding venous return. Keep head of bed elevated 30 degrees to reduce jugular venous pressure and decrease ICP.
    a. Minimize suctioning, keep procedure less than 15 seconds, and, if ordered, instill lidocaine via endotracheal (ET) tube before suctioning. Coughing and suctioning are associated with increased intrathoracic pressure, which is associated with ICP spikes. Inject 5 to 10 mL of lidocaine into ET tube before suctioning to dampen the cough response.
    b. Minimize other stimuli, such as alarms, television, radio, and bedside conversations, which may precipitously increase ICP (stimuli that create elevation in ICP are patient-dependent).
14. Maintain normal blood sugar levels. Treat with sliding scale insulin or insulin drip as ordered.
15. Initiate treatment modalities, as ordered, for increased ICP (above 20 mm Hg or if there is a significant shift in pressure).
16. Pretreat prior to known activities that raise ICP and avoid taking pressure readings immediately after a procedure. Allow patient to rest for approximately 5 minutes.
17. Record ICP readings every hour and correlate with significant clinical events or treatments (suctioning, turning).

Table 15-4 Differentiating Etiology of Hyponatremia

	CEREBRAL SALT WASTING	SIADH
Volume		
Plasma	Decreased CVP < 6	Increased
Urine output	Marked increase	Normal or decreased
Sodium		
Serum	Decreased	<135 mEq/L
Urine	Marked increase	>20 mEq/L
Osmolality		
Serum	Increased or no change	Decreased (<280 mmol/L)
Urine	Increased or no change	Increased (>100 mmol/kg)
Serum K^+	Increased	Decreased or no change
Hematocrit	Increased	Decreased or no change
Treatment	Fludrocortisone	Fluid restriction Oral: Salt replacement IV: 3% saline

Evaluation: Expected Outcomes

- ICP and vital signs stable; alert and responsive.

Intracranial Monitoring

EVIDENCE BASE Kawoos, U., McCarron, R. M., Auker, C. R., & Chavko, M. (2015). Advances in intracranial pressure monitoring and its significance in managing traumatic brain injury. *International Journal of Molecular Sciences*, *16*(12), 28979–28997. Available: *http://doi.org/10.3390/ijms161226146*.

Intracranial monitoring, including ICP monitoring, is a technology that helps the nurse assess, plan, intervene, and evaluate patient responses to care. ICP monitoring is widely used. See Figure 15-1.

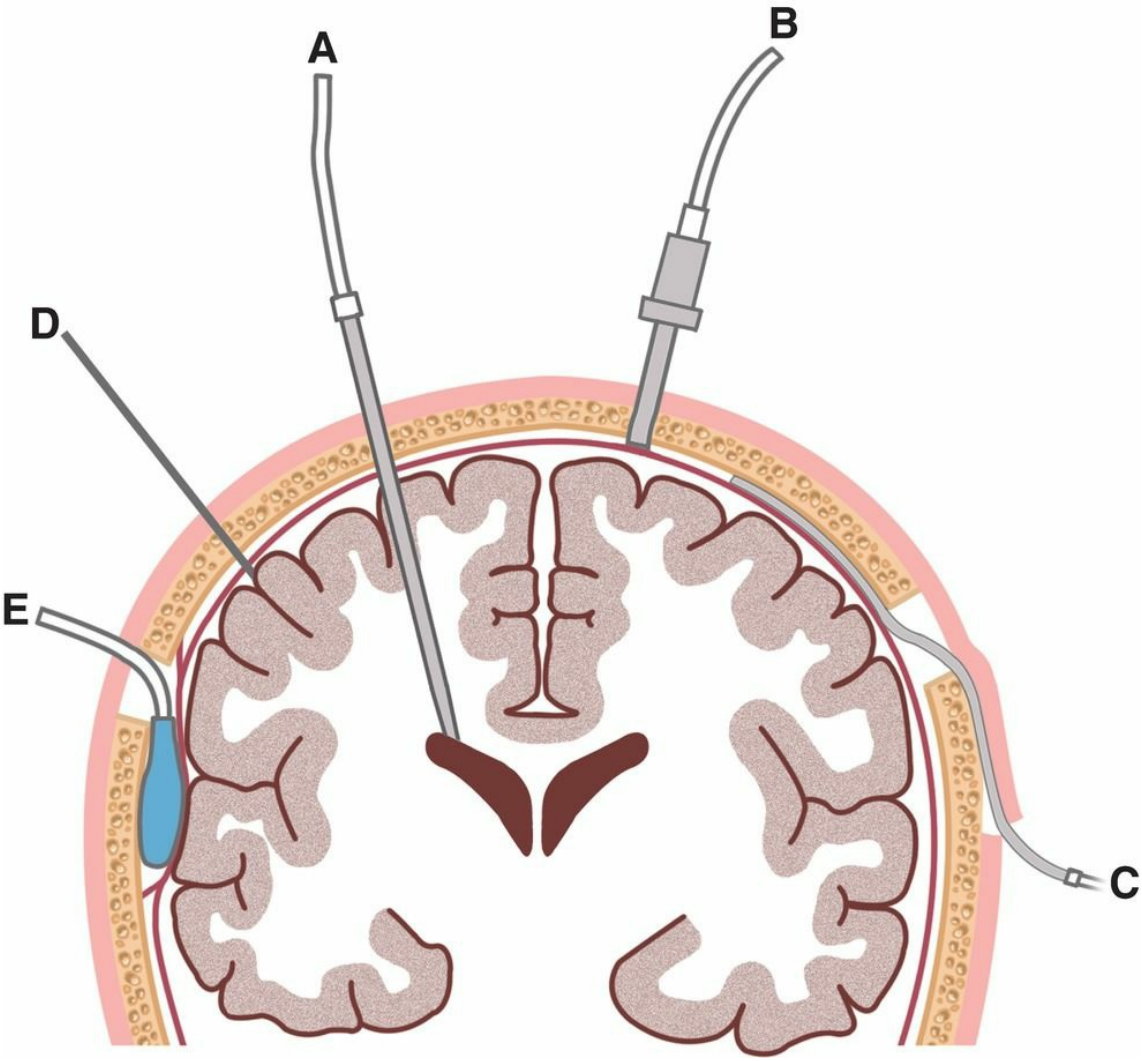

Figure 15-1. Intracranial pressure monitoring system. (*A*) Intraventricular; (*B*) subarachnoid; (*C*) subdural; (*D*) parenchymal; (*E*) epidural. (Redrawn from Diepenbrock, N.H. [2015]. Quick reference to critical care [5th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

1. External ventricular drain (EVD): catheter is inserted into lateral ventricle (right is preferred) through a drilled burr hole opening; connected to fluid-filled transducer, which converts mechanical pressure to electrical impulses and waveform; allows ventricular drainage. EVD is the most accurate method to measure ICP.
2. Subarachnoid (bolt) hollow screw inserted into SAS beneath the skull and dura through drill hole; also connected to pressure transducer system.
3. Epidural sensor inserted beneath skull but not through dura, so does not measure pressure directly; fiberoptic cable is connected directly to monitor.
4. Parenchymal device is inserted directly into brain tissue.

ICP Waveforms

ICP pulse waveforms are generated from a pressure wave transmitted through the cardiovascular system into the tissues within the intracranial cavity. See Figure 15-2.

Figure 15-2. Intracranial pressure waves. **(A)** Normal ICP waveform. **(B)** Awaves (plateau waves) are pathologic. B and Cwaves have little clinical significance.

1. The normal pulse waveform consists of three identifiable components: P-1, P-2, and P-3.
   a. P-1, the percussive wave, reflects pulsations of the choroid plexus, where CSF is produced, as transmitted from the cardiovascular system at systole. It is the highest of the three waveform components under normal conditions.
   b. P-2, the tidal wave, has a more variable shape and reflects relative brain volume. P-2 can become elevated in response to a mass lesion or when brain compliance is decreased.
   c. P-3, the dicrotic wave, follows the dicrotic notch on the downslope of the individual ICP pulse waveform and is usually the lowest waveform segment.
2. Plateau or A wave patterns are pathological, reflecting a rapid rise in ICP up to 50 to 100 mm Hg, and may be followed by a variable period during which the ICP remains elevated and then falls to baseline. Truncated patterns that do not exceed an elevation of 50 mm Hg are early indicators of neurologic deterioration. A waves are clinically significant as elevation in ICP is related to compromise in autoregulation secondary to increased cerebral blood volume and decreased cerebral blood flow.
3. B and C wave patterns are related to respiration and are of little clinical significance. B wave patterns are of shorter duration and smaller amplitude than A wave patterns and may precede A wave patterns. C wave patterns are small, rhythmic oscillations that fluctuate with changes in respiration and BP.

Other Monitoring Systems

1. Licox Brain Oxygen Monitoring System—placed in the brain tissue through a burr hole and monitors brain tissue partial pressure of oxygen ($PbrO_2$), cerebral temperature, and indirect ICP. Continual monitoring of the cerebral temperature and oxygenation levels provides direct information on the acute changes in the intracranial tissue that can potentiate secondary brain injury.
2. Microdialysis—catheter is placed into the brain tissue through a burr hole for monitoring of cerebral oxygen, glucose, lactate, lactate–pyruvate, glutamate, and glycerol. The catheter is connected to a 2.5-mL syringe and into a microinfusion pump. The pump is perfused with Ringer solution. Samples are obtained periodically for analysis.
3. Jugular venous oximetry—A fiberoptic oximetric catheter is placed into the jugular bulb of the internal jugular vein for measurement of jugular venous oxygen saturation ($SjvO_2$). $SjvO_2$ is helpful in evaluating arterial saturation, cerebral metabolic rate for oxygen, and cerebral blood flow. The normal range is between 54% and 75%. A low $SjvO_2$ is suggestive of increased brain extraction of oxygen related to systemic arterial hypoxia, decreased cerebral blood flow from hypotension or vasospasm, or an elevated ICP with a low CPP. Desaturation is thought to be associated with ischemic events and directly related to increased morbidity.

Nursing Interventions

1. Note the pattern of waveforms and any sustained elevation of pressure above 20 mm Hg.
2. Avoid overstimulation of the patient.
    a. Note the stimuli that cause increased pressure, such as bathing, suctioning, repositioning, or visitors. Adjust care, as indicated.
    b. Premedicate, as indicated.
    c. Provide rest periods between periods of care.
    d. Limit visitors as status indicates.
    e. Limit unnecessary conversation at patient's bedside.
    f. Eliminate external environmental stimuli. Close doors, turn off suction equipment when not in use, limit television or radio as status indicates.
3. Watch for developing or increasing P-2 waves and frequency of A (plateau) waves. Report these, and begin measures to lower increased ICP.

NURSING ALERT Sustained elevation in ICP greater than 20 mm Hg and CPP less than 50 mm Hg correlates with worsening outcomes following traumatic brain injury. Measures to reduce increased ICP should be performed immediately and the health care provider notified when the ICP remains elevated for more than 5 minutes.

Nursing Management of the Patient Undergoing Intracranial Surgery

Craniotomy is the surgical opening of the skull to gain access to intracranial structures to perform a biopsy, remove a tumor, relieve increased ICP, evacuate a blood clot, evaluate and treat the cause of intracranial hemorrhage, or remove epileptogenic tissue. Surgical approach is based on location of the lesion and may be supratentorial (above the tentorium or dural covering that divides the cerebrum from cerebellum) or infratentorial (below the tentorium, including the brain stem). Craniotomy may be performed by means of burr holes (made with a drill or hand tools) or by making a bony flap. *Craniectomy* is excision and removal of a portion of the skull. *Cranioplasty* is repair of a cranial defect by means of a plastic or metal plate. *Transsphenoidal surgery* is an approach that gains access to the pituitary gland through the nasal cavity and sphenoidal sinus (see Chapter 24).

Preoperative Management

1. Diagnostic findings, surgical procedure, and expectations are reviewed with the patient.
2. Presurgical shampoo with an antimicrobial agent may be ordered. Skull preparation is performed in the operating room.
3. Depending on primary diagnosis, corticosteroids may be ordered preoperatively to reduce vasogenic cerebral edema.
4. Depending on the type and location of lesion, anticonvulsants may be ordered to reduce risk of seizures.
5. The patient is prepared for the use of intraoperative antibiotics to reduce risk of infection.
6. Urinary catheterization is performed to assess urinary volume during operative period.
7. If cerebral edema develops, intraoperative or postoperative osmotic diuretic (mannitol) or corticosteroids may be ordered for its treatment.
8. Neurologic assessment is performed to evaluate and record the patient's neurologic baseline and vital signs for postoperative comparison.
9. Family and patient are made aware of the immediate postoperative care and where the physician will contact the family after surgery.
10. Supportive care is given, as needed, for neurologic deficits.

Postoperative Management

1. Respiratory status is assessed by monitoring rate, depth, and pattern of respirations. A patent airway is maintained.
2. Vital signs and neurologic status are monitored using a facility-based neurologic assessment tool; findings are documented. Arterial line may be used for blood pressure monitoring.
3. Pharmacologic agents may be prescribed to control increased ICP.
4. Incisional and headache pain may be controlled with analgesic such as an opioid or acetaminophen, as prescribed. Monitor response to medications.
5. Position head of bed at 15 to 30 degrees, or per clinical status of the patient, to promote venous drainage.

Determining appropriate position of head of bed is patient-dependent and should be adjusted based on observed changes in the patient's clinical response and ICP to positioning.

6. Turn side to side every 2 hours; positioning restrictions will be ordered by the health care provider (craniectomy patients should not be turned on the side of the cranial defect).
7. CT scan of the brain is performed if the patient's status deteriorates.
8. Oral fluids are provided when the patient is alert and swallow reflex has returned. Intake and output are monitored. Speech therapy may be ordered for bedside swallow study or radiographic swallow study.
9. Signs of infection are monitored by checking craniotomy site, ventricular drainage, nuchal rigidity, or presence of CSF (fluid collection at surgical site).
10. Periorbital edema is controlled by such measures as elevation of head of bed and cold compresses. Removal of surgical dressing and increase in activity will assist in the resolution of periorbital edema.

Potential Complications

1. Intracranial hemorrhage/hematoma.
2. Cerebral edema.
3. Infections (eg, postoperative meningitis, pulmonary, wound).
4. Seizures.
5. CN dysfunction.
6. Decreased CPP causing cerebral ischemia.

Nursing Diagnoses

- Risk for Ineffective Cerebral Tissue Perfusion related to increased ICP.
- Risk for Aspiration related to decreased swallow reflex and postoperative positioning.
- Risk for Infection related to invasive procedure.
- Acute Pain related to surgical wound.
- Constipation related to use of opioids and immobility.

Nursing Interventions

Maintaining ICP within Normal Range

1. Closely monitor LOC, vital signs, pupillary response, and ICP, if indicated. Notify health care provider if ICP is greater than 20 mm Hg or CPP is less than 50 mm Hg.
2. Teach the patient to avoid activities that can raise ICP, such as excessive flexion or rotation of the head and Valsalva maneuver (coughing, straining with defecation).
3. Administer medications, as prescribed, to reduce ICP.
4. Check ICP waveform before nursing interventions that create noxious tactile stimuli, such as suctioning, prolonged physical assessment, turning, and ROM exercises and delay interventions based on patient response.

Preventing Aspiration

1. Offer fluids only when the patient is alert and swallow reflexes have returned.
2. Have suction equipment available at bedside. Suction only if indicated. Pretreat with sedation or endotracheal lidocaine to prevent elevation of ICP.
3. Elevate head of bed to maximum of order, or per clinical status, and patient comfort.

Preventing Nosocomial Infections

1. Use sterile technique for dressing changes, catheter care, and ventricular drain management.
2. Be aware of patients at higher risk of infection—those undergoing lengthy operations, those with ventricular drains left in longer than 72 hours, and those with operations of the third ventricle.
3. Assess surgical site for redness, tenderness, and drainage.
4. Watch for leakage of CSF, which increases the danger of meningitis.
    a. Watch for sudden discharge of fluid from wound; a large leak usually requires surgical repair.
    b. Warn against coughing, sneezing, or nose blowing, which may aggravate CSF leakage.
    c. Assess for elevation of temperature and neck rigidity.
    d. Note patency of ventricular catheter system.
    e. Early removal of Foley catheter.
6. Institute measures to prevent respiratory or UTI postoperatively.

Relieving Pain

1. Medicate patient as prescribed and according to assessment findings.
2. Elevate head of bed per protocol to relieve headache.
3. Provide distractive measures for pain management.
4. Darken room if patient is photophobic.

Avoiding Constipation

1. Encourage fluids when the patient is able to manage liquids.
2. Ambulate as soon as possible.
3. Change to nonopioid agents for pain control as soon as possible.
4. Avoid Valsalva-like maneuvers.
5. Use stool softeners and laxatives, as ordered.

Family Education and Support

1. Keep the patient and family aware of progress and plans to transfer to step-down unit, general nursing unit, subacute care, or rehabilitation facility.
2. Encourage frequent visiting and interaction of family for stimulation of patient as care allows.
3. Begin discharge planning early, and obtain referral for home care nursing, social work, or physical and occupational therapy, as needed.

Evaluation: Expected Outcomes

- Normal ICP and CPP maintained between 50 and 70 mm Hg.
- Gag reflex present; breath sounds clear.
- Afebrile without signs of infection.
- Verbalizes decreased pain.
- Passed soft stool.

CRANIAL NERVE DISORDERS

Bell Palsy

Idiopathic *Bell palsy* is an acute peripheral facial paralysis of the infratemporal portion of CN VII (facial nerve) that most often occurs unilaterally. The annual incidence of Bell palsy is approximately 25 to 30 cases per 100,000 persons. It is typically a self-limiting process that improves in 3 to 6 months.

Pathophysiology and Etiology

1. Cause is unknown. Possible etiologies include sensory ganglionitis of the CNS with secondary muscle palsy, caused by inflammation, vascular ischemia, and autoimmune demyelination.
2. Most patients experience a viral prodrome (eg, upper respiratory infection, herpes simplex virus) 1 to 3 weeks before onset of symptoms.
3. Can affect anyone at any age; however, it disproportionately affects pregnant women and those who have diabetes, hypertension, or influenza.
4. Generally self-limiting. With or without treatment, most patients improve significantly within 2 weeks and about 80% recover completely within 3 months. In rare cases, the symptoms may never completely resolve or may recur. Risk factors thought to be associated with a poor outcome include (1) over age 60 years, (2) complete paralysis, and (3) decreased taste or salivary flow on the side of paralysis.

Clinical Manifestations

1. Acute onset of unilateral upper and lower facial paralysis (over a 48-hour period and reaches its peak within 72 hours). Paralysis of the ipsilateral side of the face from vertex of scalp to chin; facial muscles weak throughout the forehead, cheek, and chin; can affect speech and taste, distort face, decrease tearing, and cause posterior auricular pain.
2. Involvement of all branches of facial nerve: facial weakness, diminished taste from anterior two thirds of the tongue, decreased blink reflex, decreased lacrimation, inability to close eye, painful eye sensations, photophobia, drooling.
3. Patients may experience neck, mastoid, or ear pain or hyperacusis on the affected side.

Diagnostic Evaluation

1. History to determine previous illness, onset of paralysis, and associated symptoms.
2. Exclusion of lesions that mimic Bell palsy, such as tumor, infection (Lyme disease, meningitis), trauma, stroke, or other conditions (sarcoidosis, multiple sclerosis, Guillain-Barré syndrome) through thorough neurologic examination and CT scan or brain MRI imaging with contrast media.
3. Electrophysiologic testing, specifically action potentials, EMGs, and nerve conduction velocities, to evaluate nerve function.
4. Lyme disease serological testing history of tick bite or bilateral weakness. About 5% to 10% of untreated Lyme disease patients may develop Bell palsy.

NURSING ALERT A rapid neurologic examination should be performed to differentiate Bell palsy from other conditions that could be causing facial droop. The patient with Bell palsy should have normal LOC, motor strength (except in the area of facial nerve), sensation, and reflexes. Depending on the clinical concern a head CT scan or brain MRI may be indicated for abnormal neurologic findings beyond the facial nerve.

Management

1. Corticosteroid therapy should be initiated within 72 hours of onset to decrease inflammation (eg, prednisone 50 to 60 mg for the first 5 days, followed by a tapering dose). Acyclovir combined with prednisone may improve facial function. When using corticosteroids for the treatment of Bell palsy, caution should be used in patients with tuberculosis, peptic ulcer disease, diabetes mellitus, renal or hepatic dysfunction, or malignant hypertension. For patients who have a contraindication to steroid therapy, acyclovir alone may be given.
2. Eye care to maintain lubrication and moisture if unable to close. May need to be patched during sleep.
3. Physical therapy, electrical stimulation to maintain muscle tone.
4. Biofeedback as adjunct therapy.
5. Surgical treatment of Bell palsy may include to anastomose facial nerve to other cranial nerve (CN VII to XI or CN VII to XII, surgical closure of eyelid to protect cornea (tarsorrhaphy), facial nerve decompression, placement of gold weights into the eyelid and facial lifts. Bell palsy is usually self-limiting and therefore generally does not require surgical treatment.

Complications

1. Corneal ulceration.
2. Impairment of vision.
3. Synkinesis (an abnormal, involuntary facial muscle contraction during normal facial muscle movements).
4. Psychosocial adjustment to prolonged paralysis.

NURSING ALERT Keratitis (inflammation of the cornea), ulceration, and vision loss are major threats to a patient with Bell palsy. Protect the cornea if the eye does not close.

Nursing Assessment

1. Test motor components of facial nerve (VII) by assessing patient's smile and ability to whistle, purse lips, wrinkle forehead, and close eyes. Observe for facial asymmetry.
2. Observe patient's ability to handle secretions, food, and fluids; observe for drooling.

3. Assess patient's ability to blink and speak clearly.
4. Assess effect of altered appearance on body image.

Nursing Diagnoses

- Risk for Dry Eye related to loss of protective eye closure.
- Disturbed Body Image related to facial nerve paralysis.

Nursing Interventions

Preventing Eye Dryness and Maintaining Corneal Integrity

1. Administer and teach the patient to administer artificial tears and ophthalmic ointment as prescribed.
2. Patch eye to keep shut at night, as directed.
3. Inspect eye for redness or discharge.
4. Advise the patient to report eye pain immediately.

Enhancing Body Image

1. Encourage the patient to express feelings related to body image disturbance.
2. Encourage the patient to use mirror as means to obtain feedback about actual versus perceived appearance.
3. Perform and teach the patient to perform facial massage to alleviate feelings of stiffness and enhance recovery.

Patient Education and Health Maintenance

1. Instruct the patient to wear wraparound sunglasses to decrease normal evaporation from the eye from sun and wind, to avoid eye irritants, and to increase environmental humidity.
2. Instruct the patient in use of ophthalmic drops and ointment, proper methods of lid closure, and patching of the eye.
3. Demonstrate facial exercises (eg, raise eyebrows, squeeze eyes shut, purse lips) and stress their importance to prevent muscle atrophy.
4. For further information, refer the patient to Bell's Palsy Research Foundation (*www.bellspalsyresearch.com*).

Evaluation: Expected Outcomes

- Cornea without redness, pain, or discharge.
- Verbalizes adjustment to body image disturbance.

Trigeminal Neuralgia (Tic Douloureux)

Trigeminal neuralgia (tic douloureux) is an intensely painful neurologic condition that affects one or more branches of the fifth cranial (trigeminal) nerve. Patients experience sudden paroxysms of "lancinating" or electric shock–like facial pain localized to one or more branches of the nerve (see Figure 15-3). The pain is often precipitated by trigger points that "fire" when the patient talks, shaves, eats, touches the face, brushes the teeth, or is exposed to cold wind. Approximately 40,000 patients in the United States suffer from this condition at any particular time. The incidence is 4 to 5 cases per 100,000. Patients who present with the disease between ages 20 and 40 are more likely to suffer from a demyelinating lesion in the pons secondary to multiple sclerosis (MS).

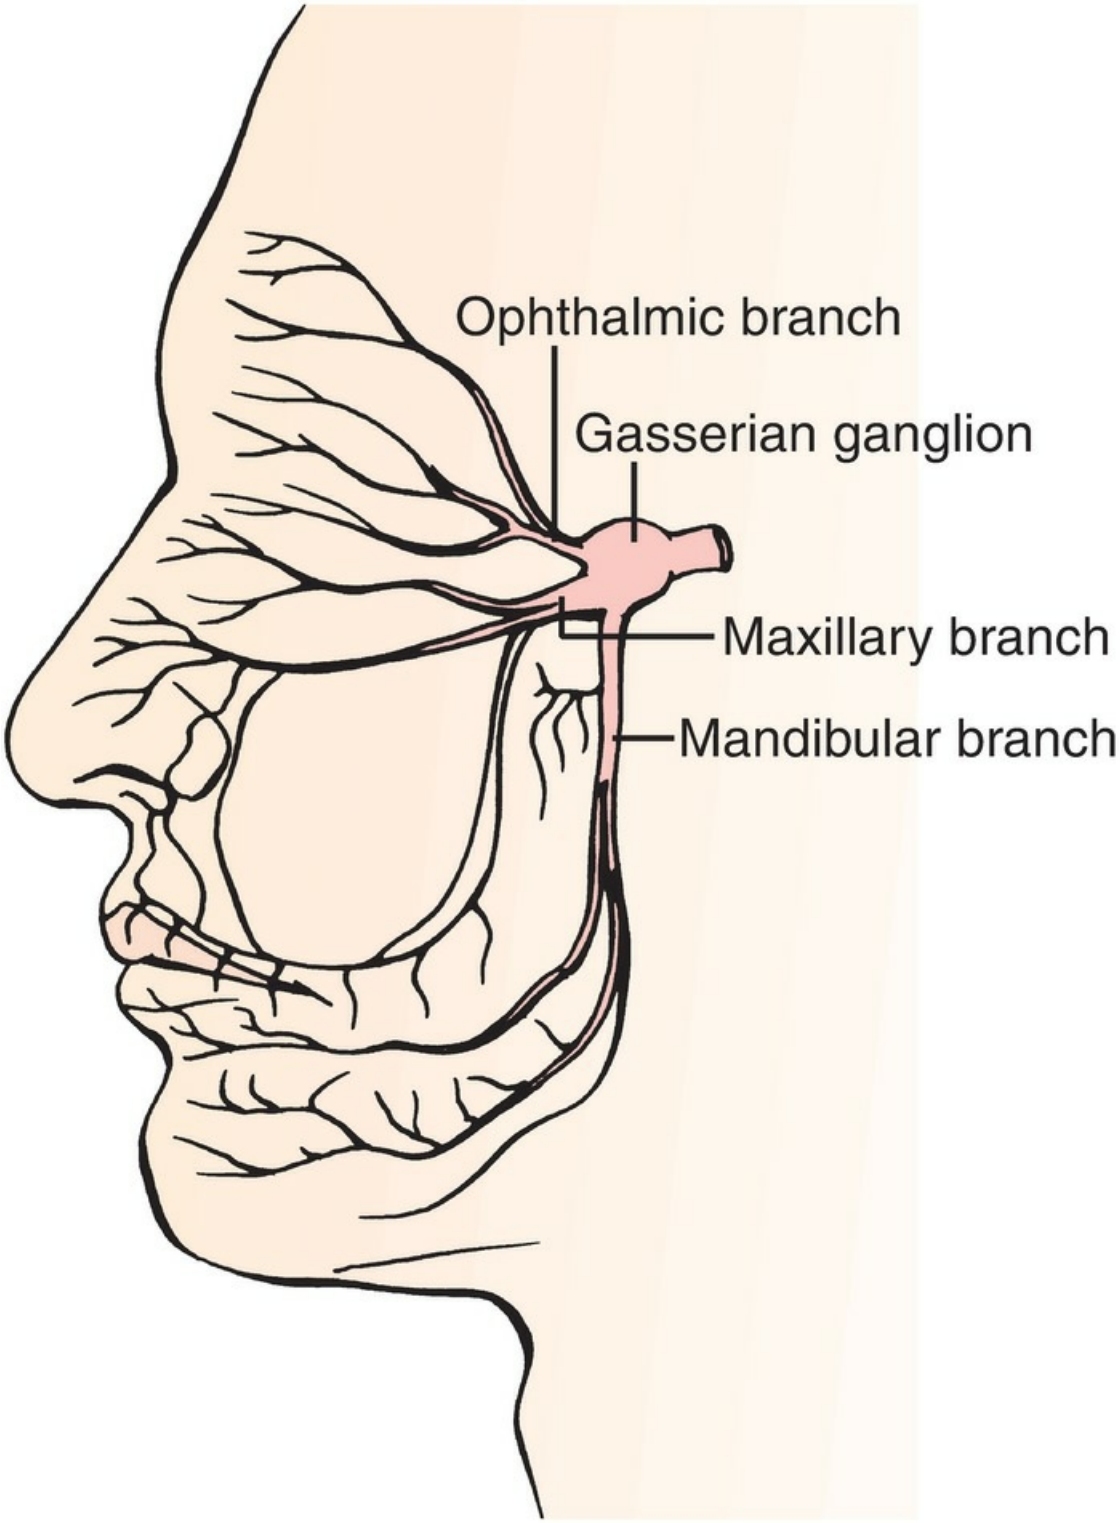

Figure 15-3. The main divisions of the trigeminal nerve are the ophthalmic, maxillary, and mandibular. Sensory root fibers arise in the gasserian ganglion.

Pathophysiology and Etiology

1. Unknown cause, but degenerative or viral origin suspected.
2. Any of the three trigeminal nerve branches can be affected:

a. V_1: ophthalmic branch; pain involves the eye and forehead.
b. V_2: maxillary branch; pain involves the cheek, upper teeth, upper gums, and nose.
c. V_3: mandibular branch; pain involves the lower jaw, side of the tongue, lower teeth, and lower gum and extends to the ear.

3. Compression from artery adjacent to the nerve strips myelin from the nerve when it pulsates. Loss of myelin acts like an uninsulated wire that "fires" abnormally in response to stimuli.

GERONTOLOGIC ALERT Trigeminal neuralgia is commonly seen in older adults. Pain typically appears to be localized to one or more teeth. Patients may seek dental care for pain relief, resulting in one or more tooth extractions without alleviation of pain.

Clinical Manifestations

1. Sudden, severe episodes of intense facial pain localized to one or more of the branches of the nerve, lasting less than 30 to 60 seconds and ending abruptly.
2. Pain may occur spontaneously or be precipitated by activation of trigger points, such as touching the face, talking, chewing, yawning, and brushing the teeth, that place pressure on the terminal end of the branch affected.
3. Pain is always unilateral and does not cross the midline. Bilateral pain is sometimes seen in patients with MS and should result in a high index of suspicion for this condition. MS and hypertension are the two risk factors found in epidemiologic studies.
4. Some patients experience numbness, particularly around the mouth.

Diagnostic Evaluation

1. History of characteristic symptoms and pattern; neurologic examination is normal. In contrast to migraine pain, persons with trigeminal neuralgia rarely suffer attacks during sleep, which is a key point in the history.
2. New classification and diagnostic grading system to make diagnosis of classic TN, secondary TN due to identifiable neurologic disorder, or idiopathic TN.

EVIDENCE BASE Cruccu, G., Finnerup, N. B., Sindou, M., et al. (2016). Trigeminal neuralgia: New classification and diagnostic grading for practice and research. *Neurology, 87*, 220–228.

---

3. Quick response to pharmacologic treatment is important to rule out atypical facial pain, vasomotor or postherpetic neuralgia, and dental pain.

4. Head CT scan and MRI of the brain out structural lesions, such as tumor, arteriovenous malformation (AVM), MS, or other disorders.

Management

Pharmacologic

1. Levetiracetam is the first line and most effective medication used to treat this condition. Other drugs such as carbamazepine, oxcarbazepine, phenytoin, baclofen, and gabapentin may be substituted.
2. Although pain generally responds to pharmacologic intervention, it gradually becomes refractory over time, or patients suffer undesirable adverse effects.

Surgical

Operative procedure selected is one that will provide the greatest chance of long-term pain relief with the fewest complications.

1. Alcohol, phenol block, or glycerol injection for pain may last several months after injection.
2. Percutaneous radiofrequency trigeminal gangliolysis directs low-voltage stimulation of nerve by electrode inserted through foramen ovale; sensory function is destroyed with goal to preserve motor function; may cause decreased corneal sensation if V1 affected; paresthesias, jaw weakness, or undesirable, painful numbness (anesthesia dolorosa). Pain may recur as nerve regenerates, necessitating repeat procedure.
3. Rhizotomy (transection of nerve root at Gasserian ganglion) causes complete loss of sensation; other complications include burning, stinging, discomfort in and around eye, herpetic lesions of face, keratitis, and corneal ulceration. Pain may recur as nerve regenerates.
4. Percutaneous balloon microcompression for selective destruction of nerve fibers that mediate light touch and trigger pain. Relieves pain in ophthalmic branch while sparing corneal sensation.
5. Microvascular decompression of trigeminal nerve. Most effective form of therapy, with 75% to 80% of patients pain-free without need for long-term medication after procedure. Treatment of choice for younger patients who are low anesthesia risk, do not want facial numbness, and are willing to accept craniotomy.
6. Gamma knife surgery is less invasive than the percutaneous procedures. It is about as effective as the percutaneous procedures; however, relief may not come for weeks to months and it is a bit more expensive.

Complications

1. Anorexia and weight loss.
2. Dehydration.
3. Anxiety, fear.
4. Depression, social isolation, and suicidal ideations in extreme cases.

Nursing Assessment

1. Take history of the pain, including duration, severity, and aggravating factors.
2. Assess nutritional status and hydration.
3. Assess for anxiety and depression, including problems with sleep, social interaction, and coping ability/skills.

Nursing Diagnoses

- Chronic Pain related to physiologic changes of the disorder.
- Imbalanced Nutrition: Less Than Body Requirements related to fear of eating.
- Powerlessness related to lack of control over painful episodes.

Nursing Interventions

Relieving Pain

1. To minimize painful episodes, review with patient potential trigger factors, and develop individualized methods of coping with identified triggers.
2. Encourage the patient to take medication regularly, including "rescue" medication for breakthrough periods.
3. Help the patient maintain a method of communication without causing pain from talking.

Maintaining Adequate Nutrition

1. To maximize nutritional intake, instruct the patient to take foods and fluids at room temperature and to chew on the unaffected side.
2. Have the patient consult with the dietitian for appropriate meal texture and composition.
3. Encourage small, frequent meals to avoid fatigue and pain.
4. Advise about use of nutritional supplements, if indicated.

Increasing Control

1. Support the patient through treatment trials.
2. Teach relaxation exercises, such as relaxation breathing, progressive muscle relaxation, and guided imagery, to relieve tension (see page 25).
3. Encourage participation in support groups (eg, Trigeminal Neuralgia Association) and facilitate a therapeutic relationship with the health care provider.

Patient Education and Health Maintenance

1. Educate the surgical patient regarding self-care after denervation procedures.
    a. Instruct the patient to inspect the eye for redness and foreign bodies three to four times per day if corneal sensation is impaired.
    b. Instruct the patient to instill lubricating eye drops every 4 hours if corneal sensation is impaired.
    c. Instruct the patient to avoid drinking hot or very cold liquids.

d. Instruct the patient to chew on unaffected side to avoid biting tongue, lips, and inside of mouth.
e. Instruct the patient who wears dentures that jaw muscle will regenerate over time; avoid having dentures refitted, but maintain regular dental checkups because pain will not be felt.
f. Instruct the patient to report any change in sensation.

2. Refer patient to the Facial Pain Association for education and support network (*www.fpa-support.org*) or the National Institute of Neurological Disorders and Stroke (*www.ninds.nih.gov*).

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Maintains weight.
- Verbalizes decreased anxiety and depression.

CEREBROVASCULAR DISEASE

Cerebrovascular Insufficiency

EVIDENCE BASE Kernan, W. N., Ovbiagele, B., Black, H. R., et al. (2014) Guidelines for the prevention of stroke in patients with stroke and transient ischemic attack: A guideline for healthcare professionals from the American heart association/American stroke association. *Stroke, 45*(7), 2160–2236.

Cerebrovascular insufficiency is an interruption or inadequate blood flow to a focal area of the brain, resulting in transient or permanent neurologic dysfunction. *Transient ischemic attack* (TIA) lasts less than 24 hours. *Ischemic stroke* is similar to myocardial infarction, in that the pathogenesis is loss of blood supply to the tissue, which can result in irreversible damage if blood flow is not restored quickly.

Pathophysiology and Etiology

1. Cerebrovascular insufficiency can be caused by atherosclerotic plaque or thrombosis, resulting in increased P_{CO_2}, decreased P_{O_2}, decreased blood viscosity, hyperthermia/hypothermia, and increased ICP.
2. Carotid arteries, vertebral arteries, major intracranial vessels, or microcirculation may be affected.
3. Cardiac causes of emboli include atrial fibrillation, mitral valve prolapse, infectious endocarditis, and prosthetic heart valve.
4. Event may be classified as TIA—transient episode of cerebral dysfunction with associated clinical manifestations lasting usually minutes to an hour, possibly up to 24 hours.
5. Symptoms persisting longer than 24 hours are classified as stroke (also known as *brain attack*).

Risk Factors for Stroke

Medical Conditions

1. Diabetes mellitus (44% risk reduction in hypertensive diabetics with controlled BP).
2. Hypertension (30% to 40% risk reduction with treatment): goal BP is lower than 140/90; if renal insufficiency or heart failure, less than 130/85; if diabetic, less than 130/80.
3. Hyperlipidemia (20% to 30% risk reduction in patients with known coronary artery disease.
4. Coronary artery disease and cardiac disorders, such as congenital heart disease, valvular conditions, endocarditis, atrial fibrillation (68% risk reduction with oral anticoagulation; 21% with aspirin).
5. History of TIA or stroke.
6. Rare: Endothelial damage (inflammation or infection, drug-induced, fibromuscular dysplasia, carotid or vertebral artery dissections).

Behaviors

1. Cigarette smoking (smoking cessation results in a 50% risk reduction in 1 year; return to baseline in 5

years).

2. Alcohol abuse.
3. Physical inactivity.
4. Cocaine use (hemorrhagic stroke).

Nonmodifiable Factors

1. Increasing age—risk doubles for each decade over age 50.
2. Gender—men are at greater risk than women.
3. Heredity—increased risk with family history of stroke.
4. Ethnic background—blacks and Hispanics at higher risk than whites.

Other

There have been reports in the literature of increased risk due to childbirth, hormone replacement therapy or contraceptive use, and migraine headaches. Chiropractic manipulation has been associated with ischemic stroke related to dissection.

DRUG ALERT Increased stroke risk has been noted in women who smoke and take oral contraceptives and who have a history of migraines.

Clinical Manifestations of Transient Ischemic Attacks

1. History of intermittent neurologic deficit, sudden in onset, with maximal deficit within 5 minutes and lasting less than 24 hours.
2. Carotid system involvement: amaurosis fugax, homonymous hemianopsia, unilateral weakness, unilateral numbness or paresthesias, aphasia, dysarthria.
3. Vertebrobasilar system involvement: vertigo, homonymous hemianopsia, diplopia, weakness that is bilateral or alternates sides, dysarthria, dysphagia, ataxia, perioral numbness.
4. Carotid bruit.
5. History of headaches lasting days before ischemia.

Diagnostic Evaluation

1. Cerebral angiography, digital subtraction angiography, CT angiography, MRA, Doppler ultrasound—all provide information about carotid arteries, vertebral arteries, and intracranial circulation.
2. Anticoagulation monitoring: partial prothrombin time (PTT) or heparin anti-Xa test to determine heparin dose, or International Normalized Ratio (INR) to monitor warfarin therapy.
3. MRI stroke protocol: consists of a standard MRI in conjunction with DWI and ADC or PWI scan (see page 348).
4. Transesophageal echocardiography to rule out emboli from heart.

Management

1. Platelet aggregation inhibitors, such as aspirin, or clopidogrel to reduce risk of stroke.
2. Surgical or endovascular intervention to increase blood flow to the brain—carotid endarterectomy, extracranial/intracranial anastomosis, transarterial stenting, or angioplasty.
3. Reduction of other risk factors to prevent stroke, such as control of hypertension, diabetes, and hyperlipidemia, and smoking cessation.
4. Treatment of arrhythmias.
5. Treatment of isolated systolic hypertension.
6. Anticoagulation agents for patients who continue to have symptoms despite antiplatelet therapy (this remains controversial) and those with major source of cardiac emboli.

Complications

1. Complete ischemic stroke (30% of TIAs will progress to stroke within 5 years of initial TIA).
2. Hemorrhagic conversion of ischemic stroke.
3. Cerebral edema.

Nursing Assessment

1. Obtain history of possible TIA; hypertensive and diabetic control; hyperlipidemia; cardiovascular disease or dysrhythmias, such as atrial fibrillation; smoking.
2. Perform physical examination, including neurologic, cardiac, and circulatory systems; be sure to listen for carotid bruit.
3. Assess the patient for history of headache and, if positive, for duration of headache.

Nursing Diagnoses

- Risk for Ineffective Cerebral Tissue Perfusion related to underlying arteriosclerosis.
- Risk for Injury related to surgical procedure.
- Readiness for Enhanced Therapeutic Regimen Management regarding therapeutic lifestyle changes.

Nursing Interventions

Improving Cerebral Perfusion

1. Teach the patient signs and symptoms of TIA and need to notify health care provider immediately. Use the acronym FAST to know what to look for: F, face weakness; A, arm weakness; S, speech difficulties; T, time—immediately seek medical assistance.
2. Administer or teach self-administration of anticoagulants, antiplatelet agents, antihypertensives, and other medication; also teach about monitoring for adverse effects and therapeutic effect.
3. Prepare the patient for surgical or endovascular intervention as indicated (see page 361).

Providing Care and Preventing Complications After Surgical Procedure

Also see "Nursing Management of the Patient Undergoing Intracranial Surgery," page 361, and "Cerebral Angiography," page 350.

1. After surgical procedure, closely monitor vital signs and administer medication as prescribed to avoid hypotension (which can cause cerebral ischemia) or hypertension (which can precipitate cerebral hemorrhage).
2. Perform frequent neurologic checks, including pupil size, equality, and reaction; handgrip and plantar flexion strength; sensation; mental status; and speech. Notify the health care provider of any deficits immediately.
3. Observe operative area closely for swelling. Mild swelling is expected, but if hematoma formation is suspected, prepare the patient for immediate surgery.
4. Medicate for pain and avoid agitation or sudden changes in position, which could affect BP.
5. Elevate head of bed when vital signs are stable.
6. Following carotid endarterectomy:
   a. Monitor for hoarseness, impaired gag reflex, or difficulty swallowing and facial weakness, which indicate CN injury.
   b. Keep head in neutral position to relieve stress on surgical site; monitor drainage.
   c. Keep tracheostomy tube at bedside and assess for stridor; hematoma formation can cause airway obstruction.
7. Following extracranial–intracranial anastomosis, avoid pressure over the anastomosis of the superior temporal artery (extracranial) and the middle cerebral artery (intracranial) to prevent rupture or ischemia of the site. If the patient wears glasses, remove the eyeglass arm on the operative side to avoid this possible pressure point.
8. Following transcranial stenting, administer medications, as directed.
   a. Heparin—bolus given intraprocedure, then possible continuous IV drip postprocedure to maintain PTT within ordered range; monitor PTT every 6 hours.
   b. Clopidogrel before procedure, as ordered. Can be given as a loading dose of 150 mg the evening before procedure, 300-mg loading dose before procedure, 75 mg daily 48 hours before procedure, or 75 mg daily 1 week before procedure. Dosing is according to surgeon preference.
   c. Daily dosing of 75 mg clopidogrel for 30 to 90 days (specific duration varies), as directed.
   d. Aspirin 81 mg daily, as directed.
9. Monitor puncture site for bleeding, hematoma, and pulse, as ordered. Apply pressure if bleeding or hematoma is noted and inform physician.

NURSING ALERT In the event of an acute neurologic deficit, the heparin drip should be stopped until an acute intracerebral bleed has been ruled out.

DRUG ALERT Loading dose of clopidogrel, intraprocedure heparin bolus, postprocedure heparin drip, and postprocedure clopidogrel daily dosing minimize the risk of thromboembolic complications following transarterial carotid stenting while increasing the risk of hemorrhagic complications. Close monitoring of neurologic status and PTT is warranted. Inform health care provider of any changes in neurologic status, PTT levels out of ordered range, and signs of bleeding.

Encouraging Lifestyle Changes to Reduce Risk

1. Help the patient begin to formulate a plan for smoking cessation.
2. Teach the patient and family members the basics of nutrition, how to read labels, and how to follow a low-fat diet (particularly one low in saturated fats).
3. Obtain a referral to a nutritionist for help with weight management and low-fat, low-sodium diet, as indicated.
4. Encourage daily activity for 30 minutes, if possible. Obtain physical therapy referral for endurance training and monitoring, as indicated.
5. Monitor INR if warfarin is prescribed, and educate the patient about the risk of bleeding.

Patient Education and Health Maintenance

1. Encourage the patient receiving long-term oral anticoagulants to comply with follow-up monitoring of INR and to report any signs of bleeding.
2. Encourage patients receiving antiplatelet agents to report any signs of bleeding.
3. Encourage the use of electric razors and toothbrushes to prevent bleeding.
4. Reinforce with patient and family the importance of accessing the medical system, by calling 911, when symptoms first occur.
5. Refer the patient to the American Stroke Association (*www.strokeassociation.org*) or the National Institute of Neurologic Disorders and Stroke (*www.ninds.nih.gov*) for additional information and support.

Evaluation: Expected Outcomes

- Alert without neurologic deficits.
- Respirations unlabored, vital signs stable, no swelling of neck; reports relief of pain.
- Expresses readiness to quit smoking and adhere to a low-fat diet.

Cerebrovascular Accident (Stroke, Brain Attack)

Stroke, *cerebrovascular accident (CVA)*, or *brain attack* is the onset and persistence of neurologic dysfunction resulting from disruption of blood supply to the brain and indicates infarction rather than ischemia. Strokes are classified as ischemic (more than 70% of strokes) or hemorrhagic (associated with greater morbidity and mortality). About 14% of strokes in the United States are of cardiac origin. About 60% of hemorrhagic strokes are the result of hypertension. Stroke is the leading cause of long-term disability and the third leading cause of death in the United States, with an annual incidence of 700,000.

Pathophysiology and Etiology

Ischemic Stroke

1. Partial or complete occlusion of a cerebral blood flow to an area of the brain due to the following:
   a. Thrombus (most common)—due to arteriosclerotic plaque in a cerebral artery, usually at bifurcation of larger arteries; occurs over several days.
   b. Embolus—a moving clot of cardiac origin (frequently due to atrial fibrillation) or from a carotid artery that travels quickly to the brain and lodges in a small artery; occurs suddenly with immediate maximum deficits.
2. Area of brain affected is related to the vascular territory that was occluded. Subtle decrease in blood flow may allow brain cells to maintain minimal function, but as blood flow decreases, focal areas of ischemia occur, followed by infarction to the vascular territory. See Figure 15-4 for cerebral circulation.
3. An area of injury includes edema, tissue breakdown, and small arterial vessel damage. The small arterial vessel damage poses a risk of hemorrhage. The larger the area of infarction, the greater the risk of hemorrhagic conversion.
4. Ischemic strokes are not activity-dependent; may occur at rest.

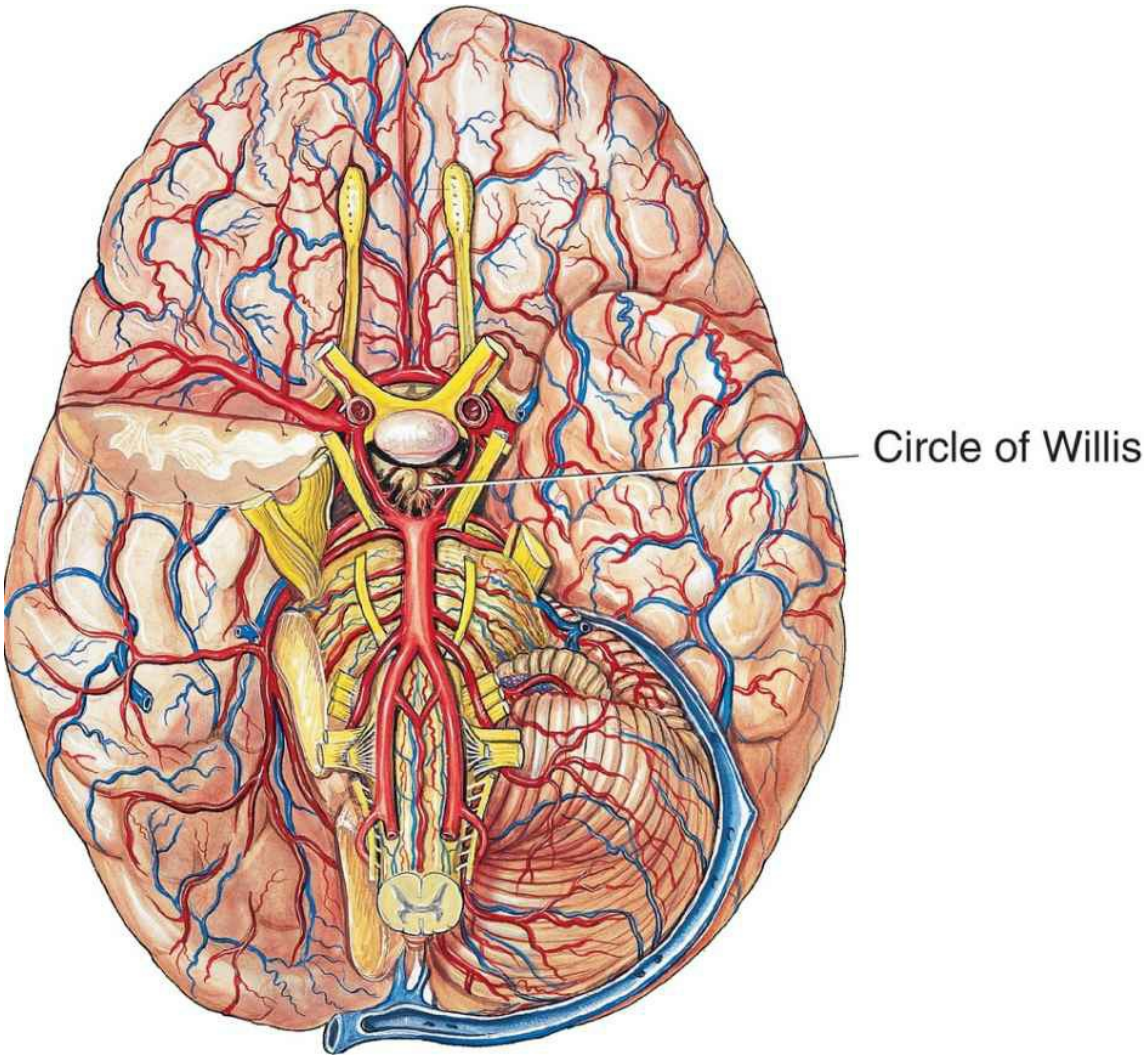

Figure 15-4. The circle of Willis as seen at the base of a brain removed from the skull.
(Anatomical Chart Company.)

NURSING ALERT Early detection of warning signs promotes early diagnosis and intervention aimed at lessening stroke mortality and morbidity.

Hemorrhagic Stroke

1. Leakage of blood from a blood vessel and hemorrhage into brain tissue, causing edema, compression of brain tissue, and spasm of adjacent blood vessels.
2. May occur outside the dura (extradural), beneath the dura mater (subdural), in the SAS, or within the brain substance (intracerebral).
3. Causal mechanisms include the following:
   a. Increased pressure due to hypertension.
   b. Head trauma causing dissection or rupture of vessel.

c. Deterioration of vessel wall from chronic hypertension, diabetes mellitus, or cocaine use.

d. Congenital weakening of blood vessel wall with aneurysm or AVM.

4. The intracranial hemorrhage becomes a space-occupying lesion within the skull and compromises brain function.

a. The mass effect causes pressure on brain tissue.

b. The hemorrhage irritates local brain tissue, leading to surrounding focal edema.

c. SAH or hemorrhage into a ventricle can block normal CSF flow, leading to hydrocephalus.

5. Hemorrhage commonly occurs suddenly while a person is active.

Clinical Manifestations

1. Clinical manifestations vary depending on the vessel affected and the cerebral territories it perfuses. Symptoms are usually multifocal. Headache may be a sign of impending cerebral hemorrhage or infarction; however, it is not always present.

2. Common clinical manifestations related to vascular territory (see Table 15-5).

a. Numbness (paresthesia), weakness (paresis), or loss of motor ability (plegia) on one side of the body.

b. Difficulty in swallowing (dysphagia).

c. Aphasia (nonfluent, fluent, global).

d. Visual difficulties of inattention or neglect (lack of acknowledgment of one side of the sensory field), loss of half of a visual field (hemianopsia), double vision, photophobia.

e. Altered cognitive abilities and psychological affect.

f. Self-care deficits.

Table 15-5 Stroke Deficits Related to Vascular Territory

CEREBRAL ARTERY	BRAIN AREA INVOLVED	SIGNS AND SYMPTOMS*
Anterior cerebral	Infarction of the medial aspect of one frontal lobe if lesion is distal to communicating artery; bilateral frontal infarction if flow in other anterior cerebral artery is inadequate	Paralysis of contralateral foot or leg; impaired gait; paresis of contralateral arm; contralateral sensory loss over toes, foot, and leg; problems making decisions or performing acts voluntarily; lack of spontaneity, easily distracted; slowness of thought; urinary incontinence; cognitive and affective disorders
Middle cerebral	Massive infarction of most of lateral hemisphere and deeper structures of the frontal, parietal, and temporal lobes; internal capsule; basal ganglia	Contralateral hemiplegia (face and arm); contralateral sensory impairment; aphasia; homonymous hemiplegia; altered consciousness (confusion to coma); inability to turn eyes toward paralyzed side; denial of paralyzed side or limb (hemiattention); possible acalculia, alexia (visual aphasia), finger agnosia, and left–right confusion; vasomotor paresis and instability
Posterior cerebral	Occipital lobe; anterior and medial portion of temporal lobe	Homonymous hemianopia and other visual defects, such as color blindness, loss of central vision, and visual hallucinations; memory deficits; perseveration (repeated performance of same verbal or motor response)
	Thalamus involvement	Loss of all sensory modalities; spontaneous pain; intentional tremor; mild hemiparesis; aphasia
	Cerebral peduncle involvement	Oculomotor nerve palsy with contralateral hemiplegia
Basilar and vertebral	Cerebellum and brain stem	Visual disturbance such as diplopia, dystaxia, vertigo, dysphagia, dysphonia

**Dependent on hemisphere involved and adequacy of collaterals.*

Diagnostic Evaluation

1. CT scan—to determine cause and location of stroke and type of stroke, ischemic versus hemorrhagic.

2. MRA or CT angiogram—noninvasive evaluation of cerebrovascular structures in ischemic stroke.
3. Carotid ultrasound—to detect carotid stenosis in ischemic stroke.
4. Cerebral angiography—invasive evaluation of cerebrovasculature to determine the extent of cerebrovascular injury/insufficiency and to evaluate for structural abnormalities.
5. PET, MRI with DWI—to localize ischemic damage in ischemic stroke.
6. CT perfusion/MR perfusion—provides evaluation of cerebral blood flow, cerebral blood volume, and mean transient time to determine the extent of ischemic changes.
7. TCD—noninvasive method used to evaluate cerebral perfusion. Useful in the bedside evaluation and to provide a means for ongoing monitoring of cerebral blood flow to document changes and trends.

Management

Acute Treatment: Ischemic Stroke

1. Support of vital functions—maintain airway, breathing, oxygenation, circulation.
   a. Maintain pulse oximetry greater than 92%. Utilize oxygen therapy, as needed.
   b. Arrhythmias are common. Telemetry may be indicated to monitor. Atrial fibrillation is the most common arrhythmia in stroke population.
2. Astute neurologic assessment utilizing the National Institute of Health Stroke Scale (*www.strokecenter.org/wp-content/uploads/2011/08/NIH_stroke_scale.pdf*) and management of increased ICP.
3. IV fluids (normal saline) at maintenance until able to tolerate oral diet. Colloids may be used for reperfusion and hemodilution.
4. Maintain BP within prescribed parameters. Limit BP fluctuations.
   a. Management of systemic hypertension with labetalol, nicardipine, or alternative IV antihypertensive agents to keep systolic BP (SBP) less than 200 mm Hg. Goal is to promote adequate cerebral perfusion to prevent further ischemia. Avoid lowering BP greater than 25% within the first 24 hours. Hemorrhagic conversion/transformation can occur and is associated with degree of necrotic tissue and vascular injury. Hyperglycemia and BP fluctuations or rapid increases in BP increase the risk of hemorrhagic conversion.
   b. Management of hypotension—SBP goal greater than 100. Vasopressor agents to maintain SBP within prescribed range. Sustained hypotensive episodes are associated with poor outcome.
   c. Pretreatment with tissue plasminogen activator (tPA)—unable to receive tPA if SBP greater than 185 mm Hg or diastolic BP greater than 110 mm Hg.
   d. Post-tPA—maintain SBP less than 180 mm Hg or diastolic BP less than 105 mm Hg for first 24 hours post tPA.
5. Thrombolytic therapy (see Box 15-3, below).
   a. Recombinant tPA administered IV is the only Food and Drug Administration (FDA)–approved medical treatment for acute ischemic stroke. Dosing: IV 0.9 mg/kg within 3 hours of onset of

symptoms.

b. Transarterial tPA within 6 hours of onset of symptoms. Benefits have been demonstrated in acute ischemic stroke related to occlusion of middle cerebral artery. Advantages include the following:
   i. Higher concentration delivered to clot.
   ii. Can be performed in conjunction with mechanical disruption of clot.
   iii. Provides precise imaging of pathology and evaluation of collateral circulation.
   iv. Defines extent of injury and recanalization.

c. Disadvantages include the following:
   i. Risk of hemorrhage related to catheter manipulation.
   ii. Dislodgement of clot.
   iii. Delay in thrombolytic therapy due to access delays.
   iv. Limited facility-based accessibility.

d. Additional treatment options (transarterial or endovascular):
   i. Abciximab—antiplatelet agent delivered intra-arterially (IA).
   ii. Verapamil—potent vasodilator injected into intracranial vessel to treat acute spasm.
   iii. Clot retrieval or manipulation of clot.
   iv. Angioplasty and stenting have been utilized in acute dissection, though data are limited.

6. Maintain normal glucose levels because hypoglycemia and hyperglycemia are associated with a poor outcome. Sliding scale insulin or insulin drip should be given to maintain normoglycemia.
7. Maintain normothermia because hyperthermia is associated with a poor neurologic outcome.
8. Deep vein thrombosis (DVT) prophylaxis—sequential stockings and low-dose heparin or low molecular weight heparin (LMWH) should be utilized. Data do not suggest any increased risk of hemorrhage in this population.
9. Focus on early rehabilitation.

BOX 15-3 Inclusion and Exclusion Criteria for tPA Therapy

INCLUSION

- Onset of symptoms
  - Within 4.5 hours IV tPA.
  - Within 6 hours IA tPA.
- Ischemic stroke with measurable deficits using the NIH Stroke Scale (see page 368).
- No hemorrhage noted on CT scan of brain.
- Clearly defined time of symptom onset.

EXCLUSION

- Head CT demonstrates early signs of infarction or hemorrhage.
- Uncontrolled hypertensive nonresponsive to IV or oral agent (systolic greater than 185 or diastolic

greater than 110 mm Hg).

- Glucose level greater than 400 mg/dL.
- Coagulopathy.
  - Heparin within past 48 hours.
  - Patient on warfarin.
  - Elevated PTT or prothrombin time.
  - Platelet count less than 100,000.
- History of previous intracranial hemorrhage, head trauma, or stroke within past 3 months.
- GI or genitourinary tract hemorrhage in the past 3 weeks.
- History of major surgery in the past 2 weeks.

Acute Treatment: Hemorrhagic Stroke

1. Support of vital functions—maintain airway, breathing, oxygenation, circulation.
   a. Maintain pulse oximetry greater than 92%. Utilize oxygen therapy, as needed.
   b. Arrhythmias are common. Telemetry may be indicated to monitor.
   c. IV fluids (normal saline) at maintenance until able to tolerate oral diet.
2. Neurologic assessment—Facility-based neurologic assessment tool should be used. Notify the health care provider of clinical deterioration. Deterioration can be related to rebleed or development of cerebral edema.
3. Reversal of coagulopathies:
   a. Obtain patient's medication history. Medications to be concerned about include warfarin, aspirin, clopidogrel, ticlopidine, and dipyridamole/aspirin.
   b. Obtain INR and platelet function analyzer (PFA-100), as ordered. Elevated INR is associated with warfarin use. PFA epinephrine greater than 164 denotes platelet dysfunction related to aspirin use and PFA adenosine diphosphate greater than 116 denotes nonaspirin platelet dysfunction and has been used to determine the effectiveness of clopidogrel or ticlopidine or the presence of von Willebrand disease.
   c. As ordered, treat with platelets, cryoprecipitate, or vitamin K to reverse coagulopathy. Prothrombin complex concentrate may be used for rapid reversal.
4. Management of BP within prescribed parameters—maintain SBP less than 160 to reduce vessel wall stressors. Goal is to prevent rebleeding while promoting adequate cerebral perfusion. Labetalol, hydralazine, nicardipine, or alternative IV antihypertensive agents may be used.
5. Neurosurgical consultation for possible evacuation of intracerebral hemorrhage may be explored.
6. Treatment of clinical seizures with phenytoin or levetiracetam. Seizures commonly occur within the first 24 hours of intracerebral hemorrhage.
7. Maintain normal glucose level because hypoglycemia/hyperglycemia is associated with a poor outcome. Sliding scale insulin or insulin drip should be given to maintain normoglycemia.
8. Maintain normothermia because hyperthermia is associated with a poor neurologic outcome. Current

data do not support the use of therapeutic, or induced, hypothermia in patients with ischemic stroke; however, research is ongoing to determine potential applications.

9. DVT prophylaxis—sequential stockings and low-dose heparin or LMWH should be utilized. Data do not suggest any increased risk of hemorrhage in this population.
10. Focus on early rehabilitation.

Subsequent Treatment

1. Aspirin is the only antiplatelet agent that has been evaluated in acute ischemic stroke. Aspirin is recommended within 24 hours poststroke. (In tPA patients, aspirin should not be given until 24 hours post tPA.) Alternative antiplatelet agents include ticlopidine, dipyridamole/aspirin 200/25, and clopidogrel.
2. Antispasmodic agents can be used for spastic paralysis.
3. Early initiation of a rehabilitation program, including physical therapy, occupational therapy, and speech therapy, and counseling, as needed.
4. Depression is common; therefore, early initiation of antidepressants can be beneficial, such as selective serotonin reuptake inhibitors.

Complications

1. Aspiration pneumonia.
2. Dysphagia in 25% to 50% of patients after stroke.
3. Spasticity, contractures.
4. DVT, pulmonary embolism.
5. Brain stem herniation.
6. Poststroke depression.

Nursing Assessment

1. Maintain neurologic flow sheet (National Institutes of Health (NIH) Stroke Scale for ischemic stroke and facility-based neurologic assessment tool for hemorrhagic stroke).
2. Assess for voluntary or involuntary movements, tone of muscles, presence of deep tendon reflexes (reflex return signals end of flaccid period and return of muscle tone).
3. Also assess mental status, CN function, sensation/proprioception.
4. Monitor bowel and bladder function/control.
5. Monitor effectiveness of anticoagulation therapy.
6. Frequently assess level of function and psychosocial response to condition.
7. Assess for skin breakdown, contractures, and other complications of immobility.

DRUG ALERT Oral anticoagulants are adjusted to maintain an INR at 2 to 3 to prevent stroke

associated with atrial fibrillation. Monitor for potential complications of intracranial and subdural hemorrhage. Report INRs that are elevated to reduce the risk of bleeding or decreased levels to adjust therapy to be more effective.

Nursing Diagnoses

- Risk for Injury related to neurologic deficits.
- Impaired Physical Mobility related to motor deficits.
- Impaired Environmental Interpretation Syndrome related to brain injury.
- Impaired Verbal Communication related to brain injury.
- Bathing, Dressing, Toileting Self-Care Deficit related to hemiparesis/paralysis.
- Imbalanced Nutrition: Less Than Body Requirements related to impaired self-feeding, chewing, swallowing.
- Impaired Urinary Elimination related to motor/sensory deficits.
- Disabled Family Coping related to catastrophic illness, cognitive and behavioral sequelae of stroke, and caregiving burden.

NURSING ALERT Use of clinical pathways maximizes stroke patient outcomes across the care continuum. Case management models of care foster interdisciplinary utilization, timeliness of referrals, patient education, patient satisfaction, and efficient use of health care resources. The specific role of the nurse in stroke recovery integrates therapeutic aspects of coordinating, maintaining, and training.

Nursing Interventions

Preventing Falls and Other Injuries

1. Maintain bed rest during acute phase (24 to 48 hours after onset of stroke) with head of bed slightly elevated and side rails in place.
2. Administer oxygen, as ordered, during acute phase to maximize cerebral oxygenation.
3. Frequently assess respiratory status, vital signs, heart rate and rhythm, and urine output to maintain and support vital functions.
4. When patient becomes more alert after acute phase, maintain frequent vigilance and interactions aimed at orienting, assessing, and meeting the needs of the patient.
5. Try to allay confusion and agitation with calm reassurance and presence.
6. Assess the patient for risk for fall status.

Preventing Complications of Immobility

Interventions to improve functional recovery require active participation of the patient and repetitive training. Functional demand and intensive training are believed to trigger CNS reorganization—responsible for late

functional recovery after stroke.

1. Maintain functional position of all extremities.
    a. Apply a trochanter roll from the crest of the ilium to the midthigh to prevent external rotation of the hip.
    b. Place a pillow in the axilla of the affected side when there is limited external rotation to keep arm away from chest and prevent adduction of the affected shoulder.
    c. Place the affected upper extremity slightly flexed on pillow supports with each joint positioned higher than the preceding one to prevent edema and resultant fibrosis; alternate elbow extension.
    d. Place the hand in slight supination with fingers slightly in flexion.
    e. Avoid excessive pressure on ball of foot after spasticity develops.
    f. Do not allow top bedding to pull affected foot into plantar flexion; may use tennis shoes in bed.
    g. Place the patient in a prone position for 15 to 30 minutes daily, and avoid sitting up in chair for long periods to prevent knee and hip flexion contractures.
    h. Encourage neutral positioning of affected limbs to promote relaxation and to limit abnormal increases in muscular tone to enhance functional recovery (reflEX-inhibiting positioning).
    i. "Forced use" is an experimental treatment designed to overcome nonuse of the hemiparetic upper extremity in regaining functional use of the affected arm with selected chronic hemiparetic patients.
    j. "Constraint-induced movement therapy" restricts the contralateral upper extremity in effort to force use of the affected arm.
2. Apply splints and braces, as indicated, to support flaccid extremities or on spastic extremities to decrease stretch stimulation and reduce spasticity.
    a. Volar splint to support functional position of wrist.
    b. Sling to prevent shoulder subluxation of flaccid arm.
    c. High-top sneaker for ankle and foot support.
3. Exercise the affected extremities passively through ROM four to five times daily to maintain joint mobility and enhance circulation; encourage active ROM exercise as able (see page 141).
4. Teach the patient to use the unaffected extremity to move the affected one.
5. Assist with ambulation, as needed, with help of physical therapy, as indicated.
    a. Check for orthostatic hypotension when dangling and standing.
    b. Gradually position the patient from a reclining position to head elevated, and dangle legs at the bedside before transferring out of bed or ambulating; assess sitting balance in bed.
    c. Assess the patient for excessive exertion.
    d. Have the patient wear walking shoes or tennis shoes.
    e. Assess standing balance and have the patient practice standing.
    f. Help the patient begin ambulating as soon as standing balance is achieved; ensure safety with a patient waist belt.
    g. Provide rest periods as patient will tire easily.

Optimizing Orientation and Awareness

1. Be aware of the patient's cognitive alterations and adjust interaction and environment accordingly.
2. Participate in cognitive retraining program—reality orientation, visual imagery, cueing procedures—as outlined by rehabilitation nurse or therapist.
3. In patients with increased awareness, use pictures of family members, clock, calendar; post schedule of daily activities where patient can see it.
4. Focus on the patient's strengths and give positive feedback.
5. Be aware that depression is common and therapy should include psychotherapy and early initiation of antidepressants.

Facilitating Communication

1. Speak slowly, using visual cues and gestures; be consistent and repeat as necessary.
2. Speak directly to the patient while facing him or her.
3. Give plenty of time for response and reinforce attempts as well as correct responses.
4. Minimize distractions.
5. Use alternative methods of communication other than verbal, such as written words, gestures, or pictures.

Fostering Independence

1. Teach the patient to use nonaffected side for activities of daily living (ADL) but not to neglect affected side.
2. Adjust the environment (eg, call light, tray) to side of awareness if spatial neglect or visual field cuts are present; approach the patient from the uninvolved side.
3. Teach the patient to scan environment if visual deficits are present.
4. Encourage the family to provide clothing a size larger than patient wears, with front closures, Velcro, and stretch fabric; teach the patient to dress while sitting to maintain balance.
5. Make sure personal care items, urinal, and commode are nearby and that patient obtains assistance with transfers and other activities, as needed.
6. Be aware that ADL require anticipatory (automatic coordination of multiple muscle groups in anticipation of a specific movement) and reactive (adjustment of posture to stimuli) postural adjustments.
7. Be aware that patients usually have clear goals in relation to functional abilities, against which all success and forward progress will be measured; help them set realistic short- and long-term goals.

Promoting Adequate Oral Intake

1. Perform a bedside swallow screen. Follow institutional protocol. If any coughing or difficulties are noted, contact speech therapy for official consult.
2. Initiate referral for a speech therapist for individuals with compromised LOC, dyspraxic speech, or speech difficulties to evaluate swallowing function at bedside or radiographically to demonstrate safe and functional swallowing mechanisms before initiation of oral diet.

3. Help the patient relearn swallowing sequence using compensatory techniques (see page 369).
    a. Place ice on tongue and encourage sucking.
    b. Progress to ice pops and soft foods.
    c. Make sure mechanical soft or pureed diet is provided, based on ability to chew.
4. Encourage small, frequent meals and allow plenty of time to chew and swallow. Dietary consults can be helpful for selection of food preferences.
5. Remind the patient to chew on the unaffected side.
6. Encourage the patient to drink small sips from a straw with chin tucked to the chest, strengthening effort to swallow while chin is tucked down.
7. Inspect mouth for food collection and pocketing before entry of each new bolus of food.
8. Inspect oral mucosa for injury from biting tongue or cheek.
9. Encourage frequent oral hygiene.
10. Teach the family how to assist the patient with meals to facilitate chewing and swallowing.
    a. Reduce environmental distractions to improve patient concentration.
    b. Provide oral care before eating to improve aesthetics and afterward to remove food debris.
    c. Position the patient so he or she is sitting with 90 degrees of flexion at the hips and 45 degrees of flexion at the neck. Use pillows to achieve correct position.
    d. Maintain position for 30 to 45 minutes after meals to prevent regurgitation and aspiration.

Attaining Bladder Control

1. Insert indwelling bladder catheterization during acute stage for accurate fluid management; remove as soon as status stabilizes.
2. Establish regular voiding schedule—every 2 to 3 hours, correlated with fluid intake—when bladder tone returns. If the patient is unable to void, intermittent catheterization can be used to empty bladder and prevent overstretching of bladder. The bladder scan device is useful in monitoring bladder capacity and identifying individuals at risk.
3. Assist with standing or sitting to void (especially males).
4. See page 148 for bladder retraining program details.

Strengthening Family Coping

1. Consult a social worker for assistance with patient/family support, to obtain copy of durable power of attorney, address guardianship, and long-term care decisions, as needed.
2. Encourage the family to maintain outside interests.
3. Teach stress management techniques, such as relaxation exercises, use of community and faith-based support networks.
4. Encourage participation in support group for family respite program for caregivers or other available resources in area.
5. Involve as many family and friends in care as possible.

6. Provide information about stroke and expected outcome.
7. Teach the family that stroke survivors may show depression in the first 3 months of recovery.

Community and Home Care Considerations

1. Hemiplegic complications resulting from stroke commonly include "frozen" shoulder; adduction and internal rotation of arm with flexion of elbow, wrist, and fingers; external rotation of the hip with flexion of the knee and plantar flexion of the ankle.
2. Perform ROM exercises and instruct the patient and family on these as well as on proper positioning.
3. Reinforce that these muscle and ligament deformities resulting from stroke can be prevented with daily stretching and strengthening exercises.
4. Depression after stroke is a major problem because it can increase morbidity. Monitor for signs of depression, such as difficulty sleeping, frequent crying, anorexia, feelings of guilt, or sadness. Notify the health care provider for possible medication therapy.
5. Continue to support family who may be caring for a hemiplegic or aphasic person at home or in long-term care for a long time. Six months after stroke, around 9% to 21% of survivors are severely disabled, fully dependent, and live in institutions.

Patient Education and Health Maintenance

1. Teach the patient and family to adapt home environment for safety and ease of use.
2. Instruct the patient of the need for rest periods throughout day.
3. Reassure the family that it is common for poststroke patients to experience emotional lability and depression; treatment can be given.
4. Encourage consistency in the environment without distraction.
5. Assist the family to obtain self-help aids for the patient.
6. Instruct the family in management of aphasia (see Box 15-4, below).
7. Educate those at risk for stroke about lifestyle modifications and medication therapy that can lower risk.
8. Refer the patient and family for more information and support to such agencies as the National Stroke Association (*www.stroke.org*).

BOX 15-4 Management of Aphasia

Aphasia is an acquired disorder of communication resulting from brain damage due to stroke, head injury, brain tumors, or brain cysts. It may involve impairment of the ability to speak, to understand speech of others, and to read, write, calculate, and understand gestures. Most aphasic individuals have difficulty with expression and comprehension to varying degrees. Fatigue has adverse effect on speech.

To enhance your communication with the patient with aphasia, keep the environment simple and relaxed, minimize distractions, and use multiple sensory channels.

Refer the family to:

American Speech-Language-Hearing Association

10801 Rockville Pike

Rockville, MD 20852

301-897-5700

www.asha.org

APHASIA SYNDROMES

- Fluent aphasia (Wernicke or receptive aphasia): Patient retains verbal fluency but may have difficulty in understanding speech. Speech is effortless and lacks clear content, information, and direction (nonsensical).
- Nonfluent aphasia (Broca or expressive aphasia): Varied degrees of difficulty in initiation of speech, difficulty in formation of words with poor articulation, and difficulty in finding appropriate words. Speech is slow and laborious. Auditory comprehension is preserved.
- Anomic or amnesiac aphasia: Characteristic feature is difficulty naming and finding words. However, grammar, comprehension, and repetition remain intact.
- Conduction aphasia: Major difficulty is with sequencing phonemes resulting in literal paraphrasic errors. Auditory comprehension remains intact; however, patient has difficulty repeating spoken language.
- Global aphasia: Severe disruption of communication (verbal speech, written, reading, and auditory comprehension).

NURSING INTERVENTIONS

- Speak at your normal rate and volume: The patient is not hard of hearing.
- Allow plenty of time to answer.
- Do not ask questions that require complex answers.
- Rote phrases can be spontaneous.
- Provide pad and pen if the patient prefers and is able to write.
- Avoid forcing speech.
- Watch the patient for clues and gestures if his or her speech is jargon; make neutral statements.
- Allow plenty of time for response.
- Ask for minimal word response.
- Encourage the patient to speak slowly.
- Expect frustration and anger at inability to communicate.
- Keep environment simple.
- Use gestures as well as language.
- Allow the patient to manipulate objects for additional sensory input.

Evaluation: Expected Outcomes

- No falls, vital signs stable.

- Maintains body alignment, no contractures.
- Oriented to person, place, and time.
- Communicates appropriately.
- Brushes teeth, puts on shirt and pants independently.
- Feeds self two thirds of meal.
- Voids on commode at 2-hour intervals.
- Family seeks help and assistance from others.

Rupture of Intracranial Aneurysm

EVIDENCE BASE Connolly, E. S., Rabinstein, A. A., Carhuapoma, R., et al. (2012). Guidelines for the management of aneurysmal subarachnoid hemorrhage: A guideline for healthcare professionals from the American Heart Association/American Stroke Association. *Stroke, 43*, 1711–1737.

Grasso, G., Alafaci, C., & Macdonald, R. L. (2017). Management of aneurysmal subarachnoid hemorrhage: State of the art and future perspectives. *Surgical Neurology International*. 8, 11.

An *intracranial aneurysm* is an abnormal localized dilation of the wall of a cerebral artery due to congenital absence of the muscle layer of the vessel. Constant blood flow against the weakened area results in growth of the aneurysm and thinning of the vessel wall. Aneurysms usually occur at a bifurcation of an artery or major branches of the circle of Willis. They may be of congenital, traumatic, arteriosclerotic, or infectious origin. Most are saccular and asymptomatic until rupture; other types are fusiform and berry (see Figure 15-5). When an aneurysm ruptures, sudden bleeding occurs in the SAS between the arachnoid and the pia, causing SAH, which produces symptoms related to meningeal irritation. Hemorrhage can extend into the ventricular system, causing obstruction of CSF flow (hydrocephalus) or into the brain tissue (intracerebral bleed), causing further neurologic compromise. Depending on the extent of SAH, cerebral vasospasm (transient thickening of intralumen of a vessel) can occur, producing decreased cerebral blood flow, ischemia, and potential infarction or delayed cerebral ischemia (DCI). Transient thickening of the vessel is believed to be in response to the circulating blood and/or its breakdown products in the CSF. Vasospasm commonly occurs 3 to 14 days after SAH and peaks on day 5. Aneurysmal SAH account for 5% of all strokes.

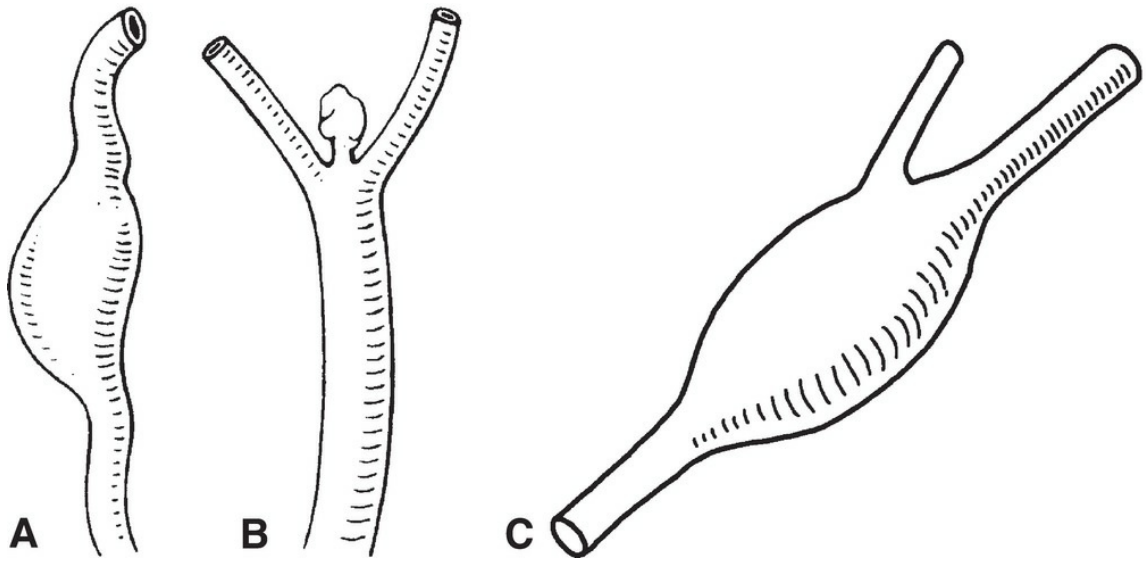

Figure 15-5. Types of aneurysms. **(A)** Saccular aneurysm; **(B)** berry aneurysm; **(C)** fusiform aneurysm.

Grading of Aneurysms

Hunt-Hess Scale is used to determine prognosis and timing of surgical or endovascular intervention.

0, Unruptured; asymptomatic discovery.

I, Asymptomatic or minimal headache with slight nuchal rigidity.

II, Moderate to severe headache, nuchal rigidity; no neurologic deficit other than CN deficit.

III, Drowsiness, confusion, or mild focal deficit (eg, hemiparesis), or combination of these findings.

IV, Stupor, moderate to severe deficit, possibly early decerebrate rigidity and vegetative disturbances.

V, Deep coma, decerebrate rigidity, moribund appearance.

Pathophysiology and Etiology

1. Etiology is believed to be multifactorial and includes structural abnormality of the cerebral vessel wall, atherosclerotic changes, hypertension, and environment. It is believed that inflammation has a role in the growth of the aneurysm.
2. Associated conditions: Polycystic disease, Ehlers-Danlos syndrome, Marfan's, Osler-Weber-Rendu syndrome, fibromuscular dysplasia, moyamoya syndrome, sickle cell anemia, collagen type III disorder, bacterial endocarditis (mycotic aneurysms), trauma (dissecting aneurysms), and familial incidence (less than 2%).
3. Risk factors for rupture
   a. Modifiable: HTN, smoking, alcohol abuse, and cocaine
   b. Nonmodifiable: sex (female), known aneurysm, size greater than 7 mm, history of previous aneurysm rupture and saccular aneurysms.
4. May become symptomatic because of pressure of enlarging aneurysm on nearby CNs or brain tissue.
5. Rupture and hemorrhage into SAS may cause increased ICP, hydrocephalus, and ischemia.
6. Vasospasm may occur within 3 to 14 days, peak day 5 days after rupture, causing ischemia (DCI) and infarction.
7. Rebleeding may occur because of lysis of clot with greatest risk for rebleeding in the first 6 to 72 hours after initial bleed (5% to 10%). Risk is greater in Hunt-Hess grades III to IV, large aneurysms, and sentinel bleed. Immediate repair of the aneurysm reduces the risk of rebleed. Seventy percent mortality after rebleed.
8. DCI is an independent variable for poor outcome.

Incidence

1. 12/100,000 incidence of aneurysms with 30,000 annual cases of SAH in the United States.
2. Age: Women 55 to 85 and men 25 to 45 and over 85.
3. 10% to 15% have multiple aneurysms.
4. Familial tendency less than 2%.

Clinical Manifestations

1. Sudden onset of severe headache, often accompanied by nausea and vomiting, but no neurologic deficits; leaking of aneurysm or AVM may cause a warning bleed.
2. Sudden, severe headache (commonly described as the "worst headache of my life"), meningeal signs (nuchal rigidity, photophobia, irritability), and neurologic dysfunction (related to vascular territory) are commonly related to SAH secondary to ruptured intracranial aneurysm, which can be catastrophic.
3. Neurologic deficit related to vascular territory (see page 372); progressive CN III, IV, VI deficits due to mass effect.
4. Sentinel bleeds—10% to 20% of patients with SAH experience an acute, sudden headache that appears days or weeks before admission for SAH. Etiology of sentinel bleed is unclear. Theories include leakage of blood from the aneurysm or expansion of the aneurysm.

Diagnostic Evaluation

1. History and physical examination.
2. CT scan—to determine presence of blood in SAS, rule out other lesions, and evaluate mass effect. Modified Fischer grade—estimates blood volume and location on CT. Assists in predicting risk for vasospasm. The Modified Fisher scale was adapted from the Fisher scale and adjusted based on clinical analysis of the occurrence of vasospasm.
   a. Grade 0: no SAH; no intraventricular hemorrhage (IVH), 0% risk of vasospasm
   b. Grade 1: focal or diffuse, thin SAH, no IVH; 24% risk of vasospasm
   c. Grade 2: thin focal (less than 1 mm) or diffuse SAH, IVH present; 33% risk of vasospasm
   d. Grade 3: thick focal (greater than 1 mm) or diffuse SAH, no IVH; 33% risk of vasospasm
   e. Grade 4: thick focal (greater than 1 mm) or diffuse SAH; 40% risk of vasospasm
3. Lumbar puncture (if no mass effect on CT)—grossly bloody CSF with more than 25,000 red blood cells (RBCs), CSF will not clear with subsequent taps as a traumatic tap would.
4. MRA or CT angiogram—noninvasive evaluation of cerebral vascular structures. Can be useful in the workup of suspected aneurysms (individuals with persistent headaches or unexplained neurologic deficits such as CN palsies). CT angiogram is the preferred study, though renal function must assessed secondary to use of contrast dye.
5. Cerebral angiogram—gold standard test; provides definitive evaluation of aneurysm etiology, presence, location, and configuration. Useful in determining the presence of vasospasm, extent of vasospasm, and collateral circulation.
6. TCD—noninvasive method to evaluate cerebral perfusion. Useful in the bedside evaluation and to provide a means for ongoing monitoring of cerebral blood flow to document changes and trends. Results are operator dependent.

Management

Unruptured

1. Evaluation of diagnostic studies is key to determine need for intervention, scheduling of elective surgical clipping, or endovascular embolization, if indicated.
2. Normalize BP if hypertensive (SBP goal 120 to 140).
3. Smoking cessation.

After Rupture

1. Intracranial aneurysm precautions to minimize the risk of rebleeding and control BP—bed rest with the head elevated, decreased environmental stimuli, avoidance of Valsalva maneuver and neck flexion, no caffeine, physical care as condition indicates.
2. Rapid repair of aneurysm should be performed by surgical clipping or endovascular embolization.
3. Management of systemic hypertension with labetalol, nicardipine, vasotec, hydralazine, or alternative IV antihypertensive agent can be used to maintain SBP less than 160 mm Hg (physician dependent), prior to definitive treatment. Debate continues on the precise SBP goal to be utilized. Close blood pressure monitoring should be maintained to prevent precipitous drop in BP.
4. Fluid goal is euvolemia. Prophylactic hypervolemia is not recommended. Fluid boluses should be considered prior to initiating vasopressor therapy. Close monitoring of intake and output (I&O), including running total I&O, and daily weights should be obtained to accurately assess fluid status. Routine use of central venous access for central venous pressure (CVP) monitoring is not recommended.
5. Neuroprotective agents.
    a. Nimodipine, a calcium channel blocker, has demonstrated reduced incidence of delayed neurologic deficits and is felt to be neuroprotective during SAH and vasospasm. The medication is administered on admission and continues for 21 consecutive days. Dosing: 60 mg orally q4h for SBP greater than 140 mm Hg and 30 mg orally q4h for SBP 120 to 140 mm Hg, or per physician orders.
        i. Nimodipine has cerebral specificity to block the influx of calcium at the intracellular space. It is the only drug approved by the FDA for treatment of vasospasm.
        ii. For optimal effect, the nimodipine should be started within 96 hours of SAH.
    b. Plasma expanders and hypervolemia to increase cerebral perfusion.
    c. The data on the neuroprotective benefits of statins, specifically simvastatin, remain controversial, though patients on statins should have the drug continued. Statins may be considered in individuals not previously on statins. Dosing: 80mg daily started within 48 hours for 14 days. Lipid panel should be performed prior to institution and a liver function panel should be obtained on day 7.
    d. Maintenance of magnesium level within normal limits. Hypomagnesium should be avoided.
6. Induced hypertension can be used in symptomatic vasospasm to prevent DCI. Colloids should be used initially with use of vasopressors as a secondary measure. Common vasopressor agents utilized are phenylephrine and norepinephrine. Fludrocortisone can be used as an oral agent to maintain SBP goal. No data exist on the specific SBP goal to be utilized. Neurologic examination should be utilized to determine specific SBP or MAP goal.

7. Management of acute obstructive hydrocephalus related to IVH by placement of ventriculostomy or EVD.
    a. Adjustment of drain to promote drainage of CSF.
    b. Intraventricular tPA-clot lysis may be used to promote CSF drainage. Current studies indicate low risk for intracranial bleeding with reduced risk for vasospasm.
    c. Surgical placement of ventricular-peritoneal shunt may be necessary.
8. Witnessed seizures: Phenytoin, fosphenytoin, or levetiracetam are the preferred medications. Duration of drug therapy is variable and levels are monitored for accurate dosing. Prophylactic use of antiepileptics is not recommended, although it may be considered. If prophylactic antiepileptics are utilized, a 3- to 7-day course or discontinuing after the aneurysm is secured is recommended.
9. Cardiopulmonary complications are common. Baseline electrocardiography should be obtained on admission. Cardiac enzymes and echocardiogram are recommended if cardiopulmonary dysfunction is suspected.
10. Maintain normal glucose level because hypoglycemia and hyperglycemia is associated with a poor outcome. Sliding scale insulin or insulin drip should be utilized to maintain blood sugar at 80 to 180. Glucose level less than 80 and greater than 200 should be avoided.
11. Maintain normothermia. Hyperthermia is associated with a poor neurologic outcome. Antipyretic agents are first-line treatment for the management of fever. External surface cooling devices or intravascular cooling devices should be employed when antipyretics are ineffective. Fever workup should be performed to evaluate for potential infectious etiology of fever.
12. DVT prophylaxis—sequential stockings and low-dose heparin or LMWH should be utilized, although remains physician-dependent. Data do not suggest any increased risk of hemorrhage in this population. Low-dose heparin or LMWH should be held prior to and after any intracranial procedure for 24 hours.

Surgical Intervention

1. Surgical obliteration of aneurysm by clipping, ligation, or IA technique.
2. Assessment of Hunt-Hess grade and medical stability assist in determining the timing of intervention, usually within 24 to 72 hours.
3. Method of treatment is determined by evaluating aneurysm size, location, neck width, condition of the patient, and associated medical conditions.
4. Surgical methods:
    a. Craniotomy is performed to access the aneurysm. Placement of titanium clips across the neck of the aneurysm or wrapping of fusiform aneurysm. Multiple-size titanium clips are available to secure aneurysm.
    b. *Advantages*: removal of intracerebral hemorrhagic/subarachnoid blood; low rate of aneurysm recurrence.
    c. *Disadvantage*: open procedure.
5. IA techniques:

a. Superselective angiography with placement of microcatheter into the aneurysm for evaluation.
b. Obliteration of the aneurysm.
    i. Multiple types of coils are available. Type and length of coil utilized are dependent on configuration of aneurysm. Coils fill the aneurysm and are detached using electronic heating. Multiple coils are placed until there is no blood flow noted on angiography to the aneurysm.
    ii. Coil embolization with aid of microstent—the microstent is used to form a bridge across the neck of the aneurysm and in fusiform aneurysms, allowing for placement of coils.
    iii. *Advantages*: minimally invasive treatment; shorter duration of anesthesia.
    iv. *Disadvantage*: potential for recurrence if aneurysm not completely occluded.
c. Interventional treatment of vasospasm.
    i. Balloon angioplasty—dilation of vessel by expansion of a transarterial balloon to treat vasospasm.
    ii. IA injection or verapamil or papaverine for temporary local vasodilation.

DRUG ALERT Heparin can be used intraprocedurally and postprocedurally, as directed, to minimize risk of thromboembolic events. Risks include thromboembolic complications and rupture of aneurysm with extension of SAH.

Complications

NURSING ALERT Mortality ranges from 20% to 50% (12% to 15% die before reaching the hospital, 25% die within 24 hours post SAH, and 45% to 50% die within 30 days). Survivors are left with a 50% chance of functional disability. Rebleed and DCI secondary to vasospasm is directly related to mortality and morbidity.

---

1. Aneurysm rebleed—risk is 4% on day 1, then 1.5% per day on days 2 to 13, 20% within 14 days, and 50% within 6 months; highest risk within first 6 hours. Seventy percent mortality in rebleed.
2. Delayed ischemic neurologic deficit occur secondary to diminished cerebral blood flow. Cerebral vasospasm and DCI are the most common cause. Greatest risk: 3 to 14 days after SAH. Current theory is that cerebral vasospasm is a reversible thickening of medial wall and smooth muscle proliferation, causing narrowing of the vessel lumen. Seventy percent to 80% of patients have radiographic vasospasm, with 30% being symptomatic or demonstrating the effects of DCI.
3. Obstructive hydrocephalus—20% to 30% of patients develop obstructive hydrocephalus. EVD placement allows for temporary CSF drainage; 18% to 26% will require placement of a ventricular-peritoneal shunt.

4. Seizures—1% to 7% at presentation. Witnessed seizures are treated with AEDs, although specific duration of treatment remains controversial. Prophylactic use of AEDs is not recommended, although it may be considered. If prophylactic AEDs are used, a 3- to 7-day course or discontinuing after the aneurysm is secured is recommended.
5. Hypernatremia related to alterations in ADH secretion or imbalance in fluid status. Close monitoring of sodium level may be indicated.
6. Hyponatremia—differentiate between SIADH and cerebral salt wasting to ensure appropriate treatment (see page 358).
7. Cardiopulmonary complications: (related to abnormal catecholamine release).
    a. Cardiovascular changes ranging from atrial fibrillation, bradycardia, and T-wave abnormalities to left ventricular dysfunction with or without myocardial failure and myocardial injury in severe cases.
    b. Neurogenic pulmonary edema.

Nursing Assessment

1. Perform and document neurologic assessment with vital signs and as patient condition warrants.
2. Monitor for changes in or decreasing LOC, CN dysfunction, pupillary abnormality, and motor deficit, which signify increased ICP, cerebral vasospasm, DCI, or expanding lesion.
3. Assess for increasing headache, which could signal rebleeding.
4. Monitor for focal neurologic deficits, which may indicate vasospasm.

Nursing Diagnoses

- Risk for Ineffective Cerebral Tissue Perfusion related to potential rebleeding, vasospasm, and IICP.
- Ineffective Tissue Perfusion (cerebral) related to disease process and vasospasm.
- Acute Pain secondary to cerebral hemorrhage, meningeal irritation, and surgical procedure.
- Anxiety of patient/family related to treatment, intracranial surgery or endovascular treatment, and uncertainty of patient outcome.

Nursing Interventions

Modifying Activity to Prevent Complications

1. Prior to treatment reduce environmental stimuli, limit stress, and decrease the risk of rebleed and/or increased ICP.
    a. Maintain complete bed rest with head elevated 30 degrees to reduce cerebral edema.
    b. Maintain quiet environment with low lighting, noise control, and limit activity to prevent photophobia, agitation, and pain.
    c. Encourage the awake patient to avoid activities that increase BP or ICP: straining, sneezing, acute flexion/rotation of the neck; assist the patient with position changes.
    d. Avoid Valsalva maneuver, which may increase ICP, by administering stool softeners to prevent straining; avoiding rectal temperatures, enemas, and suppositories; and teaching the awake patient to

exhale through mouth during defecation.

e. Avoid caffeinated beverages and extremes of temperatures.

f. Provide physical care, such as bathing and feeding, as needed.

2. Implement nursing interventions to minimize ICP and cerebral swelling (eg, elevate head of bed 30 degrees, maintain proper head and neck alignment to avoid jugular vein compression, avoid prolonged suctioning procedures, keep procedure less than 15 seconds, collaborate with physicians to use lidocaine before suctioning if intubated).
3. Medicate the patient, as ordered, during periods of extreme agitation.
4. Perform and document neurologic assessment with vital signs and as patient condition warrants, which includes monitoring LOC, CN function, pupillary function, and motor function. Insidious onset of confusion, disorientation, and decreased LOC or focal deficit associated with vascular territory associated with aneurysm bleed may indicate vasospasm (peak occurrence is 5 days after bleed, up 14 days after bleed). Speech slurring or onset of pronator drift may be first signs of deterioration.
5. Assess for signs of increased ICP, including agitation, change in LOC, bradycardia, and widening pulse pressure, and changes in respiratory pattern (Cheyne-Stokes pattern, apneustic, ataxic).
6. Monitor arterial blood gas (ABG) values for hypoxia and hypercapnia, which aggravate ICP.
7. Monitor ventriculostomy, if present, for patency, amount, and character of drainage, and correct height level every 4 hours.
8. Recognize need for maintenance of BP parameters based on status of treated versus untreated aneurysm (ie, treated, SBP 120–180 or as directed; untreated, SBP 120–160). (BP goal posttreatment remains controversial. BP goal may vary related to physician preference or be based on clinical examination.)
9. Evaluate effectiveness of antihypertensive or vasopressor therapy.
10. Perform ongoing physical assessment, including respiratory, cardiac, GI, and genitourinary (GU) function to detect potential complications.

NURSING ALERT There are no evidence-based data to support daily sampling of CSF. If CSF is cloudy or purulent, notify the health care provider. If ordered, obtain CSF samples from EVD using sterile technique and send for culture and Gram stains, white blood cell (WBC) count, RBC count, glucose, and protein analysis.

Maintaining Safety

1. Frequently monitor neurologic status based on condition, including LOC, pupillary reaction, motor and sensory function, CN function, speech, and presence of headache.
2. Administer crystalloid to maintain euvolemia.
3. Monitor BP, hemodynamic monitoring, neurologic status, and input and output status at least every hour, or as status indicates, while in the ICU.

4. Maintain safety factors based on neurologic deficits; prevent physical injury related to vision, hearing, and body awareness deficits.
5. Monitor for seizure activity and administer antiepileptic drugs (AEDs) as directed.
6. See "Nursing Management of the Patient with an Altered State of Consciousness," page 505.

Reducing Pain

1. Assess level of pain and pain relief; report any increase in headache.
2. Administer analgesics, as prescribed; if opioid is being given with sedative, monitor for CNS depression, decreased respirations, and decreased BP. Stool softeners should be given if analgesics are utilized.
3. Administer dexamethasone, as prescribed, for headache control. May be useful for headaches as a result of inflammatory changes secondary to coils.
4. Encourage distraction and relaxation techniques to promote calming effect.
5. Explain to the patient/significant other the limited use of opioids secondary to need to assess the patient's LOC at all times.
6. Encourage elevated head of bed to minimize cerebral swelling.
7. Provide cool compresses to head.
8. Assess the patient for experiences of unrelieved or increased pain; assess for any changes in neurologic signs, nuchal rigidity, photophobia, and/or changes in vision, which could signal hemorrhage, hydrocephalus, or meningeal irritation.

Reducing Anxiety

1. Provide ongoing assessment of psychosocial issues (sexuality, anxiety, fear, depression, frustration, emotional lability).
2. Be attuned to verbal and nonverbal cues from the patient/family that signal problems with coping.
3. Inform the patient regarding all treatment modalities.
4. Encourage discussion of risks/benefits with the surgeon/interventional neuroradiologist.
5. Use reassurance and therapeutic conversation to relieve fear and anxiety.
6. Provide support to the patient/family in dealing with the stress and uncertainty of hospitalization.
7. Consult social services for assistance with patient/family support to obtain copy of advance directives, including durable power of attorney, address guardianship, and long-term care decisions, as needed.
8. Prepare the patient and family for surgery or endovascular treatment.

Community and Home Care Considerations

1. Assess the level of knowledge and ability of the patient/significant other to retain information.
2. Assess ongoing home care needs.
3. Assess the need for skilled nursing or rehabilitation center placement and obtain social service referral to help with planning.
4. Provide teaching to the family and caregivers and act as liaison between health care team and family.

5. Teach the patient and family how to deal with permanent neurologic deficits, and make sure that they obtain needed supplies and services.

Patient Education and Health Maintenance

1. Instruct the patient/family on purpose and frequency of neurologic radiologic procedures.
2. Explain what an aneurysm is, signs/symptoms of rupture, and possible threats of rupture.
3. Educate the patient about activities to avoid to prevent sudden increased pressure, such as heavy lifting and straining prior to definitive treatment.
4. Encourage lifelong medical follow-up and immediate attention if severe headache develops.
5. Instruct the patient/family on need for and use of invasive monitoring and drainage systems.
6. Reinforce the need for head of bed not to be adjusted.
7. Provide educational material for procedures.
8. Set mutual goals for discharge and communicate discharge preparations with other disciplines (registered nurse, physician, physical therapist, discharge coordinator).
9. Explain medications to the patient/significant other and potential adverse effects. Explain the importance of continued nimodipine therapy and correct usage.
10. Have the patient verbalize discharge instructions regarding wound care, activity restrictions, medications, and reportable signs/symptoms.

Evaluation: Expected Outcomes

- No signs of rebleeding, increased ICP, vasospasm; vital signs and neurologic signs stable.
- Safety maintained; no seizure activity.
- Verbalizes decreased pain or control of pain to an intensity that is acceptable.
- The patient and family able to state reason for surgery/endovascular intervention, possible risks; openly discuss fears and uncertainties.

Rupture of Intracranial Arteriovenous Malformation

EVIDENCE BASE Ajiboye, N., Chalouhi, N., Starke, R. M., et al. (2014). Cerebral arteriovenous malformations: Evaluation and management. *Scientific World Journal, 2014*, Article ID 649036.

An *arteriovenous malformation (AVM)* is a system of dilated arteries and veins with dysplastic vessels. The normal capillary beds are absent, and the arterial blood flows directly into the draining veins (fistula). AVMs are congenital lesions that can enlarge over the patient's life span; these lesions are often asymptomatic until rupture. The lifetime risk of bleed in an unruptured AVM is 2% to 4% per year throughout the patient's life span, depending on size and structural configuration of the lesion.

Pathophysiology and Etiology

1. AVMs generally contain a nidus (central core) and "red" engorged veins (oxygenated veins) and have been described as a tangled mass of discolored vessels that have the appearance of a cluster of grapes.
2. The artery to venous connection, or fistula, creates increased pressure within the venous system, resulting in vascular dilation, congestion, and hypoperfusion.
3. AVMs are generally low-pressure abnormalities at birth and can progress to a high-flow, high-pressure abnormality in adulthood.
4. Parenchymal AVMs can be located in the pia matter, subcortical tissue, paraventricular region, or a combination of these regions.
5. Approximately 50% of patients with AVMs present with hemorrhage. Other signs of AVM rupture include seizures and signs of mass effect.
6. Intracerebral bleeding in a ruptured AVM tends to be superficial; cerebral vasospasm rarely occurs. The Spetzler-Martin grading system is used as a prognostic indicator as well as a tool to define risks associated with treating AVMs. Grading scale of 1 to 5: 1 = lowest risk, 5 = greatest risk for treatment (see Table 15-6).

Table 15-6 Spetzler-Martin Grading System

	POINTS
Size of Nidus	
Small	1
Medium	2
Large	3
Eloquence of Brain Tissue	
No	0
Yes	1
Deep Vascular Component	
No	0
Yes	1

Grading scale of 1 to 5: 1 = lowest risk, 5 = greatest risk for treatment.

Clinical Manifestations

1. Sudden onset of severe headache, often accompanied by nausea and vomiting, but without neurologic deficits, may be an early sign of a ruptured AVM.
2. Progressively worsening headache, as well as new onset of seizure activity due to spontaneous superficial intracerebral hemorrhage, are commonly related to a ruptured AVM.
3. May present with loss of consciousness and severe deficits if massive bleed. Focal signs or deficits are dependent on the location of the bleed and compression of adjacent brain structures (visual disturbances, CN deficits, hemiparesis, etc.).

Diagnostic Evaluation

1. History and physical examination.
2. CT scan—to determine presence of blood, rule out other lesions; increased density if blood present, may also show increased ICP or mass effect.
3. MRI and MRA or CT angiogram—noninvasive evaluation of cerebral vascular structures. Useful in the diagnosis of AVM, but does not define vascular changes and flow patterns.
4. Cerebral angiogram—gold standard test and the only diagnostic tool that provides definitive evaluation of AVM presence, location, and vascular structure. Will also evaluate flow patterns, pressure gradients, and collateral circulation and identify intranidal aneurysms and feeding vessels.

Management

Unruptured

1. Aimed at diagnostic evaluation of AVM to determine appropriate intervention—surgical, endovascular, radiosurgery, or a combination.
2. Surgical resection—dependent on location, eloquence of brain tissue, and size.
3. Endovascular management with *N*-butyl cyanoacrylate liquid polymer, polyvinyl alcohol particles, detachable coils, and balloon occlusion.

a. Staged embolization is generally performed on larger AVMs to reduce flow patterns gradually.
b. Initial embolization is aimed at protecting area at risk for rupture, reducing the nidus, or controlling the area at highest risk for bleeding.
c. Can be used as primary treatment modality or as an adjunct to surgical resection and radiosurgery.

4. Radiosurgery (gamma knife/linear accelerator)—lesions less than or equal to 2.5 to 3 cm in size. Radiation creates vessel wall injury, initiating clot formation that leads to eventual blockage of vessel (this can take 1 to 3 years to occur). During this time, the AVM remains at risk for rupture.
5. AEDs for seizures as presenting symptom—fosphenytoin, phenytoin, or levetiracetam may be given initially via IV for rapid loading. Levels should be monitored for accurate dosing.
6. Normalize BP if hypertensive.
7. Smoking cessation.

After Rupture

1. Maintenance and close monitoring of SBP within prescribed limits to prevent rebleed from hypertension and ischemia from decreased cerebral perfusion with nicardipine, labetalol, vasotec, apresoline, or alternative IV antihypertensive agents.
2. Vasopressor agents may be needed to maintain SBP within prescribed range.
3. Antiepileptics for seizures as presenting symptom—phenytoin, fosphenytoin, and levetiracetam; duration based on provider preference and location and extent of bleed.
4. Surgical intervention.
   a. Evacuation of hematoma with or without resection of AVM.
   b. Endovascular management—partial embolization of AVM, specifically area of suspected rupture.

Complications

1. Bleed or rebleed.
2. Hydrocephalus; obstructive initially requiring ventriculostomy, nonobstructive long term, may require shunt.
3. Seizures.
4. Permanent deficit or deterioration and death.

Nursing Assessment

1. Perform and document neurologic assessment with vital signs and as patient condition warrants.
2. Monitor for changes in or decreasing LOC, CN function, pupillary function, and motor function, including drift (inability to maintain unsupported position).
3. Assess for increasing headache or focal neurologic deficits, which could signal rebleeding.
4. Assess vital signs and pupillary changes frequently for development of increased ICP.

Nursing Diagnoses

- Risk for Ineffective Cerebral Tissue Perfusion related to potential rebleeding, hydrocephalus, and seizures.
- Acute Pain secondary to cerebral hemorrhage, meningeal irritation, surgical procedure.
- Anxiety of patient/family related to treatment, intracranial surgery or endovascular treatment, and uncertainty of patient outcome.

Nursing Interventions

Maintaining Cerebral Perfusion and Preventing Complications

1. Medicate the patient as ordered during periods of extreme agitation.
2. Institute seizure precautions by providing padded side rails, suction equipment, and oral airway at the bedside.
3. Perform and document neurologic assessment with vital signs and as patient condition warrants, which includes monitoring LOC, CN function, pupillary function, and motor function.
    a. Assess for signs of increased ICP, including bradycardia and widening pulse pressure, changes in respiratory pattern (Cheyne-Stokes pattern, apneustic, ataxic).
    b. Assess for subjective neurologic complaints specific to decreased perfusion (eg, diplopia, headache, blurred vision).
    c. Assess for signs and symptoms of rebleed: insidious onset of confusion, disorientation, and decreased LOC, or focal deficit associated with area of bleed.
    d. Document findings and report any changes such as drowsiness and speech slurring or onset of pronator drift, which may be first sign of deterioration.
4. Implement nursing interventions to minimize ICP and cerebral swelling (eg, elevate head of bed 30 degrees, maintain proper head and neck alignment to avoid jugular vein compression, avoid prolonged suctioning procedures, keep procedure less than 15 seconds, collaborate with physicians to use lidocaine presuctioning if intubated).
5. Monitor ABG values for hypoxia and hypercapnia, which aggravate ICP.
6. Monitor ventriculostomy, if present, to manage acute hydrocephalus, for patency, amount, and character of drainage, and correct height level every 4 hours.
    a. If CSF is cloudy or purulent or other signs of potential infection are present, contact the health care provider.
    b. Obtain CSF samples from the external ventricular device using sterile technique and send for culture and Gram stain, WBC count, glucose, and protein, as directed.
    c. Monitor results and report abnormal values.
    d. Administer prophylactic antibiotics, as ordered. Use of prophylactic antibiotics is controversial and provider dependent.
7. Recognize need for maintenance of BP parameters and evaluate effectiveness of antihypertensive or vasopressor therapy.
8. Maintain fluid volume status, evaluate electrolytes, evaluate hemoglobin and hematocrit, and monitor

input and output status at least every hour, or as status indicates

9. Maintain safety factors for neurologic deficits (eg, prevent sensory overload, physical injury related to vision, or hearing, body awareness deficits).
10. Also see "Nursing Management of the Patient with an Altered State of Consciousness," page 353.

Reducing Pain

1. Assess level of pain and pain relief; report any increase in headache.
2. Administer analgesics as prescribed; if opioid is being given with sedative, monitor for CNS depression, decreased respirations, and decreased BP.
3. Encourage distraction and relaxation techniques to promote calming effect.
4. Explain to the patient/significant other the limited use of opioids secondary to need to assess patient's LOC at all times.
5. Encourage elevated head of bed to minimize cerebral swelling.
6. Provide cool compresses to head.
7. Assess the patient for experiences of unrelieved or increased pain; assess for any changes in neurologic signs, which could signal hemorrhage, hydrocephalus, or meningeal irritation.

Reducing Anxiety

1. Provide ongoing assessment of psychosocial issues (anxiety, fear, depression, frustration, emotional lability).
2. Be attuned to verbal and nonverbal cues from the patient/family that signal problems with coping.
3. Inform the patient regarding all treatment modalities.
4. Encourage discussion of risks/benefits with the surgeon/interventional neuroradiologist.
5. Use reassurance and therapeutic conversation to relieve fear and anxiety.
6. Provide support to the patient/family in dealing with the stress and uncertainty of hospitalization.
7. Consult social services for assistance with the patient/family support and long-term care decisions, as needed.
8. Prepare the patient and family for surgery or endovascular treatment.

Community and Home Care Considerations

1. Assess level of knowledge and ability of the patient/significant other to retain information.
2. Assess ongoing home care needs.
3. Assess need for nursing home or rehabilitation center placement and obtain social service referral to help with planning.
4. Provide teaching to family and caregivers and act as liaison between health care team and family.
5. Teach the patient and family how to deal with permanent neurologic deficits and make sure that they obtain needed supplies and services.

Patient Education and Health Maintenance

1. Instruct the patient/family on purpose and frequency of neurologic/radiologic procedures.
2. Explain what an AVM is, signs/symptoms of rupture, and possible threats of rupture.
3. Educate the patient to the risk of rebleed, which is 50% within 6 months if untreated, and remains for rest of life if not definitively treated.
4. Encourage lifelong medical follow-up and immediate attention if severe headache develops.
5. Explain the need for follow-up angiograms to verify complete eradication of AVM or to define extent of eradication to facilitate treatment planning.
6. Provide educational material for procedures.
7. Set mutual goals for discharge, and communicate discharge preparations with other disciplines (registered nurse, physician, physical therapist, discharge coordinator).
8. Explain medications to the patient/significant other and potential adverse effects.
9. Have patient verbalize discharge instructions regarding wound care, activity restrictions, medications, and reportable signs/symptoms.

Evaluation: Expected Outcomes

- No signs of rebleeding, increased ICP, decreased cerebral perfusion, or seizures; vital signs stable; neurologic parameters stable.
- Verbalizes decreased pain or control of pain to an intensity that is acceptable.
- Decrease in anxiety sufficient to allow the completion of necessary procedures and to promote recovery.

INFECTIOUS DISORDERS

Meningitis

Meningitis is an inflammation of the pia mater and arachnoid membranes that surround the brain and the spinal cord. The subarachnoid space between these two meninges contains CSF that may reflect the signs and symptoms of meningitis.

Pathophysiology and Etiology

1. Viral meningitis is the most common form. More than 10,000 cases are reported annually, but the actual incidence may be as high as 75,000. It is usually self-limiting; management is supportive. It is usually caused by a nonpolio enterovirus (90%). The incidence of viral meningitis drops with age. As a general rule, the younger the patient, the greater the risk of viral meningitis. This organism is spread by the fecal–oral route and through sewage.
2. In the United States, the incidence of acute, bacterial meningitis is approximately three cases per 100,000 per year. The mortality is 10% to 30% and many who recover are left with long-term problems (eg, hearing deficit).
3. Bacterial meningitis may cause damage to the CNS from the inflammatory process rather than the pathogen. The organisms causing these infections seem to vary depending on the age and immune status of the patient. Bacterial meningitis is usually more serious than viral meningitis. It is typically caused by *Streptococcus pneumoniae* (pneumococcal meningitis), which is a gram-positive diplococcus, and *Neisseria meningitidis* (meningococcal meningitis), which is a gram-negative diplococcus.
    a. Most bacteria that cause meningitis begin by colonizing the nasopharynx and then invade the circulation and CSF, causing an inflammatory response mediated by cytokines.
    b. Bacterial meningitis can result in brain damage due to chemicals released by bacteria that kill or damage neurons, purulent exudates that may result in vasculitis and vasospasm, and increased ICP that causes cerebral edema.
4. Fungal meningitis, particularly *Cryptococcus neoformans*, affects immunosuppressed patients (eg, human immunodeficiency virus [HIV]–positive) through soil contaminated with excrement from pigeons and chickens. Cryptococcal antigen, or culture, is found in the CSF, but meningeal signs may be minimal. In HIV-positive patients, tuberculous meningitis, tuberculomas, and atypical mycobacterial infections of the brain may be noted.
5. Parasitic meningitis is usually cause by flukes, worms, or amoeba.
6. Hospital-acquired postcraniotomy meningitis, caused predominantly by gram-negative bacilli, can result in mortalities of 30%; multiple craniotomy operations place the patient at even higher risk. It develops approximately 7 to 8 days postoperatively.
7. Neoplastic meningitis affects approximately 3% to 8% of patients who have systemic cancers. The mean survival time is approximately 5 to 8 months. In neoplastic meningitis, malignant cells infiltrate the leptomeninges as a complication of breast cancer, lung cancer, malignant melanoma, non-Hodgkin lymphoma, and acute leukemia.
8. Meningitis is the primary intracranial complication of acute and chronic sinusitis (sphenoid sinusitis

most common). *S. pneumonia* and *Staphylococcus aureus* are the most common organisms.

9. *Listeria monocytogenes*, a gram-positive bacilli, may cause meningitis through contaminated hot dogs, cold meats, and unpasteurized dairy products.
10. The incidence of *Haemophilus influenzae* meningitis has decreased because of the haemophilus b conjugate vaccine.

Clinical Manifestations

1. Classic symptoms are fever, headache, and nuchal rigidity. Constitutional symptoms of vomiting, diarrhea, cough, and myalgias appear in more than 50% of patients. History of temperature elevation occurs in 76% to 100% of patients who seek medical attention. A common pattern is low-grade fever in the prodromal stage and higher temperature elevations at the onset of neurologic signs.
2. Altered mental status; confusion in older patients.
3. Petechial (appears like "rug" burn) or purpuric rash from coagulopathy, especially with *N. meningitidis*.
4. Photophobia.
5. Neck tenderness or a bulging anterior fontanel in infants.
6. Children may exhibit behavioral changes, arching of the back and neck, a blank stare, refusal to feed, and seizures. Viral meningitis can cause a red, maculopapular rash in children.
7. Positive Brudzinski and Kernig signs (see Figure 15-6).
8. Neonates may exhibit poor feeding, altered breathing patterns, or listlessness.
9. Onset may be over several hours or several days depending on the infectious agent, the patient's age, immune status, comorbidities, and other variables. Some viruses cause rapid onset of symptoms, whereas others may involve prodromal nonspecific flulike symptoms, such as malaise, myalgia, and upper respiratory symptoms. In many cases, symptoms have a biphasic pattern; the nonspecific flulike symptoms and low-grade fever precede neurologic symptoms by approximately 48 hours. With the onset of neck stiffness and headache, the fever usually returns.

KEY DECISION POINT If the patient presents with meningitis-like symptoms and appears very ill, evaluation and treatment for bacterial meningitis must be urgently initiated. Patients with bacterial meningitis are typically sicker than patients with a viral etiology, with high fever, severe headache +/- photophobia, and mental status changes. Blood and CSF cultures should be taken as soon as possible as the goal of treatment is to administer appropriate IV antibiotics within 30 minutes of presentation.

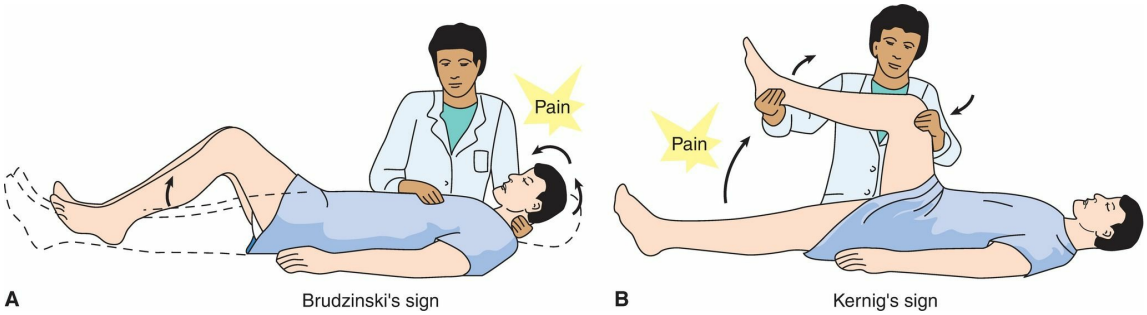

Figure 15-6. Signs of meningeal irritation include nuchal rigidity and positive Brudzinski and Kernig signs. **(A)** To elicit Brudzinski sign, place the patient supine and flex the head upward. Resulting flexion of both hips, knees, and ankles with neck flexion indicates meningeal irritation. **(B)** To test for Kernig sign, once again place the patient supine. Keeping the bottom leg straight, flex the other hip and knee to form a 90-degree angle. Slowly extend the upper leg. This places a stretch on the meninges, resulting in pain and spasm of the hamstring muscle. Resistance to further extension can be felt.

Diagnostic Evaluation

1. Complete blood count (CBC) with differential is indicated to detect an elevated leukocyte count in bacterial and viral meningitis, with a greater percentage of polymorphonuclear leukocytes (90%) in bacterial and (less than 50%) in viral meningitis (normal 0% to 15%).
2. Blood cultures are obtained to indicate the organism.
3. CSF evaluation for pressure, leukocytes, protein, glucose—CSF normally has five or fewer lymphocytes or mononuclear cells/mm^3.
   a. In acute bacterial meningitis, the CSF may indicate elevated pressure, elevated leukocytes (several thousand), elevated protein, and low glucose. A culture and smear will identify the organism. WBC differential should be done by a stained smear of sediment.
   b. In viral encephalitis, the CSF may indicate normal/moderately elevated pressure, few/elevated leukocytes (fewer than 1,000), normal or slightly elevated protein, and normal glucose.
4. MRI/CT with and without contrast rules out other disorders. A CT scan with contrast must be obtained to detect abscesses.
5. Latex agglutination may be positive for antigens in meningitis.
6. Low CD4+ counts indicate immunosuppression in HIV-positive patients and other patients with immunosuppressive disorders.
7. In patients with acquired immunodeficiency syndrome (AIDS), MRI is used to detect meningeal irritation, evidence of a sinus infection, or brain abscess.

Management

1. The assessment and management of meningitis should be approached through a team effort with nursing, infectious disease and otolaryngology specialists, neurology, internal medicine, and laboratory

and diagnostic staff. Droplet precautions are warranted for suspected *N. meningitidis* and *H. influenzae* meningitis.

2. Most patients are given IV antibiotics as soon as possible until the laboratory findings determine the type of meningitis (eg, viral, bacterial). However, cultures should be taken before initiating antibiotics.
3. To manage inflammation, dexamethasone or another corticosteroid is given via IV line.
   a. This may result in GI bleeding and mask clinical responses to treatments (eg, resolved fever).
   b. This steroid should be used before or with the first dose of antibiotics (IV 0.6 mg/kg/day in four divided doses for the first 4 days of antibiotics) and should be confined to patients older than age 6 weeks.
   c. Plasmapheresis may be used experimentally to remove cytokines in some cases.
4. Temozolomide, a second-generation alkylating agent, is effective against many cancers that result in neoplastic meningitis. External beam radiation may be used in conjunction with chemotherapy (eg, intrathecal thiotepa or methotrexate).
5. Cochlear implantation rehabilitation due to deafness caused by meningitis should be considered. Realistic goals must be set because the patient may develop only environmental sound awareness and still have to deal with learning disabilities.
6. If meningitis is suspected after neurosurgical procedures, consider potential IV line bacteremia, CSF leak, or immunosuppression.
7. Antifungal agents, such as amphotericin B and the triazoles, fluconazole, and itraconazole, are indicated for cryptococcal meningitis. Relapse is common if the patient does not have chronic suppressive therapy with fluconazole or another antifungal agent.
8. Empiric antituberculosis drugs must be initiated if infection by *Mycobacterium tuberculosis* is suspected.

NURSING ALERT Be aware that bacterial resistance to antibiotics has been increasing, making meningitis very difficult to treat in some instances.

Complications

1. Bacterial meningitis, particularly in children, may result in deafness, learning difficulties, spasticity, paresis, or CN disorders.
2. Increased ICP in AIDS patients with cryptococcal meningitis can result in severe visual losses.
3. Seizures occur in 20% to 30% of patients.
4. Increased ICP may result in cerebral edema, decreased perfusion, and tissue damage.
5. Severe brain edema may result in herniation or compression of the brain stem.
6. Purpura may be associated with disseminated intravascular coagulation.

Nursing Assessment

1. Obtain a history of recent infections such as upper respiratory infection and exposure to causative agents. Meticulous history taking is essential and must include evaluation of exposure to ill contacts, mosquitoes, ticks, and outdoor activities in areas of endemic Lyme disease, travel history with possible exposure to tuberculosis, as well as history of medication use, IV drug use, and sexually transmitted disease risk. Another important part of history is prior antibiotic use, which may alter the clinical picture of bacterial meningitis.
2. Assess neurologic status and vital signs.
3. Evaluate for signs of meningeal irritation.
4. Assess sensorineural hearing loss (vision and hearing), CN damage (eg, facial nerve palsy), and diminished cognitive function.

Nursing Diagnoses

- Hyperthermia related to the infectious process and cerebral edema.
- Risk for Imbalanced Fluid Volume related to fever and decreased intake.
- Ineffective Cerebral Tissue Perfusion related to infectious process and cerebral edema.
- Acute Pain related to meningeal irritation.
- Impaired Physical Mobility related to prolonged bed rest.

Nursing Interventions

Reducing Fever

1. Administer antimicrobial agents on time to maintain optimal blood levels.
2. Monitor temperature frequently or continuously and administer antipyretics, as ordered.
3. Institute other cooling measures, such as a hypothermia blanket, as indicated.

Maintaining Fluid Balance

1. Prevent IV fluid overload, which may worsen cerebral edema.
2. Monitor intake and output closely.
3. Monitor CVP frequently.

Enhancing Cerebral Perfusion

1. Assess LOC, vital signs, and neurologic parameters frequently. Observe for signs and symptoms of increased ICP (eg, decreased LOC, dilated pupils, widening pulse pressure).
2. Maintain a quiet, calm environment to prevent agitation, which may cause an increased ICP.
3. Prepare the patient for a lumbar puncture for CSF evaluation and repeat spinal tap, if indicated. Evaluate the patient for ICP prior to lumbar puncture.
4. Notify the health care provider of signs of deterioration: increasing temperature, decreasing LOC, seizure activity, or altered respirations.

Reducing Pain

1. Administer analgesics, as ordered; monitor for response and adverse reactions. Avoid opioids, which may mask a decrease in LOC.
2. Darken the room if photophobia is present.
3. Assist with position of comfort for neck stiffness, and turn the patient slowly and carefully with head and neck in alignment.
4. Elevate the head of the bed to decrease ICP and reduce pain.

Promoting Mobility

1. Frequently turn and reposition the patient to prevent skin breakdown.
2. Progress from passive to active exercises based on the patient's neurologic status.
3. Suggest early physical and occupational therapy referrals to promote return to optimal level of functioning.

DRUG ALERT Note and report any missed doses of antibiotics, osmotic diuretics, and steroids; administer necessary doses as soon as possible to avert deleterious consequences due to missed doses.

Community and Home Care Considerations

1. Prevent bacterial meningitis by eliminating colonization and infection with the offending organism.
   a. Administer vaccines against *H. influenzae* type B for children; *N. meningitidis* serogroups A, C, Y, and W135 for patients at high risk (especially college students, those without spleens, those who are immunodeficient); and *S. pneumoniae* for patients with chronic illnesses and older adults.
   b. Administer vaccines for travelers to countries with a high incidence of meningococcal disease and household contacts of someone who has had meningitis.
   c. Chemoprophylaxis for meningococcal disease, most commonly with rifampin, may be necessary for health care workers, household contacts in the community, day care centers, and other highly susceptible populations.
2. If maintenance antifungal prophylaxis is initiated for patients with low CD4+ counts, as seen in some patients with AIDS, the patient must understand the importance of long-term pharmacologic therapy.

Patient Education and Health Maintenance

1. Advise close contacts of the patient with meningitis that prophylactic treatment may be indicated; they should check with their health care providers or the local public health department.
2. Encourage the patient to follow medication regimen as directed to eradicate the infectious agent completely.
3. Encourage follow-up and prompt attention to infections in future.
4. Direct the patient and family to the Centers for Disease Control and Prevention.

(*www.cdc.gov/meningitis/index.html*) for support and additional information.

Evaluation: Expected Outcomes

- Afebrile.
- Adequate urine output; CVP in normal range.
- Alert LOC; normal vital signs.
- Pain controlled.
- Optimal level of functioning after resolution.

Encephalitis

Encephalitis is an inflammation of cerebral tissue, typically accompanied by meningeal inflammation. Meningoencephalitis is most commonly caused by a viral infection. Like meningitis, encephalitis can be infectious or noninfectious and acute, subacute, or chronic.

Pathophysiology and Etiology

1. In primary encephalitis, the brain or spinal cord is the predominant foci of the toxin or pathogen. Secondary encephalitis is a less serious form of encephalitis; it is caused by an infection that is spread from another part of the body.
2. Acute viral encephalitis, accounting for the vast majority of cases, is caused by a direct infection of the gray matter containing neural cells. It results in perivascular inflammation and neuronal destruction. It is more common in children and is most commonly caused by the herpes simplex virus and, to a lesser degree, by the arboviruses.
3. Brain stem encephalitis targets the basal ganglia or CNS.
4. Postischemic inflammatory encephalitis occurs because of brain inflammation following a CVA. In patients with cerebral ischemia, inflammation can result in secondary brain injury and microvascular occlusion can be caused by activated leukocytes or a microvascular thrombus. This edema can result in increased ICP and compromised cerebral perfusion.
5. West Nile virus (WNV) is an arthropod virus (arbovirus). The mosquito is the primary vector and birds are the primary hosts. Mortality can be as high as 30%.
6. *Herpes simplex encephalitis* may result from reactivation of the virus that has been dormant in the cranial and other ganglia or to reinfection. Direct spread to the brain by the olfactory or trigeminal nerve is suspected with herpes simplex virus type 1, which is responsible for almost all cases of herpes simplex encephalitis in children and adults. Mortality is as high as 75%. Herpes simplex type 2 is more common in neonates who are born to mothers with this infection during pregnancy.
7. Herpes zoster virus (varicella) is a rare cause of encephalitis.
8. Postinfectious encephalomyelitis follows a viral or bacterial infection process, but organisms do not directly affect the neural tissue in the white matter; however, perivascular inflammation and demyelination do occur in the cerebral tissue.
    a. The incidence of postinfectious encephalomyelitis has decreased considerably with immunization against measles, mumps, and rubella and because of the eradication of smallpox. It is rare in infancy.
    b. The most common cause is respiratory or GI infection 1 to 3 weeks before the acute onset of encephalomyelitis symptoms.
    c. May be caused by specific species of mosquitoes and ticks (arthropods), which may be seasonal and geographic hosts (eg, California encephalitis, St. Louis equine encephalitis).
9. *Cytomegalovirus encephalitis* should be considered in patients who have advanced HIV infection, have evidence of the cytomegalovirus in other sites, and have progressive neurologic deterioration.

10. *Toxoplasma* encephalitis is also common in patients with AIDS.

Clinical Manifestations

1. Signs and symptoms may develop hours or weeks after exposure.
2. Classic symptoms include fever, headache, and altered mental status (eg, disorientation, neurologic deficits, seizures).
3. Increased ICP may result in alteration in consciousness, nausea, and vomiting.
4. Motor weakness, such as hemiparesis, may be detected.
5. Increased deep tendon reflexes and extensor plantar response are noted.
6. Bizarre behavior and personality changes may present at onset.
7. Hypothalamic–pituitary involvement may result in hypothermia, diabetes insipidus, SIADH (see page 358).
8. Neurologic symptoms may include superior quadrant visual field defects, aphasia, dysphagia, ataxia, and paresthesias.
9. The patient with brain stem encephalitis may present with nystagmus, decreased extraocular movements, hearing loss, dysphagia, dysarthria, respiratory abnormalities, and motor involvement.
10. Limbic encephalitis may cause mood and personality changes that progress to severe memory loss and delirium.
11. In WNV, about two thirds of symptomatic patients have encephalitis with signs and symptoms of fever, vomiting, headache, nuchal rigidity, decreased LOC, CN dysfunction, and an erythematous rash. Seizures are uncommon.

Diagnostic Evaluation

1. Lumbar puncture, with evaluation of CSF, is performed to detect leukocytosis, increased mononuclear cell pleocytosis, increased proteins, and normal or slightly lowered glucose.
2. Polymerase chain reaction analysis of the virus deoxyribonucleic acid (DNA) and the detection of intrathecally produced viral antibodies are essential in diagnosing the specific virus (eg, herpes simplex virus, cytomegalovirus). Arbovirus-specific immunoglobulin (Ig)M in CSF and a fourfold change in specific IgG antibody are diagnostic for arboviral encephalitis.
3. EEG may demonstrate slow brain wave complexes in encephalitis.
4. Gadolinium-enhanced MRI differentiates postinfectious encephalomyelitis from acute viral encephalitis.
    a. Enhanced multifocal white matter lesions are seen in encephalomyelitis, which may remain for months after clinical recovery.
    b. Herpes simplex virus encephalitis typically causes medial–temporal and orbital–frontal lobe inflammation and necrosis; low-density abnormalities may be present in the temporal lobes. An MRI is preferred over a CT scan.
    c. Cytomegalovirus, seen in patients who have advanced HIV disease, may have enhanced periventricular areas.

5. Brain tissue biopsy indicates presence of infectious organisms.
6. WNV can have pleocytosis and may be seen on an MRI with enhancement of the meninges and periventricular areas. The enzyme-linked immunosorbent assay, WNV ELISA, can be done from blood or CSF; a cell culture can also be diagnostic.

Management

1. Differentiate acute viral encephalitis from noninfectious diseases, such as sarcoidosis, vasculitis, systemic lupus erythematosus, and others.
2. In patients who are immunosuppressed, such as HIV-positive patients, differentiate acute viral encephalitis from cytomegalovirus encephalitis, toxoplasmic encephalitis, and fungal infections.
   a. Patients with cytomegalovirus may be treated with ganciclovir and foscarnet, commonly used to treat cytomegalovirus retinitis in HIV-positive patients.
   b. Pyrimethamine and sulfadoxine are commonly used to treat *Toxoplasma* encephalitis.
   c. When encephalomyelitis develops, supportive care is indicated because there is no known treatment; corticosteroids may be used.
3. IV acyclovir over 10 to 21 days is indicated for herpes simplex virus. Mothers who have genital herpes simplex may be treated with acyclovir during the third trimester to avoid shedding the virus to their babies.
4. Anticonvulsants are used to manage seizures.

DRUG ALERT Acyclovir, indicated for acute viral encephalitis caused by herpes simplex type 1, inhibits replication of the virus DNA. Acyclovir should be infused over 1 hour because crystalluria and renal failure may result if administration is too rapid.

Complications

1. Sequelae of the herpes simplex virus may cause temporal lobe swelling, which can result in compression of the brain stem. This virus may also cause aphasia, major motor and sensory deficits, and Korsakoff psychosis (amnestic syndrome).
2. Relapse of encephalitis may be seen after initial improvement and completion of antiviral therapy.
3. Mortality and morbidity depend on the infectious agent, host status, and other considerations.

Nursing Assessment

1. Obtain patient history of recent infection, animal exposure, tick or mosquito bite, recent travel, and exposure to ill contacts.
2. Perform a complete physical assessment.
3. Before delivery, women should be questioned regarding a history of congenital herpes simplex virus and

examined for evidence of this virus; a cesarean delivery should be explored with the physician.

4. Vesicular lesions or rashes on neonates should be reported immediately because these could indicate active herpes simplex type 2 infection.

NURSING ALERT Although most cases of viral encephalitis only require universal precautions to prevent infection, patients that present with open lesions to the skin, as occurs in herpes simplex or herpes zoster, should have contact isolation procedures implemented.

Nursing Diagnoses

- Risk for Injury related to seizures and cerebral edema.
- Ineffective Cerebral Tissue Perfusion related to disease process.
- Hyperthermia related to infectious process.
- Impaired Environmental Interpretation Syndrome related to disease process.

Nursing Interventions

Preventing Injury

1. Maintain a quiet environment and provide care gently, avoiding overactivity and agitation, which may cause increased ICP.
2. Maintain seizure precautions with side rails padded, airway, and suction equipment at bedside.
3. Administer medications, as ordered; monitor response and adverse reactions.

Promoting Cerebral Perfusion

1. Monitor neurologic status closely. Observe for subtle changes, such as behavior or personality changes, weakness, or CN involvement, and notify the health care provider.
2. In arbovirus encephalitis, restrict fluids as directed to passively dehydrate the brain.
3. Reorient the patient frequently.
4. Provide supportive care if coma develops; may last several weeks.
5. Encourage significant others to interact with the patient and participate in the patient's rehabilitation, even while the patient is in a coma.

Relieving Fever

1. Monitor temperature and vital signs frequently.
2. Administer antipyretics and other cooling measures, as indicated.
3. Monitor fluid intake and output and provide fluid replacement through IV lines as needed. Be alert to signs of other coexisting infections, such as urinary tract infection or pneumonia, and notify health care provider so cultures can be obtained and treatment started.

4. Maintain standard precautions to prevent transmission of infection, and contact precautions may be indicated if skin lesions are present.

Managing Safe Behavior in the Environment

1. Frequently orient to person, place, time, and purpose.
2. Provide simple instructions and frequent cues to perform required activities.
3. Maintain consistency in care and avoid overstimulation.
4. Maintain constant surveillance and safety precautions.

Community and Home Care Considerations

1. Promote vaccination of patient, family, and significant others for measles, mumps, and rubella.
2. Pregnant women who have a history of genital herpes simplex, or their partners, should inform their physician of this history.
3. Contacts of rabies-infected patients should be offered rabies prophylaxis.
4. Direct the patient and family to the Encephalitis Society (*www.encephalitis.info*) for support and additional information.

Patient Education and Health Maintenance

1. Explain the effects of the disease process and the rationale for care.
2. Reassure significant others based on patient's prognosis.
3. Encourage follow-up for evaluation of deficits and rehabilitation progress.
4. Educate others about the signs and symptoms of encephalitis if epidemic is suspected.
5. To prevent WNV, advise the use of repellants when outdoors and removal of standing water that acts as a breeding ground for mosquitoes.

Evaluation: Expected Outcomes

- No seizures or signs of increased ICP.
- Alert with no neurologic deficits.
- Afebrile.
- Participating safely in ADL

Brain and Spinal Abscesses

A *brain abscess* is a free or encapsulated collection of infectious material of brain parenchyma, between the dura and the arachnoid linings (subdural abscess) or between the dura and the skull (epidural abscess). Spinal abscesses typically occur in the epidural region.

Pathophysiology and Etiology

1. Intracranial subdural abscesses, usually due to a streptococcus organism, are caused by purulent drainage between the dura and arachnoid. It can result from pus from the meninges, middle ear or mastoid, sinuses, septicemia, or skull fracture. It occurs most frequently in children and young adults.
2. Intracranial epidural abscesses, typically involving an infection of the cranium, commonly occur because of chronic mastoiditis or sinusitis, head trauma, or craniotomy. Abscesses may be related to a subdural empyema (collection of purulent drainage originating from nasal sinuses, meninges, middle ear, or skull osteomyelitis), meningitis, or intraparenchymal abscess.
3. Spinal epidural abscesses occur in the spinal canal external to the dura. Epidural penetration may seed through the blood and occur from infected adjacent tissue (eg, infected pressure ulcer), from another infected site (eg, skin), or contamination from spinal surgery or spinal instrumentation (eg, lumbar puncture). *S. aureus* is a frequent causative agent and the midthoracic vertebrae are most commonly affected.
4. Intramedullary abscesses are more common in the pediatric population and are associated with lumbosacral dermal sinuses. Approximately 20% to 30% are "cryptic" abscesses with no apparent source of infectious seeding.
5. In the initial inoculation period, organisms invade the brain parenchyma, resulting in local inflammation and edema. The resulting cerebritis develops into a necrotic lesion and then becomes encapsulated.
6. Fungal brain abscesses are commonly seen in HIV-positive patients and other populations that are immunosuppressed. Diffuse microabscesses may occur with infections caused by *Candida* species.
7. *M. tuberculosis* may cause abscesses of pus containing acid-fast bacilli (AFB) surrounded by a dense capsule. These abscesses are also found in patients who are HIV positive or have other immunosuppressive diseases.

Clinical Manifestations

1. Headache is poorly localized with a dull ache.
2. Increased ICP may result in nausea, vomiting, and decreased LOC.
3. Fever is found in less than 50% of cases.
4. Neurologic findings, such as hemisensory and paresis deficits, aphasia, and ataxia, may be present.
5. Seizures are frequently present.
6. Dental abscess, sinusitis, and otitis media may be present.
7. Signs and symptoms of a cerebral subdural empyema include severe headache, fever, nuchal rigidity, and signs of meningeal irritation (Kernig and Brudzinski sign; see page 380).

8. Patients with intracranial epidural abscess commonly present with fever, lethargy, and severe headache.
9. Spinal epidural abscesses may be evidenced by severe back pain, fever, headache, lower-extremity weakness or paralysis, nuchal rigidity, Kernig sign, and local tenderness.

Diagnostic Evaluation

1. CT scan and MRI with contrast locate the sites of abscess and follow evolution and resolution of the suppurative process.
   a. In the inflammatory stage of cerebritis, imaging reveals high signal intensity centrally (inflammation) and peripherally (edema). When an abscess develops, the capsule becomes isointense.
   b. There may be decreased ring enhancement with patients who are immunosuppressed, which may be due to a lack of inflammatory response.
   c. Microabscesses may not be detected by the CT scan or MRI.
   d. MRI with gadolinium enhancement should be considered to detect spinal epidural abscesses.
2. Blood cultures are obtained to identify the organism; positive Gram stain, leukocytosis, and elevated erythrocyte sedimentation rate (ESR) will be found.
3. Cultures are obtained from the suspected source of infection, using stereotaxic needle aspiration or brain surgery, to identify the organism and sensitivity to antimicrobials.
4. A metastatic brain abscess may be differentiated from a metastatic tumor by CT scan or MRI. Abscesses have hypodense centers with a smooth surrounding capsule, whereas tumors may have irregular borders and diffuse enhancement.
5. EEG detects seizure disorders.
6. Findings in cerebral subdural empyema include increased WBC count and increased pressure of the CSF.
7. In intracranial epidural abscesses, CT or MRI scans are useful; MRIs are usually more sensitive. Findings from the CSF may not be definitive. To avoid transtentorial herniation, lumbar puncture is not indicated until large cranial masses are ruled out.
8. Diagnostic findings in spinal epidural abscesses may include increased WBC count and ESR. The CSF may be cloudy.

Management

1. With cerebral subdural empyema or intracranial epidural abscesses, management consists of trephining (drilling through skull to evacuate purulent material), systemic antibiotics, and treatment of cerebral edema.
2. Closed stereotaxic needle biopsy, under CT guidance, may be used for drainage evacuation instead of craniotomy.
3. Spinal epidural abscesses may be managed with a laminectomy and surgical drainage, with antibiotics before and after the procedure. The abscess site is thoroughly irrigated with antibiotic solution and aerobic and anaerobic cultures are taken.

4. Radical surgical debridement, especially with fungal infections, may be indicated with antimicrobial therapy.
5. Initiation of empiric antimicrobial therapy is based on Gram stain and the suspected site of origin. Because brain abscesses are frequently caused by multiple organisms, antimicrobial therapy is directed toward the most common etiologic agents: streptococci, anaerobic bacteria (eg, *Bacteroides* species).
   a. *S. aureus* may be suspected if surgical procedures have been performed.
   b. Gram-negative bacteria (eg, *Clostridium* species) should be suspected if a cranial wound has been contaminated with soil.
   c. A 6- to 8-week course of parenteral antibiotics is typical, followed by a 2- to 3-month course of oral antimicrobial therapy.
   d. Penicillin G, metronidazole, and third-generation cephalosporins are common therapeutic agents.
6. Antifungal therapy, such as amphotericin B, is initiated for candidiasis and other fungal infections.
7. Antituberculosis pharmacotherapy, such as rifampin, isoniazid, and pyrazinamide, should be used to treat abscesses containing AFB.
8. Adjunctive therapy includes corticosteroids and osmotic diuretics to reduce cerebral edema and anticonvulsants to manage seizures.

NURSING ALERT If a subdural drain is used to provide continuous drainage of the abscess, the patient should be placed in a supine position to prevent rapid fluid shifts into the drainage device.

Complications

1. The brain abscess can rupture into the ventricular space, causing a sudden increase in the severity of the patient's headache. This complication is often fatal.
2. Papilledema may occur in less than 25% of cases, indicating intracranial hypertension.
3. Lumbar puncture may be contraindicated if there is a spinal epidural abscess because pus may be transferred into the subarachnoid space.
4. Permanent neurologic deficits, such as seizure disorders, visual defects, hemiparesis, and CN palsies, may be present.
5. There is greater mortality if the patient has acute onset of symptoms with severe mental status changes and has rapid progression of neurologic impairment.
6. Delayed treatment of a spinal epidural abscess may result in transection syndrome, in which flaccid paraplegia with sensory loss occurs at the level of the abscess.
7. In chronic otitis media, intracranial and intratemporal complications frequently result from progressive bony erosion, which may expose the dura, labyrinth, and facial nerves.

Nursing Assessment

1. Obtain history of previous infection, immunosuppression, headache, and related symptoms.
2. Perform neurologic assessment, including CN evaluation, motor, and cognitive status.

Nursing Diagnoses

- Acute Pain related to cerebral mass.
- Impaired Environmental Interpretation Syndrome related to disease process.
- Risk for Injury related to neurologic deficits.
- Anxiety related to surgery, prognosis, and relapse.

Nursing Interventions

Relieving Pain

1. Administer pain medications, as ordered.
2. Provide comfort measures, such as quiet environment, positioning with head slightly elevated, and assistance with hygiene needs.
3. Provide passive relaxation techniques, such as soft music and back rubs.

Promoting Thought Processes

1. Frequently monitor vital signs, LOC, orientation, and seizure activity.
2. Report acute changes, which can signal increased ICP, to health care provider.
3. Administer medications, as ordered, noting response and adverse reactions.
4. Prepare the patient for repeated diagnostic tests to evaluate response to therapy and surgery.

Minimizing Neurologic Deficits

1. Maintain a safe environment with side rails up, call light within reach, and frequent observation.
2. Evaluate other CN function and report changes.
3. Refer to occupational therapist, speech therapist, or other rehabilitation specialist to provide adjunct to nursing rehabilitation.

Reducing Anxiety

1. Prepare the patient and family for surgery when indicated. Encourage discussion with surgeon to understand risks and benefits of the procedure.
2. Explain postoperative progression and nursing care (see page 361).

Community and Home Care Considerations

1. Patient follow-up is essential for sinusitis, otitis media, respiratory infections, and other infectious processes that may result in a brain abscess.
2. Continue with rehabilitation to regain or compensate for neurologic deficits.
3. Continue with pharmacologic regimen in community setting.

4. Observe for recurrence of brain and spinal abscesses.

Patient Education and Health Maintenance

1. Maintain wellness with vaccinations, immunizations, and overall health.
2. Reinforce need for dental procedure prophylaxis to avoid dental abscesses.
3. Instruct on need for immediate assessment of head wounds.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Oriented to person, place, and time; follows simple commands.
- No injury related to neurologic deficits.
- Reduced anxiety regarding disease process and procedures.

DEGENERATIVE DISORDERS

Parkinson Disease

Parkinson disease is a chronic, progressive neurologic disease affecting the brain centers responsible for control and regulation of movement. It is characterized by tremor, bradykinesia, rigidity, and postural abnormalities. Parkinson can complicate the diagnosis, clinical course, and recovery from other illness. Approximately 1% of the total US population older than age 60 is affected by idiopathic Parkinson disease, and it less commonly affects people of younger ages. It is the second most common neurodegenerative disease.

Pathophysiology and Etiology

1. A deficiency of dopamine, due to degenerative changes in the substantia nigra of the brain, is thought to be responsible for the symptoms of Parkinson disease.
2. Underlying etiology may be related to a virus; genetic susceptibility; toxicity from pesticides, herbicides, methyl-phenyl-tetrahydropyridine, or welding fumes; repeated head injuries; or other unknown cause.
3. The clinical diagnosis of Parkinson disease may be difficult because older patients may have other causes of rigidity, bradykinesia, and tremor.

Clinical Manifestations

1. Bradykinesia (slowness of movement), loss of spontaneous movement, and delay in initiating movements.
2. Resting ("pill-rolling") tremor of 4 to 5 Hz. The tremor may be worse on one side of the body, affecting the limbs and sometimes involving the head, neck, face, and jaw.
3. Rigidity in performance of all movements. Rigidity is always present but increases during movement. May lead to sensations of pain, especially in the arms and shoulders.
4. Poor balance when moving abruptly or suddenly changing body position. May lead to falls.
5. Autonomic disorders—sleeplessness, salivation, sweating, orthostatic hypotension, dizziness.
6. Depression, dementia.
7. Masklike facies secondary to rigidity.
8. Gait difficulties characterized by a decreased or nonexistent arm swing; short, shuffling steps (festination); difficulty in negotiating turns; and sudden freezing spells (inability to take the next step).
9. Verbal fluency may be impaired.
10. Finger-tapping responses are slowed.
11. Micrographia (change in handwriting, with the script becoming smaller).
12. Problems with speech, breathing, swallowing, and sexual function.

Diagnostic Evaluation

1. Observation of clinical symptoms; may perform imaging studies to rule out other disorders.
2. Physical examination of upper-extremity elbow flexion/extension reveals rigidity on extension.
3. Sensorimotor assessment of grip reveals abnormally high grip forces and longer than normal to complete object lift, particularly with lighter loads.

4. Favorable response to a single dose of levodopa or apomorphine helps confirm the diagnosis.

Management

Pharmacologic

1. Anticholinergics, including trihexyphenidyl, benztropine, and procyclidine, to reduce transmission of cholinergic pathways, which are thought to be overactive when dopamine is deficient. These medications are most effective in controlling tremor but are known to cause confusion and hallucinations.
2. Amantadine, originally an antiflu medication, blocks the reuptake of dopamine or increases the release of dopamine by neurons in the brain, thereby increasing the supply of dopamine in the synapses. Widely used as an early monotherapy, its effect may be augmented by drug-free days.
3. Levodopa, a dopamine precursor, combined with carbidopa, a decarboxylase inhibitor, to inhibit destruction of L-dopa in the bloodstream, making more available to the brain. The addition of carbidopa prevents levodopa from being metabolized in the gut, liver, and other tissues and allows more to get to the brain. Therefore, a smaller dose of levodopa is required to treat symptoms and the unpleasant adverse effects are greatly reduced.
4. Bromocriptine, pramipexole, and ropinirole are dopaminergic agonists that activate dopamine receptors in the brain. Can be taken alone or in combination with levodopa–carbidopa.
5. Use of the monoamine oxidase inhibitor selegiline or deprenyl boosts the effect of levodopa–carbidopa when levodopa becomes less effective.
6. Tolcapone and entacapone are catechol-*O*-methyltransferase inhibitors for adjunct treatment. They prolong the duration of symptom relief by blocking the action of an enzyme that breaks down levodopa before it reaches the brain. Must be taken with levodopa.
7. Other medications that include levodopa include
    a. Combination formula of carbidopa/levodopa with entacapone (Stalevo), which is usseful in patients stable on both medications.
    b. An enteral suspension of carbidopa/levodopa infused directly into the small intestine, for those with advanced PD who experience unpredictable gastric emptying (requires jejunostomy tube).
    c. An extended-release capsule (Rytary) used as a secondary drug in those patients who experience early wearing off of levodopa therapy.
8. Apomorphine is an injectable, long-acting dopamine agonist, beneficial in patients experiencing early wearing off of levodopa therapy

---

DRUG ALERT History of melanoma and angle-closure glaucoma are contraindications to levodopa therapy; patients should have suspicious skin lesions removed before initiating therapy, as it may activate a malignant melanoma.

GERONTOLOGIC ALERT Older patients may have reduced tolerance to anti-Parkinson drugs and may require smaller doses. Watch for and report psychiatric reactions, such as anxiety, confusion, and hallucinations; cardiac effects, such as dizziness, orthostatic hypotension, and pulse irregularity; and blepharospasm (twitching of the eyelid), an early sign of toxicity. Other adverse effects may include dry mouth, nausea, drowsiness, and insomnia.

Surgery

1. New surgical treatments for Parkinson disease and essential tremor are promising.
2. Medial pallidotomy (electrode destroys cells in the globus pallidus) often improves long-standing symptoms, such as dyskinesia, akinesia, rigidity, and tremor, and for patients who have developed dyskinetic movements in reaction to their medications.
3. Deep brain stimulation of the thalamus decreases tremor and uncontrollable movements unresponsive to medication. Electrodes are implanted in the thalamus or globus pallidus and connected to a pacemaker-like device, which are programmed by a provider trained in DBS programming. Patients are provided the ability to adjust programs if deemed appropriate by the provider.
4. Gamma knife surgery provides concentrated gamma rays and destroys cells within the thalamus; beneficial in patients with essential tremor and who are unable to tolerate surgery
5. Brain tissue transplants are still in the experimental stages but have produced encouraging results using stem cells and genetically engineered animal cells that can be made to produce dopamine.

Complications

1. Dementia.
2. Aspiration.
3. Injury from falls.

Nursing Assessment

1. Obtain history of symptoms and their effect on functioning. Mobility, feeding, communication, and self-care difficulties will have many nursing implications (see Figure 15-7).
2. Assess CNs, cerebellar function (coordination), motor function.
3. Observe gait and performance of activities.
4. Assess speech for clarity and pace.
5. Assess for signs of depression.
6. Assess family dynamics, support systems, and access to social services.

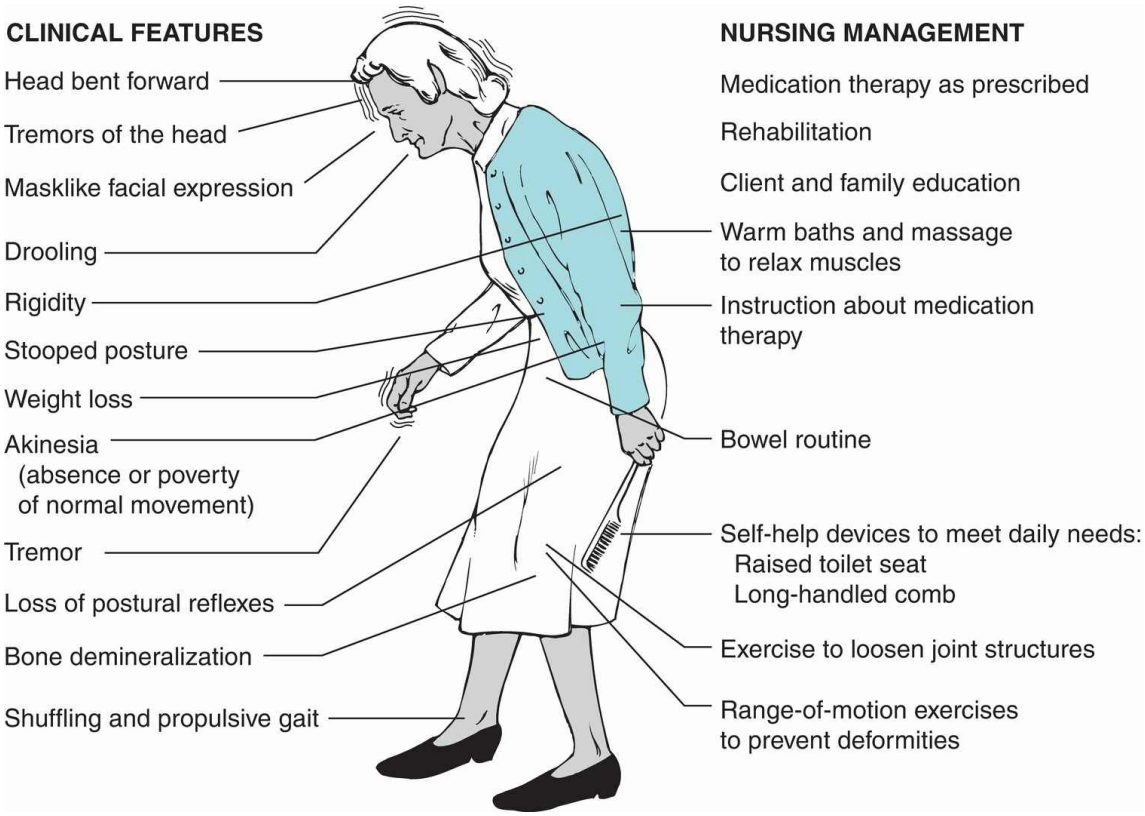

Figure 15-7. Appearance of woman with Parkinson disease. (LifeART image, 2004.)

Nursing Diagnoses

- Impaired Physical Mobility related to bradykinesia, rigidity, and tremor.
- Imbalanced Nutrition: Less Than Body Requirements related to motor difficulties with feeding, chewing, and swallowing.
- Impaired Verbal Communication related to decreased speech volume and facial muscle involvement.
- Constipation related to diminished motor function, inactivity, and medications.
- Ineffective Coping related to physical limitations and loss of independence.

Nursing Interventions

Improving Mobility and Reducing Risk of Falls

1. Encourage the patient to participate in daily exercise, such as walking, riding a stationary bike, swimming, or gardening.
2. Advise the patient to do stretching and postural exercises as outlined by a physical therapist.
3. Encourage the patient to take warm baths and receive massages to help relax muscles.
4. Instruct the patient to take frequent rest periods to overcome fatigue and frustration.
5. Teach postural exercises and walking techniques to offset shuffling gait and tendency to lean forward.
   a. Instruct the patient to use a broad-based gait.
   b. Have the patient make a conscious effort to swing arms, raise the feet while walking, use a heel-toe

gait, and increase the width of stride.

c. Tell the patient to practice walking to marching music or sound of ticking metronome to provide sensory reinforcement.

6. Assess for proper supportive footwear and safe use of mobility aid such as walker or cane.

Optimizing Nutritional Status

1. Teach the patient to think through the sequence of swallowing—close lips with teeth together lift tongue up with food on it; then move tongue back and swallow while tilting head forward.
2. Instruct the patient to chew deliberately and slowly, using both sides of mouth.
3. Tell the patient to make conscious effort to control accumulation of saliva by holding head upright and swallowing periodically.
4. Have the patient use secure, stabilized dishes and eating utensils.
5. Suggest smaller meals and additional snacks.
6. Monitor weight.
7. Suggest nutritionist and speech therapist referrals to improve oral intake and nutritional status.

Maximizing Communication Ability

1. Encourage compliance with medication regimen.
2. Suggest referral to speech therapist.
3. Teach the patient facial exercises and breathing methods to obtain appropriate pronunciation, volume, and intonation.
   a. Take a deep breath before speaking to increase the volume of sound and number of words spoken with each breath.
   b. Exaggerate pronunciation and speak in short sentences; read aloud in front of a mirror or into a tape recorder to monitor progress.
   c. Exercise facial muscles by smiling, frowning, grimacing, and puckering.

Preventing Constipation

1. Encourage foods with moderate fiber content—whole grains, fruits, and vegetables.
2. Increase water intake.
3. Obtain a raised toilet seat to encourage normal position.
4. Encourage the patient to follow regular bowel regimen that may include stool softener and other mild medications for constipation.

Strengthening Coping Ability

1. Help the patient establish realistic goals and outline ways to achieve goals.
2. Provide emotional support and encouragement.
3. Encourage use of all resources, such as therapists, primary care provider, social worker, and social support network.

4. Encourage open communication, discussion of feelings, and exchange of information about Parkinson disease.
5. Have the patient take an active role in activity planning and evaluation of treatment plan.
6. Observe for changes in depression to determine if the patient is responding to antidepressants.

Community and Home Care Considerations

1. Recommend interdisciplinary home health care program. Requires skilled assessment of needs of patient, professional nursing and therapeutic services, patient and family education, and case management to optimize patient outcomes.
2. Encourage use of soothing music to reduce pain and depression.
3. Assess safety in environment to reduce risk of falls.
4. Utilize physical therapy services to encourage safe ambulation and reduce fear of falls.
5. Encourage use of social services, respite care and health visitors, mental health counselors, and support groups to prevent caregiver strain.
6. Use occupational therapy aids to ensure mobility and safety, such as grab rails in the tub or shower, raised toilet seat, hand rails on both sides of the stairway, rope secured to foot of bed to achieve sitting position, and straight-backed wooden chairs with armrests.

NURSING ALERT Bowel and bladder management is an extremely important factor in the decision to keep the patient at home. Techniques to reduce incontinence episodes, such as having frequently scheduled toileting time, and to handle episodes of incontinence, such as having cleaning supplies and a change of clothes/briefs in the bathroom, should be taught to decrease caregiver burden.

Patient Education and Health Maintenance

1. Instruct the patient to avoid sedatives, unless specifically prescribed, which have additive effect with other medications.
2. Instruct the patient in medication regimen, signs of toxicity, and adverse reactions, such as orthostatic hypotension, dry mouth, dystonia, muscle twitching, urine retention, impaired glucose tolerance, anemia, and elevated liver function tests.
3. Encourage follow-up and monitoring for diabetes, glaucoma, hepatotoxicity, and anemia while undergoing drug therapy. Increasing episodes of freezing should be reported.
4. Teach the patient ambulation cues to avoid "freezing" in place and possibly avoid falls by doing one of the following:
   a. Raise head, raise toes, and then rock from one foot to another while bending knees slightly.
   b. Raise arms in a sudden short motion.
   c. Take a small step backward and then start forward.

d. Step sideways and then start forward.

5. Instruct the family not to pull patient during episodes of "freezing," which increases the problem and may cause falling.
6. Refer the patient/family for more information and support to such agencies as National Parkinson's Foundation (*www.parkinson.org*) and National Institute of Neurologic Disorders and Stroke (*www.ninds.nih.gov*).

Evaluation: Expected Outcomes

- Attends physical therapy sessions; does facial exercises 10 minutes twice per day.
- Eats three small meals and two snacks; no weight loss.
- Enunciation clear; speaking in four to five words per breath.
- Passes soft stool every day.
- Asks questions about Parkinson's; obtains help from family and/or friends.

Multiple Sclerosis

Multiple sclerosis (MS) is a chronic, frequently progressive neurologic disease of the CNS of unknown etiology and uncertain trajectory. MS is characterized by the occurrence of small patches of demyelination of the white matter of the optic nerve, brain, and spinal cord. MS is distinguished by exacerbations and remissions of symptoms over the course of the illness. MS is the most common CNS disease among young adults and the third leading cause of disability in the United States. It is estimated that 400,000 Americans have this disorder of the brain and spinal cord, causing disruption of electrical messages from the brain to the peripheral nervous system.

Pathophysiology and Etiology

1. *Demyelination* refers to the destruction of the myelin, the fatty and protein material that covers certain nerve fibers in the brain and spinal cord (see Figure 15-8).
2. Demyelination results in disordered transmission of nerve impulses.
3. Inflammatory changes lead to scarring of the affected nerve fibers.
4. Cause is unknown but may possibly be related to autoimmune dysfunction, genetic susceptibility, or an infectious process.
5. More prevalent in the northern latitudes and among whites.

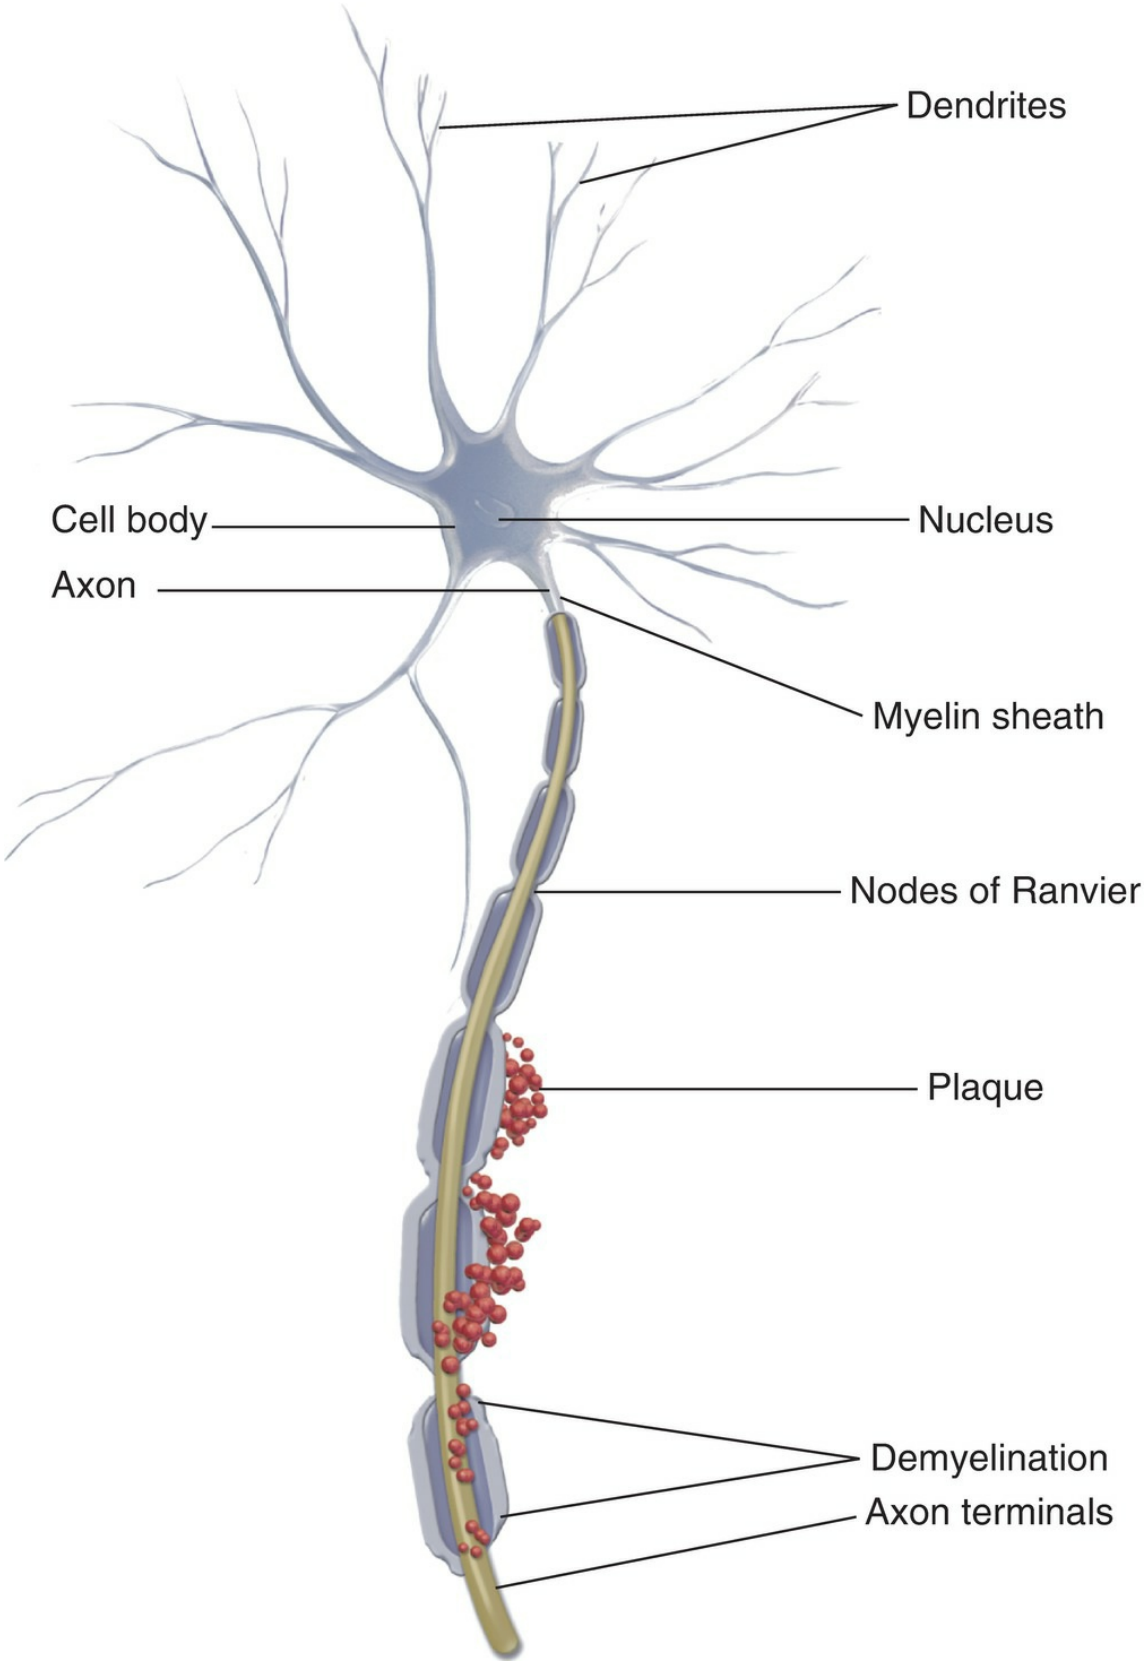

Figure 15-8. Myelin destruction of the nerve cell axon in multiple sclerosis. (Hickey, J. [2013]. Clinical Practice of Neurological & Neurosurgical Nursing [7th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Classification

The National Multiple Sclerosis Advisory Committee recognizes four clinical forms of MS:

1. Relapsing remitting (RR)—clearly defined acute attacks evolve over days to weeks. Partial recovery of function occurs over weeks to months. Average frequency of attacks is once every 2 years and neurologic stability remains between attacks without disease progression. (At the time of onset, 90% of cases of MS are diagnosed as RR.)
2. Secondary progressive (SP)—always begins as RR, but clinical course changes with increasing relapse rate, with a steady deterioration in neurologic function unrelated to the original attack. (Fifty percent of those with RR will progress to SP within 10 years; 90% will progress within 25 years.)
3. Primary progressive (PP)—characterized by steady progression of disability from onset without exacerbations and remissions. More prevalent among males and older individuals. Worst prognosis for neurologic disability. (Ten percent of cases of MS are diagnosed as PP.)
4. Progressive relapsing (PR)—the same as PP except that patients experience acute exacerbations along with a steadily progressive course (rarest form).

Clinical Manifestations

Lesions can occur anywhere within the white matter of the CNS. Symptoms reflect the location of the area of demyelination.

1. Fatigue and weakness.
2. Abnormal reflexes—absent or exaggerated.
3. Vision disturbances—impaired and double vision, nystagmus.
4. Motor dysfunction—weakness, tremor, incoordination.
5. Sensory disturbances—paresthesias, impaired deep sensation, impaired vibratory and position sense.
6. Impaired speech—slurring, scanning (dysarthria).
7. Urinary dysfunction—hesitancy, frequency, urgency, retention, incontinence; upper UTI. Urinary dysfunction affects about 90% of patients with MS and may exacerbate relapse of MS.
8. Neurobehavioral syndromes—depression, cognitive impairment, emotional lability.
9. Symptoms of MS are often unpredictable, varying from person to person and from time to time in the same person.

Diagnostic Evaluation

1. Establishing a definitive diagnosis is often difficult, with much uncertainty concerning prognosis once the diagnosis is made.
2. Serial brain MRI studies have proved to be useful for diagnosing and monitoring patients with MS—show small plaques scattered throughout white matter of CNS.
3. Magnetic resonance spectroscopy is now being studied to monitor specific pathophysiology of evolving MS plaques.

4. Electrophoresis study of CSF shows abnormal IgG antibody.
5. Visual, auditory, and somatosensory evoked potentials—slowed conduction is evidence of demyelination.

Management

MS treatment is dynamic and rapidly evolving, covering two main areas: direct treatment of MS and treatment of the effects or symptoms resulting from MS. Treatment is aimed at relieving symptoms and helping the patient function. However, a therapeutic relationship between the patient and nurse creates a critical and strong bond that is essential across the long trajectory of the illness.

Current Disease-Modifying Drugs

1. Corticosteroids or adrenocorticotropic hormone are used to decrease inflammation and shorten duration of relapse or exacerbation.
2. Immunosuppressive agents may stabilize the course.
3. Interferon beta-1a and interferon beta-1b are being used for treatment of rapidly progressing symptoms in some patients.
4. Glatiramer acetate, fingolimod, and natalizumab are immunomodulators used in RR disease.
5. Mitoxantrone, a chemotherapeutic agent used for the treatment of SP (chronic), PR, or worsening RR MS not responding to other disease-modifying drugs.

Treating Exacerbations

1. A true exacerbation of MS is caused by an area of inflammation in the CNS.
2. The treatment most commonly used to control exacerbations is IV, high-dose corticosteroids. Methylprednisolone is one of the most commonly used corticosteroids in MS.
3. Plasmapheresis (plasma exchange) is only considered for the 10% who do not respond well to standard corticosteroid treatment.

Chronic Symptom Management

1. Treatment of spasticity with such agents as baclofen, dantrolene, diazepam; physical therapy; nerve blocks and surgical intervention.
2. Control of fatigue with amantadine and lifestyle changes.
3. Treatment of depression with antidepressant drugs and counseling.
4. Bladder management with anticholinergics, intermittent catheterization for drainage, prophylactic antibiotics.
5. Bowel management with stool softeners, bulk laxative, suppositories.
6. Multidisciplinary rehabilitation management with physical therapy, occupational therapy, speech therapy, cognitive therapy, vocational rehabilitation, and complementary and alternative medicine, as indicated, to restore or maintain functions essential to daily living in individuals who have lost these capacities through the disease process.
7. Control of dystonia with carbamazepine.

8. Management of pain syndromes with carbamazepine, phenytoin, perphenazine/amitriptyline, and nonpharmacologic modalities.

Complications

1. Dysphagia and respiratory dysfunction.
2. Infections: bladder, respiratory, sepsis.
3. Complications from immobility.
4. Speech, voice, and language disorders such as dysarthria.

Nursing Assessment

1. Observe motor strength, coordination, and gait.
2. Perform CN assessment.
3. Evaluate elimination function.
4. Explore coping, effect on activity and sexual function, emotional adjustment.
5. Assess patient and family coping, support systems, and available resources.
6. Assess for anxiety, depression, sleep disturbances, cognitive impairment, and pain, which commonly occur in patients with MS.

Nursing Diagnoses

- Impaired Physical Mobility related to muscle weakness, spasticity, and incoordination.
- Fatigue related to disease process and stress of coping.
- Risk for Injury related to motor and sensory deficits.
- Risk for Aspiration related to dysphagia.
- Impaired Urinary Elimination related to the disease process.
- Interrupted Family Processes related to inability to fulfill expected roles.
- Sexual Dysfunction related to disease process.

Nursing Interventions

Promoting Motor Function

1. Perform muscle-stretching and muscle-strengthening exercises daily, or teach the patient or family to perform, using a stretch–hold–relax routine to minimize spasticity and prevent contractures.
2. Apply ice packs before stretching to reduce spasticity.
3. Tell the patient to avoid muscle fatigue by stopping activity just short of fatigue and to take frequent rest periods.
4. Encourage walking and activity and teach the patient how to use such devices as braces, canes, and walkers, when necessary.
5. Inform the patient to avoid sudden changes in position, which may cause falls due to loss of position sense, and to walk with a wide-based gait.

6. Encourage frequent change in position while immobilized to prevent contractures; sleeping prone will minimize flexor spasm of hips and knees.

Minimizing Fatigue

1. Help the patient and family understand that fatigue is an integral part of MS.
2. Plan ahead and prioritize activities. Take brief rest periods throughout the day.
3. Avoid overheating, overexertion, and infection.
4. Encourage energy-conservation techniques, such as sitting to perform activity, limiting trips up and down stairs, pulling, or pushing rather than lifting.
5. Help the patient develop a healthy lifestyle with balanced diet, rest, exercise, and relaxation.

Preventing Injury

1. Suggest use of an eye patch or frosted lens (alternate eyes) for patients with double vision.
2. Encourage regular ophthalmologic consultation to maximize vision and be aware of potential for hearing changes and assess as needed.
3. Provide a safe environment for patient with any sensory alteration.
    a. Orient the patient to the environment and keep arrangement of furniture and personal articles constant.
    b. Make sure floor is free from obstacles, loose rugs, or slippery areas.
    c. Teach the use of all senses to maintain awareness of environment.

Managing Dysphagia

1. Initiate referrals to speech/language pathologist and dietician for evaluation and treatment of swallowing problems.
2. Ensure that the patient is alert and distractions are minimized at mealtimes: provide supervision, as indicated.
3. Use safe swallowing practices, including proper positioning, double swallow, and chin tuck.
4. Monitor the patient for signs and symptoms of choking or aspiration; use suctioning as indicated.
5. Educate and counsel patients and care partners about feeding options as disease progresses.

Maintaining Urinary Elimination

1. Ensure adequate fluid intake to help prevent infection and stone formation.
2. Assess for urine retention and catheterize for residual urine, as indicated.
3. Teach the patient to report signs of UTI immediately.
4. Set up bladder-training program to reduce incontinence.
    a. Encourage fluids every 2 hours.
    b. Follow regular schedule of voiding, every 1 to 2 hours, lengthening as tolerated.
    c. Restrict fluid volume and salty foods 1 to 2 hours before bedtime.

5. See pages 148 to 149 for more information on urine retention and incontinence.

Normalizing Family Processes

1. Encourage verbalization of feelings of each family member.
2. Encourage counseling and use of church or community resources.
3. Suggest dividing up household duties and childcare responsibilities to prevent strain on one person.
4. Explore adaptation of some roles so the patient can still function in family unit.
5. Expand treatment efforts to include the whole family.
6. Support mothers with MS who often face fatigue and episodic exacerbations during their childrearing years.

Promoting Sexual Function

1. Encourage open communication between partners.
2. Discuss birth control options, if appropriate.
3. Suggest sexual activity when the patient is most rested.
4. Suggest consultation with sexual therapist to help obtain greater sexual satisfaction.

Community and Home Care Considerations

1. The nurse case manager functions as care provider, facilitator, advocate, educator, counselor, and innovator aimed at intervening in a wide variety of settings to improve patient function and mobility.
2. Teach the patient receiving interferon beta-1a and interferon beta-1b to expect adverse effects of flulike symptoms, fever, asthenia, chills, myalgias, sweating, and local reaction at the injection site. Liver function test elevation and neutropenia may also occur. Adverse effects may persist for up to 6 months of treatment before subsiding.
3. Instruct the patient receiving interferon beta-1a and interferon beta-1b in self-injection technique.
4. Teach the patient and family to use their own judgment, knowledge, and ingenuity to control MS symptoms.
5. Teach the patient and family how to conduct periodic self-assessment of daily functioning so that home care team can continue to make modifications in treatment plan.

DRUG ALERT Ensure rotation of subcutaneous injection site of disease-modifying drugs to prevent skin reactions. Avoid injections into an area of skin that is sore, reddened, infected, or damaged. Injection sites include the inner thigh, outer surface of the upper arm, stomach, or buttocks. If the patient is thin, thigh and arm sites are preferred. Use a diagram or log of the date and site location for each injection.

Patient Education and Health Maintenance

1. Encourage the patient to maintain previous activities, although at a lowered level of intensity, and

reinforce appropriate and safe use of adaptive equipment and aides.

2. Teach the patient to respect fatigue and avoid physical overexertion and emotional stress; remind the patient that activity tolerance may vary from day to day.
3. Advise the patient to avoid exposure to heat and cold or infectious agents.
4. Encourage a nutritious diet that is high in fiber to promote health and good bowel elimination.
5. Advise the patient that some medications may accentuate weakness, such as some antibiotics, muscle relaxants, antiarrhythmics and antihypertensives, antipsychotics, oral contraceptives, and antihistamines; check with health care provider or pharmacist before taking any new medications.
6. Try to include children in the education of MS and the relationship of fatigue and functional status.
7. Refer the patient/family for more information and support to such agencies as the National Multiple Sclerosis Society (*www.nmss.org*).

Evaluation: Expected Outcomes

- Performs exercises correctly without spasm.
- Rests at intervals; tolerates activity well.
- Moves about in environment without injury.
- No episodes of aspiration.
- Voids every 2 hours with no incontinent episodes.
- Family sharing care, discussing feelings.
- Reports satisfaction with sexual activity.

Amyotrophic Lateral Sclerosis

Amyotrophic lateral sclerosis (ALS), also known as Lou Gehrig disease, is an incapacitating, fatal neuromuscular disease that affects as many as 20,000 Americans, with 5,000 new cases occurring in the United States each year. ALS results in progressive muscle weakness and progressive wasting and paralysis of the muscles. It is accompanied by other LMN signs, such as atrophy or fasciculations. Approximately 80% of cases begin between ages 40 and 70. The life expectancy of an ALS patient averages 2 to 5 years.

Pathophysiology and Etiology

1. Degeneration of upper motor neurons (nerves leading from the brain to medulla or spinal cord) and LMNs (nerves leading from the spinal cord to the muscles of the body).
2. Results in progressive loss of voluntary muscle contraction and functional capacity, involving the legs, feet, arms, and hands, and those that control swallowing and breathing. Patients develop variable hyperreflexia, clonus, spasticity, extensor plantar responses, and limb or tongue fasciculations. Extraocular muscles and bladder and anal sphincter muscles typically are spared. ALS rarely affects cognitive functions.
3. Cause is unknown. Usually affects men in the fifth or sixth decade of life.
4. Nearly 10% of ALS cases are familial; the disease is transmitted in an autosomal dominant fashion. The copper/zinc SOD1 gene is mutated in 10% to 20% of these familial cases. Although the primary mechanism of SOD1-mediated neural injury is currently unknown, apoptosis, excitotoxicity, and oxidative stress are thought to play major roles in pathogenesis. Sporadic ALS shares clinical features with familial ALS. However, no SOD1 mutations or polymorphisms have been identified in these patients. Common pathways of disease pathogenesis may play a role, with different molecular abnormalities that lead to similar phenotypes.
5. Several studies have shown an inflammatory component to the affected spinal cord regions, with the presence of activated microglia, reactive astrocytes, and IgG deposition. Whether this reaction precedes or accompanies the molecular events that promote neuronal cell death is unknown.

Clinical Manifestations

1. Progressive weakness and wasting of muscles of arms, trunk, and legs.
2. Fasciculations and signs of spasticity.
3. Progressive difficulty swallowing with drooling (sialorrhea) and regurgitation of liquids through the nose, speaking (nasal and unintelligible sounds), and, ultimately, breathing.
4. CN deficits (bulbar symptoms) are present in 20% of cases (prevalence increases with age), along with dysarthria, voice deterioration, and dysphagia. (Patients with bulbar presentation have poorer prognosis; these symptoms also have a profound impact on quality of life because of nutritional risk factors, aspiration, and respiratory complications.)

Diagnostic Evaluation

1. Electromyography to evaluate denervation and muscle atrophy.
2. Nerve conduction study to evaluate nerve pathways.
3. Pulmonary function tests to evaluate respiratory function.
4. Barium swallow to evaluate ability to achieve various phases of swallowing mechanisms.
5. MRI, CT to rule out other disorders.
6. Laboratory tests: creatine kinase, heavy metal screen, thyroid function tests, CSF evaluation to rule out other causes of muscle weakness.

Management

1. There is no cure for ALS, nor is there a proven therapy that will prevent or reverse the course of the disorder.
2. Riluzole has been shown to prolong the survival of ALS patients by 2 to 3 months.

EVIDENCE BASE Miller, R. G., Mitchell, J. D., Moore, D. H. (2012). Riluzole for amyotrophic lateral sclerosis (ALS)/motor neuron disease (MND). *Cochrane Database of Systematic Reviews*, (3), CD001447.

---

3. Most treatment is palliative and symptomatic.
4. Botulinum toxin B injections into the parotid and submandibular glands, amitriptyline therapy, or low-dose radiation therapy to the salivary glands may be used to treat drooling.
5. There are insufficient data to support or refute any specific intervention for the treatment of cramps, spasticity, depression, anxiety, insomnia, pain, dyspnea, or cognitive/behavioral impairments in ALS.
6. Neuropsychological screening may be conducted to assess for cognitive and behavioral impairments.
7. Feeding gastrostomy.
8. Tracheostomy and mechanical ventilation eventually become necessary and should be discussed prior to need to ascertain the patient's wishes regarding these measures.

NURSING ALERT Although no formal research has been conducted addressing the best time to discuss care preferences and end-of-life care in ALS, it is important to elicit this information to guide the selection of various therapeutics, such as intubation, tube feeding, treatment of infection, and management of changes in LOC. Having the family or significant other present when these discussions occur can help to alleviate miscommunication or disagreements in the plan of care.

Complications

1. Respiratory failure.
2. Aspiration pneumonia.
3. Cardiopulmonary arrest.
4. Locked-in syndrome—fully conscious but unable to respond in any way.

Nursing Assessment

1. Evaluate respiratory function: rate, depth, tidal volume.
2. Perform CN assessment, particularly gag reflex and swallowing.
3. Assess voluntary motor function and strength.

Nursing Diagnoses

- Ineffective Breathing Pattern related to respiratory muscle weakness.
- Impaired Physical Mobility related to disease process.
- Imbalanced Nutrition: Less Than Body Requirements related to inability to swallow.
- Fatigue related to denervation of muscles.
- Social Isolation related to fatigability and decreased communication skills.
- Risk for Infection related to inability to clear airway.

Nursing Interventions

Maintaining Respiration

1. Monitor vital capacity frequently. Document pattern and report any decrease below patient's baseline.
2. Position patient upright, suction upper airway, and perform chest physical therapy to enhance respiratory function.
3. Encourage use of incentive spirometer to exercise respiratory muscles.
4. Assess for signs of hypoxia, such as tachypnea, hypopnea, restlessness, poor sleep, and excessive fatigue.
5. Obtain ABG values as ordered.
6. Establish the wishes of the patient in terms of life-support measures; obtain copy of advance directive for chart, if applicable.
7. Assist with intubation, tracheostomy, and mechanical ventilation when indicated (see Chapter 10).
8. Provide suctioning and routine care of a patient with artificial airway and mechanical ventilation.

Optimizing Mobility

1. Encourage the patient to continue usual activities as long as possible but modify exertion to avoid fatigue.
2. Encourage physical therapy exercises to strengthen unaffected muscles and perform ROM exercises to prevent contractures.
3. Encourage energy-conservation techniques.
4. Obtain assistive devices, as needed, to help the patient maintain independence, such as special feeding devices, remote controls, and a motorized wheelchair.

Meeting Nutritional Requirements

1. Provide high-calorie, small, frequent feedings.
2. Provide meals that are of a texture the patient can handle; semisolid food is usually easiest to swallow.
   a. Avoid easily aspirated, pureed, and mucus-producing foods (eg, milk).
   b. Try warm or cold foods that stimulate temperature receptors in mouth and may help in swallowing.
   c. Do not wash down solids with fluids—may cause choking and aspiration.
3. Allow the patient to make his or her own food selection.
4. Provide assistive devices for self-feeding when possible.
5. Make mealtimes a pleasant experience in a bright room, with quiet company so the patient may concentrate on eating and avoid undue embarrassment.
6. Examine oral cavity for food debris before and after meals, and assess swallowing function and buildup of saliva.
7. Encourage rest periods before meals to alleviate muscle fatigue.
8. Place the patient upright for meals with neck flexed to partially protect the airway.
9. Instruct the patient to take a breath before swallowing, hold breath to swallow, exhale or cough after swallow, and swallow again.
10. Tell the patient to avoid talking while eating.
11. Prepare the patient for gastrostomy or other alternate feeding methods when appropriate and desired by patient.

Minimizing Fatigue

1. Encourage activity alternating with frequent naps.
2. Encourage the patient to accomplish most important activities early in day.
3. Consult with occupational therapist about energy-conservation techniques in performing ADL.

Maintaining Social Interaction

1. Use mechanical speech aids or communication board.
2. Use an environmental control board.
3. Eye movements/blinks may be the last voluntary movement; develop a code system to serve as a communication method.
4. Because standard call lights cannot be activated by the severely debilitated ALS patient, provide adaptive call light (environmental control unit) and/or some type of constant monitoring and surveillance to meet patient's needs.
5. Allow the patient to select which social activities are meaningful.
6. Refer to counselor or psychologist for coping with communication barriers and inevitability of losses.

Preventing Aspiration and Infection

1. Consult with a speech therapist for techniques and devices to assist swallowing.

2. Discourage bed rest to prevent pulmonary stasis.
3. Perform chest physiotherapy, as tolerated.
4. Monitor for fever and tachycardia and obtain sputum, urine, and other cultures, as indicated.

Community and Home Care Considerations

1. Teach caregivers how to perform suctioning, tracheostomy care, and ventilator care in the home, as indicated. Clean technique will be used rather than sterile.
2. Teach caregivers how to perform gastrostomy feedings and care of tube.
3. Assess for adequate supplies for care and ability of caregivers to carry out procedures.
4. Encourage cleanliness in home environment and avoidance of contact with anyone with respiratory infection. Give influenza and pneumonia vaccines, as indicated.

Patient Education and Health Maintenance

1. Stress the importance of maintaining physical exercise.
2. Review with the patient and family proper eating mechanics to avoid fatigue and aspiration.
3. Inform the patient of right to make decisions early in the disease process regarding an advance directive and life-sustaining treatment.
4. Encourage the family to seek support and respite care.
5. Remind the family that the patient with ALS maintains full alertness, sensory function, and intelligence. Encourage them to maintain interaction, socialization, and stimulation and to seek out technology such as mind-activated computer-driven communication devices.
6. Refer the patient/family for more information and support to such agencies as the ALS Association (*www.alsa.org*).

Evaluation: Expected Outcomes

- Normal respiratory rate and rhythm, shallow, unlabored at rest.
- Does active ROM exercises for 15 minutes twice per day; uses assistive utensils to feed self.
- Tolerates small, frequent feedings without aspiration.
- Naps twice per day for 1 to 2 hours.
- Communicates needs effectively to staff and family.
- No signs of respiratory or urinary infection.

NEUROMUSCULAR DISORDERS

Guillain-Barré Syndrome (Polyradiculoneuritis)

Guillain-Barré syndrome (GBS) is an acute, rapidly progressing, ascending inflammatory demyelinating polyneuropathy of the peripheral sensory and motor nerves and nerve roots. GBS is most often, but not always, characterized by muscular weakness and distal sensory loss or dysesthesias. GBS is the most frequently acquired demyelinating neuropathy. It affects 1 in 100,000 people and must be identified quickly to initiate treatment and decrease life-threatening complications. Usually, GBS occurs a few days or weeks following symptoms of a respiratory or GI viral infection. Occasionally, surgery or vaccinations will trigger the syndrome. The disorder can develop over the course of hours, days, or weeks. Maximum weakness usually occurs within the first 2 weeks after symptoms appear, and by the 3rd week of the illness, 90% of all patients are at their weakest. About 30% of those with GBS have residual weakness after 3 years and the recurrence rate is approximately 3%.

Mortality results from respiratory failure, autonomic disturbances, sepsis, and complications of immobility and occurs at a rate of about 5% despite intensive medical care.

Pathophysiology and Etiology

1. Believed to be an autoimmune disorder that causes acute neuromuscular paralysis due to destruction of the myelin sheath surrounding peripheral nerve axons and subsequent slowing of transmission.
2. Viral infection, immunization, or other event may trigger the autoimmune response.
3. About 30% to 40% of cases are preceded by *Campylobacter* infection, an acute infectious diarrheal illness.
4. Cell-mediated immune reaction is aimed at peripheral nerves, causing demyelination and, possibly, axonal degeneration.

Clinical Manifestations

1. Paresthesias and, possibly, dysesthesias.
2. Acute onset of symmetric progressive muscle weakness, most often beginning in the legs and ascending to involve the trunk, upper extremities, and facial muscles; paralysis may develop.
3. Difficulty with swallowing, speech, and chewing due to CN involvement.
4. Decreased or absent deep tendon reflexes, position, and vibratory perception.
5. Autonomic dysfunction (increased heart rate and postural hypotension).
6. Decreased vital capacity, depth of respirations, and breath sounds.
7. Occasionally spasm and fasciculations of muscles.

Diagnostic Evaluation

1. History and neurologic examination. Progressive weakness, decreased sensation, decreased deep tendon reflexes.
2. Lumbar puncture for CSF examination—reveals low blood cell count, high protein.
3. Electrophysiologic studies—nerve conduction velocity shows decreased conduction velocity of peripheral

nerves.

Management

1. Plasmapheresis produces temporary reduction of circulating antibodies to reduce the severity and duration of the GBS episode.
2. High-dose Ig therapy and corticosteroids are used to reduce the severity of the episode.
3. ECG monitoring and treatment of cardiac dysrhythmias.
4. Analgesics and muscle relaxants, as needed.
5. Intubation and mechanical ventilation if respiratory paralysis develops.

Complications

1. Respiratory failure.
2. Cardiac dysrhythmias.
3. Complications of immobility and paralysis.
4. Anxiety and depression.

Nursing Assessment

1. Assess pain level due to muscle spasms and dysesthesias.
2. Assess cardiovascular function including orthostatic BPs.
3. Assess respiratory status closely to determine hypoventilation due to weakness.
4. Perform CN assessment, especially CN IX for gag reflex.
5. Assess motor strength.

Nursing Diagnoses

- Ineffective Breathing Pattern related to weakness/paralysis of respiratory muscles.
- Impaired Physical Mobility related to paralysis.
- Imbalanced Nutrition: Less Than Body Requirements, related to CN dysfunction.
- Impaired Verbal Communication related to intubation, CN dysfunction.
- Chronic Pain related to disease pathology.
- Anxiety related to communication difficulties and deteriorating physical condition.

Nursing Interventions

Maintaining Respiration

1. Monitor respiratory status through vital capacity measurements, rate and depth of respirations, breath sounds.
2. Monitor level of weakness as it ascends toward respiratory muscles.
3. Watch for breathlessness while talking, a sign of respiratory fatigue.
4. Maintain calm environment and position the patient with head of bed elevated to provide for maximum

chest excursion.

5. As much as possible, avoid opioids and sedatives that may depress respirations.
6. Monitor the patient for signs of impending respiratory failure; heart rate above 120 or below 70 beats/minute; respiratory rate above 30 breaths/minute; prepare to intubate.
7. Long-term respiratory management may be necessary with placement of a tracheostomy.

Avoiding Complications of Immobility

1. Position the patient correctly and provide ROM exercises.
2. Encourage physical and occupational therapy exercises to regain strength during the rehabilitative period.
3. Assess for complications, such as contractures, pressure ulcers, edema of lower extremities, and constipation.
4. Provide assistive devices, as needed, such as cane or wheelchair, for patient to take home.
5. Recommend referral to rehabilitation services or physical therapy for evaluation and treatment.

Promoting Adequate Nutrition

1. Assess chewing and swallowing ability by testing CN V, IX, and X; if function is inadequate, provide alternate nutrition through enteral or parenteral methods.
2. During rehabilitation period, encourage a well-balanced, nutritious diet in small, frequent feedings with vitamin supplement, if indicated.
3. Recommend referral to dietitian for evaluation and proper diet therapy.

Maintaining Communication

1. Develop a communication system with the patient who cannot speak.
2. Have frequent contact with the patient and provide explanation and reassurance, remembering that the patient is fully conscious.
3. Provide some type of patient call system. Because standard call lights cannot be activated by the severely weak patient, provide adaptive call light and/or some type of constant monitoring and surveillance to meet patient's needs.
4. Recommend referral to speech therapy for evaluation and treatment.
5. Refer to counselor, social worker, or psychologist to develop/enhance coping skills and regain sense of control.

Relieving Pain

1. Administer analgesics, as required; monitor for adverse reactions, such as hypotension, nausea and vomiting, and respiratory depression.
2. Provide adjunct pain management therapies, such as therapeutic touch, massage, diversion, and guided imagery.
3. Provide explanations to relieve anxiety, which augments pain.
4. Turn the patient frequently to relieve painful pressure areas.

Reducing Anxiety

1. Get to know the patient and build a trusting relationship.
2. Discuss fears and concerns while verbal communication is possible.
3. Reassure the patient that recovery is probable.
4. Use relaxation techniques such as listening to soft music.
5. Provide choices in care and give the patient a sense of control.
6. Enlist the support of significant others.

Community and Home Care Considerations

1. Be aware that GBS is a significant cause of new long-term disability for at least 1,000 people per year in the United States, necessitating long-term rehabilitation and community reintegration. Outcome can range from mild paresthesias to death. The chance of recovery is significantly affected by age, antecedent gastroenteritis, disability, electrophysiologic signs of axonal degeneration, latency to nadir, and duration of active disease.
2. Given the young age at which GBS sometimes occurs, the patient and family must be treated as an integral unit, assessing family communication, knowledge, adjustment, and use of support systems.
3. Include in caregiver training strategies the need for exercise, positioning, and activity to prevent secondary complications, such as contractures, DVT, hypercalcemia, and pressure ulcers.

Patient Education and Health Maintenance

1. Advise the patient and family that acute phase lasts 1 to 4 weeks, then the patient stabilizes and rehabilitation can begin; however, convalescence may be lengthy, from 3 months to 2 years.
2. Instruct the patient in breathing exercises or use of incentive spirometer to re-establish normal patterns.
3. Teach the patient to wear good supportive and protective shoes while out of bed to prevent injuries due to weakness and paresthesia.
4. Instruct the patient to check feet routinely for injuries because trauma may go unnoticed because of sensory changes.
5. Reinforce maintenance of normal weight; additional weight will further stress motor abilities.
6. Encourage the use of scheduled rest periods to avoid overfatigue.
7. Refer the patient/family for more information and support to such agencies as Guillain-Barré Syndrome Foundation International (*www.gbsfi.com*).

Evaluation: Expected Outcomes

- Normal respiratory rate and rhythm, shallow, unlabored.
- Performs assistive ROM exercises every 2 hours; no pressure ulcers or edema present.
- Gag reflex present; eating small meals without aspiration.
- Uses short phrases and head nodding to communicate effectively.
- Verbalizes decreased pain.

- Verbalizes reduced anxiety.

Myasthenia Gravis

Myasthenia gravis (MG) is a chronic autoimmune disorder affecting the neuromuscular transmission of impulses in the voluntary muscles of the body. MG is characterized by fluctuating weakness increased by exertion. Weakness increases during the day and improves with rest. Presentation and progression vary because of an antibody-mediated attack against acetylcholine receptors at the neuromuscular junction. Loss of acetylcholine receptors leads to a defect in neuromuscular transmission. Cardinal features are muscle weakness and fatigue. Evidence suggests that the frequency and recognition of MG is increasing.

Pathophysiology and Etiology

1. MG is idiopathic in most patients. Penicillamine is known to induce various autoimmune disorders, including MG.
2. Depletion of acetylcholine receptors at neuromuscular junctions brought about by an autoimmune attack (see Figure 15-9). In about 90% of patients, no specific cause can be identified, but genetic makeup is a predisposing factor, suggesting environmental factors may be involved in development of this disorder.
3. The reduced number of acetylcholine receptors results in diminished amplitude of end-plate potentials. Failed transmission of nerve impulses to skeletal muscle at the myoneural junction results in decreased muscle power, clinically manifested as extreme fatigue and weakness. The pattern of muscle involvement varies among individuals.
4. About 80% to 90% of patients with MG have serum antibodies to acetylcholine.
5. Thyroid gland abnormalities are present in 80% of patients. Thymic tumor is the most important known cause; 10% of patients with MG have a thymoma.
6. *Cholinergic crisis* can result from overmedication with anticholinergic drugs, which release too much acetylcholine at the neuromuscular junction.
7. *Brittle crisis* occurs when the receptors at the neuromuscular junction become insensitive to anticholinesterase medication.
8. Women are three times more susceptible to developing MG than men.
9. Spontaneous remissions are rare. Long and complete remissions are even less common. Most remissions (with treatment) occur during the first 3 years of disease.

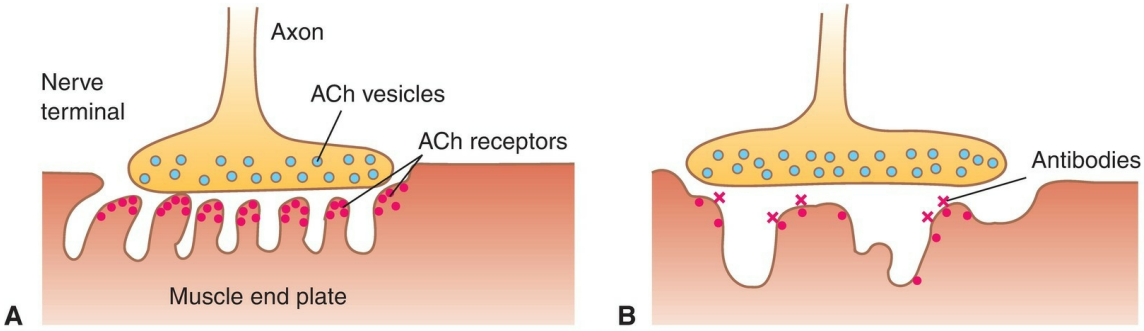

Figure 15-9. Myasthenia gravis. **(A)** Normal acetylcholine receptor site; **(B)** acetylcholine receptor

site in myasthenia gravis. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Clinical Manifestations

1. Extreme muscular weakness and easy fatigability.
2. Vision disturbances—diplopia and ptosis from ocular weakness. Extraocular muscle weakness or ptosis is present initially in 50% of patients and occurs during the course of illness in 90%. Bulbar muscle weakness is also common, along with weakness of head extension and flexion.
3. Facial muscle weakness causes a masklike facial expression. Patients may present a snarling appearance when attempting to smile.
4. Dysarthria and dysphagia from weakness of laryngeal and pharyngeal muscles.
5. Proximal limb weakness, with specific weakness in the small muscles of the hands. Patients progress from mild to more severe disease over weeks to months. Weakness tends to spread from the ocular to facial to bulbar muscles and then to truncal and limb muscles. The disease remains ocular in only 16% of patients. About 87% of patients generalize within 13 months after onset.
6. Respiratory muscle weakness can be life-threatening. Intercurrent illness or medication can exacerbate weakness, quickly precipitating a myasthenic crisis and rapid respiratory compromise.
7. Impending myasthenic crisis may be triggered by respiratory infection, aspiration, physical/emotional stress, and changes in medications. Symptoms include:
   a. Sudden respiratory distress.
   b. Signs of dysphagia, dysarthria, ptosis, and diplopia.
   c. Tachycardia, anxiety.
   d. Rapidly increasing weakness of extremities and trunk.

Diagnostic Evaluation

1. Serum test for acetylcholine receptor antibodies—positive in up to 90% of patients.
2. Electrophysiologic testing, such as EMG, shows decreased response to repetative nerve stimulation.
3. Edrophonium (Tensilon) test—IV injection of this short-acting anticholinesterase relieves symptoms temporarily. After injection, a marked but temporary improvement in muscle strength identified by performance of repetitive movements or EMG testing suggests MG. It also differentiates myasthenic crisis from cholinergic crisis.
4. Thyroid function tests should be done to evaluate for coexistent thyroid disease and CT scan to assess enlargement of thymus gland. Chest CT scan is mandatory to identify thymoma in all cases of MG. This is especially true in older individuals.

Management

1. With treatment, most patients can lead fairly normal lives.
2. Oral anticholinesterase drugs, such as neostigmine and pyridostigmine, are first-line treatments for mild

MG, enhancing neuromuscular transmission.

3. Immunosuppressive drugs, such as prednisone, are the mainstay of treatment when weakness is not adequately controlled by anticholinergic medication. Azathioprine may be added as a steroid-sparing agent. Immunosuppressant treatment is often permanent.
4. Plasmapheresis removes antibodies from the blood and is used for patients in myasthenic crisis or for short-term treatment of patients undergoing thymectomy. IV Ig is also an option and has less side effects.
5. Thymectomy is indicated for patients with tumor or hyperplasia of the thymus gland (thymectomy is not usually beneficial in late-onset patients).
6. Interventions for myasthenic crisis:
   a. Immediate hospitalization and may require intensive care.
   b. Edrophonium to differentiate crisis and treat myasthenic crisis; temporarily worsens cholinergic crisis; unpredictable results with brittle crisis.
   c. Airway management—mechanical ventilation, vigorous suctioning, oxygen therapy, postural drainage with percussion and vibration. Tracheostomy may be required, depending on duration of intubation. Maintain semi-Fowler's position, especially in obese patients.
   d. Plasmapheresis, IV Ig, and high-dose parenterally administered corticosteroids are used to reduce symptoms.
   e. Neostigmine IV for myasthenic crisis.
   f. Discontinuation of anticholinergic medications until respiratory function improves; atropine to reduce excessive secretions for cholinergic crisis.

DRUG ALERT Plasmapheresis must be carried out before IV Ig therapy because plasmapheresis will remove the IV Ig proteins that are effective in symptom reduction.

Complications

1. Aspiration.
2. Complications of decreased physical mobility.
3. Respiratory failure.

Nursing Assessment

1. Expect the patient to complain of extreme muscle weakness and fatigue.
2. Assess CN function, motor fatigability with repetitive activity, and speech. Observe eye muscles (usually affected first) for ptosis, ocular palsy, and diplopia.
3. Assess respiratory status—breathlessness, respiratory weakness, tidal volume, and vital capacity measurements.

4. Assess complications secondary to drug treatment—long-term immunomodulating therapies may predispose patients with MG to various complications.
   a. Long-term steroid use may lead to or aggravate many conditions, such as osteoporosis, cataracts, hyperglycemia, weight gain, avascular necrosis of hip, hypertension, and gastritis or peptic ulcer disease. To decrease the risk of ulcer, patients should take an H2 blocker or antacid.
   b. Increased risk for infection from immunomodulating therapy, especially if the patient is on more than one agent. Such infections include tuberculosis, systemic fungal infections, and *Pneumocystis carinii* pneumonia.
   c. Risk of lymphoproliferative malignancies may be increased with chronic immunosuppression.
   d. Immunosuppressive drugs may have teratogenic effects. In addition, risk of congenital deformity (arthrogryposis multiplex) is increased in offspring of women with severe MG.

DRUG ALERT Neonates born to women with MG need to be monitored for respiratory failure for 1 to 2 weeks after birth. Discuss these aspects with women in reproductive years prior to beginning therapy with these drugs.

Nursing Diagnoses

- Fatigue related to disease process.
- Risk for Aspiration related to muscle weakness of face and tongue.
- Impaired Social Interaction related to diminished speech capabilities and increased secretions.

Nursing Interventions

Minimizing Fatigue

1. Plan exercise, meals, and other ADL during energy peaks. Time administration of medications 30 minutes before meals to facilitate chewing and swallowing.
2. Assist the patient in developing realistic activity schedule.
3. Provide an eye patch and alternate eyes for the patient with diplopia to allow safe participation in activity.
4. Allow for rest periods throughout the day.
5. Obtain assistive devices to help the patient perform ADL.

DRUG ALERT Many medications can accentuate the weakness experienced by the patient with MG, including some antibiotics (such as ciprofloxacin, aminoglycosides, chloroquine, and procaine penicillin), antiarrhythmics (such as procainamide, beta-adrenergic blockers, and quinidine), local and

general anesthetics, muscle relaxants, and analgesics such as nonsteroidal anti-inflammatory drugs (NSAIDs). Assess function after administering any new drug, and report deterioration in condition.

Preventing Aspiration

1. Assess the patient's oral motor strength before each meal.
2. Teach the patient to position his or her head in a slightly flexed position to protect airway during eating.
3. Modify diet, as needed, to minimize risk of aspiration; for instance, soft, solid foods instead of liquids. Teach the patient that eating warm foods (not hot foods) can ease swallowing difficulties.
4. Have suction available that the patient can operate.
5. Administer IV fluids and nasogastric tube feedings to the patient in crisis or with impaired swallowing; elevate head of bed after feeding.
6. Suction the patient frequently if on a mechanical ventilator; assess breath sounds and check chest x-ray reports because aspiration is a common problem.

Maintaining Social Interactions

1. Encourage the patient to use an alternate communication method, such as flash cards or a letter board, if speech is affected.
2. Instruct the patient to speak in a slow manner to avoid voice strain; refer to speech therapy, as needed.
3. Show the patient how to cup chin in hands during speech to support lower jaw and assist with speech.
4. Teach the patient to tilt head and to carry a handkerchief to manage secretions in public.
5. Encourage family participation in care.
6. Refer the patient to the Myasthenia Gravis Foundation of America (*www.myasthenia.org*) to meet other patients with the disease who lead productive lives.

Community and Home Care Considerations

1. Assess the home environment for physical and emotional stressors, such as uncomfortable temperature, draft, or loud noises.
2. Emphasize continued follow-up and compliance with treatment regimen.
3. Identify the need for additional home care services such as respiratory therapy, physical therapy, and nutritional services.
4. Assess the patient frequently for fluctuation in condition and inform caregivers that this is common.
5. Teach the patient and family how to use home suction in case of aspiration. Make sure everyone in household knows the Heimlich maneuver.

Patient Education and Health Maintenance

1. Instruct the patient and family regarding the symptoms of crisis. Intercurrent infection or treatment with certain drugs may worsen symptoms of MG temporarily. Mild exacerbation of weakness is possible in hot weather.

2. Review the peak times of medications and how to schedule activity for best results. For patients on anticholinesterase therapy:
   a. Stress accurate dosage and times; take anticholinesterase drugs 30 to 45 minutes before meals.
   b. Tell the patient not to skip medication.
   c. Instruct the patient to avoid taking medication with fruit, coffee, tomato juice, or other medications.
   d. Inform the patient of adverse effects such as GI distress.
3. Stress the importance of activity with scheduled rest periods before fatigue develops.
4. Teach the patient ways to prevent crisis and aggravation of symptoms.
   a. Avoid exposure to colds and other infections.
   b. Avoid excessive heat and cold.
   c. Inform the dentist of condition because use of procaine is not well tolerated.
   d. Avoid emotional upset; plan ahead to minimize stress.
5. Encourage the patient to wear a MedicAlert bracelet.
6. Stress the importance of adequate nutrition; instruct to chew food thoroughly and eat slowly.
7. Advise the patient to avoid alcohol, tonic water.
8. Refer the patient/family for more information to the Myasthenia Gravis Foundation of America (*www.myasthenia.org*).

Evaluation: Expected Outcomes

- Demonstrates optimal self-care in bathing, eating, toileting, and dressing without fatigue.
- Breathes effectively; cough is effective; suctioning own secretions; lungs clear.
- Visits with friends, participates in social activities, uses alternative method of communications.

TRAUMA

Traumatic Brain Injury

EVIDENCE BASE Carney, N., Totten, A. M., O'Reilly, C., et al. (2016). *Guidelines for the management of severe traumatic brain injury* (4th ed.). Campbell, CA: Brain Injury Foundation. 1–244. Available: *https://braintrauma.org/uploads/03/12/Guidelines_for_Management_of_Severe_TBI_4th_Edition.pdf*

Kinoshita, K. (2016). Traumatic brain injury: pathophysiology for neurocritical care. *Journal of Intensive Care, 4*(29), 2–10.

Traumatic brain injury (TBI) is the disruption of normal brain function due to trauma-related injury. TBI produces compromised neurologic function, resulting in focal or diffuse symptoms. Falls are the most common etiology of injury, followed by motor vehicle accidents. TBI is the leading cause of trauma-related deaths and accounts for 40% of trauma-related injuries. The goal of treatment is to prevent secondary brain injury by providing supportive care (see Chapter 35 for emergency management of TBI). There are limited evidence-based data to direct medical management. Current practice is based on clinical experience, as the only class I evidence is that steroids should not be used

Pathophysiology and Etiology

Types of Traumatic Brain Injury

1. Concussion—transient interruption in brain activity; no structural injury noted on radiographic studies.
2. Cerebral contusion—bruising of the brain with associated swelling. Coup injury is the site of initial trauma; the contrecoup injury is the site of rebound injury. Temporal and frontal lobes are common sites.
3. Intracerebral hematoma—bleeding into the brain tissue commonly associated with edema.
4. Epidural hematoma (EDH)—blood between the inner table of the skull and dura. Frequently associated with injury or laceration of the middle meningeal artery secondary to a temporal bone fracture. EDH is commonly associated with a lucid interval, followed by unresponsiveness.
5. Subdural hematoma—blood between the dura and arachnoid caused by venous bleeding; commonly associated with additional cerebral injuries: contusion or intracerebral hematoma.
6. Diffuse axonal injury (DAI) or shear injury—axonal tears within the white matter of the brain. Frequently occurs within the corpus callosum or brain stem and at the junction of the frontal/temporal poles. Associated with prolonged coma and poor prognosis.

Mechanism of Injury and Effects

1. Mechanism of injury is related to acceleration and deceleration of the brain (soft gelatin matter) within the skull (hard external surface with sharply edged internal surface). May be caused by blunt or penetrating injury.
2. The initial insult is the primary injury and the injury related to the sequela is the secondary injury.

Cellular changes (release of oxygen-free radicals and neurotransmitters, calcium loss, and increase in lactate acid) and systemic instability (hypotension, anemia, hypoxia, hypercarbia, hypovolemia) potentiate secondary injury.

3. Neurologic deficits result from primary brain injury (contusion, hematoma, DAI, or shearing of white matter) or secondary injury (ischemia and mass effect from hemorrhage and cerebral edema of surrounding brain tissue).
4. Second impact syndrome (SIS) occurs in repetitive concussion when there is insufficient time for the brain to recover from the previous injury. SIS is common in sports-related injuries and is associated with cerebral injury and cerebral edema, which can be severe.
5. Studies have shown that mild TBI with a positive CT scan is more indicative of moderate injury, resulting in a more pronounced neurobehavioral presentation and extended neurologic recovery time beyond the typical 3 months.
6. Coagulopathy may result from increased release of intracranial thromboplastin, causing elevation in PTT and fibrinogen levels, which in turn results in clotting dysfunction, from mild bleeding to disseminated intravascular coagulation.
7. Paroxysmal sympathetic hyperactivity (PSH) or sympathetic storming may result from uncontrolled release of sympathetic hormones spontaneously or in response to some stressor. PSH results in tachycardia, tachypnea, hyperthermia, diaphoresis, agitation, and dystonia.
8. DI—reduced secretion of ADH with excessive fluid and electrolyte loss through the kidneys due to edema or compression of the pituitary/hypothalamic region; may cause severe dehydration.
9. SIADH—oversecretion of ADH with normal to increased intravascular volume (hypervolemic state) and dilutional hyponatremia (see page 358).
10. Cerebral salt wasting—increase in urinary secretion of sodium accompanied by volume depletion (hypovolemic state) (see page 358).

Classification

See page 354 for GCS.

1. Mild (GCS 13 to 15, with loss of consciousness to 15 minutes).
2. Moderate (GCS 9 to 12, with loss of consciousness for up to 6 hours).
3. Severe (GCS 3 to 8, with loss of consciousness greater than 6 hours).

Associated Injuries: Extracranial Trauma

1. Facial trauma and skull fractures—occur in 20% of major TBI. Temporal skull is thinnest; frontal and occipital bones are the thickest.
    a. Linear fracture—fracture through entire thickness of bone that runs in linear pattern.
    b. Basilar skull fracture.
        i. Anterior fossa results in contusions around the eyes (raccoon eyes) and risk of rhinorrhea.
        ii. Posterior fossa results in contusions around the ears (Battle sign) and risk of otorrhea.

c. Depressed fracture—displacement of fracture past the inner table of the skull; risk of dural tear, CSF leak, and intracranial injury; may be closed or open.
d. Facial fractures—orbital (LeForte I to II), mandible, zygoma, maxillary, nasal fractures.

2. Vascular injuries—vertebral or carotid artery dissection.
3. Spine fracture with or without SCI.
4. Soft tissue injuries.

Clinical Manifestations

1. Disturbances in consciousness: confusion to coma.
2. Headache, vertigo.
3. Agitation, restlessness.
4. Respiratory irregularities.
5. Cognitive deficits (confusion, aphasia, reading difficulties, writing difficulties, acalculi [inability to perform simple arithmetic] and memory deficits such as retrograde and antegrade amnesia and difficulty learning new information).
6. Pupillary abnormalities.
7. Sudden onset of neurologic deficit.
8. Coma and coma syndromes.
9. Otorrhea may indicate leakage of CSF from ear (otorrhea) due to posterior fossa skull fracture; rhinorrhea may indicate leakage of CSF from nares (rhinorrhea) due to anterior fossa skull fracture.
10. Raccoon eyes and Battle sign indicate skull base fractures.
11. Episodes of altered LOC, tachycardia, tachypnea, hyperthermia, agitation due to sympathetic storming (aggravated stress response).
12. Abnormal bleeding due to coagulopathy.
13. Cardiac arrhythmias due to increased release of catecholamines in stress response.

Diagnostic Evaluation

1. CT scan to identify and localize lesions, edema, bleeding.
2. Skull and cervical spine films to identify fracture, displacement.
3. Neuropsychological tests during rehabilitation phase to determine extent of cognitive deficits.
4. MRI to identify and diagnose DAI (rarely performed because it does not alter medical management).
5. CBC, coagulation profile, electrolyte levels, serum osmolarity, ABG values, and other laboratory tests to monitor for complications and guide treatment.

Management

1. Airway—assess and maintain patent airway.
   a. Intubate for GCS less than 8 (comatose) or clinical signs of respiratory failure.

b. Placement of nasogastric tube with intubation to prevent aspiration.

2. Breathing—all intubated patients should have ventilatory support.
   a. Oxygen, as needed, to maintain PaO_2 greater than 100 mm Hg.
   b. Maintain $PaCO_2$ 35 to 45 mm Hg.
   c. Avoid use of hyperventilation.
   d. Consider early tracheostomy if anticipate intubation greater than 2 weeks.
3. Circulation—prevent hypotension.
   a. Maintain SBP above 90 mm Hg. This may be maintained with use of fluid or vasopressors.
   b. Maintain normovolemia.
   c. Treat symptomatic anemia with packed RBC.
   d. Treat symptomatic arrhythmias.
4. Management of increased ICP and cerebral edema.
5. Management of PSH with medications, such as oxycodone (opiate), propranolol (beta-adrenergic blocker), clonidine (alpha-adrenergic antagonist), dantrolene (muscle relaxant), and bromocriptine or amantadine (dopamine-receptor agonists). Response to medications varies.
6. Supportive care—rehabilitation services, skin care.
7. Nutritional support should be initiated within 3 to 5 days; 25 kcal/kg via nasogastric feeding tube. Conversion to gastrostomy tube if anticipated need for alternative feeds is greater than 1 to 2 weeks.
8. Antibiotics, as ordered, to prevent infection with open skull fractures or penetrating wounds.
9. Surgery to evacuate intracranial hematomas, debridement of penetrating wounds, elevation of skull fractures, or repair of CSF leaks.
10. Treatment of hypernatremia (due to DI, dehydration, diaphoresis) with fluid replacement, vasopressin therapy.
11. Treatment of hyponatremia.
    a. Cerebral salt wasting: monitor daily fluid status, fluid administration, oral salt replacement, and IV saline 0.9% or 3% (250 to 500 mL over 3 to 5 hours).
    b. SIADH: monitor daily fluid status, fluid restriction, oral salt replacement, IV saline 2% or 3% bolus over 3 to 5 hours.
12. Seizure prophylaxis is not recommended to prevent posttraumatic seizures, as it has been shown to inhibit cognitive recovery; however, prophylactic antiepileptics are ordered in some cases; duration is 7 days.
    a. If seizure activity is witnessed and there is associated temporal lobe injury or penetrating injuries, antiepileptics are recommended.
    b. Given IV for rapid loading and should be converted to enteric route. Phenytoin, fosphenytoin sodium, and levetiracetam are commonly used. Dilantin levels should be monitored for accurate dosing. (Note: there are no evidence-based data to support the use of levetiracetam for prophylaxis.)

Complications

1. Infections: systemic (respiratory, urinary), neurologic (meningitis, ventriculitis).
2. Increased ICP, hydrocephalus, brain herniation.
3. Posttraumatic seizures and seizure disorder.
4. Permanent neurologic deficits: cognitive, motor, sensory, speech.
5. Neurobehavioral alterations: impulsivity, uninhibited aggression, emotional lability.
6. Persistent PSH.
7. Disseminated intravascular coagulation.
8. DI, SIADH, cerebral salt wasting.
9. Death.

Nursing Assessment

1. Monitor for signs of increased ICP—altered LOC, abnormal pupil responses, vomiting, increased pulse pressure, bradycardia, hyperthermia.
2. Monitor for signs of PSH—altered LOC, diaphoresis, tachycardia, tachypnea, hypertension, hyperthermia, agitation, and dystonia. PSH is generally seen in severe TBI (GCS 3 to 8) or minimally responsive patients.
3. Monitor cardiac status for hypotension and arrhythmias (bradycardia, elevated T waves, premature ventricular contractions, premature atrial contractions, and sinus arrhythmias)—common and frequently asymptomatic. Tachycardia with hypotension is indicative of hypovolemia; patient should be evaluated for additional source of blood loss.
4. Be alert for DI—excessive urine output, dilute urine (specific gravity less than 1.005), hypernatremia.
5. Be alert for hyponatremia and assess etiology (SIADH or cerebral salt wasting); see page 358.
6. Monitor laboratory findings and report abnormal values:
   a. Abnormal PTT, PT, and fibrinogen levels indicating coagulopathy.
   b. Electrolyte imbalance—alterations in serum potassium (hypokalemia) and sodium (hypernatremia/hyponatremia) levels are common.
   c. Anemia—related to additional trauma or may be dilutional.
   d. Elevated WBC count—indicating infection related to trauma or invasive procedures.
   e. Hypoxia or hypercarbia.
7. Perform CN, motor, sensory, and reflex assessment.
8. Assess for behavior that warrants potential for injury to self or others.

NURSING ALERT Regard every patient who is unresponsive with a brain injury as having a potential spinal cord injury. Cervical collar and spine precautions should be maintained until spinal fracture

has been ruled out. A significant number of patients are under the influence of alcohol at the time of injury, which may mask the nature and severity of the injury.

Nursing Diagnoses

- Ineffective Cerebral Tissue Perfusion related to increased ICP.
- Ineffective Breathing Pattern related to increased ICP or brain stem injury.
- Imbalanced Nutrition: Less Than Body Requirements related to compromised neurologic function and stress of injury.
- Impaired Environmental Interpretation Syndrome related to physiology of brain injury.
- Risk for Injury related to altered thought processes.
- Compromised Family Coping related to unpredictability of outcome.

Nursing Interventions

Maintaining Adequate Cerebral Perfusion

1. Maintain a patent airway.
2. Monitor ICP, as ordered (see page 359).
3. Monitor cerebral oxygenation, temperature, or neurochemicals, as ordered. Provide oxygen therapy to maintain PaO_2 above 100 and carbon dioxide within normal range.
4. Maintain SBP above 90 to enhance cerebral perfusion and administer treatment for arrhythmias if the patient is symptomatic. Evaluate for source of blood loss if the patient is tachycardic and hypotensive.
5. Monitor LOC, CN function, and motor and sensory function as per GCS or neurologic flow sheet; identify emerging trends in neurologic function; and communicate findings to medical staff.
6. If the patient has severe TBI, monitor for signs of PSH (abnormal stress response) and identify triggers and effective treatment modalities. Institute nursing measures that have been found to be helpful, such as maintaining normothermia, pretreating before known trigger, applying cool compress to forehead, and providing relaxing music.
7. Monitor response to pharmacologic therapy, including antiepileptic levels, as directed.
8. Monitor laboratory data, CSF cultures, and Gram stains, if applicable, and institute prompt antibiotic therapy, as directed.
9. Monitor for hypernatremia and administer fluid replacement, as directed. If due to DI, vasopressin may be utilized.
10. Monitor for hyponatremia. Determine if hyponatremia is related to SIADH or cerebral salt wasting. Administer fluids/restrict fluids and administer oral or IV salt replacement, as directed. Administer 250 to 500 mL 2% or 3% saline solution over 3 to 5 hours. Central venous access is required for 3% saline to prevent damage to peripheral vein wall.
11. Monitor coagulation panel and replace clotting factors at room temperature, as directed.
12. Assess dressings and drainage tubes after surgery for patency, security, and characteristics of drainage.

13. Institute measures to minimize increased ICP, ischemic changes, cerebral edema, seizures, or neurovascular compromise, such as careful positioning, to avoid flexing head, reducing hip flexion (can reduce venous drainage, causing congestion), and spreading out care evenly over 24-hour period.

NURSING ALERT PSH places the patient at high risk for secondary brain injury, cardiac abnormalities, weight loss, skin breakdown, and infection. Be alert to triggers (suctioning, turning, hyperthermia, infection, auditory stimuli) and treat promptly to control symptoms.

NURSING ALERT Severe states of hypernatremia and hyponatremia can cause further neurologic compromise (seizures, nausea, confusion, irritability/agitation, coma). Close monitoring of laboratory values is indicated to evaluate trends and maintain normal range. Hypernatremia and hyponatremia should not be reversed quickly because the rapid change can create rebound cerebral edema and be detrimental to the patient. Rapid increase in serum sodium level can cause central pontine myelinolysis and results in severe damage of myelin sheath of white matter in pons.

Maintaining Respiration

1. Monitor respiratory rate, depth, and pattern of respirations; report any abnormal pattern, such as Cheyne-Stokes respirations or periods of apnea.
2. Assist with intubation and ventilatory assistance, if needed.
3. Obtain frequent ABG values to maintain PaO_2 greater than 100 mm Hg and $PaCO_2$ 35 to 45 mm Hg.
4. Positive end-expiratory pressure (PEEP) (5 to 8 cm) is felt to be physiological and not detrimental; however, excessive PEEP can create increases in intrathoracic pressure, diminish venous drainage, reduce mean arterial pressure (MAP), and increase ICP.
5. Turn the patient every 2 hours and assist with coughing and deep breathing.
6. Suction the patient, as needed.

Meeting Nutritional Needs

1. Nutritional support should be initiated by day 5 and should provide 140% of energy requirements (100% in paralyzed patient), with 15% in the form of protein. Supplements should provide 25 kcal/kg.
   a. Continuous enteric feedings.
      i. Elevate the head of the bed during feedings.
      ii. Check residuals to prevent aspiration.
      iii. Monitor for diarrhea.
      iv. Transgastric jejunal feedings reduce the risk of ventilator associate pneumonia.
   b. Consider IV hyperalimentation—for patients unable to tolerate nasogastric feedings.

c. Oral feeding—started when adequate swallowing mechanism is demonstrated.

2. Administer H_2-blocking agents to prevent gastric ulceration and hemorrhage from gastric acid hypersecretion.
3. Consult with dietitian to provide adequate calories and nitrogen supplement.
4. Monitor glucose levels frequently, utilizing fingerstick samples and glucometer. Insulin (IV drip/sliding scale) may be required to regulate serum glucose levels within a normal range to avoid hypoglycemia and hyperglycemia, which worsens the effects of secondary brain injury.
5. Perform bedside dysphagia screen to evaluate swallow function before initiation of oral foods. Consult speech therapist for bedside or radiographic swallow study if patient fails swallow screen or appears at risk for dysphagia. Assessment of swallowing function decreases risk of aspiration. Speech therapy is essential for retraining and developing adaptive techniques.

NURSING ALERT Caloric needs of a patient with a head injury increase by 100% to 200%. Consult your dietitian to institute nutritional support within the first 5 days after injury to support the recovery process. Weight loss is generally in the form of muscle loss and can be as much as 25 to 30 pounds (11.3 to 13.6 kg).

Promoting Cognitive Function

1. Periodically assess the patient's LOC and compare to baseline.
2. Be aware of the patient's cognitive alteration and adjust interaction and environment accordingly.
3. Provide meaningful stimulation using all senses—visual, olfactory, gustatory, acoustic, and tactile.
4. Observe the patient for fatigue or restlessness from overstimulation.
5. Involve the family in sensory stimulation program to maximize its effectiveness.
6. Decrease environmental stimuli when the patient is in agitated state.
7. Reorient to surroundings using repetition, verbal and visual cues, and memory aids; routinely orient the patient after awakening.
8. Use pictures of family members, clock, and calendar as outlined by occupational and speech therapist.
9. Encourage the family to provide items from home to increase sense of identity and security.
10. Anticipate the need for additional help with toileting, eating, and performing ADL due to cognitive impairment.
11. Break down ADL into simple steps that patient can progressively take part in.
12. Structure the environment and care activities to minimize distraction and provide consistency.
13. Identify and maintain usual patterns of behavior—sleep, medication use, elimination, food intake, and self-care routine.
14. Refer the patient for cognitive retraining, if appropriate.

Preventing Injury

1. Instruct the family regarding the behavioral phases of recovery from brain injury, such as restlessness and combativeness.
2. Investigate for physical sources of restlessness, such as uncomfortable position, signs of UTI, or pressure ulcer development.
3. Reassure the patient and family during periods of agitation and irrational behavior.
4. Pad side rails and wrap hands in mitts if patient is agitated. Maintain constant vigilance and avoid restraints, if possible.
5. Keep environmental stimuli to a minimum to avoid confusion and agitation. Veil beds can be useful in reducing injury in the agitated patient.
6. Provide adequate light if the patient is hallucinating.
7. Avoid sedatives to avoid medication-induced confusion and altered states of cognition.

Strengthening Family Coping

1. Refer the family to community support services, such as respite care, faith-based groups, city and state social services, and resources on the Internet. Suggest the Brain Injury Association of America (*www.biausa.org*) for further information.
2. Assist the family members to establish stress management techniques that can be integrated into their lifestyle, such as ventilation of feelings, use of respite care, relaxation techniques.
3. Consult with social worker or psychologist to assist the family in adjusting to patient's permanent neurologic deficits.
4. Help the family assist the patient to recognize current progress and not focus on limitations.

Community and Home Care Considerations

1. Observe for signs of postconcussion syndrome (PCS), which include headache, decreased concentration, irritability, dizziness, insomnia, restlessness, diminished memory, anxiety, easy fatigability, and alcohol intolerance.
2. Be aware that persistence of these symptoms can interfere with relationships and employability of the patient.
3. Encourage the patient and family to report these symptoms and obtain additional support and counseling, as needed. PCS may persist as long as 2 years.
4. Act as liaison to coordinate all home care services the patient will need while keeping in touch with the patient's primary care provider, neurologist, and neurosurgeon.
5. Provide the necessary education to caregivers in tube feedings, positioning, ROM exercises, and so forth.
6. Make sure that coaches and parents from community recreation programs and schools are familiar with and follow guidelines for sports-related concussion (see Table 15-7).

Table 15-7 American Academy of Neurology Guidelines for Sports-Related Concussion

SEVERITY	RECOMMENDATIONS
Grade 1	
Transient confusion without loss of consciousness and resolution of symptoms within 15 minutes	• Removal from game and only returned to the game if remaining asymptomatic after 15 minutes • If second grade 1 concussion occurs, removal from sports activity until asymptomatic for 1 week
Grade 2	
Transient confusion without loss of consciousness and symptoms persisting longer than 15 minutes	• Removal from sporting event and further workup if symptoms do not resolve in 1 week • No sporting activity for 1 week • If grade 2 occurs after a grade 1 concussion, removal from sporting event and no sporting activities for 2 weeks
Grade 3	
Loss of consciousness	• Removal from sporting event • Return to sporting activities if asymptomatic for 1 week (brief loss of consciousness) • Return to sporting activities if asymptomatic for 2 weeks (prolonged loss of consciousness) • Unconsciousness with neurologic findings should be transported to nearest emergency for full evaluation • Removal from sporting activity for 1 year and discouraged from future participation in contact sports if any structural findings on computed tomography scan or magnetic resonance imaging

Patient Education and Health Maintenance

1. Review the signs of increased ICP with the family.
2. Reinforce the lability of cognitive, language, and physical functioning of the person with brain injury and the lengthy recovery period.
3. Teach the family techniques to calm the agitated patient.
   a. Therapeutic use of touch, massage, and music.
   b. Elimination of distractions (television, radio, alarms, crowds).
   c. Provide one-on-one communication.
   d. Distract patients.

Evaluation: Expected Outcomes

- No signs of increased ICP.
- Respirations—24 breaths/minute, regular.
- Tube feedings tolerated well without residual.
- Oriented to person, place, and time.
- Less agitated; side rails maintained.
- Family reports using respite care.

Spinal Cord Injury

EVIDENCE BASE Fehlings, M. G., Tetreault, L. A., Wilson, J. R., et al. (2017). A Clinical Practice Guideline for the Management of Acute Spinal Cord Injury: Introduction, Rationale, and Scope. *Global Spine Journal*, 7(3S), 84S–94S.

Spinal cord injury (SCI) is a traumatic injury to the spinal cord that may vary from a mild cord concussion with transient numbness to immediate and complete tetraplegia. The most common sites are the cervical areas C5, C6, and C7, and the junction of the thoracic and lumbar vertebrae, T12 and L1. Injury to the spinal cord may result in loss of function below the level of cord injury (see Figure 15-10). SCI requires comprehensive and specialized care. The Model Spinal Cord Injury System is a network of comprehensive, federally funded, regional SCI centers in the United States. The Department of Veterans Affairs operates 23 SCI centers. (Also see Chapter 35 for emergency management of SCI.)

Figure 15-10. Levels of spinal cord innervation.

Pathophysiology and Etiology

1. The estimated annual incidence of SCI is about 11,000 new cases per year, and the prevalence is approximately 35 cases per million people in the United States. The mean age is 33 and approximately 80% are males. The primary etiologies are vehicular crashes (39%), falls (29.5%), violence (14.4%), and sports-related injuries (8.4%). Most injuries result in tetraplegia; 50% are complete. (A complete SCI is absence of motor and sensory function at the lowest sacral segment affected; see below for a description of incomplete SCI.) About 90% of these patients are discharged to noninstitutional settings.
2. The life expectancy for an individual with SCI is lower (80% to 85%) than that of a person without SCI. The leading causes of death are pneumonia, emboli, and septicemia.
3. SCI may result from trauma, vascular disorders, infectious conditions, tumor, and other insults.
4. SCI can affect upper motor neurons (UMNs) or LMNs. UMNs extend from the motor strip in the cerebral cortex of the brain through the corticospinal tract in the spinal cord, where they synapse with interneurons in the ventral horn. LMNs originate in the ventral horn, exit the spinal cord at each segment, and extend to the neuromuscular junction. Each LMN innervates 10 to 2,000 muscle fibers.
   a. Spasticity results from injury above T12 or a UMN lesion (intact reflex arch below level of inury).
   b. Flaccidity/reflex loss results from injury at L1 or a LMN injury.

GERONTOLOGIC ALERT Older patients are at greater risk for altered glucose metabolism, loss of bone minerals leading to fractures, musculoskeletal pain and weakness, and greater loss of function with spinal cord injury.

Clinical Manifestations

1. Patients with tetraplegia have damage to the cervical segments of nerves (C1–C8) in the spinal canal. Function may be impaired in the upper extremities, trunk, pelvic organs, and lower extremities.
2. Patients with paraplegia have damage to the thoracic, lumbar, or sacral segments of nerves in the spinal cord. The arms are unaffected, but function may be impaired in the trunk, pelvic organs, and lower extremities.
3. The International Standards for Neurological Classification of Spinal Cord Injury, promoted by the American Spinal Injury Association (ASIA), are used (available: *http://asia-spinalinjury.org/wp-ontent/uploads/2016/02/International_Stds_Diagram_Worksheet.pdf*). The ASIA Impairment Scale is based on completeness of injury and motor/sensory function.
   ASIA A—complete; absent sensory and motor function in the sacral segments S4–S5.
   ASIA B—incomplete; intact sensory but absent motor function below the neurologic level of injury (LOI) and includes level S4–S5.

ASIA C—incomplete; intact motor function distal to neurologic LOI, and more than half of key muscles distal to LOI have muscle grade less than 3.

ASIA D—incomplete; intact motor function distal to neurologic LOI, and more than half of key muscles distal to LOI have muscle grade greater than or equal to 3.

ASIA E—normal; intact motor and sensory function.

4. Sacral sensation is intact if there is deep sensation and sensation at the anal mucocutaneous junction; sacral motor is intact if the patient has voluntary contraction of the external anal sphincter with digital stimulation.
5. The zone of partial preservation (ZPP) indicates areas of partial sensory/motor innervation below the LOI; the ZPP is applicable only to complete injuries.
6. The neurologic level of injury is the lowest neural level with normal sensory and motor function on both sides of the body. When describing the LOI, the neurologic level is noted unless stated specifically that the skeletal LOI, which is the level of greatest vertebral damage, is being discussed.
7. Various syndromes (incomplete injuries) may characterize the clinical presentation (see Table 15-8).
8. Sensation function (eg, sensitivity of pinprick/light touch) is tested on each of the 28 dermatomes on both sides of the body. The following grading is suggested: 0 = Absent; 1 = Impaired; 2 = Normal. The external anal sphincter should also be tested (sensory incomplete if sensate).
9. Motor function is tested on each of the 10 paired myotomes on both sides of the body. The following grading is suggested: 0 = Total paralysis; 1 = Contraction visible or palpable; 2 = Active movements and full ROM without gravity; 3 = Active movement and full ROM against gravity; 4 = Active movement and full ROM with moderate resistance; 5 = Normal motor with active movement and full ROM against full resistance. The external anal sphincter tone should also be tested (motor incomplete if contraction).
10. Most recovery occurs within 6 months of injury; patients with incomplete injuries have greater recovery than patients with complete injuries.
11. Instability exists when ligamentous structures and vertebra cannot protect the vulnerable spinal cord and movement can further damage the injured spinal cord; stability exists when ligamentous structures and vertebra can protect the spinal cord from further neurologic injury.
12. Vertebral fractures may be simple, compressed or wedge, dislocated (vertebra overrides another vertebra), subluxed (vertebra partially dislocated over another vertebrae), comminuted (vertebrae shattered), or teardrop (vertebrae chipped). Jefferson fractures, which may occur with head injuries, involve the C1 level.

Table 15-8 Incomplete Spinal Cord Clinical Syndromes

SYNDROME	AFFECTED SITE	DEFICIT	PRESERVATION
Central cord	Central cervical spinal cord	More motor deficit in upper extremities than lower extremities caused by medial damage of corticospinal tract	Sacral sensory; lower extremities have better motor function than upper extremities because of lateral sparing of corticospinal tract
Brown-Sequard	Hemisection of spinal cord	Ipsilateral motor function and fine touch, vibration, and proprioception (posterior tract); contralateral sensory function pain and temperature (spinothalamic tract)	Ipsilateral sensory function of pain and temperature (spinothalamic tract); contralateral motor function, fine touch, vibration, and proprioception (posterior tract)
Anterior cord	Main anterior spinal artery of anterior spinal cord affecting anterior two thirds of spinal cord	Variable motor deficit; variable sensory deficit of pain and temperature (spinothalamic tract)	Posterior one third of spinal cord (posterior spinal artery); sensory function of proprioception, light touch, vibration (posterior tract)
Conus medullaris	Conus and lumbar nerve roots in spinal cord	Variable motor deficit; bowel, bladder, and lower-extremity reflexes (flaccid)	Lesions of proximal conus may be reflexic (eg, butocavernosa, micturition)
	Lumbosacral nerve roots in spinal cord (distal from conus medullaris)	Variable motor deficit; bowel, bladder, and lower-extremity reflexes (flaccid)	Lesions proximal to level of injury may be reflexic (eg, bulbocavernosus, micturition)

Diagnostic Evaluation

1. CT of spine—to detect boney injury and dislocation
2. MRI of spine—to detect soft tissue injury, hemorrhage, edema, bony injury; syringomyelia (cystic degeneration in spinal cord) may present as cord compression, syrinx (cavity) at the fracture site, and kyphosis at fracture site.
3. Electrophysiologic monitoring to determine function of neural pathways.
4. Urodynamic studies may include urine flow to detect bladder outlet obstruction and/or impaired bladder contractility; cystometrogram to determine bladder sensation, compliance, and capacity; and sphincter EMG and other studies. The gold standard in urodynamics is to measure bladder and urethral pressure under fluoroscopy monitoring.
5. If DVT or pulmonary emboli are suspected, an ultrasound of the lower extremity or ventilation/perfusion scan is performed.
6. Heterotopic ossification may be diagnosed in the inflammatory stages using ultrasound. Alkaline phosphatase and ESR are typically elevated.
7. Nutritional status should be assessed using nutritional history, anthropometric measurements, prealbumin (half-life 12 to 36 hours), and transferrin (half-life 6 to 10 days).
8. Total lymphocyte count and creatinine height index are also used to establish nutritional risk.

Management

Requires a multidisciplinary approach because of multiple-system involvement and the psychosocial aspects of catastrophic injuries.

NURSING ALERT Patients sustaining an SCI have better outcomes when treated by a multidisciplinary SCI team. Once the patient is stabilized, the option of transferring the patient to an SCI facility should be provided to the patient and/or family.

Immediately After Trauma (Less Than 1 Hour)

1. Immobilization with rigid cervical collar, sandbags, and rigid spine board to transport from the field to acute care facility. Monitor for respiratory failure, hypotension, and/or bradycardia and treat appropriately.

Acute Phase (1 to 24 Hours)

1. Maintenance of pulmonary and cardiovascular stability.
   a. Intubation and mechanical ventilation, if needed.
   b. Vasopressors to maintain adequate perfusion to sustain mean MAP greater than 85 mm Hg.
   c. Medical stabilization before spinal stabilization and decompression.
2. Spinal cord immobilization—use of skeletal tongs.
   a. Crutchfield and Vinke tongs require predrilled holes in the skull under local anesthesia; Gardner-Wells and Heifitz tongs do not.
   b. Weight is added to traction gradually to reduce the vertebral fracture; weight maintained at a level to ensure vertebral alignment. Lateral spine films are taken after the addition of weight to assess spinal alignment.
3. Rigid kinetic turning bed can be used to immobilize patients with thoracic and lumbar injuries.
4. Surgical interventions are considered when the patient has vertebral instability that may result in further neurologic damage; an injury that is incomplete at onset may become complete if instability exists. The objectives are to remove all of the bony and soft tissues that are compressing the spinal cord, thereby minimizing the possibility of deteriorating neurologic status, and stabilize the vertebra surrounding the spinal cord so that rehabilitation may begin as soon as possible. Goals of treatment of the spinal fractures are aimed at protecting the neural elements and preventing deformity and instability.
   a. Surgical Timing: current practice is early surgical intervention (less than 24 hours), though there is no class I evidence that clearly defines the timing of surgery. STATSCIS (Surgical Treatment of Acute Spinal Cord Injury Study), a prospective, nonrandomized clinical trial, revealed that early surgical decompression (within 24 hours) is safe, with 19.8% demonstrating neurologic improvement (greater than 2 grade improvement AIS) compared to 8.8% in the late decompressive group (2012).

EVIDENCE BASE Fehlings M. G., Vaccaro, A., Wilson, J., Singh, A., Cadotte, D. W., Harrop, J. S., …Rampersaud, R. (2012). Early versus delayed decompression for traumatic cervical spinal cord injury: Results of the Surgical Timing in Acute Spinal Cord Injury Study (STASCIS). *PLoS One, 7*(2), e32037. Available: *http://dx.doi.org/10.1371/journal.pone.0032037*

---

   b. Decompression, typically using the anterior approach in cervical instances, may be accomplished by removing the bony structures and soft tissues (eg, fusion, decompression laminectomy). Realignment of the soft tissues and vertebral column is required.

c. Stabilization, typically done using the posterior approach, involves the use of wires, bone grafts, plates, screws, and other fixation devices to prevent movement at the damaged bony site.

5. Methylprednisolone sodium. (Solu-Medrol) is not recommended (class I evidence) in SCI related to high rate of significant complications
   a. Higher rate of hyperglycemia, GI hemorrhage, wound infections, and higher mortality in concomitant TBI (class I evidence).
   b. Higher rate of pneumonia, steroid-induced myelopathy (class II evidence).
6. Management of neurogenic bladder—Foley catheter.
7. Pressure ulcer prevention—pressure reduction mattress or kinetic turning frame.
8. Prevention of DVT and its sequelae is an important aspect of the treatment of patients who have sustained SCI because of the high risk of thromboembolic complications.
   a. Class I, II, and III evidence support the utilization of external device in conjunction with LMWH/adjusted-dose heparin within 1 to 2 days post injury.

EVIDENCE BASE Hadley, M. N., Walters, B. C., Aarabi, B., Dhall, S. S., Gelb, D. E., Harrigan, M. R., et al. (2013). Guidelines for the management of acute cervical spine and spinal cord injuries. *Neurosurgery, 72*(2), 1–94.

Subacute Phase (within 1 Week)

1. Stiff orthosis is utilized for external stabilization of cervical fractures. Devices include the Halo brace, Minerva collar, extended Philadelphia collar, and fabricated orthosis. Device is selected based on the type of fracture and extent of instability. Average length of time in a halo brace is 12 weeks, followed by a Philadelphia collar for 4 weeks. Halo brace is used for cervical injuries (see Figure 15-11).
   a. Graphite rings are MRI compatible, lightweight, and radiolucent.
   b. Some halos are now open posteriorly, which reduces the incidence of cervical fracture displacement.
   c. The ring is attached to stainless steel pins (two anterior pins, two posterior pins) and attached to a vest by four connecting rods (also MRI compatible and radiolucent).
   d. Torque wrenches connect the rods to the ring and vest; pressures are typically 8 inches/pound for pins (2 to 5 inches/pound in children) and locking bolts are 28 inches/pound.
   e. Pins and locking bolts must be retightened approximately 24 to 48 hours after placement and periodically thereafter.
   f. Pin sites should be cleaned daily with half-strength hydrogen peroxide or soap and water.
2. H_2-receptor blockers to prevent gastric irritation and hemorrhage.
3. Early mobilization and passive exercise as soon as patient is surgically and medically stable.
4. Hyperalimentation, if unable to tolerate enteric feeds, to retard negative nitrogen balance.
5. Interventions to help prevent thromboembolism include compression hose, compression boots, range of

motion, adjusted-dose heparin, or LMWH.

a. Prior to applying mechanical compression, tests to exclude the presence of lower-extremity DVT should be performed if thromboprophylaxis has been delayed for more than 72 hours after injury.

b. Vena cava filters are not recommended, though may be utilized in patients who have not achieved success with anticoagulant prophylaxis or who have a contraindication to anticoagulation. They are not a substitute for thromboprophylaxis due to morbidity related to DVT (eg, postphlebitic syndrome) and propagation of vena caval embolism.

Figure 15-11. Halo brace. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Chronic Phase (Beyond 1 Week)

1. Segmental instrumentation systems are used in conjunction with a body jacket and are used for patients with thoracolumbar injuries.
2. To prevent thrombophlebitis in the chronic phase, compression boots should be continued for 2 weeks; anticoagulants should also be continued based on risk category.
    a. Minimum of 8 weeks from time of injury for those with incomplete or complete motor injury with no additional risk factors.
    b. For those with complete motor injury with additional risk factors, anticoagulants should be continued for 12 weeks.
3. Management of complications may include treatment of infections with antibiotics; treatment of respiratory compromise with phrenic nerve pacing, mechanical ventilation, and other methods; pressure ulcer treatment; management of heterotopic ossification with calcium chelators and anti-inflammatory agents; drainage of syringomyelia; management of spasticity with oral or intrathecal antispasmodics, surgical procedure, or spinal cord stimulation; and management of central neuropathic pain with antiepileptics, minor sedatives, antidepressants, nerve block, or surgical procedure.
4. Spasticity should be managed by
    a. Maintaining calm, stress-free environment.
    b. Allowing ample time for activities such as positioning and transferring.
    c. Performing joint ROM exercises with slow, smooth movements.
    d. Avoiding temperature extremes.
    e. Administering muscle relaxants, such as baclofen (via pump or orally), diazepam, and dantrolene, as prescribed.
    f. Botulism toxin injections can be utilized.
    g. Clonidine has been used to manage spasticity and facilitate walking in patients with incomplete injuries.
5. External sphincterotomy may be used for detrusor–sphincter dyssynergia. Other options include urethral stents and balloon dilatation.
6. Resistive inspiratory muscle training shows promise in promoting respiratory muscle strength and reducing sleep-induced breathing disturbances in patients with tetraplegia. Resistive training devices are used to perform respiratory maneuvers at scheduled times during the day.
7. Rehabilitation includes medical and psychosocial support, physical therapy, urologic evaluation, occupational therapy, and multiple other interventions to facilitate an increased level of function and community participation.

Complications

1. Spinal shock lasting a few hours to a few weeks noted by loss of all reflex, motor, sensory, and autonomic activity below the level of the lesion.
2. Respiratory arrest, pneumonia, atelectasis requiring mechanical ventilation with cervical injury.
3. Cardiac arrest may result from initial trauma, worsening of initial injury from edema, concomitant

injuries, and other illnesses.

4. Thromboembolic complications—in 15% of patients.
5. Infections—respiratory, urinary, pressure ulcers, sepsis.
6. Autonomic dysreflexia—exaggerated autonomic response to stimuli below the level of the lesion in patients with lesions at or above T_6 is a medical emergency and can result in dangerous elevation of BP.
7. Autonomic dysfunction resulting in orthostatic hypotension, thermodysregulation, and vasomotor abnormalities.
8. Urologic—bladder storage pressure greater than 35 to 40 cm due to neurogenic bladder may result in renal deterioration; SCI patients who have indwelling urinary catheters are at increased risk of bladder cancer.
9. Paralytic ileus—common in subacute and acute stage.
10. Heterotopic ossification—bony overgrowth that occurs below the level of injury any time after SCI.
11. Syringomyelia—cystic formation in the spinal cord may occur any time after SCI.
12. Depression—occurs in 25% of men and 47% of women with SCI.
13. Pressure ulcers may occur in up to 35% of patients with SCI.
14. Spasticity may result in contractures.
15. Amenorrhea occurs in 60% of women with SCI, usually temporary.
16. Neuropathic pain occurs in 34% to 94% of patients with SCI.
17. Complications can arise from the halo apparatus in persons with cervical injuries.
    a. Pin/ring loosening—can result from bone reabsorption. Signs and symptoms include increased pain, altered pin position, and drainage.
    b. Infection—can result from bacterial infections. Signs and symptoms include drainage and erythema.
    c. Skull/dural penetration—can result from inner table penetration, usually due to a fall. Signs and symptoms include a headache, visual disturbances, and CSF leak from the pin site.
    d. Dysphagia and respiratory problems—can result from halo or vest positioning. Signs and symptoms include difficulty swallowing and respiratory distress.

Nursing Assessment

1. Assess cardiopulmonary status and vital signs to help determine degree of autonomic dysfunction, especially in patients with tetraplegia.
2. Determine LOC and cognitive function indicating TBI or other pathology.
3. Perform frequent motor and sensory assessment of trunk and extremities—extent of deficits may increase because of edema and hemorrhage. Later, increasing neurologic deficits and pain may indicate development of syringomyelia.
4. Note signs and symptoms of spinal shock, such as flaccid paralysis, urine retention, absent reflexes.
5. Assess bowel and bladder function.
6. Assess quality, location, and severity of pain.

7. Perform psychosocial assessment to evaluate motivation, support network, financial, or other problems.
8. Assess for indicators of powerlessness, including verbal expression of no control over situation, depression, nonparticipation, dependence on others, passivity.

Nursing Diagnoses

- Ineffective Breathing Pattern related to paralysis of respiratory muscles or diaphragm.
- Impaired Physical Mobility related to motor dysfunction.
- Risk for Impaired Skin Integrity related to immobility and sensory deficit.
- Urinary Retention related to neurogenic bladder.
- Constipation or Bowel Incontinence related to neurogenic bowel.
- Risk for Injury related to autonomic dysreflexia and orthostatic hypotension.
- Powerlessness related to loss of function, long rehabilitation, depression.
- Sexual Dysfunction related to erectile dysfunction and fertility changes.
- Chronic Pain related to neurogenic changes.

Nursing Interventions

Attaining an Adequate Breathing Pattern

1. For patients with high-level lesions, continuously monitor respirations and maintain a patent airway. Be prepared to intubate if respiratory fatigue or arrest occurs.
2. Frequently assess cough and vital capacity. Teach effective coughing, if patient is able (see Box 15-5).
3. Provide adequate fluids and humidification of inspired air to loosen secretions.
4. Suction, as needed; observe vagal response (bradycardia—should be temporary).
5. When appropriate, implement chest physiotherapy regimen to assist pulmonary drainage and prevent infection.
6. Monitor results of ABG values, chest x-ray, and sputum cultures.
7. Tape halo wrench to body jacket or halo traction in the event the jacket must be removed for basic or advanced life support or respiratory distress.

BOX 15-5 Assisted Coughing

Many patients with tetraplegia have an impairment of the diaphragmatic and intercostal muscles. The result is a weak or ineffective cough. To increase the mechanical effectiveness of the patient's cough, perform or teach the assisted cough technique.

1. Place the patient in supine, low semi-Fowler's position.
2. Place the heels of your hands on the costophrenic angle of the patient's rib cage.
3. With the patient's head turned away, ask the patient to hyperventilate and exhale once or twice. Allow your hands to move with the patient.
4. During the next breath, ask the patient to take a deep breath and cough while exhaling.

5. As the patient coughs, thrust your hands down and in (inferiorly and medially) to add power to the diaphragm during exhalation.
6. Allow one or two normal breaths and repeat the procedure.

NURSING ALERT Incorrect hand placement may cause injury to the internal organs, ribs, and xiphoid process.

Promoting Mobility

1. Place the patient on firm bed until spinal cord stabilization. After stabilization, turn every 2 hours on a pressure reduction surface, ensuring good alignment. Specialized beds, such as a kinetic turning bed, may be used.
2. Logroll the patient with unstable SCI.
3. Perform ROM exercises to prevent contractures and maintain rehabilitation potential.
4. Monitor BP with position change in the patient with lesions above midthoracic area to prevent orthostatic hypotension.
5. Encourage physical therapy and practicing of exercises as tolerated. Functional electrical stimulation may facilitate independent standing and walking.
6. Encourage weight-bearing activity to prevent osteoporosis and risk of kidney stones.

NURSING ALERT Never attempt to reposition the patient by grasping a halo or any other stabilization device. This may result in severe damage to the brain, head, or vertebra.

Protecting Skin Integrity

1. Pay special attention to pressure points when repositioning patient. Seating and mobility requirements must be determined.
2. Obtain pressure relief mattress and appropriate wheelchair and cushion.
3. Inspect for pressure ulcer development daily over bony prominences, including the back of the head, ears, trunk, heels, and elbows. Observe under stabilization devices for pressure areas, particularly on the scapulae. Use a risk assessment tool to determine risk of developing pressure ulcer.
4. Keep the skin clean, dry, and well lubricated.
5. Turn the patient a minimum of every 2 hours and instruct him to perform wheelchair weight shifts every 15 minutes. Place the patient in prone position at intervals, unless contraindicated.
6. Institute treatment for pressure ulcers immediately and relieve pressure to promote healing.

Promoting Urinary Elimination

1. Consider use of intermittent catheterization, typically beginning every 4 hours, as an alternative to an indwelling catheter.
2. If the patient has an upper motor neuron lesion (above L1) and no indwelling catheter, promote reflex voiding by tapping the bladder, gently pulling the patient's pubic hair, or stroking the patient's inner thigh.
3. If the patient has a lower motor neuron lesion (L1 or below) and no indwelling catheter, promote voiding by using a bladder Crede method by gently compressing the suprapubic area to promote voiding.
4. Encourage fluid intake of 3,000 to 4,000 mL of fluid per day (2,000 mL/day if intermittent catheterization is used) to prevent infection and urinary calculi. Space fluids out over 24-hour period to avoid bladder overdistention. Juices should be encouraged to help decrease urinary pH (inhibiting stone production) and bacterial adherence to a catheter.
5. Monitor for urine retention by percussing the suprapubic area for dullness, catheterizing for residual urine after voiding, or using noninvasive devices such as the .
6. Prophylactic antibiotics for prevention of recurrent UTIs are not supported because of the increase in resistant organisms.
7. The use of biofilms and other materials that inhibit adhesion of pathogens to catheters is being explored.

Promoting Bowel Elimination

1. Assess bowel sounds and note abdominal distention. Paralytic ileus is common immediately after injury.
2. Encourage intake of high-calorie, high-protein, and high-fiber (15 g) diet when food is tolerated.
3. Assess for loose stool oozing from rectum and perform rectal examination to check for fecal impaction; remove fecal matter, if necessary.
4. Institute a bowel program as early as possible.
    a. Schedule bowel care at the same time of day to develop a predictable outcome.
    b. Stimulate the gastrocolic reflex 30 minutes before bowel care with food or liquid intake.
    c. Perform bowel care with the patient in a bowel chair or in left side-lying position; the procedure should not take more than 2 hours.
    d. Use abdominal massage, deep breathing, warm fluids, and leaning forward in the chair to enhance success.
5. For patients with upper motor neuron lesions, perform reflexic bowel care.
    a. Insert a glycerin or bisacodyl suppository or mini-enema (4 mL).
    b. Alternatively, use digital stimulation with gloved, lubricated finger—perform a semicircular motion against posterior rectal wall. Repeat every 5 to 10 minutes until evacuation is complete.
    c. For patients with lower motor neuron lesions, perform areflexic bowel care, by perform manual stool elimination.
6. Have the patient perform Valsalva maneuver (after urinary elimination to prevent vesicoureteral reflux of urine).

7. For chronic constipation without relief from more conservative approaches, consider a bulk-forming agent or laxative 8 hours before bowel care.

Preventing Autonomic Dysfunction and Orthostatic Hypotension

1. Be alert to signs of autonomic dysreflexia (see Box 15-6), try to avoid triggers, assess for causes, and treat, as directed.
2. Be alert for, prevent, and manage orthostatic hypotension, especially in patients with cervical SCI.
3. Use tilt table, as ordered, to gradually increase the patient's ability to tolerate sitting after acute SCI.
4. Other conservative strategies consist of use of embolic hose, abdominal binder, and high-salt diet.
5. Administer a sympathomimetic, such as ephedrine or pseudoephedrine, as ordered, before the patient is transferred to wheelchair.

BOX 15-6 Autonomic Dysreflexia

Be aware of and try to prevent common causes of autonomic dysreflexia whenever possible:

- Bladder distention, UTI, bladder or kidney stones.
- Urinary abnormalities or procedures.
- Bowel distention, bowel impaction.
- Constrictive clothing, shoes, or apparatus.
- Noxious stimuli such as pain, strong smells, pressure.

Be alert for signs and symptoms of autonomic dysreflexia:

- Sudden and significant increase in systolic and diastolic BP 20–40 mm Hg above the patient's baseline. (Normal SBP for a person with tetraplegia is 90–110 mm Hg.) In children and adolescents, a systolic increase of greater than 15–20 mm Hg above baseline is significant.
- Pounding headache.
- Bradycardia and/or cardiac arrhythmias.
- Profuse sweating, piloerection, and flushing above the level of injury (LOI).
- Blurred vision and spots in visual field.
- Nasal congestion.
- Apprehension and anxiety.

Take the following actions if autonomic dysreflexia occurs:

- Check BP; if elevated, call health care provider immediately.
- Immediately sit the patient up.
- Loosen clothing and other constrictive apparatus.
- Monitor BP every 2 to 5 minutes.
- Check the urinary system—catheterize patient (use 2% lidocaine jelly and wait 2 minutes); if catheter in place, check for kinks in tubing obstructing drainage; if catheter blockage suspected, gently irrigate with

10–15 mL normal saline (use 5–10 mL in children younger than age 2); replace catheter if not draining adequately.

- If BP remains greater than 150 mm Hg systolic, check for impaction (use 2% lidocaine jelly and wait 2 minutes). Remove stool.
- If BP remains greater than 150 mm Hg systolic, administer immediate-release nifedipine 10 mg (bite and swallow), nitroglycerin ointment 2% 1 inch (2.5 cm) above the LOI, or another antihypertensive agent.
- If autonomic dysreflexia is still unresolved, check for additional causes (eg, pressure ulcer, ingrown toenail).

After the episode of autonomic dysreflexia, document the following:

- Monitor BP for at least 2 hours for recurrent hypertension or symptomatic hypotension. Notify the health care provider as indicated.
- Provide patient teaching for prevention and treatment of complication.
- Make sure all caregivers understand autonomic dysreflexia and that the patient carries an identification card indicating LOI and emergency information.

DRUG ALERT Caution should be exercised for patients with SCI who are taking tricyclic antidepressants because of autonomic dysfunction. SCI patients are more vulnerable to anticholinergic adverse effects and orthostatic hypotension. In addition, numerous potential drug reactions are associated with monoamine oxidase inhibitors and SCI.

Empowering the Patient

1. Explain all procedures to the patient. Answer questions.
2. Make sure that the patient plays an integral part in decision-making about care plan. Allow the patient to make modifications to treatment plan when possible.
3. Schedule procedures and planning sessions when the patient is rested and experiencing decreased anxiety.
4. Praise the patient for incremental gains in function or participation.
5. Discuss stress management techniques, such as relaxation therapy, counseling, and problem solving.
6. Refer to vocational training program if the patient expresses an interest.
7. Use peer counseling for patient to gain support from others with SCI.
8. Be alert for signs of depression (problems with sleep, loss of interest, guilt, loss of energy, lack of concentration, change in appetite, feeling sad) or risk for suicide and refer to mental health counselor. Administer antidepressant medications, as directed.
9. Explore the use of hands-free environmental control units to control environment (eg, turn on television).

Minimizing Alteration in Sexuality and Fertility

1. Encourage the patient to discuss alternate expression of feelings with partner.
2. Advise bowel care and urinary elimination before intercourse.
3. Advise women that 90% regain regular menstrual cycles by 1 year. Pregnancy can occur and delivery occurs in 40% before 37 weeks' gestation. Autonomic dysreflexia may occur as a complication of delivery.
4. Refer the patient to a urologist or other health care provider to explore sexuality options.
    a. Women with SCI experience little sensation during sexual intercourse, but fertility and ability to bear children are usually not affected.
    b. Men with SCI may consider implantation of a penile prosthesis or an assistive device to obtain an erection. Sildenafil has been used to manage erectile dysfunction in men with SCI. Ejaculation is more common with lower motor neuron or incomplete injuries; men with injuries at T_{10} and above may ejaculate with vibrostimulation.

Reducing Pain

1. Assess pain using consistent pain scale. Report changes from baseline or new location or type of pain.
2. Manage neurogenic pain with pharmacologic agents, as directed.
3. Help the patient assess the effects of nonpharmacologic treatment such as acupuncture.

Community and Home Care Considerations

Promoting Optimal Function

1. Determine short- and long-term functional goals. Expected outcomes should relate to motor recovery, level of functional independence, social integration, and quality of life.
2. Monitor neurologic status, including functional outcomes, periodically throughout the patient's life span. Functional outcomes may relate to
    a. Respiratory, bowel, bladder, and skin.
    b. Bed/wheelchair mobility, transfers, positioning.
    c. Standing and ambulation.
    d. Independent ADL, such as eating, grooming, bathing, and dressing.
    e. Communication, including speech, computer skills, handwriting, telephone.
    f. Transportation, including driving, adapted vehicle use, public transportation.
    g. Homemaking, including meal planning and preparation and chores.
3. Periodically evaluate the need for an increased level of assistance and equipment as the patient with an SCI ages.
4. Assist the patient in arranging modifications necessary to his or her home and in obtaining financial assistance for modifications to the environment.
5. Coordinate continued rehabilitation effort to ensure social support, ongoing pharmacologic treatment, and monitoring for long-term complications, such as depression; vocational training; and adaptation to

home and work environments. Use Functional Independence Measure or other instrument to set and achieve goals with the patient in ADL, transferring, locomotion, and other functional aspects.

6. Teach bowel care and urinary elimination procedures to the patient and all caregivers to ensure continuity.
7. Teach care of traction and immobilization devices.
8. Enlist help of occupational therapist, physical therapist, vocational therapist, recreational therapist, and other specialists, as needed.
9. Alert caregivers that autonomic dysreflexia is a complication that may occur up to several years after SCI involving T6 and above. Teach the patient and caregivers preventive and emergency treatment measures.

Patient Education and Health Maintenance

1. Teach the patient and family about the physiology of nerve transmission and how the SCI has affected normal function, including mobility, sensation, and bowel and bladder function.
2. Reinforce that rehabilitation is lengthy and involves compliance with therapy to increase function.
3. Explain that spasticity may develop 2 weeks to 3 months after injury and may interfere with routine care and ADL.
4. Teach the patient to protect skin from pressure ulcer development by frequent repositioning while in bed, weight-shifting and liftoffs every 15 minutes while in a wheelchair, and avoiding shear forces and friction.
5. Teach inspection of skin daily for development of pressure ulcers, using a mirror, if necessary.
6. Encourage sexual counseling, if indicated, to promote satisfaction in personal relationships.
7. Teach importance of seat belts.

Evaluation: Expected Outcomes

- Respirations adequate, ABG values within normal limits.
- Repositioning hourly, no orthostatic changes.
- No evidence of pressure ulcers or DVT.
- Reflex (or areflexic) voiding without retention.
- Bowel evacuation controlled.
- No episodes of autonomic dysreflexia.
- Verbalizes feeling of control over condition.
- Patient and partner exploring sexuality and sexual options.
- Reports pain at or lower than 2 to 3 level on a scale of 1 to 10.

Vertebral Compression Fractures

Vertebral fractures commonly occur with trauma but can also be associated with osteoporosis or cancer.

Pathophysiology and Etiology

1. The vertebral body is made up of cancellous (soft) and outer cortical (hard) bone. The fracture creates an area of weakness within the vertebral column.
2. This weakness is further stressed and compressed with normal biomechanical stresses (weight-bearing activities from standing, sitting, and lifting). Over time, the fracture loses height, compressing the vertebral body.
3. The periosteum layer of the bone contains many pain receptors and, with weight-bearing activities that apply pressure on the fractured bone, stimulates the nerve endings, thereby producing pain.
4. Risk factors include:
    a. Osteoporosis—women over age 50; men over age 70; prolonged use of steroids.
    b. Metastatic cancer—breast, lung, renal, prostrate, melanoma, multiple myeloma.
5. Other risk factors include the following:
    a. Smoking.
    b. Inactivity.
    c. Poor nutrition.

Clinical Manifestations

General Considerations

1. A vertebral body may fracture without causing debilitating pain.
2. Symptoms depend on location, extent of fracture, progression of fracture, and effect on surrounding structures.
3. Most symptomatic fractures result in pain, although the development of instability can result in sensory changes, loss of reflex, and muscle weakness from canal compromise.

Cervical

1. Pain and stiffness in the neck, top of shoulders, and region of the scapula.
2. Pain with rotation, flexion, and extension.
3. Paresthesias and numbness of upper extremities.
4. Weakness of upper extremities.

Thoracic/Lumbar

1. Middle to lower back pain at site of fracture.
2. Pain aggravated with activity and relieved with rest and flexion.
3. Progressive kyphosis or postural deformity of the lumbar spine. Progressive thoracic kyphosis decreases

lung capacity and can compromise pulmonary function.

4. Point tenderness to palpation on clinical examination.

Diagnostic Evaluation

1. Plain x-rays (anteroposterior and lateral views)—evaluate vertebral structure, height loss, and alignment.
2. CT scan—evaluation of extent of fracture and canal involvement.
3. MRI—differential diagnosis includes infectious process or metastatic lesion. MRI has greater sensitivity for soft tissue abnormalities.
4. Bone scan—evaluation of microscopic changes within the bone. Identification of additional metastatic lesions, infectious process, microscopic fractures.

Management

Conservative Treatment

1. Orthosis/brace; heat or ice to affected area.
2. Physical therapy.
3. Anti-inflammatory drugs.
4. Analgesics, opioids may be necessary during acute phase.
5. Treatment and prevention of osteoporosis.

Surgical/Invasive Intervention

1. Surgical intervention—spinal instrumentation is not considered an option in patients with advanced osteoporosis secondary to the risk of nonfusion and hardware failure.
2. Vertebroplasty—injection of methyl methacrylate (bone cement) with barium (radiopaque) into vertebral body aimed at providing stabilization of vertebral body.
3. Kyphoplasty—partial restoration of vertebral height using percutaneous placement of a balloon into vertebral body, inflation of the balloon with radiopaque solution (creates a cavity), and deflation and removal of the balloon followed by insertion of methyl methacrylate with barium. May be done under moderate sedation or general anesthesia. Reduced risk of glue leakage secondary to creation of the cavity.

Complications

1. Pulmonary embolus due to leakage of cement into venous system following vertebroplasty or kyphoplasty.
2. Spinal cord or nerve root compromise due to leakage of cement following vertebroplasty or kyphoplasty.
3. Muscular spasms related to preprocedure deconditioning and postprocedure change in posture.

Nursing Assessment

1. Perform repeated assessments of motor function and sensation.
2. Assess for localized tenderness.

3. Assess pain level on scale of 1 to 10.

Nursing Diagnoses

- Acute Pain related to area of compression.
- Risk for impaired breathing pattern related to invasive procedure and complications.

Nursing Interventions

Minimizing Pain

1. Administer or teach self-administration of analgesics as prescribed; inform patient about potential adverse effects (sedation, constipation, GI upset). Advise use of over-the-counter stool softeners.
2. Administer or teach self-administration of anti-inflammatories, as prescribed; advise taking with food or antacid to prevent GI upset.
3. Teach self-administration of muscle relaxants, as prescribed; inform patient about potential adverse effects of sedation.
4. Instruct in proper application and use of orthosis, if ordered.
5. Apply moist ice or heat to affected area of back, per patient-defined relief of pain.
6. Inspect skin several times a day, especially under stabilization devices, for redness and evidence of pressure sore development. Pressure ulcers can cause severe pain.
7. Educate the patient about vertebroplasty or kyphoplasty, as indicated.
    a. One to two small punctures with a large-bore needle will be made at site of vertebral body to be treated. Level will be verified using fluoroscopy before insertion of bone cement.
    b. Routine postprocedure care will include assessment of vital signs and neurologic function, pain control, and ambulation, as ordered. Assess movement and sensation of extremities. Report any new deficit. CT of spine may be ordered if encroachment on spinal cord or nerve root is suspected.
8. Encourage compliance with physical therapy treatments, as ordered.

Preventing Respiratory Complications Postoperatively

1. Monitor vital signs and assess respiratory status and report any breathing difficulties. Chest x-ray or CT of chest (PE protocol) may be ordered if pulmonary embolus is suspected.
2. Administer analgesics and NSAIDs to control pain from incision and muscular inflammation due to procedure. Differentiate increased respiratory rate due to pain and anxiety rather than hypoxemia.
3. Enforce bed rest for 2 to 3 hours; patient may turn side to side, as directed; gradually increase activity, as tolerated.
4. Position for comfort. May apply heat or ice to affected muscles if spasm occurs and administer muscle relaxant, as indicated.
5. Report any increasing pain, weakness, or breathing difficulties. Auscultate lungs and report abnormalities.

Patient Education and Health Maintenance

1. Advise the patient of 10- to 25-pound lifting restriction for 1 week after vertebroplasty/kyphoplasty, as ordered, and to avoid strenuous activities; level of activity may be increased gradually as status indicates.
2. Demonstrate proper body mechanics to be used for bending, reaching, and lifting in all activities.
3. Alternate ice and heat for 20-minute intervals five to six times per day, as needed.
4. No soaking baths for 1 week to enhance wound healing of puncture sites.
5. Encourage the patient to do stretching and strengthening exercises for back and aerobic exercise for endurance on a daily basis.
6. Physical therapy may be indicated for reconditioning, heat therapy, and massage.
7. Instruct the patient to report any changes in neurologic function or recurrence of pain.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Vital signs stable, respirations unlabored, out of bed without difficulty.

Peripheral Nerve Injury

Peripheral nerve injury (PNI) is an injury to nerves in the upper extremity (eg, radial, ulnar, median) or lower extremity (eg, peroneal, sciatic, femoral, tibial). PNI may include damage to major nerves, the nerve root, the plexus (eg, brachial or lumbar), and other peripheral sites.

Pathophysiology and Etiology

1. The incidence of PNI is approximately 2% to 3% in populations with multiple injuries. Males have higher incidence than females.
2. PNI damage may occur by congenital, traumatic, chemical, pathologic, thermal, or mechanical means. Focal trauma is the most common of all PNI. Injuries can be direct (eg, gunshot) or indirect (eg, casting).
3. The most frequently injured site is the upper extremity, specifically the upper arm. Childhood PNIs occur predominantly in the lower extremities.
4. Injury to the nerve causes impairment in axonal function and, possibly, disruption of myelination. Approximately 50% of motor nerves and 75% of cutaneous nerves are myelinated. Schwann cells contain multiple axons. Myelinated axons enhance conduction between nodes, accelerating transmission compared to nonmyelinated axons. Fibers are classified according to diameter, conduction speed, myelination, and target.
5. Sensory regeneration, as opposed to motor regeneration, may take years following a PNI.
6. Nerve injuries are classified according to the Sunderland system, which establishes grades of nerve function on which to base recovery and need for surgery.
    a. First-degree PNI (neurapraxia)—there is a conduction impairment, but the anatomy is intact. Complete recovery is anticipated in 3 months.
    b. Second-degree PNI (axonotmesis)—wallerian degeneration occurs distal to the PNI site and axons disintegrate. Complete recovery is anticipated.
    c. Third-degree PNI—scarring occurs in the endoneural tube. Axons recover 1 inch (2.5 cm) per month. Incomplete recovery is anticipated.
    d. Fourth-degree PNI (eg, crush injury)—axonal regeneration is blocked by scar tissue. Surgical repair is typically required.
    e. Fifth-degree PNI (eg, penetrating trauma)—the peripheral nerve is severed. Surgical intervention is required.
7. Compression neuropathy depends on the amount and extent of compression force. Edema, connective tissue thickening, and segmental demyelization of large fibers occur.
8. Useful function can be achieved when up to 75% of axons are damaged.

Clinical Manifestations

1. Flaccid paralysis.

2. Absent deep tendon reflexes.
3. Atonic/hypotonic muscles.
4. Progressive muscle atrophy.
5. Fasciculations peak 2 to 3 weeks after injury.
6. Trophic changes: skin is warm and dry 3 weeks after injury and then becomes cold and cyanotic with loss of hair, brittle fingernails, and ulceration.
7. Causalgia (chronic pain syndrome): Neuropathic pain may be crawling, electric, tingling, or burning. (It typically follows the cutaneous sensory nerve distribution of the PNI.)
8. Specifics to area affected:
    a. Radial nerve injury—weakness in extension, possible wrist drop, inability to grasp objects/make a fist, impaired sensation over posterior forearm and dorsum of the hand.
    b. Brachial plexus—difficulty in abduction of shoulder, weakness with supination and flexion of the forearm (upper trunk) or extension of the forearm (middle trunk), or paralysis and atrophy of small muscles of the hand (lower trunk).
    c. Median and ulnar nerve injuries—sensory (median nerve) and motor (ulnar) loss of function in the hand (pronation, opposition of thumb, paralysis of finer flexor muscles).
    d. Femoral—weakness of knee and hip extension, atrophy of quadriceps, absence of knee jerk, loss of sensation of anterior aspect of the thigh.
    e. Common peroneal—footdrop, sensory loss on dorsum of foot, difficulty with eversion.
    f. Sciatic—footdrop, pain across gluteus and thigh, loss of knee flexion, weakness/paralysis of muscles below knee.
9. Chronic nerve compression may begin with intermittent signs and symptoms; these may only occur in specific maneuvers such as digital pressure or position. For example, damage to the brachial plexus, entrapped at the supra/infraclavicular junction, may elicit symptoms following arm elevation for 1 minute. In carpal tunnel syndrome (compression of the median nerve), wrist flexion or external pressure applied proximally to the carpal tunnel may evoke symptoms.

Diagnostic Evaluation

1. The electrodiagnostic examination consists of nerve conduction studies (sensory, motor, mixed) and needle electrode examination.
    a. The electrodiagnostic examination tests only large myelinated axons; it does not assess pain, temperature, or paresthesia.
    b. It can confirm PNI occurrence and determine the type of axon, pathophysiology, severity, location, and injury prognosis.
2. Muscle ultrasonography evaluates the extent of muscle involvement and assesses acute nerve injuries.
3. MRI and electrophysiologic studies such as electroneurography and EMG detect the site and degree of nerve injury.
4. Muscle imaging may detect atrophy and mesenchymal alteration of skeletal muscles.

5. Tinel sign (tapping the axons of the regenerating nerve produces a paresthesia in the normal distribution of the nerve) reveals the rate of axonal regeneration.

Management

1. Microsurgery reapproximates the severed peripheral nerve endings. The sooner the repair is performed, the better the chance of recovery. Microsurgical repair can be done with tension-free coaptation using technology such as carbon dioxide laser welding, fibrin gluing, and ring coupling. Autogenous nerve grafts are the gold standard.
2. Primary nerve repair (neurorrhaphy) may be done within 1 week of injury (eg, open wounds—except gunshots). Secondary nerve repair is performed after 1 week (eg, crush injury with soft tissue damage). In partially transected nerves, surgery may be delayed 2 to 3 months to determine whether regeneration will take place.
    a. Nerve grafting—Two neurorrhaphy sites are used. Thin, cutaneous nerve grafts with large fascicles and minimal connective tissue are optimal. Common donor sites include the sacral nerve (lateral aspect of the foot), lateral antebrachial cutaneous nerve (lateral forearm), and the median antebrachial cutaneous nerve (medial arm and elbow). Small segments of nerve grafts may be placed to create a bridge to facilitate axonal and Schwann cell growth. Nerve "conduits," connectors of nerve sites, may be composed of bone, vein, artery, silicone, or other material.
    b. End-to-side neurorrhaphy—the severed nerve's distal end is attached to the side of a healthy nerve.
    c. Nerve transfer—Ideally, the donor nerve fascicles are in close proximity to the target muscle motor end plate or target sensory nerve. If the patient has multiple nerve injuries, such as a complete brachial plexus injury, nerve transfer priority is given to promoting elbow flexion, shoulder abduction, and external rotation, respectively. Sensory nerve priorities are given to the ulnar thumb and radial index finger.
3. Tissue expansion is used to compensate for tissue deficit.
4. Insulin-like growth factor and acidic fibroblast growth factor have enhanced regeneration when administered systemically or topically and other factors are being investigated.
5. Corticosteroids may be used to decrease edema.
6. Occupational therapy may be consulted to splint or cast the patient. Splinting (eg, hands) or casting may be indicated to reduce tension on the PNI site and facilitate healing. Day splints are typically functional splints; night splints are positioning splints. Splint material depends on the amount of resistance to be exerted by the orthosis, the splint size, and the patient's compensatory movements.
    a. Radial nerve splint—volar or dorsal cock-up splints are indicated if wrist extension is impaired.
    b. Median nerve splint—a thumb opposition splint preserves the function of the hand grip.
    c. Ulnar nerve splint—this functional and positioning splint prevents "claw hand" deformity and contractures of fingers four and five.
7. Flexibility is primarily due to connective tissues stretching as opposed to muscle contraction. Passive and active ROM exercises are essential to provide stretch and prevent contractions. Ultrasound diathermy

may be used on deep muscles, and topical heat may be used for superficial muscles to promote stretching. Progressive resistance and strengthening, including isometric activities, are used to restore function. Functional electrical stimulation may also be used.

8. Fibrosis, caused by edema, may be minimized by elevating the affected limb. Using static graduated compression devices (eg, sleeves, gloves, hose) or sequential compression devices, distal to proximal wrapping, may also minimize edema. Likewise, massage may reduce edema.
9. Desensitization techniques (eg, scheduled exposure to irritating textures, vibration) may be used to manage hyperesthesia. Sensory reeducation may be protective (compensatory). Sensory restoration is progressive, with temperature and pain returning first, followed by transient light touch and vibration.
10. Neuropathic pain may be managed by traditional analgesics, antidepressants (eg, tricyclic), anticonvulsants (eg, gabapentin), topical and transdermal agents (eg, capsaicin), NSAIDs, alpha-adrenergic agonists (eg, clonidine), calcium channel blockers (eg, nicardipine), or transcutaneous electrical stimulation.
11. Carpal tunnel syndrome management may include activity modification, NSAIDs, serial steroid injections, vitamin B_6, diuretics, and a wrist splint for 6 months. Endoscopic surgical release of the ligament may also be an option.
12. Complex peripheral injuries, such as injury to the brachial plexus, may require multimodal treatment, including surgery, pain management, and functional rehabilitation. A multidisciplinary team approach is most effective in maximizing outcomes.

Complications

1. Infection, if injury is penetrating and site becomes contaminated.
2. Compartment syndrome due to edema or positioning.
3. Muscle atrophy/flaccid paralysis; disuse syndrome.
4. Sensory deficit.
5. Contractures.
6. Chronic pain.
7. Nerve damage resulting from surgical repair.

Nursing Assessment

1. Perform frequent neurovascular checks of the affected extremity (pressure, vibration, and two-point discrimination sensation; motor function, strength; pulses; temperature; capillary refill; degree of swelling).
2. Assess degree of pain on a scale of 0 to 10.
3. Test reflexes of affected extremity.
4. Observe for signs of infection if there is an open wound.
5. Assess for concomitant injuries such as head or skeletal trauma.

Nursing Diagnoses

- Risk for Peripheral Neurovascular Dysfunction.
- Chronic Pain related to injury.
- Risk for Infection secondary to tissue disruption, surgery.

Nursing Interventions

Protecting Neurovascular Function

1. Administer corticosteroids and diuretics, as ordered, to decrease swelling and development of compartment syndrome.
2. Keep extremity elevated to promote venous drainage.
3. Perform neurovascular check to evaluate status of injury.
   a. Incorporate Tinel sign into assessment.
   b. Report any changes in condition.
4. Postoperatively assist rehabilitation team in reeducating nerves and muscles to achieve function.
5. Observe for paresthesias, pain, or altered skin integrity in areas of splinting and casting.

Promoting Comfort

1. Administer and teach self-administration of analgesics, as ordered.
2. Elevate extremity.
3. Avoid exposing denervated areas to temperature extremes.
4. Apply such devices as splints and slings, as ordered.
5. Maintain mobility with ROM exercises. Perform gently, following administration of analgesics.

Preventing Infection

1. Assess wound and dressing frequently for erythema, warmth, swelling, odor, and drainage.
2. Monitor temperature with vital signs for hyperthermia and tachycardia, indicating infection.
3. Encourage deep-breathing exercises and ambulation to prevent pulmonary complications.

Patient Education and Health Maintenance

1. Teach management of wound and dressing and casts or splints.
2. Review analgesia schedule and need for elevation of injured area.
3. Teach exercises for involved area.
4. Suggest assistive devices to promote independence.
5. Stress the importance of complying with long-term rehabilitation, physical therapy, and follow-up evaluations.
6. Support a community accident prevention program, including the use of seat belts, industrial regulations, and sports and recreational safety measures.

Evaluation: Expected Outcomes

- Stable neurovascular status; functional use of extremity.
- Patient reports adequate relief of pain.
- Wound/surgical site free of erythema, drainage, odor.

CENTRAL NERVOUS SYSTEM TUMORS

Brain Tumors

EVIDENCE BASE Hayat, M. A. (2015). *Tumors of the central nervous system glioma, meningioma, neuroblastoma, and spinal tumors (Vol. 14)*. New York: Springer.

Stupp, R., Brada, M., van den Bent, M. J., Tonn, J. C., & Pentheroudakis, G. (2014). High-grade glioma: ESMO clinical practice guidelines for diagnosis, treatment and follow-up. *Annuals of Oncology, 25*(suppl 3), ii93–iii101.

Intracranial neoplasms are the result of abnormal proliferation of cells within the CNS. A *tumor* is a mass of cancerous cells within the brain. It is believed that there is a 2- to 3-cm surrounding area of cancer cells with the potential to develop into a tumor. Tumors require blood to grow and recruit a vascular supply to support the metabolic needs of the tumor. Intracranial tumors are primary or metastatic tumors and malignancy depends on cell type and location. Primary tumors include tumors of the brain itself, the skull or meninges, the pituitary gland, and the blood vessels. Metastatic tumors spread from the primary site of cancer (breast, lung, prostate, kidney) through the vascular supply and lymphatic systems. Defining primary cancer cell type determines the treatment modality and influences the overall prognosis.

Primary CNS tumor etiology remains unknown. Glioma research has identified a genetic mutation of p53 on chromosome 17 occurs in 50% of all cancers. Loss of heterozygosity of chromosome arm 10q also has been reported in gliomas, although research continues into potential genetic mutation and growth factors, as well as attempting to identify a tumor marker. No known environmental risks have been identified. Primary CNS tumors rarely metastasize outside the CNS.

Pathophysiology and Etiology

Tumors may originate in the CNS or metastasize from elsewhere in the body (50% of all brain tumors) and may be benign or malignant; all tumors produce effects of space-occupying lesion (edema, increased ICP). Malignancy may be related not only to cell type and invasiveness but also to location and operative accessibility (ie, the tumor is located in an area of the brain that will not tolerate compression of the brain structures or is not surgically accessible). The World Health Organization grading scale is currently used to classify gliomas, although other grading scales are available. The grading system evaluates the probability of tumor recurrence and malignancy from low (Grades I to II) to high (Grades III to IV). Tumors arise from any tissue of the CNS. See Figure 15-12.

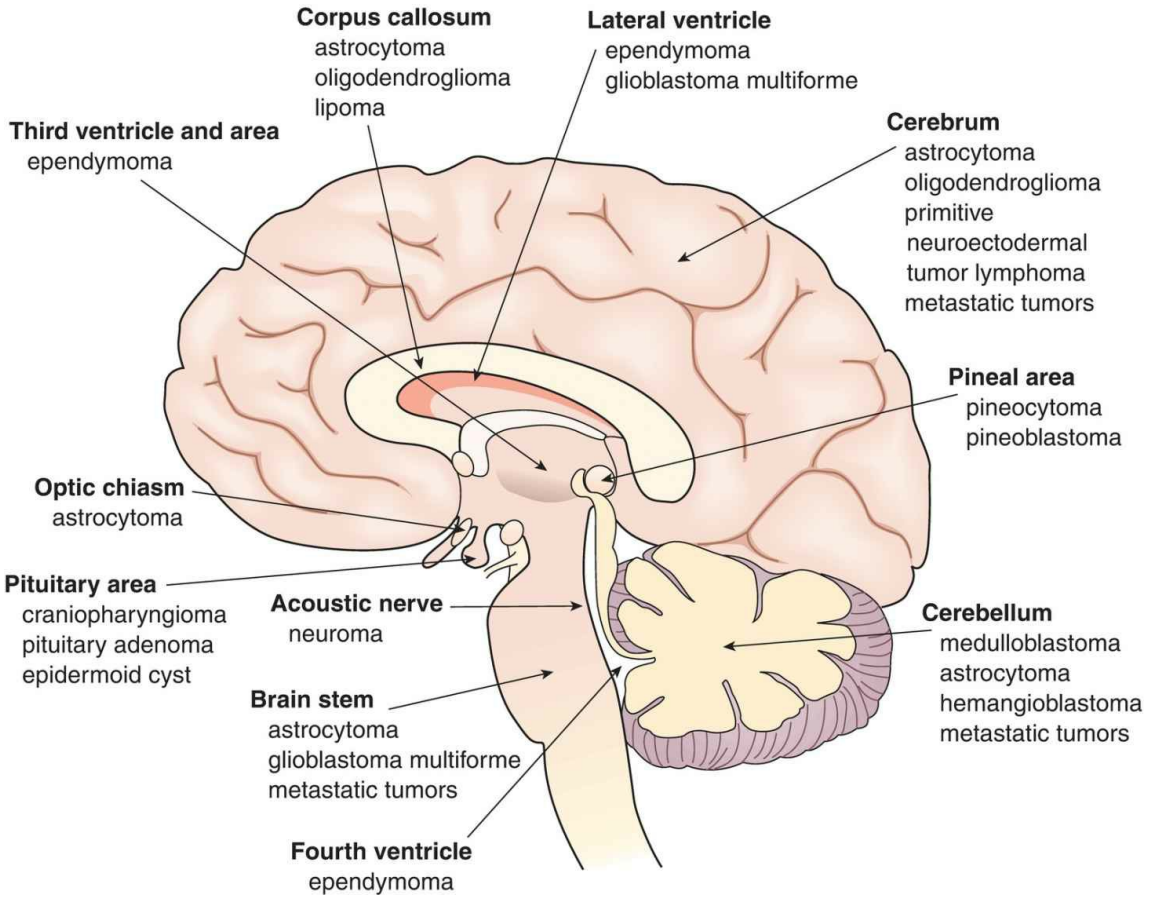

Figure 15-12. Common brain tumor sites.

1. Gliomas—tumors of the neuroepithelial/glial cells (supportive tissue of the brain; account for 40% to 50% of intracranial neoplasms):
   a. Astrocytoma—overgrowth of the astrocyte cells (connective tissue) of the brain. Tumors are graded on a scale from I to IV that defines growth pattern, invasiveness, infiltration, cell differentiation, margination, and necrosis.
      i. Grade I (polycystic astrocytoma)—slow-growing tumor with well-defined cells and minimal infiltration
      ii. Grade II (astrocytoma)—some atypical cells with higher rate of recurrence and risk of advancing to Grade III or IV with recurrence
      iii. Grade III (anaplastic astrocytoma) that is highly invasive and infiltrative, with poorly marginated borders and a rapid growth pattern and risk of advancing to Grade IV with recurrence
      iv. Grade IV (glioblastoma multiforme)—a malignant tumor that is highly invasive, infiltrative, and poorly marginated, with necrosis and a very rapid growth pattern (accounts for 55% of gliomas).
   b. Oligodendroglioma—overgrowth of oligodendroglial cells with calcification. Begins as a less invasive tumor but demonstrates malignancy as it progresses. The frontal and temporal lobes of the cerebrum are common locations. Rare in children.

Ependymoma (5% to 6% of intracranial gliomas)—overgrowth of the ependymal cells of the brain.

c. Slow growing; commonly occurs in the floor of the 4th ventricle; presents with signs and symptoms of increased ICP and hydrocephalus; 69% of cases occur in children.

d. Mixed gliomas—two or more cell types within a tumor.

e. Medulloblastoma—most common pediatric malignant tumor. Commonly located in the 4th ventricle/cerebellar vermis; rapid growth pattern, highly invasive; high risk for metastasis within CSF.

f. Hemangioblastoma—rare, benign tumor commonly located in the posterior fossa; von Hippel-Lindau disease is multiple hemangiomas within CNS.

g. Colloid cyst—a rare cyst that contains neuroepithelial cells; occurs in the third ventricle.

2. Meningioma—arises from meningeal lining of the brain. Can involve the skull; accounts for 20% of primary brain tumors (90% are benign; 10% are atypical or anaplastic). Higher incidence in females ages 40 to 70. Rare in children.

   a. Grade I meningiomas are benign, slow-growing, encapsulated lesions without brain tissue infiltration—but may have a dural tail.

   b. Grade II (atypical meningiomas), rapid-growing tumors with increased miotic activity and higher risk of recurrence after resection; risk of advancing to anaplastic tumor.

   c. Grade III (anaplastic meningioma), which has malignant features and invasion of brain tissue.

3. Peripheral nerve tumors—generally benign tumors that occur secondary to nerve sheath overgrowth.

   a. Acoustic neuroma/schwannoma, located on CN VIII.

   b. Neurofibromatosis type 1 (von Recklinghausen).

   c. Neurofibromatosis type 2.

4. Pituitary tumors.

   a. Pituitary adenoma, occurs primarily in the anterior of the pituitary and can be

      i. Secreting tumor—prolactin (causes amenorrhea/galactorhhea in women, impotence in men, and infertility in both genders) adrenocorticotrophic hormone (causes Cushing syndrome) or growth hormone (causes acromegaly).

      ii. Nonsecreting tumor.

   b. Craniopharyngioma (considered a developmental tumor)—a benign cystic lesion with calcification, occurring in the anterior pituitary margin. Fifty percent occur in children.

5. Germ cell tumors and tumor-like cysts.

   a. Dermoid cysts—occur in the ectodermal layer and contain hair and sebaceous glands.

   b. Epidermoid cysts containing cell debris and keratin.

   c. Pineal tumor—overgrowth of germ cells, pineal cells, or mixed germ types (includes teratomas) within the pineal region (more common in children and males).

   d. Cordoma—rare neoplasm that contains embryonic remnant occurring along the neuraxis.

6. Hematopoietic tumors—include primary malignant lymphoma (rare, diffusely infiltrating tumor of the brain, occurs in adults, high rate of recurrence) and secondary lymphoma associated with AIDS.

7. Secondary CNS tumors/metastatic lesions—commonly from lung cancer (40% to 50%), breast cancer (14% to 20%), melanoma (10%), renal (5%), and undetermined primary sites (10% to 15%). Single lesions common with lung and breast cancer, can have multiple lesions that are unresectable. Indicate systemic spread of primary cancer.

Clinical Manifestations

Manifestations depend on the location and biologic nature of the tumor. If the tumor is in a noneloquent area of the brain or is slow growing, specific symptoms may not develop until the late stages of the process. Instead, the tumor may produce generalized symptoms related to the increasing size of the tumor and the expanding area of cerebral edema surrounding the margins of the tumor. This is referred to as the "mass" effect of the tumor.

1. Generalized symptoms (due to increased ICP)—headache (especially in the morning), vomiting, papilledema, malaise, altered cognition, and consciousness.
2. Focal neurologic deficits (related to region of tumor):
    a. Parietal area—sensory alterations, speech and memory disturbances, neglect, visuospatial deficits, right–left confusion, depression.
    b. Frontal lobe—personality, behavior, and memory changes; contralateral motor weakness; expressive aphasia.
    c. Temporal area—memory disturbances, auditory hallucinations, receptive aphasia, complex partial seizures, visual field deficits.
    d. Occipital area—visual agnosia and visual field deficits.
    e. Cerebellar area—coordination, gait, and balance disturbances, dysarthria.
    f. Brain stem—dysphagia, incontinence, cardiovascular instability, respiratory depression, coma, CN dysfunction.
    g. Hypothalamus—loss of temperature control, diabetes insipidus, SIADH.
    h. Pituitary/sella turcica—visual field deficits, amenorrhea, galactorrhea, impotence, cushingoid symptoms, elevated growth hormone, panhypopituitarism.
3. Referred symptoms (related to the vasogenic [extracellular] edema surrounding the tumor).
4. Seizures.

Diagnostic Evaluation

1. CT—with and without contrast to visualize tumor, hemorrhage, shift of midline, cerebral edema.
2. MRI—to visualize tumor; more useful than CT
3. EEG—to detect locus of irritability, if seizures are present.
4. Angiography—to detect and evaluate the vascular supply of the tumor.
5. MR spectroscopy—evaluates the neurochemicals located within a core segment of the lesion; useful in differentiating tumors from infectious lesions.
6. Functional MRI—evaluates the functional eloquence of the brain tissue affected by the tumor, and the

tissue at risk, for mass effect.

7. Skull radiography—to determine bone involvement, identify pineal shift, helpful in children.
8. Stealth-guided surgery or stereotactic biopsy surgery—needed for definitive diagnosis, cell type.

Management

Effectiveness of treatment depends on tumor type and location, capsulation, or infiltrative status. Tumors in vital areas, such as the brain stem, or nonencapsulated and infiltrating tumors, may not be surgically accessible and treatment may produce severe neurologic deficits (blindness, paralysis, mental impairment). Treatment is usually multimodal.

NURSING ALERT Treatment of high-grade gliomas is palliative. There is no current treatment modality that provides a definitive cure. Treatment is aimed at improving duration of survival.

---

1. Surgery—removal/debulking by way of craniotomy, stealth guidance, laser resection, or ultrasonic aspiration.
   a. Craniotomy: goal is gross total resection of the tumor for maximum removal of tumor cells. Biopsy may be performed on tumors in eloquent locations; whereas surgery may not be an option for some tumors secondary to location. Gross total resection is associated with longer survival compared with subtotal resection in glioblastoma multiforme; 10% are inoperable based on location of the tumor.
   b. Awake craniotomy—allows intraoperative brain mapping.
   c. Image-guided surgery—computer-generated intraoperative localization of lesion.
   d. Laser resection or ultrasonic aspiration—may augment surgical resection.
   e. Endovascular treatment—useful in embolization of the arterial feeders to the meningiomas to reduce surgical risk related to blood loss.
2. Radiation therapy—external radiation to tumor bed with 2- to 3-cm border.
   a. Conventional therapy daily for 6 weeks; shorter to brain stem.
   b. Prophylactic radiation to brain stem for other brain tumors with high risk of metastasis.
   c. Brachytherapy—can use radioisotopes implanted through interstitial catheters to permit high doses for high-grade malignant tumors.
3. Radiosurgery—stereotactic radiosurgery by way of linear accelerator scalpel, proton beam, or gamma knife delivers a single, high dose of radiation to a precisely targeted tumor area. Destroys only targeted abnormal tissue, limiting damage to surrounding brain tissue.
4. Chemotherapy (the blood–brain barrier limits the effectiveness of chemotherapy agents).
   a. Metastatic tumors—single or combination drug therapy; may require autologous bone marrow transplantation (aspirated before chemotherapy and reinfused afterward to treat bone marrow depression).

b. Primary glioma—may be used as adjunct to surgery and radiation.
    i. Temozolomide (Temodar), an oral agent, is considered first line in chemotherapy for glioblastoma multiforme.
    ii. Carmustine (BCNU) wafers are biodegradable chemotherapy wafers that are surgically placed into the tumor bed during tumor debulking. Up to 8 wafers are placed in the space where the tumor was located and they slowly break down over time.
    iii. Bevacizumab (Avastin), has been approved by the FDA for the treatment of recurrent glioblastoma multiforme. Studies demonstrate a reduction in cerebral edema though there is no change in length of survival
    iv. Immunotherapy (epidermal growth factor receptor variant III) remains investigational, though has shown promising results in phase II studies.

5. Shunting procedure—to manage hydrocephalus, which may be obstructive or nonobstructive depending on location, tumor type, degree of necrosis, and associated edema and inflammation.
6. Supportive therapy and medications.
    a. Antiepileptics for treatment of seizure activity; may be utilized for prophylaxis.
    b. Dexamethasone to reduce swelling and reduce radiation edema; also given during end stage to enhance quality of life.
    c. The presence of tumors creates a hypercoaguable state. Prophylactic use of anticoagulant may or may not be ordered, though may be required in the presence of DVT or PE.
7. Investigational therapies currently in progress:
    a. Currently, there are over 50 ongoing trials evaluating the effectiveness of immunotherapy.
    b. Use of combination therapy of bevacizumab and lomustine is currently in phase III of evaluation.

Complications

1. Increased ICP and brain herniation; death.
2. Neurologic deficits from expanding tumor or treatment.

Nursing Assessment

1. Assess vital signs and signs of increased ICP (see page 357).
2. Assess CN function, LOC, mental status, affect, and behavior.
3. Monitor for seizures.
4. Assess level of pain using visual analogue scale (0 to 10) or face scale, as indicated.
5. Assess level of anxiety.
6. Assess patient and family patterns of coping, support systems, and resources.
7. If treated with chemotherapy, assess bone marrow function by monitoring neutrophil and platelet counts.

Nursing Diagnoses

- Acute Pain related to brain mass, surgical intervention.
- Risk for Decreased Cerebral Tissue Perfusion related to physiologic effects of tumor, altered LOC, possible seizures, increased ICP, and sensory and motor deficits.
- Anxiety related to diagnosis, surgery, radiation, and/or chemotherapy.
- Imbalanced Nutrition: Less Than Body Requirements related to compromised neurologic function and stress of injury.
- Disabled Family Coping related to changes in roles and structure.

Nursing Interventions

Also see care of the undergoing chemotherapy (page 112), radiation (page 122), and craniotomy (page 361).

Relieving Pain

1. Provide analgesics around the clock at regular intervals that will not mask neurologic changes.
2. Maintain the head of the bed at 15 to 30 degrees to reduce cerebral venous congestion.
3. Provide a darkened room or sunglasses if the patient is photophobic.
4. Maintain a quiet environment to increase patient's pain tolerance.
5. Provide scheduled rest periods to help the patient recuperate from stress of pain.
6. Instruct the patient to lie with the operative side up.
7. Alter diet, as tolerated, if the patient has pain on chewing.
8. Collaborate with the patient on alternative ways to reduce pain such as use of music therapy.

Preventing Injury

1. Report any signs of increased ICP or worsening neurologic condition to health care provider immediately.
2. Adjust care to reduce risk of increased ICP; body positioning without flexion of head, reduce hip flexion, distribute care throughout the 24-hour period to allow ICP to return to baseline.
3. Monitor laboratory data, CSF cultures, and Gram stains, and communicate results to medical staff.
4. Monitor intake and output, osmolality studies, and electrolytes; prevent overhydration, which can worsen cerebral edema.
5. Monitor response to pharmacologic therapy, including drug levels.
6. Initiate seizure precautions; pad the side rails of the bed to prevent injury if seizures occur; have suction equipment available.
7. Maintain availability of medications for management of status epilepticus (see page 424).
8. Initiate fall precautions; side rails up at all times, call light within reach at bedside, assist with toileting on a regular basis.
9. Gradually progress patient to ambulation with assistance as tolerated, enlist help from physical therapist, occupational therapist early, as indicated, to prevent falls.
10. If the patient is dysphagic or unconscious, initiate aspiration precautions: elevate head of the bed 30

degrees and position the patient's head to the side to prevent aspiration.

11. If dysphagic, position the patient upright and instruct in sequenced swallowing to maintain feeding function (see page 505).
12. Maintain oxygen and suction at the bedside in case of aspiration.
13. For the patient with visual field deficits, place materials in visual field.

Minimizing Anxiety

1. Provide a safe environment in which the patient may verbalize anxieties.
2. Help the patient to express feelings related to fear and anxiety.
3. Answer questions and provide written information.
4. Include the patient/family in all treatment options and scheduling.
5. Introduce stress management techniques.
6. Provide consistency in care and continually provide emotional support.
7. Assess the patient's usual coping behaviors and provide support in these areas.
8. Consult with social worker for community resources.

NURSING ALERT Anxiety and depression prior to and following surgery are associated with shorter postsurgical survival in patients with glioblastoma multiforme. Screening assessments can be performed with standard instruments and levels indicating a high risk of anxiety or depression should be reported to the health care provider.

Optimizing Nutrition

1. Medicate for nausea before position changes, radiation, or chemotherapy, and as needed.
2. Maintain adequate hydration within guidelines for cerebral edema.
3. Offer small, frequent meals as tolerated.
4. Consult with dietitian to evaluate food choices and provide adequate caloric needs through enteral or parenteral nourishment if unable to take oral nutrition.
5. Alter consistency of diet, as necessary, to enhance intake.

Strengthening Family Coping

1. Recognize stages of grief.
2. Foster a trusting relationship.
3. Provide clear, consistent explanations of procedures and treatments.
4. Encourage family involvement in care from the beginning.
5. Establish a means of communication for family with patient when verbal responses are not possible.
6. Consult with social worker and mental health provider if the family needs assistance in adjusting to

neurologic deficits.

7. Assist the family to use stress management techniques and community resources such as respite care.
8. Encourage discussion with health care provider about prognosis and functional outcome.
9. Discuss development of advance directive and durable power of attorney (DPA). Maintain positive attitude and define that rationale as a way to allow for patient-defined extent of care in the advent of deterioration.

Patient Education and Health Maintenance

1. Explain the adverse effects of treatment.
2. Encourage close follow-up after diagnosis and treatment.
3. Explain the importance of continuing corticosteroids and how to manage adverse effects, such as weight gain and hyperglycemia.
4. Encourage the use of community resources for physical and psychological support, such as transportation to medical appointments, financial assistance, and respite care.
5. Refer the patient/family for more information and support to such agencies as the National Institute of Neurologic Disorders and Stroke (*www.ninds.nih.gov*) and the National Brain Tumor Foundation (*www.braintumor.org*).

Evaluation: Expected Outcomes

- Reports satisfactory comfort level.
- No new neurologic deficits, seizures, falls, or other complications.
- Expresses decreased anxiety.
- Nutritional intake meeting metabolic demands.
- Patient and family verbalize understanding of treatment and available resources.

Tumors of the Spinal Cord and Canal

Tumors of the spinal cord and canal may be extradural (existing outside the dural membranes), including chordoma and osteoblastoma; intradural–extramedullary (within the SAS), including meningiomas, neurofibromas, and schwannomas; or intramedullary (within the spinal cord), including astrocytomas, ependymomas, and neurofibromatosis "dumbbell tumors." Vascular tumors can affect any part of the spinal cord or canal.

Pathophysiology and Etiology

1. Astrocytomas, characterized by asymmetrical expansion in the spinal cord, are more common in children than adults. Ependymomas, usually with a cyst, are the most common intramedullary tumor in the adult but are rare in children. These tumors are central in the spinal cord.
2. Vascular tumors can affect the spinal cord in various ways. Hemangioblastomas often cause edema and syrinx (fluid-filled cavity) formation. Cavernomas are located on the dorsal surface of the spinal cord.
3. Approximately 85% of all patients with cancer develop bony metastasis, with the spinal column as the primary site. Spinal cord compression due to cancer typically presents with incomplete paraplegia involving the thoracic spine.
4. Cause for abnormal cell growth is unknown.
5. Extradural tumors spread to the vertebral bodies.
6. Spinal cord and/or nerve compression can result.

Clinical Manifestations

Depends on location and type of tumor and extent of spinal cord compression.

1. Back pain that is localized or radiates; may be absent in more than 50% of patients.
2. Weakness of extremity with abnormal reflexes.
3. Sensory changes.
4. Bladder, bowel, or sexual dysfunction.

Diagnostic Evaluation

1. A plain x-ray or CT scan can detect a pathologic fracture, collapse, or destruction resulting from a mass.
2. MRI is sensitive to tumor detection.

Management

1. Two surgical approaches may be used to manage spinal cord tumors:
    a. Anterior decompression is typically indicated because most spinal cord tumors are anterior.
    b. The posterolateral approach may be used for excision of thoracic tumors. Endoscopy, or other surgical techniques using instrumentation, can be used to visualize the anterior part of the cord. In thoracic tumors above T_5, posterolateral decompression negates the need for an anterior thoracotomy or sternotomy.

2. Intraoperative somatosensory-evoked potentials and motor-evoked potentials can be used to "map" the optimal spinal cord site for incision and identify sensory and motor tracts within the spinal cord. This mapping reduces the neurologic deficits that are frequently associated with tumor incisions.
3. Various techniques are used to remove spinal cord tumors, including the following:
    a. Intramedullary tumors are totally resected. Corticosteroids are administered before and after surgery. MRI verifies tumor characteristics preoperatively (eg, exact level). Microsurgical laser techniques, ultrasound, and x-rays may be used intraoperatively. In surgery, every effort must be made to keep the anterior spinal artery intact.
    b. Vascular tumors may be managed in different ways. Hemangioblastomas are usually removed from the outside inward by exterior coagulation and progressive tumor shrinkage before removal. Cavernomas are usually removed by exterior coagulation and progressive tumor shrinkage before removal but from the inside outward.
    c. Neoplastic tumors may be treated with radiation or surgically excised using an anterior approach because these tumors typically cause anterior cord compression.
4. Radiation therapy may be used over 2 to 4 weeks; dosing protocols vary. Spinal radiation before surgical decompression may adversely affect wound healing. In patients who have a good functional status, radiotherapy to a malignant spinal cord tumor can significantly improve survival time.
5. Corticosteroids, such as dexamethasone and prednisone in moderate to high doses, are indicated for use before radiation therapy to improve the ambulation rate in the paretic patient.
    a. Corticosteroids are not typically used in nonparetic ambulatory patients.
    b. They are tapered over 2 weeks before discontinuing.
6. Chemotherapy is considered experimental.
7. When compared to patients with traumatic SCI, the rehabilitation of patients with spinal cord tumors is shorter; however, cancer patients have more limited functional improvement than SCI patients.

Complications

1. Spinal cord infarction secondary to compression.
2. Nerve or spinal compression from tumor expansion.
3. Tetraplegia or paraplegia due to spinal cord compression.

Nursing Assessment

1. Perform motor and sensory components of the neurologic examination.
2. Assess pain using scale of 0 to 10, as indicated.
3. Assess autonomic nervous system relative to level of lesion—pupillary responses, vital signs, bowel, and bladder function.
4. Assess for spinal or nerve compression—progressive increase in pain, paralysis or paresis, sensory loss, loss of rectal sphincter tone, and sexual dysfunction.

Nursing Diagnoses

- Anxiety related to surgery and outcome.
- Pain related to nerve compression.
- Risk for Peripheral Neurovascular Dysfunction related to nerve compression.
- Impaired Urinary Elimination related to spinal cord compression.
- Risk for Infection and Risk for Injury related to surgery.

Nursing Interventions

Relieving Anxiety

1. Provide an accepting environment for patient to verbalize anxieties.
2. Provide explanations regarding all procedures. Answer questions or refer the patient to someone who can answer questions.
3. Refer to cancer and SCI support groups, as needed.
4. Provide the patient/family with written information regarding disease process and medical interventions.
5. Reduce environmental stimulation.
6. Promote periods of rest to enhance coping skills.
7. Involve the family in distraction techniques.
8. Provide options in care when possible.

Relieving Pain

1. Administer analgesics, as indicated, and evaluate for pain control.
2. Instruct the patient in the use of patient-controlled analgesia, if available.
3. Instruct the patient in relaxation techniques, such as deep breathing, distraction, and imagery.
4. Position patient off surgical site postoperatively.

Compensating for Sensory Alterations

1. Reassure the patient that the degree of sensory/motor impairment may decrease during the postoperative recovery period as the amount of surgical edema decreases.
2. Instruct the patient with sensory loss to visually scan the extremity during use to avoid injury related to lack of tactile input.
3. Instruct the patient with painful paresthesias in appropriate use of ice, exercise, and rest.
4. Assess the patient with sensory and motor alterations and refer to physical therapy for assistance with ADL, ambulation.

Achieving Urinary Continence

1. Assess the urinary elimination pattern of the patient.
2. Instruct the patient in the therapeutic intake of fluid volume and relationship to elimination.
3. Instruct the patient in an appropriate means of urinary elimination and bowel management (see page

356).

Preventing Postoperative Complications

1. Provide routine postoperative care to prevent complications.
2. Monitor surgical site for bleeding, CSF drainage, signs of infection.
3. Keep surgical dressing clean and dry.
4. Clean surgical site, as ordered.
5. Pad the bed rails and chair if the patient experiences numbness or paresthesias to prevent injury.
6. Support the weak/paralytic extremity in a functional position.

Patient Education and Health Maintenance

1. Encourage the patient with motor impairment to use adaptive devices.
2. Demonstrate proper positioning and transfer techniques.
3. Instruct the patient with sensory losses about dangers of extreme temperatures and the need for adequate foot protection at all times.
4. If the patient has suspected or confirmed neurofibromatosis, suggest referral to genetic counselor. Also, encourage follow-up for MRI every 12 months to monitor disease progression.
5. Refer to cancer and SCI support groups, as needed.

Evaluation: Expected Outcomes

- Asks questions and discusses care options.
- Reports that pain is relieved.
- Reports decreased paresthesias; ambulatory postoperatively.
- Voids at intervals without residual urine.
- Incision healing, skin intact.

OTHER DISORDERS

Seizure Disorders

Seizures (also known as *epileptic seizures* and, if recurrent, *epilepsy*) are defined as a sudden alteration in normal brain activity that causes distinct changes in behavior and body function. Seizures are thought to result from disturbances in the cells of the brain that cause cells to give off abnormal, recurrent, uncontrolled electrical discharges.

Pathophysiology and Etiology

Altered Physiology

1. The pathophysiology of seizures is unknown. It is known, however, that the brain has certain metabolic needs for oxygen and glucose. Neurons also have certain permeability gradients and voltage gradients that are affected by changes in the chemical and humoral environment.
2. Factors that change the permeability of the cell population (ischemia, hemorrhage) and ion concentration (Na^+, K^+) can produce neurons that are hyperexcitable and demonstrate hypersynchrony, producing an abnormal discharge.
3. A seizure may manifest itself as an altered behavior, motor, or sensory function relating to any anatomic location in the brain.

Classification

The International League Against Epilepsy developed an international classification of epileptic seizures that divides seizures into two major classes: partial-onset seizures and generalized-onset seizures. Partial-onset seizures begin in one focal area of the cerebral cortex, whereas generalized-onset seizures have an onset recorded simultaneously in both cerebral hemispheres.

1. *Simple-partial seizures* can have motor, somatosensory, psychic, or autonomic symptoms *without impairment* of consciousness.
2. *ComplEX-partial seizures* have an *impairment* (but not a loss) of consciousness with simple-partial features, automatisms, or impairment of consciousness only.
3. *Generalized seizures* have a loss of consciousness with convulsive or nonconvulsive behaviors.
4. Simple-partial seizures can progress to complEX-partial seizures and complEX-partial seizures can secondarily become generalized.

Etiology

The etiology may be unknown or due to one of the following:

1. Trauma to head or brain resulting in scar tissue or cerebral atrophy.
2. Tumors.
3. Cranial surgery.
4. Metabolic disorders (hypocalcemia, hypoglycemia/hyperglycemia, hyponatremia, anoxia).
5. Drug toxicity, such as theophylline, lidocaine, penicillin.

6. CNS infection.
7. Circulatory disorders.
8. Drug withdrawal states (alcohol, barbiturates).
9. Congenital neurodegenerative disorders.
10. Nonepileptogenic behaviors, which can emulate seizures but have a psychogenic, rather than an organic, origin.

Clinical Manifestations

Manifestations are related to the area of the brain involved in the seizure activity and may range from single abnormal sensations, aberrant motor activity, altered consciousness or personality to loss of consciousness, and convulsive movements.

1. Impaired consciousness.
2. Disturbed muscle tone or movement.
3. Disturbances of behavior, mood, sensation, or perception.
4. Disturbances of autonomic functions.

Diagnostic Evaluation

1. EEG with or without video monitoring—locates epileptic focus, spread, intensity, and duration; helps classify seizure type.
2. MRI, CT scan—to identify lesion that may be cause of seizure.
3. SPECT or PET scan—additional tests to identify seizure foci.
4. Neuropsychological studies—to evaluate for behavioral disturbances.
5. Serum laboratory studies or lumbar puncture—to evaluate for infectious, hormonal, or metabolic etiology.

Management

1. Pharmacotherapy—antiepileptic drugs (AEDs) selected according to seizure type (see Table 15-9, pages 420 to 423).
2. Biofeedback—useful in the patient with reliable auras.
3. Surgery considered in patients who are refractory to antiepileptic medications or require the use of more than two AEDs. Standardized surgical procedures include anteromesial temporal resection, corpus callosotomy, hemispherectomy.
4. Stimulation surgery—in those who are refractory to medication and not candidates for traditional surgery.
    a. Vagal nerve stimulation—sends regular electrical impulses to the brain via the Vagus nerve to reduce seizures.
    b. Intracranial neurostimulator—new procedure that monitors electrical activity of the brain and is programmed to deliver impulses at a certain rate and pulse width to reduce seizures.

Table 15-9 Antiepileptic Drugs

GENERIC NAME	DOSAGE FORMS	USUAL DOSES	HALF-LIFE	USUAL TARGET RANGE	MECHANISM OF ACTION	INDICATIONS	DOSE-RELATED ADVERSE EFFECTS
Carbamazepine	• Suspension 100 mg/5 mL • Tablet 200 mg • Chewtab 100 mg • Extended-release tablets 100, 200, 400 mg • Extended-release sprinkle capsules 200, 300 mg	• 10–40 mg/kg/day divided bid for extended-release; tid to qid for immediate-release	Initial 20–50, then 5–14 hr; induces own metabolism over first 2 wk	4–12 mcg/mL	Modulates sodium channels	• Simple-partial • Complex partial • Generalized tonic/clonic seizures	Double or blurred vision, lethargy (reduced by slow-dose titration)
Clonazepam	• Tablets 0.5, 1, 2 mg	• 0.01–0.3 mg/kg/day divided tid or given QHS • 0.5 mg PO tid—adults maximum 20 mg/day	20–40 hr	20–70 mcg/mL	Enhances GABA	• Myoclonic • Lennox-Gastaut syndrome • Atonic • Absence	Drowsiness (50%), ataxia (30%), behavioral disturbances (25%), movement disorders, slurred speech, hypersecretion
Diazepam (rectal)	• Pediatric rectal gel 2.5, 5, 10 mg • Adult rectal gel 10, 15, 20 mg	• 2–5 y/o—0.5 mg/kg • 6–11 y/o—0.3 mg/kg • >12 y/o—0.2 mg/kg	30–60 hr	Not applicable	Enhances GABA	• Acute repetitive seizures	Sedation
Ethosuximide	• Capsule 250 mg • Solution 250 mg/5 mL	• 15–40 mg/kg/day divided bid	30–60 hr	40–100 mcg/mL	Reduces current in the T-type calcium channel	• Absence	GI distress, drowsiness, hiccups, sedation
Felbamate	• Tablets 400, 600 mg • Suspension 600 mg/5 mL	• 15–45 mg/kg/day (or 1,200–3,600 mg) divided tid to qid; usual maximum 60 mg/kg/day	14–23 hr	30–100 mcg/mL	Blocks glycine binding to the NMDA receptors; modulates sodium channel, enhances GABA	• Lennox-Gastaut syndrome • Complex partial seizures	Anorexia, weight loss, vomiting, insomnia, headache, somnolence; rare cases of aplastic anemia (25 cases per 100,000) and liver failure (8 cases per 100,000) have also been seen
Gabapentin	• Capsule 100, 300, 400 mg • Tablets 600, 800 mg • Solution 250 mg/5 mL	• Initially 10–20 mg/kg/day divided tid to qid; titrate up to 40–60 mg/kg/day; usual maximum 90 mg/kg/day	5–9 hr	4–20 mcg/mL	Not known	• Partial seizures with or without secondary generalized tonic/clonic seizures	Somnolence, dizziness, ataxia, nystagmus, weight gain, nausea, vomiting, blurred vision, tremor, slurred speech, peripheral edema, dyspepsia, hiccups
Lamotrigine	• Tablets 25, 100, 150, 200 mg • Chew tablets 2, 5, 25 mg	• 200–500 mg/day divided bid • 2–15 mg/kg/day; start dose slowly	12–50 hr up to 70 hr with VPA	3–20 mcg/mL	Blocks sodium channels and blocks release of glutamate	• Simple-partial seizures • Complex partial seizures • Generalized tonic/clonic seizures • Lennox-Gastaut syndrome • Absence	Fatigue, drowsiness, ataxia, dizziness, headache, nausea, vomiting, double or blurred vision, nystagmus
Lacosimide	• 50, 100, 150, 200 mg tablets. Oral solution 10 mg/mL; Injection solution 10 mg/mL.	• 200–400 mg/d in two divided doses.	12–16 hr	10–20 mcg/mL	Modulates Na^+ channels	• Adjunctive treatment focal seizures with or without secondary generalization in patients 16 yr and older in age.	Dizziness, ataxia, fatigue, headache. Tremor, somnolence, balance disorder, memory impairment, vertigo, asthenia, gait disturbance, depression and bradycardia. Blurred vision, diplopia, nystagmus. Nausea, vomiting, and diarrhea
Levetiracetam	• Tablets 250, 500, 750 mg	• Initially 10 mg/kg PO divided bid or 500 mg PO bid; increase every 2 wks to 40–60 mg/kg/day	Adults 7 hr	5–50 mcg/mL	Inhibits propagation of seizure by unknown mechanism	• Partial-onset seizures	Somnolence (14.8%), asthenia (14.7%), coordination difficulties (3.4%), dizziness, nervousness, behavioral problems, decreased blood counts
Lorazepam	• Tablets 0.5, 1, 2 mg • Solution 2 mg/mL • Injection 2, 4 mg/mL	• 0.05–0.1 mg/kg/dose; 4 mg/dose maximum may repeat in 10–15 min	10–20 h	50–240 mcg/mL	Enhances GABA	• Status epilepticus	Sedation with risk of respiratory depression, amnesia, abnormal behavior, withdrawal reactions
Oxcarbazepine	• Tablets 150, 300, 600 mg	• Adult initially 300 mg PO bid, increase weekly to a usual maintenance dose of 1,200–2,400 mg/day • Child initially 10 mg/kg/day; titrate to a dose of 30–60 mg/kg/day	Parent 1–2½ hr; Metabolite 8–15 hr	10–35 mcg/mL for the monohydroxy derivative	Modulates sodium channels	• Partial-onset seizures	Headache, drowsiness, fatigue, nausea, dizziness, hyponatremia (hematologic toxicity not observed to date); dermatological reactions (rash)
Phenobarbital C-IV	• Capsule 16 mg • Elixir 15 mg/5 mL, 20 mg/5 mL • Tablet 8, 15, 16, 30, 32, 60, 65, 100 mg • Injection 30, 60, 65, 130 mg/mL	• 2–6 mg/kg/day divided qid to bid (high end of range for infants/young children)	40–140 hr	15–40 mcg/mL	Enhances GABA	• Generalized tonic/clonic seizures • Simple-partial seizures • Complex partial seizures	Sedation, mental dullness, cognitive impairment, hyperactivity, ataxia
Phenytoin, Fosphenytoin	• Injection 50 mg/mL (Fosphenytoin is 50 mg/mL phenytoin equivalent) • Suspension 125 mg/5 mL, 30 mg/5 mL • Chew tablets 50 mg • Capsules 30, 100 mg	• 4–12 mg/kg/day divided bid to tid for children getting PO; qid to bid for adults getting PO; divided q8h for IV dosing	5–34 hr	10–20 mcg/mL total 1–2 mcg/mL free (for patients with protein binding)	Modulates sodium channels	• Generalized tonic/clonic seizures • Complex partial seizures • Simple-partial seizures	Nystagmus, ataxia, lethargy, propylene glycol in IV preparation can cause myocardial depression, bradycardias, other electrocardiogram changes, hypotension, rash
Primidone	• Suspension 250 mg/5 mL • Tablets 50, 250 mg	• 10–25 mg/kg/day divided bid to tid; maximum 2 mg/day	4–20 hr (PEMA ½ 30–36 hr)	5–20 mcg/mL	Enhances GABA	• Generalized tonic/clonic seizures • Simple-partial seizures • Complex partial seizures	Same as phenobarbital
Rufinamide	200 and 400 mg film-coated tablets. Oral suspension: 40 mg/mL	1,800–3,200 mg twice a day. Children: 45 mg/kg/d.	6–10 h	10–25 mcg/mL	Modulates Na^+ Channel	Adjunctive treatment focal seizures with or without secondary generalization. In children >4 yrs. used as adjunctive treatment of seizures associated with Lennox-Gastaut syndrome	Somnolence, coordination abnormalities. Dizziness, gait disturbances, and ataxia. Vomiting, rash, headache, increased risk of suicide thoughts or behavior. Contraindicated in patients with familial short QT syndrome
Tiagabine	• Tablets 2, 4, 12, 16, 20 mg	• Adult 32–56 mg/day divided bid to qid (start with a 4 mg PO qid, adjust weekly) • Child 0.1 mg/kg/day divide tid, increase to 0.6 mg/kg/day (1 mg/kg/day with enzyme inducers)	2–9 hr	5–70 mcg/mL	Inhibits neuronal and glial uptake of GABA	• Partial-onset seizures	Sedation, dizziness, memory impairment, inattention, emotional lability, headache, abdominal pain, anorexia, tremor
Topiramate	• Tablets 25, 100, 200 mg • Sprinkle capsules 15, 25 mg	• Children initiate at 0.5–1 mg/kg/day divided bid; usual dose is 6–12 mg/kg/day divided bid to tid • Adult: 200–800 mg/day divided bid; initiate slowly with 25 mg qh, increase weekly	12–30 hr	2–25 mcg/mL	Modulates sodium channels, enhances GABA activity, and modulates NMDA receptor	• Partial-onset seizures • Lennox-Gastaut syndrome • Generalized tonic/clonic • Juvenile myoclonic epilepsy	Speech and language problems, difficulty with concentration and attention, confusion, fatigue, paresthesias, weight loss
VPA/divalproex sodium	• Solution 250 mg/5 mL • Capsule 250 mg • Sprinkle 125 mg • Extended-release 500 mg • Tablet 125, 200, 500 mg	• 15–60 mg/kg/day divided bid to tid	7–20 hours	50–150 mcg/mL	Unknown (may modulate sodium channel, enhance GABA)	• Generalized tonic/clonic seizures • Absence • Myoclonic • Partial-onset seizures • Lennox-Gastaut syndrome	GI upset, lethargy, changes in menstrual cycle, thrombocytopenia
Vigabatrin	• Tablet 500 mg scored	• Adult: 2–4 mg/day divided bid • Children: 1–2 mg/day or 40–100 mg/kg/day	5–7 hr	Not known	Inhibits GABA-transaminase (preventing GABA metabolism)	• Infantile spasms due to tuberous sclerosis	Drowsiness, fatigue, ataxia, behavioral changes, weight gain, psychosis (in predisposed patients and upon abrupt withdrawal), hematologic, visual field problems
Zonisamide	• Capsule 100 mg	• Adult 200–400 mg/day PO bid (max 600 mg), initially 100 mg PO qid and adjust every 2 wk • Children initially 1 mg/kg/day, adjust every 2 wk (maximum 15 mg/kg/day)	27–60 hr	15–40 mcg/mL	Modulates sodium and T-type calcium channels	• Partial-onset seizures • Generalized seizures • Absence • Myoclonic • Lennox-Gastaut • Infantile spasms	Drowsiness, psychosis (2%)

GABA, gamma-aminobutyric acid; NMDA, N-methyl-D-aspartate; PEMA, phenylethylmalonamide; VPA, valproic acid.

Complications

1. Status epilepticus (see Box 15-7).
2. Injuries due to falls, especially head injuries.
3. SUDEP: Sudden unexplained death in epilepsy patients.

Nursing Assessment

1. Obtain seizure history, including prodromal signs and symptoms, seizure behavior, postictal state, history of status epilepticus.
2. Document the following about seizure activity:
   a. Circumstances before attack, such as visual, auditory, olfactory, or tactile stimuli; emotional or psychological disturbances; sleep; hyperventilation.
   b. Description of movement, including where movement or stiffness started; type of movement and parts involved; progression of movement; whether beginning of seizure was witnessed.
   c. Position of the eyes and head; size of pupils.
   d. Presence of automatisms, such as lip smacking or repeated swallowing.
   e. Incontinence of urine or feces.
   f. Duration of each phase of the attack.
   g. Presence of unconsciousness and its duration.
   h. Behavior after attack, including inability to speak, any weakness or paralysis (Todd paralysis), sleep.
3. Investigate the psychosocial effect of seizures.
4. Obtain history of drug or alcohol abuse.
5. Assess compliance and medication-taking strategies.

DRUG ALERT Nonadherence to medication regimen as well as toxicity of antiepileptic medications can increase seizure frequency. Obtain drug levels before implementing medication changes.

BOX 15-7 Emergency Management of Status Epilepticus

Status epilepticus (acute, prolonged, repetitive seizure activity) is a series of generalized seizures without return to consciousness between attacks. The term has been broadened to include continuous clinical and/or electrical seizures lasting at least 5 minutes, even without impairment of consciousness. Status epilepticus is considered a serious neurologic emergency. It has high mortality and morbidity (permanent brain damage, severe neurologic deficits). Factors that precipitate status epilepticus in patients with pre-existing seizure disorder include medication withdrawal, fever, metabolic or environmental stresses, alcohol or drug withdrawal, and sleep deprivation.

NURSING INTERVENTIONS

- Establish airway and maintain blood pressure (BP).
- Obtain blood studies for glucose blood urea nitrogen, electrolytes, and anticonvulsant drug levels to determine metabolic abnormalities and serve as a guide for maintenance of biochemical homeostasis.
- Administer oxygen—there is some respiratory depression associated with each seizure, which may

produce venous congestion and hypoxia of the brain.

- Establish IV lines and keep open for blood sampling, drug administration, and infusion of fluids.
- Administer IV anticonvulsant (lorazepam, phenytoin, diazepam) *slowly* to ensure effective brain tissue and serum concentrations.
    - Give additional anticonvulsants, as directed—effects of lorazepam are of short duration.
    - Monitor anticonvulsant drug levels regularly.
- Monitor the patient continuously; depression of respiration and BP induced by drug therapy may be delayed.
- Use mechanical ventilation, as needed.
- If initial treatment is unsuccessful, general anesthesia may be required.
- Assist with search for precipitating factors.
    - Monitor vital and neurologic signs on a continuous basis.
    - Use electroencephalographic monitoring to determine nature and abolition (after diazepam administration) of epileptic activity.
    - Determine (from family member) if there is a history of epilepsy, alcohol/drug use, trauma, recent infection.

Nursing Diagnoses

- Ineffective Cerebral Tissue Perfusion related to seizure activity.
- Risk for Injury related to seizure activity.
- Ineffective Coping related to psychosocial and economic consequences of epilepsy.

Nursing Interventions

Maintaining Cerebral Tissue Perfusion

1. Maintain a patent airway until the patient is fully awake after a seizure.
2. Provide oxygen during the seizure if color change occurs.
3. Stress the importance of taking medications regularly.
4. Monitor serum levels for therapeutic range of medications.
5. Monitor the patient for toxic adverse effects of medications.
6. Monitor platelet and liver functions for toxicity due to medications.

Preventing Injury

1. Provide a safe environment by padding side rails and removing clutter.
2. Place the bed in a low position.
3. Do not restrain the patient during a seizure.
4. Do not put anything in the patient's mouth during a seizure.
5. Place the patient on his or her side during a seizure to prevent aspiration.

6. Protect the patient's head during a seizure. If seizure occurs while ambulating or from chair, cradle head or provide cushion/support for protection against head injury.
7. Stay with the patient who is ambulating or who is in a confused state during seizure.
8. Provide a helmet to the patient who falls during seizure.
9. Manage the patient in status epilepticus.

Strengthening Coping

1. Consult with social worker for community resources for vocational rehabilitation, counselors, support groups.
2. Teach stress-reduction techniques that will fit into the patient's lifestyle.
3. Initiate appropriate consultation for management of behaviors related to personality disorders, brain damage secondary to chronic epilepsy.
4. Answer questions related to use of computerized video EEG monitoring and surgery for epilepsy management.

Community and Home Care Considerations

1. Counsel patients with uncontrolled seizures about driving or operating dangerous equipment. Be familiar with state laws regarding driving while on or tapering AEDs.
2. Assess home environment for safety hazards in case the patient falls, such as crowded furniture arrangement, sharp edges on tables, and glass. Soft flooring and furniture and padded surfaces may be necessary.
3. Provide instructions on safety precautions while performing activities alone to prevent injury, drowning, or choking.
4. Support the patient in discussion about seizures with employer, school, and so forth.

NURSING ALERT Sudden unexpected death in epilepsy (SUDEP) can be reduced by decreasing the number of seizures that a patient experiences and by taking medications, as prescribed. Although multiple medications may be required to reduce seizure frequency, it should be considered within the context of quality of life and risk reduction.

Patient Education and Health Maintenance

1. Encourage the patient to determine existence of trigger factors for seizures (eg, skipped meals, lack of sleep, emotional stress, menstrual cycle).
2. Remind the patient of the importance of following medication regimen.
3. Tell the patient to avoid alcohol because it interferes with metabolism of antiepileptic medications.
4. Encourage the patient and family to discuss feelings and attitudes about epilepsy.

5. Encourage the patient to carry or wear a MedicAlert card or bracelet.
6. Encourage a moderate lifestyle that includes exercise, mental activity, and nutritional diet.
7. For the surgical candidate, reinforce instructions related to surgical outcome of the specific surgical approach (temporal lobectomy, corpus callosotomy, hemispherectomy, and extratemporal resection).
8. Refer the patient/family for more information and support to such agencies as the Epilepsy Foundation of America (*www.efa.org*).

Evaluation: Expected Outcomes

- Takes medication as ordered, drug level within normal range.
- No injuries observed.
- Reports using support services and stress-management techniques.

Narcolepsy

Narcolepsy is a neurologic disorder characterized by abnormalities of REM sleep, some abnormalities of non-REM sleep, and excessive daytime sleepiness.

Pathophysiology and Etiology

1. Recent advances suggest that this common sleep disorder may be a neurodegenerative or autoimmune disorder resulting in the loss of hypothalamic neurons that contain a peptide, hypocretin (orexin). Hypocretin plays a central role in the timing of sleep and wakefulness and inhibits REM sleep. The deficiency in hypocretin contributes to the abnormalities of sleep and wakefulness in narcolepsy.
2. Genetic susceptibility—associated with class II human leukocyte antigens.
3. Although considered a hypersomnia disorder, the person does not experience excessive amounts of sleep in a 24-hour period. Typically, patients with narcolepsy have a normal amount of sleep over 24 hours. They have abnormal REM sleep that intrudes into wakefulness.
4. Onset is usually between ages 15 and 25.

Clinical Manifestations

1. Four classic symptoms (all symptoms not present in all patients):
   a. Excessive daytime sleepiness is usually the first symptom.
   b. Cataplexy (abrupt loss of muscle tone after emotional stimulation such as laughter, anger).
   c. Sleep paralysis (powerless to move limbs, speak, open eyes, or breathe deeply while fully aware of condition).
   d. Hypnagogic hallucinations (drowsiness before sleep, usually visual or auditory).
2. Symptoms enhanced by high temperature, indoor activity, and idleness.
3. Clinical manifestations may abate, but never phase out completely.
4. Patient may complain of inability to focus vision or thought process rather than have a feeling of sleepiness.
5. Nocturnal sleep disturbance—occurs 2½ to 3 hours after falling asleep.
   a. After being awake for 45 to 60 minutes, the patient will fall back to sleep for another 2½ to 3 hours and then awaken again.
   b. This is believed to be the source of the daytime somnolence.

Diagnostic Evaluation

1. An overnight polysomnogram in a sleep disorders lab is included in the evaluation to assess nighttime sleep—indicates the underlying cause for the complaint of sleepiness. The polysomnogram helps evaluate sleep quality and excludes other disorders, such as sleep apnea.
2. The polysomnogram is followed the next day by a multiple sleep latency test to assess daytime sleepiness —indicates severity of the problem. Patients are given four or five opportunities to nap every 2 hours.

Patients with narcolepsy typically fall asleep more rapidly than the norm of 10 to 15 minutes.

Management

1. Long-term treatment is required. Mutual goal-setting is imperative because not everyone derives benefit from treatment. Even with medication, patients may never attain normal levels of alertness.
2. Nonpharmacologic therapy includes support groups, short naps (10 to 20 minutes, three times daily), caffeinated beverages, exercise, sleep hygiene techniques, and avoidance of heavy meals.
3. Stimulants prescribed may include pemoline, methylphenidate, dextroamphetamine, and methamphetamine.
4. Antidepressants for cataplexy; protriptyline, desipramine, fluoxetine.

Complications

1. Injury related to falling asleep.
2. Psychosocial problems such as disturbed relationships, loss of employment, and depression.

Nursing Assessment

1. Obtain history of sleep and activity pattern.
2. Assess emotional status and social interactions.
3. Assess response to medication and lifestyle treatment.

Nursing Diagnoses

- Disturbed Sleep Pattern related to disease process.
- Fatigue related to disrupted nighttime sleep.
- Ineffective Coping related to interference with activity.

Nursing Interventions

Promoting Normal Sleep–Wake Cycle

1. Review daily schedule to determine periods of sleep and cataplexy. Advise to wake at the same time daily.
2. Help the patient establish nondrug therapies (exercise, diet) that will fit into lifestyle.
3. Make sure that the bedroom is dark, cool, and quiet to facilitate sleep.
4. Administer or teach self-administration of prescribed medications.
    a. Advise of adverse effects of amphetamines, such as nervousness, irritability, tremors, and GI upset.
    b. Warn the patient to take only as prescribed and not to increase dosage because of tolerance and drug dependence.

Reducing Fatigue

1. Schedule 10- to 20-minute rest periods two or three times per day. Help the patient incorporate naps into lifestyle.

2. Encourage the patient to incorporate small amounts of caffeinated beverages at intervals and smaller, more frequent meals rather than large, heavy meals during the day to maintain energy.
3. Plan diversional activities and relaxation during fatigued periods.

Strengthening Coping

1. Encourage active participation in selection of treatment modalities.
2. Assist the patient in identifying trigger factors of worsening symptoms.
3. Teach problem solving strategy to promote sense of control over activities and symptoms during the day.
4. Review patient coping mechanisms and reinforce positive ones.
5. Assist the patient to discuss information about narcolepsy with friends, family, school, and employers to help reduce anxiety and/or embarrassment about his or her condition.
6. Encourage the use of support groups and community resources, such as the American Sleep Association (*www.sleepassociation.org*).

Patient Education and Health Maintenance

1. Review the normal sleep cycle and the pathophysiology of narcolepsy.
2. Stress the importance of nonpharmacologic measures as an adjunct to treatment.
3. Inform the patient of rights of employment conditions under the Americans with Disabilities Act (see page 160).
4. Advise caution with using alcohol, working with machinery, or using dangerous equipment to prevent injury to self or others during sleepiness or cataplexy.
5. If the patient drives, advise using caution and avoiding lengthy trips.
6. Encourage the patient to wear a MedicAlert bracelet.
7. Encourage follow-up with health care provider, specialist, and mental health counselor, as needed.

Evaluation: Expected Outcomes

- Complies with medication regimen.
- Reports working without undue fatigue.
- Identifies trigger factors.

Headache Syndromes

Headaches are one of the most common complaints of people seeking health care. Pain in the head is a symptom of underlying pathology. The International Headache Society instituted a classification system that is the standard for defining various types of headaches. It divides headaches into two categories: primary headache disorders, which include migraine, tension-type headache, and cluster headache, and secondary headache disorders. Identifying the etiology of headaches requires an understanding of the characteristics of each type of headache.

EVIDENCE BASE Tepper, S. J., & Tepper, D. E. (2014). *The cleveland clinic manual of headache therapy*. New York: Springer.

Pathophysiology and Etiology

Primary Headaches

Diagnosis is generally based on the characteristic clinical history and elimination of other pathology such as stroke, intracranial bleed, AVM, or brain tumor.

1. Migraine headache—consists of initial vasospasm followed by dilation of intracranial and extracranial arteries; occurs in about 10% of the population.
   a. Caused by hyperactivity to the neurotransmitter serotonin; familial predisposition.
   b. Attack may consist of any of five phases: prodrome, aura, headache, resolution, and postdrome.
   c. Classified with or without aura (usually visual); aura is due to reduced cortical neuronal activity.
2. Tension headache—due to irritation of sensitive nerve endings in the head, jaw, and neck from prolonged muscle contraction in the face, head, and neck; mild or moderate intensity that does not prohibit activity.
   a. Precipitating factors include fatigue, stress, and poor posture.
   b. Characterized by hatband distribution.
3. Cluster headache—release of increased histamine results in vasodilation.
   a. Usually unilateral, recurring.
   b. Occurs more often in men.

Secondary Headaches

Headache due to a neurologic or systemic disease.

1. Mass lesion (tumor, abscess, AVM, subdural or EDH).
2. Intracranial infection (bacterial/viral/fungal meningitis or encephalitis).
3. Inflammation (giant cell arteritis, vasculitis).
4. Cerebrovascular disease (SAH, intracranial hemorrhage, occlusive vascular disease).

5. Increased ICP.
6. Low-pressure headache (postlumbar puncture, trauma-induced).
7. Sinus infection, viral infection such as influenza, systemic illness.

Clinical Manifestations

1. Migraine: sensory, motor, or mood alterations precede headache; gradual onset of severe unilateral, throbbing headache; may become bilateral.
   a. Migraine with aura (classic migraine), characteristic aura may include scintillating scotoma (area of decreased vision surrounded by area of less abnormal or normal vision with zigzag appearance), hemianopsia (loss of half of field of vision), and paresthesias; headache follows aura in less than 1 hour; usually lasts less than a day.
   b. Migraine without aura (common migraine), nausea, vomiting, and photophobia may accompany moderate to severe headache; worsened by activity; may last 4 to 72 hours and greatly impair activities.
   c. Either type of migraine may be triggered in women by hormonal fluctuations (menses, pregnancy), excess or lack of sleep, change in eating habits, and certain food additives.
2. Tension/muscle contraction: dull, bandlike, constricting, persistent pain and pressure in the back of the head and neck, across forehead, bitemporal areas; may be tender points of head or neck.
   a. Not aggravated by activity, but may be worsened by noise and light.
   b. No nausea and vomiting, but may be associated with anorexia.
3. Cluster headache: sudden, sharp, burning, excruciating, unilateral pain; always involving facial area from neck to temple and often occurs during the evening or night; more frequent in men.
   a. Occurs in clusters of 2 to 8 weeks followed by headache-free periods.
   b. Associated with unilateral excessive tearing, redness of the eye, stuffiness of nostril on affected side, facial swelling, flushing, and sweating.
   c. Attacks last several minutes to several days. Multiple attacks may occur in 1 day.

Diagnostic Evaluation

1. Skull/sinus films to rule out lesions, sinusitis.
2. CT scan/MRI to rule out lesions, hemorrhage, chronic sinusitis.
3. ESR and other blood studies to help determine inflammatory process with temporal arteritis.

NURSING ALERT "Red flags" for possible serious cause of headache (hemorrhage, stroke, tumor, infection) include altered level of consciousness; neurologic findings such as weakness, facial droop, dysarthria, or aphasia; nausea and vomiting; new onset of or change in characteristic headaches; and patient reporting that it is "the worst headache of my life." These patients should be evaluated with a brain CT scan.

Management

Pharmacologic Treatment

Medications are intended to reduce the frequency, severity, and duration of the headache. Effectiveness of medication is individualized. Some persons may need a combination of medications.

1. Aspirin, acetaminophen, and NSAIDs for mild to moderate pain of tension, sinus, or mild vascular headaches.
2. Some drugs may abort vascular headaches if taken at the onset, including methysergide, a serotonin antagonist; ergotamine, a vasoconstrictor; or 5HT-agonists such as sumatriptan.
3. Sumatriptan is available in subcutaneous injection and nasal inhalation, as well as in oral form.
4. Other oral 5HT-agonists include zolmitriptan, naratriptan, and rizatriptan.
5. Inhalation of 100% oxygen may abort a cluster headache.
6. Some drugs may be used continuously as prophylactic treatment for recurrent migraines, including beta-adrenergic blockers, calcium channel blockers, and antidepressants.
7. Antihistamines and decongestants may be effective for sinus headaches.
8. Corticosteroids may be used for temporal arteritis.
9. Occasionally, opioid analgesics, muscle relaxants, and antianxiety agents may be needed for severe pain.
10. Vitamin supplements including magnesium and Vitamin B_2 may be beneficial in preventing headache episodes.

DRUG ALERT Vasoconstrictors and 5HT-agonists used to abort vascular headaches are contraindicated in patients with uncontrolled hypertension, coronary artery disease, and peripheral vascular disease.

Nonpharmacologic Management

1. Relaxation techniques, guided imagery, paced breathing.
2. Biofeedback, cognitive therapy.
3. Trigger identification and control of such factors as intake of alcohol (red wine), skipped meals, oversleeping, or undersleeping. Anticipatory guidance in proper sleep hygiene
4. To prevent migraine: avoidance of monosodium glutamate, mixed spices such as “seasoned salt,” nitrates and nitrites commonly contained in bacon, hot dogs, or deli meats.
5. Rest in a quiet, dark room at onset of headache.
6. If caffeine user, spread caffeine intake evenly over the day.
7. Routine exercise program.

Complications

1. Usually none from primary headaches.

Nursing Assessment

1. Obtain a history of related symptoms, triggering factors, degree of pain, and medications used.
2. Perform a complete neurologic examination to detect any focal deficits or signs of increased ICP that indicate tumor or hemorrhage.
3. Assess coping mechanisms and emotional status.

Nursing Diagnoses

- Acute Pain related to headache.
- Ineffective Coping related to chronic and/or disabling pain.

Nursing Interventions

Controlling Pain

1. Reduce environmental stimuli: light, noise, and movement to decrease severity of pain.
2. Suggest light massage for tight muscles in neck, scalp, or back for tension headaches.
3. Apply warm, moist heat to areas of muscle tension.
4. Encourage patient to lie down and attempt to sleep.
5. Teach progressive muscle relaxation to treat and prevent tension headaches.
    a. Alternately tense and relax each group of muscles for a count of five, starting with the forehead and working downward to the feet.
    b. Try to maintain a state of relaxation of each muscle group until the whole body feels relaxed.
    c. Relaxation of just head and neck may also be helpful if time is limited.
6. Teach patient the cause of headache and proper use of medication.
7. Encourage adequate rest once headache is relieved to recover from fatigue of the pain.

Promoting Positive Coping

1. Encourage patient to become aware of triggering factors and early symptoms of headache, so it can be prevented or promptly treated. Hunger, lack of exercise, and erratic sleep schedules may trigger headaches.
2. Encourage adequate nutrition, rest and relaxation, and avoidance of stress and overexertion to better cope with headaches.
3. Implement problem solving to help patient manage problems that arise in social or work situations related to headaches.
4. Review coping mechanisms and strengthen positive ones.
5. Promote use of headache diary.

Patient Education and Health Maintenance

1. Teach proper administration of medication.
    a. Self-injection of sumatriptan given subcutaneously with autoinjector.
    b. Oral inhalation technique of ergotamine through metered-dose inhaler.
    c. Nasal spray dosing of sumatriptan.
2. Teach about adverse effects of medications.
    a. GI upset, gastritis, and possible ulcer formation with NSAIDs—take with food.
    b. Numbness, coldness, paresthesias, and pain of extremities with ergot derivatives—report to health care provider.
    c. Chest pain, wheezing, flushing with sumatriptan—report to health care provider.
    d. Hypotension with beta-adrenergic blockers and calcium channel blockers—arise slowly, do not exceed prescribed dosage, do not discontinue beta-adrenergic blockers abruptly.
3. Advise avoidance of alcohol, which can worsen headaches.
4. Teach about foods that are high in tyramine, which may trigger migraines—aged cheese, red wine, some processed meats. Some food additives such as nitrates may also trigger migraines, and many people identify their own individual triggers.
5. Teach patient how to perform relaxation techniques to reduce stress and promote inner well-being.
6. Refer patient for more information to the International Headache Society (*http://www.ihs-headache.org/*).

Evaluation: Expected Outcomes

- Reports fewer, less-severe headaches.
- Describes use of positive coping mechanisms.

Herniated Intervertebral Disk

Herniation of the intervertebral disk (ruptured disc) is a protrusion of the nucleus of the disk into the annulus (fibrous ring around the disk) with subsequent nerve compression. The herniation may occur in any portion of the vertebral column (see Figure 15-13). The pressure on spinal nerve roots or the spinal cord causes severe, chronic, or recurrent back and leg pain.

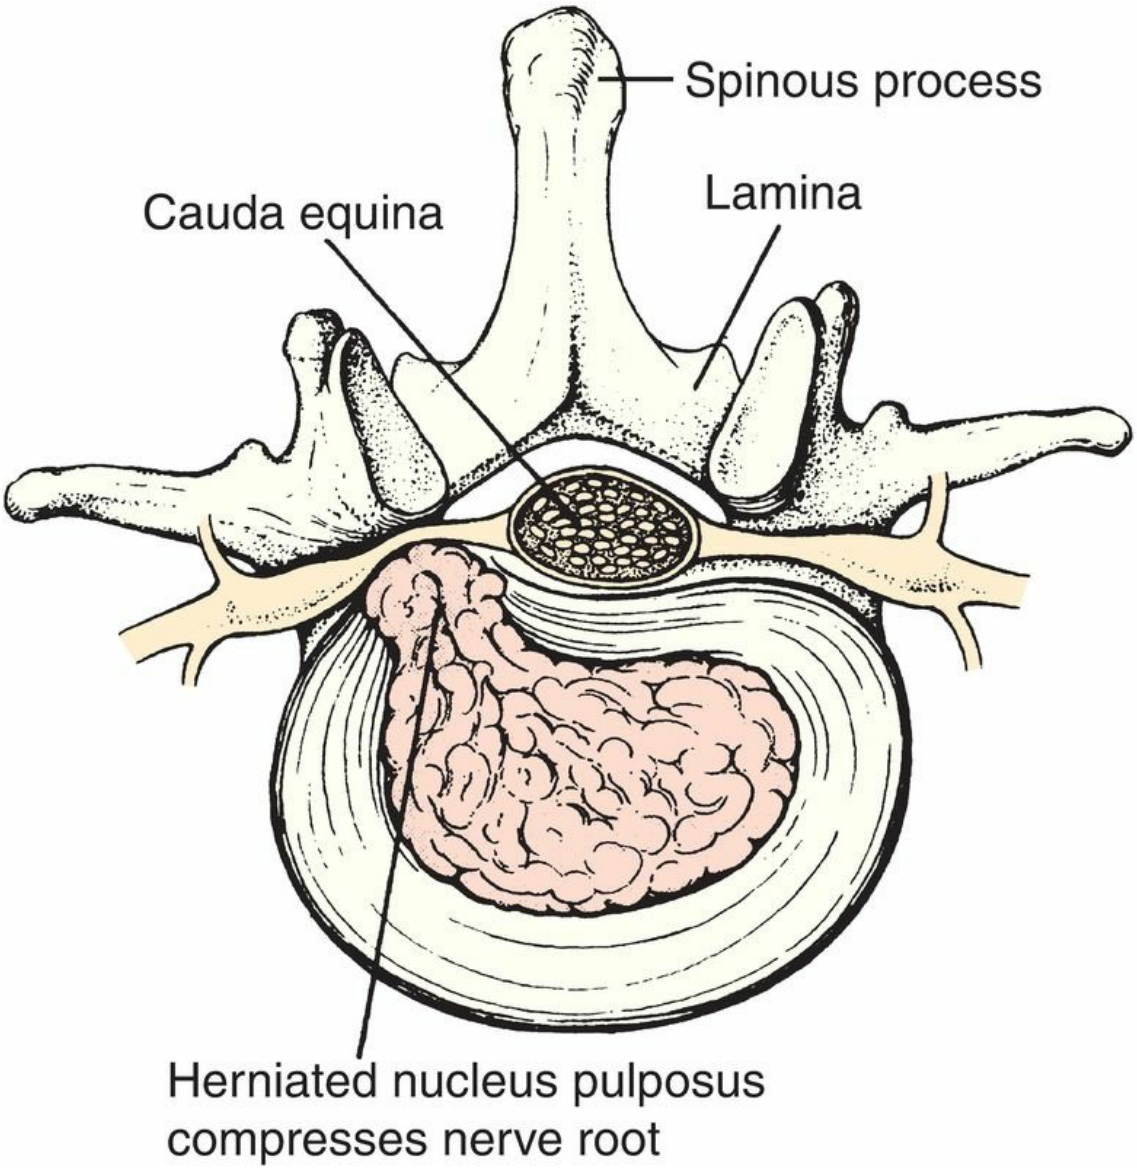

Figure 15-13. Ruptured vertebral disk. (Smeltzer, S., and Bare, B. [2000]. Brunner and Suddarth's textbook of medical-surgical nursing [9th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

1. The intervertebral disk is a cartilaginous plate made up of gelatinous material in the center, known as the nucleus pulposus, and is encapsulated in the fibrous annulus.

2. About 90% of herniated disks involve the lumbar and lumbosacral spine. The most common site is the L4–L5 disk space. The cause of a herniated lumbar disk is usually a flexion injury, but many patients do not recall experiencing a traumatic event. Cervical herniation is less common; but when it does occur, it is usually in individuals age 45 or older.
3. Risk factors for herniation include
   a. Degeneration (aging), trauma, and congenital predisposition.
   b. Biomechanical factors, such as twisting and repetitive motions in occupational settings.
   c. Sedentary occupations.
   d. Obesity.
   e. Smoking.
4. The herniation compresses the spinal nerve root, usually restricted to one side and, with further degeneration of the disk, may eventually produce pressure on the spinal cord.
5. This sequence may take months to years, producing acute and chronic symptoms.

Clinical Manifestations

General Considerations

1. An intervertebral disk may herniate without causing symptoms.
2. Symptoms depend on location, size, rate of development, and effect on surrounding structures.
3. Most symptomatic disk herniations result in pain, sensory changes, loss of reflex, and muscle weakness that resolve without surgery.

Cervical

1. Pain and stiffness in the neck, top of shoulders, and region of the scapula.
2. Pain in upper extremities and head.
3. Paresthesias and numbness of upper extremities.
4. Weakness of upper extremities.

Lumbar

1. Lower back pain with varying degrees of sensory and motor dysfunction.
2. Pain radiating from the lower back into the buttocks and down the leg, referred to as sciatica.
3. A stiff or unnatural posture.
4. Some combination of paresthesias, weakness, and reflex impairment.
5. Positive straight-leg raise test: pain occurs in leg below the knee when leg is raised from a supine position.

NURSING ALERT Cauda equina syndrome is an urgent condition caused by an acute compression

of the cauda equina area of the spinal cord by massive disk extrusion. Symptoms include progressive sensory and motor loss of lower extremities, saddle anesthesia (loss of sensation around perineum), bowel and/or bladder incontinence, or sexual dysfunction. It must be recognized early and compression must be relieved to prevent permanent loss of these functions. If patients report such symptoms, emergent assessment and intervention is indicated.

Diagnostic Evaluation

1. CT scan or MRI—demonstrates herniation; MRI has greater sensitivity.
2. Electromyography—localizes specific spinal nerve involvement.
3. Myelogram—rarely done, but demonstrates herniation and pressure on spinal cord or nerve roots.

Management

Nonpharmacologic Measures

1. Bed rest on a firm mattress (2 days usually sufficient) usually results in improvement in 80% of patients.
2. Heat or ice massage to affected area.
3. Cervical collar or possibly cervical traction is widely used, although efficacy is not proven.
4. Physical therapy may be prescribed to maximize function and assist the patient in recovery.
5. Epidural steroid injection may be administered by interventional radiologist, particularly with the presence of radiculopathy, radiating/shooting pain down the extremity, to relieve symptoms.
6. Nonpharmacologic and pharmacologic measures may be used together for 4 to 6 weeks as conservative management if there is no progressive neurologic deficit.
    a. More than 90% of low back pain episodes resolve completely by 4 to 6 weeks and those with herniated disc may experience spontaneous remission of pain.
    b. Surgical intervention is reserved for those with neurologic deficits or persistent symptoms over 6 weeks and is designed to relieve radicular (sciatic) pain.

Pharmacotherapy

1. Anti-inflammatory drugs, such as ibuprofen or prednisone.
2. Muscle relaxants, such as diazepam or cyclobenzaprine.
3. Analgesics; opioids may be necessary for several days during acute phase.

Surgical Intervention

1. May be done if there is progression of neurologic deficit or failure to improve with conservative management.
2. Surgical procedures include discectomy (decompression of nerve root), laminectomy, spinal fusion, microdiscectomy, and percutaneous discectomy.
3. Hemilaminectomy with excision of the involved disk is the surgical procedure most often indicated for lumbar disk disease.

Chemonucleolysis

1. Less common invasive treatment for lumbar disk herniation.
2. Injection of chymopapain into herniated disk that produces loss of water and proteoglycans from the disk, reducing the size of the disk and subsequent pressure on the nerve root.
3. May cause severe complications, such as transverse myelitis, allergic reactions, and persistent muscle spasm.

Alternative and Complementary Measures

1. Acupuncture.
2. Manipulative therapy.
3. Massage therapy for adjunct pain relief.
4. Homeopathic remedies.
5. Various nutritional supplements.

Complications

1. Permanent neurologic dysfunction (weakness, numbness).
2. Chronic pain with associated psychosocial issues.
3. Cauda equina syndrome.

Nursing Assessment

1. Perform repeated assessments of motor function, sensation, and reflexes to determine progression of condition.
2. Assess level at which straight-leg raise test is positive; generally, radiation of pain below knee at 45 degrees of elevation is considered positive for nerve root involvement; positive at lesser elevation may indicate worsening condition.
3. Assess pain level on scale of 0 to 10.

Nursing Diagnoses

- Acute Pain related to area of compression.
- Impaired Physical Mobility related to pain and disease physiology.
- Deficient Knowledge related to impending surgery.
- Risk for Infection and other complications of surgical procedure.

Nursing Interventions

Minimizing Pain

1. Administer or teach self-administration of anti-inflammatory drugs, as prescribed, and with food or antacid to prevent GI upset.
2. Administer or teach self-administration of prescribed muscle relaxant; observe safety because drowsiness

may result.

3. Administer or teach self-administration of analgesics, as prescribed; be prepared for sedation.
4. Encourage regular activity with limits of pain.
5. Apply dry or moist heat to affected area of back, as desired.
6. Encourage relaxation techniques, such as imagery and progressive muscle relaxation.

Maintaining Mobility

1. Encourage ROM exercises while in bed.
2. Properly fit and use a cervical collar (if appropriate to level of injury).
3. Apply a back brace or cervical skin traction, if ordered.
4. Inspect skin several times a day, especially under stabilization devices, for redness and evidence of pressure ulcer development.
5. Provide good skin care to pressure-prone areas.
6. Assist the patient with activities at bedside and discourage lifting or straining of any kind.
7. Encourage compliance with physical therapy treatments and activity restrictions, as ordered.

Preparing the Patient for Surgery

1. Educate the patient about surgical procedure.
    a. Procedure is generally short.
    b. Small incision will be made on front or back of neck for cervical herniation; second incision may be on hip if a bone graft is taken from iliac crest for spinal fusion.
    c. Routine postoperative care will include frequent assessment of vital signs and neurologic function, frequent turning and deep breathing, pain control, and ambulation on the first postoperative day.
2. Document baseline neurologic assessment to compare with after surgery.
3. Explain your actions to the patient as you prepare the operative area, administer preoperative medications, and perform any other preoperative order.

Preventing Complications Postoperatively

1. Monitor vital signs and surgical dressing frequently because hemorrhage is a possible complication.
2. If the patient has a wound drainage system, check tubing frequently for patency and secure vacuum seal.
3. Assess movement and sensation of extremities regularly, report new deficit.
4. Administer analgesics and steroid medications to control pain from incision and swelling around nerve roots and spinal cord due to surgery.
5. Maintain cervical collar, if ordered.
6. Logroll the patient to reposition frequently and encourage coughing and deep breathing.
7. Position the patient for comfort with a small pillow under his or her head (but avoid extreme neck flexion) and pillow under knees to take pressure off lower back.
8. Provide fluids as soon as gag reflex and bowel sounds are noted.

9. Assess for hoarseness, which suggests that cervical surgery resulted in a recurrent laryngeal nerve injury; this injury may cause an ineffective cough.
10. Watch for dysphagia due to edema of the esophagus and provide dietary modifications, as necessary.
11. Make sure that the patient voids after surgery; report urine retention.
12. Encourage ambulation as soon as possible by having the patient lie on the side close to the edge of the bed and push up with arms while swinging legs toward floor in one motion; alternate walking with bed rest, discourage sitting.
13. Report any sudden reappearance of radicular pain (may indicate nerve root compression from slipping of bone graft or collapsing of disk space) or burning back pain radiating to buttocks (may indicate arachnoiditis).

Community and Home Care Considerations

1. Demonstrate and encourage back strengthening, aerobic exercise (walking, biking, swimming), and endurance exercises.
2. Make sure that the patient avoids heavy lifting and bending/twisting from the waist and uses proper body mechanics in all activities.
3. Discourage prolonged bed rest and inactivity.
4. Refer for vocational counseling, if indicated.
5. If cervical skin traction is ordered for home use, teach the patient how to apply the chinstrap and head halter. The weight should hang freely over the back of a chair or doorknob near the head of the bed. Make sure the patient maintains proper alignment of the neck and removes traction before moving the head.

Patient Education and Health Maintenance

1. Educate the patient regarding lifestyle changes—smoking cessation, increased activity, weight loss.
2. Provide instructions regarding back anatomy and back care to reduce symptoms.
3. Teach the patient the importance of cervical collar use and other conservative measures to try to reduce inflammation and heal disk herniation.
4. Tell the patient who has had a cervical disk herniation to avoid extreme flexion, extension, or rotation of the neck and to keep the head in neutral position during sleep.
5. Encourage the patient with a lumbar disk herniation to maintain ADL within pain limits, but lifting and sitting for prolonged periods are discouraged.
6. Encourage the patient to do stretching and strengthening exercises of extremities and abdomen after acute symptoms have subsided. The back can be gently stretched by lying on the back and bringing the knees up toward the chest.
7. Teach the patient about proper body mechanics and the use of leg and abdominal muscles rather than the back. Knees should be bent on lifting and load should be carried close to midtrunk.
8. Encourage follow-up with physical therapy, as indicated, for reconditioning and work hardening.

9. Tell the patient to avoid the prone position, long car rides, and sitting in a soft chair.
10. Instruct the patient to report any changes in neurologic function or recurrence of radicular pain.
11. Encourage good nutrition, avoidance of obesity, and proper rest to reduce risk of recurrence.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Maintains mobility with active lifestyle.
- Expresses understanding of preoperative preparation and postoperative care.
- Incision healing without signs of infection; patient ambulating with minimal pain.

Chronic (Open-Angle) Glaucoma
Retinal Detachment
Other Problems of the Retina and Vitreous
Eye Trauma

INTRODUCTION

Terms and Abbreviations

Definitions of Terms

1. *Accommodation:* Focusing apparatus of the eye that adjusts to objects at different distances by means of increasing the convexity of the lens (brought about by contraction of the ciliary muscles).
2. *Ametropia:* Abnormal vision.
    a. *Myopia:* Nearsightedness: rays of light coming from an object at a distance of 20 feet or more are brought to a focus in front of the retina.
    b. *Hyperopia:* Farsightedness: rays of light coming from an object at a distance of 20 feet or more are brought to a focus in back of the retina.
3. *Astigmatism:* Uneven curvature of the cornea causing the patient to be unable to focus horizontal and vertical rays of light on the retina at the same time.
4. *Emmetropia:* Normal vision: rays of light coming from an object at a distance of 20 feet (6 m) or more are brought to focus on the retina by the lens (see Figure 16-1).
5. *Presbyopia:* The elasticity of the lens decreases with increasing age; an emmetropic person with presbyopia will read the paper at arm's length and will require prescription lenses to correct the problem.
6. *Strabismus:* Deviation of the eye so that the visual axes are not physiologically coordinated.
7. *Vision:* Passage of rays of light from an object through the cornea, aqueous humor, lens, and vitreous humor to the retina and its appreciation in the cerebral cortex.
8. *Visual acuity:* Measurement of a person's ability to see at a distance or near (reading distance) and is measured against a standard of a normal person's visual ability.

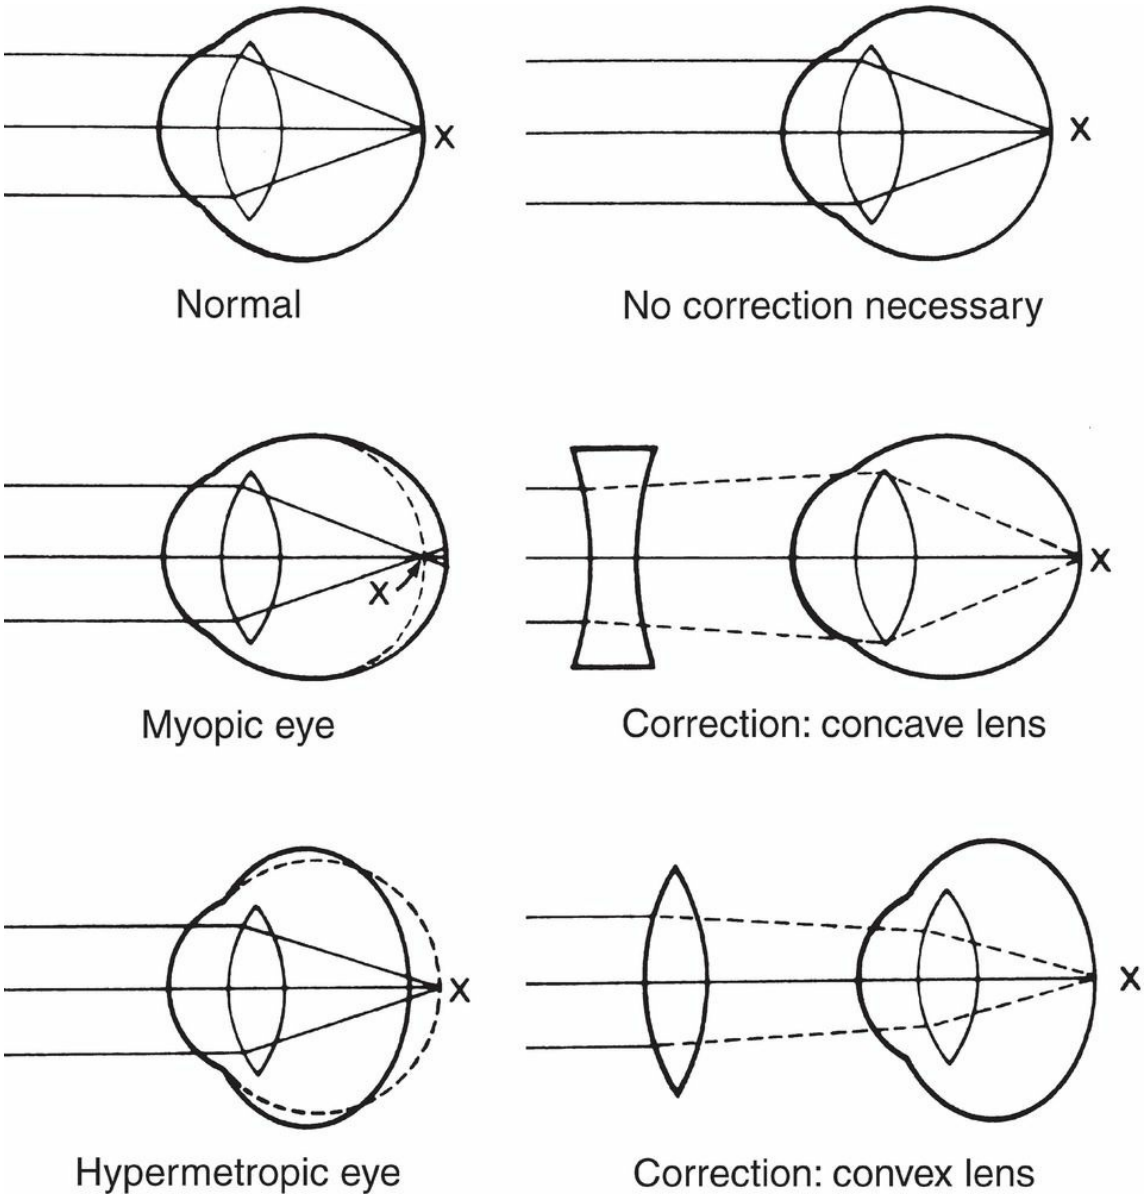

Figure 16-1. Normal vision and refractory errors.

Common Abbreviations

OD (oculus dexter) or RE—right eye.

OS (oculus sinister) or LE—left eye.

OU (oculus unitas)—both eyes.

IOP—intraocular pressure.

IOL—intraocular lens.

EOL—extraocular lens.

VA—visual acuity.

Eye Care Specialists

1. **Ophthalmologist:** Physician specializing in diagnosis, surgery, and treatment of the eye; may specialize

in a specific part of the eye or disorder, such as a cornea specialist or glaucoma specialist.

2. **Optometrist:** Doctor of optometry who can examine, diagnose, and manage visual problems and diseases of the eye but does not perform surgery.
3. **Optician:** Technician who fits, adjusts, and gives eyeglasses or other devices on the written prescription of an ophthalmologist or optometrist.
4. **Ocularist:** Technician who makes ophthalmic prostheses.

Subjective Data

EVIDENCE BASE American Society of Ophthalmologic Registered Nurses. (2014). *Essentials of ophthalmic nursing. Book 1* (2nd ed.). San Francisco, CA: Author.

Subjective data for eye assessment include complaints of altered vision or other symptoms, associated lifestyle and other factors, and recent and past health history.

Presenting Symptoms

1. Explore the chief complaint from patient by asking the following questions:
   a. Is there pain, foreign body sensation (scratchy, something in the eye), photophobia, dryness, redness, itchiness, lacrimation, or drainage?
   b. Is there blurred vision, double vision, loss of vision, or change in vision in a portion of the visual field?
   c. Are there other visual symptoms such as glare, halos, floaters?
   d. Is there difficulty in functioning, such as driving or reading, because of visual problem?
2. Review related systems.
   a. Neurologic: Are there scintillations, scotomas, transient ischemic attacks, headache, sensory or motor dysfunction?
   b. Ear, nose, and throat: Any nasal congestion, rhinitis, sinus pain, dry mouth?
   c. Integumentary: Are there changes in skin and mucous membranes?
   d. Endocrine: Any complaints of polyuria, polydipsia; signs of hyperthyroidism (see page 709)?
   e. Musculoskeletal: Is there joint pain or swelling?

History

1. Review ocular history.
   a. Have there been previous eye injuries, surgeries, and ocular procedures?
   b. Is patient using glasses or contact lenses?
   c. Was there childhood poor vision or patching of the eye?
   d. Are there current visual problems such as glaucoma, cataracts, macular degeneration, or diabetic retinopathy?
2. Obtain medication history, including nonprescription, herbal, topical, and inhalant products.
3. Determine allergies to medications; note type of reaction.
4. Determine history of systemic conditions such as diabetes, cardiovascular disease, arthritis, Marfan syndrome, albinism, sickle cell anemia.

5. Obtain family history of ocular conditions such as glaucoma, cataracts, macular degeneration, color blindness, retinitis pigmentosa, retinoblastoma, nystagmus, keratoconus, choroideremia, corneal dystrophies, and other chronic diseases.
6. Perform functional assessment.
    a. Depending on the patient's circumstance, administer the National Eye Institute Visual Function Questionnaire (VFQ-25) available at *www.rand.org/health/surveys_tools/vfq.html*, or other valid visual functioning questionnaires such as the VF-14.
    b. This helps determine the need for surgery based on the extent to which the eye disorder interferes with the patient's ability to carry out a visually dependent activity of daily living such as driving and reading.

GERONTOLOGIC ALERT Question older patients about driving. Change in driving pattern, such as avoidance of night driving and less rush-hour driving, may indicate visual dysfunction as well as impaired reflexes and ability to concentrate in complex situations. A common complaint is not being able to read road signs in time to respond to them.

Ocular Examination

See Figure 16-2. Also see "Adult Physical Assessment," page 45.

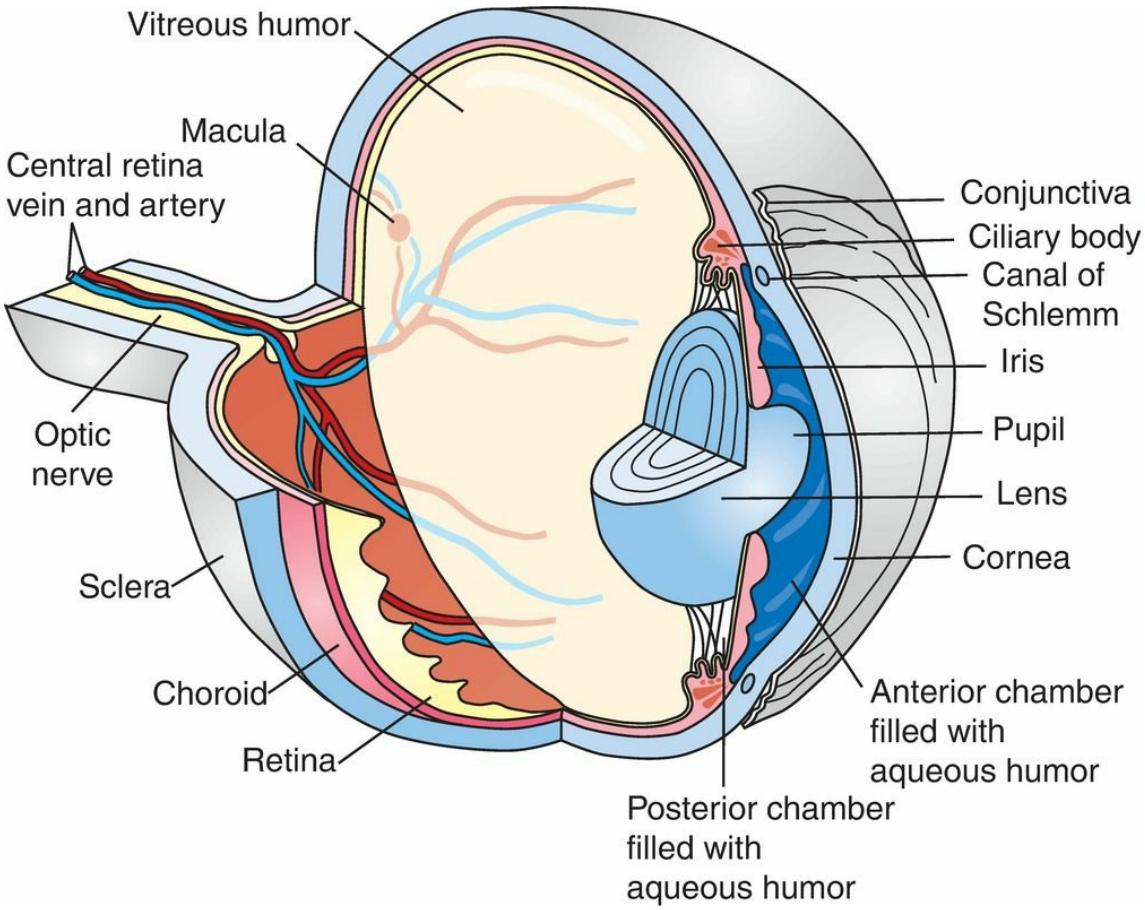

Figure 16-2. Three-dimensional cross-section of the eye. (Smeltzer, S., and Bare, B. [2000]. *Brunner and Suddarth's textbook of medicalsurgical nursing* [9th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

NURSING ALERT Every patient who seeks medical attention for an eye complaint should have visual acuity tested.

External Examination

Includes examination of the eye and accessory organs without the aid of special apparatus.

Visual Acuity at Distance (Snellen Chart and Other Methods)

1. Letters and objects are of different sizes that can be seen by the normal eye at a distance of 20 feet (6 m) from the chart.
2. Letters appear in rows and are arranged, so the normal eye can see them at distances of 30, 40, and 50

feet (9, 12, and 15 m), and so forth.

3. Each eye is tested separately, with and without correction (glasses or contact lenses), whereas the nontesting eye is completely occluded.
4. Test the right eye (OD) first and then the left eye (OS).
5. A person who can identify letters of the size 20 at 20 feet (6 at 6 m) is said to have 20/20 (6/6) vision.
6. If vision is less than 20/200 (6/60), additional tests may be recorded as:
    a. Counting fingers (CF)—at feet (meters).
    b. Hand motion (HM)—ability to detect hand movement at a certain distance.
    c. Light perception and projection (LP).
    d. Light perception only.
    e. No light perception.

Visual Acuity at Near (Jaeger Chart and Other Methods)

1. Letters and objects are of different sizes that can be seen by the normal eye at a reading distance of 14 inches from the chart.
2. Letters appear in rows and are arranged, so the normal eye can read them at different levels on the Jaeger chart.
3. Each eye is tested separately, with and without correction (glasses or contact lenses), whereas the nontesting eye is completely occluded.
4. Test the right eye (OD) first and then the left eye (OS).
5. The vision is documented in Jaeger or Snellen notation where J1+ is equivalent to 20/20, J2 equivalent to 20/30, and so forth.

Visual Fields

Determines function of optic pathways and identifies loss of visual field and functional capacity.

1. Equipment—light source and test objects. May be performed manually or as automated visual fields.
2. Peripheral field—useful in detecting decreased peripheral vision in one or both eyes.
    a. Patient is seated 18 to 24 inches (45.5 to 61 cm) in front of the examiner.
    b. The left eye is covered, whereas the patient focuses with the right eye on a spot about 12 inches (30.5 cm) from the eye.
    c. A test object is brought in from the side at 15-degree intervals through a complete 360 degrees.
    d. The patient signals when he or she sees the test object and again when the object disappears through the 360 degrees.

Color Vision Tests

These tests are done to determine the person's ability to perceive primary colors and shades of colors. It is particularly significant for people whose occupation requires discerning colors, such as artists, interior decorators, transportation workers, surgeons, and nurses. (Useful in diagnosing diffuse retinal dysfunction and

various types of optic neuropathies.)

1. Equipment.
   a. Polychromatic plates—dots of primary colors printed on a background of similar dots in a confusion of colors.
   b. Individual colored disks—each disk is matched to its next closest color.
2. Procedure.
   a. Various polychromatic plates are presented to the patient under specified illumination.
   b. The patterns may be letters or numbers that the normal eye can perceive instantly, but that are confusing to the person with a perception defect.
3. Outcome.
   a. Color blindness—person can't perceive the figures.
   b. Red-green blindness—8% of males, 0.4% of females.
   c. Blue-yellow blindness—rare.

Refraction

Refraction is a clinical measurement of the error of focus in an eye.

1. Refraction and internal examination may be accomplished by instilling a medication with cycloplegic and mydriatic properties into the conjunctiva of the eye. Tropicamide or cyclopentolate are two such medicines that cause ciliary muscle relaxation, pupil dilation (mydriasis), and lowered accommodative power (cycloplegia).
2. In older children and adults, refraction without the use of drugs is preferred.
3. Visual screening through a multiple pinhole card can help refractive causes of decreased vision versus decreased vision secondary to organic disease.
4. The refractive state of the eye can be determined in two ways:
   a. Objectively—through retinoscopy or by automatic refraction (special instrument that measures, computes, and prints out refraction errors of each eye).
   b. Subjectively—trial of lenses to arrive at the best visual image.

Internal Examination

Ophthalmoscopic Examination

1. Direct ophthalmoscopy—uses a strong light reflected into the interior of the eye through an instrument called an ophthalmoscope.
2. Indirect ophthalmoscopy—allows the examiner to obtain a stereoscopic view of the retina. Light source is from a head-mounted light. The examiner views the retina through a convex lens held in front of the eye and a viewing device on the head mount. The image appears inverted. This method of examination allows the examiner to use binocular vision with depth perception and a wider viewing field.
3. Clinical significance:

a. Detection of cataracts, vitreous opacities, corneal scars.
b. Close examination for the pathologic changes in retinal blood vessels that may occur with diabetes or hypertension.
c. Examination of the choroid for tumors or inflammation.
d. Examination of the retina for retinal detachment, scars, or exudates and hemorrhages.

Slit-Lamp Examination

1. Special equipment that magnifies the cornea, sclera, and anterior chamber and provides oblique views into the trabeculum for examination by the ophthalmologist.
2. Helps detect disorders of the anterior portion of the eye.
3. The room is generally darkened and the pupils are dilated.
4. The patient sits with chin and forehead resting against equipment supports.

Tonometry

1. Measures IOP, which depends on the amount of aqueous humor secreted into the eye and ease by which it leaves.
2. Tonometry is indicated as one of the measurements to screen for glaucoma, assess the development of glaucoma if suspected, evaluate glaucoma therapy, and diagnose phthisis and drug-induced IOP increase.
3. Normal tension is considered less than or equal to 20 mm Hg.
4. Tonometry techniques.
   a. Goldmann applanation tonometry (see Figure 16-3).
      i. This is the most effective measuring method for determining IOP; however, it requires a biomicroscope and a trained interpreter. May be part of the slit-lamp examination or done by hand-held device.
      ii. After instillation of topical anesthesia, the cornea is flattened by a known amount (3.14 mm).
      iii. The pressure necessary to produce this flattening is equal to the IOP, counterbalancing the tonometer.
   b. Schiotz tonometry (rarely used at present).
   c. Electronic tonometer that provides a digital reading of IOP, such as the Tono-Pen.
   d. Pneumatonometer or air applanation tonometry—requires no topical anesthesia and measures tension by sensing deformation of the cornea in reaction to a puff of pressurized air.
   e. Perkins hand-held tonometer.
   f. Finger tension—pressure determined by use of digital pressure.

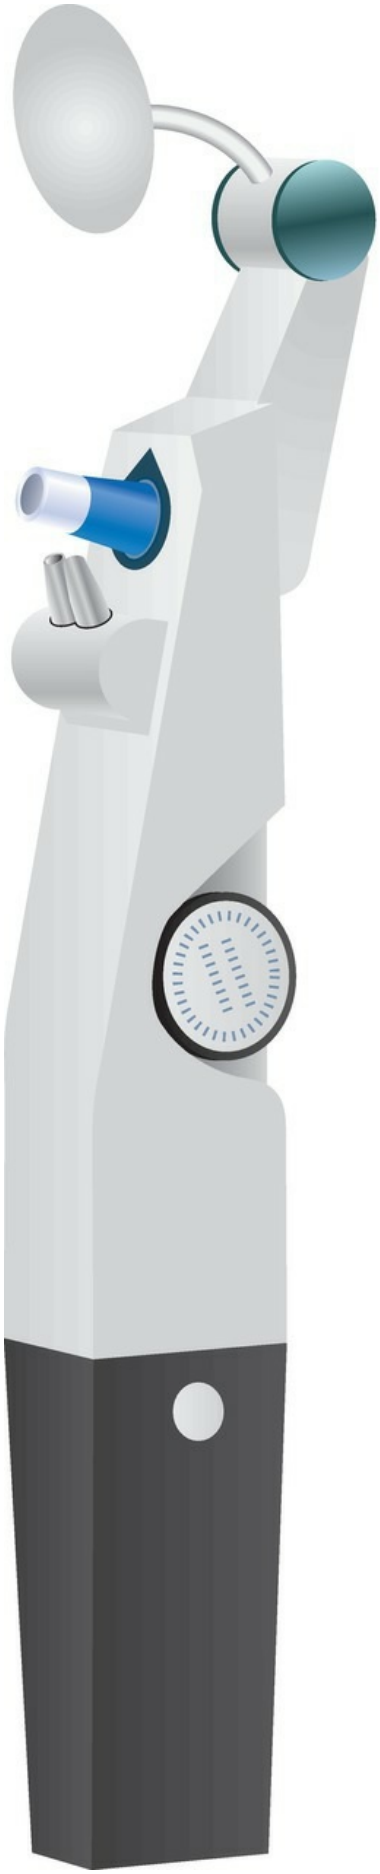

Figure 16-3. Example of an applanation tonometer.

Radiology and Imaging

Several imaging studies beyond the basic eye examination may be done to further evaluate eye disease.

Fluorescein Angiography

Description

1. Provides information concerning vascular obstructions, microaneurysms, abnormal capillary permeability, and defects in retinal pigment permeability.
2. Introduction of sodium fluorescein IV administration over several minutes, usually through a brachial vein.
3. Indirect ophthalmoscopy using a blue filter may be done and photographs of the ocular fundus are obtained.

Nursing and Patient Care Considerations

1. Advise the patient that a series of eye drops will be given to dilate the pupil for better visualization of the retina. The patient will be positioned in a special chair with head immobilized.
2. Dye will be injected into the arm over several minutes. Photographs will be taken during injection and up to 1 hour after injection.
3. Adverse effects include nausea because of dye injection, burning in eye from eye drop instillation, blurred vision and photophobia for 4 to 8 hours because of pupil dilation, and possible yellow skin and urine discoloration for up to 48 hours after dye injection.

DRUG ALERT Serious reactions, such as hoarseness, respiratory obstruction, tachycardia, and anaphylactic reaction leading to death may result from sodium fluorescein IV administration.

Eye and Orbit Sonography

Description

1. Sound waves are used in the diagnosis of intraocular and orbital lesions. Three types of ultrasonography are used in ophthalmoscopy:
   a. A-scan—uses stationary transducers to measure the distance between changes in acoustic density. This is used to differentiate between benign and malignant tumors and to measure the length of the eye to determine the power of an IOL.
   b. B-scan—moves linearly across the eye; increases in acoustic density are shown as an intensification on the line of the scan that presents a picture of the eye and the orbit.
   c. IOL Master technology—evaluates the length of the eye, surface curvature, and IOL power; has increased the accuracy of biometry by fivefold. It is also less technician-dependent for accuracy.

2. Abnormal patterns are seen in alkali burns, detached retina, keratoprosthesis, thyroid ophthalmopathy, foreign bodies, vascular malformations, benign and malignant tumors, and a variety of other conditions.

Nursing and Patient Care Considerations

1. Advise the patient that topical anesthetic drops are applied to the eye before the procedure so the patient will not feel the transducer contacting the eye.
2. The procedure may take as little as 8 to 10 minutes or 30 minutes or longer, if a lesion is detected, to locate the lesion.
3. Warn patient not to rub eyes until the anesthetic has worn off to avoid trauma to the eye.

Electroretinography

Description

Used to evaluate hereditary and acquired disorders of the retina; an electrode is placed over the eye to evaluate the electrical response to light.

Nursing and Patient Care Considerations

1. Advise the patient that the eyes are propped open and patient will be positioned lying or sitting down.
2. Topical anesthetic drops are instilled.
3. A cotton wick electrode saturated in saline is applied to the cornea.
4. Various intensities of light are produced and the electrical potential is measured.
5. Caution the patient not to rub eyes for up to 1 hour after procedure to avoid trauma while eyes are anesthetized.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 16-1–16-5.

PROCEDURE GUIDELINES 16-1

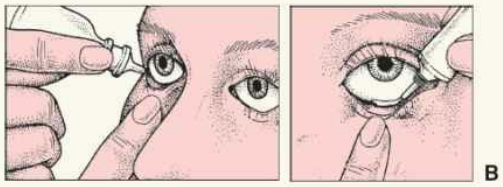
Instillation of Eye Medications

EQUIPMENT

- Sterile solution or medication (most medications have accompanying dropper or are in squeeze bottle or tube)
- Small gauze squares or tissues

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Inform the patient of the need and reason for instilling drops or ointment.	1. Allays fear and enlists cooperation.
2. Allow the patient to sit with head tilted backward or to lie in a supine position.	2. Provides a position of comfort and safety for the patient and accessibility for the nurse.
3. Verify the patient's identification.	3. Prevents error.
4. Check written prescription and bottle, vial, or tube for correct medication.	4. Avoids medication error.
5. Check prescription, designating eye requiring drops.	5. Order may be written with abbreviation. OD (oculus dexter)—right eye OS (oculus sinister)—left eye OU (oculus uterque)—both eyes
6. Wash hands before instilling medication.	6. Prevents transfer of microorganisms to patient.
Performance phase	
1. Remove cap from container and place on clean surface.	1. Prevents contamination of lid.
2. If eyedropper is used, fill eyedropper with medication by squeezing bulb.	2. Eye droppers are used less frequently than dropper bottles.
3. Using forefinger, pull on skin below lower lid.	3. Exposes inner surface of lid and cul-de-sac.
4. Instruct patient to look upward.	4. Prevents medication from hitting sensitive cornea and prevents blepharospasm.
5. Drop medication amount prescribed into center of lower lid (cul-de-sac) (see Figure A).	5. Prevents medication from hitting sensitive cornea.



A B

6. If ointment is to be instilled, squeeze out 1/8-inch ribbon of medication (size of grain of rice) from the tube into the lower lid without touching the eye with the end of the tube (see Figure B).	6. Prevents contamination of the tube. Avoids dispensing excessive ointment; clouds vision.
7. Instruct patient to close eyes slowly but not to squeeze or rub them. Open eye.	7. Squeezing or rubbing would express medication from eye and increase lacrimal drainage from the eye; closing allows medication to be distributed evenly over eye.
8. Clear any excess medication with gauze or tissues.	8. Prevents possible skin irritation.
9. If additional eye drops are ordered, wait 30 sec between each drop.	9. Allows time for absorption of medication.

NURSING ALERT Parietal occlusion (place finger over lacrimal duct for 1 minute) may be necessary after instilling drops if systemic absorption is to be avoided, prolonged corneal contact is desired, or taste or smell of medication is distressing.

Nursing Action	Rationale
Follow-up phase	
1. Wash hands after instilling medication.	1. Prevents transfer of microorganisms to self or other patients.
2. Record time, type, strength, and amount of medication and the eye into which medication was instilled.	2. Provides documentation in the medication record.

EVIDENCE BASE American Society of Ophthalmologic Registered Nurses. (2011). *Ophthalmic procedures in the office and clinic* (3rd ed.). Dubuque, IA: Kendall/Hunt.

PROCEDURE GUIDELINES 16-2

Irrigating the Eye (Conjunctival Irrigation)

EQUIPMENT

- An eyedropper, aseptic bulb syringe, or plastic bottle with prescribed solution depending on the extent of irrigation needed (usually more than 1,000 mL for each eye)
- For copious use (ie, chemical burns), sterile normal saline or prescribed solution and IV setup with attached tubing
- Irrigating lens for chemical injury (contraindicated for particulate matter)
- Litmus paper
- Basin, towels

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Verify the eye to be irrigated and the solution and amount of irrigant. Work as quickly as possible and have equipment ready ahead of time if chemical injury is suspected.	1. Prevents error.
2. The patient may sit with head tilted back or lie in a supine position.	2. Facilitates flow of solution over the eye.
3. Instruct the patient to tilt head toward the side of the affected eye.	3. Prevents fluid from draining into unaffected eye.
DRUG ALERT Topical anesthetic drops may be instilled prior to irrigation according to policy or order. If used, do not allow patient to rub eye for 45 minutes to avoid injury.	
Performance phase	
1. Test pH using plain litmus paper in cul-de-sac of affected eye.	1. Serves as a baseline. Alkaline (pH > 7) is more damaging than acidic (pH < 7).
2. Wash eyelashes and lids with prescribed solution at room temperature; a curved basin should be placed on the affected side of the face to catch the outflow.	2. Any materials on the lids and lashes should be washed off before exposing conjunctiva.
3. Evert the lower conjunctival sac. (If feasible, have the patient pull down lower lid with index finger.)	3. Exposes inner surfaces of lower lid and conjunctival sac (involves the patient and gives a sense of control).
4. Instruct the patient to look up; avoid touching eye with equipment.	4. Prevents injury to the sensitive cornea.
5. Allow irrigating fluid to flow from the inner canthus to the outer canthus along the conjunctival sac.	5. Prevents solution from flowing toward the unaffected eye.
6. Use only enough force to flush secretions from conjunctiva. (Allow patient to hold receptacle near the eye to catch fluid.)	6. Prevents eye injury (involves the patient in the treatment).
7. Occasionally, have patient close eyes.	7. Allows upper lid to meet lower lid with the possibility of dislodging additional particles.
8. Wait 1 min after irrigation and retest pH.	8. If pH is not 7, repeat irrigation.
Follow-up phase	
1. Pat eye dry and dry the patient's face with a soft cloth.	1. Provides comfort.
2. Record kind and amount of fluid used as well as its effectiveness.	2. Provides documentation of nursing actions.
EVIDENCE BASE American Society of Ophthalmic Registered Nurses. (2011). *Ophthalmic procedures for the office and clinic* (3rd ed.). Dubuque, IA: Kendall/Hunt.	

PROCEDURE GUIDELINES 16-3

Application of an Eye Patch, Eye Shield, and Pressure Dressing to the Eye

EQUIPMENT

- Eye covering to be used (shield, oval patches)
- Tape Scissors
- Tincture of benzoin or skin protectant (optional)

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Wash hands.	1. Prevents contamination.
2. Explain procedure to patient.	2. Allays fear and ensures cooperation.
3. Verify patient and eye to be patched.	3. Prevents error.
4. Instill ointment, if directed, prior to patching.	4. May be ordered to protect cornea from abrasion or prevent infection.
5. Shave the male face and apply tincture of benzoin, as indicated.	5. Enhances ability for tape to stick and protect the skin from tape.
Performance phase	
1. For eye patch:	
a. Instruct patient to close both eyes.	a. It may be difficult to close only the affected eye.
b. Place patch over affected eye.	b. May need two or more patches, depending on the depth of the eye compared with the surrounding bones.
c. Secure the patch with two or more strips of tape applied downward and diagonally from midforehead to cheek.	c. Although transparent tape is easy to remove and adhesive tape is most secure, hypoallergenic tape should be used if patient has had reaction to tape in past.
2. For eye shield:	
a. Apply over dressings or directly over the undressed eye, fastening with two or more strips of tape.	a. Used primarily to protect the eye. Some shields may be bent to rest over bony prominences. Tape placed around edges of the shield will not obstruct vision through holes in the shield.
b. Be sure that there are no rough edges against the skin.	b. Prevents abrasion. Use skin protectant, as indicated.
3. For pressure dressing:	
a. Have the patient close both eyes tightly.	a. Prevents eye from opening before dressing is secured.
b. Fold patch in half (short end to short end) and place over closed eyelid (with fold line at eyebrow). Cover with additional unfolded patches.	b. Provides pressure dressing bulk.
c. Apply strips of tape firmly from check to forehead, overlapping each strip.	c. Secures dressing and applies pressure.
Follow-up phase	
1. Trim tape and monitor for security of patch or shield.	1. For patient's safety and comfort.
2. Advise patient that because depth perception will be impaired, he or she should perform activities carefully and report any foreign body sensation.	2. Prevent accidents or corneal abrasion if eyelid opens and patch rubs against cornea.

EVIDENCE BASE American Ophthalmic Association of Registered Nurses. (2011). *Ophthalmic procedures for the office or clinic* (3rd ed.). Dubuque, IA: Kendall/Hunt.

PROCEDURE GUIDELINES 16-4

Removing a Particle from the Eye and Fluorescein Staining

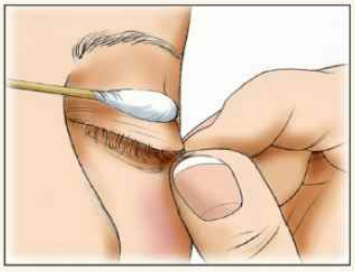
EQUIPMENT

- Local anesthesia
- Hand lens
- Sterile fluorescein strips and illumination source

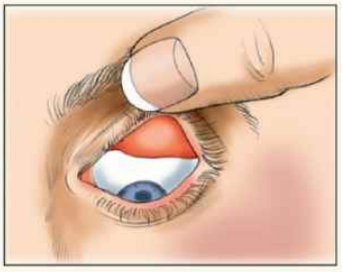
- Cotton applicator
- Normal saline
- Antibiotic solution

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
NURSING ALERT It is important to take a patient history to determine the nature of the foreign body. If the particle is metal or entered the eye with projectile force, trauma to the eye could result. It may be necessary for the ophthalmologist to remove the foreign body immediately without attempting this method to prevent further injury.	
1. Perform hand hygiene.	1. Prevents contamination.
2. Explain procedure to patient.	2. Allays fear and ensures cooperation.
3. Instill anesthetic eye drops, as directed.	3. Facilitates comfort.
Performance phase	
Removal of particle	
1. As patient looks upward, place your finger below the lower lid and pull downward to expose the conjunctival sac. Inspect for particles using a hand lens.	1. Particles are often washed downward by the upper lid.
2. With small cotton applicator dipped in saline, remove particle by gently wiping across conjunctival surface.	2. Prevents trauma. Saline promotes adherence of a particle.
3. If offending particle is not found, proceed to examine upper lid.	
a. Have the patient look downward.	a. Moves sensitive cornea down and away from area of activity.
b. Encourage the patient to relax; move slowly and reassure patient that procedure will not be painful.	b. Relaxation prevents squeezing the lids shut, a maneuver that contracts the orbicularis muscle, making eversion of lid impossible.
c. Place cotton applicator stick horizontally on outer surface of upper lid. Apply pressure about 1 cm above lid margin (see Figure A).	c. Because the upper tarsal plate extends 0.4 to 0.5 inch (10 to 12 mm) above the lid margin, pressure must be applied at least ½ inch (1 cm) above the lid margin for easy eversion of lid.
d. Grasp upper eyelashes with forefinger and thumb and pull the upper lid outward and upward over cotton applicator (see Figure B). Remove particle, if present.	d. Because particles may be washed under the lid, visual exposure assists in detection. Eyelid will remain everted by itself during inspection and removal.
e. Ask the patient to look up and blink.	e. Returns eyelid to neutral position.



A



B

Nursing Action	Rationale
Fluorescein staining	
1. Use fluorescein strip to detect corneal abrasion.	1. Green stain will indicate if abrasion is present.
2. Apply a drop of saline to the strip; pull the lower eyelid down and gently touch the tip of the strip to the inner aspect of the eyelid.	2. Moistening the strip enhances release of the dye.
3. Ask the patient to blink several times to distribute the dye.	3. Dye will be dispersed over the conjunctive and cornea.
4. Cornea is viewed through a slit lamp, Woods lamp, or other blue filter light to best illuminate area of abrasion and ulceration.	4. Breaks in the epithelium will cause aqueous humor to color the fluorescein dye green under blue light.
Follow-up phase	
1. Apply antibiotic ointment, as directed.	1. Prevents potential serious infection from break in cornea.
2. Apply patch, if indicated.	2. Rest eye and protect cornea for healing.

EVIDENCE BASE American Society of Ophthalmic Registered Nurses. (2011). *Ophthalmic procedures for the office and clinic* (3rd ed.). Dubuque, IA: Kendall/Hunt.

PROCEDURE GUIDELINES 16-5

Removing Contact Lenses

EQUIPMENT

- Containers
- Labels
- Normal saline
- Towel
- Good lighting
- Eye suction cup (optional)

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. If patient is able, have him or her sit upright with towel in lap. If patient is incapacitated, use recumbent position.	1. Towel will catch lens if it slips away.
2. Perform hand hygiene.	2. Prevents contamination of conjunctiva.
3. Explain procedure to patient.	3. Allays fear if patient is conscious.
Performance phase	
1. For hard lens with patient sitting:	
a. Open eyelids with two fingers and determine if lens is in normal position; if not, gently manipulate it over pupil.	a. Will need to be removed through area of greatest lid opening.
b. Place one finger at the outer canthus (temporal) and have the patient open both eyes widely.	
c. While applying traction toward the ear, ask the patient to look toward nose and blink.	c. Lens should become dislodged or pop out when blinks.
2. For hard lens with patient lying recumbent and use of suction cup:	2. If patient is incapacitated and not able to cooperate with steps in #1, use of suction cup may be necessary.
a. Make sure suction cup has been properly cleaned and disinfected.	a. Should be washed with soap and water and wiped with alcohol after each use and stored in clean container.
b. Moisten suction cup with normal saline.	b. Attracts lens.
c. Separate eyelids with your fingers and gently manipulate lens over pupil, if necessary.	c. Will remove more easily and without trauma if centered.
d. Apply suction cup to lens to obtain suction and gently lift to remove lens.	d. Lifting will maintain suction and prevent trauma. Tilting will break suction.
3. For soft lens:	
a. Open eyelids and determine position of lens.	a. Soft lens may be difficult to see and may be creased and displaced.
b. Retract the lower lid and place your index finger on the lower edge of the lens and attempt to slide it off the cornea onto the sclera.	b. Lens should be removed from the sclera to avoid trauma. Having the patient look up (if possible) will facilitate this.
c. If the lens is adherent to eye or misshaped, apply normal saline drops or commercial rewetting solution.	c. Will loosen lens and prevent trauma with manipulation.
d. Pinch the lens between your thumb and index finger and gently remove it from the eye.	d. Soft lenses will not pop out on their own.
Follow-up phase	
1. Retrieve lens and put lens (lenses) in containers containing solution labeled right and left.	1. So patient may be able to use lenses again after proper cleaning.
2. Make sure patient is comfortable following the procedure.	2. Eyes should not be dry or lids retracted. Cool compress may be soothing.
3. Perform hand hygiene.	3. Prevents contamination to nurse or other patients.
4. Ensure safe disposition of the lenses.	4. So lenses will not be lost or thrown away.

EVIDENCE BASE American Society of Ophthalmic Registered Nurses. (2011). *Ophthalmic procedures in the office and clinic* (3rd ed.). Dubuque, IA: Kendall/Hunt.

Common Eye Procedures

Instillation of Medications

1. Ophthalmic medications may be used for diagnostic and therapeutic purposes:
   a. To dilate or contract the pupil.
   b. To relieve pain, discomfort, itching, and inflammation.
   c. To act as an antiseptic in cleansing the eye.
   d. To combat infection.
2. Solution or ointment is administered using clean technique.
   a. Use one finger to pull downward on skin of lower lid.
   b. Drop solution or squeeze out 1/8 inch ribbon of ointment into center of conjunctival sac.
   c. Instruct the patient to close eye slowly but do not squeeze lids tightly or rub them.

See Figure 16-4 and Table 16-1.

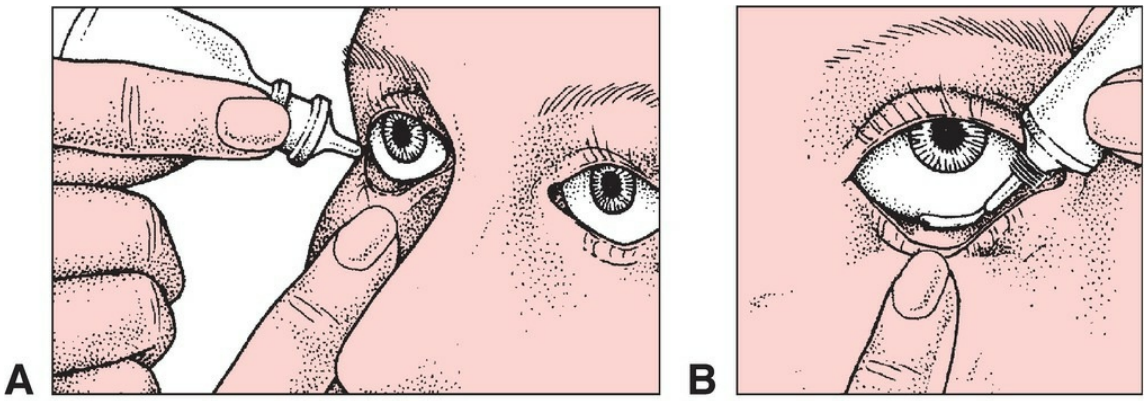


Figure 16-4. Instilling eye medication: **(A)** solution (drops) and **(B)** ointment.

Table 16-1 Ophthalmic Pharmacologic Agents*

PHARMACOLOGY	ACTION	PRODUCTS
Sympathomimetics	Given topically for the treatment of glaucoma. Immediate effect is decrease in production of aqueous humor. Long-term effect is an increase in outflow of aqueous humor. May be used in combination with miotics, beta-adrenergic blockers, carbonic anhydrase inhibitors, or hyperosmotic agents.	• Epinephrine • Dipivefrin • Phenylephrine
Miotics, direct-acting	Cholinergic agents given topically that affect the muscarinic receptors of the eye; results include miosis and contraction of the ciliary muscle. In narrow-angle glaucoma, miosis opens the angle to improve aqueous outflow. Contraction of the ciliary muscle enhances the outflow of aqueous humor by indirect action of the trabecular network—the exact mechanism is unknown. Primary use of miotics is in glaucoma but can be used to counter the effects of cycloplegics/mydriatics.	• Acetylcholine • Carbachol • Pilocarpine
Miotics, cholinesterase inhibitors	Topical agents that inhibit the enzyme cholinesterase, causing an increase in the activity of the acetylcholine already present in the body. Causes intense miosis and contraction of the ciliary muscle. Decrease in IOP that is seen as a result of increased outflow of aqueous humor. Used for treatment of open-angle glaucoma, conditions where the outflow of aqueous is obstructed; post iridectomy problems; and accommodative esotropia (inward deviation of one eye).	• Demecarium bromide • Isoflurophate • Physostigmine
Beta-adrenergic blockers	Act on the beta receptors of the adrenergic nervous system. Two types of beta sites: B_1 and B_2. The B_1 site is primarily the myocardium resulting in decreased heart rate and cardiac output. B_2 primarily bronchial and vascular smooth muscle resulting in bronchoconstriction, decreased blood pressure. There are two types of ophthalmic beta-adrenergic blockers: cardioselective blocker (betaxolol) acts only on B_1 sites and may on rare occasions cause cardiac effects if absorbed systemically. All other nonselective blockers act on B_1 and B_2 sites and cause significant cardiac and pulmonary effects if absorbed systemically. Used for treatment of increased IOP by decreasing the formation of aqueous humor and causing a slight increase in the outflow facility.	• Betaxolol • Levobunolol • Timolol • Carteolol
Carbonic anhydrase inhibitors	Oral agents that act to inhibit the action of carbonic anhydrase. Suppression of this enzyme results in a decreased production of aqueous humor. Used in combination regimen to treat glaucoma and postoperative rise in IOP.	• Acetazolamide • Methazolamide
Osmotic diuretics	Osmotic agents given intravenously used for reduction of IOP in acute attack of glaucoma or before ocular surgery where preoperative reduction of IOP is indicated.	• Mannitol • Glycerin
Prostaglandin analogues	Newer agents used in the lowering of IOP presumably by increasing uvealscleral flow or filtration of aqueous. Used in open-angle glaucoma resistant to other agents.	• Latanoprost • Travoprost • Bimatoprost • Unoprostone
Mydriatics	Topical agents that result in dilation of the pupil, vasoconstriction, and an increase in the outflow of aqueous humor. Used for pupillary dilatation for surgery and examination.	• Phenylephrine
Cycloplegic mydriatics	Topical agents that block the reaction of the sphincter muscle of the iris and the muscle of the ciliary body to cholinergic stimulation, resulting in dilatation of the pupil (mydriasis) and paralysis of accommodation (cycloplegia). Used in conditions requiring pupil to be dilated and kept from accommodation.	• Atropine • Homatropine • Scopolamine • Cyclopentolate • Tropicamide
Ophthalmic anti-infectives	Topical agents used for treatment of ophthalmic infections. Commercial products are intended for treatment of superficial ocular problems, such as conjunctivitis and blepharitis. Extemporaneous (compounded) drops are used for more serious topical infections (ie, corneal ulcer, endophthalmitis [intraocular infection]).	*Antibiotics* • Bacitracin • Chloramphenicol • Ciprofloxacin • Erythromycin • Gentamicin • Gatifloxacin • Levofloxacin • Moxifloxacin

		• Neomycin/polymyxin/bacitracin • Norfloxacin • Sulfacetamide • Tobramycin *Antifungal* • Amphotericin B • Fluconazole • Natamycin *Antiviral* • Trifluridine • Vidarabine
Local anesthetics	Block the transmission of nerve impulses. Used topically to provide local anesthetic for tests, such as tonometry, and for procedures of short duration. Injections used in ophthalmology for retrobulbar blocks.	*Topical* • Proparacaine • Tetracaine injection • Lidocaine
Ophthalmic steroid anti-inflammatories	Mostly corticosteroids. Used topically to relieve pain and photophobia as well as suppress other inflammatory processes of the conjunctiva, cornea, lid, and interior segment of the globe.	• Dexamethasone • Fluorometholone • Loteprednol • Prednisolone acetate
Nonsteroidal anti-inflammatory drugs (NSAIDs)	Act by inhibiting an enzyme involved in the synthesis of prostaglandins, which are key in the body's response to inflammation. These drugs, given topically, are analgesics and anti-inflammatories.	• Diclofenac sodium • Flurbiprofen • Ketorolac • Suprofen
Anti-allergy medications	There are a number of different types of drugs, given topically, in this category, including antihistamine, mast cell stabilizers, NSAID anesthetic, and astringents (some in combination).	*Antihistamines* • Emedastine • Levocabastine • Olopatadine • Pheniramine *Mast cell stabilizers* • Cromolyn • Lodoxamide *Astringent* • Zinc sulfate
Vasoconstrictors	Topical agents that contract local blood vessels, resulting in less redness and irritation.	• Naphazoline
Alpha-selective adrenergic agonist agents	Topical agents that mimic the effects of endogenous adrenergic compounds by selectively binding to alpha-2 receptors, resulting in aqueous formation, pupil diameter, and ocular flow. Commonly used for lowering elevated IOP.	• Apraclonidine hydrochloride • Brimonidine tartrate
Anti-VEGF agents	Slow growth of abnormal blood vessels under the retina by blocking the effects of VEGF to slow vision loss and possibly improve vision in wet age-related macular degeneration.	• Bevacizumab • Pegaptanib • Ranibizumab

**All pharmacologic agents should be reviewed from manufacturer's information or drug reference source before administration for contraindications, adverse reactions, and cautions.*

IOP, intraocular pressure; VEGF, vascular endothelial growth factor.

Irrigation of the Eye

1. Ocular irrigation is often necessary for the following:
   a. To irrigate chemicals or foreign bodies from the eyes.
   b. To remove secretions from the conjunctival sac.
   c. To treat infections or relieve itching.
   d. To provide moisture on the surface of the eyes of an unconscious patient.
2. Use prescribed solution or 1,000 mL of normal saline solution with IV tubing.
3. Test pH with litmus paper before flushing if chemical injury is suspected and after irrigation until pH is 7.
4. Evert the lower conjunctival sac and have the patient look up, and then direct the irrigating solution from the inner canthus toward the outer canthus along the lower conjunctival sac.

Application of Dressing or Patch

1. One or both eyes may need shielding for the following:
    a. To keep an eye at rest, thereby promoting healing.
    b. To prevent the patient from touching eye.
    c. To absorb secretions.
    d. To protect the eye.
    e. To control or lessen edema.
2. Instill ointment if directed and make sure that eye is closed before securing gauze patch or eye shield with tape strips placed diagonally from midforehead to outer cheek.

Removing a Particle from the Eye

1. Typically, removing a foreign body from the eye is an uncomplicated first-aid measure.
    a. As the patient looks upward, place your finger below the lower lid and pull downward to expose the conjunctival sac.
    b. Inspect for particles using a light and magnifying lens.
    c. Remove particle with cotton-tipped applicator moistened in saline by gently wiping across the conjunctival sac.
2. If no offending particle is found, proceed to the upper lid.
    a. As the patient looks downward, place the cotton applicator horizontally on the upper lid and gently pull the lid outward and upward over the applicator (see Figure 16-5).
    b. Remove particle if found and return eyelid to neutral position.
3. If a particle appears to be embedded, medical intervention is required, that is, local anesthetic, antibiotic therapy, and clinical expertise in using other instruments.
4. The cornea should be evaluated for abrasion from the foreign body by use of fluorescein staining, even if a foreign body cannot be found.

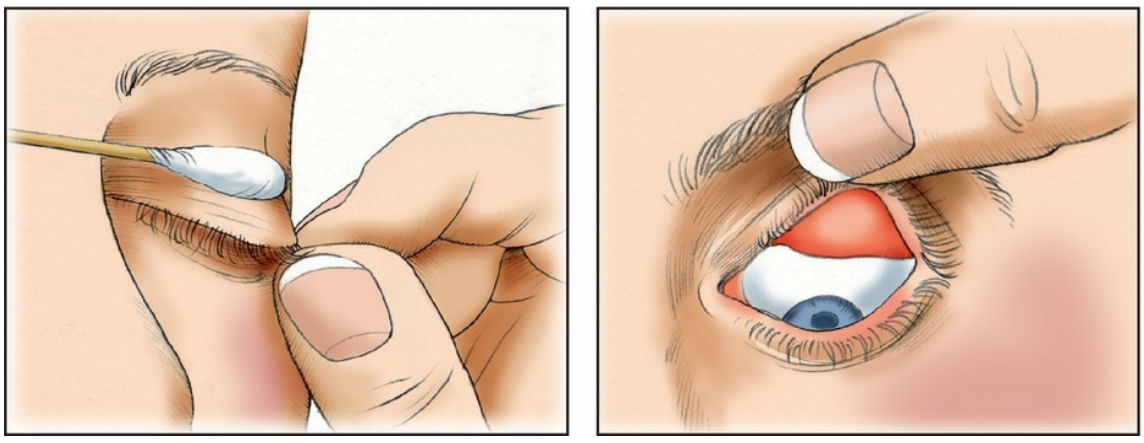

Figure 16-5. Removing a particle from the eye.

Removing Contact Lenses

1. Because contact lenses need regular cleaning and changing, if a person is injured and incapacitated because of an accident, sickness, or other cause, the lenses should be removed.
2. Determine the type of lens from the patient or family.
    a. Soft corneal lenses are widely used. The diameter covers the cornea plus a portion of the sclera of the eye. Extended- and daily-wear soft lenses are available.
    b. Rigid or gas-permeable lenses are usually smaller than the cornea of the eye, although some are made to extend beyond the cornea onto the sclera of the eye. These lenses need to be removed promptly.
3. Do not remove lenses if the iris is not visible on opening the eyelids; await the arrival of an ophthalmologist. If patient is to be transported, note that contacts are in the eyes. (Write out the message and tape it to the patient or send with transporter.)
4. To remove soft lenses, retract the lower lid and attempt to slide the lens off the cornea using your index finger, and then pinch the lens between 2 fingers and gently remove it.

Ocular Surgery

Common types of ocular surgery are described, followed by a nursing process overview for any patient having ocular surgery. Also see the following entries for specific surgical care: conditions of the eyelids, page 441; cataract, page 442; retinal detachment, page 448; and acute glaucoma and chronic glaucoma, page 446.

Corneal Transplantation (Keratoplasty)

Description

1. The transplantation of a donor cornea, usually obtained at autopsy, to repair a corneal scar, burn, deformity, or dystrophy.
2. Types of grafts.
   a. Full thickness (6.5 to 8 mm)—most common.
   b. Partial-thickness lamellar.
3. Fresh cornea is the preferred tissue; it is removed from the donor within 12 hours after death and used within 24 hours.
4. Special solutions for storage of fresh cornea are available, which may extend storage up to 3 days.
5. *Cryopreservation* is the care and handling of a corneal graft by freezing to retain its transparency.

Complications

1. Hemorrhage.
2. Graft dislocation.
3. Infection.
4. Postoperative glaucoma.
5. Graft rejection—may occur 10 to 14 days postoperatively; signs and symptoms include decreased vision, ocular irritation, corneal edema, and red sclera.

Refractive Surgery

Description

1. A variety of procedures used to correct nearsightedness, farsightedness, and astigmatism; may eliminate need for glasses or contact lenses, especially with aging.
2. May not be appropriate with corneal disease, retinal disease, glaucoma, severe diabetes, uncontrolled vascular disease, autoimmune disease, or pregnancy.
3. There is no guarantee on desired effect, but complication rate is extremely low.
4. Procedures are quick, performed in physician's office or clinic, and most people are back to full activity in 1 to 3 days.
5. Specific procedures are used to correct nearsightedness, farsightedness, or astigmatism.
6. May eliminate need for glasses, especially with aging.

Types of Procedures

1. Radial keratotomy.
    a. Procedure designed to provide correction of myopia (nearsightedness).
    b. The cornea is anesthetized topically, and under a microscope, the surgeon marks the visual axis.
    c. Eight to sixteen radial incisions are made into the corneal surface to flatten it. This permits images to fall on the retina instead of in front of it.
    d. Time to optimal correction is about 3 months. (Procedure is being performed much less frequently now with the development of laser surgery for refraction.)
2. Excimer photorefractive keratectomy.
    a. Limited to correcting myopia and some astigmatism.
    b. The front surface of the corneal epithelium is removed (by laser, manual scraping, or both).
    c. The laser is then used to change the corneal curvature by vaporizing the tissue (reshaping or sculpting the cornea).
    d. Optimal visual recovery about 6 months.
3. Laser-assisted in situ keratomileusis (LASIK); also laser-automated lamellar keratoplasty (laser ALK).
    a. Procedure is designed to treat a wider range of prescriptions than the other refractive procedures.
    b. Microsurgical instrument (microkeratome) is used to create a corneal flap.
    c. A cool laser beam (using an excimer laser) reshapes the cornea and the flap is then closed.
    d. The excimer laser can remove corneal tissue with an accuracy of up to 0.25 microns.
    e. Only about 50 microns of tissue are removed to achieve the desired correction.
    f. Refractive recovery about 3 months.
4. Holmium laser thermokeratoplasty (Holmium LTK).
    a. Tissue is heated, not vaporized.
    b. Cornea is marked to pinpoint where to aim the laser.
    c. The laser heats only selected portions of the cornea to shrink collagen fibers around the cornea edges.

Vitrectomy

1. This procedure is performed for conditions such as unresolved hemorrhage with diabetic retinopathy, intraocular foreign body, and vitreoretinal adhesions.
2. It involves the removal of all or part of the vitreous humor, the transparent, gelatin-like substance behind the lens.
3. As the vitreous is removed, saline is infused to replace the vitreous. At the end of the procedure, gas, air, or silicone oil may be introduced into the eye to act as a tamponade to keep the retina in place.
    a. If gas is used, the patient may be restricted to prone position (for at least 50 minutes of each hour) for 1 to 6 weeks until the SF6 gas is absorbed.
    b. If air or oil is used, a semi-Fowler's position is allowed.
4. Precautions should be taken to prevent increased IOP, which would disrupt healing.

a. Avoid straining to have bowel movement or bend over.
b. Avoid coughing or sneezing or sudden movements of the head.
c. Monitor for headache, which may be a sign of increased IOP.

Enucleation

1. Complete removal of the eyeball, usually performed due to trauma, infection, tumor such as melanoma, or prevention of sympathetic ophthalmia.
2. At surgery, the eye is removed by opening the conjunctiva and extraocular muscles, severing the optic nerve, and removing the eyeball.
3. A ball implant is then covered by the muscles and maintains the contour of the eye. The conjunctiva is then closed and a plastic conformer is placed to maintain the integrity of the eyelid.
4. An individualized prosthesis can be fitted 4 to 6 weeks later and a second procedure may be done to improve ocular motility.
5. Care considerations include acceptance of body image, adjustment to mononuclear vision, and care of the enucleated socket and prosthesis, including the following:
   a. Inspecting eye and lid.
   b. Instilling medication.
   c. Irrigating site to remove mucus.
   d. Removing the prosthesis.
   e. Using aseptic technique when performing care.
6. Complications include hemorrhage, infection, and implant extrusion.

Nursing Assessment

1. Collect subjective and objective data about patient's general state of health.
2. Ascertain what symptoms the patient has been having (eye pain, visual loss, drainage, history of trauma) and how that has impacted usual activity.
3. Assess the patient's mobility and self-care ability.
4. Assess visual, as well as other sensory impairments, which may impact safety and independence.
5. Gather data regarding usual support systems used by the patient. Is family near? Do friends visit regularly? Is increased supervision required after surgery because of visual impairment?
6. Review patient's medications and determine if anticoagulants have been taken. They are usually stopped just prior to retinal surgery; however, they are usually continued for patients undergoing cataract surgery.

Nursing Diagnoses

- Deficient Knowledge of postoperative expectations and continuing care.
- Risk for Injury related to increased IOP and altered vision.
- Impaired Environmental Interpretation Syndrome related to visual disturbance.
- Fear of blindness related to invasive procedure to eye.

- Bathing, Dressing, Feeding Self-Care Deficit related to reduced or altered vision.

Nursing Interventions

Preparing for Surgery

1. Explain to the patient preoperative orders as well as postoperative expectations. (These will be specific for each type of surgery and particular health care provider.)
   a. Eye surgery is usually performed under local anesthesia and that he or she will be awake but sedated and must remain still during procedure.
   b. Postoperatively, a specific position in bed may be maintained for a few hours.
      i. The patient may be required to lie on the unoperated side
      ii. Following vitrectomy, the patient may be required to lie prone for at least 50 minutes of every hour. Advise the patient that he or she stand up to use bathroom and shower but must keep nose pointing to the ground. Although this is a difficult restriction to follow, it's the only way to improve visual outcome with this procedure.
      iii. Following some surgeries, supine position may be required with only a small pillow.
2. Instruct the patient to wash hair the evening before surgery; long hair of female patients should be arranged so it is off the face. There may be restrictions on using makeup to prevent makeup flakes from entering the operative site, thereby increasing the risk for infection and inflammation.
3. Check agency surgical policy regarding skin preparation. Patients may be requested to shower with antibacterial soap the evening before or morning of surgery.
4. Check that operative permit is correct and signed with specified eye having surgery noted. Ask patient which eye (do not suggest an eye). Verification can prevent two thirds of wrong site incidents.
5. Remove dentures, contact lenses, or eye prosthesis and metal objects before patient goes to the operating room based on facility policy and type of anesthesia. (Wedding band can usually be taped in place.)
6. Inform the patient if eye bandages are necessary postoperatively.
   a. Eye patch used following keratoplasty.
   b. Pressure patch used after vitrectomy. Drainage is expected for 2 days postoperatively.
   c. Pressure dressing and ice used after enucleation.
7. Administer preoperative medications, including eye drops, as prescribed.
8. Position bed side rails (up) after administering medications and place the call bell next to the patient.
9. Be available to answer questions the patient may have relating to the surgery or postoperative period.

NURSING ALERT For patients requiring bed rest (ie, after keratoplasty, eye injury, retinal detachment surgery), measures should be taken to prevent pulmonary and/or circulatory complications. This may include range-of-motion exercises, anti-embolism stockings, and pneumatic compression devices.

Preventing Injury Postoperatively

1. Position the patient, as permitted, for specific surgery.
   a. Prone if vitrectomy was done with gas to hold retina in place.
   b. Semi-Fowlers for vitrectomy with air or oil was used.
2. Position side rails (up) to offer the patient a sense of security.
3. Place the call bell next to the patient; have the patient call the nurse rather than risk increased IOP from the stress and strain of attempting to be self-sufficient.
4. Advise the patient to avoid bending over, quick movements of the head, or straining that may cause increase in IOP. Medicate, if indicated, for excessive coughing or sneezing. (May not be a concern for current, small-incision cataract surgery.)
5. Monitor for headache, which may be a sign of IOP.
6. Instruct caregivers to tell the patient when they enter and leave the room.
7. Avoid activities such as combing hair that may cause tension on sutures or operative site.
8. Apply cold compresses to control edema and associated discomfort following vitrectomy.

Compensating for Altered Vision

1. Orient the patient to any new environment—room arrangement and people.
2. Encourage self-care within the patient's limits.
3. Supervise attempts of the patient to feed himself or herself and in other self-care activities.

GERONTOLOGIC ALERT Be aware that older people may have additional sensory/perceptual alterations, such as hearing loss and decreased position sense, which increases their risk of falls and feeling of isolation.

Reducing Fear

1. Be aware that dependence on sight is recognized when one faces diminishment or loss of sight.
2. Recognize that patients' concern of surgical outcome may be manifested differently, for example, fear, depression, tension, resentment, anger, or rejection.
3. Encourage the patient to express feelings.
4. Demonstrate interest, empathy, and understanding.
5. Reassure the patient that rehabilitative programs and personnel are available.
6. Refer patient to the local blind or low-vision association for training and adaptive equipment.

Increasing Self-Care Activities

1. Provide diversional and occupational therapy to keep the patient occupied mentally within the limits of decreased vision.

2. Encourage rest periods, as necessary.
3. Provide adequate diet and fluids to promote proper elimination and decreased straining.
4. Discourage the patient from smoking, shaving with a straight edge, and use of pointed objects near eyes for safety reasons.
5. Caution the patient against rubbing eyes or wiping them with soiled tissues.
6. Instruct the patient to wear dark glasses if eyes are light sensitive.
7. Maintain safe environment—doors should be completely open or closed, floors kept clear of articles.

Patient Education and Health Maintenance

1. Advise the patient to consult ophthalmologist before undertaking diversional or recreational therapy that may be fatiguing to the eyes—such as reading, working on computer, and craft work.
2. Emphasize that lights should not be too bright or glaring.
3. Before the patient leaves the hospital, provide discharge instructions about medications, including topical antibiotics, corticosteroids, and pain medications.
4. Instruct the patient and family on instillation of eye medications, proper cleansing of the eyelids and lashes, and application of an eye shield or patch.
5. Provide instructions on massaging the eyelid in the postoperative period following eyelid surgery.
6. Assure patient of temporary bruising and swelling of eyelids.
7. Ensure that patient has follow-up information about eyeglasses, prosthesis fitting, and follow-up visits. Advise patient that improved vision may not occur quickly following keratoplasty.
8. Advise watching for signs of graft rejection 10 to 14 days following keratoplasty: decreased vision, irritation, corneal edema, and redness of sclera.
9. Educate the patient about talking books, records, tapes, and audio machines available from most public libraries without charge.

TRANSITIONAL CARE ALERT Confirm the following with the patient and family before discharge:

Is a return appointment date with health care provider confirmed?

Are prescriptions for patient's medications in hand or have been sent to pharmacy?

Do the patient and family member know how to use the prescribed medications?

Does the patient understand the restrictions placed on him or her and the reasons for them (positioning, straining, return to usual activities)?

Does the patient understand visual limitation and expected outcome?

Do the patient and family know what signs and symptoms to report to health care provider between appointments (ie, pain, temperature above 101°F [38.3°C], discharge from surgical area)?

Evaluation: Expected Outcomes

- Complies with preoperative routine; asks appropriate questions.
- Describes precautions that must be taken as safety measures, carries cane to prevent possible falls.
- Demonstrates improved vision in accordance with expectations of the surgery.
- Appears relaxed and positive concerning outcome of surgery.
- Manages self-care with minimal assistance.

COMMON EYE DISORDERS

Conditions of the Conjunctiva and Eyelids

The *eyelids* are the outermost defense mechanisms of the eyes, functioning as a physical barrier as well as to maintain moisture and disperse tears. The *palpebral conjunctiva* lines the upper and lower lids and the bulbar conjunctiva forms a protective coating over the sclera. The conjunctiva responds to infections, inflammatory disorders, and environmental irritants. Blood vessels in the conjunctiva dilate readily, causing redness, and pain receptors respond to inflammatory changes. Inflammatory disorders are outlined in Table 16-2. Structural disorders that may be amenable to surgery include:

Table 16-2 Conditions of the Eyelids and Conjunctiva

CONDITION	TREATMENT AND NURSING CONSIDERATIONS
Blepharitis	
An inflammatory reaction of the eyelid margin caused by bacteria (usually *Staphylococcus aureus*) or seborrheic skin condition, resulting in flaking, redness, irritation, and possibly recurrent styes of the upper or lower lid, or both.	Diagnostic culture usually not necessary. Mild cases treated with eyelid margin scrub at least once daily (baby shampoo may be used). If *S. aureus* is likely, antibiotic ointment is prescribed one to four times per day to eyelid margin. Teach patient to scrub eyelid margin with cotton swab to remove flaking and then apply ointment with cotton swab, as directed.
Hordeolum (Stye)/Chalazion	
The term "stye" refers to an inflammation or infection of the glands and follicles of the eyelid margin. External hordeolum involves the hair follicles of the eyelashes; chalazion is a granulomatous (chronic) infection of the meibomian glands. Bacteria, usually *Staphylococcus*, and seborrhea are the causes. Pain, redness, foreign body sensation, and a pustule may be present.	Treatment usually consists of warm soaks to help promote drainage, good handwashing and eyelid hygiene, and possible application of antibiotic ointment. In some cases, incision and drainage in the office with local anesthetic may be necessary. Teach patient how to clean eyelid margins and not to squeeze the stye.
Conjunctivitis	
Inflammation or infection of the bulbar (covering the sclera and cornea) or palpebral (covering inside lids) conjunctiva. May be allergic; bacterial (*S. aureus*, *Streptococcus pneumoniae*, *Haemophilus influenzae*, and others); gonococcal; viral (adenovirus, herpes simplex, coxsackievirus, and others); or irritative (topical medication, chemicals, wind, smoke, contact lenses, ultraviolet light) causes. Trachoma is caused by *Chlamydia trachomatis* and is a major cause of blindness worldwide, but is rare in North America. Symptoms of conjunctivitis vary from mild pruritus and tearing to severe drainage, burning, hyperemia, and chemosis (edema). The term "pink eye" usually refers to infectious conjunctivitis.	Fluorescein staining may be done to rule out ulceration or keratitis (involvement of cornea). Culture if purulent exudate; special culture for *Neisseria gonorrhoeae*. Warm soaks (10 minutes four times per day) used when crusting and drainage present; cold compresses helpful for allergic and irritative causes. If topical antibiotic ordered, teach patient instillation technique. Urge good handwashing to prevent spread. Allergic conjunctivitis treated with topical or oral antihistamines, vasoconstrictors, and mast cell stabilizers.

- Entropion—inward turning of the eyelid margin.
- Ectropion—outward turning of the eyelid margin.
- Ptosis (blepharoptosis)—drooping of the upper eyelid.
- Lagophthalmos—inadequate closure of the eyelids.
- Pinguecula—overgrowth of tissue on the conjunctiva.
- Ptergium—overgrowth of tissue on the cornea

Pathophysiology and Etiology

1. Entropion and ectropion are classified as congenital, involutional, paralytic (CN VII palsy), cicatricial, or mechanic. Caused by severe eye disease, trauma, surgery, chemical burn.
2. Ptosis is classified according to the underlying cause and timing of onset described as acquired or congenital. General causes include neurologic, muscular, and autoimmune disorders; eye socket tumors may also cause ptosis.

3. Pinguecula is a degenerative lesion and ptergium is a fibrovascular lesion; both typically result from ultraviolet light exposure.

Clinical Manifestations

1. Sagging and/or irritation of eyelid.
2. Redness, tearing, burning of the eye.
3. Superficial punctate keratitis (inflammation of cornea).
4. Yellowish nodules in bulbar conjunctiva (pinguecula); wing shaped folds of tissue across limbus of the cornea (pinguecula).
5. Loss of superior field of vision with ptosis or reduce visual acuity may be seen with pinguecula.
6. Lashes roll back against the ocular surface after eye lid is released—positive digital inversion test (entropion).

Diagnostic Evaluation

1. External examination detecting appearance and function of eyelids.
2. Inspection of the conjunctiva, sclera, and cornea, followed by slit-lamp examination.
3. Lid position measurements—margin-reflex distance (MRD), palpebral fissure, levator function, and distance between upper lid crease to lid margin.
4. Cranial nerve (CN) testing for extraocular movements (3rd, 4th, 6th CN) and visual fields (2nd CN).
5. Pharmacologic testing—phenylephrine or cocaine test to rule out Horner syndrome and edrophonium (Tensilon) test to rule out myasthenia gravis as causes of ptosis.

Management

1. Lubricating agents to treat inflammation of the cornea.
2. Massaging of eyelid, especially with cicatricial ectropion to help stretch scarring and improve anatomical position.
3. Manual inversion of eyelid margin for entropion.
4. Treatment of trichiasis by removing lashes with fine forceps.
5. Taping upper eyelid in ptosis.
6. Surgical management for ectropion and entropion.
    a. Ectropion and entropion repair—involves a horizontal tightening technique of the lower lid.
    b. Lateral canthoplasty (elongation of the eye opening).
    c. Lower lid retractor insertion.
7. Surgical management for ptosis.
    a. Approach depends of the cause and degree of ptosis and considers the object of the surgery, which is to balance the lid position in primary gaze.
    b. Complications of surgery include overcorrection and undercorrection of the eyelids, corneal or

conjunctival irritation, abnormal contour of the eyelids, lagophthalmos.

8. Surgical excision of ptergium may be necessary due to large size. Other options include stontium beta-irradiation or mitomycin-C administration.
9. Surgery for pinguecula is indicated when tissue growth passes the limbus and invades the Bowman's layer of the cornea.

For nursing management see page 439.

Disorders of the Cornea and Uveal Tract

The *cornea* is the outermost tissue that functions in vision. It must remain clear and smooth to admit light to the retina. Blood vessels are contained in the *limbus* (periphery). Epithelial layers of the cornea repair rapidly, but if they are penetrated, infection can rapidly spread inward and vision may be lost.

The *uveal tract* is made up of the iris, which controls pupil size; ciliary body, which secretes aqueous humor and controls accommodation; and choroid layer, which provides vasculature to the anterior uveal tract. Disorders of the uveal tract may cause pupil changes, problems with accommodation, clouding of the anterior chamber or vitreous, and more serious problems because of adhesions (see Table 16-3).

Table 16-3 Conditions of the Cornea and Uveal Tract

CONDITION	TREATMENT AND NURSING CONSIDERATIONS
Corneal Abrasion and Ulceration (Keratitis)	
Loss of epithelial layers of cornea because of some type of trauma—contact with fingernail, tree branch, spark or other projectile, or overwearing contact lens. May lead to corneal ulceration and secondary infection into cornea (keratitis), which may lead to blindness. Symptoms are pain, redness, foreign body sensation, photophobia, increased tearing, and difficulty opening eye.	Treatment is urgent. Fluorescein staining and examination with Woods lamp or slit lamp to identify the abrasion or ulceration. Antibiotic ointment may be instilled and eye patched for 24 hr. No benefit to patching has been found for simple abrasions, however. Cycloplegic drops may also be used in large abrasions or ulcers. Abrasion heals in 24–48 hr. Ulceration should be followed by an ophthalmologist. Make sure that patch is secure enough so patient cannot open eyelid, but not so tight that patient "sees stars." Teach patient to use topical antibiotic (or antiviral in cases of herpes simplex dendritic keratitis) after patch is removed, and follow-up as directed. Review safety practices, such as wearing protective eye shields, not rubbing eyes, using contact lenses properly, and washing hands frequently.
Iritis/Uveitis	
Uveitis is an inflammation of the intraocular structures. It is classified by involved structures (1) anterior uveitis—iris (iritis) or iris and ciliary body (iridocyclitis), (2) intermediate uveitis—structures posterior to the lens (pars plantis or peripheral uveitis), and (3) posterior uveitis—choroid (choroiditis), retina (retinitis), or vitreous near the optic nerve and macula. Anterior uveitis is most common and is usually unilateral. Posterior uveitis is usually bilateral. Causes of uveitis are infections; immune-mediated disorders, such as ankylosing spondylitis, Crohn disease, Reiter syndrome, and lupus; and trauma, or it may be idiopathic. Onset is acute with deep eye pain, photophobia, conjunctival redness, small pupil that does not react briskly, ciliary flush (redness around limbus), and decreased visual acuity.	Urgent ophthalmology evaluation is needed. Inflammation is treated with a topical corticosteroid and a cycloplegic agent. Teach patient how to instill medications and adhere to dosing schedule to prevent permanent eye damage. Suggest sunglasses to decrease pain from photophobia. Encourage follow-up for IOP measurements because corticosteroids can increase IOP.

Cataract

Clouding or opacity of the crystalline lens that impairs vision.

Pathophysiology and Etiology

1. Senile cataract—commonly occurs with aging.
2. Congenital cataract—occurs at birth.
3. Traumatic cataract—occurs after injury.
4. Aphakia—absence of crystalline lens.
5. Additional risk factors for cataract formation include diabetes; ultraviolet light exposure; high-dose radiation; and drugs such as corticosteroids, phenothiazines, and some chemotherapy agents.

Clinical Manifestations

1. Blurred or distorted vision.
2. Glare from bright lights.
3. Gradual and painless loss of vision.
4. Previously dark pupil may appear milky or white.

Diagnostic Evaluation

1. Slit-lamp examination—to provide magnification and visualize opacity of lens.
2. Tonometry—to determine IOP and rule out other conditions.
3. Direct and indirect ophthalmoscopy to rule out retinal disease.
4. Perimetry—to determine the scope of the visual field (normal with cataract).

Management

General

1. Surgical removal of the lens is indicated.
    a. When a cataract interferes with activities, the patient is a candidate for cataract surgery.
    b. Because cataract often occurs in both eyes, surgery is recommended when vision in the better eye causes problems in daily activities. Surgery is done on only one eye at a time.
2. Cataract surgery is usually done under either regional block or topical anesthesia, with or without IV sedation, and on an outpatient basis.
3. Oral medications may be given to reduce IOP.
4. IOL implants are usually implanted at the time of cataract extraction, replacing thick glasses that may provide suboptimal refraction.
5. In the rare instance that intraocular lens implant is not used, the patient will be fitted with appropriate eyeglasses or a contact lens to correct refraction after the healing process.

Surgical Procedures

1. There are two types of extractions:
    a. Intracapsular extraction—the lens as well as the capsule are removed through a small incision. (This technique is rarely used in the United States.)
    b. Extracapsular extraction—the lens capsule is incised and the nucleus, cortex, and anterior capsule are extracted.
        i. The posterior capsule is left in place and is usually the base to which an IOL is implanted.
        ii. A conservative procedure of choice, simple to perform, is usually done under local anesthesia.
2. Phacoemulsification is usually used to remove the lens.
    a. A hollow needle vibrating at ultrasonic speed is used to emulsify the lens.
    b. Then the emulsified particles are irrigated and aspirated from the anterior chamber.
3. Cryosurgery is rarely used to remove the lens. A pencil-like instrument with a metal tip is supercooled (–35°C) and then touched to the exposed lens, freezing it so the lens is easily lifted out.

Intraocular Lens Implantation

1. The implantation of a synthetic lens (IOL) is designed for distance vision; the patient may wear prescription glasses for reading and near vision. Intraocular lens implant restores binocular vision.
2. Previously, most IOLs were spherical with the front surface curved. Aspheric IOLs increase contrast sensitivity.
    a. In 2003, the FDA approved the use of the multifocal IOL. The lens incorporates more than one optical power to permit focusing at different distances.
    b. In 2004, the FDA approved an aspheric IOL. The lens can reduce postoperative spherical aberrations and, therefore, improve the ability to see in varying light conditions, such as rain, snow, fog, twilight, and nighttime darkness.
    c. In 2005, the FDA approved the first toric IOL, which is designed to correct astigmatism.
    d. Sophisticated calculations are required to determine the prescription for the lens.
    e. Numerous types of IOLs are available. Designs and materials change as new developments occur.
3. Advantages of the IOL include:
    a. Provides an alternative for the person who cannot wear contact lenses.
    b. Cannot be lost or misplaced like conventional glasses.
    c. Provides superior vision correction and better depth perception than glasses.
4. Complications (specific to implantation):
    a. Pain from inflammation of various eye structures—usually controlled by nonsteroidal anti-inflammatories, but systemic antibiotics and immunosuppression may be required.
    b. Rosy vision (glare) because of keeping pupil from full constriction; excessive light enters pupil, causing a dazzling of macula (minute corneal opacity).
    c. Degeneration of the cornea.

d. Malpositioning or dislocation of lens.

5. Implants may not be advisable for patients with severe myopia, history of chronic iritis, retinal detachment, diabetic retinopathy, glaucoma, and complications during surgery.

Contact Lens

Extended-wear contact lens is an option for those who do not receive IOL implants. They restore binocular vision and result in magnification of images in the range of 7% to 10%.

The patient will need to take the lens out for cleaning periodically or, if the patient is an older adult or debilitated, will need to follow-up at intervals for cleaning at the ophthalmologist's office.

Complications

1. Blindness.

Nursing Assessment

Preoperative

1. Assess knowledge level regarding procedure.
2. Determine visual limitations and effect on daily living.
3. Assess anxiety and fears about loss of vision and surgery.

Postoperative

1. Assess pain level.
   a. Sudden onset—may be due to ruptured vessel or suture and may lead to hemorrhage.
   b. Severe pain—accompanied by nausea and vomiting; may be caused by increased IOP and may require immediate treatment.
2. Assess visual acuity in unoperated eye.
3. Assess for signs of infection—fever, inflammation, pain, drainage.
4. Assess the patient's functional level and ability to be independent.

Nursing Diagnoses

- Deficient Knowledge of operative course.
- Delayed Surgical Recovery related to complications.

Nursing Interventions

Preparing the Patient for Surgery

1. Orient the patient and explain procedures and plan of care to decrease anxiety.
2. Instruct the patient not to touch eyes to decrease contamination.
3. Obtain conjunctival cultures, if requested, using aseptic technique.
4. Administer preoperative eye drops—antibiotic, mydriatic–cycloplegic, and other medications—mannitol

solution IV, sedative, antiemetic, and opioid, as directed. Explain medication actions to patient.

Preventing Complications Postoperatively

1. Medicate for pain, as prescribed, to promote comfort.
2. Administer medication to prevent nausea and vomiting, as needed.
3. Notify the health care provider of sudden pain associated with restlessness and increased pulse, which may indicate increased IOP, or fever, which may indicate infection.
4. Caution the patient against coughing or sneezing to prevent increased IOP.
5. Advise the patient against rapid movement or bending from the waist to minimize IOP. The patient may be more comfortable with head elevated 30 degrees and lying on the unaffected side.
6. Allow the patient to ambulate as soon as possible and to resume independent activities.
7. Assist the patient in maneuvering through environment with the use of one eye while eye patch is on (1 to 2 days).
8. Encourage the patient to wear eye shield at night to protect operated eye from injury while sleeping.

Patient Education and Health Maintenance

Promoting Independence

1. Advice the patient to increase activities, as tolerated, unless given restrictions by the surgeon.
2. Caution against activities that cause patient to strain (eg, lifting heavy objects, straining at defecation, and strenuous activity) for up to 6 weeks, as directed.
3. Instruct the patient and family about proper eye drop or ointment instillation.
4. Advise the patient to bring all medications to follow-up visits to permit dosage adjustments by ophthalmologist. Discontinued medications can then be discarded to prevent confusion.

Adjusting to Visual Change

1. Inform the patient receiving corrective lenses that fitting for temporary corrective lenses for the first 6 weeks will occur several days after surgery.
   a. Prescription for permanent lenses will be determined 6 to 12 weeks after surgery.
   b. Prescription for a permanent contact lens will be determined about 3 to 6 weeks after surgery.
2. Encourage the patient to wear dark glasses after eye dressings are removed to provide comfort from photophobia because of lack of pupil constriction from mydriatic–cycloplegic drops.

Adjusting to the Eyeglasses

1. Stress the importance of patience in the coming weeks of adjustment—it is easy to become frustrated.
2. Tell the patient that if glasses are to be worn, they will cause the perceived image to be about one third larger than normal. Glasses cannot restore binocular vision as an intraocular lens implant or contact lens will because of the discrepancy of image size between the treated eye and untreated eye.
3. If glass is used in the prescription, it is heavier and thicker than the more expensive plastic cataract

eyeglass lenses.

4. Instruct the patient to look through the center of corrective glasses and to turn head when looking to the side because peripheral vision is markedly distorted.
5. It is necessary to relearn space judgment—walking, using stairs, reaching for articles on the table (such as a cup of coffee), and pouring liquids—because of loss of binocular vision and peripheral distortion.
6. Advise patients to use handrails while walking and doing steps and to reach out slowly for objects to be picked up.

Becoming Familiar with Contact Lenses

Teach the patient that:

1. With contact lenses, magnification is only about 7% to 10%; peripheral vision is not distorted so binocular vision is achieved and spatial distortion is usually not an issue.
2. Patients do need to learn how to remove daily-wear and extended-wear lenses or return to the ophthalmologist's office for replacement of extended-wear lens periodically.

Becoming Familiar with Intraocular Lens

1. Teach the patient that with an intraocular lens, magnification problems are negligible. Both the operated eye and the unoperated eye can work together after cataract surgery with lens implantation, and the preoperative glasses can usually be worn in the recuperative period.
2. Advise the patient that eyeglasses may not be required for distance but may be needed for reading and writing.
3. Caution the patient against straining of any type. Bend knees only if necessary to reach for something on the floor.
4. Recommend sponge bathing. Avoid getting soap in the eyes.
5. Advice avoidance of tilting head forward when washing hair; tilt head slightly backward. Vigorous shaking of the head is to be avoided.

Evaluation: Expected Outcomes

- Vision maximized and distortions or limitations in vision described by patient.
- Independent activities demonstrated, denies discomfort.

Acute (Angle-Closure) Glaucoma

A condition in which an obstruction occurs at the access to the trabecular meshwork and the canal of Schlemm. IOP is normal when the anterior chamber angle is open, and glaucoma occurs when a significant portion of that angle is closed. Glaucoma is associated with progressive visual field loss and eventual blindness if allowed to progress. This is most commonly an acute painful condition (about 10% of glaucoma cases), not to be confused with chronic open-angle glaucoma (about 90% of cases).

Pathophysiology and Etiology

1. Mechanical blockage of anterior chamber angle results in accumulation of aqueous humor (fluid).
2. Anterior chamber is anatomically shallow in most cases.
3. The shallow chamber with narrow anterior angles is more prone to physiologic events that result in closure.
4. Angle closure occurs because of pupillary dilation or forward displacement of the iris.
5. Angle closure can occur in subacute, acute, or chronic forms.
6. Episodes of subacute closure may precede an acute attack and cause transient blurred vision and pain but no increased IOP.
7. Acute angle closure causes a dramatic response with sudden elevation of IOP and permanent eye damage within several hours if not treated.
8. Within several days, scar tissue forms between the iris and cornea, closing the angle. The iris and ciliary body begin to atrophy, the cornea degenerates because of edema, and the optic nerve begins to atrophy.

Clinical Manifestations

1. Pain in and around eyes because of increased ocular pressure; may be transitory attacks.
2. Rainbow of color (halos) around lights.
3. Vision becomes cloudy and blurred.
4. Pupil mid-dilated and fixed.
5. Nausea and vomiting may occur.
6. Hazy-appearing cornea because of corneal edema.
7. Although onset may have initial subclinical symptoms, severity of symptoms may progress to cause acute symptoms of increased IOP—nausea and vomiting, sudden onset of blurred vision, severe pain, profuse lacrimation, and ciliary injection.

NURSING ALERT Acute angle-closure glaucoma is a medical emergency and requires immediate treatment. Untreated, it can result in blindness in less than 1 week.

Diagnostic Evaluation

1. Tonometry—elevated IOP, usually greater than 50 mm Hg.
2. Ocular examination may reveal a pale optic disk.
3. Gonioscopy (using special instrument called gonioscope) to study the angle of the anterior chamber of the eye.

NURSING ALERT Dilatation of pupils is avoided if the anterior chamber is shallow. This is determined by oblique illumination of the anterior segment of the eye. A flashlight is shined across the iris from the temporal side. If the iris is bulging (with a shallow anterior chamber), a crescent shadow appears on the nasal side of the iris.

Management

Pharmacologic

1. Emergency pharmacotherapy is initiated to decrease eye pressure before surgery.
2. Medications are based on the patient's condition but may include:
   a. Parasympathomimetic drugs used as miotic drugs—pupil contracts; iris is drawn away from cornea; aqueous humor may drain through lymph spaces (meshwork) into canal of Schlemm.
   b. Carbonic anhydrase inhibitor—restricts action of enzyme that is necessary to produce aqueous humor.
   c. Beta-adrenergic blockers—nonselective—may reduce production of aqueous humor or may facilitate outflow of aqueous humor.
   d. Hyperosmotic agents—to reduce IOP by promoting diuresis.

Surgery

1. Surgery is indicated if:
   a. IOP is not maintained within normal limits by medical regimen.
   b. There is progressive visual field loss with optic nerve damage.
2. Types of surgery include:
   a. Peripheral iridectomy—excision of a small portion of the iris whereby aqueous humor can bypass pupil; treatment of choice. Typically a laser procedure.
   b. Trabeculectomy—partial-thickness scleral resection with small part of trabecular meshwork removed and iridectomy. Necessary if peripheral anterior adhesions (synechiae) have developed due to repeated glaucoma attacks.
   c. Laser iridotomy—multiple tiny laser incisions to iris to create openings for aqueous flow; may be repeated.

3. Other eye is usually operated on eventually as a preventive measure.

Complications

Uncontrolled IOP that can lead to optic atrophy and total blindness.

Nursing Assessment

1. Evaluate the patient for severe pain, nausea, and vomiting and signs of increased IOP.
2. Assess visual symptoms and effect on daily activity.
3. Establish history of onset of attack and previous attacks.
4. Assess the patient's level of anxiety and knowledge base of glaucoma and treatment.

Nursing Diagnoses

- Acute Pain related to increased IOP.
- Fear related to pain and potential loss of vision.

Nursing Interventions

Relieving Pain

1. Notify the health care provider immediately of the patient's condition.
2. Administer opioids and other medications, as directed. Medications that may cause nausea and vomiting are avoided. The patient may be medicated with antiemetic if nausea occurs.
3. Explain to the patient that the goal of treatment is to reduce IOP as quickly as possible.
4. Explain procedures to the patient.
5. Reassure the patient that, with reduction in IOP, pain and other signs and symptoms should subside.
6. Explain adverse effects of medications:
    a. Mannitol (IV)—transient blurred vision, rhinitis, thirst, nausea, transient circulatory overload, and headache.
    b. Acetazolamide or methazolamide (oral)—drowsiness, anorexia, paresthesia, stomach upset, tinnitus, fluid and electrolyte imbalance, rare kidney, or liver dysfunction.
    c. Pilocarpine (topical)—burning and redness of eye, headache, constricted pupil, poor vision in dim light, retinal detachment, and rare lens opacity.

Relieving Fear

1. Provide reassurance and calm presence to reduce anxiety and fear.
2. Prepare the patient for surgery, if necessary.
3. Describe procedure to the patient; surgery will likely be done on outpatient basis.
    a. Patch will be worn for several hours and sunglasses may help with photophobia.
    b. Vision will be blurred for first few days after the procedure.
    c. Frequent initial follow-up will be necessary for tonometry to make sure control of IOP.

Patient Education and Health Maintenance

1. Instruct the patient in use of medications. Stress the importance of long-term medication use to control this chronic disease. Patients commonly forget that eye drops are medications and that glaucoma is a chronic illness.
2. Remind the patient to keep follow-up appointments.
3. Instruct the patient to seek immediate medical attention if signs and symptoms of increased IOP return —severe eye pain, photophobia, and excessive lacrimation.
4. Advise the patient to notify all health care providers of condition and medications and to avoid use of medications that may increase IOP, such as corticosteroids and anticholinergics (such as antihistamines), unless the benefit outweighs the risk (see Table 16-4).

Table 16-4 Drugs That Elevate Intraocular Pressure

MEDICATION	ROUTE	EFFECT
Corticosteroids	Oral, inhalant, intravenous, intravitreal, periocular topical solutions (creams and drops)	Elevates IOP
Viscoelastic agents	Intraocular	Elevates IOP
Alpha-chymotrypsin	Intraocular	Transient elevation of IOP
Topamax (anticonvulsant)	Oral	Elevates IOP
Anticholinergics	Topical	Causes angle-closure glaucoma
Sulfonamides	Oral	Causes angle-closure glaucoma
Tricyclic antidepressants	Oral	Causes acute angle-closure glaucoma
Monoamine oxidase inhibitors	Oral	Causes acute angle-closure glaucoma
Antihistamines	Oral	Causes acute angle-closure glaucoma
Antiparkinsonian	Oral	Causes acute angle-closure glaucoma
Antipsychotics	Oral	Causes acute angle-closure glaucoma
Antispasmolytic	Oral	Causes acute angle-closure glaucoma
Cycloplegic agents	Topical	Contraindicated in narrow-angle glaucoma
Mydriatic agents	Topical	Contraindicated in narrow-angle glaucoma
Sympathomimetic agents	Topical	Contraindicated in narrow-angle glaucoma

Evaluation: Expected Outcomes

- Pain is decreased.
- Describes treatment regimen and verbalizes reduced fear.

Chronic (Open-Angle) Glaucoma

Glaucoma is characterized as a disorder of increased IOP, degeneration of the optic nerve, and visual field loss. Incidence increases with age—2% at age 40, 7% at age 70, and 8% at age 80.

Pathophysiology and Etiology

1. Degenerative changes occur in the trabecular meshwork and canal of Schlemm, causing microscopic obstruction.
2. Aqueous fluid cannot be emptied from the anterior chamber, increasing IOP.
3. IOP varies with activity and some people tolerate elevated IOP without optic damage (ocular hypertension), whereas others exhibit visual field defects and optic damage with minimal or transient IOP elevation.
4. The risk of eye damage increases with age, family history of glaucoma, diabetes, and hypertension.

Clinical Manifestations

1. Mild, bilateral discomfort (tired feeling in eyes, foggy vision).
2. Slowly developing impairment of peripheral vision—central vision unimpaired.
3. Progressive loss of visual field.
4. Halos may be present around lights with increased ocular pressure.

Diagnostic Evaluation

1. Tonometry—IOP usually greater than 24 mm Hg but may be within normal limits.
2. Ocular examination—to check for clipping and atrophy of the optic disk.
3. Visual fields testing for deficits.

NURSING ALERT Because of the relative ease of developing chronic glaucoma asymptomatically, encourage people of all ages to have an eye examination that includes measurement of eye pressure (tonometry) periodically to facilitate early detection and treatment to prevent loss of eyesight.

Management

1. Commonly treated with a combination of topical miotic agents (increase the outflow of aqueous humor by enlarging the area around trabecular meshwork) and oral carbonic anhydrase inhibitors and beta-adrenergic blockers (decrease aqueous production).
2. Remission may occur; however, there is no cure. The patient should continue to see health care provider at 3- to 6-month intervals for control of IOP.
3. If medical treatment is not successful, surgery may be required, but is delayed as long as possible.

4. Types of surgery include:
    a. Laser trabeculoplasty.
        i. An outpatient procedure, treatment of choice if increased ocular pressure unresponsive to medical regimen only.
        ii. As many as 100 superficial surface burns are placed evenly at junction of pigmented and nonpigmented trabeculum meshwork for 360 degrees in anesthetized eye, which allows increased outflow of aqueous humor.
        iii. Maximum decrease in IOP is achieved in 2 to 3 months, but IOP may rise again in 1 to 2 years.
    b. Iridencleisis—an opening is created between anterior chamber and space beneath the conjunctiva; this bypasses the blocked meshwork and aqueous humor is absorbed into conjunctival tissues.
    c. Cyclodiathermy or cyclocryotherapy—the ciliary body's function of secreting aqueous humor is decreased by damaging the body with high-frequency electrical current or supercooled probe applied to the surface of the eye over the ciliary body.
    d. Corneoscleral trephine (rarely done)—a permanent opening at the junction of the cornea and sclera is made through the anterior chamber so aqueous humor can drain.

DRUG ALERT Using beta-adrenergic blocker eye drops in the treatment of glaucoma can cause an adverse reaction in patients taking oral beta-adrenergic blockers for cardiovascular disease. Monitor vital signs because the risk for bradycardia exists.

Nursing Assessment

1. Assess frequency, duration, and severity of visual symptoms.
2. Assess the patient's knowledge of disease process and anxiety about the diagnosis.
3. Assess the patient's motivation to participate in long-term treatment.

Nursing Diagnosis

- Deficient Knowledge about glaucoma and surgical procedure.

Nursing Interventions

Providing Information about Glaucoma

1. Review the normal anatomy and physiology of the eye as well as the changes that occur in the drainage of aqueous humor with glaucoma.
2. Make sure that the patient understands that, although asymptomatic, IOP could still be elevated and damage to the eye could be occurring. Therefore, ongoing use of medication and follow-up are essential.
3. Teach the patient the action, dosage, and adverse effects of all medications. Make sure of adequate

administration of eye drops by watching the patient give return demonstration.

   a. Timolol and betaxolol—adverse effects include headache, eye irritation, decreased corneal sensitivity, blurred vision, bradycardia, palpitations, bronchospasm, hypotension, and heart failure.
   b. Pilocarpine—adverse effects include eye irritation, blurring, and redness; headache; pupil constriction; poor vision in dim light; possible hypertension and tachycardia; and rare retinal detachment and lens opacity.
   c. Acetazolamide and methazolamide—adverse effects include drowsiness, anorexia, paresthesia, stomach upset, tinnitus, fluid and electrolyte imbalance, and rare kidney and liver dysfunction.

4. Discuss visual defects with the patient and ways to compensate. Vision loss is permanent and treatment is aimed at stopping the process.
5. Inform the patient that surgery is done on an outpatient basis and recovery is quick. Prolonged restrictions are not required.
   a. After surgery, elevation of head 30 degrees will promote aqueous humor drainage after a trabeculectomy.
   b. Additional medications after surgery include topical steroids and cycloplegics to decrease inflammation and to dilate the pupil.

Patient Education and Health Maintenance

1. Patient must remember that glaucoma cannot be cured, but it can be controlled.
2. Remind the patient that periodic eye checkups are essential because pressure changes may occur.
3. Alert the patient to avoid, if possible, circumstances that may increase IOP:
   a. Upper respiratory infections.
   b. Emotional upsets—worry, fear, anger.
   c. Exertion, such as snow shoveling, pushing, and heavy lifting.
4. Recommend the following:
   a. Continuous daily use of eye medications as prescribed.
   b. Moderate use of the eyes.
   c. Exercise in moderation to maintain general well-being.
   d. Unrestricted fluid intake: alcohol and coffee may be permitted unless they are noted to cause increased IOP in the particular patient.
   e. Maintenance of regular bowel habits to decrease straining.
   f. Wearing a medical identification tag indicating the patient has glaucoma

Evaluation: Expected Outcomes

- Verbalizes understanding of glaucoma as a chronic disease; demonstrates proper instillation of ophthalmic medications.

Retinal Detachment

Retinal detachment is defined as detachment of the sensory area of the retina (rods and cones) from the pigmented epithelium of the retina. A break in the continuity of the retina may first occur from small degenerative holes and tears, which may lead to detachment.

Pathophysiology and Etiology

1. Spontaneous detachment may occur due to degenerative changes in the retina or vitreous.
2. Trauma, inflammation, or tumor causes detachment by forming a mass that mechanically separates the retinal layers.
3. Diabetic retinopathy commonly leads to retinal degeneration and tears disrupting the integrity of the retina.
4. Myopia and loss of a lens from a cataract (aphakia) also predisposes to retinal tears and detachment because the posterior chamber is enlarged, leading to vitreous pull.
5. After detachment occurs, that portion of the retina cannot perceive light because the blood and oxygen supply is cut off; hence, part of visual field is lost.
6. Detachment occurs most commonly in patients over age 40.

Clinical Manifestations

1. Retinal detachment may occur slowly or rapidly, but without pain.
2. The patient complains of flashes of light or blurred, "sooty" vision because of stimulation of the retina by vitreous pull.
3. The patient notes sensation of particles moving in line of vision (more so than usual—"floaters" that a person can see floating across field of vision when looking at a light background).
4. Delineated areas of vision may be blank.
5. A sensation of a veillike coating coming down, coming up, or coming sideways in front of the eye may be present if detachment develops rapidly.
   a. This veillike coating, or shadow, is commonly misinterpreted as a drooping eyelid or elevated cheek.
   b. Straight-ahead vision may remain good in early stages.
6. Unless the retinal holes are sealed, the retina will progressively detach; ultimately, there will be a loss of central vision as well as peripheral vision, leading to legal blindness.

Diagnostic Evaluation

Indirect ophthalmoscopy shows gray or opaque retina. The retina is normally transparent. Slit-lamp examination and three-mirror gonioscopy magnify the lesion.

Management

General

1. Sedation, bed rest, and eye patch may be used to restrict eye movements.
2. Surgical intervention may be indicated.
3. Return of visual acuity with a reattached retina depends on:
    a. Amount of retina detached before surgery.
    b. Whether the macula (area of central vision) was detached.
    c. Length of time the retina was detached.
    d. Amount of external distortion caused by the scleral buckle.
    e. Possible macular damage as a result of diathermy of cryocoagulation.
4. Surgical reattachment is successful approximately 90% to 95% of the time. If the retina remains attached 2 months postoperatively, the condition is likely to be corrected and is unlikely to recur.

Surgical Procedures

1. Photocoagulation—a light beam (either laser or xenon arc) is passed through the pupil, causing a small burn and producing an exudate between the pigment epithelium and retina.
2. Electrodiathermy—an electrode needle is passed through the sclera to allow subretinal fluid to escape. An exudate forms from the pigment epithelium and adheres to the retina.
3. Cryosurgery or retinal cryopexy—a supercooled probe is touched to the sclera, causing minimal damage; as a result of scarring, the pigment epithelium adheres to the retina.
4. Scleral buckling—a technique whereby the sclera is shortened to allow a buckling to occur, which forces the pigment epithelium closer to the retina (often accompanied by vitrectomy).

Complications

1. Glaucoma.
2. Infection.

Nursing Assessment

Preoperative

1. Assess for history of trauma or other risk factors.
2. Assess level of anxiety and knowledge level regarding procedures.
3. Determine visual limitations and obtain visual description from patient to determine assistance needed.

Postoperative

1. Assess pain level.
2. Assess visual acuity if unoperated eye not patched.
3. Determine the patient's ability to ambulate and assume independent activities, as tolerated.

Nursing Diagnoses

- Anxiety related to visual deficit and surgical outcome.

- Delayed Surgical Recovery related to complications.

Nursing Interventions

Reducing Anxiety Before Surgery

1. Instruct the patient to remain quiet in prescribed position. (Detached area of retina remains in dependent position.) Assist with all activities and offer frequent reassurance.
2. Patch both eyes. Make sure that the patient is oriented to surroundings and can call for assistance.
3. Describe preoperative procedures before carrying them out.
4. Wash the patient's face with antibacterial solution.
5. Administer preoperative medications, as ordered.
6. Instruct the patient not to touch eyes.

Preventing Postoperative Complications

1. Caution the patient to avoid bumping head.
2. Encourage the patient not to cough or sneeze or to perform activities that will increase IOP.
3. Assist the patient with activities, as needed.
4. Encourage ambulation and independence.
5. Administer medications for pain, nausea, and vomiting, as prescribed.
6. Provide sedate, diversional activities such as radio, audio books.
7. If the patient's anticoagulation therapy has been stopped, provide preventative measures such as compression stockings, leg exercises, and carefully monitor for signs and symptoms of thrombosis and embolism..

Patient Education and Health Maintenance

1. Encourage self-care at discharge, if done in an unhurried manner. (Avoid falls, jerks, bumps, or accidental injury.)
2. Instruct the patient about the following:
    a. Rapid eye movements should be avoided for several weeks.
    b. Driving is restricted.
    c. Within 3 weeks, light activities may be pursued.
    d. Within 6 weeks, heavier activities and athletics are possible. Define such activities for the patient.
    e. Avoid straining and bending head below the waist.
    f. Use meticulous cleanliness when instilling eye medications.
    g. Apply a clean, warm, moist washcloth to eyes and eyelids several times a day for 10 minutes to provide soothing and relaxing comfort.
    h. Symptoms that indicate a recurrence of the detachment: floating spots, flashing light, and progressive shadows. Recommend that the patient contact health care provider if they occur.

3. Advise on follow-up. The first follow-up visit to the ophthalmologist should occur in 2 weeks, with other visits scheduled thereafter.

Evaluation: Expected Outcomes

- Verbalizes understanding of treatment.
- Follows activity restrictions.

Other Problems of the Retina and Vitreous

The retina is a multilayered structure that receives images and transmits them to the brain. It is nourished by retinal arteries and veins. Problems result from inflammation, trauma, vascular changes, congenital defects, and aging. Central lesions affect the macula, impairing central vision, near vision, and color discrimination. Peripheral lesions impair peripheral vision, causing blind spots, night blindness, and eventual tunnel vision. See Table 16-5 for treatment of individual disorders.

Table 16-5 Other Conditions of the Retina and Vitreous

CONDITION	TREATMENT AND NURSING CONSIDERATIONS
Vitreous Hemorrhage	
Bleeding into the vitreous may occur due to trauma, sickle cell disease, hypertension, diabetic retinopathy, retinal tear or detachment, intraocular lens displacement, and clotting abnormalities. It causes decrease or loss of vision in affected eye.	The underlying cause is treated and surgery to repair the retina may include photocoagulation, cryotherapy, scleral buckle, or vitrectomy. (See "Retinal Detachment," page 448.) Assist the patient with visual deficit and activity and position restrictions before surgery. Maintain eye patches, activity restriction, and medication administration after surgery.
Central Retinal Artery Occlusion	
Sudden occlusion of the central retinal artery causes painless loss of vision in one eye with loss of light perception. It may have been preceded by episodes of transient blindness (amaurosis fugax) for 10–15 min. It is caused by an embolus, usually from the ipsilateral carotid artery.	Treatment consists of massaging the globe in an attempt to break up the embolus or move it distally, inhalation of a mixture of 95% oxygen and 5% CO_2 to get the retinal vessels to dilate, and IV infusion of acetazolamide to lower IOP. Place the patient in Trendelenburg position and monitor vital signs, as directed. Offer reassurance and assist with additional testing and treatment, as indicated.
Central Retinal Vein Occlusion	
Occlusion of the central retinal vein or a branch causes sudden (over several hours), painless decrease in visual acuity. Usually occurs in people with hypertension or other vascular disorders.	Urgent ophthalmologic evaluation is needed. Photocoagulation may be used to prevent local hemorrhage and promote neovascularization. Corticosteroids are used to treat retinal edema and an aspirin or anticoagulant may be used to prevent further occlusive disease. Encourage regular screening for glaucoma in follow-up as a complication from scar tissue formation after photocoagulation.
Macular Degeneration	
Age-related changes in the choroid deprive the fovea centralis of blood supply, causing a dry (atrophic) form (onset over several years) or wet (exudative) form (onset over several days to weeks with neovascularization and hemorrhaging). Central and near vision are affected, but some peripheral vision remains bilateral.	Support patient and family. Be realistic about prognosis—there is no cure but treatment may include laser, anti-VEGF therapy, diet, and vitamins (AREDS formulation) to slow the progression of the disease. Anti-VEGF therapy involves intraocular injection of medication every few weeks; can be painful and may raise the risk of infection. Refer patient to the local chapter of The Lions Club or other agencies for vision rehabilitation in order to assist with adaptive devices for low vision.
Retinitis	
Inflammation of the retina, usually caused by cytomegalovirus as a complication of human immunodeficiency virus disease. Symptoms include blurred vision, floaters and/or flashes in the eye, and loss of peripheral vision and eventually blindness. Determination of the progression of the disease is made by direct and indirect ophthalmoscopy and intravenous fluorescein angiography.	Antiviral medications can help control the symptoms and slow the progression of retinitis. Other treatment modalities include vitrectomy, silicone oil injection, and retinal detachment repair. Nursing interventions focus on patient education of drug side effects, care of central venous lines for intravenous medication, and monitoring blood count and for signs of kidney damage. Patient may be referred to community resources for low-vision assistance.
Diabetic Retinopathy	
A vascular disorder of the retina that leads to diminished vision as a complication of diabetes mellitus. Classified as nonproliferative or proliferative and typically occurs in four stages.	See page 740. Untreated diabetic retinopathy may cause complications such as retinal detachment, vitreous hemorrhage, clinically significant macular edema, glaucoma, and blindness.

AREDS, Age-Related Eye Disease Study; IOP, intraocular pressure; VEGF, vascular endothelial growth factor.

NURSING ALERT Central retinal artery occlusion is a medical emergency. Vision may be salvaged if treated within 24 hours of onset.

Nursing Assessment

1. Take history of eye problems, general health, and family history of eye disease.
2. Obtain functional history of how eye problem may be impairing work, recreation, and other activities.
3. Assess bilateral visual acuity, peripheral vision, and color discrimination.
4. Assist with pupil dilation and ophthalmoscopy, as directed.

Nursing Diagnoses

- Risk for Injury related to sudden visual loss.
- Readiness for Enhanced Self-Care related to gradual visual loss.
- Risk for Injury related to visual impairment.
- Anxiety related to fear of further visual loss.

Nursing Interventions

Ensuring Safety following Sudden Loss of Vision

1. Orient the patient to the layout of the facility and explain procedures.
2. Assist with self-care activities and educate patient on how to call for assistance.
3. Have personal articles placed nearby and take care not to move things without alerting the patient.
4. Ensure clear path for patient to move and ambulate; remove obstacles; provide ambulation aide as needed.
5. Help the patient understand visual weaknesses, such as where blind spots are and how to compensate by turning head to scan environment, using magnifying glass, having environment brightly lit.
6. Use side rails and direct visual supervision, if needed.
7. Assist the patient on stairs, make sure wearing good footwear, and obtain occupational therapy referral if needed.

Compensating for Gradual Loss of Vision

1. Discuss strategies/modifications to carry out usual activities.
2. Engage support people in assistance with patient activity.
3. Refer patients with vision less than 20/70 to the Blind Association or other resource for education and assistive devices.
4. Advise patient to memorize environment while some vision is intact, and then do not rearrange furniture or change environment.

Relieving Anxiety

1. Keep the patient informed during the diagnostic process.
2. Educate about resources such as local blind association.
3. Encourage participation in support groups.

Patient Education and Health Maintenance

1. Encourage frequent follow-up with ophthalmologist.
2. Advise the patient to use corrective lenses as directed and keep lens prescription up to date and to have a spare pair of glasses available.
3. Warn the patient against straining eyes by excessive exposure to the sun, reading, or computer work.
4. Rest eyes, as needed.
5. Report sudden deterioration in vision or other changes: sudden loss of vision, increase in floaters, flashes of light, sharp pain.

Evaluation: Expected Outcomes

- Performs daily activities without injury.
- Increasing independence with self-care activities.
- Reports understanding of disease and acceptance of treatment plan.

Eye Trauma

Trauma to the eye may be caused by blunt or sharp injury or chemical or thermal burns. The eyelids, protective layers, surrounding soft tissue, or the globe itself may be injured. Vision may be impaired by direct injury or latent scarring. See Table 16-6 for specific conditions.

Table 16-6 Eye Trauma

CONDITION	CLINICAL MANIFESTATIONS	MEDICAL MANAGEMENT
Blunt Contusion		
Bruising of periorbital soft tissue	• Swelling and discoloration of the tissue • Bleeding into the tissue and structures of the eye • Pain • Diagnosis: Tests must determine if injury to parts of eye and systemic trauma	• Treatment to reduce swelling • Pain management dependent on structures involved *Note:* If there is any possibility of a ruptured globe, a loose patch and shield should be placed and ocular manipulation discouraged until ophthalmologist assessment completed.
Hyphema		
Presence of blood in the anterior chamber	• Pain • Blood in anterior chamber • Increased intraocular pressure	• Usually spontaneous recovery • If severe, bed rest or chair rest with bathroom privileges, eye shield, interior chamber paracentesis, topical steroids, and cycloplegics
Orbital Fracture		
Fracture and dislocation of walls of the orbit, orbital margins, or both	• May be accompanied by other signs of head injury • Rhinorrhea • Contusion • Diplopia • Diagnosis: x-ray, computed tomography	• May heal on own if no displacement or impingement on other structures • Surgery (repair the orbital floor with plate freeing entrapped orbital tissue)
Foreign Body		
On cornea (25% all ocular injuries), conjunctiva Intraocular particles penetrate sclera, cornea, globe	• Severe pain • Lacrimation • Foreign body sensation • Photophobia • Redness • Swelling *Note:* Wood and plant foreign body may cause severe infection within hours.	• Medical emergency • Removal of foreign body through irrigation, cotton-tipped applicator, or magnet • Treatment of intraocular foreign body depends on size, magnetic properties, tissue reaction, location • Surgical removal
Laceration/Perforation		
Cutting or penetration of soft tissue or globe	• Pain • Bleeding • Lacrimation • Photophobia	• Medical emergency • Surgical repair—method of repair depends on severity of injury • Antibiotics—topically and systemically

Ruptured Globe		
Concussive injury to globe with tears in the ocular coats, usually the sclera	• Pain • Altered intraocular pressure • Limitation of gaze in field of rupture • Hyphema • Hemorrhage (poor prognostic sign) • Diagnosis: computed tomography, ultrasound	• Medical emergency • Surgical repair • Vitrectomy • Scleral buckle • Antibiotics • Steroids • Enucleation
Burns		
Chemical—caused by alkali or acid agent	• Pain • Burning • Lacrimation • Photophobia	• Medical emergency • Copious irrigation until pH is 7 • Severe scarring may require keratoplasty • Antibiotics
Thermal—usually burn to eyelids—may be first-, second-, or third-degree	• Pain • Burned skin • Blisters	• First aid—apply sterile dressings • Pain control • Leave fluid blebs intact • Suture eyelids together to protect eye—if perforation a possibility • Skin grafting with severe second- and third-degree burns
Ultraviolet—excessive exposure to sunlight, sunlamp, snow blindness, welding	• Pain—delayed several hours after exposure • Foreign body sensation • Lacrimation • Photophobia *Note:* Symptoms occur sometime after exposure.	• Pain relief • Condition self-limiting • Bilateral patching with antibiotic ointment and cycloplegics

Nursing Assessment

1. Obtain history of mechanism of injury as well as extent of other injuries.
2. Assess level of pain and visual symptoms.
3. Perform neurologic assessment and assess vital signs.
4. Assess visual acuity.

Nursing Diagnoses

- Acute Pain from tissue trauma.
- Fear related to loss of vision.

Nursing Interventions

Relieving Pain

1. Medicate for pain, as directed; however, monitor for respiratory depression, hypotension, and decreased level of consciousness if opioid analgesic is used.
   Note: Medications that depress the central nervous system may be contraindicated if head injury is suspected.
2. Provide ice and cool compresses to relieve swelling and pain.
3. Provide additional comfort measures, such as positioning, dimmed lights, and quiet environment.
4. Irrigate and patch eye, as directed.
5. Monitor vital signs and neurologic status, as indicated.
6. Watch for and report signs of infection, such as fever, drainage, increased pain, warmth, and redness.

Reducing Fear

1. Provide psychological support and assist with self-care activities, as needed.
2. Describe procedures and treatments to the patient and family.
3. Maintain safe environment.
4. Prepare the patient for surgery, as indicated (see page 440).

Patient Education and Health Maintenance

1. Teach the patient how to administer medications such as topical antibiotics.
2. Instruct on use of patch or shield.
3. Advise the patient to report increase in pain, decrease in vision, redness, and fever.
4. Teach safety measures with decreased visual acuity.
5. Advise the use of corrective lenses, as prescribed.
6. Stress follow-up care.
7. Attempt to prevent future trauma with protective eyewear.

Evaluation: Expected Outcomes

- Rests comfortably, reports less pain.
- Cooperates with procedures.

Vestibular Labyrinthitis

Malignant Disorders

Cancer of the Oral Cavity, Oropharynx, Nasopharynx, and Paranasal Sinuses

Neck Dissection for Head and Neck Malignancy

Cancer of the Larynx

OVERVIEW AND ASSESSMENT

History

Obtaining a history, including the patient's signs and symptoms, current health patterns, and previous past medical history, will help in identifying ear, nose, and throat (ENT) problems and developing an individualized plan of care.

Key Signs and Symptoms

1. Epistaxis.
    a. When did the bleeding first begin? Did it occur spontaneously or occur after facial or nasal trauma, nose blowing, digital manipulation, or recent nasal or sinus surgery? In many cases, anterior bleeding commonly flows from the nasal vestibule and, in reclining position, will drip into the throat. Posterior bleeding commonly causes dripping into the oropharynx when upright or supine. Nasal endoscopy or examination via anterior rhinoscopy is performed to confirm the site of bleeding.
    b. Unilateral or bilateral? What side of the nose is the bleeding coming from, and, if bilateral, on what side did it begin? Ask the patient about measures employed to control the bleeding thus far.
    c. Assess current medication history: Is the patient taking acetylsalicylic acid (ASA/aspirin), nonsteroidal anti-inflammatory drugs (NSAIDs), antiplatelet agents, or anticoagulants? When was the last dose taken?
    d. Is there a history of current oxygen therapy? Is there a history of chronic bleeding disorders? Obtain results of recent blood work: complete blood count (CBC), prothrombin time (PT), international normalized ratio (INR), or partial prothrombin time (PTT).
2. Headache.
    a. Exactly what parts of the head or face hurt? Is it pain or a pressure sensation? Use the PQRST Method of Pain Assessment with emphasis on location, duration, and symptom onset.
    b. Assess for associated neck, dental, or jaw pain; nausea; vomiting; visual changes; and/or sensitivity to light or sound. Assess for associated nasal congestion, postnasal drip, or clear or purulent rhinorrhea. Assess for history of migraine disease.
3. Sore throat—Assess onset and duration of symptoms, previous medical treatment, and symptom response.
    a. Is it accompanied by swollen glands, high fever, nasal congestion, and postnasal drip? Assess for associated weight loss; head, neck, or ear pain; voice changes; neck mass; trismus; or difficulty breathing. Has the patient been able to eat or drink?
    b. Is it acute or chronic? Was there any exposure to others with throat infection?
4. Nasal congestion.
    a. Is it acute or chronic? Accompanied by fever and purulent drainage? Assess severity and duration of symptoms, associated purulent or clear rhinorrhea, fever, facial pain or sinus tenderness, itchy eyes, sneezing, or postnasal drip. If symptoms are chronic, assess if worsened with changes in barometric pressure, vary with seasons, or brought on by odors or allergen exposure.

b. Assess for current/chronic history of use of nasal sprays containing oxymetazoline or if the patient is experiencing anosmia/microsmia (loss of sense of smell or diminished sensitivity). Ask if the patient has had previous history of nasal polyps, previous nasal or sinus surgery, or nasal fracture.

5. Hoarseness.
   a. Assess history of recent surgical procedures involving the head or neck, recent endotracheal intubation, radiation treatment to the head/neck, history of tobacco/alcohol use, occupation as vocal performer, or history of lung disease with use of inhaled steroids, chronic or recent antibiotic therapy, and symptoms of gastroesophageal reflux.
   b. Is it acute (less than 2 weeks), recurrent, or chronic (more than 2 weeks)? Assess onset and duration of symptoms, subjective impairment in communication, or voice-related quality.
   c. Assess for recent URI symptoms, associated dysphagia, odynophagia (pain with swallowing), globus sensation (sensation of something in the throat), throat pain, weight loss, ear pain, neck mass or enlarged lymph nodes in neck, hemoptysis, or shortness of breath.
6. Earache (otalgia).
   a. Is it worsened by manipulation of the auricle or is it a deep, throbbing pain? Is there otorrhea? Assess onset and duration of pain using the PQRST Pain Scale. Assess for associated erythema or edema of the external ear canal or external auricle, pruritus, hearing loss, or otorrhea. Is the pain intermittent or constant?
   b. Were there preceding upper respiratory infection symptoms? Is the pain associated with hearing loss, aural fullness, vertigo, headache, or fluctuation of hearing? Have there been any recent dental procedures?
   c. Assess history for nighttime bruxism (grinding teeth), clenching of the jaw or teeth, malocclusion, or pain worsened with movement of the jaw, dental pain, or swelling of the muscles of mastication.
   d. Assess for ear pain that occurs with swallowing and associated symptoms of head and neck cancer.
7. Hearing loss.
   a. Was it sudden or gradual in onset? Assess subjective onset of hearing loss. Did the patient experience sudden or gradual onset of the hearing loss? Is there associated tinnitus, vertigo, aural fullness, or ear pain?
   b. Unilateral or bilateral? Assess for history of noise exposure; recreational shooting; occupational, acoustic trauma; or history of chronic otitis media. Assess for history of familial/hereditary hearing loss.
8. Dizziness.
   a. Is the patient light-headed or experiencing vertigo (as if the room or self is spinning)? Assess for subjective light-headedness, room spinning, or imbalance. Are symptoms acute or chronic and associated with symptoms of fluctuation of hearing, aural fullness, or tinnitus (symptoms of Ménière disease).
   b. Is the dizziness associated with a change in head or body position? Do symptoms occur with rolling over in bed, looking up or bending over, or when going from sitting to standing? Are there feelings of

presyncope, history of syncopal episode when rising from sitting to standing? Are there changes in blood pressure associated with lying, sitting, and standing?

c. Assess for duration of symptoms and associated nausea, vomiting, headache, or focal neurological symptoms.

NURSING ALERT Hoarseness for longer than 4 weeks, or earlier if serious cause is suspected, is an indication for ENT evaluation and laryngoscopy.

Current Health Patterns

1. Inquire about nutrition; dental care; normal mouth care habits; dental caries; use of partial or full dentures; and stress-related grinding, clenching, or clamping of teeth.
2. Ask about history of alcohol, smoking, use of a pipe, and smokeless tobacco. Is there a personal history of human immunodeficiency virus (HIV), sexually transmitted disease, recreational drug use, or human papillomavirus (HPV)?
3. Determine personal hygiene about ears. Are cotton swabs or other objects used for cleaning or to relieve itching? Does the patient wear hearing aids or ear plugs?
4. Is there any loud noise exposure? Is there history of noise exposure via recreational shooting or in the patient's occupation? Ask about use of noise protection when exposed to prolonged and loud noise. Is there family history of hearing loss?
5. Does the patient frequently strain voice through talking, singing, or shouting? Is the patient a singer?
6. What medications is the patient taking? Have antibiotics been used? For how long?

Past Medical History

1. Is there a history of allergic rhinitis, other allergy symptoms, immunotherapy, chronic or recurrent sinusitis, previous nasal surgery, chronic otitis media, chronic pharyngitis, history of snoring, or obstructive sleep apnea?
2. Is there any immunosuppressive illness, such as diabetes mellitus, cancer, HIV infection, autoimmune disease, recent radiation, or chemotherapy?
3. Is there a history of previous thyroid, carotid artery, or other surgery involving the laryngeal nerve?
4. Any history of previous or recent head, facial, or nasal trauma?

See Chapter 5 , page 47, for physical assessment of the ears, nose, throat, and neck.

Diagnostic Tests

Audiometry

Description

1. Audiometry is the most basic and accurate testing to determine and measure hearing ability. The results are plotted on a graph known as an audiogram. Testing is performed by an audiologist. The following points below describe aspects of audiometry:
    a. Pure tone threshold audiometry is the lowest level at which sound is heard across various sound frequencies. This is compared to normative data to measure hearing loss and used to monitor hearing sensitivity over time.
    b. Speech audiometry provides information about the patient's communication ability. Speech reception threshold is defined as the softest level at which the patient can repeat a word. Speech recognition or speech discrimination is the percentage of words that a patient can repeat accurately at the comfortable listening level. This helps to determine ability to understand conversational speech.
    c. Pure tone testing is performed by presenting pure tones via air and bone conduction. Air conduction testing is done by presenting pure tones at various octave levels from 250 to 8,000 Hz through a transducer, such as insert earphone or cushion headphone. The patient sits in a soundproof booth, and the audiologist presents tones and the patient is asked to indicate when the sound is heard. Testing by bone conduction is done with use of a bone oscillator, which is placed on the mastoid of the test ear, and pure tones are presented at 500, 1,000, 2,000, and 4,000 Hz.
    d. Immittance testing includes tympanometry and acoustic reflex testing.
        i. Acoustic reflex testing measures the response of the stapedius muscle in response to auditory signals. It provides information about the acoustic and the facial nerves, as well as information about a conductive or sensorineural hearing loss.
        ii. Tympanometry measures the changes that occur to the tympanic membrane and middle ear when changes in air pressure are introduced into the ear canal. It can provide information about eustachian tube dysfunction, middle ear fluid, tympanic membrane perforation, patency of pressure-equalizing tubes, and middle ear disease such as otosclerosis.

Nursing and Patient Care Considerations

1. The patient wears earphones and signals upon hearing a tone.
2. A soundproof room is used to increase accuracy.
3. No special patient preparation or participation is necessary for tympanometry.

Cineradiography

Description

1. This motion study is performed to study the functional dynamics of the pharynx and esophagus.
2. It provides a more physiologic examination than esophagram (barium swallow). Mucosal detail is seen

better with cineradiography, whereas video capture allows more dynamic evaluation with less radiation.

3. "Modified barium swallow" evaluates laryngotracheal aspiration while a speech pathologist provides various consistencies of food and swallowing techniques. An esophagram evaluates the pharyngeal and esophageal mucosa.

Nursing and Patient Care Considerations

1. The patient is usually kept NPO the night before surgery.
2. The patient will be given radioprotective gear to prevent radiation from reaching other parts of the body.

Electronystagmography

Description

1. *Electronystagmography* is the recording of eye movements, specifically nystagmus, during various oculomotor and vestibular testing. Videonystagmography is the recording of eye movements using infrared video image analysis in three dimensions. The pattern of nystagmus, in conjunction with the patient's neurotological examination and clinical history, may provide information about the underlying etiology of the patient's symptoms.
2. Used to establish the diagnosis of Ménière disease, vestibular neuronitis or labyrinthitis, benign paroxysmal positional vertigo (BPPV), or migraine-associated vertigo and to assist in ruling out vestibular pathology in a patient with symptoms of dizziness.
3. The test takes place in a dimly lit room, with the patient on an examination table, and lasts for 60 to 90 minutes.
4. Electrodes are placed on the forehead and lateral to each eye in electronystagmography (ENG) testing. Video goggles are used in videonystagmography. Eye movements are recorded in response to various position changes and visual stimuli, with eyes open and eyes closed.
5. Caloric testing is the evaluation of nystagmus induced by warm or cold water irrigation into the external ear canals. Caloric testing can also be obtained by instilling cool and warm air into the ear canal. Caloric testing is used to measure the degree of vestibular dysfunction. Testing of patients with a normally functioning vestibular system will induce vertigo.
6. The audiologist may perform the vertebral artery test with older adults, patients who have history of neck trauma, or patients in whom vertebral artery disease is suspected. Patients who elicit symptoms when the head is hyperextended may not be able to have portions of the positional testing completed.

Nursing and Patient Care Considerations

1. Patient preparation includes avoiding a heavy meal before the procedure and avoiding caffeine and alcohol for 48 hours before the procedure.
2. Medications that may affect the vestibular system, such as sedatives, antianxiety agents, narcotics, and medications ordered for dizziness, may be held for several days before the procedure.
3. The patient will receive instructions from the facility/provider who will be administering the test for specific medications that will need to be held and for how long before testing is performed. The patient

should be counseled in the importance of following these preprocedure instructions, as they may affect the accuracy of the testing.

GENERAL PROCEDURES AND TREATMENT MODALITIES

Nasal Surgery

Types of Surgery and Indications

Facial Trauma and Nasal Fractures

1. Nasal bone fractures are common after blows to the nose during sports activities, interpersonal altercations, motor vehicle accidents, or falls. These can be diagnosed via physical examination or nasal/facial images, including high-resolution CT scans (3-D reconstuction can be generated).
2. Nasal fractures are treated with observation, closed reduction, closed reduction with septoplasty, or open reduction with or without internal stabilization, based on the severity of the injury. The best time to perform surgery is within the first few hours after injury or after 7 to 10 days when acute edema begins to resolve. Closed reduction should be performed before fibrosis of fracture lines, usually within 2 weeks after injury but up to 3 weeks after is diagnosed.
    a. Observation should be performed 7 to 10 days after the injury, especially when the swelling has subsided, to prevent missing a deformity.
    b. Closed reduction is effective for noncomminuted and mild nasal fractures with or without dorsal septal disruption.
3. Repair and stabilization of other maxillofacial fractures usually require an operating room procedure for wiring or plating.

Nasal Septal Surgery

1. Septoplasty is an intranasal procedure performed under general anesthesia to remove portions of, straighten, or trim the septal bone and/or cartilage. Silastic splints are sutured on either side of the septum to stabilize the repositioned septum. The splints are removed several days postoperatively. This surgery is performed to treat chronic nasal obstruction and may be done in conjunction with sinus surgery to promote a clear nasal airway.
2. Submucosal turbinate reduction or excision of middle turbinate concha bullosa is an intranasal procedure performed under local or general anesthesia in the operating room to surgically trim, excise, or reduce tissue in the nasal cavity that contributes to nasal obstruction. May be done in conjunction with septoplasty.

Rhinoplasty

1. Involves changing the nose's external appearance. Grafted cartilage or bone harvested from other parts of the body may be used.
2. A septorhinoplasty may be done when there are external and internal nasal deformities.

Sinus Surgery

1. Functional endoscopic sinus surgery (FESS) is corrective sinus surgery performed under general anesthesia in the operating room using direct visualization via a rigid nasal endoscope or, more recently, with assistance of image-guided systems. Image-guided systems utilize CT scans to provide surgeon with

intraoperative landmarks and map.

2. Diseased mucosa is removed and the natural sinus ostia are widened to facilitate the normal sinus drainage patterns.
3. In addition to nasal and sinus conditions, surgery may also be used to treat traumatic optic neuropathy, fluid (CSF) leaks, nasolacrimal duct obstruction, dysthyroid orbitopathy, posterior orbital lesions, and choanal atresia.
4. Packing may be placed intraoperatively depending on surgeon's preference and amount of bleeding. Packing is usually very small, filling only the area adjacent to the sinus ostia, so is not visible except for a retrieval string extending outside the nasal ala.
5. Balloon catheter sinuplasty: The procedure uses a small balloon catheter to open blocked sinus passageways. The procedure is done to widen and restructure the blocked passageways without surgical removal of bone and tissue (see Figure 17-1).
6. Other approaches to the sinuses, such as the Caldwell-Luc procedure (opening under lip to enter maxillary sinus and strip out diseased mucosa), may be performed but newer techniques are more often utilized. A nasoantral window (creating an opening between the maxillary sinus and the anterior inferior nose), and anterior/posterior ethmoidectomies may be performed, as well as opening and draining the frontal or sphenoid sinuses. The patient with historically extensive postoperative nasal and sinus packing is rarely seen, and this is now used only in selected complicated cases with extensive bleeding.

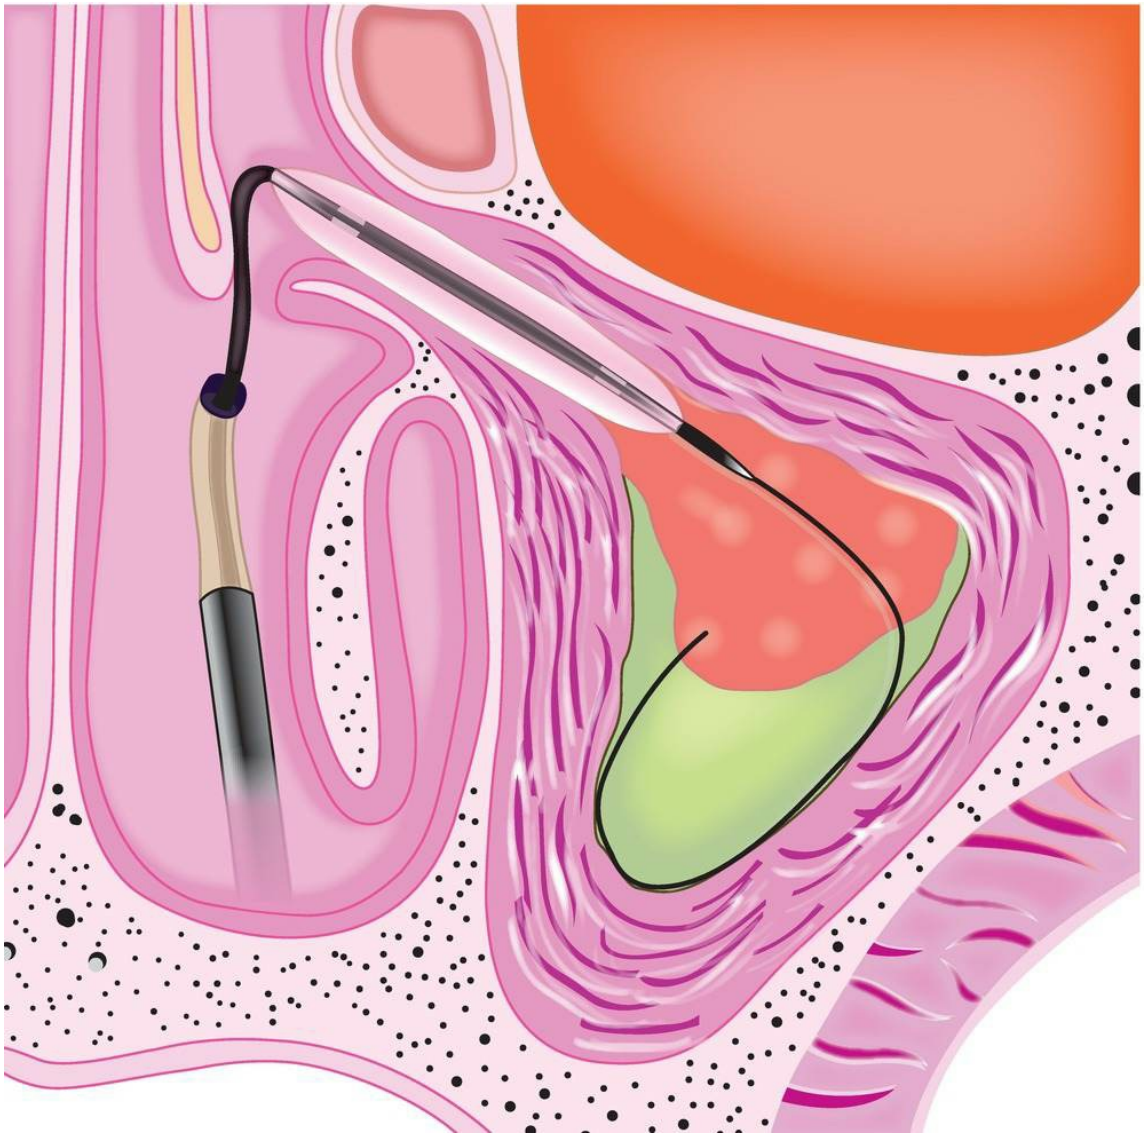

Figure 17-1. Balloon catheter sinus surgery. A catheter is introduced through the nose and into the sinus ostia, where the balloon is inflated to enlarge the sinus opening and promote drainage.

Preoperative Management

1. The head of the bed should be raised to promote drainage, lessen edema, and make the patient more comfortable.
2. Intermittent cold compresses and pain medications should be utilized, as ordered.
3. Antibiotics may be used preoperatively to reduce bacterial colonization of nose and sinuses.
4. The patient should be advised that a sensation of pressure may be felt in the nasal area during surgery performed under local anesthetic.
5. The patient should be counseled about the possible use of packing with some surgeries, which may be removed several days postoperatively.
6. Instructions for stopping aspirin, NSAIDs, and antiplatelet and anticoagulant medications will be provided by the surgeon and individualized after collaboration with the patient's cardiologist or primary

care provider.

NURSING ALERT In most cases, the patient should avoid use of aspirin, nonsteroidal anti-inflammatory drugs, anticoagulants, antiplatelet agents, and herbal medications such as *Ginkgo biloba*, garlic, green tea, and any other drugs that may affect platelet function before surgery. If the patient has taken these medications within a week of surgery, make sure the surgeon is notified.

Complications

1. Hematoma/hemorrhage: septal hematoma or postoperative bleeding. A septal hematoma will need to be drained by the surgeon immediately if this should occur.
2. Local infection—contaminated nasal packing is an excellent culture medium for pathogens. Most patients are treated postoperatively with antibiotics, but this is surgeon-specific.
3. Aspiration.
4. Pressure necrosis (from packing) may occur, but the current trend is toward less packing.
5. Blindness from orbital hematoma or unintended orbital involvement in endoscopic sinus surgery.
6. CSF rhinorrhea from unintended or traumatic violation of the cribriform plate. This is commonly referred to as a CSF leak.
7. Pulmonary decompensation.

Nursing Diagnoses

- Ineffective Breathing Pattern (nasal airway clearance) related to nasal packing and swelling.
- Risk for Aspiration related to bleeding, inability to blow nose.
- Deficient Knowledge related to performance of nasal hygiene.
- Impaired Oral Mucous Membrane related to mouth breathing.
- Risk for Infection related to alterations in nasal/sinus mucous membranes and drainage patterns.

Nursing Interventions

Facilitating Breathing and Comfort

1. Keep the head elevated (three to four pillows) day and night to minimize swelling. This also promotes comfort.
2. Apply cold compresses or ice packs intermittently for 24 hours to lessen edema and discoloration and to promote comfort. (Use great caution and only with approval of surgeon after rhinoplasty.)
3. Advise the patient that packing will be removed within 1 week of placement.
4. Encourage the use of a humidifier to relieve crusting of nasal mucosa and prevent irritation from dryness in nose and throat.
5. Encourage relaxation techniques and deep-breathing exercises for anxiety associated with nasal passages

being blocked.

6. Be alert for worsening pulmonary conditions, such as asthma, chronic obstructive pulmonary disease (COPD), and sleep apnea, when the nose is congested or packed.
7. Encourage use of non-narcotic analgesics, and caution use of opiods, which may cause respiratory depression. Medicate with analgesics as prescribed. Topical decongestants may be prescribed to relieve nasal congestion in the first few days postoperatively. Pain after nasal surgery is usually mild to moderate.

Preventing Bleeding and Aspiration

1. Monitor closely for bleeding; check for increased swallowing, blood dripping down back of throat (use flashlight and tongue blade), and expectoration of large amounts of clots and blood.
2. Change the 4 × 4 gauze pad under the nose as it becomes soaked with blood; bleeding should gradually decrease. Teach family and patient that blood will be bright red at first and will gradually lessen over the next several days.
3. Notify the surgeon if bleeding increases. Expect a temporary minor increase in bleeding with vomiting, sneezing, ambulation, or crying in the first 48 hours.
4. Teach the patient that mild nausea is normal postoperatively and may be from anesthesia, pain medications, or swallowing of blood; however, be alert for continuous trickle of blood postnasally.
5. Instruct the patient not to blow the nose but to blot secretions with tissue and spit out any secretions collecting in oropharynx.
6. Regularly observe and document visible packing retrieval strings external to nose, taped to cheek, if present. Postoperative instructions should be given upon discharge with appointments for postoperative splint removal or sinus debridement, if indicated. The surgeon will discuss activity and work restrictions specific to the patient.

Ensuring Proper Nasal Hygiene

1. Encourage the patient to use a vaporizer to help relieve crusting of nasal mucosa from dryness.
2. Remind the patient that sneezing, straining, and nose blowing increase venous pressure and can result in bleeding/hematoma.
3. Advise the patient to keep the mouth open while sneezing if unable to control sneezing.
4. Teach the patient an appropriate method of nasal hygiene as approved by surgeon. After FESS, the patient will need regular appointments for sinus debridement by the surgeon. Advise the patient that sinus irrigation will need to be done to control nasal crusting and to facilitate healing
5. In general, the patient may gently clean the nasal ala area with saline and/or peroxide for comfort, but large crusts should be removed by surgeon or allowed to work themselves free.
6. Instruct the patient to avoid environmental irritants, especially smoke.

PATIENT EDUCATION GUIDELINES 17-1

Nasal Saline Irrigation

This procedure will help clear nasal passages of crusted drainage that may be blocking the sinus opening.

Perform this once or twice per day to feel less nasal congestion and to help sinuses drain.

1. Prepare saline solution right before irrigation. *Commercially prepared sinus irrigation kits are readily available that contain packets and sinus rinse bottle.*
2. Mix ½ tsp table salt and ¼ tsp baking soda with 8 ounce warm distilled or sterilized water until well dissolved. Do not use tap water.
3. Lean forward from the waist over a sink.
4. Fill a bulb syringe (1 ounce infant ear or nasal bulb) or rinse bottle with the saline solution by squeezing it in the solution and letting it fill by suction. If using sinus rinse kit, follow instructions.
5. Insert the tip of the filled syringe into one nostril, aimed toward the eye away from the nasal septum.
6. Squeeze the syringe gently and feel the solution run backward in the nose and out the other nostril and possibly down the back of the throat and out of the mouth.
7. When comfortable with this procedure, you may be able to rotate head forward, backward, and from side to side to irrigate the sinuses as well as the nose.

Nose irrigation with bulb syringe or sinus irrigation kit.

Protecting Oral Mucous Membranes

1. Administer frequent mouth care because the patient is forced to breathe through the mouth.
2. Use flexible straw to sip mouthwash for rinsing purposes.
3. Encourage fluid intake and use of lip protectant.

Preventing Infection

1. Be alert for uncontrolled postoperative pain, fever, foul odor or taste in mouth, or unusual drainage.
2. Administer or encourage prophylactic antibiotics on time, if ordered.
3. Advise patient to keep follow-up appointment for splint removal, packing removal, and sinus

debridement.

Patient Education and Health Maintenance

1. Tell the patient to notify the surgeon immediately for uncontrolled postoperative pain, any visual changes postoperatively, fever, unilateral clear nasal discharge with leaning the head forward, uncontrolled excessive nasal bleeding, dyspnea, or blanching or necrosis of the external nasal tissues or the palate while packing is in place.
2. After Caldwell-Luc procedure or rhinoplasty, advise the patient that numbness in operative area may be present for several weeks to months.
3. Instruct the patient to avoid strenuous activity, lifting, and trauma to nose.
4. After splint removal, avoid trauma to nose and sleep in supine position. The operating surgeon will provide more specific postoperative instructions.
5. Excessive sun exposure should also be avoided after rhinoplasty for 1 year because of a tendency for hyperpigmentation.
6. If a nasal splint is present, tell the patient to avoid getting it wet; do not attempt to remove it.
7. Advise the patient that postoperative follow-up may need to continue for several weeks to months to monitor for excess scar formation or cosmetic deformity.

Evaluation: Expected Outcomes

- Mouth breathing without difficulty.
- No excessive bleeding; protects airway without aspiration.
- Nasal and palatal tissues free from blanching or darkening.
- Oral mucous membranes dry, but pink and intact.
- Afebrile; no signs of infection.

Ear Surgery

Ear surgery may involve the tympanic membrane, the middle ear cavity, the mastoid, or the inner ear. It may be done for perforation of the eardrum to facilitate drainage and remove diseased tissue in cases of infection or cholesteatoma, to relieve vertigo, or to treat hearing loss.

Types of Surgery

1. Myringotomy—creating a surgical opening into tympanic membrane (with knife or laser) for possible drainage tube insertion.
2. Tympanoplasty—reconstruction of diseased or deformed middle ear components (see Table 17-1).
    a. Type I (myringoplasty)—purpose is to close perforation by placing a graft over it to create a closed middle ear to improve hearing and decrease risk of infection and cholesteatoma. Perforation is closed using one of the following:
        i. Fascia from temporalis muscle (this is the most commonly used material).
        ii. Vein grafts from hand or forearm.
        iii. Epithelium from auditory canal (eustachian tube).
    b. Type II to V—suitable replacement (polyethylene, Teflon or titanium prosthesis, bone, cartilage) is used to maintain continuity of conduction sound pathway. The necessity of a two-stage procedure is determined.
        i. First stage—eradication of all diseased tissues; area is cleaned out to achieve a dry, healed middle ear.
        ii. Second stage—performed 4 to 6 months after first stage; reconstruction, using grafts.
3. Mastoidectomy—removal of mastoid process of temporal bone.
    a. Simple or cortical mastoidectomy is done via a postauricular approach, but the bony ear canal is left intact.
    b. Modified radical mastoidectomy or canal wall down mastoidectomy is done with a meatoplasty for the best results. A wide excision of the mastoid and diseased middle ear contents through a postauricular incision is performed with the bony canal being drilled out. A new larger ear canal is created that gives better access to the areas where cholesteatoma usually occurs (the attic and antrum).
4. Stapedectomy—removal of footplate of stapes and insertion of a graft or prosthesis.
5. Stapedotomy—removal of the stapes suprastructure, allowing a hole to be created with a laser in the stapes footplate. The base of the prosthesis will be inserted into the opening, and the other end will be crimped around the incus.
6. Labyrinthectomy—destruction of the labyrinth (inner ear) through the middle ear and aspiration of the endolabyrinth.
7. Endolymphatic decompression and shunt—release of pressure on the endolymphatic system in the labyrinth and creation of a shunt for fluid to the subarachnoid space or the mastoid.

8. Cochlear implant—implantation of electronic device that bypasses the damaged cochlea and stimulates auditory nerve.
9. Osseointegrated implantation for placement of a hearing implant for single-sided deafness or for conductive hearing loss (Baha system or Oticon implantable hearing system).

Table 17-1 Types of Tympanoplasty

	MIDDLE EAR DAMAGE		REPAIR PROCESS
Type	**Tympanic Membrane**	**Ossicles**	
I	Perforated	Normal	• Close perforation—myringoplasty
II	Perforated	Erosion of malleus and/or incus	• Close perforation; graft against incus or whatever remains of malleus
III	Tympanic membrane destroyed or widely perforated	Rest of ossicular chain destroyed but stapes are intact and mobile.	• Grafts implanted to contact the normal stapes • Tympanostapedopexy
IV	Tympanic membrane destroyed or widely perforated	Ossicular chain destroyed. Head, neck, and crura of stapes destroyed. Stapes footplate mobile.	• Expose mobile stapes footplate—graft implanted. Air pocket between graft and round window provides protection. • The cavum minor operation
V	Tympanic membrane destroyed or widely perforated	Ossicular chain destroyed. Head, neck, and crura of stapes destroyed. Stapes footplate fixed.	• Make opening in horizontal semicircular canal; graft seals off middle ear to give sound protection for round window. • Tympanoplasty and fenestration of lateral semicircular canal

Preoperative Management

1. Hearing function is fully evaluated.
2. Antibiotics are given to treat infection.
3. The patient is prepared emotionally for the effects of surgery.
4. Careful assessment for signs of acute infection is performed, which may delay surgery.

Postoperative Management

1. Antibiotics may be continued to prevent local and central nervous system (CNS) infection.
2. Patients are advised to have limited activity for the first 24 hours to decrease symptoms of nausea and vertigo (if the inner ear was disturbed) or to prevent disruption of prosthesis.
3. Analgesics, antiemetics, and antihistamines are given, as needed.
4. The patient is positioned to promote drainage but maintain some immobility. Using two extra pillows to elevate the head, thereby preventing edema for 2 weeks, is a good idea.
5. The patient is often seen 7 to 10 days after surgery to remove any metal stent placed. Additional packing may be removed up to 6 weeks postoperatively if prosthesis or graft procedure was performed. Often, an eardrop will be used to slowly dissolve remaining packing over a period of 6 to 8 weeks to give some weight to the grafted tympanic membrane.
6. Hearing will be reevaluated after edema has subsided and healing has occurred. The time frame for this varies by procedure but may be as long as 3 to 4 months after surgery to allow for healing.
7. With an osseointegrated implant, a fitting of the outer processor is usually delayed by 2 to 3 months to allow the bone to osseointegrate around the implant. In children, or in radiated bone, this may be done

in two stages separated by 6 months to allow for a slower rate of bone growth.

8. Cochlear implant activation and placement of the outer speech processor and external transmitter occurs approximately 4 weeks after surgery to allow for healing.

Complications

1. Infection: local, CNS (meningitis, brain abscess).
2. Hearing loss.
3. Facial nerve paralysis—rare.
4. Dizziness—usually temporary.

Nursing Diagnoses

- Acute Pain related to surgical incision and swelling.
- Risk for Infection related to invasive procedure.
- Risk for Injury related to vertigo.

Nursing Interventions

Relieving Pain

1. Administer or teach self-administration of analgesic, as indicated, postoperatively.
2. Tell the patient to expect pain to subside within first few hours with simple procedures or within first day or 2 with major procedures.
3. Position the patient for comfort following the instructions from the surgeon.
   a. On side with surgical ear upward to maintain graft position and immobility.
   b. Lying on side with surgical ear down to promote drainage from ear canal.
   c. Position of patient preference.
4. Elevate the head of bed to reduce swelling and pressure.
5. Advise the patient to avoid sudden movement. Use pillows for support.

Preventing Infection

1. Reinforce external dressings, as needed, until after first changed by surgeon, then change when saturated to prevent bacterial growth in damp dressings.
2. Loosely pack cotton or gauze in ear canal, as indicated, without causing increased pressure.
3. Do not probe or insert anything into ear canal.
4. Administer or teach self-administration of antibiotics, as prescribed. Do not use eardrops unless specifically ordered postoperatively.
5. Wash hands before ear care and instruct the patient not to touch ear.
6. Take care not to get the dressing or ear wet.
7. Advise the patient not to blow the nose, which could cause nasopharyngeal secretions to be forced up the

eustachian tube into the middle ear.

8. Instruct the patient to report any increased pain, fever, ear inflammation, or drainage, indicating local infection.
9. Be alert for headache, fever, stiff neck, or altered level of consciousness, which may indicate CNS infection.

Ensuring Safety

1. Be aware that dizziness or vertigo may occur for the first several days postoperatively.
2. Maintain side rails up while the patient is in bed.
3. Assist the patient with ambulation for the first time after surgery and as needed thereafter.
4. Encourage the patient to move slowly because sudden movements may exacerbate vertigo.
5. Administer or teach self-administration of antiemetics and antihistamines, as ordered and as needed; watch for sedation.
6. Instruct the patient not to blow nose, cough, lean forward, or perform Valsalva maneuver to avoid disrupting graft or prosthesis, aggravating vertigo, or forcing bacteria up the eustachian tube. If coughing or blowing nose is necessary, do so with open mouth to relieve pressure.

Patient Education and Health Maintenance

1. Advise the patient that there may be a temporary hearing loss for a few weeks after surgery because of tissue edema, packing, and so forth. The effects of a hearing restoration operation will not be known for several weeks and additional rehabilitation may be necessary to optimize results.
2. Advise the patient to protect the ear, perform dressing changes, or place loose cotton in outer ear, as indicated. Replace cotton twice daily or sooner if saturated by drainage.
3. Encourage follow-up for packing removal, as directed.
4. Instruct the patient to avoid sudden pressure changes in the ear.
    a. Do not blow the nose.
    b. Do not fly in a small plane. The date for which a patient may fly is individualized by their surgery and surgeon's preference.
    c. Do not dive.
5. Advise against smoking.
6. Tell the patient to protect ears when going outdoors for the 1st week. A cotton ball is all that is needed.
7. Tell the patient to avoid getting the ear wet until completely healed.
8. Tell the patient to avoid crowds or exposure to colds so upper respiratory infection is prevented.
9. Instruct the patient about signs and symptoms of complications to report.
    a. Return of tinnitus.
    b. Vertigo.
    c. Fluctuations of hearing ability.

d. Fever, headache, ear inflammation, increased pain, stiff neck.
e. Facial drooping or numbness.

10. Advise the patient that facial nerve paralysis may be temporary and to increase fluid intake through a straw during this time.

Evaluation: Expected Outcomes

- Verbalizes relief of pain.
- No signs of infection.
- Ambulates without difficulty.

CONDITIONS OF THE MOUTH AND JAW

Candidiasis

EVIDENCE BASE Sawant, B. & Khan, T. (2017). Recent advances in delivery of antifungal agents for therapeutic management of candidiasis. *Biomedicine and Pharmacotherapy*, 96, 1478–1490.

Candidiasis is an opportunistic fungal infection commonly caused by *Candida albicans*. It may be localized in the mouth and pharynx but may also occur in the esophagus. Candidiasis can become a source of systemic dissemination, particularly in high-risk persons.

Pathophysiology and Etiology

1. Commonly seen in individuals with immunosuppression from disease states or treatment regimens such as diabetes, cancer, or HIV and those receiving radiation therapy and/or chemotherapy.
2. May be caused by altered oral environment from xerostomia, use of inhaled steroids for asthma and COPD, or chronic antibiotic therapy, preexisting infections, poor oral hygiene or nutritional status, or wearing dentures.

Clinical Manifestations

1. Oral examination reveals diffuse, white, painless plaques. Underlying mucosa may be erythematous.
2. May be asymptomatic but may result in mild oral discomfort, burning, or alterations in taste.
3. Patients with disease spread beyond the oral cavity may present with chest pain, pain and difficulty with swallowing, or hoarseness.

Diagnostic Evaluation

1. Microscopic smear of plaques shows characteristic hyphae.
2. Oral fungal culture positive for *C. albicans*.
3. Occasionally, biopsy of lesions may be necessary to rule out leukoplakia (premalignant plaques).

Management

1. Topical antifungal medications such as nystatin suspension or clotrimazole troches are most often used.
2. Systemic treatment is indicated if topical agents fail or for esophageal cases with fluconazole, ketoconazole (used cautiously in immunosuppressed patients), or amphotericin B.
3. Topical oral rinses or preparations containing combinations of hydrocortisone, diphenhydramine, antifungals, or antibiotics may be used to enhance healing and to lessen discomfort.
4. Viscous lidocaine may be used topically to coat the oral mucosa before meals to lessen pain and enhance oral intake.
5. Oral prostheses may also be treated to avoid harboring and reintroducing infection.

Complications

1. Candidal infection throughout the GI tract.
2. Candidal sepsis in patients who are immunocompromised.

Nursing Assessment

1. Carefully examine oral cavity daily to monitor lesions as well as response to prescribed antifungal therapy.
2. Assess level of pain; administer analgesics, as prescribed; and monitor response to analgesics.
3. Assess nutritional status and effect of pain on oral intake. Monitor oral intake, nutritional and hydration status, weight loss/gain, and signs of dehydration.
4. Teach patients that are prescribed inhaled steroid therapy for asthma/COPD to rinse mouth after each use to prevent oropharyngeal candidiasis.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to oral discomfort.
- Deficient Knowledge related to antifungal therapy.

Nursing Interventions

Attaining Adequate Nutrition

1. Administer analgesics, as prescribed, 30 to 60 minutes before meals.
2. Provide soft foods, soothing liquids; avoid temperature extremes.
3. Provide gentle suctioning if pain becomes so severe that patient cannot handle secretions and provide intravenous (IV) fluids.

Ensuring Adequate Therapy

1. Administer antifungal agents, as prescribed. Observe the patient for proper use of topical preparation.
    a. Make sure that mouth is clean and free of food debris before administering drug.
    b. For swish-and-swallow preparations, tell the patient to swish and hold in the mouth for at least 10 minutes before swallowing.
    c. For troches, have the patient suck until dissolved.
2. Observe for signs and symptoms of systemic drug adverse effects: nausea, vomiting, diarrhea. Renal, bone marrow, cardiovascular, hepatic, or neurologic toxicities may occur in patients receiving systemic therapy with underlying chronic disease states.
3. Explain the importance of continuing therapy for duration prescribed.

Patient Education and Health Maintenance

1. Instruct high-risk patients about daily oral examination and signs and symptoms to observe.
2. Teach the patient to avoid highly seasoned foods, extremes in temperature, alcoholic beverages, and

smoking, all of which irritate the oral mucosa.

3. Encourage good oral hygiene.
4. May need to refrain from wearing dentures because of oral discomfort.
5. Encourage the patient on long-term systemic antifungal therapy to follow up for liver function test monitoring, as directed.

Evaluation: Expected Outcomes

- Adequate intake of liquids and soft foods as evidenced by stable body weight and signs of dehydration.
- Swishes oral suspension for 10 minutes before spitting or swallowing.

Herpes Simplex Infection (Type 1)

Also known as *cold sores* or *fever blisters*, herpes simplex virus (HSV; usually type 1) is commonly associated with lip and oral lesions 80% of the time. HSV1 causes genital outbreaks in 20% of the cases.

Pathophysiology and Etiology

1. After a primary infection and the patient produces antibodies, the virus remains latent in the sensory ganglia.
2. Recurrent herpes labialis may be precipitated by sun exposure, fever, oral trauma, fatigue, emotional upset, hormonal changes, and other factors.
3. The spread of HSV1 is through respiratory droplets or exposure to infected saliva via a break in the skin or mucous membranes.
4. HSV type 2 (and rarely HSV type 1) is associated with genital lesions and is sexually transmitted.

Clinical Manifestations

1. Prodromal period—tingling, soreness, and burning in area where lesion will develop.
2. Small vesicles appear on erythematous, edematous base, frequently near the mucocutaneous junction of the lips and oral mucosa. Lesions may be spread to genitalia during oral sex.
3. Lesions may be quite severe in the immunosuppressed.
4. Vesicles rupture, causing painful ulcerations.
5. Lesions heal spontaneously in 7 to 14 days, but reoccur.

Diagnosis and Management

1. No diagnostic tests are necessary but serologic testing may be done. The diagnoses of herpes simplex is made from viral culture from skin vesicles, serology, or monoclonal antibody testing.
2. Treatment may not be necessary if cases are mild and are usually short lived.
3. Comfort measures, such as mild oral or topical analgesics.
4. Good hygiene to prevent spread to self and others.
5. Antiviral agents, including acyclovir, famiciclovir, and valacyclovir, are available to decrease the duration of symptoms.
6. Penciclovir 1% cream—FDA approved; applied every 2 hours while awake at earliest sign. If used within 1 hour of outbreak, will decrease duration of viral shedding.
7. Acyclovir 5% cream may be used on topical lesions. Oral or IV antivirals may also be used if clinically indicated.

Nursing Interventions and Patient Education

1. Advise adequate rest and nutrition and avoidance of identified triggers.
2. Advise that virus is transmitted through close contact, such as kissing and sharing food and cups, so

avoid these from prodromal period until well healed.

3. Recommend good hand washing and hygiene.
4. Apthous ulcers or canker sores—not caused by HSV1.

Temporomandibular Disorders

Temporomandibular disorders are conditions affecting the jaw joint that consist of one or more of the following:

1. Myofascial pain—pain in the muscles serving the jaw (temporalis, masseter, medial and lateral pterygoids), neck, and shoulder.
2. Internal derangement of the jaw joint (dislocated or displaced joint disk or injured condyle).
3. Degenerative joint disease (eg, arthritis).

Pathophysiology and Etiology

1. Causes include rheumatoid or osteoarthritis; scleroderma; ankylosing spondylitis; trauma; teeth clenching or bruxism (teeth grinding). Neoplasms and acute infections such as parotitis, dental infections, and peritonsillar abscesses cause referred ear pain and should be differentiated from temporomandibular disorders.
2. Any mental and physical stresses can induce or exacerbate symptoms.
3. Above factors result in inflammation and muscle spasm of temporomandibular joint (TMJ).

Clinical Manifestations

1. Pain at the joint, temples, mandible, or masticatory muscles may worsen with jaw movement. Referred muscle spasm of the neck, trapezius, and sternocleidomastoid muscle causes discomfort.
2. Clicking or crepitus from opening and closing of the jaw or popping of the joint.
3. Limitation of movement, dislocation, or jaw locking.
4. May be associated with headaches, earaches, or tinnitus.
5. Change in the bite where the upper and lower teeth do not match in the normal comfortable way.
6. May experience deteriorating oral hygiene or halitosis from limited oral opening (trismus), making dental hygiene difficult.
7. May experience difficulty chewing because of limited jaw excursion, resulting in altered diet and weight loss.
8. Jaw clicking alone is common and requires no workup or intervention if asymptomatic.

Diagnostic Evaluation

1. Diagnosis can usually be achieved by history and physical examination without extensive testing. Provocative maneuvers performed on physical examination that reproduce pain with opening and closing of the jaw are generally suggestive of TMJ arthralgia.
2. Dental and TMJ x-rays may or may not be helpful.
3. Occlusal analysis evaluates for malocclusion of the jaw and teeth in a bite position.
4. CT scan and magnetic resonance imaging (MRI) are usually normal unless there is underlying degenerative changes, fracture, or neoplasm of jaw or cervical spine.
5. Arthrography (joint x-rays using dye).

6. Arthroscopy (endoscopic invasive joint examination).

Management

1. Initial management employs jaw rest (soft, no-chew diet for 2 weeks, plus avoiding extreme jaw movements, such as wide yawning and gum chewing).
2. Anti-inflammatory/analgesic medications such as ibuprofen.
3. Application of warm, moist heat or ice packs.
4. Muscle relaxants may be prescribed.
5. Therapeutic night guard or splint—to realign malocclusion or joint disk and to optimize muscle relaxation.
6. Physical therapy for gentle stretching and relaxing exercises with or without ultrasound (deep-heat) therapy—to enhance analgesia and muscle relaxation and to promote local tissue metabolism.
7. Transcutaneous electrical nerve stimulation reduces muscle spasm of head, neck, and back and reduces pain.
8. In general, conservative reversible measures above are employed as long as possible before progressing to invasive/surgical management.
    a. Arthroscopy—investigational procedure to visualize joint, reposition disk, lyse adhesions, or debride joint.
        i. Reserved for conditions not improved by medical management.
        ii. Complications include cranial nerve (CN) VII damage with facial paralysis and paresis, perforation of the external auditory canal, and piercing of the middle cranial fossa.
    b. Surgery—to remove the disk or reshape bony prominences.
9. Complications include malocclusion, CN VII damage, and infection.

Nursing Interventions and Patient Education

1. Assess the character, frequency, location, and duration of pain. Evaluate what triggers and relieves the pain. Determine how effective previous treatments have been.
2. Explore the effect of the disorder on the patient's lifestyle, especially eating habits. Assist the patient to alter methods of oral hygiene and eating if severe trismus is present.
3. Instruct the patient on the indications, dosages, and adverse effects of analgesics and anti-inflammatory medications.
4. Teach the patient proper use of heat therapies. Cold applications may be preferred by some patients to reduce pain and spasm.
5. Encourage the patient to perform active mouth opening, protrusion, and lateral movement exercises of the jaw for 5 minutes, four to five times per day, as prescribed, to stretch muscles and reduce spasm.
6. Encourage the use of soft food and liquid supplements during times of acute pain exacerbated by eating. Advise reduction of foods that require excessive chewing, such as raw vegetables, tough meat, nuts. Discourage gum chewing.

7. Explore tension-reducing modalities with the patient, especially progressive muscle relaxation to reduce muscle tension and spasm.
8. Encourage follow-up with dentist, oral surgeon, ENT specialist, or other caregiver, as indicated.
9. Encourage proper use of the night guard or dental splint, including periodic appointments to assess fit.
10. May need MedicAlert bracelet and preoperative anesthesia consultation for elective surgeries if maximum jaw opening is less than 30 mm, limiting access for airway intubation.

Maxillofacial and Mandibular Fractures

Fractures of the maxillofacial bones or mandible may occur as the result of industrial, athletic, and vehicular accidents; violent acts; and falls.

Pathophysiology and Etiology

1. Maxillofacial fractures usually occur due to blow to the cheek or face.
2. Mandibular fractures frequently occur due to blow to the chin.
3. May be nondisplaced or displaced, usually closed, and includes soft tissue injury.
4. May also occur as part of planned surgical reconstruction for jaw problems.
5. Injuries sustained in altercations or motor vehicle accidents may be associated with alcohol intoxication or recreational drug use.

Clinical Manifestations

1. Malocclusion, asymmetry, abnormal mobility, crepitus (grating sound with movement), pain, or tenderness.
2. Tissue injury: swelling, ecchymosis, bleeding, and pain.

Diagnostic Evaluation

1. CT is the gold standard for evaluating the extent of injuries.
2. Panorex can also be used is CT is not available.

Management

1. Maintenance of adequate respiratory functioning—may include oxygen support, endotracheal intubation, or tracheostomy. See Chapter 35 , page 936.
2. Control of bleeding—usually accomplished with direct pressure.
3. Reduction of the fracture—usually closed reduction.
4. Immobilization—depends on location, type, and severity of the fracture.
    a. Barton bandage with a Kling or stockinette bandage.
    b. Interdental fixation with rubber bands or wiring.
    c. Intermaxillary fixation with rubber bands or wiring.
    d. Interosseous fixation with open reduction.
5. Maintenance of adequate nutritional intake with liquid or soft diet—to maintain immobilization of fracture site.
6. Pain control—to promote comfort.
7. Control of infection with antibiotics in the presence of positive cultures.

Complications

1. Airway obstruction, aspiration.
2. Hemorrhage, infection.
3. Disfigurement.
4. Extraocular muscle entrapment/orbital globe displacement with resultant visual disturbance.
5. Acute drug or alcohol withdrawal.

Nursing Assessment

1. Obtain description of injury and review chart and diagnostic tests for extent of injury.
2. Continually assess respiratory status.
3. Assess level of pain.
4. Assess visual acuity and extraocular movement.
5. Assess for tremors, delirium or hallucinations, anxiety, and seizure activity related to alcohol or drug withdrawal.

Nursing Diagnoses

- Risk for Aspiration related to immobilization of jaw.
- Imbalanced Nutrition: Less Than Body Requirements related to pain, injury, and immobilization.
- Acute Pain related to injury and surgical intervention.
- Disturbed Body Image related to disfigurement of injury or surgical repair.
- Risk for Infection related to surgery.

Nursing Interventions

Preventing Aspiration

1. Maintain effective airway.
    a. Elevate head of bed 30 to 45 degrees or position leaning over a bedside stand to reduce edema and improve handling of secretions.
    b. Make sure suctioning equipment is readily accessible; teach patient oral and nasal suctioning; position on side or upright during suctioning.
    c. Administer antiemetic, as prescribed, for nausea and vomiting to prevent aspiration.
    d. Make sure wire cutters or scissors are present for immediate removal of the wires or rubber bands if the airway becomes obstructed. (Vertical rubber bands or wires should be cut.)
    e. Make sure that a method for calling the nurse (call bell) is within easy access for the patient at all times in case of emergency.
2. Monitor blood pressure, pulse, respirations, and temperature to note early onset of infection or aspiration.

Maintaining Nutritional Status

1. Administer liquid diet, as prescribed; place straw against teeth or through any gaps in the teeth. Teeth

may initially be sensitive to hot and cold.

2. Position in upright position before, during, and for 45 to 60 minutes after all feedings.
3. Evaluate ongoing nutritional and hydration status; weight; intake, output, and specific gravity; laboratory values—24-hour urea nitrogen, transferrin level, electrolytes, and albumin.
4. Advance to blenderized diet, as tolerated.
5. Make environment as pleasant as possible to enhance appetite—remove all sources of odor, decrease interruptions, position comfortably.

Increasing Comfort

1. Administer liquid or a suspension of analgesics, as prescribed—avoid opioids on an empty stomach, which may cause nausea and vomiting.
2. Administer diazepam as prescribed to reduce anxiety and control reflex muscle spasm.
3. Apply paraffin wax to the ends of wire fixation devices to decrease irritation to the gums and oral mucosa.
4. Apply petroleum jelly to the lips to decrease dryness and prevent cracking.

Strengthening Body Image

1. Provide firm reassurance regarding progress to reduce anxiety and allay fears.
2. Avoid unrealistic promises in relation to scars or disfigurement.
3. Allow the patient to choose the first time for looking in the mirror.
4. Provide privacy, as requested. The patient may be sensitive to appearance.
5. Provide alternative form of communication, such as magic slate or picture board, because maxillomandibular fixation limits articulating ability, making speech difficult to understand.

Preventing Infection

1. Provide mouth care every 2 hours while awake for the first several days, then four to six times per day.
2. Initially, provide mouth care with warm normal saline mouth swishes.
3. As diet is progressed, remove collected debris with a pressurized water stream cleaner and encourage the patient to brush teeth with a soft, child-size toothbrush.
4. Observe facial injuries for swelling, erythema, pain, or warmth to detect onset of infection.
5. Change facial dressings as needed to prevent soiling with secretions, food, or drainage, which may promote bacterial growth.

Patient Education and Health Maintenance

1. Encourage adequate nutrition—inform the patient and family that foods can be blenderized and thinned with juices or broths to a consistency that can be taken through a straw.
2. Explore with the patient options for maintaining proper oral care; encourage the patient to practice the options of choice.
3. Discuss the use of antiemetic medications to prevent nausea and vomiting, stressing the complications

this could cause.

4. Make sure the patient has wire cutters or scissors at all times and knows how to use them should airway obstruction occur.
5. Encourage follow-up health care visits, including counseling for alcohol or drug abuse.

Evaluation: Expected Outcomes

- No evidence of aspiration.
- Tolerates fluids through straw; maintains adequate body weight.
- Expresses relief of pain.
- Views self in mirror; notices improvement in appearance.
- No signs of infection; oral hygiene maintained.

PROBLEMS OF THE NOSE, THROAT, AND SINUSES

Rhinopathies

Rhinopathies are disorders of the nose that interrupt its normal functions of olfaction and warming, filtering, and humidifying inspired air. These include *allergic rhinitis*, *nonallergic rhinitis*, *vasomotor rhinitis*, and other conditions.

Pathophysiology and Etiology

1. Allergic rhinitis—immunoglobulin E (IgE)-mediated response causing release of vasoactive substances from mast cells (see page 791).
2. Non–IgE-mediated allergy/sensitivity—exposure to irritants such as tobacco smoke, perfumes, soaps, hair sprays, air pollution, or certain foods may produce symptoms of nasal congestion, postnasal drip, or rhinorrhea but are not caused by inhalant allergy.
3. Nonallergic rhinitis includes infectious rhinitis, rhinitis medicamentosa, rhinitis of pregnancy, or vasomotor rhinitis.
    a. Infectious—viral (common cold), bacterial (purulent rhinitis).
    b. Drug-induced (rebound rhinitis; rhinitis medicamentosa)—caused by excessive use of topical nasal decongestants. These products include oxymetazoline and phenylephrine. Many systemic medications may induce nasal congestion and stuffiness and include specific beta-blockers, antihypertensives, and antidepressants.
    c. Vasomotor rhinitis—consists of symptoms caused by autonomic instability with disruption of the normal balance of sympathetic and parasympathetic innervation. This produces nasal congestion, rhinorrhea, and postnasal drip. Symptoms may be manifested on exposure to cold weather or eating spicy, hot, or cold foods (gustatory rhinitis).
    d. Rhinitis of pregnancy—nasal congestion resulting from estrogen-mediated mucosal engorgement, especially in the last trimesters of pregnancy, may also occur with oral contraceptive use, postmenopausal estrogen therapy, and during the last portion of the menstrual cycle. Edema of the nasal mucosa and turbinate congestion occur.
    e. Nonallergic rhinitis with eosinophilia syndrome—patients have symptoms of rhinitis, negative allergy testing, but large number of eosinophils in nasal secretions. Treatment is similar to those with vasomotor rhinitis.

Manifestations of Allergic Rhinitis

1. Hypersecretion—wet, running/dripping nose or postnasal drip.
2. Eyes—edema of the conjunctivae, tearing and itching of the eyes, increase in vascularity, fine allergic shiners, or dark staining under eyes.
3. Nasal cavity—congestion, pressure, or stuffiness (see Figure 17-2). Chronic nasal crusting and erythema around outer nares and turbinates are often swollen, edematous with pale or bluish hue. Allergic salute often seen in children caused by upward lifting of the tip of the nose with the hand.
4. Oral cavity—chronic mouth breathing, enlarged lymph tissue in the oropharynx, prominent vascularity,

or cobblestoning in posterior pharynx.

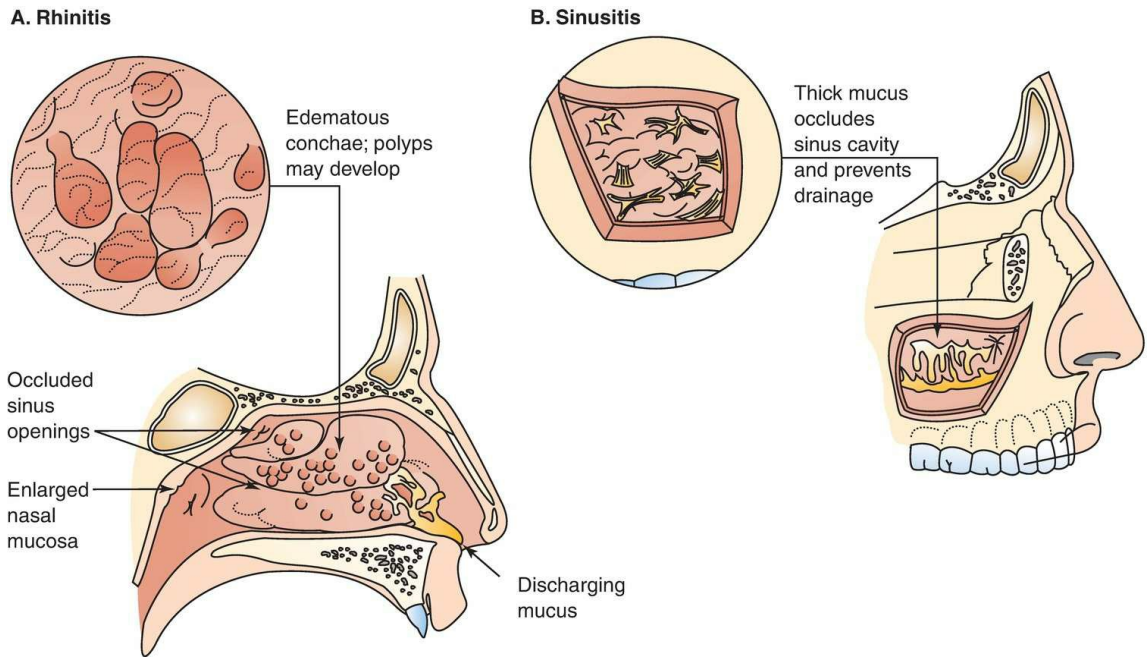

Figure 17-2. Rhinitis and sinusitis. **(A)** The mucous membranes lining the nasal passages become inflamed, congested, and edematous, blocking sinus openings and obstructing air passage. **(B)** The sinus cavity mucous membranes are also marked by inflammation and congestion, with thickened mucous secretions filling the sinus cavities and further occluding the openings. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Management

1. Treatment of underlying cause.
   a. Allergy—antihistamines (see Chapter 28).
   b. Nonallergic rhinitis—treatment modalities can include avoidance if caused by chemical, food, or other irritants.
2. Topical decongestants (for short-term use); systemic decongestants—topical or systemic decongestants may be used for short-term usage only, no more than 2 to 3 days, in patients with various forms of nonallergic rhinitis.
3. Intranasal corticosteroids—used in the treatment of allergic and nonallergic rhinitis because of their antinflammatory effects.
4. Vasomotor rhinitis—treated with ipratropium, which blocks vagally mediated reflexes that cause congestion.

DRUG ALERT Severe rebound nasal obstruction may occur with overuse of topical decongestants.

Stress the importance of only using for 2 to 3 days, as directed.

Nursing Interventions and Patient Education

1. Educate patients about avoidance measures for known or suspected allergens or irritants such as smoke.
2. Do not overuse topical nasal sprays and drops.
3. Advise about adverse effect of systemic decongestants is stimulation of sympathetic nervous system—insomnia, nervousness, palpitations.
4. Be aware that intranasal corticosteroids do not cause significant systemic absorption in usual doses but occasionally may cause nasal fungal infections and in rare cases cause nasal septal perforation and epistaxis.
5. Educate patients about correct administration technique for nasal sprays, particularly to direct the tip of the spray bottle away from the septum, toward the outward corner of the eye or toward the ear.

Epistaxis

Epistaxis refers to nosebleed or hemorrhage from the nose. It most commonly originates in the anterior portion of the nasal cavity.

Pathophysiology and Etiology

1. Local causes:
    a. Dryness leading to crust formation—bleeding occurs with removal of crusts by nose picking, rubbing, or blowing.
    b. Trauma—direct blows.
2. Systemic causes are less common—hypertension, arteriosclerosis, renal disease, bleeding disorders. Episodic epistaxis is mostly commonly seen with patients on antiplatelet, anticoagulant, and antithrombolytic agents. Osler-Weber-Rendu syndrome or hereditary hemorrhagic telangiectasia, hemophilia, von Willebrand disease, and liver disease are examples of bleeding disorders that can predispose patients to frequent episodes of epistaxis.
3. Most nosebleeds are anterior; posterior bleeds are more difficult to control.

Diagnostic Evaluation

1. Inspection with nasal speculum to determine site of bleeding or nasal endoscopy by otolaryngologist. Important to determine which side bled first.
2. Laboratory evaluation to exclude blood dyscrasias and coagulopathy.

Management

Depends on severity and source of bleeding in nasal cavity.

1. The patient is placed in an upright posture, leaning forward to reduce venous pressure, and instructed to breathe gently through the mouth to prevent swallowing of blood. The patient is asked to sit on a 90-degree angle, while the nasal ala, or the soft part of the anterior nose, is pinched and pressure is applied for 10 to 15 minutes, or as needed to control the bleeding.
2. With anterior bleeds, the patient is instructed to compress the soft part of nose with index finger and thumb for 5 to 10 minutes to maintain pressure on the nasal septum.
3. A cotton pledget soaked with a vasoconstricting agent may be inserted into each nostril and pressure is applied if bleeding is not controlled. After 5 to 10 minutes, the cotton is removed and the site of bleeding is identified. Oxymetazoline, in combination with a topical anesthetic agent such as lidocaine, may be sprayed directly into the nasal cavity or applied on pledgets or cotton balls. Suction may be used to evacuate the bloody contents of the nasal cavity to visualize the source of bleeding.
4. The blood vessel may be cauterized with use of silver nitrate sticks or with electrocautery.
5. If bleeding continues despite use of pressure or cautery, anterior or posterior packing may be placed into the nasal cavity or nasopharynx. Packing is usually kept in for 72 hours or more. Balloon tamponade may be required to apply pressure over a larger area.

6. Surgical ligation of vessels may be required if bleeding is unable to be controlled with above measures.

NURSING ALERT Monitor the patient for a vasovagal episode during insertion and with removal of nasal packing. This is best prevented with reclining the patient back when symptoms first occur.

Complications

1. Rhinitis; maxillary and frontal sinusitis.
2. Orthostatic hypotension from sudden blood loss.

Nursing Interventions and Patient Education

1. Monitor vital signs and assist with control of bleeding. Assess for changes in blood pressure and pulse indicative of hypovolemia.
2. Be aware that packing is uncomfortable and painful and may be in place for 48 to 72 hours. Antibiotics may be prescribed to prevent secondary infection from packing.
3. Nosebleed precautions and postprocedure instructions should be given to the patient. Instructions for holding specific antiplatelet and anticoagulant medications will be coordinated in conjunction with the patients' clinical history. The patient should be advised to avoid sneezing with mouth closed, blowing nose, removing the packing, and avoiding any strenuous activity.
4. Monitor patient with posterior packing for hypoxia (from aspiration of blood, sedation, and preexisting pulmonary dysfunction). Patients who require posterior balloon packing are admitted for observation and monitoring. These patients are at risk for soft palate necrosis and airway obstruction. If coagulopathies are found on blood work, these are corrected while the patient is hospitalized. Monitor PT, INR, and PTT, if ordered.
5. Instruct the patient as follows for self-management of minor bleeding episodes:
   a. Sit up and lean forward while compressing the soft part (lower half) of nose between index finger and thumb.
   b. If bleeding continues, moisten a small piece of cotton with vasoconstricting nose drops (phenylephrine or oxymetazoline) and place inside the nose.
   c. Apply pressure to the bleeding site 5 to 10 minutes.
6. Instruct the patient to avoid blowing or picking nose after a nosebleed.
7. Advise patients prone to nosebleeds to:
   a. Apply a lubricant to nasal septum twice daily to reduce dryness. Nasal saline spray may also be advised a few days after nasal cautery is performed and on a regular basis if patient has recurrent episodes.
   b. A bedside humidifier is recommended, especially if the environmental air is dry.
   c. If the patient uses chronic oxygen therapy or CPAP, a humidifier may be recommended on the

oxygen delivery or CPAP delivery system.

Sinusitis

Rhinosinusitis is defined as a symptomatic inflammation of the sinuses and nasal cavity. It may be precipitated by congestion from viral upper respiratory infection and/or nasal allergy. A patient with chronic allergic disease may be prone to recurrent episodes of sinusitis or chronic rhinosinusitis. Obstruction of the sinus ostia (resulting from mucosal swelling and/or mechanical obstruction) leads to retention of secretions and is the usual precursor to sinusitis.

Rhinosinusitis is classified by duration as acute (less than 4 weeks), subacute (4 to 12 weeks), or chronic (more than 12 weeks). Acute rhinosinusitis can be classified as bacterial or viral.

Clinical Manifestations

Acute Sinusitis

1. Defined as up to 4 weeks of purulent, nonclear nasal drainage with nasal congestion and/or facial pain/pressure/fullness (see Figure 17-3). There may be both symptoms of nasal congestion and facial pain, and symptoms are present for 10 days or more. There may be chronic exacerbations of symptoms within the 4 weeks.
2. Nasal congestion or obstruction is defined as subjective symptoms of difficulty breathing through nose and/or red and edematous nasal mucosa visualized on physical examination.
3. Anosmia (lack of smell) may be reported.
4. Other symptoms that may be present include fever, cough, ear pressure, maxillary dental pain, and fatigue.
5. Viral rhinosinusitis is differentiated from bacterial by duration—symptoms for 10 days or less without worsening symptoms. Bacterial rhinosinusitis manifests for 10 days with worsening symptoms.

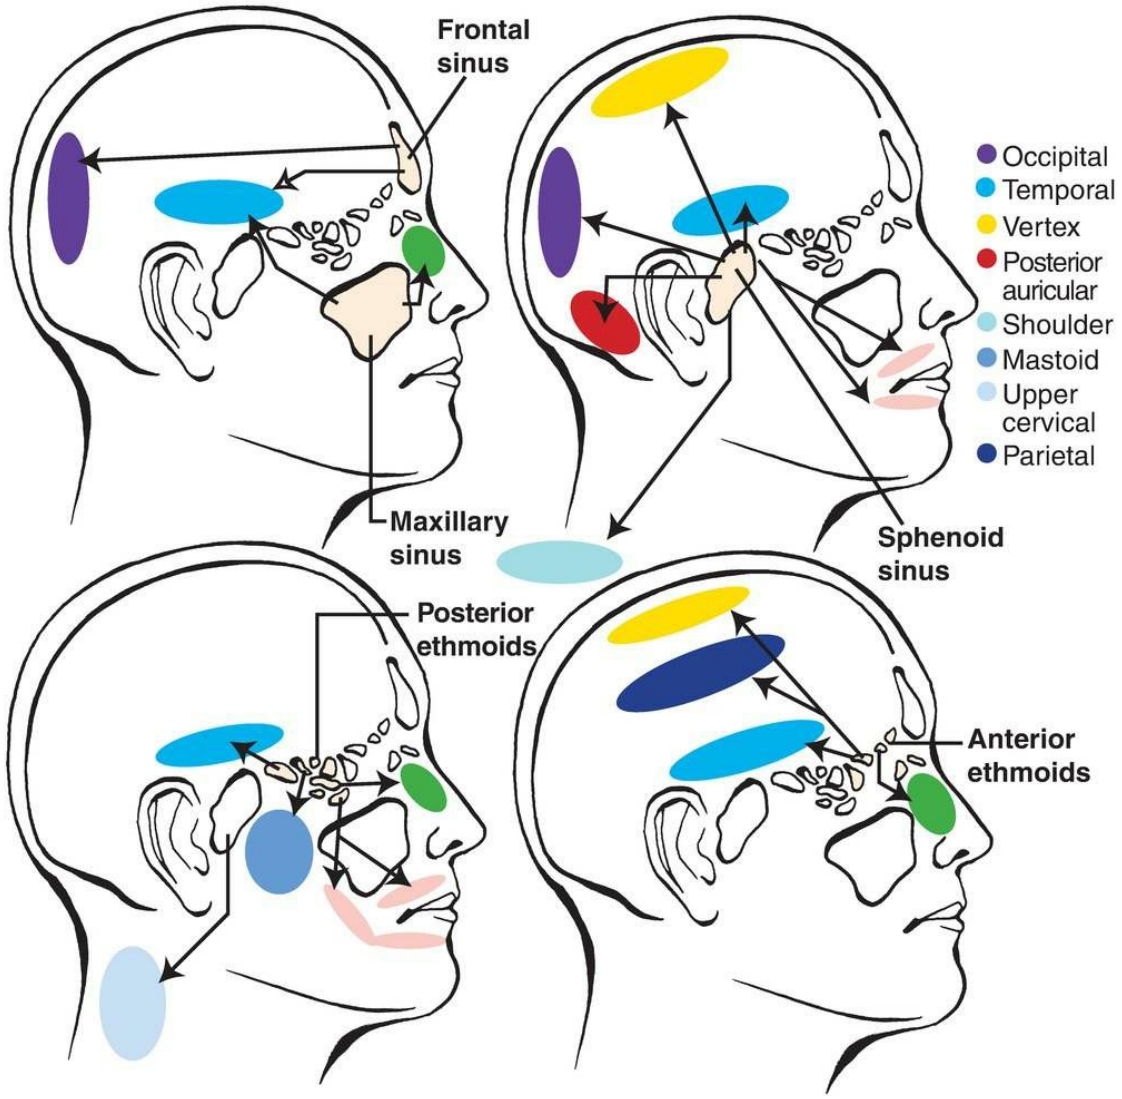

Figure 17-3. Referred pain from the paranasal sinuses.

(From Galen, B. [1997]. Chronic recurrent sinusitis: Recognition and treatment. Lippincott's Primary Care Practice, 1 [2], 183–197.)

Chronic Rhinosinusitis

1. Mucopurulent nasal drainage, nasal obstruction, facial pain/pressure/fullness and/or decreased sense of smell. May also have malaise and ear pain or pressure and cough. Patients may have recurrent episodes or continued symptoms for 12 weeks or more.
2. Symptoms may or may not be present but are nondiagnostic of chronic rhinosinusitis.

Diagnostic Evaluation

1. Sinus plain film consisting of Caldwell, Waters, and lateral views may be obtained but not routinely recommended for acute, isolated, or noncomplicated cases. X-rays may reveal air–fluid level, mucosal thickening, or opacification of one or more sinus cavities.
2. CT scanning recommended when complication is suspected or in patients with chronic sinus disease.
3. Nasal endoscopy, performed by an ENT specialist, is used to evaluate the nasal and sinus cavity and to

obtain cultures of material for the purpose of directing appropriate antibiotic therapy.

4. CT with contrast or MRI with gadolinium may be obtained if cranial extension suspected.

Management

1. Topical decongestant spray or drops or systemic decongestants may be used to treat the nasal congestion associated with rhinosinusitis. Topical therapy should be limited to no more than 3 successive days of use as increased use beyond 3 days may cause rebound nasal congestion (rhinitis medicamentosa).
2. Topical nasal corticosteroids are frequently used in chronic sinusitis and may be used in acute cases. Nasal corticosteroids have been shown to decrease severity of symptoms when used with appropriate antibiotic therapy.
3. Antibiotics—amoxicillin is the initial drug of choice in adults with acute rhinosinusitis. For penicillin-allergic patients, sulfamethoxazole–trimethoprim or macrolide antibiotics may also be used as first-line therapy. The most common organisms identified in patients with acute bacterial rhinosinusitis are *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis*. Other less common organisms include *Staphyloccocus aureus* and anaerobes.
4. Usually 10- to 14-day course for acute sinusitis; azithromycin or fluoroquinolones may be prescribed for 3 to 5 days.
5. Prolonged therapy for chronic sinusitis (up to several months).
6. Analgesics—pain may be significant.
7. Warm compresses; cool vapor humidity for comfort and to promote drainage; nasal saline irrigation.
8. Surgical interventions (for chronic sinusitis when conservative treatment is unsuccessful).
    a. Endoscopic sinus surgery—endoscopic removal of diseased tissue from affected sinus; used to treat chronic sinusitis of maxillary, ethmoid, and frontal sinuses.
    b. Nasal antrostomy (nasal–antral window)—surgical placement of an opening under inferior turbinate to provide aeration of the antrum and to permit exit for purulent materials.
    c. For nursing care, see page 458.

Complications

1. Extension of infection to the orbital contents and eyelids.
2. Bone infection (osteomyelitis) may spread by direct extension or through blood vessels. Frontal bone commonly affected.
3. CNS complications include meningitis, subdural and epidural purulent drainage, brain abscess, and cavernous sinus thrombosis (acute thrombophlebitis originating from an infection in an area having venous drainage to cavernous sinus).

NURSING ALERT Watch for lid edema, edema of ocular conjunctiva, drooping lid, limitation of extraocular motion, vision loss; may indicate orbital cellulitis, which necessitates immediate treatment.

Nursing Interventions and Patient Education

1. Teach the patient signs and symptoms of acute, bacterial rhinosinusitis versus signs and symptoms of rhinitis. Educate the patient in regard to symptoms that prompt medical attention.
2. Advise the patients about adverse reactions of antibiotic therapy including side effects, drug interactions, and symptoms that prompt medical attention.
3. Stress the importance of complying with antibiotic therapy for complete duration and following up for recurrence.
4. Teach the patient with recurrent sinusitis how to irrigate nasal passages with saline to remove crusted mucus near the sinus openings and enhance drainage (page 458).

Pharyngitis

Pharyngitis is an inflammation of the pharynx, including palate, tonsils, and posterior wall of the pharynx, most commonly caused by acute infection, usually transmitted through respiratory secretions. Streptococcal pharyngitis (*strep throat*) and rhinoviruses (the common cold) are frequent causes. Pharyngitis is diagnosed in 11 million emergency rooms and outpatient office visits per year.

Pathophysiology and Etiology

1. Acute bacterial pharyngitis is usually caused by group A beta-hemolytic streptococci.
2. Other bacterial causes include *H. influenzae*, *M. catarrhalis*, *Corynebacterium diphtheriae* (diphtheria), *Neisseria gonorrhoeae* (gonorrhea), and other groups of streptococcus. Transmission of *N. gonorrhoeae* is through oral contact with genital secretions; it is a sexually transmitted disease.
3. Viral pharyngitis is common and causes include rhinovirus, adenovirus, parainfluenza virus, coxsackievirus, coronavirus, and others.
4. More chronic causes are irritation from postnasal drip of allergic rhinitis and chronic sinusitis, chemical irritation, and systemic diseases.

Clinical Manifestations

1. For acute bacterial infections, abrupt onset of sore throat and fever, usually above 100.4°F (38.0°C), and exposure to *Streptococcus* within the preceding 2 weeks is suggestive of streptococcal pharyngitis.
   a. Throat pain is aggravated by swallowing.
   b. Pharynx appears reddened with edema of uvula; tonsils enlarged and reddened; pharynx and tonsils may be covered with exudate (see Figure 17-4).
   c. Palatal petechiae and a scarlatiniform rash are highly specific but uncommonly seen.
2. Varying degrees of sore throat, nasal congestion, fatigue, and fever with other bacterial and viral causes.
3. Cough, conjunctivitis, and diarrhea are common with viral causes.
4. Swollen, palpable, and tender cervical lymph nodes in most cases. Anterior cervical lymph node swelling and enlargement are common.

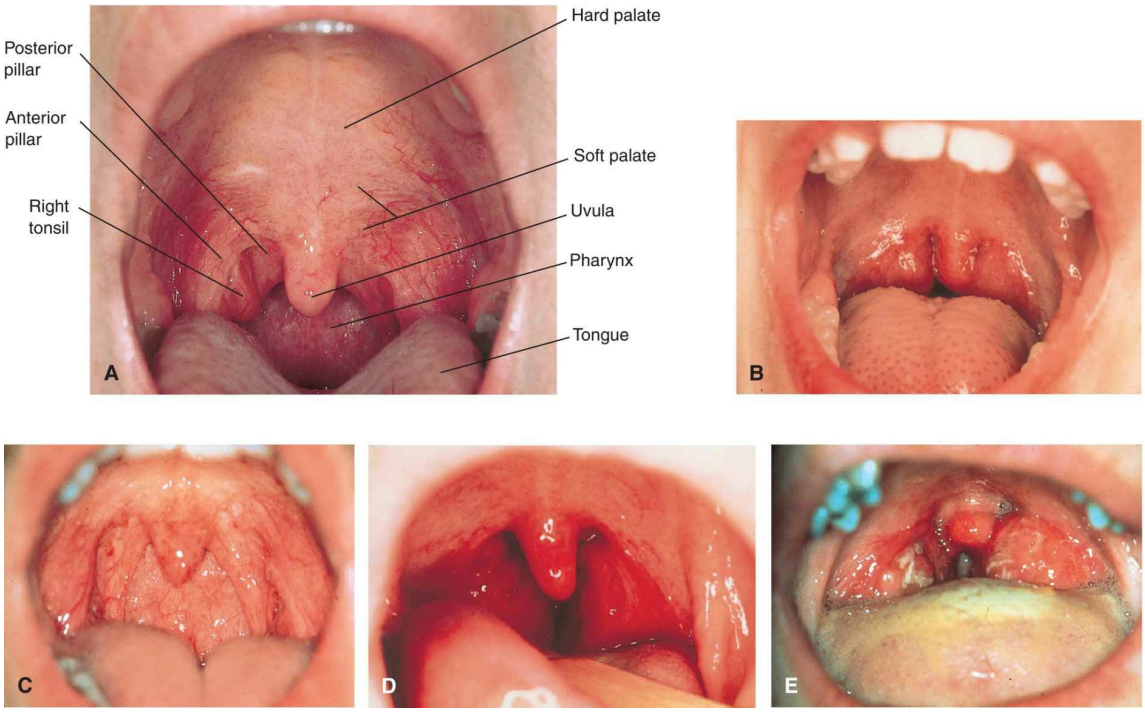

Figure 17-4. Assessment of pharyngitis. **(A)** Normal throat. **(B)** Normal large tonsils without redness. **(C)** Mild redness without exudate. **(D)** Intense redness without exudate. **(E)** Redness with exudate on tonsils (probably indicates group A streptococcal infection). (**A:** Smeltzer, S., and Bare, B. [2000]. Brunner and Suddarth's textbook of medical-surgical nursing [9th ed.]. Philadelphia: Lippincott Williams & Wilkins; **B–E:** The Wellcome Collection, National Medical Slide Bank, London, UK.)

Diagnostic Evaluation

1. Throat culture or rapid streptococcal antigen detection test to rule out streptococci. Rapid strep tests provide results within 5 minutes; false-negative rate is higher than with culture method.
2. Gonococcal antigen detection test to rule out gonococcal pharyngitis, if genital gonococcal infection or positive sexual contact is suspected.
3. Viral testing is not practical, and viral causes are self-limiting.

Management

1. For streptococcal pharyngitis, penicillin V 250 mg four times a day orally for 10 days or penicillin G benzathine in a single intramuscular (IM) dose of 2.4 million units appears to shorten duration of symptoms and prevents rheumatic fever.
2. Amoxicillen, amoxicillen-clavulanate, macrolides, erythromycin and cephalosporins are used for bacterial pharyngitis.

Complications

1. Acute rheumatic fever.

2. Peritonsillar abscess/cellulitis.
3. Acute glomerulonephritis.
4. Scarlet fever.
5. Sinusitis, otitis media, and mastoiditis.

NURSING ALERT Acute rheumatic fever, a complication of streptococcal pharyngitis, can be prevented if patient is treated adequately with penicillin and, possibly, another antibiotic. Unfortunately, there is no evidence that antibiotic therapy will prevent acute glomerulonephritis.

Nursing Interventions and Patient Education

1. Advise the patient to have any sore throat with fever evaluated, especially in the absence of cold symptoms.
2. Encourage compliance with full course of antibiotic therapy, despite feeling better in several days, to prevent complications.
3. Advise lukewarm saline gargles and use of antipyretic/analgesics, as directed, to promote comfort.
4. Encourage bed rest with increased fluid intake during fever.

EAR DISORDERS

See additional online content: Procedure Guidelines 17-1

PROCEDURE GUIDELINES 17-1

Irrigating the External Auditory Canal

PURPOSES

To facilitate removal of cerumen or foreign body and improve hearing.

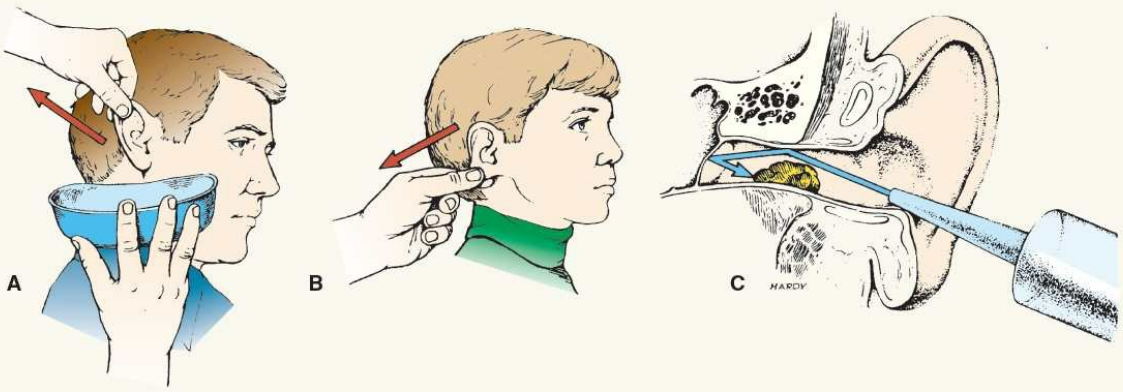
NURSING ALERT Assess if patient has a history of tympanic membrane perforation, myringotomy tube, mastoid surgery, immunocompromise, radiation therapy to the area, is taking an anticoagulant, or has had complications from a previous ear irrigation. Discuss with health care provider before proceeding with the irrigation.

EQUIPMENT AND SOLUTIONS

- Kind and amount of solution desired (usually warm water)
- Ear syringe and irrigation device
- Protective towels
- Cotton balls and cotton-tipped applicators
- Solution bowl or emesis basin
- Bag for disposable items

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. After explaining procedure to the patient, place in a position of sitting or lying with head tilted forward and toward affected ear.	1. Ear should be accessible and able to drain into basin.
2. Position protective towels.	2. Water often runs down neck onto clothing.
Performance phase	



Ear irrigation. **(A)** *The external auditory canal in the adult can best be exposed by pulling the earlobe upward and backward.* **(B)** *The same exposure can be achieved in the child by gently pulling the auricle of the ear downward, outward, and backward.* **(C)** *An enlarged diagram showing the direction of irrigating fluid against the side of the canal.* Note: *This is more effective in dislodging cerumen than if the flow of solution were directed straight into the canal.*

1. Use a cotton applicator to remove any discharge on outer ear.	1. Prevents carrying discharge deeper into canal.
2. Place basin close to the patient's head and under the ear.	2. Provides a receptacle to receive irrigating solution.
3. Test temperature of solution. It should be comfortable to the inner aspect of wrist area (approximately 98.6° F [37° C] or body temperature).	3. Solutions that are hot or cold are most uncomfortable and may initiate a feeling of dizziness.

Nursing Action	Rationale
NURSING ALERT Take special care not to irrigate an older adult's ear with cool water because dizziness may be pronounced.	
4. Ascertain whether impaction is due to a foreign hydroscopic (attracts or absorbs moisture) body before proceeding.	4. If water contacts such a substance, it may cause it to swell and produce intense pain.
5. Gently pull the outer ear upward and backward (adult) or downward and outward (child).	5. Straightens the ear canal (see Figure A).
6. Place tip of syringe or irrigating catheter just inside canal (no more than 8 mm); gently direct stream of fluid against sides of canal.	6. Decreases direct force of irrigation against eardrum and possibility of rupturing it.
7. Observe for signs of pain or dizziness.	7. Discontinue treatment if they occur.
8. If irrigating does not dislodge the wax, instill several drops of prescribed cerumenolytic and repeat as directed.	8. Softens and loosens impaction; may be effective in as little as 15 min.
Follow-up phase	
1. Dry external ear.	
2. Remove soiled equipment and make the patient comfortable.	2. Large amount of brown cerumen may be returned in irrigation solution.
3. Patient should lie on irrigated (affected) side for a few minutes after procedure to allow any remaining solution to drain out.	3. Narrow or tortuous ear canals may drain slowly; retained solution may be uncomfortable and lead to infection.
4. Document effectiveness of the treatment, condition of the canal, and tympanic membrane.	4. For future reference about effectiveness of procedure and patient's condition.

EVIDENCE BASE Schwartz, S. R., Magit, A. E., Rosenfeld, R. M., et al. (2017). Clinical practice guideline (update): Earwax (cerumen impaction). *Otolaryngology—Head and Neck Surgery, 156*(1 Suppl), S1–S29.

Hearing Loss

Hearing loss ranks high as a health disability. There are multiple causes, and the range of hearing loss varies from mild hearing loss to profound hearing loss with complete inability to understand the spoken word. Two major types of hearing loss are conductive and sensorineural. There are 37.5 million Americans with hearing loss.

Classification of Hearing Loss

1. Conductive loss—any condition interfering with sound transmission through the external auditory canal or transmission of tympanic membrane vibrations through the middle ear ossicles to the inner ear.
2. Sensorineural (perceptive) loss—hearing loss due to disease of the inner ear or nerve pathways; sensitivity to and discrimination of sounds are impaired. Hearing aids usually are helpful.
3. Combined or mixed hearing loss—combination of the above.
4. Sudden sensorineural hearing loss—30-dB hearing loss in one or both ears in three contiguous frequencies that occurs within 3 days or less. It can be caused by an acute viral infection or vascular event.

See Table 17-2 for tuning fork tests that assist in differentiating conductive from sensorineural hearing loss.

Table 17-2 Tuning Fork Tests

EAR CONDITION	WEBER TEST	RINNE TEST
Normal, no hearing loss	No shifting of sounds laterally	Sound perceived longer by *air* conduction
Conductive loss	Shifting of sounds to poorer ear	Sound perceived as long or longer by *bone* conduction
Sensorineural loss	Shifting of sounds to better ear	Sound perceived longer by *air* conduction

Presbycusis

A progressive, bilaterally perceptive hearing loss of older adults, usually involving high frequencies, that occurs with the aging process.

1. An audiogram should be obtained by a professional audiologist to evaluate the degree of hearing loss, word discrimination ability, and identification of any hearing loss suggestive of a retrocochlear etiology.
2. The patient should be counseled by an otolaryngologist in collaboration with an audiologist, who can make recommendations for hearing amplification.
3. Helpful aids should be considered, such as a telephone amplifier, radio and television earphone attachments, and a buzzer instead of a doorbell.
4. Understanding and help from family members are important.

Otosclerosis

Otosclerosis is defined as an abnormal growth of bone of the middle ear that prevents the ossicles, or middle ear bones, from working properly and impeding movement of the stapes. Causes progressive hearing loss in one or both ears, vertigo, and tinnitus.

The cause is unknown, but there is a familial tendency, and women are affected more often than men.

Clinical Manifestations

1. Young adults present with a history of slow, progressive hearing loss of soft-spoken tones, with no signs of middle ear infection. In women of childbearing age, often progresses during pregnancy.
2. Audiometry findings substantiate conductive or mixed hearing loss.

Management

1. No known medical treatment exists for this form of deafness, but amplification with a hearing aid may be helpful.
2. Surgery—stapedotomy or stapedectomy.
   a. The removal of otosclerotic lesions at the footplate of stapes or complete removal of the stapes and the creation of a tissue implant with prosthesis to maintain suitable conduction.
   b. To perform such delicate surgery, an otologic binocular microscope is used.

Cochlear Implant

A *cochlear implant* is a device that emits auditory signals for profoundly deaf people (see Figure 17-5). The single-electrode system bypasses the damaged cochlear system and stimulates the remaining auditory nerve fibers. This results in the perception of sound.

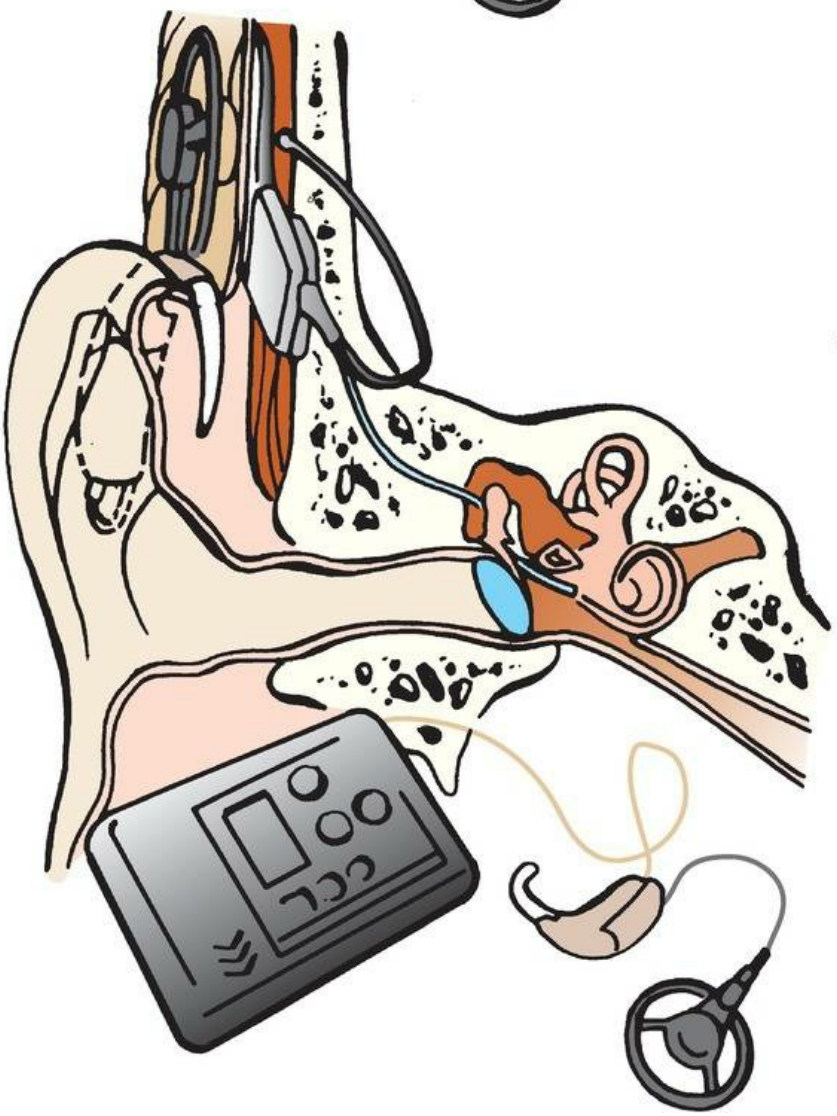


Figure 17-5. Nucleus 24 cochlear implant system. Sounds are picked up by the small, directional microphone located in the headset at the ear. A thin cord carries the sound from the microphone to the speech processor, a powerful miniaturized computer. The speech processor filters, analyzes, and digitizes the sound into coded signals that are sent from the speech processor to the transmitting coil. The transmitting coil sends the coded signals as FM radio signals to the cochlear implant under the skin. The cochlear implant delivers the appropriate electrical energy to the array of electrodes, which have been inserted into the cochlea. The electrodes along the array stimulate the remaining auditory nerve fibers in the cochlea. The resulting electrical sound information is sent through the auditory system to the brain for interpretation. The entire process takes microseconds.

Description

1. Purpose is for the patient to detect louder environmental sounds but will not restore normal hearing. Many recipients continue to rely on lip-reading to make sense of the sound input being received. Some patients are able to rely entirely on hearing with their cochlear implant device and may even be able to use the telephone.
2. The microphone and sound processor are positioned externally; the electrode array is implanted internally and inserts into the cochlea. The receiver–stimulator is inserted into a bony well created in the mastoid behind the ear.
3. Electrical stimuli converted from the sound processor are sent inside the body to the implanted electrode. These electrical signals stimulate the auditory nerve fibers, which are interpreted by the brain.
4. Success rate is highly variable, which has made the cochlear implant controversial. As of 2012, over 324,000 devices have been implanted and registered worldwide.

Patient Criteria

There are no standardized criteria for patient selection. Some data that are considered include the following:

1. Severe to profound sensorineural hearing loss in both ears.
2. Little to no benefit with hearing aids.
3. No medical contraindications.
4. Physically healthy adult or child as young as age 8 months.
5. No evidence of brain impairment that would prevent useful processing of the information delivered. Some would argue that implantation in those with mental impairment would still allow more awareness of environmental sounds, making them safer.
6. Reasonable expectations and optimism; motivation must be present.

Nursing Interventions

1. Encourage the prospective patient to visit with someone who is currently using an implant to learn its positive and negative results.

2. Explain the rehabilitation process; usually begins 2 months after surgery. Included are:
    a. Adjustment of controls.
    b. Operation and maintenance of stimulator unit.
    c. Listening critically and learning lip-reading.
    d. Learning discrimination of sounds through cochlear implant. Understanding speech through cochlear implant is not possible with this device alone.
    e. Many people trained with such an implant can lip-read more easily and can distinguish voices and environmental sounds.
3. Pneumococcal vaccination is important for all cochlear implant candidates and recipients. This should be given at least 2 weeks prior to surgery.
4. For care after surgery, see page 460.

Other Implantable Devices

1. Osseointegrated devices transmit sound from an external device, worn above the ear, through the skin and into the skull to the inner ear. This device is indicated in those with conductive hearing loss when a hearing aid is contraindicated such as chronic ear infection, those with aural atresia or microtia without the normal ear canal needed to carry sound to the middle ear, and those with single-sided deafness.
2. Semi-implantable hearing aids are being tested for conductive and mixed hearing loss.

Maximizing Communication with the Person Who is Hearing Impaired

When hearing loss is permanent or not amenable to medical or surgical intervention, aural rehabilitation is necessary for the patient to maintain communication and prevent isolation. Aural rehabilitation is a multifaceted process that includes auditory training (listening skills), speech reading (formerly called lip-reading), and the use of hearing aids. Nurses strive to maintain effective communication with patients. These suggestions promote better communication.

When the Person Is Hearing Impaired and Able to Lip-Read

1. Face the person as directly as possible when speaking.
2. Place yourself in good light so the person can see your mouth.
3. Do not chew, smoke, or have anything in your mouth when speaking.
4. Speak slowly and enunciate distinctly.
5. Provide contextual clues that will assist the person in following your speech. For example, point to a tray if you are talking about the food on it.
6. To verify that the patient understands your message, write it for him or her to read (ie, if you doubt that the patient is understanding you).

When the Person is Hearing Impaired and Difficult to Understand

1. Pay attention when the person speaks; facial and physical gestures may help you understand what person is saying.

2. Exchange conversation with person when it is possible to anticipate replies. This is particularly helpful in your initial contact with person and may help you become familiar with speech peculiarities.
3. Anticipate context of speech to assist in interpreting what the person is saying.
4. If unable to understand the person, resort to writing or include in your conversation someone who does understand; request that the person repeat that which is not understood.

Organizations That Help the Hearing Impaired

- Alexander Graham Bell Association for the Deaf (*www.agbell.org*)
- American Speech-Language-Hearing Association (*www.asha.org*)
- National Association of the Deaf (*www.nad.org*)

Community and Home Care Considerations

1. Prevention of hearing loss should be discussed in the community—in schools, the workplace, and community gatherings.
2. Preventable hearing loss includes
   a. Noise-induced hearing loss—long periods of exposure to loud noise from machinery or engines.
   b. Acoustic trauma—single exposure to intense noise such as an explosion or amplified music.
3. Prevention involves avoidance of both types of noise, generally noise above 85 or 90 dB.
4. Teach people to be aware of their surroundings and avoid noisy places or turn off sources of noise in the environment whenever possible.
5. Teach proper use of ear protection including earplugs and headsets both in the workplace and elsewhere.
6. Advise people that the Occupational Safety and Health Administration requires ear protection when noise exposure is above the legal limits, so workers have a right to protective equipment.

Otitis Externa

Otitis externa is an inflammation/infection of the external ear, pinna, and/or ear canal.

Pathophysiology and Etiology

1. Bacterial causes: Most common causes are *Pseudomonas aeruginosa*, *Proteus mirabilis*, and *S. aureus*.
2. May be caused by fungal source: *Aspergillus niger*, *C. albicans*.
3. Commonly caused by chronic dermatologic conditions, such as seborrhea, psoriasis, eczema, or contact dermatitis. Allergic reaction to topical otic such as neomycin/polymyxin preparations may also occur in some patients.
4. Trauma to the ear canal, usually from cleaning the canal.
5. Stagnant water in ear canal after swimming or from water irrigation for cerumen removal is a common etiology.
6. Necrotizing malignant otitis externa is a serious infection into deeper tissue adjacent to the ear canal, including cellulitis and osteomyelitis. It is usually caused by *Pseudomonas* and may be seen in diabetic patients, older patients, debilitated patients, or patients with compromised immune systems.
7. Methicillin-resistant *S. aureus* otorrhea has been a common cause of chronic ear drainage. Treatment is based on culture and sensitivity of the ear drainage.

Clinical Manifestations

1. Otalgia or ear pain, increased by manipulation of auricle or tragus; hearing loss and aural fullness. Itching may also be present.
2. Periauricular lymphadenopathy.
3. Foul-smelling white to purulent drainage otorrhea. Drainage may be thick and purulent or thin and white, depending on the causative organism.
4. Red, swollen ear canal with discharge on otoscopic examination; ear canal can be swollen shut.

Management

1. Instillation of isopropyl alcohol drops (dries moisture), acetic acid solution (restores acidity), or topical antibiotics (curbs infection). A combination of these treatments may be used depending on the cause. Antifungal agents, in ointment, powder, or drop form, may be used.
    a. Prophylactic use of alcohol drops or acetic acid solution by swimmers or those prone to otitis externa may be indicated.
    b. Antibiotic drops include combination products containing polymyxin, neomycin, and hydrocortisone; ciprofloxacin; and ofloxacin. Tobramycin preparations may be used with methicillin-resistant infections (confirmed by culture and sensitivity).
    c. A 10-day course of treatment is usually indicated.
    d. Parenteral antibiotics will be used for necrotizing otitis externa.

2. If canal is swollen and tender, an antibiotic solution containing a corticosteroid is chosen to reduce inflammation and swelling. If acute inflammation and closure of the ear canal prevent drops from saturating canal, a wick may need to be inserted by an ENT specialist so drops will gain access to walls of entire ear canal.
3. Burow solution (aluminum acetate solution) or topical corticosteroid cream or lotion may be used in otitis externa caused by dermatitis.
4. Fungal infections may be treated with a topical antifungal such as nystatin or ketoconazole.
5. In chronic otitis externa, debris from ear canal may need to be removed through suction after pain and swelling have subsided. Avoid water irrigation, as this promotes bacterial and fungal growth from stagnant moisture.
6. Warm compresses and analgesics may be needed.

Nursing Interventions and Patient Education

1. Demonstrate proper application of eardrops.
2. Advise the patient that otitis externa can be prevented or minimized by thoroughly drying the ear canal after coming into contact with water or moist environment.
3. Teach the patient to use prophylactic eardrops after swimming to assist in preventing swimmer's ear, as directed by health care provider.
4. Advise the use of properly fitting earplugs for recurrent cases.
5. Teach proper ear hygiene: clean auricle and outer canal with washcloth only; do not insert anything smaller than finger wrapped in washcloth in ear canal. Avoid inserting cotton swabs or sharp objects into ear canal because:
   a. Cerumen may be forced against the tympanic membrane, causing impaction.
   b. The canal lining may be abraded, making it more susceptible to infection.
   c. The tympanic membrane may be injured.

PATIENT EDUCATION GUIDELINES 17-2

Instilling Ear Drops

1. Hold the medication bottle between your hands for 1 to 2 minutes to warm drops before administering.
2. Lie on side with affected ear facing upward. Shake drops. Pull ear up and back, and then, instill drops by squeezing the bulb the ordered number of times.
3. Pump tragus by pushing on the flap of skin protecting the ear canal five to six times to ensure drops reach eardrum.
4. Remain on side for 1 to 2 minutes. Repeat, if necessary, on opposite ear.

Impacted Cerumen and Foreign Bodies

Cerumen impaction is defined as accumulation of cerumen, or "ear wax," that causes symptoms of ear pain, fullness, or hearing loss and/or prevents visualization of the tympanic membrane.

Etiology and Clinical Manifestations

1. Cerumen is a mixture of glandular secretions from the ear canal mixed with squamous epithelium. Cerumen builds up over a period of time, causing a decrease in hearing acuity and a feeling that the ear is plugged.
    a. May be underlying seborrhea or other dermatologic condition that causes flaking of skin that mixes with cerumen and becomes obstructive.
    b. Cerumen may be pushed back into external canal and cover tympanic membrane by action of cotton swab.
2. Insect may fly or crawl into the ear, causing initial low rumbling sound; later, feeling that ear is plugged and decreased hearing acuity. Foreign bodies may be placed into the ear canal, especially by children, and include food particles, small objects, or tips of cotton swabs.
3. The patient often seeks treatment for symptoms related to the foreign body or impacted cerumen.

Management

1. Accumulated cerumen does not have to be removed unless it causes symptoms, interferes with examination of the ear drum, or interferes with hearing. May be removed by curette or by irrigation with a syringe or electronic irrigation device (see Figure 17-6).
    a. Avoid directing irrigation stream directly at tympanic membrane, rather direct stream at wall of canal.
    b. Use warm water at approximately body temperature.
2. Foreign bodies may be removed by instrumentation or irrigation by health care provider.
    a. Insects—treat by instilling oil drops to smother insect, which then can be removed with ear spatula or irrigation.
    b. Vegetable foreign bodies (eg, peas)—irrigation is contraindicated because vegetable matter absorbs water, which would further wedge it in the canal.
    c. Only a skilled person should attempt to remove foreign body to prevent tympanic membrane perforation and trauma to canal.
    d. General anesthesia may be required to remove foreign bodies from young children, if they are unable to cooperate.

Figure 17-6. Using an electronic irrigation device to irrigate the external auditory cavity.

NURSING ALERT Do not attempt to irrigate ear or instill anything into external canal if eardrum may be perforated; otoscopic examination should be done to rule out tympanic membrane rupture or acute infection. If the tympanic membrane is unable to be visualized and perforation is suspected, or acute infection is suspected, do not irrigate and refer to ENT specialist. Some antibiotic eardrops are contraindicated if the tympanic membrane is not intact.

Nursing Interventions and Patient Education

1. Teach proper ear hygiene, especially not putting anything in ears.
2. Explain the normal protective function of cerumen.
3. If patient has a problem with cerumen buildup and has been advised by health care provider to use a ceruminolytic periodically, make sure that the patient is getting cerumen out of the ear before more medication is instilled. A bulb syringe may be used by the patient at home to help remove softened cerumen.
4. Advise the patient to report persistent fever, pain, drainage, or hearing impairment.

Acute Otitis Media

Acute otitis media is an inflammation and infection of the middle ear caused by the entrance of pathogenic organisms, with rapid onset of signs and symptoms. Acute otitis media or acute suppurative otitis media is infection of the middle ear caused by contamination from bacteria from the middle ear fluid through the eustachian tube.

Pathophysiology and Etiology

1. Pathogenic organisms gain entry into the normally sterile middle ear, usually through a dysfunctional eustachian tube.
2. Organisms include *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, and *S. aureus*.
3. In serous (secretory) otitis media, no purulent infection occurs, but blockage of the eustachian tube causes negative pressure and transudation of fluid from blood vessels and development of effusion in the middle ear.

Clinical Manifestations

1. Pain is usually the first symptom.
2. Fever may rise to 104˚F to 105˚F (40˚C to 40.6˚C).
3. Purulent drainage (otorrhea) is present if tympanic membrane is perforated.
4. Irritability may be noted in the young person.
5. Headache, hearing loss, anorexia, nausea, and vomiting may be present.
6. Purulent effusion may be visible behind tympanic membrane or tympanic membrane may be reddened and bulging on otoscopic examination.
7. History may reveal previous upper respiratory infection, allergic rhinitis, eustachian tube dysfunction, history of reflux, adenoid hypertrophy, history of cleft palate, smoking in household, sibling otitis media in children, or child in daycare. Patients who have received radiation therapy of the head and neck or experienced barotrauma or those with nasopharyngeal tumor may develop middle ear effusions.

Diagnostic Evaluation

1. Pneumatic otoscopy shows a tympanic membrane that is full, bulging, and opaque with impaired mobility (or retracted with impaired mobility).
2. Cultures of discharge through ruptured tympanic membrane may suggest causative organism.

Management

1. Antibiotic treatment—amoxicillin is first-line treatment; cephalosporins, macrolides, or trimethoprim–sulfamethoxazole may be used in patients with penicillin allergy.
2. Amoxicillin/clavulanate and cephalosporins are used for treatment failure due to increasing rate of beta-lactamase–producing bacteria that inactivate penicillin and other antibiotics.
3. Usual treatment course is 10 days.

4. Follow-up is indicated to determine effectiveness of therapy.
5. Nasal or topical decongestants and antihistamines have a limited role in promoting eustachian tube drainage.
6. Surgery—myringotomy with placement of pressure-equalizing tubes.
    a. An incision is made into the posterior inferior aspect of the tympanic membrane for relief of persistent effusion. A pressure-equalizing tube may be inserted to prevent recurrent episodes.
    b. Performed in selected patients to prevent recurrent episodes or in patients with middle ear effusion for 3 months or more.
    c. May be done because of failure of patient to respond to antimicrobial therapy; for severe, persistent pain; and for persistent conductive hearing loss.

Complications

1. Perforation of tympanic membrane.
2. Chronic otitis media and mastoiditis.
3. Conductive hearing loss.
4. Meningitis and brain abscess.

Nursing Assessment

1. Obtain history of upper respiratory infection, previous ear infections, allergies, and progression of symptoms.
2. Assess fever and level of pain.
3. Obtain baseline hearing evaluation, if indicated.

Nursing Diagnosis

- Acute Pain related to inflammation and increased middle ear pressure.

Nursing Interventions

Relieving Pain

1. Administer or teach self-administration of anti-inflammatories and other analgesics, as prescribed.
2. Administer or teach self-administration of antibiotics, as prescribed. Oral corticosteroids may be prescribed, as well as nasal steroids.
3. Encourage the use of local warm compresses or heating pad to promote comfort and help resolve infectious process.
4. Be alert for such symptoms as headache, slow pulse, vomiting, and vertigo, which may be significant for sequelae that involve the mastoid or the brain.

Patient Education and Health Maintenance

1. Encourage follow-up after treatment to ensure resolution.

2. Advise the patient that sudden relief of pain may indicate tympanic membrane rupture. Do not instill anything in ear and call health care provider.
3. Instruct the patient to follow up for recurrence of symptoms, such as pain, fever, and ear congestion.

Evaluation: Expected Outcomes

- Verbalizes relief of pain at follow-up visit.

Chronic Otitis Media and Mastoiditis

Chronic otitis media is a chronic inflammation of the middle ear with tissue damage, usually caused by repeated episodes of acute otitis media. It may be caused by an antibiotic-resistant organism or a particularly virulent strain of organism. It may be associated with tympanic membrane perforation. *Mastoiditis* is inflammation of the mastoid air cells of the temporal bone adjacent to the ear.

Pathophysiology and Etiology

1. The accumulation of pus inflammatory exudate under pressure in the middle ear cavity may result in necrosis of tissue, with damage to the tympanic membrane and possibly the ossicles.
   a. The most common organisms are *S. pneumoniae*, *H. influenzae*, and *Moraxella catarrhalis*.
   b. Other organisms may be present, such as *Pseudomonas*, *Proteus*, and *Bacteroides* species.
2. Persistent rupture of the tympanic membrane and damage to the ossicles lead to conductive hearing loss.
3. Extension of infection may occur into the mastoid cells (mastoiditis).
4. Cholesteatoma may form (mass of squamous epithelium and desquamated debris in the middle ear), which may cause erosion of the ossicles or inner ear.

Clinical Manifestations

1. Painless or dull ache, decreased hearing, tendernss of mastoid.
2. Otorrhea may be odorless or foul smelling.
3. Vertigo and pain may be present if CNS complications have occurred.
4. History will indicate several episodes of acute otitis media and possible rupture of tympanic membrane.
5. Fever and postauricular erythema and edema.

Diagnostic Evaluation

1. Conductive hearing loss is present through audiometric tests.
2. CT of temporal bone may show mastoid pathology, for example, cholesteatoma or opacification of mastoid cells.
3. Culture of exudate from middle ear (through ruptured tympanic membrane or at time of surgery).

Management

Note: If advanced chronic ear disease is left untreated, inner ear and life-threatening CNS complications may develop because of erosion of surrounding structures.

Medical Therapy

1. Antibiotic and steroid eardrops may control middle ear infection and inflammation, but when mastoiditis develops, parenteral antibiotic therapy is necessary.
2. Eardrops containing neomycin, garamycin, tobramycin, and quinolones, such as ciprofloxacin, are instilled into the middle ear when the tympanic membrane is ruptured. Otic drops containing antibiotics

or antibiotic powder preparations may be used for infection and otorrhea. Local cleaning using microscope and instrumentation is mainstay of treatment and done by ENT specialist.

3. IV antibiotics must cover beta-lactamase–producing organisms—ampicillin–sulbactam, cefuroxime—based on culture results.

Surgical Interventions

1. Indicated when cholesteatoma is present.
2. Indicated when there is pain, profound deafness, dizziness, sudden facial paralysis, or stiff neck (may lead to meningitis or brain abscess).
3. Types of procedures:
   a. Simple mastoidectomy—removal of diseased bone and insertion of a drain; indicated when there is persistent infection and signs of intracranial complications.
   b. Radical mastoidectomy—removal of posterior wall of ear canal, remnants of the tympanic membrane, and the malleolus and incus.
   c. Posteroanterior mastoidectomy—combines simple mastoidectomy with tympanoplasty (reconstruction of middle ear structures).

Complications

1. Acute and chronic mastoiditis.
2. Cholesteatoma.
3. CNS infection (meningitis, intracranial abscess).
4. Postoperatively—facial nerve paralysis, bleeding, vertigo.

Nursing Assessment

1. Assess for history of ear infection and treatment compliance. Identify factors that may prevent compliance with treatment in the future—lack of money/prescription coverage, lack of transportation, lack of knowledge on severity of infection, and so forth.
2. Assess for ear drainage and patency of tympanic membrane.
3. Assess for hearing loss.
4. Palpate for mastoid tenderness.

For nursing process related to patients undergoing surgical treatment, see “Care Related to Ear Surgery,” page 460.

Patient Education and Health Maintenance

1. Teach the patient to keep the ear dry—use ENT-approved or molded ear plugs during showering, washing hair, and swimming—to prevent any water from gaining access to middle ear.
2. Encourage the patient to follow up for frequent ear cleaning.
3. Stress the importance of adhering to antibiotic schedule and to notify the home care nurse or health care

provider if there is any problem with venous access or a dose is missed for any reason.

4. Advise of complications and to report headache, change in mental status or arousal, or increased ear pain.
5. Stress the importance of follow-up hearing evaluations and early intervention for any signs of ear infection in the future.

Ménière Disease

Ménière disease (or *endolymphatic hydrops*) is a chronic inner ear disease characterized by spontaneous episodes of vertigo, fluctuating hearing loss, aural fullness, and tinnitus.

Pathophysiology and Etiology

1. Cause is unknown.
2. Fluid distention of the endolymphatic spaces of the labyrinth destroys cochlear hair cells. Pathology of the disease is endolymphatic hydrops, which is thought to be caused by overaccumulation of endolymphatic fluid and distention of the endolymphatic-containing areas in the cochlea and vestibular organs.
3. Usually unilateral, later may become bilateral. Diagnoses primarily based on clinical symptoms but audiometry and ENG are traditionally obtained.
4. Occurs most frequently between ages 30 and 60.
5. Severity of attacks may diminish over the years, but hearing loss increases.

Clinical Manifestations

1. Sudden attacks occur, in which the patient feels that the room is spinning (vertigo); may last 30 minutes to several hours or days.
2. Aural fullness, tinnitus, and reduced hearing or fluctuating hearing loss occurs on involved side.
3. Headache, nausea, vomiting, and disequilibrium may be present.
4. The most comfortable position for the patient is lying down.
5. After multiple attacks, tinnitus and impaired hearing may be continuous.

Diagnostic Evaluation

1. ENG or EcOG (see page 456), along with the patients' history and neurotologic exam, is used to establish diagnosis of Ménière disease.
2. Audiogram may reveal low-frequency sensorineural hearing loss in affected ear.
3. CT scan and MRI to rule out acoustic neuroma. Only MRI of internal auditory canal with gadolinium can differentiate Ménière disease symptoms from the symptoms of an intracranial lesion.

Management

Medical

1. The patient can be asked to keep a diary noting presence of aural symptoms (eg, tinnitus, distorted hearing) when episodes of vertigo occur.
2. Administration of a vestibular suppressant to control symptoms.
   a. Meclizine up to 25 mg four times a day.
   b. Diphenhydramine 25 to 50 mg three or four times a day.

c. Lorazepam may be helpful as vestibular suppressant.

3. Intratympanic injections of aminoglycosides and corticosteroids can improve vertigo control.
4. Streptomycin (IM) or gentamicin (transtympanic injection) may be given to selectively destroy vestibular apparatus if vertigo is uncontrollable.
5. An antiemetic, such as promethazine, may be needed to reduce nausea, vomiting, and resistant vertigo.

DRUG ALERT In general, meclizine is not recommended on a long-term basis, as it prevents central nervous system compensation. Meclizine may be used for symptomatic relief on a short-term basis.

Surgical

1. Conservative—endolymphatic subarachnoid or mastoid shunt to relieve symptoms without destroying function.
2. Destructive surgery.
   a. Labyrinthectomy—recommended if the patient experiences progressive hearing loss and severe vertigo attacks so normal tasks cannot be performed; results in total deafness of affected ear.
   b. Vestibular nerve section—neurosurgical suboccipital approach to the cerebellopontine angle for intracranial vestibular nerve neurectomy.

Complications

1. Irreversible hearing loss.
2. Disability and social isolation due to vertigo and hearing loss.
3. Injury due to falls.

Nursing Assessment

1. Assess for frequency and severity of attacks.
2. Provide screening hearing tests.
3. Evaluate effect on the patient's activities and potential for fall or injury.

Nursing Diagnoses

- Risk for Injury related to sudden attacks of vertigo.
- Social Isolation related to fear of attack and hearing loss.

Nursing Interventions

For care related to labyrinth surgery, see page 460.

Ensuring Safety

1. Help the patient recognize an aura so that he or she has time to prepare for an attack.

2. Encourage the patient to lie down during attack, in safe place, and lie still.
3. Put side rails up on bed if in hospital.
4. Have the patient close eyes if this lessens symptoms.
5. Inform the patient that the dizziness may last for varying lengths of time. Maintain safety precautions until attack is complete.

Minimizing Feelings of Isolation

1. Provide encouragement and understanding. Show the patient that you understand the seriousness of this disorder, even though there is little that can be done to ease the discomfort.
2. Assist the patient to identify specific triggers to control attacks.
   a. Remind the patient to move slowly because jerking or making sudden movements may precipitate an attack.
   b. Avoid noises and glaring, bright lights, which may initiate an attack.
   c. Control environmental factors and personal habits that may cause stress or fatigue.
   d. If there is a tendency to allergic reactions to foods, eliminate those foods from the diet.
3. Avoid oversedation of the patient through polypharmacy with sedatives, anticholinergics, and opioids that may increase risk of falling if attack occurs.
4. Teach the patient to be aware of other sensory cues from the environment, visual, olfactory, and tactile, if hearing is affected.

Patient Education and Health Maintenance

1. Teach about medication therapy, including adverse effects of vestibular suppressants—drowsiness, dry mouth.
2. Advise sodium restriction as adjunct to vestibular suppressant therapy.
3. Advise the patient to keep a log of attacks, triggers, and severity of symptoms.
4. Encourage follow-up hearing evaluations and provide information about surgical care if planned.
5. Teach the patient hearing-conservation methods—avoid loud noises, wear earplugs if necessary, avoid smoking, and avoid use of ototoxic drugs, such as aspirin, quinine, and some antibiotics.

Evaluation: Expected Outcomes

- Lays down with side rails up and eyes closed during attack; resolves without injury.
- Identifies dietary triggers and follows treatment plan.

Vestibular Labyrinthitis

Labyrinthitis is an inflammation of the inner ear caused by a viral or bacterial infection. It is characterized by hearing loss, vertigo, and usually nausea and vomiting.

See Box 17-1, for other causes of vertigo, including BPPV.

BOX 17-1 Vertigo

Vertigo is a type of dizziness characterized by the illusion of movement: a perception either that the surroundings are moving while the body remains still or that one's body is moving while the surroundings remain still. It is caused by vestibular dysfunction—in either the peripheral vestibular system (inner ear) or the central vestibular system (brain stem and cerebellum).

- Common causes of vertigo of peripheral origin include Ménière disease, labyrinthitis, acoustic neuroma, and benign paroxysmal positional vertigo (BPPV).
- Causes of central vertigo include multiple sclerosis, basilar migraine, transient ischemic attack or stroke of the basilar artery, brain tumor, trauma, and cerebral hemorrhage.
- Other causes of dizziness are vasovagal syncope, hypovolemia, autonomic neuropathy of diabetes, severe anemia, aortic stenosis, hypoglycemia, hypoxia, hypocarbia, multiple sensory deficits, adverse drug effects, and emotional illness.

BPPV is the most common cause of vertigo. Its onset is sudden, it can be severe in intensity, and it is always related to change in position of the head. It can be diagnosed by thorough history and physical examination, including some provocative maneuvers such as the Dix-Hallpike maneuver. Diagnostic tests are required only to rule out central vestibular dysfunction and dizziness caused by other disorders. Patients with BPPV may be very concerned about their symptoms and are at risk for injury due to imbalance.

NURSING CONSIDERATIONS

- Ensure safety by creating an uncluttered environment, using side rails and handrails as necessary, using proper footwear, and encouraging the patient to call for help.
- Teach patient to avoid sudden position changes, including simple head movements, such as looking up or turning over in bed.
- Discourage use of alcohol and sedating drugs, which may further impair safe ambulation.
- Most episodes of BPPV last seconds to minutes and completely resolve within 3 months; however, if severe or prolonged, suggest referral to a physical therapist for vestibular rehabilitation.

Pathophysiology and Etiology

1. Bacterial labyrinthitis is usually associated with acute otitis media or cholesteatoma. Infectious organisms may enter the inner ear through the oval or round window. Bacterial meningitis can cause labyrinthitis by spread of the bacterial infection via the cochlear aqueduct and internal auditory canal.
2. Viral labyrinthitis can occur as a result of viral illnesses of the respiratory tract system and may include

measles, mumps, rubella, or herpetic infections of the facial or acoustic nerve. This may be seen in Ramsey-Hunt syndrome.

3. Vestibular neuronitis or neuritis is a disorder of the vestibular nerve (CN XII) characterized by severe, sudden onset of vertigo with normal hearing. Etiology most commonly from viral illness but may be attributed to other causes. The course is usually self-limiting. The patient may have an unsteady gait but is able to walk. (This is differentiated by cerebellar disease, in which the patient has vertigo and nystagmus and is usually unable to walk.) Treatment is supportive with meclizine, benzodiazepines, antiemetics, or vestibular rehabilitation.

Clinical Manifestations

1. Sudden onset of incapacitating vertigo, with varying degrees of nausea and vomiting, hearing loss, and tinnitus.
2. Persists; does not occur in episodic attacks like Ménière disease.

Management

1. The rare cases of bacterial labyrinthitis are treated with antibiotics, as with the suspected predisposing infection.
   a. Bacterial labyrinthitis is treated by antibiotics, antiemetics, vestibular suppressants, and vestibular rehabilitation.
   b. Diagnostic imaging may include CT of temporal bone, MRI of internal auditory canal with gadolinium, and lumbar puncture, if bacterial meningitis is suspected.
2. Viral and physiologic causes are treated with symptomatic support. In patients with viral labyrinthitis, management may include antiviral therapy, antiemetics, vestibular suppressants, and, later in illness, vestibular rehabilitation.
3. A vestibular suppressant and antiemetic medication such as meclizine, diazepam, or promethazine may be needed, as with Ménière disease.
4. Audiometric evaluation should be obtained with all patients with vertigo to differentiate between vestibular labyrinthitis and vestibular neuronitis. MRI of brain and internal auditory canal is obtained when asymmetrical hearing loss is present to rule out acoustic neuroma.

Complications

1. Permanent hearing loss.
2. Injury from fall.

Nursing Assessment

1. Assess frequency and severity of attacks and how patient handles them.
2. Assess for fever related to bacterial infection.
3. Assess for additional neurologic symptoms—visual changes, change in mental status, sensory and motor deficits—that may indicate CNS pathology.

4. Assess for effectiveness of vestibular stimulants and antiemetics.
5. If fall occurs, assess for injury.

Nursing Diagnoses

- Risk for Injury related to gait disturbance secondary to vertigo.
- Anxiety related to sudden onset of symptoms.
- Risk for Deficient Fluid Volume related to vomiting and impaired intake.
- Bathing and Hygiene Self-Care Deficit related to vertigo.

Nursing Interventions

Preventing Injury

1. At onset of attack, have the patient lie still in darkened room with eyes closed or fixed on stationary object until the vertigo passes.
2. Make sure that the patient can obtain help at all times through use of call system, close proximity to staff, or companion.
3. Remove obstacles in the patient's environment.
4. Make sure that sensory aids are available—glasses, hearing aid, proper lighting.
5. Use side rails while the patient is in bed.
6. Administer medications, as directed; assess for and avoid oversedation.

Minimizing Anxiety

1. Explain the physiology behind vertigo and the possible triggers.
2. Support patient and family through the diagnostic process.
3. Assist the patient to adjust activities to minimize the impact.
4. Teach stress-reduction techniques, such as deep breathing, talking and asking questions, and distraction.

Ensuring Adequate Fluid

1. Keep diet light while vertigo is present.
2. Administer antiemetics, as directed.
3. Assess intake and output, as indicated.
4. Encourage fluids and small feedings while patient is feeling better.

Encouraging Safe Self-Care

1. Encourage activity while vertigo is minimal; rest during attacks.
2. Set up environment for the patient's safety and convenience—chair near sink, walker to hold on to while walking, if necessary, and so forth.
3. Assist the patient with hygiene and other care, as needed.

Patient Education and Health Maintenance

1. Teach patients with viral labyrinthitis that attacks are self-limiting, will become less severe, and should leave no permanent disability.
2. Teach safety measures during vertigo attacks.
3. Tell the patient that vertigo is best tolerated while lying flat in bed in a darkened room, with eyes closed or looking at stable object.
4. Teach patients how to take medications and to avoid other CNS depressants such as alcohol.
5. Encourage follow-up.

Evaluation: Expected Outcomes

- Rests in bed during attack with side rails up.
- Verbalizes feelings and questions about treatment.
- Takes fluids, light diet every 4 hours, after medication administration.
- Performs appropriate hygiene and dressing by him- or herself at bedside.

See additional online content: Procedure Guidelines 17-2

PROCEDURE GUIDELINES 17-2

Emergency First Aid for the Laryngectomee

EQUIPMENT (IF AVAILABLE)

- Suction equipment
- Sterile disposable catheter
- # 14 to # 16 F (adult)
- Sterile gloves
- Sterile saline
- Portable mask and bag

PROCEDURE

Nursing Action	Rationale
Performance phase	
1. Place the patient on his or her back on a firm surface, head straight, chin up. Expose the neck down to the sternum.	1. Facilitates access to the laryngeal stoma and observation of thoracic movement.
2. Position a blanket or any article of clothing under the shoulders.	2. Promotes extension of the neck area, permitting access.
3. Make a rapid assessment of the situation:	
a. Is victim wearing a tracheostomy or laryngectomy tube?	a. In a laryngectomee, tube removal cannot cause immediate danger.
b. Has patient been operated on recently?	b. If so, tracheostomy tube cannot be removed.
c. Check for tracheal obstruction. Clean stomal opening of mucus and encrusted matter.	c. Mucus and other material may account for obstruction. Use clean cloth or handkerchief—never tissue.
4. Start mouth-to-neck breathing promptly: position yourself at side of victim. Place your mouth and lips/mask tightly over neck opening or around the tracheal tube if the person is wearing one.	4. Seconds count. Do not remove the tube.
5. If suction equipment is available, insert a soft rubber tube 3–5 inches (7.5–12.5 cm) into opening for a few seconds.	5. A partially open airway transporting air to the victim is infinitely better than a clean airway that does not supply air at this crucial time.
6. Blow in a sufficient amount of air to see chest rise; then release and allow chest to fall.	6. Indicates ventilation.
7. For the first 5 seconds, repeat every 1–2 seconds; then slow down to a steady pace of every 4–5 seconds (12–20 times/minute).	7. Allows air to exhale passively.
8. Continue until spontaneous breathing returns.	
Follow-up phase	
1. When spontaneous breathing occurs, provide oxygen from a portable supply.	1. Relieves hypoxemia.
2. If breathing fails again, resume mouth-to-neck breathing.	
3. You can also use a manual resuscitation bag with an infant-size mask.	3. Attach infant-size mask; be sure that there is a tight seal against neck opening. Because a tight seal is difficult to maintain and because pressure of the mask on the major blood vessels of the neck may interfere with blood supply to the brain, mouth-to-neck breathing is safer and better.
4. Watch the chest rise.	4. Easiest way to detect spontaneous breathing.
5. Observe the patient constantly.	

Cancer of the Oral Cavity, Oropharynx, Nasopharynx, and Paranasal Sinuses

Cancer of the oral cavity may arise from the lips, buccal mucosa, gums, retromolar trigone, hard palate, floor of the mouth, salivary glands, and anterior two thirds of the tongue. Cancer of the oropharynx may arise from the tonsillar fossa, pharyngeal wall, and palatal arch (soft palate, uvula, and anterior border of the anterior tonsillar pillar). Cancer of the nasopharynx may arise from the fossa of Rosenmuller. Cancer of the paranasal sinuses may arise from the maxillary sinuses (80%) or, less commonly, in the ethmoid, frontal, and sphenoid sinuses.

Pathophysiology and Etiology

EVIDENCE BASE National Cancer Institute. (2017). Cancer Stat Fact: Oral Cavity and Pharynx Cancer. *Surveillance, epidemiology and end results program (SEER)*. Bethesda, MD: Author. Available: https://seer.cancer.gov/statfacts/html/oralcav.html.

---

1. Oral and oropharyngeal cancer accounts for approximately 3% of all cancers diagnosed annually in the United States. About 48,000 people will be diagnosed with oral cavity and pharynx cancer and about 9,500 will have died from this disease in 2016. Prevalence is greater in men and between the ages of 55 to 64. Approximately 90% are squamous cell carcinoma.
   a. High-risk factors include use of tobacco and excessive alcohol (particularly in combination), use of smokeless tobacco (snuff), pipe smoking, marijuana use, exposure to HPV (causes greater than 60% of all oropharyngeal cancers in the United States), poor oral hygiene, and genetic factors.
   b. Overall survival rate depends on the primary location of the tumor and the stage of the disease at diagnosis. On average, 64% of those with this disease will survive more than 5 years.
2. Nasopharyngeal carcinoma is most prevalent in persons from Chinese or Asian ancestry because of a diet high in preservation (eg, salted fish). These types of cancers have a high genetic predisposition.
   a. Strong association with the Epstein-Barr virus.
   b. The most common presentation is neck mass. Blood-stained saliva or sputum is the second-most common presentation.
   c. Occurs 75% of the time in males, usually between ages 30 and 60. Overall survival rate is 50% to 90%, depending on the stage of disease at diagnosis.
3. Malignant paranasal sinus tumors are rare and have relatively poor survival outcomes. They are usually squamous cell in origin.
   a. The majority of cancer occurs in the maxillary sinus (50% to 70%), in the nasal cavity (15% to 30%), and ethmoid sinus (10% to 20%).
   b. Pathology is classified into epithelial and nonepithelial categories, with many subsets being attributable to environmental or occupational toxins.

c. Overall survival rate is 27% to 94%, with the higher stage of cancer contributing to poorer prognosis.

Clinical Manifestations

1. Commonly asymptomatic in early stages.
2. Oral cancer—nonhealing, nonpainful crusting and ulcerated leukoplakic and erythemic lesions.
3. Cancer of the lip—presence of a lesion that fails to heal.
4. Cancer of the tongue—swelling, ulceration, areas of tenderness or pain, bleeding, abnormal texture, or limited movement of the tongue.
5. Floor of the mouth cancer—red, slightly elevated, mucosal lesion with ill-defined borders, leukoplakia, indurated, ulceration, or wartlike growth.
6. Cancer of the tonsil—swelling, neck mass, wartlike growth, odynophagia, otalgia.
7. Cancer of the retromolar trigone area—trismus, otalgia, dysphagia, odynophagia.
8. Cancer of the pharyngeal wall—dysphagia, odynophagia, otalgia, neck mass.
9. Cancer of the nasopharynx—epistaxis, unilateral serous otitis, unilateral nasal blockage, loss of sense of smell (CN I), eye movement abnormalities (CN III, IV, and V), and tongue movement impairment and dysphagia (CN IX, X, and XII).
10. More advanced stages characterized by ulceration, bleeding, pain, induration, CN impairments, dysphagia, odynophagia, weight loss, and/or cervical lymphadenopathy (neck mass).

Diagnostic Evaluation

1. Careful inspection of the oral cavity with indirect mirror examination of pharynx.
2. Flexible or rigid nasopharyngoscopy to directly examine the nasopharynx and pharynx.
3. Excisional biopsy of suspected tissue is the gold standard.
4. Radiologic studies: CT, with or without contrast as clinically indicated, MRI and possibly FDG-PET/CT for stage III-IV disease.

Management

EVIDENCE BASE National Comprehensive Cancer Network. (2017). *NCCN guidelines: Head and neck cancers*. Fort Washington, PA: Author. Available: *www.nccn.org*.

Selection of treatment depends on the size and site of lesion and how extensively surrounding tissues are involved.

1. Oral cavity cancer treatment consists of the following:
   a. Surgery to remove the primary disease plus any neck lymph nodes, or definitive radiotherapy.
   b. For more advanced cancer, surgery followed by chemoradiation or multimodal clinical trials is

recommended.

2. Surgical resection of nasopharyngeal cancer may be difficult because of the location and the relationship to many important structures.
   a. Radiation therapy is the treatment of choice in early-stage cancers of these areas.
   b. For more advanced nasopharyngeal cancer, the recommendation is to perform multimodal clinical trials, or concurrent chemoradiation, or induction chemotherapy followed by chemoradiation.
   c. If metastasis is present, clinical trials are recommended, or concurrent platinum-based combination chemotherapy, or concurrent chemoradiation.
3. Oropharynx cancer (base of tongue cancer, tonsil, posterior pharyngeal wall and soft palate) cancer should be tested for human papillomavirus (HPV) status to determine prognosis; however, this does not affect the treatment recommendations.
   a. For low-grade cancer, the treatment choice is definitive radiation, or transoral or open resection of the primary tumor with neck dissection followed by chemoradiation, or multimodal clinical trials.
   b. For high-grade cancers, the treatment choices remain the same as above except for the addition of induction chemotherapy with radiation or systemic chemotherapy and radiation therapy.
4. Paranasal sinus cancer treatment usually consists of minimally invasive or open surgery followed by radiation; chemotherapy may also be utilized.

Complications

1. Second primary cancers of the larynx, hypopharynx, esophagus, and lungs.
2. Secondary to treatment:
   a. Surgery—transient salivary outflow obstruction, infection, voice changes, fistula formation, loss of swallowing, cosmetic defects.
   b. Radiation (early effects)—taste alterations, mucositis, xerostomia, dysphagia, odynophagia, anorexia, dermatitis, fatigue, pain.
   c. Radiation (late effects)—thyroid dysfunction, radiation caries, osteoradionecrosis, xerostomia, trismus, nasopharyngeal stenosis, CSF leak and other neurologic complications, tissue fibrosis, trismus, laryngeal edema, vascular complications.
   d. Chemotherapy—nausea, vomiting, dehydration, skin reaction, mucositis, hyperuremia, liver abnormalities, weight loss, anorexia, myelosuppression, peripheral neuropathy, hypomagnesemia, ototoxicity, nephrotoxicity, alopecia, and cognitive effects.

Nursing Assessment

1. Obtain complete history, noting risk factors such as smoking and alcohol use, exposure to Epstein-Barr virus, diet, high-risk sexual behavior, and exposure to environmental toxins.
2. Question the patient regarding changes in swallowing, smell or taste, salivation, discomfort when eating, sore throat, foul breath odor, weight loss, epistaxis, unilateral nasal obstruction, changes in hearing, neck mass, changes in tongue movement, and changes in vision.

3. Note the quality of voice patterns and odor of breath.
4. Inspect the oral cavity: erythema, red velvety areas; white patches; crusting, bleeding; swelling; record the size, location, and description.
5. Use nasal speculum to inspect the nares for obstruction.
6. Palpate the cervical lymph nodes for size, firmness, or tenderness.

Nursing Diagnoses

- Acute Pain related to malignant infiltration, lesions, difficulty swallowing, surgery, radiation therapy.
- Imbalanced Nutrition: Less Than Body Requirements related to pain, difficulty in chewing or swallowing, history of alcohol abuse, dysphagia, xerostomia.
- Disturbed Body Image related to changes in facial contour, cosmetic defect from surgery, CN deficits.

Nursing Interventions

Also see page 480 if radical neck dissection has been performed.

Achieving an Acceptable Level of Comfort

1. Provide systemic analgesics or analgesic gargles, as prescribed.
2. If ordered by the provider, perform mouth care with soft toothbrush and flossing between teeth.
3. If the patient cannot tolerate brushing and flossing:
   a. Gently lavage oral cavity with a catheter inserted between the patient's cheek and gums with warm water or salt water rinses.
4. Provide management of excessive salivation and mouth odors.
   a. Insert a gauze wick in corner of mouth; place basin conveniently to catch drooling; replace frequently to absorb and direct excess saliva.
   b. Suction secretions with a soft rubber catheter, if not allergic to latex, as needed; instruct the patient on suctioning methods.
5. Provide management of decreased salivation, if necessary.
   a. Encourage intake of fluids, particularly water, if not contraindicated.
   b. Instruct the patient to avoid dry, bulky, and irritating foods.
   c. Offer lemon lozenges or chewing gum to stimulate salivation.
   d. Encourage use of humidifier.
   e. Suggest foods with sauces and gravies to make them moist and easier to swallow.
6. Maintain a clean and odor-free environment by removing soiled dressings, tissues, and gauzes and providing room deodorants.

Improving Nutritional Status

1. Handle feeding problems in one or a combination of the following ways, as ordered:
   a. IV fluid to prevent dehydration.

b. Nasogastric (NG) tube feedings or prophylactic placement of gastrostomy tube for feedings.
c. Orally—serve meals high in protein and vitamin content and low in acidity and salt.

2. Provide mouth care before and after eating.
3. Allow the patient to have meals in privacy, if desired.
4. Offer easily chewed foods; mash or blenderize, if necessary.
5. Add herbs or sweeteners to enhance flavor.
6. Provide methods to compensate for decreased salvation by offering the following:
   a. Sip fluids, especially water, and carry water bottle throughout day.
   b. Avoid dry, bulky, and irritating foods.
   c. Use lemon lozenges or chewing gum to stimulate salvation.
   d. Use cholinergic stimulants or saliva substitutes as prescribed.
   e. Use a humidifier.
   f. Add gravy and sauces to food.
7. Encourage daily fluoride treatment as prescribed while undergoing radiation.
8. Have patient remove dentures if mucositis is present.
9. If swallowing difficulties persist, consult the speech–language pathologist.
10. Monitor weight, intake and output, and laboratory tests, such as 24-hour urine for urea nitrogen, C-reactive protein, albumin, prealbumin, transferrin level, and electrolytes.
11. Maintain a clean and odor-free environment by removing soiled material and using room deodorizer.

EVIDENCE BASE Buglione M., Cavagnini R., Di Rosario F., et al. (2016). Oral toxicity management in head and neck cancer patients treated with chemotherapy and radiation: Dental pathologies and osteoradionecrosis (Part 1) literature review and consensus statement. *Critical Reviews in Oncology/Hematology, 97*, 131–142.

Buglione M., Cavagnini R., Di Rosario F., et al. (2016). Oral toxicity management in head and neck cancer patients treated with chemotherapy and radiation: Xerostomia and trismus (Part 2). Literature review and consensus statement. *Critical Reviews in Oncology/Hematology, 102*, 47–54.

Strengthening Body Image

1. Assess the patient's reaction to condition.
   a. Evaluate the patient's apprehension and offer emotional support.
   b. Correct misinformation.
   c. Determine therapeutic care plan for the patient's rehabilitation.
2. Recognize that face and neck surgery can be disfiguring and the patient often is embarrassed, withdrawn, and depressed.

3. Assist the patient in caring for personal appearance.
4. Observe closely for indications of the patient's needs, which may be communicated in other ways, such as acting out or withdrawn behavior.
5. Allow verbalization of fears, anger, and distaste with body changes in a nondefensive manner.
6. Communicate acceptance of appearance in an honest manner.
7. Encourage the patient's family and friends to visit so patient is aware that others care about him or her.
8. Provide diversional activities.

Community and Home Care Considerations

1. Teach mouth care procedure and dressing care to maintain cleanliness and prevent odor.
2. Emphasize adequate nutrition—proper consistency, proper seasoning, and right temperature. Show the family how to prepare food in blender or food processor, as necessary. Teach tube-feeding procedure, if applicable.
3. If suctioning is required, instruct as to method, use, and care of equipment and obtain supplies for family.
4. Provide detailed instructions and demonstration to the patient and caregiver on incisional care.
5. Assess for signs of obstruction, hemorrhage, infection, and depression and teach caregivers what to do about them if they occur.
6. If the patient is undergoing radiation therapy, encourage them to perform appropriate skin care, avoid exposure to potential chemical irritants, limit direct sun exposure, and avoid application of lotions, ointments, or fragrances to the head and neck region, which might alter the depth at which the maximum radiation dose is delivered.
7. Encourage the radiated patient to use sialogogues such as hard candy to stimulate saliva flow. Pilocarpine may be prescribed to prevent xerostomia for patients who have completed radiation therapy.

Patient Education and Health Maintenance

1. Encourage cessation of high-risk behaviors to all—smoking, alcohol consumption, use of smokeless tobacco, pipe smoking.
2. Emphasize the need for routine follow-up examinations with specialists, dentist (for the use of fluoride trays during radiation), and speech pathologist, if indicated.

Evaluation: Expected Outcome

- Reports adequate comfort levels, is pain-free, and handles secretions adequately.
- Achieves adequate nutritional status, able to eat prescribed diet.
- Verbalizes acceptance of body image, demonstrates behaviors that reflect positive self-esteem (eg, shaves, dresses, applies makeup).

Neck Dissection for Head and Neck Malignancy

Systematic removal of lymph nodes with their surrounding fibrofatty tissue from the various compartments of the neck. The goal of neck dissection is to eradicate metastases involving the cervical lymph nodes. Metastases originate from primary lesions involving the oral cavity, pharynx, and larynx. The cervical lymph nodes are grouped into six major levels (I to VI) with additional division into two sublevels (A and B) of levels I, II, and V.

Surgical Procedures

1. Resection of lesion is the primary intervention.
2. Radical neck dissection—removal of lymph nodes in levels I through V and internal jugular vein (IJ), sternocleidomastoid muscle (SCM), and the spinal accessory nerve (CN XI).
3. Modified radical neck dissection—removal of lymph nodes in levels I through V, and preservation of one or more of IJ, SCM, CN XI.
4. Selective neck dissection—en bloc removal of one or more lymph node (LN) groups that are at greatest risk for harboring metastasis.
5. Commonly followed by postoperative radiation therapy. In some instances where resection is impossible, radiation therapy is the sole treatment for head and neck malignancy.
6. Surgical reconstruction may be performed with a rotational flap, skin graft, or free flap to promote healing and improve aesthetics.

Preoperative Management

1. Interventions to improve nutritional status preoperatively include nutritional supplements, hyperalimentation, alcohol withdrawal, and counseling.
2. The patient's general health status is evaluated and underlying conditions, such as cirrhosis, diabetes mellitus, pulmonary, and cardiovascular disease, are identified and treated, if possible.
3. The patient is evaluated for level of understanding of disease process, treatment regimen, and follow-up care.
4. Emotional preparation for major surgery, long rehabilitation, and change in body image is provided.

Postoperative Management

1. A major goal of postoperative management is protection of the airway. After the patient has fully recovered from anesthesia, the endotracheal tube is removed (unless respiratory compromise occurs).
2. The patient is closely monitored for hemorrhage. Wound drainage is facilitated with a negative pressure drain. The drain is removed when output is less than 25 mL in a 24-hour period.
3. Prophylactic antibiotics are given to prevent infection because of extensive incision, lymph node resection, and close proximity to oral secretions.
4. Oral nutritional supplements, enteral feedings, or hyperalimentation is provided until oral intake is adequate and nutritional status is improved.

5. Provide adequate pain control with analgesics, in addition to narcotics as needed. When the patient is taking narcotics, provide stool softeners and/or laxatives to prevent narcotic-induced constipation.
6. Shoulder range of motion assessment is performed to determine if cranial nerve XI (spinal accessory) has been weakened during surgery. Physical therapy will provide strengthening exercises.

Complications

1. Surgery—air leaks, bleeding, chylous fistula, facial or cerebral edema, blindness, carotid artery rupture, and damage to nerves such as the phrenic, vagus, brachial plexus, spinal accessory, and cutaneous nerves and the mandibular branch of the facial, hypoglossal, or lingual nerves.
2. Radiation.
    a. Early—radiation mucositis, xerostomia erythema, desquamation, dysphagia, secondary infection, oral pain.
    b. Long-term—atrophy, fibrosis, salivary dryness, hoarseness, difficulty swallowing, bone pain, osteonecrosis, pathologic fractures, limitation of movement, poor wound healing.

Nursing Diagnoses

- Ineffective Breathing Pattern related to laryngeal edema, secretions, presence of a tracheostomy.
- Risk for Infection related to surgery, proximity of secretions to suture line, radiation.
- Imbalanced Nutrition: Less Than Body Requirements related to anorexia, inability to swallow, pain on swallowing.
- Disturbed Body Image related to surgical scarring, radiation changes.

Nursing Interventions

Maintaining Effective Breathing Pattern

1. Place the patient in Fowler position.
2. Observe for signs of respiratory embarrassment, such as dyspnea, cyanosis, edema, hoarseness, or dysphagia.
3. Provide supplemental oxygen by face mask, if necessary; if tracheostomy is present, provide humidified air or oxygen by tracheostomy collar or adequate ambient humidification.
4. Auscultate for decreased breath sounds, crackles, or wheezes; auscultate over the trachea in the immediate postoperative period to assess for stridor indicative of edema.
5. Encourage deep breathing and coughing.
6. Assist the patient in assuming a sitting position to bring up secretions.
7. Suction secretions orally or aseptically through a tracheostomy if patient is unable to cough them up.

Preventing Infection

1. Assess vital signs for indication of infection—increased heart rate, elevation of temperature.
2. Inspect wound for hemorrhage, drainage, or tracheal constriction; reinforce dressings, as needed.

3. Inspect incision for signs of infection—increased pain and tenderness, redness, warmth, swelling, drainage.
4. If a drain is used, expect approximately 80 to 120 mL of serosanguineous secretions to be drawn off during the first postoperative day; this diminishes with each day. Ensure that the drain is stripped at the insertion site at least three times per day to prevent clotting. Assess for color and amount of drainage.
    a. The initial output will be serosanguineous and eventually will turn serous. If the fluid appears milky, the surgeon should be notified right away as this may be indicative of a chyle leak.
    b. A high output of several hundred milliliters or more per day may also indicate chyle leak. If the output is less than 600 mL of chyle per day, the leak is initially managed conservatively with closed-wound drainage, pressure dressings, and zero-fat nutritional support. Parenteral alimentation through a central line may also be utilized to further reduce chylous output.
5. Aseptically clean skin area around drain exit, using saline or prescribed solution.
6. Make sure that the incision site remains clean and dry; remove secretions immediately.

Improving Nutritional Status

1. Postoperatively provide IV fluids and hyperalimentation, tube feedings through NG tube or gastrostomy tube, or oral feedings as soon as swallowing is established.
2. Provide mouth care before and after meals.
3. Assess for excessive or decreased salivation, which may impair swallowing.
4. Make sure that emergency suctioning and airway equipment is available at the bedside during meals in the event of choking or aspiration. Utilize speech–language therapist to evaluate dysphagia.
5. Position the patient in an upright position, supporting shoulders and neck with pillows, if necessary.
6. Ask whether the patient would prefer privacy during meals.
7. Provide an environment that is clean and free from interruptions and odor.
8. Assist with oral intake, providing easily chewed foods. Mash or blenderize meals, if necessary.

Strengthening Body Image

1. Respect the patient's desire for privacy during treatments, dressing changes, and feedings.
2. Prepare visitors for the patient's change in appearance.
3. If the patient has difficulty speaking, assist with alternate communication methods and allow adequate time for communication.
4. Observe for lower facial paralysis; this may indicate facial nerve injury.
5. Watch for shoulder dysfunction, which may follow resection of spinal accessory nerves.
    a. Use muscle exercises provided by the physical therapist and muscle reeducation postoperatively.
    b. Work with the patient to obtain good functional range of motion.
6. Encourage the patient to verbalize concerns and feelings.
    a. Consult the health care provider to determine the nature and extent of explanation and prognosis that has been given to the patient.

b. Encourage the patient to seek confirmation of personal philosophy and religious beliefs because this may provide answers.
c. Accentuate the positive.
d. Encourage the patient to participate in the plan of care.
e. Recognize that a great effort has to be made in behavior modification to change a lifestyle that included alcohol consumption and cigarette smoking. Provide educational material and support.

Community and Home Care Considerations

1. Determine if the patient requires home care for drain care and/or home physical therapy.
2. If the patient has a permanent tracheostomy, instruct the patient and caregivers about the following:
   a. Need for increased humidification in the home environment.
   b. Avoiding activities that may cause aspiration (eg. swimming).
3. Referral for speech-language pathologist to meet ongoing communication needs.

Patient Education and Health Maintenance

Exercises

1. Instruct the patient and family regarding exercises to prevent limited range of shoulder motion and discomfort (see Figure 17-7).
2. Perform exercises morning and evening. Initially, exercises are done only once; the number is increased by one each day until each exercise is done 10 times.
3. After each exercise, the patient is instructed to relax.

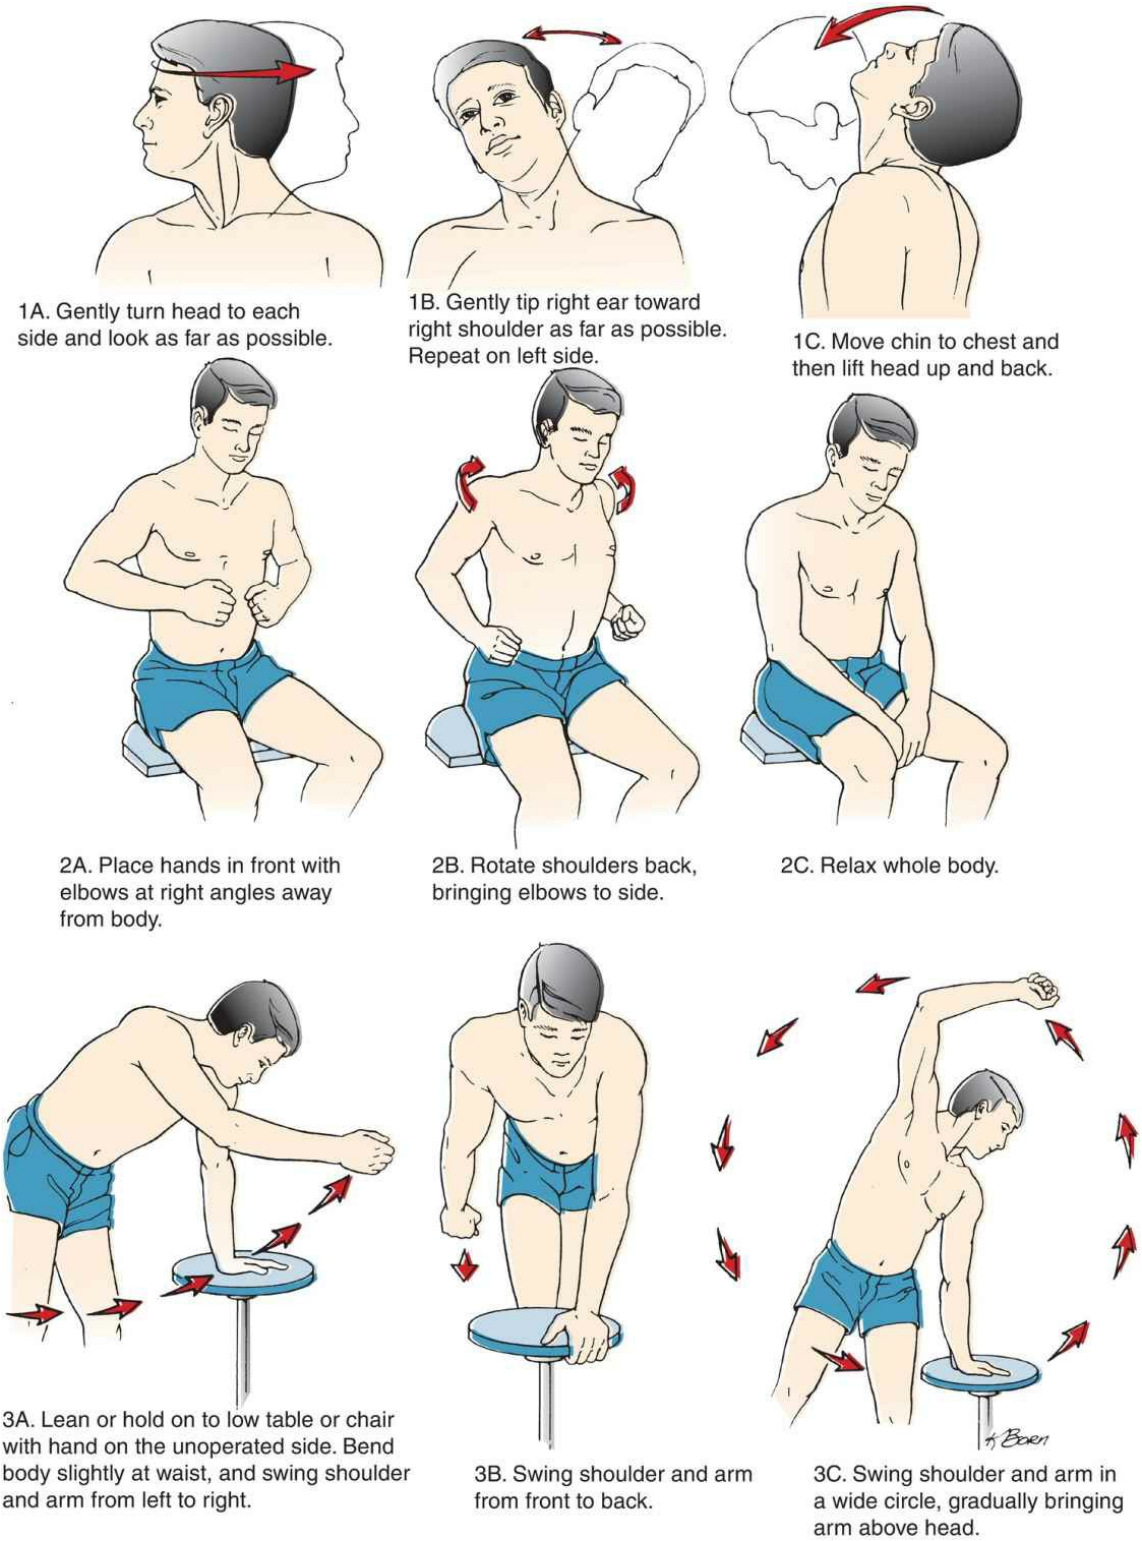

Figure 17-7. Rehabilitation exercises after head and neck surgery to regain maximum shoulder function and neck motion.

Follow-Up Visits

1. Emphasize the need for frequent follow-up visits and completion of radiation therapy, if prescribed.
2. Recommend a dental follow-up to ensure good oral hygiene and dental rehabilitation, if indicated.

Evaluation: Expected Outcomes

- Maintains adequate breathing pattern; absence of dyspnea, shortness of breath; is able to handle secretions.
- Is free from signs and symptoms of infection; vital signs stable; incision is clean, dry, without redness or drainage.
- Is adequately hydrated; maintains stable nutrition and weight; can tolerate diet without choking or aspiration.
- Discusses concerns about condition; verbalizes positive aspects of self.

Cancer of the Larynx

Cancer of the larynx is a malignant growth of the vocal cords. It accounts for 0.8% of all cancers. The supraglottic larynx refers to the area above the vocal cords including the epiglottis. The subglottic larynx refers to the area below the vocal cords to about the first tracheal ring. When treated early, the likelihood of cure is great. The National Cancer Institute at the National Institutes of Health estimated that in 2017, there were approximately 13,360 new cases diagnosed in the United States and 3,660 persons were estimated to die from the disease. The 5-year survival rate is estimated to be 61%.

EVIDENCE BASE National Cancer Institute. (2017). Cancer Stat Facts: Larynx Cancer. *Surveillance, epidemiology and end results program*. Bethesda, MD: Author. Available: https://seer.cancer.gov/statfacts/html/laryn.html.

Pathophysiology and Etiology

1. Occurs predominantly in men older than age 60.
2. Most patients have a history of smoking and heavy alcohol intake. Other risk factors include laryngopharyngeal reflux; industrial exposure to diesel exhaust, asbestos, organic solvents, sulfuric acid, mustard gas, certain mineral oils, metal dust, asphalt, wood dust, stone dust, mineral wool, and cement dust; genetic susceptibility; and diet.
3. In North America, about two thirds of carcinomas of the larynx arise in the glottis, almost one third arise in the supraglottic region, and about 3% arise in the subglottic region of the larynx.
4. When limited to the vocal cords, spread is slow because of lessened blood supply.
5. When cancer involves the supraglottis, cancer spreads more rapidly to the lymph nodes of the neck than does glottis cancer.

Clinical Manifestations

Depend on tumor location; sequence in appearance related to pattern and extent of tumor growth.

Supraglottic Cancer

1. Tickling sensation in throat.
2. Dryness and fullness (lump) in throat.
3. Painful swallowing (odynophagia) associated with invasion of extralaryngeal musculature.
4. Coughing on swallowing.
5. Pain radiating to ear (late symptom).

Glottic Cancer (Cancer of the Vocal Cord)

1. Most common cancer of the larynx.

2. Hoarseness or aphonia (loss of voice).
3. Aspiration.
4. Dyspnea.
5. Pain (in later stages).

Subglottic Cancer (Uncommon)

1. Coughing.
2. Short periods of difficulty in breathing.
3. Hemoptysis; fetid odor, which results from ulceration and disintegration of tumor.

Diagnostic Evaluation

1. Indirect mirror examination of larynx may indicate lesion.
2. Direct laryngoscopy and biopsy to identify lesion.
3. CT scan and other special radiologic tests to detect tumor.
4. The T, N, M classification system is used for staging (see page 112). In larynx cancer, prognosis can be predicted by the tumor size and nodal involvement. If lymph nodes are involved, the prognosis is usually poorer than when no lymph nodes are involved.

Management

General Considerations

Depends on sites and stages of cancer. Early malignancy may be removed endoscopically.

1. Early glottic squamous cell carcinoma (SCC, defined as stage I or II disease) may be treated with either radiation therapy or surgery, with or without neck dissection. Surgical treatment goal of early glottic SCC is to preserve the larynx and is referred to as conservation laryngeal surgery or partial laryngectomy.
2. Advanced glottic SCC (stage III or IV disease) is associated with poor prognosis. T3 glottic carcinomas have a low risk of nodal metastasis. T3 tumors may be treated with concurrent chemotherapy and radiation therapy, surgery, induction chemotherapy, or multimodal clinical trials. T4 glottic carcinoma is treated with total laryngectomy and usually postoperative radiation therapy, with or without chemotherapy.
3. According to the National Comprehensive Cancer Network, the patient should be examined every 1 to 3 months for the first year after treatment, every 2 to 6 months in the 2nd year, every 4 to 8 months in the 3rd, 4th, and 5th years, and every 12 months thereafter.

EVIDENCE BASE National Comprehensive Cancer Network. (2017). *NCCN guidelines: Head and neck cancers*. Fort Washington, PA: Author. Available: *www.nccn.org/professionals/physician_gls/pdf/head-and-neck.pdf*.

Surgery

1. Laser excision for early-stage disease.
2. Partial laryngectomy—removal of small lesion on true cord, along with a substantial margin of healthy tissue.
3. Supraglottic laryngectomy—removal of all laryngeal structures superior to the floor of the ventricle, maintaining both true vocal cords, both arytenoids, the base of the tongue, and the hyoid bone. Is performed for T1, T2, or selected T3 supraglottic tumors. An acceptable alternative to supraglottic laryngectomy is transoral laser microsurgery for T1–T2 and selected T3 tumors.
4. Hemilaryngectomy—removal of one true vocal cord, false cord, one half of thyroid cartilage, arytenoid cartilage.
5. Total laryngectomy—removal of entire larynx (epiglottis, false or true cords, cricoid cartilage, hyoid bone; two or three tracheal rings are usually removed when there is extrinsic cancer of the larynx [extension beyond the vocal cords]). A radical neck dissection may also be performed because of metastasis to cervical lymph nodes.
6. Total laryngectomy with tracheoesophageal puncture (TEP). During surgery, a puncture is made in the posterior wall of the trachea, which is also the anterior wall of the esophagus. A voice prosthesis or a red rubber catheter is inserted into the puncture. The red rubber catheter serves two purposes: to mature the track until a voice prosthesis is inserted and to provide enteral feedings until the patient is allowed to swallow. If a voice prosthesis is inserted at the time of surgery, the patient is fed through either a nasogastric or gastrostomy tube.

Complications

1. Pharyngocutaneous fistula may develop after any surgical procedure that involves entering the pharynx or esophagus.
   a. Monitor for saliva collecting beneath the skin flaps or leaking through suture line into neck drains.
   b. Management—NG tube or gastrostomy feeding, meticulous local wound care with frequent dressing changes, promotion of drainage.
2. Hemorrhage (carotid artery rupture) or hematoma formation.
   a. A major postoperative complication (eg, skin necrosis or salivary fistula) usually precedes carotid artery rupture.
   b. Management—immediate wound exploration in operating room.
3. Drain failure.
4. Infection.
5. Wound dehiscence—patients who have been radiated prior to surgery and/or who are malnourished are more at risk for wound dehiscence.
6. Complications of radiation—edema of the larynx, soft tissue and cartilage necrosis, skin reaction, chondritis.
7. Long-term complications:

a. Stomal stenosis.
b. Pharyngoesophageal stenosis and stricture.
c. Hypothyroidism.

Nursing Assessment

1. Ask about alcohol intake, smoking and drug history, and chronic illnesses.
2. Take a nutrition history and 24-hour food intake recall. Review results of laboratory test. Weigh the patient.
3. Observe ability to swallow.
4. Review recommendations of speech–language pathologist for communication.
5. Assess for independence, self-assuredness, and willingness to try new things; these are strengths on which to build.
6. Assess reality of the patient's expectations.
7. Assess patient's ability to care for self, particularly concerning stomal care.
8. Assess the patient's social support system. Who will be home with the patient after discharge?

Nursing Diagnoses

- Readiness for Enhanced Knowledge about laryngectomy.
- Ineffective Breathing Pattern related to artificial airway, accumulation of secretions, inability to cough secondary to surgical procedure.
- Imbalanced Nutrition: Less Than Body Requirements related to impaired swallowing secondary to surgical alteration of pharynx and larynx; laryngeal edema and pain; radiation-induced mucositis.
- Impaired Verbal Communication related to surgery or absence of larynx; presence of artificial airway.
- Deficient Knowledge related to stoma care and living with effects of laryngectomy.

Nursing Interventions

Preparing for Total Laryngectomy

1. Collaborate with the surgeon in preparing the patient; interpret and reiterate what surgeon and speech–language pathologist have explained.
   a. Inform the patient that breathing will occur through an opening (tracheostoma) in the neck.
   b. Advise the patient that speech will be altered by surgery.
2. Expect reactions of anxiety and depression because the psychosocial effects of voice loss are substantial.
3. Practice a means of communication (pad and pencil, sign language, pictures, word cards, artificial larynx) that can be used until speech therapy begins.
4. Arrange for the patient to be visited by laryngectomee (one who has had larynx removed) for support.
5. Provide portable battery-operated suction machine, suction catheter kits, and other supplies from a home care company and educate patient on suctioning procedure prior to the patient's discharge. Initiate

referral for home care nursing and other community services.

6. Provide information about other community support services such as the International Association of Laryngectomees or Supporting Patients with Oral Head and Neck Cancer.
7. Reinforce information about alternative modes of communication.
   a. Artificial larynx, using either neck or intraoral placement: Electrolarynx provides communication assistance in early postoperative period or later to those unable to learn alternative method.
   b. TEP with voice prosthesis: A one-way valved voice prosthesis is inserted through TEP to allow the patient to shunt pulmonary air into esophagus for voice production (see Figure 17-8).
   c. Esophageal speech is accomplished by training the patient to force air down the esophagus and release it in a controlled manner.

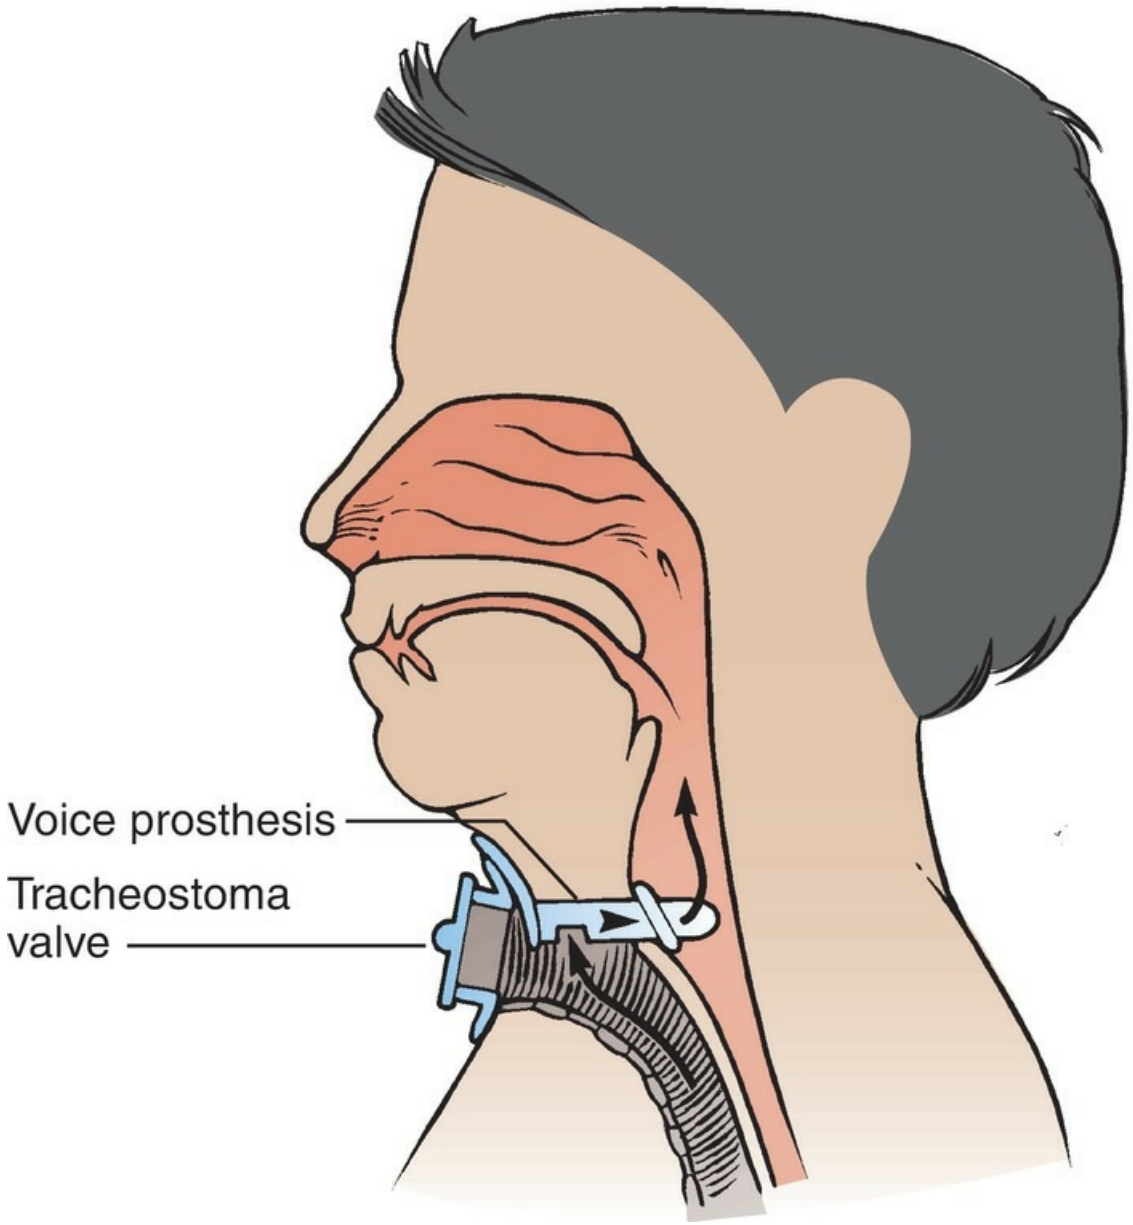

Figure 17-8. Schematic representation of tracheoesophageal puncture speech. When the patient

plugs the stomal opening, air is forced from the lungs through a one-way valve voice prosthesis. Air travels into the esophagus and out the mouth, creating speech.

Improving Breathing Pattern

1. Monitor for signs of difficulty breathing—suprasternal and intercostal retractions, tachypnea, dyspnea, tachycardia, and changes in sensorium.
2. Auscultate trachea/chest for evidence of stridor or wheezing and for absence of breath sounds.
3. Make sure the patient uses a specific signal to indicate need for suctioning; enter on nursing care plan.
4. Suction secretions according to the prescriber's orders to prevent accumulation of mucus which may lead to mucus pluging.
    a. Also suction nasal secretions because the patient is unable to blow nose.
    b. Remove crusts from stoma at least three times daily to prevent webbing of mucus across the stoma.
5. Use chest physical therapy, as necessary, to remove secretions.
6. Assist the patient in secretion removal.
    a. Teach the patient to bend forward until stoma is below lung level and to exhale rapidly. This aids in secretion removal from lungs.
    b. Teach the patient to wipe resultant secretions away from tracheostoma with a handkerchief.
7. Encourage breathing exercises because most patients have been heavy smokers.
8. Supply constant humidification to moisten tracheostoma and avoid viscous secretions; tracheal air will require additional warmth and moisture.
9. Keep calm and maintain sense of security.
    a. Reassure the patient that someone is always near to assist.
    b. Have call bell within reach.
10. Remind patient that they are now a neck breather and can no longer breathe out of their nose or mouth.
11. In the event of airway obstruction, clear the stoma and ventilate through stoma.

Facilitating Adequate Nutrition

1. Monitor IV fluids during first few postoperative days.
2. Administer fluids and nutrients by NG or gastrostomy tube.
    a. Tube feedings may be started after bowel sounds are heard and continued until sufficient healing of pharynx has occurred (approximately 7 to 14 days) and patient is ready to resume oral feedings.
    b. Avoid manipulating NG tube as it is resting on or near suture line.
    c. Clean nostrils and lubricate with water-soluble lubricant.
    d. Clean crust on outside of tube.
    e. Pay attention to oral hygiene, with regular toothbrushing and prescribed antiseptic mouthwashes.
3. Assure the patient that swallowing is safe and may feel differently than before surgery. Some structures and muscles removed during surgery may cause the patient to "work harder" to swallow.

a. Patients may need more liquids to wash down foods.
b. It may be easier to eat smaller, more frequent meals.
c. A modified barium swallow may be ordered several days after surgery to be sure adequate healing has occurred and that there are no leaks or fistulas opening into the airway.
d. After a total laryngectomy, there is a separation of the airway (trachea) from the esophagus; and theoretically, there is no risk for aspiration. However, if a TEP is present and occupied by either a voice prosthesis or red rubber catheter, leakage around the TEP site could occur.

4. The speech–language pathologist will educate the patient and family about the presence, care, and maintenance of the TEP and any potential problems.

Providing Alternative Communication

1. Advise the patient to communicate by writing or with artificial larynx until voice work can begin with speech–language pathologist.
2. Discourage forced whispering, which increases pharyngeal tension.
3. Encourage the patient to join local laryngectomy support group (eg, Lost Chord Club, New Voice Club, International Association of Laryngectomees), which gives opportunity to practice new speech and serves as a bridge between therapy and return to social life.
4. Inform the patient of the various communication methods:
   a. An electrolarynx, which is placed against the neck, cheek, or in the mouth for a monotone, mechanical sound, can be used immediately after surgery. The speech–language pathologist will provide instruction on the use of the device.
   b. Esophageal speech is the act of air charging, which is achieved by thrusting the tongue back and forcing a bolus through the cricopharyngeus. The air bolus then is regurgitated through the pharyngoesophageal segment, which vibrates to produce sound.
   c. Tracheoesophageal speech, which is the most common voice restoration option, involves placing a one-way valve voice prosthesis into the TEP. The patient takes a breath and occludes the stoma with either a finger or stoma button. This air is forced through the voice prosthesis into the pharynx, which vibrates and produces sound.

Providing Information about Laryngectomy

1. Inform the patient that it is very important to keep the stoma clear of mucus. This is accomplished through regular tracheal suctioning and by cleaning mucus from the stoma several times per day.
2. A laryngectomy or tracheostomy tube may be worn if there is neck edema and narrowing of the stoma. The tube is not always permanent. The type of tube used is determined by the provider or speech–language pathologist.
3. Demonstrate procedure for cleaning and changing tube.
   a. See page 173 for tracheostomy tube care. A laryngectomy tube is cleaned the same way as an inner cannula.
   b. Place gauze dressing under tube to absorb secretions, as prescribed. Change when it becomes soiled

to prevent skin irritation and odor.

c. Encourage the patient to change the laryngectomy or tracheostomy fastener when soiled.

4. Tracheostoma care—teach the patient to:
   a. Wash hands before touching stoma to prevent infection.
   b. Wet washcloth with warm water; wring dry and gently wipe stoma. Do not use soap, tissues, or cotton balls because these may enter airway.
   c. Apply petroleum around exterior of stoma to prevent skin irritation.
   d. Report excessive redness, swelling, purulent secretions, or bleeding.
5. Stoma cover.
   a. Stoma cover is necessary to filter air and increase humidity of air; also necessary for hygienic purposes.
   b. Stoma cover can be crocheted, made of cotton cloth, or commercially available as foam filters.
   c. For men: ascot or turtleneck sweaters may be worn. When a regular shirt is worn, the second button from the top can be sewed over the buttonhole as though it were fastened. This leaves a wide opening through which a handkerchief can be inserted when coughing.
   d. For women: a variety of fashionable scarves, jewelry, high-neck dresses, and turtleneck sweaters can be worn.
6. Bowel care: discuss high-fiber diet and use of stool softener because patient with tracheostoma is usually not able to hold breath to "bear down" for bowel movement.
7. If the patient snored before surgery, he or she will no longer snore after laryngectomy because air no longer passes through the nose and mouth. For the same reason, the patient may have difficulty sniffing and blowing his or her nose. The speech–language pathologist can provide techniques for briefly sniffing through the nose.
8. Swallowing after laryngectomy will resume no sooner than 5 days after surgery. A barium swallow may be ordered to detect a leak in the internal incision line. Swallowing may be a little slower and/or more difficult. The speech–language pathologist will provide swallowing therapy.

Community and Home Care Considerations

1. Provide humidification in the home; use heat-moisture exchanger, a humidifier, or cool mist vaporizer, especially in bedroom and when dry heat is used.
2. Tell the patient to avoid cold air; cover tracheostoma with thin layer of foam or other cover to warm and humidify air.
3. Encourage the patient to drink fluids liberally (2 to 3 quarts [2 to 3 L]) to help liquefy secretions.
4. Have the patient always keep stoma covered for hygienic management of secretions and to keep dust and foreign matter from entering trachea.
5. Place a protective shield over stoma before bathing, showering, or shampooing hair and while getting a haircut or shaving. Use an electric razor instead of blade because shaving cream can irritate.
6. Swimming is to be avoided as there is no way to prevent water from entering the stoma.

7. Ensure working smoke detectors are available in the home as the sense of smell is decreased.

Patient Education and Health Maintenance

1. Tell the patient to expect some loss of smell and taste sensation.
2. Advise the patient to check with health care provider before taking medication because many drugs (such as antihistamines and cold products) tend to dry the mucous membranes of the stoma.
3. Warn the patient to seek immediate attention for pain, difficulty breathing or swallowing, appearance of pus or blood-streaked sputum.

Evaluation: Expected Outcomes

- Verbalizes understanding of tracheostoma and communication options.
- Breathes quietly; no evidence of noisy secretions.
- Swallows soft foods; maintains weight.
- Makes needs known; speech therapy has started.
- Manages tracheostomal care; has made provisions for home humidification and tracheostomal supplies.

Diverticular Disease

Peritonitis

Irritable Bowel Syndrome

Ulcerative Colitis

Crohn Disease

Colorectal Cancer

Anorectal Conditions

Hemorrhoids

Other Conditions of the Anorectum

OVERVIEW AND ASSESSMENT

The gastrointestinal (GI) system is composed of the alimentary canal and its accessory organs. The alimentary canal begins at the mouth and extends through the pharynx, esophagus, stomach, small intestine, colon, and rectum and ends at the anus. The accessory organs include the tongue, salivary glands, liver, gallbladder, and pancreas.

The functions of the GI system include ingestion and propulsion of food; mechanical and chemical digestion of food; synthesis of nutrients, such as vitamin K; absorption of nutrients into the bloodstream; and the storage and elimination of nondigestible waste products from the body through feces.

STANDARDS OF CARE GUIDELINES 18-1

Gastrointestinal Dysfunction

When caring for a patient after abdominal surgery or with any type of GI disorder:

- Make sure that adequate bowel sounds are present before allowing anything by mouth. Periodically reassess for bowel sounds, bloating, nausea, vomiting, and abdominal distension or tenderness.
- Monitor food/fluid intake and output as indicated.
- Periodically monitor weight, and watch for trend in weight loss or weight gain.
- Assess stools for frequency, consistency, color, and amount.
- Report increase in pain, fever, nausea, vomiting, bloating, change in stools, or signs of wound infection to health care provider promptly.
- Monitor complete blood count, electrolytes, albumin, and protein as directed.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Subjective Data

A comprehensive health history should be obtained to elicit subjective data related to major manifestations of GI problems. Common manifestations include nutritional problems, abdominal pain, indigestion, nausea, vomiting, diarrhea, constipation, bloody bowel movements, change in bowel habits, weight loss, and dysphagia. See Standards of Care Guidelines 18-1, page 488.

Nutritional Problems

1. Characteristics: What is your typical 24-hour food intake? What is your usual weight? Has there been a recent weight gain or loss? If a recent weight change, how many pounds and over what time period? How is your appetite?
2. Associated factors: Explore other factors that may influence weight changes—food preferences; family/individual routines associated with eating; cultural and religious values; psychological factors, such as depression, anxiety, stress; physical factors, such as activity level, health status, dental problems, allergies; access/transportation to grocery stores; eating habits, self-imposed dietary restrictions; body image; nutritional knowledge; and finances.
3. History: Any history of eating disorders? Any family history of ulcer, GI cancer, inflammatory bowel disease, obesity?

Abdominal Pain

1. Characteristics: Can you describe the pain (sharp, dull, superficial, or deep)? Is the pain intermittent or continuous? Was the onset sudden or gradual? Can you point to where the pain is located? What makes the pain better, worse?
2. Associated factors: Are there other symptoms associated with the pain—fever, chills, night sweats, nausea, vomiting, diarrhea, constipation, anorexia, weight loss, dyspepsia, black tarry stools or blood in the stool?
3. History: Any family history of GI cancer, ulcer disease, inflammatory bowel disease? Any previous history of tumors, malignancy, ulcers?

Indigestion (Dyspepsia)

1. Characteristics: Have you experienced any of the following symptoms—a feeling of fullness, heartburn, excessive belching, flatus, nausea, a bad taste, mild or severe pain? How is your appetite? If pain or tenderness, where is it located? Does the pain radiate to any other areas? What precipitating factors are associated with the pain? What makes the symptoms better, worse? Are the symptoms associated with food intake? If associated with food, the amount and type?
2. Associated factors: Is there nausea, vomiting, dysphagia, blood in bowel movements, or diarrhea? Is there a history of alcohol, nonsteroidal anti-inflammatory drug (NSAID), bisphosphonate, or aspirin use?
3. History: Any family history of cancer or inflammatory bowel disease? Any history of bowel obstruction? Any previous abdominal surgeries?

Nausea and Vomiting

1. Characteristics: Is the nausea or vomiting associated with certain stimuli, such as specific foods, odors, activity, or a certain time of day? Does it occur before or after food intake? How many times per day does vomiting occur? What specific fluids/foods can be tolerated when vomiting occurs? What is the amount, color, odor, and consistency of the vomitus (see Table 18-1)?
2. Associated factors: Is there fever, headache, dizziness, weakness, or diarrhea? Missed menstrual period? Any weight loss? Any new medications? Any psychological stress, depression, or emotional problems?
3. History: Any history of gallbladder disease? Ulcer disease? GI cancer? Unprotected intercourse?

Table 18-1 Nature of Vomitus

COLOR/TASTE/ CONSISTENCY	POSSIBLE SOURCE
Yellowish or greenish	• May contain bile • Medication—senna
Bright red (arterial)	• Hemorrhage, peptic ulcer
Dark red (venous)	• Hemorrhage, esophageal or gastric varices
"Coffee grounds"	• Digested blood from slowly bleeding gastric or duodenal ulcer
Undigested food	• Gastric tumor • Ulcer, obstruction • Gastric paresis
"Bitter" taste	• Bile
"Sour" or "acid"	• Gastric contents
Fecal components	• Intestinal obstruction

Diarrhea

1. Characteristics: How long has the diarrhea been present? Determine the frequency, consistency, color, quantity, and odor of stools. Are there blood, mucus, pus, or food particles in the stools? Does this represent a change in bowel habits? Any nocturnal diarrhea? What makes the diarrhea worse, better? Any associated weight loss? (see Box 18-1 on page 489).
2. Associated factors: Any fever, nausea, vomiting, abdominal pain, abdominal distention, flatus, cramping, urgency with straining? Is the patient taking antibiotics? Has there been any recent travel to foreign countries? (Mexico, South America, Africa, and Asia are countries with the highest risk of traveler's diarrhea.) Is the patient experiencing emotional stress or anxiety? Are there any recently prescribed medications?
3. History: Is there a history of celiac disease, colon cancer, ulcerative colitis, Crohn disease, malabsorption syndrome? Has the patient undergone surgery recently (eg, bariatric surgery)?

DRUG ALERT Obtain history of over-the-counter (OTC), herbal, or "natural" products the

patient may be taking. Ginger is commonly used as an antiemetic and, although generally safe, it can cause heartburn. Licorice root is used for upset stomach and to soothe ulcers but can cause sodium and fluid retention and loss of potassium. Goldenseal is used as an antidiarrheal but can cause a number of adverse reactions, including skin and mucous membrane irritation, interference with anticoagulation, and cardiac and nervous system excitability. Also, many herbs can impair absorption of other medicines. Remind patients that herbal products are not found naturally in the body or in significant amounts in the daily diet, so should be treated like drugs.

BOX 18-1 Causes of Diarrhea and Constipation

CAUSES OF DIARRHEA

- Infectious agents (*Escherichia coli*, *Salmonella*, *Shigella*, *Campylobacter*, *Giardia*, *Amoeba*, *Clostridium difficile*, *Yersinia*, *Cyclospora*, *Cryptosporidium*, *Rotavirus*).
- Drugs (antibiotics, magnesium).
- Fecal impaction.
- Bowel disease (irritable bowel syndrome [IBS], ulcerative colitis, Crohn disease).
- Malabsorption syndromes (lactose intolerance, celiac sprue, fat malabsorption).
- Short bowel syndrome.
- Malignant syndromes (Zollinger-Ellison syndrome, carcinoid syndrome).

CAUSES OF CONSTIPATION

- Inadequate fluid intake.
- Psychological factors.
- Electrolyte imbalances.
- Hormonal abnormalities, such as hypothyroidism.
- Mechanical bowel obstruction, such as ileus.
- Drugs (laxative abuse, anticholinergic agents, calcium channel blockers, opiates).
- Loss of innervation (Hirschsprung disease).
- Neuromuscular (paralysis, spinal cord injury or sacral lesion, multiple sclerosis).
- Anorectal disorders (hemorrhoids, fecal impaction, cancer, abscess, fissures).
- Sedentary lifestyle.

Constipation

1. Characteristics: What is the frequency, consistency, color of the stools? Is there a change in bowel habits? If a change, has this been gradual or sudden? What is the size of the stools? Have there been dietary changes? Is there blood or mucus in the stools? Any laxative use?
2. Associated factors: Are there periods of diarrhea? Is there abdominal pain or distention? Is the patient experiencing stress? Is there a change in activity level? Does the patient have a regular time for

defecation? Does the patient use antacids containing calcium or an anticholinergic? Have there been any fevers, chills, night sweats, or weight loss?

3. History: Any family history of colorectal cancer? Any history of depression or metabolic disorders, such as hypothyroidism or hypercalcemia?

Dysphagia

1. Characteristics: Is the onset acute or gradual? Is the problem with swallowing intermittent or continuous? Is this associated with solid foods, liquids, or both? Has there been any nasal regurgitation? Where does the food stick: neck (cricopharyngeal), midesophagus, or sternal xiphoid process?
2. Associated factors: Is there any regurgitation, heartburn, chest or back pain, weight loss? Any hoarseness, voice change, or sore throat? Have there been any fevers, chills, night sweats, or weight loss?
3. History: Is there a family history of esophageal cancer? Is there a history of stroke, palsy, or any other neurologic conditions? Is there a history of alcohol or tobacco intake?

Physical Examination

When performing a physical examination of the abdomen, include the following: inspection of the abdomen, auscultation of all four abdominal quadrants, percussion for tympany or dullness, light and deep palpation.

NURSING ALERT Auscultation should be performed before percussion and palpation, which may stimulate bowel sounds. Deep palpation in noted areas of tenderness or pain should be performed last.

Key Findings

1. Tenting of the skin when the skin is rolled between the thumb and index finger. Tenting may indicate dehydration.
2. Mouth lesions, missing teeth, and swollen or bleeding gums may contribute to weight loss and nutritional deficiencies.
3. Body weight may indicate obesity or such problems as anorexia nervosa or malignancy.
4. Palpable mass may indicate an enlarged organ, inflammation, malignancy, hernia.
5. Rebound tenderness, guarding, and rigidity may indicate appendicitis, cholecystitis, peritonitis, pancreatitis, duodenal ulcer.
6. Protuberant or bulging abdomen or flanks can indicate ascites. Two physical assessment skills that may help to confirm the presence of ascites are testing for shifting dullness and testing for a fluid wave.
7. Distention and absence of bowel sounds may indicate intestinal obstruction.

Characteristics of Stool

1. The appearance of blood in the stool may be characteristic of its source.
    a. Upper GI bleeding—tarry black (melena).
    b. Lower GI bleeding—bright red blood.
    c. Lower rectal or anal bleeding—blood streaking on the surface of stool or on toilet paper.
2. Other characteristics of stool may indicate a particular GI problem.
    a. Bulky, greasy, foamy, foul smelling, gray with silvery sheen—steatorrhea (fatty stool).
    b. Light gray “clay-colored” (because of the absence of bile pigments, acholic)—biliary obstruction.
    c. Mucus or pus visible—chronic ulcerative colitis, shigellosis.
    d. Small, dry, rocky-hard masses—constipation, obstruction.
    e. Marble-size stool pellets—IBS.

Laboratory Tests

Laboratory tests for GI disorders include a variety of stool studies and blood tests.

EVIDENCE BASE Rex, D., Boland, C., Dominitz, J., et al. (2017). Colorectal cancer screening: Recommendations for physicians and patients from the U.S. Multi- Society Task Force on Colorectal Cancer. *The American Journal of Gastroenterology*, 112, 1016–1030.

Fecal Immunochemical Test (FIT) for Occult Blood Detection

Description

An immunochemical test card has antibodies that detect human hemoglobin in stool. This test is used to screen for colon cancer when colonoscopy is not an option. FIT is preferred over the stool guaiac tests because of higher sensitivity and ease of use (eg, no dietary restrictions).

Nursing and Patient Care Considerations

1. Advise patient not to collect specimen during menstruation or if hemorrhoidal bleeding is present. Usually, at least two stool specimens need to be collected, on separate occasions.
2. Collect specimen or advise patient regarding proper collection of specimen.
   a. Check expiration date of collection kit.
   b. Sit on toilet and proceed with bowel movement so that stool will be on top of collection paper. Do not put toilet paper in specimen.
   c. Use the sample probe and brush across the stool sample so that the groove of probe is filled with stool (obtain sample from several different locations within the stool).
   d. Insert probe back into the sample container and tighten the lid of the container, or place stool on the card depending on the type of collection kit being used.
   e. Write the date on sample container label.
3. Follow manufacturer instructions for processing.

Stool Guaiac Tests for Occult Blood

Description

Commercially available guaiac-impregnated slides or wipes test feces for blood. May be used as another option for colon cancer screening.

Nursing and Patient Care Considerations

1. Advise patient about the test preparation procedure. Common practices are listed below. For 3 days before the test and during the stool collection period:
   a. Diet should have a high-fiber content.

b. Avoid red meat in the diet.
c. Avoid foods with a high peroxidase content, such as turnips, cauliflower, broccoli, horseradish, and melon.
d. Avoid iron preparations, iodides, bromides, aspirin, NSAIDs, or vitamin C supplements greater than 250 mg/day.
e. Avoid enemas or laxatives before stool specimen collection.

2. Collect sample or advise patient on collection procedure.
   a. A wooden applicator is used to apply a stool specimen to the slide or a special wipe is used and placed in the packet.
   b. Avoid urine or toilet tissue contamination.
3. When hydrogen peroxide (denatured alcohol–stabilizing mixture) is added to samples, any blood cells present liberate their hemoglobin, and a bluish ring appears on the electrophoretic paper. Read precisely at 30 seconds.
4. Three stool samples are taken because of the possibility of intermittent bleeding and false-negative results.
   a. A single positive test is an indication for further diagnostic evaluation for GI lesions.
   b. False-positive results occur in about 10% of tests.
   c. Test may become false negative in 10% of specimens tested 4 or more days after streaking on paper.

Stool DNA Test

Description

This test detects DNA associated with colon cancer. Cells are shed from the tumor into the intestinal lumen as stool passes through. The procedure is similar to guaiac tests. The specificity of this type of testing is inferior to the FIT and colonoscopy so is not used as commonly.

Other Common Stool Studies

Description

There are multiple types of stool analyses that are helpful in detecting conditions affecting the GI tract, liver, and pancreas. Basic stool examination is for amount, consistency, and color. Normal color varies from light to dark brown, but various foods and medications may affect stool color. Additional testing may include tests for ova and parasites; stool cultures that can identify viruses and bacteria; fecal leukocytes; fecal fat, which can help in the diagnosis of malabsorption syndromes; and stool for *Helicobacter pylori*, which is performed at least 4 weeks after treatment to confirm eradication.

Nursing and Patient Care Considerations

1. Use a tongue blade to place a small amount of fresh stool in a container. The container may be sterile or may have a preservative depending on which test has been ordered. Remind patient not to mix urine or toilet paper in the specimen.

2. Save a sample of fecal material if unusual in appearance, contains worms or blood, blood streaked, unusual in color, or has excess mucus; show to health care provider.
3. For accurate specimen results, the vials must be sent to the laboratory as soon as possible. Certain stool studies allow for refrigeration of the sample, but this is test dependent.
4. Send specimens to be examined for parasites to the laboratory immediately, so the parasites may be observed under a microscope while viable, fresh, and warm.
5. Consider that barium, bismuth, mineral oil, and antibiotics may alter the results.

Hydrogen Breath Test

Description

1. The hydrogen breath test is used to evaluate carbohydrate malabsorption and maldigestion, to detect the presence of excess bacteria in the small intestine, and to estimate small bowel transit time.
2. A substance, such as lactulose, lactose, or another carbohydrate, is ingested and, after a certain time period, exhaled gases are measured.
3. The test measures the amount of hydrogen, methane, and carbon dioxide produced in the colon, absorbed in the blood, and then exhaled in the breath. The levels of hydrogen and methane are indicators of bacterial metabolism in the small intestine.
4. This test is diagnostic for lactose intolerance, other carbohydrate malabsorption syndromes, and small intestine bacterial overgrowth (SIBO).

Nursing and Patient Care Considerations

1. Patient should have nothing by mouth (NPO) for 12 hours before the procedure.
2. Patient should not smoke after midnight before the test.
3. Antibiotics should not be used for 4 weeks, and laxatives/enemas should not be used for 1 week before the test. These products may alter the laboratory results.
4. Appropriate diet instructions should be given before discharge if the test is positive.

Helicobacter pylori Testing

Description

1. Diagnostic tests for *H. pylori* include a serum antibody test, urea breath test, and fecal antigen test. Alternatively, if an endoscopy is being performed, then biopsies of the gastric mucosa can be evaluated for *H. pylori* with rapid urea testing; histology review by a pathologist, or culture; or polymerase chain reaction testing.
2. A positive serum antibody test may not differentiate between current and past disease.
3. The urea breath test and fecal antigen test are useful in detecting active *H. pylori* prior to treatment with antibiotics. Both of these tests can be used to confirm eradication after antibiotic therapy has been completed.

Nursing and Patient Care Considerations

1. Symptomatic patients and patients with an active or past history of ulcer disease or with gastric MALT lymphoma should be tested for *H. pylori*. Endoscopy may be necessary for patients with symptoms of weight loss, anemia, or occult blood loss and for patients older than 50.
2. It is recommended that negative *H. pylori* test results in a patient with ulcer-related complications be confirmed by a second test.
3. Describe the procedure for urea breath testing to the patient.
    a. Antibiotics, proton pump inhibitors, and bismuth preparations must be held for 2 weeks prior to testing.
    b. Foods and fluids should be held for at least 1 hour prior to testing.
    c. A baseline breath sample will be taken by having the patient breathe into a container, then patient will ingest a carbon-labeled urea substance, and a final breath sample will be taken shortly after ingestion.
    d. The whole process takes about 40 minutes.
4. When confirming eradication of *H. pylori*, testing should not be done earlier than 4 weeks posttreatment.
5. False-positive results from *H. pylori* breath testing may be caused by achlorhydria or urease production associated with other GI disorders.

EVIDENCE BASE Chey, W. D., Leontiadis, G. I., Howden, C. W., et al. (2017). Treatment of H. pylori infection. *American Journal of Gastroenterology*, *112*, 212–238.

Radiology and Imaging Studies

Upper GI Series and Small Bowel Series

Description

1. Upper GI series and small bowel series are fluoroscopic x-ray examinations of the esophagus, stomach, and small intestine after the patient ingests barium sulfate.
2. As the barium passes through the GI tract, fluoroscopy outlines the GI mucosa and organs.
3. Spot films record significant findings.
4. Double-contrast studies administer barium first, followed by a radiolucent substance, such as air, to produce a thin layer of barium to coat the mucosa. This allows for better visualization of any type of lesion.

Nursing and Patient Care Considerations

1. Explain the procedure to patient.
2. Instruct patient to maintain low-residue diet for 2 to 3 days before test and a clear liquid dinner the night before the procedure.
3. Emphasize NPO after midnight before the test.
4. Encourage patient to avoid smoking before the test.
5. Explain that the health care provider may prescribe all opioids and anticholinergics to be withheld 24 hours before the test because they interfere with small intestine motility. Other medications may be taken with sips of water, if ordered.
6. Explain that the patient will be instructed at various times throughout the procedure to drink the barium (480 to 600 mL).
7. Explain that a cathartic will be prescribed after the procedure to facilitate expulsion of barium.
8. Instruct patient that stool will be light in color for the next 2 to 3 days from the barium.
9. Instruct patient to notify health care provider if he has not passed the barium in 2 to 3 days because retention of the barium may cause obstruction or fecal impaction.
10. Note that a water-soluble iodinated contrast agent (eg, Gastrografin) may be used for a patient with a suspected perforation or colonic obstruction. Barium is toxic to the body if it leaks into the peritoneum with perforation. It can also worsen an obstruction; thus, it is not used if an obstruction is suspected.

Barium Enema

Description

1. Fluoroscopic x-ray examination visualizing the entire large intestine is administered after the patient is given an enema of barium sulfate.
2. Can visualize structural changes, such as tumors, polyps, diverticula, fistulas, obstructions, and ulcerative colitis.

3. Air may be introduced after the barium to provide a double-contrast study.

Nursing and Patient Care Considerations

1. Explain to patient:
   a. What the x-ray procedure involves.
   b. That proper preparation provides a more accurate view of the tract and that preparations may vary.
   c. That it is important to retain the barium so all surfaces of the tract are coated with opaque solution.
2. Instruct patient on the objective of having the large intestine as clear of fecal material as possible:
   a. Patient may be given a low-fiber, low-fat diet 1 to 3 days before the examination.
   b. The day before the examination, intake may be limited to clear liquids (no drinks with red dye).
   c. The day before the examination, an oral laxative, suppository, and/or cleansing enema may be prescribed.
3. Patient will be NPO after midnight the day of the procedure.
4. An enema or cathartic may be ordered after the barium enema to cleanse bowel of barium and prevent impaction.
5. Inform patient that barium may cause light-colored stools for several days after the procedure.

NURSING ALERT If barium enema and upper GI series are both ordered, the upper GI series is done last so that barium traveling down the digestive tract does not interfere with the results of the barium enema.

Ultrasonography (Ultrasound)

Description

1. A noninvasive test that focuses high-frequency sound waves over an abdominal organ to obtain an image of the structure.
2. Ultrasound can detect small abdominal masses, fluid-filled cysts, gallstones, dilated bile ducts, ascites, and vascular abnormalities.
3. Doppler ultrasonography may be ordered for vascular assessment.

Nursing and Patient Care Considerations

1. An ultrasound should be done prior to barium studies or at least 24 hours after barium administration because it may interfere with the images.
2. Abdominal ultrasound usually requires patient to be NPO for at least 6 hours before the procedure.
3. Change position of patient, as indicated, for better visualization of certain organs.

Computed Tomography

Description

1. Computed tomography (CT) is an x-ray technique that provides excellent anatomic definition and is used to detect tumors, cysts, and abscesses.
2. The CT scan can also reveal masses, dilated bile ducts, pancreatic inflammation, and some gallstones.
3. It identifies changes in intestinal wall thickness and mesenteric abnormalities.
4. Ultrasound and CT can be used to perform guided needle aspiration of fluid or cells from lesions anywhere in the abdomen. The fluid or cells are then sent for laboratory tests (eg, cytology or culture).

Nursing and Patient Care Considerations

1. Instruct patient to fast for 4 hours before the procedure. Patient can take usual medications with a sip of water, but should hold diabetic medications.
2. A pregnancy test should be obtained on females of childbearing potential. If pregnant, do not proceed with scan and notify health care provider.
3. Ask if there are known allergies to iodine or contrast media. Intravenous (IV) administration of contrast medium may be performed to provide better visualization of body parts. If allergic, notify the technician and health care provider immediately.
4. Instruct patient to report symptoms of itching or shortness of breath if receiving contrast media, and observe patient closely.

Endoscopic Procedures

EVIDENCE BASE Society of Gastroenterology Nurses and Associates, Inc. (2014). *Standards of clinical nursing practice and role delineations*. Chicago, IL: Author. Available: *www.sgna.org/Portals/0/Education/PDF/Standards-Guidelines/SGNA_StandardsofClinicalNursingPractice_2014_Final.pdf.*

Endoscopy is the use of a flexible tube (the fiberoptic endoscope) to visualize the GI tract and to perform certain diagnostic and therapeutic procedures. Images are produced through a video screen or telescopic eyepiece. The tip of the endoscope moves in four directions, allowing for wide-angle visualization. The endoscope can be inserted through the rectum or mouth, depending on which portion of the GI tract is to be viewed. Capsule endoscopy utilizes an ingestible camera device rather than an endoscope.

Endoscopes contain multipurpose channels that allow for air insufflation, irrigation, fluid aspiration, and the passage of special instruments. These instruments include biopsy forceps, cytology brushes, needles, wire baskets, laser probes, and electrocautery snares.

Endoscopic functions other than visualization include biopsy or cytology of lesions, removal of foreign objects or polyps, control of internal bleeding, and opening of strictures.

Capsule Endoscopy

Description

1. Adjunctive diagnostic tool used to detect abnormalities of the small bowel (angiodysplasias, areas of active bleeding, polyps, ulcerations, tumors or causes of diarrhea, and nutritional malabsorption).
2. The procedure involves swallowing a capsule (camera device), which passes through the digestive system while taking pictures of the intestine.
3. Images are transmitted to sensor array abdominal leads, which are attached to a Walkman-like recording device belted to the patient's waist.
4. After approximately 8 hours, the recording device is removed and is connected to a computer to download the images for review. The capsule will be excreted naturally through the digestive tract.

NURSING ALERT Capsule endoscopy is contraindicated for patients with small bowel obstruction, dysphagia, fistulas, severe delayed gastric emptying, gastrectomy with gastrojejunostomy, or GI stricture. There is a risk of trapping the capsule, delayed passage, or impaired peristalsis. Pacemakers or implanted defibrillators may alter the quality and quantity of study information.

Nursing and Patient Care Considerations

1. Give patient instructions on bowel prep. Inform patient that a good bowel prep allows for better pictures. Patient will be NPO for about 12 hours before swallowing the camera.
2. Oral medications are discontinued 2 hours before the study. Antispasmodics, bismuth preparations, and antidiarrheal medications should be held for 24 hours before the study. Iron preparations and Carafate should be held 5 days before the study to prevent mucosal staining.
3. Instruct patient not to smoke 24 hours before the procedure to prevent mucosal staining.
4. Instruct patient to avoid strenuous activity, heavy lifting, bending or stooping, or immersion in water while wearing the leads and recorder. This is to prevent detachment of the leads or damage of the recorder.
5. After ingesting the capsule, patient is instructed not to eat or drink for at least 2 hours and then can advance to clear liquids. After 4 hours, patient can have a light snack and medications. When the procedure is completed, patient can resume a normal diet.
6. During the capsule endoscopy procedure, instruct the patient to check the blinking light on the top of the data recorder every 15 minutes. Avoid radio equipment (ham radio or broadcasting towers), which may interfere with the capsule's signal.
7. The capsule is naturally excreted within 1 to 3 days. Patient should be instructed to call the physician for the following symptoms: abdominal bloating or pain, chest pain, vomiting, or fever. These symptoms may indicate that the capsule has obstructed the GI tract.

NURSING ALERT The patient should verify excretion of the capsule before undergoing MRI.

Esophagogastroduodenoscopy

Description

1. Allows for visualization of the esophagus, stomach, and duodenum.
2. Esophagogastroduodenoscopy (EGD) can be used to diagnose acute or chronic upper GI bleeding, esophageal or gastric varices, polyps, malignancy, ulcers, gastritis, esophagitis, esophageal stenosis, and gastroesophageal reflux.
3. Instruments passed through the scope can be used to perform a biopsy or cytologic study, remove polyps or foreign bodies, control bleeding, or open strictures.

Nursing and Patient Care Considerations

1. Ensure that patient is NPO for 6 to 12 hours before the procedure to prevent aspiration and allow for complete visualization of the stomach.
2. Remove dentures and partial plates to facilitate passing the scope and preventing injury.
3. As an outpatient, advise that someone must accompany the patient to drive home because of the patient

being sedated.

4. Inform the health care provider of any known allergies and current medications. Medications may be held until after the test is completed.
5. Obtain prior x-rays, and send with patient.
6. Describe what will occur during and after the procedure:
   a. The throat will be anesthetized with a spray or gargle.
   b. An IV sedative will be administered.
   c. Patient will be positioned on the left side with a towel or basin at the mouth to catch secretions.
   d. A plastic mouthpiece will be used to help relax the jaw and protect the endoscope. Emphasize that this will not interfere with breathing.
   e. Patient may be asked to swallow once while the endoscope is being advanced. Then, the patient should not swallow, talk, or move the tongue. Secretions should drain from the side of the mouth, and the mouth may be suctioned.
   f. Air is inserted during the procedure to permit better visualization of the GI tract. Most of the air is removed at the end of the procedure. Patient may feel bloated, burp, or pass flatus from remaining air.
   g. Keep patient NPO according to protocol until patient is alert and gag reflex has returned.
   h. May resume regular diet after gag reflex returns and fluids are tolerated.
   i. May experience a sore throat for 24 to 36 hours after the procedure. When the gag reflex has returned, throat lozenges or warm saline gargles may be prescribed for comfort.
7. Monitor vital signs every 30 minutes for 3 to 4 hours, and keep the side rails up until patient is fully alert.
8. Monitor patient for abdominal or chest pain, cervical pain, dyspnea, fever, hematemesis, melena, dysphagia, light-headedness, or a firm distended abdomen. These may indicate complications.
9. Instruct patient on the above listed signs and symptoms and advise to report immediately should any occur, even after discharge.
10. Possible complications include perforation of the esophagus or stomach, pulmonary aspiration, hemorrhage, respiratory depression or arrest, infection, cardiac arrhythmias or arrest.

NURSING ALERT Perforation of the GI tract is a complication of endoscopy. Assess for abdominal or chest pain, dyspnea, fever, tachycardia, light-headedness, and distended abdomen. Report immediately.

Flexible Sigmoidoscopy and Colonoscopy

1. Sigmoidoscopy is the visualization of the anal canal, rectum, sigmoid colon, and proximal colon through a fiberoptic sigmoidoscope.

2. Colonoscopy is the visualization of the entire large intestine, sigmoid colon, rectum, and anal canal. It is used as a screening test for colon cancer because it can be used to identify and remove potentially precancerous and cancerous polyps.
3. Sigmoidoscopy or colonoscopy can be used to diagnose malignancy, polyps, inflammation, or strictures.
4. Colonoscopy is used for surveillance in patients with a history of chronic ulcerative colitis, previous colon cancer, or colon polyps.
5. Lower GI endoscopy can be used to perform biopsy, remove foreign objects, or obtain diagnostic specimens.
6. Colonoscopy requires bowel preparation for a couple of days before the procedure and use of conscious sedation during the procedure. The bowel preparation usually includes approximately 1 gallon of an iso-osmolar electrolyte solution (Colyte, GoLYTELY, or NuLYTELY) to consume over a 3- to 4-hour period the day before the procedure, a clear liquid diet the day before, and an oral laxative the night before (protocols vary). Alternate prep may also be used.
7. CT colonography, also known as virtual colonoscopy, is evolving as a noninvasive screening method.

DRUG ALERT Sodium phosphate preps should be avoided in people with congestive heart failure, renal impairment, and in others that may be more sensitive to electrolyte imbalances.

Endoscopic Ultrasound

Description

1. This procedure is a combination of endoscopy and ultrasonography to visualize the GI tract and can be used to evaluate the upper GI tract or the lower GI tract.
2. An ultrasonic transducer is built into the distal end of the endoscope.
3. This procedure allows for high-quality resolution and imaging of the walls of the esophagus, stomach, duodenum, small intestines, and colon. Adjacent abdominal structures can also be studied.
4. Endoscopic ultrasound (EUS) is also indicated to evaluate and stage lesions of the GI tract.

Nursing and Patient Care Considerations

1. Verify patient's compliance with the pretest bowel preparation the day before the procedure, usually an oral laxative (such as magnesium citrate) and a clear liquid diet.
2. Patient must be NPO after midnight.
3. Explain to patient that a feeling of fullness will occur when water is introduced into the GI tract. This eliminates airspace and provides for high resolution.
4. If an upper EUS is performed, maintain the NPO status until the gag reflex returns. A lower EUS can be performed using a rectal approach.
5. Observe patient for a change in vital signs, bleeding, pain, vomiting, and abdominal distention or

rigidity.

6. Make sure that patients who have had endoscopic procedures requiring sedation have a caregiver to drive them home after the procedure.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 18-1–18-5

PROCEDURE GUIDELINES 18-1

Administering an Enema

EQUIPMENT

- Prepackaged enema or enema container
- Disposable gloves
- Water-soluble jelly
- Waterproof pad
- Bath blanket
- Bedpan or commode
- Washcloth and towel
- Basin
- Toilet tissue

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Assess the patient's bowel habits (last bowel movement, laxative usage, bowel patterns) and physical condition (hemorrhoids, mobility, external sphincter control).	1. Helps distinguish chronic constipation from new or acute condition. Enema should not be given if there is a suspicion of appendicitis or bowel obstruction.
2. Provide for privacy and explain procedure to patient.	2. Provides comfort and cooperation.
Performance phase	
1. Wash hands.	1. Promotes hygiene.
2. Place patient on left side with right knee flexed (Sims' position). Place waterproof pad underneath patient and cover with bath blanket.	2. Allows for enema solution to flow by gravity along the natural curve of the sigmoid colon and rectum.
3. Place bedpan or bedside commode in position for patients who cannot ambulate to the toilet or who may have difficulty with sphincter control.	3. Allows for easy accessibility.
4. Remove plastic cover over tubing, and lubricate tip of enema tubing 3 to 4 inches (7.5 to 10 cm) unless prepackaged (tip is already lubricated). Even prepackaged enema may need more lubricant.	4. Prevents trauma and eases application.
5. Apply disposable gloves.	5. Standard precautions.
6. Separate buttocks and locate rectum.	
7. Instruct patient that you will be inserting tubing and to take slow, deep breaths.	7. Allows for patient relaxation and readiness.
8. Insert tubing 3 to 4 inches for adult patients.	8. Prevents tissue trauma of rectum.
9. Slowly instill the solution using a clamp and the height of the container to adjust flow rate if using an enema bag and tubing. For high enemas, raise enema container 12 to 18 inches (30.5 to 45.5 cm) above anus; for low enemas, 12 inches. If using a prepackaged enema, slowly squeeze the container until all solution is instilled.	9. Rapid infusion can cause colon distention and cramping. Container elevated past 12 to 18 inches and controller on tubing not regulated contribute to rapid infusion.
10. Lower container or clamp tubing if patient complains of cramping.	10. Slows instillation and allows fluid time to disperse.
11. Withdraw rectal tubing after all enema solution has been instilled and instruct patient to hold solution as long as possible and that a feeling of distention may be felt.	11. Promotes better results.
12. Discard supplies in the appropriate trash receptacle.	12. Maintains hygiene; minimizes patient embarrassment.
13. Assist patient on the bedpan or to the bedside commode or toilet when urge to defecate occurs.	13. Prompt action will prevent soiling.
14. Observe enema return for amount, fecal content. Instruct patient not to flush toilet until the nurse has seen the results.	14. If enema has not had sufficient time to absorb, result may be mostly clear with little fecal material. One or two repeat enemas may be ordered, if much fecal matter is expected, and discontinued when return turns clear.

Nursing Action	Rationale
Follow-up phase	
1. Document the type of enema given, volume, and results on the appropriate chart forms.	1. For continuity of care.
2. Assess and document presence or absence of abdominal distention after enema was given.	2. Relief of abdominal distention indicates success of gas relief.
3. Assist the patient with washing perineum and rectal area, if indicated; may also need a clean gown or linen change.	3. Fecal soiling may result, especially in bedridden patients.

NURSING ALERT Enemas should not be given routinely to treat constipation because they disrupt normal defecation reflexes, and the patient becomes dependent.

PROCEDURE GUIDELINES 18-2

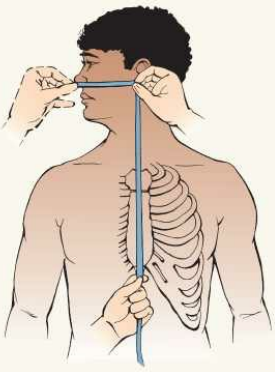
Nasogastric Intubation

EQUIPMENT

- Nasogastric (NG) tube—usually single-lumen Levin or double-lumen Salem sump tube
- Anesthetic jelly or spray or water-soluble lubricant
- Suction equipment, if ordered
- Clamp for tubing
- Towel, tissues, and emesis basin
- Glass of water and straw
- Hypoallergenic tape: ½ inch and 1 inch
- Bio-occlusive transparent dressing
- 60-mL syringe
- pH paper
- Penlight
- Disposable gloves and face shield
- Normal saline

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Ask if patient has ever had nasal surgery, trauma, a deviated septum, or bleeding disorder.	1. Nasogastric tubes may be contraindicated in patients with nasopharyngeal or esophageal obstruction, severe uncontrolled coagulopathy, or severe maxillofacial trauma.
2. Explain procedure to the patient, and tell how mouth breathing, panting, and swallowing will help in passing the tube.	2. Improves comfort and compliance.
3. Place the patient in a sitting or high-Fowler's position; place a towel across chest.	3. Facilitates passage of tube into esophagus.
4. Determine with the patient what sign he might use, such as raising the index finger, to indicate "wait a few moments" because of gagging or discomfort.	4. Provides a method of communication, which is reassuring to the patient.
5. Remove dentures; place emesis basin and tissues within the patient's reach.	5. Dentures may become loose and interfere with tube insertion.
6. Inspect the tube for defects; look for partially closed holes or rough edges.	6. Irrigation and suction may be affected by defective tube.
7. Determine the length of the tube needed to reach the stomach (see accompanying figure).	7. Prevents coiling of tube in stomach or tube ending in esophagus.
8. Have the patient blow nose to clear nostrils.	8. Facilitates passage through the nose.
9. Inspect the nostrils with a penlight, observing for any obstruction. Occlude each nostril, and have the patient breathe.	9. Helps determine which nostril is more patent.
10. Wash your hands. Put on disposable gloves (face shield should also be considered).	10. Protects nurse from patient's secretions.
11. Hold the end of the NG tube at the tip of the patient's nose, extend the tube to the earlobe and then down to the xiphoid process. Mark this distance on the tubing with tape.	11. The measurement will help ensure that the end of the tube reaches the stomach.



Measuring nasogastric tube length.

Nursing Action	Rationale
Performance phase	
1. Lubricate the first 2 to 3 inches of the tube with water-soluble lubricant. Avoid occluding the tube's holes with lubricant.	1. Lubrication reduces friction between the mucous membranes and tube and prevents injury to the nasal passages. Using a water-soluble lubricant prevents oil aspiration pneumonia if the tube accidentally slips into trachea.
2. With patient's head in a neutral position, insert tube into nostril and gently pass tube into the posterior nasopharynx, directing downward and backward toward the ear.	2. The passage of the tube is facilitated by following the natural contours of the body. The slower the advancement of the tube at this point, the less likelihood of putting pressure on the turbinates, which could cause pain and bleeding.
3. When tube reaches the pharynx, the patient may gag; allow patient to rest for a few moments.	3. Gag reflex is triggered by the presence of the tube.
4. Have the patient tilt head slightly forward. Offer several sips of water through a straw, or permit patient to suck on ice chips, unless contraindicated. Advance tube as patient swallows.	4. Flexed head position partially occludes the airway, and the tube is less likely to enter trachea. Swallowing closes the epiglottis over the trachea and facilitates passage of tube into the esophagus. Actually, when the tube passes the cricopharyngeal sphincter into the esophagus, it can be slowly and steadily advanced even if the patient does not swallow.
5. Gently rotate the tube 180 degrees to redirect the curve.	5. Prevents the tube from entering the patient's mouth.
6. Continue to advance tube gently each time the patient swallows.	6. Facilitates forward movement and prevents trauma and discomfort.
KEY DECISION POINT Be especially cautious with tube insertion in patients with craniofacial trauma, reduced cough and gag reflexes, confusion, presence of endotracheal tube, decreased consciousness, and uncooperative behavior. If obstruction appears to prevent tube from passing, do not use force. Rotating tube gently may help. If unsuccessful, remove tube and try another nostril. If there are any signs of distress while passing the tube, such as gasping, coughing, or cyanosis, immediately remove tube. The tube may have entered the trachea.	
7. Continue to advance the tube when the patient swallows, until the tape mark reaches the patient's nostril.	7. Reference point where the tube was measured.
8. To check whether the tube is in the stomach:	
a. Ask the patient to talk.	a. If the patient cannot talk, the tube may be coiled in throat or passed through vocal cords.
b. Obtain aspirate with 60-mL syringe and check for gastric fluid characteristics. If stomach contents cannot be aspirated, reposition the patient. Attempt to aspirate again.	b. Gastric fluid characteristics: pH ≤ 5 and gastric fluid characteristics of grassy green, clear and colorless, or brown.
c. X-rays may be obtained to confirm tube placement.	c. Consider x-ray confirmation of tube placement in patients with risk factors for malpositioning of tubes.
NURSING ALERT Never place the end of the tube in water while checking placement. If the tube is in the trachea, the patient could aspirate.	
9. After tube is passed and the correct placement is confirmed, attach the tube to suction or clamp the tube.	9. Clamping can be done using a clamp, plastic plug, or folding the tube over and slipping the bend into the tube end.

Nursing Action	Rationale
10. Anchor tube with the following:	10. Prevents the patient's vision from being disturbed; prevents tubing from rubbing against nasal mucosa. This will ensure tape being secure. Do not tape to forehead, which could cause necrosis of the nostril.
a. Hypoallergenic tape; split lengthwise and only halfway, attach unsplit end of tape to nose, and cross split ends around tubing. Apply another piece of tape to bridge of nose.	
b. Bio-occlusive transparent dressing where it exits the nose.	
11. Anchor the tubing to the patient's gown. Use a rubber band to make a slipknot to anchor the tubing to the patient's gown. Secure the rubber band to the patient's gown using a safety pin.	11. Permits mobility of patient. This prevents tugging on the tube when the patient moves.
12. Clamp the tube until the purpose for inserting the tube takes place.	
13. Attach the larger lumen of the Salem sump tube to suction equipment if ordered. Low continuous suction or high intermittent suction may be used with the Salem sump tube. If the Levin tube is used, low intermittent suction is recommended.	13. Prevents gastric mucosal damage, if a vacuum forms and the tube adheres to the gastric wall.
Follow-up phase	
1. Assure the patient that most discomfort will lessen with time.	
2. Irrigate the tube at regular intervals (every 4 hr unless otherwise indicated) with small volumes of prescribed fluid. Remember to always check placement first.	2. Ensures tube patency.
a. If the tube is a Salem sump, it will require periodic placing of 10 to 20 cc of air through the vent port (blue port or smaller lumen). Do not instill water into the vent and, if the vent is draining fluid, instill air to clear it.	
b. Check the Salem sump tube patency by placing the vent port next to your ear.	b. A soft hissing sound is heard if the tube is patent. If the port hangs downward and the tube backs up, stomach contents will spill over the patient.
3. Cleanse nares and provide mouth care every shift.	3. Promotes patient comfort and decreases risk of infection.
4. Apply petroleum jelly to nostrils, as needed, and assess for skin irritation or breakdown.	4. Keeps tissue soft and prevent crusting and skin breakdown.
5. Keep head of bed elevated at least 30 degrees.	5. Minimizes gastroesophageal reflux.
6. Record the time, type, and size of tube inserted. Document placement checks after each assessment, along with amount, color, consistency of drainage.	6. Ensures proper tube and placement at all times, and assists in evaluation of tube effectiveness.

EVIDENCE BASE Simons, S. R., & Abdallah, L. M. (2012). Bedside assessment of enteral tube placement: Aligning practice with evidence. *American Journal of Nursing, 112(2)*, 40–46.

PROCEDURE GUIDELINES 18-3

Nasogastric Tube Removal

EQUIPMENT

- Towel
- Disposable gloves
- Lip pomade
- Mouth hygiene materials

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Make sure that gastric or small bowel drainage is not excessive in volume.	1–3. Tube may not be discontinued unless drainage is minimal, bowel sounds are present, and patient is passing flatus.
2. Make sure, by auscultation, that audible peristalsis is present.	
3. Determine whether the patient is passing flatus, which indicates peristalsis.	
4. Verify the health care provider's order for removal.	4. Complies with the Joint Commission National Patient Safety Goals.
Performance phase	
1. Place a towel across the patient's chest and inform about the withdrawal.	1. No doubt, the patient will be happy to have progressed to this stage.
2. Apply disposable gloves.	2. Provides protection from contaminated body fluids.
3. Turn off suction; disconnect and clamp tube.	3. Prevents fluids from leaking from tube.
4. Remove the tape from the patient's nose.	
5. Instruct the patient to take a deep breath and hold it.	5. This maneuver closes the epiglottis.
6. Slowly, but evenly, withdraw tubing and cover it with a towel as it emerges. (As the tube reaches the nasopharynx, you can pull quickly.)	6. Covering the tubing helps dispel patient's nausea.
7. Provide the patient with materials for oral care and lubricant for nasal dryness.	7. Mouthwash and a nasal lubricant will be appreciated by the patient.
8. Dispose of equipment in appropriate receptacle.	
9. Document time of tube removal and the patient's reaction.	
10. Document tube removal and color, consistency, and amount of drainage in suction canister.	9–10. For continuity of care.
11. Continue to monitor the patient for signs of GI difficulties.	11. Recurrence of nausea or vomiting may require reinsertion of nasogastric tubing. Changes in vital signs may suggest infection.

PROCEDURE GUIDELINES 18-4

Nasointestinal Intubation (Small-Bore Feeding Tubes)

EQUIPMENT

- Type of tube ordered by health care provider
- 30-mL or 60-mL luer lock or tip syringe
- Water-soluble lubricant
- Tape, rubber band, clamp, safety pin
- Glass of water
- Stethoscope

NURSING ALERT Intestinal feeding tubes are soft, flexible, small-diameter (8 or 12 French) tubes with a longer length than gastric feeding tubes (measuring up to 47 inches [120 cm] as compared with approximately 30 inches [76 cm] for a gastric feeding tube). Some tubes are weighted at the distal end of the tube. All tubes should be routinely pretested for patency and function before passage.

PROCEDURE

Nursing Action	Rationale
Preparatory and performance phases (by health care provider—nurse assisted)	
1. Tube preparation:	
a. Do not ice plastic tubes.	a. Become too stiff to work with.
b. Inject 10 mL of water into the tube.	b. Removes air that may cause gas.
c. Insert guidewire or stylet into tube, making sure it is positioned snugly against tube.	c. Aids in insertion.
d. Dip weighted tip into glass of water.	d. Activates lubricant.
2. Similar to passing a short nasogastric tube and taping to patient (see Procedure Guidelines 18-2, pages 652 to 654).	
3. After the tube enters the stomach, it passes by peristalsis and gravity into the small intestine. Change patient's position from Fowler's to a position in which the patient is lying on his or her right side.	3. Assists in advancing the tubing to and through the pylorus; tilting to the right is helpful.
4. Obtain an x-ray of the abdomen after tube insertion. Stylet should remain in place until position is confirmed.	4. Confirms placement.
5. When tube placement has been confirmed, mark the tube at the nare exit site.	5. Helpful in reassessment of tube position. Check that the mark on the tube remains at the exit site.
Nursing/patient care considerations	
1. Be aware of risk of aspiration in an unconscious patient.	1. Inserted tube prevents total closure of airway.
2. Instruct patient on complications associated with tube feedings, such as nausea, vomiting, diarrhea.	2. Feedings that are too large or too fast cause these symptoms.
3. A continuous drip infusion delivered with an infusion pump may lessen the risk of aspiration, abdominal distention, and/or diarrhea.	3. Controls the volume and rate of infusion.
4. If abdominal distention, vomiting, or diarrhea occurs, notify the health care provider; the rate of infusion may need to be adjusted.	4. May indicate paralytic ileus.

PROCEDURE GUIDELINES 18-5

Irrigating a Colostomy

EQUIPMENT

- Reservoir for irrigating fluids; irrigator bag or enema bag if irrigator bag not available
- Irrigating fluid: 500- to 1,500-mL lukewarm water or other solution prescribed by health care provider. (Volume is titrated based on patient tolerance and results; average amount is 1,000 mL.)
- Irrigating tip: Cone tip or soft rubber catheter #22 or #24 with shield to prevent backflow of irrigating solution. (Use only if cone not available. The cone is the preferred method to avoid possibility of bowel perforation.)
- Irrigation sleeve (long, large-capacity bag with opening at top to insert cone or catheter into stoma); available in different styles: snap-on, self-adhering to skin, or held in place by belt
- Large tail closure
- Water-soluble lubricant

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain the details of the procedure to the patient and answer any questions.	1. Relieves anxiety and promotes compliance.
2. Select a consistent time, free from distractions. If the patient is learning to irrigate for bowel control, choose the time of day that will best fit into the patient's lifestyle.	2. Establishes regularity.
3. Have the patient sit in front of the commode on chair or on the commode itself, providing privacy and comfort.	
4. Hang irrigating reservoir with prescribed solution so the bottom of the reservoir is approximately at the level of the patient's shoulder and above the stoma. *Note:* Colostomy irrigation may also be performed to empty the colon of its contents (feces, gas, mucus) before a diagnostic procedure or surgery and to cleanse the colon after fecal impaction removal or with constipation.	4. Height of irrigation bag regulates pressure of irrigant.
Performance phase	
1. Remove pouch or covering from stoma and apply irrigation sleeve, directing the open tail into the commode.	1. Allows water and feces to flow directly into commode.
2. Open tubing clamp on the irrigating reservoir to release a small amount of solution into the commode.	2. Removes air from the setup; avoids air from being introduced into the colon, which can cause crampy pain.
3. Lubricate the tip of the cone/catheter, and gently insert into the stoma. Insert catheter no more than 3 inches (7.5 cm). Hold cone/shield gently, but firmly, against stoma to prevent backflow of water.	3. Prevents intestinal perforation and irritation of mucous membranes.
4. If catheter does not advance easily, allow water to flow slowly while advancing catheter. NEVER FORCE CATHETER. Dilating the stoma with lubricated, gloved pinky finger may be necessary to direct cone/catheter properly.	4. Slow rate relaxes bowel to facilitate passage of catheter.
5. Allow water to enter colon slowly over a 5- to 10-min period. If cramping occurs, slow flow rate or clamp tubing to allow cramping to subside. If cramping does not subside, remove cone/catheter to release contents.	5. Cramping may occur from too rapid flow, cold water, excess solution, or colon ready to function.
6. Hold cone/shield in place 10 sec after water is instilled, then gently remove cone/catheter from stoma.	6. Discourages premature evacuation of fluid.
7. As feces and water flow down sleeve, periodically rinse sleeve with water. Allow 10 to 15 min for most of the returns, then dry sleeve tail and apply tail closure.	7. Prevents caking of feces on the sleeve.
8. Leave sleeve in place for approximately 20 more minutes while patient gets up and moves around.	8. Ambulation stimulates peristalsis and completion of irrigation return.
9. When returns are complete, clean stomal area with mild soap and water; pat dry; reapply pouch or covering over stoma.	9. Cleanliness and dryness promote comfort.

Nursing Action	Rationale
Follow-up phase	
1. Clean equipment with soap and water; dry and store in well-ventilated area.	1. This will control odor and mildew, prolonging the life of equipment.
2. If applicable, the patient should use a pouch until the colostomy is sufficiently controlled.	2. It may take several months to establish control. The patient can then use minipouch, stoma cap, or gauze covering as desired.

Relieving Constipation and Fecal Impaction

One method of evacuating the lower bowel is an enema, the installation of a solution into the rectum and sigmoid colon. If fecal impaction is discovered on exam, manual disimpaction may be performed to remove stool and promote bowel elimination (see Figure 18-1). However, it is best to try to prevent constipation by using fiber, laxatives, or stool softeners so that enemas and manual disimpaction are not needed.

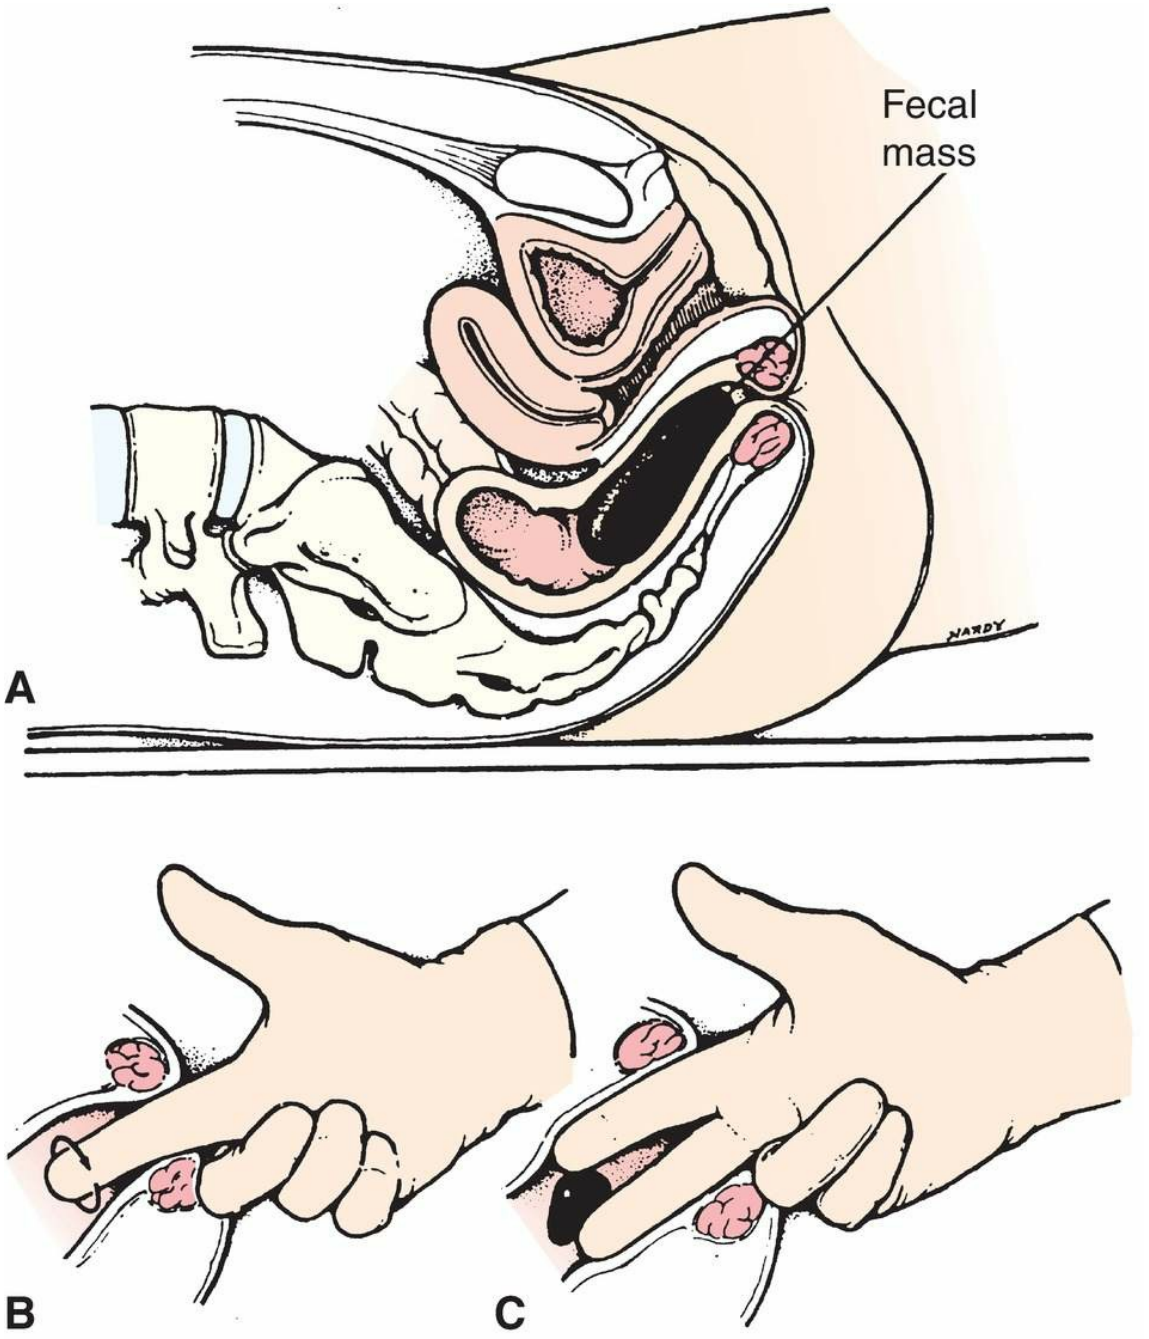


Figure 18-1. Fecal impaction. **(A)** Note shaded area inside rectal sphincter, which indicates fecal impaction. **(B)** By gently stimulating the rectal wall with a gloved index finger and using a circular motion, it is possible to loosen fecal material. **(C)** It may be necessary to gently insert two fingers in an attempt to crush the fecal mass. A scissor-like motion is used.

Purposes of Enema Administration

1. Bowel preparation for diagnostic tests or surgery to empty the bowel of fecal content.
2. Delivery of medication into the colon (such as enemas containing steroids to treat ulcerative proctitis or a sodium polystyrene sulfonate enema to decrease the serum potassium level).
3. To soften the stool (oil-retention enemas).
4. To relieve gas (tidal, milk and molasses, or Fleet enemas).
5. To promote defecation and evacuate feces from the colon for patients with constipation or an impaction (not a first-line therapy).

Nursing and Patient Care Considerations

1. Consider manual removal of fecal impaction in the following patients at risk:
   a. Older adults with chronic constipation or insufficient hydration or who are inactive.
   b. Orthopedic patients who have been in traction or in body casts.
   c. When barium has not been adequately removed after radiologic examination.
   d. Patients with neurologic or psychotic disorders.
2. Fecal impaction can occur with a descending/sigmoid colostomy. The fingers may be used to break up feces through the stoma, followed by cleansing irrigation.
3. Contraindications of manual removal of fecal impaction include:
   a. Pregnancy.
   b. After genitourinary, rectal, perineal, abdominal, or gynecologic surgery.
   c. Myocardial infarction, coronary insufficiency, pulmonary embolus, heart failure, heart block.
   d. GI or vaginal bleeding.
   e. Blood dyscrasias, bleeding disorders.
   f. Hemorrhoids, fissures, and rectal polyps.
4. Prepare for enema administration by helping the patient to lying position on left side with knees bent. Lubricate 3 to 4 inches (7.5 to 10 cm) of the tip of enema tubing with water-soluble lubricant, even if prelubricated.
5. Insert enema tip 3 to 4 inches into the rectum and instill slowly, to avoid cramping and rectal spasm. When completely instilled, ask the patient to hold the enema solution as long as possible, before gently withdrawing the tubing.
6. Ensure that patient can safely transfer to bathroom, commode, or bed pan when the overwhelming urge to defecate is felt.

NURSING ALERT Be aware that manual removal of fecal impaction may cause syncope because of stimulation of the vagus nerve.

Nasogastric and Nasointestinal Intubation

EVIDENCE BASE Emergency Nurses Association. (2015). *Clinical practice guideline: Gastric tube placement verification*. Des Plaines, IL: Author. Available: *www.ena.org/practice-research/research/CPG/Documents/GastricTubeCPG.pdf.*

Nasogastric (NG) intubation refers to the insertion of a tube through the nasopharynx into the stomach. NG intubation has multiple purposes including stomach decompression, stomach lavage (irrigation because of active bleeding or poisoning), medication administration, and short-term feeding. Extended-use NG tubes are made of a flexible, soft plastic material with manufacturer's recommendations that may include leaving the tube in place for up to 30 days before changing the tube.

Nasointestinal (NI) intubation is performed by a health care provider and may be assisted by a nurse. A small-bore tube is inserted into the duodenum or jejunum for the purpose of feeding and maintaining nutrition. It can be done manually, endoscopically, or fluoroscopically. Using fluoroscopy is considered the "gold standard" or preferred method of insertion. Intestinal feeding tubes are soft, flexible, small-diameter (8 or 12 French) tubes with a longer length than gastric feeding tubes (measuring up to 47 inches [120 cm] as compared with approximately 30 inches [76 cm] for a gastric feeding tube). Some tubes are weighted at the distal end of the tube, so they will be carried by peristalsis. All tubes should be routinely pretested for patency and function before passage.

Nursing and Patient Care Considerations

1. Before inserting the tube, ensure unobstructed nasal passage, then approximate the distance to the stomach by measuring from the tip of the patient's nose to the earlobe and down to the xiphoid process, and then mark this point on the tube with tape (see Figure 18-2). Lubricate the first 2 to 3 inches of the tube with water-soluble lubricant.
2. With the patient's head in neutral position, insert the tube into the nostril and slowly direct the tube backward and downward. The patient may gag as the tube passes the pharynx, allow the patient to rest, tilt the head slightly forward, and take a sip of water. Turn the tube 180 degrees and continue to advance the tube slowly to predetermined mark.
3. If patient is unconscious, advance the tube between respirations to make sure it does not enter the trachea.
    a. You will need to stroke the unconscious patient's neck to facilitate passage of the tube down the esophagus.
    b. Watch for cyanosis while passing the tube in an unconscious patient. Cyanosis indicates the tube has entered the trachea.
4. If patient has a nasal condition that prevents insertion through the nose, the tube is passed through the

mouth.

   a. Remove dentures, slide the distal end of the tube over the tongue, and proceed the same way as a nasal intubation.
   b. Make sure to coil the end of the tube and direct it downward at the pharynx.

5. Be aware that pain or vomiting after the tube is inserted indicates tube obstruction or incorrect placement; may need to be pulled back or removed.
6. If the NG tube is not draining, reposition tube by advancing or withdrawing it slightly (with a physician's order). After repositioning, always check for placement.
7. Recognize the complications when the tube is in for prolonged periods: nasal erosion, sinusitis, esophagitis, esophagotracheal fistula, gastric ulceration, and pulmonary and oral infections.
8. Assess the color, consistency, and odor of gastric contents. Coffee ground–like contents may indicate GI bleeding. Report findings immediately.
9. The tube should be irrigated before and after medication administration through the tube.
   a. Medications should be given in liquid form, if possible.
   b. Clamp the tube for 30 to 45 minutes to ensure medication absorption before reconnecting to suction, if ordered.
10. Check GI function by auscultating for bowel sounds on a regular basis after the tube has been clamped for 30 minutes.
11. When discontinuing an NG tube, remove all tape and have the patient take a deep breath, hold it, and pull steady and slowly (covering it with a towel as it emerges) and then more quickly when it reaches the pharynx.

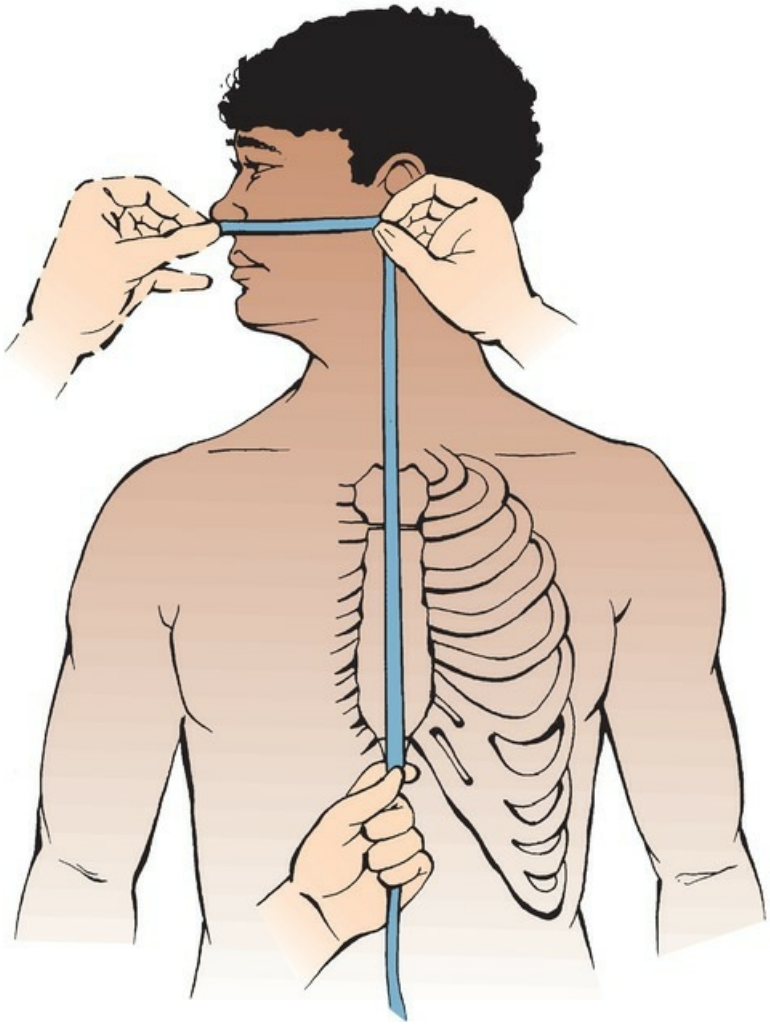

Figure 18-2. Measuring NG tube length.

Caring for the Patient Undergoing Gastrointestinal Surgery

Types of Procedures

Gastric Surgeries

1. Total gastrectomy—complete excision of the stomach with esophageal–jejunal anastomosis.
2. Subtotal or partial gastrectomy—a portion of the stomach excised:
   a. Billroth I procedure—gastric remnant anastomosed to the duodenum.
   b. Billroth II procedure—gastric remnant anastomosed to the jejunum.
3. Gastrostomy (Janeway or Spivak)—rectangular stomach flap created into abdominal stoma, used for intermittent tube feedings.

Hernia Surgeries

1. Herniorrhaphy—surgical repair of a hernia with suturing of the abdominal wall.
2. Hernioplasty—reconstructive hernia repair with mesh sewn over the defect for reinforcement.

Bowel Surgeries

1. Appendectomy—excision of the vermiform appendix.
2. Bowel resection—segmental excision of small and/or large bowels with varied approaches:
   a. Anastomosis of proximal and distal ends of the bowel.
   b. Anastomosis of proximal and distal ends of the bowel with temporary diverting loop ostomy.
   c. Both ends of bowel exteriorized to the abdominal wall with proximal ostomy and distal mucous fistula.
   d. Hartmann procedure—proximal large bowel as ostomy; distal end of large bowel oversewn inside abdomen as Hartmann pouch.
3. Low anterior resection—subtotal resection of the rectum with colorectal or coloanal anastomosis.
4. Abdominoperineal resection—a combined abdominal and perineal approach for removal of the rectum and anus with permanent colostomy.
5. Subtotal colectomy—partial removal of the large bowel or colon.
6. Total colectomy—complete removal of the large bowel or colon with varied approaches:
   a. Ileorectal anastomosis—colon removal with the ileum anastomosed to the rectum.
   b. Proctocolectomy—colon removal including the rectum and anus with permanent ileostomy.
   c. Ileal reservoir—anal anastomosis. (Colon removal, subtotal proctectomy, possible distal rectal mucosectomy, creation of pelvic reservoir from two, three, or four loops of the ileum with anastomosis at anal canal. Usually, a temporary loop ileostomy is performed as fecal diversion to protect the reservoir and the ileal–anal anastomosis. After takedown of temporary loop ileostomy [2 to 3 months postoperatively], the reservoir stores feces and patient eliminates under voluntary control through the anus [see page 525].)

d. Kock or Barnett continent internal reservoir (BCIR) procedures—proctocolectomy, creation of a continent small bowel reservoir with nipple valve abdominal stoma used for stool removal through routine intubation. (Continence is provided through the nipple valve.)

7. Roux-en-Y jejunostomy—the jejunum severed with distal end exteriorized as permanent stoma for intermittent tube feedings; proximal end reanastomosed to GI tract distal to stoma to reestablish pathway.

Laparoscopic Surgery

1. GI surgical procedures are increasingly being assisted by the use of a laparoscope, either partially or totally. The laparoscope is usually inserted through a 1-cm umbilical incision with additional trocars used for visualization and assistance. Dissection is performed with endocautery, scissors, or laser.
2. Advantages may include reduction in postoperative pain, shorter hospital and recuperative periods, decreased risk of infection, and improved cosmetic outcome. The direct cost of a laparoscopic procedure may be greater than an open procedure; however, the overall cost of the procedure and recuperative period may be lower due to a more rapid recovery.
3. Contraindications may include obesity, internal adhesions, and bowel obstruction with distention.
4. Cholecystectomies and appendectomies are routinely done through laparoscopy; hernia repairs can be done using the laparoscope. Other GI surgeries, including ostomies and bowel resections (may include select cancer patients), are increasingly being done through this surgical approach.

Preoperative Management

1. All diagnostic tests and procedures are explained to promote cooperation and relaxation.
2. The patient is prepared for the type of surgical procedure as well as postoperative care (IV, patient-controlled analgesia pump, NG tube, surgical drains, incision care, possibility of ostomy).
3. Measures to prevent postoperative complications are taught, including coughing, turning, and deep breathing; using the incentive spirometer; and splinting the incision.
4. IV fluids or total parenteral nutrition (TPN) before surgery may be ordered to improve fluid and electrolyte balance and nutritional status.
5. Intake and output is monitored.
6. Preoperative laboratory studies are obtained.
7. Bowel cleansing will be initiated 1 to 2 days before surgery for better visualization. Preparation may include diet modifications, such as liquid or low residue, oral laxatives, suppositories, enemas, or polyethylene glycoelectrolyte solution (Colyte, GoLYTELY).
8. Antibiotics are ordered to decrease the bacterial growth in the colon.
9. An ostomy specialty nurse is consulted if patient is scheduled for an ostomy to initiate early understanding and management of postoperative care.
10. Patient may not have anything by mouth after midnight the night before surgery. Medications may be withheld, if ordered. This will keep the GI tract clear.

Postoperative Management and Nursing Care

1. Physical assessment is completed at least once per shift, or more frequently, as indicated.
    a. Monitor vital signs for signs of infection and shock—fever, hypotension, tachycardia.
    b. Monitor intake and output for signs of imbalance, dehydration, and shock. Include all drains in evaluating intake and output.
    c. Assess the abdomen for increased pain, distention, rigidity, and rebound tenderness because these may indicate postoperative complications. Report abnormal findings.
    d. Expect diminished or absent bowel sounds in the immediate postoperative phase.
    e. Evaluate dressing and incision. Check for purulent or bloody drainage, odor, and unusual tenderness or redness at incision site, which may indicate bleeding or infection.
    f. Evaluate for passing of flatus or feces.
    g. Monitor for nausea and vomiting. Note the presence of fecal smell or material in vomitus because it may indicate an obstruction.
    h. Check NG aspirate, vomitus, and stools for signs of bleeding. Record and report findings if present.
2. Laboratory values are monitored and patient is evaluated for signs and symptoms of electrolyte imbalance.
3. Wound drains, IV lines, and all other catheters are monitored and evaluated for signs of infection or infiltration.
4. To maintain patency of NG tube, the tube may be irrigated with 30 mL of normal saline solution every 2 hours and as needed. If there are large amounts of NG output, IV replacement may be necessary.
5. Subcutaneous heparin may also be ordered to prevent embolus. Antiembolism stockings may be used.
6. Turning, coughing, deep breathing, and incentive spirometry are performed every 2 hours. Dangling at bedside is encouraged the night of surgery, and an attempt at ambulation the first postoperative day is made, unless ordered otherwise.
7. Patient-controlled analgesia for pain control or other analgesics, as ordered, are administered to promote comfort.
8. Wound dressing is changed every day or as needed, maintaining aseptic technique.
9. Diet is advanced, as ordered, after presence of bowel sounds indicates GI tract has regained motility. After 1 to 2 days of NPO postoperatively, the usual diet progression is ice chips, sips of water, clear liquids, full liquids, soft or regular diet.
10. Dietary education includes fiber, avoiding gas-producing foods, and maintaining adequate fluid intake.
11. Reinforcement of teaching and assistance with ostomy care, if indicated.
12. Administration of medications, as ordered, which may include a stool softener or laxative when bowel function has returned.

NURSING ALERT Because of the type of abdominal surgery and location of the suture line, the health care provider may order not to irrigate or manipulate the NG tube.

Complications

1. Paralytic ileus or obstruction.
2. Peritonitis or sepsis.
3. Anastomotic leakage, which may result in peritonitis.

Nursing Diagnoses

- Acute Pain related to surgical incision.
- Imbalanced Nutrition: Less Than Body Requirements related to dietary modifications after surgery.
- Impaired Skin Integrity related to surgical incision.
- Constipation related to surgery.
- Risk for Infection related to surgical incision.
- Deficient Fluid Volume related to surgical procedure.

Nursing Interventions

Promoting Comfort

1. Assess pain location, intensity, and characteristics, and make sure they are appropriate for postoperative stage.
2. Administer prescribed pain medications, and provide instructions if using a patient-controlled analgesia pump, to keep patient comfortable.
3. Assess the effectiveness of the pain medications. If ordered, promethazine can potentiate the effectiveness of pain medication.
4. Encourage the patient to change positions frequently and to splint incision when turning, coughing, or deep breathing to minimize discomfort.

Improving Nutritional Status

1. Monitor intake and output each shift, or more frequently if indicated, to maintain fluid balance.
2. Advance diet as tolerated.
3. Weigh the patient daily to ensure adequate calorie intake.
4. Provide snacks or high-protein, high-calorie supplements and assist in menu selection, if needed.
5. Instruct the patient to avoid gas-producing foods, and encourage ambulation.

Improving Skin Integrity

1. Assess wound for signs of erythema, swelling, and purulent drainage, which may indicate infection.

2. Change surgical dressing every 24 hours, and as needed, to protect the skin from drainage and decrease risk of infection.
3. Apply dressings around drains and tubes to protect the skin from leakage, if indicated.
4. Turn the patient frequently or encourage position changes to prevent skin breakdown over bony prominences.

Promoting Bowel Elimination

1. Assess for presence of bowel sounds to evaluate return of bowel function.
2. Ask the patient if passing flatus rectally or through an ostomy—also indicative of return of bowel function.
3. Evaluate for abdominal distention, nausea, or vomiting, which may indicate obstruction.
4. Monitor stool for frequency, amount, and consistency.
5. Administer stool softener or laxative, as ordered, to promote comfort with elimination.
6. Encourage diet with adequate fiber and fluid content for natural laxative effect.
7. Encourage and assist with ambulation to promote peristalsis.

Preventing Infection

1. Monitor temperature every shift or as ordered, and review previous readings to recognize early increases.
2. Change surgical dressings every 24 hours, or more frequently, as indicated. Maintain aseptic technique to avoid contamination.
3. Monitor wound for signs and symptoms of infection, such as redness, swelling, purulent drainage, odor, and pain.
4. Obtain a wound culture, as ordered.
5. Monitor the patient with a Foley catheter for signs and symptoms of urinary tract infection (UTI), such as concentrated, cloudy urine; hematuria; fever. If Foley is discontinued, monitor for the above plus complaints of burning and frequency.
6. Assist the patient in washing perineum daily, and as needed if incontinence is present, for increased comfort and hygiene.
7. Assess breath sounds and monitor for crackles.
8. Instruct the patient to turn, cough, deep-breathe, and use incentive spirometer every 2 hours to minimize complications.
9. Encourage early ambulation to initiate bowel function and reduce risk of embolus.
10. Administer antibiotics, as ordered, to maintain constant blood level.

Maintaining Fluid Volume

1. Monitor intake and output every 8 hours, or more frequently, if ordered, to assess recent status. Include amount of wound drainage from dressing changes and drains that may be in place.
2. Assess the patient for signs of dehydration—flushed, dry skin; tenting of the skin; oliguria; tachycardia,

hypotension, and rapid respirations; increase in hematocrit, blood urea nitrogen (BUN), and electrolytes; fever; weight loss.

3. Monitor laboratory results and report abnormal findings.
4. Assess the patient for signs of electrolyte imbalance—nausea or vomiting, cardiac dysrhythmia, tremor, seizures, anorexia, malaise, weakness, irregular pulse; changes in behavior, mental status.
5. Weigh the patient daily to ensure adequate caloric intake.
6. Administer parenteral fluids, enteral feedings, and blood products, as ordered, to maintain volume during period of decreased oral intake.

Community and Home Care Considerations

1. Reinforce discharge instructions and the importance of postoperative regimen to include health provider follow-up appointments and laboratory and other scheduled tests or therapies.
2. A person who has undergone a total gastrectomy needs lifelong parenteral administration of vitamin B_{12} to prevent pernicious anemia. This may also apply to people with the terminal ileum removed and sometimes for those with ileostomies.
3. Change dressing and reinforce ostomy care as directed by health care provider. Report any signs of infection—unusual drainage, redness, warmth, increased pain, swelling.
4. Instruct to gradually increase activities of daily living (ADLs). No heavy lifting (more than 10 pounds), pushing, pulling, or driving for 6 to 8 weeks postoperatively.
5. Referral to additional community resources if applicable (support groups, meal programs, social services).

Patient Education and Health Maintenance

1. Review signs and symptoms of wound infection so early intervention may be instituted.
2. Explain signs and symptoms of other postoperative complications to report—elevated temperature, nausea or vomiting, abdominal distention, changes in bowel function and stool consistency or color.
3. Instruct the patient to report promptly blood in the stool or the coughing up of blood.
4. Teach the patient regarding wound and/or ostomy care, if applicable, to promote healing and self-confidence.
5. Encourage the patient to turn, cough, deep-breathe; use incentive spirometer; and ambulate. Discuss the importance of these functions during the recovery period.
6. Review dietary changes, such as increased fiber content and fluid intake, and their importance in improving bowel function.
7. Review actions and adverse effects of prescribed medications to encourage compliance and understanding of management.
8. Assess the need for home health follow-up and initiate appropriate referrals if indicated.

Evaluation: Expected Outcomes

- Verbalizes increased comfort (using a 0 to 10 pain scale, with 0 being no pain and 10 being the highest

score to measure pain).

- Consumes 50% to 75% of each meal; no weight loss.
- Incisional flaps approximated and healing ridge present.
- Passing flatus and stool.
- No signs and symptoms of infection.
- Vital signs stable; fluid and electrolytes in balance.

Caring for the Patient Undergoing Ostomy Surgery

See Standards of Care Guidelines 18-2.

STANDARDS OF CARE GUIDELINES 18-2

Care of the Patient with an Ostomy

- Prepare patient and patient's family preoperatively by explaining the surgical procedure, stoma characteristics, and ostomy management with a pouching system.
- Have ostomy specialty nurse mark an optimal stoma site.
- Postoperatively, monitor the stoma color and amount and color of stomal output every shift; document and report any abnormalities.
- Periodically change a properly fitting pouching system over the ostomy to avoid leakage and protect the peristomal skin. Use this time as an opportunity for teaching.
- Assess peristomal skin with each pouching system change, document findings, and treat any abnormalities (skin breakdown because of leakage, allergy, or infection) as indicated.
- Teach patient and/or caregiver self-care skills of routine pouch emptying, cleansing skin and stoma, and changing of the pouching system until independence is achieved.
- Instruct patient and family in lifestyle adjustments regarding gas and odor control, procurement of ostomy supplies, and bathing, clothing, and travel tips.
- Encourage patient to verbalize feelings regarding the ostomy, body image changes, and sexual issues.
- Inform patient of community resources, such as United Ostomy Association, local and mail-order ostomy supply dealers, ostomy specialty nurses, American Cancer Society, and Crohn's & Colitis Foundation.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Types of Fecal Ostomies

Colostomy

See Figure 18-3.

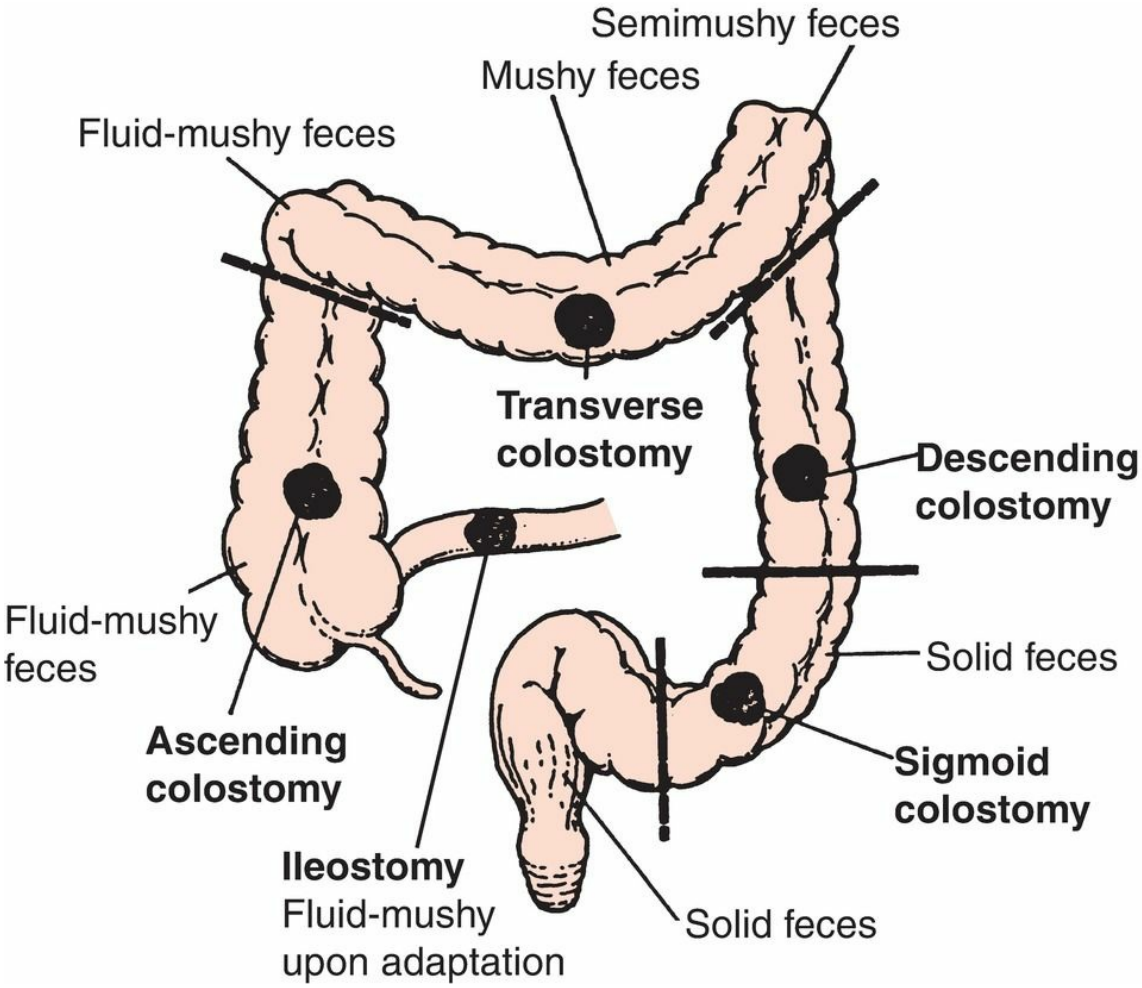

Figure 18-3. A diagrammatic representation of the placement of fecal ostomies and nature of discharge at these sites.

1. A surgically created opening between the colon and the abdominal wall to allow fecal elimination. It may be a temporary or permanent diversion.
2. A colostomy may be placed in any segment of the large intestine (colon), which will influence the nature of fecal discharge. The more right-sided the colostomy, the looser the stool. Transverse and descending/sigmoid colostomies are the most common types.
3. A colostomy may be performed as part of an abdominoperineal resection for rectal cancer, a fecal diversion for unresectable cancer, a temporary measure to protect an anastomosis, or a surgical treatment for inflammatory bowel diseases, trauma, perforated diverticulitis, ischemic bowel, cancer, and congenital conditions.

Ileostomy

1. A surgically created opening between the ileum of the small intestine and the abdominal wall to allow elimination of small bowel effluent.
2. An ileostomy is usually formed at the terminal ileum of the small bowel and is usually placed in the right lower quadrant of the abdomen. Stool from an ileostomy drains frequently (average four to five times per

day) and contains proteolytic enzymes, which can be harmful to the skin.

3. Diagnoses that may require a temporary or permanent ileostomy include ulcerative colitis, Crohn disease, familial polyposis, cancer, congenital defects, and trauma.

Characteristics of Stomas

1. A stoma is the part of the intestine (small or large) that is brought above the abdominal wall to become the outlet for discharge of intestinal waste. Stoma is often used interchangeably with "ostomy."
2. Normal stomal characteristics: pink-red, moist, bleeds slightly when rubbed, no feeling to touch, stool functions involuntary, and postoperative swelling gradually decreases over several months.
3. Stoma classifications:
   a. End stoma: After the bowel is divided, the proximal bowel is exteriorized to abdominal wall, everted (which exposes mucosal lining), and sutured to the dermis or subcutaneous tissue. There is only one opening that drains stool. The distal bowel is either surgically removed or sutured closed within abdominal cavity.
   b. Double-barrel stoma: After the bowel is divided, the proximal and distal ends of the bowel are exteriorized to abdominal wall, everted, and sutured to the dermis or subcutaneous tissue. If the stomas are brought up next to each other requiring them to be pouched together, they are referred to as a double-barrel stoma; if the stomas are apart to be pouched separately, they may be referred to as an end stoma (proximal), which drains stool, and a mucous fistula (distal), which drains mucus. This type of stoma is usually temporary.
   c. Loop stoma: A bowel loop is brought to the abdominal wall through an incision and stabilized temporarily with a rod, catheter, or a skin or fascial bridge. The anterior wall of the bowel is opened surgically or by electrocautery to expose the proximal and distal openings. The posterior wall of the bowel remains intact and separates the functioning proximal opening and the nonfunctioning distal opening. This type of stoma is usually temporary.

Preoperative Management and Nursing Care

1. Prepare the patient for general abdominal surgery (see page 496). Have the patient see an ostomy specialty nurse.
   a. An ostomy specialty nurse has the title of certified ostomy care nurse or certified wound, ostomy, and continence nurse (CWOCN, previously known as a certified enterostomal therapy nurse). These nurses play a vital role in the rehabilitation of patients with ostomies and related problems.
   b. The Wound Ostomy and Continence Nurses Society has an official publication called the *Journal of Wound, Ostomy, and Continence Nursing* (*www.wocn.org*).
2. Administer replacement fluid, as ordered, before surgery because of possible increased output during the postoperative phase.
3. Provide low-residue diet before NPO status.
4. Explain that the abdomen may be marked by the ostomy specialty nurse or surgeon to ensure proper

positioning of the stoma. *Note:* The abdominal location of the stoma is usually determined by anatomical location of the bowel segment (eg, a sigmoid colostomy is ideally located in left lower abdominal quadrant).

5. Other considerations when selecting a stoma include:
   a. Positioning within rectus muscle.
   b. Avoidance of bony prominences, such as iliac crest and costal margin.
   c. Clearance from umbilicus, scars, and deep creases, observed in lying, sitting, and standing positions.
   d. Positioning on a flat pouching surface.
   e. Avoidance of beltline when possible.
   f. Positioning within patient's visibility to optimize independent ostomy care.
6. Support the patient and family with the many psychosocial considerations of ostomy surgery.

Postoperative Management and Nursing Care

1. Administer general abdominal surgery care (see page 496).
2. Assess stoma every shift for color and record findings:
   a. Normal color: pink-red.
   b. Dusky: dark red; purplish hue (ischemic sign).
   c. Necrotic: brown or black; may be dry (notify health care provider to determine extent of necrosis).
3. Apply pouching system as close to stoma as possible without it being rubbed. It is acceptable to have a 1/16- to 1/8-inch clearance to prevent constriction, which can contribute to edema (see Figure 18-4).
4. Check for abdominal distention, which reduces blood flow to stoma through mesenteric tension.
5. Evaluate and empty drains and ostomy pouch frequently to promote patency and maintain seal.
6. Monitor intake and output with extreme accuracy because output may remain high during early postoperative period.
7. Suction and irrigate NG tube frequently, as ordered, to relieve pressure and decrease gastric contents.
8. Offer continued support to patient and family.

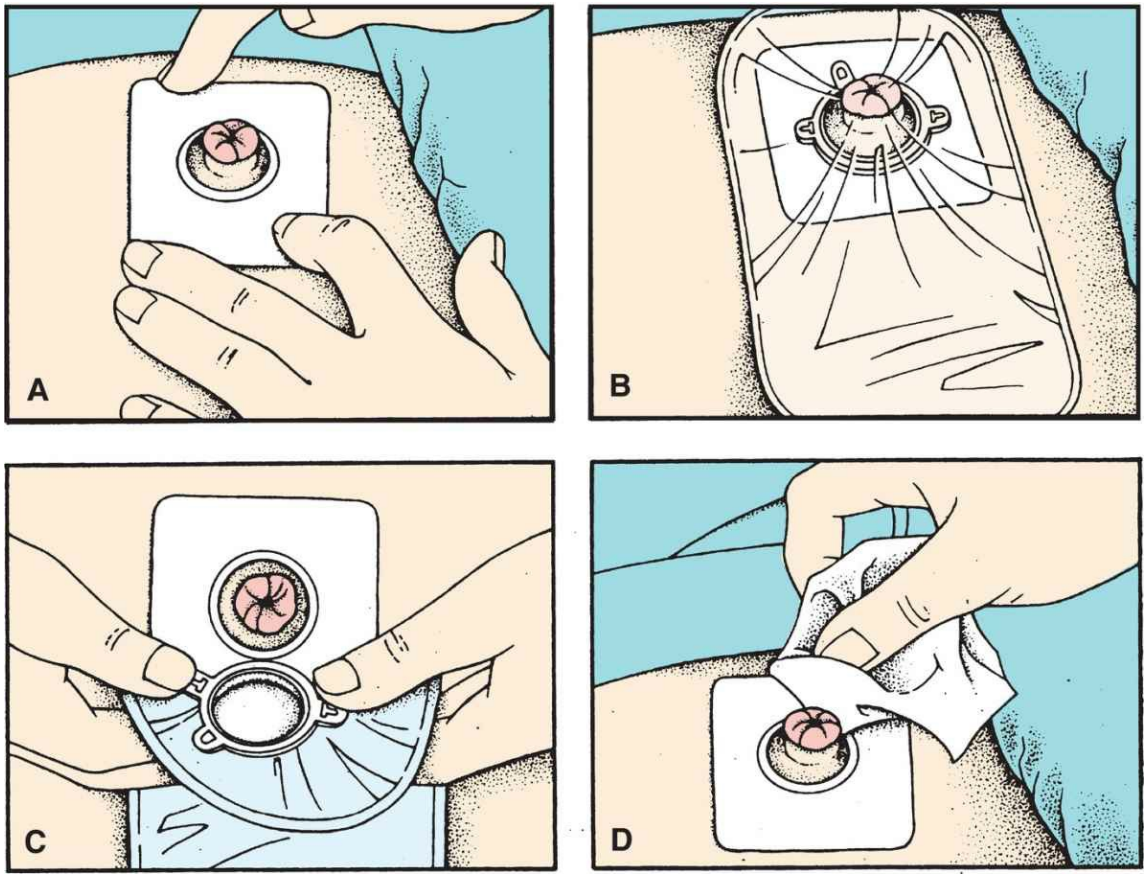

Figure 18-4. Changing a two-piece pouching system. Pouching systems are varied by manufacturer and chosen according to patient needs. Systems are one-piece or two-piece and disposable or reusable. A disposable, one-piece pouch is commonly used with backing as adhesive tape, skin barrier, or both. A disposable two-piece system consists of a skin barrier wafer with or without a tape border and a pouch. Reusable systems consist of double-backed adhesive disks, cement, or belt to provide a seal and can be used for weeks to months. **(A)** A wafer with flange (1.5 to 4 inch) is applied after cleaning and drying of peristomal skin. **(B)** A transparent or opaque drainable pouch is positioned over stoma at desired angle. **(C)** Pouch may be removed without removal of wafer. **(D)** Stoma may be assessed without removing wafer.

Complications

1. Mucocutaneous separation (between the skin and stoma).
2. Stomal ischemia.
3. Stomal stricture or stenosis (usually a long-term complication).
4. Stomal prolapse.
5. Peristomal hernia.
6. Stomal laceration.
7. Stomal retraction.
8. Peristomal skin breakdown from exposure to fecal output, allergic reaction to products, or infection, such

as candidiasis.

Nursing Diagnoses

- Deficient Knowledge related to surgical procedures and ostomy management.
- Disturbed Body Image related to change in structure, function, and appearance.
- Impaired Skin Integrity related to irritation of peristomal skin by drainage and equipment.
- Imbalanced Nutrition: Less Than Body Requirements related to increased output and inadequate intake.
- Sexual Dysfunction related to altered body structure.

Nursing Interventions

Educating the Patient

1. Review the surgical procedure with the patient and discuss the information that the surgeon and other providers have given. Clarify any misunderstandings.
2. Avoid overwhelming the patient with information.
3. Include family in discussions, when appropriate.
4. Use available educational materials, including pictures and drawings, if the patient is receptive.
5. Involve the ostomy specialty nurse (CWOCN) in ostomy teaching and reinforce information, including lifestyle modifications.
6. Use a team approach; the need for information may come from many disciplines.
7. Assess the patient's response to teaching. If the patient is not interested, provide alternative times for teaching and review.
8. Introduce gradual steps toward achieving independent ostomy management. The patient may progress through the following steps:
    a. Observe stoma, pouch change, and emptying procedure.
    b. Learn tail closure application and removal.
    c. Empty and rinse pouch.
    d. Assist with pouching system change until independent.
9. Consider the psychosocial issues of the patient and their effect on learning.

Promoting a Positive Self-Image

1. Encourage the patient to verbalize feelings about the surgical outcome. Acknowledge that it is normal to have negative feelings toward ostomy surgery; empathize with the patient.
2. Describe behaviors to attain a sense of control such as resuming ADLs.
3. Provide support during initial viewing of the stoma and encourage the patient to touch the area.
4. Encourage spouse or significant other to view the stoma.
5. Arrange a visit by a United Ostomy Association ostomy visitor if the patient desires. This is preferably

done preoperatively.

6. Offer counseling, as necessary, and encourage the patient to use normal support systems, such as family, church, and community groups.

Maintaining Skin Integrity

1. Select pouching system based on type of ostomy and condition of stoma and skin (see Figure 18-3).
2. Empty pouch when one-third to one-half full to avoid overfilling, which interferes with pouch seal.
   a. Remove tail closure from pouch tail.
   b. Cuff bottom of pouch tail.
   c. Drain stool from pouch.
   d. Clean pouch tail with toilet tissue or wipe (may rinse pouch if desired).
   e. Uncuff pouch and reapply tail closure.
3. Treat peristomal skin breakdown as needed.
   a. Dust skin breakdown with skin barrier powder (eg, Stomahesive powder).
   b. Seal powder with water or skin sealant (eg, Skin-Prep). May be applied one to three times per day, depending on the severity of the skin breakdown.
   c. Allow skin to dry before applying pouching system.

NURSING ALERT When peristomal skin is exposed to excess moisture, candidiasis can occur. It presents as an erythematous rash, which may include papules, pustules, or white patches. Patients may complain of pruritus. The treatment procedure is the same as for skin breakdown, using a prescribed antifungal powder (nystatin) in place of the skin barrier powder. The antifungal powder should be used at each pouching system change and continued 2 weeks after the condition has cleared. Positive identification of *Candida albicans* can be done through a culture or microscopic visualization. Treatment is usually initiated without culture or scraping if the signs and symptoms are classic.

Maximizing Nutritional Intake

1. Review dietary habits with the patient to determine patterns, preferences, and bowel irritants.
2. Advise the patient to avoid foods that stimulate elimination, such as nuts, seeds, and certain fruits.
3. Recommend consistency in dietary habits as well as moderation.
4. Coordinate consult with nutritionist, as needed.
5. Weigh daily; monitor vital signs and electrolytes to determine patient's nutritional status.

Achieving Sexual Well-Being

1. Encourage the patient and significant other to express feelings about the ostomy.
2. Discuss ways to conceal pouch during intimacy, if desired: pouch covers, special ostomy underwear. May

briefly use small-capacity pouch (minipouch or cap).

3. Recommend different positions for sexual activity to decrease stoma friction and skin irritation.
4. Review, when appropriate, that an ostomy in a woman does not prevent a successful pregnancy.
5. Recommend counseling as needed.

Patient Education and Health Maintenance

Skin Care

1. Instruct the patient to inspect peristomal skin with each pouching system change.
2. Review techniques for treating peristomal skin problems.
3. Recommend alternative products if patient develops allergic reaction to an ostomy product.
4. Teach the patient to notify health care provider when skin care problems do not resolve by usual methods.

Colostomy Irrigation

1. Teach colostomy irrigation procedure, to patients with a descending or sigmoid colostomy. Reinforce its purposes of cleansing the colon and stimulating the colon to move at a desired time regularly to regain control of fecal elimination.
   a. Irrigation may occur every day or every other day depending on bowel pattern.
   b. It usually takes 1 to 2 months to establish control.
   c. Patients with a preoperative history of regular, formed bowel movements are more likely to realize success.
2. Set up patient in front of commode with irrigation sleeve directed into the commode, and lubricate tip of the enema before gently inserting no more than 3 inches into stoma.
3. Allow solution to flow in slowly, over 5 to 10 minutes, and slower if cramping occurs.
4. Remove tubing and allow fecal matter to drain for 10 to 15 minutes before closing sleeve, which should be left in place for 20 more minutes before cleansing stoma and applying usual colostomy bag.

Odor Control

1. Encourage pouch hygiene through rinsing, keeping pouch tail free of stool, airing of reusable pouches, discarding odor-impregnated pouches.
2. Recommend the use of pouch deodorants, room deodorizers, and oral deodorizers, such as bismuth subgallate or parsley.
3. Avoid use of pinholes in pouch.

Gas Control

1. Suggest avoidance of straws, excessive talking while eating, chewing gum, and smoking to reduce swallowed air.
2. Instruct about gas-forming foods, such as beans and cabbage, and eliminate when appropriate. It takes

about 6 hours for gas to travel from the mouth to colostomy.

3. Recommend using the arm over stoma to muffle gas sounds when appropriate.

ADLs

Educate the patient about the following:

1. Resumption of normal bathing habits (tub or shower) with or without pouching system.
2. Picture framing the edges of the pouching system with waterproof tape, if needed, for bathing or swimming.
3. Clothing modifications are usually minimal. Girdles without stays and panty hose are acceptable.
4. Carrying an ostomy supply kit during work or travel in case of an emergency.
5. Participating in sports as desired. Caution must be exercised with contact sports. During vigorous activities, a belt or binder may provide extra security.
6. For additional information and support, refer to the United Ostomy Association, a self-help group for ostomates and other interested people, at *www.uoa.org*. The official membership publication is the *Ostomy Quarterly*. Encourage ostomy patients to participate in a local chapter. Chapters usually publish a local newsletter, conduct monthly meetings, and provide trained ostomy visitors on request by health care providers.
7. Ostomy manufacturers offer literature covering a wide variety of ostomy-related topics.
8. Encourage the patient to maintain contact with health care providers.

Evaluation: Expected Outcomes

- Verbalizes knowledge regarding ostomy surgery and general care of ostomy.
- Can view ostomy.
- No skin breakdown around ostomy.
- Plans menus with nutritionist; weight stable.
- Discusses intimacy concerns with partner.

ESOPHAGEAL DISORDERS

Esophageal varices are covered in Chapter 19, page 536.

Gastroesophageal Reflux Disease and Esophagitis

Gastric contents flow back into the esophagus, and sometimes further back into the mouth and lungs, in gastroesophageal reflux disease (GERD) because of incompetent lower esophageal sphincter (LES). Esophagitis, or inflammation of the esophageal mucosa, may result.

Pathophysiology and Etiology

1. Gastroesophageal reflux associated with an incompetent LES—gastric contents reflux (flow backward) through the LES into the esophagus.
2. Can be the result of impaired gastric emptying from gastroparesis or partial gastric outlet obstruction.
3. The acidity of gastric content and amount of time in contact with esophageal mucosa are related to the degree of mucosal damage.
4. Inflammation and ulceration of the esophagus may result, causing esophagitis.
5. May be caused by motility disorders (scleroderma, esophageal spasm).

Clinical Manifestations

GERD

1. The most common symptom is heartburn (pyrosis), typically occurring 30 to 60 minutes after meals and in reclining positions. May have complaints of spontaneous reflux (regurgitation) of sour or bitter gastric contents into the mouth.
2. Other typical symptoms include globus (sensation of something in the throat), mild epigastric pain, dyspepsia, and nausea and/or vomiting.
3. Dysphagia is a less common symptom.
4. Atypical symptoms include chest pain, hoarseness, recurrent sore throat, frequent throat clearing, chronic cough, dental enamel loss, bronchospasm (asthma/wheezing), and odynophagia (sharp substernal pain on swallowing).
5. Symptoms that may suggest other disease etiologies need further evaluation: atypical chest pain (rule out possible cardiac causes), dysphagia, odynophagia, GI bleeding, shortness of breath, or weight loss (rule out cancer or esophageal stricture).

Esophagitis

1. Esophagitis is an acute or chronic inflammation of the esophagus. Severity of symptoms may be unrelated to the degree of esophageal tissue damage.
2. Symptoms vary according to etiology of esophagitis. Symptoms include dysphagia, odynophagia, severe burning, chest pain.
3. Causes of esophagitis other than GERD:
   a. Infectious—*Candida*, herpes, human immunodeficiency virus, cytomegalovirus.
   b. Chemical (alkali or acid) or radiation therapy.

c. Medication-induced—may include doxycycline, ascorbic acid, quinidine, potassium chloride, bisphosphonates, tetracycline.

Diagnostic Evaluation

1. Uncomplicated GERD may be diagnosed on patient history of typical symptoms.
2. Endoscopy can visualize inflammation, lesions, or erosions. Biopsy can confirm diagnosis.
3. Esophageal manometry measures LES pressure and determines if esophageal peristalsis is adequate. This study should be used before patients undergo surgical treatment for reflux. This test is also done before a pH probe for determination of correct catheter placement.
4. Acid perfusion (Bernstein test)—onset of symptoms after ingestion of dilute hydrochloric acid and saline is considered positive. This test differentiates between cardiac and noncardiac chest pain.
5. Ambulatory 24-hour pH monitoring is performed when GERD is suspected but not responding to standard therapies, prior to antireflux surgery, or when the patient's symptoms may not be typical. It determines the amount of gastroesophageal acid reflux and has a 70% to 90% specificity rate.
   a. The Bravo pH capsule system is a catheter-free system in which a capsule containing a radiotelemetry pH sensor is inserted into the esophagus. This sensor transmits signals to an external pager-size receiver, allowing the patient to be catheter-free during the 24 hours of pH testing.
   b. The Bravo pH capsule system is contraindicated for patients with pacemakers, implantable defibrillators, or neurostimulators. It is also contraindicated for patients with a history of severe esophagitis, varices, obstructions, bleeding diatheses, or strictures.
6. Barium esophagography—use of barium with radiographic studies to diagnose mechanical and motility disorders. This test is not recommended in diagnosing GERD.

NURSING ALERT The patient should not undergo MRI within 30 days of Bravo capsule pH monitoring.

Management

Treatment goals include eliminating symptom, healing esophageal damage (if present), and preventing complications and relapse.

Lifestyle Modifications

1. Head of bed raised 6 to 8 inches (15 to 20 cm).
2. Do not lie down for 2 to 3 hours after eating—time frame for greatest reflux.
3. Bland diet—avoid garlic, onion, peppermint, fatty foods, chocolate, coffee (including decaffeinated), citrus juices, colas, and tomato products.
4. Avoid overeating—causes LES relaxation.
5. No tight-fitting clothes.

6. Weight loss.
7. Smoking cessation.
8. Reduce alcohol.

Pharmacologic Treatment

1. Antacids—reduce gastric acidity. Use on an as-needed basis. Provide symptomatic relief, but do not heal esophageal lesions.
2. Histamine-2 (H_2)-receptor antagonists, such as ranitidine, cimetidine, famotidine, nizatidine—decrease gastric acid secretions. Provide symptomatic relief. May require lifelong therapy.
3. If symptoms do not respond to H_2-receptor antagonist, change to a once-per-day proton pump inhibitor (PPI), such as omeprazole, esomeprazole, pantoprazole, rabeprazole, or lansoprazole, to block gastric acid secretion.
4. PPIs have been shown to be more effective than H_2-receptor antagonists in achieving faster healing rates for erosive esophagitis.
5. Drug maintenance therapy may be needed depending on the severity of disease and recurrence of symptoms after initial drug therapy is stopped.
6. Use the lowest effective drug dose of H_2-receptor blocker or PPI.

DRUG ALERT Patients with renal insufficiency and older patients may need decreased dosing of H_2-receptor antagonists.

DRUG ALERT PPIs should be taken 30 minutes before a meal for optimal control of gastric acidity. Impaired absorption of calcium may occur with PPI use, leading to fracture risk. Calcium citrate is recommended because it is not dependent on an acid environment for absorption.

Endoscopic and Surgical Treatment

1. Nissen fundoplication and bariatric surgery (for the obese patient) are the most common surgical therapies for long-term management of GERD. Surgery is not recommended for those who do not respond to PPI therapy.
   a. Upper portion of the stomach is wrapped around the distal esophagus and sutured, creating a tight LES.
   b. This procedure can be performed laparoscopically.
   c. Combined with vagotomy–pyloroplasty if associated with gastroduodenal ulcer.
   d. Antireflux surgery may not eliminate the need for future pharmacologic treatment.

2. Many endoscopic therapies for the treatment of GERD have not been efficacious and are no longer used. In the United States, there are only two endoscopic therapies being used:
    a. The Stretta procedure is a radiofrequency energy delivery system used to provide a thermal burn to the gastroesophageal junction.
    b. Transoral incisionless fundoplication (TIF) is done using the EsophyX device on an endoscope to tighten the GE valve, thereby reducing reflux.

Complications

1. Esophageal stricture formation.
2. Ulceration of the esophagus, with or without fistula formation.
3. Aspiration may be complicated by pneumonia.
4. Development of Barrett esophagus—presence of columnar epithelium above the gastroesophageal junction associated with adenocarcinoma of the esophagus.

Nursing Interventions and Patient Education

1. Teach the patient about prescribed medications, adverse effects, and when to notify the health care provider. PPIs may interact with carbamazepine, cyclosporine, diazepam, diclofenac, digoxin, iron, ketoconazole, lidocaine, methotrexate, metoprolol, nifedipine, phenytoin, propranolol, quinidine, theophylline, and warfarin.
2. Inform the patient about medications that may exacerbate symptoms. Anticholinergics may further impair functioning of the LES, allowing reflux; antihistamines, antidepressants, antihypertensives, antispasmodics, and some neuroleptics and antiparkinsonian drugs decrease saliva production, which may decrease acid clearance from the esophagus.
3. Advise the patient to sit or stand when taking any solid medication (pills, capsules): emphasize the need to follow the drug with at least 100 mL of liquid.
4. Familiarize the patient and family with foods and activities to avoid, such as fatty foods, garlic, onions, alcohol, coffee, chocolate, and peppermint.
5. Caution the patient against straining, bending over, tight-fitting clothes, and smoking.
6. Encourage the patient to sleep with the head of the bed elevated (not pillow elevation).
7. Encourage a weight reduction program, if the patient is overweight, to decrease intra-abdominal pressure.

Hiatal Hernia

A hiatal hernia is a protrusion of a portion of the stomach through the hiatus of the diaphragm and into the thoracic cavity.

Pathophysiology and Etiology

1. There are two types of hiatal hernias (see Figure 18-5):
   a. Sliding hernia: The stomach and gastroesophageal junction slip up into the chest (most common).
   b. Paraesophageal hernia (rolling hernia): Part of the greater curvature of the stomach rolls through the diaphragmatic defect.
2. Caused by muscle weakening because of aging or other conditions, such as esophageal carcinoma or trauma, or following certain surgical procedures.

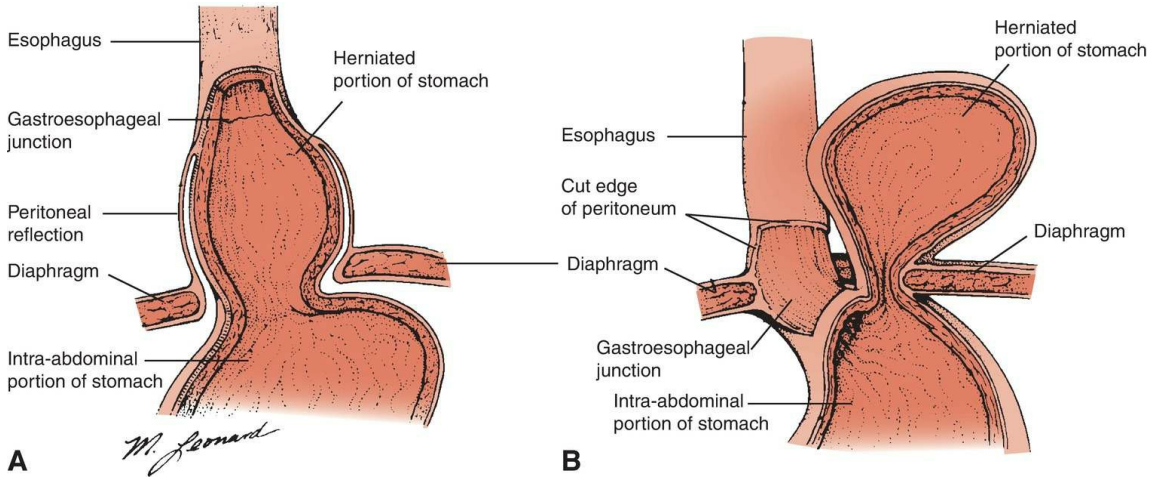

Figure 18-5. Hiatal hernia. **(A)** Sliding hernia. **(B)** Paraesophageal hernia.

Clinical Manifestations

1. May be asymptomatic.
2. Heartburn (with or without regurgitation of gastric contents into the mouth).
3. Dysphagia, chest pain.

Diagnostic Evaluation

1. Barium study of the esophagus outlines hernia.
2. Endoscopic examination visualizes defect.

Management

1. Elevation of the head of the bed (6 to 8 inches [15 to 20 cm]) to reduce nighttime reflux.
2. Antacid therapy to neutralize gastric acid.
3. H_2-receptor antagonist (cimetidine, ranitidine) if patient has esophagitis.

4. Surgical repair of hernia if symptoms are severe.

Complications

1. Aspiration of reflux contents.
2. Ulceration, hemorrhage.
3. Gastritis.
4. Stricture.
5. Incarceration of the portion of the stomach in the chest.

Nursing Interventions and Patient Education

1. Instruct the patient on the prevention of reflux of gastric contents into the esophagus by:
    a. Eating smaller meals.
    b. Avoiding stimulation of gastric secretions by omitting caffeine and alcohol.
    c. Refraining from smoking.
    d. Avoiding fatty foods: promote reflux and delay gastric emptying.
    e. Refraining from lying down for at least 1 hour after meals.
    f. Losing weight, if obese.
    g. Avoiding bending from the waist and/or wearing tight-fitting clothes.
2. Advise the patient to report to health care facility immediately for the onset of acute chest pain, which may indicate incarceration of a large paraesophageal hernia.

Esophageal Trauma and Perforations

Esophageal trauma or perforations are injuries to the esophagus caused by external or internal insult.

Pathophysiology and Etiology

1. External: Stab or bullet wounds, crush injuries, blunt trauma.
2. Internal:
    a. Swallowed foreign objects (coins, pins, bones, dental appliances, caustic poisons).
    b. Spontaneous or postemetic rupture—usually in the presence of underlying esophageal disease (reflux, hiatal hernia).
    c. Mallory-Weiss syndrome—nonpenetrating mucosal tear at the gastroesophageal junction. Caused by an increase in transabdominal pressure from lifting, vomiting, or retching. Alcoholism is a predisposing condition.

Clinical Manifestations

1. Pain at the site of injury or impaction, aggravated by swallowing—chest pain, may be severe.
2. Dysphagia or odynophagia.
3. Persistent foreign object sensation.
4. Subcutaneous emphysema and crepitus of the face, neck, or upper thorax—noted in cervical, thoracic, and esophageal perforations.
5. Temperature elevation occurring within 24 hours of trauma.
6. Blood-stained saliva or excessive salivation.
7. Hematemesis; previous history of vomiting or retching—Mallory-Weiss syndrome.
8. Respiratory difficulty if there is pressure on the tracheobronchial tree from injury or edema.

Diagnostic Evaluation

1. History of recent esophageal trauma.
2. Chest x-ray to look for foreign body.
3. Esophagogram to outline trauma.
4. Endoscopy to directly visualize trauma.

Management

1. Maintenance of adequate respiratory functioning; may require oxygen support or endotracheal intubation —to ensure an open airway in the presence of edema of the neck.
2. Replacement of fluids. May need blood transfusion. Bleeding may stop spontaneously; if not, endoscopic hemostatic therapy or surgery is indicated.
3. Restoration of the continuity of the esophagus by removing the cause.
4. For external wound injury, emergency first aid wound care and surgical repair may be indicated.

5. For swallowed foreign bodies:
    a. Barium swallow determines location of foreign body; usually removed through endoscopy.
    b. Some patients with a history of food impaction may be treated with a spasmolytic such as IV glucagon.
6. For chemical ingestion:
    a. If lye or other caustic or organic solvent was swallowed, do not try to induce vomiting.
    b. Treat with IV fluids and analgesics.
    c. A gastrostomy may be performed, either as a temporary or a permanent means of feeding the patient.
    d. Resulting strictures may be relieved by dilating the narrow esophagus.
    e. Reconstructive surgery may be necessary to create a new passageway for food between the pharynx and stomach.

Complications

1. Airway occlusion.
2. Shock.
3. Perforation with mediastinitis or pleural effusion.
4. Stricture formation.
5. Abscess or fistula formation.

Nursing Assessment

1. Assess the following to determine status of patient:
    a. Vital signs.
    b. Respiratory status.
    c. Bleeding.
    d. Ability to swallow—choking, gagging.
2. Monitor the patient for hypovolemic shock.

Nursing Diagnoses

- Deficient Fluid Volume related to blood loss from injury.
- Imbalanced Nutrition: Less Than Body Requirements related to esophageal injury.
- Ineffective Breathing Pattern related to pain and trauma.
- Acute Pain related to injury.

Nursing Interventions

Maintaining Fluid Volume

1. Administer IV fluids and blood transfusion for volume replacement, if indicated.
2. Monitor intake and output. Urine output should be greater than 30 mL/hour.

3. Monitor laboratory results (electrolytes, hemoglobin, and hematocrit) and report abnormal findings.

Maintaining Nutritional Status

1. Monitor daily weights and skin turgor.
2. Administer parenteral hyperalimentation as prescribed—to prevent gastric reflux into the esophagus, which may occur with enteral feedings.
3. Encourage progression of diet through NG, esophagostomy, or oral feedings when esophagoscopy or esophagogram reveals healing of the esophagus.
4. Continue to monitor intake and output.

Maintaining Respiratory Function

1. Auscultate the lungs and trachea for stridor, crackles, or wheezes. Assess respiratory rate, depth, use of accessory muscles, and skin color.
2. Position the patient in semi-Fowler position to facilitate breathing and reduce neck edema.
3. Monitor vital signs frequently for signs and symptoms of shock and infection.
4. Administer oxygen as prescribed.
5. Have emergency airway equipment at bedside.

Reducing Pain

1. Administer analgesics as prescribed—IV analgesia may be required to control pain and allow the esophagus to rest.
2. Provide reassurance and support.
3. Assess and record pain relief.
4. Evaluate for symptoms that may indicate spillage of digestive contents into the mediastinum, pleura, or abdominal cavity—sudden onset of acute pain.

Patient Education and Health Maintenance

1. Instruct the patient on the indications and adverse effects of analgesics.
2. Inform the patient on the signs and symptoms to report on possible complications: increase in severity or nature of pain and difficulty breathing or swallowing.
3. Teach patient with dysphagia how to swallow (see Box 18-2). This assists the patient who has difficulty swallowing after injury or surgical correction of the oropharynx or upper esophagus (also helpful with neurologic deficit or stroke).
4. Teach the patient about tests or surgical procedures that may be performed.

BOX 18-2 Teaching a Patient with Dysphagia How to Swallow

1. Sit the patient upright and the head in midline and forward position, chin pointed toward the chest.
2. Instruct the patient to smell the food before each bite; hold each bite for a few seconds; hold lips together firmly; concentrate on swallowing; then, swallow.

3. If the patient has an increase in saliva during the meal, instruct the patient to collect the saliva with the tongue and consciously swallow it between bites throughout the meal.
4. If the patient complains of a dry mouth during meals, instruct him to move tongue in a circular fashion against the insides of the cheeks to stimulate salivation.
5. Caution the patient against talking during the meal or with the mouth full of food.
6. Advise the following tips about food and fluid intake:
    a. Try foods that hold some shape and are moist enough to prevent crumbling but dry enough to hold a bolus shape—casseroles, custards, scrambled eggs.
    b. Use mugs and glasses with spouts or use a straw.
    c. Avoid sticky foods—peanut butter, chocolate, milk, ice cream.
    d. Moisten dry foods with margarine, gravy, or broths.
    e. Liquids such as juices can be thickened with sherbet.
    f. Safely try warm and cold foods and fluids, which are thought to maximally stimulate receptors that activate swallowing mechanism.

Evaluation: Expected Outcomes

- Urine output greater than 30 mL/hour; electrolytes stable.
- No further weight loss, tolerating parenteral feedings well.
- Lungs clear; respirations unlabored.
- States pain decreased to level of 2 or 3 on 0 to 10 scale.

Motility Disorders of the Esophagus

Primary motility disorders include achalasia, diffuse esophageal spasm, and those of nonspecific origin. Secondary motility disorders may be caused by neuromuscular, GI, endocrine, or connective tissue disorders.

Pathophysiology and Etiology

Primary Motility Disorders

1. Achalasia refers to excessive resting tone of the LES, incomplete relaxation of the LES with swallowing, and failure of normal peristalsis in the lower two thirds of the esophagus. The pathology is related to defective innervation of the myenteric plexus innervating the involuntary muscles of the esophagus.
2. Diffuse esophageal spasm is a motor disorder in which high-amplitude, nonpropulsive, nonperistaltic tertiary contractions (a form of aperistalsis) are present. LES functioning is frequently normal.

Secondary Motility Disorders

1. Neuromuscular dysfunction includes myasthenia gravis, Parkinson disease, muscular dystrophy, amyotrophic lateral sclerosis, and cerebral palsy.
2. Connective tissue disorders include scleroderma.
3. GI causes include GERD.
4. Other secondary causes include the autonomic neuropathy of diabetes mellitus.

Clinical Manifestations

Achalasia

1. Gradual onset of dysphagia with solids and liquids.
2. Substernal discomfort or a feeling of fullness.
3. Regurgitation of undigested food during a meal or within several hours after a meal.
4. Weight loss.

Diffuse Esophageal Spasm

1. Intermittent dysphagia for solids or liquids—does not progress to continuous dysphagia.
2. Aggravation of symptoms (large volume of food and hot or cold liquids).
3. Anterior chest pain.

Secondary Motility Disorders

Symptoms of esophagitis from gastroesophageal reflux.

Diagnostic Evaluation

Achalasia

1. Chest x-ray, which may show an enlarged, fluid-filled esophagus.

2. Barium esophagography showing dilation, decreased or absence of peristalsis, decreased emptying, and a "bird beak" narrowing of the distal esophagus.
3. Esophageal manometry to confirm the diagnoses suspected.
4. EUS or a chest CT for suspected tumor.

Diffuse Esophageal Spasm

1. Barium esophagography showing simultaneous contractions of the esophagus having a "corkscrew" or "rosary bead" appearance.
2. Esophageal manometry showing intermittent contractions with episodes of normal peristalsis.

Secondary Motility Disorders

Diagnostic workup may include barium esophagography or manometry.

Management

Achalasia

1. Drug therapy using calcium channel blockers such as nifedipine to reduce LES pressure. This type of treatment is usually best for patients presenting with mild symptoms and a nondilated esophagus or patients who are medically unstable to undergo invasive therapies.
2. Esophageal dilation using a balloon-tipped catheter is the preferred treatment for most patients.
3. Surgical therapy (Heller myotomy of the LES) may be used on patients who do not respond to balloon dilation. This surgery requires a laparotomy or thoracotomy or may be done through a thoracoscope.

Diffuse Esophageal Spasm

1. Drug therapy using nitrates and calcium channel blockers is the primary treatment.
2. Dilation may provide some symptom relief.
3. Surgical myotomy is used rarely for patients with a debilitating disorder who are able to withstand a surgical procedure.

Other Motility Disorders

1. Treatment of the gastroesophageal reflux.
2. Dilation may be required for peptic stricture.

Complications

1. Malnutrition.
2. Pneumonia, lung abscess, bronchiectasis from nocturnal regurgitation causing aspiration.
3. Esophagitis and esophageal diverticula.
4. Perforation from dilation procedure.
5. Peptic stricture or Barrett esophagus from severe erosive esophagitis.

Nursing Assessment

1. Assess for difficulty with swallowing, vomiting, weight loss, chest pain associated with eating.
2. Inquire as to what facilitates passage of food, such as position changes, use of liquids.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to dysphagia.
- Acute Pain related to heartburn or surgical procedure.

Nursing Interventions

Improving Nutritional Status

1. Direct the patient to eat sitting in an upright position; eat slowly and chew food thoroughly.
2. Avoid food and beverages that precipitate symptoms.
3. Suggest that the patient sleep with head elevated to avoid reflux or aspiration.
4. Provide a bland diet and tell the patient to avoid alcohol as well as spicy, very hot, and very cold foods, to minimize symptoms.
5. Eliminate sources of tension as a precipitating factor producing stress during mealtimes.
6. Administer pharmacologic agents as prescribed.

Promoting Comfort

1. Assess the patient for discomfort, chest pain, regurgitation, and cough. If a surgical procedure was performed, assess for incisional pain.
2. Provide appropriate postoperative care. Incisional approach determines the nature of postoperative care (eg, an incision through the chest implies nursing care similar to that given to a patient with a thoracotomy [see page 184]).
3. Administer analgesics as ordered.
4. Assess for effectiveness of pain medication.

Patient Education and Health Maintenance

1. Encourage lifestyle activity changes similar to those for patients with reflux (see page 503).
2. See Box 18-2 on page 505 to help the patient with dysphasia with swallowing.
3. Provide information on all diagnostic procedures or surgery performed.

Evaluation: Expected Outcomes

- Demonstrates proper positioning for eating; describes dietary habits that minimize symptoms; compliant with medications regimen.
- States pain decreased to 2 or 3 on 0 to 10 scale.

Esophageal Diverticulum

An esophageal diverticulum is an outpouching of the esophageal wall, usually in the cervical posterior side, secondary to an obstructive or inflammatory process.

Pathophysiology and Etiology

1. *Zenker diverticulum*—protrusion of pharyngeal mucosa at the pharyngoesophageal junction between the interior pharyngeal constrictor and cricopharyngeal muscle.
2. Mid or distal esophageal diverticula may develop above strictures or may be secondary to motility disorders.

Clinical Manifestations

Zenker Diverticulum

1. Difficulty in swallowing, fullness in the neck, throat discomfort, a feeling that food stops before it reaches the stomach, and regurgitation of undigested food.
2. Belching, gurgling, or nocturnal coughing brought about by diverticulum becoming filled with food or liquid, which is regurgitated and may irritate the trachea.
3. Halitosis and foul taste in the mouth caused by food decomposing in a pouch (diverticulum).
4. Weight loss because of nutritional depletion.

GERONTOLOGIC ALERT Hoarseness, asthma, and pneumonitis may be the only signs of esophageal diverticula in older adults.

Mid or Distal Esophageal Diverticula

Generally no symptoms.

Diagnostic Evaluation

1. Barium esophagogram outlines diverticulum.
2. Endoscopy is not indicated and may be dangerous because of the possibility of rupture.

Management

Zenker Diverticulum

1. Small Zenker diverticula may not be treated, but the underlying cause is treated with dilation or myotomy.
2. For larger Zenker diverticula, transverse cervical diverticulectomy or diverticulopexy with suspension and cricopharyngeal myotomy may be done.

a. Caution is taken to avoid injury to common carotid artery and internal jugular vein.
b. The sac is dissected free and then excised flush with esophageal wall.

3. For mid or distal esophageal diverticula, underlying primary condition must be treated.

Complications

1. Aspiration pneumonia.
2. Malnutrition.
3. Lung abscess.

Nursing Assessment

1. Obtain history of dysphagia, coughing, throat discomfort, choking, and regurgitation of food.
2. Evaluate for halitosis.
3. Determine what measures assist the patient with food intake and what foods and fluids the patient can tolerate.
4. Evaluate weight loss and dietary habits.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to dysphagia.
- Acute Pain related to symptoms and surgical procedure.

Nursing Interventions

Improving Nutritional Status

1. Provide frequent, small meals, which are better tolerated.
2. Elevate head of bed for 2 hours after eating.
3. Monitor intake and output.
4. Weigh daily.

Maintaining Comfort and Preventing Complications

1. Preoperatively, or if the condition is nonoperative, implement nursing interventions similar to those for esophagitis.
2. Postoperatively, wound care is similar to that of other surgical incisions of the same anatomical position (eg, thoracotomy [see page 184).
3. Administer appropriate pain medications and assess effectiveness.
4. Patient may need oral suctioning to control drooling.
5. Maintain NG tube if in place.
   a. Irrigate the tube as ordered.
   b. Do not manipulate NG tube because of location of the tube and suture line.

Patient Education and Health Maintenance

1. Instruct patient regarding treatment of esophagitis caused by gastroesophageal reflux (see page 502).
2. Instruct patient on importance of good oral hygiene.

Evaluation: Expected Outcomes

- Tolerates oral feedings; maintains weight.
- States pain decreased to 2 or 3 on 0 to 10 scale.

Cancer of the Esophagus

Malignant lesions of the esophagus occur in two main types that are defined histologically: squamous cell and adenocarcinoma.

Pathophysiology and Etiology

1. Adenocarcinoma is the most common type of esophageal cancer in the United States comprising 60% of all cases.
2. Squamous cell carcinoma cases have decreased significantly in the United States because of changes in lifestyle such as reduction of smoking and alcohol use.
3. Highest rate in the United States occurs in Caucasian men who are usually older than age 60.
4. Cause is unknown but has been associated with:
    a. Barrett esophagus.
    b. Achalasia.
    c. GERD.
    d. Chronic use of alcohol and tobacco (squamous cell carcinoma).
    e. Other head and neck cancers.

Clinical Manifestations

1. Dysphagia is the usual presenting symptom, although it is a late sign, by which time there often is regional or systemic involvement.
2. Mild, atypical chest pain associated with eating precedes dysphagia but is rarely significant enough for the patient to seek health care.
3. Pain on swallowing (odynophagia).
4. Progressive weight loss.
5. Hoarseness (if laryngeal involvement).
6. Lymphadenopathy (supraclavicular or cervical) or hepatomegaly with metastatic involvement.
7. Later symptoms—hiccups, respiratory difficulty, foul breath, and regurgitation of food and saliva.

Diagnostic Evaluation

1. Chest x-ray may show adenopathy, mediastinal widening, metastasis, or a tracheoesophageal fistula.
2. Endoscopy with cytology and biopsy.
3. Surveillance endoscopy of Barrett esophagus is beneficial for early detection of malignant changes.
4. Barium esophagram may show polypoid, infiltrative, or ulcerative lesion requiring biopsy.
5. CT scanning may be helpful in delineating the extent of the tumor as well as in identifying presence of adjacent tissue invasion and metastases.

Management

1. The goal of treatment may be cure or palliation, depending on the staging of the tumor and the patient's overall condition in relation to nutritional, cardiovascular, pulmonary, and functional status.
2. The wide variability in treatment reflects the overall poor results from any one approach.
3. Surgery.
    a. Lesions of the middle and lower esophagus are excised with use of the thoracotomy approach with esophagogastrectomy or colon interposition (section of the colon is used to replace the excised portion of the esophagus).
    b. Lesions of the cervical esophagus are excised with a bilateral neck dissection and esophagogastrectomy; laryngectomy and thyroidectomy may be necessary.
    c. A two-step approach may be selected when resection with a cervical esophagostomy and feeding gastrostomy are performed initially; subsequent reconstructive surgery is performed.
4. Radiation, chemotherapy, or their combination; combination therapy appears to have better results.
5. Palliative treatment of dysphagia through dilation done by endoscopy or laser therapy.
6. The goal of palliative treatment is to reduce the complications of the tumor to improve quality of life. Any one or a combination of the aforementioned therapies can be used for palliative treatment.

Complications

1. Preoperatively: Malnutrition, aspiration pneumonitis, hemorrhage, sepsis, and tracheoesophageal fistula.
2. Postoperatively: Pneumonia, dumping syndrome, nutritional deficiencies, reflux esophagitis, and anastomosis leakage.

Nursing Assessment

1. Obtain history of symptoms, such as dysphagia, pain, cough, and hoarseness.
2. Evaluate for dietary changes and weight loss.
3. Assess support system and personal coping mechanisms.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to disease process and treatment.
- Risk for Infection related to chronic disease, invasive procedures, and treatment.
- Ineffective Coping related to dealing with cancer.

Nursing Interventions

Improving Nutritional and Fluid Status

1. Provide the preoperative patient with a high-protein, high-calorie diet as tolerated. Nutritional supplements may be indicated. TPN may be ordered if unable to take food or fluids orally.
2. Postoperatively, administer IV fluids as prescribed. Initially, the patient may require large volumes if extensive excision of lymph nodes was performed. TPN may be ordered.
3. Assess for bowel sounds; administer fluids per NG tube and liquid feedings through jejunostomy, as

prescribed.

4. Encourage patient in advancing diet from liquids to soft foods.
5. Remind patient to remain in upright position for approximately 2 hours after eating to avoid reflux.
6. Provide mouth care for patient comfort and hygiene.

Monitoring for Complications

1. Monitor blood pressure (BP), pulse, respiration, and temperature to note early onset of hemorrhage, infection, dysrhythmias, aspiration, or anastomosis leakage.
2. Observe drainage from incision and/or chest tube for bleeding or purulence.
3. Monitor arterial blood gas (ABG) levels, manage pain, suction, provide chest physiotherapy, and provide oxygen as indicated.

Strengthening Individual Coping

1. Encourage patient to utilize support system during treatment and recovery process.
2. Provide information about laryngectomy, gastrostomy, and other procedures related to surgery, as indicated.
3. Provide training in relaxation techniques and diversional therapy for anxiety and pain control after surgery.
4. Refer to the American Cancer Society (*www.acs.org*) for additional information and sources of support.

Patient Education and Health Maintenance

1. Encourage the patient to avoid overeating, take small bites, chew food well, and avoid chunks of meat and stringy raw vegetables and fruit.
2. Depending on type of surgery, small, frequent meals may be better tolerated.
3. Encourage rest postoperatively and advancing activities as tolerated.
4. Instruct the patient regarding signs and symptoms of complications to report: nausea, vomiting, elevated temperature, cough, and difficulty swallowing.

Evaluation: Expected Outcomes

- Good skin turgor; eating small, frequent meals; gaining weight.
- Vital signs stable; incision without drainage.
- Performing self-care with the help of support people.

GASTRODUODENAL DISORDERS

Gastrointestinal Bleeding

GI bleeding is not just a gastroduodenal disorder but may occur anywhere along the alimentary tract. Bleeding is a symptom of an upper or lower GI disorder. It may be obvious in emesis or stool, or it may be occult (hidden).

Pathophysiology and Etiology

1. Trauma anywhere along the GI tract.
2. Erosions or ulcers.
3. Rupture of an enlarged vein such as a varicosity (esophageal or gastric varices).
4. Inflammation, such as esophagitis (caused by acid or bile), gastritis, inflammatory bowel disease (chronic ulcerative colitis, Crohn disease), and bacterial infection.
5. Alcohol and drugs (aspirin-containing compounds, NSAIDs, anticoagulants, corticosteroids).
6. Diverticular disease.
7. Cancers.
8. Vascular lesions or disorders, such as bowel ischemia, aortoenteric fistula, and arteriovenous malformations.
9. Mallory-Weiss tear.
10. Anal disorders, such as hemorrhoids or fissures.

Clinical Manifestations

Characteristics of Blood

1. Bright red: vomited from high in the esophagus (hematemesis); passed from the rectum or distal colon (coating stool).
2. Dark red: higher up in the colon and small intestine; mixed with stool.
3. Shades of black ("coffee ground"): vomited from the esophagus, stomach, and duodenum.
4. Tarry stool (melena): occurs in patient who accumulates excessive blood in the stomach.

Signs and Symptoms of Bleeding

1. Massive bleeding.
    a. Acute, bright red hematemesis or large amount of melena with clots in the stool.
    b. Rapid pulse, drop in BP, hypovolemia, and shock.
2. Subacute bleeding.
    a. Intermittent melena or coffee-ground emesis.
    b. Hypotension.
    c. Weakness and dizziness.
3. Chronic bleeding.

a. Intermittent appearance of blood.
b. Increased weakness, paleness, or shortness of breath.
c. Occult blood.
d. Iron deficiency anemia.

Diagnostic Evaluation

1. It is not difficult to diagnose bleeding, but it may be difficult to locate the source of bleeding.
2. History: change in bowel pattern, presence of pain or tenderness, recent intake of food and what kind (eg, red beets), alcohol consumption, and drugs (eg, aspirin or steroids).
3. Complete blood count (CBC) (hemoglobin, hematocrit, platelets) and coagulation studies (partial thromboplastin time, prothrombin time with international normalized ratio) may show abnormalities.
4. An NG tube may be used to determine if bleeding is occurring in the upper GI tract; however, there is not good evidence to support this practice and its utility is falling by the wayside.
5. Endoscopy: identifies source of bleeding, determines risk of rebleeding, and provides endoscopic therapy, if needed.
6. Colonoscopy: identifies source of lower GI bleeding and allows for therapy if needed.
7. Imaging may detect cause of bleeding.
8. Test of stool for occult blood.

Management

Based on Etiology

1. If aspirin or NSAIDs are the cause, discontinue medication and treat bleeding.
2. If ulcer is the cause, assess medications, dietary and lifestyle modifications, and for *Helicobacter pylori*.
3. Therapeutic endoscopic procedure (cautery, injection).
4. Surgery may be indicated for cancers, inflammatory diseases, and vascular disorders.

Emergency Intervention

1. Patient remains on NPO status.
2. IV lines and oxygen therapy initiated.
3. If life-threatening bleeding occurs, treat shock; administer blood replacement, intra-arterial vasopressin or embolization.
4. Surgical therapy, if indicated.

Other Measures

1. Electrocoagulation using a heater probe.
2. Injection of sclerosant or epinephrine.
3. Banding or clips.
4. Intravenous PPIs are sometimes used to reduce risk of rebleeding.

5. IV antibiotics may be given to reduce risk for secondary infections, which can occur after GI bleeding, and thereby reduce risk for mortality.
6. Beta-blockers may be given to reduce rebleeding risk in those with esophageal/gastric varices.
7. Surgery is indicated when more conservative measures fail.

Complications

1. Hemorrhage.
2. Shock.
3. Death.
4. Infection.

Nursing Assessment

1. Obtain history regarding:
   a. Change in bowel patterns or hemorrhoids.
   b. Change in color of stools (dark black, red, or streaked with blood).
   c. Alcohol consumption.
   d. Medications, such as aspirin, NSAIDs, antibiotics, anticoagulants, and corticosteroids.
   e. Hematemesis.
   f. Other medical conditions.
2. Evaluate for presence of abdominal pain or tenderness.
3. Monitor vital signs and laboratory tests for changes that indicate bleeding (hemoglobin, hematocrit, platelet count, coagulation studies).
4. Test for occult blood, if indicated.
5. Assess output as renal perfusion may be affected.

Nursing Diagnoses

- Deficient Fluid Volume related to blood loss.
- Imbalanced Nutrition: Less Than Body Requirements related to nausea, vomiting, and diarrhea.

Nursing Interventions

Attaining Normal Fluid Volume

1. Maintain NG tube and NPO status to rest GI tract and evaluate bleeding.
2. Monitor intake and output, as ordered, to evaluate fluid status.
3. Monitor vital signs, as ordered.
4. Observe for changes indicating shock, such as tachycardia, hypotension, increased respirations, decreased urine output, and change in mental status.
5. Administer IV fluids and blood products, as ordered, to maintain volume.

Attaining Balanced Nutritional Status

1. Weigh daily to monitor caloric status.
2. Administer IV fluids, TPN, if ordered, to promote hydration and nutrition while on oral restrictions.
3. Begin liquids when patient is no longer NPO. Advance diet as tolerated. Diet should be high-calorie and high-protein. Small, frequent feedings may be indicated.
4. Offer snacks; high-protein supplements.

Patient Education and Health Maintenance

1. Discuss the cause and treatment of GI bleeding with patient.
2. Instruct patient on reporting signs and symptoms of GI bleeding: melena, emesis that is bright red or "coffee-ground" color, rectal bleeding, weakness, fatigue, and shortness of breath.
3. Instruct patient on how to test stool or emesis for occult blood, if applicable.

Evaluation: Expected Outcomes

- Intake and output equal; vital signs stable.
- Tolerates small feedings; weight stable.

Peptic Ulcer Disease

Peptic ulcer disease refers to ulcerations in the mucosa of the lower esophagus, stomach, or duodenum (see Figure 18-6).

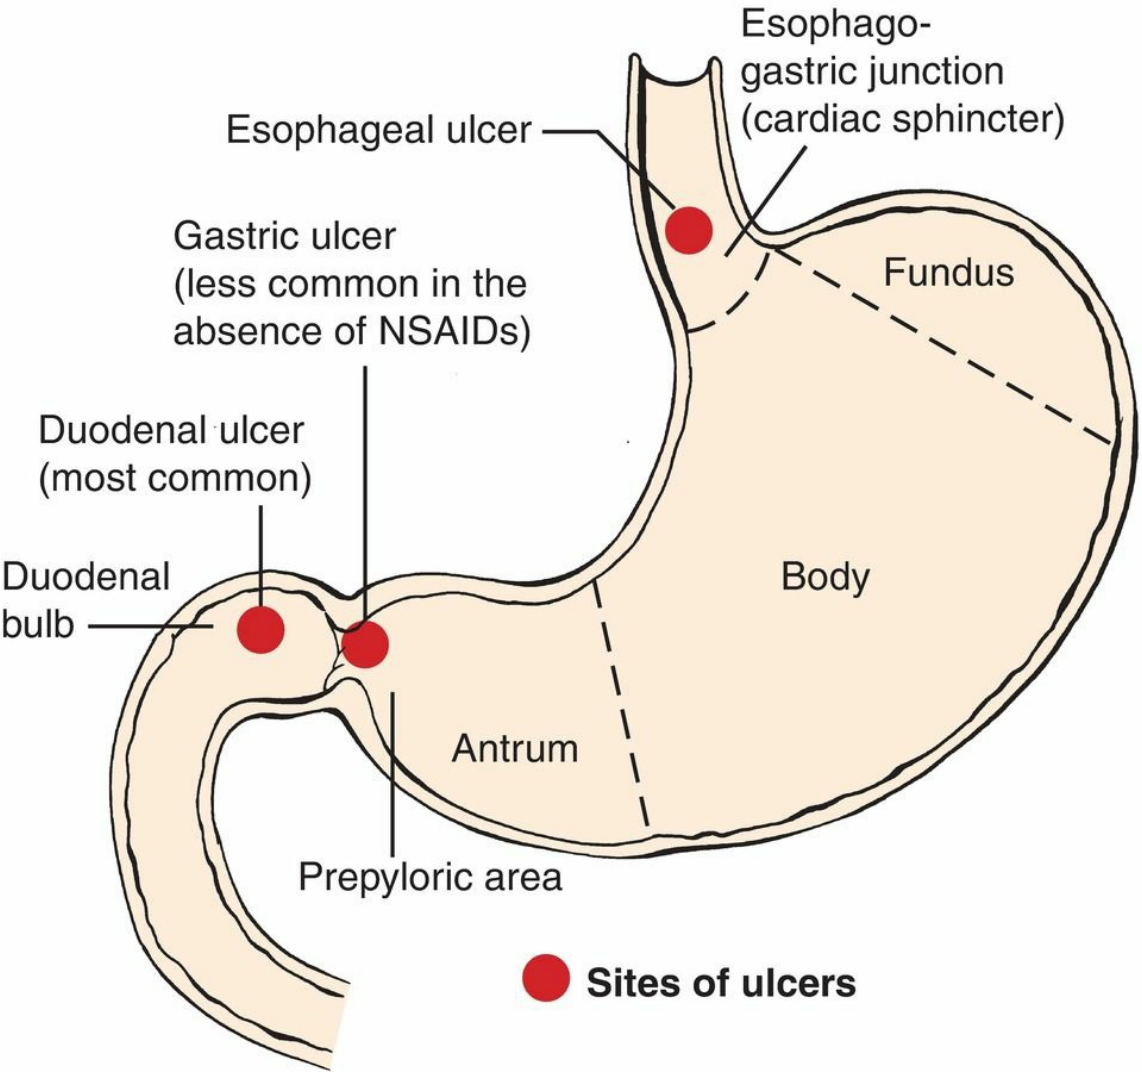

Figure 18-6. Esophageal, gastric, and duodenal ulcer sites.

Pathophysiology and Etiology

1. Etiology of peptic ulcer disease is multifactorial.
   a. *H. pylori* infection—present in most patients with peptic ulcer disease.
   b. NSAID-induced injury—presents as a chemical gastropathy.
   c. Acid secretory abnormalities (especially in duodenal ulcers).
   d. Zollinger-Ellison syndrome (hypersecretory syndrome) should be considered in refractory ulcers.
2. Risk factors may include drugs (NSAIDs, prolonged high-dose corticosteroids), family history, Zollinger-Ellison syndrome, cigarettes, stress, O blood type, and lower socioeconomic status.

3. Studies are inconclusive in determining an association between ulcer formation and diet or the intake of alcohol and caffeine.

Clinical Manifestations

1. Gnawing or burning epigastric pain occurring 1½ to 3 hours after a meal.
2. Nocturnal epigastric, abdominal pain or burning; may awaken patient at night, usually around midnight to 3 A.M.
3. Epigastric tenderness on examination.
4. Early satiety, anorexia, weight loss, heartburn, and belching (may indicate reflux disease).
5. Dizziness, syncope, hematemesis, or melena (may indicate hemorrhage).
6. Anemia.

NURSING ALERT Sudden, intense midepigastric pain radiating to the right shoulder may indicate ulcer perforation.

Diagnostic Evaluation

1. Upper GI endoscopy with possible tissue biopsy and cytology.
   a. PyloriTek, a biopsy urea test, is up to greater than 97% specific and greater than 96% sensitive for detection of *H. pylori*.
   b. Point-of-service test with results within 1 hour.

EVIDENCE BASE Serim Research Corporation. (2012). PyloriTek for *H. pylori*. Available: *www.serim.com/products_overview.aspx?fid=2.*

---

2. Upper GI radiographic examination (barium study).
3. Serial stool specimens to detect occult blood.
4. Gastric secretory studies (gastric acid secretion test and fasting serum gastrin level)—elevated in Zollinger-Ellison syndrome.
5. Serology to test for *H. pylori* antibodies or stool test to assess for *H. pylori* antigen.
6. C-urea breath test to detect *H. pylori*.

DRUG ALERT Stop antisecretory PPI at least 2 weeks before the C-urea breath test. It can cause false-negative test result.

Management

General Measures

1. Eliminate use of NSAIDs or other causative drugs.
2. Eliminate cigarette smoking (impairs healing).
3. A well-balanced diet with meals at regular intervals. Avoid dietary irritants.

Drug Therapy

Multiple drug regimens are used to treat *H. pylori* (see Table 18-2, page 511), usually involving triple therapy with two antibiotics and a proton pump inhibitor for 10 to 14 days to eradicate the bacteria.

Table 18-2 Medication Considerations for *H. pylori* Therapy

COMMON DRUG REGIMEN	DOSING	NURSING CONSIDERATIONS
Omeprazole 20 mg Amoxicillin 1,000 mg Clarithromycin 500 mg	bid × 14 d bid × 14 d bid × 14 d	• Antibiotics: Metronidazole and clarithromycin may cause unpleasant metallic taste, nausea, and vomiting; it may help to eat small, frequent meals, suck on sugar-free candy, take with food. Avoid alcohol within 72 hours of taking metronidazole; can cause severe reaction. Clarithromycin may interact with lovastatin, salmeterol, phenytoin, and other medications; do not drink grapefruit juice during therapy. Tetracycline may increase sensitivity to sun; food and dairy products decrease absorption. Report inability to take antibiotic or vomiting doses. Report watery or bloody diarrhea, which may indicate pseudomembranous colitis.
PPI (standard dose) Bismuth subsalicylate 300 mg Metronidazole 250 mg Tetracycline 500 mg	bid × 10 to 14 d qid × 10 to 14 d qid × 10 to 14 d qid × 10 to 14 d	• Proton pump inhibitors: may cause dizziness, headache, and stomach upset. Best taken before meals. Do not take with certain drugs such as antiepileptics and warfarin. • Bismuth subsalicylate: Interacts with many drugs such as antiepileptics, salicylates, corticosteroids. May turn stool black. May interfere with radiologic testing of the GI tract. Report ringing in the ears may indicate salicylate toxicity.
DRUG ALERT Avoid treatment if patient may be pregnant.		

DRUG ALERT Antibiotic resistance is a problem that has led to longer therapy and research into alternative drug regimens.

Surgery

1. Surgical interventions may be indicated for hemorrhage, obstruction, perforation, and acid reduction (see Figure 18-7, page 511). Surgery may also be indicated with ulcer disease of long duration or severity or difficulty with medical regimen compliance.
2. Gastroduodenostomy (Billroth I).
   a. Partial gastrectomy with removal of antrum and pylorus of the stomach.
   b. The gastric stump is anastomosed with the duodenum.
3. Gastrojejunostomy (Billroth II).

a. Partial gastrectomy with removal of antrum and pylorus of the stomach.

b. The gastric stump is anastomosed with the jejunum.

4. Antrectomy.

a. Gastric resection includes a small cuff of duodenum, the pylorus, and the antrum (lower half of the stomach).

b. The duodenal stump is closed and the jejunum is anastomosed to the stomach.

5. Total gastrectomy.

a. Also called an esophagojejunostomy.

b. Removal of the stomach with attachment of the esophagus to the jejunum or duodenum.

6. Pyloroplasty.

a. A longitudinal incision is made in the pylorus, and it is closed transversely to permit the muscle to relax and to establish an enlarged outlet.

b. Often, a vagotomy is performed at the same time.

7. Vagotomy.

a. The surgical division of the vagus nerve to eliminate the impulses that stimulate HCL secretion.

b. There are three types: *selective vagotomy*, which severs only the branches that interrupt acid secretion; *truncal vagotomy*, which severs the anterior and posterior trunks to decrease acid secretion and gastric motility; and *parietal vagotomy*, which severs only the part of vagus that innervates the parietal acid–secreting cells.

c. Traditionally performed by laparotomy, the vagotomy procedure can also be done using a laparoscope.

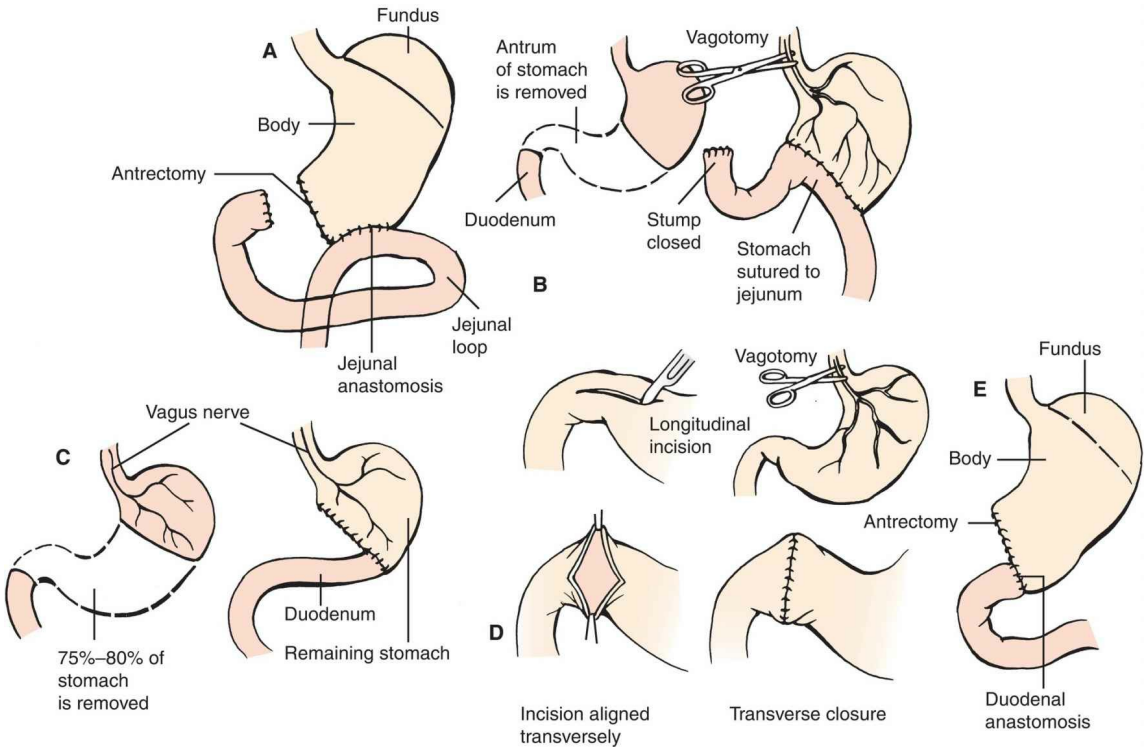

Figure 18-7. Surgical procedures for peptic ulcer. **(A)** Gastrojejunostomy (Billroth II). The jejunum is anastomosed to the gastric stump after a partial gastrectomy (removal of antrum and pylorus). **(B)** Antrectomy and vagotomy. The resected portion includes a small cuff of the duodenum, the pylorus, and the antrum (about one half of the stomach). The stump of the duodenum is closed by suture, and the side of the jejunum is anastomosed to the cut end of the stomach. **(C)** Subtotal gastrectomy. The resected portion includes a small cuff of the duodenum, the pylorus, and from two thirds to three quarters of the stomach. The duodenum or side of the jejunum is anastomosed to the remaining portion of the stomach. **(D)** Vagotomy and pyloroplasty. A longitudinal incision is made in the pylorus, and it is closed transversely to permit the muscle to relax and to establish an enlarged outlet. This compensates for the impaired gastric emptying produced by vagotomy. **(E)** Gastroduodenostomy (Billroth I). The duodenum is anastomosed to the gastric stump after removal of the antrum and pylorus (partial gastrectomy).

Complications

1. GI hemorrhage.
2. Ulcer perforation.
3. Gastric outlet obstruction.

Nursing Assessment

1. Determine location, character, and radiation of pain, factors aggravating or relieving pain, how long it lasts, and when it occurs.
2. Ask about eating patterns, regularity, types of food, and eating circumstances.
3. Ask about medications (especially aspirin, steroids, or anti-inflammatory drugs).
4. Inquire about a history of illnesses, including previous GI bleeds.
5. Obtain psychosocial history.
6. Perform physical assessment with documentation of positive abdominal findings.
7. Take vital signs, including lying, standing, and sitting BPs and pulses, to determine if orthostasis is present due to bleeding.

Nursing Diagnoses

- Deficient Fluid Volume related to hemorrhage.
- Acute Pain related to epigastric distress secondary to hypersecretion of acid, mucosal erosion, or perforation.
- Diarrhea related to GI bleeding.
- Imbalanced Nutrition: Less Than Body Requirements related to the disease process.
- Deficient Knowledge related to physical, dietary, and pharmacologic treatment of disease.

Nursing Interventions

Avoiding Fluid Volume Deficit

1. Monitor intake and output continuously to determine fluid volume status.
2. Monitor stools for blood and emesis.
3. Monitor hemoglobin and hematocrit and electrolytes.
4. Administer prescribed IV fluids and blood replacement, as prescribed.
5. Insert NG tube as prescribed, and monitor the tube drainage for signs of visible and occult blood.
6. Administer medications through the NG tube to neutralize acidity, as prescribed.
7. Prepare the patient for saline lavage, as ordered.
8. Observe the patient for an increase in pulse and a decrease in BP (signs of shock).
9. Prepare the patient for diagnostic procedure or surgery to determine or stop the source of bleeding.

Achieving Pain Relief

1. Administer prescribed medication.
2. Provide small, frequent meals to prevent gastric distention if not NPO.
3. Advise the patient about the irritating effects of certain drugs and foods.

Decreasing Diarrhea

1. Monitor the patient's elimination patterns to determine effects of medications.
2. Monitor vital signs and watch for signs of hypovolemia.
3. Administer antidiarrheal medication as prescribed.
4. Watch for signs and symptoms of impaired skin integrity (erythema, pain, pruritus) around the anus to promote comfort and decrease risk of infection.

Achieving Adequate Nutrition

1. Eliminate foods that cause pain or distress; otherwise, the diet is usually not restricted.
2. Provide small, frequent meals that neutralize gastric secretions and may be better tolerated.
3. Provide high-calorie, high-protein diet with nutritional supplements, as ordered.
4. Administer parenteral nutrition, as ordered, if bleeding is prolonged and patient is malnourished.

Educating the Patient about the Treatment Regimen

1. Explain all tests and procedures to increase knowledge and cooperation and minimize anxiety.
2. Review the health care provider's recommendations for diet, activity, medication, and treatment. Allow time for questions and clarify any misunderstandings.
3. Give the patient a chart listing medications, dosages, times of administration, and desired effects to promote compliance.

Patient Education and Health Maintenance

1. Teach the patient the signs and symptoms of bleeding and when to notify the health care provider.

2. Promote healthy lifestyle changes to include adequate nutrition, cessation of smoking, decreased alcohol consumption, and stress reduction strategies.
3. Explain the purpose, dosage, and adverse effects of each medication prescribed.

Evaluation: Expected Outcomes

- Vital signs stable; fluid volume maintained.
- Pain free.
- No more than two to three loose stools per day.
- Eats small, frequent meals each day; reports no loss of weight.
- Describes peptic ulcer disease, its treatment, and complications; complies with treatment regimen.

Gastric Cancer

Malignant tumor of the stomach.

Pathophysiology and Etiology

1. Risk factors include:
    a. Chronic atrophic gastritis with intestinal metaplasia.
    b. Pernicious anemia or having had gastric resections (more than 15 years).
    c. Gastric adenomatous polyps (more common in men).
    d. Incidence increases with age.
    e. Cigarette smoking.
    f. Family history of gastric cancer.

Clinical Manifestations

1. Typically, patient presents with same symptoms as gastric ulcer; later, on evaluation, the lesion is found to be malignant.
2. Progressive loss of appetite, noticeable change in or appearance of common GI symptoms—gastric fullness (early satiety) and dyspepsia lasting longer than 4 weeks.
3. Blood (usually occult) in the stools.
4. Vomiting—may indicate pyloric obstruction or cardiac–orifice obstruction. Occasionally, vomiting has a coffee-ground appearance because of slow leaks of blood from ulceration of the cancer.
5. Later manifestations include the following:
    a. Pain, usually induced by eating and relieved by vomiting.
    b. Weight loss, loss of strength, anemia, metastasis (usually to the liver), hemorrhage, and obstruction.
    c. Abdominal or epigastric mass.

Diagnostic Evaluation

1. History—weight loss and fatigue over several months.
2. Upper GI radiography and endoscopy—afford visualization and provide means for obtaining tissue samples for histologic and cytologic review.
3. Imaging, such as bone or liver scan—may determine extent of disease.

Management

1. The only successful treatment of gastric cancer is surgical removal. Gastric resection is surgical removal of part of the stomach.
2. If tumor has spread beyond the area that can be excised surgically, cure is not possible.
    a. Palliative surgery, such as subtotal gastrectomy with or without gastroenterostomy, may be performed to maintain continuity of the GI tract.

b. Surgery may be combined with chemotherapy to provide palliation and prolong life.

Complications

1. If surgery is performed, possible risk of hemorrhage or infection.
2. Dumping syndrome following gastrectomy.
3. Metastasis and death.

Nursing Assessment

1. Assess for anorexia, weight loss, and GI symptoms (gastric fullness, dyspepsia, vomiting).
2. Evaluate for pain, noting characteristics/location.
3. Check stool for occult blood.
4. Monitor CBC to assess for anemia.

Nursing Diagnoses

- Pain related to disease process or surgery.
- Risk for Injury, Shock, and Other Complications related to surgery and impaired gastric tissue function.
- Imbalanced Nutrition: Less Than Body Requirements related to malignancy and treatment.

Nursing Interventions

Promoting Comfort and Wound Healing

1. Turning, coughing, and deep breathing every 2 hours to prevent vascular and pulmonary complications and promote comfort.
2. Institute NG suction, if ordered, to remove fluids and gas in the stomach and prevent painful distention.
3. Administer parenteral antibiotics, as ordered, to prevent infection.
4. Administer analgesics, as ordered.

Preventing Shock and Other Complications

1. Shock and hemorrhage.
    a. Monitor changes in BP, pulse, and respiration.
    b. Observe the patient for evidence of changes in mental status, pallor, clammy skin, and dizziness.
    c. Check the dressings and suction canister frequently for evidence of bleeding.
    d. Administer IV infusions and blood replacement, as prescribed.
2. Cardiopulmonary complications.
    a. Encourage the patient to cough and take deep breaths to promote ventilatory exchange and enhance circulation.
    b. Assist the patient to turn and move, thereby mobilizing secretions.
    c. Promote ambulation, as prescribed, to increase respiratory exchange.

3. Thrombosis and embolism.
    a. Initiate a plan of self-care activities to promote circulation.
    b. Encourage early ambulation to stimulate circulation.
    c. Prevent venous stasis by use of elastic stockings, if indicated.
    d. Check for tight dressings or binder that might restrict circulation.
4. Dumping syndrome—a complex reaction that may occur because of excessively rapid emptying of gastric contents. Manifestations include nausea, weakness, perspiration, palpitation, some syncope, and possibly diarrhea. Instruct the patient as follows:
    a. Eat small, frequent meals rather than three large meals.
    b. Suggest a diet high in protein and fat and low in carbohydrates, and avoid meals high in sugars, milk, chocolate, and salt.
    c. Reduce fluids with meals, but take them between meals.
    d. Take anticholinergic medication before meals (if prescribed) to lessen GI activity.
    e. Relax when eating; eat slowly and regularly.
    f. Take a rest after meals.
5. Phytobezoar formation (formation of gastric concretion composed of vegetable matter) can be seen with partial gastrectomy and vagotomy. After a gastric resection, the remaining gastric tissue is not able to disintegrate and digest fibrous foods. This undigested fiber congeals to form masses that become coated by mucus secretions of the stomach.
    a. Avoid fibrous foods, such as citrus fruits (skins and seeds), because they tend to form phytobezoars.
    b. Stress the importance of adequate chewing.

Attaining Adequate Nutritional Status

1. Administer parenteral nutrition, if ordered.
2. Follow prescribed diet progressions.
    a. Give fluids by mouth when audible bowel signs are present.
    b. Increase fluids according to the patient's tolerance.
    c. Offer a diet with vitamin supplements when the patient's condition permits.
    d. Avoid high-carbohydrate foods, such as milk, which may trigger dumping syndrome.
    e. Offer diet, as prescribed—usually high in protein and calories to promote wound healing.

Patient Education and Health Maintenance

1. Emphasize the importance of coping with stressful situations. Provide information about support groups.
2. Review nutritional requirements with the patient.
3. Stress the importance of IM vitamin B_{12} supplements after gastrectomy to prevent surgically induced pernicious anemia.
4. Encourage follow-up visits with the health care provider.

5. Recommend annual blood studies and medical checkups for any evidence of pernicious anemia or other problems.
6. Instruct on measures to prevent dumping syndrome.

Evaluation: Expected Outcomes

- States pain decreased to 2 or 3 on 0 to 10 scale.
- Vital signs stable; no evidence of complications.
- Tolerating small, frequent meals.

Intestinal Conditions

Abdominal Hernias

An abdominal hernia occurs when the contents of the abdomen, usually the small intestine, push through a weak point in the muscular wall of the abdomen. The weakness of the abdominal wall can be congenital in nature, because of acquired weakness (eg, aging or trauma) or because of increased intra-abdominal pressure (eg, because of heavy lifting, obesity, pregnancy, straining, coughing, ascites, or proximity to tumor).

Pathophysiology and Etiology

Classification by Site

1. Inguinal—a hernia into the inguinal canal that is more common in males (see Figure 18-8). This type of hernia is further differentiated based on the causative factor.
   a. Indirect inguinal—congenital hernia that occurs when the entrance of the inguinal canal does not close after birth, causing a weakness in the abdominal wall. Through this weakened area, the hernia extends down the inguinal canal and often into the scrotum or labia.
   b. Direct inguinal—caused by degeneration of the abdominal muscles allowing the small intestine to pass through the posterior inguinal wall into the groin.
2. Femoral—hernia follows the tract below the inguinal ligament through the femoral canal.
3. Umbilical—intestinal protrusion at the umbilicus because of failure of umbilical orifice to close. Occurs most often in obese women, in children, and in patients with increased intra-abdominal pressure from cirrhosis and ascites.
4. Ventral or incisional—intestinal protrusion because of weakness at the abdominal wall; may occur after impaired incisional healing because of infection or drainage.
5. Peristomal—hernia through the fascial defect around a stoma and into the subcutaneous tissue.

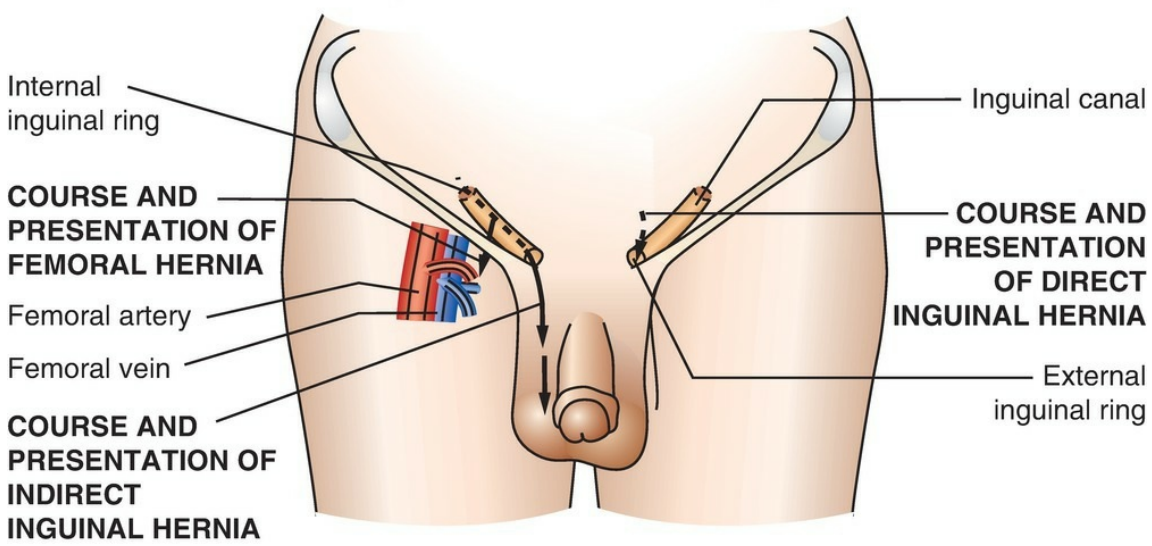

Figure 18-8. Direct and indirect inguinal hernia. (Bickley, L. [2003]. *Bates' guide to physical examination and history taking* [8th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Classification by Severity

1. Reducible—the protruding mass can be placed back into the abdominal cavity.
2. Irreducible—the protruding mass cannot be moved back into the abdomen.
3. Incarcerated—an irreducible hernia in which the intestinal flow is completely obstructed.
4. Strangulated—an irreducible hernia in which the blood and intestinal flow are completely obstructed; develops when the loop of the intestine in the sac becomes twisted or swollen and a constriction is produced at the neck of the sac.

Clinical Manifestations

1. Bulging over herniated area appears when the patient stands or strains and disappears when supine.
2. Hernia tends to increase in size and recurs with intra-abdominal pressure.
3. Strangulated hernia presents with pain, vomiting, swelling of hernial sac, lower abdominal signs of peritoneal irritation, and fever.

Diagnostic Evaluation

1. Usually diagnosed by clinical manifestations:
2. Abdominal x-rays—reveal abnormally high levels of gas in the bowel.
3. Laboratory studies (complete blood count, electrolytes)—may show hemoconcentration (increased hematocrit), dehydration (increased or decreased sodium), and elevated white blood cell (WBC) count, if strangulated.

Management

1. Mechanical (reducible hernia only).
    a. A truss is an appliance with a pad and belt that is held snugly over a hernia to prevent abdominal contents from entering the hernial sac. A truss provides external compression over the defect and should be removed at night and reapplied in the morning before patient arises. This nonsurgical approach may be used only when a patient is not a surgical candidate.
    b. Peristomal hernia is often managed with a hernia support belt with Velcro, which is placed around an ostomy pouching system (similar to a truss).
    c. Conservative measures—no heavy lifting, straining at stool, or other measures that would increase intra-abdominal pressure.
2. Surgical—recommended to correct hernia before strangulation occurs, which then becomes an emergency situation.
    a. Herniorrhaphy—removal of hernial sac; contents replaced into the abdomen; layers of muscle and fascia sutured. Laparoscopic herniorrhaphy is a possibility and often performed as outpatient

procedure.

b. Hernioplasty involves reinforcement of suturing (often with mesh) for extensive hernia repair.
c. Strangulated hernia requires resection of ischemic bowel in addition to repair of hernia.

Complications

1. Bowel obstruction.
2. Recurrence of hernia.

Nursing Assessment

1. Ask the patient if hernia is enlarging and uncomfortable, reducible or irreducible; determine relationship to exertion and activities.
2. Assess bowel sounds and determine bowel pattern.
3. Determine if the patient is exhibiting signs and symptoms of strangulation, such as distention, fever, nausea, and vomiting.

Nursing Diagnoses

- Chronic Pain related to bulging hernia (mechanical).
- Acute Pain related to surgical procedure.
- Risk for Infection related to emergency procedure for strangulated or incarcerated hernia.

Nursing Interventions

Achieving Comfort

1. Fit the patient with truss or belt when hernia is reduced, if ordered.
2. Trendelenburg position may reduce pressure on hernia, when appropriate.
3. Emphasize to the patient to wear truss under clothing and to apply before getting out of bed when hernia is reduced.
4. Give stool softeners, as directed.
5. Evaluate for signs and symptoms of hernial incarceration or strangulation.
6. Insert NG tube for incarcerated hernia, if ordered, to relieve intra-abdominal pressure on herniated sac.

Relieving Pain Postoperatively

1. Have the patient splint the incision site with hand or pillow when coughing to lessen pain and protect site from increased intra-abdominal pressure.
2. Administer analgesics, as ordered.
3. Teach about bed rest, intermittent ice packs, and scrotal elevation as measures used to reduce scrotal edema or swelling after repair of an inguinal hernia.
4. Encourage ambulation as soon as permitted.
5. Advise the patient that difficulty in urinating is common after surgery; promote elimination to avoid

discomfort, and catheterize if necessary.

Preventing Infection

1. Check dressing for drainage and incision for redness and swelling.
2. Monitor for other signs and symptoms of infection: fever, chills, malaise, and diaphoresis.
3. Administer antibiotics, if appropriate.

Patient Education and Health Maintenance

1. Advise that pain and scrotal swelling may be present for 24 to 48 hours after repair of an inguinal hernia.
   a. Apply ice intermittently.
   b. Elevate scrotum and use scrotal support.
   c. Take medication prescribed to relieve discomfort.
2. Teach to monitor self for signs of infection: pain, drainage from incision, and temperature elevation. Also, report continued difficulty in voiding.
3. Inform that heavy lifting should be avoided for 4 to 6 weeks. Athletics and extremes of exertion are to be avoided for 8 to 12 weeks postoperatively, per provider instructions.

Evaluation: Expected Outcomes

- Hernia effectively reduced with truss or belt; patient comfortable.
- Verbalizes pain decreased to 2 or 3 on 0 to 10 scale.
- No swelling present; afebrile and no drainage from incision.

Intestinal Obstruction

Intestinal obstruction is an interruption in the normal flow of intestinal contents along the intestinal tract. The block may occur in the small or large intestine, may be complete or incomplete, may be mechanical or paralytic, and may or may not compromise the vascular supply. Obstruction most frequently occurs in the young and the old.

Pathophysiology and Etiology

Types and Causes

1. Mechanical obstruction—a physical block to passage of intestinal contents without disturbing blood supply of the bowel. High small bowel (jejunal) or low small bowel (ileal) obstruction occurs four times more frequently than colonic obstruction (see Figure 18-9). Causes include:
    a. Extrinsic—adhesions from surgery, hernia, wound dehiscence, masses, volvulus (twisted loop of the intestine). Up to 70% of small bowel obstructions are caused by adhesions.
    b. Intrinsic—hematoma, tumor, intussusception (telescoping of intestinal wall into itself), stricture or stenosis, congenital conditions (atresia, imperforate anus), trauma, inflammatory diseases (Crohn, diverticulitis, ulcerative colitis).
    c. Intraluminal—foreign body, fecal or barium impaction, polyp, gallstones, meconium in infants.
    d. In postoperative patients, approximately 90% of mechanical obstructions are due to adhesions. In nonsurgical patients, hernia (most often inguinal) is the most common cause of mechanical obstruction.
2. Paralytic (adynamic, neurogenic) ileus.
    a. Peristalsis is ineffective (diminished motor activity perhaps because of toxic or traumatic disturbance of the autonomic nervous system).
    b. There is no physical obstruction and no interrupted blood supply.
    c. Disappears spontaneously after 2 to 3 days.
    d. Causes include:
        i. Spinal cord injuries; vertebral fractures.
        ii. Postoperatively after any abdominal surgery.
        iii. Peritonitis, pneumonia.
        iv. Wound dehiscence (breakdown).
        v. GI tract surgery.
3. Strangulation—obstruction compromises blood supply, leading to gangrene of the intestinal wall. Caused by prolonged mechanical obstruction.

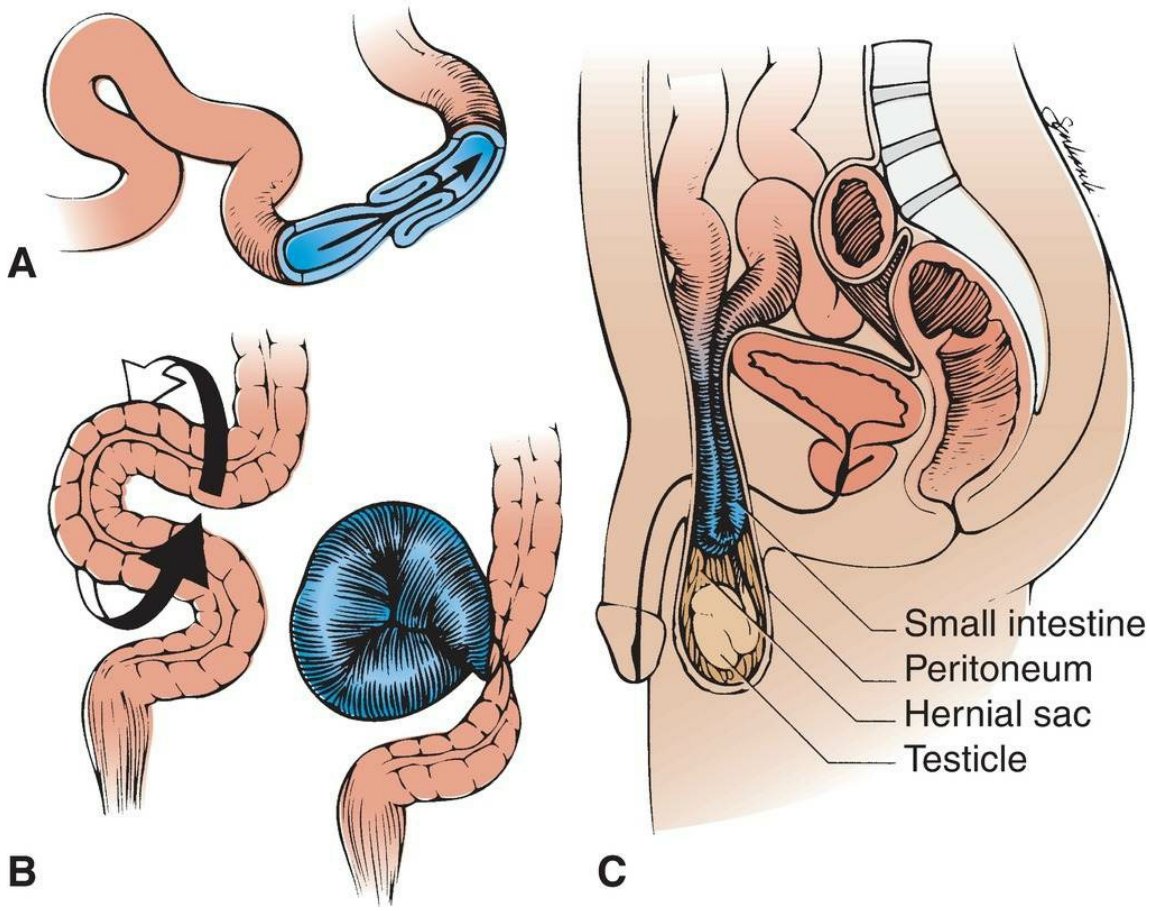

Figure 18-9. Three causes of intestinal obstruction. **(A)** Intussusception. Note shortening of the colon by the movement of one segment of the bowel into another. **(B)** Volvulus of the sigmoid colon. The twist is counterclockwise in most cases of sigmoid volvulus. **(C)** Hernia (inguinal). Note that the sac of the hernia is a continuation of the peritoneum of the abdomen and that the hernial contents are the intestine, omentum, or other abdominal contents that pass through the hernial opening into the hernial sac.

Altered Physiology

1. Increased peristalsis, distention by fluid and gas, and increased bacterial growth proximal to obstruction. The intestine empties distally.
2. Increased secretions into the intestine are associated with diminution in the bowel's absorptive capacity.
3. The accumulation of gases, secretions, and oral intake above the obstruction causes increasing intraluminal pressure.
4. Venous pressure in the affected area increases and circulatory stasis and edema result.
5. Bowel necrosis may occur because of anoxia and compression of the terminal branches of the mesenteric artery.
6. Bacteria and toxins pass across the intestinal membranes into the abdominal cavity, thereby leading to peritonitis.
7. "Closed loop" obstruction is a condition in which the intestinal segment is occluded at both ends,

preventing either the downward passage or the regurgitation of intestinal contents.

Clinical Manifestations

Fever, peritoneal irritation, increased WBC count, toxicity, and shock may develop with all types of intestinal obstruction.

1. Simple mechanical—high small bowel: colic (cramps); mid- to upper abdomen, some distention, early bilious vomiting, increased bowel sounds (high-pitched tinkling heard at brief intervals), minimal diffuse tenderness.
2. Simple mechanical—low small bowel: significant colic (cramps), midabdominal, considerable distention, vomiting slight or absent, later feculent, increased bowel sounds and "hush" sounds, minimal diffuse tenderness.
3. Simple mechanical—colon: cramps (mid- to lower abdomen), later-appearing distention, and then vomiting may develop (feculent); increase in bowel sounds; minimal diffuse tenderness.
4. Partial chronic mechanical—may occur with granulomatous bowel in Crohn disease. Symptoms are cramping, abdominal pain, mild distention, and diarrhea.
5. Strangulation symptoms are initially those of mechanical obstruction, but progress rapidly—pain is severe, continuous, and localized. There is moderate distention, persistent vomiting, usually decreased bowel sounds, and marked localized tenderness. Stools or vomitus becomes bloody or contains occult blood.

Diagnostic Evaluation

1. Fecal material aspiration from NG tube.
2. Abdominal and chest x-rays.
   a. May show presence and location of small or large intestinal distention, gas, or fluid.
   b. "Bird beak" lesion in colonic volvulus.
   c. Foreign body visualization.
3. Contrast studies—small bowel follow-through with water-soluble contrast (eg, Gastrografin) can be both diagnostic and therapeutic.
4. Laboratory tests.
   a. Electrolytes, BUN, and creatinine may be abnormal because of hypovolemia and vomiting.
   b. Elevated WBC counts because of inflammation; marked increase with necrosis, strangulation, or peritonitis.
   c. Lactate level may be increased if ischemia of small bowel is present.
5. Flexible sigmoidoscopy or colonoscopy may identify the source of the obstruction such as tumor or stricture.

Management

Nonsurgical Management

1. Correction of fluid and electrolyte imbalances with normal saline or Ringer solution with potassium as required.
2. NG suction to decompress bowel and decrease risk of perforation.
3. Treatment of shock and peritonitis.
4. TPN may be necessary to correct protein deficiency from chronic obstruction, paralytic ileus, or infection.
5. Analgesics and sedatives, avoiding opiates because of GI motility inhibition.
6. Antibiotics to prevent or treat infection.
7. Ambulation for patients with paralytic ileus to encourage return of peristalsis.

Surgery

Consists of relieving obstruction. Options include:

1. Closed bowel procedures: lysis of adhesions, reduction of volvulus, intussusception, or incarcerated hernia.
2. Enterotomy for removal of foreign bodies or bezoars.
3. Resection of the bowel for obstructing lesions or strangulated bowel with end-to-end anastomosis.
4. Intestinal bypass around obstruction.
5. Temporary ostomy may be indicated (see "Caring for the Patient Undergoing Ostomy Surgery," page 498).

Complications

1. Dehydration because of loss of water, sodium, and chloride.
2. Peritonitis.
3. Shock because of loss of electrolytes and dehydration.
4. Death because of shock.

Nursing Assessment

1. Assess the nature and location of the patient's pain and the presence or absence of distention, flatus, defecation, emesis, and obstipation.
2. Listen for high-pitched bowel sounds, peristaltic rushes, or absence of bowel sounds.
3. Assess vital signs.

GERONTOLOGIC ALERT Watch for air–fluid lock syndrome in older patients, who typically remain in the recumbent position for extended periods. Fluid collects in dependent bowel loops and peristalsis is too weak to push fluid "uphill." Conduct frequent checks of the patient's level of responsiveness; decreasing responsiveness may offer a clue to an increasing electrolyte imbalance or impending shock.

Nursing Diagnoses

- Acute Pain related to obstruction, distention, and strangulation.
- Risk for Deficient Fluid Volume related to impaired fluid intake, vomiting, and diarrhea from intestinal obstruction.
- Ineffective Breathing Pattern related to abdominal distention, interfering with normal lung expansion.
- Risk for Ineffective Gastrointestinal Perfusion.

Nursing Interventions

Achieving Pain Relief

1. Administer prescribed analgesics.
2. Provide supportive care during NG intubation to assist with discomfort.
3. To relieve air–fluid lock syndrome, turn the patient from supine to prone position every 10 minutes until enough flatus is passed to decompress the abdomen. A rectal tube may be indicated.
4. To reduce fear and anxiety associated with pain, recognize the patient's concerns and initiate measures to provide emotional support. Encourage presence of support person.

Maintaining Electrolyte and Fluid Balance

1. Measure and record all intake and output.
2. Administer IV fluids and parenteral nutrition as prescribed.
3. Monitor electrolytes, urinalysis, hemoglobin, and blood cell counts, and report any abnormalities. Collect stool samples to test for occult blood, if ordered.
4. Monitor urine output to assess renal function and to detect urine retention because of bladder compressions by the distended intestine.
5. Monitor vital signs; a drop in BP may indicate decreased circulatory volume because of blood loss from strangulated hernia.
6. Record amount and consistency of stools.

Maintaining Proper Lung Ventilation

1. Keep the patient in Fowler position to promote ventilation and relieve abdominal distention.
2. Maintain NG tube as prescribed to decompress bowel.
3. Monitor ABG levels for oxygenation levels, if ordered.

Ensuring Gastrointestinal Perfusion to Prevent Complications

1. Prevent infarction by carefully assessing the patient's status; pain that increases in intensity or becomes localized or continuous may herald strangulation.
2. Detect early signs of peritonitis, such as rigidity and tenderness, in an effort to minimize this complication.
3. Avoid enemas, which may distort an x-ray or make a partial obstruction worse.

4. Observe for signs of shock—pallor, tachycardia, hypotension.
5. Watch for signs of:
    a. Metabolic alkalosis (slow, shallow respirations; changes in sensorium; tetany).
    b. Metabolic acidosis (disorientation; deep, rapid breathing; weakness; and shortness of breath on exertion).

Patient Education and Health Maintenance

1. Explain the rationale for NG suction, NPO status, and IV fluids initially. Advise the patient to progress diet slowly as tolerated once home.
2. Advise plenty of rest and slow progression of activity as directed by surgeon or other health care provider.
3. Teach wound care, if indicated.
4. Encourage the patient to follow-up as directed and to call surgeon or health care provider if increasing abdominal pain, vomiting, or fever occurs prior to follow-up.

Evaluation: Expected Outcomes

- Maintains position of comfort; states pain decreased to 3 or 4 on 0 to 10 scale.
- Urine output greater than 30 mL/hour; vital signs stable.
- Respirations 24 breaths/minute and unlabored with head of bed elevated 45 degrees.
- Alert, lucid, vital signs stable, abdomen firm, not rigid.

Appendicitis

Appendicitis is inflammation of the vermiform appendix caused by an obstruction of the intestinal lumen from infection, stricture, fecal mass, foreign body, or tumor.

Pathophysiology and Etiology

1. Obstruction is followed by edema, infection, and ischemia.
2. As intraluminal tension develops, necrosis and perforation usually occur.
3. Appendicitis can affect any age group; most common in adolescents/young adults, especially males.

Clinical Manifestations

1. Generalized or localized abdominal pain in the epigastric or periumbilical areas and upper right abdomen. Within 2 to 12 hours, the pain localizes in the right lower quadrant and intensity increases.
2. Anorexia, moderate malaise, mild fever, nausea, and vomiting.
3. Usually, constipation occurs, occasionally diarrhea.
4. Rebound tenderness, involuntary guarding, generalized abdominal rigidity.

Diagnostic Evaluation

1. Physical examination consistent with clinical manifestations.
2. WBC count reveals moderate leukocytosis (10,000 to 16,000/mm^3) with shift to the left (increased immature neutrophils).
3. Urinalysis to rule out urinary disorders.
4. Abdominal x-ray may visualize shadow consistent with fecalith in appendix; perforation will reveal free air.
5. Abdominal ultrasound or CT scan can visualize the appendix and rule out other conditions, such as diverticulitis and Crohn disease. Focused appendiceal CT can quickly evaluate for appendicitis.

GERONTOLOGIC ALERT In older adults, be aware of vague symptoms: milder pain, less pronounced fever, and leukocytosis with shift to the left on differential.

Management

1. Surgery (appendectomy) is indicated.
   a. Simple appendectomy or laparoscopic appendectomy in absence of rupture or peritonitis.
   b. An incisional drain may be placed if an abscess or rupture occurs.
2. Preoperatively maintain bed rest, NPO status, IV hydration, possible antibiotic prophylaxis, and analgesia.

Complications

1. Perforation (in 95% of cases).
2. Abscess.
3. Peritonitis.

Nursing Assessment

1. Obtain history for location and extent of pain.
2. Auscultate for presence of bowel sounds; peristalsis may be absent or diminished.
3. On palpation of the abdomen, assess for tenderness anywhere in the right lower quadrant, but usually localized over McBurney point (point just below midpoint of line between the umbilicus and iliac crest on the right side). Assess for rebound tenderness in the right lower quadrant as well as referred rebound when palpating the left lower quadrant.
4. Assess for positive psoas sign by having the patient attempt to raise the right thigh against the pressure of your hand placed over the right knee. Inflammation of the psoas muscle in acute appendicitis will increase abdominal pain with this maneuver.
5. Assess for positive obturator sign by flexing the patient's right hip and knee and rotating the leg internally. Hypogastric pain with this maneuver indicates inflammation of the obturator muscle.

Nursing Diagnoses

- Acute Pain related to inflamed appendix.
- Risk for Infection related to perforation.

Nursing Interventions

Preoperative nursing care is listed; for postoperative care, see "Caring for the Patient Undergoing Gastrointestinal Surgery," page 496.

Relieving Pain

1. Monitor pain level, including location, intensity, pattern.
2. Assist patient to comfortable positions, such as semi-Fowler and knees up.
3. Restrict activity that may aggravate pain, such as coughing and ambulation.
4. Apply ice bag to the abdomen for comfort.
5. Give antiemetics and analgesics, as ordered, and evaluate response.
6. Avoid indiscriminate palpation of the abdomen to avoid increasing the patient's discomfort.

DRUG ALERT Do not give analgesics/antipyretics to mask fever, and do not administer cathartics because they may cause rupture.

Preventing Infection

1. Monitor frequently for signs and symptoms of worsening condition indicating perforation, abscess, or peritonitis: increasing severity of pain, tenderness, rigidity, distention, ileus, fever, malaise, and tachycardia.
2. Administer antibiotics, as ordered.
3. Promptly prepare the patient for surgery.

Patient Education and Health Maintenance

1. Instruct the patient to avoid heavy lifting for 4 to 6 weeks after surgery.
2. Instruct the patient to report symptoms of anorexia, nausea, vomiting, fever, abdominal pain, incisional redness, or drainage postoperatively.

Evaluation: Expected Outcomes

- Verbalizes decreased pain to 2 or 3 on 0 to 10 scale with positioning and analgesics.
- Afebrile; no rigidity or distention.

Diverticular Disease

EVIDENCE BASE Stollman, N., Smalley, W., Hirano, I., et al. (2015). American Gastroenterology Association Institute guidelines on the management of acute diverticulitis. *Gastroenterology, 149*, 2944–1949.

Diverticular disease is a wide-spectrum disease encompassing all problems that can be caused by diverticula. A *diverticulum* is a pouch or saccular dilation of the colon wall. *Diverticulosis* is a condition exhibiting multiple diverticula without inflammation. *Diverticulitis* is inflammation and infection of one or more diverticula. Diverticular disease is usually categorized into complicated or uncomplicated disease.

Pathophysiology and Etiology

Diverticulosis

1. Marks the formation of diverticula, which are herniations of the mucosal and submucosal layers of the colon developing at weak points where nutrient blood vessels penetrate the colon wall (see Figure 18-10).
2. Causes for diverticular disease are unclear, but data suggest excessive intraluminal pressure plays a key role. A contributing factor may be a low-residue diet, which reduces fecal residue, narrows the bowel lumen, and leads to higher pressure intra-abdominally during defecation.
3. The risk of developing diverticulosis is about 40% by age 60 and more than 60% of those 80 years and older.

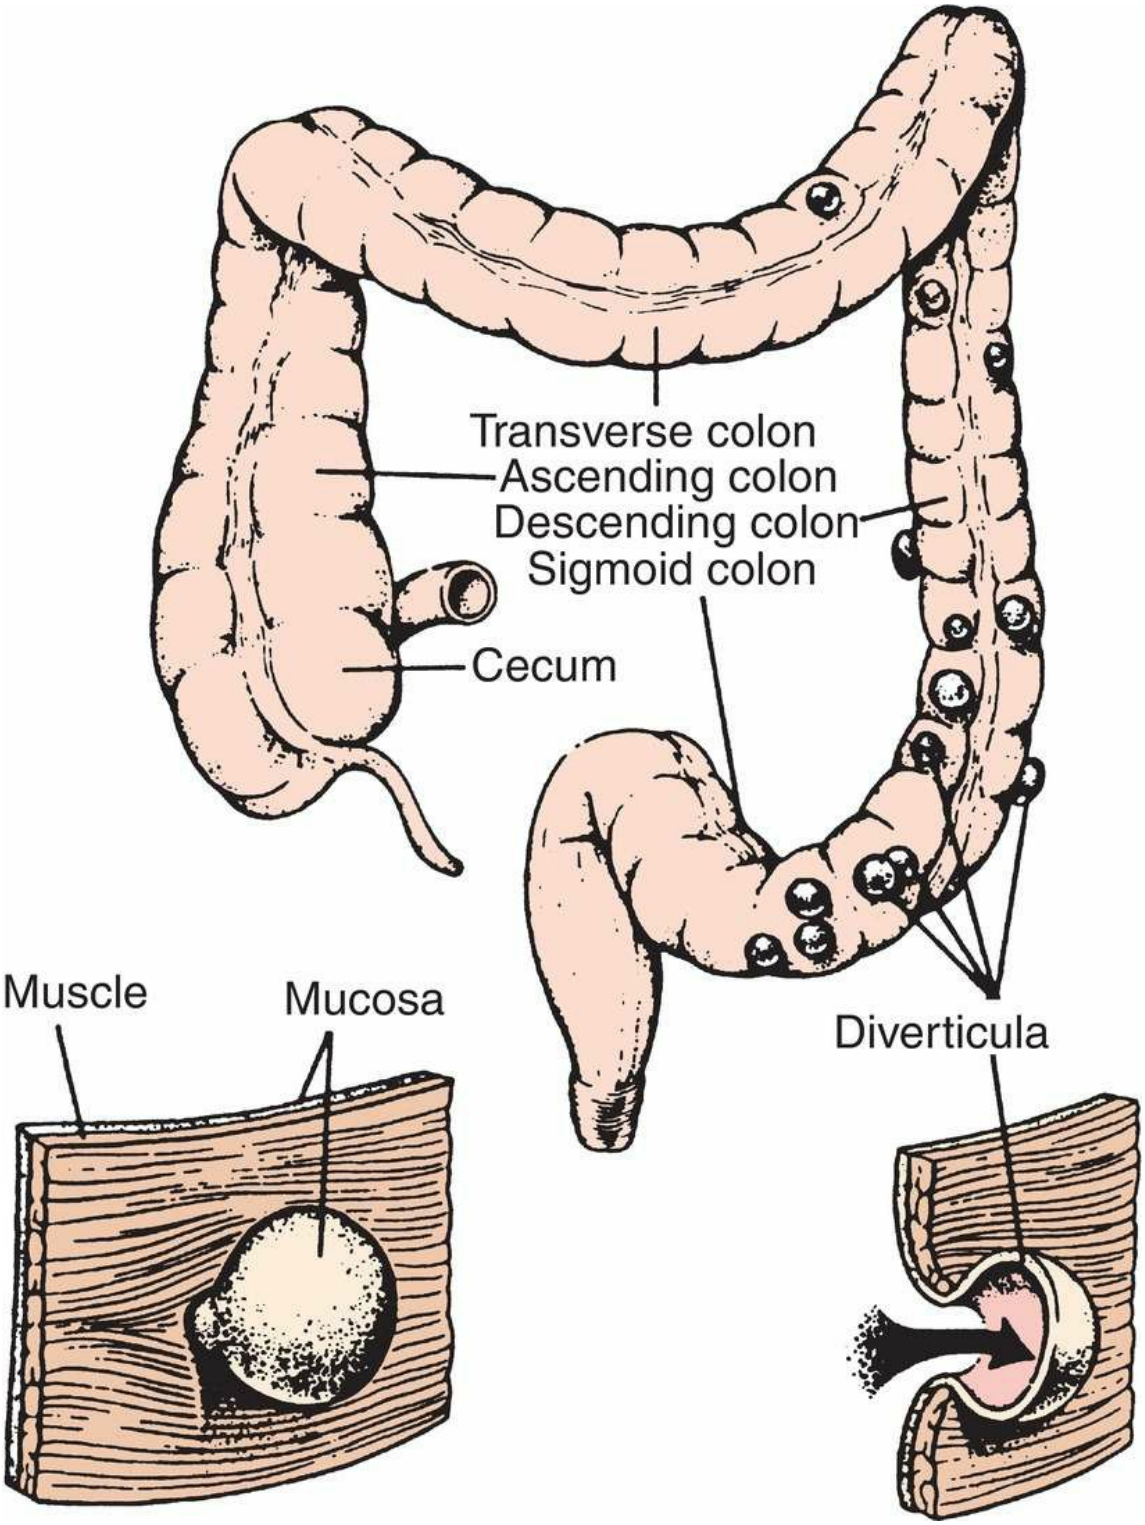

Figure 18-10. Diverticula are most common in the sigmoid colon; they diminish in number and size as the colon approaches the cecum. Diverticula are rarely found in the rectum.

Diverticulitis

1. Results when one or more diverticula become inflamed and usually perforate the thin diverticular wall, which consists of mucosal and serosal layers. The exact cause is unknown, but postulated to be caused by stasis or obstruction of the diverticula leading to bacterial overgrowth, inflammation, and ischemia.

2. Complicated diverticulitis refers to diverticular disease that has led to abscess, perforation, fistula, stricture, or obstruction.
3. Uninflamed or minimally inflamed diverticula may erode adjacent arterial branches causing acute massive rectal bleeding.
4. It is estimated that 10% to 25% of people with diverticulosis will develop diverticulitis.

Clinical Manifestations

Diverticulosis

1. May be asymptomatic.
2. Crampy abdominal pain.
3. Bowel irregularity—constipation or diarrhea.
4. Periodic abdominal distention.
5. Sudden massive hemorrhage may be the first symptom.

Diverticulitis

1. Left lower quadrant pain.
2. Low-grade fever, chills, leukocytosis.
3. Sometimes, an abdominal mass is palpable.
4. Urinary frequency and dysuria are associated with bladder involvement in the inflammatory process.
5. Ruptured diverticula produce abscesses or peritonitis with abdominal rigidity; signs of shock and sepsis (hypotension, chills, high fever). Near a blood vessel, a rupture may cause massive hemorrhage.
    a. Sepsis may spread through the portal vein to the liver, causing liver abscesses.
    b. Sometimes, fistulae form with the bladder, the adjacent small bowel, the vagina, and the perianal area or skin.
    c. Chronic diverticulitis may cause adhesions that narrow the bowel's opening and can cause partial or complete bowel obstruction.

Diagnostic Evaluation

1. Laboratory studies: WBC may show leukocytosis with shift to the left; hemoglobin/hematocrit may be low with chronic or acute bleeding.
2. CT scan is the preferred imaging study because it is the most accurate in correctly identifying diverticulitis and in staging its severity. CT guidance can also be used if an abscess needs to be drained.
3. Sigmoidoscopy/colonoscopy—to rule out carcinoma and confirm diagnosis. These studies should not be done during an acute attack. A waiting period of 6 weeks after resolution of symptoms is preferred.
4. Barium enema (after infection subsides)—may visualize diverticular sacs, narrowing of colonic lumen, partial or complete obstruction, or fistulae.

NURSING ALERT In patients with acute diverticulitis, a barium enema may rupture the bowel.

Management

Diverticulosis

1. High-fiber diet with possible avoidance of large seeds or nuts, which may obstruct diverticular sac.
2. Bran therapy, psyllium preparation, or stool softeners, such as docusate sodium (Colace), to avoid constipation.
3. Encourage adequate fluid intake.
4. Intestinal diverticulosis with pain usually responds to a liquid or low-residue diet and stool softeners to relieve symptoms, minimize irritation, and reduce progression to diverticulitis.

Uncomplicated Diverticulitis

1. Medical management.
   a. If symptoms are mild, treatment can occur as an outpatient. Usually, a broad-spectrum antibiotic is given for 7 to 14 days.
   b. If fever or systemic symptoms, patient should be treated in the hospital with intravenous broad-spectrum antibiotic.
2. Surgical management.
   a. Elective resection may be considered, but this is dependent on severity of disease, risk of subsequent attacks, age, comorbidities, and complications of the disease.

Complicated Diverticulitis

Treatment is dependent upon the associated complication that has occurred.

1. Abscess—may be managed with bowel rest and antibiotics while under close observation; however, percutaneous drainage may be needed if patient becomes septic. Sigmoid resection may also be recommended.
2. Perforation—surgical resection of the diseased area with colostomy (Hartmann procedure) is the most widely accepted treatment. Surgical resection with primary anastomosis may be done if patient is a good candidate. Recent studies show that laparoscopic lavage may be an alternative to resection, but further studies are needed.
3. Fistulae—usually require surgical resection depending on type of fistula and its associated symptoms.
4. Stricture/obstruction—if the obstruction is complete, surgery is required. If a partial obstruction has occurred, bowel rest, intravenous hydration, and antibiotics may successfully treat symptoms; however, surgery may be required later.
5. Hemorrhage—NPO, IV therapy, blood transfusion as necessary, and NG tube placement. Colonoscopy to identify source of bleeding.

a. If colonoscopy is not successful in identifying source of bleeding, a technetium 99–labeled red blood cell scan will be done.
b. Mesenteric angiography is an alternative study that may be used and has potential to be therapeutic, because the bleeding source can be thrombosed if identified.
c. Surgical resection is not typical, because this type of hemorrhage is usually self-limited.

Complications

1. Hemorrhage from colonic diverticula, usually in the right colon.
2. Bowel obstruction.
3. Fistula formation (colovesical fistula is the most common).
4. Septicemia.

Nursing Assessment

1. Have the patient describe the amount of fiber and fluid intake per day and past and present bowel patterns. Any constipation, diarrhea, or alternating of both?
2. Ask if experiencing abdominal cramping or pain, bloody stools, or stool/gas passage from the vagina or in urine.
3. Watch for signs and symptoms of peritonitis: increasing abdominal pain, guarding, rebound tenderness, abdominal distention, and nausea/vomiting.
4. Monitor vital signs: temperature may be elevated; tachycardia and hypotension may indicate peritonitis/massive bleeding.

Nursing Diagnoses

- Acute Pain related to intestinal discomfort, diarrhea, and/or constipation.
- Risk for Deficient Fluid Volume related to diarrhea, fluid and electrolyte loss, nausea, and vomiting.
- Constipation or Diarrhea related to the disease process.
- Deficient Knowledge of the relationship between diet and diverticular disease.

Nursing Interventions

Achieving Pain Relief

1. Observe for signs and location of pain, type, and severity, and intervene when appropriate.
   a. Administer nonopiate analgesics as prescribed (opiates may mask signs of perforation).
   b. Administer anticholinergics, as prescribed, to decrease colon spasm.
2. Auscultate bowel sounds to monitor bowel motility.
3. Palpate abdomen to determine rigidity or tenderness because of perforation or peritonitis.

Maintaining Fluid Balance

1. Maintain NPO status and NG suction until bowel sounds return.

2. Provide IV fluid as directed and prepare for blood transfusion if indicated.
3. Monitor intake and output, including NG aspirate.
4. Report any occult or frank blood in stool, tachycardia, drop in BP, fever, or increased pain.

Promoting Normal Bowel Elimination

1. Follow prescribed diet that is high in soft residue and low in sugar.
   a. Provide lists of these foods to enhance familiarity with proper dietary control.
   b. Emphasize that proper food intake influences how well the intestinal tract functions.
2. Inform the patient that bran products will add bulk to the stool and can be taken with milk or sprinkled over cereal.
3. Monitor food intake and weight periodically to determine caloric status.
4. Advise the patient to establish regular bowel habits to promote regular and complete evacuation.
5. Observe and record color, consistency, and frequency of stools.
6. Encourage fluids if constipated to promote bowel stimulation.

Increasing Understanding of Disease

1. Explain the disease process to the patient and its relationship to diet.
2. Have the patient continue periodic medical supervision and follow-up; report problems and untoward symptoms.
3. Refer to nutritionist, as needed.

Patient Education and Health Maintenance

1. Instruct on high-residue diet choices.
2. Emphasize the importance of establishing regular bowel habits.
3. Advise the patient to report left lower quadrant pain, generalized abdominal tenderness, and fever.

Evaluation: Expected Outcomes

- Expresses relief of pain and has a decrease in symptoms.
- No change in vital signs; stool negative for occult blood.
- Reports near-normal bowel function; no diarrhea or constipation.
- Delineates the general nature of diverticulosis and can list dietary regimen that helps or aggravates the condition.

Peritonitis

Peritonitis occurs when bacteria or other microorganisms cause a generalized or localized inflammation of the peritoneum, the membrane lining the abdominal cavity and abdominal organs (see Figure 18-11).

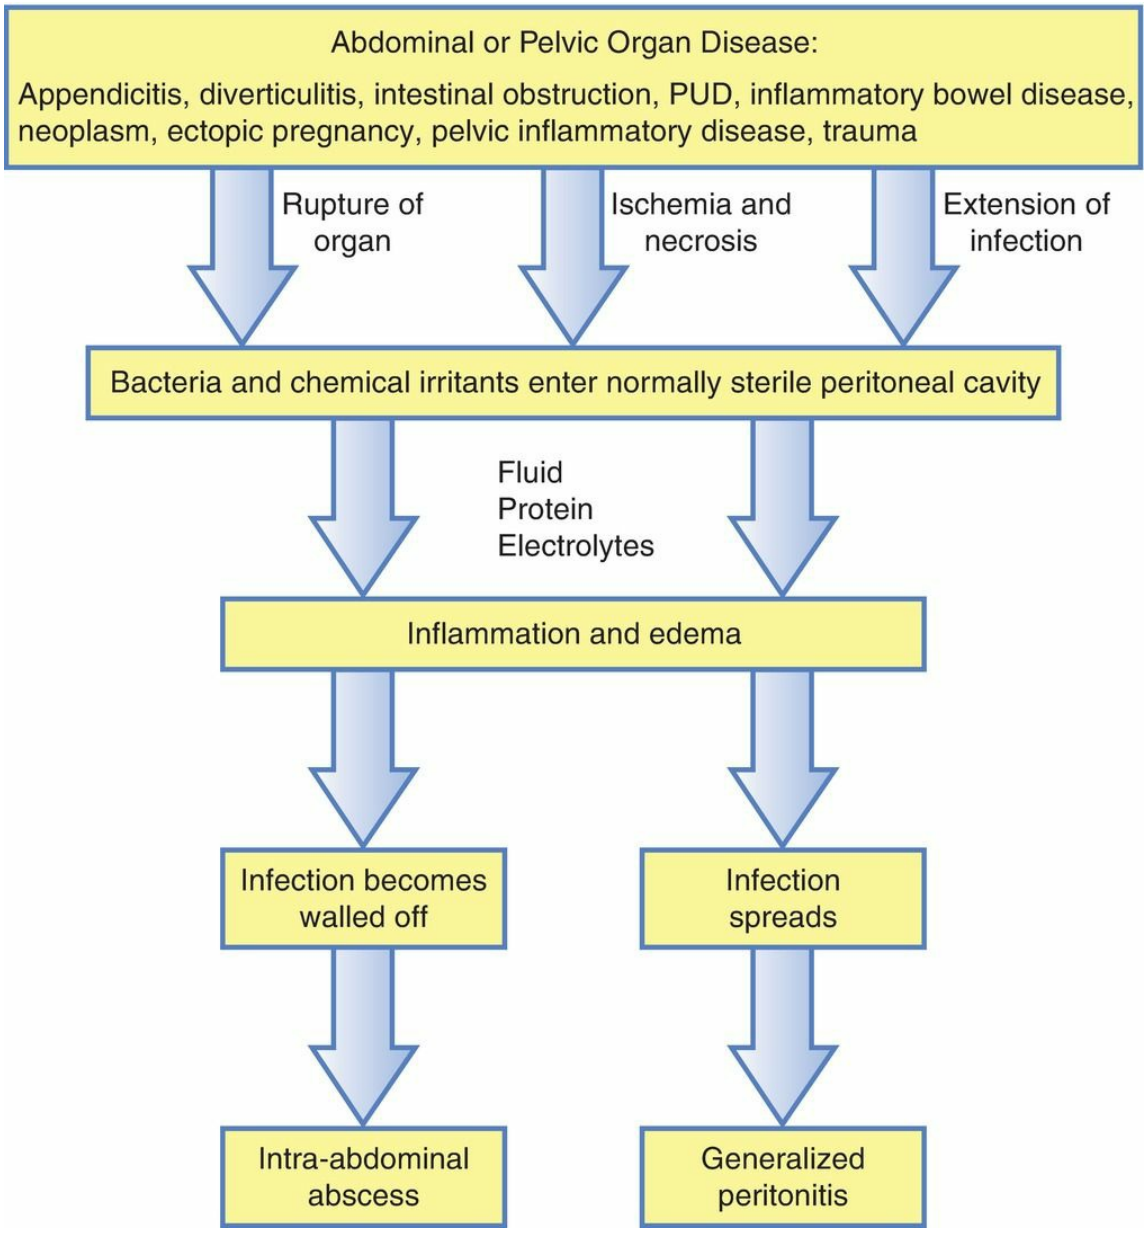

Figure 18-11. Pathophysiology of peritonitis.

Pathophysiology and Etiology

1. Primary peritonitis, also known as spontaneous bacterial peritonitis (SBP), occurs when bacteria cross through the intestinal wall into the peritoneum, causing infection. SBP can occur in patients with cirrhosis, nephrotic syndrome, and ovarian diseases (eg, cancer).
2. Secondary peritonitis is due to perforation, rupture of an organ, trauma, or peritoneal dialysis.

Clinical Manifestations

1. Initially, local type of abdominal pain tends to become constant, diffuse, and more intense.
2. The abdomen becomes extremely tender and muscles become rigid; rebound tenderness and ileus may be present; the patient lies very still, usually with legs drawn up.
3. Percussion: Resonance and tympany because of paralytic ileus; loss of liver dullness may indicate free air in the abdomen.
4. Auscultation: Decreased bowel sounds.
5. Nausea and vomiting often occur; peristalsis diminishes; anorexia is present.
6. Elevation of temperature and pulse as well as leukocytosis.
7. Fever; thirst; oliguria; dry, swollen tongue; signs of dehydration.
8. Weakness, pallor, diaphoresis, and cold skin are the results of the loss of fluid, electrolytes, and protein into the abdomen.
9. Hypotension, tachycardia, and hypokalemia may occur.
10. With generalized peritonitis, large volumes of fluid may be lost into abdominal cavity (ascites). Shallow respirations may result from abdominal distention and upward displacement of the diaphragm.

Diagnostic Evaluation

1. WBC count to determine if leukocytosis is present (leukopenia if severe).
2. ABG levels may show hypoxemia or metabolic acidosis with respiratory compensation.
3. Urinalysis may indicate urinary tract problems as primary source.
4. Peritoneal aspiration (paracentesis) to demonstrate blood, pus, bile, bacteria (Gram stain), amylase.
5. Abdominal x-rays may show free air in the peritoneal cavity, gas and fluid collection in small and large intestines, generalized bowel dilation, intestinal wall edema.
6. CT scan of the abdomen or sonography may reveal intra-abdominal mass, abscess, ascites.
7. Radionuclide scans (gallium, hepatobiliary iminodiacetic acid, and liver/spleen scan) may identify an intra-abdominal abscess.
8. Chest x-ray may show elevated diaphragm.
9. Exploratory laparotomy may be performed to identify the underlying cause.

Management

1. Treatment of inflammatory conditions preoperatively and postoperatively with antibiotic therapy may prevent peritonitis. Broad-spectrum antibiotic therapy to cover aerobic and anaerobic organisms is the initial treatment, followed by specific antibiotic therapy after culture and sensitivity results.
2. Bed rest, NPO status, and respiratory support, if needed.
3. IV fluids and electrolytes, possibly TPN.
4. Analgesics for pain; antiemetics for nausea and vomiting.
5. NG intubation to decompress the bowel.

6. Possibly rectal tube to facilitate passage of gas.
7. Operative procedures to close perforations, remove infection source (ie, inflamed organ, necrotic tissue), drain abscesses, and lavage peritoneal cavity.
8. Abdominal paracentesis may be done to remove accumulating fluid.
9. Blood transfusions, if appropriate.
10. Oral feedings after return of bowel sounds and passage of gas and/or feces.

Complications

1. Intra-abdominal abscess formation (ie, pelvic subphrenic space).
2. Septicemia.
3. Hypovolemic problems.
4. Renal or liver failure.
5. Respiratory insufficiency.

Nursing Assessment

1. Assess for abdominal distention and tenderness, guarding, rebound, hypoactive or absent bowel sounds to determine bowel function.
2. Observe for signs of shock—tachycardia and hypotension.
3. Monitor vital signs, ABG levels, CBC, electrolytes, and central venous pressure to monitor hemodynamic status and assess for complications.

Nursing Diagnoses

- Acute Pain related to peritoneal inflammation.
- Deficient Fluid Volume related to vomiting and interstitial fluid shift.
- Imbalanced Nutrition: Less Than Body Requirements related to GI symptomatology.

Nursing Interventions

Achieving Pain Relief

1. Place the patient in semi-Fowler position before surgery to enable less painful breathing.
2. After surgery, place the patient in Fowler position to promote drainage by gravity.
3. Provide analgesics as prescribed.

Maintaining Fluid and Electrolyte Volume

1. Keep the patient NPO to reduce peristalsis.
2. Provide IV fluids to establish adequate fluid intake and to promote adequate urine output, as prescribed.
3. Record accurately intake and output, including the measurement of vomitus and NG drainage.
4. Minimize nausea, vomiting, and distention by use of NG suction, antiemetics.
5. Monitor for signs of hypovolemia: dry mucous membranes, oliguria, postural hypotension, tachycardia,

diminished skin turgor.

Achieving Adequate Nutrition

1. Administer TPN, as ordered, to maintain positive nitrogen balance until patient can resume oral diet.
2. Reduce parenteral fluids and give oral food and fluids per order when the following occur:
   a. Temperature and pulse return to normal.
   b. Abdomen becomes soft.
   c. Peristaltic sounds return (determined by abdominal auscultation).
   d. Flatus is passed and patient has bowel movements.

Patient Education and Health Maintenance

1. Teach the patient and family how to care for open wounds and drain sites, if appropriate.
2. Assess the need for home care nursing to assist with wound care and assess healing; refer as necessary.
3. Encourage follow-up as directed and reporting of increased pain, fever, and anorexia.

Evaluation: Expected Outcomes

- Minimal analgesics needed; abdomen soft, nontender, and no distention.
- Balanced intake and output; no evidence of dehydration or electrolyte imbalances.
- Bowel sounds present; tolerating soft diet.

Irritable Bowel Syndrome

Irritable bowel syndrome is a functional bowel disorder characterized by abdominal pain and altered bowel function. It is the most common functional GI disorder and is estimated to affect 20% of Americans.

Pathophysiology and Etiology

The exact etiology of IBS is unknown. Pathophysiologic processes include abnormal GI motility, heightened visceral hypersensitivity, and abnormal central nervous system processing. IBS is not a life-threatening disorder, and surgery is not necessary. It does not transform into inflammatory bowel disease and does not increase the risk for colorectal cancer and occurs in 70% of females, with greatest prevalence in youth and middle age.

Clinical Manifestations

1. Functional abnormalities vary and may come and go, leading to a chronic problem.
2. Symptoms may include:
    a. Lower abdominal pain.
    b. Diarrhea, constipation, or alternating of both.
    c. Bloating, distention.
    d. Mucous drainage.
    e. Fecal urgency, feeling of incomplete evacuation.
3. Patients usually have a characteristic pain pattern ranging from pain in the postprandial period, occurring before or at the time of bowel movement, or arising during times of stress or anxiety.
4. Symptoms that occur after eating may be associated with certain foods.

Diagnostic Evaluation

Overview

Diagnosis can be made based on symptom criteria alone.

1. Careful medical history.
2. Rectal examination—normal or tenderness at left lower quadrant abdomen, which may reflect a spasm in the sigmoid colon.
3. If patient fulfills the Rome III diagnostic criteria for IBS (see below), and there are no warning signs of other disease processes, the diagnosis is confirmed.
4. Traditional warning signs, which could signal other organic diseases include fever, chills, night sweats, bleeding, obvious anemia, weight loss, and onset occurring in patients older than age 50.

Rome III Diagnostic Criteria

1. Recurrent abdominal pain or discomfort at least 3 days per month in the past 3 months associated with two or more of the following:

a. Improvement with defecation.
b. Onset associated with a change in frequency of stool.
c. Onset associated with a change in form (appearance) of stool.

2. Symptoms described above for the past 3 months with symptom onset at least 6 months prior to diagnosis.
3. Discomfort means an uncomfortable sensation not described as pain. In pathophysiology research and clinical trials, a pain/discomfort frequency of at least 2 days a week during screening evaluation for subject eligibility.

EVIDENCE BASE Hayee, B. (2015). Managing irritable bowel syndrome in primary care: A clinical update. *Nursing In Practice,* 83.

Tests to Rule Out Other Disease Processes

1. CBC to test for anemia.
2. Sedimentation rate and C-reactive protein to detect inflammation.
3. Stool testing for ova and parasites; fecal occult blood testing.
4. Serology testing for celiac disease.
5. Barium enema—should be done when warning signs are present.
6. Flexible sigmoidoscopy/colonoscopy—should be done when warning signs are present.

Management

Treatment is focused on relieving symptoms. Treating the patient's most predominant symptoms determines the most successful therapy.

1. Pain—predominant symptom:
   a. Anticholinergic drugs: dicyclomine or hyoscyamine taken before meals; should be used only for limited periods such as during a flareup.
   b. Combination agents: phenobarbital, hyoscyamine, atropine, and scopolamine or chlordiazepoxide and clidinium bromide are second-line agents.
   c. Nonopioid agents: acetaminophen, tramadol, gabapentin, carbamazepine, and anti-inflammatory agents.
   d. Tricyclic antidepressants: desipramine, doxepin, and amitriptyline.
2. Constipation—predominant symptom:
   a. Fiber: psyllium, ispaghula husk, and polycarbophil.
   b. Osmotic laxatives: lactulose, sorbitol, and lubiprostone.
3. Diarrhea—predominant symptom:

a. Loperamide—reduces stool consistency and improves stool consistency.
b. Cholestyramine—binds bile salts.

4. Eliminate irritating dietary substances, such as caffeine, fatty foods, fructose, or lactose, which may cause such symptoms as spasms, cramps, bloating, and/or diarrhea.
5. A regular exercise routine can improve gastric emptying and relieve constipation and stress.

DRUG ALERT Opioids should not be used to treat abdominal pain in patients with IBS because of possibility of drug interaction or dependency leading to addiction.

Complications

1. This disorder is associated with:
   a. Psychological distress.
   b. Sexual dysfunction.
   c. Interference with work and sleep.
   d. Decreased quality of life.
2. Unnecessary surgery because of misdiagnosis (such as cholecystectomy, appendectomy, or partial colectomy).

Nursing Assessment

1. Assess the patient for contributing factors that may affect symptoms, such as diet, emotions, professional and personal relationships, fears, concerns, financial stressors, and problems at home or work.
2. Record specific symptoms that the patient is experiencing to determine best treatment options.
3. Explore pain characteristics: frequency, duration, location, timing, and intensity.

Nursing Diagnoses

- Chronic Pain related to functional disorder.
- Constipation or Diarrhea related to change in bowel motility.
- Ineffective Coping related to anxiety, stress, and depression.

Nursing Interventions

Minimizing Pain or Discomfort

1. Assess and evaluate abdominal pain using a pain scale.
2. Review pain medications for proper usage and possibility of adverse effects—drowsiness and dry mouth with anticholinergics, combination agents, and tricyclic antidepressants; bloating, abdominal pain, gas, diarrhea, or constipation with other medications.

Decreasing Diarrhea or Constipation

1. Monitor amount, consistency, and frequency of stool.
2. Encourage exercise and adequate fluid/fiber intake to promote bowel motility for constipation.
3. Encourage adequate fluid intake to prevent fluid volume deficit and electrolyte imbalance for diarrhea.

Providing Supportive Care

1. Validate the patient's complaints and express interest in diagnosis.
2. Follow-up and reassess the patient's complaints and status of treatment goals.
3. Refer the patient for pain management, psychological counseling, or behavior management therapy if indicated.

Patient Education and Health Maintenance

1. Educate the patient on the diagnosis and the natural course of IBS.
2. Instruct the patient about all prescribed medications, including purpose, dosage, and adverse effects.
3. Encourage the patient to participate in stress-reducing activities, such as exercise, relaxation techniques, and music therapy.
4. Encourage participation in counseling sessions to deal with anxiety and depression.
5. Suggest ways for the patient to learn coping skills and stress management.

Evaluation: Expected Outcomes

- Expresses pain is controlled for ADLs.
- Relates that bowel symptoms are manageable with treatment plan.
- Verbalizes strategies to deal with the psychological components of disorder.

Ulcerative Colitis

EVIDENCE BASE Bressler, B., Marshall, J., Bernstein, C., et al. (2015). Clinical practice guidelines for the medical management of nonhospitalized ulcerative colitis: The Toronto consensus. *Gastroenterology*, *148*, 1035–1058.

Ulcerative colitis is a chronic, idiopathic, diffuse inflammatory disease of the mucosa and, less frequently, the submucosa of the colon and rectum. If only the rectum is involved, it may be called ulcerative proctitis.

Pathophysiology and Etiology

1. The exact cause of ulcerative colitis is unknown. Possible theories include:
   a. Genetic predisposition.
   b. Environmental factors (viral or bacterial pathogens, dietary).
   c. Immunologic imbalance or disturbances.
   d. Defect in intestinal barrier causing hypersensitive mucosa and increased permeability.
   e. Defect in repair of mucosal injury, which may develop into a chronic condition.
2. Multiple crypt abscesses develop in intestinal mucosa that may become necrotic and lead to ulceration and perforation.
3. May manifest as a systemic disease with inflammatory changes of connective tissue (see Figure 18-12). Most common in young adulthood and middle age, with peak incidence at ages 20 to 40.
4. Incidence greatest in whites of Jewish descent.

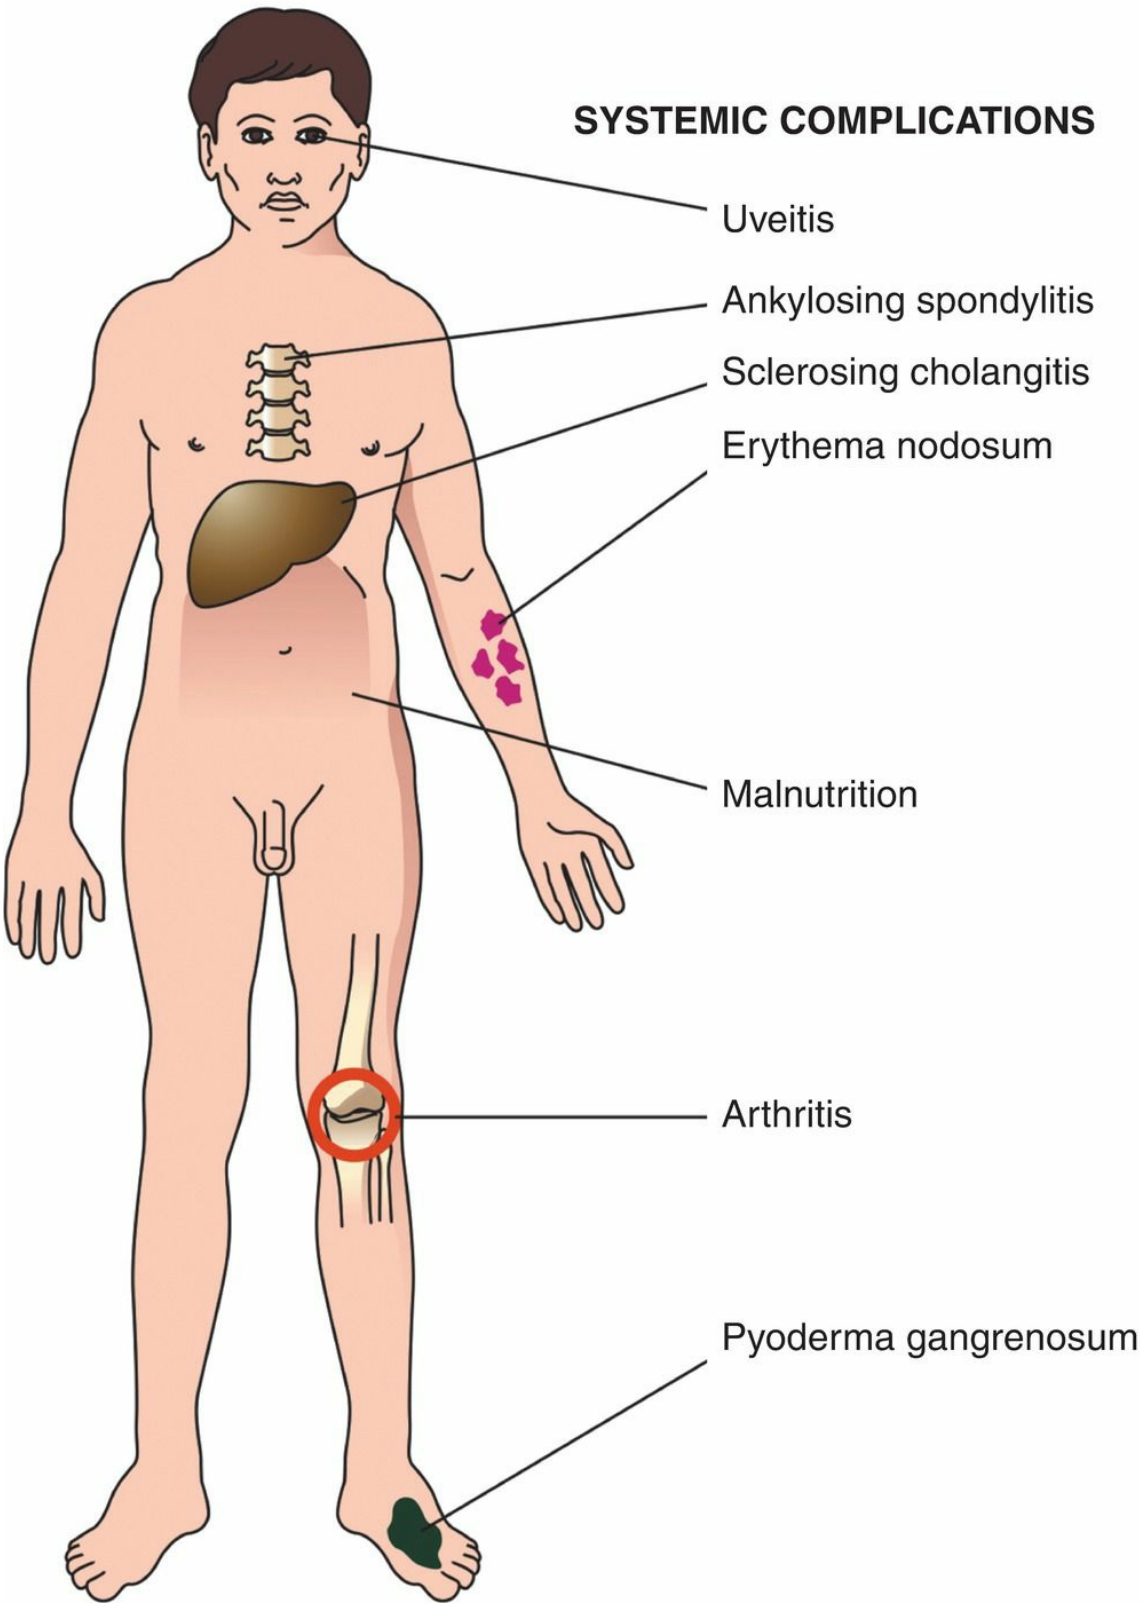

Figure 18-12. GI and systemic complications of ulcerative colitis. (Rubin, R., & Strayer, D.S. [2011]. Rubin's Pathology: Clinicopathologic Foundations of Medicine [6th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Clinical Manifestations

1. Bloody diarrhea is a key symptom.
2. Tenesmus (painful straining), sense of urgency, and frequency.
3. Increased bowel sounds; the abdomen may appear flat, but, as condition continues, the abdomen may appear distended.
4. There often is weight loss, fever, dehydration, hypokalemia, anorexia, nausea and vomiting, iron deficiency anemia, and cachexia (general lack of nutrition and wasting with chronic disease).
5. Crampy abdominal pain.
6. The disease usually begins in the rectum and sigmoid and spreads proximally, at times, involving the entire colon. Anal area may be irritated and reddened; left lower abdomen may be tender on palpation.
7. There is a tendency for the patient to experience remissions and exacerbations.
8. Increased risk of developing colorectal cancer.
9. May exhibit extracolonic manifestations of eye (iritis, uveitis), joint (polyarthritis), and skin complaints (erythema nodosum, pyoderma gangrenosum).

Diagnostic Evaluation

Diagnosis is based on a combination of laboratory, radiologic, endoscopic, and histologic findings.

Laboratory Tests

1. Stool examination to rule out enteral pathogens; fecal analysis positive for blood during active disease.
2. CBC—hemoglobin and hematocrit may be low because of bleeding; WBC may be increased.
3. Elevated erythrocyte sedimentation rate (ESR).
4. Decreased serum levels of potassium, magnesium, and albumin may be present.

Other Diagnostic Tests

1. Barium enema to assess extent of disease and detect pseudopolyps, carcinoma, and strictures. May show absence of haustral markings; narrow, lead-pipe appearance; superficial ulcerations.
2. Flexible proctosigmoidoscopy/colonoscopy findings reveal mucosal erythema and edema, ulcers, and inflammation that begins distally in the rectum and spreads proximally for variable distances. Pseudopolyps and friable tissue may be present.
3. Histological findings from biopsies of the colon include changes in crypt height, loss of crypts, and neutrophils infiltrates in the crypts.
4. CT scan can identify complications such as toxic megacolon.
5. Rectal biopsy—differentiates from other inflammatory diseases or cancer.

Management

General Measures

1. Bed rest, IV fluid replacement, clear liquid diet.
2. For patients with severe dehydration and excessive diarrhea, TPN may be recommended to rest the

intestinal tract and restore nitrogen balance.

3. Treatment of anemia—iron supplements for chronic bleeding and blood replacement for massive bleeding.

Drug Therapy

1. Aminosalicylates (5-ASA)—first-line therapy for acute and maintenance therapy. Oral and rectal formulations are available. Dose-related adverse effects include vomiting, anorexia, headache, fever, rash, dyspepsia, and lowered sperm count (sulfasalazine).
2. Corticosteroids—initial agent used in the management of moderate to severe ulcerative colitis. Used to induce remission of symptoms and can be used concomitantly with 5-aminosalicylic acid preparations. Not used for maintenance therapy because of potential side effects. Enema available for proctitis and left-sided colitis.
3. Immunosuppressive drugs—purine analogues, azathioprine, and 6-mercaptopurine may be indicated when the patient is refractory or dependent on corticosteroids.
4. Anti-TNF therapy—when other agents are not effective, these drugs (eg, infliximab, adalimumab) can be used to induce and maintain remission of symptoms. Side effects can include opportunistic infections, headache, rash, and arthralgias.

Surgical Measures

1. Surgery is recommended when patients fail to respond to medical therapy, if clinical status is worsening, for uncontrollable adverse effects of medications, severe hemorrhage, perforation, toxic megacolon, dysplasia, or cancer.
2. Noncurative approaches (possible curative, reconstructive procedure at later date):
   a. Temporary loop colostomy for decompression if toxic megacolon present without perforation.
   b. Subtotal colectomy, ileostomy, and Hartmann pouch.
   c. Colectomy with ileorectal anastomosis.
3. Reconstructive procedures—curative:
   a. Total proctocolectomy with permanent end ileostomy.
   b. Total proctocolectomy with continent ileostomy (Kock or BCIR).
   c. Total colectomy with ileal reservoir—anal (or ileal reservoir–distal rectal) anastomosis—procedure of choice. Multiple reservoir shapes can be surgically created; however, the J-shaped pouch (reservoir) is the easiest to construct (see Figure 18-13).
   d. The ultimate surgical goal is to remove the entire colon and rectum to cure patient of ulcerative colitis.

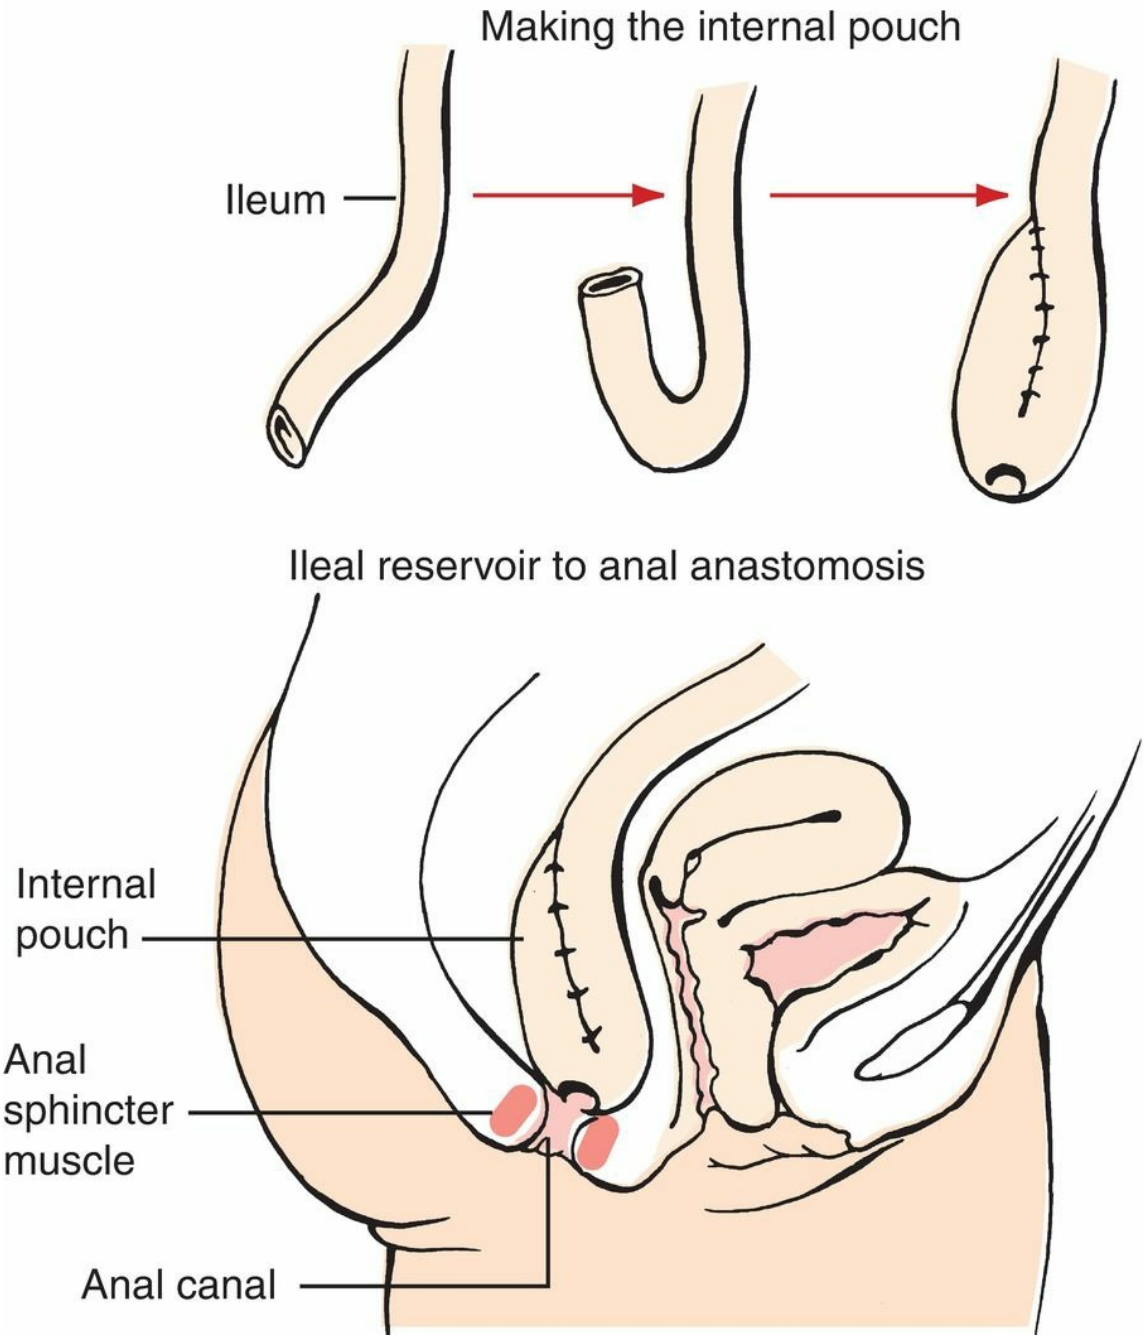

Figure 18-13. Ileal reservoir–anal anastomosis. This reservoir is constructed of two loops of the small intestine forming a J configuration (J pouch).

Complications

1. Perforation, hemorrhage.
2. Toxic megacolon (life-threatening)—fever, tachycardia, abdominal distention, peritonitis, leukocytosis, dilated colon on abdominal x-ray.
3. Abscess formation, stricture, anal fistula.
4. Malnutrition, anemia, electrolyte imbalance.
5. Skin lesions (erythema nodosum, pyoderma gangrenosum).

6. Arthritis, ankylosing spondylitis.
7. Colon malignancy.
8. Liver disease (sclerosing cholangitis).
9. Eye lesions (uveitis, conjunctivitis).
10. Growth retardation in prepubertal children.
11. Possible infertility in females.

Nursing Assessment

1. Review nursing history for patterns of fatigue and overwork, tension, family problems that may exacerbate symptoms.
2. Assess food habits and use of any dietary or herbal supplements used as alternative therapies that may have a bearing on triggering symptoms (milk intake may be a problem). Many patients use vitamins, herbs, and homeopathic remedies without realizing the effect on bowel function.
3. Determine the number and consistency of bowel movements and any rectal bleeding present.
4. Listen for hyperactive bowel sounds; assess weight.

Nursing Diagnoses

- Chronic Pain related to disease process.
- Imbalanced Nutrition: Less Than Body Requirements related to diarrhea, nausea, and vomiting.
- Deficient Fluid Volume related to diarrhea and loss of fluid and electrolytes.
- Risk for Infection related to disease process and surgical procedures.
- Ineffective Coping related to fatigue, feeling of helplessness, and lack of support system.

Nursing Interventions

Promoting Comfort

1. Follow prescribed treatment of reducing or eliminating food and fluid and instituting parenteral feeding or low-residue diets to rest the intestinal tract.
2. Give sedatives and tranquilizers, as prescribed, not only to provide general rest but also to slow peristalsis.
3. Be aware of skin breakdown around the anus, which causes discomfort.
    a. Cleanse the skin gently after each bowel movement.
    b. Apply a protective emollient, such as petroleum jelly, skin sealant, or moisture barrier ointment.
4. Relieve painful rectal spasms (produced by frequent diarrheal stools) with anodyne suppositories, as prescribed.
5. Report any evidence of sudden abdominal distention—may indicate toxic megacolon.
6. Reduce physical activity to a minimum, or provide frequent rest periods.
7. Provide commode or bathroom next to bed because urgency of movements may be a problem.

Achieving Nutritional Requirements

1. Maintain an acutely ill patient on parenteral replacement of vitamins, fluids, and electrolytes (potassium), as prescribed.
2. When resuming oral fluids and foods, select those that are nonirritating to the mucosa (mechanically, thermally, and chemically). If this fails, an elemental diet may be prescribed to provide low residue to rest the lower intestinal tract.
3. Avoid dairy products if the patient is lactose intolerant.
4. Provide a well-balanced, low-residue, high-protein diet to correct malnutrition.
5. Determine which foods the patient can tolerate and modify diet plan accordingly.
6. Bolster with supplemental vitamin therapy, including vitamins C, B complex, and K, as prescribed.
7. Possibly avoid cold fluids, which may increase intestinal motility.
8. Administer prescribed medications for symptomatic relief of diarrhea.

Maintaining Fluid Balance

1. Maintain accurate intake and output records.
2. Weigh daily; rapid increase or decrease may relate to fluid imbalance.
3. Monitor serum electrolytes and report abnormalities.
4. Observe for decreased skin turgor, dry skin, oliguria, decreased temperature, weakness, and increased hemoglobin, hematocrit, BUN, and specific gravity, all of which are signs of fluid loss leading to dehydration.

Minimizing Infection and Complications

1. Give antibacterial drugs as prescribed.
2. Administer corticosteroids as prescribed.
3. Provide conscientious skin care after severe diarrhea.
4. For severe proctitis, instill rectal steroids, as prescribed, to produce a remission of symptoms.
5. Administer prescribed therapy to correct existing anemia.
6. Observe for signs of colonic perforation and hemorrhage—abdominal rigidity, distention, hypotension, and tachycardia.

Providing Supportive Care

1. Recognize psychological needs of the patient.
    a. Fear, anxiety, and discouragement.
    b. Hypersensitivity may be evident.
2. Acknowledge the patient's complaints.
3. Encourage the patient to talk; listen and offer psychological support.
4. Answer questions about the permanent or temporary ostomy, if appropriate.
5. Initiate patient education about living with chronic disease.
6. Include the patient as part of the health care team to provide continuity of care, communication, and

periodic evaluation.

7. Offer educational and emotional support to family members.
8. Refer for psychological counseling, as needed.

Community and Home Care Considerations

Pouchitis

1. Patients undergoing one of the continent restorative procedures (Kock, BCIR, or ileal reservoir–anal anastomosis) must be alert for a common late postoperative complication called pouchitis.
2. The symptoms include increased stool output, cramps, and malaise.
3. It is thought to be related to stasis within the pouch/reservoir and usually responds to metronidazole.
4. Assess for these symptoms and notify health care provider.

Food Blockage

1. Patients with a temporary or permanent ileostomy must be alert for signs and symptoms of a food blockage.
   a. This is a mechanical blockage of undigested foodstuffs at the level of the fascia.
   b. It is most likely to occur in the first 6 weeks postoperatively when the bowel is edematous; however, patients with an ileostomy must be aware that it can occur at any time if precautions are not taken.
2. Symptoms may include spurty, watery stool with strong odor, decreased or no stool output, abdominal discomfort, cramping or bloating, and stomal swelling. Nausea and vomiting are late symptoms and require immediate attention.
3. Treatment includes:
   a. Avoiding solid foods and drinking clear liquids when symptoms occur. Patients with ileostomies must never take laxatives.
   b. Applying a pouching system with a larger opening to allow for stomal swelling.
   c. Gently massaging the abdomen around the stoma and/or pulling the knees to the chest and rocking the body back and forth.
   d. A warm shower or bath may help with relaxation.
   e. If the blockage lasts for more than 2 to 3 hours or if nausea/vomiting occurs, seek medical attention immediately. Usually, an ileostomy lavage is done by the health care provider or ostomy specialty nurse to relieve the blockage.
4. It is best to instruct the patient how to prevent a food blockage by limiting certain foods the first few months after surgery—Chinese vegetables, skins and seeds, fatty meats, bean hulls, popcorn, and other foods that do not digest well.
5. Instruct the patient to avoid problem foods, chew food well, drink plenty of fluids while eating, eat possible problem foods in small amounts, and reintroduce problem foods slowly into the diet.
6. Some patients may need to avoid problem foods permanently.

Patient Education and Health Maintenance

1. Teach the patient about chronic aspects of ulcerative colitis and each component of care prescribed.
2. Encourage self-care in monitoring symptoms, seeking annual checkup, and maintaining health (eg, immunizations).
3. Alert the patient to possible postoperative problems with skin care, aesthetic difficulties, and surgical revisions.
4. Inform patients that early indications of relapse, such as bleeding or increased diarrhea, should be reported immediately so treatment may be initiated.
5. If the patient has an ileostomy, provide information about the local chapter of the United Ostomy Association (*www.uoa.org*).
6. Encourage the patient to share experiences with others undergoing similar procedures.
7. For further information and support, refer to the Crohn and Colitis Foundation of America at *www.ccfa.org*.

Evaluation: Expected Outcomes

- Reports lessening of pain; functions well with minimal analgesics.
- Demonstrates improved food and fluid intake; avoids roughage intake.
- Controls diarrhea; maintains fluid and electrolyte balance.
- Afebrile, no skin breakdown, vital signs stable, no abdominal rigidity.
- Shows improved psychological outlook; participates in counseling, if desired; uses support systems.

Crohn Disease

Crohn disease is a chronic, idiopathic inflammatory disease that can affect any part of the GI tract. It is predominantly a transmural disease of the bowel wall. Other names for this disease include *regional enteritis*, *granulomatous colitis*, *transmural colitis*, *ileitis*, and *ileocolitis*.

Pathophysiology and Etiology

1. The exact etiology is unknown for this disease. It is thought to be multifactorial with the following theories:
   a. Genetic predisposition.
   b. Environmental agents, such as infections (viral or bacterial overload) or dietary factors, may trigger the disease.
   c. Immunologic imbalance or disturbances.
   d. Defect in the intestinal barrier that increases the permeability of the bowel.
   e. Defect in the repair of mucosal injury, leading to chronic condition.
   f. Cigarette smoking is a risk factor in developing disease and increases exacerbations. In contrast, cigarette smoking seems to have a protective effect with ulcerative colitis.
2. Intestinal tissue is thickened and edematous; ulcers enlarge, deepen, and form transverse and longitudinal linear ulcers that intersect, resembling a cobblestone appearance. The deep penetration of these ulcers may form fissures, abscesses, and fistulae. The healing and fibrosis of these lesions may lead to stricture (see Figure 18-14).
3. The rectum is typically spared from disease, and "skip lesions" are discontinuous areas of diseased bowel.
4. Transmural inflammation is a characteristic finding of this disease as well as granulomas.
5. Involvement of the upper GI tract (mouth, esophagus, stomach, and duodenum) is rare, and, if present, there is usually disease elsewhere.
6. May occur at any age; however, peak incidence is in the third decade, with a smaller peak in the fifth decade.
7. Most common in whites and those of Jewish descent.
8. The clinical presentation can be divided into three patterns:
   a. Inflammatory.
   b. Fibrostenotic (stricturing).
   c. Perforating (fistulizing).
9. Recurrences tend to fall into the same pattern for each individual patient and may provide an approach to treatment.

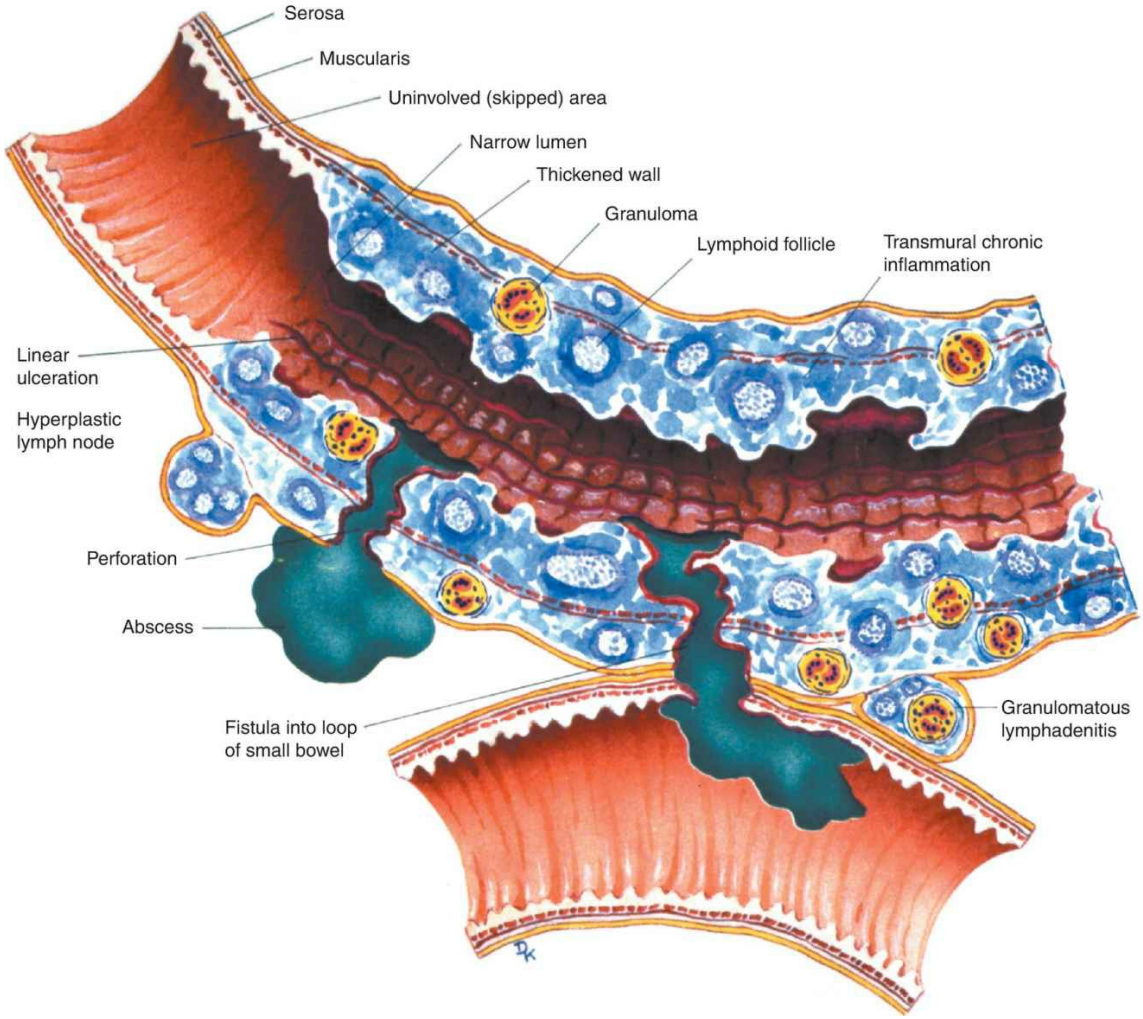

Figure 18-14. Transmural intestinal changes in Crohn disease. (Rubin, R., & Strayer, D.S. [2011]. Rubin's Pathology: Clinicopathologic Foundations of Medicine [6th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Clinical Manifestations

These are characterized by exacerbations and remissions—may be abrupt or insidious.

1. Crampy intermittent pain.
2. Chronic diarrhea—usual consistency is soft or semiliquid. Bloody stools or steatorrhea (because of malabsorption) may occur.
3. Fever may indicate infectious complication such as abscess.
4. Fecal urgency and tenesmus.
5. Other symptoms include anorexia, weight loss, malaise, nausea, arthralgias, and hematochezia.
6. Rectal examination may reveal a perirectal abscess, fistula, fissure, or skin tags (which represent healed perianal lesions).
7. The *inflammatory pattern* may display malabsorption, weight loss, and less abdominal pain; *fibrostenotic pattern* may display a partial small bowel obstruction, diffuse abdominal pain, nausea, vomiting, and

bloating; *perforating pattern* may display a sudden profuse diarrhea because of enteroenteric fistula, fever, and localized tenderness because of abscess, or other fistulizing symptoms, such as pneumaturia and recurrent UTIs.

Diagnostic Evaluation

1. The diagnosis is based on a combination of laboratory, radiologic, endoscopic, and histologic findings.
2. CBC may show mild leukocytosis, thrombocytosis, anemia.
3. Elevated ESR, hypoalbuminemia.
4. Stool analysis may reveal leukocytes but no enteric pathogens; guaiac-positive stool. Fecal calprotectin to assess amount of inflammation (disease activity).
5. Upper GI and small bowel follow-through barium studies may show the classic "string sign" at the terminal ileum, which suggests a constriction of an intestinal segment.
6. A barium enema may permit visualization of lesions in the large intestine and terminal ileum.
7. CT of the abdomen and pelvis is helpful with diagnosis but is more often used to evaluate complications, such as abscess or fistulae.
8. Colonoscopy is the procedure of choice. Typical findings include presence of skip lesions, cobblestoning, ulcerations, and rectal sparing.
9. Biopsy may reveal granulomas, infiltration of lymphocytes, and monocytes.

Management

Medical Management

1. The goals of medical management include managing symptoms, reducing complications, inducing remissions, improving nutrition, and avoiding surgical interventions when possible. Management is also based on location and severity of disease and extraintestinal complications.
2. Weight loss, water and electrolyte imbalances, and iron, vitamin, mineral, and protein deficiencies occur in 80% of patients.
3. During acute episodes, bowel rest is usually required.
4. Nutritional replacements may include an elemental diet (Vivonex) administered orally or through an NG tube.
5. TPN may be ordered.
6. For milder cases, a low-residue diet may be indicated and avoidance of untolerated foods. Nutritional supplements may be ordered to provide additional nutrients and calories.

Drug Therapy

1. There is no known cure for this disease; it is primarily treated with medications. The disease severity and the area of the GI tract influence drug therapy (see Table 18-3, page 529).
2. 5-Aminosalicylic acid (5-ASA)—can be used in mild disease but poor evidence to support use.
3. Corticosteroids—to reduce inflammation; given orally, by IV line, or by suppository, retention enema, or

foam, depending on the severity of disease. Steroids should be tapered off whenever possible.

4. Immunomodulators (6-mercaptopurine, azathioprine, methotrexate, cyclosporine, and tacrolimus)—used in patients who are steroid-dependent or steroid-refractory. Assists with fistula improvement or healing.
5. Antidiarrheals (loperamide, cholestyramine, or codeine [but try to avoid])—decrease stool frequency in mild to moderate disease; use with caution.
6. Miscellaneous drugs—antispasmodics (dicyclomine), bulking agents (psyllium), or tricyclic antidepressants (amitriptyline) for treatment of abdominal pain.
7. Infliximab and adalimumab—monoclonal antibodies that block the activity of the inflammatory agent and tumor necrosis factor. They are indicated for moderate to severe disease not responding to traditional therapies and for patients with draining fistulae.

Table 18-3 Drugs Used to Treat Inflammatory Bowel Disease

CATEGORY	ROUTE	DRUG	ADVERSE EFFECTS	CONSIDERATIONS
5-ASA drugs	Oral	Sulfasalazine	Headache, diarrhea, abdominal pain, abdominal cramping, malaise, hair loss, rash, orange discoloration of urine, bone marrow suppression, photosensitivity, and decreased sperm motility in men.	• Monitor CBC for signs of bone marrow suppression. • Recommend daily sunscreen use. • Decreased sperm motility is reversible upon drug discontinuation. • Urine discoloration is harmless.
	Oral	Olsalazine	Headache, diarrhea, abdominal pain, abdominal cramping, malaise, rash, joint pain, and nephrotoxicity. Rare cases of hepatitis have been reported to the FDA.	• Use with caution in patients with renal insufficiency
	Oral	Mesalamine and balsalazide	Headache, diarrhea, abdominal pain, abdominal cramping, malaise, rash, arthralgias, and nephrotoxicity	• Use mesalamine with caution in patients with renal insufficiency. Researchers have yet to determine the safety of balsalazide in patients with renal impairment. • Asacol tablets may be excreted whole in stool. Ask patients to report frequent passage of whole tablets.
	Rectal	Mesalamine	Abdominal pain, cramping, rectal bleeding, fever, and nephrotoxicity.	• Effective for distal disease (inflammation in the rectum and sigmoid colon). • Most adverse effects are mild and transient. • Available in both enema and suppository form for topical treatment of distal disease. The enema form allows coverage from the rectum to the sigmoid colon; suppositories suppress rectal inflammation.
Corticosteroids	Oral	Prednisone, methylprednisolone, and budesonide	Cushingoid appearance, hypertension, acne, water retention, weight gain, hair loss, increased appetite, hypokalemia, gastric irritation, ulcer formation, adrenal suppression, decreased resistance to infection. Complications associated with prolonged use include osteoporosis, cataract development, growth retardation, peptic ulceration, hyperglycemia, hypertension, aseptic joint necrosis, and glaucoma.	• May be administered in IV form when the gastrointestinal tract isn't able to absorb drugs properly. • Budesonide is approved for treating mild to moderately active Crohn disease of the terminal ileum. Because of budesonide's first-pass metabolism, systemic adverse effects are less common than those that occur with conventional steroids. • Corticosteroids aren't indicated for maintenance therapy in treating IBD secondary to associated long-term adverse effects.
	IV	Hydrocortisone and methylprednisolone		
	Rectal	Hydrocortisone/pramoxine and hydrocortisone		
Immune-modulating agents	Oral	6-Mercaptopurine and azathioprine	Bone marrow suppression, increased vulnerability to infection, rash, fever, malaise, arthralgias, hepatic dysfunction, nausea, vomiting, diarrhea, pancreatitis, hair loss, and neoplasm development.	• Monitor for bone marrow suppression. • Pregnancy category D. • Testing available that evaluates the patient's ability to metabolize the drug, determines therapeutic levels, and monitors for hepatotoxicity.
Biologic agents	IV	Infliximab	Infusion-related reactions: pruritus, rash, chest pain, hypotension, hypertension, dyspnea, headache, nausea, vomiting, fatigue, and fever.	• Infusion reactions usually resolve with decreasing the rate of infusion.
	SQ	Adalimumab	Other potential adverse effects (rare): autoantibody development (lupus-like syndrome) and increased susceptibility to infection.	• Perform tuberculosis (TB) skin test prior to first dose because of the drug's ability to allow latent TB to become active; a positive skin test (>5-mm induration) indicates the need for treatment for latent TB, before initiation of infliximab therapy. • Do not administer to patients with an active infection.

Adapted with permission from Rayhorn, N., & Rayhorn, D. (2002). Inflammatory bowel disease: Symptoms in the bowel and beyond. The Nurse Practitioner, 27 (11), 24–25.

Surgery

Indicated only for the complications of Crohn disease. Approximately 70% of Crohn disease patients will eventually require one or more operations to relieve obstruction, close fistulae, drain abscesses, repair perforations, manage hemorrhage, or widen strictures. Depending on the patient, surgical options include:

1. Segmental bowel resection with anastomosis.
2. Subtotal colectomy with ileorectal anastomosis.
3. Total colectomy with ileostomy for severe disease in the colon and rectum (see page 498 for care of the ostomy patient).
4. Kock pouch and ileal reservoir–anal anastomosis are contraindicated in Crohn patients. These procedures require the use of the small intestine in which Crohn disease may develop.

Complications

1. Abscess (occurs in 20%) and fistulae (occur in 40%).
2. Strictures—may result from inflammation, edema, abscess, and adhesions, but usually from fibrostenosis.
3. Hemorrhage, bowel perforation, intestinal obstruction.
4. Nutritional deficiencies: poor caloric intake because of food avoidance, malabsorption of bile salts and fat, vitamin B_{12} deficiency with ileal disease, short-gut syndrome after extensive surgical resections.
5. Dehydration and electrolyte disturbances.
6. Peritonitis and sepsis.

Nursing Assessment

1. Assess frequency and consistency of stools to evaluate volume losses and effectiveness of therapy.
2. Have the patient describe the location, severity, and onset of abdominal cramping or pain.
3. Ask the patient about weight loss and anorexia; weigh daily to monitor changes.
4. Have the patient describe foods eaten to elicit dietary exacerbations.
5. Determine if the patient smokes, including duration and amount.
6. Ask about family history of GI diseases.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to pain, nausea.
- Deficient Fluid Volume related to diarrhea.
- Chronic Pain related to the inflammatory disease of the small intestine.
- Ineffective Coping related to feelings of rejection and embarrassment.

Nursing Interventions

Achieving Adequate Nutritional Balance

1. Encourage a diet that is low in residue, fiber, and fat and high in calories, protein, and carbohydrates, with vitamin and mineral supplements.
2. Monitor weight daily.
3. Provide small, frequent feedings to prevent distention.
4. Have the patient participate in meal planning to encourage compliance and increase knowledge.

5. Prepare the patient for elemental diet or TPN if the patient is debilitated.

Maintaining Fluid and Electrolyte Balance

1. Monitor intake and output.
2. Provide fluids, as prescribed, to maintain hydration (1,000 mL/24 hours is minimum intake to meet body fluid needs).
3. Monitor stool frequency and consistency.
4. Monitor electrolytes (especially potassium) and acid–base balance because diarrhea can lead to metabolic acidosis.
5. Watch for cardiac dysrhythmias and muscle weakness because of loss of electrolytes.

Controlling Pain

1. Administer medications for control of inflammatory process, as prescribed.
2. Observe and record changes in pain—frequency, location, characteristics, precipitating events, and duration.
3. Monitor for distention, increased temperature, hypotension, and rectal bleeding—all signs of obstruction because of the inflammation.
4. Clean rectal area and apply ointments, as necessary, to decrease discomfort from skin breakdown.
5. Prepare the patient for surgery if response to medical and drug therapy is unsatisfactory.
6. Surgery is determined specifically for each patient.
7. Recurrence of the disease is possible after surgery.

Providing Psychosocial Support

1. Offer understanding, concern, and encouragement—this person is often embarrassed about frequent and malodorous stools and often is fearful of eating.
2. Facilitate supportive psychological counseling, if appropriate.
3. Encourage the patient's usual support people to be involved in management of the disease and seek additional support groups as needed.
4. Encourage health-promoting behavior.

Patient Education and Health Maintenance

1. Provide comprehensive education about anatomy and physiology of the GI system, the chronic disease process, drug therapy, potential complications, and potential surgery.
2. Instruct patient about all prescribed medications, including the purpose, dosage, and adverse effects as well as to discuss use of any OTC drugs with health care provider.
3. Encourage regular follow-up and to report signs of complications: increasing abdominal distention, cramping pain, diarrhea, malaise, anorexia, fever, and passing stool through the urethra or vagina.
4. Explain the importance of adequate hydration and nutrition (based on individual tolerance) and monitoring weight.

5. Encourage the patient to participate in stress-reducing activities, such as exercise, relaxation techniques, music therapy.
6. For further information and support, refer to Crohn's & Colitis Foundation at *www.ccfa.org*.

Evaluation: Expected Outcomes

- Improved nutritional intake; weight stable.
- Adequate fluid intake; no evidence of dehydration; electrolyte levels within normal limits.
- Demonstrates relief of pain and manageable symptoms.
- Verbalizes improved attitude toward ways to live with the disease.

Colorectal Cancer

Colorectal cancer refers to malignancies of the colon and rectum. This type is the third leading cause of death in the United States. Colorectal tumors are nearly all adenocarcinomas. Lymphoma, carcinoid, melanoma, and sarcomas account for only 5% of colorectal lesions.

Pathophysiology and Etiology

1. Risk factors include:
   a. Age: Risk increases sharply after age 45 in African Americans, 50 in others.
   b. Previous history of resected colorectal cancer or adenomatous polyps.
   c. Family history of colorectal cancer or adenomatous polyps, especially if one first-degree relative diagnosed before age 60 or two first-degree relatives diagnosed at any age.
   d. Familial adenomatous polyposis (FAP; also a variant called Gardner syndrome) is an inherited condition characterized by multiple adenomatous polyps of the colon, in which cancer will inevitably develop in all affected individuals.
   e. Hereditary nonpolyposis colorectal cancer (HNPCC)—hereditary condition with a markedly increased risk of developing colorectal cancer as well as other cancers, such as endometrial, ovarian, renal, pancreatic, gastric, and small intestinal. There are few or no adenomatous polyps, and the bowel may undergo rapid change from normal tissue to polyp to cancer.
   f. Chronic ulcerative colitis—increasing risk after 10-year history.
   g. Incidence is higher in industrialized countries and lower in underdeveloped countries. Reason unclear but may be related to diet. The Western diet, which is high in refined grains, processed and red meats, high-fat dairy products, desserts, and fried foods, has been shown to increase risk of colorectal cancer.
   h. Immunodeficiency disease.
2. Colorectal lesions occur most frequently in the rectum and sigmoid areas; however, it appears there is a trend toward increasing frequency of right-sided lesions.
3. Most adenocarcinomas are ulcerative in appearance. A left-sided lesion tends to be annular and scarlike; a right-sided lesion tends to be a cauliflower-like mass that protrudes into the bowel lumen.
4. A lesion starts in the mucosal layers of the colonic wall and eventually penetrates the wall and invades surrounding structures and organs (bladder, prostate, ureters, vagina). Cancer spreads by direct invasion, lymphatic spread, and through the bloodstream. The liver and lungs are the most common metastatic sites.

EVIDENCE BASE Kahi, C. J., Boland, C. R., Bominitz, J. A., et al. (2016). Colonoscopy surveillance after colorectal cancer resection: Recommendations of the US multi-society task force on colorectal cancer. *American Journal of Gastroenterology*, *111*(3), 337–346.

Clinical Manifestations

Colorectal cancer is often asymptomatic. If present, symptomatology varies according to the location of the lesion and the extent of involvement.

1. Right-sided lesions—change in bowel habits, usually diarrhea; vague abdominal discomfort; black, tarry stools; anemia; weakness; weight loss; palpable mass in right lower quadrant.
2. Left-sided lesions—change in bowel habits, often increasing constipation with bouts of diarrhea because of partial obstruction; bright, streaked red blood in stool; cramping pain; weight loss; anemia; palpable mass.
3. Rectal lesions—change in bowel habits with possible urgent need to defecate, alternating constipation and diarrhea, and narrowed caliber of stool; bright red blood in stool; feeling of incomplete evacuation; rectal fullness progressing to dull constant ache.

Diagnostic Evaluation

1. Fecal immunochemical test—replaces the older guaiac-based tests.
2. Flexible sigmoidoscopy—can be used if colonoscopy is declined.
3. Colonoscopy with biopsy—diagnostic procedure of choice after strong suspicious clinical history or abnormal barium enema. CT colonography, also known as virtual colonoscopy, may be used for screening.
4. Pelvic MRI and endorectal ultrasonography—provide information about cancer penetration and pararectal lymph nodes.
5. Carcinoembryonic antigen (CEA)—70% of patients have elevated CEA levels. The CEA level monitors possible recurrence or metastasis.
6. CT scan of the abdomen, liver, lungs, and brain—may reveal metastatic disease.

Management

Surgical Resection

Treatment of choice for those with resectable lesions. Regional lymph node dissection determines staging and guides decisions regarding adjuvant therapy. Surgical options include:

1. Laparotomy with wide segmental bowel resection of tumor, including regional lymph nodes and blood vessels (right hemicolectomy, transverse colectomy, left hemicolectomy, or sigmoid resection).
2. Transanal excision—select people with tumors less than 1¼ inches (3 cm) and well differentiated less than 3 inches (7.5 cm) from the anal verge and localized to the rectal wall may avoid laparotomy.
3. Low anterior resection for upper rectal lesions—may include temporary loop colostomy to protect anastomosis with second procedure for takedown of colostomy.
4. Colonic J pouch—may be offered as a new surgical technique for rectal cancer (see page 525).
5. Select patients may be offered laparoscopic cancer surgery, although this remains controversial.
6. Abdominoperineal resection with permanent end colostomy for lower rectal lesions when adequate

margins cannot be obtained, or there is involvement of anal sphincters. Because of improved stapling devices used deep in the pelvis, abdominoperineal resection accounts for fewer than 5% of colorectal resections.

7. Temporary loop colostomy to decompress bowel and divert fecal stream, followed by later bowel resection, anastomosis, and takedown of colostomy.
8. More extensive surgery involving the removal of other organs if cancer has spread, such as liver wedge, bladder, uterus, and/or small intestine, may be performed.
9. Unresectable colorectal cancer—diverting colostomy or ileostomy as palliation for obstructing tumor, laser fulguration, or the placement of an expandable wire stent.
10. Total proctocolectomy or ileal reservoir–anal anastomosis procedure for patients with FAP and chronic ulcerative colitis before colorectal cancer develops.

Other Therapy

1. Radiation therapy may be used preoperatively to improve resectability of the tumor and may be used postoperatively as adjuvant therapy to treat residual disease.
2. Chemotherapy may be used as adjuvant therapy to improve survival time.
   a. Used for residual disease, recurrence of disease, unresectable tumors, and metastatic disease.
   b. Drug combinations may include 5-fluorouracil plus levamisole or 5-fluorouracil plus leucovorin.
   c. A newer drug, irinotecan, is being used in protocols for advanced colorectal cancer.
3. Blood replacement of whole blood or packed red blood cells if severe anemia exists.

Complications

1. Obstruction.
2. Hemorrhage.
3. Anemia.
4. Metastasis.

Nursing Assessment

1. Interview patient regarding dietary habits and family and medical history to identify risk factors.
2. Question the patient regarding symptomatology of colorectal cancer, changes in bowel habits, rectal bleeding, tarry stools, abdominal discomfort, weight loss, weakness, and anemia.
3. Palpate the abdomen for tenderness (usually not tender), presence of mass.
4. Test stool for occult blood.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to malignancy effects and weight loss.
- Constipation and/or Diarrhea related to change in bowel lumen.
- Chronic pain related to malignancy, inflammation, and possible intestinal obstruction.

- Fatigue related to anemia, radiation, chemotherapy, and metastatic disease.
- Fear related to diagnosis, prognosis, potential for complications.

Nursing Interventions

Achieving Adequate Nutrition

1. Meet the patient's nutritional needs by serving a high-calorie, low-residue diet for several days before surgery, if condition permits.
2. Observe and record fluid losses, such as may be sustained by vomiting and diarrhea.
3. Maintain hydration through IV therapy and record urine output. Metabolic tissue needs are increased, and more fluids are needed to eliminate waste products.
4. Serve smaller meals spaced throughout the day to maintain adequate calorie and protein intake if not NPO.
5. Encourage the patient to participate in meal planning to promote compliance.
6. Adjust diet before and after treatments, such as chemotherapy or radiation. Serve clear liquids, bland diet, or NPO, as prescribed.
7. Instruct the patient to take prescribed antiemetic, as needed, especially if receiving chemotherapy.

Relieving Constipation or Diarrhea

1. Monitor amount, consistency, frequency, and color of stool.
2. For constipation, use laxatives or enemas, as needed, and encourage exercise and adequate fluid/fiber intake to promote bowel motility.
3. For diarrhea, encourage adequate fluid intake to prevent fluid volume deficit and electrolyte imbalance.
4. For diarrhea related to radiation or chemotherapy, administer antidiarrheal medications and discuss foods that may slow transit time of bowel, such as bananas, rice, peanut butter, and pasta.

NURSING ALERT Antidiarrheal medications and foods to control diarrhea are contraindicated for the patient with an obstructing lesion. Use these measures only postoperatively after lesion resection for control of diarrhea related to cancer therapy.

Relieving Pain

1. Assess type and severity of pain and administer analgesics, as needed.
2. Evaluate effectiveness of analgesic regimen.
3. Investigate different approaches, such as relaxation techniques, repositioning, imaging, laughter, music, reading, and touch, for control or relief of pain.

Maintaining Energy Level

1. Institute an individualized activity plan after assessing the patient's activity level and tolerance, noting shortness of breath or tachycardia.
2. Allow for frequent rest periods to regain energy.
3. Administer blood products or recombinant human erythropoietin, as ordered, if fatigue is related to severe anemia.

Minimizing Fear

1. Encourage the patient and family to express feelings and fears together and separately.
2. Acknowledge that it is normal to have negative feelings toward cancer, surgery, colostomy, and treatment options.
3. Provide information and answer questions regarding disease process, treatment modalities, and complications. Offer diverse educational materials, such as brochures and videotapes.
4. Refer for counseling, if desired.
5. Genetic testing can confirm a hereditary diagnosis such as FAP or HNPCC.

Patient Education and Health Maintenance

1. Provide detailed information or resources about treatment modalities of radiation and chemotherapy.
2. Teach and demonstrate to the patient and/or family the skills necessary for colostomy management, which may include colostomy irrigation. The ostomy specialty nurse can provide formal education in this area.
3. Initiate a home care nursing referral to assist with wound care, to manage treatment adverse effects, and to continue teaching colostomy care.
4. Become an advocate for colon cancer prevention by educating the public about screening. Beginning at age 45 for African Americans and age 50 for others, men and women should follow one of the following American Cancer Society guidelines for early detection of colon cancer.
   a. Flexible sigmoidoscopy every 5 years.
   b. Colonoscopy every 10 years.
   c. Double-contrast barium enema every 5 years.
   d. Computed tomographic colonography (CTC) every 5 years.
   e. Alternately, stool-based testing can be done annually, but if positive, a colonoscopy must follow. Tests include guaiac-based fecal occult blood test (gFOBT) with high sensitivity for cancer, FIT with high sensitivity for cancer, and stool DNA (sDNA) with high sensitivity for cancer (interval uncertain pending further research).
5. For additional information and support, refer to the American Cancer Society at *www.cancer.org*.

EVIDENCE BASE Smith, R. A., Manassram-Baptiste, D., Brooks, D., et al. (2015). Cancer screening in the United States, 2015: A review of current American Cancer Society guidelines and issues in

cancer screening. *CA—Cancer Journal for Clinicians, 65*, 30–54.

Evaluation: Expected Outcomes

- Exhibits weight gain and improves nutritional status by adequate dietary intake.
- Has regular soft bowel movements.
- Minimal pain, controlled with analgesics or other techniques.
- Able to perform ADLs with adequate amounts of energy; no shortness of breath on exertion.
- Sleeping well; able to discuss feelings and fears related to surgery, prognosis, and treatment options.

ANORECTAL CONDITIONS

Hemorrhoids

Hemorrhoids are vascular masses in the lower rectum or anus. External hemorrhoids appear outside the external sphincter, whereas internal hemorrhoids appear above the internal sphincter (see Figure 18-15). When blood within the hemorrhoids becomes clotted because of obstruction, the hemorrhoids are referred to as thrombosed.

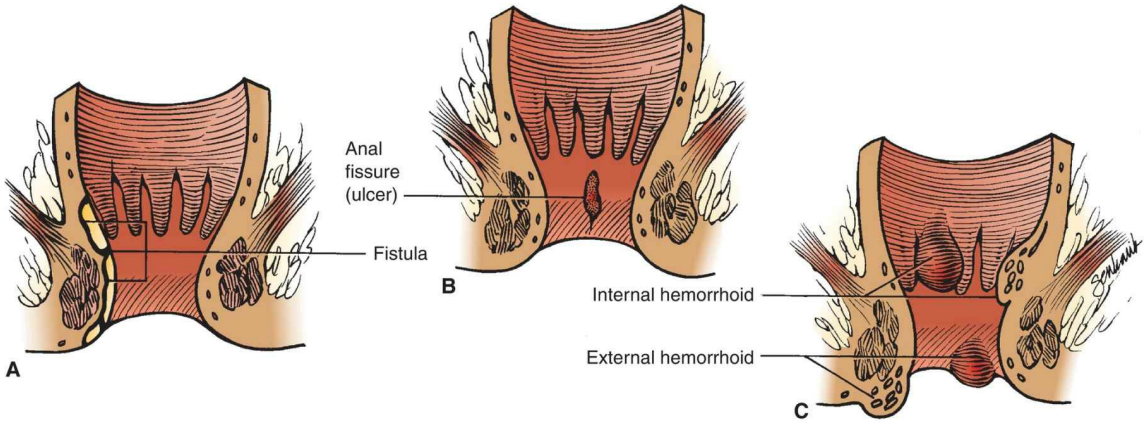

Figure 18-15. Various types of anal lesions. **(A)** Fistula. **(B)** Fissure. **(C)** External and internal hemorrhoids.(Smeltzer, S., & Bare, B. [2003]. Brunner and Suddarth's textbook of medical-surgical nursing [10th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

1. The exact pathogenesis remains controversial. Theories include:
   a. Abnormal dilation of veins of internal hemorrhoidal venous plexus.
   b. Abnormal distention of the arteriovenous anastomoses.
   c. Downward displacement or prolapse of anal cushions.
   d. Destruction of the anchoring connective tissue system.
2. Predisposing factors include:
   a. Pregnancy, prolonged sitting/standing.
   b. Straining at stool, chronic constipation/diarrhea.
   c. Anal infection, rectal surgery, or episiotomy.
   d. Hereditary factor.
   e. Exercise.
   f. Coughing, sneezing, vomiting.
   g. Loss of muscle tone because of age.
   h. Anal intercourse.
3. Increased intra-abdominal pressure causes engorgement in the vascular tissue lining the anal canal.
4. Loosening of vessels from surrounding connective tissue occurs with protrusion or prolapse into anal

canal.

Clinical Manifestations

1. Bleeding during or after defecation, bright red blood on stool because of injury of mucosa covering hemorrhoid (most common).
2. Visible (if external) and palpable mass.
3. Constipation and anal itching.
4. Sensation of incomplete fecal evacuation.
5. Infection or ulceration, mucus discharge.
6. Pain noted more in external hemorrhoids.
7. Sudden rectal pain because of thrombosis in external hemorrhoids.

Diagnostic Evaluation

1. History and visualization by external examination through anoscopy or proctosigmoidoscopy.
2. Barium enema or colonoscopy to rule out more serious colonic lesions causing rectal bleeding.

Management

Asymptomatic hemorrhoids require no treatment.

Medical

1. Bowel habits should be regulated with nonirritating stool softeners and high-fiber diet to keep stools soft.
2. Frequent, warm sitz baths to ease pain and combat swelling.
3. Analgesics as needed.
4. Topical creams, lotions, pads, and suppositories containing such active ingredients as witch hazel, zinc monohydrate, pramoxine hydrochloride, glycerol stearate, phenylephrine, and hydrocortisone, to reduce swelling and provide comfort.
5. Control of itching by improved anal hygiene measures and control of moisture.
6. Avoid prolonged use of topical anesthetics on hemorrhoids or fissures because they often produce hypersensitive (allergic) perianal skin rashes with severe itching.
7. Manual reduction of external hemorrhoids if prolapsed.
8. Injection of sclerosing solutions (phenol 5%) to produce scar tissue and decrease prolapse.
9. Cryodestruction (cryosurgery)—freezing of hemorrhoids.
    a. Profuse drainage and swelling occur.
    b. Foul-smelling discharge may last for 7 to 10 days after cryosurgery.
10. Other procedures include infrared coagulation (infrared radiation) and bipolar diathermy (heat).

Surgical

1. Surgery may be indicated when the following conditions exist:
    a. Prolonged bleeding.
    b. Disabling pain.
    c. Intolerable itching.
    d. Prolapse.
2. Rubber ring ligation is the treatment of choice.
    a. During anoscopy, the apex of the hemorrhoid is grasped and drawn through a drum.
    b. A trigger device expels two rubber bands, which encircle the base of the hemorrhoid.
    c. After a period of time, the hemorrhoid sloughs away.
3. Dilation of the anal canal and lower rectum under general anesthesia is another treatment.
    a. This procedure is not advocated for patients whose main complaints are prolapse or incontinence.
    b. It also is not recommended for aging patients with weak sphincters.
4. Incision and removal of clot from acutely thrombosed hemorrhoid.
5. Hemorrhoidectomy—excision of internal/external hemorrhoids.

Complications

1. Hemorrhage, anemia.
2. Incontinence.
3. Prolapse and strangulation.

Nursing Interventions and Patient Education

1. After thrombosis or surgery, assist with frequent positioning, using pillow support for comfort.
2. Provide analgesics, warm sitz baths, or warm compresses to reduce pain and inflammation.
3. Apply anal pads, creams, or suppositories, as ordered, to relieve discomfort.
4. Observe anal area postoperatively for drainage and bleeding; report if excessive.
5. Administer stool softener/laxative to assist with bowel movements soon after surgery to reduce risk of stricture.
6. Encourage regular exercise, high-fiber diet, and adequate fluid intake (8 to 10 glasses/day) to avoid straining and constipation.
7. Discourage regular use of laxatives—firm, soft stools dilate the anal canal, decreasing stricture formation.
8. Determine the patient's normal bowel habits, and identify predisposing factors to educate patient about changes necessary to prevent recurrence of symptoms.

Other Conditions of the Anorectum

See Table 18-4, pages 534 to 535.

Table 18-4 Anorectal Disorders

CONDITION	ETIOLOGY	CLINICAL MANIFESTATIONS	MANAGEMENT	NURSING CONSIDERATIONS
Fissure				
Linear laceration of anal epithelium; typically located in the posterior midline	• Constipated stools may tear anal lining • Perineum strain during childbirth • Tuberculosis, syphilis, and Crohn disease are less common causes	• Tearing acute pain during and after bowel movement; discomfort may continue several hours after bowel movement • Spotting of bright red blood with stool; spasm of anal canal; burning	• Promotion of regular, soft bowel movements through stool softeners, suppositories, high-fiber diet, bulking agents • Topical creams • Fissurectomy; sphincterotomy	• Assist with warm sitz baths and local application of anesthetic ointment to reduce pain • Instruct to eat high-fiber foods and drink fluids to prevent constipation
Abscess				
Localized area of pus from inflammation of anorectal tissue	• Infection develops from abrasion from foreign object, such as enema tip or fishbone • Acute phase of anal fistula, suspect Crohn disease • Tuberculosis or actinomycosis	• Painful, reddened bulge or swelling near the anus; pain increases with sitting; moderate to severe pain • Purulent drainage	• Incision and drainage of purulent exudate • Placement of drainage catheter for 7 to 10 days; possible packing dressing • Warm sitz baths; pulsed lavage	• Wound assessment • Pain medications as needed • Alert for passage of bowel movements, postoperatively
Fistula				
Abnormal tubelike passage from the skin near the anus into anal canal	• Often preceded by anal abscess • May be associated with inflammatory bowel disease, cancer, or foreign body • Hidradenitis suppurativa	• Purulent drainage from opening • Itching and pain	• Fistulotomy • Fistulectomy • Bowel rest to allow fistula to heal; possible fecal diversion temporarily	• Wound assessment • Pain medications as needed • Alert for passage of bowel movements, postoperatively
Anal condylomas; venereal warts				
	• Infectious cauliflower-like papillomas; probably sexually transmitted papillomavirus • Differentiate from syphilitic warts, hemorrhoids, and anal/skin cancers	• Thrive in moist, macerated surfaces, as with purulent drainage • Often recur • Rarely invade the urethra, bladder, or rectum	• Application of podophyllum resin (may be painful) • Electrofulguration • Alpha-interferon injections/synergistic with podophyllum resin • Fluorouracil	• Encourage good anal hygiene and frequent use of talc dusting powder • Schedule follow-up visits to assess area periodically for recurrence
Proctitis				
Acute or chronic inflammation of rectal mucosa	• Common infecting organisms: *Neisseria gonorrhoeae*, *Chlamydia*, herpes simplex virus, *Treponema pallidum* (syphilis) • Radiation	• Anorectal pain; purulent, mucoid, or bloody discharge; pruritus; tenesmus • Diarrhea and/or constipation	• Treatment specific to isolated organism—antibiotics, antivirals • Bulking agents, antispasmodics	• Review medications • Assist with examination and treatment
Stricture				
Narrowing of the anorectal lumen, preventing dilation of sphincter	• Usually results from scarring after anorectal surgery (hemorrhoidectomy) or inflammation • Congenital anomalies	• Constipation, ribbon stools, may not completely evacuate stools • Pain with bowel movement; itching	• Treatment of inflammatory cause • Dilation by digital, instrumentation, or balloon methods • If stenosis severe, may need plastic surgery to anal canal	• Prevention of stenosis after anal surgery facilitated by anal hygiene, warm sitz baths, and dilation • Postoperative care includes stool softeners, warm sitz baths, and wound care
Rectal Prolapse				
Mucosal membrane protrudes through the anus	• The support structures are weakened (sphincters and muscles), leading to rectal intussusception • Conditions may include neurologic disorders, chronic diseases, aging	• Associated with constipation and straining; rectal fullness • Bloody diarrhea; rectal ulcer secondary to intussusception	• Treatment depends on underlying cause • Sclerosing agent injection may fix the rectum in place • Surgery may include sphincter repair or resection of prolapsed tissue	• Diet/fluid instructions to avoid constipation • Teach perineum-strengthening exercises

Hepatic, Biliary, and Pancreatic Disorders

Overview and Assessment

Assessment of Accessory Organ Dysfunction

Laboratory Tests

Radiology and Imaging Studies

Other Diagnostic Tests

Hepatic Disorders

Hepatitis

Hepatic Cirrhosis

Bleeding Esophageal Varices

Liver Cancer

Fulminant Liver Failure

Biliary Disorders

Cholecystitis, Cholelithiasis, Choledocholithiasis

Care of the Patient Undergoing Cholecystectomy

Pancreatic Disorders

Acute Pancreatitis

Chronic Pancreatitis

Pancreatic Cancer

OVERVIEW AND ASSESSMENT

Assessment of Accessory Organ Dysfunction

The liver and its bile ducts, the gallbladder, and the pancreas are called accessory glands in the GI system. Their function is to aid digestion through the delivery of bile and enzymes to the small intestine. The liver plays additional roles in detoxification of chemicals and synthesis and storage of important nutrients. The pancreas also functions as an endocrine gland, as discussed in Chapter 24 .

Effects of Aging on Liver and Gallbladder

Liver function tests generally remain within normal range, but a number of other physiologic changes occur within the hepatic and biliary systems with aging.

1. Decline in liver volume and size.
2. Decrease in blood flow.
3. Reduced drug metabolism.
4. Decline in capability of drug clearance.
5. Slower repair of damaged liver cells after injury.
6. Decreased production and flow of bile with decline in gallbladder contraction after meals.
7. Atypical clinical presentation of gallbladder and bile duct disorders.
8. Increased cholesterol secretion in bile leading to increased occurrence of gallstones.
9. Slower clearance of hepatitis B surface antigen, if infected.
10. Rapid progression of hepatitis C infection with lower response rate to therapy.

GERONTOLOGIC ALERT Use caution with administering potentially hepatotoxic drugs, such as acetaminophen, to older adults.

History

1. Was the patient born between the years of 1945 and 1965?
2. Have there been blood transfusions (before 1992)? Are there known blood disorders? GI bleeding?
3. Has there been contact with a person who has an infection such as hepatitis? Any unprotected sexual activity or ingestion of potentially contaminated food?
4. Has there been drug or chemical toxicity, such as carbon tetrachloride, chloroform, phosphorus, arsenicals, ethanol, halothane, isoniazid, or acetaminophen? Have amanita mushrooms been ingested recently? Are certain medications being taken, such as phenothiazine derivatives, sulfonamides, antidiabetic drugs, propylthiouracil, monoamine oxidase inhibitors, methyldopa, azathioprine, corticosteroids, thiazide diuretics, estrogens, and valproic acid? Any antiviral medications taken for Aquired Immune Deficiency Syndrome such as didanosine or antineoplastic agents, as many of these drugs can cause hepatic, biliary, and pancreatic gastrointestinal symptoms?

5. Is there a history of nonsterile needle puncture, as in subcutaneous ("skin popping"), intramuscular ("muscling"), or intravenous (IV) drug use? Tattoos?
6. Does medical history include gallstones, hepatitis, pancreatitis, Wilson disease, Budd-Chiari syndrome, biliary cirrhosis, liver surgery, or transplantation?
7. Any family history of gallstones, pancreatitis, gallbladder, or pancreatic cancer or related cancers such as breast or ovarian cancer?
8. Is there a history of organ transplantation (before 1992)?
9. How much alcohol is or has been ingested during the patient's life and what specific type of alcohol (i.e., beer, wine, liquor)?

Common Manifestations

1. Any jaundice—yellow color of sclera and skin, pruritus, dark tea-colored urine, light gray or clay-colored (acholic) stool?
2. Any dyspepsia, anorexia, nausea, vomiting, right upper quadrant or epigastric pain, or pain radiating to the back or shoulder blade? What is the relationship of pain to eating or to position?
3. Has there been fatigue, malaise, loss of vigor and strength, easy bruising, or weight loss?
4. Any fever, chills, headache, myalgias, arthralgias, photophobia?
5. Any steatorrhea—stools that are loose, greasy, foamy, orange in color, and foul smelling and that float?

Physical Examination Findings

1. Skin—yellow sclera or skin? Rashes or scratches on body from severe scratching because of pruritus? Any signs of bruising or petechiae on body, palmar erythema, or overt bleeding?
2. Neurologic—what is the level of consciousness (LOC)? Any asterixis (flapping tremor elicited when the arms are extended and wrists dorsiflexed)?
3. Abdomen—any tenderness or liver enlargement in the right upper quadrant? Any ascites? Any palpable masses in the abdomen? Any fluid wave?
4. Peripheral vascular—any edema, anasarca, or telangiectasia?

Laboratory Tests

See Table 19-1, page 538.

Table 19-1 Liver Diagnostic Studies

TEST AND PURPOSE	NORMAL	NURSING CONSIDERATIONS
Bile Formation and Secretion		
Serum Bilirubin		
Measures bilirubin in the blood; this determines the ability of the liver to take up, conjugate, and excrete bilirubin. Bilirubin is a product of the breakdown of hemoglobin.		
Direct (conjugated)—soluble in water	0–0.3 mg/dL	• Abnormal in biliary and liver disease, causing jaundice clinically.
Indirect (unconjugated)—insoluble in water	0–1 mg/dL	• Abnormal in hemolysis and in functional disorders of uptake or conjugation.
Total serum bilirubin	0.1–1.2 mg/dL	• Used as screening test for liver or biliary dysfunction.
Urine Bilirubin		
Not normally found in urine, but if direct serum bilirubin is elevated, some spills into urine.	None (0)	• Tea-colored urine; when specimen is shaken, yellow-green tinted foam can be observed. • If the patient is receiving phenazopyridine, mark the laboratory slip to this effect because there may be a false- positive bilirubin result.
Urobilinogen		
Formed in small intestine by action of bacteria on bilirubin. Related to amount of bilirubin excreted into bile.	Urine urobilinogen <1 mg in 2-hr specimen or 0.5 to 4 mg/dL in 24-hr specimen Fecal urobilinogen 50 to 300 mg/24 hr	• Random urine specimen is collected over 2-hr after lunch, or a total level is collected over a 24-hr period. • Place specimen in dark brown container and send it to laboratory immediately or refrigerate to prevent decomposition. • If the patient is receiving antimicrobials, mark laboratory slip to this effect because production of urobilinogen can be falsely reduced.
Protein Studies		
Albumin and Globulin Measurement		
Is of greater significance than total protein measurement.		• As one increases, the other decreases.
Albumin—produced by liver cells	3.5–5.5 g/dL	• Albumin ↓ (decrease) in cirrhosis, chronic hepatitis
Globulin—produced in lymph nodes, spleen, bone marrow, and Kupffer cells of liver	2.5–5.9 g/dL	• Globulin ↑ (increase) in cirrhosis, chronic obstructive jaundice, viral hepatitis
Coagulation		
Prothrombin Time (PT)		
Prothrombin and other clotting factors are manufactured in the liver; its rate is influenced by the supply of vitamin K.	9.6–12.5 sec	• PT may be prolonged in liver disease, in which case it will not return to normal with vitamin K. It may also be prolonged in malabsorption of fat and fat-soluble vitamins, in which case it will return to normal with vitamin K.
Calculated from PT		
International Normalized Ratio (INR)	0.8–1.2	• Used to monitor warfarin therapy.
Fat Metabolism		
Cholesterol		
Measures lipid metabolism by determining serum cholesterol levels.	140–200 mg/dL	• Serum cholesterol level is decreased in parenchymal liver disease. • Serum lipid level is increased in biliary obstruction.
Liver Detoxification		
Serum Alkaline Phosphatase		
Because bile disposes this enzyme, any impairment of liver cell excretory function will cause an elevation. In cholestasis or obstruction, increased synthesis of enzyme causes very high levels in blood.	30–120 IU/L	• Elevated to more than three times normal in extrahepatic obstructive jaundice, intrahepatic cholestasis, liver metastasis, or granulomas. Also elevated in osteoblastic diseases, Paget disease, and hyperparathyroidism.

Enzyme Production These enzymes are found in high concentration in the liver as well as some other tissues. Liver injury results in enzyme release into blood.		
Aspartate aminotransferase (AST)	0–37 IU/L	• An elevation in these enzymes indicates liver cell damage.
Alanine aminotransferase (ALT)	0–40 IU/L	• Some drugs such as opioids may also cause a rise in AST and ALT.
Lactate dehydrogenase (LDH)	105–333 IU/L	• LDH is found in liver, heart, kidney, muscle, and blood cells.
Gamma glutamyl transpeptidase (GGT)	0–51 IU/L	• GGT is also found in the kidneys, pancreas, and bile ducts but is most sensitive to alcohol-induced liver damage.
Ammonia (NH3), serum	0–32 mmol/L	• Ammonia levels rise when the liver is unable to convert ammonia to urea.

CA 19-9

Description

A tumor antigen found in serum; used as a marker to assess the efficacy of treatment in pancreatic cancer, surgical outcomes, and survival.

Nursing and Patient Care Considerations

1. Tell patient a blood test will be taken and the results will be ready in 1 to 2 days.
2. Not a screening test for pancreatic cancer, this is an adjunct with other tests to provide support for a diagnosis of pancreatic cancer and to better measure the recurrence of pancreatic cancer after treatment.
3. Antigen level may be elevated with benign conditions including biliary tract obstruction, thyroid disease, inflammatory bowel disease, and acute or chronic pancreatitis.

Alpha-fetoprotein

Description

An oncofetal antigen found in serum that appears when a tumor returns to a more primitive state. Alpha-fetoprotein (AFP) is elevated in 70% to 95% of hepatocellular carcinomas (primary liver cancer).

Nursing and Patient Care Considerations

1. Tell patient a blood test will be taken and the results will be ready in 1 to 3 days.
2. Not a screening test for primary liver cancer, this is an adjunct with other tests to provide support for a diagnosis of primary liver cancer and to detect/ predict liver metastasis.
3. AFP may also be elevated in certain tumors of the gonads (testes and ovaries), retroperitoneum, and mediastinum.

Radiology and Imaging Studies

Ultrasonography

Description

1. A noninvasive test that focuses high-frequency sound waves over an area in the abdomen to generate an image of the structure.
2. Ultrasound of the abdomen can detect gallstones, dilated bile duct, fluid-filled cysts, ascites, and small abdominal masses.
3. This test is the preferred diagnostic procedure. It is rapid and accurate, and does not expose the patient to radiation. It can be used safely in patients with liver dysfunction and jaundice.
4. It is reported to be able to detect gallstones with 95% accuracy.
5. Ultrasound with Doppler can assess the patency of the portal vein, hepatic artery, hepatic vein, and direction of blood flow. It can be used to diagnose patients with Budd-Chiari syndrome or vessel thrombosis after major liver surgery or liver transplant.

Nursing and Patient Care Considerations

1. The patient should have nothing to eat or drink for 4 to 8 hours prior to the exam, and a fat-free meal is preferred the evening before the test, in order to minimize air in the stomach and bowel, which would obscure images of the gallbladder, liver, pancreas, and spleen. Medications may be taken with small sips of water.
2. Explain to the patient that a gel is applied to the skin over the selected area and a wandlike transducer is swept across the area of interest.
3. Ultrasound pictures will be obtained.

Hepatobiliary Scan

Description

1. A noninvasive nuclear medicine study (also referred to as a hepatobiliary iminodiacetic acid [HIDA] scan) using radioactive materials to evaluate gallbladder function and aid in the diagnosis of hepatobiliary disorders, such as common bile duct obstruction, acute and chronic cholecystitis, bile leaks, bile reflux, and hepatocellular dysfunction after liver transplantation.
2. A radioactive agent is administered in an IV line. It is taken up by the hepatocytes and excreted rapidly through the biliary tract.
3. The biliary tract is scanned, and images of the gallbladder and biliary tract are obtained.

Nursing and Patient Care Considerations

1. Patient should have nothing by mouth (NPO) for at least 4 hours before the procedure to optimize emptying of gallbladder.
2. If possible, no opiates should be administered for at least 8 hours before the procedure because of opiate

effects on smooth muscle motility of biliary tree and gallbladder.

3. Inform the patient that the scan takes approximately 2 to 4 hours and additional images may need to be taken up to 24 hours later.

Endoscopic Retrograde Cholangiopancreatography

Description

1. Endoscopic retrograde cholangiopancreatography (ERCP) involves visualization of the common bile, pancreatic, and hepatic ducts with a flexible fiber-optic endoscope inserted into the esophagus, passed through the stomach, and into the duodenum.
2. The common bile duct and the pancreatic duct are cannulated, and contrast medium is injected into the ducts, permitting visualization and radiographic evaluation.
3. Done to detect extrahepatic biliary obstruction, such as calculi, tumors of the bile duct, strictures or injuries to the bile duct; intrahepatic biliary obstruction caused by stones or tumor; and pancreatic disease, such as chronic pancreatitis, pseudocyst, pancreatic duct anomalies, or tumor.
4. May be combined with a therapeutic biliary or pancreatic procedure, such as endoscopic sphincterotomy, placement of biliary or pancreatic stents, tissue biopsy, removal of fluid for cytology, or retrieval of retained gallstones from the common bile duct.

Nursing and Patient Care Considerations

Preprocedure

1. Assess for allergies to iodine, seafood, or contrast media to determine the need for premedication with antihistamines or steroids (per facility protocol) to prevent a reaction.
2. Patient must be NPO for at least 6 hours before the procedure. Withhold medications according to provider order.
3. Any patient receiving heparin should have the infusion stopped for 4 to 6 hours before the procedure. If patient is receiving warfarin, aspirin, clopidogrel, or other platelet-inhibiting or blood-thinning medication, a recent international normalized ratio (INR)/partial prothrombin time (PTT) must be available.
4. Make sure that dentures are removed; instruct the patient to gargle and swallow topical anesthetic to decrease gag reflex, as ordered.
5. Verify that the patient has a signed consent form before sedation is given.
6. Establish baseline vital signs.
7. Establish IV access.
8. Administer antibiotic prophylaxis, as ordered.
9. If outpatient procedure, the patient must have a responsible adult to drive him or her home as patient is not allowed to drive or operate machinery for 24 hours because of the effects of mild sedation.

Postprocedure

1. Monitor and document vital signs.
2. Observe for and report abdominal distention and signs of perforation, GI bleeding, or possible pancreatitis, including chills, fever, pain, vomiting, hypotension, and tachycardia. Notify the health care provider immediately.
3. Maintain NPO status until the patient is alert and gag reflex returns. Check for gag reflex by applying gentle pressure with a tongue depressor placed on the back of the tongue.

Endoscopic Ultrasound

Description

1. In endoscopic ultrasound (EUS), a high-frequency ultrasound probe is placed at the tip of an endoscope to assess the pancreas through the GI lumen. This helps to provide images of the pancreas and adjacent organs.
2. It is useful in staging pancreatic tumors and establishing the size of the tumor, its extension into adjacent structures, local and regional nodal involvement, and any blood vessels that may be involved.
3. Tissue may also be obtained by fine needle aspiration through EUS guidance to confirm the diagnosis of a pancreatic malignancy.

Nursing and Patient Care Considerations

1. Instruct the patient that tissue may be obtained for analysis.
2. Verify that the patient has a signed consent form for the procedure and tissue aspiration before sedation is given.
3. Preprocedure and postprocedure care is the same as for ERCP.

Magnetic Resonance Cholangiopancreatography

Description

1. A noninvasive, nonradiation radiologic technique that produces images of the pancreatic ducts and biliary tree similar in appearance to those obtained from an ERCP with the advantage of providing images of the surrounding parenchyma.
2. Magnetic resonance cholangiopancreatography (MRCP) can detect the level and presence of biliary obstruction, but cannot offer therapeutic intervention.
3. MRCP does not require the administration of contrast material and provides ideal imaging for patients with allergies to iodine-based contrast materials or kidney disease. Noniodine contrast agent may be given to enhance the picture of the biliary anatomy or secretin may be given as it stimulates exocrine secretion of the pancreas and improves visualization of the pancreatic duct by increasing its caliber.

Nursing and Patient Care Considerations

Preprocedure

1. Confirm that the patient does not have a pacemaker or internal defibrillator because the magnetic field

could cause malfunction.

2. Confirm that the patient does not have any metal hardware in or on the body, such as intracranial aneurysm clips, intraocular metal fragments, cochlear ear devices, metal joint replacements, retained bullets or shrapnel, or steel sutures, because this may cause artifact and a distorted picture from the magnetic pull by the metal.
3. Remove all metal attachments from the patient, such as watch, jewelry, piercings, cell phone, IV poles, and infusion devices.
4. Confirm that the patient does not have a fear of enclosed spaces (claustrophobia) or anxiety as the patient may not be able to undergo the procedure or may require a sedative.
5. The patient must be NPO for at least 4 hours before the procedure.
6. Inform the patient that the test takes about 10 to 30 minutes.

Postprocedure

1. The patient may resume usual activities.
2. The health care provider will notify the patient of the results when available, usually in 1 to 3 days.

Positron Emission Tomographic (PET) Scan

Description

1. Positron emission tomography (PET) is an imaging technique that uses positively charged radioactive particles to detect subtle changes in the body's metabolism and chemical activities.
2. Fluorodeoxyglucose 18F (18F-FDG) is injected via IV line as a radiotracer and has a short half-life of 110 minutes and is cleared rapidly from the body.
3. The radiotracer used most often for PET scan has a glucose component; because malignant tumors use glucose and grow at a faster rate than normal tissue, PET scans are able to locate areas of high tracer uptake, which represents tumor growth.
4. A PET scan provides a black-and-white or color-coded image of the function of a particular area of the body, rather than its structure. Functional change precedes structural change in tissues and organs; therefore, PET scans can detect abnormalities earlier than a computed tomography (CT) scan or magnetic resonance imaging (MRI).
5. PET scan application in hepatic, biliary, and pancreatic disease includes the detection of cancer—particularly when other conventional imaging findings are negative—and response to cancer treatment. PET scan can also be used to evaluate the physiology of the heart and brain at baseline or following an event to determine remaining function.

Nursing and Patient Care Considerations

Preprocedure

1. The patient should begin a limited carbohydrate diet 24 hours prior to the procedure. The test provides images showing where certain molecules are in the body, including where glucose is located. This is

greatly affected by the level of sugar in the blood; therefore, the diet the day before the scan impacts the quality of pictures.

2. The patient must be NPO, except for plain water, for at least 6 hours before the procedure.
3. Patients with diabetes or patients with glucose intolerance may require adjustments in diet and oral hypoglycemic or insulin dosage on the day of the test as blood glucose levels must be no higher than 200 mg/dL. Adjustments should be made on an individual basis.
4. Patients are not to do exercise of any sort for the 48 hours prior to the exam. This includes even nominal exercise such as golf and gardening.
5. Advise the patient to remove jewelry or other items containing metal.
6. Inform the patient that scanning time varies from 15 minutes to 2 hours, depending on the areas to be scanned, but the total time in the imaging center is longer (2 to 3 hours).
7. Caution the patient that it is essential to arrive on time for this test because the FDG tracer is radioactive only for a short time. Some centers order the tracer on a per case basis, scheduling delivery of the radiotracer to coincide with the patient's time of arrival.
8. Inform the patient that an IV line will be used to inject the radiotracer. To allow the radiotracer to disperse throughout the body, the scan will be performed 30 to 60 minutes after the injection.
9. Make sure that a bowel preparation has been carried out, if ordered. A urinary catheter may be inserted for a pelvic PET scan.
10. Inform the patient that the radiotracer is rapidly cleared from the body and that the test has no adverse effects.

Postprocedure

1. The patient may resume usual activities.
2. The patient may be encouraged to increase fluid intake to assist in flushing out the radiotracer.

Percutaneous Transhepatic Cholangiography

Description

1. Percutaneous transhepatic cholangiography (PTC) is a fluoroscopic examination of the intrahepatic and extrahepatic biliary ducts after injection of contrast medium into the biliary tree through percutaneous needle injection.
2. Helps to distinguish obstructive jaundice caused by liver disease from jaundice caused by biliary obstruction, such as from a tumor, injury to the common bile duct, stones within the bile ducts, or sclerosing cholangitis.
3. A biliary catheter may be placed during the procedure to drain the biliary tree, called percutaneous transhepatic biliary drainage (PTBD). This relieves jaundice, decreases pruritus, improves nutritional status, allows easy access into the biliary tree for further procedures, and can be used as an anatomic landmark and stent of a surgical anastomosis to allow for healing.

Nursing and Patient Care Considerations

Preprocedure

1. Assess for allergies to iodine, seafood, or contrast media to determine need to be premedicated with antihistamines or steroids (per facility protocol) to prevent reaction.
2. The patient must be NPO for at least 4 hours before the procedure.
3. Verify that the patient has had all questions answered and has a signed consent form before sedatives are given.
4. Inform the patient that the procedure takes 30 to 60 minutes.
5. Establish baseline hemoglobin, hematocrit, and platelet count.
6. Make sure prothrombin time (PT) and INR are within normal limits.
7. Establish baseline vital signs.
8. Establish an IV line.
9. Administer antibiotic prophylaxis, as ordered.

Postprocedure

1. Monitor and document vital signs and assess puncture site for bleeding, hematoma, or bile leakage.
2. Assess for and report signs of peritonitis from bile leaking into the abdomen (fever, chills, diffuse abdominal pain, tenderness, distention), or cholangitis (infection in the biliary tree) from bacteria in the bile being released into the GI tract and then into the bloodstream.
3. Continue antibiotic prophylaxis per facility protocol.
4. If the patient has PTBD, monitor the catheter exit site for bleeding or bile drainage and monitor drainage in bile bag for color, amount, and consistency. The drainage initially may have some blood mixed with bile but should clear within a few hours. The liver makes 700 to 1,000 mL of bile in 24 hours, and there should be adequate drainage when bile is draining into a bile bag (called external drainage).
    a. Report frank blood and blood clots that appear in the bile bag.
    b. Large amounts of bile drainage may require fluid replacement.
    c. Maintain patency and security of biliary catheter; perform routine care and dressing at catheter exit site.
    d. Perform routine flushing of biliary catheter per order.
    e. Cap off the end of the biliary catheter to allow internal drainage of bile, if indicated. Teach the patient the care and flushing of biliary catheter and signs of complications, if indicated.
5. Signs of complications include fever, chills, persistent jaundice, inability to flush the catheter, bleeding from the catheter, redness or discharge from the catheter site, leakage around the exit site of the catheter, and dislodgment of the catheter.
6. Notify the health care provider immediately if the patient complains of abdominal bloating and exquisite abdominal tenderness as the patient may be bleeding into the abdomen.

NURSING ALERT Do not aspirate from a PTBD catheter because this draws bacteria from the bowel back through the liver and may cause cholangitis. Gently push solution into the PTBD catheter to prevent increased pressure within the biliary tree.

Other Diagnostic Tests

Transient Elastography

Description

1. Noninvasive measure superior to traditional ultrasound in evaluating the liver. The probe measures the velocity as this wave passes through the liver.
2. Can replace biopsy to evaluate fibrosis and cirrhosis.
3. Used for initial assessment of liver scarring, as well as follow-up for progression of disease.

Nursing and Patient Care Considerations

1. Technical limitations of the test preclude its use in patients who have ascites, individuals who are morbidly obese, and/or patients who have large amounts of chest wall fat.
2. Ensure that the patient has NPO for at least 2 hours before the procedure.
3. Inform the patient that the test takes about 10 minutes and causes no discomfort.
4. Following the procedure, the patient may resume normal activity and diet.

Liver Biopsy

EVIDENCE BASE Dohan, A., Guerrache, Y., Boudiaf, M., Gavini, J. P., Kaci, R., & Soyer, P. (2014). Transjugular liver biopsy: Indications, technique and results. *Diagnostic and Interventional Imaging, 95*(1), 11–15.

Description

Liver biopsy is the gold standard for diagnosis of cirrhosis or cancer. Sampling of liver tissue through needle aspiration establishes a diagnosis of liver disease through histologic review. The sample may be taken from the liver directly (percutaneous) or through the internal jugular vein (transjugular). Both forms of biopsy include the risks of an invasive procedure: pain, risk for bleeding, and requires close monitoring and observation. The transjugular liver biopsy utilizes fluoroscopy and is a safer option for patients with diffuse liver disease and severe alteration in coagulation or massive ascites.

Nursing and Patient Care Considerations

Preprocedure

1. Establish baseline hemoglobin level, hematocrit, and platelet count.
2. Any patient receiving heparin should have the infusion stopped for 4 to 6 hours before the procedure. If the patient is receiving warfarin, aspirin, clopidogrel, or other platelet-inhibiting or blood-thinning medication, a recent INR, PTT and PT must be available and within normal limits.

3. Verify informed consent.
4. Establish baseline vital signs.
5. Inform the patient that cooperation in holding breath for about 10 seconds during the procedure is important to obtain biopsy without damaging the diaphragm.
6. An IV may be inserted for sedation, as needed.

Postprocedure

1. Position the patient on right side with pillow supporting lower rib cage for several hours following transcutaneous biopsy to prevent bleeding
2. Neck discomfort is common following transjugular liver biopsy. Utilize positioning and nonpharmacologic methods to promote comfort.
3. Check vital signs and observe biopsy site frequently for bleeding or drainage.
4. Report increasing pulse, decreasing blood pressure (BP), increasing pain, and apprehension, which may indicate hemorrhage.

Fine Needle Aspiration

Description

1. The removal of fluid from a cyst or the removal of cells from a mass to establish a diagnosis through histologic review.
2. A fine needle is inserted into the suspicious area, and a small sample is withdrawn.
3. The needle is guided by fluoroscopy, CT scan, or ultrasound and can usually reach most internal organs with minimal risk to the patient.

Nursing and Patient Care Considerations

Preprocedure

1. Establish baseline hemoglobin, hematocrit, and platelet count.
2. Verify informed consent.
3. Establish baseline vital signs.
4. Tell the patient that a mild sedative may be given and a pain block may be performed in the area where the needle will be placed.
5. Encourage the patient to cooperate with body position to obtain the necessary cells.
6. An IV may be inserted for sedation, as needed. If performed as an outpatient procedure, the patient must have a responsible adult to drive him or her home as the patient is not allowed to drive or operate machinery for 24 hours after procedure because of the effects of sedation.

Postprocedure

1. Monitor vital signs per facility protocol.
2. Assess the patient for any signs of complications, including pain, hypotension, tachycardia, and

abdominal distention or hematoma at the biopsy site.

3. Inform the patient that bruising or some discomfort may be experienced at the biopsy site.
4. Instruct the patient on resuming anticoagulants based on health care provider directions.

HEPATIC DISORDERS

See additional online content: Procedure Guidelines 19-1, 19-2

PROCEDURE GUIDELINES 19-1

Assisting with Abdominal Paracentesis

EQUIPMENT

- Sterile paracentesis tray and gloves
- Local anesthetic
- Drape or cotton blankets
- Collection bottle (vacuum bottle)
- Skin preparation tray with antiseptic
- Specimen bottles, laboratory forms, and labels

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain procedure to the patient. Make sure that consent form has been signed.	1. Ensures patient's understanding and consent for the procedure and reduces patient's fear and anxiety.
2. Record the patient's vital signs.	2. Provides baseline values for later comparison.
3. Have the patient void before treatment is begun.	3. Lessens the danger of accidentally piercing the bladder with the needle or trocar.
4. Position patient in Fowler's position with back, arms, and feet supported.	4. Patient is more comfortable and a steady position can be maintained.
5. Drape patient with sheet exposing abdomen.	5. Minimizes exposure of patient and keeps patient warm.
Performance phase	
1. Assist in preparing skin with antiseptic solution.	1. This is considered a minor surgical procedure that requires aseptic precautions.
2. Open sterile tray and package of sterile gloves; provide anesthetic solution.	
3. Have collection bottle and tubing available and supplies for labeling.	
4. Assess pulse and respiratory status frequently during procedure; watch for pallor, cyanosis, or syncope (faintness).	4. Indicates shock. Keep emergency drugs available.
5. Provider administers local anesthesia and introduces needle or trocar.	
6. Needle or trocar is connected to tubing and vacuum bottle or syringe; fluid is slowly drained from peritoneal cavity.	6. Drainage is usually limited to 1 to 2 L to relieve acute symptoms and minimize risk of hypovolemia and shock.
7. Apply dressing when needle is withdrawn.	7. Elasticized adhesive patch is effective, serving as waterproof adhering dressing.
8. Usually, a dressing is sufficient; however, if the trocar wound appears large, the provider may close the incision with sutures.	8. Prevents blood loss and aids healing.
Follow-up phase	
1. Assist patient to a comfortable position after treatment.	1. There may be minor pain at incision site.
2. Record amount and characteristics of fluid removed, number of specimens sent to laboratory, and patient's condition during treatment.	2. Documentation is important for continuity of care.
3. Check blood pressure and vital signs every ½ hr for 2 hr, every hour for 4 hr, and every 4 hr for 24 hr.	3. Close observation will detect hemodynamic instability and possible development of shock.
4. Watch for leakage or scrotal edema after paracentesis.	4. Indicates complication. If seen, report at once.

PROCEDURE GUIDELINES 19-2

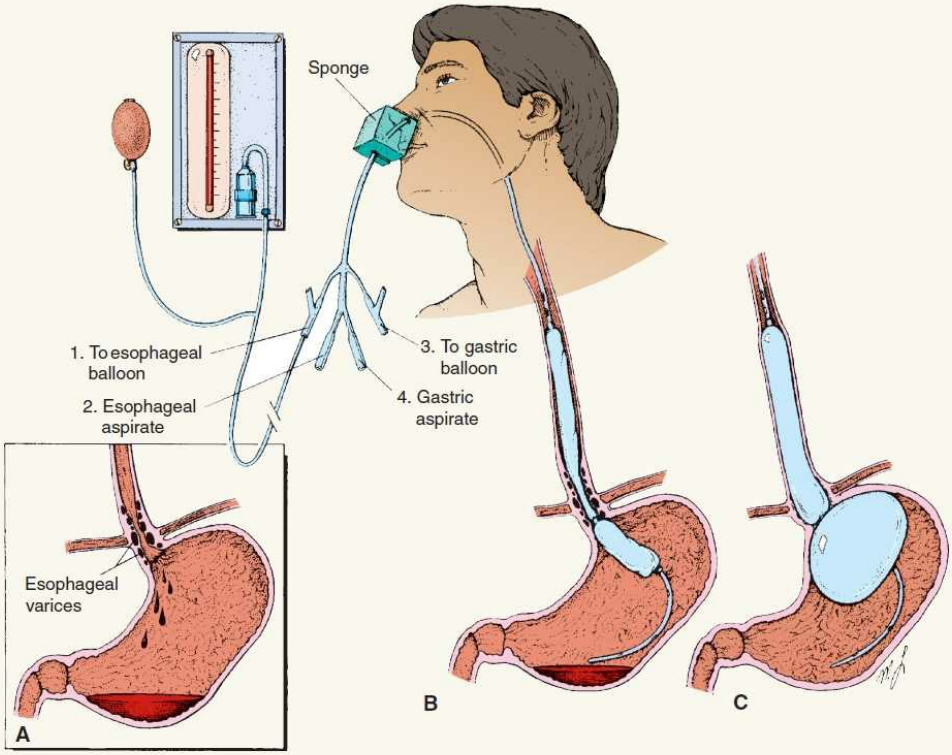
Using Balloon Tamponade to Control Esophageal Bleeding (Sengstaken-Blakemore Tube Method, Minnesota Tube Method)

EQUIPMENT

- Esophageal balloon (Sengstaken-Blakemore or Minnesota)
- Basin with cracked ice
- Clamps for tubing
- Water-soluble lubricant
- Syringe (50 mL with catheter tip)
- Towel and emesis basin
- Glass of water and straw
- Adhesive tape
- Device to apply traction (eg, football helmet)
- Large scissors (for emergency deflation)
- Manometer (to measure balloon pressure)

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain procedure, provide support, and reassure patient that bleeding will be controlled.	1. Should allay fear and anxiety.
2. Advise patient to breathe through the mouth and swallow periodically. (See accompanying figure.)	2. Assists with passing of the tube.
3. Elevate head of bed slightly, unless patient is in shock.	3. Elevating head may worsen shock.



Esophageal varices and their treatment by a compressing balloon tube (Sengstaken-Blakemore). **(A)** Dilated veins of the lower esophagus. **(B)** The tube is in place in the stomach and the lower esophagus but is not inflated. **(C)** Inflation of the tube causing compression of the veins. It may be necessary to pass an additional tube through the other nostril to aspirate. *Note:* The Minnesota four-lumen esophagogastric tamponade tube has an additional outlet for aspiration of the esophagus. Smeltzer, S., & Bare, B. (2000). *Brunner and Suddarth's textbook of medical-surgical nursing* (9th ed.). Philadelphia: Lippincott Williams & Wilkins.

Nursing Action	Rationale
Performance phase	
1. Check balloons by trial inflation under water to detect leaks.	1. This is best done under water because it is easier to see escaping air bubbles.
2. Chill the tube, then lubricate it before the provider passes it via mouth or nose (preferable).	2. Chilling makes the tube more firm and lubrication lessens friction.
3. Provide the patient with a few sips of water.	3. Helps pass the tube more easily.
4. After the tube has entered the stomach, verify its placement by irrigating the gastric tube with air while auscultating over the stomach.	4. It is imperative that the tube is in the stomach so that the gastric tube is not inflated in the esophagus.
5. After obtaining x-ray film of the lower chest and upper abdomen to verify placement in the stomach, inflate gastric balloon (200 to 250 mL) with air; gently pull tube back to seat balloon against gastroesophageal junction.	5. Exerts force against the cardia.
6. Clamp gastric balloon; mark tube location at nares.	6. Prevents air leakage and tube migration. The mark on the tube allows easy visualization of movement of the tube.
7. Apply gentle traction to the balloon tube and secure it with a foam rubber cube at the nares or tape it to the faceguard of a football helmet.	7. Prevents the tube from migrating with peristalsis and assists in exerting proper pressure.
8. Attach Y-connector to esophageal balloon opening. Attach syringe to one arm of the Y-connector and manometer to the other. Inflate esophageal balloon to 25 to 35 mm Hg. Clamp esophageal balloon.	8. Maintains enough pressure to tamponade bleeding while preventing esophageal necrosis.
9. Apply suction to gastric aspiration opening. Irrigate at least hourly.	9. Suctioning and irrigating the tube can remove old blood from the stomach and prevent hepatic encephalopathy; allows monitoring of bleeding status.
10. *[If using Sengstaken-Blakemore tube]* Insert a nasogastric (NG) tube, positioning it above the esophageal balloon and attach to suction.	10. Suctions saliva accumulated above the esophageal balloon, which may be aspirated, and checks for bleeding above the esophageal balloon.
11. *[If using a Minnesota tube]* Attach fourth port, esophageal suction port, to suction.	11. Removes esophageal secretions.
a. Label each port.	a. Prevents accidental deflation or irrigation.
b. Tape scissors to head of bed.	b. Airway occlusion may occur if the esophageal balloon is pulled into the hypopharynx. If this occurs, the esophageal balloon tube must be cut and removed immediately.
ADDITIONAL NURSING RESPONSIBILITIES	
1. Maintain *constant* vigilance while balloons are inflated in the patient.	6. Keep head of bed elevated to avoid gastric regurgitation and to diminish nausea and a sensation of gagging.
2. Keep balloon pressures at required level to control bleeding. (Clamps help to maintain pressure.)	7. Maintain nutritional and electrolyte levels parenterally.
3. Observe and record vital signs; monitor color and amount of NG lavage fluid (subtracting lavage input) for evidence of bleeding.	8. Maintain NG suction or suction to esophageal suction port to aspirate any collected saliva.
4. Be alert for chest pain—may indicate injury or rupture of esophagus.	9. Note nature of breathing; if counterweight pulls the tube into oropharynx, the patient may be asphyxiated.
5. Irrigate suction tube, as prescribed; observe and record nature and color of aspirated material.	

Hepatic disorders may disrupt normal liver function, which include the following:

- Storage of vitamins A, B, D; iron; and copper.
- Synthesis of plasma proteins, including albumin and globulins.
- Synthesis of the clotting factors vitamin K and prothrombin.
- Storage of glycogen and synthesis of glucose from other nutrients (gluconeogenesis).
- Breakdown of fatty acids for energy.
- Production of bile.
- Detoxification and excretion of waste products.

Hepatitis

EVIDENCE BASE Eastern Association for the Study of the liver (2017). Clinical Practice Guidelines on the management of Hepatitis B virus infection. *Journal of Hepatology*, 67, 270–298.

Hepatitis is defined as inflammation of the liver. Viral infection is the most common cause associated with a broad spectrum of clinical manifestation from non-symptom producing infection, through icteric hepatitis, to hepatic necrosis. Five types of viral hepatitis have been identified.

Pathophysiology and Etiology

Type A Hepatitis

1. Hepatitis A (HAV) is caused by a ribonucleic acid (RNA) virus of the enterovirus family.
2. Mode of transmission is primarily fecal–oral, usually through the ingestion of food or liquids contaminated with the virus.
   a. Prevalent in underdeveloped countries or in instances of overcrowding and poor sanitation.
   b. Infected food handler can spread the disease, and people can contract it by consuming water or shellfish from contaminated waters.
   c. Commonly spread by person-to-person contact and, rarely, by blood transfusion. Vaccines are available.
3. Incubation period is 15 to 28 days, with the average being 28 days.
4. Occurrence is worldwide, usually among children and young adults.
5. Mortality is 0% to 1%, with recovery as the rule.

Type B Hepatitis

1. Hepatitis B (HBV) is a double-shelled particle containing deoxyribonucleic acid. This particle is composed of the following:
   a. HBcAg—hepatitis B core antigen (antigenic material in an inner core).
   b. HBsAg—hepatitis B surface antigen (antigenic material in an outer coat).
   c. HBeAg—hepatitis B envelop antigen (an independent protein circulating in the blood).
2. Each antigen stimulates a specific antibody:
   a. Anti-HBc—hepatitis B core antibodies (persists during the acute phase of illness; may indicate continuing HBV in the liver).
   b. Anti-HBs— hepatitis B surface antibodies (detected during late convalescence; usually indicates recovery and development of immunity).
   c. Anti-HBe—hepatitis B envelop antibodies (usually signifies reduced infectivity).

3. Significance:
    a. HBsAg—usually detected transiently in blood of 80% to 90% of infected people; may be noted in blood for months or years, indicating that the patient has acute or chronic hepatitis B or is a carrier.
    b. HBeAg—if absent, the patient is an asymptomatic carrier. If present, it indicates highly infectious period of acute, active hepatitis. If it persists, it indicates progression to chronic state.
4. Mode of transmission is primarily through blood (percutaneous and mucosal route).
    a. Oral route through saliva or through breast-feeding.
    b. Sexual activity through blood, semen, saliva, or vaginal secretions. Hepatitis B is recognized as a sexually transmitted infection.
    c. Homosexual men and those with HIV are at high risk.
5. Incubation period is 45 to 160 days (average of 120 days).
6. Occurrence is for all ages, but it mostly affects young adults worldwide. Vaccines are available.
7. Fifteen to twenty-five percent of chronically infected persons develop chronic liver disease, including cirrhosis, liver failure, or liver cancer. It causes 1,800 deaths per year in the U.S. and is the main cause of cirrhosis and hepatocellular carcinoma worldwide.

Type C Hepatitis

1. Hepatitis C (HCV) is RNA virus of the enterovirus family.
2. Mode of transmission is through blood and body fluids. Previously was transmitted though blood products but since 1992, the commercial blood supply has been tested; now, the rate of transmission through blood transfusions is less than 1%.
    a. Current transmission through sharing of needles with IV drug use or from accidental needle sticks in the health care setting.
    b. Vertical transition from mother to fetus.
    c. Less common causes include hemodialysis; sharing personal care items that may have come in contact with another person's blood, such as razors or toothbrushes; or sexual intercourse with an infected person.
3. Incubation period varies from 14 to 180 days (average 45 days).
4. Occurs in all age groups.
    a. May occur sporadically or in epidemic proportions.
    b. Increasing number of cases diagnosed in Baby Boomer generation, born between the years of 1945 and 1965; 75% to 85% of newly infected persons develop chronic hepatitis.
    c. There is currently no vaccine available.
    d. As many as 20% of those infected with HCV will develop cirrhosis or liver cancer.

Type D Hepatitis (Delta Hepatitis)

EVIDENCE BASE Kushner, T., Serper, M., & Kaplan, D. E. (2015). Delta hepatitis within the Veterans Affairs medical system in the United States: Prevalence, risk factors, and outcomes. *Journal of Hepatology, 63*(3), 586–592.

1. Hepatitis D virus (HDV) is a defective RNA agent that appears to replicate only with the hepatitis B virus. It requires HBsAg to replicate.
   a. Occurs along with HBV or may superinfect a chronic HBV carrier.
   b. Cannot outlast a hepatitis B infection.
   c. May be acute or chronic.
2. Mode of transmission and incubation are the same as for HBV.
3. Rarely seen in the United States because of high rates of hepatitis B vaccination beginning in infancy. Occurrence in the United States is primarily in IV drug users, veterans who have served in high-infection areas, or patients requiring multiple transfusions.
4. The highest incidence exists in the Mediterranean, the Middle East, and South America. Prevalence is low in North America and Northern Europe, South Africa, and Eastern Asia.
5. Mortality—accounts for 50% of fulminant hepatitis, which has a high mortality.

Type E Hepatitis

1. Nonenveloped, single-strand RNA virus.
2. Mode of transmission is fecal–oral.
3. Incubation is 15 to 60 days (mean 40 days).
4. Occurrence is primarily in India, Africa, Asia, and Central America, but may be found in recent travelers to these areas and is more common in young adults. More severe cases occur in pregnant women (third trimester) and those with preexisting chronic liver disease.
5. Most people recover completely. In those with severe cases, mortality rates can be as high as 30%.

Autoimmune Hepatitis

1. In addition to viral hepatitis, autoimmune hepatitis (AIH) has also been identified. It is a chronic form of hepatitis that is progressive and fluctuates with degree of liver damage.
2. Although the cause of AIH is unknown, it is thought to be self-antigen mediated.
3. Treatment usually consists of anti-inflammatory or immunosuppressive agents, which may need to be taken throughout the patient's life.
4. AIH may lead to chronic or fulminant liver failure and transplantation.

Clinical Manifestations

Type A Hepatitis

1. May have no symptoms.
2. Prodromal symptoms: fatigue, anorexia, malaise, headache, low-grade fever, nausea, and vomiting.
3. Highly contagious during this period, usually 2 weeks before the onset of jaundice.
4. Icteric phase: jaundice, tea-colored urine, clay-colored stool, and right upper quadrant tenderness.
5. Symptoms may be mild in children; adults are more likely to have severe symptoms and a prolonged course of disease.

Type B Hepatitis

1. An estimated 30% of the world's population shows serological evidence of HBV current or past infection. Symptom onset usually more insidious and prolonged compared with HAV but may be asymptomatic.
2. Prodromal symptoms: fatigue, anorexia, transient fever, abdominal discomfort, nausea and vomiting, headache; can last 1 week to 2 months.
3. Extrahepatic manifestations may include myalgias, photophobia, arthritis, angioedema, urticaria, maculopapular eruptions, skin rashes, and vasculitis.
4. Icteric phase: Jaundice.
5. In rare cases, it may progress to abrupt and severe hepatic failure, also called fulminant hepatitis.
6. May become chronic active or chronic persistent (asymptomatic) hepatitis.

Type C Hepatitis

1. Similar to those associated with HBV but usually less severe.
2. Symptoms usually occur 6 to 7 weeks after exposure but may be attributed to another viral infection and not diagnosed as hepatitis.
3. Genotype 1 HCV is the most common infection, accounting for approximately 70% to 75% of all hepatitis C infections.
4. Approximately 60% to 85% of people infected with HCV go on to develop a chronic infection. (Complications of chronic HCV include cirrhosis, decompensated liver disease, and hepatocellular carcinoma.)
5. In patients with HCV who do not receive treatment, the estimated risk of developing hepatocellular carcinoma after 20 years is 1% to 3%.
6. It is recommended that high-risk individuals be tested for HCV because many may remain asymptomatic for approximately 20 years.

Type D Hepatitis

1. Similar to HBV but more severe.
2. With superinfection of chronic HBV carriers, causes sudden worsening of condition and rapid progression of cirrhosis.

Diagnostic Evaluation

1. Elevated serum transferase levels (aspartate transaminase [AST], alanine transaminase [ALT]) for all

forms of hepatitis.

2. Radioimmunoassays that reveal immunoglobulin (Ig) M antibodies to hepatitis virus in the acute phase of HAV.
3. Radioimmunoassays to include HBsAg, anti-HBc, and anti-HBsAg detected in various stages of HBV (see Figure 19-1).
4. Hepatitis C antibody—may not be detected for 6 weeks after exposure; antibody test used for screening purposes for past exposure of current infection. Positive results should be confirmed by nucleic acid testing for HCV RNA, which indicates active infection.
5. Antidelta antibodies of HBsAg for HDV or the detection of IgM in acute disease and IgG in chronic disease.
6. Hepatitis E IgM.
7. Liver biopsy to detect chronic active disease, progression, and response to therapy.

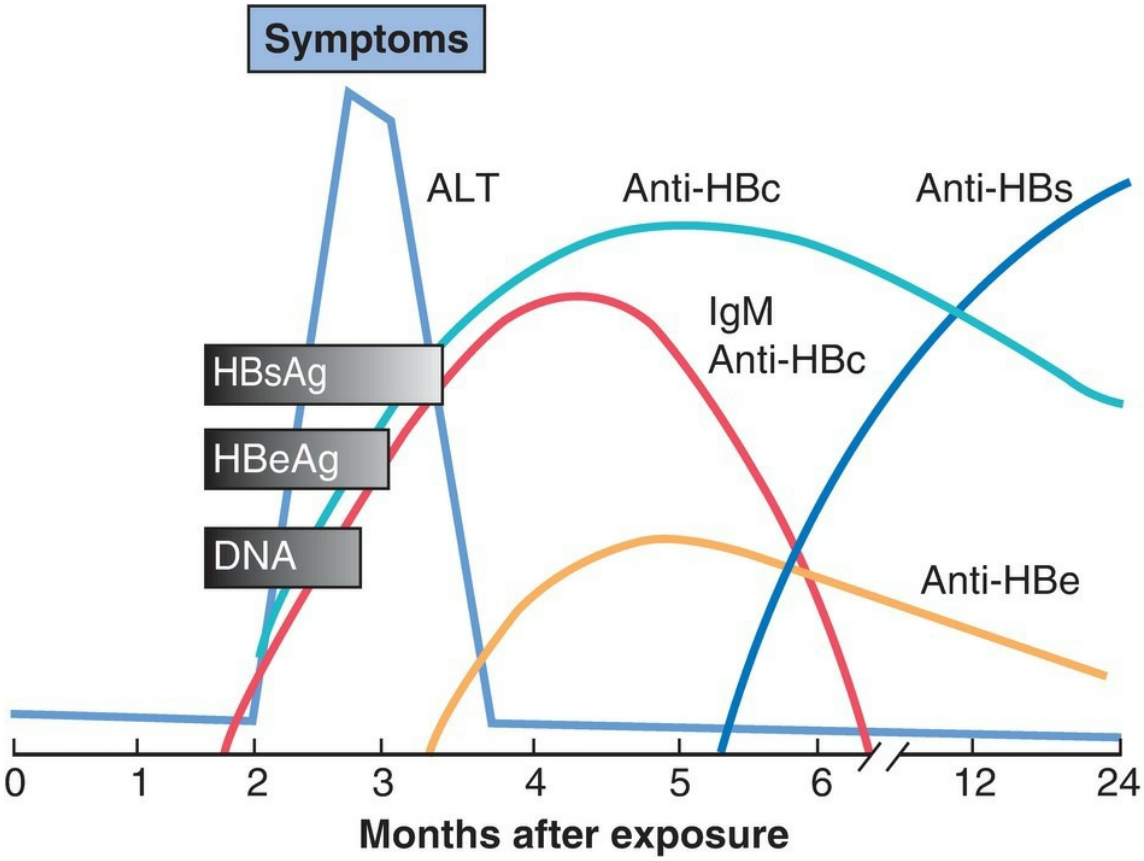


Figure 19-1. Time course for clinical, laboratory, and virologic features of acute hepatitis B infection. ALT, alanine aminotransferase; anti-HBc, antibody to hepatitis B core antigen; anti-HBe, antibody to hepatitis Be antigen; anti-HBs, antibody to hepatitis B surface antigen; HBeAg, hepatitis Be antigen; HBsAg, hepatitis B surface antigen. (Betts, R.F., Chapman, S.W., Penn, R.L. [2003]. Reese and Betts' a practical approach to infectious diseases [5th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Management

All Types of Hepatitis

1. Rest according to the patient's level of fatigue.
2. Therapeutic measures to control dyspeptic symptoms and malaise.
3. Hospitalization for protracted nausea and vomiting or life-threatening complications; enteral feedings may be necessary.
4. Small, frequent feedings of a high-calorie, low-fat foods.
5. Vitamin K is administered if INR/PT is prolonged.
6. IV fluid and electrolyte replacement, as indicated.
7. Administration of antiemetic for nausea.
8. After jaundice has cleared, gradual increase in physical activity. This may require many months.

Patients with HBV

1. First-line therapy is nucleoside analogs (NA) with high barrier to drug resistance, such as entecavir, or tenofovir. NAs with a low barrier to resistance, including lamivudine, adefovir, or telbivudine, can lead to drug resistance and are not recommended.
2. All patients should be vaccinated for hepatitis A.

EVIDENCE BASE Terrault, N. A., Lok, A. S. F., McMahon, B. J., & Chang, K. M. (2018). Update on prevention, diagnosis, and treatment of chronic hepatitis B: AASLD 2018 hepatitis B guidance. *Hepatology*, 67(4), 1560-1599.

Patients with HCV

EVIDENCE BASE AASLD/IDSA HCV Guidance Panel. (2015). Hepatitis C Guidance: AASLD-IDSA recommendations for testing, managing, and treating adults infected with Hepatitis C virus. *Hepatology, 62*(3), 932–954.

---

1. HCV infection will clear spontaneously clear in 20% to 50% of patients. In at least two thirds of patients, this will occur within 6 months of the estimated time of infection (median, 16.5 weeks).
2. Antiviral treatment is recommended for all patients with chronic HCV infection, except those with limited life expectancy due to nonhepatic causes.
3. First-line treatment no longer includes pegylated interferon and ribavirin, as the flulike side effects and treatment course of 48 weeks were intolerable to most patients.

4. Treatment of the virus is guided by genotype and presence or absence of cirrhosis. A 12-week course of multiple direct acting antivirals includes elbasvir/grazoprevir, ledipasvir/sofosbuvir, or simeprevir/sofosbuvir. Ninety percent of all patients who complete treatment achieve sustained virologic response (SVR).
5. Close monitoring including complete blood count, liver function tests, and HCV viral load during the treatment period is imperative.
6. Patients should be vaccinated against hepatitis A and B if they do not have immunity. Patients who complete treatment can still recontract the disease, making education on prevention important.

Complications

1. Dehydration, hypokalemia.
2. Chronic "carrier" hepatitis or chronic active hepatitis.
3. Cholestatic hepatitis.
4. Fulminant hepatitis (liver transplantation may be necessary).
5. HBV and HCV chronic infections have a higher risk of developing hepatocellular carcinoma.

Nursing Assessment

1. Assess for systemic and liver-related symptoms.
2. Obtain history on risk factors, such as IV drug use, sexual activity, travel to endemic countries, and ingestion of possible contaminated food or water to assess for any mode of transmission of the virus.
3. Assess size and texture of liver to detect enlargement or characteristics of cirrhosis.
4. Obtain vital signs, including temperature.

Nursing Diagnoses

All Types of Hepatitis

- Imbalanced Nutrition: Less Than Body Requirements related to effects of liver dysfunction.
- Deficient Fluid Volume related to nausea and vomiting.
- Activity Intolerance related to anorexia and liver dysfunction.
- Deficient Knowledge related to transmission.

Patients with HBV

- Risk for Bleeding related to coagulopathy because of impaired liver function.
- Acute confusion related to encephalopathy because of impaired liver function.

Nursing Interventions

Maintaining Adequate Nutrition

1. Encourage frequent small feedings of high-calorie, low-fat diet. Avoid large quantities of protein during acute phase of illness as the body is unable to metabolize protein by-products.

2. Encourage eating meals in an upright sitting position to decrease pressure on the liver.
3. Encourage taking pleasing meals in an environment with minimal noxious stimuli (i.e., odors, noise, interruptions).
4. Administer or teach self-administration of antiemetics, as prescribed.

DRUG ALERT Avoid the use of phenothiazines as an antiemetic in patients with liver dysfunction, such as prochlorperazine, which have a cholestatic effect and may cause or worsen jaundice. Metoclopramide is preferred.

Maintaining Adequate Fluid Intake

1. Provide frequent oral fluids, as tolerated.
2. Administer IV fluids for patients with inability to maintain oral fluids, as prescribed.
3. Monitor intake and output.

Maintaining Adequate Rest and Activity

1. Promote periods of rest during symptom-producing phase, according to level of fatigue.
2. Promote comfort by administering or teaching self-administration of analgesics as prescribed.
3. Provide emotional support and diversional activities when recovery and convalescence are prolonged.
4. Encourage gradual resumption of activities and mild exercise during convalescent period.

Ensuring Prevention of Disease Transmission

1. Educate the patient about disease and about disease transmission.
2. Emphasize the self-limiting nature of most forms of hepatitis and the need for follow-up of liver function tests.
3. Stress importance of proper public and home sanitation and of proper preparation and dispensation of foods.
4. Encourage specific protection for close contacts.
    a. Immunoglobulin or vaccine should be administered as soon as possible (within 2 weeks) to household contacts of HAV patients.
    b. Hepatitis B immune globulin as soon as possible to blood or body fluid contacts of HBV patients, followed by HBV vaccine series.
5. Explain precautions to the patient and family about transmission and prevention of transmission to others.
    a. Good hand washing and hygiene after using the bathroom.
    b. Avoidance of sexual activity (especially for HBV) until free of HBsAg.
    c. Avoidance of sharing needles, drug paraphernalia, eating utensils, and toothbrushes to prevent blood

or body fluid contact (especially for HBV and HCV).

6. Report all cases of hepatitis to public health officials.

Preventing and Controlling Bleeding

1. Monitor and teach the patient to monitor and report signs of bleeding.
2. Monitor PT/INR and administer vitamin K, as ordered.
3. Avoid trauma that may cause bruising, limit invasive procedures, if possible, and maintain adequate pressure on needlestick sites.

Monitoring Thought Processes

1. Monitor for signs of encephalopathy—lethargy and somnolence with mild confusion and personality changes, such as excessive sexual or aggressive activity and loss of usual inhibitions. Lethargy may alternate with excitability, euphoria, or unruly behavior.
2. Monitor for worsening of condition, from stupor to coma; assess for asterixis.
3. Maintain calm, quiet environment and reorient the patient, as needed.

Patient Education and Health Maintenance

1. Identify persons at high risk for each type of hepatitis and advise prevention and screening.
2. Educate adolescents about the risk of piercing and tattooing in transmission of HCV.
3. Encourage vaccination for HBV with series of three injections (at birth, 1 month, and 6 months) for high-risk patients, such as health care workers or institutionalized persons, as well as vaccination of all children at birth or in adolescence.
4. Instruct all patients who have received a blood transfusion to refrain from donating blood for 12 months. Anyone testing positive for hepatitis B or C is ineligible to donate blood.
5. Stress the need to follow precautions with blood and secretions until the patient is deemed free of HBsAg.
6. Explain to HBV carriers that their blood and secretions will remain infectious.
7. For additional information, refer to the local public health department, American Red Cross, or the Centers for Disease Control and Prevention (*www.cdc.gov*).

Evaluation: Expected Outcomes

- Tolerates small carbohydrate feedings.
- No vomiting, tolerates fluids.
- Maintains self-care and light ambulation.
- Family members seek active immunization.
- No signs of bleeding.
- Lethargic but oriented, no tremor.

Hepatic Cirrhosis

EVIDENCE BASE National Institute for Health and Care Excellence. (2016). NICE guideline: Cirrhosis in over 16s: Assessment and management. Available: *http://nice.org.uk/guidance/ng50.*

It is a chronic disease with diffuse destruction and fibrotic regeneration of hepatic cells. (see Figure 19-2). As necrotic tissue is replaced by fibrotic tissue, normal liver structure and vasculature are altered, impairing blood and lymph flow, resulting in hepatic insufficiency and portal hypertension.

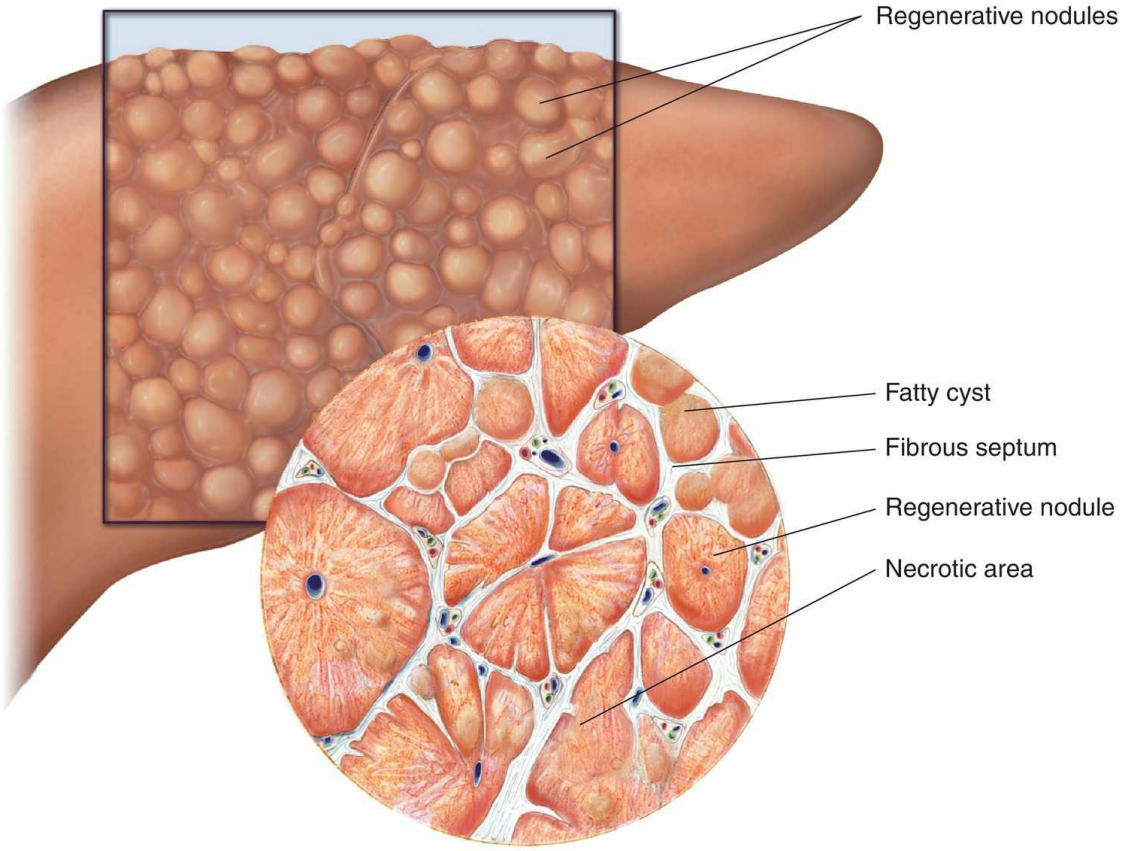

Figure 19-2. Fibrotic changes to liver tissue in cirrhosis. (Anatomical Chart Company.)

Pathophysiology and Etiology

1. Laënnec cirrhosis (macronodular), also known as alcoholic cirrhosis.
   a. Fibrosis—mainly around central veins and portal areas.
   b. Usually due to chronic alcohol toxicity and malnutrition.
2. Postnecrotic cirrhosis (micronodular).
   a. Broad bands of scar tissue.

b. Because of previous acute viral hepatitis or drug-induced massive hepatic necrosis.

3. Biliary cirrhosis.
   a. Scarring around bile ducts and lobes of the liver.
   b. Results from chronic biliary injury and obstruction of the intrahepatic or extrahepatic biliary system.
   c. Partial or total obstruction of the bile ducts can lead to infectious cholangitis and cirrhosis, which is much rarer with Laennec's or postnecrotic chirrhosis.

Clinical Manifestations

1. Onset is insidious; may take years to develop.
2. Early symptoms include fatigue, anorexia, ankle edema in the evening, epistaxis and bleeding gums, and weight loss.
3. Later signs and symptoms because of chronic failure of the liver and obstruction of portal circulation.
   a. Chronic dyspepsia, constipation, or diarrhea.
   b. Esophageal varices, dilated cutaneous veins around the umbilicus (caput medusa), internal hemorrhoids, ascites, splenomegaly, and pancytopenia.
   c. Plasma albumin is reduced, leading to edema and contributing to ascites.
   d. Anemia and poor nutrition lead to fatigue and weakness, wasting, and depression.
   e. Deterioration of mental function from lethargy to delirium to coma and eventual death.
   f. Estrogen–androgen imbalance causes spider angiomata and palmar erythema; menstrual irregularities in females; testicular and prostatic atrophy, gynecomastia, loss of libido, and impotence in males.
4. Bleeding tendencies, such as nosebleeds, easy bruising, hematemesis, occult blood in stool, or profuse hemorrhage from stomach and esophageal varices.

Diagnostic Evaluation

1. CT scan is helpful to determine the size of the liver and its irregularities and in detection of a mass.
2. Transient elastography to diagnose cirrhosis.
3. Liver biopsy detects degree of destruction and fibrosis of hepatic tissue in those who are not candidates for transient elastography.
4. Gastrointestinal endoscopy to determine esophageal varices.
5. Paracentesis to examine ascitic fluid for cell, protein, and bacterial counts.
6. PTC differentiates extrahepatic from intrahepatic obstructive jaundice.
7. Laparoscopy allows direct visualization of the liver.
8. Serum liver function test results may be elevated, but normal enzymes do not rule out cirrhosis.

Management

1. Minimize further deterioration of liver function through the withdrawal of toxic substances, alcohol, and medications.

2. Correction of nutritional deficiencies with vitamins and nutritional supplements and a high-calorie and moderate- to high-protein diet.
3. Treatment of ascites and fluid and electrolyte imbalances.
    a. Restrict sodium and water intake, depending on amount of fluid retention.
    b. Diuretic therapy, frequently with spironolactone, a potassium-sparing diuretic that inhibits the action of aldosterone on the kidneys. Furosemide or toresemide, loop diuretics, may also be used in conjunction with spironolactone to help balance potassium depletion.
    c. Abdominal paracentesis to remove fluid and relieve symptoms. A tunneled cuffed catheter with a one-way valve and a closed drainage system may be placed for chronic symptom management.
    d. Administration of albumin to maintain osmotic pressure.
4. Transjugular intrahepatic portosystemic shunt (TIPS), an interventional radiologic procedure, may be performed in patients whose ascites is resistant to other forms of treatment. TIPS is a percutaneously created connection within the liver between the portal and systemic circulations.
    a. Used for patients with complications related to portal hypertension.
    b. Complications include bacterial infections, shunt obstruction, encephalopathy, and increase in coagulopathies.
5. Symptomatic relief measures such as analgesics, antipruritic, and antiemetic medications.
6. Treatment of other problems associated with liver failure. Administer lactulose, rifaximin, or neomycin for hepatic encephalopathy.
7. Liver transplantation may be necessary.

Complications

1. Hyponatremia and water retention.
2. Bleeding esophageal varices.
3. Coagulopathies.
4. Spontaneous bacterial peritonitis (SBP).
5. Hepatic encephalopathy, which may be precipitated by the use of sedatives, sepsis, or electrolyte imbalance.

Nursing Assessment

1. Obtain history of precipitating factors, such as alcohol use, hepatitis, or biliary disease. Establish present pattern of alcohol intake.
2. Assess mental status through interview and interaction with the patient.
3. Perform abdominal examination, assessing for ascites (see Figure 19-3).
4. Observe for bleeding.
5. Assess daily weight first thing in the morning and abdominal girth measurements.

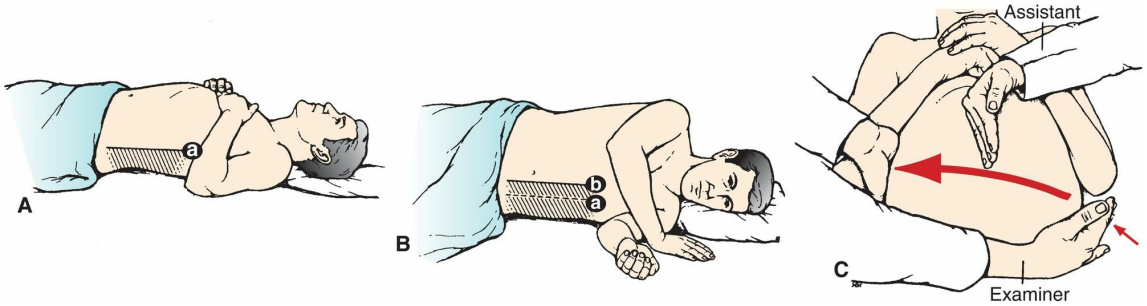

Figure 19-3. Assessing for ascites. **(A)** To percuss for shifting dullness, each flank is percussed with the patient in a supine position. If fluid is present, dullness is noted at each flank. The most medial limits of the dullness should be marked as indicated in *a*. The patient should then be shifted to the side. **(B)** Note what happens to the area of dullness if fluid is present; the area of dullness begins at *b*. **(C)** To detect the presence of a fluid wave, the examiner places one hand alongside each flank. A second person then places a hand, ulnar side down, along the patient's midline and applies light pressure. The examiner then strikes one flank sharply with one hand, while the other hand remains in place to detect any signs of a fluid impulse. The assistant's hand should dampen any wave impulses traveling through the abdominal wall, unless fluid is present.

Nursing Diagnoses

- Activity Intolerance related to fatigue, general debility, and discomfort.
- Imbalanced Nutrition: Less Than Body Requirements related to anorexia and GI disturbances.
- Impaired Skin Integrity related to edema, jaundice, and compromised immunologic status.
- Risk for Bleeding related to altered clotting mechanisms.
- Acute Confusion related to deterioration of liver function and increased serum ammonia level.

Nursing Interventions

Promoting Activity Tolerance

1. Encourage alternating periods of rest and ambulation.
2. Maintain some periods of bed rest with legs elevated to mobilize edema and ascites.
3. Encourage and assist with gradually increasing periods of exercise.

Improving Nutritional Status

1. Encourage the patient to eat multiple, small, frequent high-calorie, moderate-protein meals.
2. Suggest small, frequent feedings and attractive meals in an aesthetically pleasing setting at mealtimes.
3. Encourage oral hygiene before meals.
4. Administer or teach self-administration of medication for nausea, vomiting, diarrhea, or constipation.

Protecting Skin Integrity

1. Note and record degree of jaundice of skin and sclera and scratches on the body.
2. Encourage frequent skin care, bathing without soap, and massage with emollient lotions.

3. Advise the patient to keep fingernails short.
4. Administer antipruritic medications as ordered.

Preventing Bleeding

1. Observe stools and emesis for color, consistency, and amount; test for occult blood.
2. Be alert for symptoms of anxiety, epigastric fullness, weakness, and restlessness, which may indicate GI bleeding.
3. Observe for external bleeding: ecchymosis, leaking needlestick sites, epistaxis, petechiae, and bleeding gums.
4. Keep the patient quiet and limit activity if signs of bleeding are exhibited.
5. Administer vitamin K, as prescribed.
6. Stay in constant attendance during episodes of bleeding.
7. Institute and teach measures to prevent trauma:
   a. Maintain safe environment.
   b. Gentle blowing of nose.
   c. Use of soft toothbrush.
8. Use small-gauge needles for injections and maintain pressure over site until bleeding stops.
9. Management of bleeding from esophageal varices can include endoscopic variceal ligation (banding) or injection sclerotherapy.

Promoting Improved Thought Processes

1. Limit sedatives and promote sleep/wake cycles to prevent delirium.
2. Protect from sepsis through good hand washing and prompt recognition and management of infection.
3. Monitor fluid intake and output and serum electrolyte levels to prevent dehydration and hypokalemia (may occur with the use of diuretics), which may precipitate hepatic coma.
4. Keep environment warm.
5. Pad the side rails of the bed, keep the bed in the lowest position, and provide careful nursing surveillance to ensure the patient's safety.
6. Assess LOC and frequently reorient, as needed.
7. Administer lactulose or neomycin through a retention enema or nasogastric (NG) tube, as ordered, for elevated ammonia levels and decreasing LOC.

DRUG ALERT Opioids, sedatives, and barbiturates are used cautiously in the restless patient with cirrhosis to prevent precipitation of hepatic coma.

TRANSITIONAL CARE ALERT Patients with cirrhosis should be monitored closely to prevent readmission. Patient education must include daily weights, good nutrition, and avoiding liver toxic medications, herbal supplements, and alcohol. The support of community health nursing and the family are vital.

Patient Education and Health Maintenance

1. Advise the patient to avoid substances (over-the-counter medications, herbs, illicit drugs, toxins) that may affect liver function.
2. Stress the necessity of giving up alcohol completely.
3. Urge acceptance of assistance from a substance use program.
4. Involve the person closest to the patient because recovery usually is not easy and relapses are common.
5. Provide written dietary instructions.
6. Encourage daily weighing for self-monitoring of fluid retention or depletion.
7. Discuss adverse effects of diuretic therapy.
8. Emphasize the importance of rest, a sensible lifestyle, and an adequate, well-balanced diet.
9. Stress the importance of continued follow-up for laboratory tests and evaluation by a health care provider.

Evaluation: Expected Outcomes

- Ambulates three times daily.
- Tolerates small, frequent meals.
- Skin without breakdown or scratches.
- No bleeding or bruising; results of stool tests are negative for occult blood.
- Drowsy but easily aroused and oriented.

Bleeding Esophageal Varices

Esophageal varices are dilated tortuous veins usually found in the submucosa of the lower esophagus; however, they may develop higher in the esophagus or extend into the stomach.

Pathophysiology and Etiology

1. Nearly always because of portal hypertension, which may result from obstruction of the portal venous circulation and cirrhosis of the liver.
    a. Because of increased obstruction of the portal vein, venous blood from the intestinal tract and spleen seeks an outlet through collateral circulation, which creates new pathways of return to the right atrium and causes an increased strain on the vessels in the submucosal layer of the lower esophagus and upper part of the stomach.
    b. These collateral vessels are tortuous and fragile and bleed easily.
2. Other causes of varices are abnormalities of the circulation in the splenic vein or superior vena cava and hepatic venothrombosis.
3. Mortality is high because of further deterioration of liver function to hepatic coma and complications, such as aspiration pneumonia, sepsis, and renal failure.

Clinical Manifestations

1. Hematemesis—vomiting of bright red blood.
2. Melena—passage of black, tarry stools, which indicates that blood has been in the GI tract for at least 14 hours.
3. Bright red rectal bleeding from hypermotility of the bowel or rectal varices.
4. Blood loss may be sudden and massive, causing shock.

Diagnostic Evaluation

1. Upper GI endoscopy for patients with a suspected upper GI source of bleeding.
2. Hemoglobin and hematocrit may be decreasing, and liver function tests can be abnormal.

Management

EVIDENCE BASE Tulachan S. S., Bhagatwala J., & Sridhar S. (2018). Endoscopic Management of Esophageal Varices and Variceal Hemorrhage. In: Sridhar S., Wu G. (Eds.), *Diagnostic and Therapeutic Procedures in Gastroenterology* (pp. 165–178). Clinical Gastroenterology. Totowa, N.J.: Humana Press.

---

1. Restoration of circulating blood volume with blood transfusions and IV fluids.
2. Use of IV vasoconstrictors, such as octreotide or vasopressin to control bleeding. These medications may

be used to reduce portal pressure by decreasing splanchnic blood flow and to increase clotting and hemostasis. Vasopressin has a significant vasoconstrictive effect on other organs, such as the heart and intestine.

3. Gastric lavage to remove blood from the GI tract and to enhance visualization for endoscopic examination.
4. Endoscopic esophageal ligation (variceal banding) may be urgent or nonurgent and is usually the first-line treatment to control acute bleeding. The procedure may need to be repeated until all varices are obliterated. The goal is to achieve rapid hemostasis and prevent early rebleeding.
5. Esophageal balloon tamponade, whereby balloons are inflated in the distal esophagus and the proximal stomach to collapse the varices and induce hemostasis. This procedure should be reserved for patients who are known, without a doubt, to be bleeding from esophageal varices and in whom all forms of conservative therapy have failed.
   a. Complications include esophageal necrosis, perforation, aspiration, asphyxiation, and stricture.
   b. If hemostasis is not achieved within 2 hours, another treatment should be immediately considered. Tamponade should not be used for more than 24 hours.
   c. Patients must be continuously monitored in intensive care setting.
6. Endoscopic sclerotherapy—during endoscopy, a sclerosing agent is injected directly into the varix to promote thrombosis and sclerosis of bleeding sites.
   a. To control bleeding and reduce the frequency of subsequent variceal hemorrhages, but repeated treatments may be required.
   b. Complications include esophageal ulceration, stricture, and perforation.
7. Portal systemic shunt (portocaval or portorenal) done through TIPS procedure or surgically, to treat portal hypertension and bleeding.
8. Evaluation for liver transplantation if TIPS or surgical shunt do not control portal hypertension.
9. Beta-adrenergic blocker therapy to reduce the resting pulse.
10. High-dose proton pump inhibitor (PPI) therapy for long-term management of erosive gastropathy.
11. Antibiotics, as patients with variceal hemorrhage are at high risk for SBP.

NURSING ALERT Precaution must be taken during balloon tamponade therapy to ensure that the patient does not pull or inadvertently displace the tube. Keep scissors taped to the head of the bed. In the event of *acute respiratory distress*, use the scissors to cut across tubing (to deflate both balloons) and remove tubing.

Complications

1. Exsanguination or recurrent hemorrhage.
2. Portal systemic encephalopathy.

3. Spontaneous bacterial peritonitis.

Nursing Assessment

1. Monitor vital signs and respiratory status.
2. Assess LOC and impending signs of liver failure.

Nursing Diagnoses

- Ineffective Tissue Perfusion related to GI bleeding.
- Risk for Aspiration related to GI bleeding and intubation.
- Anxiety related to fear of unknown procedures and consequences of GI bleeding.

Nursing Interventions

Maintaining Adequate Tissue Perfusion

1. Assess BP, heart rate, skin condition, and urine output for signs of hypovolemia and shock.
2. Monitor frequently the patient receiving vasopressin infusion for complications: hypertension, bradycardia, abdominal cramps, chest pain, or water intoxication.
3. Observe the patient for straining, gagging, or vomiting; these increase pressure in the portal system and increase risk of further bleeding.
4. Check all GI secretions and stool for occult and frank blood.
5. Administer infusion of blood products, as prescribed.
6. Administer vitamin K and fresh frozen plasma (FFP), as prescribed.

Preventing Aspiration

1. Assess respirations and monitor oxygen saturation of blood.
2. Note and report occurrence of signs of obstructed airway or ruptured esophagus from the esophageal balloon: changes in skin color, respirations, breath sounds, LOC, or vital signs; chest pain.
3. Check location and inflation of esophageal balloon; maintain traction on tubes, if applicable.
4. Have scissors readily available. Cut tubing and remove esophageal balloon immediately if the patient develops acute respiratory distress.
5. Keep head of bed elevated to avoid gastric regurgitation and aspiration of gastric contents.
6. When using the Sengstaken-Blakemore esophageal balloon tube, ensure removal of secretions above the esophageal balloon: position NG tube in the esophagus for suctioning purposes; provide intermittent oropharyngeal suctioning.
7. Inspect nares for skin irritation; clean and lubricate frequently to prevent bleeding.

Reducing Anxiety and Fear

1. Explain all procedures to the patient.
2. Provide care in a concerned, nonjudgmental manner.

3. Remain with the patient or maintain close observation and place call bell within the patient's reach.
4. Work swiftly and confidently, not hurriedly and anxiously.
5. Provide alternate means of communication if tubes or other equipment interfere with the patient's ability to talk.
6. Use touch and other tactile stimuli to provide reassurance to the patient.
7. Use protective restraints to prevent dislodging of tubes in a confused, combative patient.

Patient Education and Health Maintenance

1. Discuss signs and symptoms of recurrent bleeding and the need to seek emergency medical treatment if these occur.
2. Instruct the patient to avoid behaviors that increase portal system pressure: straining, gagging, and Valsalva maneuver.
3. Explain to the patient that alcohol consumption can cause further complications.
4. Encourage the patient to abstain from alcohol consumption; discuss support organizations such as Alcoholics Anonymous.

Evaluation: Expected Outcomes

- BP stable; urine output adequate.
- Airway maintained without aspiration.
- Cooperates and indicates understanding of treatment.

Liver Cancer

EVIDENCE BASE Yu, S. J. (2016). A concise review of updated guidelines regarding the management of hepatocellular carcinoma around the world: 2010–2016. *Clinical and Molecular Hepatology, 22*(1), 7–17.

Cancer of the liver, or *hepatocellular carcinoma* (HCC), is a primary cancer of the liver and is relatively uncommon in the United States. It is the 5th most common malignancy and second leading cause of cancer-associated death around the world, with more than 600,000 deaths reported internationally each year.

Cholangiocarcinoma is a primary malignant tumor of the bile ducts, which can be intrahepatic or extrahepatic. This type of cancer is uncommon in the United States but is more commonly seen in Asia.

Liver metastasis may occur from a primary site, which is found in about one half of all late cancer cases. Neoadjuvant therapy is given to shrink metastatic liver tumor to make them more amenable to resection.

Pathophysiology and Etiology

1. Incidence of primary cancer of the liver is increasing in the United States.
2. Alcoholic cirrhosis, HBV, HCV, biliary cirrhosis, and chronic liver injury have been implicated in its etiology.
3. Rarer associated causes are metabolic syndrome; hemochromatosis; $alpha_1$-antitrypsin deficiency; aflatoxins; chemical toxins, such as vinyl chloride and Thorotrast; carcinogens in herbal medicines; nitrosamines; and ingestion of hormones, as in oral contraceptives.
4. Arises in normal tissue as a discrete tumor or in end-stage cirrhosis in a multinodular pattern.
5. Liver metastasis reaches the liver by way of the portal system, lymphatic channels, or by direct extension from an abdominal tumor.

Clinical Manifestations

1. Depends on the state of the liver in which it arises; without cirrhosis and with good liver function, carcinoma of the liver may grow to huge proportions before becoming symptomatic, but in a cirrhotic patient, the lack of hepatic reserve usually leads to a more rapid course.
2. The most common presenting symptom is right upper quadrant abdominal pain, usually dull or aching, and may radiate to the right shoulder.
3. A right upper quadrant mass, weight loss, abdominal distention with ascites, fatigue, anorexia, malaise, and unexplained fever.
4. Jaundice is present only in a minority of patients at diagnosis in primary cancer of the liver. In cholangiocarcinoma, the presenting symptom is usually painless obstructive jaundice.
5. With portal vein obstruction, ascites and esophageal varices occurs.

Diagnostic Evaluation

1. Increased levels of serum bilirubin, alkaline phosphatase, and liver enzymes.
2. AFP is the principal tumor marker for hepatocellular carcinoma and is elevated in 70% to 95% of patients with the disease.
3. Ultrasonography and CT along with MRI are the most useful noninvasive tests to detect liver cancer and assess if the tumor can be surgically resected.
4. PET scan to look for recurrent or metastatic disease.
5. Percutaneous needle biopsy or biopsy assisted by ultrasonography or CT scan.
6. Laparoscopy with liver biopsy may be performed.

Management

EVIDENCE BASE National Comprehensive Cancer Network. (2016). Clinical practice guidelines in oncology: Hepatobiliary cancers. Available: *www.nccn.org/professionals/physician_gls/f_guidelines.asp.*

Nonsurgical Treatment

Varying degrees of success with nonsurgical management. These therapies may prolong survival and improve the patient's quality of life by reducing pain, but the overall effect is palliative.

1. Indicated in patients who are not surgical candidates because of inadequate hepatic reserve or tumor location. Regional therapies are used to reduce the size of the tumor and make surgical excision possible.
2. Radiofrequency ablation uses heat produced by a radiofrequency electrode to kill tumors. This can be performed by the percutaneous or laparoscopic approach and is used for relatively small tumors.
3. Hepatic artery occlusion and embolization with the use of chemotherapeutic agents or radiofrequency to treat nonresectable liver tumors.
4. Radiation therapy can help reduce pain and discomfort of large unresectable tumors.
5. Systemic treatment with a multikinase inhibitor, sorafenib is able to improve the median overall survival by approximately 3 months.
6. Clinical trials on chemotherapy administered systemically or intra-arterially, to the site of the tumor, continue to show low efficacy in liver cancer.
7. Percutaneous alcohol injection direct into the tumor is an ablative procedure that is safe for treating small liver tumors, but efficacy is limited.
8. PTBD is used to drain obstructed biliary ducts in patients with inoperable tumors or in patients considered poor surgical risks.
9. Percutaneous or endoscopic placement of internal stents may also palliate a patient with obstructed bile ducts with a terminal diagnosis.

Surgical Treatment

EVIDENCE BASE Zheng, J., Kuk, D., Gönen, M. et al. (2017). Actual 10-Year survivors after resection of hepatocellular carcinoma. *Ann Surg Oncol*, 24(5), 1358–1366.

---

1. Surgery is the best treatment for patients who meet the following criteria: tumor size is less than 5 cm, lack of macrovascular involvement, and confined to the liver with no extrahepatic disease.
   a. The 5-year survival rate is 50%; recurrence and metastasis are frequent.
   b. Surgery is an option only after the extent of the tumor and hepatic reserve have been considered.
2. Surgical resection may be along anatomic divisions of the liver or nonanatomic resections.
3. Percutaneous portal vein embolization may be performed prior to surgery of large liver tumors. Cutting off blood supply to the diseased portion of the liver allows enlargement of the nondiseased portion of the liver. An adequate amount of liver is needed to sustain a patient and prevent postoperative complications.
4. Liver transplantation is an accepted treatment for liver cancer, especially if hepatic reserve is low and the patient meets the surgical criteria.
   a. The Model for End-stage Liver Disease (MELD) is a severity scoring system for chronic liver disease that uses a patient's laboratory values for serum bilirubin, serum creatinine, and the INR to predict 3-month survival.
   b. MELD is used by the United Network for Organ Sharing (UNOS) for prioritization of patients awaiting liver transplantation in the United States.
   c. Patients may be treated with nonsurgical therapies including embolization or radiation while waiting for a liver transplant.

Complications

1. Malnutrition, biliary obstruction with jaundice.
2. Sepsis, liver abscesses.
3. Acute blood loss.
4. Fulminant liver failure, metastasis.

Nursing Assessment

1. Obtain history of hepatitis, alcoholic liver disease and cirrhosis, exposure to toxins, or other potential causes.
2. Assess for signs and symptoms of malnutrition, including recent weight loss, loss of strength, anorexia, and anemia.
3. Assess for abdominal pain, any right shoulder pain, and enlargement of the liver.
4. Assess for fever, jaundice, ascites, or bleeding.

5. Note any change in mental status as a sign of hepatic encephalopathy.

Nursing Diagnoses

- Acute and Chronic Pain related to growth of tumor.
- Imbalanced Nutrition: Less Than Body Requirements related to anorexia.
- Excess Fluid Volume related to ascites and edema.
- Altered Mental Status related to metabolic imbalance.

Nursing Interventions

Care of the patient after liver surgery is similar to general abdominal surgery (see page 496).

Controlling Pain

1. Administer pharmacologic agents, as ordered, to control pain, considering metabolism through a liver with decreased function.
   a. Titrate drugs carefully, using lowest dose that is effective.
   b. Monitor for signs of drug toxicity, particularly respiratory depression and decreased LOC.
2. Provide nonpharmacologic methods of pain relief, such as massage, heat/cold, and guided imagery.
3. Position the patient for comfort, usually in semi-Fowler position.
4. Assess the patient's response to pain-control measures.

Improving Nutritional Status

1. Encourage the patient to eat small meals and take liquid supplements as able.
2. Assess and report changes in factors affecting nutritional needs: increased body temperature, pain, signs of infection, stress level. Encourage additional calories, as tolerated.
3. Monitor daily weight.

Relieving Excess Fluid Volume

1. Monitor vital signs and record accurate fluid intake and output.
2. Restrict sodium and fluid intake, as prescribed.
3. Administer diuretics and replacement potassium and phosphate, as prescribed.
4. Administer albumin and protein supplements, as prescribed, to draw fluid from interstitial to intravascular space.
5. Measure and record abdominal girth daily at the level of the umbilicus.
6. Weigh daily, watching for increases that indicate increased fluid retention such as abdominal and lower-extremity edema.
7. Monitor laboratory tests as directed, and report abnormal values.

Improving Mental Status

1. Assess the patient's LOC and changes in behavior.

2. Limit noise and environmental stimuli.
3. Frequently reorient to person, place, and time.
4. Speak slowly and clearly while allowing the patient to respond.
5. Provide for precautions to prevent falls and promote safety.

Patient Education and Health Maintenance

1. Instruct the patient and family on preparation for surgery, reinforce and clarify surgical procedure proposed, and review postoperative instructions.
2. Instruct the patient and family on nonsurgical treatment, if appropriate.
3. Explore pain management options.
4. Inform the patient of signs and symptoms of complications.
5. Instruct the patient in continued surveillance for recurrence.
6. Instruct the patient and family in care of tubes or drains.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Tolerates small feedings; no weight loss.
- Abdominal girth decreased; urine output greater than intake.
- Patient safety maintained.

Fulminant Liver Failure

Fulminant liver failure is acute necrosis of the liver cells without preexisting liver disease, resulting in the inability of the liver to perform its many functions.

Pathophysiology and Etiology

1. Drug-related hepatotoxicity accounts for more than 50% of acute liver failure cases, including acetaminophen toxicity (42%) and idiosyncratic drug reactions (12%). Idiosyncratic reactions to poisons, chemicals, and such medications as, tetracycline, isoniazid, halogenated anesthetics, monoamine oxidase inhibitors, valproate, amiodarone, methyldopa, and amanita mushrooms.
2. HBV is the most common cause worldwide.
3. Ischemia and hypoxia because of hepatic vascular occlusion, hypovolemic shock, acute circulatory failure, septic shock, or heat stroke may be causes.
4. Miscellaneous causes include hepatic vein obstruction, Budd-Chiari syndrome, acute fatty liver of pregnancy, AIH, partial hepatectomy, complication of liver transplantation.
5. Progression of hepatocellular injury and necrosis is rapid, with development of hepatic encephalopathy within 8 weeks of onset of disease. In contrast, subfulminant hepatic failure indicates patients with liver disease for up to 26 weeks before the development of hepatic encephalopathy.
6. Survival rate has improved to approximately 60%.

Clinical Manifestations

1. Right upper quadrant tenderness.
2. Malaise, anorexia, nausea, vomiting, fatigue.
3. Jaundice.
4. Tea-colored urine that is frothy when shaken.
5. Pruritus caused by bile salts deposited on skin.
6. Steatorrhea and diarrhea because of decreased fat absorption.
7. Peripheral edema or ascites as the fluid moves from the intravascular to the interstitial spaces, secondary to hypoproteinemia or portal hypertension.
8. Easy bruising, petechiae, melena or hematemesis caused by clotting deficiency.
9. Hypotension, tachycardia due to reduced systemic vascular resistance.
10. Altered LOC, ranging from irritability and confusion to stupor, somnolence, and coma.
11. Change in deep tendon reflexes—initially hyperactive, become flaccid, asterixis.
12. Fetor hepaticus—breath odor of acetone.
13. Portal systemic encephalopathy, also known as hepatic coma or hepatic encephalopathy, can occur in conjunction with cerebral edema.
14. Cerebral edema may lead to signs of increased intracranial pressure (ICP) (eg, papilledema, hypertension, and bradycardia). This is commonly the cause of death because of brain stem herniation and/or

respiratory arrest.

Diagnostic Evaluation

1. Prolonged PT/INR; sensitive markers of hepatic failure.
2. Decreased platelet count.
3. Elevated AST and ALT result from hepatocellular necrosis.
4. Elevated ammonia and bilirubin levels.
5. Hypoglycemia due to impaired glycogen production and gluconeogenesis.
6. Dilutional hyponatremia or hypernatremia, hypokalemia, hypocalcemia, and hypomagnesemia.

Management

EVIDENCE BASE Stine, J. G., Lewis, J. H. (2015). Current and future directions in the treatment and prevention of drug-induced liver injury: A systematic review. *Expert Review of Gastroenterology and Hepatology, 25*, 1–20.

---

1. Acetaminophen overdose treated with *N*-acetylcysteine (NAC).
2. Airway protection as encephalopathy worsens and coma ensues. May require intubation and mechanical ventilation.
3. Oral or rectal administration of lactulose to minimize formation of ammonia and other nitrogenous by-products in the bowel.
4. Rectal administration of neomycin to suppress urea-splitting enteric bacteria in the bowel and decrease ammonia formation.
5. Cerebral edema management may include head of bed elevated to 30 degrees, ICP monitoring, administration of an osmotic diuretic such as mannitol, or barbiturates.
6. Careful hemodynamic monitoring and administration of vasopressors as ordered.
7. Low-molecular-weight dextran or albumin followed by a potassium-sparing diuretic (spironolactone) to enhance fluid shift from interstitial back to intravascular spaces.
8. Pancreatic enzymes, if diarrhea and steatorrhea are present, to permit better tolerance of fats in the diet.
9. Cholestyramine to promote fecal excretion of bile salts to decrease itching.
10. Antacids, PPIs, and histamine-2 (H_2) antagonists to reduce the risk of bleeding from stress ulcers.
11. Restriction of sodium while maintaining adequate caloric intake with hypertonic intravenous dextrose solution, enteral tube feedings, or total parenteral nutrition.
12. Supplemental vitamins (A, B complex, C, and K) and folate.
13. Infusion of FFP to maintain PT/INR; cryoprecipitate, as needed to manage coagulopathy.
14. Additional medical interventions, depending on the patient's condition, may include hemodialysis,

hemofiltration, hemoperfusion, or plasmapheresis.

15. Liver transplantation has become the treatment of choice.
16. Current research under way regarding use of liver support dialysis.

Complications

1. Acute respiratory failure.
2. Infections and sepsis.
3. Cardiac dysfunction, hypotension.
4. Hepatorenal failure.
5. Hemorrhage.

Nursing Assessment

1. Obtain history of exposure to medications, chemicals, or toxins; exposure to infectious hepatitis; and course of illness.
2. Assess respiratory status, LOC, and vital signs.
3. Assess for ascites, edema, jaundice, bleeding, asterixis, and presence or absence of reflexes.
4. Assess results of arterial blood gas (ABG) tests, electrolytes, INR, hemoglobin level, and hematocrit.

Nursing Diagnoses

- Deficient Fluid Volume related to hypoproteinemia, peripheral edema, ascites.
- Ineffective Breathing Pattern related to anemia and decreased lung expansion from ascites.
- Imbalanced Nutrition: Less Than Body Requirements related to GI adverse effects and decreased absorption, storage, and metabolism of nutrients.
- Risk for Impaired Skin Integrity related to malnutrition, deposition of bile salts, peripheral edema, decreased activity.
- Risk for Infection related to altered immune response.
- Risk for Injury related to encephalopathy.

Nursing Interventions

Maintaining Adequate Fluid Volume

1. Monitor vital signs frequently.
2. Weigh the patient daily and keep an accurate intake and output record; record frequency and characteristics of stool.
3. Measure and record abdominal girth at the level of the umbilicus daily.
4. Assess and record peripheral edema.
5. Restrict sodium and fluids; replace electrolytes, as directed.
6. Administer low-molecular-weight dextran or albumin and diuretics, as prescribed.

7. Assess for signs and symptoms of hemorrhage or bleeding.

Improving Respiratory Status

1. Monitor respiratory rate, depth, use of accessory muscles, nasal flaring, and breath sounds.
2. Monitor ABG values, hemoglobin level, and hematocrit, report abnormalities.
3. Elevate head of the bed to lower diaphragm and decrease respiratory effort.
4. Turn the patient frequently to prevent stasis of secretions.
5. Administer oxygen therapy, as directed.

Improving Nutritional Status

1. Enlist a nutrition specialist to help evaluate nutritional status and needs.
2. Encourage the patient to eat in an upright sitting position to decrease abdominal tenderness and feeling of fullness.
3. Provide small, frequent meals or dietary supplements.
4. Provide mouth care if the patient has bleeding gums or fetor hepaticus.
5. Restrict intake of sodium.
6. Provide enteral and parenteral feedings, as needed.

Maintaining Skin Integrity

1. Inspect skin for alteration in integrity.
2. Provide good skin care.
3. Bathe with mild soap and apply soothing lotions.
4. Keep the patient's fingernails short to prevent scratching from pruritus. Mitts can be applied for those with confusion.
5. Administer medications, as prescribed, for pruritus.
6. Assess for signs of bleeding from broken areas on the skin.
7. Turn and position the patient frequently to prevent pressure ulcers.
8. Avoid trauma and friction to the skin.

Preventing Infection

1. Be alert for signs of infection, such as fever, cloudy urine, abnormal breath sounds.
2. Use good hand washing and aseptic technique when caring for a break in the skin or mucous membranes.
3. Restrict visits with anyone who may have an infection.
4. Encourage the patient not to scratch the skin.

Preventing Injury

1. Maintain close observation, bed side rails up, and nurse call system within reach.
2. Assist with ambulation, as needed, and avoid obstructions to prevent falls.
3. Have a well-lit room and frequently reorient the patient.

4. Observe for subtle changes in behavior or change in sleeping pattern to detect increasing encephalopathy.

Patient Education and Health Maintenance

1. Teach the patient and family to notify health care provider of increased abdominal discomfort, bleeding, increased edema or ascites, hallucinations, or lapses in consciousness.
2. Instruct the patient to avoid activities that increase the risk of bleeding: scratching, falling, forceful nose blowing, aggressive tooth brushing, and use of straight-edged razor.
3. Advise limiting activities when fatigued and encourage use of frequent rest periods.
4. Maintain close follow-up for laboratory testing and evaluation by health care provider.

Evaluation: Expected Outcomes

- BP stable, urine output adequate.
- Respirations unlabored.
- Tolerates multiple small feedings per day.
- Skin intact without abrasions.
- No fever or signs of infection.
- No falls.

BILIARY DISORDERS

The gallbladder and bile ducts constitute the biliary system. The gallbladder stores and concentrates bile produced by the liver. The hormone cholecystokinin, secreted by the small intestine, stimulates contraction of the gallbladder and relaxation of the sphincter of Oddi for delivery of bile into the small intestine.

Bile assists in the emulsification (breakdown) of fat; absorption of fatty acids, cholesterol, and other lipids from the small intestine; and excretion of conjugated bilirubin from the liver.

Common terms related to the gallbladder and bile ducts are as follows:

Cholecyst—gallbladder.

Cholecystitis—inflammation of the gallbladder.

Cholelithiasis—presence or formation of gallstones in the gallbladder.

Cholecystectomy—removal of the gallbladder.

Cholecystostomy—drainage of the gallbladder through a tube.

Choledocho—common bile duct.

Choledochotomy—incision into the common bile duct.

Choledocholithiasis—presence of stones in the common bile duct.

Choledocholithotomy—incision of the common bile duct for the extraction of an impacted gallstone.

Choledochoduodenostomy—surgical formation of a communication between the common bile duct and the duodenum.

Choledochojejunostomy—surgical formation of a communication between the common bile duct and the jejunum.

Cholelithiasis, Cholecystitis, Choledocholithiasis

These conditions refer to stones or inflammation of the biliary system (see Figure 19-4). Cholecystitis may be acute or chronic.

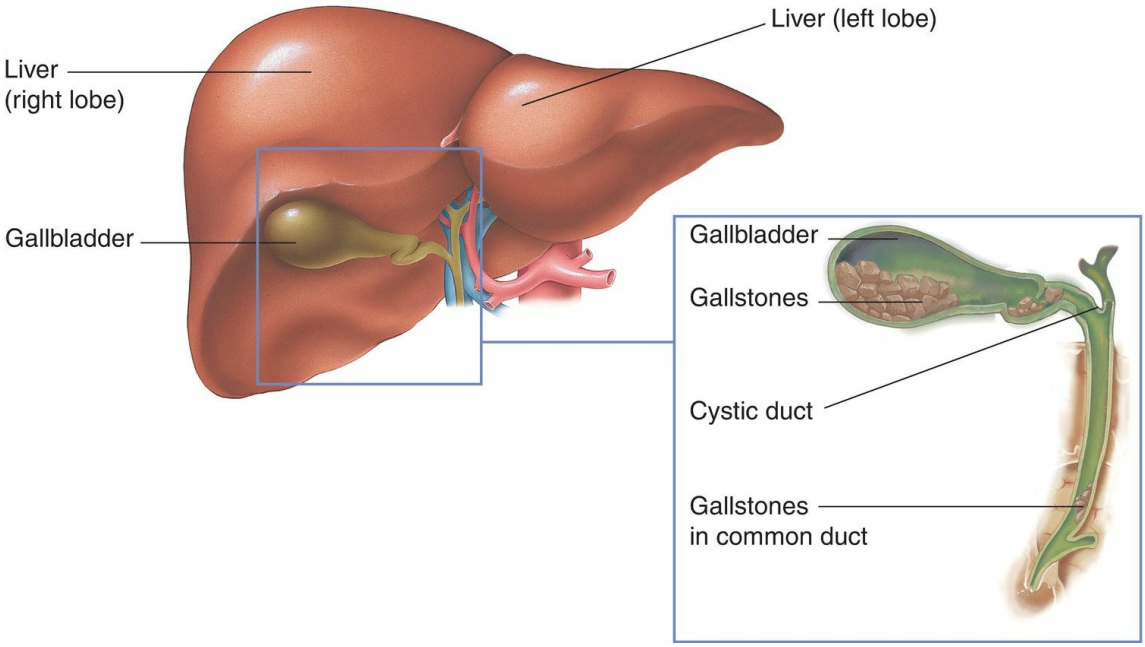

Figure 19-4. Cholelithiasis and choledocholithiasis. (Anatomical Chart Company.)

Pathophysiology and Etiology

Cholelithiasis

1. Cholesterol stones occur when cholesterol supersaturates the bile in the gallbladder and precipitates out of the bile. The cholesterol-saturated bile predisposes to the formation of gallstones and acts as an irritant, producing inflammatory changes in the gallbladder.
    a. Cholesterol stones make up 80% of gallstones in the United States.
    b. Four times more women than men develop cholesterol stones.
    c. Women are usually older than age 40, and obese.
    d. Stone formation increases in users of contraceptives, estrogens, and cholesterol-lowering drugs, which are known to increase biliary cholesterol saturation.
    e. Gallstones are associated with high-calorie diets, type 2 diabetes mellitus, dyslipidemia, hyperinsulinism, obesity, and metabolic syndrome.
    f. Bile acid malabsorption, genetic predisposition, and rapid weight loss are also risk factors for cholesterol gallstones.
2. Pigment stones occur when free bilirubin combines with calcium.
    a. Found in patients with cirrhosis, hemolysis, and infections in the biliary tree.
    b. These stones cannot be dissolved.

3. An estimated 10% to 15% of adults in the United States have gallstones, with 1 million new cases discovered each year.
    a. Incidence of stone formation increases with age because of increased hepatic secretion of cholesterol and decreased bile acid synthesis.
    b. Increased risk in patients with malabsorption of bile salts with GI disease, post gastric bypass, with bile fistula, with gallstone ileus, with carcinoma of the gallbladder, or in those who have had ileal resection or ileal bypass.

Cholecystitis

1. Acute cholecystitis, an acute inflammation of the gallbladder, is most commonly caused by gallstone obstruction.
    a. Secondary bacterial infection may occur and progress to empyema (purulent effusion of the gallbladder).
2. Acalculous cholecystitis is acute gallbladder inflammation without obstruction by gallstones.
    a. Occurs after major surgical procedures, severe trauma, or severe burns.
3. Chronic cholecystitis occurs when the gallbladder becomes thickened, rigid, and fibrotic and functions poorly. Results from repeated attacks of cholecystitis, calculi, or chronic irritation.

Choledocholithiasis

1. Small gallstones can pass from the gallbladder into the common bile duct and travel to the duodenum. More commonly, they remain in the common bile duct and can cause obstruction, resulting in jaundice and pruritus.
2. Common bile duct stones are frequently associated with infected bile and can lead to cholangitis (inflammation/infection in the biliary system).
3. Patients experience biliary pain in the upper abdomen, jaundice, chills and fever, mild hepatomegaly, abdominal tenderness, and, occasionally, rebound tenderness.

Clinical Manifestations

1. Gallstones that remain in the gallbladder are usually asymptomatic.
2. Biliary colic can be caused by gallstones.
    a. Steady, severe, aching pain or sensation of pressure in the epigastrium or right upper quadrant, which may radiate to the right scapular area or right shoulder.
    b. Begins suddenly and persists for 1 to 3 hours until the stone falls back into the gallbladder or passes through the cystic duct.
3. Acute cholecystitis causes biliary colic pain that persists more than 4 hours and increases with movement, including respirations.
    a. Also causes nausea and vomiting, low-grade fever, and jaundice (with stones or inflammation in the common bile duct).
    b. Right upper quadrant guarding and Murphy sign (inability to take a deep inspiration when

examiner's fingers are pressed below the hepatic margin) are present.

4. Chronic cholecystitis causes heartburn, flatulence, and indigestion. Repeated attacks of symptoms may occur resembling acute cholecystitis.

Diagnostic Evaluation

1. Ultrasonography, CT scan, and HIDA scan may show stones or inflammation.
2. MRCP is a noninvasive exam that can identify gallstones anywhere in the biliary tract.
3. ERCP or PTC to visualize location of stones and extent of obstruction.
4. Elevated conjugated bilirubin and alkaline phosphatase because of obstruction.
5. Elevated amylase and lipase levels, with gallstone pancreatitis.
6. White blood cell count and blood cultures if sepsis.

Management

1. Supportive management may include IV fluids, NG suction, pain management with nonsteroidal anti-inflammatory drugs (NSAIDs) or oral antispasmodics, and antibiotics.
2. A cholecystostomy tube may be placed percutaneously into the gallbladder to decompress the organ in preparation for future surgery. This may be placed by interventional radiology.
3. Oral therapy with chenodeoxycholic acid, ursodeoxycholic acid, or a combination of both to decrease the size of existing cholesterol stones or to dissolve small ones.
   a. Indicated for patients at high risk for surgery because of comorbid conditions.
   b. Major adverse effects include diarrhea, abnormal liver function tests, and increases in serum cholesterol.
   c. Six to twelve months of therapy, may eventually result in dissolution of small gallstones, but with a recurrence rate of more than 50%.
4. Surgical management.
   a. Cholecystectomy, open or laparoscopic.
   b. Intraoperative cholangiography and choledochoscopy for common bile duct exploration.
   c. Placement of a T tube in the common bile duct to decompress the biliary tree and allow access into the biliary tree postoperatively.
5. After cholecystectomy, intracorporeal lithotripsy may be used to fragment retained stones in the common bile duct by pulsed laser or hydraulic lithotripsy applied through an endoscope directly to the stones. The stone fragments are removed by irrigation or aspiration. Retained stones may also be removed by basket retrieval through the endoscopic or percutaneous transhepatic biliary approach.

Complications

1. Cholangitis.
2. Gangrene, empyema, or perforation of the gallbladder.
3. Biliary fistula through the duodenum or jejunum.

4. Gallstone ileus.
5. Adenocarcinoma of the gallbladder.

Nursing Assessment

1. Obtain history and demographic data that may indicate risk factors for biliary disease.
2. Assess the patient's pain for location, description, intensity, and relieving and exacerbating factors.
3. Assess for signs of dehydration: dry mucous membranes, poor skin turgor, and low urine output with elevated specific gravity.
4. Assess sclera and skin for jaundice.
5. Monitor temperature and WBC count for indications of infection.

Nursing Diagnoses

- Acute Pain related to biliary colic or stone obstruction.
- Deficient Fluid Volume related to nausea and vomiting and decreased intake.

Nursing Interventions

Also see Care of the Patient Undergoing Cholecystectomy.

Relieving Pain

1. Assess pain location, severity, and characteristics.
2. Administer medications or monitor patient-controlled analgesia (PCA) to control pain.
3. Assist in attaining position of comfort.

Restoring Normal Fluid Volume

1. Administer IV fluids and electrolytes, as prescribed.
2. Administer antiemetics, as prescribed, to decrease nausea and vomiting.
3. Maintain NG decompression, if needed.
4. Begin food and fluids, as tolerated, after acute symptoms subside or postoperatively.
5. Observe and record amount of biliary tube drainage, if applicable.

Patient Education and Health Maintenance

1. Instruct the patient in care of tubes or catheters that may be in place at discharge.
    a. Observe for bleeding or drainage around insertion site.
    b. Replace dressing per facility protocol.
    c. Report change or decrease in drainage.
2. Review discharge instructions for activity, diet, medications, and follow-up.
3. Emphasize symptoms of complications to be reported, such as increased or persistent pain, fever, abdominal distention, nausea, anorexia, jaundice, unusual drainage.

4. Encourage follow-up, as indicated.

Evaluation: Expected Outcomes

- Verbalizes reduced pain level.
- Tolerates oral fluids and solid food; adequate urine output.

Care of the Patient Undergoing Cholecystectomy

EVIDENCE BASE Benner, P., & Kautz, D. (2015). Postoperative care of patients undergoing same-day laparoscopic cholecystectomy. *AORN Journal, 102*(1), 15–32.

Cholecystectomy is surgical removal of the gallbladder for acute and chronic cholecystitis. Laparoscopic cholecystectomy is the most commonly performed abdominal surgery in industrialized countries, with almost 900,000 procedures performed annually.

Procedure

1. Open laparotomy—gallbladder removed after making an abdominal incision.
2. Laparoscopy—gallbladder removed from a small opening just above the umbilicus through the use of a laparoscope for viewing (see Figure 19-5).
   a. Three other small punctures are made in the abdomen to place other special instruments used to assist in the manipulation and removal of the gallbladder.
   b. The organs in the abdomen can be viewed through the laparoscope and via a television monitor through a camera attached to the laparoscope.
3. If the patient is scheduled for a laparoscopic cholecystectomy, consent is also obtained for a traditional open cholecystectomy in case the gallbladder is not accessible through the laparoscopic technique.
4. After cholecystectomy, bile ducts will eventually dilate to accommodate the volume of bile once held by the gallbladder to aid in the digestion of fats.

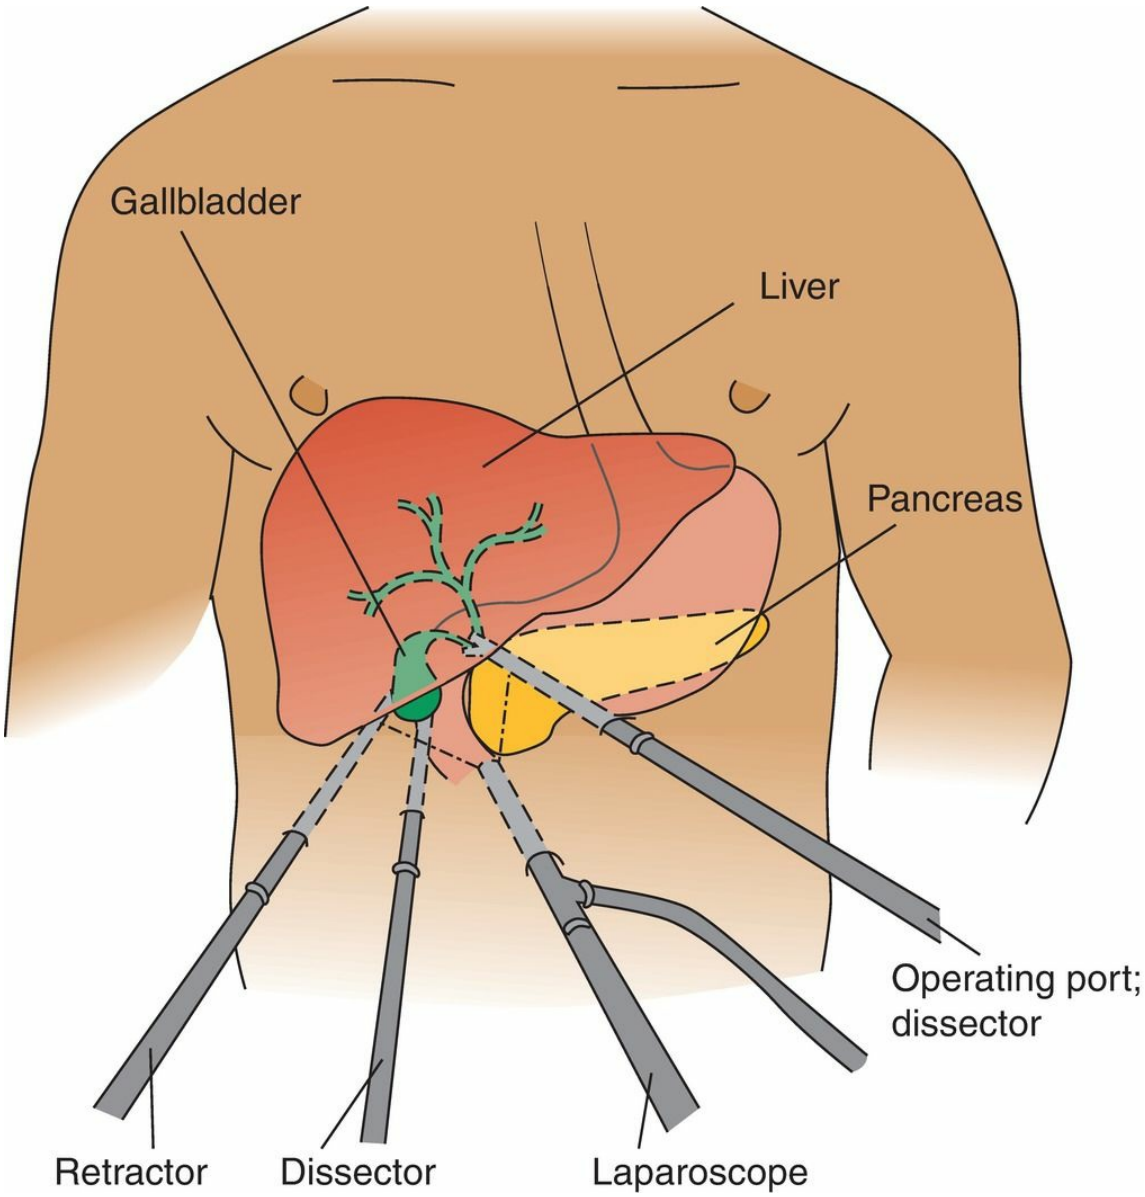

Figure 19-5. Laparoscopic cholecystectomy. The surgeon makes four small incisions (less than ½ inch each) in the abdomen and inserts a laparoscope with a miniature camera into the opening. The camera apparatus displays the gallbladder and adjacent tissues on a screen allowing the surgeon to visualize the organ for removal.

Preoperative Management

1. IV fluids are given before surgery to improve hydration status if the patient has been vomiting.
2. Antibiotics are ordered for acute cholecystitis.
3. Educate the patient about the procedure and what to expect postoperatively.
4. The patient must remain NPO from midnight the night before surgery and must void before surgery.

Postoperative Management

1. Postoperatively, the patient is evaluated for the following:

a. Vital signs, LOC.
b. Level of pain.
c. Appearance of wound or puncture sites: wound drain or T-tube patency (if common bile duct exploration also performed), security and drainage (if present).
d. Intake and output.
e. Postoperative nausea and vomiting

2. Early ambulation is encouraged to prevent thromboembolism, to facilitate voiding, and to stimulate peristalsis.
3. Monitor for complications including: incisional infection, hemorrhage, and bile duct injury (persistent pain, fever, abdominal distention, nausea, anorexia, or jaundice).

Potential Complications

1. Infection, hemorrhage, or bile duct injury.
2. Pneumonia or atelectasis.
3. Deep vein thrombosis or pulmonary embolism.
4. Impaired wound healing.

Nursing Diagnoses

- Acute Pain related to surgical procedure.
- Risk for Infection related to surgical procedure.
- Impaired Skin Integrity related to surgical procedure.
- Imbalanced Nutrition: Less Than Body Requirements related to surgical procedure, wound pain, or tube drainage.

Nursing Interventions

Relieving Pain

1. Assess pain location, level, and characteristics.
2. Administer prescribed pain medications or monitor PCA.
3. Encourage splinting of incision when moving.
4. Encourage ambulation as soon as prescribed to decrease abdominal distention and to promote bowel motility.
5. Instruct the patient that usual activities can normally be resumed within 5 to 7 days after laparoscopic cholecystectomy or within 4 to 6 weeks of open cholecystectomy.
   a. Sexual activity may be resumed when pain has abated.
   b. Obtain specific instructions for wound care; activity, such as heavy lifting; strenuous activity; showers and tub baths; and driving per surgeon's protocol.

Preventing Infection

1. Assess wound dressings for any increased or purulent drainage.
2. Assess wound drain or T-tube site for drainage, and note amount, color, and odor.
3. Assess bile drainage from T tube into bile bag:
    a. Report decrease in drainage.
    b. Maintain T-tube patency and security.
4. Report right upper quadrant pain, abdominal distention, fever, chills, or jaundice, as these may indicate a bile duct injury.
5. Administer antibiotics, as prescribed.
6. Encourage use of incentive spirometer, coughing and deep breathing, and ambulation to decrease risk of pulmonary infection.

Maintaining Skin Integrity

1. Assess wounds for healing.
2. Perform wound care as prescribed.
3. Assess for adequate hydration.
4. Assess and report any signs of redness, swelling, pain, or drainage from the wounds.

Providing Adequate Nutrition

1. Assess for nausea and vomiting and administer antiemetics, as prescribed.
2. Encourage fluid intake and advance to regular diet, as tolerated.
3. Administer replacement fluids for bile drainage from T tube, if indicated.
4. Clamp T tube, when indicated, and assess tolerance of food and color of stools.

Patient Education and Health Maintenance

1. Teach the patient and family that rapid postoperative recovery should be expected.
2. Advise the patient and family to notify the surgeon immediately of any subtle change in the patient's postoperative course or persistent symptoms. A bile duct injury should be suspected after a laparoscopic cholecystectomy in patients who do not show the expected recovery during the early postoperative period.
3. Advise the patient to advance diet, as tolerated. Fats can be taken *as tolerated* because the bile ducts dilate to accommodate storage of bile, as needed.

Evaluation: Expected Outcomes

- Verbalizes decreased pain.
- No fever or signs of infection.
- Wound healing without drainage.
- Tolerates fluids and small solid feedings.

PANCREATIC DISORDERS

The pancreas secretes enzymes, including amylase and lipase, through the pancreatic duct when stimulated by cholecystokinin and secretin to aid in digestion of carbohydrates and fat in the small intestine. The pancreas also secretes hormones, such as insulin and glucagon, which help to regulate and maintain normal serum glucose.

Acute Pancreatitis

Acute pancreatitis is an inflammation of the pancreas, ranging from mild edema to extensive hemorrhage, resulting from various insults to the pancreas. It is defined by a discrete episode of abdominal pain and serum pancreatic enzyme elevations. The structure and function of the pancreas usually return to normal after an acute attack. Chronic pancreatitis occurs when there is persistent cellular damage to the pancreas (see Table 19-2 for comparison).

Table 19-2 Acute Versus Chronic Pancreatitis: Comparing Findings

	ACUTE PANCREATITIS	CHRONIC PANCREATITIS
Definition	• Inflammation that leads to swelling of the pancreas • Autodigestion—enzymes normally secreted by the pancreas become activated inside the pancreas and start to digest the pancreatic tissue	• Associated with widespread scarring and destruction of pancreatic tissue • Affects more men than women
Etiology	• Gallstones passing through the common bile duct • Alcohol misuse • Viral infection, hereditary conditions, traumatic injury, certain medications (especially estrogens, corticosteroids, thiazide diuretics, and azathioprine), pancreatic or common bile duct surgical procedures, or ERCP • Underlying pancreatic tumor • Hypercalcemia • Hypertriglyceridemia • Idiopathic	• Alcohol misuse (70% of patients) • Hereditary pancreatitis • Ductal destruction (from trauma, stones, tumors) • Tropical pancreatitis • Systemic diseases (cystic fibrosis, systemic lupus erythematosus, hyperparathyroidism) • Congenital conditions such as pancreas divisum • Hypercalcemia • Hypertriglyceridemia • Idiopathic
Symptoms	• Sudden attack of constant, severe upper abdominal pain that may radiate to the back • Pain that is sudden and steady • Pain that may be aggravated by walking or lying down and relieved by sitting or leaning forward (proning) • Other possible symptoms: nausea, vomiting, diarrhea, bloating, fever, diaphoresis, and jaundice	• Constant, dull mid to upper abdominal pain; may also have back pain • Pain that worsens with eating food or drinking alcohol; lessens with sitting or leaning forward (proning) • As disease progresses, attacks of pain that last longer and occur more frequently • May have nausea, vomiting • Weight loss
Course	• Mild disease in 85% of patients with rapid recovery within a few days of onset of illness	• Destruction of pancreatic tissue that slowly progresses from chronic inflammatory damage
Diagnosis	• Medical history • Social history • Serum amylase and lipase • Serum triglycerides • Ultrasound, CT scan, MRI	• Medical history • Social history • Liver function tests • Fecal elastase test • Abdominal x-ray that may reveal calcium deposits in the pancreas • Imaging studies, such as ultrasound, CT scan, ERCP, EUS, MRI/MRCP • CEA and CA 19-9 to assess for pancreatic cancer
Treatment	• Depends on severity as acute pancreatitis may be mild, moderate, or severe • IV fluids • Pain medication • Diet advancement based on pain and nausea • Surgery for such complications as necrosis, infection, bleeding	• Pain management • Nutritional support and diet modification with smaller, frequent, low-fat meals • Pancreatic enzymes • Diabetes control • Pancreatic duct drainage procedures or excision of damage of all or part of the pancreas • Alcohol abstinence

Complications	• Severe acute pancreatitis may lead to:
	  • Multiple organ system failure, such as lung, liver, kidney, and heart
	  • Infected pancreatic necrosis
	  • Pancreatic abscess
	  • Pancreatic pseudocysts
	  • Pancreatic fistula
	  • Pancreatic ascites
	  • Damage to surrounding organs, such as small bowel, colon, and duodenum (due to inflammation)
		• Malnutrition from poor absorption of nutrients, especially fats
		• Frequent bowel movements that are loose, greasy, foul-smelling (steatorrhea)
		• Insulin-dependent diabetes
		• Increased risk of pancreatic cancer
		• Pseudocyst
		• Bleeding from the stomach
		• Increased risk of venous thromobembolism
		• Possible bouts of acute pancreatitis

Prognosis	• Can usually fully recover without recurrence if cause is removed	• Can maintain quality of life with supportive care and adherence to medical regimen

Pathophysiology and Etiology

1. Excessive alcohol consumption is the most common cause in the United States.
2. Also commonly caused by biliary tract disease, such as cholelithiasis and acute and chronic cholecystitis.
3. Less common causes are bacterial or viral infection, blunt abdominal trauma, peptic ulcer disease, ischemic vascular disease, hypertriglyceridemia (greater than 1,000 g/dL), hypercalcemia; the use of

corticosteroids, thiazide diuretics, and oral contraceptives; surgery on or near the pancreas or after instrumentation of the pancreatic duct by ERCP; tumors of the pancreas or ampulla; and (rarely) hereditary pancreatitis.

4. Mortality is high (10%) because of shock, anoxia, hypotension, or multiple organ dysfunction.
5. Attacks may resolve with complete recovery, may recur without permanent damage, or may progress to chronic pancreatitis.
6. Autodigestion of all or part of the pancreas is involved, but the exact mechanism is not completely understood.

Clinical Manifestations

(Depends on severity of pancreatic damage.)

1. Abdominal pain, usually constant, midepigastric or periumbilical, radiating to the back or flank. The patient assumes a fetal position or leans forward while sitting (known as "proning") to relieve pressure of the inflamed pancreas on celiac plexus nerves. Pain can be mild to incapacitating.
2. Nausea and vomiting.
3. Fever.
4. Involuntary abdominal guarding, epigastric tenderness to deep palpation, and reduced or absent bowel sounds.
5. Dry mucous membranes; hypotension; cold, clammy skin; cyanosis; and tachycardia, which may reflect mild to moderate dehydration from vomiting or capillary leak syndrome (third space loss).
6. Shock may be the presenting manifestation in severe episodes, with respiratory distress and acute renal failure.
7. Purplish discoloration of the flanks (Turner sign) or of the periumbilical area (Cullen sign) occurs in extensive hemorrhagic necrosis of the pancreas.

Diagnostic Evaluation

1. A minimum of 2 out of 3 criteria must be met to diagnose acute pancreatitis: Abdominal pain; elevated serum lipase (or amylase) at least 3 times greater than the upper limit of normal; characteristic findings of acute pancreatitis on CT scan or MRI.
2. Serum glucose, bilirubin, alkaline phosphatase, lactate dehydrogenase, AST, ALT, potassium, and cholesterol may be elevated.
3. Serum albumin, calcium, sodium, magnesium, and, possibly, potassium may be low because of dehydration, vomiting, and the binding of calcium in areas of fat necrosis.
4. Elevated C-reactive protein (CRP) level in the first 72 hours is suggestive of severe acute pancreatitis and is predictive of a worse clinical course.
5. Abdominal x-ray to detect an ileus or isolated loop of small bowel overlying pancreas. Pancreatic calcifications or gallstones may suggest an alcohol or biliary etiology.
6. Abdominal ultrasound to determine if the patient has gallstones or obstruction in the common bile duct.

7. Chest x-ray for detection of pulmonary complications. Pleural effusions are common, especially on the left, but may be bilateral.

Management

EVIDENCE BASE Crockett, S. D, Wani, S., Gardner, T. B., et al. (2018). American Gastroenterological Association Institute guideline on initial management of acute pancreatitis. *Gastroenterology*, 154(4), 1096–1101.

Depending on severity of the episode, management focuses on alleviation of symptoms and support of the patient to prevent complications.

1. Aggressive hydration, defined as 250 to 500 mL/hour of isotonic crystalloid solution should be provided to all patients, unless contraindicated, for the first 24 to 48 hours.
2. Adequate oxygenation, which is often reduced by pain, anxiety, acidosis, abdominal pressure, or pleural effusions.
3. Pain control to alleviate pain and anxiety, which increases pancreatic secretions.
4. NG intubation and suction to relieve gastric stasis, distention, and ileus, if needed. Maintenance of alkaline gastric pH with PPIs or H_2-receptor antagonists and antacids to suppress acid drive of pancreatic secretions and to prevent stress ulcers.
5. Begin oral or enteral nutrition within 24 hours. This may help to protect the gut mucosal barrier and limit bacterial movement, reducing the risk for complications of acute pancreatitis.
6. Supportive pharmacotherapy.
    a. Electrolyte replacements, as needed.
    b. Sodium bicarbonate to treat metabolic acidosis.
    c. Insulin to treat hyperglycemia.
    d. Antibiotic therapy for documented infection or sepsis.
7. Cholecystectomy is indicated during the hospital admission for acute gallstone pancreatitis.
8. Surgical intervention if complications occur.
    a. Incision and drainage of abscess and infected pseudocysts.
    b. Debridement or pancreatectomy to remove necrotic pancreatic tissue.

Complications

1. Pancreatic ascites, abscess, or pseudocyst.
2. Acute necrotic collections or walled-off pancreatic necrosis.
3. Pulmonary infiltrates, pleural effusion, acute respiratory distress syndrome.
4. Hemorrhage with hypovolemic shock.

5. Acute renal failure.
6. Sepsis and multiple-organ dysfunction syndrome.

Nursing Assessment

1. Obtain history of gallbladder disease, alcohol use, hypertriglyceridemia, or precipitating factors.
2. Assess GI symptoms, including nausea and vomiting, diarrhea, and passage of stools containing fat.
3. Assess characteristics of abdominal pain.
4. Assess nutritional and fluid status.
5. Assess respiratory rate and pattern and breath sounds.

GERONTOLOGIC ALERT The incidence of severe, systemic complications of pancreatitis increases with age. Assess for any changes in mental status in an older person with pancreatitis as an indicator of an underlying complication. Acute pancreatitis in an older person without other precipitating factors may indicate an underlying pancreatic tumor obstructing the pancreatic duct.

Nursing Diagnoses

- Acute Pain related to disease process.
- Deficient Fluid Volume related to vomiting, self-restricted intake, fever, and fluid shifts.
- Ineffective Breathing Pattern related to severe pain and pulmonary complications.
- Imbalanced Nutrition: Less Than Body Requirements related to fear of eating, malabsorption, and glucose intolerance.

Nursing Interventions

Controlling Pain

1. Administer opioid analgesics, as ordered, to control pain.
2. Assist the patient to a comfortable position.
3. Maintain patency of NG suction to remove gastric secretions and to relieve abdominal distention, if indicated.
4. Provide frequent oral hygiene and care.
5. Administer antacids, PPIs, or H_2-receptor antagonists, as prescribed.
6. Report increase in severity of pain, which may indicate hemorrhage of the pancreas, rupture of a pseudocyst, or inadequate dosage of the analgesic.

Restoring Adequate Fluid Balance

1. Monitor and record vital signs, skin color, and temperature.
2. Monitor intake and output and weigh daily.

3. Evaluate laboratory data for hemoglobin, hematocrit, albumin, calcium, potassium, sodium, and magnesium levels and administer replacements, as prescribed.
4. Observe and measure abdominal girth if pancreatic ascites is suspected.
5. Report trends in falling BP or urine output or rising pulse because this may indicate hypovolemia and shock or renal failure.

Improving Respiratory Function

1. Assess respiratory rate and rhythm, effort, oxygen saturation, and breath sounds frequently.
2. Position in upright or semi-Fowler position to enhance diaphragmatic excursion.
3. Administer oxygen supplementation, as prescribed, to maintain adequate oxygen levels.
4. Report signs of respiratory distress immediately.
5. Instruct the patient in coughing and deep breathing to improve respiratory function.

Nutrition

1. Assess nutritional status, history of weight loss, and dietary habits, including alcohol intake.
2. Administer antacids or H_2-receptor antagonists to prevent neutralization of enzyme supplements, as indicated.
3. Monitor intake and output and daily weight.
4. Assess for GI discomfort with meals and character of stools.
5. Monitor blood glucose levels and teach balanced, low concentrated carbohydrate diet and insulin therapy as indicated.
6. Identify foods that aggravate symptoms, and teach low-fat diet.

TRANSITIONAL CARE ALERT Patients with acute pancreatitis are often critically ill with long hospitalization, requiring extended rehabilitation. Assess the need for supportive services such as subacute care, home care, and outpatient rehabilitation. Identify risk factors for readmission such as lack of supportive caregiver, insurance, transportation, education, and financial resources, as well as the presence of alcohol or drug addiction. Engage social worker as well as community agencies for follow-up and ongoing problem solving after the patient leaves the hospital.

Patient Education and Health Maintenance

1. Instruct the patient to gradually resume a low-fat diet.
2. Instruct the patient to increase activity gradually, providing for daily rest periods.
3. Reinforce information about the disease process and precipitating factors. Stress that subsequent bouts of acute pancreatitis may destroy the pancreas, cause additional complications, and lead to chronic pancreatitis.

4. If pancreatitis is a result of alcohol use, the patient needs to be reminded of the importance of eliminating all alcohol; advise about Alcoholics Anonymous or other substance use counseling.

Evaluation: Expected Outcomes

- Verbalizes reduced pain level.
- BP stable; urine output adequate.
- Respirations unlabored; breath sounds clear.

Chronic Pancreatitis

Chronic pancreatitis is defined as the persistence of pancreatic cellular damage after acute inflammation and decreased pancreatic endocrine and exocrine function. Prevalence of chronic pancreatitis is 50 per 100,000 people.

Pathophysiology and Etiology

1. Chronic pancreatitis often develops in patients between the ages of 30 and 40, and is more common in men.
2. Alcohol misuse is the most common cause; less common causes are hyperparathyroidism, hereditary pancreatitis, malnutrition, and trauma to the pancreas.
3. With chronic inflammation, destruction of the secreting cells of the pancreas causes maldigestion and malabsorption of protein and fat and possibly diabetes mellitus if islet cells of the pancreas have been affected.
4. As cells are replaced by fibrous tissue, obstruction of the pancreatic and common bile ducts and duodenum may result.

Clinical Manifestations

1. Pain is usually located in the epigastrium or left upper quadrant, frequently radiating to the back; similar to that observed in acute pancreatitis, but more constant and occurring at unpredictable intervals. As the disease progresses, recurring attacks of pain will be more severe, more frequent, and of longer duration.
2. Weight loss, nausea, vomiting, and anorexia.
3. Malabsorption and steatorrhea occur late in the course of the disease.
4. Glucose intolerance.

Diagnostic Evaluation

1. Serum amylase and lipase may be normal to low because of decreased pancreatic exocrine function.
2. Fecal fat analysis determines need for pancreatic enzyme replacement.
3. Bilirubin and alkaline phosphatase may be elevated if biliary obstruction occurs.
4. Secretin and cholecystokinin stimulatory test results are abnormal.
5. Plain abdominal x-ray to determine diffuse calcification of the pancreas.
6. CT scan identifies pancreatic structural changes, such as calcifications, masses, ductal irregularities, enlargement, and pseudocysts.
7. ERCP defines ductal anatomy and localizes complications, such as pancreatic pseudocysts and ductal disruptions.

Management

1. Alcohol abstinence and tobacco cessation.
2. Pain management, including supportive behavioral therapy.

3. Small meals and hydration with correction of nutritional deficiencies.
4. Pancreatic enzyme replacement.
5. Treatment of diabetes mellitus.
6. Endoscopic placement of pancreatic stent allowing free flow of pancreatic juices through distorted and irregular/narrowed pancreatic duct.
7. Surgical interventions to reduce pain, restore drainage of pancreatic secretions, correct structural abnormalities, and manage complications.
    a. Pancreatojejunostomy—side-to-side anastomosis of pancreatic duct to jejunum to drain pancreatic secretions into jejunum.
    b. Revision of sphincter of ampulla of Vater by a sphincteroplasty, in which the sphincter is sewn open to allow free flow of pancreatic juices.
    c. Drainage of pancreatic pseudocyst into nearby structures or by external drain.
    d. Resection of part of pancreas (Whipple procedure, distal pancreatectomy) or removal of entire pancreas (total pancreatectomy).
    e. Autotransplantation of islet cells.

Complications

1. Pancreatic pseudocyst formation.
2. Pancreatic ascites and pleural effusions.
3. GI hemorrhage.
4. Biliary tract obstruction.
5. Pancreatic fistula.
6. Splenic vein thrombosis.
7. Pancreatic cancer.
8. Diabetes mellitus.

Nursing Assessment

1. Assess level of abdominal pain.
2. Assess nutritional status.
3. Assess for steatorrhea and malabsorption.
4. Assess for signs and symptoms of diabetes mellitus.
5. Assess current level of alcohol intake and motivation and resources available to abstain from drinking such as Alcoholics Anonymous.

Nursing Diagnoses

For surgical care, see “Care of the Patient Undergoing Gastrointestinal Surgery” (page 495).

- Acute and Chronic Pain related to chronic and unrelenting insult to pancreas.

- Imbalanced Nutrition: Less Than Body Requirements related to fear of eating, malabsorption, and glucose intolerance.
- Anxiety related to surgical intervention or not knowing when pain may recur.

Nursing Interventions

Controlling Pain

1. Assess and record the character, location, frequency, and duration of pain.
2. Determine precipitating and alleviating factors of the patient's pain.
3. Explore the effect of pain on the patient's lifestyle and eating habits.
4. Administer or teach self-administration of analgesics, as ordered, to control pain.
5. Use nonpharmacologic methods to promote relaxation, such as distraction, imagery, and progressive muscle relaxation.
6. Assess response to pain-control measures and refer to pain management clinic, if indicated.

Improving Nutritional Status

1. Assess nutritional status, history of weight loss, and dietary habits, including alcohol intake.
2. Administer pancreatic enzyme replacement with meals, as prescribed.
3. Administer antacids, PPIs, or H_2-receptor antagonists to prevent neutralization of enzyme supplements, as indicated.
4. Monitor intake and output and daily weight.
5. Assess for GI discomfort with meals and character of stools.
6. Monitor blood glucose levels and teach balanced, low–concentrated carbohydrate diet and insulin therapy, as indicated.
7. Identify foods that aggravate symptoms and teach low-fat diet.

DRUG ALERT Warn the patient that dangerous hypoglycemic reaction may result from use of insulin while drinking alcohol and skipping meals.

Relieving Anxiety about Surgical Intervention

1. Describe planned surgical intervention and the expected results.
   a. Decreased pain.
   b. Ability to eat better and improve general condition.
2. Prepare the patient for adverse effects and complications of surgery.
   a. Total pancreatectomy will cause permanent diabetes mellitus, dependence on insulin, severe malabsorption, and the need for lifelong pancreatic enzyme replacement. Consultation and close monitoring by endocrinologist and diabetic educator.

b. Malnutrition and debility increase the patient's risk for poor healing and complications of surgery.

3. Assist the patient to prepare for surgery by encouraging abstinence of alcohol and intake of nutritional and vitamin supplements.
4. Encourage the patient to enlist the help of support network and strengthen appropriate coping mechanisms.
5. After surgery, provide meticulous care to prevent infection, promote wound healing, and prevent routine complications of surgery.

Patient Education and Health Maintenance

1. Instruct the patient regarding correct use of analgesics.
2. Instruct in proper administration of pancreatic enzyme replacement.
   a. Take just before or during meals.
   b. May be enteric coated. Do not crush or chew tablets; powder may be sprinkled on food if swallowing tablets is difficult.
   c. Take with antacid, PPI, or H_2-receptor antagonist, as directed, to prevent pancreatic enzyme from being destroyed by gastric acid secretions.
3. Advise the patient to monitor number and characteristics of stools; report increased stools or food intolerance.
4. Diabetic teaching with follow-up to monitor progression of condition, if applicable.
5. Stress that treatment will be ineffective if alcohol consumption is continued.

Evaluation: Expected Outcomes

- Verbalizes reduced pain level.
- Weight stabilized or weight gain noted.
- Verbalizes understanding of effects of surgical procedure.

Pancreatic Cancer

Cancer of the pancreas is a highly lethal malignancy that may arise in the head (about 70% of cases) or body and tail of the pancreas. Adenocarcinoma of the cells that line the ducts of the pancreas is the most common (85%) type. Pancreatic cancer is the fourth leading cause of cancer deaths in the United States because 90% of tumors are not resectable at the time of diagnosis.

Pathophysiology and Etiology

1. Incidence is increasing with 50,000 cases diagnosed each year in the United States.
2. Occurs more commonly in males than females, in blacks than in whites.
3. Usually occurs between ages 60 and 80 but can be found in younger patients.
4. Smoking, prolonged exposure to industrial chemicals, high-fat diet, diabetes mellitus, and chronic pancreatitis are considered risk factors. A small percentage of pancreatic cancer is inherited.
5. Obesity and physical inactivity are now considered risk factors for pancreatic cancer.
6. Obstruction of bile flow may occur with tumors in the head of the pancreas because of compression of the distal common bile duct.
7. Obstruction of pancreatic duct produces pain and exocrine dysfunction.

Clinical Manifestations

1. Symptoms are commonly vague and nonspecific, preventing early detection.
2. Weakness, weight loss, anorexia, nausea, vomiting, and abdominal pain may occur.
3. Pain usually occurs in the upper abdomen and is gnawing or boring and may radiate around the flank to the back.
    a. Pain is usually worse at night, and patients tend to lie with knees to chest position or may lean forward when seated (proning) to relieve pain.
    b. Pain may become more localized, severe, and unremitting as the disease progresses.
4. Early satiety and a feeling of bloating after eating may occur.
5. Hepatomegaly.
6. Biliary obstruction produces jaundice, dark tea-colored urine, clay-colored stools, and pruritus.
7. Depression and lethargy may be present.

Diagnostic Evaluation

1. Liver function tests elevated; coagulation studies may be prolonged.
2. Carcinoembryonic antigen (CEA) and CA 19-9—may be elevated.
3. Transabdominal ultrasonography detects tumors larger than 1 cm.
4. ERCP defines anatomy and allows placement of biliary stent for unobstructed flow of bile by tumor in the head of the pancreas prior to surgery or as palliation in patients not deemed surgical candidates.
5. MRCP—defines anatomy without contrast dye.

6. Abdominal CT scan to assess resectability.
7. PET scan to differentiate cancer from cyst as well as to assess for recurrence or metastatic disease.
8. Biopsy through percutaneous fine needle aspiration or EUS for cytology and to confirm malignancy.

Management

The goal of treatment may be cure or palliation, depending on the staging of the tumor. Despite advances in treatment, the 5-year survival rate is 5% in nonoperative cases and 20% to 30% in those who undergo surgery.

Surgery

Surgical resection is the only potentially curative treatment. Unfortunately, because of the late presentation of the disease, only 15% to 20% of patients are candidates for pancreatectomy.

1. Whipple procedure (pancreaticoduodenectomy) is the removal of the head of the pancreas and distal portion of the common bile duct including the gallbladder, duodenum, and the distal stomach with anastomosis of the remaining pancreas, stomach, and common bile duct to the jejunum (see Figure 19-6). If the gallbladder is present, it is also removed. Modifications of the conventional pancreaticoduodenectomy procedure have been developed in an attempt to improve outcomes or minimize the morbidity associated with the operation.
    a. Stomach and pylorus may be preserved—pylorus-preserving pancreaticoduodenectomy This procedure may decrease the incidence of postoperative dumping, marginal ulceration, and bile reflux gastritis.
    b. Subtotal stomach-preserving pancreaticoduodenectomy—preserve as much stomach as possible while minimizing problems related to delayed gastric emptying.
2. Total pancreatectomy, including a splenectomy, may be performed for diffuse tumor throughout the pancreas.
3. Distal pancreatectomy is the removal of the distal pancreas and spleen for tumors localized in the body and tail.
4. Palliative bypass for nonresectable tumors: choledochojejunostomy or cholecystojejunostomy for obstructive jaundice or gastrojejunostomy for gastric outlet obstruction.

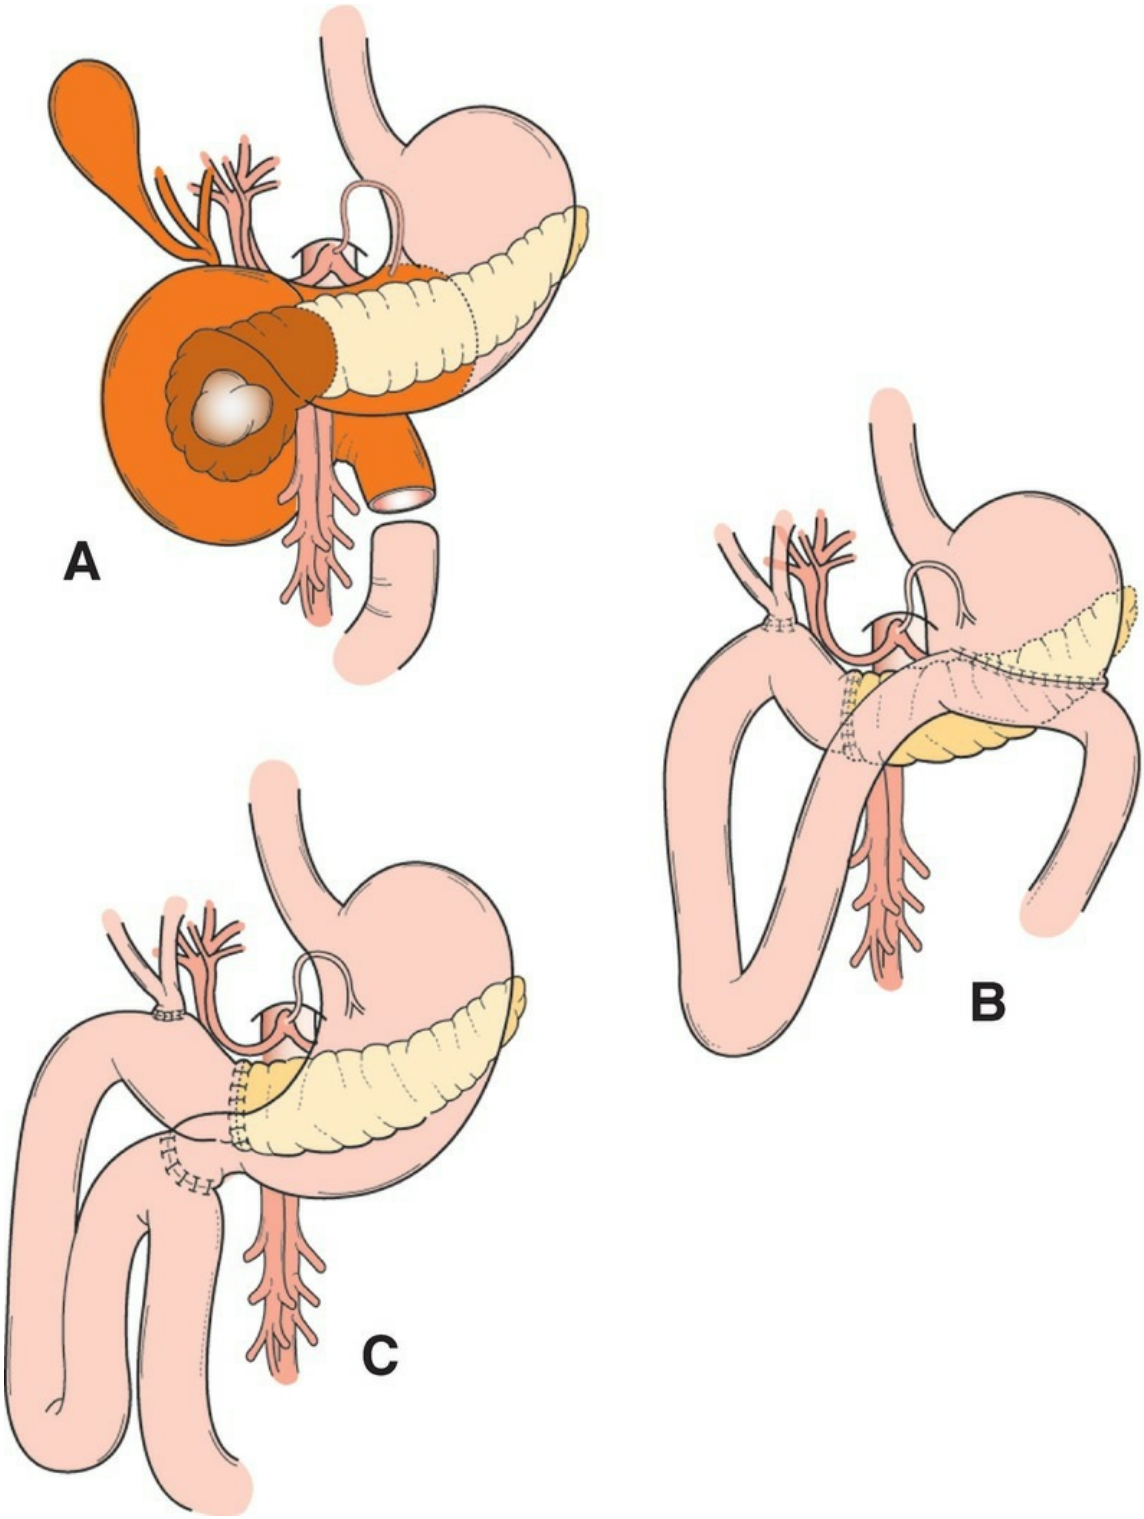

Figure 19-6. Pancreaticoduodenectomy. **(A)** The standard pancreaticoduodenectomy (Whipple procedure) involves a wide area of resection around the tumor, including the gallbladder, distal stomach including the pyloric region, duodenum, and head of the pancreas, as indicated. **(B)** Anastomoses of the common bile duct, fundus of the stomach, and body and tail of the pancreas to the jejunum. **(C)** Pylorus-preserving variant involves conservation of the stomach, including the pyloric valve anastomosed to the jejunum.

Other Measures

1. Chemotherapy alone or in combination with radiation therapy may be given before surgery to shrink tumors that involve major blood vessels.
2. Chemotherapy combined with radiation therapy may be given for resectable tumors after surgery for microscopic or undetectable disease left behind.
3. Chemotherapy and radiation therapy may be given for tumors deemed unresectable at the time of surgery and after palliative bowel bypass surgery.
4. Chemotherapy may be given alone for treatment of unresectable or metastatic disease.
5. Radiation therapy may be used alone.
    a. External beam irradiation for local control, to reduce pain, and to palliate obstruction.
    b. Intraoperative radiation therapy given after the pancreas resection has also been used in some centers.
6. Endoscopic or percutaneous stent placement for relief of biliary or duodenal obstruction.
7. Chemical splanchnicectomy, injection of alcohol into the celiac plexus, numbs the nerves in the area of the pancreas to provide temporary pain relief.
    a. May be performed intraoperatively by the surgeon or percutaneously under CT guidance as an outpatient procedure by an anesthesia pain service.
8. Immunotherapies under investigation that show promising results include immune modulators, therapeutic vaccines, monoclonal antibodies, oncolytic viruses, adjuvant immunotherapies, and cytokines.

EVIDENCE BASE National Cancer Institute Physician Data Query (PDQ), American Cancer Society Facts & Figures 2016, National Comprehensive Cancer Network (NCCN) Guidelines for Patients, *ClinicalTrials.gov*, CRI grantee progress reports.

TRANSITIONAL CARE ALERT With the high mortality rate associated with pancreatic cancer, it is suggested to involve the palliative care specialists early in the course of treatment. Palliative care includes pain and symptom management as well as goals of care discussion regarding end of life care and hospice when appropriate. Earlier involvement has been shown to improve patients' symptom management, prevent unnecessary admissions to the hospital, and provide support to the patient and family.

Complications

1. Biliary, gastric, and duodenal obstruction.
2. Metastasis and liver failure/ ascites secondary to metastasis.
3. Portal hypertension and pain because of encasement of major blood vessels and celiac nerve plexus in the area of the pancreas.

4. Venous thromboembolism: incidence of VTE is four- to sevenfold higher in pancreatic cancer as in other common adenocarcinomas.
5. Malnutrition, weight loss, anorexia, and cachexia.

Nursing Assessment

1. Obtain history for risk factors, pain, and symptoms of pancreatic dysfunction.
2. Assess nutritional status, including diet history, anorexia, weight loss, nausea and vomiting, steatorrhea, skin turgor.
3. Evaluate laboratory results for alterations in glucose, pancreatic enzymes, liver function, and coagulation studies.
4. Assess psychosocial status to determine depression, usual coping strategies, support systems, and experience with past serious illness.
5. Assess use of alternative therapies or over-the-counter medications.

DRUG ALERT The efficacy of herbal medications to treat or cure pancreatic cancer has not been proven. Little is known about the interaction of herbal medications with conventional medications or treatments. Herbal medications may interact with chemotherapy drugs and compromise treatment. If a patient is using alternative treatments or herbal medications, this must be known to all health care providers.

Nursing Diagnoses

- Acute Pain related to pancreatic tumor or surgical incision.
- Imbalanced Nutrition: Less Than Body Requirements related to disease process and surgical intervention.
- Deficient Fluid Volume related to hypoproteinemia, surgical alterations.
- Impaired Tissue Integrity related to malnutrition, surgical incisions, and altered pancreatic or bile drainage.

Nursing Interventions

For surgical care, see “Care of the Patient Undergoing Gastrointestinal Surgery” (page 495).

Controlling Pain

1. Administer opioids, as ordered, or monitor PCA.
2. Teach relaxation techniques, such as relaxation breathing, progressive muscle relaxation, and imagery, as adjuncts for pain relief.
3. Assist with frequent turning and comfortable positioning.
4. Administer adjuvant medications, such as antidepressants and anxiolytics, as prescribed.
5. Assess the patient’s response to pain and symptom-control measures.

6. Consider palliative care or hospice services for symptom management if the patient no longer benefits from therapy.

Improving Nutritional Status

1. Administer parenteral nutrition, as prescribed, preoperatively and postoperatively, if indicated.
2. Monitor serum glucose level for hyperglycemia or hypoglycemia.
3. Progress diet slowly when oral intake is tolerated; observe for nausea, vomiting, and gastric distention.
4. Administer high-protein, high-carbohydrate diet with vitamin supplements and pancreatic enzymes, as prescribed.
5. Encourage use of spices to stimulate taste buds, provide cool foods to decrease odor, use plastic utensils if the patient complains of metallic taste from treatments, and offer small, frequent meals.
6. Provide appetite stimulant, such as megestrol, as needed.
7. Monitor serum albumin.
8. Weekly weights.
9. Assess for fat and protein malabsorption: stools that float, have greasy appearance, are orange in color, and are foul smelling.

Attaining Adequate Fluid Volume

1. Monitor vital signs and record accurate intake and output.
2. Monitor wound drain output.
3. Evaluate laboratory values for hypoalbuminemia, hyponatremia, hypochloremia, and metabolic alkalosis; replace electrolytes, as prescribed.
4. Administer fluid replacement, as indicated.
5. Report change in vital signs or increased pain: may indicate hemorrhage, leak from anastomosis, or tumor progression.

Maintaining Tissue Integrity

1. Observe skin for jaundice, breakdown, irritation, or excoriation.
2. Administer antipruritic medication, provide frequent skin care with mild soap and with thorough rinsing, apply emollient lotions, trim fingernails short to prevent scratching.
3. Inspect skin around drains for irritation and protect skin from leakage of fluids from drains or tubes.
4. Inspect surgical dressings and incision for bleeding, drainage, or signs of infection.
5. Prevent tension on anastomoses by monitoring for abdominal distention and maintaining patency of surgically placed tubes and drains.
6. Maintain aseptic technique in handling wound dressings and drainage of all secretions.

Community and Home Care Considerations

1. Educate the patient and family about course of disease and support them through the process.

2. Provide assistive devices and direct care to help with energy conservation. Patients who die of pancreatic cancer may have progressive weight loss from anorexia leading to severe cachexia, fatigue, and muscle wasting, which is refractory to any intervention.
3. Assess for bowel obstruction, which may also deplete energy and lower nutritional status. Notify health care provider of reduced bowel activity, increased pain, or abdominal distention.
4. Emphasize to the patient and family that pain can always be managed and patients need not die in pain. The plan for pain management should be aggressive and should provide the patient an optimal quality of life.
5. Encourage the family to take advantage of palliative care or hospice services.

Patient Education and Health Maintenance

1. Instruct the patient and family on self-care measures for pancreatic insufficiency.
    a. Glucose monitoring, insulin administration, signs and symptoms of hypoglycemia and hyperglycemia.
    b. Pancreatic enzyme replacement; high-protein, high-carbohydrate diet.
2. Teach wound and drain care, as needed.
3. Explore options for pain management.
4. Coordinate referral for home care for any wound or drain care, new diabetic management, new medications, change in diet, or referral for palliative care or hospice services.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Weight stable.
- Vital signs stable; urine output adequate.
- Incision intact without drainage or bleeding.

General Procedures and Treatment Modalities

Enteral Feeding

Parenteral Nutrition

Nutritional Disorders

Obesity

Eating Disorders

Malabsorption Syndrome

Vitamin and Mineral Deficiencies

OVERVIEW AND ASSESSMENT

See additional online content: Procedure Guidelines 20-1–20-3

PROCEDURE GUIDELINES 20-1

Administration of Enteral (Tube) Feedings: Intermittent or Continuous

EQUIPMENT

- Tube feeding formula
- Graduated containers
- 60-mL catheter-tipped syringe
- Water
- Stethoscope
- Gavage feeding bag (optional)
- Gloves
- For continuous tube feeding:
- Tube feeding bag and tubing and feeding pump

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Remove formula from refrigerator and allow to warm to room temperature. Check expiration date.	1. Room temperature formula is less likely to cause intolerance; use prepared dietary formulas within 24 hours.
2. Explain procedure to patient.	2. Promotes patient trust and allays patient anxiety.
3. Wash hands. Don gloves.	3. Prevents bacterial contamination of formula.
4. Protect patient from spillage.	4. Protects exposed areas of skin and/or clothing from damage with formula.
5. Shake formula container.	5. Shaking eliminates separation of formula.
6. Elevate head of bed 30 to 45 degrees.	6. Prevents aspiration.
7. Using the catheter-tipped syringe, inject 30 cc of air while listening with a stethoscope positioned at the epigastric area (for nasogastric [NG] tubes). For nasointestinal tubes, 20 mL of air may be injected, but auscultation site may be displaced laterally and inferiorly.	7. Auscultation of a "whooshing" or bubbling sound assists in confirmation of proper tube placement. Should patient burp immediately after injection of air, suspect esophageal placement of tube.
8. If NG tube is used, aspirate stomach contents to check gastric residual. Also observe the position of the tube in the nose or mouth to ensure proper placement.	8. If residual gastric contents exceed 200 mL for intermittent tube feedings, hold feeding and notify health care provider. Residual should not be obtained with intestinal placement.
9. If residual is within normal limits and stomach or intestinal placement has been confirmed, return gastric contents to stomach through syringe using gravity to assist flow. If residual is >200 mL, replace 200 mL and discard the rest. Flush tube with 30 mL of water. If there is a question about the tube placement, notify the health care provider and obtain an order for an x-ray.	9. Returning gastric contents to stomach prevents acidbase and electrolyte imbalance.
Performance phase	
1. For intermittent or bolus tube feeding, attach barrel of catheter-tipped syringe to pinched-off feeding tube.	1. Pinching off the feeding tube prevents air from entering the stomach and causing distention.
2. Fill catheter-tipped syringe with formula and allow fluid to flow in by gravity.	2. The rate of flow is regulated by raising or lowering the syringe.
3. Pour additional formula into barrel of syringe when it is three-quarters empty.	3. Prevents air from entering stomach.
4. After administering the prescribed amount of formula, flush tubing with at least 30 cc of water.	4. Prevents clogging of feeding tube.
5. If using a gavage bag for intermittent feeding, fill bag with prescribed amount of feeding, purge feeding bag tubing of air, attach distal end to feeding tube, and regulate to run over at least 10–20 minutes.	5. Prevents distention from air in stomach or too rapid administration.
6. For continuous tube feeding, fill bag with 4 hours of tube feeding (or prepare ready-to-hang container), flush tubing, attach to volume control infuser according to manufacturer's instructions, attach distal end to feeding tube, and start. Flush with 30–60 ml of water every 4 hours after first checking residual.	6. Prevents bacterial contamination. Maintains tube patency.
7. After intermittent feeding is completed, cover end of feeding tube with plug or clamp.	7. Prevents leakage.

Nursing Action	Rationale
Follow-up phase	
1. Rinse equipment with warm water, and dry. Replace every 24 hours or per facility policy.	1. Limits bacterial contamination.
2. Maintain head of bed elevation for 30–60 minutes after feeding is completed. If continuous feeding, maintain head elevation continuously.	2. Prevents aspiration.
3. Document type and amount of feeding, amount of water given, and patient tolerance of procedure.	3. Ensures continuity of care. Sensation of fullness, nausea, or vomiting may indicate intolerance.
4. Monitor breath sounds, bowel sounds, gastric distention, diarrhea or constipation, intake and output, daily weight, and serum chemistry results.	4. Evaluates for aspiration, effect on GI system, and therapeutic effect of feedings.

GASTROSTOMY OR JEJUNOSTOMY CARE

Nursing Action	Rationale
Performance phase	
1. Special care of ostomy tube insertion site should include:	
a. Cleaning around tube with prescribed cleansing solution every shift and as needed.	a. Prevent peristomal infection.
b. Applying sterile 4″ × 4″ gauze pad and taping in place.	b. Collects any drainage.
c. Applying skin barrier should peristomal skin become excoriated.	c. Prevent breakdown of peristomal tissue.
d. Taping of tube to skin or skin barrier with hypoallergenic tape.	d. Anchor and secure tube.

PROCEDURE GUIDELINES 20-2

Administration of Parenteral Nutrition

EQUIPMENT

- Volume control infuser
- Bag of parenteral nutrition (PN)
- Bag of IV lipids (if not using 3-in-1 nutrient admixture [NA])
- Administration tubing with Luer-lock connections
- 1.2 um filter for solutions containing albumin or lipids, 0.22 um filter for solutions without lipids
- Hypoallergenic tape, 1 inch
- Clean gloves
- Sterile dressing kit to include:
- Alcohol swab sticks (3)
- Povidone-iodine sticks (3)
- Sterile gloves
- Transparent dressing

PROCEDURE

Nursing Action	Rationale
To change bag and bottle:	
Preparatory phase	
1. Remove NA from refrigerator at least 1 hour before hanging. Check date and patient's name.	1. Decreases incidence of hypothermia, pain, and venospasm.
2. Inspect fluid for cracking or creaming. Verify that PN/ NA matches current orders.	2. Indicates fluid separation, do not use. If infusing PN, solution should be clear without clouding.
3. Wash hands.	3. Prevents bacterial contamination.
Performance phase	
1. Using strict sterile technique, attach I.V. tubing (with filter) to NA bag and purge of air.	1. Prevents air embolus. *Note:* Tubing should be changed on a regular basis (every 2–3 days). Filter will be different for PN because lipids are not included.
2. Close all clamps on new tubing. Insert tubing into volume control infuser.	2. Prevents free flow of PN fluid.
3. If venous access device (VAD) has a clamp at proximal end, clamp tubing.	3. Prevents air embolus if VAD is inserted in a central vein.
4. If no clamp is available on central VAD, instruct patient to perform Valsalva's maneuver (bear down and hold breath) while new tubing is connected.	4. Valsalva maneuver creates positive pressure, preventing air from being sucked into tubing.
5. Sterilely connect tubing to hub of VAD, making sure the connection is securely fastened using Luer-lock connections.	5. Prevents disconnection of tubing.
6. Open all clamps and regulate flow through volume control infuser.	6. Ensures appropriate administration rate.
Follow-up phase	
1. Monitor administration hourly, assess integrity of fluid and administration system and patient tolerance and complications.	1. See Table 20-3, page 753, for complications of PN.
2. Document tubing change and rate of fluid administration, presence of complications, and any treatment given.	2. For continuity of care.
Patient education	
1. Teach patient signs and symptoms of complications, including sepsis, phlebitis, extravasation, and to report changes to nursing personnel.	1. Patient can assist nursing personnel in monitoring therapy and in detecting complications.
2. If patient is to be discharged to home with NA, begin instruction regarding proper storage, handling, and administration of NA. Include family members as appropriate.	2. Long-term therapy may be indicated in burns, emaciation due to cancer treatment, and other conditions. Home care nurses will reinforce your teaching.

Nursing Action	Rationale
To change central venous catheter dressing:	
Preparatory phase	
1. Obtain equipment.	1. Have all equipment readily available.
2. Explain procedure to patient.	2. Allays anxiety and enlist cooperation.
3. Place patient in a comfortable supine position and turn head away from site.	3. Turning patient's head away from site will decrease possible microbial contamination of site.
4. Wash hands.	4. All precautions are taken to prevent contamination.
5. Put on mask (optional).	5. Helps prevent possible microbial contamination of site.
Performance phase	
1. Put on clean gloves and carefully remove old dressing.	1. Protects nurse from contamination.
2. Inspect insertion site for complications.	2. Observe for edema, erythema, tenderness, and leakage of fluid.
3. Clean insertion site with each alcohol swab beginning at insertion site and moving outward in a circular pattern.	3. Moves potential contaminants away from insertion site.
4. Repeat using each povidone-iodine swab.	4. Removes bacteria from insertion site.
5. Allow to dry.	5. Allows adhesive dressing to adhere securely.
6. Remove adhesive backing of transparent dressing. Center dressing over site.	6. Application of transparent dressing provides a bacterial barrier while allowing full visualization of insertion site.
7. Loop and tape tubing to skin using hypoallergenic tape. Do not tape over dressing.	7. Prevents dislodgment of tubing.
Follow-up phase	
1. Document dressing change and observation of insertion site.	1. For continuity of care.
2. Observe insertion site frequently for signs of complications.	2. Observe for edema, erythema, tenderness, and leakage of fluid.
Patient education	
1. Teach patient signs and symptoms of infection, phlebitis, and fluid extravasation and to report changes to nursing personnel.	1. Patient may be first to notice complications.
2. If patient is to be discharged to home with NA, begin instruction regarding sterile dressing change. Include family members as appropriate.	2. Because risk of sepsis is so great, sterile technique is still required for home dressing changes.

PROCEDURE GUIDELINE 20-3

Skin and Mucous Membrane Care

EQUIPMENT

- Water-soluble lubricant
- Toothbrush and toothpaste
- Cotton-tip applicators
- Nonalcohol-based mouthwash

GAUZE DRESSING AND TAPE

Nursing Action	Rationale
Performance phase—mouth care	
1. Assess mouth for redness, dryness, or fissures every shift. Report irritated tissues.	1. To monitor status of mucous membranes for any irritation.
2. Lubricate lips with water-soluble lubricant.	2. To prevent cracking and dryness of mucous membranes.
3. Brush patient's teeth, tongue, and gums at least two times daily with toothbrush and toothpaste.	3. Oral hygiene.
4. If patient is able, rinse mouth with nonalcohol-based mouthwash, or clean mouth with mouth swab every 2 to 4 hr.	4. Oral hygiene.
Performance phase—nasal tubes	
1. Assess nose for redness, dryness, or fissures every shift. Report irritated tissues.	1. To monitor status of skin.
2. Use a cotton swab moistened with warm water to clean the outside edges of the nares.	2. To cleanse nares and prevent infection.
3. Lubricate nares with water-soluble lubricant.	3. To prevent skin breakdown
4. Wash skin with soap and warm water, making sure you do not move the tube, rinse well and pat dry.	4. To cleanse skin.
5. Replace tape.	5. To prevent dislodgement of nasal tube
Performance phase—stoma site care (gastrostomy or jejunostomy)	
1. Inspect the surrounding skin for redness, tenderness, swelling, irritation, purulent drainage, or gastric leakage; immediately report skin irritation or infection and provide treatment.	1. To monitor status of peristomal skin.
2. Clean skin with soap and water or antiseptic of choice—begin next to stoma site, using a spiral pattern and moving outward; clean under skin disk with cotton swab.	2. To cleanse skin and prevent infection.
3. Dry thoroughly; leave area open to air; use a dressing only if ordered; change dressing frequently and clean skin; determine and correct cause of leakage.	3. To prevent infection.
4. For G-tube only, no sutures in place, gently rotate the tube 360 degrees by rolling between thumb and index finger and ensure a slight in and out play of the tube.	4. To prevent scar tissue from forming.
5. Document a. Date/time of care b. Condition of stoma site/surrounding skin c. Location of skin disk on tube, indicated by centimeter marking d. Feeding tube French size e. Patient tolerance of procedure	5. To document care, condition and any procedure(s) performed.

EVIDENCE BASE Cambell, S. M. (2015). *Best Practices for Managing Tube Feeding. A Nurse's Pocket Manual.* Abbott Nutrition.

Nutrition Overview

Knowledge of nutrients and the basic principles of nutrition is important in the role of patient teaching for disease prevention and health promotion. The principles also help to provide an understanding and background to diseases affected by a person's nutritional status. The basic food groups and their placement on a plate help to serve as a guide to basic, healthy nutrition.

Key Principles

1. Nutrients, including carbohydrates, fats, proteins, vitamins, and minerals, have specific functions within the body. They work together to provide energy, regulate metabolic processes, and synthesize tissues.
2. Nutrition influences all body systems favorably and unfavorably. Examples of unfavorable effects include the link between cholesterol and heart disease or salt intake and high blood pressure (BP). Favorable effects are many, such as the association of fiber intake with improved GI function and the role of folic acid in preventing neural tube defects.
3. Nutritional needs vary in response to metabolic changes, age, sex, growth periods, stress (trauma, disease, pregnancy, lactation), and physical condition.
4. Nutritional supplements may be needed depending on disease states, dietary intake, and other factors.
5. The types of foods eaten and eating patterns are developed during a lifetime and are determined by psychosocial, cultural, religious, and economic influences.
6. The nurse works with the registered dietitian to promote optimum nutrition for each patient.

MyPlate and the Dietary Guidelines for Americans

1. Dietary guidelines were first developed in 1958 and were based on four basic food groups: grains, vegetables and fruits, meat, and milk. In 2010, the Department of Health and Human Services and U.S. Department of Agriculture (USDA) Dietary Guidelines for Americans were restructured and divided the four basic food groups into five food groups, which now consist of grains, fruits, vegetables, protein, and dairy. Although the guidelines have been reformatted, it still holds true that a well-balanced diet consists of foods from each of these groups and is composed of foods low in fat, cholesterol, and sodium and high in fiber (*www.dietaryguidelines.gov*). See Chapter 3, page 23, for more specific information about the guidelines.
2. In response to growing scientific knowledge regarding the linkage of diet and disease, the USDA developed the MyPlate Plan (see Figure 20-1). It reflects making food choices for a healthy lifestyle and includes basic information on how to build a healthy plate by cutting back on foods high in solid fats, added sugars, and salt; eating the right amount of calories; and being physically active. Additionally, the 2015–2020 *Dietary Guidelines* have added five overarching Guidelines to encourage healthy eating patterns such that individuals can enjoy foods that meet their personal, cultural, and traditional preferences and fit within their budget:
    a. Follow a healthy eating pattern across the life span.
    b. Focus on variety, nutrient density, and amount.

c. Limit calories from added sugars and saturated fats and reduce sodium intake.

d. Shift to healthier food and beverage choices.

e. Support healthy eating patterns for all.

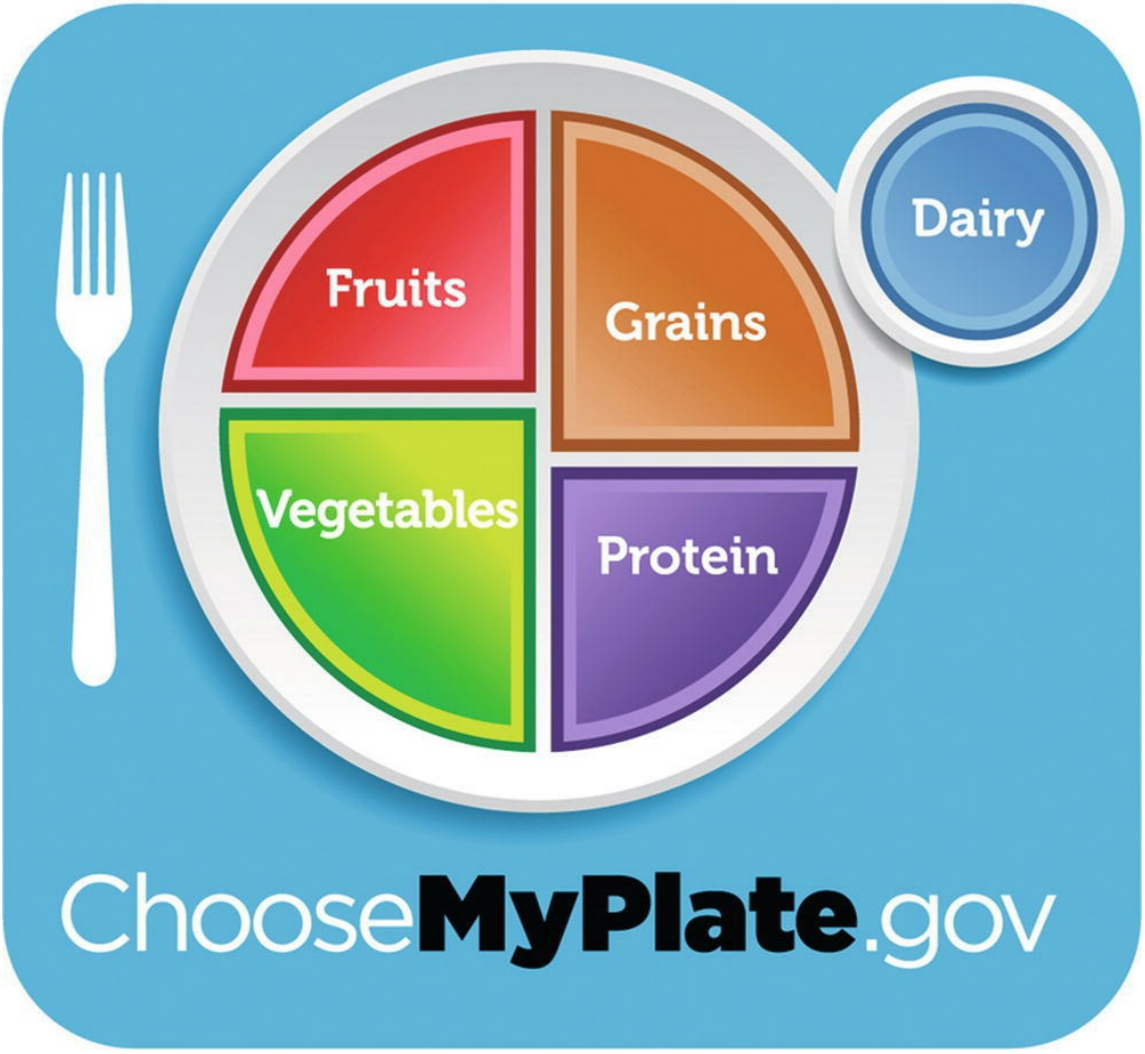

Figure 20-1. MyPlate illustrates healthy eating. (U.S. Department of Agriculture.)

Nutritional Assessment

Nutrition assessment is an ongoing process designed to identify a person's nutritional status and the significance on the person's well-being. Although there are many methods and tools for assessing nutritional status, there is no universal method or "gold standard." Weight loss is perhaps the most validated parameter of nutritional status. However, multiple factors must be evaluated and considered to determine risk for or degree of malnutrition. One such factor is determining nutritional intake.

There are many methods to assess the nutritional status including the type and amount of food consumed. Techniques to capture nutritional intake may include a 24-hour recall of foods eaten, a food diary kept by the patient for several days, or a food frequency questionnaire that reflects food-intake patterns. In addition to these specific tools, the following information is useful to determine nutritional patterns and status.

Key History Points

1. General background information—name, age, sex, family composition, socioeconomic status, occupation.
2. General health status and any chronic conditions, including diabetes and associated dietary restrictions as well as any hospitalizations.
3. Cultural and religious factors influencing dietary patterns.
4. Family history of diseases, including diabetes and obesity.
5. Current medications, over-the-counter products, and herbal supplements.
6. Food habits.
    a. Typical daily intake, including meal frequency, meal timing, and meal location.
    b. Snacking patterns.
    c. Food intolerance or dislikes.
    d. Nutritional supplements, including vitamins, minerals, fortified beverages, and foods.
    e. Alcohol consumption.
    f. Use of specific diets or dietary restrictions.
7. Food purchase and preparation.
    a. Who purchases and prepares food and where food is purchased.
    b. Facilities for food storage and preparation.
    c. Factors influencing the types of food purchased.
8. Nutritionally related problems.
    a. General well-being, energy level.
    b. Changes in appetite.
    c. Weight change during the past 6 months.
    d. Difficulty chewing or swallowing, use of dentures.
    e. Change in sense of taste or smell.

f. Eructation, flatulence, nausea, vomiting, diarrhea, constipation, or abdominal pain or swelling in relation to food intake.

g. Bowel habits.

Physical Examination and Anthropometrics

1. Perform a systematic physical examination, observing for a wide variety of physical findings associated with nutritional status.
   a. Listlessness, apathy.
   b. Cognitive and sensory deficits.
   c. Poor muscle tone or wasting of muscle.
   d. Dull, brittle hair; hair may be thin or sparse, easily plucked.
   e. Rough, dry, and scaly skin or dermatitis.
   f. Ecchymosis.
   g. Premature whitening of hair.
   h. Cheilosis (fissures at angles of mouth).
   i. Stomatitis (inflammation of mouth).
   j. Inflammation and easy bleeding of gums.
   k. Glossitis (inflammation of tongue).
   l. Dental caries and poor dentition.
   m. Spoon-shaped, brittle, ridged nails.
   n. Skeletal deformities such as bowlegs.
2. Perform anthropometry, as indicated. (Anthropometry comes from the word *anthropology* and is the science that studies the size, weight, and proportions of the human body to determine body fat mass, lean mass, and nutritional status.) Types of anthropometric measurements include height and weight, skin-fold thickness, and circumferential tests.
3. Height and weight are determined on patient admission and are later used as a baseline for comparisons in nutritional status.
   a. Height should be measured with a stadiometer.
   b. Weight should be measured using a consistent and reliable scale and at a consistent time, standing with shoes and overgarments removed.
   c. Unintended weight loss of more than 10% of body weight during 6 months is considered clinically significant and may be associated with physiologic abnormalities and increased morbidity and mortality.
4. Body mass index (BMI) is weight in kilograms divided by height in meters squared (see Table 20-1).
   a. BMI of less than 18.5 is classified as underweight.
   b. BMI of 18.5 to 24.9 is classified as normal weight.
   c. BMI of 25 to 29.9 is classified as overweight.

d. BMI of 30 to 39.9 is classified as obese.

e. BMI greater than 40 is classified as extremely obese.

5. Metabolism is generally faster in younger people, and for this reason, babies and children have higher energy requirement needs than do adults. Requirement needs are based on many factors including age, gender, activity level, and disease state. Exact measurements of caloric requirements for infants can be obtained by using charts; these estimate the body surface area by height and weight and the standard basal metabolic rate for a given weight (see Appendix B, page 1502).

6. Skin-fold thickness provides an estimate of body fat based on the amount of fat in subcutaneous tissue using calibrated calipers to measure the thickness of the skin at designated sites (see Figure 20-2).

   a. Grasp skin and subcutaneous fat, pulling it away from the underlying muscle, and place the caliper jaws over the skin-fold flap.

   b. Take the reading within 2 to 3 seconds and without using excessive pressure.

   c. Repeat the reading twice and take an average of the three readings to increase accuracy.

7. Skin-fold sites include the following:

   a. Vertical measurements:

      i. Triceps: On the posterior midline of the upper arm, midpoint between the acromion and olecranon processes.

      ii. Abdomen: Two cm to the right of the umbilicus.

      iii. Thigh: On the anterior midline of the thigh, midway between the proximal border of the patella the inguinal crease (hip).

   b. Diagonal measurements:

      i. Subscapular: Just below the inferior border of the left scapula.

      ii. Chest/Pectoral: One half the distance between the anterior axillary line and the nipple (in men); or one third the distance between the anterior axillary line and the nipple (in women).

      iii. Suprailiac: In line with the natural angle of the iliac crest taken in the anterior axillary line immediately superior to the iliac crest.

8. Circumferential tests provide information on the amount of skeletal muscle and adipose tissue. Mid-upper arm circumference (MAC)—an indirect estimate of the body's muscle mass:

   a. Place a tape measure around the midpoint of the nondominant upper arm and secure it snugly.

   b. To calculate, multiply the triceps skin fold by 3.14 and subtract the product from the MAC.

   c. Adult standards are 16.5 mm for women and 12.5 mm for men.

9. Advanced body composition analysis is a set of advanced techniques that provide various measurements including total body fat, muscle mass percentages, bone weight, and visceral adipose tissue (VAT) score among other measurements of body composition. Methods may include the following:

   a. Dual-energy X-ray absorptiometry (DEXA).

   b. Underwater (hydrostatic) weighing.

   c. Air displacement plethysmography (ADP).

d. Bioelectrical impedance analysis (BIA).

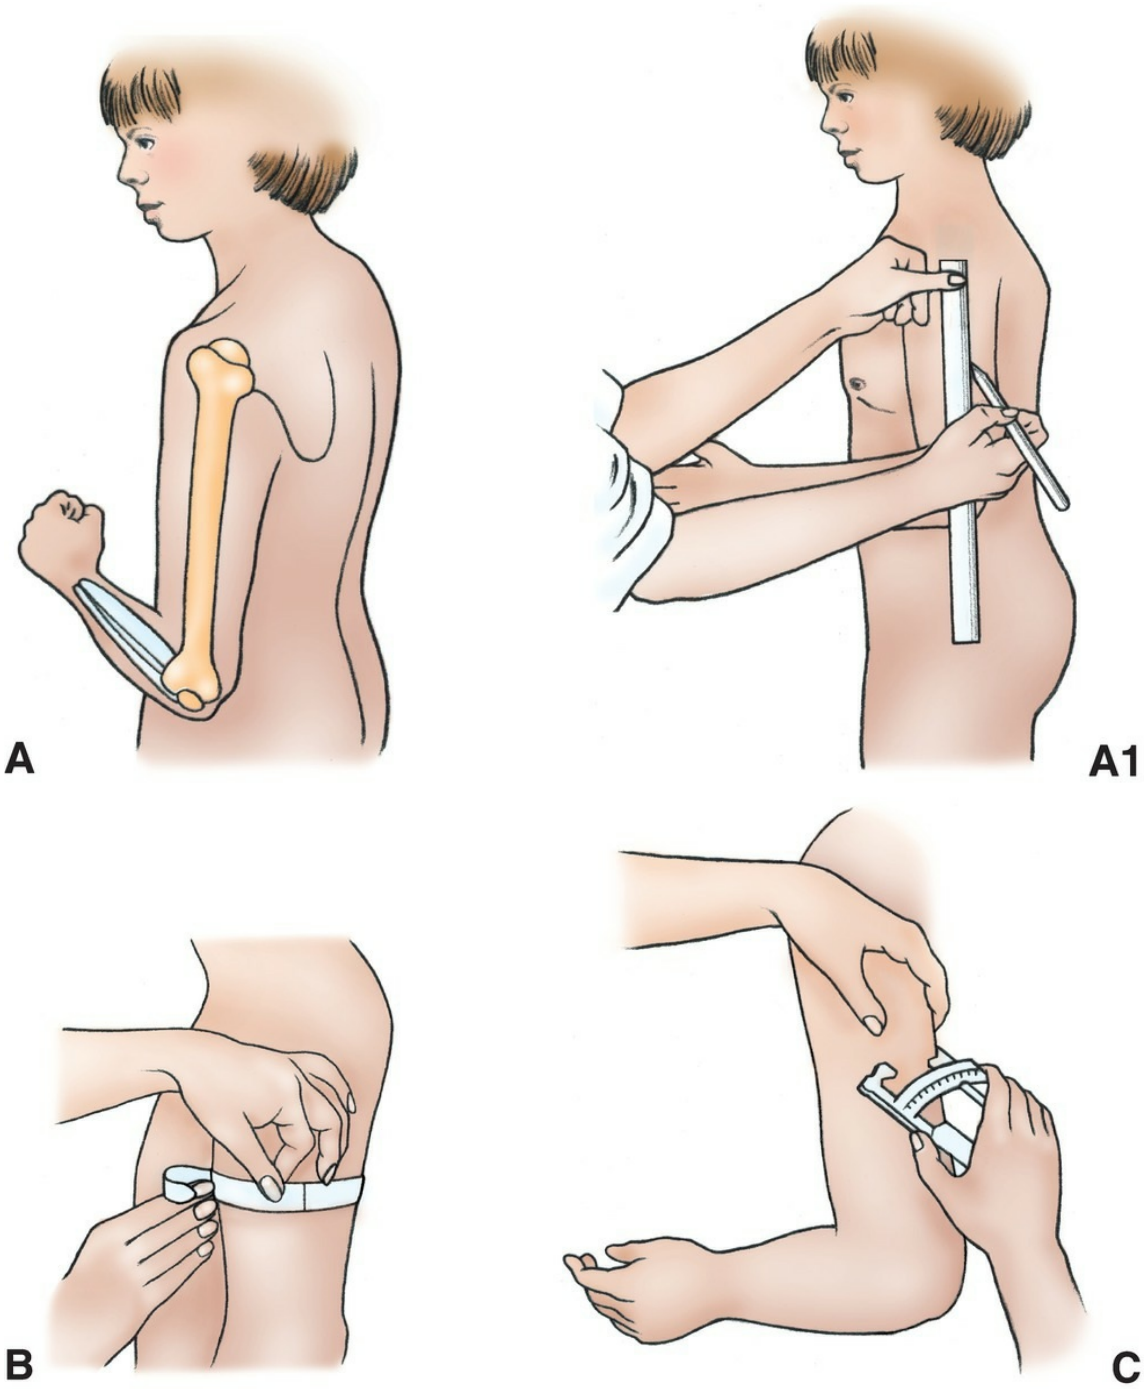

Figure 20-2. Anthropometric measurements. **(A and A1)** Marking the midpoint of the upper arm. **(B)** Obtaining the mid–upper arm circumference. **(C)** Measuring triceps skin-fold thickness.

Table 20-1 Body Mass Index (BMI)*

WEIGHT	5′	5′3″	5′6″	5′9″	6′	6′3″
140	27	25	23	21	19	18
150	29	27	24	22	20	19
160	31	28	26	24	22	20
170	33	30	28	25	23	21
180	35	32	29	27	25	23
190	37	34	31	28	26	24
200	39	36	32	30	27	25
210	41	37	34	31	29	26
220	43	39	36	33	30	28
230	45	41	37	34	31	29
240	47	43	39	36	33	30
250	49	44	40	37	34	31

**Body mass index = weight (kg)/height (m^2).*

Laboratory Tests

1. Serum albumin, prealbumin.
    a. Albumin is a protein made by the liver and is responsible for maintaining blood volume and serum electrolyte balance. The half-life of albumin is about 21 days. A decrease in nutritional status may result in a drop in albumin synthesis. However, in chronic malnutrition, serum albumin levels are typically normal or high.
    b. Prealbumin is also made by the liver and is a more sensitive but expensive test that measures more recent nutritional status. Its half-life is 2 to 3 days.
2. Hemoglobin—made by the liver; decreased amounts are related to iron deficiency anemia or other defect in hemoglobin synthesis or dilution of the blood such as during pregnancy.
3. Serum transferrin—another transport protein made by the liver; responsible for binding iron to plasma and transporting it to the bone marrow. Reduced levels are found in catabolic states and some chronic diseases.
4. Twenty-four-hour urine creatinine—an increase in this measure indicates increased tissue breakdown.
5. Twenty-four-hour urine urea nitrogen or total urinary nitrogen—this test can be used to determine nitrogen balance.

NURSING ALERT Serum albumin, prealbumin, and transferrin levels measure visceral proteins that inversely correlate with metabolic stress, such as inadequate nutrition, but do not directly measure nutritional status.

General Procedures and Treatment Modalities

The inability to take nutrients through the oral route either totally or in part may require alternative means to enhance and maintain nutritional status. Alternative methods of nutritional support include enteral feeding and parental nutrition. The decision as to which method is used will depend on many factors including the patient's acuity and nutritional status.

Enteral Feeding

Administration of nutrients directly into the stomach, duodenum, or jejunum through a tube is more physiologically beneficial and cost-effective than is parenteral feeding. Enteral feeding carries less risk of infection than does parenteral feeding and maintains a functional GI tract by preventing mucosal atrophy and biliary and hepatic dysfunction. Enteral therapy is appropriate for patients with at least a minimally functional GI tract who cannot take adequate nutrition by mouth.

Enteral therapy has become utilized more frequently as more commercially available enteral formulas have been developed and long-term enteral feeding tubes have become safer and more easily inserted.

Clinical Indications

1. Increased metabolic needs and inability to take adequate oral diet—trauma, burns, cancer, sepsis.
2. Coma or mechanical ventilation.
3. Head/neck surgery.
4. Malabsorption.
5. Obstruction of esophagus or oropharynx.
6. Severe anorexia nervosa.
7. Dysphagia.

Sites of Tube Insertion

Short-Term Nutritional Support (<30 days)

1. Nasogastric (NG) feeding—tubes are passed through the nose or mouth (orogastric) into the stomach and secured in place.
    a. Tube placement must be verified by x-ray before use. Aspiration of contents for pH or auscultation of air injected through tube has been shown to be of limited value. New techniques that are available include colorimetric carbon dioxide detectors and electronic capnographics, both of which measure end-tidal carbon dioxide to determine if the tube has gone into the trachea.
    b. If there is a question about tube placement in the respiratory tract, the tube should be removed.
2. Nasoenteric feeding (ie, nasoduodenal or nasojejunal)—tube is passed through the nose into duodenum or jejunum and secured in place. X-ray is usually needed to verify correct tube placement.

Long-Term Nutritional Support (>30 days)

1. Gastrostomy—insertion of a tube surgically, radiologically, or by a percutaneous endoscopic procedure into the stomach.
2. Gastrostomy button—small device inserted through gastrostomy stoma to allow for long-term feeding with minimal effect on body image.
3. Jejunostomy—insertion of a tube directly into the jejunum either surgically or by a percutaneous endoscopic procedure. Jejunostomy feedings are generally by continuous infusion using a feeding pump.

Types of Tubes

1. Large-bore NG polyurethane tube—size 12 to 18F, used very short term (eg, Salem Sump).
2. Small-bore NG tube—made of polyurethane, silicone, or polyvinyl chloride with a tungsten-weighted tip or nonweighted tip, size 8 to 12F and 30 to 36 inches (76 to 91.5 cm) long.
3. Nasointestinal tube—made of silicone, polyurethane, or polyvinyl chloride with a tungsten-weighted tip or nonweighted tip, size 8 to 12F and 40 to 60 inches (101.5 to 152.5 cm) long.
4. Gastrostomy tube—catheter made of silicone, polyurethane, polyvinyl chloride, or latex; a balloon on the distal end to stabilize tube may be used and ranges from 5 to 30 mL capacity, size 14 to 28F. Adults usually have 20F tubes, and children usually start with 14F.
5. Gastrostomy button—silicone; ranging from 18 to 28F and 1 inch (2.5 cm) long; useful for person wanting minimal alteration in body image.
6. Jejunostomy tube—size ranging from 5 to 14F with or without a balloon (a balloon may obstruct lumen of jejunum). A plain red rubber catheter is occasionally used as a short-term jejunostomy tube, and some gastrostomy tubes may be used for jejunostomy.

Delivery Systems for Feeding Solution

1. Intermittent or continuous infusion of feeding solution by gravity is accomplished by hanging container of feeding solution from an intravenous (IV) pole and adjusting delivery rate by a flow regulator.
2. Continuous feeding by controller feeding pump allows uniform flow, particularly of viscous solutions.
3. Bolus feeding involves enteral formula poured into barrel of a large (60 mL) syringe attached to a feeding tube and allowed to infuse by gravity.

NURSING ALERT Bolus feeding may precipitate dumping syndrome, particularly if given into the small intestine. Dumping syndrome occurs when hyperosmolar substances enter the intestine quickly, causing an influx of water into the GI tract that can result in nausea, vomiting, bloating, cramping, and diarrhea. Dumping syndrome may also cause dizziness, nervousness, and nausea.

Community and Home Care Considerations

Teach patient and family:

1. Technique for administration of tube feeding (intermittent, continuous, bolus).
2. Signs and symptoms of potential complications.
3. Need to assess tube placement and residual before each feeding (for gastric feedings only).
4. Principles of medical asepsis, including careful hand washing, refrigeration of formula, cleaning of equipment with soap and water, and thorough drying between feedings.
5. When the gastrostomy or jejunostomy tube insertion site is well healed, surrounding skin can be cleaned with soap and water.

6. Gauze dressing can be applied, as needed.
7. Leakage around tube or signs of peristomal skin irritation should be reported.

Complications

See Table 20-2.

Table 20-2 Complications of Enteral Feeding and Treatment

COMPLICATIONS	CAUSES	INTERVENTIONS
Tube displacement	Tube migration into the esophagus	• Observe for eructation of air when injecting air to test for tube placement in the stomach. • Aspirate gastric contents; if none is obtained, suspect esophageal placement.
	Tube placement into the respiratory tract	• Observe for gagging, dyspnea, inability to speak, coughing when tube insertion attempted. • Obtain chest x-ray.* • Withdraw tube and attempt reinsertion with the patient's head flexed forward.*
Tube obstruction	Tube kinking	• Obtain chest x-ray to confirm and withdraw and reinsert new tube.*
	Tube clogging	• Flush tube every 4 hr with 30 mL of water and after administration of intermittent feeding and medication administration. • Administer medications in liquid form if possible. Crush medications finely (if crushable). • Attempt to declog by administering water first. If unsuccessful, then administer pancreatic enzyme/bicarbonate mixture.
Aspiration	Patient lying flat	• Elevate HOB 30 to 45 degrees during continuous feedings or for 30 to 60 min after bolus feeds.
	Absent or depressed gag reflex	• Elevate HOB 30 to 45 degrees during continuous feedings or for 30 to 60 min after bolus feeds.
	Reflux	• Elevate HOB 30 to 45 degrees during continuous feedings or for 30 to 60 min after bolus feeds. • Administer proton pump inhibitor per provider orders.
	Improper tube placement	• Confirm proper placement with x-ray imaging. • Tape tube in place.
Vomiting	Tube migration into the esophagus	• See interventions for tube displacement above.
	Decreased absorption	• Auscultate for decreased bowel sounds, observe for abdominal distention. • Consider decreasing amount of tube feeding.* • Consider administration on a continuous basis.* • Consider placement of a small-bore, weighted-tip nasointestinal tube.*
	Rapid rate of infusion	• Administer no faster than 200 to 300 mL during 10 to 20 min. • Consider administration on a continuous basis.*
	Excessive infusion of air	• If giving a bolus feeding, pinch tubing off when refilling syringe with formula. • If giving continuous feeding, make certain bag does not empty before closing off tubing.
	Patient position	• Maintain the patient at 30- to 45-degree angle of head elevation during and 30 to 60 min after feeding. If administering continuous feeding, maintain head elevation at all times.
	Nausea	• Antiemetics.
	Obstruction	• Assess for distention and decreased bowel sounds; obtain x-ray.
	Constipation	• Assess for impaction and review frequency of bowel movements.
Diarrhea	Drug therapy	• Evaluate drug regimen for possible causes of drug-induced diarrhea from antibiotics, elixirs with high osmolarity, elixirs with sorbitol, magnesium-containing antacids.
	High osmolarity of formula	• Begin administration of formula at slow rate.* • Consider continuous feeding rather than intermittent.*
	Lactose intolerance	• Administer lactose-free formula. (Few commercial formulas contain lactose.)
	Bacterial contamination of formula	• Change administration set daily or per facility protocol. • Maintain strict medical asepsis, including careful hand washing before administration of formula. • Allow formula to hang no longer than 8 hr (unless it is a "ready-to-hang" container that can hang for 24 to 48 hr).
	Rapid infusion rate	• Administer slowly; consider continuous rather than intermittent infusion.*
	Fecal impaction	• Manually clear the impaction.
	Clostridium difficile	• Administer antibiotics.

Constipation	Lack of fiber	• Ensure that the patient is not impacted and administer formula with fiber.*
	Decreased fluid intake	• Increase intake of water.*
	Drug therapy	• Evaluate drug regimen for possible cause, including aluminum-containing antacids or lack of stool softener.
Hyperglycemia	Diabetes, impaired metabolism	• Monitor serum glucose, assess for dehydration caused by hyperosmotic diuresis; observe for symptoms of hyperglycemia, including polyuria, polydipsia. • Administer insulin.* • Observe for hypercapnia (increased respirations, elevated Pco_2).
Hypernatremia	Dehydration	• Assess for signs and symptoms of dehydration (I&O, daily weight, skin turgor, blood urea nitrogen, CVP, tachycardia, hypotension). • Rehydrate with extra water via the feeding tube or, if the patient is severely hypernatremic, use IV route. • Rehydrate with D5W or hypotonic saline solutions.*
Hyponatremia	Overhydration, excessive sodium loss (diaphoresis, nasogastric suction)	• Observe for signs and symptoms of hypervolemia (shortness of breath, rales, I&O, daily weight, peripheral edema, elevated CVP). • Observe for signs and symptoms of hyponatremia (lethargy, headaches, mental status change, nausea, vomiting, abdominal cramping). • Replace sodium, administer diuretics, or, depending on the cause of hypernatremia, restrict fluids.*
Hyperkalemia	Metabolic acidosis/renal insufficiency	• Observe for signs and symptoms of hyperkalemia (dysrhythmias, nausea, diarrhea, muscle weakness). • Treat underlying cause. • Administer exchange resin, glucose, and insulin.* • Choose lower potassium formula.
Hypokalemia	Diarrhea, refeeding syndrome	• See interventions for diarrhea. • If severe, replace potassium.*

**Obtain orders from health care provider.*

CVP, central venous pressure; H_2, histamine; HOB, head of bed; I&O, intake & output.

Parenteral Nutrition

Parenteral nutrition is the introduction of nutrients, including amino acids, lipids, dextrose, vitamins, minerals, and water, through a venous access device (VAD) directly into the intravascular fluid to provide nutrients required for metabolic functioning of the body.

Clinical Indications

1. Patient cannot tolerate enteral nutrition because of:
    a. Paralytic ileus.
    b. Intestinal obstruction.
    c. Acute pancreatitis and enteral feedings not possible.
    d. Severe malabsorption.
    e. Persistent vomiting and jejunal route not possible.
    f. Enterocutaneous fistula and enteric feeding not possible.
    g. Inflammatory bowel disease.
    h. Short-bowel syndrome.
2. Hypermetabolic states for which enteral therapy is either not possible or inadequate, such as burns, trauma, or sepsis.
3. In these situations, additional components are added to the enteral therapy, or individualized solutions are developed to meet the nutritional needs of the patient.

Methods of Parenteral Nutrition

Total Nutrient Admixture

1. Given through a central vein, commonly into the superior vena cava, total nutrient admixture (TNA) is a parenteral formula that combines carbohydrates in the form of a concentrated (20% to 70%) dextrose solution; proteins in the form of amino acids (3% to 15%); lipids in the form of an emulsion (10% to 30%), including triglycerides, egg phospholipids, glycerol, and water; and vitamins and minerals.
2. Central TNA is indicated for patients requiring parenteral feeding for 7 or more days.

Peripheral Parenteral Nutrition

1. Given through a peripheral vein, this parenteral formula combines a less concentrated dextrose solution with amino acids, vitamins, minerals, and lipids.
2. Unlike TNA given centrally, peripheral parenteral nutrition provides fewer calories and, occasionally, a larger percentage of calories is supplied by lipids rather than by carbohydrates.
3. Indicated for patients requiring parenteral nutrition for fewer than 7 days who do not already have enteral access.

Total Parenteral Nutrition

1. Total parenteral nutrition (TPN) combines dextrose, amino acids, vitamins, and minerals and is given through a central IV line.
2. If lipids are needed, they are given intermittently or mixed with the TPN solution through a central IV line.

Fat Emulsion (Lipids)

1. Ten percent, twenty percent, or thirty percent emulsion composed of triglycerides, egg phospholipids, glycerol, and water. It also contains vitamin K.
2. May be given centrally or peripherally.

Complications

See Table 20-3 on page 571.

Table 20-3 Complications of Total Parenteral Nutrition and Treatment

COMPLICATIONS	CAUSES	INTERVENTIONS
Sepsis	• High glucose content of fluid • Venous access device contamination	• Monitor temperature, white blood cell count, insertion site for signs and symptoms of infection. • Maintain strict surgical asepsis when changing dressing and tubing. • Consider removal of venous access device with replacement in alternate site.* • If blood cultures positive, consider institution of antibiotic therapy.*
Electrolyte imbalance	• Iatrogenic • Effect of underlying diseases (ie, fistula, diarrhea, vomiting) • Blood sample contaminated by parenteral nutrition	• Monitor electrolyte levels at least daily initially. • Monitor signs and symptoms of electrolyte imbalance. • Treat underlying cause.* • Change concentration of electrolytes in total parenteral nutrition (TPN) as necessary to address blood levels.*
Hyperglycemia	• Insufficient insulin secretion • High glucose content of fluid • Blood sample contaminated by parenteral nutrition	• Monitor blood glucose frequently. • Administer exogenous insulin per addition to TPN, subcutaneously or through a separate IV drip.* • Decrease glucose content of fluid if warranted.*
Hypoglycemia	• Abrupt discontinuation of parenteral nutrition administered through a central vessel	• Reduce rate of parenteral nutrition by 50% × 2 hr, then discontinue. • If TPN/peripheral parenteral nutrition must be stopped abruptly, hang a separate dextrose solution if insulin has been administered.
Hypervolemia	• Iatrogenic • Underlying disease (ie, heart failure, renal failure)	• Monitor intake and output, daily weights, central venous pressure (CVP), breath sounds, peripheral edema. • Consider administering more concentrated solution.*
Hyperosmolar diuresis	• High osmolarity of parenteral nutrition	• Monitor intake and output, daily weights, CVP. • Consider decreasing concentration or increasing amount of fluid administered.*
Hepatic dysfunction	• IV nutrition	• Monitor liver function tests, triglyceride levels, presence of jaundice. • Consider alteration in macronutrients.*
Hypercapnia	• Excessive calorie delivery	• Consider reducing total calories.*
Lipid intolerance	• Low birth weight or premature neonate • History of liver disease • History of elevated triglycerides	• Monitor for bleeding (check stools for occult blood, coagulation studies, platelet levels). • Monitor oxygen levels for impaired oxygenation. • Monitor for fat overload syndrome: monitor triglyceride levels and liver function tests, hepatosplenomegaly, decreased coagulation, cyanosis, dyspnea. • Monitor allergic reaction: nausea, vomiting, headache, chest pain, back pain, fever. • Administer lipid-containing solutions slowly initially, while observing for symptoms.
Lipid particulate aggregation	• Unstable mixture of dextrose solution with lipid emulsion	• Observe for cracking or creaming of fluid and discontinue use of fluid with these characteristics.

**Obtain orders from health care provider.*

Delivery Systems for Parenteral Nutrition

1. Central VADs:

a. Insertion of long-term VADs, such as Hickman, Broviac, or Groshong catheters.
b. Peripherally inserted central catheters (peripherally inserted central catheter lines) may be used.
c. Multilumen, central VADs can allow concomitant administration of TNA and other solutions, including medications or blood, each running through a separate lumen.

2. Peripheral IV access:
   a. Insertion of an angiocatheter into a vein in the arm or leg.
   b. Midline catheters of longer length and with the ability to remain in place for more than 3 days.
3. Delivery of parenteral nutrition should be controlled by a volume control infuser.
4. Filters should be used whenever possible.
   a. A 0.22-micron filter may be used for TPN (without added fat emulsion).
   b. A 1.2-micron filter may be used for TNA or fat emulsion.

Nursing Interventions and Patient Education

1. Use strict sterile technique to attach IV tubing (with filter) to parenteral nutrition bag, purge air, make sure all clamps are closed, and then close clamp on VAD before attaching IV tubing to VAD. If central VAD is being used, have the patient bear down and hold breath to perform the Valsalva maneuver, which prevents air from being sucked into tubing.
2. Regulate flow and monitor administration hourly for patient tolerance and development of complications.
3. Change central VAD dressing according to facility protocol, maintaining sterility.
   a. The patient should be in supine position with head turned away from dressing.
   b. Clean the skin first with alcohol, then povidone iodine, starting at the insertion site and moving outward in a circular pattern.
   c. Apply a transparent dressing over the insertion site when skin is thoroughly dry.
   d. Loop and tape tubing outside of dressing.

NUTRITIONAL DISORDERS

Nutritional disorders can have a negative impact on the health and well-being of a person. In addition, some nutritional disorders may in turn lead to the development of other diseases or health issues. If not identified and treated in a timely fashion, these disorders can have a devastating effect.

Obesity

1. Obesity is a local, national, and global epidemic that impacts all ages, races, and socioeconomic classes and both genders. *Obesity* is an overabundance of body fat and is typically measured by a person's BMI (weight in kilograms divided by height in meters squared). A BMI greater than 30 is considered obese. Obesity has become a global health issue affecting both rich and poor countries. Current global estimates find that nearly 500 million adults are obese, with a projected increase to 1 billion obese adults by 2030. According to the Centers for Disease Control, the prevalence of obesity among US adults was 36.5% during the time period 2011–2014, with an overall higher incidence noted among women (38.3%) as compared to men (34.3%). During the same time period, there was a 17% prevalence rate among youth ages 2 to 19 years.

EVIDENCE BASE Ogden, C. L., Carroll, M. D., Fryar, C. D., & Flegal, K. M. (2015). Prevalence of obesity among adults and youths, United States 2011–2014. *NHCS Data Brief,* (219), 1–8.

Pathophysiology and Etiology

Increasing evidence reveals that obesity is a multifactorial disease and may be the result of several different factors. Such factors may include the following:

1. Heredity and genetic factors.
    a. Identical twins raised separately are more likely to have similar amounts of body fat than are fraternal twins raised separately.
    b. Genetic defects in certain disorders such as Bardet-Biedl syndrome and Prader-Willi syndrome can directly cause obesity.
2. Environmental factors.
    a. Some evidence shows that children reared by parents with obesity have an increased tendency toward obesity.
    b. Increased availability of high-fat, high-calorie foods.
    c. Reduction in physical activity.
    d. Modern-day conveniences (ie, riding lawnmowers, escalators, elevators, etc.).
3. Psychological factors.
    a. Depression.
    b. Anxiety.
    c. Anger.
    d. Posttraumatic stress.
    e. Boredom.
4. Physiologic factors.

a. Endocrine abnormalities (rare causes of obesity)—Cushing syndrome, polycystic ovary syndrome, hypothyroidism, hypogonadism, or hypothalamic lesions.
b. Age—advancing age may be associated with obesity, usually due to changes in activity level and metabolic rate, or in women because of hormonal changes; early childhood and the start of puberty may also be associated with obesity.

5. Pharmacologic factors.
   a. Corticosteroids.
   b. Antidepressants.
   c. Hormones and other medications.

Clinical Manifestations

1. BMI greater than 30, depending on body composition.
2. Increased weight is correlated with increased incidence of comorbid conditions.
   a. Cardiovascular disease.
   b. Type 2 diabetes mellitus.
   c. Hypertension.
   d. Obstructive sleep apnea.
   e. Osteoarthritis.
   f. Gastroesophageal reflux disease.
   g. Gallbladder disease.
   h. Cancer of the breast, endometrium, prostate, and colon.
   i. Stroke.
   j. Dyslipidemia.
   k. Stress urinary incontinence.
   l. Infertility.
   m. Depression (may be a cause of obesity as well as caused by obesity).
3. Metabolic syndrome (insulin resistance syndrome)—a group of characteristics that when co-occuring increase the risk of coronary artery disease, stroke, and type 2 diabetes.
   a. Obesity.
   b. Hypertension.
   c. Insulin resistance.
   d. High triglycerides.

Diagnostic Evaluation

1. Nutritional assessment—a systematic method for obtaining, verifying, and interpreting data needed to identify nutrition-related problems and their causes and significance.
2. Anthropometric and physical assessment—to evaluate increased body fat and effects of obesity on body.

3. Selected hormonal studies (thyroid, adrenal)—to assess for potential underlying cause.

Management

Conservative Measures

1. Diet therapy—has been controversial, but a well-balanced diet containing all the major food groups is still advised and recommended as a first-step therapy.
   a. A 1,000-calorie deficit per day is required to lose 2.2 pounds (1 kg) of body weight per week.
   b. Diet therapy should be individualized to the patient; however, the overall goal is to create a calorie deficit through reduced calorie intake or increased calorie expenditure.
   c. A balance of food groups is essential to maintain vitamin and nutrient balance. Nutrient supplementation may be necessary (calcium, vitamin D, iron, B_{12}, zinc, and folate).
   d. Food preparation should include seasoning with herbs, onion, garlic, and pepper, and foods should be baked, broiled, steamed, or sautéed using minimal oil.
   e. Food attractively arranged on smaller plates, using whole rather than processed foods and eaten slowly, will assist the overall process.
   f. Eliminating entire food groups from the diet, such as carbohydrates (in many popular protein- and fat-based diets), will eventually result in craving of those foods eliminated, disruption of normal metabolic processes, and quick weight gain when the food is added to the diet.
2. Exercise—Regular physical activity is an important component in weight loss and weight maintenance along with reduced caloric intake. The most recent recommendations from the American College of Sports Medicine (2011) are to incorporate moderate aerobic physical activity to include a minimum of 150 minutes per week and goal of 300 minutes per week, including strength training 2 to 3 times per week. Physical activity may also add other health benefits if done on a regular basis such as improved cardiovascular status and emotional well-being.

EVIDENCE BASE Garber, C. E., Blissmer, B., Deschenes, M., et al. (2011). Quantity and quality of exercise for developing and maintaining cardiorespiratory, musculoskeletal, and neuromotor fitness in apparently healthy adults: Guidance for prescribing exercise. *Medicine and Science in Sports and Exercise, 43*(7), 1334–1359.

---

3. Behavior modification is a cornerstone of any successful diet.
   a. Identify and eliminate situations or cues leading to overeating or high-calorie foods with use of a food diary.
   b. Provide positive reinforcement of proper dietary habits.
   c. Should a lapse in diet habits occur, focus on a prompt and positive return to appropriate dietary habits.

d. Stress-reduction techniques, such as visual imagery or progressive muscle relaxation; peer support may be helpful.

Pharmacotherapy

1. Anorexia medications include amphetamines, sympathomimetics, and norepinephrine-releasing agents or reuptake inhibitors; reduce appetite and stimulate weight loss initially.
   a. However, tolerance may develop and weight may be regained when the drugs are discontinued.
   b. Numerous long-term studies have failed to show long-term success with these agents.
2. Phentermine products are available in prescription form and primarily act on chemicals in the brain to decrease appetite. Phentermine products also have a stimulant component and should not be used in uncontrolled hypertension, advanced heart disease, history of drug abuse, or with monoamine oxidase (MAO) inhibitors.
3. Phentermine–topiramate extended release is an FDA-approved drug available in prescription form. This drug combines the effects of phentermine with the weight loss effects of topiramate (a medication used to treat seizures).
4. Naltrexone hydrochloride and bupropion hydrochloride, branded as Contrave, is a combination of two medications, naltrexone (used to treat narcotic and alcohol dependency) and bupropion (an antidepressant), to help decrease appetite and control eating.
5. Liraglutide was FDA approved in 2014 and is an injectable medication used for the management of diabetes. Liraglutide decreases the production of glucagon, which in turn slows down the emptying of the stomach. It also works in the brain to reduce the amount of food consumed.
6. Lorcaserin is a serotonin 2C receptor agonist that works on chemicals in the brain to decrease appetite. It is available in short and long acting forms.
7. Orlistat, a pancreatic lipase inhibitor, blocks the breakdown of fat in the GI system; about 30% of dietary fat is eliminated.
   a. Adverse effects include oily or fatty stool, flatulence, and GI distress.
   b. Long-term safety of the drug has not been determined, but addition of a fat-soluble vitamin supplement (vitamins A, D, E, and K and beta carotene) taken 1 hour before or 2 hours after orlistat will prevent a theoretical vitamin deficiency.
   c. Should not be used in cases of cholestasis or malabsorption.
   d. Orlistat is available over the counter in a lower dosage than originally prescribed.
   e. These medications are only adjunct to diet and exercise therapy.
8. Several other medications used to treat depression, seizures, and/or diabetes have been prescribed off-label to help promote weight loss. These medications have not been approved by the FDA for the treatment of obesity:
   a. Bupropion—an antidepressant medication.
   b. Topiramate—an anticonvulsant medication.
   c. Zonisamide—an anticonvulsant medication.

d. Metformin—an oral medication used to treat diabetes.

9. Sibutramine is no longer available in the United States because of studies that identified an increased risk of developing cardiovascular events such as heart attack or stroke.

Metabolic and Bariatric Surgery

Numerous surgical procedures have been used to help treat obesity and metabolic disorders. Although gastric bypass has been considered the gold standard for years, many new surgical treatment options have emerged, lending to a greater availability of treatment options (see Figure 20-3). These surgical therapies are generally reserved for patients with severe obesity (i.e., BMI > 35 with comorbid conditions or BMI > 40) who cannot lose weight and maintain weight loss through the above therapies. Bariatric surgery has proven to be a safe and effective means for weight loss when performed by an experienced surgeon within a multidisciplinary center. In addition to the anatomical and mechanical changes created by the various procedures, there is increasing evidence of metabolic or hormonal changes that lead to weight loss. Metabolic/hormonal changes associated with these surgeries include a decrease in the hormone ghrelin, which produces a decrease in hunger, and an increase in PYY and GLP-1 creating an increase in satiety.

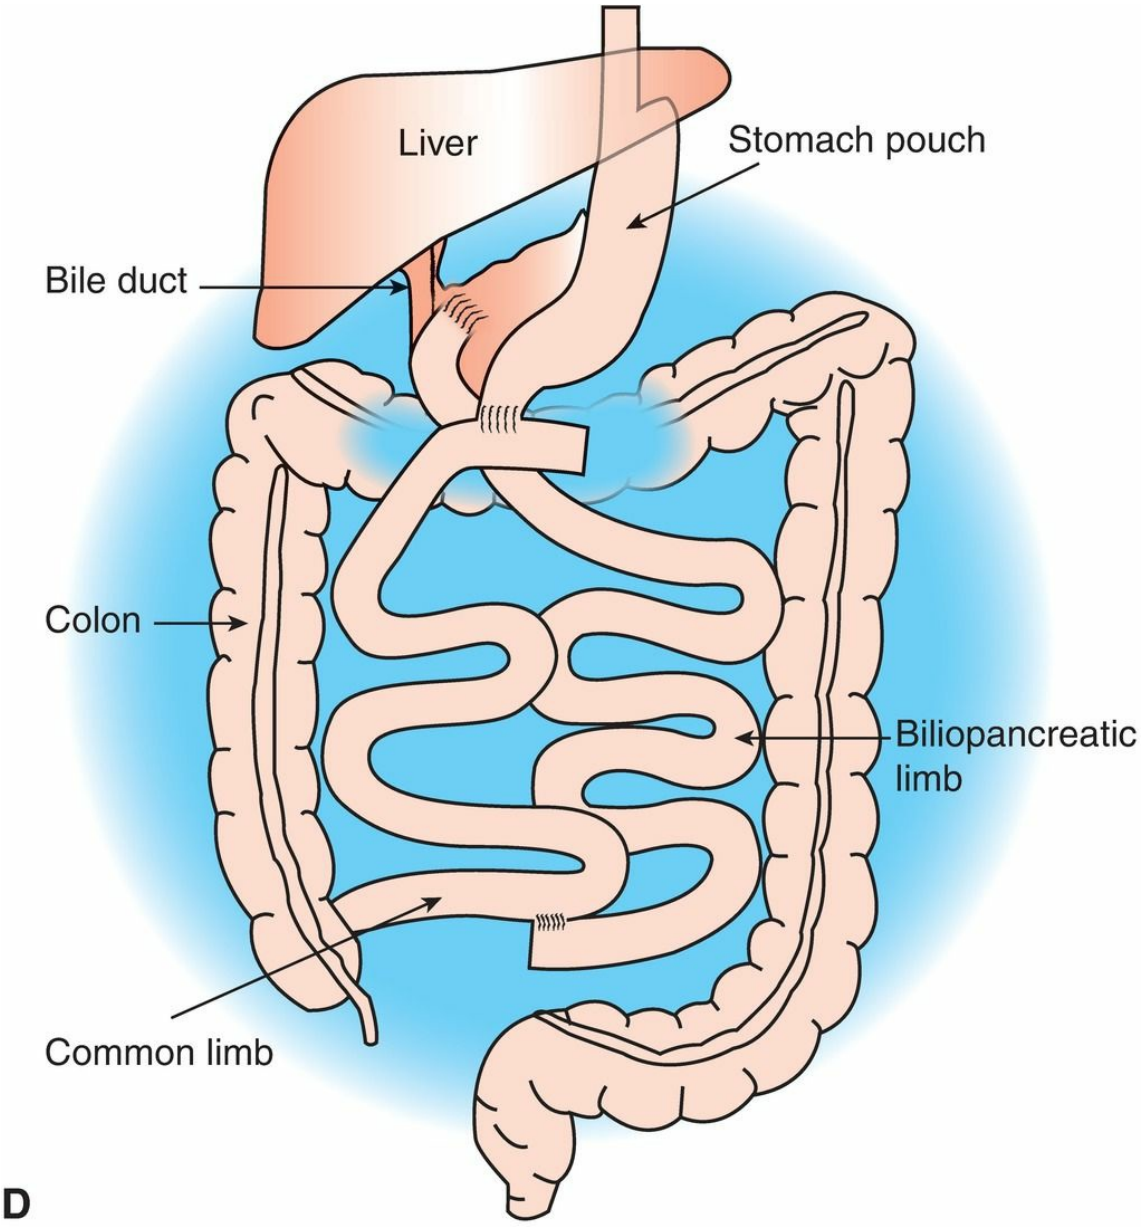

Figure 20-3. Bariatric procedures. **(A)** Adjustable gastric band. **(B)** Gastric bypass with Roux-en-Y anastomosis. **(C)** Sleeve gastrectomy. **(D)** Biliopancreatic diversion with duodenal switch.

1. Roux-en-Y gastric bypass—a restrictive and malabsorptive procedure in which a small 1- to 2-ounce pouch/stomach (normal size = 30 to 50 ounces) is created by stapling and completely separating the smaller proximal stomach pouch from the larger distal stomach pouch. To this proximal pouch, a portion of the jejunum or Roux limb is attached, thus bypassing the distal stomach pouch and allowing the new pouch to empty food contents into the bowel. The biliopancreatic limb is then anastomosed to the Roux limb, thus creating a "Y" configuration and a method of elimination of digestive juices from the distal stomach and duodenum.
2. Adjustable gastric banding—a silicone band or "belt" is placed at the gastroesophageal junction, creating a small upper segment of the stomach. An access port or reservoir, which is connected to the band by tubing, is placed midabdomen just under the skin, which allows for band adjustments to create a

narrower passage into the larger remaining stomach. This in turn slows the emptying process from the upper segment into the lower segment of the stomach thus causing satiety with a smaller amount of food. Hormonal changes with this surgery initially increase ghrelin production, which increases hunger.

3. Sleeve gastrectomy—a restrictive procedure in which a "sleeve" is created by stapling the stomach into a long tube from the esophagus to the duodenum. The remnant stomach is removed, whereas the pylorus remains intact and allows for normal emptying of stomach contents.
4. Biliopancreatic diversion with duodenal switch (BPD/DS)—a primarily malabsorptive procedure with some restrictive qualities. The BPD/DS is a complex surgical procedure in which a partial gastrectomy is performed along with the division and rerouting of the small intestine (ie, duodenum—hence duodenal switch). This inhibits the absorption of calories and some nutrients, but allows for normal absorption of other key nutrients such as protein, calcium, iron, and vitamin B_{12}. In contrast to the gastric bypass, the BPD/DS maintains the pyloric valve, which prevents complications such as dumping syndrome, marginal ulcers, and/or stomal stenosis from occurring.
5. Other—there are several investigational procedures for severe obesity on the horizon that may add viable options for weight loss in the future but are not recognized as of yet.

Medical Devices

1. vBloc Neuromodulation is a medical device implanted surgically on the lower stomach. The device functions by blocking the vagus nerve and hence creating a sensation of fullness and decreased hunger. vBloc is currently approved by the FDA for a BMI 40 to 45 or 35 to 39.9 with comorbid conditions.
2. Intragastric balloons are available as single or double balloons that are inserted endoscopically into the stomach for no longer than 6 months. The balloon(s) mimic a sleeve gastrectomy by filling a portion of the stomach to reinforce proper portion control and a sensation of fullness. Both single (Orbera) and double (ReShape Dual Balloon) balloons are FDA approved but are not typically covered by insurance. Prior history of metabolic and bariatric surgery may be a contraindication for these products.
3. AspireAssist is an FDA-approved endoluminal device in which a modified PEG tube is placed endoscopically into the stomach and then connected to a small handheld device. The device is activated approximately 20 to 30 minutes postprandial by a discreet button enabling the emptying of up to 30% of the meal into the toilet. The AspireAssist is for patients with a BMI 35 to 55.

Complications

1. Obesity is a risk factor for many comorbid conditions including diabetes, gallbladder disease, osteoarthritis of weight-bearing joints, hypertension, CAD, obstructive sleep apnea, metabolic syndrome, as well as several other conditions.
2. Vitamin and mineral deficiencies because of surgical intervention, severely restricted diet, or noncompliance with recommended regimen.
    a. A moderate, well-balanced weight reduction diet will generally not cause deficiencies, although a multiple vitamin/mineral supplement may be used.
    b. A low-calorie diet (fewer than 800 to 1,000 calories per day) will require careful monitoring and

vitamin/mineral supplements.

c. Complications of bariatric surgery may include marginal ulcers, anastomotic leaks, fistulas, infection, pulmonary emboli, chronic nausea and vomiting, vitamin D and B_{12} deficiency, thiamine, copper, and iron deficiency. A daily vitamin and mineral supplement is necessary.

Nursing Assessment

1. Obtain a complete nutritional assessment (may be in collaboration with a registered dietitian).
2. Assess behavioral and emotional components of eating, coping mechanisms, and past successes and failures with dieting.

Nursing Diagnoses

- Imbalanced Nutrition: More Than Body Requirements related to high-calorie, high-fat diet, and limited exercise.
- Deficient Fluid Volume related to weight loss surgery.
- Readiness for Enhanced Self-Concept related to appearance and weight.

Nursing Interventions

Modifying Nutritional Intake

1. Assist the patient in assessing current dietary habits and identifying poor dietary habits.
2. Assist the patient in developing appropriate diet plan based on likes and dislikes, activity level, and lifestyle.
3. Suggest behavior modification strategies, such as exercise (ie, walking) during lunch break, preventing access to quick snacks, eating only at mealtimes at the table.
4. Provide emotional support to the patient during weight-reduction efforts through positive reinforcement and creative problem solving.
5. Provide the patient with alternative coping mechanisms, including stress-reduction techniques such as progressive relaxation and guided imagery.
6. Assess the patient's ability to tolerate exercise through measurement of vital signs before, during, and after exercise and ask about symptoms of shortness of breath and chest pain.
7. Discourage fad dieting.

Preventing Complications Postoperatively

1. Provide initial postoperative care as for gastrointestinal surgery (see page 494).
2. Administer IV fluids, as directed. Record intake and output.
3. Start oral fluids per surgeon's protocol (this will vary from facility to facility and surgeon to surgeon). General progression for most patients will be to start with small sips and gradually advance to larger sips of clear liquids.
4. Advance diet as per surgeon's protocol. Confirmation of the bariatric diet stages with the facility's

bariatric program and/or surgeon is crucial, as this will vary from facility to facility and surgeon to surgeon.

5. Observe for and report increased abdominal pain, distention, or alteration in abdominal drain output (if utilized), which may indicate leakage or bleeding at anastomosis or staple sites or obstruction.
6. Monitor vital signs, breath sounds, and wounds for signs of infection, pneumonia or other potential complications.
7. Watch for and report signs of dehydration (thirst, oliguria, dry mucous membranes) and hypokalemia (muscle weakness, anorexia, nausea, decreased bowel sounds, and dysrhythmias).
8. Warn the patient that overeating may cause vomiting or painful esophageal distention. Dumping syndrome may occur especially in the postoperative roux-en-y gastric bypass patient with food products that are high in fat or high in sugar.
9. Stress the importance of good dietary habits and behavior modification to lose weight because metabolic and bariatric surgery is only an adjunct to treatment.
10. Encourage close, long-term follow-up for monitoring of weight loss and nutritional status. Additional long-term complications may include marginal ulcers, hernias, strictures, and/or malnutrition.

TRANSITIONAL CARE ALERT Following bariatric surgery, educate the patient on the importance of strict adherence to diet protocol and to avoid premature advancement to the another stage without discussing with the surgeon, dietitian, or other staff member. Encourage the patient to meet fluid (48 to 64 oz fluid/day) and protein (individualized) goals. Advise the patient to notify the surgeon for fever (greater than 101°F); tachycardia (heart rate greater than 100); severe abdominal pain; nausea or vomiting; difficulty breathing or ability to catch breath; or any redness, drainage, or swelling from incisions. Prevention and prompt attention to signs of complications can prevent readmission and adverse outcomes.

Strengthening Self-Concept

1. Direct patient education and conversation in a nonjudgmental manner.
2. Get to know the patient and point out the positive aspects of patient's health and well-being.
3. Encourage the patient to make change in weight for the positive health aspects, not just for cosmetic reasons.
4. Make referral to behavioral health professional and support groups as needed.
5. Be a good role model—show a healthy attitude toward sensible eating, exercise, and other healthy practices.
6. Be sensitive to discrimination, behaviors, and attitudes toward people with obesity.

Patient Education and Health Maintenance

1. Discuss fat, carbohydrate, and protein, their inclusion in common foods, and their calories per gram.

2. Describe the five basic food groups and their placement in the MyPlate plan.
3. Explain the purpose of a balanced diet and the need for vitamins and minerals from food sources; supplement needed following bariatric surgery.
4. Review the health hazards of obesity.
5. Advise the patient of plateau period that may occur without weight loss for some time, but advise the patient not to get discouraged.
6. Tell the patient to keep a food diary to show to nutritionist and to weigh self no more than once per week.
7. If the patient is interested in liquid diets or herbal supplements to lose weight, encourage discussion with health care provider. Some preparations may contain ephedra, a powerful stimulant that may cause increased BP, significant adverse effects, and many drug interactions.
8. Refer to such organizations as Obesity Action Coalition (*www.obesityaction.org*) and the National Institutes of Diabetes and Digestive and Kidney Disease: Weight-control Information Network (*http://win.niddk.nih.gov/publications/gastric.htm*) for further information on weight loss options.

Evaluation: Expected Outcomes

- Loses 10% to 15% excess body weight during the first month.
- No abdominal distention, nausea or vomiting, or wound infection.
- Verbalizes feeling good about self, secondary to change in diet and exercise habits.

Eating Disorders

Disordered eating can run the full gamut from starvation as noted in anorexia nervosa, to overeating behaviors such as binge-eating disorder—or may include a combination of both as seen in bulimia nervosa. Eating disorders can affect both genders but are generally more prevalent among women than among men. Lifetime prevalence is estimated at 0.3% for anorexia, 0.9% for bulimia, and 1.6% for binge-eating disorder. The disordered eating may develop during childhood or later in life, but is more common during teens or young adulthood, and may be chronic or intermittent during many years. There are multiple causes that may be attributable to the eating disorder including genetic, biological, hormonal, environmental, behavioral, psychological, and social etiologies. See Table 20-4 on page 577 for comparison of the three most common eating disorders.

Table 20-4 Comparison of Eating Disorders

DISORDER/DESCRIPTION	PATHOPHYSIOLOGY/ETIOLOGY	CLINICAL MANIFESTATIONS
Anorexia nervosa: characterized by self-induced weight loss >15% of normal weight for age and height and is associated with high morbidity and mortality. Anorexia is characterized by periods of starvation and may be mixed with episodes of binging and purging.	• Semistarvation state with glucose and protein sparing, fat utilization, endocrine changes, and fluid and electrolyte disturbances. Results in: • Loss of fat stores • Decreased protein synthesis • Decrease in thyroid hormone • Hypothalamic or pituitary dysfunction—decrease in follicle-stimulating hormone (FSH), luteinizing hormone (LH), and estrogen	• Extremely restricted eating • Extreme thinness (emaciation) • Relentless pursuit of thinness and unwillingness to maintain a normal or health weight • Intense fear of gaining weight • Distorted body image, a self-esteem that is heavily influenced by perceptions of body weight and shape, or a denial of the seriousness of low body weight • Amenorrhea, bradycardia, hypotension, cold intolerance
Bulimia nervosa: characterized by recurrent episodes of binge eating and feeling of loss of control ever eating behavior during these episodes. The binging episodes lead to self-disgust and are typically followed by inappropriate methods to prevent weight gain, including self-induced vomiting, excessive use of laxatives, diuretics, fasting, or excessive exercise.	• Onset of illness typically occurs in late adolescence or early 20s • Ten times more common in young women than in young men • May be associated with a personal or family history of obesity, substance abuse, depression, anxiety, or mood disorders • Self-induced vomiting • Starvation may be as evident as in anorexia nervosa • Eating binges may occur as often as several timers per day and be present for many months	• Physical signs may include calluses or skin changes on hand and fingers, loss of dental enamel, swollen lymph nodes, and bad breath or mouthwash smell on breath because of self-induced vomiting • Endocrine changes, such as amenorrhea, may be present
Binge-eating disorder (BED): disordered eating that results in a loss-of-control eating episode(s). BED is not associated with inappropriate compensatory behaviors, however, is often associated with some type of psychopathology.	• Presence of comorbid psychopathology: specific phobia, social phobia, unipolar major depression, posttraumatic stress disorder, alcohol abuse, or dependence • Increased risk for developing chronic pain, diabetes mellitus, and hypertension • More likely to be obese • Binge episodes at least once a week for 3 mo	• Eating unusually large amounts of food in a specific amount of time • Eating even when full or not hungry • Eating fast during binge episodes • Eating until uncomfortably full • Eating alone or in secret to avoid embarrassment • Feeling distressed, ashamed, or guilty about eating • Frequently dieting, possibly without weight loss

Although this section focuses on anorexia nervosa, bulimia nervosa, and binge-eating disorder, there are other disordered or maladaptive eating behaviors, including pica, orthorexia, and Prader-Willi Syndrome. Pica is a disorder of eating objects with no nutritional value, such as dirt, paper, or ice. Orthorexia is the unhealthy obsession of consuming healthy foods. Prader-Willi Syndrome is a genetic disorder that produces hormonal symptoms such as a constant hunger, leading to obesity. Another category of eating disorders on the rise is OSFED or other specified feeding or eating disorder and includes subtypes such as atypical anorexia nervosa,

purging disorder, and night eating syndrome.

Diagnostic Evaluation

1. Serum chemistry for electrolytes, blood urea nitrogen (BUN), and creatinine and bicarbonate—may be abnormal, indicating fluid and electrolyte imbalances.
2. Hormonal tests may include thyroid function tests, luteinizing hormone (LH), follicle-stimulating hormone (FSH), estrogen, and testosterone.
3. Serum glucose and lipid testing to determine body's response to dietary intake.
4. Electrocardiogram to determine arrhythmias caused by electrolyte imbalance.

Management

Although pathophysiology, etiology, and symptoms may differ somewhat between each eating disorder, the assessment, diagnosis, and treatment and therapies are very similar. Paramount to the entire process, however, is the multidisciplinary clinical approach that should include nurses, nutritionists, behavioral health providers, advanced practice providers, physicians, and other health care providers who specialize in treating patients with eating disorders.

1. Dietary modification and nutritional counseling to achieve gradual weight gain and/or normal eating habits.
    a. Balanced diet with incremental inclusion of foods previously perceived as restricted by the patient.
    b. Increased activity, exercise gradually.
2. Enteral or parenteral feeding as needed if prescribed diet cannot be maintained by the patient and physical status warrants. Enteral feeding is preferred and is used more frequently.
3. Individual counseling focuses on patient's need to control weight, alteration in body image, and associated diagnoses, including depression and suicidal ideation.
4. Psychological counseling and support, such as talk therapy or behavioral therapy.
    a. Assist the patient to develop insight into behavior and a more realistic body image.
    b. Assist the patient to develop effective coping strategies and problem-solving mechanisms.
5. Antidepressants, antianxiety, and other pharmacologic agents for associated psychiatric problems may be tried.
    a. Selective serotonin uptake inhibitor (SSRI) such as fluoxetine to treat bulimia nervosa.
    b. Stimulant such as lisdexamfetamine (Vyvanse) to treat binge-eating disorder.
6. Inpatient treatment (preferably on specialized eating disorder unit) is recommended if weight is less than 75% ideal; marked orthostatic hypotension; bradycardia less than 40; sustained tachycardia greater than 100; inability to maintain core body temperature of 98.6˚F (37˚C); suicidal or no response to outpatient therapy.

Complications

1. Fluid and electrolyte imbalance.

a. Hypokalemia, hyponatremia, hypochloremia.
b. Hyperkalemia.
c. Metabolic alkalosis.
d. Dehydration.

2. Cardiac disturbances.
   a. Dysrhythmias, bradycardia, tachycardia.
   b. Hypotension.
   c. Cardiac arrest.
3. Nutritional imbalance.
   a. Obesity.
   b. Cachexia.
4. Seizures due to hyponatremia.
5. Increased risk of infection related to a decrease in white blood cells.
6. Endocrine dysfunction.
   a. Amenorrhea, decreased estrogen in females.
   b. Decreased testosterone in males, decreased libido.
   c. Decreased thyroid hormone.
7. Esophageal tear or gastric rupture.
8. Dental erosion.
9. Comorbid psychiatric conditions.
   a. Depression.
   b. Anxiety disorders.
   c. High risk for suicide.

Nursing Assessment

1. Perform a complete nutritional assessment. Obtain a detailed dietary history and complete review of systems, including psychological, gynecologic, endocrine, GI systems, activities of daily living, and exercise history.
2. Perform physical examination, including vital signs, height and weight, heart rate and rhythm, bowel sounds, and observation for hematemesis and dental caries (which may indicate self-induced vomiting).
3. Evaluate fluid and electrolyte status and manifestations of associated problems.
4. Assess for signs and symptoms of depression, anxiety, personality disorder, and associated eating behaviors and history of family dysfunction.

Nursing Diagnoses

1. Imbalanced Nutrition: More or Less Then Body Requirements related to binge/purge behavior and/or self-restricted intake.

2. Disturbed Body Image related to weight.
3. Ineffective Coping related to lack of control over eating habits.
4. Risk for Suicide related to psychological distress.

Nursing Interventions

Attaining Appropriate Weight

1. Assist the patient to select well-balanced diet and maintain appropriate eating habits.
2. Encourage small, frequent meals or snacks of high-calorie foods and beverages. Liquid nutritional supplements may be best tolerated.
3. Monitor and assess daily intake and output, weight (before breakfast), urine for ketones, and serum electrolytes to determine physical response to nutritional interventions.
4. Provide positive reinforcement for appropriate eating behaviors.
5. Provide positive reinforcement for improved intake and weight gain or stabilization of weight.
6. Assess bowel function. Promote fluids and activity to prevent constipation if the patient cannot tolerate food high in fiber.
7. Teach the patient risks associated with abnormal eating behavior and the benefits of maintaining healthful nutritional and exercise habits.

Fostering a Healthy Body Image

1. Establish a trusting relationship and provide for patient's safety and security needs.
2. Encourage the patient to verbalize feelings about body image, self-concept, fears, and frustrations.
3. Emphasize the importance of counseling, stress management, assertiveness training, and other therapies over a long term to strengthen body image and acceptance.

Improving Coping

1. Encourage the patient to set realistic goals for weight and appearance. Involve the patient in treatment plan, offering choices to increase sense of control.
2. Assist the patient to identify and implement alternative coping strategies in times of stress, including expression and exploration of feelings, problem solving, appropriate use of exercise, and relaxation techniques.
3. Set limits so that the patient will fell in control of self. Be alert for lying and manipulation that the patient may display to preserve control.
4. Include family in counseling and teaching sessions, as appropriate.

Preventing Suicide

1. Assess level of risk by obtaining the history of past suicide attempts, recent suicidal thoughts, and current ideation, plan, and possible method.
2. Maintain level of observance called for by situation.

3. Make sure that access to sharp objects is prohibited.
4. Make sure that a crisis intervention team is on call, if needed.

Patient Education and Health Maintenance

1. Teach principles of nutrition and healthful diet and eating habits. Discuss food matter-of-factly to avoid reinforcing patient's preoccupation with food.
2. Teach the effect of starvation on both physiologic and psychological functioning.
3. Involve patient's family and significant others in the treatment plan, as appropriate.
4. Describe the dangers of using laxatives and diuretics in weight control, such as electrolyte imbalances, dehydration, and bowel atony.
5. Stress the importance of maintaining follow-up visits and counseling.
6. Refer to such agencies as American Anorexia-Bulimia Association (*www.aaba.org*), Eating Disorder Information Center (*www.nedic.ca*), Eating Disorders Awareness and Prevention (*www.edap.org*), National Association of Anorexia Nervosa and Associated Disorders (*www.anad.org*), and National Eating Disorder Association (*www.nationaleatingdisorders.org*).

Evaluation: Expected Outcomes

- Well-balanced dietary intake without evidence of vomiting.
- Gain of 1 pound (0.5 kg) during first week (anorexia nervosa).
- Verbalizes satisfaction with body image and weight.
- Verbalizes appropriate problem-solving approach.
- Denies suicidal ideation and thoughts.

Malabsorption Syndrome

Malabsorption syndrome is a group of symptoms and physical signs that occur because of poor nutrient absorption in the small intestine, particularly fat absorption, with a resultant decrease in absorption of fat-soluble vitamins A, D, E, and K. Poor absorption of other nutrients, including carbohydrates, minerals, and other vitamins and proteins, may also occur. *Celiac sprue*, and *lactose intolerance* are common types of malabsorption syndromes.

Pathophysiology and Etiology

Malabsorption has multiple etiologies, including gallbladder, liver, or pancreatic disease, lymphatic obstruction, vascular impairment, and bowel resection. Two common causes:

1. Celiac sprue—malabsorption of nutrients resulting from atrophy of villi and microvilli of the small intestine because of an intolerance to gluten found in common grains, such as wheat, rye, oats, and barley (see Chapter 48).
2. Lactose intolerance—typically of genetic origin, this digestive enzyme deficiency prevents the digestion of lactose found in milk, causing osmosis of water into the lumen of the intestine.

Clinical Manifestations

1. Steatorrhea.
2. Abdominal distention and pain.
3. Flatulence.
4. Anorexia, weight loss, edema.
5. Vitamin deficiency—fat soluble (A, D, E, K).
6. Protein deficiency and negative nitrogen balance.
7. Anemia, weakness, and fatigue due to poor absorption of iron, folic acid, and vitamin B_{12}.

Diagnostic Evaluation

1. Fecal fat analysis—72-hour stool collection; fecal fat may be increased.
2. M2A Imaging System—a device that provides images via a receiver and recorder tracing the transit of a capsule that is swallowed by the patient. Used to evaluate and diagnose malabsorption syndromes as well as other gastrointestinal diseases.
3. Lower GI series (barium enema)—may be used to evaluate the colon.
4. Serum measurement of vitamin levels, total protein, and albumin may be decreased.
5. Prothrombin time may be prolonged because of vitamin K deficiency.

Management

1. Treatment of the underlying cause, if possible, by eliminating causative agents, such as grains or milk.
2. Promotion of adequate nutritional intake through a carefully designed diet that substitutes alternatives to

the offending agent and that ensures replacement of deficient nutrients through oral, enteral, or parenteral therapy.

3. Medications such as pancreatic enzymes.

Complications

1. Dehydration.
2. Electrolyte imbalance with possible cardiac dysrhythmias.
3. Protein deficiency with muscle atrophy and edema.
4. Vitamin deficiency with tetany, bleeding, anemia, and osteoporosis.
5. Skin breakdown.

Nursing Assessment

1. Assess fluid and electrolyte status through careful monitoring of intake and output, daily weight, serum electrolytes, vital signs, and other signs and symptoms of dehydration and electrolyte imbalance.
2. Assess GI function through observation of frequency and characteristics of stool, bowel sounds, and distention, pain, and other associated symptoms.
3. Assess nutritional status.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to malabsorption of nutrients.
- Deficient Fluid Volume related to loss of fluid through stool.
- Acute Pain related to abdominal distention and cramps.
- Risk for Impaired Skin Integrity related to irritation of anal area by stool.

Nursing Interventions

Improving Nutritional Status

1. Ensure that diet is free from causative agents, such as dairy or wheat products.
2. Provide diet high in missing nutrients, including proteins, carbohydrates, fats, vitamins, and minerals.
3. Teach the patient to use substitute products for causative agents, such as gluten-free flour, corn, soybean, and lactose-free milk substitutes.
4. Monitor weight and characteristics of stool closely.

Restoring Fluid Balance

1. Monitor intake and output and urine-specific gravity.
    a. Include watery stool in output.
    b. Be aware that edema is caused by low serum proteins, not fluid overload.
2. Monitor vital signs frequently, based on condition.
3. Be alert for dehydration—orthostatic hypotension, tachycardia, decreased skin turgor, dry mucous

membranes, thirst, oliguria.

4. Observe for signs and symptoms of potential electrolyte disturbances—nausea, vomiting, dysrhythmias, tremors, seizures, anorexia, weakness—and report abnormal results of serum electrolytes.
5. Administer IV fluids or parenteral or enteral nutrition, as ordered.

Relieving Pain

1. Assess timing, frequency, and character of pain and its relationship to food.
2. Encourage Fowler position and frequent change in position for comfort.
3. Administer analgesics, antidiarrheals, and antiflatulents, as ordered.

Maintaining Tissue Integrity

1. Provide meticulous perineal care after each stool with application of hydrophobic ointments, if necessary, to prevent skin breakdown.
2. Give careful attention to general skin condition, assessing for redness, breakdown, and poor turgor, and maintain general skin integrity through cleanliness, lubrication, padding of bony prominences, frequent turning, and adequate hydration and nutrition.

Patient Education and Health Maintenance

1. Provide nutritional counseling for the patient and family, particularly if symptoms are secondary to food intolerance; stress which foods to avoid and the importance of carefully reading all food labels, recommend appropriate food substitutions, and necessary nutritional supplements.
2. Advise regarding signs and symptoms that indicate worsening of disease—increased frequency of stool, diarrhea or steatorrhea, increased pain.
3. Suggest such support groups as the Celiac Sprue Association (*www.csaceliacs.org*) and the Crohn's and Colitis Foundation of America (*www.ccfa.org*).

Evaluation: Expected Outcomes

- Maintains weight and energy level.
- Vital signs stable; urinary output adequate.
- Verbalizes decreased pain after meals.
- No skin breakdown noted.

Vitamin and Mineral Deficiencies

Vitamins are organic compounds found in food needed for growth, reproduction, good health, and resistance to infection. Minerals are inorganic compounds found in nature and serve a variety of physiologic functions. Specific requirements depend on age, activity, metabolic rate (increased fever), and special processes, such as pregnancy, lactation, and disease processes.

See Table 20-5 on pages 580 to 585 for vitamin and mineral needs for healthy adults age 19 or older. Needs are different for children and pregnant or lactating women.

Table 20-5 Vitamin and Mineral Requirements and Imbalances

VITAMIN, RDA, AND EAR	FUNCTION	CLINICAL MANIFESTATIONS OF IMBALANCE	DIAGNOSTIC EVALUATION	MANAGEMENT
Vitamin A (Retinol) RDA: 700–900 mcg EAR: 500–625 mcg fat soluble	• Tissue maintenance via antioxidant ability • Helps regulate the immune system • Skeletal and soft tissue growth and development • Visual adaptation to light and dark • Supports reproductive function	*Deficiency:* Night blindness, xerophthalmia, keratinization, generalized mucosa dryness/damage, vomiting, diarrhea, weight loss, urinary and vaginal infections, tooth decay, follicular hyperkeratosis, fatigue *Toxicity:* Hair loss, joint pain, dry skin, mouth soreness, anorexia, vomiting, liver damage	*Deficiency:* • History and physical findings are helpful in diagnosis of most vitamin imbalances • Serum level <35 mg/dL suggests vitamin deficiency	*Deficiency:* • Replacement therapy of 30,000 international units to treat night blindness • Good dietary sources of vitamin A are green and yellow fruits and vegetables and liver • In patients with malabsorption of fat-soluble vitamins and patients with low dietary intake of vitamin A, IV supplements are required
Vitamin B_1 (Thiamine) RDA: 1.1–1.2 mg EAR: 0.9–1.0 mg water soluble	• Carbohydrate metabolism • Necessary for neurologic, gastric, cardiac, and musculoskeletal function	*Deficiency:* Appetite loss, constipation, dyspnea, fatigue, irritability, nervousness, memory loss, paresthesias, muscle pain, beriberi, blurred or double vision, difficulty swallowing, nausea, vomiting *Toxicity:* Large doses may be given generally without difficulty, although anaphylaxis has been reported	*Deficiency:* • Erythrocyte transketolase activity <15% to 20%	*Deficiency:* • Treat underlying cause • High-protein diet with supplemental B complex vitamins • Food sources rich in thiamine are brewer's yeast, meat, wheat germ, enriched grains and beans • Parenteral therapy with 50 to 100 mg/day followed by 5 to 10 mg/day PO
Vitamin B_2 (Riboflavin) RDA: 1.1–1.3 mg EAR: 0.9–1.1 mg water soluble	• Carbohydrate metabolism • Promotes growth, red blood cell formation, and healthy eyes and skin	*Deficiency:* Sore throat, cheilosis, dermatitis, burning and itching of eyes, tearing and vascularization of corneas; late-stage symptoms include neuropathy and growth retardation *Toxicity:* None known	*Deficiency:* • Erythrocyte glutathione activity >1.2 to 1.3 • Decreased urinary riboflavin levels	*Deficiency:* • Good dietary sources of B_2 are dairy products, vegetables, enriched grains, eggs, nuts, liver • Oral supplements of 5 to 15 mg/day
Vitamin B_6 (Pyridoxine) RDA: 1.3–1.7 mg EAR: 1.1–1.4 mg water soluble	• Required for protein metabolism • Maintains neurologic function and RBC production	*Deficiency:* Anemia, weakness, glossitis, cheilosis, irritability, seizures *Toxicity:* Neuromuscular damage, peripheral neuropathy	*Deficiency:* • Pyridoxal phosphate levels <50 ng/mL	*Deficiency:* • Oral supplementation: 10 to 20 mg • Good dietary sources of B_6 are bananas, brewer's yeast, fish, meat, whole grains, liver • Individuals taking oral contraceptives or isoniazid may need to supplement their diets with pyridoxine • Pregnancy also increases need
Vitamin B_{12} (Cobalamin) RDA: 2.4 mcg EAR: 2.0 mcg water soluble	• Maintains neurologic function and RBC development via hemoglobin synthesis	*Deficiency:* Megaloblastic anemia, memory impairment, confusion, depression, fatigue, nervousness, decreased reflex response, balance impairment, speech difficulties, demyelination of the large fibers of the spinal cord, anorexia, vomiting, weight loss, yellowing of skin, abdominal pain, dyspnea, diarrhea, glossitis, burning of lips or mouth, palpitations, tachycardia, sore tongue, weakness *Toxicity:* None	*Deficiency:* • Serum levels of <100 pg/mL • Decreased hematocrit with elevation of MCV • Schilling test also measures absorption of radioactive B_{12}	*Deficiency:* • B_{12} 200 mcg/day IM for 1 wk, then every month for life if deficiency is due to pernicious anemia • Oral vitamin B_{12} may be necessary for strict vegetarians • Good dietary sources of B_{12} are eggs, fish, organ meats, lean meat, dairy products
Biotin RDA: 30 mcg EAR: Not established water soluble	• Metabolism of proteins, fats, and carbohydrates	*Deficiency:* Dry skin, fatigue, grayish skin discoloration, muscle pain, depression, insomnia, anorexia *Toxicity:* None	—	*Deficiency:* • Good sources of biotin are egg yolks, vegetables, yeast, milk, grains
Folate (Folic Acid) RDA: 400 mcg EAR: 320 mcg water soluble	• RBC formation • DNA and RNA synthesis and support of cell growth and reproduction • Prevention of birth defects	*Deficiency:* Glossitis, diarrhea, megaloblastic anemia, digestive problems, fatigue, palpitations, restless leg syndrome *Toxicity:* Inactivation of anticonvulsants, masking of vitamin B_{12} deficiency	*Deficiency:* • Serum level <3 ng/mL	*Deficiency:* • Nutritional supplementation: 1 mg/day PO • Avoid alcohol • Good sources of folate are citrus fruits, eggs, milk, green leafy vegetables, dairy products, organ meats, seafood, whole grains, yeast
Niacin RDA: 14–16 mg EAR: 11–12 mg water soluble	• Metabolism of carbohydrates, fats, and proteins • Works with thiamine and riboflavin for the production of cellular energy • Promotes skin, neurologic, and GI function	*Deficiency:* Apathy, fatigue, appetite loss, headaches, indigestion, muscle weakness, nausea, insomnia, dermatitis, diarrhea, confusion, disorientation, memory impairment, glossitis, stomatitis, pellagra *Toxicity:* Liver damage, flushing	*Deficiency:* • Serum levels <30 mcg/100 mL • Diminished or absent metabolites in urine	*Deficiency:* • Good sources of niacin are eggs, lean meats, organ meats, poultry, seafood, fish, dairy products, nuts, whole and enriched grains, brewer's yeast • Nutritional supplementation: 10 to 150 mg • Supplemental niacin may also be necessary when taking oral contraceptives
Pantothenic Acid RDA: 5 mg EAR: Not established water soluble	• Vital for overall metabolism • Aids in formation of carbohydrates, proteins, and fats • Aids in cortisone production, ATP production, stress tolerance, vitamin utilization, hemoglobin synthesis	*Deficiency:* Diarrhea, hair loss, respiratory infections, nervousness, muscle cramps, premature aging, intestinal disorders, eczema, kidney disorders *Toxicity:* None	—	*Deficiency:* • This vitamin is widely available in foods, especially organ meats, legumes, vegetables, fruits
Vitamin C RDA: 75–90 mg EAR: 60–75 mg water soluble	• Antioxidant action decreases cellular dysfunction • Promotes wound healing • Aids in connective tissue, bone, tooth, and cartilage formation • Promotes capillary integrity • Promotes nonheme iron absorption	*Deficiency:* Bleeding gums, tooth decay, hemarthrosis, low infection resistance, bruising, anemia, delayed wound healing, anorexia, joint pain, lethargy, perifollicular hemorrhage *Toxicity:* GI distress	*Deficiency:* • Serum levels <0.2 mg/100 dL	*Deficiency:* • Nutritional supplementation: 100 to 1,000 mg/day of vitamin C • Good sources of vitamin C are citrus fruits, green leafy vegetables, broccoli, tomatoes, peppers, potatoes, strawberries • Avoid smoking
Vitamin D RDA: 15 mcg EAR: 10 mcg fat soluble	• Regulates calcium and phosphate absorption and metabolism and bone formation • Aids in renal phosphate clearance, myocardial function, nervous system maintenance, and normal blood clotting	*Deficiency:* Rickets, osteomalacia, weakness, spasm/twitching of eyes, burning in mouth, sweating *Toxicity:* Hypercalcemia, bone pain, nausea, vomiting, itching, thirst, agitation, weakness. Calcifications in soft tissue can be fatal	*Deficiency:* • Low levels of vitamin D (serum 25 [OH] D) • Radiographic bone deformities • Abnormal bone densitometry	*Deficiency:* • Nutritional supplementation: ergocalciferol, 25 mcg/day PO • Good sources of vitamin D are egg yolks, yeast, enriched milk, fish liver oils • Exposure to sunlight
Vitamin E (Tocopherol) RDA: 15 mg EAR: 12 mg fat soluble	• Antioxidant action decreases cellular dysfunction • Aids in RBC formation	*Deficiency:* Neuromuscular disturbances, including decreased reflexes, vibratory and position sense, ataxia, night blindness, fatigue, leg weakness or cramps, dry skin *Toxicity:* Interference with vitamin K	*Deficiency:* • Serum levels <0.5 mg/dL	*Deficiency:* • Nutritional supplementation: 100 to 400 international units/day PO • Parenteral therapy may be necessary to treat neurologic symptoms • Good sources of vitamin E are vegetable oils, milk, eggs, meat, fish, green leafy vegetables
Vitamin K RDA: 90–120 mcg EAR: Not established fat soluble	• Promotes coagulation through the formation of prothrombin and other clotting factors	*Deficiency:* Abnormal bleeding times, hemorrhage, epistaxis, hematemesis, and bleeding at any orifice or puncture site are possible *Toxicity:* No tolerable upper limit has been established	*Deficiency:* • Prothrombin time extended longer than PTT	*Deficiency:* • Administration of vitamin K 15 mg subcutaneously • Good sources of vitamin K are green leafy vegetables, liver, wheat germ, cheeses, egg yolks, soybean oil
Minerals				
Calcium AI: 1,000–1,200 mg EAR: 800–1,000 mg	• Aids in bone and tooth formation, muscle contraction, blood coagulation, nerve impulse transmission, cardiac function, cell membrane permeability, enzyme activation	*Deficiency:* Tooth decay, muscle cramps, tetany, nervousness and delusion, cardiac palpitations, heart failure, and paresthesias *Toxicity:* Constipation, loss of appetite, nausea, vomiting, dry mouth, renal calculi	*Deficiency:* • Dual-energy x-ray absorptiometry (DEXA) for bone mineral density *Toxicity:* • Serum level >10.5 mg/dL	*Deficiency:* • Oral supplements of 1 to 2 g/day of elemental calcium • In severe hypocalcemia, 10 mL of 10% calcium gluconate IV administered no faster than 2 mL/min • Good sources of calcium are milk products, green leafy vegetables, legumes, tofu processed with calcium *Toxicity:* • Force fluids, diuretics, and limit dietary intake; administration of phosphate salts and glucocorticoids may also be necessary
Chloride AI: 2,000–2,300 mg	• Helps keep the body's acid–base balance • Helps with metabolism	*Deficiency:* Extremely rare but can cause loss of appetite, weakness, and lethargy *Toxicity:* May result in fluid retention	*Deficiency:* • Serum levels <98 *Toxicity:* • Serum levels >108	• No specific treatment.
Chromium AI: 20–35 mcg EAR: Not established	• Maintains serum glucose levels • Maintains fat metabolism	*Deficiency:* Glucose intolerance, vertigo, abdominal pain, shock, convulsions, ataxia, dermatitis *Toxicity:* Unknown	*Deficiency:* • Serum levels <0.3 mg/mL	*Deficiency:* • Nutritional supplementation: 50 to 200 mg/day • Good sources of chromium are brewer's yeast, whole grains, cereals
Copper RDA: 900 mcg EAR: 700 mcg	• Hemoglobin synthesis • Maintenance of hemostasis • Energy production	*Deficiency:* Hypochromic anemia, bone disease, weakness, skin lesions, altered respiratory status *Toxicity:* Nausea, vomiting, diarrhea, abdominal pain, malaise	*Deficiency:* • In addition to diminished serum levels, 24-hour urine samples showing levels of urinary excretion of copper below 15 to 60 mcg/24 hr	*Deficiency:* • Nutritional supplementation: 0.1 mg/kg/day PO • IV supplementation: 1 to 2 mg/day • Good sources of copper are nuts, seeds, organ meats, seafood
Iodine RDA: 150 mcg EAR: 95 mcg	• Thyroid hormone synthesis	*Deficiency:* Hypothyroidism or goiter, nervousness, irritability, obesity, cold hands and feet, chills, brittle hair, fatigue, bradycardia, decreased cardiac output, thick tongue, hoarseness, poor memory, hearing loss, anorexia *Toxicity:* Goiter	*Deficiency:* • Low T_3 and T_4 levels • Thyroid scan	*Deficiency:* • Nutritional supplementation: 50 to 100 mg daily PO • Good sources of iodine are iodized salt, seafood
Iron RDA: 8–18 mg EAR: 5–8.1 mg	• Hemoglobin synthesis • Cellular oxidation • Transportation of oxygen	*Deficiency:* Iron deficiency anemia, fatigue, tachycardia, palpitations, dyspnea, susceptibility to infection, brittle nails *Toxicity:* Iron poisoning; nausea, vomiting, gastrointestinal irritation, constipation, diarrhea	*Deficiency:* • Decreased hemoglobin, hematocrit, iron, and ferritin levels and increased total iron-binding capacity	*Deficiency:* • Nutritional supplementation: ferrous sulfate 325 mg PO tid; Imferon 250 mg/day IM for each gram of hemoglobin below normal • IV supplementation: 1.5 to 2 g over 4 to 6 hr • Good sources of iron are egg yolks, fish, organ meats, wheat germ, beef, peas, chicken, turkey, legumes, spinach
Magnesium RDA: 310–420 mg EAR: 265–350 mg	• Parathyroid hormone regulation • Acid–base balance • Enzyme activation • Smooth muscle regulation • Metabolism of carbohydrates and protein • Cell growth and reproduction	*Deficiency:* Tetany, tremors, confusion, depression, tachycardia, dysrhythmias, seizures *Toxicity:* Nausea, vomiting, drowsiness, muscle weakness, decreased deep tendon reflexes, hypotension, respiratory depression	*Deficiency:* • Serum levels <1.3 mEq/L *Toxicity:* • Serum levels >2.1 mEq/L	*Deficiency:* • Nutritional supplementation: 1 to 2 g IV during 15 min • Good sources of magnesium are nuts, meat, whole grains, green vegetables, seafood, dairy products *Toxicity:* • Supportive measures
Phosphorus RDA: 700 mg EAR: 580 mg	• Nerve and muscle activity • Vitamin utilization • Kidney function • Metabolism of carbohydrates, proteins, and fats • Cell growth and repair • Myocardial contraction • Energy production • Bone and tooth formation • Acid–base balance • Red blood cell function	*Deficiency:* Anorexia, weakness, tremor, paresthesias, anemia, mental status change, hypoxia, osteomalacia *Toxicity:* Tetany, soft tissue calcification, seizures, renal damage	*Deficiency:* • Serum levels <2.5 mg/dL *Toxicity:* • Serum levels >4.5 mg/dL	*Deficiency:* • Nutritional supplementation: PO or IV phosphate • Good sources of phosphate are dairy products, eggs, fish, grains, meat, poultry, cheeses, beans, cocoa, chocolate, liver, milk, peas, nuts *Toxicity:* • Administration of phosphate-binding agents • Hemodialysis or peritoneal dialysis
Potassium AI: 4,700 mg	• Muscle contraction • Cardiac function • Protein synthesis • Nerve impulse transmission • Carbohydrate metabolism • Acid–base balance • Major intracellular cation	*Deficiency:* Muscle weakness, fatigue, malaise, flaccidity, mental confusion, irritability, depression, dysrhythmias, hypotension, nausea, vomiting, anorexia, decreased GI motility, muscle cramps, paresthesias, hyperglycemia, polyuria, metabolic alkalosis *Toxicity:* Muscle weakness, paralysis, paresthesias, nausea, vomiting, diarrhea, metabolic acidosis, prolonged cardiac conduction, ventricular dysrhythmias	*Deficiency:* • Serum levels <3.5 mEq/L *Toxicity:* • Serum levels >5 mEq/L	*Deficiency:* • Nutritional supplementation: PO or IV; IV replacement generally at a rate of 10 mEq/hr with careful cardiac monitoring and frequent measurements of serum potassium levels • Good sources of potassium are bananas, oranges, beef, prunes, beans, seafood, raisins *Toxicity:* • Infuse calcium gluconate 10% (10 mL) • Sodium bicarbonate infusion • Insulin and glucose infusion • Oral or rectal exchange resins • Hemodialysis or peritoneal dialysis
Sodium AI: 1,300–1,500 mg	• Maintains fluid balance • Cell membrane permeability and absorption of glucose • Bioelectric potential of tissues • Cardiac function • Acid–base balance • Regulation of neuromuscular function	*Deficiency:* Muscle weakness, irritability, headache, seizures, nausea, vomiting, malaise, abdominal cramping, hypotension, tachycardia *Toxicity:* Flushed skin, oliguria, agitation, thirst, dry mucous membranes, seizures	*Deficiency:* • Serum levels <135 mEq/L *Toxicity:* • Serum levels >145 mEq/L	*Deficiency:* • Restrict free water intake • Infuse 0.9% saline solution if the patient is hypovolemic • Infuse 3% saline and administer diuretic if sodium levels significantly low • Demeclocycline may be used to block ADH in the renal tubules to promote water excretion *Toxicity:* • Administer salt-free solutions such as D5W followed by 0.45% saline solution • Low-sodium diet • Administer vasopressin if diminished ADH is the cause
Zinc RDA: 8–11 mg EAR: 6.8–9.4 mg	• Cellular metabolism • Maintenance of taste and smell • Burn and wound healing • Gonadal function • Maintenance of serum vitamin A concentration • Acid–base balance • Protein digestion • Promotion of growth	*Deficiency:* Fatigue, hair loss, poor wound healing, impaired growth, bone deformities, loss of taste, anorexia, iron deficiency anemia, hypogonadism, hyperpigmentation *Toxicity:* Diminished deep tendon reflexes, malaise, decreased level of consciousness, diarrhea, leukopenia	*Deficiency:* • Serum levels <75 mcg/dL	*Deficiency:* • Nutritional supplementation: zinc sulfate 200 mg PO tid • Good sources of zinc are liver, seafood, beans, lentils, oatmeal, wheat bran, egg yolks, peas, chicken, and milk *Toxicity:* • Supportive measures

ADH, antidiuretic hormone; AI, adequate intake; ATP, adenosine triphosphate; DRI, dietary reference intake; EAR, estimated average requirement; IM, intramuscular; IV, intravenous; MCV, mean corpuscular volume; PO, by mouth; PTT, partial thromboplastin time; RBC, red blood cell; RDA, recommended daily allowance; tid, three times per day.

Dietary reference intake tables have been developed by the Food and Nutrition Board at the Institute of Medicine of the National Academies and include the following:

Recommended dietary allowance—the average daily dietary intake level sufficient to meet the nutrient requirements of nearly all (97% to 98%) healthy individuals in a group.

Adequate intake—amount believed to cover the needs of all healthy individuals in the groups, but lack of data or uncertainty in the data prevents being able to specify with confidence the percentage of individuals covered by this intake.

Estimated average requirement—average daily nutrient intake level estimated to meet the requirements of half of the healthy individuals in a group.

OVERVIEW AND ASSESSMENT

See additional online content: Procedure Guidelines 21-1

PROCEDURE GUIDELINES 21-1

Technique for Obtaining Clean-Catch Midstream Voided Specimen

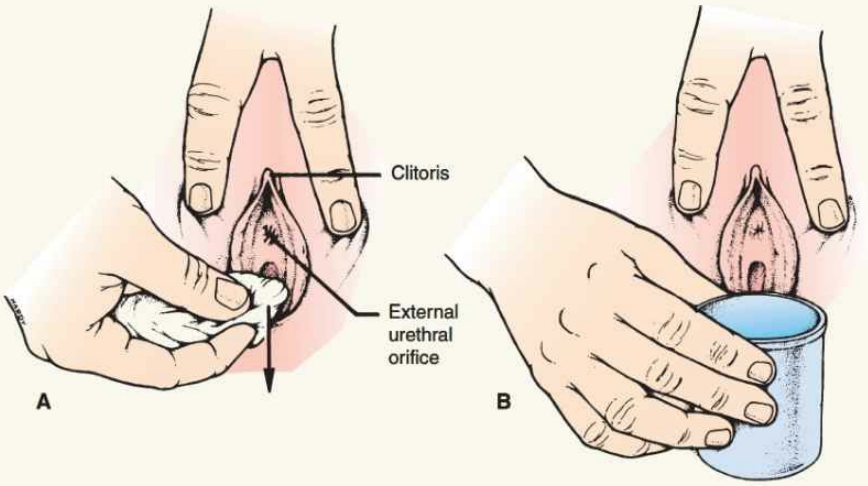
A clean-catch midstream specimen is the most clinically effective method of securing a voided specimen for urinalysis. Because
it is not a simple procedure, it requires thorough patient education as well as active assistance of the female patient.

EQUIPMENT

- Antiseptic solution or liquid soap solution
- Sterile water
- 4″Ã— 4″ gauze pads
- Disposable gloves for nurse assisting female patient
- Sterile specimen container

PROCEDURE

Nursing Action	Rationale
Male patient	
1. Instruct the patient to expose the glans and cleanse the area around the meatus. Wash the area with mild antiseptic solution or liquid soap. Rinse thoroughly. If uncircumcised, retract foreskin.	1. The urethral orifice is colonized by bacteria. Urine readily becomes contaminated during voiding. Rinse antiseptic solution or soap solution thoroughly because these agents can inhibit bacterial growth in a urine culture.
2. Allow the initial urinary flow to escape.	2. The first portion of urine washes out the urethra and contains debris.
3. Collect the midstream urine specimen in a sterile container.	3. The midstream sample reflects the status of the bladder.
4. Avoid collecting the last few drops of urine.	4. Prostatic secretions may be introduced into urine at the end of the urinary stream in men.
Female patient	



Obtaining a clean-catch midstream urine specimen in the female patient. **(A)** *Instruct the patient to hold the labia apart and wash from high up front toward the back with gauze soaked in soap.* **(B)** *The collection cup is held so that it does not touch the body, and the sample is obtained only while the patient is voiding with the labia held apart. Note: If the nurse is assisting the patient, gloves are worn.*

1. Ask the patient to separate her labia to expose the urethral orifice. If no one is available to assist patient, she may sit backward on the toilet seat facing the water tank or sit on (straddle) the wide part of the bedpan.	1. Keeping the labia separated prevents labial or vaginal contamination of the urine specimen. By straddling the toilet seat or bedpan, patient's labia are spread apart for cleansing.
2. Clean the area around the urinary meatus with pads soaked with antiseptic/soap solution. Rinse thoroughly.	2. The urethral orifice is colonized by bacteria. Urine readily becomes contaminated during voiding. a. Avoids contamination from the anus.

Nursing Action	Rationale
3. While the patient keeps the labia separated (see accompanying figure), instruct her to void forcibly.	3. Helps wash away urethral contaminants.
4. Allow initial urinary flow to drain into bedpan (toilet) and then catch the midstream specimen in a sterile container, making sure that the container does not come in contact with the genitalia.	4. The first portion of urine washes out the urethra. Have the patient remove the container from the stream while she is still voiding.
Follow-up phase	
1. Send specimen to laboratory immediately.	1. A culture should be performed as soon as possible to avoid multiplication of urinary bacteria and lysis of cells.

Subjective Data

Subjective data include characterization of symptoms, history of present illness, past medical and surgical history, demographic data, and lifestyle factors. Signs and symptoms involving the urinary tract may be due to disorders of the kidneys, ureters, or bladder; surrounding structures; or disorders of other body systems. See Standards of Care Guidelines 21-1.

STANDARDS OF CARE GUIDELINES 21-1

Renal Impairment

- Be aware that systemic factors, urologic status, and renal function affect urine output. Notify health care provider of decreased urine output.
- Patients at risk for renal impairment include those with cardiovascular disease, diabetes, and hypertension; postoperative patients; hypotensive patients; and those with prostate and other diseases of the urinary tract.
- Thorough assessment of the urinary tract includes:
  - Hourly intake and output measurement.
  - Assessment of color, clarity, and specific gravity of the urine.
  - Palpation of the abdomen for suprapubic tenderness.
  - Percussion of the flanks for costovertebral angle tenderness.
  - Prostate examination.
  - Subjective assessment for symptoms, such as urgency, frequency, nocturia, hesitancy, dribbling, decreased force of stream, hematuria, and incontinence.
- Be alert to drugs or agents that may impair urinary and renal function, such as nonsteroidal anti-inflammatory drugs, anticholinergics, sympathomimetics, aminoglycoside antibiotics, antifungals, calcineurin inhibitors, angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, chemotherapeutic agents, and contrast media.
- Report abnormal urinalysis, urine culture, and renal function test results to health care provider promptly.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Changes in Micturition (Voiding)

Changes in the Amount or Color of Urine

1. Hematuria—blood in the urine, may be gross (visible by color change) or microscopic.
   a. Considered a serious sign and requires evaluation.
   b. Color of bloody urine depends on several factors including the amount of blood present and the anatomical source of the bleeding.
   c. Microscopic hematuria is the presence of red blood cells (RBCs) in urine, which can be seen only

under a microscope; urine appears normal.

   d. Hematuria may be due to a systemic cause, such as blood dyscrasias, anticoagulant therapy, or extreme exercise.
   e. Painless hematuria may indicate neoplasm in the urinary tract.
   f. Hematuria is common in patients with urinary tract stone disease, malignancy, acute infection, glomerulonephritis, trauma to the kidneys or urinary tract, thrombosis and embolism involving renal artery or vein, and polycystic kidney disease.

2. Polyuria—large volume of urine voided in a given time.
   a. Volume is out of proportion to usual voiding pattern and fluid intake.
   b. Demonstrated in diabetes mellitus, diabetes insipidus, chronic renal disease, use of diuretics.
3. Oliguria—small volume of urine.
   a. Output between 50 and 500 mL/24 hours.
   b. May result from acute renal failure, CKD stage V, shock, dehydration, fluid and electrolyte imbalance, or obstruction.
4. Anuria—absence of urine output.
   a. Output less than 50 mL/24 hours.
   b. Indicates serious renal dysfunction requiring immediate medical or surgical intervention, or CKD stage V.

Symptoms Related to Irritation of the Lower Urinary Tract

1. Dysuria—painful or uncomfortable urination.
   a. Burning sensation seen in a wide variety of inflammatory and infectious urinary tract conditions.
2. Frequency—voiding occurs more frequently than usual when compared with patient's usual pattern or with a generally accepted norm of once every 3 to 6 hours.
   a. Determine if habits governing fluid intake have been altered—it is essential to know normal voiding pattern to evaluate frequency.
   b. Increasing frequency can result from a variety of conditions, such as infection and diseases of the urinary tract, metabolic disease, hypertension, medications (diuretics).
3. Urgency—strong desire to urinate that is difficult to postpone.
   a. Because of inflammatory conditions of the bladder, prostate, or urethra; acute or chronic bacterial infections; neurogenic voiding dysfunctions; chronic prostatitis or bladder outlet obstruction in men; overactive bladder; and urogenital atrophy in postmenopausal women.
4. Nocturia—urination at night that interrupts sleep.
   a. Causes include urologic conditions affecting bladder function, poor bladder emptying, bladder outlet obstruction, or overactive bladder.
   b. Metabolic causes include decreased renal concentrating ability or heart failure, hyperglycemia, and remobilization of dependent edema.

5. Strangury—slow and painful urination; only small amounts of urine voided. Wrenching sensation at end of urination produced by spasmodic muscular contraction of the urethra and bladder.
   a. Blood staining may be noted.
   b. Seen in numerous urological conditions, including severe cystitis, interstitial cystitis, urinary calculus, and bladder cancer.

Symptoms Related to Obstruction of the Lower Urinary Tract

1. Weak stream—decreased force of stream when compared to usual stream of urine when voiding.
2. Hesitancy—undue delay and difficulty in initiating voiding.
   a. May indicate compression of the urethra, outlet obstruction, neurogenic bladder.
3. Terminal dribbling—prolonged dribbling or urine from the meatus after urination is complete. May be caused by bladder outlet obstruction.
4. Incomplete emptying—feeling that the bladder is still full even after urination. Indicates urinary retention, overactive bladder, or a condition that prevents the bladder from emptying well; may lead to infection.
5. Urinary retention—inability to void.

Involuntary Voiding

1. Urinary incontinence—involuntary loss of urine; may be due to pathologic, anatomical, or physiologic factors affecting the urinary tract (see page 148).
2. Nocturnal enuresis—involuntary voiding during sleep. May be physiologic during early childhood; thereafter, may be functional or symptomatic of obstructive or neurogenic disease (usually of the lower urinary tract) or dysfunctional voiding.

Urinary Tract Pain

1. Kidney pain—may be felt as a dull ache in costovertebral angle or may be a sharp, colicky pain felt in the flank area that radiates to the groin or testicle. Because of distention of the renal capsule; severity related to how quickly it develops.
2. Ureteral pain—felt in the back and/or abdomen and can radiate to the groin, urethra, penis, scrotum, or testicle.
3. Bladder pain (lower abdominal pain or pain over suprapubic area)—may be due to bladder infection, overdistended bladder, or bladder spasms.
4. Urethral pain—from irritation of the bladder neck, from foreign body in canal, or from urethritis because of infection or trauma; pain increases when voiding.
5. Pain in scrotal area—because of inflammatory swelling of the epididymis or testicle, torsion of the testicle, testicular mass, or scrotal infection. May also be referred pain from neurological, renal, or gastrointestinal (GI) source.
6. Testicular pain—because of injury, mumps, orchitis, torsion of the spermatic cord, testes, or testes appendix.

7. Perineal or rectal discomfort—because of acute or chronic prostatitis, prostatic abscess, or trauma.
8. Pain in glans penis—usually from prostatitis; penile shaft pain results from urethral problems; may also be referred pain from ureteral calculus.

Related Symptoms

1. GI symptoms related to urologic conditions include nausea, vomiting, diarrhea, abdominal discomfort, paralytic ileus.
2. Occur with urologic conditions because the GI and urinary tracts have common autonomic and sensory innervation and because of renointestinal reflexes.
3. Fever and chills may also occur with infectious processes.

History

Seek the following historical data related to urinary and renal function:

1. What are patient's present and past occupations? Look for occupational hazards related to the urinary tract—contact with chemicals, plastics, tar, rubber; also truck or school bus drivers, dry cleaners, farmers.
2. What is patient's smoking history?
3. What is the past medical and surgical history, especially in relation to urinary problem?
4. Is there any family history of renal disease?
5. What childhood diseases did patient have?
6. Is there a history of urinary tract infections (UTIs)? Did any occur before age 12?
7. Did enuresis continue beyond the age when most children gain control?
8. Any history of genital lesions or sexually transmitted diseases (STDs)?
9. For the female patient: Number of children? Vaginal or cesarean delivery? Any forceps deliveries? When? Any signs of vaginal discharge? Vaginal/vulvar itch or irritation? Family history of pelvic organ prolapse ("dropped" bladder or uterus) or urinary incontinence?
10. Does patient have diabetes mellitus? Hypertension? Allergies? Neurologic disease or dysfunction? Vascular disease?
11. Has patient ever been hospitalized for a UTI? What diagnostic tests were performed? Cystoscopy? Urodynamics? Kidney x-ray procedures? Was patient catheterized for a time? Were antibiotics administered via intravenous (IV) or oral route?
12. Has patient ever had surgery for bladder or prostate problems or traumatic injuries involving the pelvis?
13. Is patient taking any prescription or over-the-counter (OTC) drugs or herbal preparations that may affect renal or urinary function? Have any drugs been prescribed for renal or urinary problems?
14. Is patient at risk for UTI?

Objective Data

Objective data should focus on physical examination of the abdomen, the genitalia, and rectal exam in some cases. Complete body system assessment may be indicated in some conditions such as renal failure. See Chapter 5 .

Laboratory Tests

Common laboratory studies pertaining to renal and urologic disorders include blood and urinary excretion tests for renal function, prostate-specific antigen, and urinalysis.

Tests of Renal Function

Description

1. Renal function tests are used to determine effectiveness of the kidneys' excretory functioning, to evaluate the severity of kidney disease, and to follow patient's progress.
2. There is no single test of renal function; rather, optimal results are obtained by combining a number of clinical tests.

Nursing and Patient Care Considerations

Renal function may be within normal limits until about 50% of renal function has been lost (see Table 21-1).

Table 21-1 Tests of Renal Function

There is no single test of renal function because this function is subject to variation. The rate of change of renal function is more important than the result of a single test.

TEST	PURPOSE/RATIONALE	TEST PROTOCOL
Renal concentration test • Specific gravity • Osmolality of urine	• Both tests evaluate the ability of the kidney to dilute or concentrate urine. • Values are elevated in prerenal states, including dehydration. Concentration ability is lost (resulting in low values) in CKD and some types of AKI despite changes in volume status.	• Fluids may be withheld 12 to 24 hours to evaluate the concentrating ability of the tubules under controlled conditions. Specific gravity measurements of urine are taken at specific times to determine urine concentration.
Creatinine clearance	• Provides a reasonable approximation of rate of glomerular filtration. • Measures volume of blood in mL cleared of creatinine in 1 min. • Most sensitive indication of early renal disease.	• Collect all urine over 24-hour period. • Draw one sample of blood within the period.
Serum creatinine	• A test of renal function reflecting the balance between production and filtration by renal glomerulus. • Most sensitive test of renal function.	• Obtain sample of blood serum.
Serum urea nitrogen (blood urea nitrogen [BUN])	• Serves as index of renal excretory capacity. • Serum urea nitrogen depends on the body's urea production and on urine flow. (Urea is the nitrogenous end product of protein metabolism.) • Affected by protein intake, hydration status, and catabolism.	• Obtain sample of blood serum.
Protein	• Random specimen may be affected by dietary protein intake. Proteinuria >300 mg/24 hours may indicate renal disease.	• Collect all urine over 24-hour period.
Microalbumin/creatinine ratio	• Sensitive test for the subsequent development of proteinuria; >25 mg/g for females and >17 mg/g for males predicts early nephropathy.	• Collect random urine specimen.
Urine casts	• Mucoproteins and other substances present in renal inflammation; help to identify type of renal disease (eg, red cell casts present in glomerulonephritis, fatty casts in nephrotic syndrome, white cell casts in pyelonephritis).	• Collect random urine specimen.

There is no single test of renal function because this function is subject to variation. The rate of change of renal function is more important than the result of a single test.

Prostate-Specific Antigen

Description

1. Prostate-specific antigen (PSA) is an amino acid glycoprotein that is measured in the serum by a simple blood test.
2. An elevated PSA indicates the presence of prostate disease but is not exclusive to prostate cancer.
3. Level rises continuously with the growth of prostate cancer.
4. Normal serum PSA level is less than 4 ng/mL.
5. Patients who have undergone surgical treatment for prostate cancer are monitored every 6 to 12 months with PSA levels for recurrence. Cancer recurrence is suspected with PSA greater than 0.2 ng/mL on two occasions (test is repeated for possible lab error).

Nursing and Patient Care Considerations

1. No patient preparation is necessary.
2. Current or recent UTI, prostatitis, digital rectal exam, or urethral instrumentation can cause an artificial elevation of PSA.
3. Clinical laboratories may differ slightly in methods used for determining PSA; patients having serial PSA should be sent to the same laboratory.

Urinalysis

Description

Involves examination of the urine for overall characteristics, including appearance, pH, specific gravity, and osmolality as well as microscopic evaluation for the presence of normal and abnormal cells.

1. Appearance—normal urine is clear. Foamy urine can be seen with proteinuria. Cloudy urine may or may not be pathologic.
    a. Nonpathologic causes: normal urine may develop cloudiness on refrigeration, from standing at room temperature, or from precipitation of phosphates in alkaline urine (phosphaturia).
    b. Pathologic causes: because of pus (pyuria), blood, epithelial cells, bacteria, fat, colloidal particles, phosphate, or lymph fluid (chyluria).
2. Odor—normal urine has a faint aromatic odor.
    a. Characteristic odors produced by ingestion of asparagus.
    b. Cloudy urine with ammonia odor: urea-splitting bacteria such as *Proteus*, causing UTIs.
    c. Offensive odor: may be due to bacterial action in the presence of pus.
    d. Acetone scent can be detected in diabetic ketoacidosis.
3. Color—varies with urine concentration and is affected by metabolites, medications, and certain foods.
    a. Normal urine is clear yellow or amber because of the pigment urochrome.
    b. Dilute urine is pale yellow or clear.
    c. Concentrated urine is tea-colored and may be a sign of insufficient fluid intake.
    d. Blue, blue-green: medication, namely amitriptyline, propofol, indomethacin, and methenamine;

pseudomonas infection.

e. Red or red-brown: because of blood pigments, porphyria, bleeding lesions in urogenital tract, some drugs such as phenazopyridine and foods (beets).

f. Yellow-brown, green-brown, or tea colored: may reveal obstructive lesion of bile duct system, obstructive jaundice, or hepatitis.

g. Dark brown or black: because of malignant melanoma, leukemia, methemoglobin or medications, namely methyldopa, levodopa.

4. pH of urine—reflects the ability of the kidney to maintain normal hydrogen ion concentration in plasma and extracellular fluid; indicates *acidity* or *alkalinity* of urine.

   a. pH should be measured in fresh urine because the breakdown of urine to ammonia causes urine to become alkaline.

   b. Normal pH is 4.5 to 8.0.

   c. Urine acidity (pH less than 4.5) or alkalinity (pH greater than 8.0) has relatively little clinical significance unless the patient is being treated for renal calculus disease or being evaluated for renal tubular acidosis.

5. Specific gravity (SG)—reflects the kidney's ability to concentrate or dilute urine; may reflect degree of hydration or dehydration.

   a. Normal specific gravity ranges from 1.005 to 1.030.

   b. Specific gravity is low and matches the specific gravity of plasma at 1.010 (isosthenuria) in late stages of chronic kidney disease (CKD).

   c. Volume depletion will cause the SG to be elevated, and volume overload will result in a low SG.

6. Osmolality—indication of the amount of osmotically active particles in urine (number of particles per unit volume of water). It is similar to specific gravity but is considered a more precise test and only 1 to 2 mL of urine are required. Osmolality can range from 50 to 1200 mOsm/kg.

Nursing and Patient Care Considerations

1. Freshly voided urine provides the best results for routine urinalysis; some tests may require a first morning specimen.
2. The urine should be refrigerated to ensure accurate results if urine sample cannot be delivered to lab immediately.
3. Obtain sample of about 30 mL.
4. Urine culture and sensitivity tests are typically performed using the same specimen obtained for urinalysis; therefore, use clean-catch or catheterization technique.
5. Patients with urinary diversions, especially ileal conduit diversions, require catheterized urine specimen. The urinalysis will normally demonstrate bacteria if the specimen is collected from intestinal diversion.

Radiology and Imaging Studies

These tests include simple x-rays, x-rays with the use of contrast media, ultrasound, nuclear scans, and imaging via computed tomography (CT) and magnetic resonance imaging (MRI). Patient age and pregnancy status help dictate imaging choice.

EVIDENCE BASE McCarthy, C., Baliyan, V., Kordbacheh, H., et al. (2016). Radiology of renal stone disease. *International Journal of Surgery, 36*, 638–646.

X-Ray of Kidneys, Ureters, and Bladder

Description

1. Consists of plain film of the abdomen.
2. Delineates size, shape, and position of the kidneys.
3. Reveals deviations, such as radiopaque calcifications (stones), tumors, or kidney displacement.
4. Not reliable as sole imaging modality to diagnose stones as it will not show radiolucent stones.

Nursing and Patient Care Considerations

1. No preparation is needed.
2. Usually done before other testing.
3. Patient will be asked to wear a gown and remove all metal from the x-ray field.

Pyelogram

Description

1. Antegrade pyelogram: Injection of small amount of radiopaque contrast directly into the renal pelvis, usually via an existing nephrostomy tube.
2. Retrograde pyelogram: Injection of radiopaque contrast material through ureteral catheters, which have been passed into ureters by means of cystoscopic manipulation.
3. The radiopaque solution is introduced by syringe injection. May require sedation.
4. Mostly used to determine location and severity of an obstruction in the urinary system.
5. Used in place of previously used intravenous pyelogram (IVP) for visualization of the collecting system.

Nursing and Patient Care Considerations

1. Contraindicated in patients with UTI.
2. May require sedation.
3. Allergic reactions are rare as only a small amount of dye is absorbed into the body.

Cystourethrogram

Description

1. Visualization of the urethra and bladder by x-ray after retrograde instillation of contrast material through a catheter. An examination of only the bladder is a *cystogram* and of only the urethra is a *urethrogram*.
2. Used to identify injuries, vesicoureteral reflux, tumors, or structural abnormalities of the urethra or bladder or to evaluate emptying problems or incontinence (voiding cystourethrogram).

Nursing and Patient Care Considerations

1. Carries risk of infection because of instrumentation.
2. Allergy to contrast material is a contraindication.
3. Additional x-rays may be taken after the catheter is removed and patient voids (voiding cystourethrogram).
4. Provide reassurance to allay patient's embarrassment.

Renal Angiography

Description

1. IV catheter is threaded through the femoral and iliac arteries into the aorta or renal artery.
2. Contrast material is injected to visualize the renal arterial supply.
3. Evaluates blood flow dynamics, demonstrates abnormal vasculature, and differentiates renal cysts from renal tumors.
4. May be done prior to renal transplant or to embolize a kidney before nephrectomy for renal tumor.

Nursing and Patient Care Considerations

1. NPO after midnight before the examination; clear liquids permitted up to 2 hours before exam. Adequate hydration is essential.
2. Continue oral medications (special orders needed for diabetic patients).
3. IV access required.
4. May not be done on the same day as other studies requiring barium or contrast material.
5. Maintain bed rest for approximately 4 hours after the examination, with the leg kept straight on the side used for groin access.
6. Observe frequently for hematoma or bleeding at access site. Keep sandbag at bedside for use if bleeding occurs.

Renal Scan

Description

1. Radiopharmaceuticals (also called radiotracers or isotopes) are injected intravenously.
    a. Tc-DTPA, Tc^{99m}-DMSA is used for anatomical or MAG3 visualization and evaluation of

glomerular filtration.

b. Other radiopharmaceuticals may also be used depending on the purpose of the scan.

2. Assesses renal function and not used to assess for renal anatomy, mass, or stones.
3. Studies are obtained with a scintillation camera placed posterior to the kidney with patient in a supine, prone, or sitting position.

Nursing and Patient Care Considerations

1. Patient should be well hydrated. Give several glasses of water or IV fluids, as ordered, before scan.
2. Furosemide or captopril may be administered in conjunction with the scan to determine their effects.

Ultrasound

Description

1. Uses high-frequency sound waves passed into the body and reflected back in varying frequencies based on the composition of soft tissues. Organs in the urinary system create characteristic ultrasonic images that are electronically processed and displayed as an image.
2. Abnormalities, such as masses, malformations, stones, or obstructions, can be identified; useful in differentiating between solid and fluid-filled masses.
3. A noninvasive technique without the use of radiation.

Nursing and Patient Care Considerations

1. Ultrasound examination of the prostate is performed using a rectal probe. A laxative or enema may be ordered to be given within hours of the examination.
2. Ultrasound examination of the bladder requires that the bladder be full.
3. Patient should not have had any studies using barium for 2 days before ultrasound of the kidney or bladder.

Computed Tomography and Magnetic Resonance Imaging

CT urogram has replaced IVP and is now the radiographic modality of choice to visualize the kidneys, ureter, and bladder. Noncontrast CT known as “stone survey” is the preferred method for evaluating urolithiasis. MRI may be ordered to evaluate for tumors.

See descriptions on page 166.

Other Tests

Other tests that may be done to evaluate disorders of the renal and urologic systems include cystoscopy, urodynamic testing, and needle biopsy of the kidney.

Cystoscopy

Description

1. *Cystoscopy* is a method of direct visualization of the urethra and bladder by means of a cystoscope that is inserted through the urethra into the bladder. It has a self-contained optical lens system that provides a magnified, illuminated view of the bladder.
2. Uses include:
   a. To inspect the bladder wall directly for tumor, stone, or ulcer and to inspect the urethra for abnormalities or to assess degree of prostatic obstruction.
   b. To allow insertion of ureteral catheters for radiographic studies or before abdominal or GU surgery.
   c. To see configuration and position of ureteral orifices.
   d. To remove calculi from the urethra, bladder, and ureter.
   e. To diagnose and treat lesions of the bladder, urethra, and prostate.
   f. To perform endoscopic prostate surgeries including transurethral resection of the prostate (TURP) (see page 601).

Nursing and Patient Care Considerations

1. Simple cystoscopy is usually performed in an office setting. More complicated cystoscopies, involving resections or ureteral catheter insertions, are done in the operating room suite, where IV sedation or spinal or general anesthesia may be used.
2. Patient's genitalia are cleaned with an antiseptic solution just before the examination. A local topical anesthetic (lidocaine gel) is instilled into the urethra before insertion of cystoscope.
3. Because fluid flows continuously through the cystoscope, patient may feel an urge to urinate during the examination.
4. Contraindicated in patients with known UTI.
5. Nursing interventions after cystoscopic examination:
   a. Monitor for complications: urinary retention, urinary tract hemorrhage, infection within the prostate or bladder.
   b. Expect patient to have some burning on voiding, blood-tinged urine, and urinary frequency from trauma to mucous membrane of the urethra.
   c. Administer or teach self-administration of antibiotics prophylactically, as ordered, to prevent UTI.
   d. Advise warm sitz baths or analgesics, such as ibuprofen or acetaminophen, to relieve discomfort after cystoscopy. Increase hydration.
   e. Provide routine catheter care if urine retention persists and an indwelling catheter is ordered.

Urodynamics

Description

Urodynamics is a term that refers to any of the following tests that provide physiologic and functional information about the lower urinary tract. They measure the ability of the bladder to store and empty urine. Most urodynamic equipment uses computer technology with results visible in real time on a monitor.

1. Uroflowmetry (flow rate)—a record of the volume of urine passing through the urethra per unit of time (mL/s). It is shown on graph paper and gives information about the rate and flow pattern of urination. It is used to evaluate obstructive voiding. Minimum volume of urine needed for accurate test is 150 mL.
2. Cystometrography—recording of the pressures exerted during filling and emptying of the urinary bladder to assess its function. Data about the ability of the bladder to store urine at low pressure and the ability of the bladder to contract appropriately to empty urine are obtained.
    a. A small catheter is placed through the urethra (or suprapubic area) into the bladder. The residual volume is measured if patient recently voided, and the catheter is left in place.
    b. The catheters are connected to urodynamic equipment designed to measure pressure at the distal end of the catheter.
    c. Water, saline, or contrast material is infused at a slow rate into the bladder.
    d. When the bladder feels full, patient is asked to "void." A normal detrusor contraction of the bladder appears as a sharp rise in bladder pressure on the graph. If the patient is unable to void, the test may be considered normal because it is difficult to void normally with catheters in place.
3. Sphincter electromyography (EMG)—measures the activity of the pelvic floor muscles during bladder filling and emptying. EMG activity may be measured using surface (patch) electrodes placed around the anus or with percutaneous wire or needle electrodes.
4. Pressure-flow studies—involve all of the above components, along with the simultaneous measurement of intra-abdominal pressure by way of a small tube with a fluid-filled balloon that is placed in the rectum. This permits better interpretation of actual bladder pressures without the influence of intra-abdominal pressure.
5. Video urodynamics—use all of the above components. The fluid used to fill the bladder is contrast material, and the entire study is performed under fluoroscopy, providing radiographic pictures in combination with the recording of bladder and intra-abdominal pressures. Video urodynamics are reserved for patients with complicated voiding dysfunction.

Nursing and Patient Care Considerations

1. Contraindicated in patients with UTI.
2. Frequently performed by nurses; essential to provide information and support throughout the test to ensure clinically significant results.
3. Patients may have burning on urination afterward (because of instrumentation); encourage fluids.
4. Short-term antibiotics are commonly given to prevent infection.

Needle Biopsy of the Kidney

Description

Performed by percutaneous needle biopsy through renal tissue with ultrasound guidance or by open biopsy through a small flank incision; useful in securing specimens for electron and immunofluorescent microscopy to determine diagnosis, treatment, and prognosis of renal disease.

Nursing and Patient Care Considerations

1. Prebiopsy nursing management.
    a. Ensure that coagulation studies, platelet count, and hematocrit results are reported to provide baseline values and to identify patients at risk for postbiopsy bleeding.
    b. Establish an IV line, as ordered.
    c. Ensure that patient is NPO for several hours before the procedure, as ordered.
    d. Describe the procedure to patient, including holding breath (to prevent movement of the thorax) during insertion of the biopsy needle.
    e. Instruct patient to urinate before the procedure.
2. Postbiopsy nursing management.
    a. Place patient in a supine position immediately after biopsy and on bed rest for 8 to 24 hours to minimize bleeding.
    b. Take vital signs every 5 to 15 minutes for the first hour and then with decreasing frequency if stable to assess for hemorrhage, which is a major complication.
    c. Watch for rise or fall in blood pressure (BP), anorexia, vomiting, or development of dull, aching discomfort in the abdomen.
    d. Assess for flank pain (usually represents bleeding into the muscle) or colicky pain (clot in the ureter).
    e. Assess for backache, shoulder pain, or dysuria.
    f. Persistent bleeding may be suspected when an enlarging hematoma is palpable through the abdomen.
    g. If perirenal bleeding develops, avoid palpating or manipulating the abdomen after the first examination has determined that a hematoma exists.
    h. Collect serial urine specimens to evaluate for hematuria.
    i. Assess for any patient complaints, especially frequency and urgency on urination.
    j. Keep fluid intake at 3,000 mL daily, if tolerated, unless patient has renal insufficiency.
    k. Hematocrit and hemoglobin may be ordered to assess for anemia prior to discharge.
3. Instruct patient on the following after biopsy:
    a. Avoid strenuous activity, strenuous sports, and heavy lifting for at least 2 weeks.
    b. Notify health care provider if any of the following occur: flank pain, hematuria, light-headedness and fainting, rapid pulse, or any other signs and symptoms of bleeding.
    c. Report for follow-up 1 to 2 months after biopsy; will be checked for hypertension and the biopsy area is auscultated for a bruit.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 21-2–21-4

PROCEDURE GUIDELINES 21-2

Catheterization of the Urinary Bladder

EQUIPMENT

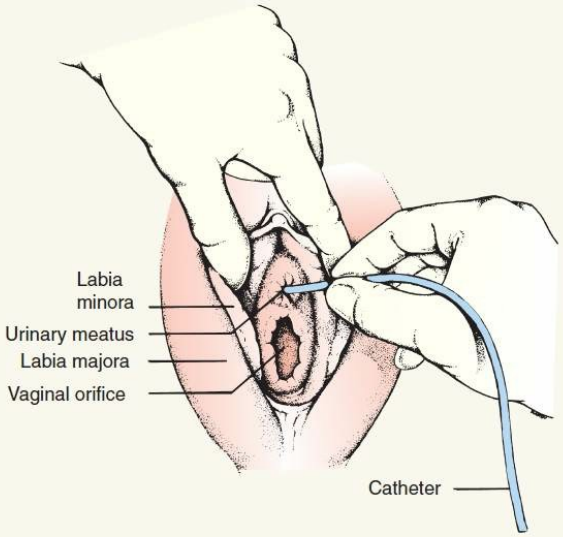
- Sterile gloves
- Disposable sterile catheter set with single-use packet of lubricant
- Antiseptic solution for periurethral cleaning (sterile)
- Sterile container for culture
- Gloves, drape, pads
- Bath blanket or sheet for draping
- Standing lamp (preferred) or flashlight

Selection of catheter size

Use the smallest catheter capable of providing adequate drainage.

PROCEDURE

Nursing Action	Rationale
Female patient	
Preparatory phase	
1. Wash hands. Explain procedure to the patient.	1. The patient will feel reassured if the procedure is explained and if she is handled gently and considerately.
2. Open catheter tray using aseptic technique. Place waste receptacle in accessible place.	2. Catheterization requires the same aseptic precautions as a surgical procedure. The principal danger of catheterization is urinary tract infection, which is associated with increased morbidity and longer, more costly hospitalization.
3. Place the patient in a supine position with knees bent, hips flexed, and feet resting on bed in a "frog's-legs" position. Drape the patient.	3. Position should allow visualization of the vulva.
4. Direct light for visualization of the genital area.	
5. Position moisture-proof pad under the patient's buttocks.	5. Absorb urine, if necessary.
6. Put on sterile gloves.	6. Prevents bacterial contamination.
Performance phase	



Catheterization of urinary bladder in the female patient.

Nursing Action	Rationale
1. Separate labia minora so urethral meatus is visualized; one hand is to maintain separation of the labia until catheterization is finished.	1. Helps prevent labial contamination of the catheter (see accompanying figure).
2. Clean around the urethral meatus with a povidone–iodine solution, unless the patient is allergic to iodine—in which case, clean with soap and water.	2. Bacteria that normally colonize the distal urethra may be introduced into the bladder during or immediately after catheter insertion. Inadequate preparation of the urethral meatus is a major cause of infection.
a. Manipulate cleaning pads or cotton balls with forceps, cleaning with downward strokes from anterior to posterior.	a. Prevents introducing bacteria from the perineum into the urethra.
b. Dispose of cotton pad after each use.	
c. If the patient is sensitive to iodine, benzalkonium chloride or other cleaning agent such as chlorhexidine may be used.	
3. Introduce well-lubricated catheter 2 to 3 inches (5 to 7.5 cm) into urethral meatus using strict aseptic technique.	3. A well-lubricated catheter reduces friction and trauma to the meatus. The female urethra is a relatively short canal, measuring 1¼ to 1½ inches (3 to 4 cm) in length.
a. Avoid contaminating surface of catheter.	
b. Make sure that the catheter is not too large or too tight at urethral meatus.	b. Too large a catheter may cause painful distention of the meatus and cause damage to the uroepithelium.
4. Allow some bladder urine to flow through the catheter before collecting a specimen.	4. Obtains representative bladder sample.
Male patient	
Preparatory phase	
1. Lubricate the catheter well with lubricant or prescribed topical anesthetic.	1. Prevents urethral trauma (decreasing the opportunity for bacterial invasion).
2. Wash off the glans penis around the urinary meatus with an iodophor solution using forceps to hold cleaning pads. Clean the urethral meatus from tip to foreskin with downward stroke on one side. Discard pad. Repeat as required. Keep the foreskin retracted.	2. Reduces risk of bacterial transmission when the catheter enters the urethra. Use of forceps maintains sterility of the dominant hand.
3. Grasp shaft of penis (with nondominant hand) and elevate it. Apply gentle traction to penis while the catheter is passed.	3. Straightens the penile urethra and facilitates catheterization. Maintaining a grasp of the penis prevents contamination and retraction of penis.
4. Using sterile gloves, insert the catheter into the urethra; advance the catheter 6 to 10 inches (15 to 25 cm) until urine flows	4. The male urethra length varies within wide limits; the average length is about 8 inches (20 cm).
KEY DECISION POINT If resistance is felt at the external sphincter while trying to advance the catheter, increase the traction on the penis slightly and apply steady, gentle pressure on the catheter. Ask the patient to strain gently (as if passing urine) to help relax the sphincter. Some resistance may be due to spasm of external sphincter, which should subside. If you are unable to pass the catheter at all, there may be a urethral stricture or other form of urethral pathology. Withdraw the catheter and notify the health care provider. Consultation with a urologist for possible dilation is indicated.	
5. When urine begins to flow, advance the catheter another 1 inch (2.5 cm).	5. Advancing the catheter ensures its position in the bladder.
6. Replace (or reposition) the foreskin.	6. Paraphimosis (retraction and constriction of the foreskin behind the glans penis), secondary to catheterization, may occur if the foreskin is not replaced.

Nursing Action	Rationale
Follow-up phase	
1. Remove the catheter gently when urine ceases to flow.	1. Minimizing trauma to the urethra and time the catheter is in contact with the urethral mucosa will minimize chance of infection.
2. Dry the area; make the patient comfortable.	2. Some urine may have leaked while withdrawing catheter or lubricating gel may need to be cleared.
3. Send specimen to laboratory, as indicated.	3. Proper processing of specimen will assure accuracy of test.
4. Record time, procedure, amount, and appearance of urine.	4. For continuity of care.

COMMUNITY AND HOME CARE CONSIDERATIONS

- The caregiver or patient can catheterize using clean technique; however, Medicare guidelines now allow for reimbursement of sterile catheters for each catheterization to prevent UTI.
- Assemble catheter (usually flexible, red rubber catheter; clear plastic, firmer catheter may be used by men), lubricant, and liquid soap.
- Clean the area around the urethral meatus with liquid soap, if desired.
- Wash hands; wear unsterile gloves if desired.
- Catheterize; remove the catheter when drainage ceases.
- Wash the catheter with soap and water; rinse and dry well with paper towel.
- Store in a new sealable plastic bag.
- Nurse catheterizing patient in home usually maintains sterile technique.
- Replace catheters as often as possible, at least once per month.

EVIDENCE BASE Gupta, K., Hooton, T. M., Naber, K. G., et al. (2011). International clinical practice guidelines for the treatment of acute uncomplicated cystitis and pyelonephritis in women: A 2010 update by the Infectious Diseases Society of America and the European Society for Microbiology and Infectious Diseases. *Clinical Infectious Diseases*, *52*(5), 103–120.

PROCEDURE GUIDELINES 21-3

Management of the Patient with an Indwelling (Self-Retaining) Catheter and Closed Drainage System

EQUIPMENT

- Catheter tray with closed system of urinary drainage
- Gauze pads
- Antibacterial solution for cleaning
- Single-use packet of lubricant

PROCEDURE

Nursing Action	Rationale
General considerations	
1. Catheterize the patient (pages 778–780) using a catheter that is preconnected to a closed drainage system.	1. A closed drainage system is one that is closed to outside air.
a. Advance catheter almost to its bifurcation (for male patient).	a. Prevents the balloon from becoming trapped in the urethra.
b. Inflate the balloon according to manufacturer's directions. Make sure the catheter is draining properly before inflating the balloon, and then withdraw the catheter slightly.	b. Inadvertent inflation of the balloon within the urethra is painful and causes urethral trauma.
2. Secure the indwelling catheter to the patient's thigh using tape, strap, adhesive anchor, or other securement device.	2. Properly securing the catheter prevents catheter movement and traction on the urethra.
a. Allow some slack of the tubing to accommodate the patient's movements.	
b. Keep the tubing over the patient's leg.	b. This tubing position helps prevent kinking or forming loops of stagnant urine.
 In the male patient, the indwelling catheter is taped to the thigh to straighten the angulation of the penoscrotal junction, thus reducing pressure on the urethra exerted by the catheter.	
Care of the indwelling catheter	
1. Clean around the area where the catheter enters urethral meatus (meatal–catheter junction) with soap and water during the daily bath to remove debris.	1. Suppurative drainage and encrustation occur at the exit of any tube. Infectious organisms can migrate to the bladder along the outside of any indwelling catheter; however, excessive manipulation of the catheter may promote migration of bacteria.
2. Avoid using powders and sprays on the perineal area.	2. Powder can encrust and cause soreness and infection.
3. Avoid pulling on the catheter during cleaning.	3. Pulling on the catheter may be painful. Backward and forward displacement of the catheter introduces contaminants into the urinary tract.
To obtain urine for culture	
1. Clamp the drainage tubing below the aspiration (sampling) port for a few minutes to allow urine to collect.	1. Avoid separating the catheter and connecting tube. Disconnection of the catheter and tubing is a major cause of urinary tract infection (UTI).
2. Clean the aspiration port with povidone–iodine or 70% alcohol.	2. Prevents introduction of contaminants into closed system.
3. Insert a needleless syringe into the aspiration port of the catheter tubing and aspirate a small volume of urine for culture.	

Nursing Action	Rationale
4. Remove from syringe and release urine carefully into sterile specimen container.	4. Prevents contamination of specimen, which will alter the results.
5. Unclamp the drainage tube.	5. Prevents retention of urine and potential infection.
6. Send specimen to laboratory immediately.	6. The specimen should be marked as a "catheterized specimen" because the presence of any number of colonies of an organism indicates a UTI.
To irrigate the catheter	
Note: This is not done unless ordered to relieve obstruction or if persistent gross hematuria is anticipated (bleeding after bladder or prostate surgery). If frequent irrigations are necessary to keep the catheter open, the catheter may need to be changed to a larger size.	
1. Wash hands. Put on gloves.	1. Protects the nurse and patient.
2. Using aseptic technique, pour sterile irrigating solution into sterile container.	2. Care is taken to prevent bacterial contamination because solution is introduced directly into the bladder.
3. Clean around the catheter and drainage tubing connection with alcohol swabs.	
4. Disconnect the catheter from drainage tubing. Cover tubing with a sterile cap.	4. Prevents contamination.
5. Place a sterile drainage basin under the catheter.	5. You are opening the closed system and must maintain sterility.
6. Connect a large-volume syringe to the catheter and irrigate catheter using prescribed amount of sterile irrigant.	6. Instill 60 mL irrigating solution at a time. Instill the solution forcibly to remove blood clots from the bladder; irritation and spasms may occur.
7. Remove the syringe and place the end of the catheter over the drainage basin, allowing returning fluid to drain into the basin.	7. Provides gravitational flow.
8. Repeat the irrigation procedure until fluid is clear or according to order. For clot irrigation, pull back gently on the syringe.	8. After prostatic surgery, the goal of irrigation is to clear bloody fluid that may clot.
9. Disinfect the distal end of the catheter and end of drainage tubing; reconnect the catheter and tubing. Dispose of irrigation solution and syringe. Remove gloves. Wash hands.	9. Prevents contamination of catheter and transfer of any bacteria to another patient.
10. Document type and amount of irrigating solution, color and character of returning fluid, presence of sediment/blood clots, and patient's reaction.	10. For continuity of care.
Changing the catheter	
Change the catheter according to the needs of the patient.	Facility policy may vary.
Maintaining a closed drainage system	
1. Wash hands immediately before and after handling any part of the system. Wear clean, disposable gloves when handling the drainage system.	1. Hands are the major route of transmission of Gram-negative bacteria.
2. Maintain unobstructed urine flow.	2. Urine flow must be downhill.
a. Keep the drainage bag in a dependent position, below the level of the bladder.	a. Raising the bag will cause reflux of contaminated urine from the bag into the patient's bladder.
b. Urine should not be allowed to collect in the tubing because a free flow of urine must be maintained to prevent infection.	b. Improper drainage occurs when the tubing is kinked or twisted, allowing pools of drainage to collect in the loops of tubing.
c. Keep the bag off the floor.	c. Prevents bacterial contamination.

Nursing Action	Rationale
3. Empty the bag at regular intervals, making sure that the drainage valve/spout is not contaminated.	3. Care is taken to maintain a closed system to prevent catheter-acquired infection and to prevent transmission of infection to other patients.
a. Wash hands; put on gloves.	
b. Disinfect spigot. Empty the bag in a separate collecting receptacle for each patient. Disinfect spigot again.	b. Each patient should have own collecting receptacle that is labeled and kept in the bathroom, not on the floor—to prevent cross-contamination.
c. Avoid letting the drainage bag touch the floor.	
d. Change the drainage bag if contamination occurs, if the urine flow becomes obstructed, or if the connecting junctions start to leak.	
Preventing cross-contamination	
1. Wash hands before and after handling the catheter and drainage system and between patients.	1. Many UTIs are due to extrinsically acquired organisms transmitted by cross-contamination.
2. Identify patients at risk.	2. Female, older, debilitated, and critically ill patients; those in the postpartum state; and patients with obstructed or neurologically impaired bladders are at risk for infection.

COMMUNITY AND HOME CARE CONSIDERATIONS

For care of catheter at home, instruct the patient to:

- Wash hands before and after handling the catheter.
- Wash around urinary opening daily, taking care to avoid pulling on the catheter during cleaning and removing encrustation around the catheter.
- Drink 8 to 12 glasses of fluids daily; increase fluid intake if urine becomes dark and concentrated.
- Wipe all connecting junctions with alcohol before changing from leg-bag drainage to overnight drainage bag.
- Keep the drainage bag at a lower level than the bladder; do not place the bag on your chair.
- Avoid letting the bag lie on its side because urine may flow back into the drainage tube.
- Usually, the catheter is changed every 4 to 6 weeks or when obstruction or malfunction occurs.
- The interval between catheter cleaning and changes may be decreased if there is heavy encrustation.
- Call health care provider if fever or cloudy, bloody, or odoriferous urine develops. In the male patient, the indwelling catheter is taped to the thigh to straighten the angulation of the penoscrotal junction, thus reducing pressure on the urethra exerted by the catheter.

EVIDENCE BASE Wein, A. J., Kavoussi, L. R., Partin, A. W., Peters, C. A., et al. (Eds.). (2017). *Campbell-Walsh urology* (11th ed., Vols. 1–4). Philadelphia, PA: W.B. Saunders.

PROCEDURE GUIDELINES 21-4

Assisting the Patient Undergoing Suprapubic Bladder Drainage

EQUIPMENT

- Sterile suprapubic drainage system package (disposable)
- Skin germicide for suprapubic skin preparation; sterile gloves
- Local anesthetic agent, if needed

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Place the patient in a supine position with one pillow under the head.	1. Allows access to suprapubic area but reduces muscle tension.
2. Expose the abdomen.	
Performance phase (by health care provider)	
1. The bladder is distended with 300 to 500 mL sterile saline in a urethral catheter, which is removed, or the patient is given fluids (PO or via IV line) before the procedure.	1. Distention of the bladder makes the bladder easier to locate by the suprapubic route.
2. The suprapubic area is surgically prepared. After the skin is dried, the needle entry point is located.	2. The needle entry point is in the midline, ¾ to 1¼ inches (2 to 3 cm) above the symphysis pubis and directly over the palpable bladder.
3. The skin and subcutaneous tissues are infiltrated with local anesthesia.	3. An adequate level of local anesthesia is achieved to facilitate catheter introduction.
4. A small incision may be made.	
5. The catheter is introduced via a guidewire, needle, or cannula through the incision and advanced in a slightly caudal direction.	5. Entrance into the bladder is usually felt and can be verified by free flow of urine.
6. The catheter is advanced until the flange is against the skin where it is secured with tape, a body seal system, or sutures.	6. Another method is to advance a long needle into the bladder until urine flow verifies the needle is in the bladder.
7. The catheter is connected to a sterile drainage system.	7. Aseptic technique must be maintained to prevent infection.
8. Secure drainage tubing to lateral abdomen with tape.	8. Prevents undue tension on the catheter.
9. If the catheter is not draining properly, withdraw the catheter 1 inch (2.5 cm) at a time until urine begins to flow. Do not dislodge the catheter from the bladder.	9. The catheter tip may be pinned against the wall of the bladder.
10. Drainage may be maintained continuously for several days.	10. Because of risk of infection, this is not a long-term option for urinary drainage.
11. If a "trial of voiding" is requested, the catheter is clamped for 4 hr.	11. Usually, patients will void earlier after surgery with suprapubic drainage than with indwelling catheters.
a. Have the patient attempt to void while the catheter is clamped.	
b. After the patient voids, unclamp the catheter and measure residual urine.	b. Determines the effectiveness of voiding.
c. Usually, if the amount of residual urine is <100 mL on two separate occasions (AM and PM), the catheter may be removed.	c. If larger residual, the patient is not ready for catheter removal.
d. If the patient reports pain or discomfort, or if the residual urine is over the prescribed amount, the catheter is usually left open.	d. Facilitates urinary drainage and prevent infection due to urinary stasis.
12. When the catheter is removed, a sterile dressing is placed over the site. Usually the tract will close within 48 hr.	12. Suprapubic drainage is considered more comfortable than an indwelling urethral catheter. It allows greater patient mobility, and there is less risk of bladder infection.
13. Monitor for complications.	13. Complications of this procedure: inadvertent peritoneal and bowel damage, leakage around catheter, kinking of catheter, hematuria, abdominal wall abscess.

EVIDENCE BASE Wein, A. J., Kavoussi, L. R., Partin, A. W., Peters, C. A., et al. (Eds.). (2017). *Campbell-Walsh urology* (11th ed., Vols. 1–4). Philadelphia, PA: W.B. Saunders.

Catheterization

Catheterization may be done to relieve acute or chronic urinary retention, to drain urine preoperatively and postoperatively, to determine the amount of residual urine after voiding, or to determine accurate measurement of urinary drainage in critically ill patients.

Catheterization of Female

1. Engage assistance if needed for positioning patient with knees bent and legs spread with light directed onto the vulva. Maintain strict sterile technique using prepackaged indwelling catheter tray, or sterile straight catheter, sterile gloves, lubricant, and cleansing components set up on sterile field as indicated. Nondominant hand usually used for spreading labia and dominant hand remains sterile. See Figure 21-1.
2. Cleanse urethral meatus with povidone–iodine or other cleansing solution via cotton balls manipulated with sterile forceps.
3. Introduce well-lubricated catheter 2 to 3 inches (5 to 7.5 cm) into the urethral meatus using sterile gloved hand, watching for flow of urine.
4. Obtain specimen and secure the catheter and drainage bag as indicated. Note the amount of urine drained.

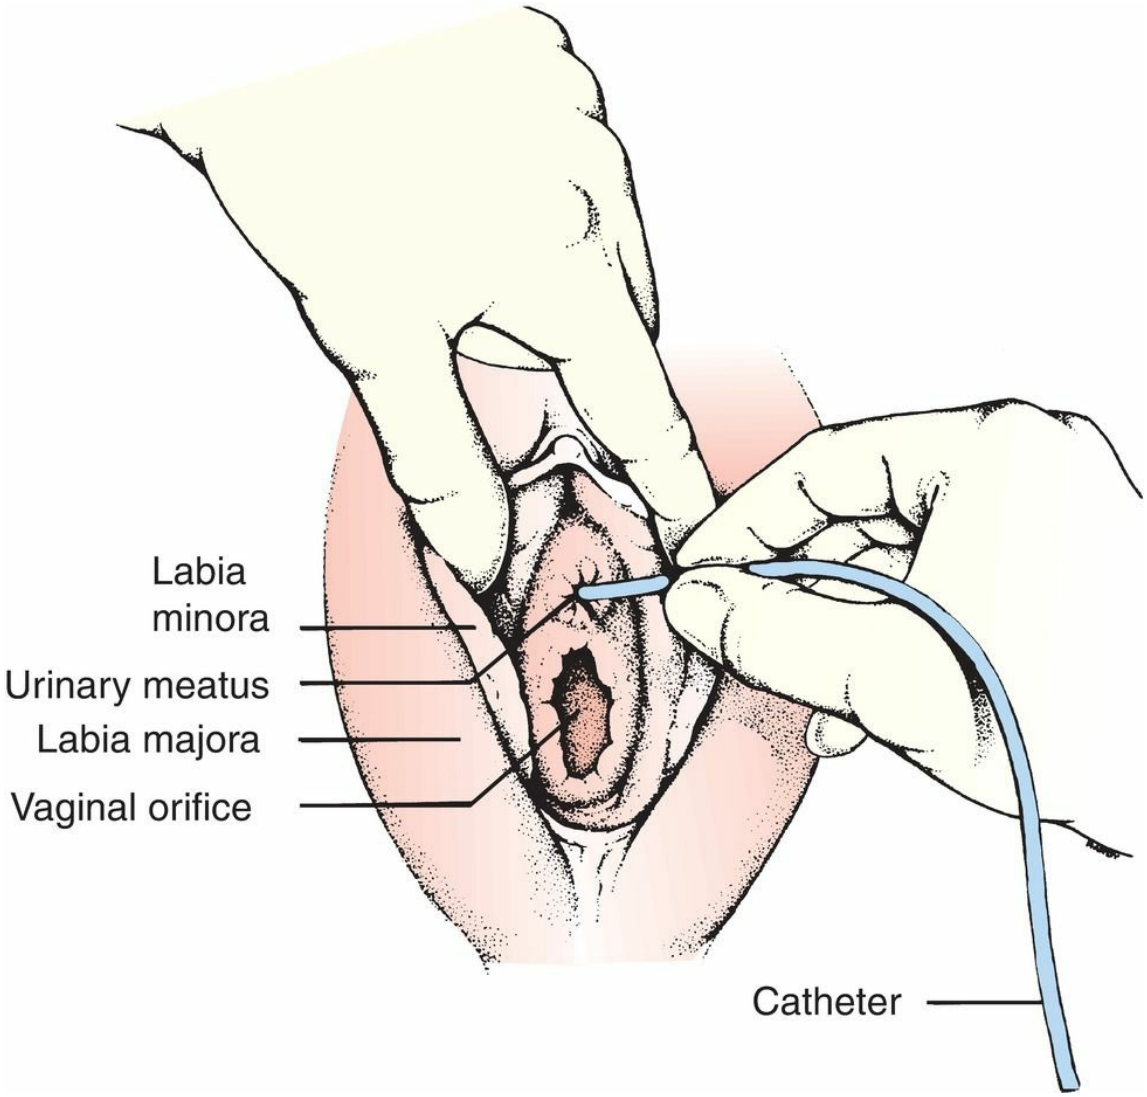


Figure 21-1. Urethral catheterization of the female patient.

Catheterization of Male

1. Grasp the shaft of the penis with nondominant hand; elevate it, retracting the foreskin, if present.
2. Cleanse with downward motion from urethral meatus, using a new sterile cotton ball with each stroke.
3. Apply gentle traction as you insert the well-lubricated catheter 6 to 10 inches (15 to 25 cm) with your sterile hand. Watch for urine flow and advance the catheter another 1 inch (2.5 cm).
4. Obtain specimen and secure the catheter and drainage bag as indicated. Note the amount of urine drained.

Suprapubic Catheterization

1. Establishes drainage from the bladder by introducing a catheter percutaneously through the anterior abdominal wall into the bladder.
2. May be done for acute urinary retention when urethral catheterization is not possible; for urethral trauma, stricture, or fistula to divert flow of urine from the urethra; or for obtaining an uncontaminated

urine specimen for culture.

3. Once the surgical tract is healed, the catheter may be changed by the nurse monthly.

Dialysis

Dialysis refers to the diffusion of solute molecules through a semipermeable membrane, passing from the side of higher concentration to that of lower concentration. The purpose of dialysis is to maintain fluid, electrolyte, and acid–base balance and to remove endogenous and exogenous toxins. It is a substitute for some kidney excretory functions but does not replace the kidneys' endocrine functions. Methods of dialysis include:

1. Peritoneal dialysis.
    a. Continuous ambulatory peritoneal dialysis (CAPD).
    b. Automated peritoneal dialysis (APD)/continuous cycling peritoneal dialysis—uses APD machine to do multiple exchanges overnight, with or without a prolonged dwell time during the day.
2. Hemodialysis (see page 595).
3. Continuous renal replacement therapy (CRRT)—this includes slow continuous ultrafiltration, continuous venovenous hemofiltration, continuous venovenous hemodialysis, and continuous venovenous hemodiafiltration. These use extracorporeal blood circulation through a small-volume, low-resistance filter to provide continuous removal of solutes and fluid in the intensive care setting. Historically, CRRT required arterial and venous access (arteriovenous) and was driven by the patient's mean arterial pressure (MAP). This approach is rarely practiced today as pump-assisted equipment that only requires venous access is the standard of care.
    a. CRRT is indicated for hemodynamically unstable patients who cannot tolerate the rapid fluid shifts that occur with intermittent dialysis and in oliguric patients who require large amounts of hourly IV fluids or parenteral nutrition. CRRT is often better tolerated by critically ill patients because it is a slower and less aggressive process for removal of fluid and solutes than hemodialysis.
    b. CRRT is accomplished by insertion of a large-gauge double-lumen catheter into the internal jugular, subclavian, or femoral vein. A roller-type pump is used to propel blood through the system and anticoagulation may be used to prevent clotting. This is the current standard of care because of consistent blood flow rates.
    c. Care for the patient on CRRT is provided in an intensive care setting, with special attention given to assessing and calculating fluid and electrolyte balance, aggressively managing hypotension, preventing hemorrhage, monitoring for heat loss through the extracorporeal circulation, assessing for infection, and preventing clotting.

Continuous Ambulatory Peritoneal Dialysis

Continuous ambulatory peritoneal dialysis (CAPD) is a form of intracorporeal dialysis that uses the peritoneum as the semipermeable membrane (see Figure 21-2).

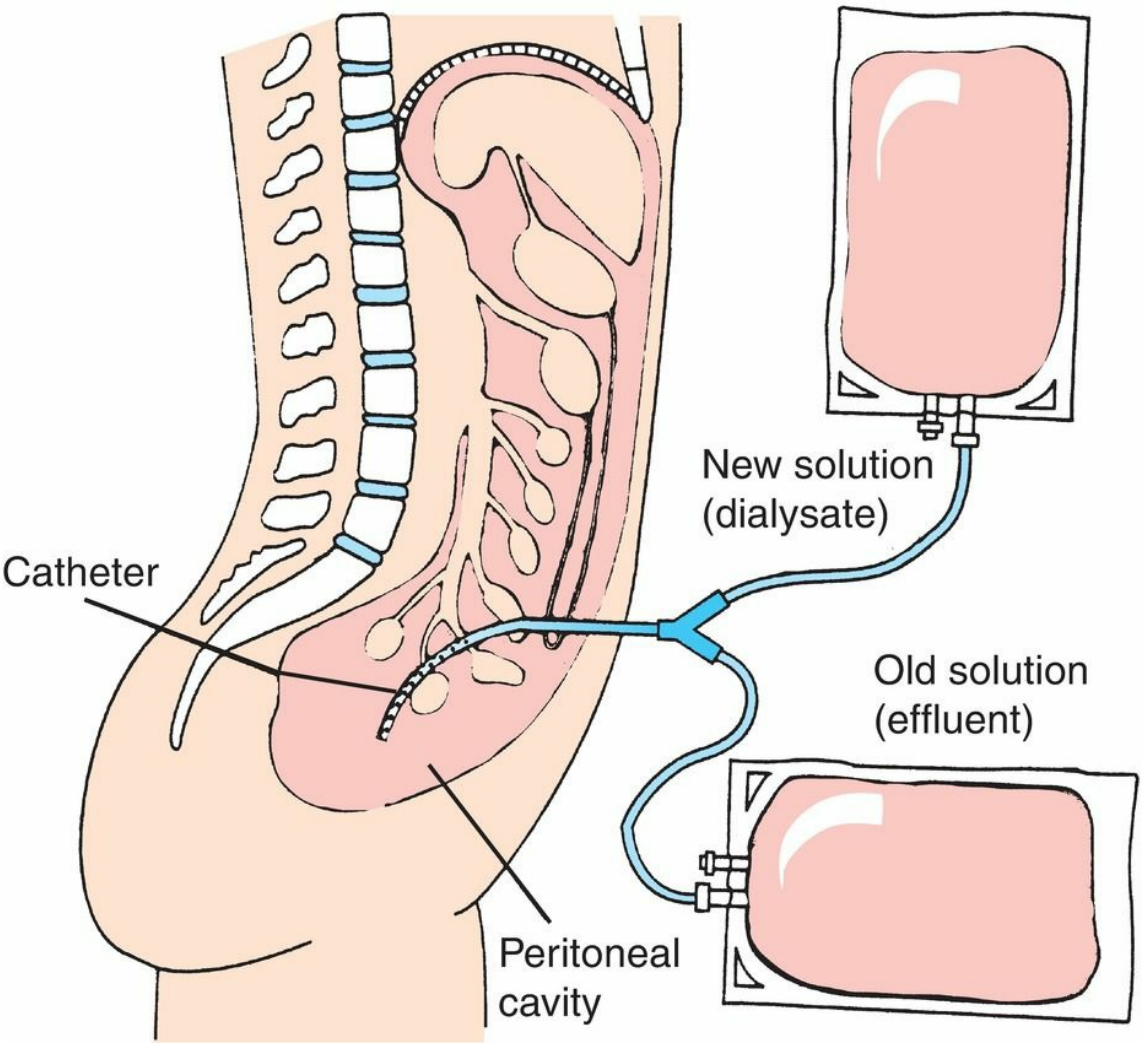

Figure 21-2. Continuous ambulatory peritoneal dialysis. The peritoneal catheter is implanted through the abdominal wall. Fluid infuses into the peritoneal cavity and drains after a prescribed time. (Porth, C. [1998]. *Pathophysiology: Concepts of altered health states* [5th ed.]. Philadelphia, PA: Lippincott-Raven Publishers.)

Procedure

1. A permanent indwelling catheter is implanted into the peritoneum; the internal cuff of the catheter becomes embedded by fibrous ingrowth, which stabilizes it and minimizes leakage.
2. A tube for connecting the catheter to an administration set is attached via a locking mechanism to the distal end of the peritoneal catheter, called the transfer set. It remains with the patient (attached to the catheter tubing) and must be changed at regular intervals per manufacturer recommendations without contamination. Specific transfer sets may only fit administration tubing from the same manufacturer, but there are devices available to make the transfer set compatible with other PD systems.
3. There are many types of administration sets, the most common being the double bag system. The double bag system has a preattached bag of dialysate solution and drainage, which has been shown to reduce peritonitis rates.

4. In CAPD, a patient is prescribed a set number of exchanges (fill, drain, and dwell) throughout the day.
5. During the fill, the dialysate bag is raised to shoulder level and infused by gravity into the peritoneal cavity (approximately 10 minutes for a 2-L volume).
6. During the dwell time, diffusion and osmosis occur. The typical dwell time is 4 to 6 hours.
7. At the end of the dwell time, the dialysate fluid is drained from the peritoneal cavity by gravity. Drainage of 2 L plus ultrafiltration takes about 10 to 20 minutes if the catheter is functioning optimally.
8. After the dialysate is drained, a fresh bag of dialysate solution is infused using aseptic technique and the procedure is repeated.
9. Patient performs four to five exchanges daily, 7 days per week, with an overnight dwell time allowing uninterrupted sleep; most patients become unaware of fluid in the peritoneal cavity.

Advantages Over Hemodialysis

1. Physical and psychological freedom and independence.
2. More liberal diet and fluid intake.
3. Relatively simple and easy to use.
4. Satisfactory biochemical control of uremia.

Complications

1. Infectious peritonitis, exit-site and tunnel infections.
2. Noninfectious catheter malfunction, obstruction, dialysate leak.
3. Peritoneal–pleural communication; hernia formation.
4. GI bloating, distention, nausea.
5. Hypervolemia, hypovolemia.
6. Bleeding at catheter site.
7. Bloody effluent secondary to internal bleeding. In female patients, this may occur during menstruation.
8. Obstruction may occur if the omentum becomes wrapped around the catheter or the catheter becomes caught in a loop of bowel.

Patient Education

1. The use of CAPD as a long-term treatment depends on prevention of recurring peritonitis.
    a. Use strict aseptic technique when performing bag exchanges. All persons in the room, including patient, must wear a mask any time connecting or disconnecting the transfer set to or from another system.
    b. Perform bag exchanges in clean, closed-off area without pets and other activities.
    c. Wash hands before touching bag.
    d. Inspect bag and tubing for defects and leaks.
2. Do not omit bag changes—this will cause inadequate control of renal failure.
3. Some weight gain may accompany CAPD—the dialysate fluid contains a significant amount of dextrose,

which adds calories to daily intake.

4. Report signs and symptoms of peritonitis—cloudy peritoneal fluid, abdominal pain or tenderness, malaise, fever.

Hemodialysis

Hemodialysis is a process of cleansing the blood of accumulated waste products. It is used for patients with end-stage renal failure or for acutely ill patients who require short-term dialysis.

Procedure

1. Patient's access is prepared and cannulated.
2. Heparin may be administered to prevent circuit clotting.
3. Blood flows through a semipermeable dialyzer in one direction, and dialysis solution surrounds the membranes and flows in the opposite direction.
4. Dialysis solution consists of highly purified water to which sodium, potassium, calcium, magnesium, chloride, and dextrose have been added. Bicarbonate is added to achieve the proper pH balance.
5. Through the process of diffusion, solutes in the form of electrolytes, metabolic waste products, and acid–base components can be removed or added to the blood.
6. Excess water is removed from the blood (ultrafiltration).
7. The blood is then returned to the body through patient's access.

Requirements for Hemodialysis

1. Access to patient's circulation.
2. Dialysis machine and dialyzer with semipermeable membrane.
3. Appropriate dialysate bath.
4. Time—approximately 4 hours, three times weekly.
5. Place—dialysis center or home (if feasible).

Methods of Circulatory Access

1. Arteriovenous fistula (AVF)—creation of a vascular communication by suturing a vein directly to an artery (see Figure 21-3).
   a. Usually, radial artery and cephalic vein are anastomosed in nondominant arm; vessels in the upper arm may also be used. Leg vessels are used if unable to place in UE.
   b. Over time, the venous limb of the fistula system dilates. By means of two large-bore needles inserted into the dilated venous limb, blood may be obtained and passed through the dialyzer. The arterial end is used for arterial flow and the distal end for reinfusion of dialyzed blood.
   c. Maturation of AVF requires at least 6 to 8 weeks; a central vein catheter is used in the interim.
2. Arteriovenous graft—arteriovenous connection consisting of a tube graft usually made from an autologous saphenous vein or from polytetrafluoroethylene. Ready to use in 3 to 4 weeks.
3. Central vein catheters (CVC)—direct cannulation of veins (subclavian, internal jugular, or femoral) is

used for temporary dialysis access. Tunneled catheters may be placed for permanent dialysis access in patients who refuse or are not candidates for AVF/AVG placement. CVC access is the least preferred permanent access because of increased risk of clotting and infection.

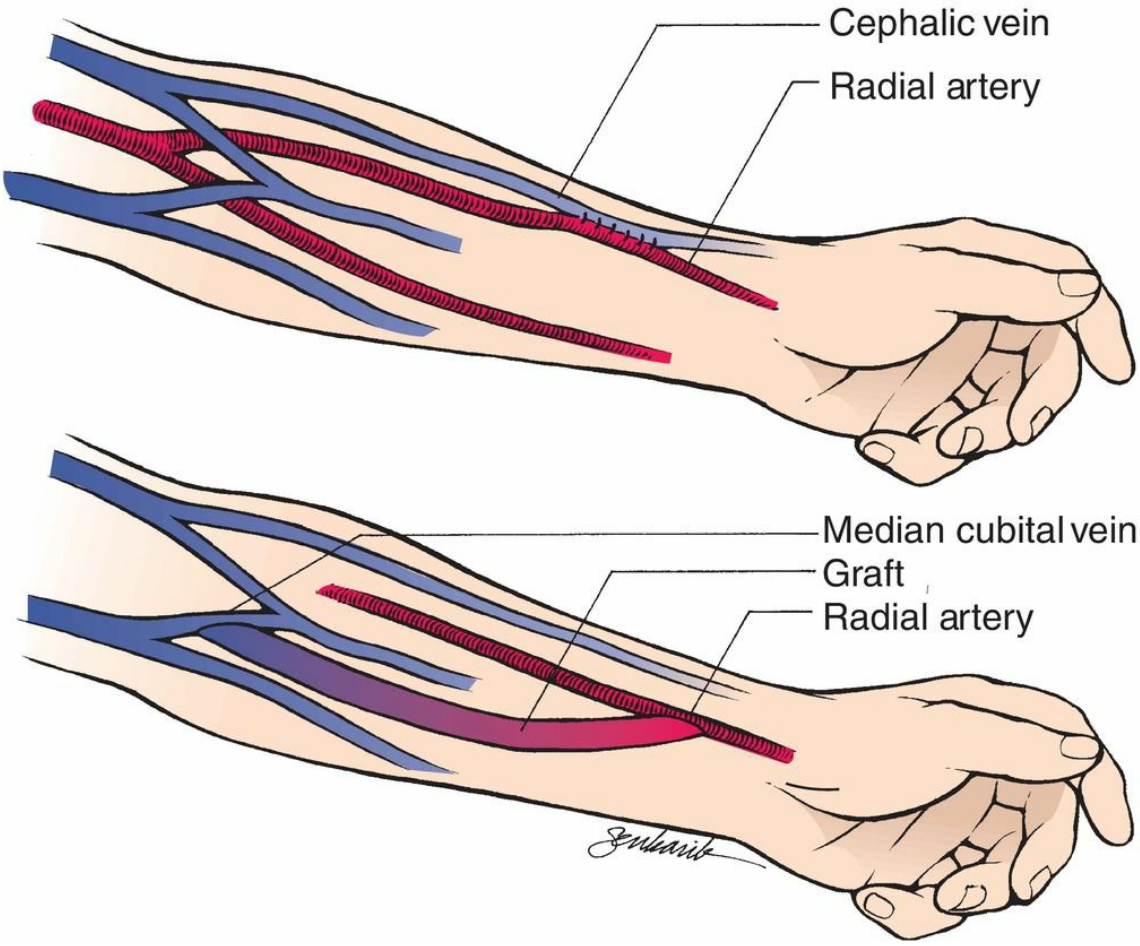

Figure 21-3. An internal arteriovenous fistula **(top)** is created by a side-to-side anastomosis of the artery and vein. A graft **(bottom)** can also be established between the artery and vein. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Complications of Vascular Access

1. Infection.
2. Clotting.
3. Central vein thrombosis or stenosis.
4. Stenosis or thrombosis of AVF/AVG.
5. Ischemia distal to the vascular access (steal syndrome).
6. Aneurysm or pseudoaneurysm.
7. Hemorrhage.

Monitoring During Hemodialysis

1. Involves constant monitoring of dialysis access, hemodynamic status, electrolyte, and acid–base balance as well as maintenance of sterility and a closed system.
2. Performed by specially trained nurses and dialysis technicians who are familiar with the protocol and equipment being used.

Chronic Hemodialysis Management

1. Dietary management involves restriction or adjustment of protein, sodium, potassium, phosphorous, or fluid intake. Ongoing consultation with a dietician is standard.
2. Careful adjustment of medications that are normally excreted by the kidney or are dialyzable. Certain medications are contraindicated.
3. Surveillance for complications:
    a. Arteriosclerotic cardiovascular disease, heart failure, disturbance of lipid metabolism (hypertriglyceridemia), coronary heart disease, stroke.
    b. Infections, systemic, or localized.
    c. Anemia.
    d. GI complications: Gastric ulcers, GI bleeding, constipation, and diarrhea.
    e. Bone problems (renal osteodystrophy)—from alterations in mineral metabolism.
    f. Electrolyte imbalances.
    g. Hypertension.
    h. Hypervolemia/pulmonary edema.
    i. Psychosocial problems: depression, anxiety, suicide, alteration in body image, and sexual dysfunction.
4. Hepatitis B and hepatitis C surveillance. All patients are encouraged to be vaccinated against hepatitis B.
5. Support agencies are American Association of Kidney Patients (*www.aakp.org*), National Kidney Foundation (*www.kidney.org*), National Kidney and Urologic Diseases Information Clearing House (*www.niddk.nih.gov*).

Kidney Surgery

Kidney surgery may include partial or total nephrectomy (removal of the kidney), kidney transplantation for end-stage renal disease (ESRD), procedures to remove stones or tumors, and procedures to insert drainage tubes (nephrostomy). Incisional approaches vary but may involve the flank, thoracic, and abdominal regions. Nephrectomy is most commonly performed for malignant tumors of the kidney but may also be indicated for trauma and kidneys that no longer function because of obstructive disorders and other renal disease. Nephrectomy is also the procedure of choice to remove a healthy kidney for donation to a transplant recipient. The absence of one kidney does not result in impaired renal function when the remaining kidney is normal and healthy.

Many surgical procedures were previously performed as "open" procedures, but are now being done with laparoscopic "keyhole" surgeries. An endoscope is introduced and the abdomen is inflated with carbon dioxide. Instruments are passed through other sites or a sleeve may be used, which allows a hand to be introduced at the operative site. Advantages are decreased postoperative pain, decreased blood loss, and, in some cases, decreased length of hospital stay.

Preoperative Management

1. Patient is prepared for surgery, and consent is witnessed. Preoperative antibiotics and bowel cleansing regimen may be prescribed.
2. Risk factors for thromboembolism are identified (smoking, oral contraceptive use, varicosities of lower extremities), and antiembolism stockings may be applied. Leg exercises are taught, and the patient is prepared for pneumatic/sequential compression stockings that will be used postoperatively.
3. Pulmonary status is assessed (presence of dyspnea, productive cough, other related cardiac symptoms), and deep breathing exercises, effective coughing, and use of incentive spirometer are taught.
4. If embolization of the renal artery is being done preoperatively for patients with renal cell carcinoma, the following symptoms of postinfarction syndrome are observed for (may last up to 3 days):
    a. Flank pain.
    b. Fever.
    c. Leukocytosis.
    d. Hypertension.

Postoperative Management

1. Vital signs are monitored and incisional area is assessed for evidence of bleeding or hemorrhage.
2. Possible pulmonary complications of atelectasis, pneumonia, and pneumothorax are observed. Pulmonary clearance through deep breathing, percussion, and vibration is maintained. Chest tube drainage may be used in patients who have an open procedure (the proximity of the thoracic cavity to the operative area may result in the need for chest tube drainage postoperatively).
3. Patency of urinary drainage tubes is maintained (nephrostomy, suprapubic, or urethral catheter). Ureteral stents may be used.

4. Respiratory status and lower extremities are assessed for thromboembolic complications.
5. Bowel sounds, abdominal distention, and pain are monitored, which may indicate paralytic ileus and need for nasogastric decompression.
6. For kidney transplantation patients, immunosuppressant drugs are ordered.
    a. A combination of medications is used, including a corticosteroid; calcineurin inhibitor, such as tacrolimus or cyclosporine; and mycophenolate mofetil.
    b. Early signs of rejection include temperature greater than 100.4°F (38°C), decreased urine output, weight gain of 3 pound (1.5 kg) or more overnight, pain or tenderness over the graft site, hypertension, increased serum creatinine.

NURSING ALERT Use frequent and close observation of BP, pulse, and respiration to recognize hemorrhage (and shock)—chief danger after renal surgery. Watch for pain, sanguineous drainage from drain sites, or expanding pulsatile flank mass. Prepare for rapid blood and fluid replacement and reoperation.

Nursing Diagnoses

- Acute Pain related to surgical incision.
- Impaired Urinary Elimination related to urinary drainage tubes or catheters.
- Risk for Infection related to incision, potential pulmonary complications, and possibly immunosuppression.
- Risk for Imbalanced Fluid Volume related to fluid replacement needs and transplanted/remaining kidney function.

Nursing Interventions

Relieving Pain

1. Assess pain location, level, and characteristics. Transient renal colic-like pain may be caused by passage of blood clots down the ureter; however, report any persistent increasing or unrelievable pain, which may indicate obstruction of urinary drainage or hemorrhage.
2. Administer pain medications; evaluate effectiveness of patient-controlled analgesia (PCA).
3. Encourage patient to ambulate; splint incision to move or cough.

Promoting Urinary Elimination

1. Maintain patency of urinary drainage tubes and catheters while in place. Prevent kinking or pulling.
2. Use handwashing and asepsis when providing care and handling urinary drainage system (especially important for patient taking immunosuppressants).
3. Make sure indwelling catheter is dependent and draining.
    a. Report decrease in output or excessive clots.

   b. Be alert for signs of urinary infection, such as cloudy urine, fever, or bladder or flank ache.
4. Intervene to encourage removal of catheter when patient becomes ambulatory.
5. Maintain adequate fluid intake, IV or oral, when allowed.

Preventing Infection

1. Monitor for fever, elevated leukocyte count, abnormal breath sounds.
2. Administer antibiotics, as prescribed.
3. Assist patient with use of incentive spirometer, coughing and deep breathing, and ambulation to decrease risk of pulmonary infection. Provide meticulous care to chest tube sites.
4. Change dressings promptly if drainage is present—drainage is an excellent culture medium for bacteria.
5. Obtain specimens for bacteriologic testing of urine, wounds, sputum, and discontinued catheters, drains, and IV lines as indicated. Before removing catheters or urinary drains, disinfect skin around entry site, then remove. Using aseptic technique, cut off tip of catheter or drain and place in sterile container for laboratory culture.
6. Monitor vascular access to hemodialysis to ensure patency and watch for evidence of infection.
7. For kidney transplantation patients, provide antimicrobial therapy.
   a. Oral antifungals to prevent mucosal candidiasis, which commonly occurs due to immunosuppression.
   b. Antiviral medications are routinely used to prevent cytomegalovirus infection.
8. Provide regular skin care and assist with hygiene.

Maintaining Fluid Balance

1. Closely monitor intake and output, especially after kidney transplantation.
   a. Expect normal urine output to be 30 to 100 mL/hour.
   b. Report oliguria with less than 30 mL/hour or polyuria of 100 to 500 mL/hour.
2. Monitor serum electrolyte results and electrocardiogram (ECG) for changes associated with electrolyte imbalance.
   a. T-wave inversion and U waves with hypokalemia; tall peaked T waves with hyperkalemia.
   b. Report arrhythmias or other cardiac symptoms immediately.
3. Monitor BP and heart rate, central venous pressure (CVP), and pulmonary artery pressure (if indicated) to anticipate adjustment of fluid replacement.
4. Avoid using dialysis access extremity for IV lines, intra-arterial monitoring, or restraints.
5. Although rare, hemodialysis may be required in the postoperative period if the transplanted kidney does not function immediately.

Patient Education and Health Maintenance

After Nephrectomy

1. Provide information about continued recovery from surgery, including engaging in regular exercise, refraining from heavy lifting or strenuous activities, and resuming normal dietary intake.

2. Promote wearing a MedicAlert bracelet and inform all health care providers of solitary kidney status.
3. Encourage close follow-up and need to seek medical attention for any signs of urinary infection, urinary obstruction, or urinary tract disease if there is only one kidney present to prevent damage to that kidney.

After Kidney Transplantation

1. Explain and reinforce symptoms of rejection—fever, chills, sweating, lassitude, hypertension, weight gain, peripheral edema, decrease in urine output.
   a. Hyperacute rejection—occurs within minutes or hours of transplantation and is rarely treatable.
   b. Accelerated rejection—occurs 24 hours to 5 days after transplantation and is treated by plasmapheresis and IV immunoglobulin G.
   c. Acute T-cell–mediated rejection (90% of all rejection episodes)—occurs days to weeks after transplantation and is treated by IV steroids or additional immunosuppression.
   d. Chronic rejection—occurs months to years after transplantation and results in slowly declining function of the allograft.
2. Observe for symptoms of urine leak, such as sudden loss of kidney function, pain over transplant site, and copious drainage of yellow fluid from the wound.
3. Explain continued protection of vascular access graft, which may still be enlarged, tender to palpation, and associated with edema of overlying tissues.
4. Encourage compliance with laboratory tests (blood urea nitrogen [BUN], creatinine, serum chemistry, hematology, bacteriology, cyclosporine, or tacrolimus levels) to monitor patient's immune status and detect early signs of rejection.
5. Instruct patient and family about prescribed immunosuppressant and complications of therapy—infection or incomplete control of rejection.
   a. Review immunosuppressive medications in detail, including color identification of pills, dose schedules, adverse effects, and the necessity for taking the medication.
   b. Review other medications, such as histamine-2 (H_2) blockers or proton pump inhibitors (PPIs), to prevent stress ulcers and prophylaxis for *Candida* and community-acquired infections.
6. Review in detail postoperative self-care regimen (may be inpatient or outpatient), including adequate fluid intake, daily weight, measurement of urine, stool test for occult blood, prevention of infection, exercise.
7. Instruct to report immediately:
   a. Decrease in urinary output.
   b. Weight gain, edema.
   c. Malaise, fever.
   d. Graft swelling and tenderness (visible and palpable below the skin).
   e. Changes in BP readings.
   f. Respiratory distress.
   g. Anxiety, depression, change in appetite or sleep.

8. Discuss with health care provider the feasibility of participating in contact sports because of the risk of trauma to the transplanted kidney.
9. Stress that follow-up care after transplantation is a lifelong necessity.
10. For additional support and information, refer to American Association of Kidney Patients (*www.aakp.org*) and the United Network for Organ Sharing (*https://unos.org*).

Evaluation: Expected Outcomes

- Verbalizes relief of pain.
- Urinary drainage clear without clots.
- Absence of fever or signs of infection.
- Vital signs stable; urine output 50 mL/hour.

Urinary Diversion

EVIDENCE BASE Wein, A. J., Kavoussi, L. R., Partin, A. W., et al. (Eds.). (2017). *Campbell-Walsh urology* (11th ed., Vols. 1–4). Philadelphia, PA: W.B. Saunders.

Urinary diversion refers to diverting the urinary stream from the bladder so that it exits by way of a new avenue. A number of operative procedures may be performed to achieve this (see Figure 21-4). Methods of urinary diversion include:

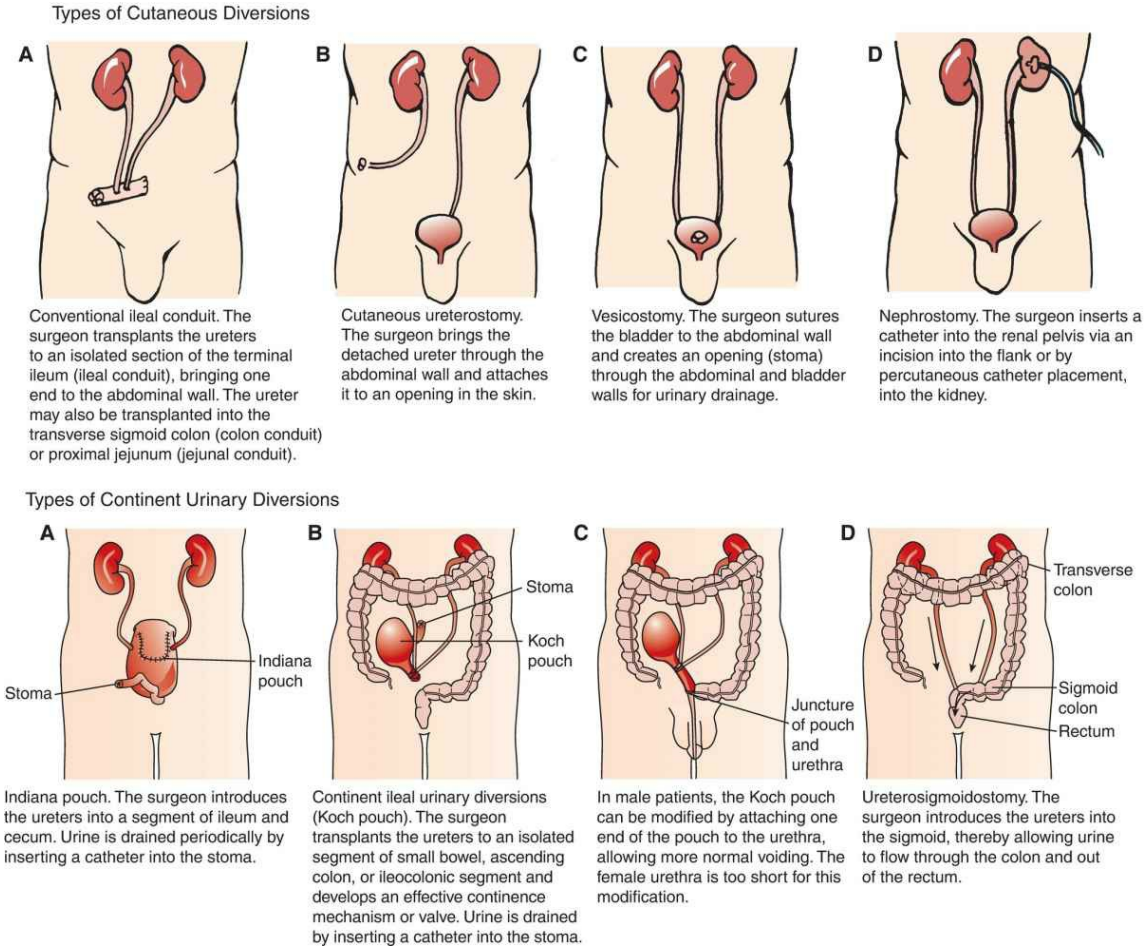

Figure 21-4. Methods of urinary diversion. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

1. Ileal conduit (or "Bricker loop")—most common; transplants the ureters into an isolated section of the terminal ileum, bringing one end through the abdominal wall to create a stoma. Urine flows from the kidney into the ureters, then through the ileal conduit, and exits through urinary stoma. The ureters may

also be transplanted into a segment of the transverse colon (colon conduit).

2. Nephrostomy—insertion of a catheter into the renal pelvis by way of an incision into the flank or by percutaneous catheter placement into the kidney. They are rarely placed for long periods of time; they are a short-term method of diverting urine away from an obstruction or lesion below the level of the renal pelvis.
3. Continent urinary diversion procedures—create a urinary reservoir from an intestinal segment that is either brought to the skin using a valve mechanism that permits catheterization or is anastomosed directly to the proximal urethra.
    a. Continent urinary reservoir (Kock pouch, Indiana pouch, Mainz pouch, and others)—transplants the ureters into a pouch created from small bowel or large and small bowel. Mechanisms to discourage ureteral reflux are used to implant the ureters into the pouch, including an intussuscepted nipple valve or tunneling the ureters through the teniae of the bowel. The existing ileocecal valve, or a surgically created intussuscepted nipple valve, provides the continence mechanism. Patient does not have to wear an external appliance, but the procedure does require intermittent self-catheterization of the pouch.
    b. Orthotopic bladder replacement (hemi-Kock pouch, neobladder, and others)—pouch created from small or large and small bowel is anastomosed to urethral stump; voiding is through the urethra. Patient usually has nocturnal incontinence; not all patients are candidates for this procedure.

Preoperative Management

1. Functional assessment should be performed including degree of manual dexterity and visual acuity along with cognitive function—essential for stoma care or self-catheterization postoperatively.
2. Patient's psychosocial resources are evaluated, including available support persons, education, occupation, and economic resources (including insurance coverage of ostomy supplies, if needed), coping strengths, attitudes toward urinary diversion.
3. Bowel preparation is performed to prevent fecal contamination during surgery and the potential complication of infection.
    a. Clear liquids only and prescribed laxatives for mechanical cleansing of the bowel.
    b. Antibiotics, as prescribed (nonabsorbable; active against enteric organisms), to reduce bacterial count in the bowel lumen.
4. Adequate hydration is ensured, including IV infusions, to ensure urine flow during surgery and to prevent hypovolemia.
5. The procedure is explained by the surgeon and the WOCN (wound, ostomy, continence nurse) before surgery.
    a. For ileal or colon conduit, the stoma site is planned preoperatively with patient standing, sitting, and lying—to place the stoma away from bony prominences, skin creases, and scars and where the patient can see it.
    b. Stoma site may also be marked even though continent urinary diversion procedure is planned, in case

findings during surgery prevent continent procedure and standard ileal or colon conduit is necessary.

Postoperative Management

1. Patient is assessed for immediate postoperative complications: wound or UTI, urinary or fecal anastomotic leakage, small bowel obstruction, paralytic ileus, deep vein thrombosis, pulmonary embolism, and necrosis of stoma.
2. Intake and output are monitored including amount of urinary output, patency of drainage catheters, and degree of hematuria.
3. Pelvic gravity or suction drains are evaluated—sudden increase in drainage suggests an anastomotic leak; send specimen of drainage for creatinine, if ordered. (Presence of measurable creatinine in the drainage indicates urine in drainage, confirming a urine leak.)
4. Ureteral stents are used to protect ureterointestinal anastomoses; stents will emerge from stoma or through separate wound (stents are not visible in orthotopic bladder replacement patients). They are removed in 3 weeks.

Nursing Diagnoses

- Impaired Urinary Elimination related to urinary diversion.
- Acute Pain related to surgery.
- Disturbed Body Image related to urinary diversion.
- Sexual Dysfunction related to reconstructive surgery and impotence (in men).

Nursing Interventions

Achieving Urinary Elimination

For ileal or colon conduit patients:

1. Maintain a transparent urostomy pouch over the stoma postoperatively to allow for easy assessment.
2. Inspect the stoma for color and size; whether it is flush, nippled, or retracted; and the condition of the skin around the stoma. Document baseline information for subsequent comparison.
    a. Stoma should be red, wet with mucus, soft, and slightly rubbery to the touch (stoma lacks nerve ending, so feeling in stoma is absent).
    b. Cyanotic stoma indicates poor circulation.
    c. Necrotic stoma is blue-black or tan-brown.
3. Report bleeding, necrosis, sloughing, suture separation.
4. Check patency of ureteral stents.
5. Keep the pouch on at all times, and observe normal urine (but not fecal) drainage at all times.
    a. Connect pouches to drainage bag when patient is in bed and record urine volume hourly.
    b. Initial urostomy pouch remains in place for several days postoperatively; it is changed every 3 to 4 days when patient teaching begins.

For continent urinary diversion patients:

1. Maintain patency of drainage catheters placed into internal urinary pouch during surgery; irrigate with 30 mL saline every 2 to 4 hours to prevent obstruction from mucous accumulation.
2. Assess stoma—should be very small and flush.
3. Record urine output and character of urine.
4. Monitor output of pelvic drain (on gentle suction or gravity drainage) every 8 hours.
5. Advise patient that approximately 3 weeks after surgery, the drainage catheter is removed from the pouch after a radiographic study ("pouch-o-gram") confirms healing of all anastomoses.

Controlling Pain

1. Administer analgesic medications or teach use of and monitor PCA (IV or epidural).
2. Assess response to pain control.
3. Provide positioning for comfort, alternating with ambulation, as able.

Resolving Body Image Issues

1. Assess patient's reaction to looking at new urinary stoma, if applicable; provide reassurance and support.
2. Be on the alert for difficulty coping, which may be manifested in irritability or lack of motivation to learn.
    a. Give extra support until patient can cope.
    b. Reinforce the concept that the stoma will be manageable.
    c. Acknowledge feelings of fear and anxiety as normal.
3. Encourage patient to participate gradually in care of stoma or catheters.
4. Encourage verbalization of feelings and concerns related to urinary diversion.
5. If possible, arrange for patient to speak with another patient who has undergone the same surgery; this provides realistic expectations and support for a positive outcome.
6. Help patient and family to gain independence through learning to manage the ostomy. Provide for demonstrations, supervised practice, written instructions, and return demonstrations until patient is independent in self-care.

Coping with Sexual Dysfunction

1. Be aware that many men experience impotence as a result of surgery; provide information or referrals about options including medications, pharmacologic erection programs, and penile prostheses.
2. Allow patient to express feelings related to loss of sexual function and encourage discussion with partner.
3. Tell women that they may usually resume sexual activity after healing is complete.

Patient Education and Health Maintenance

For Ileal or Colon Conduit Patients

1. Obtain and familiarize patient with the appropriate equipment. Most urostomy pouching systems are

disposable. The choice of pouch is determined by location of stoma, patient activity, body build, and economic status.

   a. Two-piece pouches consist of a skin barrier (or wafer) that fits around the stoma and adheres to the skin and a pouch that snaps onto the skin barrier.
   b. One-piece pouches may be precut for the correct stoma size and include the adhesive; the pouch is applied directly to the peristomal skin.

2. Assist patient to determine stoma size (for ordering correct appliance). The stoma will shrink considerably as edema subsides and the size is recalibrated several times during the first 3 to 6 weeks postoperatively.
   a. Measuring guides are included with most urostomy pouches.
   b. The inside diameter of the skin barrier should not be more than 1/16 inch larger than the diameter of the stoma.
3. Teach how to change the pouch.
   a. Change pouch early in the morning before taking fluids or before evening meal—urine output is lower at these times.
   b. Prepare the new pouching system according to manufacturer's directions.
   c. Wash the peristomal skin with non–cream-based soap and water. Rinse and pat dry. *The skin must be dry or appliance will not adhere*.
   d. A gauze or tissue wick may be applied over the stoma to absorb urine while the appliance is being changed. Keep the skin free from direct contact with urine. Suggest the use of tampons to soak up urine from stoma while changing pouch at home, if desired; however, do not insert into stoma.
   e. Center the skin barrier directly over the stoma and apply it carefully. Apply gentle pressure around appliance for secure adherence.
   f. Apply a belt to keep pouch in place, if desired; it is especially useful in patients with soft abdomens.
4. Advise that additional adhesives, such as pastes or cements, are not usually necessary with a well-fitting pouch.
5. Tell patient that frequency of pouch changes depends on the type of pouch used—generally pouches should be changed every 3 to 4 days.
6. Advise emptying the pouch when it is one third to one-half full to prevent weight of urine from loosening adhesive seal—open drain valve (spigot) for periodic emptying.
7. Teach how to attach outlet on pouch to a bedside urinary drainage container with plastic tubing (at least 5 feet to allow turning) and how to secure tubing to the leg to prevent twisting or kinking.
   a. Position the drainage bottle lower than the level of the bed to enhance flow by gravity.
   b. Clean nighttime drainage equipment with vinegar and water. Rinse well.
8. Advise patient to drink liberal amounts of fluids to flush the conduit free of mucus and reduce possibility of urinary infection.
9. Teach that the stoma may bleed if it is bumped or rubbed; report bleeding that continues for several

hours.

10. Advise carrying spare pouches in handbag or pocket and bringing an extra pouch to every visit with health care provider.
11. Advise wearing cotton (rather than nylon) underwear or the use of specially made underwear for ostomy patients that prevents contact between plastic pouch and skin. Heavy girdles are not allowed because they may cause chafing of the stoma and prevent free flow of urine.
12. Advise reporting problems with peristomal skin or with leakage from the pouch or the development of fever, chills, pain, change in color of urine (cloudy, bloody), and diminishing urine output.
13. For additional information and support, refer to United Ostomy Associations of America (*www.ostomy.org*).

For Continent Ileal Urinary Reservoir Patients

1. Teach irrigation of catheter; this must be done every 4 to 6 hours at home.
2. Teach how to change stoma dressing.
3. Instruct in use of leg bag or bedside urinary drainage bag while catheter remains in place.
4. Teach how to catheterize continent urinary diversion when healing is verified:
   a. Red rubber or plastic, straight, or coudé catheters are used.
   b. Apply a small amount of water-soluble lubricant to the tip of the catheter.
   c. Use clean technique; wash hands before each catheterization.
   d. Maintain schedule of catheterizations during initial "training" period to allow the pouch to adapt gradually to holding larger amounts of urine (every 2 hours during day and every 3 hours at night; increase by 1 hour each week for 5 weeks).
   e. After training period, catheterize four to five times per day; pouch should not hold more than 400 to 500 mL.
   f. Irrigate pouch with saline through catheter once per day to clear it of accumulated mucus.
5. Teach patient to report problems such as leakage of urine from stoma between catheterizations.
6. Tell patient to shower or bathe normally, wear normal clothing; only a small dressing or an adhesive bandage needs to be worn over the stoma.
7. Advise patient to drink 8 to 10 glasses of water daily.

For Orthotopic Bladder Replacement

1. Teach patient to irrigate Foley catheter that will stay in place for 3 weeks after surgery; irrigate with 30 mL saline every 4 to 6 hours.
2. Instruct in use of leg bag or bedside drainage bag while catheter remains in place.
3. Instruct on how to change dressing.
4. After healing of pouch is confirmed and catheter is removed, teach patient to "void."
   a. Voiding is accomplished by abdominal straining; mucus is expected in voided urine.
   b. Voiding schedule must be maintained for the first 5 to 6 weeks (every 2 hours during day and every 3

hours at night; increase by 1 hour each week).

c. Incontinence is anticipated after catheter is removed; usually more pronounced when patient is asleep and muscles are relaxed.

5. Teach patient to perform pelvic floor exercises, which must be done faithfully for the rest of his or her life; as pelvic floor sphincter muscles strengthen, incontinence subsides. Most patients continue to have small amounts of nocturnal incontinence.
   a. Contract pelvic floor muscles (as if stopping stream of urine or flatus) for 5 seconds; then, relax for 5 to 10 seconds.
   b. Repeat approximately 15 to 20 times for one set, and do three sets per day.
   c. May require referral to physical therapist to assist in the process.
6. Provide information about absorbent products that may be used temporarily; also, teach about preventive skin care.
7. Instruct in clean self-catheterization, which may be needed if the urethra becomes obstructed with mucus; pouch should be irrigated with saline if catheterization is necessary.
8. Reassure patient that time, patience, and continued adherence to voiding and exercise schedule will result in continence.

Evaluation: Expected Outcomes

- Urine draining by way of urinary diversion.
- Verbalizes good pain control.
- Discusses feelings about change in body image; seeks support through family.
- Verbalizes reasonable expectations about sexual function.

Prostatic Surgery

Prostatic surgery may be done for benign prostatic hyperplasia (BPH) or prostate cancer. Surgical approach depends on size of the gland, severity of obstruction, age, underlying health, and prostatic disease.

Surgical Procedures

EVIDENCE BASE Wein, A. J., Kavoussi, L. R., Partin, A. W., et al. (Eds.). (2017). *Campbell-Walsh urology* (11th ed., Vols. 1–4). Philadelphia, PA: W.B. Saunders.

---

1. TURP (formerly the most common procedure) is done without an incision by means of endoscopic instrument.
2. Photovaporization of the prostate (PVP) is starting to replace TURP; it is done through a cystoscope, using a laser to vaporize diseased prostatic tissue.
3. Transurethral microwave thermotherapy (TUMT) of the prostate and transurethral needle ablation (TUNA) of the prostate are both office-based procedures that use heat to destroy diseased prostatic tissue.
4. Indigo interstitial laser therapy of the prostate is another procedure that is done on an outpatient basis.
5. Open prostatectomy.
   a. Suprapubic—incision into suprapubic area and through bladder wall; commonly done for BPH.
   b. Perineal—incision between the scrotum and rectal area; may be done for poor surgical risk patients, but causes highest incidence of urinary incontinence and impotence.
   c. Radical retropubic—incision at the level of symphysis pubis; may preserve nerves responsible for sexual function; done for prostate cancer.
6. Robotic radical prostatectomy uses a laparoscopic approach for removal of cancerous prostate.

Preoperative Management

1. Information about the procedure and the expected postoperative care, including catheter drainage, irrigation, and monitoring of hematuria, is discussed.
2. Complications of surgery are discussed.
   a. For radical and laparoscopic prostatectomy, incontinence or dribbling of urine may occur for up to 1 year after surgery; pelvic floor (Kegel) exercises help regain urinary control.
   b. For TURP and PVP, retrograde ejaculation—seminal fluid released into the bladder and eliminated in the urine rather than through the urethra during intercourse occurs in 75% or patients; impotence is usually not a complication but occurs in 5% to 10% of TURP and PVP patients and can be as high as 75% in those undergoing radical prostatectomy.
3. Bowel preparation is given or patient is instructed in home administration and fasting after midnight.

4. Optimal cardiac, respiratory, and circulatory status should be achieved to decrease risk of complications.
5. Prophylactic antibiotics are ordered.

Postoperative Management

1. Urinary drainage is maintained and observed for signs of hemorrhage.
2. Wound care is provided to prevent infection.
3. Pain is controlled and early ambulation is promoted.
4. Surveillance is maintained for complications.
    a. Wound infection and dehiscence.
    b. Urinary obstruction or infection.
    c. Hemorrhage.
    d. Thrombophlebitis, deep vein thrombosis, and pulmonary embolism.
    e. Urinary incontinence, sexual dysfunction.

Nursing Diagnoses

- Impaired Urinary Elimination related to surgical procedure and urinary catheter.
- Risk for Infection related to surgical incision, immobility, and urinary catheter.
- Acute Pain related to surgical procedure.
- Anxiety related to urinary incontinence, difficulty voiding, and erectile dysfunction.

Nursing Interventions

Facilitating Urinary Drainage

1. Maintain patency of urethral catheter placed after surgery.
    a. For TURP and open prostatectomy for BPH, monitor flow of three-way closed irrigation and drainage system (see Figure 21-5) if used. Continuous irrigation helps prevent clot formation, which can obstruct catheter, cause painful bladder spasms, and lead to infection.
    b. If Foley is obstructed and with a health care provider order, manually irrigate with 50 to 60 mL irrigating fluid using aseptic technique.
    c. Avoid overdistention of the bladder, which could lead to hemorrhage.
    d. Administer anticholinergic medications to reduce bladder spasms, as ordered.
2. Assess degree of hematuria and any clot formation; drainage should become light pink within 24 hours.
    a. Report bright red bleeding with increased viscosity (arterial)—may require surgical intervention.
    b. Report increase in dark red bleeding (venous)—may require traction of the catheter so the inflated balloon applies pressure to prostatic fossa.
    c. Prepare for blood transfusion if bleeding persists.
3. Administer IV fluids, as ordered, and encourage oral fluids when tolerated to ensure hydration and urine output.

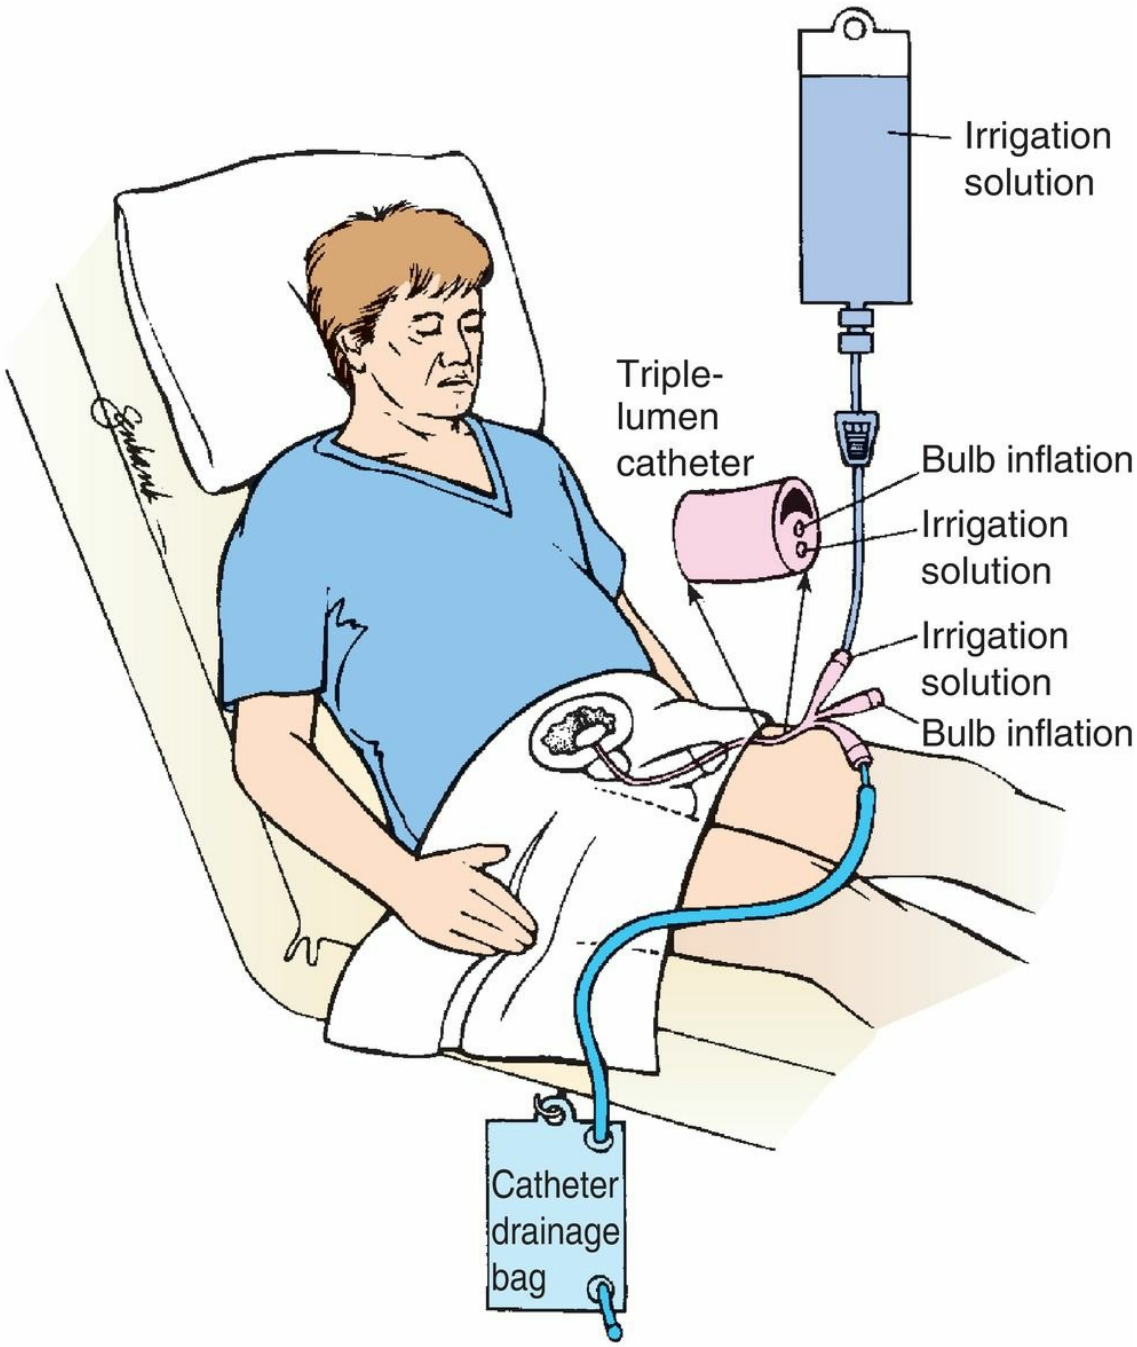

Figure 21-5. A three-way system for bladder irrigation. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

DRUG ALERT Anticholinergic medications are contraindicated in patients with narrow angle-closure glaucoma.

Preventing Infection

1. After open prostatectomy, provide frequent monitoring of vital signs, intake and output, and observation of incisional dressing, if present.
2. Encourage ambulation to prevent venous thrombosis, pulmonary embolism, and pneumonia.
3. Observe urine for cloudiness or odor and obtain urine for evaluation of infection, as ordered.
4. Administer antibiotics, as prescribed.
5. Report testicular pain, swelling, and tenderness, which could indicate epididymitis from spreading infection.
6. Assist with perineal care if perineal incision is present to prevent contamination by feces.

Relieving Pain

1. Administer pain medication or monitor PCA, as directed.
2. Position patient for comfort and tell him or her to avoid straining, which will increase pelvic venous congestion and may cause hemorrhage.
3. Administer stool softeners to prevent discomfort from constipation.
4. Make sure catheter is secured to patient's thigh and tubing is not creating traction on catheter, which will cause pain and potential hemorrhage.

NURSING ALERT Avoid rectal temperatures, enemas, or rectal tubes postoperatively to prevent hemorrhage or disruption of healing.

Reducing Anxiety

1. Provide realistic expectations about postoperative discomfort and overall progress.
    a. Tell patient to avoid sexual intercourse, straining at stool, heavy lifting, and long periods of sitting for 6 to 8 weeks after surgery.
    b. Advise follow-up visits after treatment because urethral stricture or bladder neck contracture may occur.
2. Reassure patient that urinary incontinence and frequency, urgency, and dysuria are expected after removal of catheter and should gradually subside.
3. Reassure patient that there may be measures to help.
4. Reinforce the risks for impotence as told by the surgeon. Remind patient that erectile function may not return for 12 months.
5. Encourage patient to express fears and anxieties related to potential loss of sexual function and to discuss concerns with partner.
6. Advise that options are available to restore sexual function if impotence persists.

Patient Education and Health Maintenance

1. Advise patient that PVP is commonly done on an outpatient basis; patient may go home the evening of surgery.
2. Reinforce instructions provided on catheter care, maintaining patency, and catheter irrigation.
    a. For open, radical, and laparoscopic prostatectomy patients, the catheter will be removed in 2 to 3 weeks. A cystogram may be performed to confirm healing of anastomosis prior to removing catheter.
    b. Advise that stress incontinence may occur after catheter is removed and is more pronounced when abdominal pressure is increased, such as with coughing, laughing, straining.
    c. For patients who experience urgency before surgery, caution that they may have urge incontinence for several weeks postoperatively.
    d. Discuss the use of absorbent products to contain urine leakage around catheter and after catheter is removed.
3. Teach measures to regain urinary control. Teach patient to perform pelvic floor exercises correctly. Have patient squeeze the pelvic floor muscles (as if stopping stream of urine or flatus) for 5 seconds and then relax for 5 to 10 seconds. This should be done 15 to 20 times, three times per day. Caution against using abdominal muscles (straining or Valsalva maneuver), which increases incontinence.
4. Reinforce availability of options such as medications for urinary urgency and oral medicine such as sildenafil, vacuum erectile device, penile injections, and penile prosthesis to restore sexual function.
5. Encourage prostate cancer patients to have a PSA blood test 3 months after surgery and yearly thereafter.

Evaluation: Expected Outcomes

- Clear yellow drainage by way of catheter.
- Incision without drainage; afebrile.
- Verbalizes good pain relief.
- Verbalizes realistic expectations for urinary and sexual functioning.

RENAL AND UROLOGIC DISORDERS

Acute Kidney Injury

Acute kidney injury (AKI) is a clinical syndrome in which there is a sudden decline in renal function. This results in disturbances in fluid and electrolyte balance, acid–base homeostasis, blood pressure regulation, erythropoiesis, and mineral metabolism. It is frequently associated with an increase in BUN and creatinine, oliguria, hyperkalemia, and sodium and fluid retention.

Pathophysiology and Etiology

Causes

See Figure 21-6.

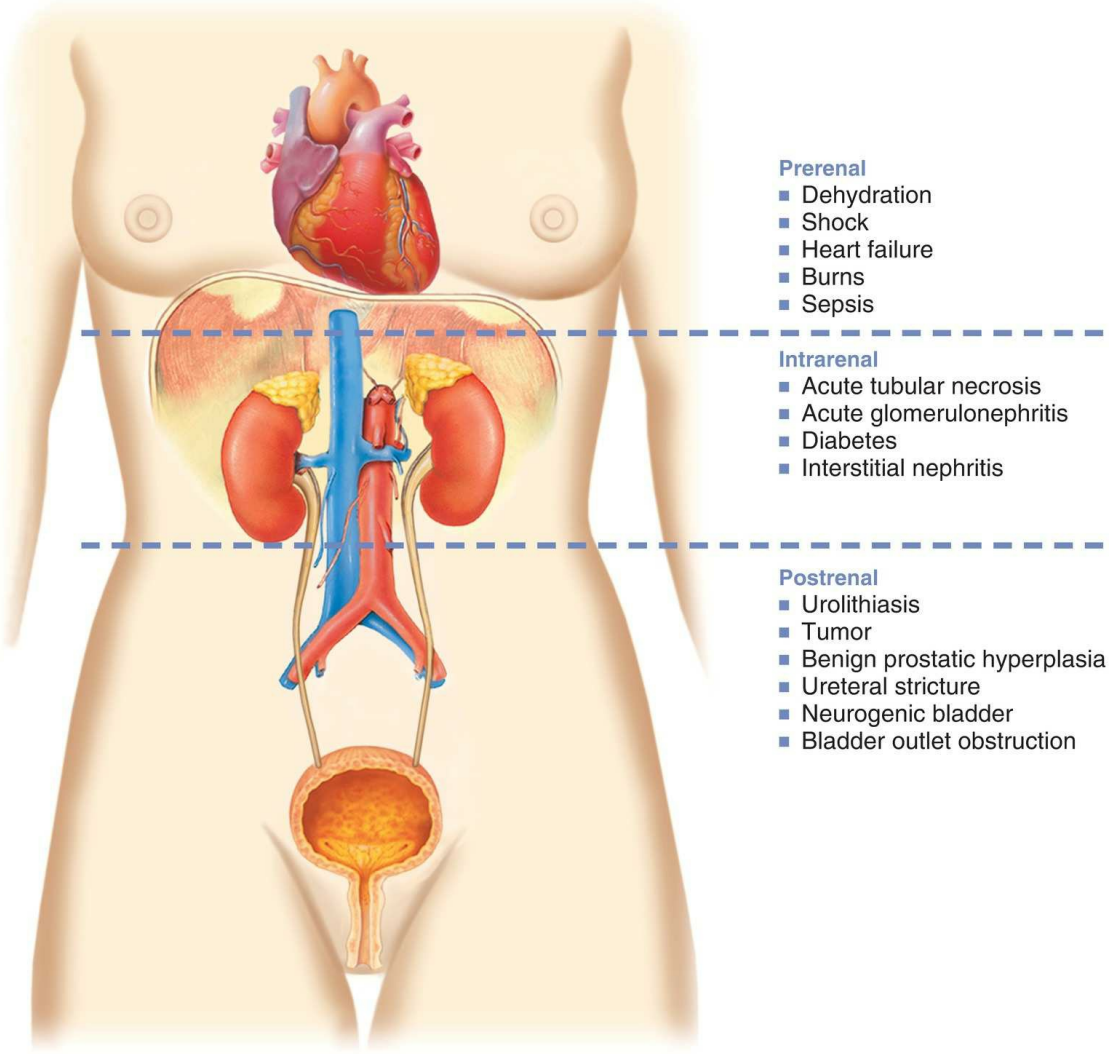

Figure 21-6. Causes of acute renal failure.

1. Prerenal causes—result from conditions that decrease renal blood flow (hypovolemia, shock, hemorrhage, burns, impaired cardiac output, diuretic therapy, and renal artery disorders).
2. Intrarenal causes—result from injury to renal tissue and are usually associated with intrarenal ischemia, toxins, immunologic processes, systemic disorders, trauma, and vascular disorders.
3. Postrenal causes—arise from obstruction or disruption to urine flow anywhere along the urinary tract.

Clinical Course

1. Onset: begins when the kidney is injured and lasts from hours to days.
2. Oliguric–anuric phase: urine volume less than 400 to 500 mL/24 hours.
   a. Accompanied by rise in serum concentration of elements usually excreted by the kidney (urea, creatinine, organic acids, and the intracellular cations—potassium and magnesium).
   b. In approximately 50% patients with AKI, urine output remains greater than 500 cc/day. This is called nonoliguric AKI. These patients often have less complications and better prognosis for recovery than oliguric patient.

3. Diuretic phase
    a. Characterized by high urine output because of the kidney's inability to concentrate urine.
    b. Close monitoring of fluid volume and electrolytes is essential.
4. Recovery phase.
    a. Usually lasts several months to 1 year.
    b. Complete recovery of renal function may occur or they may be some residual deficits because of scarring of kidney tissue.
    c. Avoiding secondary insults to the kidney, such as nephrotoxic drugs, contrast dye, hypotension, and infection, is important to minimize permanent kidney damage.

Clinical Manifestations

1. Prerenal—signs and symptoms consistent with hypovolemia may be present such as decreased tissue turgor, dryness of mucous membranes, weight loss, hypotension, oliguria or anuria, reduced jugular venous distention, and tachycardia. However, if the prerenal cause is related to vasodilation, third spacing of fluid, or cardiovascular disease, signs/symptoms of increased extracellular fluid may be present.
2. Intrarenal—presentation based on the cause; edema usually present.
3. Postrenal—findings may include a distended bladder, an abdominal mass, and an enlarged prostate. Renal colic may be present with nephrolithiasis.

Diagnostic Evaluation

1. Urinalysis—reveals proteinuria, hematuria, casts, increased WBC and nitrate (possible infection), glycosuria, and pH. Also can give clues of hydration status (specific gravity).
2. Rising serum creatinine and BUN levels.
3. Urine chemistry examinations to help distinguish various forms of acute renal failure.
4. Renal ultrasonography—for estimate of renal size, to evaluate for masses, and to exclude a treatable obstructive uropathy.
5. CT/MRI to evaluate for masses or vascular disorders and renal angiography to evaluate for renal artery stenosis.
6. Renal biopsy in selected cases of unexplained proteinuria.

Management

Preventive Measures

1. Identify patients with preexisting renal disease.
2. Initiate adequate hydration before, during, and after any procedure requiring NPO status.
3. Avoid exposure to nephrotoxins. Be aware that many drugs or their metabolites are excreted by the kidneys.
4. Prevent and treat shock with blood and fluid replacement. Prevent prolonged periods of hypotension.

5. Close monitoring of urinary output and hydration status (CVP, edema, pulmonary exam) in critically ill patients.
6. Ensure adequate hydration if contrast dye studies are indicated and attempt to avoid scheduling consecutive dye studies. Patients at most risk for contrast-induced nephropathy (CIN) are those with baseline renal impairment, diabetes, elderly patients, and patients with heart failure.
7. Avoid infections; give meticulous care to patients with indwelling catheters and IV lines.
8. Take every precaution to make sure that the right person receives the right blood to avoid severe transfusion reactions, which can precipitate renal complications.

DRUG ALERT Nonsteroidal anti-inflammatory drugs (NSAIDs) may reduce glomerular filtration rate in people at risk for renal insufficiency, causing renal failure.

Corrective and Supportive Measures

1. Correct reversible cause of acute renal failure (eg, improve renal perfusion, maximize cardiac output, surgical relief of obstruction).
2. Be alert for and correct underlying fluid excesses or deficits.
3. Correct and control acid/base and electrolyte imbalances: hyperkalemia, hypocalcemia, hyperphosphatemia, and metabolic acidosis.
4. Restore and maintain MAP greater than 65.
5. Support nutrition.
6. Adjust renally excreted medication dosages/frequency. Timing of medications may also be adjusted in patient receiving intermittent hemodialysis.
7. Initiate hemodialysis, peritoneal dialysis, or CRRT if indicated.

Complications

1. Infection.
2. Metabolic acidosis.
3. Anemia.
4. Arrhythmias because of electrolyte imbalances including hyperkalemia, hypocalcemia, and metabolic acidosis.
5. Electrolyte and mineral (sodium, potassium, calcium, phosphorus, magnesium) abnormalities.
6. Hypervolemic complications: pulmonary edema and HTN.
7. GI bleeding because of stress ulcers and platelet abnormalities.
8. Multiple organ system failure.

Nursing Assessment

1. Determine if there is a history of cardiac disease, hypovolemia, trauma, malignancy, sepsis, benign prostatic hypertrophy, abdominal tumors, kidney stones, or intercurrent illness.
2. Determine if patient has been exposed to potentially nephrotoxic drugs (antibiotics, NSAIDs, contrast agents, solvents).
3. Conduct an ongoing physical examination for tissue turgor, pallor, alterations in mucous membranes, BP, heart rate changes, pulmonary edema, and peripheral edema.
4. Monitor intake and output.

Nursing Diagnoses

- Risk for Imbalanced Fluid Volume.
- Risk for Electrolyte Imbalance related to kidney injury.
- Risk for Infection related to alterations in the immune system and host defenses.
- Imbalanced Nutrition: Less Than Body Requirements related to catabolic state, anorexia, and malnutrition associated with acute kidney injury.
- Risk for Bleeding related to GI mucosal irritation and altered platelet function.
- Acute Confusion related to the effects of uremic toxins on the central nervous system (CNS).
- Knowledge deficit of disease, treatment, prognosis, and monitoring.

Nursing Interventions

Monitoring and Maintaining Fluid Balance

See Table 21-2.

Table 21-2 Signs and Symptoms of Fluid and Electrolyte Imbalances

	DEFICIT	EXCESS
Volume	Acute weight loss (>5%), drop in body temperature, dry skin and mucous membranes, postural hypotension, longitudinal wrinkles or furrows of tongue, oliguria or anuria	Acute weight gain (>5%), edema, hypertension, distended neck veins, dyspnea, rales
Sodium	Abdominal cramps, muscle weakness, apprehension, convulsions, hypotension and tachycardia, oliguria or anuria	Agitation, muscle irritability, dry, sticky mucous membranes, HTN, tachycardia, edema, dyspnea, thirst, rough and dry tongue, increased viscosity of saliva
Potassium	Anorexia, abdominal distention, intestinal ileus, muscle weakness, tenderness, and cramps; dizziness, hypotension, cardiac arrhythmias	Diarrhea, intestinal colic, irritability, nausea, muscle weakness, flaccid paralysis, cardiac arrhythmias and arrest
Calcium	Irritability, laryngospasm, positive Chvostek and Trousseau signs, tingling of extremities, tetany	Lethargy, mental confusion, anorexia, nausea, vomiting, abdominal pain and distention, constipation, bone pain
Bicarbonate	Deep, rapid breathing (Kussmaul), shortness of breath on exertion, stupor, weakness (metabolic acidosis)	Depressed respirations, muscle hypertonicity, tetany (metabolic alkalosis)
Magnesium	Positive Chvostek sign, seizures, disorientation, seizures, hyperactive deep tendon reflexes, dysrhythmias	Hypotension, bradycardia, lethargy, hypoactive deep tendon reflexes, respiratory depression

1. Monitor for signs and symptoms of hypervolemia.
   a. Crackles on auscultation of lungs; engorged neck veins (jugular venous distention); periorbital edema; ascites; edema of extremities/sacrum.
   b. Elevated blood pressure.
   c. Elevated CVP.

2. Assess for evidence of hypovolemia.
    a. Dry mucous membranes; poor skin turgor.
    b. Hypotension; orthostatic blood pressure changes.
3. Monitor urinary output and urine specific gravity, as ordered; measure and record intake and output including urine, gastric suction, stool, and wound drainage.
4. Monitor serum and urine electrolyte concentrations.
5. Weigh patient daily to provide an index of fluid balance.
6. Adjust fluid intake to avoid volume overload and volume depletion.
    a. Fluid restriction is usually initiated in oliguric patients.
    b. During oliguric–anuric phase, give only enough fluids to replace losses (usually 400 to 500 mL/24 hours plus measured fluid losses).
    c. Fluid allowance should be distributed throughout the day.
    d. Restrict salt and water intake if there is evidence of extracellular excess.
7. Provide patient education on fluid and sodium restriction, if indicated.

Maintaining Electrolyte and Acid–Base Balance

1. Monitor and replace serum electrolytes ordered.
    a. Evaluate for signs and symptoms of hyperkalemia (see table above).
    b. Notify health care provider of value above 5.5 mg/L.
    c. Watch for ECG changes—tall, tented T waves; depressed ST segment; wide QRS complex.
    d. Administer sodium bicarbonate or glucose and insulin to shift potassium into the cells, as ordered.
    e. Administer cation exchange resin (sodium polystyrene sulfonate) orally or rectally to provide more prolonged correction of elevated potassium, as ordered.
    f. Instruct patient about the importance of following prescribed diet, avoiding foods high in potassium.
    g. Prepare for dialysis when rapid lowering of potassium is needed.
    h. Administer blood transfusions *during* dialysis to prevent hyperkalemia from stored blood.
2. Monitor acid–base status as directed.
    a. Arterial blood gas (ABG) or venous blood gas.
    b. CO_2 on chemistry panel approximates ABG bicarbonate level.
3. Prepare for ventilator therapy if severe acidosis is present.
4. Administer oral alkalizing medications or IV sodium bicarbonate as ordered.
5. Be prepared to implement dialysis for uncontrolled acidosis.

Preventing and Monitoring for Infection

1. Monitor for signs of infection.
2. Remove bladder catheter as soon as possible; monitor for UTI.
3. Use intensive pulmonary hygiene—high incidence of lung edema and infection.

4. Carry out meticulous wound care.
5. If antibiotics are administered, care must be taken to adjust the dosage for renal impairment.

Maintaining Adequate Nutrition

1. Work collaboratively with dietitian to direct nutritional support.
2. Protein sources should be of high biologic value—rich in essential amino acids (fish, eggs, meat)—so that the patient does not rely on tissue catabolism for essential amino acids.
3. Encourage small frequent meals if the patient is experiencing nausea or reflux symptoms.
4. Weigh patient daily.
5. Monitor BUN, creatinine, electrolytes, serum albumin, prealbumin, total protein, and transferrin.
6. Be aware that food and fluids containing large amounts of sodium, potassium, and phosphorus may need to be restricted.

Monitoring For and Preventing GI Bleeding

1. Examine all stools and emesis for gross and occult blood.
2. Administer H_2-receptor antagonist or PPIs, as directed as prophylaxis for gastric stress ulcers. If an H_2-receptor antagonist is used, care must be taken to adjust the dose for the degree of renal impairment.
3. Prepare for endoscopy when GI bleeding occurs.

Monitoring Cognition and Orientation

1. Speak to the patient in simple orienting statements, using repetition when necessary.
2. Monitor for and report mental status changes—somnolence, lassitude, lethargy, and fatigue progressing to irritability, disorientation, twitching, seizures.
3. Use seizure precautions—padded side rails and airway and suction equipment at bedside, if indicated.
4. Prepare for dialysis, which may help prevent confusion related to uremia.

Patient Education and Health Maintenance

1. Explain to patient that he/she may have residual defects in kidney function and that AKI puts him/her at increased risk for CKD.
2. Educate patient on importance of follow-up with their provider for ongoing monitoring of renal function.
3. Advise avoidance of any medications unless specifically prescribed.
4. Provide education on means to slow the progression of kidney disease in patient with residual deficits in kidney function.
    a. Avoid or minimize exposure to nephrotoxins such as NSAIDs, radiocontrast dye, some antibiotics, some chemotherapeutic agents, and some anticonvulsants.
    b. Maintain good blood pressure control (target HgbA1c of 7).
    c. Monitor for and aggressively treat UTIs.

d. Avoid intravascular volume depletion.

e. Smoking cessation.

f. Low-sodium diet.

g. Maintain healthy BMI (20 to 25 kg/m^2).

Evaluation: Expected Outcomes

- BP stable; no edema or shortness of breath.
- Serum electrolytes and arterial blood gas values within normal range.
- No signs of infection.
- Adequate caloric intake, stable weight, and normal total protein and albumin level.
- Stool negative for occult; Hgb level stable.
- Alert and oriented × 3.

Chronic Kidney Disease

Chronic kidney disease (CKD) is a progressive deterioration of renal function, which, if left untreated, eventually results in death because of uremia (an excess of urea and other nitrogenous wastes in the blood) and its complications. The treatment for end-stage renal disease (ESRD) is dialysis or kidney transplantation. According to the National Kidney Foundation, approximately 30 million Americans have some type of CKD. Most cases are asymptomatic until later stages and most people die from other comorbidities (ie, cardiac disease, DM) before reaching ESRD.

Pathophysiology and Etiology

Causes

1. Hypertension.
2. Diabetes mellitus.
3. Glomerulopathies (from lupus or other disorders).
4. Interstitial nephritis.
5. Hereditary renal disease, polycystic disease.
6. Obstructive uropathy.
7. Developmental or congenital disorder.

Clinical Course and Consequences of Decreasing Renal Function

1. Rate of progression varies based on underlying cause and severity of that condition.
2. Stages 1 to 5 based on glomerular filtration rate (GFR); stage 5 is most severe: end-stage renal disease.
3. Retention of sodium and water causes volume overload, which can lead to edema, heart failure, hypertension, and HTN.
4. Metabolic acidosis results from the kidney's inability to excrete hydrogen ions, produce ammonia, and conserve bicarbonate.
5. Decreased GFR causes increase in serum phosphate with reciprocal decrease in serum calcium, which can lead to bone demineralization.
6. Erythropoietin production by the kidney decreases, causing anemia.
7. Uremia affects the CNS, which, if left untreated, can cause altered cognitive function, personality changes, seizures, and coma.

Clinical Manifestations

1. GI—anorexia, metallic taste in the mouth, nausea, vomiting, diarrhea, constipation, ulceration of GI tract, and hemorrhage.
2. Cardiovascular—hyperkalemic ECG changes, hypertension, pericarditis, pericardial effusion, pericardial tamponade.
3. Respiratory—pulmonary edema, pleural effusions, pleural rub.

4. Neuromuscular—fatigue, sleep disorders, headache, lethargy, muscular irritability, peripheral neuropathy, seizures, coma.
5. Metabolic and endocrine—changes in insulin metabolism, decreased vitamin D_3 levels (resulting in decreased calcium absorption), secondary hyperparathyroidism (high parathyroid hormone levels), hyperlipidemia, sex hormone disturbances causing decreased libido, impotence, amenorrhea.
6. Electrolyte and acid–base disturbances—metabolic acidosis, hyperkalemia, hypermagnesemia, hypocalcemia (see page 605).
7. Dermatologic—pallor, hyperpigmentation, pruritus, ecchymosis, uremic frost (deposits of urate crystals on the skin from untreated ESRD).
8. Skeletal abnormalities—bone demineralization from metabolic acidosis and renal osteodystrophy.
9. Hematologic—anemia, impaired platelet function causing increased bleeding tendencies, and white blood cell dysfunction, resulting in a state of immunosuppression.
10. Psychosocial functions—personality and behavior changes, alteration in cognitive processes.

Diagnostic Evaluation

1. CBC for anemia.
2. Elevated serum creatinine, BUN, phosphorus, potassium.
3. Decreased serum calcium, bicarbonate, and proteins, especially albumin.
4. ABG levels—metabolic acidosis: low blood pH, low carbon dioxide, low bicarbonate.
5. Spot urine for protein/creatinine ratio. Findings can be validated with 24-hour urine collection.

Management

The goal is to conserve renal function as long as possible and prevent complications.

1. Detection and treatment of underlying causes of renal failure (eg, glycemic control, optimal blood pressure management).
2. Dietary regulation—protein restriction may be beneficial prior to initiation of dialysis to minimize uremic symptoms. Other dietary restrictions include sodium, potassium, and phosphorus restrictions and possible fluid restriction (ESRD).
3. Treatment of associated conditions:
    a. Anemia—erythropoiesis-stimulating agents, such as epoetin alfa and darbepoetin; PO or IV iron administration.
    b. Acidosis—replacement of bicarbonate stores by oral administration of sodium bicarbonate.
    c. Hyperkalemia—restriction of dietary potassium; administration of cation exchange resin.
    d. Phosphate retention and hypocalcemia—dietary PO_4 restriction, administration of phosphate-binding agents; IV or PO vitamin D_3 or vitamin D_3 analogs.
4. Prevent fluid overload through sodium and fluid restriction. May give diuretics pre-ESRD.
5. Maintenance dialysis or kidney transplantation when symptoms can no longer be controlled with

conservative management.

6. Provide patient education on lifestyle measures to help slow progression of CKD (see AKI, page 602).

Complications

1. Cardiovascular events (ie, myocardial infarction, heart failure, cerebral vascular accident)—leading cause of death in patients with CKD.
2. Bleeding: GI bleeding; vascular access bleeding in ESRD.
3. Infection: pulmonary, urinary, and systemic; access related.

Nursing Assessment

1. Obtain history of chronic disorders and underlying health status.
2. Assess degree of renal impairment and involvement of other body systems by obtaining a review of systems and reviewing laboratory results.
3. Perform a thorough physical examination, including vital signs, cardiovascular, pulmonary, GI, neurologic, dermatologic, and musculoskeletal systems.
4. Assess psychosocial response to disease process including availability of resources and support network.

Nursing Diagnoses

- Excess Fluid Volume related to disease process.
- Imbalanced Nutrition: Less Than Body Requirements related to anorexia, nausea, vomiting, and restricted diet.
- Impaired Skin Integrity related to changes in oil and sweat glands and retained skin pigments.
- Constipation related to fluid restriction and ingestion of phosphate-binding agents.
- Risk for Injury because of hemodynamic instability, increased bleeding tendency, muscle cramps, and altered cognition.

Ineffective Therapeutic Regimen Management related to difficulty making lifestyle changes related to diet, medication regimen, and dialysis treatment schedule or medical appointments.

Nursing Interventions

Maintaining Fluid and Electrolyte Balance

See interventions related to AKI, page 604.

Maintaining Adequate Nutritional Status

See interventions related to AKI, page 605.

Maintaining Skin Integrity

1. Keep skin clean while relieving itching and dryness.
    a. Soap for sensitive skin.

b. Oatmeal baths.
c. Bath oil added to bathwater.

2. Apply ointments or creams for comfort and to relieve itching.
3. Keep nails short and trimmed to prevent excoriation.
4. Keep hair clean and moisturized.
5. Administer antihistamines for relief of itching, if indicated, but discourage patient from taking any OTC drugs without discussing with health care provider.

Preventing Constipation

1. Encourage high-fiber diet, bearing in mind the potassium content of some fruits and vegetables, such as apricots, dried fruit, and potato skins.
2. Medications.
   a. Commercial fiber supplements may be prescribed.
   b. Use stool softeners, as prescribed.
   c. Avoid laxatives and cathartics that cause electrolyte toxicities (compounds containing magnesium or phosphorus).
3. Increase activity as tolerated.

Prevent Injury

1. Inspect patient's gait, range of motion, and muscle strength.
2. Administer analgesics, as ordered, and provide massage/heat/IV fluid for severe muscle cramps.
3. Increase activity as tolerated—avoid immobilization because it increases bone demineralization.
4. Check orthostatic blood pressures. Alert provider to orthostatic BP changes and tachycardia.
5. Monitor for signs and symptoms of bleeding.

Increasing Understanding of and Compliance with Treatment Regimen

1. Prepare patient for dialysis or kidney transplantation.
2. Offer hope while providing realistic expectations.
3. Assess patient's understanding of treatment regimen as well as concerns and fears.
4. Explore alternatives that may reduce or eliminate adverse effects of treatment.
   a. Adjust schedule so rest can be achieved after dialysis.
   b. Offer smaller, more frequent meals to reduce nausea and facilitate taking medication.
5. Encourage strengthening of social support system and coping mechanisms to lessen the impact of the stress of CKD.
6. Provide social work and nutritionist referral.
7. Contract with patient for behavioral changes if noncompliant with therapy.
8. Discuss option of supportive psychotherapy for depression or anxiety.
9. Promote decision-making by patient.

10. Refer patients and family members to renal support agencies.

Patient Education and Health Maintenance

1. To promote adherence to the therapeutic program, teach the following:
   a. Weigh self every morning to monitor for fluid overload.
   b. Fluid restriction requirements.
   c. Methods to adhere to fluid restrictions: measure allotted fluids and save some for ice cubes. Thirst-quenching strategies: sucking on ice; sugarless candy or gum; frozen grapes; rinsing mouth with water; avoiding high-sodium intake.
2. For further information and support, refer to the National Kidney Foundation (*www.kidney.org*).
3. Encourage all people in the following at-risk patient groups to obtain screening for CKD: older adults, Native Americans, African Americans, Latinos, people with diabetes, people with hypertension, those with autoimmune disease, and those with family history of kidney disease. More information on the National Kidney Foundation's Clinical Practice Guidelines for Chronic Kidney Disease can be obtained from *www.kidney.org/professionals/kdoqi/index.cfm*.

Evaluation: Expected Outcomes

- BP stable; no excessive weight gain.
- Tolerates small meals and adheres to protein restriction.
- No skin excoriation; reports relief of itching.
- Regular soft bowel movements.
- Ambulates without falls.
- Asks questions and reads education materials about CKD and its treatment.

Acute Glomerulonephritis

Acute *glomerulonephritis* (GN) refers to a group of kidney diseases in which there is an inflammatory reaction in the glomeruli because of an immunologic mechanism.

Pathophysiology and Etiology

1. Occurs after an infection elsewhere in the body or may develop secondary to systemic disorders.
2. An antigen–antibody reaction produces immune complexes that lodge in the glomeruli, producing thickening of and damage to the glomerular basement membrane; the renal vasculature, interstitium, and tubular epithelium may also be affected.
3. Immune complexes activate a variety of secondary mediators, such as complement pathways, neutrophils, macrophages, prostaglandins, and leukotrienes. These affect vascular tone and permeability, resulting in tissue injury.
4. Eventual scarring and loss of filtering surface may lead to renal failure.

Clinical Manifestations

1. Mild disease is frequently discovered accidentally through a routine urinalysis.
2. Pharyngitis or impetigo from group A streptococcus (if postinfectious GN).
3. Tea-colored urine, oliguria.
4. Periorbital edema, edema of extremities.
5. Fatigue and anorexia.
6. Hypertension, headache.

Diagnostic Evaluation

1. Urinalysis for hematuria (microscopic or gross), proteinuria, cellular elements, and various casts.
2. Twenty-four–hour urine for protein (increased) and creatinine clearance (may be reduced) outline the degree of renal function.
3. Elevated BUN and serum creatinine levels, low albumin level, increased antistreptolysin titer (increased in postinfectious GN from reaction to streptococcal organism) and, in some cases, decreased serum complement.
4. Needle biopsy of the kidney reveals obstruction of glomerular capillaries from proliferation of endothelial cells.

Management

1. Management is symptomatic and includes antihypertensives, diuretics, drugs for management of hyperkalemia, H_2 blockers, and phosphate-binding agents.
2. Antibiotic therapy is initiated to eliminate infection (if still present).
3. Fluid intake is restricted.

4. Potassium and sodium intake is restricted in presence of hyperkalemia, edema, or signs of heart failure.

Complications

1. Hypertension and heart failure.
2. Endocarditis can occur in postinfectious GN.
3. Fluid and electrolyte imbalances: hyperkalemia, hyperphosphatemia, hypocalcemia, hypervolemia.
4. Malnutrition.
5. Hypertensive encephalopathy and seizures.
6. ESRD.

Nursing Assessment

1. Obtain medical history; focus on recent infections or symptoms of chronic immunologic disorders (systemic lupus erythematosus, scleroderma).
2. Assess urine specimen for blood, protein, color, and amount.
3. Perform physical examination, specifically looking for signs of edema, hypertension, and hypervolemia (engorged neck veins, elevated jugular venous pressure, adventitious lung sounds, gallop rhythm).
4. Evaluate ECG and serum laboratory values for electrolyte imbalance.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related catabolic state, anorexia, and malnutrition related to acute glomerulonephritis.
- Excess Fluid Volume related to sodium retention and decreased glomerular filtration rate.

Nursing Interventions

Maintaining Adequate Nutritional Status

See interventions related to AKI, page 605.

Improving Fluid Balance

1. Carefully monitor fluid balance: strict intake and output and replace fluids according to patient's fluid losses (urine, feces, other drainage, and take into account insensible loss if rapid breathing or sweating) and record daily body weight, as prescribed.
2. Monitor pulmonary artery pressure and CVP during acute hospitalizations.
3. Monitor for signs and symptoms of heart failure: distended neck veins, tachycardia, gallop rhythm, enlarged and tender liver, crackles at bases of lungs.
4. Monitor for hypertension; observe for hypertensive encephalopathy and any evidence of seizure activity.

NURSING ALERT Hypertensive encephalopathy is a medical emergency, and treatment is aimed

at reducing BP without impairing renal function.

Patient Education and Health Maintenance

1. Explain that patient must have follow-up evaluations of BP, urinary protein, and creatinine and serum electrolyte concentrations to determine if there is exacerbation of disease activity.
2. Encourage patient to treat any infection promptly.
3. Tell patient to notify health care provider of signs of fluid accumulation or uremia (nausea, vomiting, decreased appetite, difficulty concentrating, pruritus).

Evaluation: Expected Outcomes

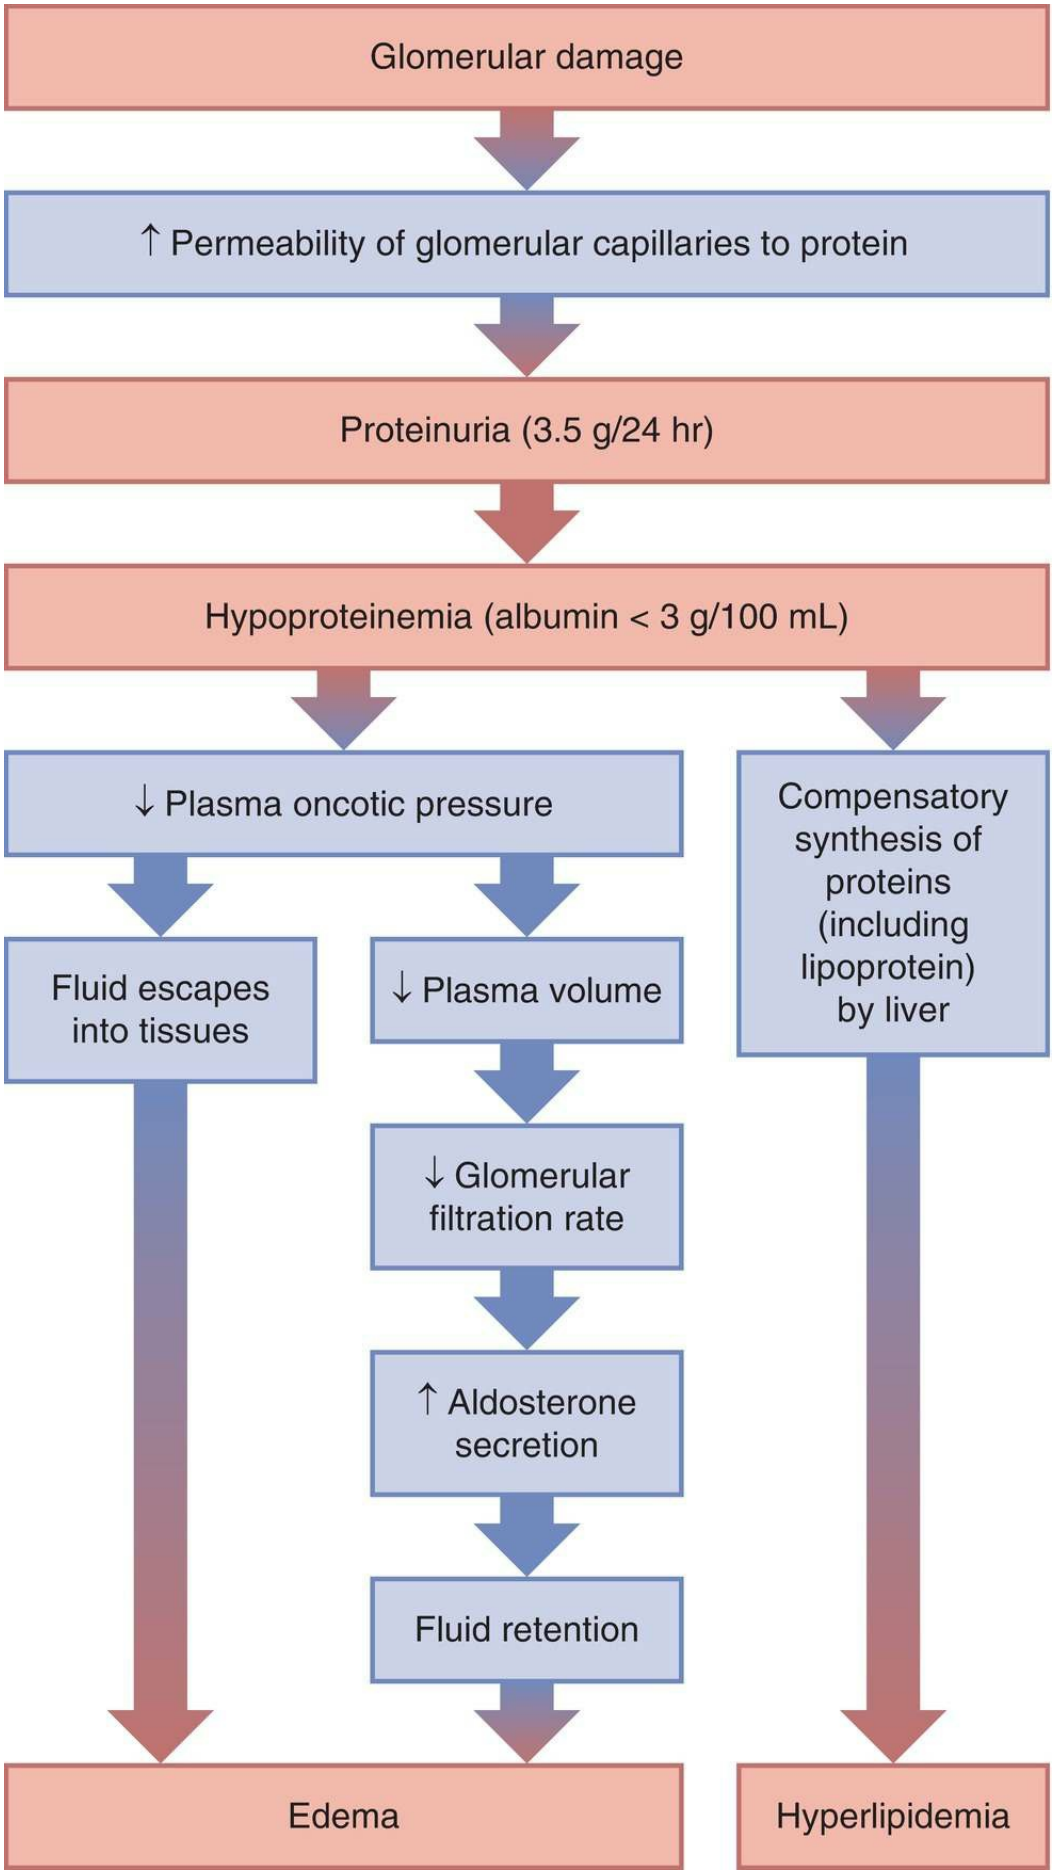
- Urine output adequate; vital signs stable.
- No edema, shortness of breath, or adventitious heart or lung sounds.

Nephrotic Syndrome

Nephrotic syndrome is a clinical disorder characterized by marked increase of protein in the urine (proteinuria), decrease in albumin in the blood (hypoalbuminemia), edema, and excess lipids in the blood (hyperlipidemia). These occur as a consequence of excessive leakage of plasma proteins into the urine because of increased permeability of the glomerular capillary membrane.

Pathophysiology and Etiology

1. Seen in any condition that seriously damages the glomerular capillary membrane.
    a. Chronic glomerulonephritis.
    b. Diabetes mellitus with intercapillary glomerulosclerosis.
    c. Amyloidosis of the kidney.
    d. Systemic lupus erythematosus.
    e. Preeclampsia.
    f. Viral infections (hepatitis B, hepatitis C, or human immunodeficiency).
2. Hypoalbuminemia results in decreased oncotic pressure, causing generalized edema as fluid moves out of the vascular space (see Figure 21-7).
3. Decreased circulating volume then activates the renin–angiotensin system, causing retention of sodium and further edema.
4. Decreased plasma oncotic pressure stimulates synthesis of proteins (including lipoproteins) resulting in hypercholesterolemia. Impaired metabolism and clearance of lipids may also play a role in nephrotic syndrome hyperlipidemia.



Glomerular damage
↑ Permeability of glomerular capillaries to protein
Proteinuria (3.5 g/24 hr)
Hypoproteinemia (albumin < 3 g/100 mL)
↓ Plasma oncotic pressure
Compensatory synthesis of proteins (including lipoprotein) by liver
Fluid escapes into tissues
↓ Plasma volume
↓ Glomerular filtration rate
↑ Aldosterone secretion
Fluid retention
Edema
Hyperlipidemia

Figure 21-7. Pathophysiology of the nephrotic syndrome. (Rubin, E., & Farber, J.L. [1999]. *Pathology* [3rd ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Clinical Manifestations

1. Insidious onset of pitting dependent edema, periorbital edema, and ascites; weight gain.
2. Fatigue, headache, malaise, irritability.
3. Marked proteinuria—leading to depletion of body proteins.
4. Hyperlipidemia (increased cholesterol and triglycerides)—may lead to accelerated atherosclerosis.

Diagnostic Evaluation

1. Urinalysis—marked proteinuria, microscopic hematuria, urinary casts, appears "foamy."
2. Twenty-four–hour urine for protein (increased) and creatinine clearance (may be decreased).
3. Protein electrophoresis and immunoelectrophoresis of the urine to categorize the proteinuria.
4. Needle biopsy of the kidney—for histologic examination of renal tissue to confirm diagnosis.
5. Serum chemistry—decreased total protein and albumin, normal or increased creatinine, increased triglycerides, and altered lipid profile.

Management

1. Treatment of causative glomerular disease.
2. Diuretics (used cautiously) and angiotensin-converting enzyme inhibitors (ACEI) to control proteinuria (ACEI used only in chronic disease).
3. Corticosteroids or immunosuppressive agents to decrease proteinuria.
4. General management of edema.
   a. Sodium and fluid restriction.
   b. Infusion of salt-poor albumin.
   c. Dietary protein supplements if indicated.
5. Diet low in saturated fats.
6. Lipid-lowering agents.

Complications

1. Hypovolemia.
2. Thromboembolic complications—renal vein thrombosis, venous and arterial thrombosis in extremities, pulmonary embolism, coronary artery thrombosis, and cerebral artery thrombosis secondary to loss of hemostasis control proteins such as antithrombin III, protein S, and protein C.
3. Altered drug metabolism because of decrease in plasma proteins.
4. Progression to CKD and possibly ESRD.

Nursing Assessment

1. Obtain history of onset of symptoms including changes in characteristics of urine and onset of edema.
2. Perform physical examination looking for evidence of edema and hypovolemia.
3. Assess vital signs, daily weights, intake and output, and laboratory values.

Nursing Diagnoses

- Risk for Deficient Fluid Volume intravascularly related to disease process.
- Risk for Infection related to treatment with immunosuppressive agents.

Nursing Interventions

Increasing Circulating Volume and Decreasing Edema

1. Monitor daily weight, intake and output, and urine specific gravity.
2. Monitor CVP (if indicated), vital signs, orthostatic BP, and heart rate to detect hypovolemia.
3. Monitor serum BUN and creatinine to assess renal function.
4. Administer diuretics or immunosuppressive agents, as prescribed, and evaluate patient's response.
5. Infuse IV albumin, as ordered.
6. Enforce mild to moderate sodium and fluid restriction if edema is severe.

Preventing Infection

1. Monitor for signs and symptoms of infection.
2. Monitor temperature routinely.
3. Monitor CBC with diff as ordered.
4. Use aseptic technique for all invasive procedures and educate patient on the importance of strict handwashing.

Patient Education and Health Maintenance

1. Teach patient signs and symptoms of nephrotic syndrome; also, review causes, purpose of prescribed treatments, and importance of long-term therapy to prevent ESRD.
2. Instruct patient in adverse effects of prescribed medications and methods of preventing infection if taking immunosuppressive agents.
3. Carefully review with patient and family dietary and fluid restrictions; consult dietitian for assistance in meal planning.
4. Discuss the importance of maintaining exercise, decreasing cholesterol and fat intake, and changing other risk factors, such as smoking, obesity, and stress, to reduce risk of severe thromboembolic complications.
5. In patients with severe disease, prepare for dialysis and possible transplantation.

Evaluation: Expected Outcomes

- Vital signs remain stable; edema decreased.
- No signs of infection.

URINARY DISORDERS

Lower Urinary Tract Infections

EVIDENCE BASE National Institute for Clinical Excellence. (2015). Urinary tract infections in adults. Available: *www.nice.org.uk/guidance/qs90.*

A *urinary tract infection* (UTI) is caused by the presence of pathogenic microorganisms in the urinary tract with or without signs and symptoms. Lower UTIs may predominate at the bladder (cystitis) or urethra (urethritis).

Bacteriuria refers to the presence of bacteria in the urine (10^3 bacteria/mL of urine or greater generally indicates infection).

In *asymptomatic bacteriuria*, organisms are found in urine, but patient has no symptoms.

Recurrent UTIs may indicate the following:

Unresolved—bacteria fails to respond to antimicrobial therapy.

Recurrent—reinfection after eradication of pathogens.

Pathophysiology and Etiology

1. Ascending infection after entry by way of the urinary meatus.
   a. Women are more susceptible to developing acute cystitis because of shorter length of urethra; anatomical proximity to the vagina, periurethral glands, and rectum (fecal contamination); and the mechanical effect of coitus.
   b. Women with recurrent UTIs typically have gram-negative organisms at the vaginal introitus; there may be some defect of the mucosa of the urethra, vagina, or external genitalia of these patients that allows enteric organisms to invade the bladder.
   c. Poor voiding habits may result in incomplete bladder emptying, increasing the risk of recurrent infection.
   d. Acute infection in women most commonly arises from organisms of the patient's own intestinal flora (*Escherichia coli*).
2. Although *E. coli* causes 86% of UTIs, other pathogens, such as *Klebsiella* species, *Proteus* species, and *Staphylococcus saprophyticus*, may also cause these infections.
3. In men, obstructive abnormalities (strictures, prostatic hyperplasia) are the most frequent cause.
4. UTI is a considerable source of nosocomial infection and sepsis in older adults.
5. Upper urinary tract disease may occasionally cause recurrent bladder infection.

Clinical Manifestations

1. Dysuria, frequency, urgency, and nocturia.

2. Suprapubic pain and discomfort.
3. Microscopic or gross hematuria.

GERONTOLOGIC ALERT The only sign of UTI in the older patient may be mental status changes.

Diagnostic Evaluation

1. Urine dipstick may react positively for blood, white blood cells (WBCs), and nitrates, indicating infection.
2. Urine microscopy shows RBCs and many WBCs per field without epithelial cells that indicates urogential contamination.
3. Urine culture is used to detect presence of bacteria and for antimicrobial sensitivity testing; however, it is not necessary in all cases.
4. Patients with indwelling catheters may have asymptomatic bacterial colonization of the urine without UTI. In these patients, UTI is diagnosed and treated only when symptoms are present.

NURSING ALERT Urinalysis showing many epithelial cells is likely contaminated by vaginal secretions in women and is therefore inaccurate in indicating infection. Urine culture may be reported as contaminated as well. Obtaining a clean-catch, midstream specimen is essential for accurate results, and catheterization may be necessary in some patients.

Management

1. Antibiotic therapy according to sensitivity results.
   a. A wide variety of antimicrobial drugs are available.
   b. Urinary infections usually respond to drugs that are excreted in urine in high concentrations; a potentially effective drug should rapidly sterilize the urine and thus relieve the patient's symptoms.
2. For uncomplicated infection:
   a. First-line therapy for women with uncomplicated cystitis includes a 5-day course of nitrofurantoin or a 3-day course of co-trimoxazole or a fluoroquinolone such as ciprofloxacin, although fluoroquinolones are often reserved for serious infections. A single dose of fosfomycin has also shown effectiveness in women.
   b. Seven to ten days of therapy is recommended for women over age 65.
   c. Men are treated with 7 to 10 days of antibiotic therapy.
   d. Follow-up culture to prove treatment effectiveness may be indicated.

e. Adverse effects include nausea, diarrhea, drug-related rash, and vaginal candidiasis.

3. Pregnant women are usually treated for 7 to 10 days.
4. Women with recurrent infections may be treated longer, undergo diagnostic testing to rule out a structural abnormality, or be maintained on a daily dose of antibiotic as prophylaxis.
5. For complicated infection, see treatment of pyelonephritis (see page 613).
6. For severe discomfort with voiding, phenazopyridine may be ordered to reduce bladder irritation three times per day for 2 days.

Complications

1. Pyelonephritis.
2. Hematogenous spread resulting in sepsis.

Nursing Assessment

1. Determine if patient has a history of UTIs in childhood or during pregnancy or has had recurrent infections.
2. Question about voiding habits, personal hygiene practices, and methods of contraception (use of diaphragm or spermicides is associated with development of cystitis).
3. Ask if patient has any associated symptoms of vaginal discharge, itching, or irritation—dysuria may be a prominent symptom of vaginitis or infection from sexually transmitted pathogens, rather than UTI.
4. Examine for suprapubic tenderness, as well as abdominal tenderness, guarding, rebound, or masses that may indicate more serious process.

Nursing Diagnoses

1. Acute Pain related to inflammation of the bladder mucosa.
2. Deficient Knowledge related to prevention of recurrent UTI.

Nursing Interventions

Relieving Pain

1. Administer or teach self-administration of antibiotic—eradication of infection is usually accompanied by rapid resolution of symptoms.
2. Encourage patient to take prescribed analgesics and antispasmodics, if ordered.
3. Encourage rest during the acute phase if symptoms are severe.
4. Encourage plenty of fluids to promote urinary output and to flush out bacteria from urinary tract.

Increasing Understanding and Practice of Preventive Measures

1. For women with recurrent UTIs, give the following instructions:
   a. Reduce vaginal introital concentration of pathogens by hygienic measures.
   b. Wash genitalia in shower or while standing in bathtub—bacteria in bath water may gain entrance

into the urethra.

   c. Cleanse around the perineum and urethral meatus after each bowel movement, with front-to-back cleansing to minimize fecal contamination of periurethral area.

2. Drink liberal amounts of water to lower bacterial concentrations in the urine.
3. Avoid bladder irritants—coffee, tea, alcohol, cola drinks, and aspartame.
4. Decrease the entry of microorganisms into the bladder during intercourse.
   a. Void immediately after sexual intercourse.
   b. A single dose of an oral antimicrobial agent may be prescribed after sexual intercourse.
5. Avoid external irritants such as bubble baths, talcum powders, perfumed vaginal cleansers, or deodorants.
6. Patients with persistent bacteria may require long-term antimicrobial therapy to prevent colonization of periurethral area and recurrence of UTI.
   a. Take antibiotic at bedtime after emptying the bladder to ensure adequate concentration of drug overnight because low rates of urine flow and infrequent bladder emptying predispose to multiplication of bacteria.
   b. Use self-monitoring tests (dipsticks) at home to monitor for UTI.

Patient Education and Health Maintenance

1. Advise women with simple, uncomplicated cystitis that they do not require follow-up as long as symptoms are completely resolved with antibiotic therapy. Men usually need follow-up cultures and possibly additional testing if more than one episode of infection.
2. Instruct patient to void frequently (every 2 to 3 hours) and to empty bladder completely because this enhances bacterial clearance, reduces urine stasis, and prevents reinfection. Infrequent voiding distends the bladder wall, leading to hypoxia of bladder mucosa, which is then more susceptible to bacterial invasion.
3. Instruct patients who have had UTIs during pregnancy to have follow-up studies.
4. Female patients with uncomplicated but recurrent cystitis may self-administer a 2- or 3-day course of antibiotics when symptoms begin, if prescribed.
5. Cranberry juice or capsules may help to prevent cystitis by altering the bladder mucosa so that the bacteria cannot attach. Acidophilus and cranberry capsules are available in health food and vitamin stores.

Evaluation: Expected Outcomes

- Verbalizes relief of symptoms.
- Verbalizes self-care measures to prevent recurrence.

Interstitial Cystitis/Bladder Pain Syndrome

EVIDENCE BASE Hanno, P. M., Erickson, D., Moldwin, R., & Faraday, M. M. (2015). American Urological Association. Diagnosis and treatment of interstitial cystitis/bladder pain syndrome: AUA guideline amendment. *The Journal of Urology, 193*(5), 1545–1553.

Interstitial cystitis (also called *painful bladder syndrome*) is a syndrome of chronic, cystitis-like symptoms in the absence of bacterial infection. It is a diagnosis of exclusion.

Pathophysiology and Etiology

1. The etiology of interstitial cystitis is unknown. However, theories include an inflammatory or autoimmune process that alters the normal configuration of cells in the bladder epithelium, although infectious, neurological, psychological, and vascular origins are also considered possible.
   a. One plausible theory is a neurogenic origin, in which an initial peripheral inflammatory response later activates the sacral nerves to continue to respond without evidence of continued inflammation.
   b. Mast cell involvement in the inflammatory response also seems a plausible etiology, with many patients having a concomitant history of allergies.
2. The bladder is normally lined with a gel-like substance composed of glycosaminoglycans (heparin, hyaluronic acid, and chondroitin) that acts as an impermeable barrier to irritating solutes such as potassium.
3. Disruption to the bladder epithelium leads to irritant seepage, which produces the symptoms.
4. The bladder wall is chronically inflamed with no evidence of bacterial infection.
5. Occurs far more frequently in women than in men.

Clinical Manifestations

1. History of slow, progressive increase in urinary frequency and urgency. Urgency may be extreme; frequency (as many as 16 times per day) and nocturia increase with duration of symptoms.
2. Symptoms of suprapubic pain and pressure occurring for at least 3 to 6 months.
   a. Bladder pain may be continuous, may increase prior to voiding when the bladder is full, or may present as diffuse perineal, vaginal, suprapubic, or lower back pain.
   b. Pain is usually relieved by voiding.
3. Symptoms are exacerbated by sexual intercourse and at the time of menstruation.
4. Symptoms may be present for 5 to 7 years before diagnosis is made.

Diagnostic Evaluation

1. Tender bladder base during pelvic examination, assessed by palpation of the anterior vaginal wall.

2. Urinalysis and urine culture to rule out infection.
3. Cystoscopy under anesthesia with bladder biopsies and bladder distention; presence of bleeding or ulcerations on bladder distention is characteristic of some cases of interstitial cystitis.
4. Urodynamic tests commonly reveal a small bladder capacity with early sensation of urgency and, in some cases, poor detrusor function with incomplete bladder emptying.
5. In potassium sensitivity testing, symptoms are produced when potassium is placed in the bladder; however, the use of this test is controversial as inflammation also produces a positive test.
6. Diagnosis is usually made by ruling out other potential causes of symptoms, including radiation or chemical cystitis, gynecologic or urologic malignancies, STD, and urolithiasis.

Management

1. Treatment is individualized and focused on symptom control.
2. Dietary modification to identify foods that act as triggers can be accomplished through an elimination diet. Possible triggers are citrus fruits, tomatoes, caffeinated beverages, carbonated beverages, chocolate, and spicy foods.
3. Bladder retraining (increasing intervals between voiding) is commonly necessary to increase bladder capacity that has been diminished by frequent voiding; pelvic floor strengthening with Kegel exercises can help with urgency and frequency.
4. Oral administration of pentosan polysulfate relieves symptoms in some patients, with maximal effect seen after 3 to 6 months; many continue this therapy for years. If no improvement after 3 to 6 months, the drug is discontinued.
5. Antihistamines may be beneficial for patients who have allergies. Hydroxyzine has been beneficial in patients.
6. Tricyclic antidepressants such as amitriptyline may be helpful for their analgesic, anticholinergic, and antihistaminic effects. Gabapentin is also used for chronic pain.
7. Bladder distention during cystoscopy under general anesthesia relieves symptoms in 30% to 50% of patients, especially those with small bladder capacity. Relapse commonly occurs 3 months' posttreatment, however, and the effectiveness of this treatment diminishes with repeated use.
8. Intravesical therapy with various substances, including silver nitrate and dimethyl sulfoxide, may be used.
9. Transcutaneous electrical nerve stimulation has demonstrated some relief for the pain syndrome associated with interstitial cystitis.
10. Stress management techniques such as yoga and meditation.

DRUG ALERT Pentosan polysulfate has anticoagulant properties; therefore, it should not be used by patients taking other anticoagulant drugs or in conditions associated with increased risk for bleeding. Reversible alopecia may occur as well but resolves once the drug is discontinued.

Complications

1. Psychosocial problems related to pain, urgency, and frequency.
2. Secondary bacteriuria.

Nursing Assessment

1. Assess voiding patterns including frequency, nocturia, and urgency (a voiding diary is helpful). Determine if symptoms increase in relation to certain foods, menstrual cycle, or sexual intercourse.
2. Assess level of pain using a scale of 1 to 10; determine if pain increases during or after voiding and if bladder spasms occur. Some practitioners may use a symptom questionnaire such as the O'Leary-Sant Interstitial Cystitis Symptom and Problem Index or the Pelvic Pain and Urgency/Frequency questionnaire.
3. Perform abdominal examination and assist with pelvic examination, if indicated, to rule out gynecologic causes and to identify location of pain on palpation.
4. Assess impact on relationships and quality of life.

Nursing Diagnoses

- Chronic Pain related to disease process.
- Impaired Urinary Elimination related to frequency, urgency, dysuria, and nocturia.
- Ineffective Coping related to interruption of lifestyle and chronic, unrelenting symptoms.

Nursing Interventions

Controlling Pain

1. Administer pharmacologic agents, as ordered, to relieve pain and other symptoms. Counsel patient on adverse effects, such as drowsiness, with antihistamines and tricyclic antidepressants.
2. Instruct patient in comfort and preventive measures, such as application of heating pad, avoidance of bladder irritants (caffeine, alcohol, chocolate, and acidic or spicy foods), and avoidance of known allergens.
3. If prescribed, teach patient self-catheterization and the self-administration of intravesical medications.

Improving Urinary Elimination

1. Encourage patient to use a voiding diary as well as a dietary record to make associations between intake of certain foods or fluids and increase in symptoms.
2. Set up bladder retraining program to increase bladder capacity and reduce symptoms.
    a. Have patient start with every 10- to 15-minute voiding intervals during the day.
    b. Instruct patient to gradually (every week or two) increase intervals by 15 minutes.
    c. The ultimate goal (over a period of about 3 months) should be voiding intervals of 3½ hours during the day.
    d. Teach Kegel exercises to help strengthen supporting muscles. Warm baths and perineal massage may

help with relaxation before exercises.

e. Make a referral for biofeedback training, if needed, to enhance Kegel exercises.

3. Advise patient to restrict fluids only when necessary because of impending limited access to toilet facilities; normal fluid intake should be encouraged otherwise.
4. Assess patient's response to pharmacologic therapy.

Strengthening Coping

1. Inquire about patient's ability to work and carry on roles as spouse, parent, etc., based on frequency and discomfort.
2. Explore with patient positive coping strategies for self and family in dealing with chronic illness.
3. Encourage counseling, as needed.

Patient Education and Health Maintenance

1. Teach patient mechanism of action and adverse effects of pharmacologic therapies.
2. Teach self-catheterization using clean technique, if needed, to self-administer medications or accomplish complete bladder emptying.
3. Provide information about food and fluids known to be bladder irritants.
4. Refer for additional information and support to agencies such as Interstitial Cystitis Association (*www.ichelp.org*).

Evaluation: Expected Outcomes

- Verbalizes some relief of pain.
- Verbalizes less urgency, frequency, and nocturia.
- Identifies coping strategies.

Acute Bacterial Pyelonephritis

Bacterial pyelonephritis is an acute infection and inflammatory disease of the kidney and renal pelvis involving one or both kidneys.

Pathophysiology and Etiology

1. Enteric bacteria, such as *E. coli*, are the most common pathogen; other gram-negative pathogens include *Proteus* species, *Klebsiella*, and *Pseudomonas*. Gram-positive bacteria are less common, but include *Enterococcus* and *Staphylococcus aureus*.
2. Bacterial infection usually ascends from the lower urinary tract; however, hematogenous migration is possible (particularly with *S. aureus*).
3. Pyelonephritis can result from urinary obstruction such as vesicoureteral reflux (incompetence of ureterovesical valve, which allows urine to regurgitate into ureters, usually at the time of voiding), other renal disease, trauma, or pregnancy.
4. Low-grade inflammation with interstitial infiltrations of inflammatory cells may lead to tubular destruction and abscess formation.
5. Chronic pyelonephritis may result in scarred, atrophic, and nonfunctioning kidneys.

Clinical Manifestations

1. Fever, chills.
2. Flank pain (with or without radiation to the groin).
3. Nausea, vomiting, anorexia, abdominal pain, diarrhea.
4. Costovertebral angle tenderness (unilateral or bilateral).
5. Urgency, frequency, and dysuria may be present.

GERONTOLOGIC ALERT Older patients may not exhibit the usual febrile response to pyelonephritis, but have nonspecific GI or pulmonary symptoms instead.

Diagnostic Evaluation

1. Urinalysis (dipstick or microscopic) to identify leukocytes, bacteria, nitrites, and RBCs and WBCs in urine; white cell casts may also be seen.
2. Urine culture to identify causative bacteria.
3. CBC shows elevated WBC count consisting of neutrophils and bands.
4. CT scan of the abdomen—with contrast—is the imaging study of choice. Other studies include intravenous urography (IVU) or renal ultrasound to evaluate for urinary tract obstruction; other radiologic or urinary tests may be conducted, as necessary.

5. Blood cultures may be drawn, if indicated.

Management

1. For severe infections (dehydrated, cannot tolerate oral intake) or complicating factors (suspected obstruction, pregnancy, advanced age, immunocompromised), inpatient antibiotic therapy is recommended.
    a. Usually, immediate treatment is started with an IV fluoroquinolone, aminoglycoside, or extended-spectrum cephalosporin to cover the prevalent gram-negative pathogens; may be subsequently adjusted according to culture results.
    b. An oral antibiotic may be started 24 hours after fever has resolved and oral therapy continued for 2 weeks.
2. Oral antibiotic therapy is acceptable for outpatient treatment.
    a. A fluoroquinolone or co-trimoxazole is used—10 to 14 days is the usual length of treatment.
3. Repeat urine cultures should be performed after the completion of therapy.
4. Supportive therapy is given for fever and pain control and hydration.

Complications

1. Bacteremia with sepsis.
2. Papillary necrosis leading to renal failure.
3. Renal abscess requiring treatment by percutaneous drainage or prolonged antibiotic therapy.
4. Perinephric abscess.
5. Paralytic ileus.

Nursing Assessment

1. Monitor symptoms and assess ability to tolerate oral fluids and food.
2. Obtain urologic history that could suggest recurrent infections or urinary tract obstruction.
3. Obtain vital signs; monitor for impending sepsis.
4. Assess bowel sounds for possible paralytic ileus.

Nursing Diagnoses

- Hyperthermia because of infection.
- Acute Pain related to renal swelling and edema.

Nursing Interventions

Reducing Body Temperature

1. Administer or teach self-administration of antibiotics, as prescribed, and monitor for effectiveness and adverse effects.
2. Assess vital signs frequently and monitor intake and output; administer antiemetic medications to control

nausea and vomiting.

3. Administer antipyretic medications, as prescribed and according to temperature.
4. Report fever that persists beyond 72 hours after initiating antibiotic therapy; further testing for complicating factors will be ordered.
5. Use measures to decrease body temperature, if indicated: cooling blanket, application of ice to armpits and groins, and so forth.
6. Correct dehydration by replacing fluids, orally if possible, or via IV administration.
7. Monitor CBC, blood cultures, and urine studies for resolving infection.

Relieving Pain

1. Administer or teach self-administration of analgesics and monitor their effectiveness.
2. Use comfort measures, such as positioning, for local relief of flank pain.
3. Assess patient's response to pain control measures.

Patient Education and Health Maintenance

1. Explain to patient possible causes of pyelonephritis and its signs and symptoms; also, review signs and symptoms of lower UTI.
2. Review antibiotic therapy and importance of completing prescribed course of treatment and having follow-up urine cultures.
3. Explain preventive measures, including good fluid intake, personal hygiene measures, and healthy voiding habits.

Evaluation: Expected Outcomes

- Afebrile within 48 hours.
- Verbalizes reduced pain.

Nephrolithiasis and Urolithiasis

Nephrolithiasis refers to renal stone disease; *urolithiasis* refers to the presence of stones in the urinary system. Stones, or calculi, are formed in the urinary tract from the kidney to bladder by the crystallization of substances excreted in the urine.

EVIDENCE BASE Turk, C., Knoll, T., Petrik, A., et al. (2015). Guidelines on urolithiasis. European Association of Urology. Available: *http://uroweb.org/wp-content/uploads/22-Urolithiasis_LR_full.pdf*

Pathophysiology and Etiology

1. Most stones (75%) are composed mainly of calcium oxalate crystals; the rest are composed of calcium phosphate salts, uric acid, struvite (magnesium, ammonium, and phosphate), or the amino acid cysteine.
2. Causes and predisposing factors:
    a. Hypercalcemia and hypercalciuria caused by hyperparathyroidism, renal tubular acidosis, multiple myeloma, and excessive intake of vitamin D, milk, and alkali.
    b. Chronic dehydration, poor fluid intake, and immobility.
    c. Diet high in purines and abnormal purine metabolism (hyperuricemia and gout).
    d. Genetic predisposition for urolithiasis or genetic disorders (cystinuria).
    e. Chronic infection with urea-splitting bacteria (*Proteus vulgaris* and *mirabilis*).
    f. Chronic obstruction with stasis of urine and foreign bodies within the urinary tract.
    g. Excessive oxalate absorption in inflammatory bowel disease and bowel resection or ileostomy.
    h. Living in mountainous, desert, or tropical areas.
3. Stones may be found anywhere in the urinary system and vary in size from mere granular deposits (called sand or gravel) to bladder stones the size of an orange.
4. One of three patients with stones are men; in both sexes, the peak age of onset is 40 to 60 years.
5. Most stones migrate downward (causing severe colicky pain when the stone obstructs the ureter) and are discovered in the lower ureter. Spontaneous stone passage can be anticipated in 80% to 90% of patients with calculus less than 5 mm in size.
6. Some stones may lodge in the renal pelvis, ureters, or bladder neck, causing obstruction, edema, secondary infection, and, in some cases, nephron damage.
7. Those with stones for the first time have a 50% risk of recurrence within the next 7 to 10 years.

Clinical Manifestations

1. Pain pattern depends on site of obstruction (see Figure 21-8).
    a. Renal stones produce an increase in hydrostatic pressure and distention of the renal pelvis and

proximal ureter causing renal colic. Pain relief is immediate after stone passage.

b. Ureteral stones produce symptoms because of obstruction as they pass down the ureter (ureteral colic).

c. Bladder stones may be asymptomatic or produce symptoms similar to cystitis.

2. Obstruction—stones blocking the flow of urine will produce symptoms of colic, chills, and fever.

3. GI symptoms include nausea, vomiting, diarrhea, and abdominal discomfort—because of renointestinal reflexes and shared nerve supply (celiac ganglion) between the ureters and intestine.

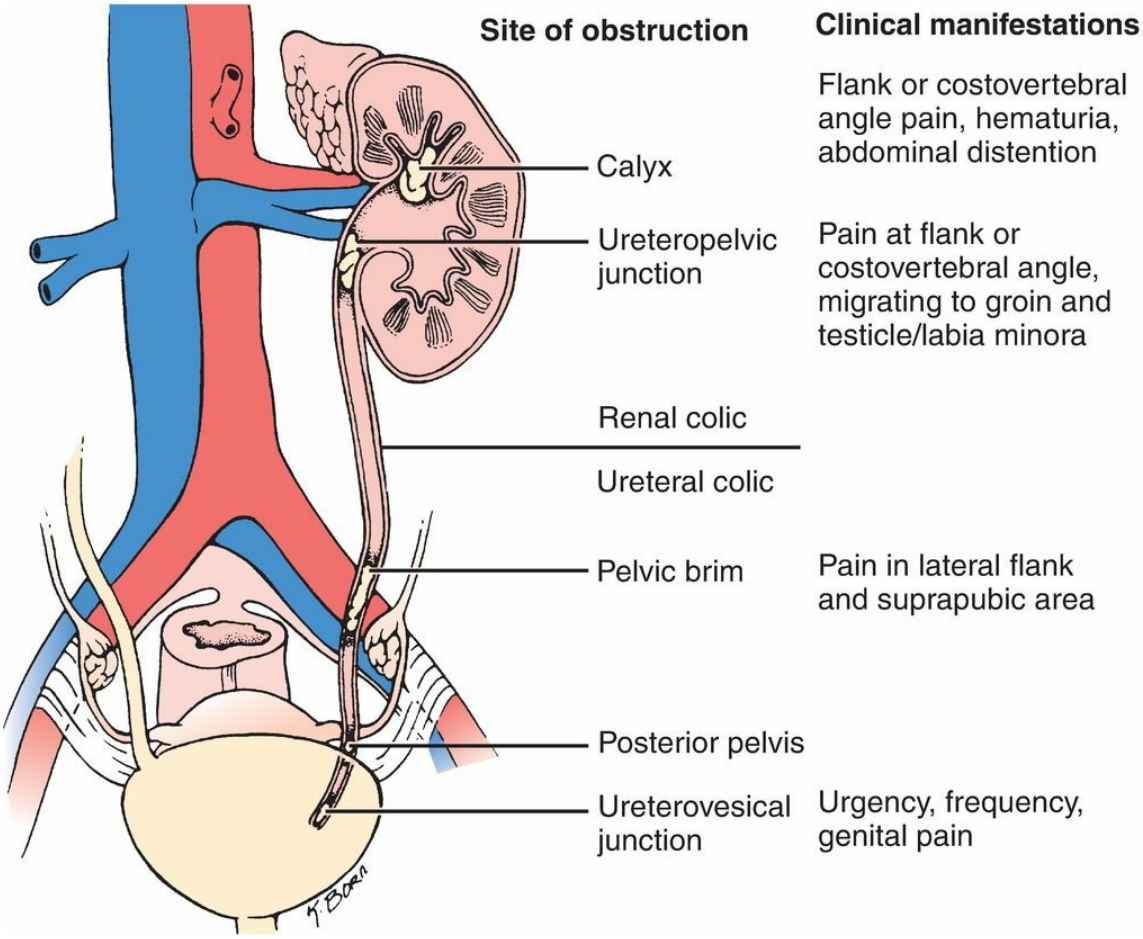


Figure 21-8. Areas where calculi may obstruct the urinary system. The ensuing clinical manifestations depend on the site of obstruction. Stones that have broken loose may obstruct the flow of urine, cause severe pain, and injure the kidney. (Creason, C. [2010]. *Stedman's medical terminology: steps to success in medical language*. Philadelphia, PA: Lippincott Williams & Wilkins.).

Diagnostic Evaluation

1. Kidney, ureters, and bladder radiography may show stone.

2. IVU—to determine site and evaluate degree of obstruction.

3. Regular ultrasound may be as sensitive with good technique; however, it won't show radiolucent stones.

4. Spiral CT scan stone study—special noncontrast CT technique to assess for stone in the ureter; it is the

study of choice and will show all stones.

   a. Requires no preparation and is noninvasive.

   b. Takes only 10 minutes.

5. Analysis of available stone material—crystals can be identified by polarization microscopy, x-ray diffraction, and infrared spectroscopy.
6. Urinalysis—hematuria and pyuria; pH less than 5.5 may indicate uric acid stone; more than 7.5 may indicate struvite stone; urine culture and drug sensitivity studies to detect infection.
7. Serum kidney function tests; electrolytes, calcium, phosphorus, uric acid, and magnesium levels; serum parathyroid hormone may also be evaluated.

Management

General Principles

1. If it is a small stone (less than 5 mm) and able to treat as outpatient, 80% to 90% of patients will pass stone spontaneously with hydration, pain control, and reassurance.
2. Patient may be hospitalized for intractable pain, persistent vomiting, high-grade fever, obstruction with infection, bilateral ureteral calculi, and solitary kidney with obstruction.

Extracorporeal Shock Wave Lithotripsy (ESWL)

1. Noninvasive procedure used for both renal and ureteral radiopaque stones less than 2 cm and greater than 4 mm.
2. High-energy shock waves are directed at the kidney stone, disintegrating it into minute particles that pass in the urine. (A shock wave is a large, condensed wave of energy produced by high-speed motion.)
3. Patient is placed on specially designed table and immersed in a water bath or placed on an adjustable stretcher positioned over a cushion of water.

   a. In water bath model, shock waves travel through water surrounding the patient.

   b. In cushion model, a layer of gel lies between the stretcher and water; shock waves move through the cushion and gel.

4. Position of the kidney stone is located by fluoroscopy and the shock waves are targeted directly at the stone. The shock waves do not affect soft tissue.
5. Eliminates need for surgery in majority of patients and can be repeated for recurrent stones with no apparent risk to kidney structure or function. Long-term adverse effects may include increased risk of hypertension or diabetes.
6. Complications include pain from both the procedure and passing stone fragments, urinary infection, and perirenal hematoma (bleeding around the kidney).
7. Contraindications to ESWL include pregnancy and uncorrected bleeding disorders.

Percutaneous Nephrolithotomy

For stones in renal collecting system or upper portion of ureter and larger than 2 cm in diameter (see Figure

21-9).

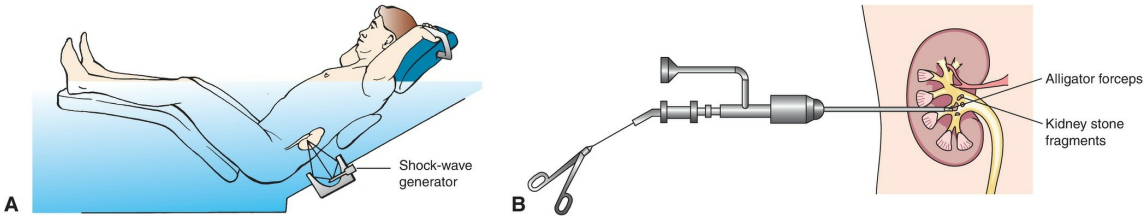

Figure 21-9. (A) Extracorporeal shock wave lithotripsy for renal calculi dissolution. **(B)** A percutaneous nephrostomy tract permits access to the collecting system of the kidney for removal of renal calculi under direct vision via a nephroscope. (Smeltzer, S., & Bare, B. [2003]. *Brunner and Suddarth's textbook of medical-surgical nursing* [10th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

1. Under fluoroscopic guidance, a needle is advanced into collecting system; guide wire is advanced into renal pelvis or ureter.
2. Tract is dilated with mechanical dilators or high-pressure balloon dilator until nephroscope can be inserted up against stone.
3. Stones can be broken apart with hydraulic shock waves or a laser beam administered by way of nephroscope; fragments are removed using forceps, graspers, or basket.
4. May be combined with ESWL.
5. Complications include hemorrhage, infection, and extravasation of urine.

Ureteroscopy

1. Used for distal ureteral calculi; may be used for midureteral calculi.
2. Flexible or rigid ureteroscopes are used in conjunction with baskets or graspers.
3. Electrohydraulic, ultrasonic, or laser equipment may also be used to fragment stone.
4. A stent may be inserted and left in place after surgery to maintain patency of the ureter.

Open Surgical Procedures

Indicated for only 1% to 2% of all stones; rarely performed, most likely to be done percutaneously or laparoscopically, if indicated.

1. Pyelolithotomy—removal of stones from kidney pelvis.
2. Nephrolithotomy—incision into the kidney for removal of stone.
3. Nephrectomy—removal of the kidney; indicated when the kidney is extensively and irreparably damaged and is no longer a functioning organ; partial nephrectomy sometimes done.
4. Ureterolithotomy—removal of stone in the ureter.
5. Cystolithotomy—removal of stone from the bladder.

Complications

1. Obstruction—from remaining stone fragments.
2. Infection—from dissemination of infected stone particles or bacteria resulting from obstruction.
3. Impaired renal function—from prolonged obstruction before treatment and removal.
4. Perirenal hematoma—from bleeding around the kidney caused by trauma of shock waves or laser treatments.

Nursing Assessment

1. Obtain history, focusing on history of calculi, family history of calculi, episodes of dehydration, prolonged immobility, UTI, dietary, bleeding history, and medication history.
2. Assess pain location and radiation; assess level of pain using a scale of 1 to 10. Observe for presence of associated symptoms: nausea, vomiting, diarrhea, abdominal distention.
3. Monitor for signs and symptoms of UTI, such as chills, fever, dysuria, frequency. Examine urine for hematuria.
4. Observe for signs and symptoms of obstruction, such as frequent urination of small amounts, oliguria, anuria.

Nursing Diagnoses

- Acute Pain related to inflammation, obstruction, and abrasion of urinary tract by migration of stones.
- Impaired Urinary Elimination related to blockage of urine flow by stones.
- Risk for Infection related to obstruction of urine flow and instrumentation during treatment.

Nursing Interventions

Controlling Pain

1. Give prescribed NSAID or opioid analgesic (orally or via IV patient-controlled analgesia) until cause of pain can be removed.
    a. Monitor patient closely for increasing pain; may indicate inadequate analgesia.
    b. Large doses of opioids are typically required to relieve pain; so, monitor for respiratory depression and drop in BP.
2. Encourage patient to assume position that brings some relief.
3. Reassess pain frequently using pain scale.
4. Administer antiemetics (usually given orally IV, but rectal suppository may be given), as indicated, for nausea.

Maintaining Urine Flow

1. Administer fluids orally or via IV line (if vomiting) to reduce concentration of urinary crystalloids and ensure adequate urine output.
2. Monitor total urine output and patterns of voiding. Report oliguria or anuria.
3. Strain all urine through strainer or gauze to harvest the stone; uric acid stones may crumble. Crush clots

and inspect sides of urinal/bed pan for clinging stones or fragments.

4. For outpatient treatment, patient may use a coffee filter to strain urine.
5. Help patient to walk, if possible, because ambulation may help move the stone through the urinary tract.

NURSING ALERT Avoid overhydration, which may result in increased distention at stone location, causing an increase in pain and associated symptoms.

Controlling Infection

1. Administer parenteral or oral antibiotics, as prescribed during treatment, and monitor for adverse effects.
2. Assess urine for color, cloudiness, and odor.
3. Obtain vital signs and monitor for fever and symptoms of impending sepsis (tachycardia, hypotension).

Patient Education and Health Maintenance

Recovery from Surgical Interventions for Stone Disease

1. Encourage fluids to accelerate passing of stone particles.
2. Teach about analgesics that still may be necessary for colicky pain, which may accompany passage of stone debris.
3. Warn that some blood may appear in urine for several weeks.
4. Encourage frequent walking to assist in passage of stone fragments.
5. Teach patient to strain urine through a coffee filter or stone strainer and to save stone for analysis.
6. Teach patient to take alpha-adrenergic blockers to help dilate the ureter, thus improving stone passage.

Prevention of Recurrent Stone Formation

1. For patients with calcium oxalate stones:
   a. Instruct on diet—avoid excesses of calcium and phosphorus; maintain a low-sodium diet (sodium restriction decreases amount of calcium absorbed in the intestine). (*Note:* Patient should not decrease calcium intake; rather, he or she should maintain regular intake.)
   b. Teach purpose of drug therapy—thiazide diuretics to reduce urine calcium excretion through the kidneys.
2. For patients with uric acid stones:
   a. Teach methods to alkalinize urine to enhance urate solubility.
   b. Instruct on testing urine pH.
   c. Teach purpose of taking allopurinol—to lower uric acid concentration.
   d. Provide information about reduction of dietary purine intake (reduce red meat, fish, and fowl intake).
3. For patients with infected (struvite) stones:

a. Teach signs and symptoms of urinary infection (in patients with neurologic or spinal cord disease, teach use of dipsticks to evaluate urine for nitrites and leukocytes); encourage patient to report infection immediately; must be treated vigorously.
   b. Try to avoid prolonged periods of recumbency—slows renal drainage and alters calcium metabolism.
4. For patients with cystine stones (occur in *cystinuria*, a hereditary disorder of amino acid transport):
   a. Teach patient to alkalinize urine by taking sodium bicarbonate tablets to increase cystine solubility; instruct patient how to test urine pH with a pH indicator.
   b. Teach patient about drug therapy with D-penicillamine—to lower cystine concentration or dissolution by direct irrigation with thiol derivatives.
   c. Explain importance of maintaining drug therapy consistently.
5. For all patients with stone disease:
   a. Explain the need for consistently increased fluid intake (24-hour urinary output greater than 2 L)—lowers the concentration of substances involved in stone formation.
      i. Drink enough fluids to achieve a urinary volume of 2,000 to 3,000 mL or more every 24 hours.
      ii. Drink larger amounts during periods of strenuous exercise and in hot, humid weather because of perspiration.
   b. Encourage a diet low in sugar and animal proteins—refined carbohydrates appear to lead to hypercalciuria and urolithiasis; animal proteins increase urine excretion of calcium, uric acid, and oxalate.
   c. Increase consumption of fiber—inhibits calcium and oxalate absorption.
   d. Save any stone passed for analysis. (Only patients with more than one episode of urolithiasis are advised to have a metabolic evaluation.)
   e. Can discontinue urine straining once stone is passed.

Evaluation: Expected Outcomes

- Verbalizes reduced pain level.
- Urine output adequate with low specific gravity.
- Afebrile; urine clear.

Renal Cell Carcinoma

Renal cell carcinoma accounts for 85% of primary malignant renal tumors, occurring twice as more frequently in men than in women. Most renal cell tumors are found in the renal parenchyma and develop with few (if any) symptoms.

Pathophysiology and Etiology

1. Unknown etiology; tobacco exposure, through use of cigarettes or chew, causes a twofold increase in risk. Obesity and hypertension are additional risk factors for developing renal cell cancer. Exposure to asbestos, solvents, and cadmium also increases risk.
2. Occurs most frequently in persons between ages 50 and 70.
3. Early-stage renal cancer usually diagnosed incidentally during CT scan or sonogram for an unrelated health problem.
4. Incidence is 10% to 20% higher in African American men.

Clinical Manifestations

1. Many renal tumors produce no symptoms.
2. Weight loss, fever, and night sweats—from systemic effects of renal cancer.
3. Classic triad (late symptoms, occurs in only 7% to 10% of patients):
   a. Hematuria—intermittent or continuous, microscopic or gross.
   b. Flank pain—from distention of renal capsule, invasion of surrounding structures.
   c. Palpable mass in the flank or abdomen.
4. Hematuria, dyspnea, cough, and bone pain with advanced disease.

Diagnostic Evaluation

1. Ultrasonography—helpful in differentiating renal cyst from renal tumor.
2. Three-phase CT scan with and without IV contrast—primary technique for detecting, diagnosing, categorizing, and staging a renal mass.
3. IVP—used as a screening procedure and rarely performed, IVP alone may fail to detect some renal tumors.
4. MRI—determines if thrombosis is in renal vein and evaluates for vascular extension.

Management

The goal is to eradicate the tumor and prevent metastasis.

Radical Nephrectomy

Removal of the kidney and associated tumor, adrenal gland, surrounding perirenal fat, Gerota fascia, and possibly regional lymph nodes—provides maximum opportunity for disease control.

1. Performed through a vertical midline, subcostal, thoracoabdominal, or flank incision.

2. See page 596 for care of patient after renal surgery.
3. Increasingly done laparoscopically.
4. Partial nephrectomy is done for localized tumors as nephron sparing.

Renal Artery Embolization

Preoperative occlusion of renal artery followed by nephrectomy—limited to patient with large vascular tumor in which the renal artery may be difficult to reach early in procedure.

1. Catheter is advanced into renal artery.
2. Embolizing material (Gelfoam, steel coils) is injected into artery and carried with arterial blood flow to occlude the tumor vessels.
3. Monitor for postinfarction syndrome (lasts 2 to 3 days)—severe abdominal pain, nausea, vomiting, diarrhea, fever.
4. Complications — arterial obstruction, bleeding, diminution of renal function.

Chemotherapy and Immunotherapy

Renal cell carcinomas are generally refractory to chemotherapeutic agents, radiation, and hormonal manipulation.

1. Interleukin-2—lymphokine that stimulates growth of T lymphocytes—may offer some benefit to patients with metastatic renal cancer, although toxicity is severe.
2. Sunitinib and sorafenib inhibit vascular endothelial growth factor and platelet-derived growth factors.
   a. Main adverse effects include rash, diarrhea, and hand–foot skin rash.
   b. Possible 3- to 5-month increase in survival.

Cryoablation

1. Freezing of tumor with liquid nitrogen or argon gas through percutaneous needles placed into tumors, using ultrasound guidance.
2. Appropriate for tumors 3.5 cm or less in size.

Thermal Ablation

1. Use of heat through percutaneous needles to cause tissue necrosis, thus killing tumor cells.
2. Appropriate for tumors 3.5 cm or less in size.

Complications

Metastasis to the lung, bone, liver, brain, and other areas.

Nursing Assessment

1. Assess for clinical manifestations of systemic disease—fatigue, anorexia, weight loss, pallor, fever, and bone pain—as well as evidence of metastasis.
2. Assess cardiopulmonary and nutritional status before surgery.

3. Monitor for adverse effects and complications of diagnostic tests and treatment.
4. Assess pain control and coping ability.

Nursing Diagnoses

- Anxiety related to diagnosis of cancer and possibility of metastatic disease.
- Acute Pain and Hyperthermia related to postinfarction syndrome.

Also see page 596 for nursing diagnoses and interventions related to renal surgery.

Nursing Interventions

Reducing Anxiety

1. Explain each diagnostic test, its purpose, and possible adverse reactions. Ensure that informed consent has been obtained, as indicated.
2. Assess patient's understanding about diagnosis and treatment options. Answer questions, and encourage a more thorough discussion with health care provider, as needed.
3. Encourage patient to discuss fears and feelings; involve family and significant others in teaching.

Controlling Symptoms of Postinfarction Syndrome

1. Administer analgesics, as prescribed, to control flank and abdominal pain.
2. Encourage rest and assist with positioning for 2 to 3 days until syndrome subsides.
3. Obtain temperature every 4 hours and administer antipyretics, as indicated.
4. Restrict oral intake and provide IV fluids while patient is nauseated.
5. Administer antiemetics, as ordered.

Patient Education and Health Maintenance

1. Ensure that patient understands where and when to go for follow-up (surgeon, primary care provider, oncologist, and radiologist for metastatic workup and treatment).
2. Explain the importance of follow-up for hypertension and renal function, even if patient feels well.
3. Advise patient with one kidney to wear a MedicAlert bracelet and notify all health care providers because potentially nephrotoxic medications and procedures must be avoided.

Evaluation: Expected Outcomes

- Asks questions and verbalizes fears.
- Afebrile; states reduced pain.

Injuries to the Kidney

Trauma to the abdomen, flank, or back may produce renal injury. Suspicion is high in a patient with multiple injuries.

Pathophysiology and Etiology

1. *Blunt trauma* (falls, sporting accidents, motor vehicle accidents) can suddenly move the kidney out of position and in contact with a rib or lumbar vertebral transverse process, resulting in injury. This is the most common injury to the kidney, accounting for 80% to 85% of all renal injuries.
2. *Penetrating trauma* (gunshot and stab wounds) can injure the kidney if it lies in the path of the wound.
3. Renal trauma is classified according to severity of injury (see Figure 21-10):
    a. Grade I (most common): renal contusion or bruising with normal radiographic imaging.
    b. Grade II: perirenal hematoma or laceration that extends into renal cortex.
    c. Grade III: laceration extends into renal cortex and renal medulla.
    d. Grade IV: laceration extends into collecting system, urine extravasation; requires surgical management.
    e. Grade V: shattered kidney or avulsion of renal artery or renal vein/artery injury; requires surgical management.
4. Eighty percent of patients with renal trauma will have injuries to other organ systems also necessitating treatment.

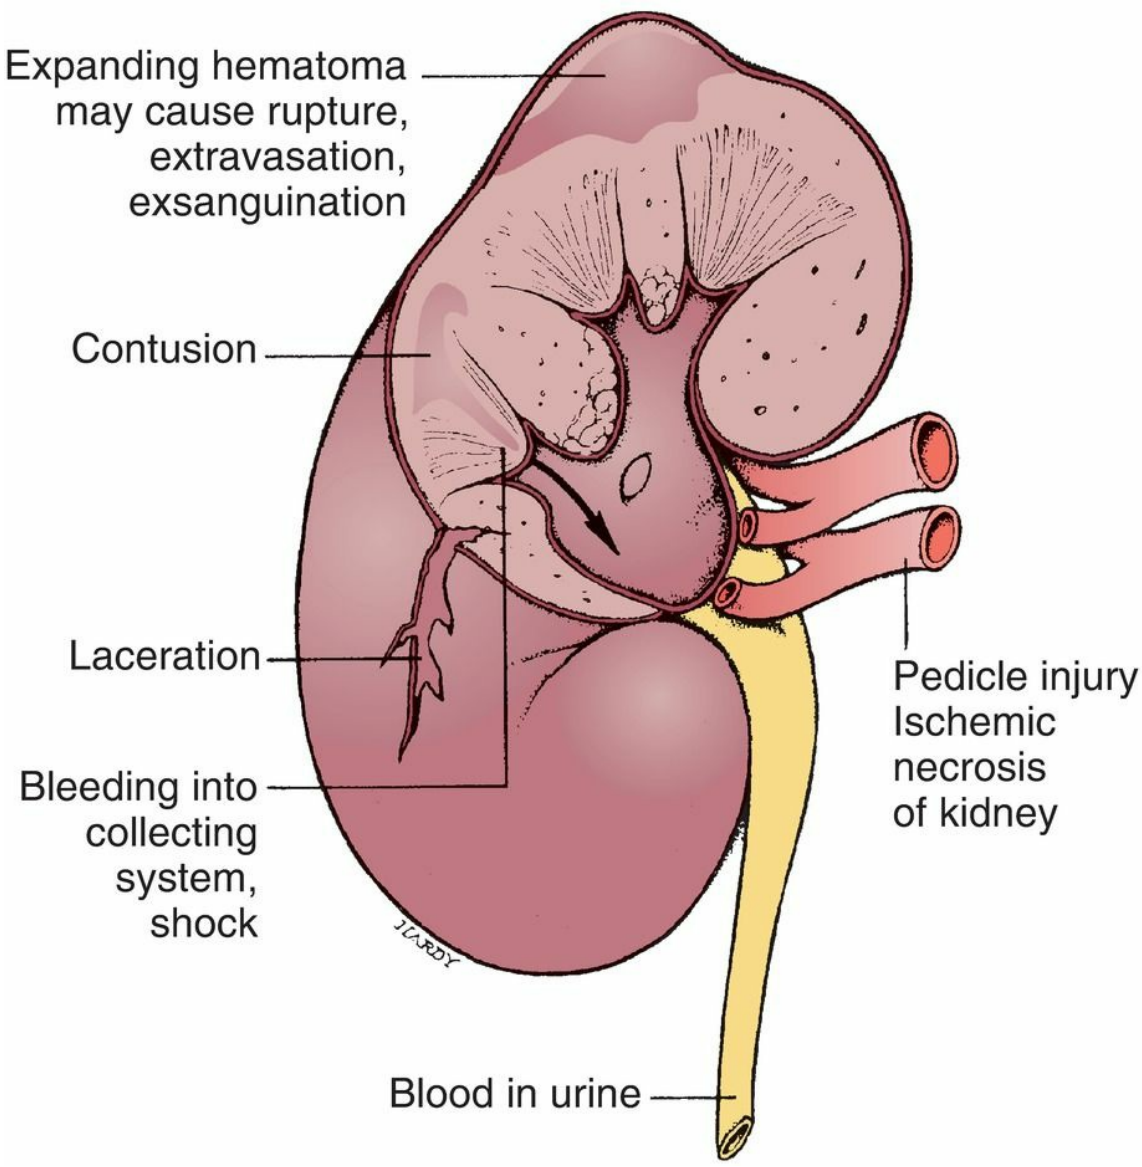

Figure 21-10. Types and physiologic effects of renal injuries: contusion, laceration, rupture, and pedicle injury. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical–surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Clinical Manifestations

1. Hematuria is common but not indicative of severity of injury.
2. Flank pain; perirenal hematoma.
3. Nausea, vomiting, abdominal rigidity—from ileus (seen when there is retroperitoneal bleeding).
4. Shock—from severe or multiple injuries.

Diagnostic Evaluation

1. History of injury—determine if injury was caused by blunt or penetrating trauma.
2. IVU with nephrotomograms—to define extent of injury to the involved kidney and the function of

contralateral kidney.

3. CT scan with IV contrast—differentiates between major and minor injuries.
4. Arteriography—to evaluate the renal artery, if necessary.

Management

1. Contusions and minor lacerations are managed conservatively with bed rest, IV fluids, and monitoring of serial urines for clearing of hematuria.
2. Major lacerations (grades IV and V) are surgically repaired.
3. Ruptures are surgically repaired, usually by partial nephrectomy.
4. Renal pedicle injury is a hemorrhagic emergency and requires immediate surgical repair and possible nephrectomy.

NURSING ALERT If there is a history consistent with renal injury and patient presents in shock, suspect a renal pedicle injury. This is a hemorrhagic emergency, requiring immediate treatment of shock and preparation for surgery.

Complications

1. Hemorrhage, shock with cardiovascular collapse.
2. Hematoma or urinoma formation, abscess formation.
3. Hypertension.
4. Pyelonephritis.
5. Nephrolithiasis.
6. Hydronephrosis.
7. Arteriovenous fistula.

Nursing Assessment

1. Obtain history of traumatic event and any history of renal disease.
2. Inspect for any abrasions, lacerations, or entrance and exit wounds to upper abdomen or lower thorax.
3. Monitor BP and pulse to assess for bleeding and impending shock; perirenal hemorrhage may cause rapid exsanguination.
4. Assess for presence and degree of hematuria.

NURSING ALERT Watch for any *sudden* change in patient's condition—drop in BP, increasing flank or abdominal pain and tenderness, or palpable mass in the flank. May indicate hemorrhage, which

requires surgical intervention.

Nursing Diagnoses

- Risk for Ineffective Renal Perfusion related to injury.
- Impaired Urinary Elimination related to injury.
- Acute Pain related to injury.

Nursing Interventions

Restoring and Maintaining Renal Perfusion

1. Assess vital signs frequently, including BP, heart rate, and CVP to monitor for hemorrhage and impending shock.
2. Assess abdomen and back for local tenderness and palpable mass, swelling, and ecchymosis, indicating hemorrhage or urine extravasation.
3. Outline original mass with marking pen for future comparison of size.
4. Establish IV access for support of BP with fluids or vasopressors, replacement of blood, and perfusion of kidneys.
5. Monitor serial hematocrit determinations to be sure that bleeding has stopped.

Preserving Urinary Elimination

1. Save, inspect, and compare each urine specimen—to follow the course and degree of hematuria.
    a. Label each specimen with date and time.
    b. If specimen is not grossly bloody, dipstick for blood or send to laboratory for microscopic examination.
2. Monitor intake and output carefully.
3. Give antibiotics, as directed, to discourage infection from perirenal hematoma or urinoma or severely contaminated wounds.
4. Monitor for paralytic ileus (lack of bowel sounds) caused by retroperitoneal bleeding.
    a. Keep patient NPO until bowel sounds return.
    b. Administer IV fluids to maintain urine output.

Controlling Pain

1. Administer analgesic medication, as prescribed; exercise caution with drugs that may aggravate hypotension or mask complications of hemorrhage.
2. Encourage bed rest and positioning of comfort until hematuria clears to facilitate healing of minor injuries.
3. Expect a low-grade fever with retroperitoneal hematomas as absorption of the clot occurs; administer antipyretics, as ordered, for comfort.

Patient Education and Health Maintenance

1. Instruct patient not to engage in strenuous activity for at least 1 month after blunt trauma to minimize incidence of delayed or secondary bleeding.
2. Teach patient signs and symptoms of late complications—infection and nephrolithiasis.
3. Advise patient to have BP measured frequently and consistently to monitor for hypertension.
4. Review safety precautions to prevent future injuries.

Evaluation: Expected Outcomes

- Vital signs stable.
- Serial urines clearing.
- Reports decreased pain.

Injuries to the Bladder and Urethra

Injuries to the bladder and urethra commonly occur along with pelvic fracture or may be due to surgical interventions.

Pathophysiology and Etiology

1. Bladder injuries are classified as follows:
    a. Contusion of the bladder.
    b. Intraperitoneal rupture.
    c. Extraperitoneal rupture.
    d. Combination intraperitoneal and extraperitoneal bladder rupture.
2. Urethral injuries (occurring almost exclusively in men) are classified as follows:
    a. Partial or complete rupture.
    b. Anterior or posterior urethral rupture.
3. Injuries to the bladder and urethra are commonly associated with pelvic fractures and multiple trauma.
4. Certain surgical procedures (endoscopic urologic procedures, gynecologic surgery, surgery of the lower colon and rectum) also carry a risk of trauma to the bladder and urethra.
5. Intraperitoneal bladder rupture occurs when the bladder is full of urine and the lower abdomen sustains blunt trauma. The bladder ruptures at its weakest point, the dome. Urine and blood extravasate into the peritoneal cavity.
6. Extraperitoneal bladder rupture occurs when the lower bladder is perforated by a bony fragment during pelvic fracture or with a sharp instrument during surgery. Urine and blood extravasate into the pelvic cavity.
7. Urethral rupture occurs during pelvic fracture (posterior) or when the urethra or penis is manipulated accidentally during surgery or injury (anterior).

Clinical Manifestations

1. Inability to void.
2. Gross hematuria; presence of blood at urinary meatus may indicate ruptured urethra.
3. Shock and hemorrhage—pallor, rapid and increasing pulse rate.
4. Suprapubic pain and tenderness.
5. Rigid abdomen—indicates intraperitoneal rupture.
6. Absence of prostate on rectal examination in posterior urethral rupture.
7. Swelling or discoloration of the penis, scrotum, and anterior perineum in anterior urethral rupture.

Diagnostic Evaluation

1. Retrograde urethrogram—to detect rupture of the urethra.
2. Cystogram—to detect and localize perforation/rupture of the bladder.

3. Plain film of the abdomen—may show associated pelvic fracture.
4. Abdominal CT with contrast—best study to evaluate extent of kidney injury.
5. Excretory urogram—to survey the kidneys and ureters for injury.

NURSING ALERT If ruptured urethra is suspected and/or blood at meatus observed, do not catheterize because doing so may complete a partial urethral rupture. A urethrogram must be obtained first to determine patency of the urethra.

Management

Bladder Injury

1. Treatment instituted for shock and hemorrhage.
2. Surgical intervention carried out for intraperitoneal bladder rupture. Extravasated blood and urine will first be drained and urine diverted with suprapubic cystostomy or indwelling catheter.
3. Small extraperitoneal bladder ruptures will heal spontaneously with indwelling suprapubic or urethral catheter drainage.
4. Large extraperitoneal bladder ruptures are repaired surgically.

Urethral Injury Management—Controversial

1. Immediate repair—the urethra is manipulated into its correct anatomical position with reanastomosis after evacuation of hematoma.
2. Delayed repair—suprapubic cystostomy drainage for 6 to 12 weeks allows the urethra to realign itself while hematoma and edema resolve; then, surgical reanastomosis.
3. Two-stage urethroplasty—reconstruction of the urethra occurs in two separate surgeries with urinary elimination diverted until final procedure.

Complications

1. Shock, hemorrhage, peritonitis.
2. UTI.
3. Urethral stricture disease.
4. Impotence.
5. Incontinence.

Nursing Assessment

1. Obtain vital signs; assess for evidence of shock.
2. Obtain detailed history of injury, if possible.
3. Inspect urinary meatus for evidence of bleeding. If present, do not insert Foley until retrograde

urethrogram verifies patent urethra.

4. Perform physical examination for symptoms of bladder rupture, dullness to palpation, and rebound tenderness or rigidity.

Nursing Diagnoses

- Risk for Deficient Fluid Volume related to trauma and resulting hemorrhage.
- Impaired Urinary Elimination related to disruption of intact lower urinary tract.
- Acute Pain related to traumatic injury.
- Fear related to traumatic injury and uncertain prognosis.

Nursing Interventions

Stabilizing Circulatory Volume

1. Monitor vital signs and CVP frequently, as indicated by condition.
2. Establish IV access and replace blood and fluids, as ordered.

Facilitating Urinary Elimination

1. Inspect urethral meatus for blood and, if present, do not catheterize but prepare for diagnostic evaluation and suprapubic cystostomy.
2. Obtain urine specimen, if possible, and assess for degree of hematuria and presence of infection.
3. Prepare patient for surgical repair by assisting with preoperative workup and describing postoperative experiences.
4. Postoperatively, maintain patency and flow of indwelling urinary catheters.
5. Inspect suprapubic incision and Penrose drains from perivesical areas for bleeding, extravasation of urine, or signs of infection.

Controlling Pain

1. Administer analgesics, as ordered (when patient's vital signs are stable).
2. Assess patient's response to pain control medications.
3. Position for comfort (usually semi-Fowler position), if not contraindicated by other injuries, and prevent pulling of catheter tubing.

Relieving Fear

1. Provide information to the conscious patient throughout the stabilization and evaluation phase; prepare for surgery, if impending.
2. Keep patient's family or significant others informed of condition and progress.
3. Provide information on long-term outcome of treatment.

Patient Education and Health Maintenance

1. Teach patient to care for indwelling catheters that will remain in place during healing or after surgery.

a. Empty catheter frequently.
b. Clean catheter and insertion area with soap and water.
c. Inspect urine for blood, cloudiness, or concentration.
d. Drink plenty of fluids to keep urine flowing.

2. Teach patient to report signs and symptoms of UTI.
3. Instruct patient (after surgical repair of bladder rupture) that bladder capacity may be temporarily decreased, causing frequency and nocturia; this resolves over time.
4. Explain possibility of recurrent urethral stricture disease to patients with urethral injury; instruct in daily self-catheterization to dilate the urethra, if prescribed.
5. Support patient (after severe urethral injury) if there is a chance of impotence or incontinence.

Evaluation: Expected Outcomes

- Vital signs stable.
- Adequate urine output by way of catheter.
- Verbalizes relief of pain.
- Verbalizes reduction in fear.

Cancer of the Bladder

Cancer of the bladder is the second most common urologic malignancy. Approximately 90% of all bladder cancers are transitional cell carcinomas, which arise from the epithelial lining of the urinary tract; transitional cell tumors can also occur in the ureters, renal pelvis, and urethra. The remaining 10% of bladder cancers are adenocarcinoma, squamous cell carcinoma, or sarcoma.

Pathophysiology and Etiology

1. Many bladder tumors are diagnosed when the lesions are superficial; papillary tumors are easily resected.
2. One fourth of patients with bladder cancer present with nonpapillary, muscle invasive disease.
3. Bladder tumors tend to be either low-grade superficial tumors or high-grade invasive cancers.
4. Metastasis occurs in the bladder wall and pelvis, para-aortic or supraclavicular nodes, liver, lungs, and bone.
5. Although the specific etiology is unknown, it appears that multiple agents are linked to the development of cancer of the bladder, including:
   a. Cigarette smoking—the risk of developing bladder cancer is up to four times higher in smokers.
   b. Prolonged exposure to aromatic amines or their metabolites—generally dyes manufactured by the chemical industry and used by other industries.
   c. Exposure to cyclophosphamide, radiation therapy to the pelvis, chronic irritation of the bladder (as in long-term indwelling catheterization), and excessive use of the analgesic drug phenacetin, which has been taken off the market.
6. Bladder cancer is the fourth most common cancer in men; it occurs four times more frequently in men than in women; peak incidence occurs in the sixth to eighth decades.

Clinical Manifestations

1. Painless hematuria, either gross or microscopic—most characteristic sign.
2. Dysuria, frequency, urgency—bladder irritability.
3. Pelvic or flank pain—obstruction or distant metastases.
4. Leg edema—from invasion of pelvic lymph nodes.

Diagnostic Evaluation

1. Cystoscopy for visualization of number, location, and appearance of tumors; for biopsy.
2. Urine and bladder washing for cytologic study.
3. Urine for flow cytometry—uses a computer-controlled fluorescence microscope to scan and image the nucleus of each cell on a slide; based on the fact that cancer cells contain abnormally large amounts of deoxyribonucleic acid.
4. IVU—may reveal filling defect indicative of bladder tumor; also determines status of upper tracts.
5. CT urography (three-phase CT scan)—replacing IVU or IVP as the test of choice to evaluate kidneys,

ureter, and bladder.

6. To evaluate for metastatic disease:
   a. CT scan or MRI—to evaluate extent of disease and tumor responsiveness.
   b. Chest x-ray—to evaluate for pulmonary metastases.
   c. Pelvic lymphadenectomy (during cystectomy)—most accurate for staging.

Management

Surgery

1. Transurethral resection and fulguration—endoscopic resection for superficial tumors.
   a. May be followed by intravesical chemotherapy to prevent tumor recurrence.
   b. Complications include hemorrhage, infection, bladder perforation, and temporary irritative voiding.
   c. Laser irradiation of bladder tumors is also used to destroy tumors; however, it does not allow for tumor specimen collection for pathologic analysis.
2. Partial cystectomy when lesions are located only in the dome of the bladder, away from the ureteral orifices.
3. Radical cystectomy (removal of the bladder) for invasive or poorly differentiated tumors.
   a. Requires diversion of the urinary stream (see page 596).
   b. In men, includes removal of the bladder, prostate and seminal vesicles, proximal vas deferens, and part of proximal urethra.
   c. Men may be impotent.
   d. In women, consists of anterior exenteration with removal of the bladder, urethra, uterus, fallopian tubes, ovaries, and segment of anterior wall of the vagina.
   e. May be combined with chemotherapy and radiation.

Intravesical (within the Bladder) Chemotherapy and Immunotherapy

1. Instillation of immunotherapeutic agent bacillus Calmette-Guerin (BCG) stimulates immune response to prevent recurrence of transitional cell bladder tumors. BCG is attenuated mycobacterium initially developed as a vaccine for tuberculosis and has demonstrated antitumor activity in selected cancers.
2. Instillation of antineoplastic agents, such as thiotepa, mitomycin-C, and doxorubicin, allows a high concentration of drug to come in contact with the tumor and urothelium with minimal systemic toxicity.
3. Patient is instructed as follows:
   a. Minimize fluid intake and avoid taking diuretic medications for several hours before the instillation period to maximize concentration of drug treatment period.
   b. Change position, as directed during instillation, in an effort to have drug contact as much of urothelial surface as possible.
   c. Wash hands and perineal area after voiding the medication to prevent contact dermatitis.
   d. Do not void for 2 hours after instillation; then, increase fluid intake and void frequently.

e. When using BCG, place two cups of bleach into toilet with each void for 6 hours after starting voiding to neutralize the chemotherapeutic agent and prevent possible contamination to others.
f. Course of treatment involves weekly instillations for 6 weeks followed by monthly instillations.

4. Complications from intravesical chemotherapy and immunotherapy include UTI, irritative voiding symptoms, allergic reaction, bone marrow suppression, or systemic BCG reaction. A systemic BCG reaction occurs when fever higher than 100˚F (37.8˚C) persists for more than 24 hours; it is treated with antituberculosis agents.

Systemic Chemotherapy

Metastatic bladder cancer is a chemotherapeutically responsive disease; gemcitabine and cisplatin have lower toxicity, improved tolerability, and similar overall survival to the MVDC combination (methotrexate, vinblastine, doxorubicin, and cisplatin), which had been in wide use.

Radiation Therapy

External beam radiation therapy is commonly used in combination with chemotherapy.

Complications

Regional metastasis through the pelvis as well as metastasis to the lung, liver, and bone.

Nursing Assessment

1. Assess for hematuria, irritative voiding symptoms, risk factors (especially smoking history), weight loss, fatigue, and signs of metastasis.
2. Assess coping ability and knowledge of the disease and explore feelings about impotence.

Nursing Diagnoses

- Impaired Urinary Elimination related to hematuria and transurethral surgery.
- Acute Pain related to irritative voiding symptoms and catheter-related discomfort.
- Anxiety related to diagnosis of cancer.

Nursing Interventions

Maintaining Urinary Elimination after Transurethral Surgery

1. Maintain patency of indwelling urinary drainage catheter; manual irrigation is not recommended due to dangers of bladder perforation; continuous bladder irrigation may be used, if necessary.
2. Ensure adequate hydration either orally or via IV line.
3. Monitor intake and output, including irrigation solution.
4. Monitor urine output for clearing of hematuria.

Controlling Pain

1. Administer analgesic medication for pelvic discomfort.

2. Administer anticholinergic medications or belladonna and opium suppositories to relieve bladder spasms.
3. Ensure patency of catheter drainage; do not irrigate unless specifically ordered.
4. Remove indwelling catheter as soon as possible after procedure.

Relieving Anxiety

1. Allow patient to verbalize fears and concerns about altered sexuality.
2. Provide realistic information about diagnostic studies, surgery, and treatments.

Patient Education and Health Maintenance

1. Advise patient that irritative voiding symptoms and intermittent hematuria are possible for several weeks after transurethral resection of bladder tumors.
2. Teach patient with superficial bladder cancer importance of vigilant adherence to follow-up schedule: after initial 6-week induction course of BCG, they need cystoscopy and three weekly instillations of BCG at 3 and 6 months and then every 6 months thereafter for 3 years. Yearly cystoscopy is required as 70% of superficial tumors will recur.
3. Review purpose and adverse effects of intravesical chemotherapy treatments (usually not given until after recurrence).

Evaluation: Expected Outcomes

- Urine output adequate and clear.
- Verbalizes relief of pain and bladder spasms.
- Verbalizes lessened anxiety.

CONDITIONS OF THE MALE REPRODUCTIVE TRACT

Urethritis

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted disease treatment guidelines 2015. *MMWR, 64*(3), 1–137.

Urethritis is inflammation of the urethra. It is usually an ascending infection in men. In women, it is usually associated with cystitis (see page 610) or vaginitis (see page 655).

Pathophysiology and Etiology

1. Nongonococcal urethritis—urethritis not caused by gonococcus; may be sexually transmitted:
   a. *Chlamydia trachomatis*—most clinically significant of the pathogens, three cases of chlamydia diagnosed for every one case of gonorrhea. Usually asymptomatic.
   b. *Ureaplasma urealyticum* and *Mycoplasma genitalium*—responsible for up to one third of cases.
   c. *Trichomonas vaginalis* and herpes simplex virus are other sexually transmitted organisms causing urethritis in men and women.
   d. Incubation period of 1 to 5 weeks depending on the organism; in some cases, infection may be subclinical for a period of time, particularly in men.
2. Gonococcal urethritis—caused by *Neisseria gonorrhoeae*, sexually transmitted; usually most virulent and destructive.
   a. Incubation period usually 3 to 10 days.
   b. Urethritis in homosexual men is more commonly gonococcal than nongonococcal.
3. Gonococcal and nongonococcal urethritis can both be present.
4. Nonsexually transmitted.
   a. Bacterial urethritis—may be associated with UTI.
   b. From trauma—secondary to passage of urethral sounds, repeated cystoscopy, indwelling catheter.

Clinical Manifestations

1. Can be asymptomatic.
2. Itching and burning around area of the urethra.
3. Urethral discharge: may be scant or profuse; thin, clear, or mucoid; or thick and purulent (gonococcal).
4. Dysuria and frequency.
5. Penile discomfort.

Diagnostic Evaluation

1. Gram stain—*N. gonorrhoeae* is detected as gram-positive diplococci on microscopic examination of urethral discharge or urine.

2. Culture of urethral discharge on selective medium.
3. Deoxyribonucleic acid (DNA) amplification tests on urethral voided specimen or other DNA/antibody tests of urethral discharge (currently, primary test)—to detect *C. trachomatis* and *N. gonorrhoeae*.
4. Wet mount microscopic examination of fresh urethral discharge—trichomonads may be visible and motile.
5. First voided urine for screening—either positive leukocyte esterase test by dipstick or greater than 10 WBC per high-power field by microscopy indicates urethritis.
6. In rare cases, urethroscopy may be necessary to isolate a lesion such as warts caused by human papillomavirus (HPV).

Management

1. Gonococcal urethritis: one dose oral antibiotic of cefixime 400 mg or one dose IM treatment with ceftriaxone 125 mg.
2. Chlamydial urethritis: single dose of oral antibiotic azithromycin 1 g or doxycycline 100 mg orally twice per day for 7 days.
3. Unless proven otherwise by negative testing, treatment for chlamydia is given along with treatment for gonorrhea.
4. Recurrent urethritis despite appropriate treatment for nongonococcal urethritis or confirmed presence of *T. vaginalis* treatment is one dose oral metronidazole 2 g.

DRUG ALERT Fluoroquinolones are now avoided in the treatment of gonococcal infections because of drug resistance.

Complications

Depends on cause, but may include:

1. Prostatitis, epididymitis, urethral stricture, sterility because of vas epididymal duct obstruction.
2. Rectal infection, pharyngitis, conjunctivitis, skin lesions, arthritis with gonococcal infection.
3. Long-term complications of these infections in women include pelvic inflammatory disease and infertility.

Nursing Assessment

1. Obtain history of unprotected sexual contact and assess patient's understanding of risk.
2. Assess for signs and symptoms involving urinary and reproductive tracts.
3. Perform genital and abdominal examination to assess for extent of infection.

Nursing Diagnoses

- Risk for Infection related to ascending or systemic spread of pathogens.
- Risk for Infection related to high-risk sexual activity.

Nursing Interventions

Resolving Infection and Preventing Complications

1. Collect urethral swab of discharge, urine, and blood, as ordered, for laboratory examination.
2. Use standard precautions when handling specimens.
3. Administer antibiotics, as prescribed.
    a. Usually ordered based on presumptive diagnosis before test results are obtained.
    b. Monitor for and advise patient of adverse effects or allergic reactions.

Preventing Spread of Infection

1. Encourage compliance with antimicrobial regimen for the prescribed time period.
2. Advise abstinence from sexual activity until treatment is complete and cure is established (usually 7 to 10 days).
3. Instruct the patient to avoid sexual activity with previous sexual partner until that person has been tested and treated for infection as well.
4. The use of condoms may prevent transmission, but depends on technique.

Patient Education and Health Maintenance

1. Advise safer sex practices, such as abstinence, mutual monogamy, and use of male or female condom to prevent transmission of sexually transmitted organisms as well as unintended pregnancy.
2. Emphasize the need for follow-up care if symptoms persist or return.
3. Advise patient that reporting of gonorrhea to the public health department is required by law in all of the United States and Canada.
4. Tell patient that he or she will be called on to name all sexual partners within the past 60 days and that the process will be confidential.
5. Provide written information about all STDs and ensure that patient understands the dangers of high-risk sexual behavior.

Evaluation: Expected Outcomes

- Signs of infection resolved.
- Reports sexual contacts have been treated.

Benign Prostatic Hyperplasia

Benign prostatic hyperplasia (BPH) is enlargement of the prostate that constricts the urethra, causing urinary symptoms. One in four men who reach age 80 will require treatment for BPH.

Pathophysiology and Etiology

1. The process of aging and the presence of circulating androgens are required for the development of BPH.
2. The prostatic tissue forms nodules as enlargement occurs.
3. The normally thin and fibrous outer capsule of the prostate becomes spongy and thick as enlargement progresses.
4. The prostatic urethra becomes compressed and narrowed, requiring the bladder musculature to work harder to empty urine.
5. Effects of prolonged obstruction cause trabeculation (formation of cords) of the bladder wall, decreasing its elasticity.

Clinical Manifestations

1. In early or gradual prostatic enlargement, there may be no symptoms because the bladder musculature can initially compensate for increased urethral resistance.
2. Obstructive symptoms—hesitancy, diminution in size and force of urinary stream, terminal dribbling, sensation of incomplete emptying of the bladder, urinary retention.
3. Irritative voiding symptoms—urgency, frequency, nocturia.

Diagnostic Evaluation

1. American Urologic Association Symptom Index score greater than 7 (uses rating of questions about the obstructive and irritative symptoms): 0 to 7, mild; 8 to 19, moderate; and 20 to 35, severe.
2. Rectal examination—smooth, firm, symmetric, or asymmetric enlargement of the prostate.
3. Urinalysis—to rule out hematuria and infection.
4. Serum creatinine and BUN—to evaluate renal function.
5. Serum PSA—may be elevated in patients with BPH.
6. Optional diagnostic studies for further evaluation:
    a. Urodynamics—measures peak urine flow rate, voiding time and volume, and status of the bladder's ability to effectively contract.
    b. Measurement of postvoid residual urine; by ultrasound or catheterization.
    c. Cystourethroscopy—to inspect the urethra and bladder and evaluate prostatic size.
    d. Uroflow—graphically demonstrates voiding pattern and can help characterize the severity of obstruction.

Management

1. Patients with mild symptoms (in the absence of significant bladder or renal impairment) are followed annually; BPH does not necessarily worsen in all men.
2. Pharmacologic management.
   a. Alpha-adrenergic blockers, such as doxazosin, tamsulosin, terazosin, and alfuzosin—relax smooth muscle of bladder neck and prostate to facilitate voiding.
   b. 5-alpha-reductase inhibitors such as finasteride and dutasteride—exert antiandrogen effect on prostatic cells and can reverse or prevent hyperplasia. These drugs decrease the size of the prostate and improve urinary symptoms. Effect of drug may take up to 6 months. Women should not handle drug because it can be absorbed through the skin and is pregnancy category X. In addition, patients taking dutasteride cannot donate blood.
3. Surgery (also see page 601)—options include TURP (formerly most common procedure), transurethral incision of the prostate, or open prostatectomy for very large prostates, usually by suprapubic approach.
4. PVP is starting to replace TURP; it is done through a cystoscope, using a laser to vaporize diseased prostatic tissue.
5. TUMT and TUNA are both office-based procedures that use heat to destroy diseased prostatic tissue.
6. Indigo interstitial laser therapy of the prostate is another procedure that is done on an outpatient basis.

DRUG ALERT Although prescribed for their effect on prostatic smooth muscle, alpha-adrenergic blockers (except for tamsulosin and alfuzosin) also have an antihypertensive effect. Dosage is usually titrated up from an initial small dose. It is commonly recommended that the first dose, or all once per day doses, be taken at bedtime.

DRUG ALERT Finasteride is present in semen and may have deleterious fetal effects.

Complications

1. Acute urinary retention, involuntary bladder contractions, bladder diverticula, and cystolithiasis.
2. Vesicoureteral reflux, hydroureter, hydronephrosis.
3. Gross hematuria, UTI.

Nursing Assessment

1. Obtain history of voiding symptoms, including onset, frequency of day and nighttime urination, presence of urgency, dysuria, sensation of incomplete bladder emptying, and decreased force of stream. Determine impact on quality of life.

2. Perform rectal (palpate size, shape, and consistency) and abdominal examination to detect distended bladder, degree of prostatic enlargement.
3. Perform simple urodynamic measures—uroflowmetry and measurement of postvoid residual, if indicated.

Nursing Diagnosis

- Impaired Urinary Elimination related to obstruction of the urethra.

Also see page 601 for care of the patient undergoing prostatic surgery.

Nursing Interventions

Facilitating Urinary Elimination

1. Provide privacy and time for patient to void.
2. Assist with catheter introduction with guide wire or by way of suprapubic cystotomy, as indicated.
   a. Monitor intake and output.
   b. Maintain patency of catheter.
3. Administer medications, as ordered, and monitor for and teach patient about adverse effects.
   a. Alpha-adrenergic blockers—hypotension, orthostatic hypotension, syncope (especially after first dose), potential impotence, potential retrograde ejaculation, blurred vision, rebound hypertension if discontinued abruptly.
   b. Finasteride and dutasteride—hepatic dysfunction, potential impotence, interference with PSA testing, presence in semen with potential adverse effect on fetus of pregnant woman.
4. Assess for and teach patient to report hematuria and signs of infection.

DRUG ALERT Treatment with finasteride and dutasteride decreases the PSA by half, so this should be taken into account when obtaining PSA to monitor for prostate cancer.

Patient Education and Health Maintenance

1. Explain to patient symptoms and complications of BPH—urinary retention, hydronephrosis, cystitis, increase in irritative voiding symptoms. Encourage reporting these problems and maintaining close follow-up.
2. Advise patients with BPH to avoid certain drugs that may impair voiding (see Table 21-3), particularly OTC cold medicines containing sympathomimetics such as phenylpropanolamine.
3. Advise patient that irritative voiding symptoms do not immediately resolve after relief of obstruction; symptoms diminish over time.
4. Tell patient postoperatively to avoid sexual intercourse, straining at stool, heavy lifting, and long periods of sitting for 6 to 8 weeks after surgery, until prostatic fossa is healed.

5. Advise follow-up visits after treatment because urethral stricture may occur and regrowth of prostate is possible after TURP.
6. Be aware of herbal or "natural" products marketed for "prostate health."
   a. Advise patients that saw palmetto has shown some efficacy in reducing symptoms of BPH in a number of clinical trials.
   b. The active ingredient in commercial preparations is lipidosterolic extract of *Serenoa repens*; dosage is 160 mg twice per day.
   c. It should be taken with breakfast and an evening meal to minimize GI adverse effects.
   d. Although it appears safe and there are no known drug interactions, tell patients they must discuss use of saw palmetto with their health care providers.
7. Advise patient to notify all health care providers of medications. If cataract surgery is being planned, the ophthalmologist should be aware of tamsulosin use, which may increase risk of floppy iris syndrome.

Table 21-3 Bladder Function and Drug Actions

FUNCTION	DRUG GROUPS	EXAMPLES
Detrusor Muscle		
Increased tone and contraction	Cholinergic drugs (stimulate parasympathetic receptors that cause detrusor muscle contraction)	• Bethanechol • Neostigmine
Decreased tone, possible retention	Anticholinergic drugs (block parasympathetic receptors that cause detrusor muscle contraction)	• Methantheline • Propantheline • Oxybutynin • Darifenacin • Solifenacin • Trospium
Relaxes bladder tone	Calcium channel–blocking drugs (may interfere with influx of calcium to support detrusor muscle tone)	• Nifedipine • Verapamil • Diltiazem • Tolterodine tartrate
Internal Sphincter		
Increased tone, possible retention	$Alpha_1$-adrenergic agonists (activate alpha receptors that cause contraction of muscles of the internal sphincter)	• Phenylephrine • Ephedrine • Phenylpropanolamine
Decreased tone	$Alpha_1$-adrenergic blockers	• Alfuzosin • Prazosin • Doxazosin • Terazosin • Tamsulosin
External Sphincter		
Decreased tone, possible retention	Skeletal muscle relaxants	• Baclofen • Dantrolene • Diazepam

Evaluation: Expected Outcomes

- Voiding adequate without residual urine.

Prostatitis

Prostatitis is an inflammation of the prostate gland. It is classified as bacterial prostatitis (acute or chronic) or chronic pelvic pain syndrome (without presence of bacterial invasion).

Pathophysiology and Etiology

Acute and Chronic Bacterial Invasion of the Prostate

1. From reflux of infected urine into ejaculatory and prostatic ducts.
2. From hematogenous (bloodstream) origin, lymphogenous spread, or direct extension from the rectum.
3. Secondary to urethritis—from ascent of bacteria from the urethra.
4. May be stimulated by urethral instrumentation or rectal examination of the prostate when bacteria are present.
5. May be caused by gram-negative enteric bacteria, such as *Pseudomonas aeruginosa*, *E. coli*, and *Klebsiella pneumonia*, and gram-positive cocci, such as *Streptococcus* and *Staphylococcus*; may also be caused by *C. trachomatis*.

Chronic Pelvic Pain Syndrome

Pain or discomfort without other signs of infection and no known etiologic cause; difficult to diagnose and manage.

Clinical Manifestations

1. Sudden chills and fever (moderate to high fever) and body aches with acute prostatitis.
2. Symptoms are more subtle with chronic prostatitis and chronic pelvic pain syndrome.
3. Bladder irritability—frequency, dysuria, nocturia, urgency, hematuria to varying degrees.
4. Pain in the perineum, rectum, lower back, lower abdomen, and tip of the penis.
5. Pain after ejaculation, symptoms of urethral obstruction.

Diagnostic Evaluation

1. Urinalysis.
2. Urine culture and sensitivity tests.
    a. Prostate massage is inadvisable because it can precipitate frank sepsis or bacteremia.
    b. In acute bacterial prostatitis, there are numerous WBCs and a positive culture; in chronic bacterial prostatitis, there is a lower bacterial colony count; in chronic pelvic pain syndrome, there may be WBCs but a negative culture.
3. Rectal examination commonly reveals exquisitely tender, painful, swollen (boggy) prostate that is warm to the touch (with acute bacterial prostatitis).
4. Serum WBC count is elevated in acute bacterial prostatitis.
5. Bladder scan for postvoid residual evaluates bladder emptying.

6. Transrectal ultrasound detects prostate abscess.

Management

Acute Bacterial Prostatitis

1. Antimicrobial therapy generally for 2 to 4 weeks based on drug sensitivity; commonly a fluoroquinolone or sulfamethoxazole–trimethoprim.
2. IV therapy with ampicillin or an aminoglycoside in the hospitalized patient. Patients are hospitalized if there is suspected abscess, urosepsis, or immunocompromise.
3. Urinary retention is managed with suprapubic cystostomy; urethral catheterization usually is avoided.
4. Antipyretics, analgesics, hydration, stool softeners, and sitz baths for symptom relief.

Chronic Bacterial Prostatitis

1. Usually 4 to 6 weeks of oral antibiotic therapy with ability to diffuse into prostate.
   a. Quinolones such as ciprofloxacin, levofloxacin, ofloxacin, or norfloxacin.
   b. Sulfonamide such as sulfamethoxazole–trimethoprim.
2. Oral antispasmodic agents may provide relief from urinary frequency and urgency.
3. Alpha-adrenergic blockers may help with urination.

Chronic Pelvic Pain Syndrome

1. Usually requires multiple modalities.
2. Alpha-adrenergic blockers and skeletal muscle relaxants may provide some relief of symptoms.
3. Aggressive diagnostic intervention should take place to rule out other conditions, such as cancer of the prostate or interstitial cystitis.
4. Anti-inflammatory medications such as NSAIDs are helpful.
5. Tricyclic antidepressants may be helpful for pain control.
6. Pentosan may be helpful to relieve discomfort.
7. Quinoline antibiotics may be taken for 4 to 6 weeks.
8. Pelvic floor massage and biofeedback may help relieve perineal muscle spasms.

Complications

1. Bacteriuria, urethritis, epididymitis, prostatic abscess, bacteremia, septicemia.
2. Acute urinary retention.
3. Constipation.

Nursing Assessment

1. Obtain history of previous lower UTIs or STDs and recent voiding patterns.
2. Perform examination of genitalia for urethral discharge; rectal examination (except in acute bacterial prostatitis because of tenderness and possibility of disseminating infection) to assess tenderness of the

prostate.

3. Collect specimens: urine for culture and expressed prostatic secretions. To help distinguish urethral, bladder, and prostate infections, have the patient collect the first 10 mL of urine and label this voided bladder-1. This will be a urethral specimen. Next, have the patient collect a midstream urine specimen and label this voided bladder-2. This is a bladder specimen. Have the patient urinate after a prostatic massage and label this voided bladder-3. This is a prostatic specimen.

Nursing Diagnoses

- Hyperthermia related to infectious process.
- Acute Pain related to prostatic inflammation.
- Chronic Pain related to chronic prostatitis, chronic pelvic pain syndrome.

Nursing Interventions

Reducing Fever

1. Start antibiotic therapy as soon as specimens are obtained for culture.
2. Administer antipyretic medications; use cooling measures, if necessary.
3. Keep patient well hydrated, via IV administration or orally, because of fluid loss through fever; however, avoid overhydration, which increases urine volume and reduces antibiotic concentration in urine.

Relieving Pain

1. Administer analgesic or anti-inflammatory medication, as ordered.
2. Maintain bed rest in acute prostatitis to relieve perineal and suprapubic pain.
3. Maintain high-fiber diet and give stool softeners, as needed, to prevent constipation, which increases pain.

Controlling Chronic Pain

1. Administer or teach self-administration of analgesics, anti-inflammatory agents, alpha-adrenergic blockers, or skeletal muscle relaxants as ordered.
2. Advise warm sitz baths to relieve pain and promote muscular relaxation of pelvic floor and reduce potential for urinary retention.
3. Assess patient's response to supportive measures and coping with chronic pain.

Patient Education and Health Maintenance

1. Instruct patient to take antibiotic, as prescribed; emphasize importance of completing long course of therapy to prevent recurrence and resistance of organisms.
2. Teach patient symptoms of recurrence and of disseminated spread of infection.
3. Instruct patient in comfort measures: sitz baths (10 to 20 minutes) several times daily, continued use of stool softeners, and not sitting for long periods.

4. Advise patient to avoid sexual arousal and intercourse during period of acute inflammation; sexual intercourse may be beneficial in the treatment of chronic prostatitis to stimulate the secretion of prostatic fluid and relieve prostate congestion; chronic prostatic infection is not sexually transmittable.
5. Encourage prescribed follow-up because recurrence is possible.

Evaluation: Expected Outcomes

- Afebrile.
- Verbalizes relief of pain after analgesic.
- Verbalizes reduction of chronic pain.

Cancer of the Prostate

Cancer of the prostate is the leading cause of cancer and second leading cause of cancer death among American men and is the most common carcinoma in men older than 65.

Pathophysiology and Etiology

1. The incidence of prostate cancer is 30% higher in African American men.
2. The majority of prostate cancers arise from the peripheral zone of the gland.
3. Prostate cancer can spread by local extension, by lymphatics, or by way of the bloodstream.
4. The etiology of prostate cancer is unknown; however, there is an increased risk for persons with a family history of the disease.
5. The influences of dietary fat intake, serum testosterone levels, and industrial exposure to carcinogens are under investigation.

Clinical Manifestations

1. Most early-stage prostate cancers are asymptomatic.
2. Symptoms because of obstruction of urinary flow:
   a. Hesitancy and straining on voiding, frequency, and nocturia.
   b. Diminution in size and force of urinary stream.
3. Symptoms because of metastasis:
   a. Pain in lumbosacral area radiating to hips and down legs (from bone metastases).
   b. Perineal and rectal discomfort.
   c. Anemia, weight loss, weakness, nausea, oliguria (from uremia).
   d. Hematuria (from urethral or bladder invasion, or both).
   e. Lower extremity edema—occurs when pelvic node metastases compromise venous return.

Diagnostic Evaluation

1. Digital rectal examination—the prostate can be felt through the wall of the rectum; hard nodule may be felt (see Figure 21-11).
2. Transrectal ultrasound–guided needle biopsy (through anterior rectal wall or through the perineum) for histologic study of biopsied tissue includes Gleason tumor grade if carcinoma is present.
3. Transrectal ultrasonography—sonar probe placed in the rectum.
4. PSA—a protease produced by both benign and malignant prostate tissues. An elevated PSA may be due to BPH, prostatitis, or prostate cancer.
   a. Prostate cancer is suspected if PSA is above 4; however, prostate cancer may also occur at levels under 4.0.
   b. A free PSA level can be used to help stratify the risk of an elevated PSA. The lower the free PSA level, the higher the risk for prostate cancer.

c. PSA velocity: PSA increases of 0.75 ng in 1 year could indicate prostate cancer.
d. Age-specific PSA can help stratify risk for prostate cancer as well.

5. Guidelines among various cancer, urologic, and prevention organizations such as United States Preventive Services Task Force (USPSTF) and the American Urological Association (AUA) regarding prostate cancer screening vary. The USPSTF states that there is insufficient evidence to recommend screening. ACS is not in favor of routine screening until an informed discussion with those patients wanting to be screened takes place. The National Comprehensive Cancer Network (NCCN) recommends baseline DRE/PSA at 40 years of age and annual screening at age 50. AUA recommends baseline DRE/PSA at 40 years of age. All recommend informed discussion with patients.
6. Staging evaluation—skeletal x-rays, CT scan, MRI, bone scan, analysis of pelvic lymph nodes provide accurate staging information.
7. Newer imaging study called the ProstaScint scan uses an IV infusion of monoclonal antibody to prostate-specific membrane antigen.
   a. Immediate and delayed images at 48 and 72 hours may identify soft tissue and bone metastasis for staging.
   b. Radiation is excreted through urine and feces and body fluids but is very low and not a risk to others.
   c. Patient is monitored for signs of allergic reactions following test.
8. Research is being conducted on numerous genetic and chromosomal abnormalities. Overexpression of the *AMACR* gene was found in 90% of prostate cancer patients. Testing for this gene could result in identifying prostate cancer at an earlier stage.

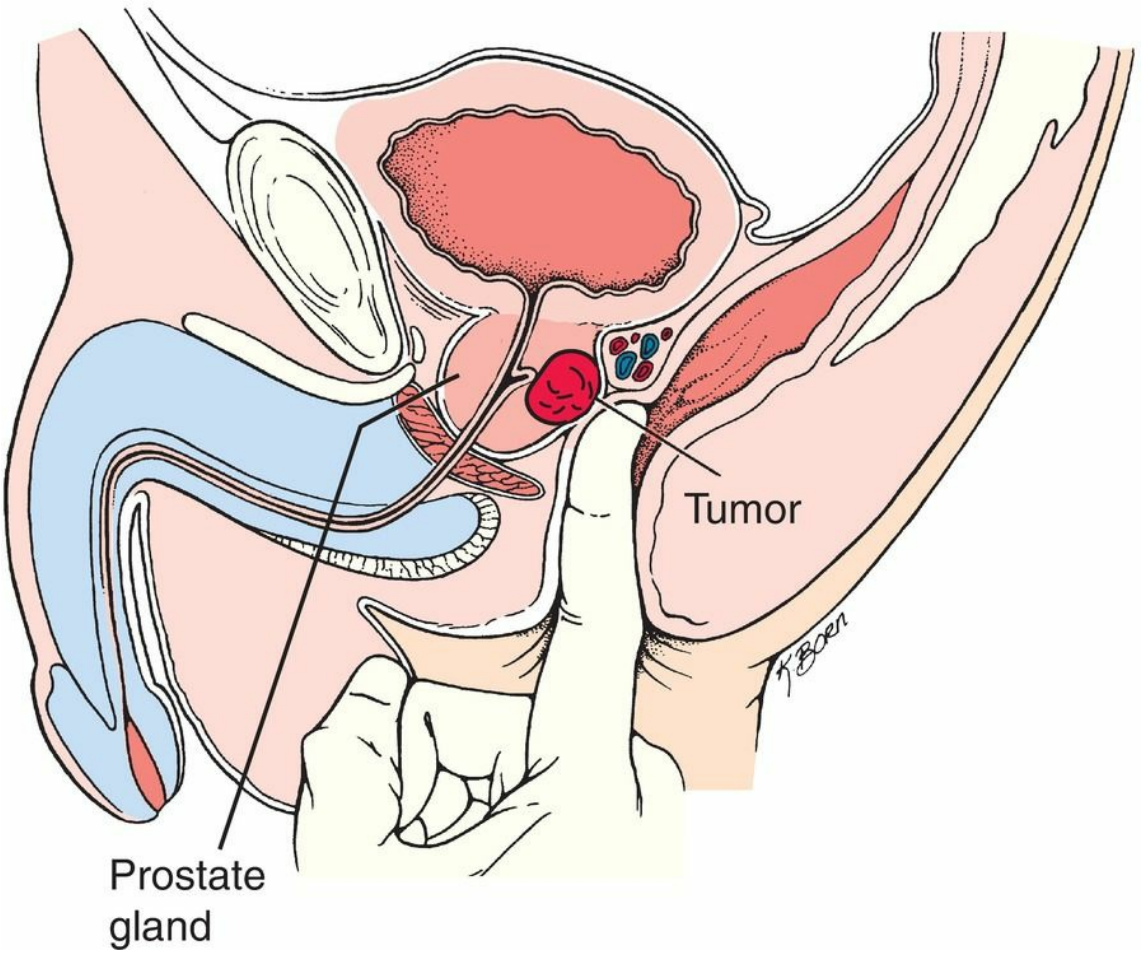

Figure 21-11. The prostate gland can be felt through the wall of the rectum. The size of the gland, overall consistency, and the presence of any firm areas and nodules are noted.

Management

Conservative Measures

1. Watchful waiting/active surveillance may be indicated in men with Gleason 6 or lower-stage prostate cancer or life expectancy of 10 years or less because prostate cancer may be slow growing and it is expected that many men will die from other causes. It is commonly recommended that these patients be followed closely with periodic PSA determinations and examination for evidence of metastases.
2. Symptom control for advanced prostatic cancer in which treatment is not effective:
   a. Analgesics and opioids to relieve pain.
   b. Short course of radiotherapy for specific sites of bone pain.
   c. IV administration of beta-emitter agent (strontium chloride 89) delivers radiotherapy directly to sites of metastasis.
   d. TURP to remove obstructing tissue if bladder outlet obstruction occurs.
   e. Suprapubic catheter placement.
   f. Zoledronic acid is given intravenously for bone metastasis pain.

Surgical Interventions

1. Radical prostatectomy—removal of entire prostate gland, prostatic capsule, and seminal vesicles; may include pelvic lymphadenectomy.
   a. Procedure is used to treat stage T_1 and T_2 prostate cancers.
   b. Complications may include urinary incontinence and impotence and possible rectal injury.
   c. Newer nerve-sparing techniques may preserve sexual potency and continence.
2. Cryosurgery of the prostate freezes prostate tissue, killing tumor cells without removing the gland.

Radiation

1. External beam radiation or intensity-modulated radiotherapy focused on the prostate—to deliver maximum radiation dose to tumor and minimal dose to surrounding tissues.
2. Brachytherapy—interstitial implantation of radioactive substances into the prostate, which delivers doses of radiation directly to tumor while sparing uninvolved tissue.
3. Used to treat stages T_1, T_2, and T_3, especially if patient is not a good surgical candidate. Both forms of radiation are used in some patients; external beam followed by brachytherapy.
4. Complications include radiation cystitis (urinary frequency, urgency, nocturia), urethral injury (stricture), radiation enteritis (diarrhea, anorexia, nausea), radiation proctitis (diarrhea, rectal bleeding), impotence, skin reaction, and fatigue.

Hormone Manipulation (Palliative)

1. Prostate cancer is a hormone-sensitive cancer. The aim of hormonal treatment is to deprive tumor cells of androgens or their by-products and thereby alleviate symptoms and retard progress of disease.
2. Bilateral orchiectomy (removal of testes) results in reduction of the major circulating androgen, testosterone. A small amount of androgen is still produced by adrenal glands.
3. Pharmacologic methods of achieving androgen deprivation—also used to reduce tumor volume before surgery or radiation therapy.
   a. Luteinizing hormone–releasing hormone (LHRH) agonists (such as leuprolide and goserelin acetate) reduce testosterone levels as effectively as orchiectomy.
   b. Antiandrogen drugs (flutamide, bicalutamide, nilutamide) block androgen action directly at the target tissues (testes and adrenals) and block androgen synthesis within the prostate gland and adrenal glands.
   c. Combination therapy with LHRH agonist and an antiandrogen blocks the action of all circulating androgen.
4. Complications of hormonal manipulation include hot flashes, nausea and vomiting, gynecomastia, sexual dysfunction, and osteoporosis.

Complications

1. Bone metastasis—vertebral collapse and spinal cord compression, pathologic fractures.

2. Complications of treatment.

Nursing Assessment

1. Obtain history of current symptoms; assess for family history of prostate cancer.
2. Palpate lymph nodes, especially in supraclavicular and inguinal regions (may be first sign of metastatic spread); assess for flank pain and distended bladder.
3. Assess comorbidities, nutritional status, and coping before treatment.

Nursing Diagnoses

- Anxiety related to fear of disease progression and treatment options.
- Sexual Dysfunction related to effects of therapy.
- Chronic Pain related to bone metastasis.

Also see page 601 for care of the patient after prostatectomy.

Nursing Interventions

Reducing Anxiety

1. Help patient assess the impact of the disease and treatment options on quality of life.
2. Give repeated explanations of diagnostic tests and treatment options; help patient gain some feeling of control over disease and decisions.
3. Help patient and family set achievable goals.
4. Convey a sense of caring and reassurance in your physical care.

Achieving Optimal Sexual Function

1. Although patient may be ill while experiencing the effects of therapy, he may wonder about sexual function. Give him the opportunity to communicate his concerns and sexual needs.
2. Let patient know that decreased libido is expected after hormonal manipulation therapy and impotence may result from some surgical procedures and radiation.
3. Expect patient's behavior to reflect depression, anxiety, anger, and regression. Encourage expression of feelings and communication with partner.
4. Suggest such options as sexual counseling, learning other methods of sexual expression, and consideration of implant, pharmacologic agents, and other options for treatment of erectile dysfunction.
5. Have patient ask urologist about penile rehabilitation after radical open or laparoscopic prostatectomy. The early incorporation of PDE5 inhibitors, vacuum erectile device, or intracavernosal injections may increase the return of postprostatectomy erections.

DRUG ALERT Yohimbine is an herbal preparation sold OTC as an aphrodisiac and treatment for

male erectile dysfunction. Caution patients that it is considered an unsafe herb by the U.S. Department of Agriculture because of its many drug and food interactions and adverse effects, including hypertension, tachycardia, and tremor.

Controlling Pain

1. Administer and teach self-administration of opioid analgesics, as ordered; oral sustained-release opioids, sustained-release transdermal patches, and subcutaneous or epidural patient–controlled infusion pumps are among the many options.
2. Encourage patient to take prescribed aspirin, acetaminophen, or NSAIDs for reduction of mild pain or to supplement opioid pain control regimen.
3. Make sure that patient is not undermedicated; help patient and family understand that addiction is not a concern in hormonally refractory or metastatic prostate cancer.
4. Teach relaxation techniques, such as imagery, music therapy, progressive muscle relaxation.
5. Use safety measures to prevent pathologic fractures from falls.
6. Encourage follow-up and palliative treatment such as radiation therapy to bony lesions for pain improvement.

Community and Home Care Considerations

EVIDENCE BASE Smith, R. A., Manassram-Baptiste, D., Brooks, D., et al. (2015). Cancer screening in the United States, 2015: A review of current American Cancer Society guidelines and issues in cancer screening. *CA—Cancer Journal for Clinicians, 65*, 30–54.

Encourage awareness of prostate cancer in the community.

1. Risks include being African American, over age 50, and having a first-degree relative with prostate cancer. High-fat diet has also been linked to prostate cancer.
2. Asymptomatic men with at least a 10-year life expectancy should have the opportunity to make an informed decision about screening.
3. If screening is desired after a detailed discussion between patient and health care provider, digital rectal examination and PSA blood testing begin at age 50 for men at average risk, at age 45 for African American men and those with a first-degree relative with history of prostate cancer, or at age 40 if a man has multiple relatives diagnosed with prostate cancer before age 65.
4. There is insufficient and conflicting evidence whether prostate cancer screening saves lives.
5. PSA less than 2.5 ng/mL indicates low risk for prostate cancer; therefore, recommendation is to repeat in 2 years.
6. If any urinary obstructions symptoms develop, patient should seek evaluation.

Patient Education and Health Maintenance

1. Teach patient importance of follow-up for check of PSA levels (every 6 to 12 months depending on pathology and recommendation of urologist) and evaluation for disease progression through periodic bone scan or CT scan. Cancer recurrence is suspected with PSA greater than 0.2 on two occasions.
2. Teach IM or subcutaneous administration of hormonal agents, as indicated.
3. If bone metastasis has occurred, encourage safety measures around the home to prevent pathologic fractures such as removal of throw rugs, use of handrail on stairs, use of night-lights.
4. Advise reporting symptoms of worsening urethral obstruction, such as increased frequency, urgency, hesitancy, and urinary retention.
5. Advise patient to monitor for signs of metastasis, such as fatigue, weight loss, weakness, pain, and bowel and bladder dysfunction.
6. For additional information and support, refer to agencies such as Us TOO International (*www.ustoo.com*); Man to Man, a program of the American Cancer Society (*www.cancer.org*); and American Urological Association Foundation (*www.urologyhealth.org*).

Evaluation: Expected Outcomes

- Discusses treatment options; asks questions.
- Verbalizes understanding of sexual dysfunction and interest in seeking sexual counseling.
- Reports pain relief after opioid administration.

Testicular Cancer

Testicular cancer is a disease that occurs in younger men between age 15 and 35. It is relatively uncommon, affecting 9 of 100,000 men annually. It is the most treatable form of urologic cancer.

Pathophysiology and Etiology

1. The majority of testicular cancers are of germ cell origin; the most common germinal tumors in adults are seminoma, embryonal carcinoma, teratoma, and choriocarcinoma (the latter three are also called *nonseminomas*).
2. The etiology of testicular tumors is unknown, but there is a relationship between cryptorchidism (failure of the testes to descend into the scrotum) and tumor occurrence.
3. Testicular tumors metastasize in a stepwise fashion to the retroperitoneal lymph nodes with subsequent involvement of the mediastinal lymph nodes, lungs, and liver.
4. Testicular germ cell tumors are considered potentially curable; seminomas are extremely responsive to radiation therapy; nonseminomas are sensitive to platinum-based chemotherapy.

Clinical Manifestations

1. Painless swelling or enlargement of the testis; accompanied by sensation of heaviness in the scrotum.
2. Pain in the testis (if patient has epididymitis or bleeding into tumor).
3. Symptoms of metastatic disease: cough or dyspnea, lymphadenopathy, back pain, GI symptoms, lower extremity edema, or bone pain.

Diagnostic Evaluation

1. Elevated serum markers of human chorionic gonadotropin, lactic acid dehydrogenate, and alpha-fetoprotein; assay of tumor markers also used for diagnosis, detection of early recurrence, staging, and monitoring response to therapy.
2. Scrotal ultrasonography—to identify location of lesion and differentiate between solid and cystic lesion.
3. Chest x-ray—to seek pulmonary or mediastinal metastasis.
4. CT scanning of the chest, abdomen, and pelvis—to evaluate retroperitoneal lymph nodes and to follow progress of therapy.

Management

Choice of treatment depends on tumor histology and stage of disease.

Surgery

1. Inguinal orchiectomy—removal of the testis and its tunica and spermatic cord.
2. Retroperitoneal lymph node dissection (RPLND) may be performed after orchiectomy in nonseminomas for staging and therapeutic purposes.
3. Complications of surgery:

a. RPLND causes infertility because of ejaculatory dysfunction.
b. Modified nerve-sparing unilateral lymphadenectomy can be done on selected patients, thus preserving ejaculation.
c. Unilateral orchiectomy eliminates half of germinal cells, thus reducing sperm count.
d. Libido and ability to attain an erection are preserved.

Radiation Therapy

1. Radiation therapy to lymphatic drainage pathways (after orchiectomy in seminomas); cure rate is close to 99%.
2. Other testicle is shielded, usually preserving fertility.

Chemotherapy

1. Cisplatin combination therapy is used in treatment of nonseminomatous primary tumor and regional lymphatic metastases and in managing distant metastatic disease.
2. Discomforts of chemotherapy include significant nausea and vomiting, alopecia, myalgia, GI cramping, and mucositis.

Complications

1. Infertility; loss of testicle.
2. Retrograde ejaculation after retroperitoneal lymphadenectomy.
3. Death from metastatic disease.

Nursing Assessment

1. Examine testicular mass; ascertain when it was discovered and if it has changed or enlarged since initial discovery.
2. Examine supraclavicular and inguinal lymph nodes for enlargement.
3. Assess for symptoms of metastatic disease.

Nursing Diagnoses

- Anxiety related to diagnosis of cancer and impending treatments.
- Disturbed Body Image related to loss of testicle and fertility.
- Risk for Injury related to complications of treatment.

Nursing Interventions

Reducing Anxiety

1. Provide realistic information about impending surgery or treatment; dispel myths associated with testicular disease; emphasize positive cure rates.
2. Refer patient to educational and support services through the American Cancer Society and local cancer

support groups.

Preserving Body Image

1. Reassure patient that orchiectomy will not diminish virility and RPLND will alter fertility and ejaculation but not libido, erection, and sensation.
2. Advise patient that testicular prosthesis can preserve look and feel of the scrotum.
3. Refer the patient for counseling, as needed, for problems and concerns with relationships, peers, or work life.
4. Discuss possible donation of sperm because of infertility issues.

Preventing Complications of Treatment

1. Provide routine postoperative care, including early ambulation, respiratory care, and administration of pain medication.
2. After RPLND, monitor for paralytic ileus, which is common after extensive resection.
   a. Auscultate bowel sounds frequently and observe for abdominal distention.
   b. Withhold oral fluids until bowel sounds have returned.
   c. Report complaints of nausea and vomiting.
   d. Begin nasogastric decompression, if indicated.
3. For nursing care involving radiation and chemotherapy, see pages 122 and 112.

Patient Education and Health Maintenance

1. Teach all young men to perform monthly testicular self-examination; after orchiectomy, patient should examine remaining testicle monthly.
2. Review schedule for radiation treatments or chemotherapy; teach patient and family possible adverse effects; discuss expectations for treatment period.
3. Provide information about retrograde ejaculation after RPLND and alternatives for fertility.

Evaluation: Expected Outcomes

- Verbalizes understanding of treatment and complications.
- No abdominal distention noted.
- Discusses concerns about sexual function with staff and partner.

Epididymitis

Epididymitis is an infection of the epididymis that usually spreads from the urethra or bladder to the epididymis by way of the ejaculatory duct and vas deferens.

Pathophysiology and Etiology

1. Occurs as a complication of UTI, urethral stricture disease, bacterial prostatitis, gonococcal or nongonococcal bacterial urethritis.
2. In men under age 35, sexually transmitted organisms are the main etiologic agents, usually *C. trachomatis* and *N. gonorrhoeae*.
3. In homosexual men, *E. coli* is a common cause.
4. In older men, the main causes are bladder outlet obstruction and urinary bacteria (*E. coli*, *P. aeruginosa*).

Clinical Manifestations

1. Unilateral scrotal pain and tenderness.
2. Edema, redness, and tenderness of the scrotum.
3. Dysuria, frequency.
4. Fever, nausea, vomiting.
5. Pyuria, bacteriuria, leukocytosis.

Diagnostic Evaluation

1. Urine culture and sensitivity.
2. Examination (Gram stain, culture, gonorrhea, and *Chlamydia* testing) of urethral discharge and expressed prostatic secretions to establish causative organism.
3. Ultrasound with Doppler to rule out testicular torsion.

Management

1. Antimicrobial therapy after collection of specimens.
    a. Treatment of choice for presumed sexually transmitted infections is combination ceftriaxone 250 mg IM in a single dose with doxycycline 100 mg orally twice per day for 10 days.
    b. For presumed *E. coli* and other infections, a quinolone, such as ciprofloxacin 500 mg orally twice a day for 10 days or co-trimoxazole for 10 days, is recommended.
2. Analgesics for pain relief.
3. Bed rest with the scrotum elevated on a towel to allow for lymphatic drainage.
4. In some cases, the spermatic cord is injected with a local anesthetic to relieve pain.

Complications

1. Spread of infection to testicle—epididymo-orchitis.

2. Infertility; risk is greater when infection is bilateral.

Nursing Assessment

1. Obtain history of STDs (or symptoms), UTI, or prostatitis; recent urologic instrumentation or surgery.
2. Assess for elevated temperature, pain level, and swollen and tender scrotum.
3. Assess for sexual behavior risk—multiple partners, nonuse of condoms, history of STDs.

Nursing Diagnosis

- Acute Pain related to scrotal inflammation.

Nursing Interventions

Relieving Pain

1. Administer or teach self-administration of analgesics, as ordered—commonly NSAIDs or acetaminophen. Assess patient's response.
2. Encourage bed rest during the acute phase.
3. Apply scrotal support to relieve edema and discomfort, to improve lymphatic drainage, and to take tension off the spermatic cord.
   a. Use rolled towel under the scrotum or scrotal bridge.
   b. Suggest a cotton-lined athletic supporter for ambulation.

Patient Education and Health Maintenance

Instruct the patient as follows:

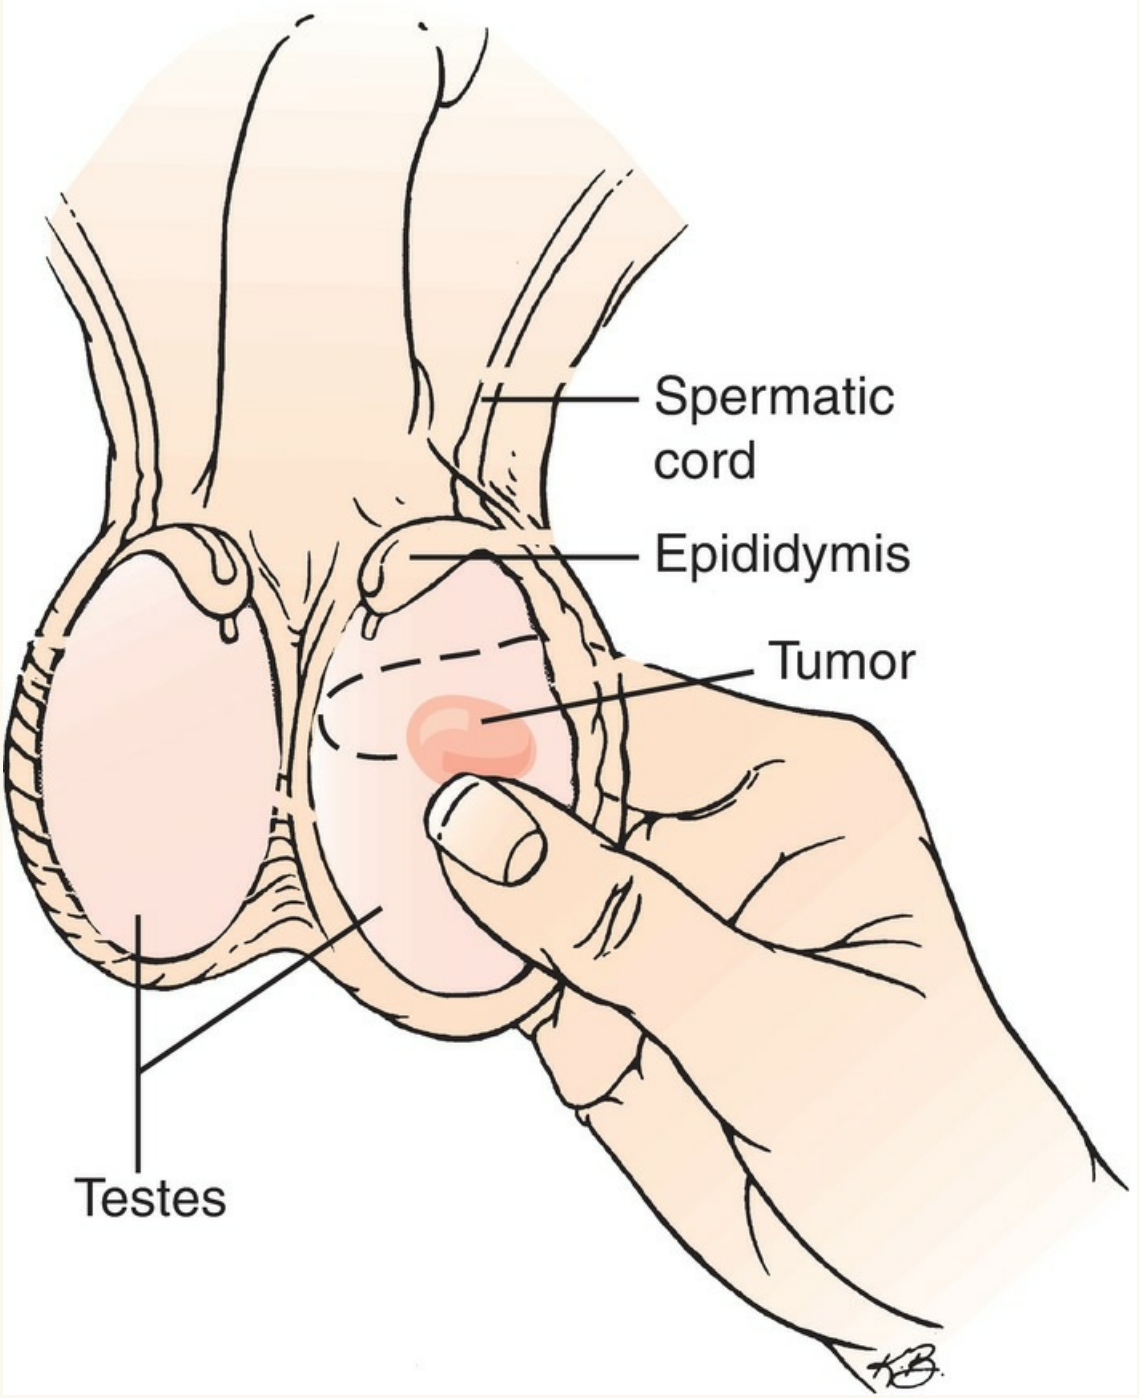
1. Avoid straining (lifting, straining at stool, and sexual activity) until infection is under control.
2. Sexual partners within the past 60 days of patients with chlamydial or gonorrheal urethritis or epididymitis should be examined and treated.
3. Follow-up with health care provider, as directed—it may take 2 to 4 weeks or longer for epididymitis to resolve completely.
4. Report signs of infection in the reproductive tract immediately to obtain treatment and prevent spread.
5. Obtain follow-up care to ensure complete resolution of infection; uncontrolled infection may impair fertility.
6. Use safer sex practices, such as abstinence, mutual monogamy, and condoms, to prevent further infection associated with sexual activity.

PATIENT EDUCATION GUIDELINES 21-1

Testicular Self-Examination

1. Examine for testicular tumor once per month, at a convenient time such as the first of the month or your birth date every month, preferably while showering or bathing.

2. Use both hands to feel the testes through the scrotal tissue.
3. Locate the epididymis; this is, the irregular cordlike structure on the top and at the back of the testicle that stores and transports sperm. The spermatic cord (and vas) extends upward from the epididymis.
4. Feel each testis between the thumb and first two fingers of each hand. The testes lie freely in the scrotum, are oval shaped, and measure 4 to 5 cm in length, 3 cm in width, and about 2 cm in thickness.
5. Note size, shape, and abnormal tenderness. An abnormality may be felt as a firm area on the front or side of the testicle.
6. Stand in front of mirror and look for changes in size/shape of the scrotum. It is normal to find one testis larger than the other.
7. Report any evidence of a small, pea-sized lump or other abnormality.



Using the fingertips and thumb, the epididymis, testes, and spermatic cord are located bilaterally.

Evaluation: Expected Outcomes

- Verbalizes relief of pain.

Genital Lesions Caused by Sexually Transmitted Diseases

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted treatment guidelines, 2015. *MMWR, 64*(3), 1–137.

Genital lesions are ulcerations or other skin or mucous membrane lesions that indicate infection with an STD and may actively shed the infecting organism.

Pathophysiology and Etiology

Causes include:

1. Syphilis—*Treponema pallidum*.
2. Chancroid—*Haemophilus ducreyi*.
3. Lymphogranuloma venereum—specific subtypes of *C. trachomatis*.
4. Genital herpes—herpes simplex virus.
5. Condylomata acuminata (genital warts)—specific subtypes of HPV.

Clinical Manifestations

See Table 21-4, for clinical manifestations, diagnosis, and treatment of genital lesions.

Table 21-4 Characteristics and Management of Genital Lesions Caused by STDs

DISORDER AND INCUBATION	CLINICAL MANIFESTATIONS	DIAGNOSIS AND TREATMENT
Herpes Genitalis		
2–20 days	Clustered vesicles on erythematous, edematous base that rupture, leaving shallow, painful ulcer that eventually crusts; mild regional lymphadenopathy; recurrent and may be brought on by stress, infection, pregnancy, sunburn.	• Diagnostic tests include Tzanck smear, viral culture, antigen test of tissue or exudate from lesion, or serum antibody tests. • No cure, but symptomatic period is diminished by acyclovir or other antiherpetic started with each recurrence; or recurrences greatly reduced or prevented by continuous treatment. • Analgesics and sitz baths promote comfort.
Syphilis		
10–90 days for primary; up to 6 months following lesion (chancre) for secondary	*Primary:* Nontender, shallow, indurated, clean ulcer; mild regional lymphadenopathy. *Secondary:* Maculopapular rash including palms and soles, mucous patches, and condylomatous lesions; fever, generalized lymphadenopathy.	• VDRL test or RPR blood test with confirmation by specific treponemal antibody tests. • Preferred treatment is benzathine penicillin G 2.4 million units IM in a single dose; erythromycin or ceftriaxone may be used in penicillin allergy.
Chancroid		
3–14 days	Bacterial disease caused by *H. ducreyi*. Vesiculopustule that erodes, leaving a tender, painful, shallow or deep, well-circumscribed ulcer with ragged, undermined borders and a friable base covered by purulent exudate; unilateral or bilateral large, tender inguinal lymph nodes (buboes) in 50% of patients.	• Identification of *H. ducreyi* on special culture media. • Treated with azithromycin, ciprofloxacin, erythromycin, or ceftriaxone IM. Single-dose regimens are available. • Apply warm soaks to buboes.
Lymphogranuloma Venereum		
3–30 days	Small, transient, nontender papule or superficial ulcer precedes firm, adherent unilateral inguinal and femoral lymph nodes (buboes) with characteristic groove in between (groove sign); may suppurate.	• Microimmunofluorescence testing of bubo aspirate, if possible. Clinical diagnosis after ruling out other causes for genital lesions and lymphadenopathy. • Treatment of choice is doxycycline, but erythromycin may be effective. • Incision and excision of buboes should be avoided: aspiration may be helpful.
Condyloma Acuminatum		
3 weeks to 3 months, possibly years before grossly visible	Single or multiple, soft, fleshy, flat or vegetating growths may occur on the penis, anal area, urethra; no lymphadenopathy.	• Diagnosed by inspection or biopsy. • Topical therapy with podofilox 0.5% for external warts, podophyllin 10% to 25% solution, or trichloroacetic acid 80% to 90% imiquimod. May require multiple applications. • Cryotherapy, electrodissection, electrocautery, carbon dioxide laser, and surgical excision may also be done. • Recurrence is common.

IM, intramuscular; HPV, human papillomavirus; RPR, rapid plasma reagin; VDRL, Venereal Disease Research Laboratory.

Nursing Considerations and Patient Education

1. Explain transmission of STDs and preventive measures, such as male or female condoms, abstinence, and mutual monogamy.
2. Encourage compliance with treatment regimen and follow-up to ensure cure before resuming sexual activity.
3. Explain that some shedding of herpes virus may occur even while asymptomatic, so patient must discuss this with partner; consider use of condoms at all times; reduce risk of transmission by abstaining at the first sign of an outbreak (tingling sensation) until 1 to 2 weeks after resolution of symptoms.
4. For additional information and support, refer to STD National Hotline at (800) 227-8922.

Carcinoma of the Penis

Carcinoma of the penis occurs primarily on the glans of the penis. Risk factors include uncircumcised, phimosis, HPV, lichen sclerosus, balanitis xerotica obliterans, increasing age, smoking, poor personal hygiene, and the accumulation of smegma under the skin of an uncircumcised penis. It primarily occurs in men older than age 50 and represents 0.5% of malignancies in men in the United States.

Pathophysiology and Etiology

1. Several types of penile lesions are potentially premalignant.
    a. Condylomata acuminata.
    b. Giant condylomata acuminata (Buschke-Löwenstein tumor).
    c. Kaposi sarcoma.
    d. Leukoplakia.
2. Erythroplasia of the glans (erythroplasia of Queyrat) is a carcinoma *in situ* of the penis and may involve the glans, prepuce, or penile shaft or may spread to the remainder of the genitalia and perineal region. It appears as a red, velvety lesion with ulcerations.
3. Bowen disease is a squamous cell carcinoma *in situ* resembling a red plague. Commonly involving the shaft of the penis.
4. Malignant lesions that ulcerate metastasize quickly to the regional femoral and iliac lymph nodes.
5. Distant metastasis occurs in the inguinal lymph nodes; in rare cases to lungs, liver, bone, or brain.

Clinical Manifestations

1. Can present as a painless, wartlike growth or ulcer on the glans or prepuce or with painful, bleeding, or exudative lesion.
2. Phimosis (constriction of foreskin with inability to retract over glans) may obscure a lesion, preventing detection until advanced stages.
3. Lymphadenopathy; secondary infection of lesions or metastatic disease.
4. Malodorous and persistent discharge from the penis is a late symptom.

Diagnostic Evaluation

1. Biopsy of penile lesion and lymph nodes.
2. Ultrasonography and MRI of inguinal lymph nodes.
3. Chest x-ray, CT or MRI scan, bone scan to assess for distant nodal metastases.
4. Positron emission tomography (PET) scans assist in primary staging or to assess for lymph node metastases.
5. Sentinel node biopsy to determine whether nonenlarged inguinal lymph nodes contain cancer.

Management

1. Localized lesions are surgically removed by partial penectomy, laser or cryotherapy, or Mohs micrographic surgery; total penectomy with perineal urethrostomy is necessary for more involved tumors.
2. Because inguinal lymphadenopathy may be due to inflammation and not malignancy, patients are prescribed a 4- to 6-week course of antibiotics after partial or total penectomy and are reassessed. If lymphadenopathy remains, then a bilateral lymphadenectomy is performed for cancer control.
3. Radiation therapy to small superficial tumors and lymph nodes may control the disease.

Complications

1. Disfigurement because of ulceration or treatment.
2. Complications of lymphadenectomy—necrosis and infection of skin flap, chronic edema of lower extremities.

Nursing Assessment

1. Obtain history of current lesion, history of STDs, and hygiene.
2. Perform genital examination for characteristics of lesion, phimosis, inguinal lymph node enlargement.
3. Assess support system and personal coping mechanisms.

Nursing Diagnoses

- Fear related to diagnosis of cancer.
- Disturbed Body Image related to partial or total penectomy.

Nursing Interventions

Resolving Fears

1. Provide patient with opportunity to acquire information about causes and prognosis of disease.
2. Interpret diagnostic and staging results to patient.
3. Encourage realistic expectations regarding outcome of treatment.

Enhancing Coping with Body Image Changes

1. Maintain a nonjudgmental approach; allow patient to ventilate feelings about loss of part or all of the penis.
2. Provide routine postoperative care confidently, watching for bleeding, monitoring urination, and anticipating pain.
3. Provide opportunity for patient to discuss alternative methods of sexual expression with knowledgeable professional.
    a. About 40% of patients are able to participate in sexual activity and stand erect to void after partial penectomy.
4. Monitor patient for symptoms of depression requiring intervention.

Patient Education and Health Maintenance

1. Instruct the uncircumcised patient about proper hygiene—importance of daily removal of all retained smegma.
2. Explain expected postoperative function of the penis in patient undergoing partial penectomy.
3. Describe how voiding will occur to patient undergoing perineal urethroplasty.
4. Provide information about follow-up and monitoring for recurrences or radiation and chemotherapy, as appropriate.

Evaluation: Expected Outcomes

- Verbalizes understanding and acceptance of diagnosis and treatment plan.
- Discusses feelings and interest in seeking counseling.

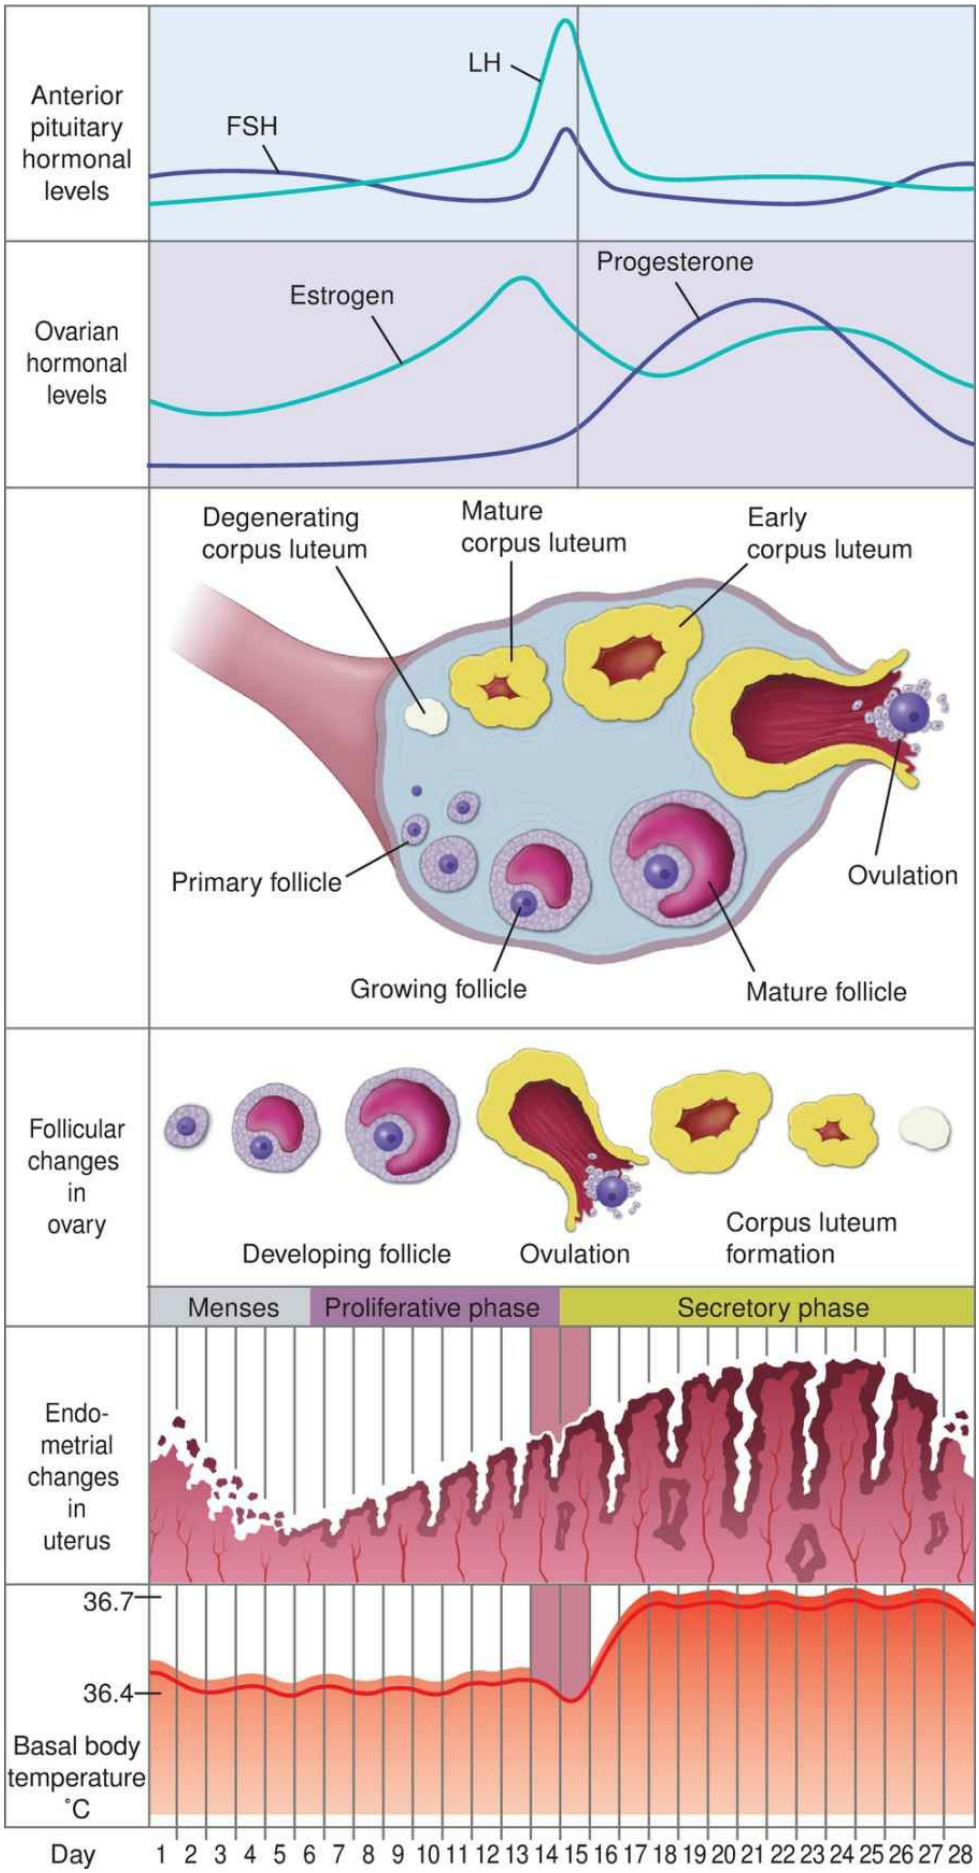
OVERVIEW AND ASSESSMENT

The Menstrual Cycle

The *menstrual cycle* is the cyclical pattern of ovarian hormone secretion (estrogen and progesterone) under the control of pituitary hormones (luteinizing hormone [LH] and follicle-stimulating hormone [FSH]) that results in thickening of the uterine endometrium, ovulation, and menstruation. Cycle length varies among women.

Phases of the Menstrual Cycle

The menstrual cycle is generally divided into two phases: follicular (or proliferative) and luteal (or secretory). See Figure 22-1. Further subdivisions of the cycle are:



Anterior pituitary hormonal levels
LH
FSH
Ovarian hormonal levels
Estrogen
Progesterone
Degenerating corpus luteum
Mature corpus luteum
Early corpus luteum
Primary follicle
Ovulation
Growing follicle
Mature follicle
Follicular changes in ovary
Developing follicle
Ovulation
Corpus luteum formation
Menses
Proliferative phase
Secretory phase
Endo-metrial changes in uterus
36.7
36.4
Basal body temperature °C
Day
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28

Figure 22-1. The menstrual cycle. (Premkumar, K. *[2011]. Anatomy & physiology: the massage connection [3rd ed.]*. Baltimore, MD: Lippincott Williams & Wilkins.)

1. Menstrual or bleeding phase (or early follicular phase): starts day 1 of the cycle and lasts approximately 5 days; endometrial sloughing and discharge occur because of low levels of estrogen and progesterone.
2. Postmenstrual phase (or early follicular phase); approximately days 5 to 8—thin endometrium. Ovarian follicles grow.
3. Proliferative phase (or mid to late follicular phase): approximately days 8 to 15; estrogen starts to increase the thickness of the endometrium. A selected ovarian follicle continues to grow. A surge in LH occurs. Transition from proliferative phase to secretory phase occurs with ovulation, the expulsion of a mature follicle (or ovum) from the ovary.
4. Secretory phase (or luteal phase, which lasts 14 days after LH surge in most women): approximately days 16 to 23; endometrium thickens because of increased progesterone; after ovulation, a corpus luteum forms and then regresses unless pregnancy occurs.
5. Premenstrual phase (or late luteal phase): days 24 to 28; levels of estrogen and progesterone begin to fall.

Characteristics of Menstruation

See Table 22-1.

Table 22-1 Characteristics of Menstruation

CHARACTERISTIC	RANGE	AVERAGE
Menarche (age at onset)	9 to 17 yr	12.5 yr
Cycle length	21 to 35 days	28 days
Flow—duration	2 to 8 days	3 to 5 days
Flow—amount	10 to 80 mL	35 mL
Menopause (age at onset)	45 to 55 yr	51 yr

Subjective Data

Explore patient's gynecologic history, current symptoms, and general history to elicit important data. Provide a private and comfortable setting for history taking before the patient undresses. Reassure the patient about confidentiality and rationale for history taking (see Chapter 5).

Gynecologic Review of Systems

1. Menstrual history: date of start of last menstrual period (LMP) or age at last menses. Documented in this manner: age at menarche × cycle length × number of days of bleeding (eg, 13 × 28 × 4). Symptoms of dysmenorrhea? Symptoms of premenstrual syndrome? Intermenstrual spotting/bleeding, postcoital bleeding, or postmenopausal bleeding?
2. Obstetric history: gravida (number of pregnancies) and para (number of term births, preterm births, miscarriages/abortions, living children) (eg, G2P1102). Difficulty conceiving or assisted reproduction? For each pregnancy, list date; gestational age at delivery; mode of delivery; maternal complications (gestational diabetes, hypertension); and fetal, delivery, or neonatal complications.
3. Cervical cytology/Papanicolaou (Pap) test history: date and result of most recent test? Diagnosis and follow-up of abnormal Pap tests? History of HPV vaccination (as age-appropriate)?
4. Sexual history: age of first sexual activity? Partner preference (men, women, or both)? Activity type? Satisfaction? Frequency? Number of partners in past year and during lifetime?
5. Methods of contraception and sexually transmitted disease (STD) prevention: desire for pregnancy testing or STD screening? Desire for other methods? Desire for preconceptual counseling? Use of condoms?
6. Screening for intimate partner violence and previous emotional, physical, or sexual abuse or assault.

Irregular Bleeding

1. Characteristics: date of LMP? Frequency, duration, and amount of flow for most recent several cycles? Previous menstrual pattern and change? What is the color and consistency of blood? What are the sizes of the clots? Significant change in quantity or quality of menstrual flow? Bleeding or spotting between periods, postcoital bleeding, or postmenopausal bleeding? Pain with bleeding? Age at menarche? Age at menopause?
2. Associated factors: pregnancy and childbirth history? Is the patient sexually active? What method of contraception is used? Is the patient taking hormone replacement or hormonal contraceptives? Any other medications? Is the patient obese or underweight? Does the patient have acne and hirsutism? History of amenorrhea? Coagulation disorders?
3. Significance: may indicate infection of the vagina or cervix; malignancy of the vulva, vagina, cervix, or uterus; benign tumor of the uterus; ovarian cyst; polyps; fibroids; adenomyosis; pregnancy; endometriosis; polycystic ovarian syndrome; thyroid, hypothalamic, or pituitary disorder; coagulopathy; endometrial hyperplasia; or perimenopausal phase.

Vaginal Discharge

1. Characteristics: color, amount, and duration of the discharge? Any odor, itching, burning, urinary symptoms, or pain? Fever? Dyspareunia (painful intercourse—vulvar, vaginal, or internal pain with intercourse)? Onset related to menses or to intercourse?
2. Associated factors: LMP? What is the sexual history, such as number of partners or new partner within the past 6 months, type of sexual activity, and symptoms in partner? Is barrier method of contraception used? Is the patient menopausal or postmenopausal? Environmental factor changes? Vaginal dryness? Does the patient take estrogen replacement? Recent use of antibiotics? Recent douching? Recent over-the-counter product use or herbal/natural remedies? History of sexually transmitted diseases?
3. Significance: may indicate normal or pathologic discharge, bacterial vaginosis, candidal vaginitis, cervicitis, gonorrhea, chlamydia, trichomoniasis, pelvic inflammatory disease (PID), or genital malignancy.

Pelvic Pain

1. Characteristics: frequency, duration, severity, and location of pain? Does the pain radiate? Was the onset sudden or gradual? What aggravates and what relieves it? Relationship to menstrual cycle, eating, physical exercise, bowel, or bladder function? Any dyspareunia? Does it feel like heaviness in the pelvis? Intensity and effect on daily activities?
2. Associated factors: LMP? Fever, nausea, vomiting, dizziness, abnormal bleeding? Urinary symptoms? Back pain? Recent significant weight loss or gain? Use of estrogen preparations? Difficulty conceiving? Did the patient perform a home pregnancy test? Use of an intrauterine device (IUD)? Any change in bowel habits or diarrhea? History of sexual abuse? Use of pain medications and home remedies?
3. Significance: may indicate condition arising from relaxed pelvic muscles, PID, endometriosis, interstitial cystitis, urinary tract infection, irritable bowel syndrome, history of sexual abuse (posttraumatic stress disorder), ectopic pregnancy, miscarriage, uterine fibroids, or cervical or uterine cancer.

Physical Examination

Physical examination for a patient with a gynecologic disorder should focus on the abdomen and genitalia. Palpate the abdomen for masses or tenderness. Request verbal permission before starting the pelvic examination. Consider using a chaperone during the examination. If the patient has presented as a victim of sexual assault, then do not ask the patient to undress nor examine the patient but ensure immediate transfer to a local emergency department with sexual assault nurse examiners or other professionals with expertise in forensic evidence collection and supportive services after assault. See Chapter 35 , page 962.

The nurse in a gynecologic or obstetric setting may perform a vaginal examination to obtain specimens for diagnostic studies and assess the patient's condition.

Laboratory Tests

CA 125

Description

Tumor antigen used as a marker for ovarian cancer.

Nursing and Patient Care Considerations

1. Tell the patient a blood test will be performed and the results will be ready in 1 to 3 days.
2. Not a specific or definitive screening test for ovarian cancer; rather, it is better used as a measure of response to treatment.
3. Level may be elevated in benign gynecologic disease, in hepatic cirrhosis, and in healthy women.
4. Should not be used as an independent screening tool.

Cervical Cytology

Description

A Pap smear of the cervix is obtained during pelvic examination to screen for cervical dysplasia or cancer. May also help to detect human papillomavirus (HPV), endometrial cancer, or infections. Classification by Bethesda system indicates any cellular abnormalities.

Bethesda System 2001

1. Specimen type—conventional smear (slide) versus liquid based.
2. Specimen adequacy.
    a. Satisfactory for evaluation—result is given but presence of other factors, such as absence of transformation zone, is also listed.
    b. Unsatisfactory for evaluation—result may not be given; lists reason, such as inadequate number of cells or obscured by blood or inflammation.
3. Interpretation of results—only a screening tool, not diagnostic.
    a. Negative for intraepithelial lesion or malignancy: no cell abnormalities.
        i. Presence of an organism (*Trichomonas*, fungal elements, shift in flora) and cellular changes consistent with HSV may also be listed.
        ii. Other nonneoplastic findings (reactive reparative changes, glandular cells, atrophy) may be described.
    b. Epithelial cell abnormalities—atypical squamous cells are common.
        i. Atypical squamous cells of undetermined significance—management options based on population and can include HPV testing, repeat Pap test in 1 year intervals, and/or colposcopy.
        ii. Atypical squamous cells, cannot exclude high-grade intraepithelial lesion—potentially more serious; do immediate colposcopy and endocervical sampling for further evaluation.
        iii. Low-grade squamous intraepithelial lesion—management options based on population and can

include repeat Pap test in 6-month intervals, HPV testing, and/or colposcopy.

iv. High-grade squamous intraepithelial lesion—management options based on population and can include colposcopy with biopsy and endocervical curettage.

v. Squamous cell carcinoma—colposcopy and biopsy.

c. Glandular cell abnormalities—atypical, not otherwise specified (NOS) or atypical, favor neoplastic (require further evaluation); colposcopy, and HPV testing. Endometrial biopsy is performed if over 35 years of age and on younger women with risk factors for endometrial neoplasia such as unexplained uterine bleeding, chronic anovulation, or in obese women.

d. Endocervical adenocarcinoma *in situ*; colposcopy, cervical biopsy, conization, and possible referral to oncologist. Hysterectomy may be performed for women who do not desire to preserve fertility.

e. Adenocarcinoma—endocervical, endometrial, extrauterine, and NOS—biopsy and conization; consider referral to gynecologic oncologist.

Nursing and Patient Care Considerations

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2012). Cervical cytology screening. *Obstetrics and Gynecology, 120*, 1222–1230.

Saslow, D., Solomon, D., Lawson, H. W., et al. (2012). American Cancer Society, American Society for Colposcopy and Cervical Pathology, and American Society for Clinical Pathology screening guidelines for the prevention and early detection of cervical cancer. *CA—Cancer Journal for Clinicians, 62*, 147–172.

---

1. Pap test should not be performed during menses, unless the liquid-based system is used.
2. Instruct the patient not to use douche, medication, tampon, or cream in the vagina and to avoid sexual intercourse for 48 hours before the examination.
3. Recommend regular screening based on established guidelines set forth by the American Cancer Society, U.S. Preventive Services Task Force, and American College of Obstetricians and Gynecologists (ACOG). The same screening guidelines apply to all women whether vaccinated against HPV or not. More frequent testing is recommended if the woman has human immunodeficiency virus (HIV), is immunosuppressed, was exposed to diethylstilbestrol in utero, or has been treated for cervical intraepithelial neoplasia (CIN) 2, CIN 3, or cervical cancer.
   a. Recommend starting Pap testing at age 21.
   b. Recommend testing every 3 years from ages 21 to 65 for women without risk factors such as DES exposure.
   c. For those aged 30 to 65 wanting to extend the screening interval, screen with a combination of HPV testing and cytology every 5 years.
   d. Discontinue screening after age 65 if adequate negative prior screening and no history of CIN 2 or greater within the last 20 years.

e. Discontinue after total hysterectomy if no dysplasia or cancer.

4. Make sure that the patient obtains results. If the patient has an abnormal smear, explain that this is not always conclusive but requires further testing based on age, such as repeat Pap test, HPV testing, colposcopy, biopsy, or conization. Encourage the patient to return for further testing.
5. Yearly examination for breast cancer screening; detection of other genital cancers, infections, and reproductive problems; and contraception management may be indicated.

Tests for Gonorrhea and Chlamydia

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted diseases treatment guidelines, 2015. Atlanta, GA: Author. Available: *https://www.cdc.gov/std/tg2015/default.htm.*

Description

1. Commonly known as deoxyribonucleic acid (DNA) probe or antigen detection tests, a single specimen can detect both STD-causing organisms. Will detect even subclinical infection; can be used as screening test.
2. Can also be done by culture method, but takes longer and requires separate specimens and special processing for each.
3. Screening for chlamydia and gonorrhea can also be done on urine specimen using amplified DNA technology. This method is more expensive, but saves time in specimen collection (especially for women) in screening centers.

Nursing and Patient Care Considerations

1. Explain the procedure to the patient before taking the specimen.
2. Specimens should be taken from the cervix without douching for 24 hours or from the male urethra before urinating.
3. Obtain specimen with cotton-tipped swab inserted and rotated in the cervical os for 10 seconds or urethral meatus in a male patient. Small-tipped swabs are available for the urethra. Send swab to laboratory in provided container with preservative.
4. For urine testing, ask the patient to provide the first 10 to 20 mL of voided urine in a specimen container (this represents a urethral specimen, ie, more likely to contain the organism, if present, without being diluted by a larger amount of urine from the bladder).
5. May also use ThinPrep as a testing vehicle.

Radiology and Imaging Studies

Hysterosalpingography

Description

1. This fluoroscopic x-ray study of the uterus and fallopian tubes is used to determine tubal patency, detect pathology in the uterine cavity, identify peritoneal adhesions, and to treat unexplained fertility.
2. A bivalve speculum is introduced while the patient is in the lithotomy position and contrast medium is injected into the uterine cavity; the medium will enter the peritoneum in 10 to 15 minutes if tubes are patent.

Nursing and Patient Care Considerations

1. Determine the date of last menstrual period; the test is done a few days after menses ends, before ovulation. Obtain pregnancy test if patient is within childbearing years, as indicated.
2. Verify that the patient does not have a history of allergy to contrast media or iodine.
3. Administer prescribed antibiotic and analgesic.
4. After procedure, apply a perineal pad for drainage of excess contrast medium or blood, and instruct the patient to notify the health care provider if bloody drainage continues after 3 days or if signs of infection are present.
5. Inform the patient that pain medication may be necessary for shoulder discomfort because of dye irritation of the phrenic nerve.

Pelvic Ultrasonography

EVIDENCE BASE American College of Radiology. (2014). ACR–ACOG–AIUM–SRU practice guideline for the performance of pelvic ultrasound. Available: *www.acr.org/~/media/ACR/Documents/PGTS/guidelines/US_Pelvic.pdf.*

Description

A noninvasive test that uses high-frequency sound waves to form images of the interior pelvic cavity; used to detect uterine, tubal, ovarian, and pelvic cavity pathology, to measure organ size, and to evaluate pregnancy.

Nursing and Patient Care Considerations

1. Inform patient that a full bladder may be necessary to make the uterus easier to visualize.
2. Instruct patient to drink 16 to 32 ounces of water (may differ among facilities) before the procedure and not to void. If transvaginal ultrasound will be performed, inform patient that a vaginal probe will be inserted to obtain more accurate measurements from internal organs. Have the patient empty her bladder prior to insertion of probe. (Probe is not used if patient is virginal.)

3. After the procedure, help the patient wipe off ultrasound gel from abdomen and allow her to empty her bladder.
4. Abnormalities are represented as different densities that differentiate solid from cystic masses and can help make a diagnosis; however, explain to the patient that further testing may be necessary.

Other Diagnostic Procedures

STANDARD OF CARE GUIDELINES 22-1

Caring for a Patient Undergoing Gynecologic Surgery

When caring for a patient undergoing gynecologic surgery, the following care is essential to prevent complications and to promote healthy adaptation:

- Discuss procedure with patient before surgery—does she know why surgery is being done? Does she know which organs will be removed or altered? Does she understand the implications for childbearing, sexuality, menopause? Answer questions and contact surgeon, if necessary.
- After the procedure, assess vital signs as frequently as indicated for signs of shock, infection, fluid overload, and atelectasis.
- Assess incision for drainage and signs of infection? (redness, oozing, warmth, increased pain).
- Assess vaginal area for excessive bleeding or foul-smelling drainage.
- Monitor intake and output.
- If patient has an indwelling catheter, ensure that it is draining clear urine greater than 30 to 50 mL/hour.
- After catheter has been removed, ensure that patient voids in adequate amounts and monitor for urinary retention or signs of infection.
- Ensure adequate IV and then oral fluids, but monitor for edema and shortness of breath, signs of fluid overload.
- Monitor level of pain and relief with analgesics, but watch for oversedation, hypotension, and decreased bowel sounds as adverse effects of opioids.
- Provide comfort measures, such as positioning, splinting incision during position changing, or coughing, applying ice pack to the perineum.
- Auscultate bowel sounds for return, signaling progression of diet. Report nausea, vomiting, and loss of or decrease in bowel sounds immediately; intervention for bowel obstruction may be needed.
- Institute thromboembolism prevention, as ordered, and monitor for calf tenderness.
- Encourage ambulation as early as possible, but encourage gradual resumption of activities, according to surgeon instructions.
- Notify surgeon of fever, shortness of breath, increased pain, excessive bleeding or drainage, foul odor, change in vital signs, urinary retention, decreased urine output, nausea and vomiting, or tender, swollen calf.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

See Standards of Care Guidelines 22-1, page 639.

Colposcopy

Description

Examination of the cervix with a bright light and magnification of 10 to 40 times; done to determine distribution of abnormal squamous epithelium and to pinpoint areas from which biopsy tissue can be taken; may be done with cervicography (photographing the cervix).

Nursing and Patient Care Considerations

1. The procedure is preferably done when the cervix is least vascular (usually 1 week after the end of the menstrual flow). Obtain pregnancy test if the patient is within childbearing years, as indicated.
2. Explain that a vaginal speculum will be inserted and that a biopsy may be taken, causing only slight discomfort.
3. Help the patient into lithotomy position, drape her appropriately, and provide emotional support throughout the procedure. Provide distraction techniques, such as music and posters (hung on the ceiling), as appropriate.
4. After the cervix and vagina are swabbed with acetic acid solution and inspected through the colposcope, biopsies may be taken. Biopsy tissue is preserved in 10% formalin, labeled, and sent to the laboratory. Saline may be used to rinse the area, and bleeding may be stopped with silver nitrate or ferric subsulfate (Monsel solution).
5. After the procedure, assist the patient to rise slowly and give the following discharge instructions:
   a. Avoid heavy lifting for 24 hours.
   b. There may be some bleeding and cramping; however, more than that of a normal period must be reported to the health care provider.
   c. Obtain the health care provider's instructions regarding douching and sexual intercourse.

Conization

Description

Excision of a cone-shaped piece of tissue from the cervix, including the area where the squamous and columnar epithelial tissue meet (transformation zone) for diagnostic and therapeutic purposes. The transformation zone is the area of most cervical cancers. The procedure can be done via scalpel, laser, or electrosurgery techniques.

Nursing and Patient Care Considerations

1. Explain to the patient that this test can be a minor surgical procedure that requires local or general anesthesia. Obtain pregnancy test if patient is within childbearing years, as indicated.
2. After excision, bleeding is controlled by cauterization or suturing and packing.
3. The patient should be observed for several hours after the procedure for excessive bleeding.
4. Instruct the patient to avoid tampons, douching, and intercourse as well as not to immerse herself in water (no swimming, hot tub, tub bath) for 2 weeks, or as directed by health care provider, to allow healing.

Hysteroscopy

Description

Endoscopic visualization of the uterine cavity used to evaluate endometrial cancer, check tubal patency, determine the cause of uterine bleeding, remove polyps or fibroids, and observe the placement and appearance of IUDs.

Nursing and Patient Care Considerations

1. Obtain pregnancy test prior to the procedure if the patient is within childbearing years, as indicated.
2. Administer prescribed sedative before the procedure, and explain that a local anesthetic will also be injected into the cervix in the operating room.
3. The patient will be assisted into the lithotomy position, and the perineum and vagina will be cleaned immediately before sterile draping.
4. Explain that instruments called sounds are inserted into the cervical canal for dilation before insertion of the hysteroscope. With the scope in place, normal saline or CO_2 gas is slowly infused into the endometrial cavity to distend it and allow for viewing.
5. Observe patient for several hours and give discharge instructions.
    a. Over-the-counter analgesics may be needed for minor discomfort if analgesic has not been prescribed.
    b. Notify the health care provider of severe cramping or bleeding, fever, or unusual discharge.

Endometrial Biopsy

Description

1. The procedure is done with or without local anesthesia to obtain cells from the uterine lining to assist in the diagnosis of endometrial cancer, menstrual disorders, and infertility.
2. During speculum examination, a uterine sound is placed, followed by a curette or Pipelle suction device to withdraw specimen (may be done several times).

Nursing and Patient Care Considerations

1. Obtain pregnancy test if patient is within childbearing years, as indicated.
2. Administer prostaglandin inhibitor to decrease postoperative uterine cramping.
3. Assist patient into the dorsal lithotomy position and explain procedure.
4. Label the specimen, place in formalin, and send to the laboratory.
5. Inform the patient that she may experience light bleeding and occasional cramping for a few days.
6. Instruct the patient to report fever, chills, and increased bleeding; no tampons, douching, or intercourse for 2 to 3 days.

GENERAL PROCEDURES AND TREATMENT MODALITIES

Fertility Control

Nurses who work with women in the gynecologic setting or in any setting may be involved in contraceptive counseling.

Basic Principles

1. *Contraception* is the prevention of fertility on a temporary basis.
2. *Sterilization* is the permanent prevention of fertility. Female and male sterilization procedures can be performed. Some procedures can be reversed but with possible complications and variable success rates.
3. Contraception effectiveness depends on motivation, which is a result of education, culture, religious beliefs, and personal situation. It is best to include both partners in any contraception decision.
4. Nurses should be familiar with contraceptive methods and educate patients without moral judgment.
5. Failure rate (pregnancy) is determined by experience of 100 women for 1 year and is expressed as pregnancies per 100 woman-years.

Contraceptive Methods

See Table 22-2.

Table 22-2 Contraceptive Methods

METHODS	DEFINITION	PROCEDURE	ADVANTAGES	DISADVANTAGES
Natural Methods				
Periodic abstinence	• Abstain from intercourse during fertile period of each cycle.	• Determine fertile period by: • Calendar method—ovulation occurs 14 days before the next menstrual period. • Cervical mucus method—increase in mucus at the time of ovulation; clear and stringy. • Basal body temperature—drops immediately before ovulation and rises 24 to 72 hr after ovulation. • Symptothermal method—combines mucus and temperature.	• No health hazards. • Inexpensive. • May be religiously acceptable. • Increased knowledge of cycles.	• 20% failure rate. • Requires consistent record-keeping. • Decrease in spontaneity.
Coitus interruptus (withdrawal method)	• Withdrawal of the penis from the vagina when ejaculation is imminent.	• Must withdraw before ejaculation so that ejaculation occurs away from female genitalia.	• No cost. • No health hazards. • Always available.	• Failure rate of 19%; pre-ejaculatory fluid may contain sperm. • Interruption of sexual act.
Lactation amenorrhea method	• Breast-feeding has a contraceptive effect due to prolactin's inhibition of luteinizing hormone, which maintains menstrual cycle.	• Three requirements: Baby is < 6 months old and is breast-fed on demand, around the clock, without formula or food supplementation, and the woman has not had her menses.	• No health hazards. • No cost.	• Need to use other method such as spermicide or barrier, which has no effect on breast milk if the three conditions are not met.
Barrier Methods				
	NURSING ALERT Warn patients who use condoms, diaphragms, and the cervical cap that latex sensitivity may be a problem—watch for itching, swelling, and generalized reactions.			
Condom—male and female	• Latex or polyurethane or processed collagenous tissue sheaths, placed over an erect penis to prevent semen from entering the vagina. • Female condom is placed in the vagina.	• Place condom over an erect penis. • Leave dead space at the tip of condom (from which air has been expelled) to allow room for ejaculate. • Use spermicide on exterior for added protection. • Grasp ring around condom at withdrawal to avoid leaving condom in the vagina.	• Failure rate is low with proper use (2% to 3%). • Prevention of STD • Inexpensive • No health hazard • May help premature ejaculation by decreasing sensitivity • Increases male involvement in contraception	• Decreased sensitivity • Interruption of sexual act • Sensitivity to latex may be a problem • Failure rate with typical use is 12%. • Female condoms are more expensive and made of polyurethane.
Diaphragm	• Rubber cap shaped like a dome with a flexible rim.	• Check for holes. • Place spermicide inside dome. • Place diaphragm against and covering cervical opening, behind lower edge of pubic bone. • Leave in place for 6 to 8 hr after intercourse.	• Failure rate with perfect use is 6% and 12% with typical use. • May reduce the risk of developing cervical cancer. • May place in the vagina several hours before intercourse. • Can use while breast-feeding.	• Occasional toxic shock or allergic reactions. • May experience pelvic discomfort. • Possible increase in urinary tract infections (UTIs) • Must be properly cleaned with soap and water, dried and stored to preserve integrity of rubber.

Cervical cap	• Rubber cap, shaped like a cup with a tall dome and flexible rim.	• Place spermicide inside cap and place cap over cervical opening prior to intercourse.	• Failure rate 14% to 29%. • Can be left in place for up to 48 hr. • Can use while breast-feeding.	• Must be properly cleaned with soap and water, dried, and stored. • Can be difficult to insert and remove.
Spermicides				
Nonoxynol 9 or octoxynol 9	• Available in a variety of forms: foam, jelly, cream, suppository, tablet.	• Place next to the cervix before intercourse; better if used with a barrier method.	• Available in a variety of forms. • Sold over the counter.	• Less effective if not used with barrier method; generally, 28% failure rate. • Some patients are allergic. • Increases risk of UTI. • Frequent use may cause genital lesions, increasing risk of HIV transmission.
Intrauterine Devices				
	• Small device made of plastic with exposed copper or progesterone release system; acts to inhibit implantation.	• Health care provider inserts device, usually at the time of menses. • Check intrauterine device string regularly—at least once per month—or after each intercourse when it is first inserted.	• Failure rate low, 1% or less. • Convenient; permits spontaneous intercourse. • Replace every 3 to 12 yr, depending on the type.	• Risk of PID for the first month and resultant tubal damage and infertility. • May cause spotting, bleeding, or pain. • Risk of spontaneous abortion. • Risk of uterine rupture (rare).
Hormones				
Combination oral contraceptives	• Tablets containing estrogen to inhibit ovulation and progestin to make cervical mucus impenetrable to sperm; lowest effective doses are used.	• Take daily in a cyclical or continuous manner.	• <1% failure rate in the first year with correct use. • Decreased pelvic pain due to endometriosis, decreased risk of ovarian and endometrial cancer, decreased bleeding due to uterine fibroids. • Aids in menstrual disorders. • Improves acne.	• Serious adverse reactions include thromboembolism, stroke, myocardial infarction, and cerebral embolism, especially for those who smoke cigarettes or are overweight. • Questionable risk of breast, cervical cancer. • May experience nausea, vomiting, headache, bloating. • Must remember to take at same time daily.
Progestin-only oral contraceptive (minipill)	• Smaller doses of progestins than in combined oral contraceptives.	• Take daily.	• As low as <1% failure rate during the first year with correct use. • Avoids estrogen-related adverse effects and possibly cardiovascular risks. • The thickened cervical mucus may reduce the risk of ascending infection with development of PID. • Safe in breast-feeding.	• May cause irregular menses, spotting, amenorrhea. • Must be taken at the same time daily (no more than 3 hr late) or protection is lost.

Combination transdermal contraceptive patch	• Estrogen and progesterone are absorbed systemically, as efficacious as oral hormones.	• Apply weekly to buttocks, inner aspect of upper arms, or abdomen for 3 weeks and then off for 1 week for menses.	• Same as oral hormones but administered weekly. • Avoids first-pass metabolism through the liver.	• Same as oral hormones. • May become loose or cause minor skin reaction. • Increased risk of DVT compared to oral method. • Women >190 pounds should not use.
Hormonal vaginal contraceptive	• Vaginal ring containing estrogen and progesterone, as effective as oral contraceptive.	• Insert ring into the vagina; remove after 3 weeks for 1 week for menses.	• Same as oral contraceptives except it is administered monthly. • Avoids first-pass metabolism through the liver.	• Same as oral contraceptives. • Requires vaginal insertion and retrieval. • May cause vaginitis, leukorrhea.
Postcoital contraception (morning-after pill)	• May be combined estrogen and progestin, high-dose estrogen, or progestin.	• More effective if started within 24 to 72 hr after intercourse, may be used up to 5 days after intercourse.	• Very effective.	• May be religiously opposed. • Can cause nausea.
Progesterone implant	• Progesterone release system made up of Silastic rod.	• Implanted in subcutaneous fat of the upper arm.	• Long term (up to 3 yr). • Convenient. • Only 0.4% failure rate.	• May cause irregular bleeding, spotting, amenorrhea, acne, headaches. • May be difficult to remove. • High initial expense.
Progesterone injection	• IM injection of long-acting progesterone.	• Injections should be every 11 to 13 weeks.	• Convenient. • <1% failure rate with correct use.	• Requires every 3-month follow-up. • May cause irregular bleeding, spotting, amenorrhea, weight gain. • Long-term effects still unknown. • High discontinuation rate in adolescents due to adverse effects and missed appointments. • Need calcium supplementation.
Progesterone Antagonist				
RU-486; mifepristone	• Drug that prevents implantation and leads to menses (medical abortion).	• Given orally within 10 days of a missed period; may be combined with prostaglandin suppository.	• Causes abortion in 95% of users up to 5 weeks after conception.	• Is an abortifacient; not a contraceptive in most cases. • May cause nausea, bleeding, incomplete abortion.

STD, sexually transmitted disease.

Sterilization Procedures

Tubal sterilization is frequently performed for birth control. Hysterectomy and oophorectomy, performed for other reasons, also result in sterility. Male sterilization by vasectomy is another option.

General Considerations

1. Approaches.
    a. Abdominal is most frequently used: may be postpartum laparotomy, minilaparotomy, or laparoscopy. Laparoscopy with electrocoagulation is frequently performed. It is a safe and effective procedure.
    b. Uterine approach utilizing hysteroscopy to visualize the tubal ostia and insert coils or plugs.
2. Techniques vary by surgeon preference.
    a. Electrocoagulation: burn section of tube with or without excision; low reversal rate.
    b. Pomeroy: the tube is tied in midsection and section removed; may be reversed.
    c. Fimbriectomy: the fimbriated end removed and end tied; irreversible.
    d. Cornual resection: removal of the section of the tube nearest to the uterus and suture cornual opening closed.
    e. Silastic bands: plastic or metal clips to occlude tube; may be reversed, although rare.
    f. Coils or plugs inserted in the tubal ostia through hysteroscopy.

Complications

a. Failure to successfully block the tubes—pregnancy or tubal pregnancy.
b. Hemorrhage, infection, uterine perforation, and damage to the bowel, bladder, or aorta.

Nursing and Patient Care Considerations

1. Assess motivation for sterilization and level of knowledge about the procedure. Informed consent is needed. The couple should be thoroughly counseled about the permanence of the procedure.
    a. Teach the patient that there is no effect on hormones and menstruation will continue.
    b. Teach patient there should not be any adverse effect on sexual response.
2. Birth control should be used prior to sterilization unless performed during the menstrual period, during a Cesarean section, immediately postpartum, or after an abortion procedure.
3. Prepare the patient to expect some abdominal soreness for several days; instruct her to report any bleeding, increasing pain, or fever.
4. Sexual intercourse and strenuous activity should be avoided for 2 weeks.

Dilation and Curettage

Dilation and curettage is a common gynecologic surgery for diagnostic and therapeutic purposes, which consists of widening the cervical canal with a dilator and scraping the uterine cavity with a curette. Performed to control uterine bleeding, secure endometrial and endocervical tissue for cytologic examination, and treat missed, incomplete, or induced abortion.

Nursing and Patient Care Considerations

1. Prepare patient for the procedure—answer questions; request that she void; administer an enema, if ordered; and administer nonsteroidal anti-inflammatory drug (NSAID) or a sedative, as directed.
2. Immediately postoperatively, monitor vital signs at frequent intervals; potential for hemorrhage exists.
3. Monitor perineal pads and the bed for amount of bleeding; report excessive amounts.
4. Offer prescribed analgesics for lower back and pelvic pain; cramping may occur for 2 to 3 days because of dilation of the cervix.
5. Instruct patient to maintain decreased activity for remainder of day to decrease cramping and bleeding.
6. Instruct patient to use perineal pads at home and to report fever (more than 100.4˚F), heavy bleeding (saturating a pad within 1 hour more than once), cramps lasting longer than 48 hours, increasing pain, and prolonged or a foul-smelling vaginal discharge.
7. Instruct patient to avoid strenuous activity until bleeding stops.
8. Inform patient that the procedure does not affect sexual functioning, but that she should refrain from sexual intercourse, douching, and tampons for at least 2 weeks, according to preference of health care provider.

Laparoscopy

Laparoscopy is the endoscopic visualization of the pelvic and abdominal cavities through a small incision below the umbilicus. It is used to diagnose pelvic pain and infertility; differentiate between ovarian, tubal, and uterine masses; evaluate genital anomalies; treat endometriosis, ectopic pregnancy, and adhesions; perform tubal sterilizations; and as a major surgical tool to treat a multitude of gynecologic indications including laparoscopically assisted hysterectomy.

Nursing and Patient Care Considerations

1. Obtain pregnancy test if the patient is within childbearing years, as indicated.
2. Prepare patient by ensuring that she has taken nothing by mouth (NPO), answering questions about the procedure, and administering a sedative and enema, if ordered.
3. Inform the patient that she may experience shoulder or abdominal discomfort after the procedure from the infusion of carbon dioxide given to separate the intestines from pelvic organs. Elevation of feet higher than shoulders after the procedure helps relieve this.
4. The patient will receive local, general, or regional anesthesia and will be placed in Trendelenburg position to displace the intestines for better visualization.
5. After the procedure, monitor bleeding and vital signs and administer analgesics, as indicated.
6. Inform patient that passing gas and bowel movements may be difficult initially because of the manipulation of the intestines; ambulation and fluids will be helpful.
7. Advise patient to report bleeding, cramping, or fever; avoid strenuous activity for 2 to 3 days; and not to have intercourse for 1 week. Additional restrictions may be advised for complex procedures.

Hysterectomy

Hysterectomy is the surgical removal of the uterus. It is the second most common operation in the United States among reproductive-age women.

Types of Hysterectomy

1. Abdominal.
    a. Subtotal/supracervical hysterectomy—corpus of the uterus is removed, but cervical stump remains.
    b. Total hysterectomy—entire uterus is removed, including the cervix; tubes and ovaries remain.
    c. Total hysterectomy with bilateral salpingo-oophorectomy—entire uterus, tubes, and ovaries are removed.
2. Vaginal—removal of the uterus and cervix through the vagina.
3. Laparoscopically assisted vaginal hysterectomy—allows for the removal of pelvic adhesions that would otherwise prevent vaginal hysterectomy.
4. Laparoscopic supracervical hysterectomy—laparoscopic removal of the uterus that spares the cervix.
5. Laparoscopic total hysterectomy—laparoscopic removal of the entire uterus and cervix.

Indications

1. Uterine fibroids, endometriosis and adenomyosis, and dysfunctional uterine bleeding—most common.
2. Uterine prolapse and chronic pelvic pain.
3. Cancer of the vagina, cervix, uterus, ovaries, or fallopian tubes.
4. Obstetric complications—rare.

Preoperative Management

1. Procedure and reason for hysterectomy, what the procedure involves, and what to expect postoperatively are explained.
2. Patient must remain NPO from midnight the night before surgery and must void before surgery.
3. An enema may be administered before surgery to evacuate the bowel and prevent contamination and trauma during surgery.
4. Vaginal irrigation is performed before surgery and skin preparation is done, if ordered.
5. Implement the Universal Protocol for Preventing Wrong Site, Wrong Procedure, and Wrong Person Surgery (see Chapter 7).
6. Preoperative medication is given to help the patient relax.

Postoperative Management

1. Postoperatively, the following assessments are made:
    a. Wound appearance and drainage.
    b. Vital signs and level of consciousness.

c. Level of pain and comfort to include nausea and vomiting.
d. Vaginal drainage (serous, bloody).
e. Intake and output.
f. Urge to void, bladder distention, and residual urine (if appropriate).
g. Clarity, color, and sediment of urine.
h. Homans sign or impaired circulation.
i. Return of bowel sounds, passage of flatus, and first bowel movement.

2. Exercise and ambulation are encouraged to prevent thromboembolus, facilitate voiding, and stimulate peristalsis.

Complications

1. Incisional/pelvic infection.
2. Hemorrhage.
3. Urinary tract injury.
4. Bowel obstruction.
5. Thrombophlebitis/venous thromboemboli.

Nursing Diagnoses

- Acute Pain related to surgical procedure.
- Impaired Urinary Elimination related to decreased sensation and stimulation.
- Risk for Infection related to surgical procedure.
- Disturbed Body Image related to alteration in female organs and hormones.
- Sexual Dysfunction related to alteration in reproductive organs and function.

Nursing Interventions

Relieving Pain

1. Assess pain location, level, and characteristics.
2. Administer prescribed pain medications. Ensure that patient knows how to use patient-controlled analgesia pump and is using it properly.
3. Encourage patient to splint incision when moving.
4. Encourage patient to ambulate as soon as possible to decrease flatus and abdominal distention.
5. Institute sitz baths or ice packs, as prescribed, to alleviate perineal discomfort.
6. Monitor level of sedation related to opioid administration—may interfere with ambulation and elimination.

Promoting Urinary Elimination

1. Monitor intake and output, bladder distention, and signs and symptoms of bladder infection.

2. Maintain patency of indwelling catheter if one is in place.
3. Catheterize patient intermittently if uncomfortable or if she has not voided in 8 hours.
4. Catheterize to check for residual urine after patient voids; should be less than 100 mL. Continue to check if more than 100 mL or bladder infection may develop.
5. Encourage patient to empty bladder around the clock, not only when feeling the urge, because of loss of sensation of bladder fullness.
6. Encourage fluid intake to decrease risk of urinary infection.

Preventing Infection

1. Assess vaginal drainage amount, color, and odor, incision site, and temperature.
2. Administer antibiotics, as prescribed.
3. Assist use of incentive spirometer, coughing and deep breathing, and ambulation to decrease risk of pulmonary infection. Monitor respirations and breath sounds for compromise.

Strengthening Body Image

1. Allow the patient to discuss her feelings about herself as a woman.
2. Encourage the patient to discuss her feelings with her spouse or significant other.
3. Reassure the patient that she will not go through premature menopause if her ovaries were not removed.

Regaining Sexual Function

1. Discuss changes regarding sexual functioning, such as shortened vagina and possible dyspareunia because of dryness.
2. Offer suggestions to improve sexual functioning.
    a. Use of water-soluble lubricants.
    b. Change position—female-dominant position offers more control of depth of penetration.

Patient Education and Health Maintenance

1. Advise patient that a total hysterectomy with bilateral salpingo-oophorectomy produces a surgical menopause. Patient may experience hot flashes, vaginal dryness, and mood swings unless short-term hormonal replacement therapy is instituted.
2. Advise patient against sitting too long at one time, as in driving long distances, because of the possibility of blood pooling in the lower extremities, which increases the risk of thromboembolism.
3. Suggest that patient delay driving a car until the third postoperative week because even pressing the brake pedal puts stress on the lower abdomen. Avoid hazardous activities when taking opioid analgesics.
4. Tell patient to expect a tired feeling for the first few days at home and not to plan too many activities for the first week. She can perform most of her usual daily activities within 4 to 6 weeks or per provider instruction. Teach patient that the recovery period differs for each individual and is dependent on medical history and any complications that may have occurred. Inform her that it may be 2 to 3 months or even a year “to feel like herself again.”

5. Tell patient not to feel discouraged if, at times during convalescence, she experiences depression, feels like crying, and seems unusually nervous. This is common but will not last. Tell patient to call her provider if the feelings persist.
6. Remind patient to ask her surgeon about strenuous or lifting activities, which are usually restricted for 4 to 6 weeks.
7. Reinforce instructions given by the surgeon on intercourse, douching, and use of tampons, which are usually discouraged for 6 to 8 weeks. Sexual intercourse should be resumed cautiously to prevent injury and discomfort. Showers are permitted, but tub baths are deferred until healing is sufficient.
8. Instruct patient to report fever higher than 100°F (37.8°C), heavy vaginal bleeding, drainage, increased pain or cramping, foul odor of discharge, and bleeding or increased drainage from incision site.
9. Emphasize the importance of follow-up visits and routine physical and gynecologic examinations.

Evaluation: Expected Outcomes

- Verbalizes decreased pain.
- Voids every 4 to 6 hours of sufficient quantity.
- No fever or signs of infection.
- Verbalizes positive statements about self and positive outlook on recovery.
- Verbalizes understanding of possible changes in sexual functioning and what to do about it.

MENSTRUAL CONDITIONS

Dysmenorrhea

Dysmenorrhea is painful menstruation; most common of gynecologic dysfunctions.

Pathophysiology and Etiology

Primary Dysmenorrhea

1. No pelvic lesion; usually intrinsic to the uterus.
2. Current research supports increased prostaglandin production by the endometrium as the chief cause.
3. May also be because of hormonal, obstructive, and psychological factors.

Secondary Dysmenorrhea

1. Caused by lesion, such as endometriosis, pelvic infection, congenital abnormality, uterine fibroids, or ovarian cyst, or may be caused by passage of a clot through undilated cervix.

Clinical Manifestations

1. Pain may be caused by increased uterine contractility and uterine hypoxia.
2. Characteristics of pain—recurrent, crampy, colicky or dull, usually in lower midabdominal region, and spasmodic or constant.
3. Nausea, vomiting, diarrhea, headache, chills, tiredness, nervousness, and lower backache may be experienced.
4. Usually self-limiting without complications.

Diagnostic Evaluation

Tests to rule out underlying cause:

1. Chlamydia and gonorrhea tests—may show infection.
2. Pelvic ultrasound—may detect tumor, endometriosis, and cysts.
3. Serum or urine pregnancy test—to rule out ectopic pregnancy.
4. Possibly, hysteroscopy and laparoscopy—primarily to detect endometriosis.

Management

The following measures are for primary dysmenorrhea; treatment of secondary dysmenorrhea is aimed at underlying pathology.

1. Nonsteroidal anti-inflammatory agents, such as ibuprofen or naproxen sodium for their antiprostaglandin action. Most effective with loading dose 1 to 2 days before onset of menses and taken on a regular schedule for 2 to 3 days.
2. Local heat, such as heating pad, to increase blood flow and decrease spasms, for 20-minute intervals with increased effectiveness with other therapies.
3. Hormonal contraceptives to decrease contractility and menstrual flow. Evidence supports decreased

dysmenorrhea symptoms with monthly oral contraceptives, extended-cycle oral contraceptives, intravaginal hormonal devices, and intrauterine hormonal systems.

4. Exercise to increase endorphin release, which decreases pain perception, and to suppress prostaglandin release.

Nursing Assessment

1. Obtain menstrual and gynecologic history that could suggest underlying pathology.
2. Assess level of pain using scale of 1 to 10; assess the patient's emotional response to pain, coping mechanisms, and ability to carry out activities.
3. Obtain vital signs, including temperature, to rule out infection.
4. Perform abdominal and pelvic examination (if indicated) to obtain specimens.

Nursing Diagnoses

- Acute Pain related to uterine contractions.
- Risk for Activity Intolerance related to pain severity and associated symptoms.
- Readiness for Enhanced Coping related to chronic, recurrent condition.

Nursing Interventions

Controlling Pain

1. Administer pharmacologic agents, as ordered, to control pain and menstrual flow.
2. Apply heating pad to lower back or abdomen, as indicated, for 20-minute intervals.
3. Assess the patient's response to pain-control measures.
4. Encourage verbalization of feelings and reassure patient through the evaluation process.
5. Encourage activity and exercise, as tolerated.

Decreasing Risk for Activity Intolerance

Instruct the patient that tolerance will increase with increased activity. The more active she is, the better she will feel.

Enhancing Coping Skills

Instruct the patient in stress-reduction techniques, breathing techniques, and lifestyle changes that may improve symptoms such as exercise, healthy eating habits, adequate sleep, and smoking cessation.

Patient Education and Health Maintenance

1. Explain to the patient possible causes of dysmenorrhea.
2. Teach the patient nonpharmacologic methods to reduce pain.
    a. Apply a heating pad to the lower midabdomen or back or take warm tub baths for 20-minute intervals.
    b. Exercise regularly (30 minutes, five or more times per week).

c. Healthy eating habits; see *www.myplate.gov*.

d. Smoking cessation.

3. Teach the patient to use prescribed medications effectively by taking medication at the beginning of discomfort and repeating as necessary, especially on the first day of menses.
4. Teach the patient adverse effects of medications.
5. Encourage patient to reduce stress through adequate sleep, good nutrition, exercise, smoking cessation, and coping with stressors.
6. Discuss patient's feelings toward menstruation (hygienic issues, inconvenience, female identity).

Evaluation: Expected Outcomes

- Verbalizes reduced pain level.
- Demonstrates participation in functional activities of daily living without intolerance.
- Describes methods to reduce pain and to increase coping skills.

Premenstrual Syndrome and Premenstrual Dysphoric Disorder

EVIDENCE BASE Hofmeister, S., & Bodden, S. (2016). Premenstrual syndrome and premenstrual dysphoric disorder. *American Family Physician, 94*(3), 236–240.

Premenstrual syndrome (PMS) is a group of behavioral, psychological, and physical symptoms that include headache, irritability, depressed mood, breast tenderness, and abdominal bloating that are clearly related to onset of menstruation.

Premenstrual dysphoric disorder (PMDD) is a severe form of PMS.

Pathophysiology and Etiology

1. Etiologic theories include hormonal imbalances, such as ovarian steroid interaction; dysfunction of neurotransmitters (such as serotonin), prostaglandins, or endorphins; psychological factors, such as attitudes and beliefs related to menstruation; and environmental factors, such as nutrition and pollution.
2. Most common in women in their thirties.
3. May occur in 20% to 32% of menstruating women. Up to 80% of women experience one or more of the symptoms during the luteal phase of their menstrual cycle.

Clinical Manifestations

1. Symptoms may begin 7 to 14 days before onset of menstrual flow; may diminish 1 to 2 days after menses begins.
2. Physical—edema of extremities, abdominal fullness, breast swelling and tenderness, headache, vertigo, palpitations, acne, backache, constipation, thirst, and weight gain.
3. Psychological and behavioral—labile mood, irritability, fatigue, lethargy, depressed mood, anxiety, crying spells, changes in appetite, and decreased concentration.
4. Diagnosis based on clinical manifestations; usually neither diagnostic laboratory nor radiological evaluation is necessary.
5. Usually self-limiting without complications.

Management

1. First-line pharmacological therapy for severe PMS or PMDD includes selective serotonin reuptake inhibitors (SSRIs) such as citalopram, escitalopram, fluoxetine, and sertraline and serotonin–norepinephrine reuptake inhibitors such as venlafaxine.
2. Drospirenone (a spironolactone derivative diuretic) combined with low-dose estrogen in oral contraceptives helps symptoms. Theoretically, longer cycles of oral contraceptives with shorter inactive phases would ameliorate symptoms by suppressing natural hormones.

3. Calcium supplementation of 1,200 mg elemental calcium per day has good evidence that supports decreased mood swings, irritability, depression, and anxiety.
4. Vitamin B_6 supplements of 50 to 100 mg daily (should not exceed 100 mg/day).
5. Cognitive–behavioral therapy has some limited evidence supporting relief of symptoms.
6. Healthy lifestyle changes, such as restriction of sodium, caffeine, tobacco, alcohol, and refined sweets, and inclusion of aerobic exercise, although often recommended, have insufficient evidence to support their efficacy in treatment of PMS symptoms.
7. High-dose daily vitamin D intake is supported by some evidence.
8. Prostaglandin inhibitors such as ibuprofen will decrease dysmenorrhea-related symptoms.
9. Spironolactone, a diuretic with androgenic effect, may decrease fluid retention and weight gain.
10. With great caution because of abuse potential, anxiolytic agents may be prescribed for use during the luteal phase for patients with anxiety symptoms.
11. Herbal supplements, for example, chasteberry, also known as *Vitex agnus-castus*, were found to be effective in one randomized controlled trial, but more studies are needed.

DRUG ALERT Paroxetine should be avoided in women of childbearing age because of increased risk of congenital abnormalities.

Nursing Assessment

1. Ask the patient to describe symptoms, their onset, and means of relief.
2. Assess the patient's diet, activity, and rest habits.
3. Assess the patient's emotional response to symptoms and methods of coping.

Nursing Diagnoses

- Deficient Knowledge related to self-care measures.
- Anxiety related to symptoms and difficulty coping with condition.

Nursing Interventions

Increasing Knowledge and Coping Skills

Use patient education as a tool to help patient increase control over symptoms.

Reducing Anxiety

1. Administer medications, as ordered; warn patient that diuretics will cause increased urination and anxiolytics may cause drowsiness or cognitive impairment.
2. Provide emotional support for patient and significant others.
3. Teach stress management and relaxation measures such as imagery and progressive muscle relaxation (see

Chapter 3).

4. Suggest counseling, as indicated.

Patient Education and Health Maintenance

1. Encourage patient to keep a diary for several consecutive months, which includes dates, cycle days, stressors, symptoms, and their severity, to determine if therapy is effective.
2. Instruct patient in the use and adverse effects of prescribed medications.
3. Teach patient possible causes of syndrome and nonprescription methods to alleviate distress, such as calcium and vitamin B_6 intake.
4. Refer for further resources and support to such groups as the National Association for Premenstrual Syndrome (UK) (*http://pms.org.uk*) or womenshealth.gov, a project of the U.S. Department of Health and Human Services Office on Women's Health (*www.womenshealth.gov*).

Evaluation: Expected Outcomes

- Verbalizes increased knowledge and sense of control over condition.
- Reduced signs and symptoms of anxiety.

Amenorrhea

Amenorrhea is the absence of menstrual flow.

Pathophysiology and Etiology

Primary Amenorrhea

1. Menarche does not occur by age 16 with pubertal development or by age 14 with absence of secondary sex characteristics.
2. May be caused by chromosomal disorders, such as Turner syndrome, agenesis of the uterus, or constitutional delay of growth and puberty.
3. Transverse vaginal septum or imperforate hymen.

Secondary Amenorrhea

1. Menstruation stops for 3 months in women with previously established regular menstrual cycles or 9 months in a woman with previously established oligomenorrhea (infrequent or longer menstrual cycles).
2. May be caused by pregnancy, lactation, menopause, or corpus luteal ovarian cysts.
3. Excessive exercise, inadequate nutrition with decreased body fat stores, and excessive weight loss may cause amenorrhea in young athletes (included in the female athlete triad: an eating disorder, amenorrhea, and osteoporosis).
4. Amenorrhea and anovulation secondary to polycystic ovary syndrome (PCOS) commonly occur in obese women but may be seen in women with normal body mass index (BMI).
5. Ovarian, adrenal, or pituitary tumors and thyroid disorders are hormonal causes.
6. Some medications, such as antipsychotics (phenothiazines), antidepressants, antihypertensives, histamine H2 blockers, opiates, chemotherapy, and hormonal contraceptives, may also induce amenorrhea.
7. It may be a result of severe depression, severe psychological trauma, physical trauma, or radiation.

Diagnostic Evaluation

1. Pregnancy test.
2. Prolactin level (elevated) with pituitary tumor.
3. Thyroid-stimulating hormone (TSH).
4. Progesterone challenge test in secondary amenorrhea if both prolactin and TSH are normal and pregnancy test is negative.
   a. Positive result—bleeding occurs; chronic anovulation is most likely.
   b. Negative result—no bleeding occurs; may indicate ovarian failure; other tests are needed.
5. Hormonal levels—LH and FSH—to determine type of hypogonadism in primary amenorrhea or to detect ovarian failure in secondary amenorrhea.
6. Genetic karyotyping to detect chromosome abnormalities in primary amenorrhea.
7. Ultrasound to identify presence of the uterus and/or outflow obstruction.

Management

Treatment is based on causative factor.

1. Discontinue causative medications if benefit of discontinuance outweighs risk.
2. Nutritional, exercise, or psychological counseling, as indicated.
   a. Recommend decreased exercise in athletes to increase body fat stores and restore normal BMI.
   b. Recommend weight reduction if obese.
3. Low-dose hormonal contraceptives to regulate cycle after underlying cause has been determined.
4. In polycystic ovarian syndrome, insulin-sensitizing agents decrease androgen levels, improve ovulation rate, and improve glucose tolerance. Clomiphene citrate is first-line for ovulation induction. Laser treatment plus eflornithine is indicated for hirsutism in PCOS.
5. Treatment of tumor or other underlying cause. Surgery, as indicated.

Complications

1. Amenorrhea increases risk for osteoporosis and endometrial hyperplasia, which may lead to atypia and cancer of the endometrium.
2. PCOS conveys risk of metabolic syndrome, type 2 diabetes, and cardiovascular disease. Improvement in ovulation rate increases the risk of pregnancy.

Nursing Assessment

1. Assess for signs of chromosomal disorders, such as abnormal genitalia, masculinization, short stature, and characteristic facies.
2. Assess for signs of pituitary tumor, such as headache, vision disturbances, dizziness, and galactorrhea.
3. Assess weight and body build, BMI, change in weight, and nutritional and exercise habits that may indicate anorexia or loss of body fat because of exercise.
4. Assess for signs of PCOS: elevated blood pressure, elevated BMI, waist circumference, stigmata of insulin resistance, and hirsutism.
5. Assess emotional status, areas of stress, and coping ability.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to inadequate nutritional intake and/or rigorous exercise.
- Imbalanced Nutrition: More Than Body Requirements related to obesity or PCOS.
- Disturbed Body Image related to lack of menses and perception of inappropriate weight.

Nursing Interventions

Meeting Nutritional Requirements

1. Explore knowledge of the food groups, behavior regarding meals, and exercise routine; point out

misconceptions, dangerous behavior, and ideas for improvement.

2. Monitor weight and BMI and return of menstrual cycles.
3. Refer for individual or group nutritional counseling as needed.

Improving Body Image

1. Explore patient's body image and coping strategies. Provide emotional support for patient and family.
2. Describe diagnostic tests and who will give results to patient.
3. Point out ineffective coping mechanisms and teach more positive coping mechanisms such as assertiveness. Instruct in relaxation techniques.

Patient Education and Health Maintenance

1. Teach patient the physiology of the normal menstrual cycle and possible causes in diagnostic workup for amenorrhea.
2. Teach proper use and adverse effects of prescribed medications.
3. Teach the patient to chart menstrual periods on a calendar and maintain regular gynecologic and medical follow-up visits.
4. Teach patients with PCOS that they should be screened for type 2 diabetes and cardiovascular risk factors such as fasting lipid levels and BMI.

Evaluation: Expected Outcomes

- Verbalizes adequate dietary intake and appropriate exercise regimen.
- Achieves normal BMI with restoration of menses.
- Verbalizes understanding of diagnostic tests and improved body image.

Abnormal Uterine Bleeding

EVIDENCE BASE American College of Obstetrics and Gynecology. (2013). Management of abnormal uterine bleeding associated with ovulatory dysfunction. *Obstetrics and Gynecology, 122*, 176–185.

Abnormal uterine bleeding (AUB) is irregular or excessively heavy menstrual bleeding. It may be acute or chronic and is abnormal in regularity, volume, frequency, or duration, and it occurs in the absence of pregnancy.

Pathophysiology and Etiology

Causes of AUB are subdivided into anovulatory and ovulatory patterns.

Anovulatory AUB

1. Common causes of anovulatory AUB include polycystic ovarian syndrome (PCOS), uncontrolled diabetes mellitus, thyroid disorders (hypo- and hyperthyroidism), hyperprolactinemia, or medications (such as antipsychotics and antiepileptics).
2. In adolescents, AUB is frequently caused by immature hypothalamic–pituitary–ovarian axis.
3. Ovarian failure in perimenopausal women frequently causes DUB. Recurrent irregular menstrual cycles are considered abnormal if they occur 8 years before menopause.
4. Anovulation may be related to hypothalamic or pituitary dysfunction, impaired follicular formation or rupture, or corpus luteum dysfunction.
5. Temporary estrogen withdrawal at ovulation may cause midcycle ovulatory bleeding.

Ovulatory AUB

1. Excessive bleeding or duration may be related to hypothyroidism, late-stage liver disease, or bleeding disorders (such von Willebrand disease).
2. Structural abnormalities, such as submucosal fibroids or endometrial fibroids, may cause AUB.
3. Approximately one half of women with ovulatory AUB have no identifiable cause.

Clinical Manifestations

Anovulatory AUB Patterns/Dysfunctional Bleeding

1. Amenorrhea—no bleeding for three cycles or more.
2. Oligomenorrhea—significantly diminished menstrual flow; infrequent intervals (greater than 35 days) or irregular intervals.
3. Metrorrhagia—bleeding from the uterus between regular menstrual periods; significant because it is usually a symptom of disease.

4. Menometrorrhagia—excessive bleeding at the usual time of menstruation and at other irregular intervals.

Ovulatory Patterns

1. Menorrhagia—excessive bleeding during regular menstruation cycles; can be increased in duration or amount.
2. Polymenorrhea—frequent menstruation occurring at intervals of less than 21 days.
3. Menometrorrhagia—excessive bleeding at the usual time of menstruation and at other irregular intervals.

Diagnostic Evaluation

Tests to rule out pathologic causes of abnormal bleeding include:

1. Pregnancy test.
2. Complete blood count (CBC) to detect anemia and platelet count.
3. TSH to rule out thyroid disorder; prolactin to rule out pituitary adenoma.
4. Thorough history and examination to look for anovulatory medical conditions (such as obesity and hirsutism—signs of PCOS) and to rule out enlarged uterus, trauma, or foreign body.
5. Other tests that may be done during physical exam include a Pap smear to rule out cervical dysplasia or malignancy; chlamydia and gonorrhea tests to rule out PID.
6. Endometrial biopsy to determine hormonal effect on the uterus and rule out malignancy.
7. Transvaginal ultrasound to rule out ovarian or uterine pathology or structural abnormality. Saline infusion sonohysterography is more sensitive and specific than transvaginal ultrasound.
8. Coagulation screen to rule out blood dyscrasias in adolescents with menorrhagia. Iron studies are not first-line, but are recommended if hematocrit and hemoglobin are low.
9. If cause is still undetermined, then hysteroscopy is recommended to detect uterine fibroids, polyps, and other lesions.

Management

Treatment is based on underlying cause.

1. Hormonal contraceptives (birth control pills or hormone-releasing IUD) to control chronic bleeding or induce regular withdrawal bleeding. Endometrial biopsy should be repeated after 3 to 6 months of treatment to monitor endometrial hyperplasia. Combination estrogen–progesterone oral contraceptives, although commonly prescribed first-line, lack adequate evidence for treatment of AUB.
2. In women who cannot take estrogen because of an increased thrombotic risk, progesterone-only administration can be effective. Cyclical oral progesterone for 21 days significantly reduces menorrhagia. For patients with menorrhagia, levonorgestrel-releasing intrauterine system is superior to oral contraceptives. Long-acting progestin injections may reduce bleeding but cause irregular spotting.
3. In emergencies, parenteral conjugated estrogen may be used to stop acute bleeding. Because of increased risk of thromboembolism, concomitant use of low molecular weight heparin may be considered.
4. Treat underlying anemia with iron, possible transfusions.

5. NSAIDs are useful to decrease menstrual flow volume in menorrhagia.
6. Tranexamic acid, an antifibrinolytic agent, has demonstrated efficacy in decreasing menorrhagia. In an underlying bleeding disorder (such as von Willebrand disease), intranasal desmopressin may be indicated.
7. Androgen therapy with a gonadotropin-releasing hormone, such as leuprolide acetate, to reduce menstrual blood loss in perimenopausal women or to reduce the size of uterine fibroids before surgery.
8. Surgical procedures, such as hysteroscopic polypectomy or resection of uterine submucosal fibroids.
9. Hysteroscopic endometrial resection (removal of diseased or abnormal tissue) or endometrial ablation (application of heat to endometrium to induce scarring) when above methods are not helpful.
    a. By 5 years postablation, one third of patients require another surgery.
    b. The uterus is preserved, but it results in infertility.
10. Hysterectomy in refractory cases.

Complications

1. Recurrent anovulation in anovulatory AUB increases the risk of endometrial cancer because of the impact of unopposed estrogen on the endometrium. Women with regular ovulation and AUB have no greater risk of endometrial cancer because the endometrium regularly sloughs.
2. Severe anemia may result from menorrhagia or menometrorrhagia.

Nursing Assessment

1. Ask patient for menstrual and gynecologic history, sexual activity, and possibility of pregnancy.
2. Assess frequency, duration, and amount of menstrual flow.
3. Assess for other symptoms of underlying pathology, such as systemic hormonal conditions, pelvic pain, fever, and abdominal masses or tenderness.
4. Assess for signs and symptoms of anemia—fatigue, shortness of breath, pallor, and tachycardia.

Nursing Diagnoses

- Fatigue related to excessive blood loss.
- Fear of bleeding through clothing related to excessive or unpredictable bleeding.

Nursing Interventions

Increasing Energy Level

1. Administer medications, as ordered. Teach patient indications and side effects.
2. Encourage good dietary intake with increased sources of iron-fortified cereals and breads, meat (especially red meat), and green, leafy vegetables.
3. Administer oral iron preparations with meals to prevent nausea and with vitamin C–rich foods or drinks to enhance absorption. Treat constipation, as necessary.
4. Monitor hemoglobin and infuse packed red blood cells, as ordered.

5. Encourage activity, as tolerated.

Relieving Fear

1. Review pattern of menstrual flow with patient and help her plan for excessive bleeding.
2. Suggest wearing double tampons (if able) and double sanitary pads.
3. Tell the patient to expect heavy gush of blood on arising from lying or reclining position.
4. Prepare the patient to carry an adequate supply of sanitary products and a change of clothing until bleeding is under control.

Patient Education and Health Maintenance

1. Teach patient the causes of AUB and about the diagnostic process to rule out pathologic causes of abnormal bleeding.
2. Teach patient to prevent anemia by eating a diet high in iron and by consuming vitamin C or citrus fruit to enhance absorption of iron.
3. Teach about hormonal therapy, related adverse effects, and what adverse effects to expect and what to expect of bleeding. Bleeding should stop within first week of hormonal contraceptives but should start again in fourth week as regular menstrual period would with cyclical contraceptives.
4. Advise the patient to keep a calendar or log of menses.

Evaluation: Expected Outcomes

- Verbalizes adequate energy to perform activities.
- Verbalizes more confidence in ability to conceal bleeding.

Menopause

EVIDENCE BASE National Collaborating Centre for Women's and Children's Health. (2015). Menopause: Diagnosis and Management. (NG23). London (UK): National Institute for Health and Care Excellence (NICE). Available: *www.nice.org.uk/guidance/ng23?unlid=97688129201610270835.*

Menopause is described as the physiologic cessation of menses. Climacteric or perimenopause is the period during which there is decline in ovarian function and the woman experiences symptoms of estrogen deficiency and, possibly, irregular cycles. Menopause has occurred if menses has not occurred for 12 months.

Pathophysiology and Etiology

1. Menopause is caused by the cessation of ovarian function and decreased estrogen production by the ovary; average age range is 45 to 55, with the average age of 51.
2. Anovulation may occur during perimenopause, disrupting menstrual cycles.
3. Artificial or surgical menopause may occur secondary to surgery or radiation involving the ovaries. Some chemotherapeutic agents also cause a chemical menopause.
4. Hysterectomy without ovary removal may result in earlier menopause because of disruption of the blood supply to the ovaries.

Clinical Manifestations

1. Genitalia—atrophy of the vulva, vagina, and urethra results in dryness, bleeding, itching, burning, dysuria, thinning of pubic hair, loss of labia minora, and decreased secretions during intercourse.
2. Sexual function—vaginal dryness, discomfort, dyspareunia, and decreased intensity and duration of sexual response, but can still have active and satisfactory function.
3. Vasomotor—60% to 75% of women experience "hot flashes," which may be preceded by an anxious feeling and accompanied by sweating. These may occur at night, causing "night sweats."
    a. Psychological—insomnia, irritability, anxiety, memory loss, fear, and depression may be experienced.
    b. Some women experience palpitations.
    c. Symptoms, severity, and personal/cultural meanings vary with each individual.

Diagnostic Evaluation

1. Levels of LH and FSH will increase, and estradiol will decrease; however, levels may fluctuate often during perimenopause, so diagnosis is based on symptoms.
2. FSH greater than 30 to 40 IU/L indicates menopause; greater than 100 IU/L indicates complete ovarian failure.
3. Laboratory studies of FSH are not necessary to diagnose the perimenopausal phase or menopause itself.

Management

Menopausal Hormone Therapy/Estrogen Replacement Therapy

1. Indicated at the smallest possible dose for the shortest time period (less than 5 years) to reduce vasomotor symptoms (with the added benefit to prevent osteoporosis). Common systemic routes of administration include oral and transdermal.
2. Progesterone cotherapy preparations (oral, transdermal; or in combination products with estrogen) are required in a cyclical dosage pattern if the uterus is intact to prevent endometrial hyperplasia and possible cancer. Continuous progesterone therapy is no longer recommended because of association with adverse breast outcomes.
3. Vaginal preparations are most effective for atrophic vaginitis. Concomitant progesterone is not indicated with vaginal estrogen because of minimal systemic absorption of estrogen.
4. Available as synthetic, animal based, and natural (plant source) products.
5. Menopausal hormone therapy is contraindicated with the following conditions:
    a. Increased risk of thromboembolic disease, previous or current idiopathic deep vein thrombosis, or pulmonary embolism.
    b. Past, current, or suspected breast cancer.
    c. Estrogen-sensitive cancers (uterine, ovarian), untreated endometrial hyperplasia, and undiagnosed genital bleeding.
    d. Active or recent angina or myocardial infarction.
    e. Untreated hypertension.
    f. Active liver disease.
    g. Hypersensitivity to active substances in menopausal hormone therapy.
    h. Porphyria cutanea tarda (absolute contraindication).
6. Data are lacking to support progesterone or progestin alone for treatment of hot flashes.

Other Measures

1. Vaginal lubricants to decrease vaginal dryness and dyspareunia.
2. Calcium and vitamin D supplements to prevent bone loss.
3. Nonhormonal treatment of menopausal symptoms that may be considered includes SSRIs for depressive symptoms, clonidine (central alpha-blocker) or gabapentin for vasomotor symptoms. These therapies are supported by evidence.
4. Dietary supplements (considered natural products by consumers)—limited data are available on efficacy and safety. The patient should discuss potential benefits and risks with a health care provider.
    a. Soy products (isoflavones)—inconsistent relief of hot flashes. May cause headache and oily skin. Contraindicated as a phytoestrogen in women with strong personal or family history of hormone-dependent cancers (breast, uterine, ovarian), thromboembolic events, or cardiovascular events.
    b. Black cohosh—has demonstrated some relief of hot flashes, but has contraindications (as above) as a

phytoestrogen. Nausea, hypotension, and spontaneous abortion are adverse effects. No safety studies were conducted beyond 6 months; thus, recommended use should not exceed 6 months.

c. Vitamin E—400 IU daily has demonstrated minimal relief of hot flashes.

DRUG ALERT Clinical trial data on the following commonly used herbal supplements have not demonstrated improved symptom relief over placebo: evening primrose, ginseng, dong quai, and red clover.

Complications

1. Osteoporosis has been clearly linked to estrogen depletion in menopause.
2. Coronary artery disease (CAD) rarely develops in women before menopause and may be associated with the effects of estrogen depletion on blood vessels.
3. Vaginal atrophy related to a dry, estrogen-depleted epithelium increases the risk for dyspareunia, recurrent vulvovaginitis, and urinary tract infections. More research is required related to the etiology and treatment of postmenopausal stress and urge urinary incontinence.
4. Psychosocial issues of menopause: risk of depression increases.

Nursing Assessment

1. Obtain history of the patient's current symptoms and menstrual cycle.
2. Obtain history for other risk factors for CAD, osteoporosis, stroke, depression, breast cancer, and uterine cancer.
3. Assess genitalia for atrophy, dryness, and elasticity.
4. Assess the patient's emotional response to menopause.

Nursing Diagnoses

- (Risk for) Sexual Dysfunction related to menopausal symptoms and psychological impact of menopause.
- Readiness for Enhanced Self-Health Management.

Nursing Interventions

Maintaining Sexuality Patterns

1. Explore with patient her feelings about menopause, clear up misconceptions about sexual functioning, and encourage her to discuss her feelings with her partner.
2. Tell the patient that sexual functioning may decrease during menopause but may even increase because of loss of fear of pregnancy and increased time if children are grown.
3. Instruct the patient how to use a water-based lubricant for intercourse to decrease dryness or discuss vaginal estrogen replacement therapy.

Increasing Self-Health Management

1. Provide patient with information related to estrogen replacement therapy, including dosage schedule, route, adverse effects, and what to expect of menstrual bleeding.
   a. Women who still have a uterus can expect a period at the end of every month if they take hormones cyclically. Progesterone cyclical cotherapy is indicated to prevent endometrial hyperplasia.
   b. Systemic preparations (oral, transdermal) are indicated for systemic symptoms, such as hot flashes and mood swings.
   c. Vaginal preparations are indicated for vaginal atrophy and may help to reduce recurrent UTIs.
2. Help patient to understand the risks versus benefits of menopausal hormone therapy, formulate questions, and initiate discussion with her health care provider about treatment options for vasomotor symptoms. Refer patient to clinical trial results from the Women's Health Initiative (*www.nhlbi.nih.gov/whi*).

Patient Education and Health Maintenance

1. Teach the patient about foods that are high in calcium and vitamin D—dairy products, dark green vegetables, salmon, and fortified foods. Encourage her to maintain weight-bearing activities several times weekly to prevent osteoporosis.
2. Counsel patient on reducing risk factors for CAD, including smoking cessation.
3. Encourage patient to keep regular medical and gynecologic follow-up visits, including all age-appropriate screenings, such as mammography, pelvic exam, dual-energy x-ray absorptiometry (DEXA) scan for osteoporosis, lipid panel, and colonoscopy.
4. Advise patient that vulvovaginal infection and trauma are possible because of the dryness of the tissue and to seek prompt evaluation if pain and discharge occur or increases.
5. Encourage patients to talk to their health care providers about concerns such as breast cancer with hormonal therapy. Also, refer the patient for information on postmenopausal hormone therapy to *https://www.nhlbi.nih.gov/files/docs/pht_facts.pdf*.
6. Encourage patients to report all use of supplements to their health care providers so they can use these preparations appropriately and safely.

GERONTOLOGIC ALERT In the postmenopausal woman, if vaginal bleeding not associated with hormone replacement occurs, encourage the patient to see her health care provider immediately because cancer may be suspected.

Evaluation: Expected Outcomes

- Verbalizes confidence in sexual function and identity.
- Verbalizes satisfactory coping with menopausal symptoms and appropriate self-health management

behaviors.

INFECTIONS AND INFLAMMATION OF THE VULVA, VAGINA, AND CERVIX

Some conditions are considered sexually transmitted, others are caused by inflammation or non–sexually transmitted infections. For syphilis, see page 632.

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted diseases treatment guidelines. Available: *www.cdc.gov/std/treatment*.

Vulvitis

Vulvitis is inflammation of the vulva.

Pathophysiology and Etiology

Causative Factors

1. Infections—*Trichomonas*, molluscum contagiosum, bacteria, fungi, herpes simplex virus (HSV), and human papillomavirus (HPV; genital warts). Also, see pages 658–661.
2. Irritants.
   a. Urine, feces, and vaginal discharge.
   b. Close-fitting, synthetic fabrics.
   c. Chemicals, such as laundry detergents, vaginal sprays, deodorants, perfumes, some soaps, chlorine, dryer sheets, and bubble bath.
3. Carcinoma.
4. Chronic dermatologic conditions, such as psoriasis or eczema.

Predisposing Factors

1. Illnesses, such as diabetes mellitus and dermatologic disorders.
2. Atrophy due to menopause.

Clinical Manifestations

1. Pruritus—more acute at night, aggravated by warmth, often associated with candidal infections.
2. Reddened, edematous tissue, possible ulceration.
3. Pain, burning, and dyspareunia.
4. Exudate—possibly profuse and purulent—involving vaginitis.
5. Lesions of molluscum contagiosum are multiple, from 1 mm to 1 cm in size, and filled with white caseous material.
6. Lesions of HSV are vesicles with an erythematous base, clustered in a somewhat linear pattern.
7. Lesions of HPV are flesh-colored, irregular, raised, soft warty-like growths.

Diagnostic Evaluation

1. Vulvar smears and cultures—may show infectious organism.
2. Biopsy of vulvar tissue—may be necessary to rule out malignancy and chronic dermatologic conditions.

Management

1. Oral or topical anti-infectives (antibiotics, antifungals, antivirals) to treat infectious agents.
2. Extremely low-dose topical steroids to treat inflammation in some cases.
3. Vaginal estrogen to treat vaginal atrophy associated with menopause.

4. Treatment of underlying disorder.
5. Molluscum contagiosum may be treated by scalpel excision, silver nitrate, electrical cautery, or curette or may be left untreated, allowing spontaneous resolution.

Complications

1. Scarring and chronic discomfort.
2. Transmission of STD to partner.

Nursing Assessment

1. Question the patient about medical history, symptoms, and sexual activity.
2. Determine use of chemical-containing products on undergarments or directly on the vulva.
3. Examine the genitalia and lymph nodes.

Nursing Diagnosis

- Acute Pain related to vulvar inflammation.

Nursing Interventions

Relieving Pain

1. Administer prescribed medications and instruct the patient on their use, method of application, and adverse effects.
2. Instruct use of sitz baths, sitting in or over warm water for 15 to 20 minutes, three to four times daily. May also use cool compresses to soothe and clean vulva.
3. Instruct the patient about the nature of the condition (eg, chronic recurrent or curable) and expectations for symptoms after treatment.

Patient Education and Health Maintenance

1. Teach the patient hygienic principles.
    a. Wipe from front to back after voiding.
    b. Use cotton with warm water and bland soap for cleansing, rinse, and pat dry. May also use fragrance-free hypoallergenic wet wipes.
2. Teach the patient to avoid chemical irritants, such as sprays, perfumed and deodorant soaps, new laundry detergents, static-control dryer sheets, and bubble bath.
3. Teach the patient to avoid mechanical irritants, such as tight clothing, synthetic fabrics, and undergarments; replace these with loose-fitting cotton undergarments. Avoid chronic moisture; change bathing suit after swimming.
4. Teach the patient how to use sitz bath and cool compresses at home and to avoid scratching.
5. Teach the patient that some infections, such as *Trichomonas*, molluscum contagiosum, and HSV, are sexually transmitted; so the partner needs to seek treatment before intercourse is resumed. Assist the

patient with health communication techniques to inform partner.

6. Educate about STD prevention and encourage screening (see Box 22-1).

BOX 22-1 Sexually Transmitted Disease Prevention Counseling

Sexually transmitted diseases can be prevented through interactive, client-centered counseling approaches that address personal risk. Key techniques to facilitate rapport include use of open-ended questions and understandable language. Most effective strategies are performed in nonjudgmental and empathetic ways, incorporating the patient's culture, language, gender, sexual orientation, age, and developmental level. Motivational interviewing techniques and assessing for readiness to change are also helpful.

The first step in counseling is taking a sexual history, including:

- Type and number of partners.
- Methods for prevention of pregnancy.
- Methods for prevention of STDs.
- Past history of STDs.
- Exposure to intravenous drug use or sex workers.

An individualized prevention plan may incorporate one or more of the following specific methods of prevention:

- Abstinence from oral, vaginal, and anal sex. Encourage abstinence until beginning a mutually monogamous lifetime relationship.
- Monogamy: to be in a long-term, mutually monogamous relationship with an uninfected person. Before starting a mutually monogamous sexual relationship, individuals may consider screening for STDs.
- Reduce the number of lifetime sexual partners.
- Pre-exposure vaccination:
    - HPV vaccine (ages 9 to 26).
    - Hepatitis B vaccine (plus hepatitis A vaccine for men who have sex with men and IV drug users).
- Proper use of male condoms (latex or polyurethane; not "natural" or "lambskin" condoms, which do not protect against viral transmission) with correct use:
    - A new condom with each new sex act.
    - Carefully handle the condom so as not to puncture it.
    - Put condom on after penis is erect.
    - Ensure adequate lubrication.
    - Use only water-based lubricants; oil-based lubricants (petroleum jelly, massage oil, cooking oils) will weaken condom.
    - Hold condom firmly at base during withdrawal to avoid slipping off.
    - Condoms with spermicidal lubricants are not recommended to prevent STDs.
- Proper use of female condoms (lubricated polyurethane or nitrile sheath with a ring on each end, ie,

inserted into the vagina): Use as a protective barrier before intimate contact.

- Adolescents and women who use nonbarrier methods of contraception (hormones, IUDs, surgery) should be counseled about barrier methods to prevent STDs because they may incorrectly perceive that they are not at risk for STDs.
- Spermicides do not prevent STD/HIV transmission; they may increase it by disrupting normal epithelium.

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted diseases (STDs). Atlanta, GA: Author. Available: *www.cdc.gov/std/treatment*.

Evaluation: Expected Outcomes

- Verbalizes increased comfort level and control of symptoms.

Bartholin Cyst or Abscess

Bartholin cyst or *abscess*, also called *bartholinitis*, is an infection of the greater vestibular gland, causing cyst or abscess formation.

Pathophysiology and Etiology

1. These glands lie on both sides of the vagina at the base of the labia minora; they lubricate the vagina.
2. If they become obstructed secondary to infection, abscess or cyst formation may occur (see Figure 22-2).
3. Abscess or cyst may spontaneously rupture or enlarge and become painful.
4. Most are sterile or abscess/cellulitis caused by mixed vaginal flora.
5. May also be caused by sexual transmission of infection (gonorrhea or chlamydia).

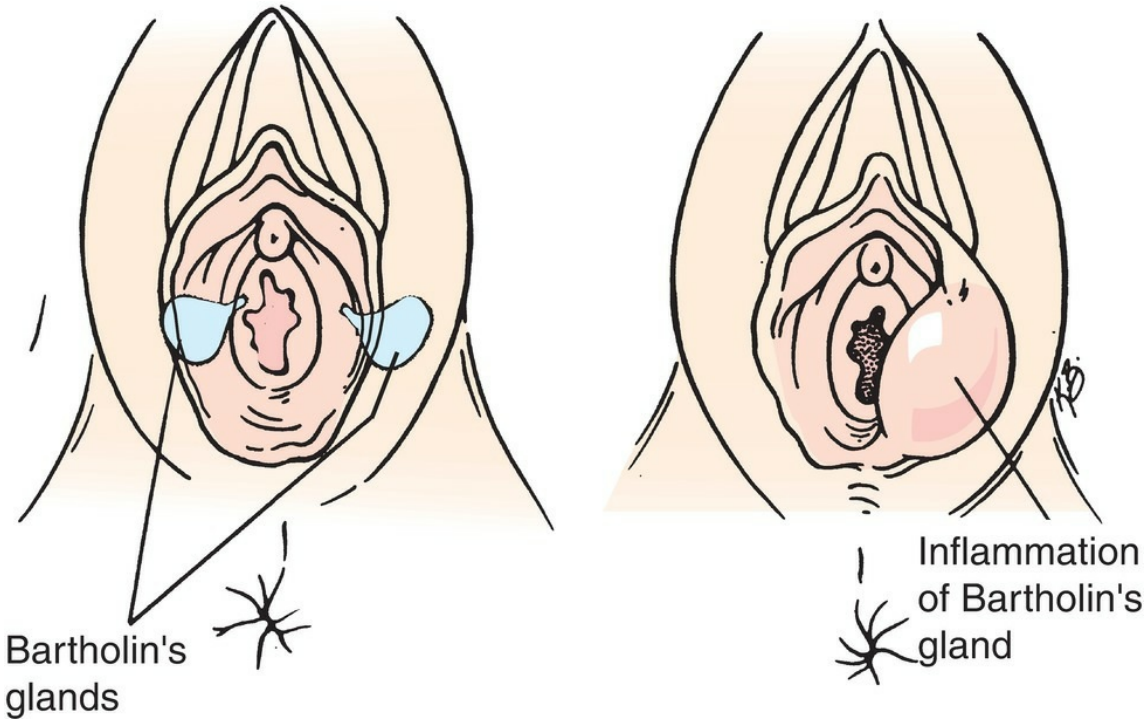


Figure 22-2. Site and infection of vestibular gland.

Clinical Manifestations

1. Asymptomatic cyst.
2. Pain, erythema, tenderness, swelling.
3. Edema, cellulitis, possible abscess formation.

Diagnostic Evaluation

1. Culture, if draining or upon excision, to identify infectious organisms.
2. If older than age 40, or recurrent, carcinoma must be ruled out by biopsy.

Management

1. May be treated conservatively with warm soaks or sitz baths if small or asymptomatic; antibiotics used if cellulitis is present.
2. May need incision and drainage; provides immediate relief, but may recur. Procedures are generally done under local anesthesia and take about 20 minutes in an outpatient office.
    a. Contents are opened and drained; culture sent. Then, sutures are closed.
        i. As an alternative, a Word catheter, Foley catheter, or Jacobi ring is inserted to keep cavity open (called fistulization).
        ii. Healing occurs around catheter and it is removed 2 to 4 weeks later to provide a new opening to the gland.
3. Marsupialization, for recurrent abscesses.
    a. Cyst is incised and sutured open to incision edges.
    b. Healing occurs from within the area of the abscess.
4. Other acceptable methods of treatment include silver nitrate gland ablation, cyst or abscess ablation or excision with a carbon dioxide laser, and needle aspiration with or without alcohol sclerotherapy.
5. Complete excision under general anesthesia if carcinoma is suspected.
6. All treatment methods heal within 2 weeks or less. Recurrence may occur in up to 20% of patients with all treatment methods. No method has been demonstrated to be superior in healing rate or recurrence rate.

Complications

Scarring from recurrent infection and rupture.

Nursing Assessment

1. Obtain history of sexual activity, including new partners and history of STDs. Risk for Bartholin gland cyst or abscess is similar to risk for STDs.
2. Inspect the labia minora for warmth, erythema, and swelling.
3. Assess for signs of other STDs—rash, genital ulcers, and vaginal discharge.

Nursing Diagnoses

- Acute Pain related to infection and enlargement of gland.

Nursing Interventions

Relieving Pain

1. Administer pain medications and antibiotics, as ordered; explain adverse effects to patient.
2. Instruct patient to apply warm soaks or to use sitz bath three to four times per day for 15 to 20 minutes to promote comfort and drainage.

3. Encourage patient to limit activity as much as possible because pain is exacerbated by activity.
4. Prepare patient for incision and drainage, if indicated. Gather supplies for procedure; assist during procedure, as necessary.
5. For marsupialization: apply ice packs intermittently for 24 hours to reduce edema and provide comfort; thereafter, warm sitz baths, a perineal heat pack, or a lamp provides comfort.

Patient Education and Health Maintenance

1. If STD is the suspected cause of infection, advise patient to instruct her partner to be tested and treated prophylactically.
2. Advise patient to abstain from intercourse until cyst or abscess has resolved, partner has been examined and treated, and patient has completed all her antibiotics (approximately 2 weeks).
3. Review principles of perineal hygiene with patient.
4. Discuss STDs and methods of prevention—abstinence, monogamy, and proper use of female or male condoms. See page 653.
5. Encourage patient to follow-up for recurrent abscess to rule out malignant lesions. Surgical treatment is commonly necessary for recurrences.

Evaluation: Expected Outcomes

- Verbalizes relief of pain.

Vaginal Fistula

A *vaginal fistula* is an abnormal, tortuous opening between the vagina and another hollow organ (see Figure 22-3).

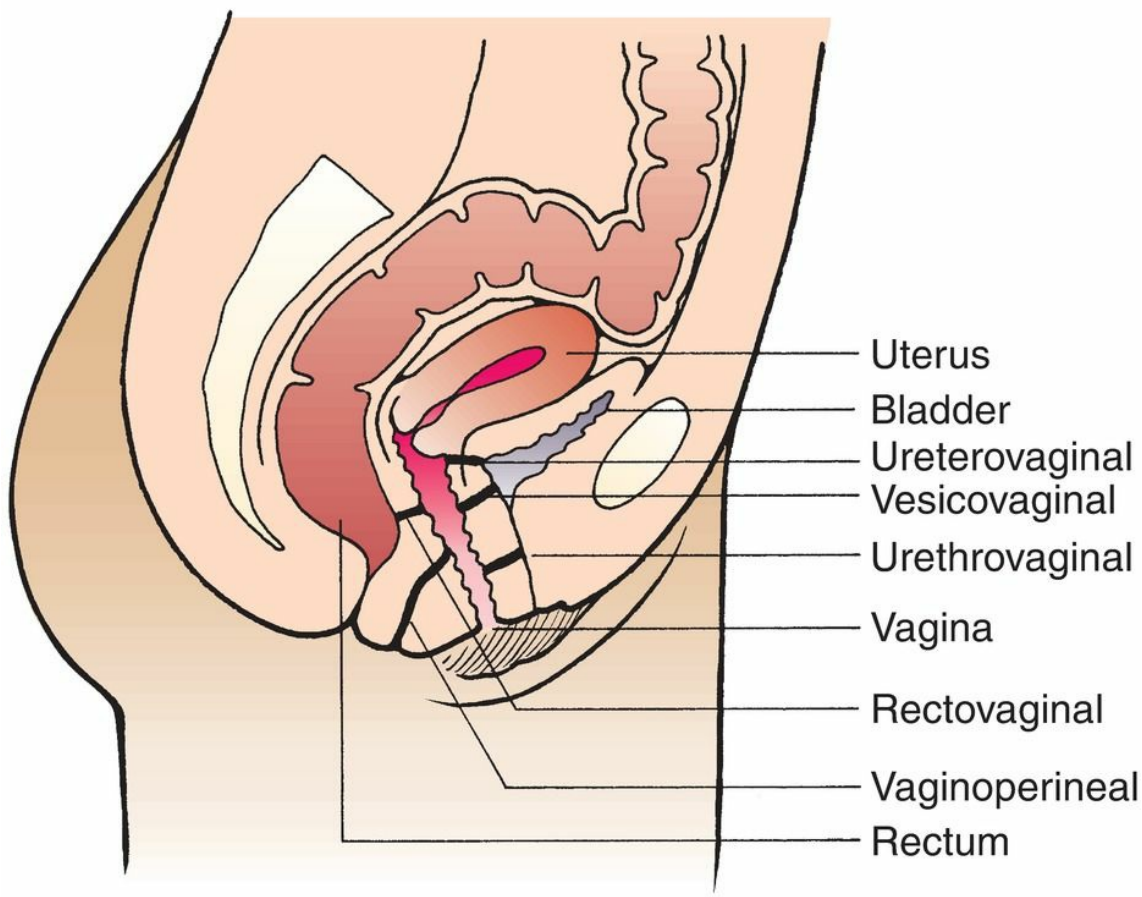

Figure 22-3. Sites of vaginal fistulas. (Smeltzer, S., & Bare, B. [2007]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

Causes

1. Obstetric injury, especially in long labors and in countries with inadequate obstetric care (rarely occurs in developed nations).
2. Pelvic surgery (rare)—hysterectomy or vaginal reconstructive procedures.
3. Carcinoma (rare)—extensive disease or complication of treatment such as radiation therapy.

Types

1. *Vesicovaginal* fistula is an opening between the bladder and vagina.
2. *Rectovaginal* fistula is an opening between the rectum and vagina.
3. *Ureterovaginal* fistula is an opening between the ureter and vagina.

4. *Urethrovaginal* fistula is an opening between the urethra and vagina.
5. *Vaginoperineal* fistula is an opening between the vagina and perineum.

Clinical Manifestations

1. Vesicovaginal—the most common type of fistula.
   a. Constant trickling of urine into the vagina.
   b. Loss of urge to void because the bladder is continuously emptying.
   c. May cause excoriation and inflammation of the vulva.
2. Rectovaginal.
   a. Fecal incontinence and flatus through the vagina; malodorous.
   b. May present as vulvar cancer.
3. Ureterovaginal fistula—rare.
   a. Urine in the vagina but the patient still voids regularly.
   b. May cause severe UTIs.
4. Urethrovaginal fistula.
   a. Dysuria.
   b. Urine in the vagina on voiding.
5. Vaginoperineal fistula—pain and inflammation of the perineum.

Diagnostic Evaluation

1. Methylene blue test—after instillation of this dye in the bladder via catheter, place tampon in the vagina. Remove after the woman has ambulated.
   a. Methylene blue appears in the vagina in vesicovaginal fistula.
   b. Methylene blue does not appear in the vagina in ureterovaginal fistula.
2. Indigo–carmine test—after a methylene blue test shows negative results, indigo carmine is injected intravenously (IV). If dye appears in the vagina, this indicates ureterovaginal fistula.
3. Cystoscopy with retrograde pyelography.
4. Intravenous pyelography (IVP)—helps to detect ureteral fistulas.

Management

1. Fistulas recognized at the time of delivery should be corrected immediately.
2. Historically, surgeries were delayed for 8 to 12 weeks to allow recovery from infection or inflammation. However, early excision and repair within 1 to 2 weeks of urine leakage have become common.
3. Surgical closure of opening via vaginal route is most common in developing nations. In developed nations, laparoscopic, vaginal, or abdominal or robot-assisted routes may be used.
4. Fecal or urinary diversion procedure may be required for large fistulas.
5. Rarely, a fistula may heal without surgical intervention.

6. Medical approach.
    a. Prosthesis to prevent incontinence and allow tissue to heal; done for patients who are not surgical candidates.
    b. Prosthesis is inserted into the vagina; it is connected to drainage tubing leading to a leg bag.

Complications

1. Hydronephrosis, pyelonephritis, and possible renal failure with ureterovaginal fistula.
2. Risk for vaginal infection and pelvic organ infection from rectovaginal fistula.

Nursing Assessment

1. Obtain obstetric, gynecologic, and surgical history.
2. Monitor intake and output and voiding pattern.
3. Assess drainage on perineal pads.
4. Watch for signs of infection (fever, chills, flank pain).

Nursing Diagnoses

- Risk for Infection related to contamination of urinary tract by vaginal flora or contamination of the vagina by rectal organisms.
- Impaired Urinary Elimination related to fistula.

Nursing Interventions

Preventing Infection

1. Encourage frequent sitz baths.
2. Perform vaginal irrigation, as ordered, and teach patient the procedure.
3. Before repair surgery, administer prescribed antibiotics to reduce pathogenic flora in the intestinal tract. A single injectable dose of gentamicin before surgery is as effective as extended use of amoxicillin, chloramphenicol, or cotrimoxazole.
4. After rectovaginal repair:
    a. Maintain patient on clear liquids, as prescribed, to limit bowel activity for several days.
    b. Encourage rest.
    c. Administer warm perineal irrigations to decrease healing time and increase comfort.

Maintaining Urinary Drainage

1. Suggest the use of perineal pads or incontinence products preoperatively.
2. After vesicovaginal repair:
    a. Maintain proper drainage from indwelling catheter (intermittent flushing with sterile normal saline) to prevent pressure on newly sutured tissue (usually for about 7 days postoperatively).
    b. Administer vaginal or bladder irrigations gently because of tenderness at operative site.

c. Maintain strict intake and output records. IV fluids or copious oral fluid intake may be recommended to maintain good bladder flow.
d. Prophylactic antibiotics to prevent infection may be recommended.

3. If medical management is indicated, teach patient the use of prosthetic device.
4. Encourage patient to express feelings about her altered route of elimination and share them with a significant other.

Patient Education and Health Maintenance

1. Teach patient to report signs of infection early.
2. Teach the patient to clean the perineum gently and to follow surgeon's instructions on when to resume sexual intercourse and strenuous activity.
3. Advise patient to keep regular follow-up appointments.

Evaluation: Expected Outcomes

- No signs of infection—afebrile and no complaints of flank pain or difficulty voiding.
- Clear urine flows from catheter postoperatively; voids without difficulty after catheter removal.

Vaginitis

Vaginitis is inflammation of the vagina caused by infectious pathogens.

Pathophysiology and Etiology

1. May be caused by sexually transmitted organisms or overgrowth of vaginal flora.
2. Normal vaginal secretions because of estrogen secretion and acidity inhibit the growth of pathogens.
3. Such conditions as diabetes, pregnancy, stress, coitus, and menopause alter normal vaginal environment.
4. Types of vaginitis (see Table 22-3).
    a. Simple (contact).
    b. Bacterial vaginosis (most often caused by *Gardnerella*).
    c. *Trichomonas*.
    d. *Candida albicans*.
    e. Atrophic.

Table 22-3 Types of Vaginitis

DESCRIPTION	MANIFESTATIONS	MANAGEMENT
Simple Vaginitis (Contact Vaginitis)		
• An inflammation of the vagina, with discharge; due to mechanical, chemical, allergic, or other noninfectious irritation, poor hygiene, imbalance in vaginal flora. • Urethritis commonly accompanies vaginitis because of the proximity of the urethra to the vagina. • Predisposing factors: contact allergens, excessive perspiration, synthetic underclothing, poor hygiene, foreign bodies (tampons, condoms, spermicides, condoms with spermicides, diaphragms that have been left in too long).	• Increased (yet minimal) vaginal discharge with itching, redness, burning, and edema. • Voiding and defecation aggravate the above symptoms.	• Stimulate the growth of lactobacilli (Doderlein bacilli) through consumption of yogurt with live active cultures. • Current evidence does not support douching. • Foster cleanliness by meticulous care after voiding and defecation. • Discontinue use of causative agent.
Bacterial Vaginosis		
• An inflammation of the vagina commonly referred to as nonspecific vaginitis because it is *not* caused by *Trichomonas*, *Candida*, or gonorrhea. It is not considered an STD. • Increased levels of *Gardnerella vaginalis* are usually responsible for symptoms.	• Vaginal discharge with odor. • Itching and burning may suggest concomitant organisms present. • It is benign in that when the discharge is wiped away, underlying tissue is healthy and pink. • Vaginal pH is >4.5. • May be asymptomatic. • Presence of "clue" cells on microscopic examination of saline slide • Positive KOH "whiff" test (fishy odor).	• Treatment only recommended for symptomatic women. • Metronidazole taken orally for 7 days or topical clindamycin or metronidazole. • Alcohol intake should be avoided during metronidazole treatment and for 24 hr after completion to avoid nausea and vertigo. Studies have demonstrated that metronidazole is not teratogenic. • Treating partners is not recommended. • Clindamycin cream weakens latex condoms. • Data do not support douching.
Trichomonas vaginalis		
• STD. A condition produced by a protozoan (pear-shaped and motile) that thrives in an alkaline environment. Recurrence may occur because of low levels of antimicrobial resistance.	• Copious malodorous discharge; may be frothy and yellow-green in color. • May have pruritus, dyspareunia, and spotting. • Red, speckled (strawberry) punctate hemorrhages on the cervix. • May also have vulvar edema, dysuria, and hyperemia secondary to irritation of discharge. • Motile organisms visible on saline microscopy. • Point of care rapid test and cultures are available.	• Destroy infective protozoa by taking oral metronidazole 2 g or tinidazole 2 g. • *Note:* Treatment during pregnancy is acceptable after the first trimester for tinidazole and throughout pregnancy for metronidazole. • Prevent reinfection by treating partner concurrently, even though male may be asymptomatic. • Avoid alcohol during treatment. • Rescreen after 3 months because of possibility of low-level antimicrobial resistance.
Candida albicans		

• A fungal infection caused by *Candida albicans*. Associated factors include:
  • Steroid therapy
  • Obesity
  • Pregnancy
  • Antibiotic therapy
  • Diabetes mellitus
  • Oral contraceptives
  • Frequent douching
  • Chronic debilitative diseases
• Characteristics
  • *C. albicans* is a normal inhabitant of the intestinal tract and therefore a frequent contaminant of the vagina.
  • Because this fungus thrives in an environment rich in carbohydrates, it is seen commonly in patients with poorly controlled diabetes.
  • This infection is observed in patients who have been on antibiotic or steroid therapy for a while (reduces natural protective organisms in the vagina).
	• Vaginal discharge is thick and irritating; white or yellow patchy, cheese-like particles adhere to vaginal walls.
	• Itching is the most common complaint.
	• May also experience burning, soreness, vulvar edema, excoriations, fissures, dyspareunia, frequency, and dysuria.
	• Microscopic examination will reveal hyphae, buds, and pseudohyphae.
	• Vaginal pH is normal (<4.5).
		• Eradicate the fungus by applying antifungal vaginal cream (clotrimazole, miconazole, or ketoconazole), suppository, or tablet for 1 to 14 nights, as ordered; or, take oral fluconazole in single dose.
		• Oral fluconazole is contraindicated in pregnancy; topical creams may be used.
		• Side effects of topical vaginal creams include burning and irritation. Systemic fluconazole is associated with GI intolerance, headaches, and rare and transitory elevations in liver function tests.
		• Azole antifungals have clinically important interactions with many medications.
		• Incorporate live culture yogurt into diet to enhance lactobacillus colonization and improve microorganism balance in the vagina.
		• Treat the symptomatic or uncircumcised partner with balanitis by applying antifungal cream under the foreskin nightly for 7 nights.
		• For severe or recurrent cases, use systemic antifungal, such as weekly fluconazole for suppression therapy.

Atrophic Vaginitis

- A common postmenopausal occurrence due to atrophy of the vaginal mucosa secondary to decreased estrogen levels; more susceptible to infection.
- Vaginal itching, dryness, burning, dyspareunia, and vulvar irritation.
- May also have vaginal bleeding.
- Vaginal mucosa appears dry and slightly paler.

NURSING ALERT In the postmenopausal woman, if vaginal bleeding occurs, encourage patient to see her health care provider immediately because bleeding is a warning sign of cancer.

- Vaginal estrogen treatment is most effective.
- The condition reverses itself under treatment, which must be maintained.
- If infection is also present, this is treated.
- If the uterus is intact and systemic estrogen therapy is used to treat additional menopausal symptoms, progesterone must be added to prevent endometrial hyperplasia due to unopposed estrogen.

STD, sexually transmitted disease.

Clinical Manifestations

Signs and symptoms vary with etiology or causative organism.

1. Vaginal itching, irritation, burning.
2. Odor and increased or unusual vaginal discharge.
3. Dyspareunia, pelvic pain, dysuria.
4. Asymptomatic.

Diagnostic Evaluation

1. History and physical examination.
2. Wet smear for microscopic examination.
   a. Saline slide: discharge mixed with saline; useful in detecting *Gardnerella* and *Trichomonas* organisms.
   b. Potassium hydroxide (KOH): useful in detecting *C. albicans*. Whiff test: if fishy odor is noted when KOH is applied, suspect *Gardnerella* organisms causing bacterial vaginosis.
3. Vaginal pH (not diagnostic, but may indicate infection)—use Nitrazine paper.
   a. Normal pH: 4.0 to 4.5.
   b. Bacterial vaginosis: greater than 4.5.
   c. *Trichomonas*: greater than 4.5.
4. Chlamydia and gonorrhea cultures or DNA probe—to rule out chlamydia or gonorrhea cervicitis.
5. Pap smear—not considered a diagnostic tool for vaginitis: it has low sensitivity and specificity to detect bacterial vaginosis and *Trichomonas*.

Management

1. Anti-infectives (oral or vaginal preparations).
2. Estrogen replacement (systemic or vaginal preparation) for atrophic vaginitis.
3. Evaluation and treatment of sexual partners for STDs, such as *Trichomonas*.
4. Vaginal recolonization with lactobacilli through ingestion of yogurt with active cultures.

Nursing Assessment

1. Obtain a health history including questions specific to the condition.
    a. Nature of discharge: cheeselike, frothy, puslike, thick or thin, or scant? Onset? Color? Odor? Other symptoms: dysuria, itching, and dyspareunia?
    b. Menstrual history.
    c. Disease history: diabetes mellitus and its control? Previous vaginal infections? STDs?
    d. Obstetric history.
    e. Sexual history: age of onset of sexual activity? New partner? Numbers of current and lifetime partners? Frequency of sexual activity? Its nature? Urogenital symptoms or infections in partner? Current barrier use?
    f. Medications and allergies. Current contraceptive use?
    g. Vaginal hygiene: use of douches, deodorants, sprays, and ointments; types of tampons, bubble bath, shower/bath soap, and nature of clothing (tight-fitting)?
2. Perform a physical examination, including a vaginal examination, and obtain vaginal and/or cervical discharge specimens, as indicated.

Nursing Diagnoses

- Acute or Chronic Pain related to vaginal irritation.
- Impaired Tissue Integrity related to vaginal infection.
- Risk-Prone Health Behavior related to sexual activity and transmission of infection.

Nursing Interventions

Relieving Pain

1. Instruct patient to discontinue use of irritating agents, such as bubble baths and vaginal douches.
2. Suggest that the patient take cool baths or sitz baths and pat dry or dry with hair dryer on low setting.
3. Encourage the patient to wear loose cotton undergarments.
4. Encourage the patient to take analgesics.
5. Provide emotional support.

Restoring Tissue Integrity

1. Teach the patient to clean the perineum and pat dry before applying medication.
2. Demonstrate application of prescribed medication.
3. Emphasize importance of taking prescribed medication for full length of therapy and as directed; teach patient adverse effects.
4. Stress importance of follow-up visits.

Reducing Risk

1. Emphasize importance of sexual abstinence and vaginal rest (nothing in the vagina) until therapy is complete and sexual partner has been treated, if indicated.

2. Tell patient use of condoms may be protective but may produce irritation.
3. Instruct the patient in the use of water-soluble lubricant if the vagina is dry and atrophic.
4. Instruct the patient that some oil-based vaginal medications may decrease the efficacy of condoms to protect against STDs and pregnancy.

Patient Education and Health Maintenance

1. Teach causes of vaginitis and its symptoms so patient can seek treatment promptly.
2. Discuss STDs and methods of prevention—abstinence, monogamy, and proper use of female or male condoms. See page 653.
3. Teach measures to prevent vaginitis.
   a. Wipe from front to back after toilet use.
   b. Keep area clean and dry.
   c. Wear loose cotton clothing to absorb moisture and provide good circulation.
   d. Change sanitary pads and tampons frequently so they do not become saturated.
   e. Avoid bubble baths, vaginal deodorants, sprays, and douches.
   f. If the patient insists on using douches (not recommended), use a mild vinegar solution (2 teaspoons white vinegar to 1 quart water) at the end of a menstrual cycle. Teach proper technique: to infuse gently to lightly bathe tissues and to avoid using a forceful stream that could push bacteria higher inside the pelvis.
4. For recurrent *Candida* infections, encourage good control if the patient has diabetes or encourage the patient to be tested for diabetes. Teach all patients to eliminate concentrated carbohydrates from diet to prevent recurrence.

Evaluation: Expected Outcomes

- Verbalizes relief of pain.
- Vaginal mucosa pink, with normal amount and color of secretions.
- Reports practice of prevention methods.

Human Papillomavirus Infection

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted diseases treatment guidelines. Available: *www.cdc.gov/std/treatment*.

Human papillomavirus (HPV) infection may be asymptomatic but frequently causes *condyloma acuminatum* or genital warts.

Pathophysiology and Etiology

1. Sexually transmitted; highly contagious.
2. More than 40 types of HPV can infect the genital tract, many are asymptomatic, and multiple types may coexist.
3. Ninety percent of visible genital warts are caused by HPV types 6 and 11. Up to 70% of cervical cancer and precancerous lesions are caused by types 16 and 18. Types 31, 33, 45, 52, 58, and others have been strongly associated with cervical dysplasia.
4. Incubation period of up to 8 months.

Clinical Manifestations

1. Single or multiple soft, fleshy painless growths of the vulva, vagina, cervix, urethra, or anal area that may be irritating or uncomfortable (see Figure 22-4).
2. May be subclinical infection and still contagious.
3. Occasional vaginal bleeding, discharge, odor, and dyspareunia.

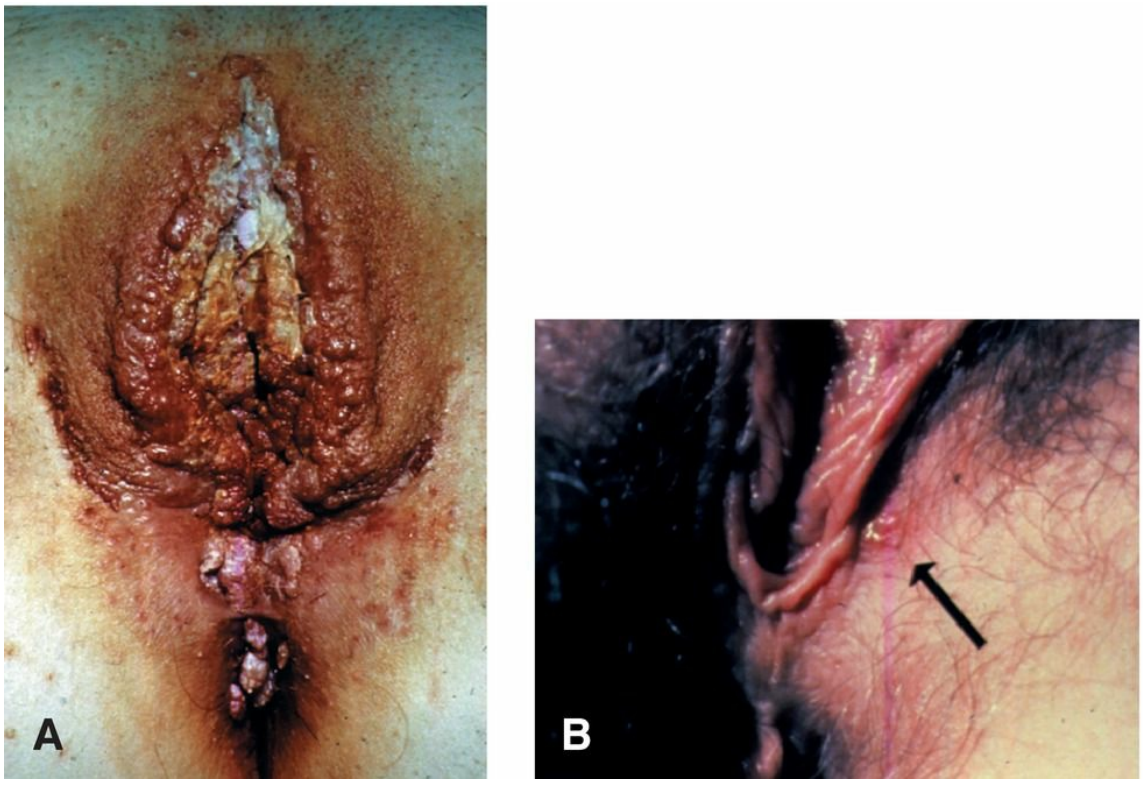

Figure 22-4. Genital lesions. **(A)** Condyloma acuminatum. **(B)** Genital herpes.

Diagnostic Evaluation

1. Pap smear—shows characteristic cellular changes (koilocytosis).
2. Acetic acid swabbing on vaginal examination will whiten lesions and make them more identifiable in genital mucosa. However, this test is not specific to HPV and is not recommended for screening.
3. Viral DNA tests to detect subclinical cases; however, the significance of positive and negative results has not been determined. HPV testing can be done from a liquid Pap smear cervical cancer screening for women older than 30 years, if the Pap smear is abnormal (known as reflex testing), to confirm the presence of HPV causing cellular changes on the cervix. HPV testing is not recommended for genital wart diagnosis.
4. Colposcopy is also used to diagnose subclinical HPV infection.
5. Anoscopy or urethroscopy may be necessary to identify anal and urethral lesions.
6. Genital warts are usually diagnosed on physical exam through visual inspection.

Management

Therapies are likely to reduce HPV infectivity but do not eradicate HPV. Treatment method is guided by provider and patient preferences.

1. External lesions may be treated by the patient with multiple applications of a topical preparation.
   a. Podofilox—applied with cotton swab or finger to visible warts twice per day for 3 days and then no treatment for 4 days; may be repeated for up to four cycles of therapy.

b. Imiquimod—applied by finger three times per week for up to 16 weeks; may be washed off 6 to 10 hours after application.
   c. Sinecatechins ointment—applied by finger three times daily for up to 16 weeks; not washed off after use.
   d. Safety of these products during pregnancy is unknown and therefore is not recommended.
2. Noncervical lesions may be treated by health care provider with topical preparations, such as podophyllin resin, trichloroacetic acid, or bichloroacetic acid.
   a. Requires multiple visits for repeat treatments.
   b. May require washing off several hours later.
3. Cryotherapy with liquid nitrogen or cryoprobe, electrocautery, laser treatment, or local excision of large warts or cervical lesions.
4. Highly recurrent, particularly in first 3 months—may require retreatment.
5. Subclinical genital HPV infection typically clears spontaneously and treatment is not recommended.
6. Three vaccines for HPV are available in the United States.
   a. Bivalent human papillomavirus vaccine types 16 and 18; recombinant.
   b. Quadrivalent vaccine human papillomavirus vaccine types 6, 11, 16, and 18; recombinant.
   c. 9-valent vaccine types 6, 11, 16, 18, 31, 33, 45, 52, and 58.
7. Vaccine schedule: ACIP recommends anyone starting the series before age 15 receives two doses of vaccine at least 6 months apart. If the two doses are received less than 5 months apart, a third dose of vaccine is recommended.
   a. The Centers for Disease Control and Prevention (CDC) recommends all vaccines for females aged 11 or 12 to 26 (licensed for ages 9 to 26).
   b. The quadrivalent vaccine is recommended for males aged 11 or 12 to 26 (licensed for ages 9 to 26).
   c. They are most effective when all doses are administered before the onset of sexual activity.

Complications

1. Implicated in cervical intraepithelial neoplasia.
2. May cause neonatal laryngeal papillomatosis if infant born through infected birth canal.
3. Obstruction of anal canal and vagina by enlarging lesions.
4. Scarring and pigment changes if treatment not employed properly.

Nursing Assessment

1. Obtain history of STDs, Pap test results, and sexual partners.
2. Inspect external genitalia for lesions; assist with vaginal examination.

Nursing Diagnosis

- Disturbed Body Image related to genital warts.

Nursing Interventions

Improving Body Image

1. Explain to the patient that the goal of therapy is to remove visible lesions; however, HPV will not be cured or eliminated. Genital warts are not life-threatening.
2. Encourage the patient to comply with treatment schedule and inspect areas for resolution of lesions or redevelopment of new lesions.
3. Advise the patient of high recurrence rate; 3-month follow-up visit is advisable; if lesions redevelop, the patient should follow up for retreatment.
4. Advise patient about proper use of male or female condoms to reduce the risk of transmission, although not fully because HPV can infect areas not covered by the condom. Condom use, abstinence, and monogamy will protect against other STDs.
5. Encourage female patients to follow up regularly for Pap tests because HPV has been associated with cervical neoplasia.
6. Advise patient of risk to neonate during delivery; patient should receive close prenatal care if pregnant.

Patient Education and Health Maintenance

1. Advise patient to discuss HPV with her partner. He should receive treatment for visible lesions. Screening for other STDs in both patient and partner is recommended.
2. Make sure patient realizes that even though lesions may be gone, she may still transmit HPV to new sexual partners. Abstinence, monogamy, and condoms are advisable to prevent transmission of all STDs. See page 653.

Evaluation: Expected Outcomes

- Presents with no visible lesions at follow-up visit.

Herpes Genitalis

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted diseases treatment guidelines. Available: *www.cdc.gov/std/treatment*.

Herpes genitalis is a viral infection that causes lesions of the cervix, vagina, and external genitalia.

Pathophysiology and Etiology

1. Caused by HSV, usually type 2, but may be type 1.
2. Sexually transmitted.
3. An estimated 50 million people are infected in the United States.
4. Recurrent infection; virus lies dormant in dorsal root ganglia of spinal nerves between outbreaks.

Clinical Manifestations

1. Lesions occur 2 to 30 days after initial exposure, sometimes with fever, malaise, lymphadenopathy, and headache for primary infection (see Figure 22-4, page 658).
2. Lesions are preceded by sensation of tingling; proceed from vesicles on erythematous, edematous base to painful ulcers that crust and heal without scars.
3. Internal lesions may cause watery discharge and dyspareunia.
4. Recurrent lesions may be stimulated by fever, stress, illness, local trauma, menses, and sunburn.
5. Infection can be asymptomatic.

Diagnostic Evaluation

1. PCR assay for HSV DNA and viral culture are preferred tests. Failure to detect HSV by PCR or culture does not rule out HSV infection because viral shedding is intermittent.
2. Pap smear and Tzanck smear are neither sensitive nor specific for HSV and therefore not recommended.
3. Type-specific glycoprotein G (gG) serological tests—to detect HSV-1 or HSV-2 antibodies in the following cases: recurrent or atypical genital symptoms with negative viral culture, clinical diagnosis of genital herpes without laboratory confirmation, partner with genital herpes, persons presenting for STD evaluation, and persons with HIV.
4. Screening in the general population for HSV1 and HSV2 is not recommended.

Management

1. Systemic antivirals, such as acyclovir, famciclovir, and valacyclovir, suppress virus and decrease length, severity, and shedding of infection.
    a. Oral therapy may be episodic—started as soon as the first episode is diagnosed and whenever the first

signs of a recurrence are recognized (within 24 hours of onset of prodromal symptoms or lesion onset).

   b. Oral therapy may be given continuously to suppress recurrences and viral shedding, which reduces transmission, especially within the first 12 months of disease onset.
   c. IV administration (acyclovir) may be necessary for severe infections (disseminated infections, pneumonitis, hepatitis, meningoencephalitis) or for immunocompromised patients.
   d. Topical treatment (acyclovir) is the least effective and not recommended.
2. Pain medication—ranges from acetaminophen and NSAID drugs to oral opioids.
3. Local comfort measures, such as lidocaine gel, sitz baths, compresses, and use of a hair dryer to area on cool setting.
4. Immunization has been under investigation. See *www.clinicaltrials.gov*.

Complications

1. Disseminated infection, meningitis, pneumonitis, and hepatitis.
2. Neonatal infection if neonate born through infected canal.

Nursing Assessment

1. Question the patient about frequency and type of sexual activity and discomfort noted.
2. Question the patient about pruritus, burning, tenderness, urinary symptoms, and unusual discharge.
3. Assess the patient's view of herpes, transmission, stigmas, misconceptions, and fears.
4. Inspect genitalia for lesions, erythema, and edema. Use a speculum to examine the vagina and cervix, as indicated.

Nursing Diagnoses

- Acute Pain related to HSV outbreak.
- Impaired Skin Integrity related to herpetic lesions.
- Anxiety related to stigma attached to herpes.
- Sexual Dysfunction related to potential transmission of herpes.

Nursing Interventions

Relieving Pain

1. Demonstrate and encourage the use of warm sitz baths to increase blood supply to the areas and facilitate healing.
2. Instruct patient to keep the area clean and dry. Pat dry with a clean towel or use blow dryer on cool setting. Wear loose cotton undergarments and loose clothing.
3. Encourage bed rest if case is severe.
4. Administer pain medications, as prescribed.
5. Encourage the patient to void in a warm sitz bath if urination is painful.

6. Insert indwelling catheter if urination is extremely painful or if retention occurs.
7. Encourage fluid intake.

Restoring Skin Integrity

1. Administer an antiviral agent and teach the patient proper use and adverse effects.
2. Keep lesions clean and dry.
3. Teach the patient not to rub or to scratch lesions.

Relieving Anxiety

1. Explore with the patient her feelings about herpes and its effects on relationships.
2. Reiterate that when the patient is feeling better physically, her feelings about herself will improve.
3. Encourage the patient to discuss antiviral suppressive therapy to reduce the risk of transmission and to reduce frequency and duration of recurrent outbreaks.
4. Discuss effects of stress on future outbreaks. Assist the patient to identify stressors in her life and how to cope with them. Review stress-reduction methods, such as relaxation, breathing, and imagery.
5. Encourage the patient to discuss her feelings with family and significant others.

Restoring Satisfying Sexual Function

1. Teach the patient to avoid intercourse from first sign of active outbreak (often a tingling sensation) to resolution of lesions (at least 2 weeks after primary infection, approximately 1 week after recurrent outbreaks).
2. Teach the patient that shedding of virus through genital secretions is possible even during asymptomatic period, so the partner must be notified.
3. Inform the patient that she and her partner should use condoms for intercourse, but condoms may not be fully protective. Encourage the patient to discuss suppressive antiviral therapy with her health care provider.
4. Explore possibility of noncoital aspects of sexual relationship.
5. Teach patient that virus may be spread through the genital–oral route.

Patient Education and Health Maintenance

1. Inform the patient that initial outbreak is usually more painful than recurrent outbreaks and that outbreaks vary from monthly to only a few times per year.
2. Teach the patient to recognize precipitating factors and change lifestyle to prevent potential triggers, if possible.
3. Remind the patient of the effects on a neonate and the importance of notifying her health care provider if she becomes pregnant.
4. Instruct the patient in methods to decrease risk of sexual transmission: abstinence, monogamy, male or female condom use, and antiviral suppressive therapy. See patient page 653. The patient must inform partner of the risk of transmission to a potential sexual partner before any intimate contact. Viral

shedding is highest during the prodromal and active lesion stages.

5. Tell the patient that oral lesions can occur with HSV2 because of transmission by oral intercourse, but that most oral cold sores are caused by HSV-1 infection.
6. Refer the patient to support groups, such as the American Social Health Association (*www.ashastd.org* or 800-227-8922).

Evaluation: Expected Outcomes

- Verbalizes decreased pain.
- Skin intact, without signs of secondary infection and scarring.
- Verbalizes reduced anxiety and more confidence.
- Reports satisfying sexual activity.

Chlamydial Infection

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted diseases treatment guidelines. Available: *www.cdc.gov/std/treatment*.

Chlamydia infection is the most common STD that occurs in women and men, particularly in adolescents and young adults. Women are asymptomatic or present with cervicitis; men are commonly asymptomatic but may present with urethritis.

Pathophysiology and Etiology

1. Chlamydia infection in women is the result of sexual intercourse, with infection entering the vagina, infecting the cervix and, possibly, spreading up through the endometrium and fallopian tubes.
2. Adolescents and young women ages 15 to 24 are at highest risk for infection, possibly because of susceptibility of cervical tissue to the organism and higher-risk sexual behaviors in this age group.
3. *C. trachomatis* is the most common sexually transmitted pathogen in men and women in the United States, with an incidence of more than 456.1 cases per 100,000 people.

Clinical Manifestations

1. May be asymptomatic or have vaginal discharge—may be clear mucoid to creamy discharge.
2. May have dysuria and mild pelvic discomfort.
3. May have intermenstrual spotting.
4. The cervix may be covered by thick mucopurulent discharge and be tender, erythematous, edematous, and friable.

Diagnostic Evaluation

1. DNA testing (or nucleic acid hybridization tests or NAATs) of cervical swab, vaginal swab, urine, or male urethral swab—most sensitive and specific; can be done simultaneously for gonorrhea.
2. Chlamydia culture from cervical exudate and cervical mucosa.
3. The CDC recommends annual screening for all sexually active women younger than age 25 and for older women at high risk (multiple sex partners or new partner).

Management

1. Antibiotic regimens include:
    a. Azithromycin 1 g orally in a single dose.
    b. Doxycycline 100 mg orally twice per day for 7 days.
    c. Alternatives include erythromycin, levofloxacin, or ofloxacin.

2. Current and/or most recent sexual partners (during 60 days or more preceding onset) should be tested and treated despite test results.

NURSING ALERT Because chlamydia infection and gonorrhea frequently coexist, especially in adolescents and young adults, treatment of both STDs is recommended.

Complications

1. PID.
2. Ectopic pregnancy or infertility secondary to untreated or recurrent PID.
3. Transmission to neonate born through infected birth canal.

Nursing Assessment

1. Obtain history of sexual activity and symptoms or infections in partner.
2. Perform abdominal and pelvic examination for tenderness caused by possible spread to pelvic organs.

Nursing Diagnosis

- Risk for Infection related to sexual activity.

Nursing Interventions

Preventing Infection Transmission

1. Advise abstinence from sexual intercourse until 7 days after treatment has been completed.
2. Ensure that partner is treated at the same time; recent partners should receive treatment despite lack of symptoms and negative chlamydia test result. Abstinence should continue until 7 days after partners have completed treatment.
3. Report case to local public health department (chlamydia is a reportable infectious disease in most of the United States).
4. Ensure that patient begins treatment and will have access to prescription and transportation for follow-up. Single-dose azithromycin as directly observed therapy is often a good choice for patients with limited access to health care resources.
5. Retesting for chlamydia is recommended 3 months after treatment to detect reinfection, particularly in adolescents and young women.

Patient Education and Health Maintenance

1. Teach about all STDs, mode of transmission, symptoms, and complications. Clarify misconceptions.
2. Explain the treatment regimen to the patient, and advise her of adverse effects and the importance of informing her partner about the need for treatment.

3. Discuss STDs and methods of prevention—abstinence, monogamy, and proper use of female or male condoms. See page 653.
4. Stress the importance of follow-up examination and retesting. Recurrence rates are highest in younger patients.
5. Encourage screening periodically for at-risk women.
6. For further information on STDs, refer patients to such agencies as the American Social Health Association (*www.ashastd.org* or 800-227-8922).

Evaluation: Expected Outcomes

- Returns for follow-up; states complied with abstinence during treatment of self and partner; verbalizes use of measures to prevent STD transmission.

Gonorrhea

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted diseases treatment guidelines. Available: *www.cdc.gov/std/treatment*.

Gonorrhea is a common STD that affects men and women, causing cervicitis in women and urethritis in men. In women, it can easily ascend to the uterus and fallopian tubes, if untreated.

Pathophysiology and Etiology

1. Gonorrhea is caused by the gram-positive diplococci *Neisseria gonorrhoeae*.
2. Infection occurs through sexual transmission, causing cervicitis in women and possible conjunctivitis, pharyngitis, and proctitis.
3. Untreated infection may lead to PID, generalized dissemination, or gonococcal arthritis.
4. Gonorrhea has an incidence of 110.7 cases per 100,000 population in the United States each year; teens and young adults are most commonly affected.

Clinical Manifestations

1. Frequently asymptomatic in women.
2. May cause mucopurulent vaginal discharge or a painful burning sensation when urinating.
3. Vaginal speculum examination may reveal cervical discharge and inflammation.
4. Cervical motion tenderness and tender pelvic organs on bimanual examination if infection has begun to ascend.

Diagnostic Evaluation

1. DNA testing (or nucleic acid hybridization tests or NAATs) of cervical swab, vaginal swab, urine, or male urethral swab (most sensitive and specific; can be done simultaneously for chlamydia).
2. Endocervical culture should be performed to provide antimicrobial susceptibility results.
3. Pharyngeal or conjunctival secretions can be tested if pharyngitis or conjunctivitis is suspected. Follow laboratory specifications for these tests.
4. Joint aspiration and blood cultures may be necessary if disseminated infection is suspected.

Management

1. Uncomplicated gonococcal infection of the cervix, urethra (in men), or rectum (in men or women) can be treated with a single-dose antibiotic, such as the following (plus treatment for coinfection with chlamydia):
   a. Cefixime 400 mg orally.

b. Ceftriaxone 250 mg IM.

c. Alternative regimens involving other cephalosporins are also approved.

2. Pharyngeal infections should be treated for coinfection with chlamydia with the following:

a. Ceftriaxone 250 mg IM single dose *plus*.

b. Azithromycin 1 g orally single dose or doxycycline 100 mg orally twice daily × 7 days.

3. Gonococcal conjunctivitis should be treated with ceftriaxone 1 g IM single dose plus concomitant chlamydial treatment.

4. Disseminated infections require IV or IM therapy, such as:

a. Ceftriaxone 1 g IM or IV every 24 hours.

b. Cefotaxime 1 g IV every 8 hours.

c. Ceftizoxime 1 g IV every 8 hours.

5. For IV or IM therapy, patient is switched to oral therapy 24 to 48 hours after improvement and then takes cefixime 400 mg orally twice daily to complete 7 days of antimicrobial therapy.

6. In all cases of suspected gonorrhea, concomitant treatment of chlamydia is recommended with appropriate second antibiotic agent.

DRUG ALERT Fluoroquinolone therapy is no longer recommended for treatment of gonorrhea in the United States because of resistance.

Complications

1. PID, ectopic pregnancy, and infertility.
2. Disseminated infection.
3. Ophthalmia neonatorum and sepsis (rare) caused by infant born through infected birth canal.

Nursing Assessment

1. Question the patient on history of STDs, STD protection, sexual activity, and usual women's health self-care practices.
2. Obtain history of symptoms in patient and partner—incubation period is usually 3 to 7 days in men, but symptoms are typically overlooked in women.
3. Assess for ability to change lifestyle practices that may have led to STD.

Nursing Diagnosis

- Risk for Infection related to sexual activity.

Nursing Interventions

Stopping Transmission of STD

1. Administer antibiotics, as prescribed, explaining adverse effects to patient.
2. Make sure that patient can obtain prescription medication at discharge.
3. Monitor for relief of pain, discharge, and other symptoms.
4. Explain importance of sexual abstinence until symptoms are resolved completely and until 7 days after therapy is complete in patient and partner.
5. Report to public health department and tell patient that information will be obtained to ensure testing of sexual contacts.

Patient Education and Health Maintenance

1. Teach patient about all possible STDs, their prevalence, and their mode of transmission. Clarify misconceptions.
2. Advise patient of complications of gonorrhea and chlamydia.
3. Discuss STDs and methods of prevention—abstinence, monogamy, and proper use of female or male condoms. See page 653.
4. Stress the importance of follow-up examination and testing to ensure eradication of infection. Encourage follow-up for routine women's health care and periodic STD screening.
5. For additional information, refer to the American Social Health Association (*www.ashastd.org*) or Centers for Disease Control and Prevention (*www.cdc.gov/std/default.htm*).

Evaluation: Expected Outcomes

- Reports resolution of symptoms and use of condoms, abstinence, or other prevention measures at follow-up visit.

PROBLEMS RESULTING FROM RELAXED PELVIC MUSCLES

Cystocele is a downward displacement (protrusion) of the bladder into the vagina (see Figure 22-5). *Urethrocele* is downward displacement of the urethra into the vagina.

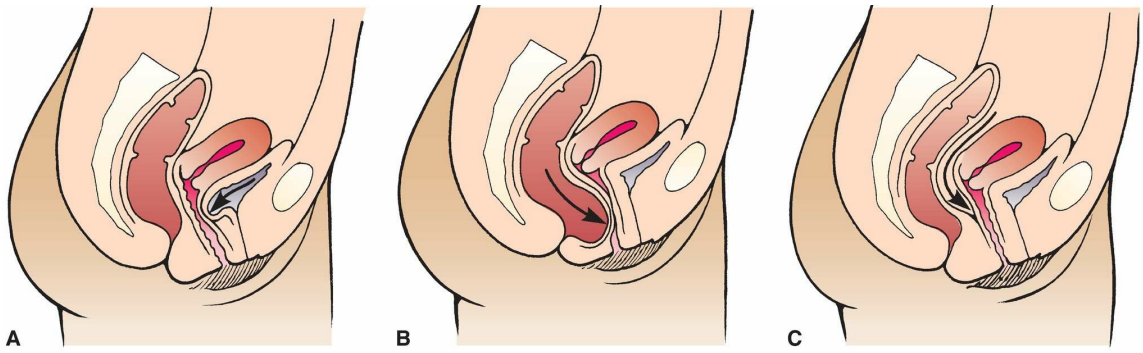

Figure 22-5. Pelvic support disorders. **(A)** Cystocele. **(B)** Rectocele. **(C)** Enterocele. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

1. Associated with obstetric trauma to fascia, muscle, and ligaments during childbirth (results in poor support).
2. Typically becomes apparent years later, when genital atrophy associated with aging occurs.
3. May also be caused by congenital defect or may appear after hysterectomy.

Clinical Manifestations

1. May be asymptomatic in early stages.
2. Pelvic pressure or heaviness, backache, nervousness, and fatigue.
3. Urinary symptoms—urgency, frequency, incontinence, and incomplete emptying.
4. Aggravated by coughing, sneezing, standing for long periods, and obesity, which increase intra-abdominal pressure.
5. Relieved by resting or by lying down.

Diagnostic Evaluation

1. Pelvic examination identifies condition.
2. Urinalysis and culture are done to rule out infection.

Management

1. Vaginal pessary—silicone (can be latex or polycarbonate) device inserted into the vagina as temporary

treatment to support pelvic organs.

   a. Prolonged use may lead to necrosis and ulceration.
   b. Should be removed and cleaned at least once weekly.

2. Estrogen therapy after menopause to decrease genital atrophy.
3. Pelvic floor muscle exercises to improve symptoms.
4. Surgery—if cystocele is large and interferes with bladder functioning.
   a. May do anterior vaginal colporrhaphy (repair of anterior vaginal wall).
   b. Complications of surgery include urinary retention and bleeding (requires vaginal packing).

Complications

Urinary incontinence and infection.

Nursing Assessment

1. Obtain history of obstetric trauma, abdominal surgery, menopause, and use of estrogen.
2. Ask about urinary symptoms and pain.
3. Observe the perineum while the patient bears down or is in upright position for bulge from the vagina.

Nursing Diagnoses

- Acute Pain related to pelvic pressure.
- Stress Urinary Incontinence related to relaxed pelvic muscles and displaced organs.
- Urinary Retention related to displaced organs.

Nursing Interventions

Relieving Pain

1. Encourage periods of rest with legs elevated to relieve strain on the pelvis.
2. Advise use of mild analgesics, as necessary.
3. Provide postoperative care.
   a. Encourage voiding every 4 to 8 hours to reduce pressure so that no more than 150 mL will accumulate in the bladder—intermittent catheterization or use of an indwelling catheter may be required.
   b. Administer perineal care to patient after each voiding and defecation.
   c. Use available sprays for anesthetic and antiseptic effects.
   d. Apply an ice pack locally to relieve congestion and discomfort.
   e. Administer analgesics, as prescribed, for relief of pain.

Controlling Incontinence

1. Teach the patient Kegel pelvic floor exercises to regain muscle tone.
   a. Practice while voiding by stopping the flow of urine for 3 to 5 seconds and then releasing for 5

seconds.

b. Patient can tighten pelvic floor muscle at any time, repeat 10 times, three times per day, and increase as able.

2. Encourage the patient to void frequently and respond to the urge to void promptly.
3. Warn the patient to avoid straining to prevent incontinence.

Preventing Urinary Retention

1. Encourage fluids to decrease bacterial flora in the bladder.
2. Catheterize patient if retention is suspected.
3. Obtain urine specimen for culture and sensitivity if infection is suspected.

Patient Education and Health Maintenance

1. Teach women to avoid straining, remain active, avoid obesity, and perform Kegel exercises to minimize pelvic relaxation in their older years.
2. Encourage prompt attention to symptoms of UTI—dysuria urgency, frequency, and foul-smelling urine.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Reports decreased frequency of incontinence.
- Voids regularly without symptoms of infection.

Rectocele and Enterocele

Rectocele is displacement (protrusion) of the rectum into the vagina. *Enterocele* is displacement of the intestine into the vagina (see Figure 22-5).

Pathophysiology and Etiology

1. Posterior vaginal wall becomes weakened, allowing displacement.
2. Weakening caused by obstetric trauma, childbirth, pelvic surgery, and aging.

Clinical Manifestations

1. Pelvic pressure or heaviness, backache, and perineal burning.
2. Constipation—may have difficulty in fecal evacuation; the patient may use fingers in the vagina to push feces up so defecation may occur.
3. Incontinence of feces and flatus—if tear between the rectum and vagina.
4. Visible protrusion into the vagina.
5. Symptoms are aggravated by standing for long periods.

Diagnostic Evaluation

1. Vaginal examination reveals condition.
2. May use Sims speculum to uplift the cervix and fully evaluate condition.

Management

1. Pessary—plastic device inserted into the vagina to aid pelvic support.
2. Estrogen replacement vaginally to prevent atrophy.
3. Pelvic floor muscle exercises to improve symptoms.
4. Surgery, if rectocele is large enough to interfere with bowel functioning: posterior colpoplasty (perineorrhaphy)—repair of posterior vaginal wall.

Complications

Total fecal incontinence.

Nursing Assessment

1. Obtain history of childbirth, pelvic surgery, and symptoms of bowel function.
2. Observe for bulge into the vagina while the patient bears down or is in upright position.
3. Monitor bowel movements.

Nursing Diagnoses

- Acute Pain related to pelvic pressure.
- Constipation related to displaced rectum or bowel.

Nursing Interventions

Relieving Pain

1. Encourage periods of rest with legs elevated to relieve pelvic strain.
2. Encourage use of mild analgesics, as needed; avoid opioids, which may worsen constipation.
3. Postoperative care:
    a. Suggest low Fowler position to reduce edema and discomfort.
    b. Administer perineal care to patient after each voiding and defecation.
    c. Heat may enhance the healing process, but use cautiously to avoid burns.
    d. Use ice packs locally to relieve congestion and discomfort.
    e. Administer analgesics and stool softeners, as ordered.

Relieving Constipation

1. Teach the patient to increase fluid and fiber in diet.
2. Encourage use of stool softeners or bulk laxatives to make passage of stool easier.

Patient Education and Health Maintenance

1. Advise the patient to follow surgeon's instructions for resuming activity and to avoid heavy lifting, straining, and intercourse until cleared.
2. Educate the patient for the future to avoid straining and obesity, which may cause return of rectocele or enterocele.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Passes soft stool daily.

Uterine Prolapse

Uterine prolapse is an abnormal position of the uterus in which the uterus protrudes downward.

Pathophysiology and Etiology

1. The uterus herniates through pelvic floor and protrudes into the vagina (prolapse) and possibly beyond the introitus (procidentia).
2. Usually caused by obstetric trauma and overstretching of musculofascial supports.
3. Degrees (see Figure 22-6).
   a. First degree—the cervix prolapses into vaginal canal.
   b. Second degree—the cervix is at the introitus.
   c. Third degree—the cervix extends over the perineum.
   d. Marked procidentia—the entire uterus protrudes outside vaginal cavity.

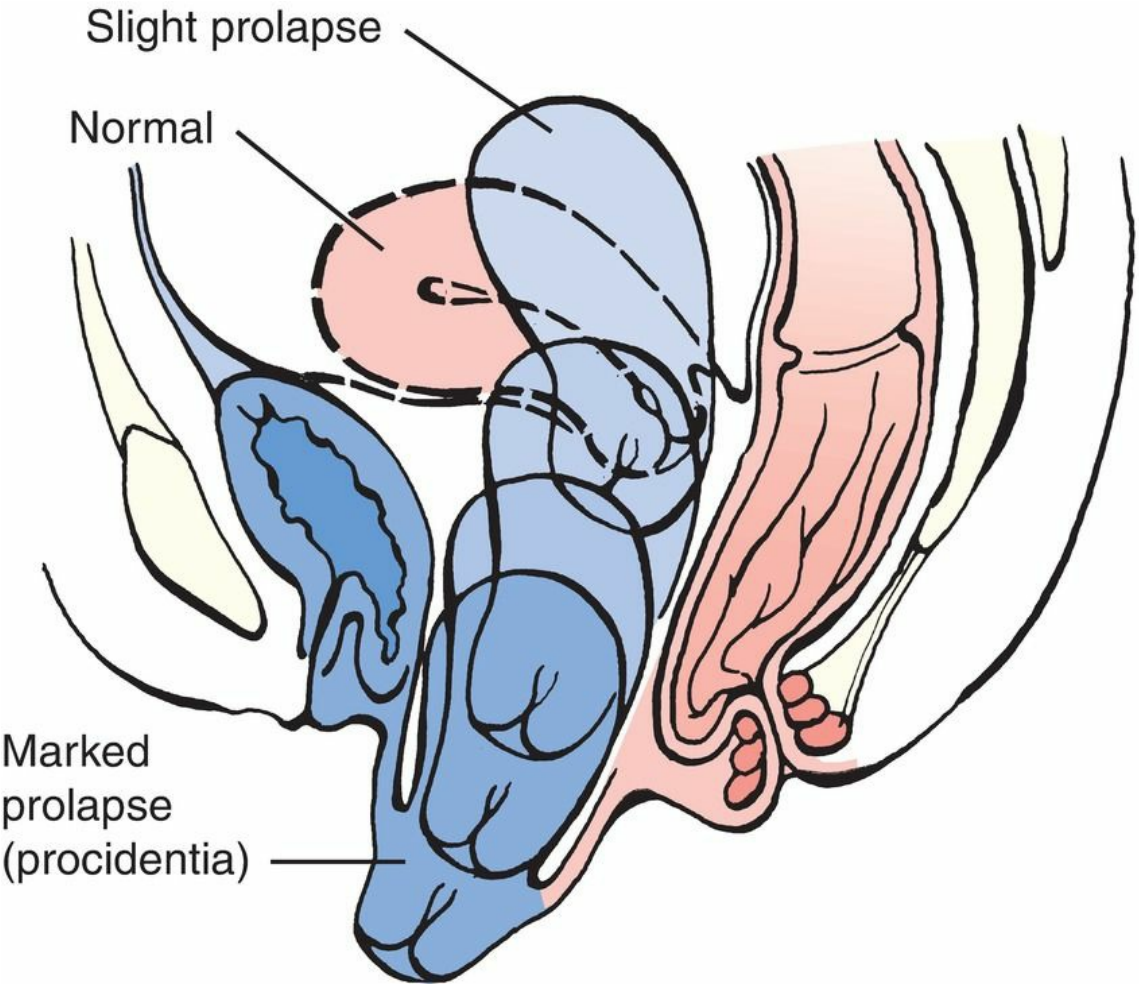

Figure 22-6. Degrees of uterine prolapse. (Reeder, S., Martin, L., & Koniak-Griffin, D. [1997]. *Maternity nursing: Family, newborn, and women's health care* [18th ed.]. Philadelphia, PA: Lippincott-Raven Publishers.)

Clinical Manifestations

1. Low backache or dyspareunia.
2. Pressure and heaviness in pelvic region.
3. Bloody discharge because of the cervix rubbing against clothing or inner thighs.
4. Urinary frequency, urgency, or repeated bladder infections.
5. Symptoms are aggravated by obesity, standing, straining, coughing, or lifting a heavy object because of increased intra-abdominal pressure.

Diagnostic Evaluation

Pelvic examination identifies condition.

Management

1. Hysterectomy or surgical correction.
2. Vaginal pessary—plastic device inserted into the vagina as temporary or palliative measure if surgery cannot be done.
3. Pelvic floor muscle exercises to improve symptoms.
4. Estrogen cream— decrease genital atrophy.

Complications

1. Necrosis of the cervix and uterus.
2. Infection.

Nursing Assessment

1. Obtain history of childbirth and surgery.
2. Ask about symptoms and aggravating factors.
3. Examine patient in lying or standing position; if the cervix not readily visible, spread labia gently; do not attempt to insert speculum.

Nursing Diagnoses

- Acute Pain related to downward pressure and exposed tissue.
- Impaired Tissue Integrity related to exposed cervix and uterus.
- Sexual Dysfunction related to loss of vaginal cavity.

Nursing Interventions

Relieving Pain

1. Administer sitz baths and explain procedure to patient.
2. Provide heating pad for lower back or lower abdomen.

3. Administer pain medications, as ordered.
4. Check for proper placement of pessary.
5. Increase fluid intake and encourage patient to void frequently to prevent bladder infection.

Maintaining Cervical and Uterine Mucosal Integrity

1. For second- and third-degree prolapse, apply saline compresses frequently.
2. Provide postoperative care.
    a. Administer perineal care to patient after each voiding and defecation.
    b. If urinary retention occurs, catheterize or use indwelling catheter until bladder tone is regained.
    c. Apply an ice pack locally to relieve congestion.
    d. Promote ambulation but prevent straining to reduce pelvic pressure.

Restoring Sexual Function

1. Discuss with patient noncoital sexual activity before treatment is instituted.
2. Explain to patient that sexual intercourse is possible with pessary; however, vaginal canal may be shortened.
3. Reinforce surgeon's instructions postoperatively about waiting to have vaginal penetration.
4. Encourage the patient to explore with partner ways to engage in sexual activity without strain and with greatest comfort.

Patient Education and Health Maintenance

1. Encourage the patient with pessary to follow up, as directed, for removal and cleaning of pessary and evaluation of any vaginal irritation or trauma.
2. Encourage all patients to report vaginal discharge, pain, or bleeding before or after treatment.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Cervix and uterus without ulceration.
- Verbalizes satisfying sexual activity.

GYNECOLOGIC TUMORS

Cancer of the Vulva

Cancer of the vulva is most commonly carcinoma of the labia majora, labia minora, or clitoris; it may also originate as a urethral tumor.

Pathophysiology and Etiology

1. Most common in postmenopausal women, with an average age of 65. Although there has recently been increased incidence in women aged 40 to 50 (which may be related to HPV screening), many new cases have been diagnosed because of increase in older population.
2. Represents 4% of gynecologic cancers.
3. The cause is unknown, but HPV has been shown to be responsible for 60% of vulvar cancers.
4. Spreads primarily through local, direct extension and lymphatic system; distant metastasis can occur late in the disease process.

Clinical Manifestations

1. Lump or mass present for several months—first is leukoplakic (white plaque or mild ulceration); becomes reddened, pigmented, and ulcerated.
2. Vulvar pruritus is a common complaint,
3. Discharge or bleeding; may be foul-smelling because of secondary infection.
4. Dysuria because of invasion of urethra with bacteria.
5. Edema of tissues.
6. Lymphadenopathy.
7. Pain or dyspareunia.

Diagnostic Evaluation

Biopsy of lesion and lymph nodes. If small, lesion may be excised at the time of biopsy. Most lesions are squamous cell carcinoma.

Management

EVIDENCE BASE National Cancer Institute. (2017). Vulvar cancer treatment (PDQ). Bethesda, MD: Author. Available: *http://cancer.gov/cancertopics/pdq/treatment/vulvar/HealthProfessional*.

Choice of surgical methods depends on the site and extent of the primary lesion and the risk of lymph node involvement. The most conservative operation that is consistent with cure of disease is chosen.

1. Precancerous lesions—vulvar intraepithelial neoplasia.
    a. Simple vulvectomy is seldom indicated.

   b. Skinning vulvectomy with possible grafting.
   c. Local excision or laser therapy or a combination.
   d. Fluorouracil cream 5% (response rate 50% to 60%).
2. Carcinoma *in situ*—noninvasive.
   a. Simple vulvectomy is seldom indicated.
   b. Skinning vulvectomy with possible grafting.
   c. Local excision or laser therapy or a combination.
   d. Fluorouracil cream 5% (response rate 50% to 60%).
3. Invasive carcinoma—radical or modified radical vulvectomy with bilateral groin lymph node resection.
   a. Pelvic nodes may also be removed if involvement is suspected.
   b. If cancer is confined to the vulva, there is a 70% to 93% 5-year survival rate after surgery (for patients with negative nodes).
4. Advanced carcinoma—pelvic exenteration or surgery and radiation as a palliative measure.
   a. Radiation therapy has an increased role in the preoperative and postoperative management.
   b. Preoperative radiation therapy can decrease the volume of disease and decrease the need for radical surgery.
   c. Postoperative radiation therapy is used for patients with positive lymph nodes and close surgical margins.
   d. Long-term outcomes of treatment compared to morbidity associated with treatment are being studied.
5. Chemotherapy alone or in combination with radiation may shrink lesion so surgery can be less extensive.
6. Cisplatin and/or 5-FU used as radiation sensitizers has been shown to increase efficacy of radiation treatment.

Complications

1. Lymphatic spread.
2. Complications after vulvectomy are common—wound infection, wound breakdown, lymphedema, leg cellulitis, and introital stenosis.

Nursing Assessment

1. Obtain history of lesion, including when the patient first noticed it and any change in appearance.
2. Obtain gynecologic history, especially about past infections.
3. Assess overall health for tolerance of treatment.
4. Assess support systems and personal coping skills.

Nursing Diagnoses

- Fear related to cancer and radical surgery.

- Impaired Tissue Integrity related to surgery.
- Sexual Dysfunction related to vulvectomy.

Nursing Interventions

Relieving Fear Preoperatively

1. Have patient describe what her understanding is about the problem; answer questions and clear up misconceptions.
2. Emphasize the positive outcomes of the prescribed treatment plan; reinforce what the surgeon has already described to her.
3. Prepare the patient for surgery and describe to her the postoperative appearance of the wound and use of drains and urinary catheter (see Figure 22-7).
    a. Provide skin preparation as directed and cleanse the vulva via a chlorhexidine shower the night before surgery; 2% chlorhexidine gluconate antiseptic solution may also be ordered.
    b. Administer bowel preparation, as ordered, to evacuate intestinal tract before surgery; there will be no bowel movement for 2 to 3 days postoperatively.

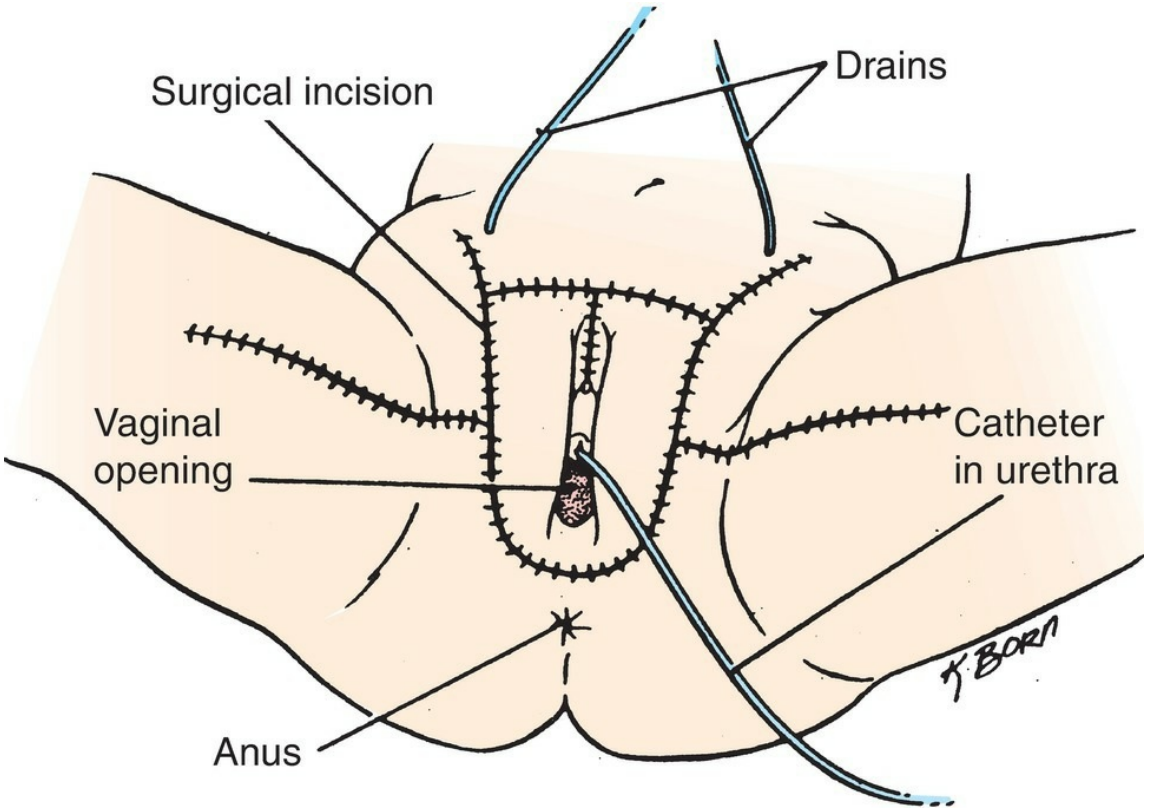

Figure 22-7. Postoperative appearance after radical vulvectomy.

Promoting Tissue Healing Postoperatively

1. Maintain drainage and compression of tissues to remove fluid that could cause edema and prevent wound healing. Empty drains, as needed (at least every 8 hours).

2. Keep wound clean and dry.
    a. Perform sterile dressing changes, as prescribed.
    b. Apply heat lamp, if prescribed, to decrease moisture and increase circulation and healing.
    c. Perform perineal care or sitz baths after each bowel movement or voiding (after catheter is removed).
    d. Maintain patency of urinary catheter, as ordered, to prevent wound contamination with urine.
    e. Encourage low Fowler position to promote comfort and reduce tension on sutures.
    f. Prevent straining with defecation by providing a low-residue diet initially and stool softeners later, as ordered.
    g. Provide deep vein thrombosis prophylaxis (anticoagulant or sequential compression device), as prescribed, and encourage leg exercises to prevent thrombus/embolus formation. Encourage careful ambulation when allowed while preventing perineal tension.

Restoring Sexual Function

1. Encourage the patient to ventilate feelings about sexual mutilation and altered functioning.
2. Tell the patient that if the vagina is still intact, vaginal intercourse is still possible.
3. Inform the patient of changes that may occur because of surgery—loss of sexual arousal if the clitoris is removed, shortening of the vagina, and decreased lubrication.
4. Help the patient explore alternate methods of sexual intimacy and encourage her to discuss feelings with her partner.

Patient Education and Health Maintenance

1. Encourage follow-up visits for additional therapy, if required.
2. Encourage regular health checkups and screening for cancer and other age-related illnesses.
3. Encourage early evaluation of any suspicious lesions, bleeding, or discharge.

Evaluation: Expected Outcomes

- Verbalizes reduced fear.
- Perineum healed without complications.
- Verbalizes understanding of anatomic changes and sexual function.

Cancer of the Cervix

Cancer of the cervix is the fourth most common gynecologic malignancy. There are about 13,000 new cases and 4,000 deaths each year in the United States.

Pathophysiology and Etiology

1. Early sexual activity, multiple sexual partners, a high-risk sexual partner, history of HIV and other STDs—especially HPV—and a history of vulvar or vaginal squamous intraepithelial neoplasia or cancer, and immunosuppression are major risk factors. There also appears to be an increased risk of cervical cancer associated with the use of oral contraceptives.
2. Incidence is higher in lower socioeconomic status and in Hispanics, African Americans, American Indians, and Alaska Natives—presumably related to decreased access to health care and screening.
3. Decreased mortality in United States, but most frequent malignancy among women in developing countries.
4. Types (see Figure 22-8):
   a. Dysplasia (precancer)—atypical cells with some degree of surface maturation.
   b. Carcinoma *in situ*—cytology similar to invasive carcinoma, but confined to the epithelium.
   c. Invasive carcinoma—stroma is involved; 69% are of the squamous cell type. Spreads by local invasion and lymphatics to the vagina and beyond.

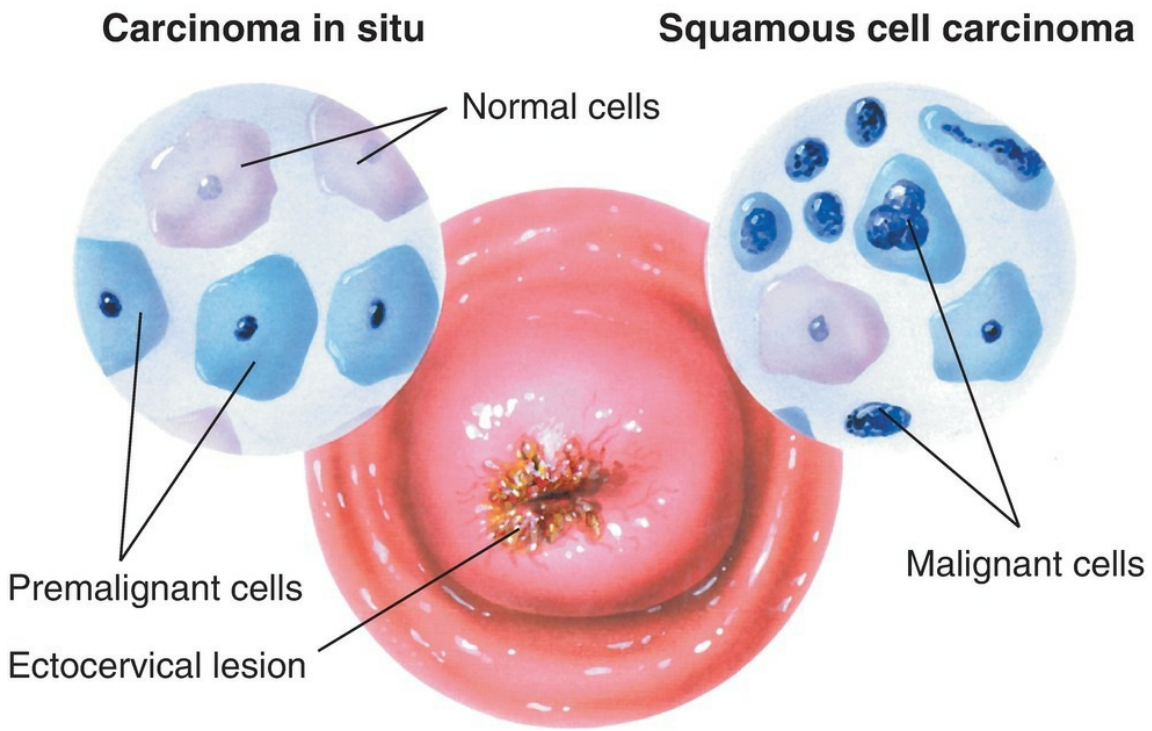

Figure 22-8. Cervical cancer. (Anatomical Chart Company.)

Clinical Manifestations

1. Early disease is usually asymptomatic, although patient may notice watery, vaginal discharge.
2. Initial symptoms include postcoital bleeding, irregular vaginal bleeding or spotting between periods or after menopause, and malodorous discharge.
3. As disease progresses, bleeding becomes more constant and is accompanied by pain that radiates to buttocks and legs as well as urinary and rectal symptoms that may be due to invasion of these organs.
4. Weight loss, anemia, edema of lower extremities, and fever signal advanced disease.

Diagnostic Evaluation

1. Pap smear—routine screening measure; abnormal results warrant further diagnostic tests, such as colposcopy and biopsy or conization.
2. Staging is done clinically rather than surgically as with other cancers. Based on physical findings on abdominal and pelvic examination.
3. Supplemental imaging can include chest x-ray, IVP, urography, colposcopy, cystoscopy, proctosigmoidoscopy, computed tomography (CT) scan with IV contrast, and barium studies of the lower colon and rectum.

Management

EVIDENCE BASE National Cancer Institute. (2017). Cervical cancer Treatment (PDQ). Bethesda, MD: Author. Available: *www.cancer.gov/cancertopics/pdq/treatment/cervical/HealthProfessional*.

Dysplasia to Carcinoma *In Situ*

1. Techniques to destroy abnormal cells in the cervical transformation zone.
2. Cryosurgery, laser therapy, electrocautery (loop electrosurgical excision procedure), or conization may be performed on outpatient basis.
3. Vaginal discharge, bleeding, pain, and cramping result from these procedures in various degrees, but postoperative convalescence is minimal.

Microinvasive Stage

1. Surgical conization—large excision of cervical tissue, may be done under local or general anesthesia.
2. Invasive cervical cancer—extent is staged and treated with hysterectomy, radiotherapy, or chemotherapy.

Other Management

1. Radiotherapy.
    a. Intracavitary (localized for earlier stage) or external (more generalized dosage to the pelvis for stages IIB through IVB).
    b. Cisplatin, a radiation sensitizer, is used to improve survival.

2. Chemotherapy—cisplatin may be used in combination with radiation for locally advanced disease or for metastatic disease in which recurrence is common. Other agents that may be used include ifosfamide, carboplatin, and topotecan.
3. Surgery.
    a. Total hysterectomy, conization, modified radical hysterectomy, and intracavitary radiation therapy may be performed for stage IA with or without oophorectomy and/or lymph node dissection.
    b. Radical hysterectomy and bilateral lymph node resections for stages IB and IIA. Radiation and chemotherapy may also be considered for these stages after hysterectomy.
    c. Pelvic exenteration for advanced cases if the patient is a candidate. Usually done for patients with isolated central recurrence.
        i. Removal of the vagina, uterus, uterine tubes, ovaries, bladder, rectum, and supporting structures and the creation of an ileal conduit and fecal stoma.
        ii. Performed for pelvic recurrence after radiation or chemotherapy.

Complications

1. Spread to the bladder and rectum; metastasis to lungs, mediastinum, bones, and liver.
2. Complications of intracavitary radiotherapy include cystitis, proctitis, vaginal stenosis, and uterine perforation.
3. Complications of external radiation include bone marrow depression, bowel obstruction, and fistula.

Nursing Assessment

1. Obtain history of Pap tests, sexual activity, and past STDs.
2. Obtain history of symptoms.
3. Assess understanding of disease and responses, such as guilt, fear, denial, and anxiety.

Nursing Diagnoses

- Anxiety related to cancer and treatment.
- Disturbed Body Image related to surgical treatment.

Nursing Interventions

Relieving Anxiety

1. Assist the patient to seek information on stage of cancer and treatment options.
2. Prepare the patient for hysterectomy or other surgery (see page 644 for nursing interventions for hysterectomy).
3. Prepare the patient for radiation therapy to the uterus (see page 669 for nursing interventions for radiation therapy).

Enhancing Body Image

1. Provide emotional support during treatment.
2. Encourage the patient to take pride in appearance by dressing and putting on makeup as able.
3. Encourage activity and socialization when the patient is able.

Patient Education and Health Maintenance

1. Explain the importance of lifelong follow-up, regardless of treatments, to determine the response to treatment and detect spread of cancer.
2. Refer to cancer support group in community.
3. Encourage all women to discuss cervical cancer screening guidelines with their health care providers (see page 637).

Evaluation: Expected Outcomes

- Reports decreased anxiety and increased decision-making ability.
- Reports continued interest in appearance and femininity.

Endometrial Cancer

Cancer of the uterus is usually adenocarcinoma of the endometrium of the fundus or body of the uterus. Most common gynecologic cancer in the United States.

Pathophysiology and Etiology

1. Most patients are postmenopausal with an average age of early 60s at the time of diagnosis.
2. Cause is unknown but associated with increased estrogen exposure as in tamoxifen use and unopposed estrogen replacement, obesity, anovulation, or estrogen-secreting tumors.
3. Hypertension and diabetes mellitus are also risk factors.

Clinical Manifestations

1. Irregular bleeding before menopause or postmenopausal bleeding is the most common complaint.
2. Watery, usually malodorous vaginal discharge.
3. Pain, fever, and bowel and bladder dysfunctions are late signs.
4. Anemia secondary to bleeding.

Diagnostic Evaluation

1. Pelvic and rectovaginal examination—enlarged uterus may be palpated.
2. Endometrial biopsy is preferred as the initial diagnostic test; however, if less than 50% of the endometrium is affected, malignancy can be missed.
3. Transvaginal ultrasound to measure endometrial thickness.
4. Dilation and curettage—if endometrial sampling cannot be performed in office, hysteroscopy may also be helpful.
5. Atypical glandular cells may be found on cervical cytology.
6. Metastatic workup—includes CA 125 (which may be elevated, especially in papillary serous carcinomas), x-ray studies, and cystoscopy.

Management

EVIDENCE BASE National Cancer Institute. (2017). Endometrial cancer treatment (PDQ). Bethesda, MD: Author. Available: *www.cancer.gov/cancertopics/pdq/treatment/endometrial/HealthProfessional*.

---

1. Staging for endometrial cancer is based on surgical aspects versus clinical staging.
   a. Emphasis is placed on histologic grade, depth of myometrial invasion, and cervical involvement.
   b. These parameters assist in prediction of lymph node involvement and help determine need for lymph node dissection.

2. Early stage I requires total abdominal hysterectomy with bilateral salpingo-oophorectomy (TAH/BSO).
3. Advanced stage I and stage II require TAH/BSO and selective lymph node dissection.
4. Radiation therapy (intracavitary or external) may be added after surgery or chosen instead of surgery for more advanced stages or for patients who are high-risk surgical candidates.
    a. Acute complications include hemorrhagic cystitis, vaginitis, enteritis, and proctitis.
    b. Chronic complications include vaginal dryness, vaginal stenosis, cystitis, bladder dysfunction, proctitis, small bowel obstruction, fistulas, strictures, and leg edema.
5. Hormonal therapy—progestational agents may alter receptor sites in the endometrium for estrogen and thus decrease growth (for metastatic disease); may provide stabilization of disease.
6. Chemotherapy—for metastatic and recurrent disease; using cisplatin, doxorubicin, and possibly paclitaxel.

Complications

Spread throughout the pelvis; metastasis to lungs, liver, bone, and brain.

Nursing Assessment

1. Obtain history of menses, pregnancy, and estrogen replacement.
2. Ask about irregular or postmenopausal bleeding and other symptoms.
3. Assess the patient's response to possible diagnosis of cancer—fear, guilt, and denial.

Nursing Diagnoses

- Fear related to cancer and treatment options.
- Acute Pain related to disease process and surgical treatment.

Nursing Interventions

Relieving Fear

1. Support patient through the diagnostic process, and reinforce information given by health care provider about treatment options.
2. Prepare patient for radiation therapy, if indicated (see below).
3. Prepare patient for hysterectomy, if indicated (see page 644).
4. Provide complete and concise explanations for all care you provide; emphasize the positive aspects of patient's recovery.

Relieving Pain

1. Administer pain medications, as prescribed, and monitor the patient's response.
2. Encourage use of relaxation techniques, such as deep breathing, imagery, and distraction, to help promote comfort.

Patient Education and Health Maintenance

1. Explain importance of reporting postmenopausal bleeding.
2. Encourage keeping follow-up visits.
3. Explain that surgery or radiation treatment does not prevent satisfying sexual activity.
4. Refer to local cancer support group or American Cancer Society (*www.acs.org*).

Evaluation: Expected Outcomes

- Verbalizes understanding of diagnosis and treatment chosen.
- Verbalizes decreased pain.

Care of the Patient Receiving Intracavitary Radiation Therapy

Procedural Considerations

1. An applicator (tandems and ovoids are most common) is positioned in the endocervical canal and vagina in the operating room with the patient under anesthesia. (High-dose remote brachytherapy is also used. This is an outpatient procedure and the treatment takes just minutes. The radioactive source is removed between treatments.)
2. After recovery from anesthesia, x-rays are taken to check correct placement.
3. Radiologist inserts radioactive material (radium or cesium) into applicator, which remains in place 24 to 72 hours. Therapy is individualized according to the stage of disease and patient's response to and tolerance of radiation.
4. External radiation over the pelvis may be supplemented to eliminate cancer spread via lymphatic system.

Nursing Interventions

Patient Preparation

1. Patients require a thorough medical evaluation before treatment to evaluate risks and precautions related to pre-existing medical problems or special needs.
2. An indwelling catheter is placed in the operating room.
3. Encourage patient to bring diversional activities because she will remain on bed rest during radiation treatment.
4. Instruct patient on radiation safety measures:
    a. Neither patient nor her secretions are radioactive, but the applicator is.
    b. Do not touch source of radiation.
    c. Notify someone immediately if source is dislodged.
    d. When applicators are removed, no radioactivity remains.
    e. Radioactivity is monitored by specially trained personnel.
    f. No pregnant women or children younger than age 18 are allowed to visit.
    g. Lead shields may be used to decrease radiation that emanates from the patient.
5. Reinforce that help is readily available.

During Radiation Treatment

1. Maintain patient on strict bed rest on her back with head of bed elevated 15 to 30 degrees. Patient may be logrolled three or four times per day. Use convoluted foam mattress.
2. Have patient bathe upper body. Perineal care and linen changes are done by the nursing staff.
3. Maintain the patient on a low-residue diet to prevent bowel movements, which could dislodge the apparatus. Encourage the patient to eat several small portions rather than few large servings. Medication to induce constipation is given.

4. Inspect indwelling catheter frequently to ensure proper drainage. A distended bladder may cause severe radiation burns.
5. Encourage fluids to prevent bladder infection.
6. Observe for signs and symptoms of radiation sickness—nausea, vomiting, fever, diarrhea, and abdominal cramping.
7. Check applicator position every 8 hours and monitor amount of bleeding and drainage (a small amount is normal).
8. Check the patient frequently to minimize anxiety, but minimize time spent at bedside to reduce radiation exposure.
9. Mild sedatives or pain medication may be given for patient comfort.

NURSING ALERT Long-handled forceps and a lead-lined container are left in the room after loading in the event the radioactive sources are dislodged. Maintain cardinal rules of time, distance, and shielding when caring for the patient.

During Radiation Removal

1. Before removal of the applicator, the patient is medicated with appropriate analgesic.
2. The radioactive sources are removed by radiation personnel and safely stored for transport.
3. The indwelling catheter is removed, and then the applicator is removed.
4. The patient is given an enema or suppository to reverse the induced constipation.
5. The patient should be evaluated for safe ambulation because of prolonged bed rest before discharge.

NURSING ALERT Rules and regulations regarding radiation safety are strictly enforced to protect patients and health care workers.

Myomas of the Uterus

Myomas (fibroids, leiomyomas, fibromyomas) are benign tumors of the uterine myometrium (smooth muscle).

Pathophysiology and Etiology

1. The most common pelvic tumor in women. Approximately 80% of women have fibroids, but many are not symptomatic.
2. May spontaneously regress after menopause.
3. Unknown cause; increased incidence in black women.

Clinical Manifestations

1. Small myomas do not cause symptoms.
2. First indication may be palpable mass.
3. Irregular bleeding—usually menorrhagia.
4. Pain may come from pressure on adjacent organs—possible heavy feeling in the pelvis or degeneration associated with vascular occlusion.
5. Secondary symptoms include fatigue because of anemia, urinary disturbances, and constipation.

Diagnostic Evaluation

1. Transvaginal ultrasound or hysteroscopy—to identify size and location of myomas.
2. Magnetic resonance imaging (MRI) may be helpful in clarifying anatomy and myoma location; however, it is expensive and best reserved for surgical planning of difficult procedures.

Management

1. Myomectomy may be done for small or accessible tumor and may be done through hysteroscopy, laparoscopy, or laparotomy. If fertility preservation is desired, abdominal myomectomy is preferred for symptomatic women.
2. Hysterectomy for large or numerous tumors.
3. Medical therapies for management of symptoms include gonadotropin-releasing hormone antagonist therapy to create hypoestrogenic environment and to try to shrink tumors. Hormonal birth control, NSAIDs, or antifibrinolytic agents are used for heavy menstrual bleeding.
4. Frequently resolve on their own postmenopausally.
5. Uterine artery embolization—transvenous procedure in which the blood supply to the myoma is obstructed and the myoma degenerates.

Complications

1. Infertility with hysterectomy.
2. Habitual abortion.

Nursing Assessment

1. Ask about pain, menstrual irregularity, possible urinary symptoms, and constipation.
2. Assess the patient's understanding of condition as benign.

Nursing Diagnosis

- Acute and Chronic Pain related to tumor growth.

Nursing Interventions

Relieving Pain

1. Teach patient proper use and adverse effects of analgesics and use of heating pad, as desired.
2. Encourage the patient to avoid long periods of standing; rest with the pelvis in dependent position periodically to achieve comfort.
3. Encourage patient to void frequently to avoid increased pressure from distended bladder.
4. Advise a high-fiber diet to prevent constipation.
5. Prepare the patient for surgery, if indicated.

Patient Education and Health Maintenance

1. Tell the patient to report increased symptoms and worsening bleeding because myomas may be enlarging and treatment may be indicated.
2. Reassure the patient that myomas do not become malignant, but she should keep regular follow-up visits for cancer screening.

Evaluation: Expected Outcomes

- Verbalizes control of pain.

Ovarian Cysts

Ovarian cysts are growths arising from ovarian components, usually benign.

Pathophysiology and Etiology

1. Commonly arise from functional changes in the ovary—from graafian follicle or from persistent corpus luteum.
2. Dermoid cysts may develop from abnormal embryonic epithelium.
3. Frequently found during childbearing years.

Clinical Manifestations

1. May be asymptomatic or cause minor pelvic pain.
2. Possible menstrual irregularity.
3. Tender, palpable mass.
4. Rupture causes acute unilateral lower abdominal pain and tenderness; may mimic mittelschmerz, PID, appendicitis, or ectopic pregnancy.
5. Discomfort during bowel movement or pressure on the bowel.

Diagnostic Evaluation

1. Pelvic sonogram to determine size and characteristics.
2. Pregnancy test to rule out ectopic pregnancy.
3. Biopsy (at the time of surgery) is done for suspicious cysts.
4. Other tests that may be ordered: CBC with diff. and CA 125.

Management

1. Cysts without malignant characteristics and cysts that measure less than 10 cm in diameter can be observed with repeat ultrasound in 2 to 3 months.
2. Surgery for large, complex, or leaking cyst by laparoscopy or laparotomy.

Complications

Rupture may cause peritoneal inflammation.

Nursing Assessment

1. Obtain history of sexual activity, use of contraception, and past episodes of PID to rule out ectopic pregnancy.
2. Obtain history of recent menses—irregular bleeding and spotting commonly signal follicular cyst; delayed menses and prolonged bleeding signal corpus luteal cyst.
3. Perform vital signs and abdominal examination for tenderness, guarding, and rebound, which may indicate rupture.

Nursing Diagnoses

- Acute Pain related to abnormal growth.
- Risk for Deficient Fluid Volume related to rupture of cyst or postoperative change in intra-abdominal pressure.

Nursing Interventions

Relieving Pain

1. Encourage the use of analgesics, as prescribed, and of heating pad, if desired.
2. Teach the patient the proper use of hormonal contraceptives, if prescribed, with adverse effects; encourage monthly follow-up visits to determine if cyst is resolving.
3. Tell the patient that heavy lifting, strenuous exercise, and sexual intercourse may increase pain.

Maintaining Fluid Volume

1. Monitor for nausea, vomiting, rigid abdomen, and change in vital signs related to rupture of cyst. Administer IV fluids, as directed, and maintain NPO status until abdominal rigidity resolves.
2. Reassure the patient that symptoms will resolve.
3. Prepare the patient with large or nonresponsive cyst for surgery, as indicated.
4. Postoperatively monitor vital signs frequently and maintain IV infusion while NPO.
5. Assess frequently for abdominal distention because of fluid and gas pooling in abdominal cavity.
6. Place the patient in semi-Fowler position for greatest comfort, and encourage early ambulation to reduce distention (help patient arise slowly to prevent orthostatic hypotension).
7. Administer antiemetics and insert a nasogastric tube, as ordered, to prevent vomiting.
8. As distention resolves, assess bowel sounds and advance oral intake slowly.

Patient Education and Health Maintenance

1. Reassure patient that in most cases ovarian function remains and she remains fertile.
2. Reassure patient about low malignancy rate of cysts.
3. Encourage the patient to report recurrent symptoms or worsening of pain if cyst is being treated medically.

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Vital signs stable; no orthostasis.

Ovarian Cancer

Ovarian cancer is a gynecologic malignancy with high mortality because of advanced disease by the time of diagnosis. It is the leading cause of morbidity of gynecologic cancers.

Pathophysiology and Etiology

1. Median age is 60 years. One of 70 women will develop ovarian cancer.
2. Cause is unknown, but about 10% of cases are associated with family history of breast, endometrial, colon, or ovarian cancer.
3. Smoking and personal history of breast, colon, or endometrial cancer are also risk factors.
4. There is also higher incidence in nulliparous women.

Clinical Manifestations

1. No early manifestations.
2. First manifestations—(vague) bloating, increased abdominal size, urinary urgency or frequency, difficulty eating or feeling full, and abdominal or pelvic pain, which may occur with other symptoms, almost daily, and are more severe than expected.
3. Late manifestations—abdominal pain, ascites, pleural effusion, and intestinal obstruction.

Diagnostic Evaluation

1. Pelvic examination to detect enlargement, nodularity, and immobility of the ovaries.
2. Pelvic sonography (transabdominal and transvaginal) is the most useful diagnostic test and CT scan is done to determine metastatic spread.
3. Color Doppler imaging may be used to detect vascular changes within the ovaries.
4. Paracentesis or thoracentesis if ascites or pleural effusion is present.
5. Laparotomy to stage the disease and determine effectiveness of treatment.
6. Increase of CA 125 signifies progression, but not as useful as diagnostic or screening tool because level can be elevated because of inflammation and other causes.

Management

1. TAH/BSO and omentectomy is usual treatment because of delayed diagnosis. Optimal debulking to less than 1 cm is the goal.
2. Chemotherapy is more effective if tumor is optimally debulked (less than 1-cm residual disease); usually follows surgery because of frequency of advanced disease; may be given IV or intraperitoneal.
3. Radiation therapy is not usually valuable.
4. Second-look laparotomy may be done after adjunct therapies to take multiple biopsies and determine effectiveness of therapy. Practice is controversial because it does not affect survival.
5. Immunotherapy is being investigated in clinical trials as stand-alone treatment or in conjunction with

other modalities.

Complications

Direct intra-abdominal or lymphatic spread and peritoneal seeding

Nursing Assessment

1. Obtain history of irregular menses, pain, and postmenopausal bleeding.
2. Ask about vague GI-related complaints.
3. Ask about history of other malignancy and family history of breast or ovarian cancer.
4. Assess the patient's general health status in terms of tolerating surgical and adjuvant therapy.

NURSING ALERT A combination of a long history of ovarian dysfunction and persistent undiagnosed GI complaints raises the suspicion for ovarian cancer. A palpable ovary in a postmenopausal woman is abnormal and should be evaluated as soon as possible.

Nursing Diagnoses

- Ineffective Coping related to advanced stage of cancer.
- Imbalanced Nutrition: Less Than Body Requirements related to nausea and vomiting from chemotherapy.
- Disturbed Body Image related to hair loss from chemotherapy.
- Acute Pain related to surgery.

Nursing Interventions

Strengthening Coping

1. Provide emotional support through diagnostic process; allow patient to express feelings and encourage positive coping mechanisms.
2. Administer anxiolytic and analgesic medications, as prescribed, and teach patient and caregivers the potential adverse effects.
3. Refer patient to cancer support group locally or American Cancer Society (*www.acs.org*) or National Cancer Institute (*www.cancer.org*).

Maintaining Adequate Nutrition

1. Administer or teach the patient or caregiver to administer antiemetics, as needed, for nausea and vomiting.
2. Encourage small, frequent, bland meals or liquid nutritional supplements as able.
3. Assess the need for IV fluids if the patient is vomiting.

4. Monitor for passage of gas and bowel movements after surgery. Bowel dysfunction related to surgery may cause nausea and anorexia.

Maintaining Body Image

1. Prepare the patient for body image changes with chemotherapy (ie, hair loss).
2. Encourage the patient to prepare ahead of time with turbans, wigs, and hats.
3. Encourage the patient to enhance her appearance with makeup, clothing, and jewelry as she is used to doing.
4. Stress the positive effects of the patient's treatment plan.

Relieving Pain

1. Prepare the patient for surgery, as indicated; explain the extent of incision, IV, catheter, packing, and drain tubes expected (see page 644 for a discussion of hysterectomy).
2. Postoperatively, administer analgesics, as needed, and explain to the patient that she may be drowsy.
3. Reposition frequently and encourage early ambulation to promote comfort and prevent adverse effects.

Patient Education and Health Maintenance

1. Explain to the patient the onset of menopausal symptoms with ovary removal.
2. Tell the patient that disease progression will be monitored closely by laboratory tests and second-look laparoscopy may be necessary.
3. Female relatives of patient should notify their physicians; biannual pelvic examinations may be necessary.

Evaluation: Expected Outcomes

- Openly discusses prognosis, asks appropriate questions, and makes plans for short-term future.
- Maintains weight.
- Verbalizes satisfaction in appearance with wig.
- Verbalizes good control over pain.

OTHER GYNECOLOGIC CONDITIONS

See additional online content: Nursing Care Plan 22-1

Nursing Care Plan 22-1

Care of the Patient with Pelvic Inflammatory Disease

Janice Smith is a 17-year-old female admitted with acute pelvic inflammatory disease (PID).

Subjective data: Janice tells you that she has severe lower abdominal pain, vaginal discharge, fever, and nausea and vomiting that have made her unable to eat or drink for 2 days. She feels weak and dizzy. She has a new sexual partner, is not using condoms, and is taking hormonal contraceptives. Her last menstrual period was 1 week ago.

Objective data: Temperature 102.2°F (39°C), pulse 98, blood pressure 94/60, respirations 24. Her lower abdomen is tender with mild guarding without rebound. Speculum examination reveals purulent cervical discharge. On bimanual examination, she has cervical motion tenderness and bilateral adnexal tenderness without masses. The presumptive diagnosis of PID is made and antibiotic therapy is prescribed.

NURSING DIAGNOSIS

Acute Pain related to pelvic inflammation and infection.

GOAL/EXPECTED OUTCOME

Pain will be reduced.

Nursing Interventions	Rationale	Evaluation: Actual Outcome
Administer analgesics as prescribed. Alert patient to adverse effect of drowsiness.	Analgesics provide pain relief. Knowledge of adverse effects enhances patient compliance.	Pain reduced from level 10 to level 3.
Assist patient to position of pelvic dependence, with head and feet elevated slightly.	Promotes drainage of infection without strain on pelvic structures.	Resting in pelvic-dependent position.
Encourage patient to apply heating pad to lower abdomen or low back.	Promotes circulation and relief of inflammation, promotes comfort.	Uses heating pad for 20-min intervals.

NURSING DIAGNOSIS

Deficient Fluid Volume related to fever and decreased oral intake.

GOAL/EXPECTED OUTCOME

Fluid balance will be restored.

Nursing Interventions	Rationale	Evaluation: Actual Outcome
Maintain IV fluids as ordered.	IV fluids replace circulating fluid volume.	Denies dizziness. BP 106/64, pulse 88.
Administer antiemetics, as prescribed.	Antiemetics prevent vomiting.	No vomiting.
Nursing Interventions	Rationale	Evaluation: Actual Outcome
Monitor intake and output.	Provides feedback on fluid replacement.	Intake equals output.
Restart oral intake with ice chips and sips of water when vomiting has ceased for 2 hr.	Will not distend stomach and produce vomiting.	Ice chips and sips of water tolerated without vomiting.

NURSING DIAGNOSIS

Risk for Infection, Reinfection, and Transmission to partners related to sexual activity.

GOAL/EXPECTED OUTCOME

Infection will not be transmitted or recur.

Nursing Interventions	Rationale	Evaluation: Actual Outcome
Administer and teach self-administration of antibiotics to patient. Advise patient to inform partner to seek evaluation and empiric treatment immediately.	Simultaneous treatment for prescribed length of therapy without missed doses ensures microbiologic cure.	No skipped doses of antibiotics.
Advise abstinence until completion of patient's and partner's antimicrobial regimens.	Abstinence is the only sure method of preventing transmission of organisms.	Reports understanding of abstinence, need for follow-up.
Nursing Interventions	**Rationale**	**Evaluation: Actual Outcome**
Tell patient to advise all partners within past 60 days to seek treatment.	All partners must receive treatment to break the chain of transmission.	All partners have been advised by patient.
Teach patient methods of preventing STDs—abstinence, monogamy, and proper use of male and female condoms. Encourage patient to consider monogamy or abstinence until in a mutually monogamous relationship.	Safe sexual behavior reduces risk of STDs.	Verbalizes monogamy. Describes proper use of condoms.

Pelvic Inflammatory Disease

EVIDENCE BASE Centers for Disease Control and Prevention. (2015). Sexually transmitted diseases treatment guidelines. Available: *www.cdc.gov/std/treatment*.

Pelvic inflammatory disease (PID) includes several inflammatory disorders of the upper female genital tract, often with infection that may involve the fallopian tubes, ovaries, uterus, or peritoneum.

Pathophysiology and Etiology

1. Incidence has been increasing; high recurrence rate because of reinfections.
2. Commonly polymicrobial; causative agents include *N. gonorrhoeae*, *C. trachomatis*, anaerobes (*Gardnerella vaginalis*), gram-negative bacteria, and *streptococci*. Cervical infection ascends through the endometrium, into the fallopian tubes, and possibly into the peritoneal cavity.
3. Predisposing factors include multiple sexual partners, early onset of sexual activity, use of IUDs (the wick promotes ascension of bacteria), and procedures such as therapeutic abortion, cesarean sections, and hysterosalpingograms.

Clinical Manifestations

1. Pelvic pain—most common presenting symptom; usually dull and bilateral.
2. Fever greater than 101°F—especially with gonococcal infections.
3. Cervical discharge—mucopurulent.
4. Irregular bleeding.
5. GI symptoms—nausea, vomiting, and acute abdomen usually signify abscess.
6. Urinary symptoms—dysuria and frequency.
7. Presentation with chlamydia may be mild.

NURSING ALERT Localized right or left lower quadrant tenderness with guarding, rebound, or palpable mass signifies tuboovarian abscess with peritoneal inflammation. Immediate evaluation and surgical intervention are necessary to prevent rupture and widespread peritonitis. Other significant causes include acute appendicitis and ectopic pregnancy.

Diagnostic Evaluation

1. Diagnostic criteria for empiric treatment of PID in women at risk for STDs are warranted if no cause for pelvic pain can be identified or if any of the following three minimum criteria are present:

a. Cervical motion tenderness.
b. Uterine tenderness.
c. Adnexal tenderness.

2. In addition to the presence of the minimum criteria, signs/symptoms of lower genital tract infection (such as cervical exudate, a friable cervix, and white blood cells on microscopic examination of cervical secretions) improve the specificity of the diagnosis.
3. Endocervical DNA testing or culture to identify organisms (*Gonorrhea* or *chlamydia*).
4. CBC may show elevated leukocytes.
5. Elevated C-reactive protein or elevated erythrocyte sedimentation rate shows inflammation.
6. Some cases may warrant endometrial biopsy, hysterosalpingostomy, transvaginal ultrasound, MRI, or laparoscopic visualization of the fallopian tubes.

Management

1. Patients with mild to moderate symptoms can be treated on an outpatient basis with oral antimicrobial regimens and timely follow-up at 48 to 72 hours after initiation of antibiotic and at completion of 2-week antibiotic course.
2. Inpatient treatment is required for surgical emergencies; abscess; pregnancy; severe infection with nausea, vomiting, and high fever; cannot take oral fluids; immunodeficient patient; or more aggressive antibiotics required to preserve fertility.
3. Parenteral antimicrobial regimens recommended by the CDC during hospitalization include the following:
   a. Cefotetan 2 g IV every 12 hours or cefoxitin 2 g IV every 6 hours *plus* doxycycline 100 mg IV or orally every 12 hours. *Note:* Doxycycline is contraindicated during pregnancy and IV infusion is painful; oral administration is preferred when possible.
   b. Clindamycin 900 mg IV every 8 hours *plus* gentamicin 2 mg/kg of body weight IV or IM as loading dose, followed by 1.5 mg/kg every 8 hours as maintenance dosage. (A single daily dose [3 to 5 mg/kg] of gentamicin may be substituted.)
4. Outpatient, oral antimicrobial regimens recommended by the CDC include:
   a. Ceftriaxone 250 mg IM single dose *plus* doxycycline 100 mg orally twice per day for 14 days, with or without metronidazole 500 mg orally twice per day for 14 days.
   b. Cefoxitin 2 g IM single dose *and* probenecid 1 g orally administered concurrently as a single dose *plus* doxycycline 100 mg orally twice daily for 14 days, with or without metronidazole 500 mg orally twice daily for 14 days.
   c. Other IM third-generation cephalosporin (ceftizoxime or cefotaxime) *plus* doxycycline 100 mg orally twice a day for 14 days, with or without metronidazole 500 mg twice a day for 14 days.
5. Parenteral therapy can be switched to oral therapy 24 to 48 hours after improvement is shown (reduced fever, decreased pain, resolution of nausea and vomiting). Ongoing oral therapy after parenteral therapy may be one of the following regimens:

a. Doxycycline 100 mg orally twice per day to complete a total of 14 days.
b. Clindamycin 450 mg orally four times per day to complete a total of 14 days.
c. With or without addition of metronidazole 500 mg orally twice per day to complete 14 days.

6. Surgical treatment or interventional drain placement may be necessary to drain abscess or later to treat adhesions or tubal damage.

TRANSITIONAL CARE ALERT If patient with PID is to be treated at home, stress the importance of follow-up, usually in 48 hours, to determine if oral antibiotic treatment is effective. Advise patient to report worsening of symptoms immediately to avoid hospitalization and further complications.

Complications

1. Abscess rupture and sepsis.
2. Infertility because of adhesions to fallopian tubes and ovaries.
3. Ectopic pregnancy caused by inability of fertilized egg to pass stricture.
4. Dyspareunia because of adhesions.

Nursing Assessment

1. Obtain history of menstruation, contraception, sexual activity (including number of partners and new partner), STD history, and symptoms in sexual partner.
2. Assess level of pain and fever; evaluate vital signs for hypotension and increased pulse, indicating hypovolemia.
3. Perform abdominal and pelvic examinations, if indicated; be alert for abdominal tenderness, rebound, guarding, or a mass.
4. Assess the patient's feelings about having an STD.

Nursing Diagnoses

- Acute Pain related to pelvic inflammation and infection.
- Deficient Fluid Volume related to fever and decreased oral intake.
- Risk for Infection related to STDs.

Nursing Interventions

Relieving Pain

1. Administer or teach the patient to self-administer analgesics as prescribed; monitor for adverse effect of drowsiness and constipation.
2. Assist to comfortable position of pelvic dependence, with upper body and legs slightly elevated.

3. Suggest heating pad to lower abdomen or low back.

Restoring Fluid Balance

1. Administer antiemetics as needed for nausea and vomiting impairing fluid intake.
2. Monitor intake and output.
3. Restart oral intake with ice chips and sips of water when vomiting has ceased for 2 hours.

Resolving Infection and Further Transmission

1. Administer or teach self-administration of antibiotics as prescribed.
2. Report sexually transmitted infection such as gonorrhea to state or local health department, and advise that patient's partners in past 60 days should be treated.
3. Review STD prevention guidelines.

Patient Education and Health Maintenance

1. Encourage compliance with antibiotic therapy for full length of prescription.
2. Stress the need for sexual abstinence and pelvic rest (nothing in the vagina, including no douching or tampons) until completion of the patient's and partner's antimicrobial regimens, resolution of the patient's and partner's symptoms, and follow-up visit.
3. Advise testing and empiric treatment of gonorrhea and chlamydia for all sexual partners (within past 60 days or more). Tell patient that diagnosis of chlamydia or gonorrhea necessitates reporting to public health department and partners will be traced.
4. Repeat patient and partner testing for gonorrhea and chlamydia is recommended 3 to 6 months after treatment completion.
5. Discuss STDs and methods of prevention—abstinence, monogamy, and proper use of female or male condoms. See page 653.

Evaluation: Expected Outcomes

- Verbalizes relief of pain.
- Vital signs stable; intake equals output.
- Reports abstinence during treatment period for self and partner and continued plan to prevent STDs.

Endometriosis

EVIDENCE BASE Dunselman, G. A., Vermeulen, N., Becker, C., et al. (2014). European Society for Human Reproduction and Embryology guideline: Management of women with endometriosis. *Human Reproduction, 29*, 400–412.

Endometriosis is the abnormal proliferation of uterine endometrial tissue outside the uterus.

Pathophysiology and Etiology

1. May also be found outside the pelvic cavity; an intact uterus is not needed to have endometriosis (see Figure 22-9).
2. Peaks in women ages 25 to 45; may occur at any age. Increased risk in siblings, women with shorter menstrual cycles, and longer duration of flow. More common in white women than black women, in women who do not exercise, and in obese women.
3. Responds to ovarian hormonal stimulation—estrogen increases it; progestins decrease it.
   a. Bleeds during uterine menstruation, resulting in accumulated blood and inflammation and subsequent adhesions and pain.
   b. Regresses during amenorrhea (ie, pregnancy and menopause) and hormonal contraceptive and androgen use.
4. Theories of origin:
   a. May be embryonic tissue remnants that differentiate as a result of hormonal stimulation and spread via lymphatic or venous channels.
   b. May be transferred via surgical instruments.
   c. May be caused by retrograde menstruation through fallopian tubes into peritoneal cavity (but this theory does not account for some types of endometriosis)
   d. Genetic predisposition may increase the likelihood in women with a first-degree relative with endometriosis.
   e. Lymphatic or vascular distribution of endometrial tissue.

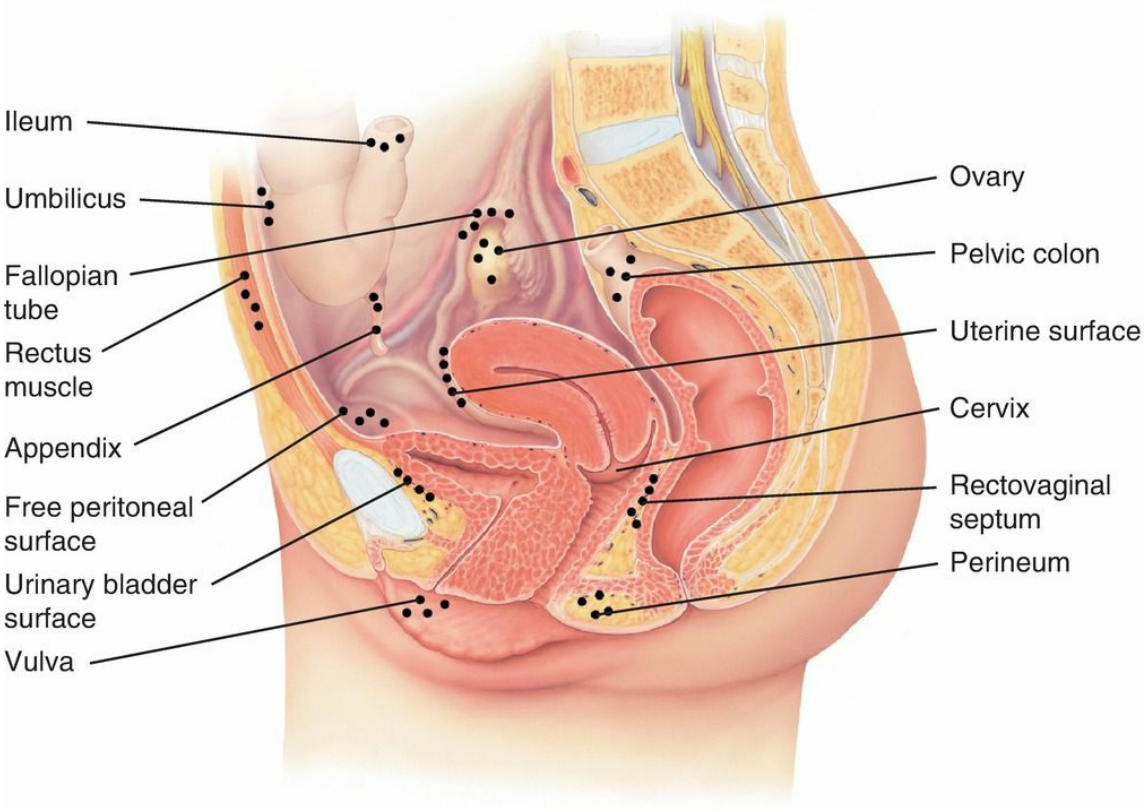

Figure 22-9. Common sites of endometriosis. Ectopic endometrial tissue can implant almost anywhere in the pelvic peritoneum. It can even invade distant sites such as the lungs. (Anatomical Chart Company.)

Clinical Manifestations

1. Depends on sites of implantation; may be asymptomatic.
2. Pelvic pain—especially during or before menstruation.
3. Dyspareunia.
4. Painful defecation—if implants are on the sigmoid colon or rectum.
5. Abnormal uterine bleeding.
6. Persistent infertility (in 30% to 40% of women with endometriosis).
7. Hematuria, dysuria, and flank pain—if bladder involved.

Diagnostic Evaluation

1. Pelvic and rectal examinations—tender, fixed nodules or ovarian mass or uterine retrodisplacement; nodules may not be palpable.
2. Transvaginal ultrasound—diagnostic tool of choice to first assess for endometriosis. MRI and CT are reserved for inconclusive ultrasound results.
3. Laparoscopy—for definitive diagnosis to view implants, obtain tissue for histologic analysis, and determine extent of disease.

Management

Medical

The goal of medical suppressive therapy is to decrease pain. However, if therapy is stopped, pain recurs. Medical therapies are ineffective for infertility associated with endometriosis.

1. Hormonal contraceptives—such as combination oral contraceptives (OCs); use small amount of estrogen and maximum amount of progestin and androgen effect to decrease implant size. OC use for more than 24 months effectively decreases endometrioma recurrence and decreases the frequency and intensity of dysmenorrhea.
2. Progestins—such as depot medroxyprogesterone acetate; create a hypoestrogenic environment. Efficacy is equivalent to OCs.
3. Nonsteroidal anti-inflammatory drugs—such as ibuprofen and naproxen sodium—decrease dysmenorrhea with antiprostaglandin action
4. If after 3 months of OCs and NSAIDs treatment has not provided adequate pain relief, then gonadotropin-releasing hormone (GnRH) agonist (leuprolide) injections may be administered during a 6-month period—create hypoestrogenic environment. Menopausal-like side effects, such as hot flashes and vaginal dryness, may not be tolerable to some women. If GnRH therapy will continue later, then norethindrone acetate add-back therapy will be added to prevent bone mineral loss and alleviate some symptoms. Calcium, vitamin D, and bisphosphonates may be added also.
5. Aromatase inhibitors, such as letrozole—inhibits the action of aromatase, which converts androgens to estrogen, thereby reducing estrogen levels in all tissues including the endometriosis. More RCTs are needed to determine its efficacy.
6. Danazol—synthetic androgen suppresses endometrial growth. Rarely used secondary to intolerable adverse effects (increased facial hair, acne, weight gain, vasomotor symptoms) and other drugs are available with better side effect profiles. Contraindicated in pregnancy.

Surgical

1. Laparoscopic surgery—preferred procedure to remove implants and lyse adhesions by excision; not curative; high recurrence rate.
2. Carbon dioxide laser laparoscopy—for minimal to moderate disease; vaporizes tissue; may be done at same time as diagnosis; good pregnancy rate.
3. Laparotomy—rarely performed; involves a larger abdominal incision than laparoscopy; for severe endometriosis or persistent symptoms.
4. Presacral neurectomy—rarely performed; to decrease central pelvic pain; preserves fertility; limited efficacy in relieving pain; severe constipation results.
5. Hysterectomy—if fertility is not desired and symptoms are severe; greater pain relief is achieved when ovaries are also removed.

Complications

1. Infertility.
2. Rupture of cyst—mimics ruptured appendix.
3. Chronic pelvic pain.
4. Dyspareunia.
5. Bowel or ureter obstruction.

Nursing Assessment

1. Obtain history of symptoms to determine spread and severity of disease.
2. Assess pain—level, location, frequency, duration, characteristics, and impact on functioning.
3. Perform abdominal examination to assess for areas of tenderness and nodules.
4. Assess for impact of endometriosis and/or infertility on patient and her relationship with significant other.

Nursing Diagnoses

- Acute and Chronic Pain related to hormonal stimulation and adhesions.
- Readiness for Enhanced Self-Care related to difficult management of disease and infertility.

Nursing Interventions

Reducing Pain

1. Teach use of analgesics and other prescribed medication, with adverse effects.
2. Encourage use of heating pad to painful areas, as needed.
3. Teach patient relaxation techniques to control pain, such as deep breathing, imagery, and progressive muscle relaxation.
4. Encourage patient to try position changes for sexual intercourse if experiencing dyspareunia.

Fostering Enhanced Self-Care

1. Include patient in treatment planning; answer questions about drug and surgical treatment so she can make informed choices.
2. Encourage adequate rest and nutrition.
3. Provide emotional support and encourage patient to discuss treatment of infertility with her physician.
4. Prepare the patient for surgery, as indicated.

Patient Education and Health Maintenance

1. Instruct the patient in the adverse effects of prescribed medication.
2. Refer patient to support groups such as Endometriosis Association (*www.endometriosisassn.org*) and reliable resources for information such as *Endometriosis.org* (*http://endometriosis.org*).

Evaluation: Expected Outcomes

- Verbalizes reduced pain.
- Verbalizes increased self-care measures.

Toxic Shock Syndrome

Toxic shock syndrome (TSS) is a rare condition caused by a bacterial toxin from *Staphylococcus aureus* or sometimes by group A *Streptococcus pyogenes* in the bloodstream; it can be life-threatening.

Pathophysiology and Etiology

1. Cause is uncertain, but 70% of cases historically were associated with menstruation and superabsorbent tampon use. Menstrual cases have declined since the withdrawal of superabsorbent tampons from the market around 1986. Now, half of TSS cases are not menstrually related.
2. TSS does occur in nonmenstruating or postmenopausal females, males, and children with conditions such as cellulitis, surgical wound infections, subcutaneous abscesses, vaginal infections, after childbirth, and with the use of contraceptive sponge or diaphragm.
3. See Figure 22-10 for pathophysiology.

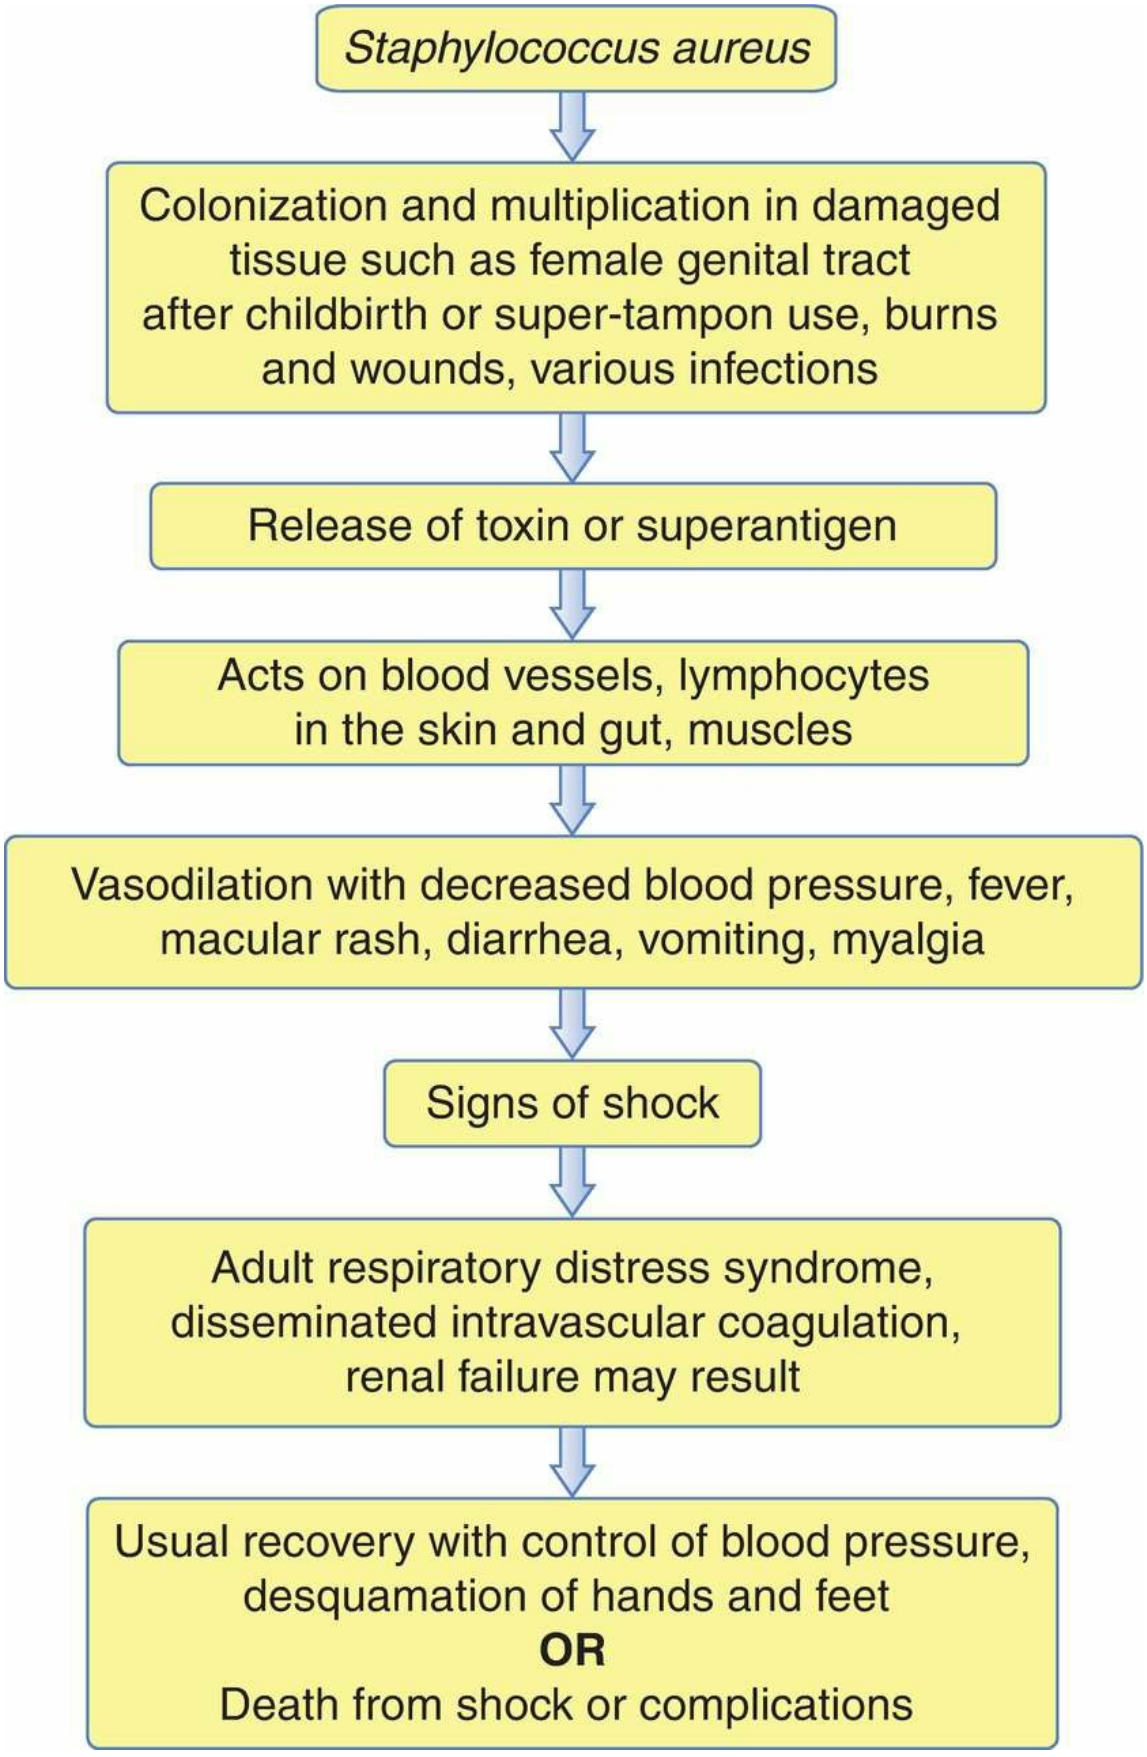

Figure 22-10. Pathophysiology of toxic shock syndrome.

Clinical Manifestations

1. Patients may initially present with fever, hypotension, and diffuse rash.
2. May have sudden onset of fever greater than 102°F (38.9°C), often with flulike symptoms (myalgias, headache, sore throat).
3. Hypotension and rapid progression to shock within 72 hours of onset.
4. Rash (similar to sunburn) that is diffuse, red, and macular; followed by desquamation, particularly of the palms and soles, 1 to 2 weeks after illness onset.
5. Mucous membrane hyperemia.
6. Vomiting and profuse watery diarrhea.
7. Rapid progression to multisystem involvement.

Diagnostic Evaluation

1. Blood, urine, throat, and vaginal or cervical cultures; possibly cerebrospinal fluid culture to detect or rule out infectious organism.
2. Tests to rule out other febrile illnesses—Rocky Mountain spotted fever, Lyme disease, meningitis, and Epstein-Barr or coxsackie virus.
3. CBC, electrolytes, blood urea nitrogen, creatinine, coagulation studies, and other tests to monitor condition.

Management

Management will be achieved in an intensive care unit because of the nature of the rapidly progressing shock, circulatory compromise, impending potential acute renal failure, and multisystem organ failure.

1. Fluid and electrolyte replacement to increase blood pressure and prevent renal failure.
2. Inotropes and vasopressor medications (ie, dopamine), as needed.
3. Intravenous antibiotics (ie, penicillins, cephalosporins, vancomycin); methicillin-resistant *Staphylococcus aureus* has been reported in some cases of TSS.
4. Mechanical ventilation in acute respiratory distress and lactic acidosis.
5. The use of steroids and immunoglobulins is controversial and under investigation.
6. Surgery may be employed to remove causative infectious site or to debride skin and soft tissue.

Complications

Cardiovascular collapse and renal failure because of shock.

Nursing Assessment

1. Determine menstrual history, use of tampons, or whether there has been recent skin infection, childbirth, or surgery.
2. Determine vital signs quickly; hemodynamic monitoring may be needed.

Nursing Diagnoses

- Hyperthermia related to infectious process.
- Deficient Fluid Volume related to toxin effects.
- Impaired Skin Integrity related to latent desquamation.

Nursing Interventions

Reducing Fever

1. Administer antipyretics and antibiotics, as ordered.
2. Use cooling measures, such as sponge baths and hypothermia blanket, if indicated.
3. Monitor core body temperature frequently.

Restoring Fluid Volume

1. Perform hemodynamic monitoring, as indicated (ie, arterial line, central venous pressure, or pulmonary artery pressure).
2. Maintain strict intake and output measurement.
3. Insert indwelling catheter to monitor urine output.
4. Administer IV fluids and vasopressors, as ordered, to control hypotension.
5. Monitor respiratory status for pulmonary edema and respiratory distress syndrome because of fluid overload from increased fluid replacement or from lactic acidosis from acute renal failure. Mechanical ventilation may be required.
6. Administer diuretics, as ordered, if edema results.

Restoring Skin Integrity

1. Tell the patient to expect desquamation of the skin, as in peeling sunburn.
2. Protect skin and avoid use of harsh soaps and alcohol that cause drying.
3. Tell the patient to apply mild moisturizer and avoid direct sunlight until healed.
4. Advise the patient that reversible hair loss may occur 1 to 2 months after TSS.

Patient Education and Health Maintenance

1. Tell the patient to expect fatigue for weeks to months after TSS.
2. Tell the patient not to use tampons in future to reduce risk of recurrence.
3. Encourage follow-up examination and cultures.
4. Teach prevention of TSS.
    a. Avoid use of tampons if menstrual flow is light. Use pads whenever possible.
    b. Alternate use of pads with tampons; avoid superabsorbent tampons.
    c. Change tampons frequently and do not wear one longer than 8 hours—4 hours maximum in heavy discharge time.

d. Be careful of vaginal abrasions that can be caused by some applicators.

e. Be alert to symptoms of TSS.

Evaluation: Expected Outcomes

- Afebrile.
- Normotensive and good urine output.
- Skin heals without scar.

OVERVIEW AND ASSESSMENT

See additional online content: Procedure Guidelines 23-1

PROCEDURE GUIDELINES 23-1

Examination of the Breast by the Nurse

PURPOSE

1. To detect abnormalities in the breasts
2. To teach a woman how to perform breast self-examination

EQUIPMENT

- Good lighting and a private, warm setting

PROCEDURE

Nursing Action	Rationale
Sitting position	
1. Wash your hands under warm water and dry them. Apply powder if they feel "sticky."	1. The breast is sensitive to cold. Powder reduces friction.
2. Have the patient undress to her waist and sit comfortably facing the examiner. Observe breasts for abnormalities.	2. Provides an opportunity to observe breasts for lack of symmetry and for gross signs such as redness, irritated nipple, dimpling, and orange-peel skin.
3. Have the patient raise her arms overhead.	3. Changes in the lower half of the breast are more visible.
4. Palpate cervical and supraclavicular area.	4. Note whether lymph nodes are enlarged, fixed, movable, or difficult to locate.
5. Palpate axillary nodes; hold the patient's forearm in your left palm while you check nodes with your right fingertips. Repeat on the other side.	5. Same as 4 above.
6. Have the patient place hands on hips and press.	6. Flexes pectoral muscles, accentuates skin dimpling or masses.
Lying position	
1. Instruct the patient to lie down with her right arm under her head. Place a small pillow under the right shoulder.	1. Spreads breast tissue evenly over chest wall.
2. With the finger pads of two or three fingers, gently palpate breast tissue beginning at the upper outer quadrant. a. Proceed in an orderly pattern around the breast and repeat the first quarter examined. b. Repeat procedure for other breast.	2. The sensitive fingers, proceeding in a kneading fashion, can detect thickened, lumpy, or "buckshot" tissue between the patient's skin and chest wall. Because most breast lesions are in the upper outer quadrant, this segment is double-checked.
3. Recognize that there is a prolongation of the axillary extension of normal breast tissue that may extend high into the axilla.	3. This is normal if symmetrical and may be abnormal if asymmetrical.
4. Check areolar area for crustiness, nipple discharge, signs of infection. If nipple discharge is observed, note if from single or multiple ducts. Hemoccult test may be used to check for hidden blood.	4. A nipple discharge may be benign or may be related to cancer.
5. Record findings and report abnormalities to the health care provider.	5. Diagram may be useful for future reference.
6. Instruct the patient in performing self-examination. Encourage her to ask questions; provide her with appropriate literature.	6. Ninety percent of women discover their own abnormalities.

Subjective Data

Obtain a nursing history about specific breast complaints and general health information from the patient to plan care and appropriate patient teaching.

Breast Manifestations

1. Palpable lumps—date noted; affected by menstruation; changes noted since detection.
2. Nipple discharge—date of onset, color, unilateral or bilateral, spontaneous or provoked.
3. Pain or tenderness—localized or diffuse, cyclic or constant, unilateral or bilateral.
4. Date of last mammogram and result.
5. Patient's practice of breast self-examination (BSE).

History

General Information

1. Age.
2. Past medical–surgical history; injuries; bleeding tendencies.
3. Medications, including current or prior use of hormonal contraceptives and hormones, over-the-counter (OTC) products, vitamins, and herbal supplements.

Gynecologic and Obstetric History

1. Menarche.
2. Date of last menses.
3. Pregnancies, miscarriages, abortions, deliveries.
4. Lactation history.
5. Prior breast history, including previous history of irradiation involving breast region.
6. Family history of breast cancer.

Examination and Screening

Perform a breast examination for any breast complaint and teach patient how to examine breasts, if desired. Although research has not shown that screening breast exams by a health professional or self-breast exams are effective in reducing mortality, examination should be done for any breast complaint. Screening breast exam may also allow women to become more comfortable and familiar with their own bodies. Mammography is the primary breast cancer screening method.

1. If a woman chooses to examine breasts once per month, exam is best done just after the menstrual period, because breasts are less engorged and a tumor is easier to detect, and at regular monthly intervals after the cessation of menses.
2. Compare inspection and palpation findings with the opposite breast.
3. Remind patient that 90% of breast lumps are not cancerous.
4. Do not neglect men when there is a breast complaint—1% of breast cancers occur in men.
5. It is acceptable for women to choose not to do BSE or to do BSE irregularly.

GERONTOLOGIC ALERT Normal breast changes in older patients include drooping, flaccid breasts caused by decreased subcutaneous tissue from decreased estrogen levels. Nipple size and erection are also reduced.

Guidelines for Early Detection

EVIDENCE BASE Smith, R., Andrews, K., Brooks, D., et al. (2017). Cancer screening in the United States, 2017: A review of current American Cancer Society guidelines and issues in cancer screening. *CA—A Cancer Journal for Clinicians, 67*, 100–121.

Meneses, K. (2016). When should I have a mammogram? Recent changes in ACS mammography guidelines: Implications for practice. *Journal of the Advanced Practitioner in Oncology, 7*, 567–570.

Women at Average Risk

1. Recommendations vary by organization.
2. American Cancer Society recommends women begin annual mammography at age 45, biennial at age 55, but should be available to women at age 40, and continue as long as life expectancy is projected to be 10 years or longer. Because of lack of evidence, clinical breast exam and breast self-exam are no longer recommended.
3. National Comprehensive Cancer Network, American College of Obstetricians and Gynecologists, and

the American College of Radiology recommend women should have annual mammographic screening beginning at age 40.

4. U.S. Preventive Services recommends women aged 50 to 74 undergo biennial screening mammography and end screening at age 75. Clinical breast exam is not recommended after age 40.

Older Women

1. Screening decisions in older women should be individualized by considering the potential benefits and risks of mammography in the context of current health status and estimated life expectancy. As long as a woman is in reasonably good health and would be a candidate for treatment, she should continue to be screened with mammography.

GERONTOLOGIC ALERT Many older women may not be aware of newer treatments for breast cancer and may fear radical mastectomy, therefore avoiding breast cancer screening. Provide information about incidence, screening, and treatment and encourage discussion with a health care provider.

Women at Increased Risk

EVIDENCE BASE Himes, D. O., Root, A. E., Gammon, A., et al. (2016). Breast cancer assessment: Calculating lifetime risk using the Tyrer-Cuzick model. *Journal for Nurse Practitioners, 12*, 581–592.

---

1. Women at increased risk for breast cancer might benefit from additional screening strategies beyond those offered to women of average risk, such as earlier initiation of screening, shorter screening intervals, or the addition of screening modalities other than mammography and physical examination, such as ultrasound or magnetic resonance imaging (MRI).
2. Screening MRI is recommended for women with an approximately 20% to 25% or greater lifetime risk of developing breast cancer, including women with a strong family history of breast or ovarian cancer, women who were treated for Hodgkin disease, women with a history of LCIS or atypical hyperplasia, and those with a prior history of breast cancer. Annual MRI should be considered in these women. Several models exist that attempt to calculate lifetime risk of breast cancer for women with identifiable factors associated with the disease. The Gail model, the Tyrer-Cuzick model, and the Claus model are examples of risk prevention models that estimate risk of breast cancer based on family history and other characteristics. These and a variety of other evidence based studies and risk calculators can be found on the National Institutes of Health, Division of Cancer Control and Population Sciences webpage *https://epi.grants.cancer.gov/cancer_risk_prediction/breast.html*.

Laboratory Tests

Nipple Discharge Cytology

Description

Secretions are smeared on a slide, fixed, and submitted for cytologic examination. There is a high rate of false-negative test results with this method.

Nursing and Patient Care Considerations

1. Wash nipple area with water and pat dry before obtaining specimen if crusting of drainage is present.
2. Gently milk breast or ask woman to express fluid to obtain a large drop on nipple.
3. Carefully touch slide to drop and draw slide across nipple to obtain smear. Spray with fixative or drop into container with fixative.
4. Inform patient of results promptly to reduce anxiety and explain that other tests may be needed.

Ductal Lavage

Description

A procedure that targets asymptomatic women at increased risk for breast cancer. Breast duct epithelial cells are collected from the nipple for cytological analysis.

Nursing and Patient Care Considerations

Advise patient to discuss questions with health care provider. This test is not widely used, and there are insufficient data at this time to recommend its use for screening.

Tumor-Specific Tests

Tests to evaluate the characteristics of a tumor and/or its potential to regrow.

1. Estrogen and progesterone receptors identify patients most likely to benefit from hormonal forms of therapy. Approximately 75% are estrogen receptor positive. A negative result is associated with a less favorable prognosis.
2. HER2—human epidermal growth factor receptor that has been demonstrated in 15% to 30% of breast cancers. Found by many investigators to be associated with poorer survival, regardless of clinical stage. May affect treatment decisions.
3. Histologic grade is reported using an Elston-Ellis modification of the Scarff-Bloom-Richardson Scale. It is a combination of nuclear grade, mitotic rate, and tubule formation with scores given for each. A low score equates to a low grade (grade I), and a higher score to a higher grade (grade III). In general, high-grade tumors are more likely to recur when compared to low-grade tumors.
4. Multiparameter gene assays (eg, Oncotype DX and MammaPrint) quantify the likelihood of distant breast cancer recurrence and measure how chemotherapy may assist with planning treatment. The Oncotype DX assay is included in the National Comprehensive Cancer Network guideline treatment

decision pathway. Breast cancer diagnostic and treatment guidelines are available at *www.nccn.org*. A similar assay for ductal carcinoma in situ (DCIS) continues under investigation. Results provide estimates of local recurrence risk and may help to select patients who are candidates for minimal therapy and may change radiotherapy recommendations. There is currently controversy regarding the overtreatment of DCIS.

5. Cancer subtyping—as determined by gene expression profiling—is currently under investigation.
6. Pathologists may use other special stains to aid in diagnosis.

Tests to Detect Metastasis

1. Increased values on liver function tests may indicate possible liver metastasis.
2. Increased calcium and alkaline phosphatase levels may indicate possible bony metastasis.
3. Additional metastatic workup may include chest x-ray, bone scan, computed tomography (CT) scan, and positron emission tomography (PET) scan.
4. Biological markers (ie, CA15.3 and CA27.29) may be used for monitoring patients with metastatic disease in conjunction with diagnostic imaging, history, and physical examination. Present data are insufficient to recommend their use alone for screening, diagnosis, or staging. However, they may be used to indicate treatment failure.

Radiology and Imaging

Mammography

Description

1. Low-dose x-ray of breast used to screen for breast abnormalities or may be used when a lump is found on physical examination. Can detect patients with clustered microcalcifications.
2. Compression of the breast is used to reduce the amount of radiation absorbed by the breast tissue and separate overlapping tissue.
3. Two views are taken routinely: craniocaudal and mediolateral; other views are done as necessary.
4. Best performed at a facility that is accredited by the American College of Radiology. The machines and staff at these facilities have met specific criteria. Computer-aided detection has been developed to aid radiologists in detecting abnormalities. Assessment categories have been developed to describe the results and provide follow-up recommendations. A category 0 is incomplete and needs additional images.
   a. Category 1 is a negative result (normal mammogram) with nothing on which to comment.
   b. Category 2 is a normal mammogram, but there is a benign finding on which to comment.
   c. Category 3 is probably benign, but short-interval follow-up may be recommended to determine stability of the finding.
   d. Category 4 describes a suspicious abnormality, and biopsy should be considered.
   e. Category 5 is highly suggestive of malignancy; appropriate action should be taken.
   f. Category 6 describes a known, biopsy-proven malignancy requiring appropriate action.
5. Mammography is not routinely done if a woman is pregnant.
6. The breasts of young women tend to be extremely dense and are poorly suited to mammography.
7. False-negative results occur even in the best facilities; figure may reach 10%.
8. Both screen film and digital mammography use x-rays to obtain images. With digital mammography, a film image is replaced with an electronic image similar to digital photography. For younger women under age 50, women with radiographically dense breasts, and premenopausal and perimenopausal women, digital mammography is more accurate than film mammography and thus has supplanted film mammography as the technology of choice. Digital tomosynthesis creates a three-dimensional picture of the breasts that may make breast cancers easier to see, and adding tomosynthesis has increased breast cancer detection and decreased false-positive results.

EVIDENCE BASE American College of Radiology. (2013). *BI-RAD Atlas* (5th ed.). Reston, VA: Author. Available: *www.acr.org.*

Nursing and Patient Care Considerations

1. Recommend regular screening based on established guidelines (see page 678). Tell patients that routine screening mammography has been shown to reduce mortality from breast cancer. Procedure takes approximately 15 minutes.
2. Remind patients not to apply deodorant, cream, or powder to breast, nipple, or underarm areas on examination day.
3. Advise that some discomfort may be felt from compressing the breast.
4. Patients should have an opportunity to become informed about the benefits, limitations, and potential harms associated with regular screening. Overdiagnosis of clinically insignificant disease is possible. Benefits are thought to outweigh the exposure to low dose of radiation.
5. Alert patient that extra views do not imply that the patient has breast cancer.

NURSING ALERT Because health teaching is an important nursing role, nurses should educate women about the importance of routine screening. Because of differences in screening guidelines, women may also need advice regarding the timing of mammograms.

Community Health Education

Implement patient teaching of importance of screening on a community level by:

1. Reinforcing that early detection is associated with decreased mortality.
2. Helping patients and families establish and maintain support networks.
3. Tailoring patient education messages to patients of different cultures.
4. Knowing the resources available and making people aware of them.
    a. National Cancer Institute—answers questions and provides booklets about cancer. Call 800-4-CANCER or go to *www.cancer.gov*.
    b. American Cancer Society—offers many services to patients and their families. Call 800-ACS-2345 for local chapter or go to *www.cancer.org*.
    c. Susan G. Komen Foundation at *www.komen.org*.

Ultrasonography

Description

1. Uses high-frequency sound waves to get an image of the breast.
2. Helps determine if a lump is a cyst or a solid mass.
3. May be used if patient is pregnant or is younger than age 35.

Nursing and Patient Care Considerations

1. Advise that this test is painless and noninvasive.
2. No preparation is necessary.

Galactography/Ductogram

1. A contrast mammogram is obtained by injection of water-soluble contrast medium into a duct for patient with persistent bloody nipple discharge. It is a time-consuming procedure that is not routinely used.
2. It may outline an intraductal papilloma.
3. Its ability to differentiate benign from malignant lesions is limited.
4. Thermography, infrared imaging of the breasts, cannot locate small, deep cancers and remains under investigation.

Magnetic Resonance Imaging

1. Produces images from the combination of a magnetic field, radio waves, and computer processing.
2. May be used in newly diagnosed breast cancer patients for presurgical planning. May help in determining extent of disease, multifocality, and unsuspected disease in the contralateral breast, and after neoadjuvant chemotherapy, may help to downstage a patient and possibly decrease the magnitude of the planned procedure.
3. Useful in high-risk women, those with dense breasts, and in those with silicone implants.
4. Because MRI is less accessible and more expensive than mammography, it is not useful for generalized screening. There may be increased false-positive results.
5. See page 166 for description of MRI.

Other Tests

In addition to laboratory tests and imaging studies, biopsy methods are commonly used to evaluate breast conditions. A biopsy is the only certain way to learn whether a breast lump or suspicious area seen on a mammogram is cancerous.

Fine Needle Aspiration

Description

1. Uses a thin needle and syringe to collect tissue or to drain lump after using a local anesthetic. If it is a cyst, removing the fluid will collapse it; no other treatment may be needed. Ultrasound may be used to locate a nonpalpable cyst.
2. Normal cyst fluid appears straw-colored or greenish. Fluid should be sent for cytology if it appears suspicious (clear or bloody); otherwise, it is discarded.
3. This office procedure uses local anesthetic with results usually within 24 hours.
4. It has limited sensitivity, possibly because of insufficient acquisition of cytologic material.

Nursing and Patient Care Considerations

1. Inform patient of small risk of hematoma and infection.
2. Adhesive bandage applied after procedure; usually no discomfort.
3. Solid lesions may warrant an excisional biopsy.

Needle Biopsy

Description

1. Office procedure uses local anesthetic and removes a small piece of breast tissue using a needle with a special cutting edge.
2. For palpable lesions with a high suspicion of malignancy. May provide a tissue diagnosis quickly—usually approximately 24 hours—without doing an excisional biopsy to plan definitive surgery.
3. Ultrasound guidance may be used for nonpalpable lesions.

Nursing and Patient Care Considerations

1. Inform patient of small risk of hematoma and infection.
2. Tell patient that several passes may be necessary to obtain specimen, with minor discomfort.
3. Pressure dressing applied after procedure.
4. Recommend use of acetaminophen or ibuprofen for postprocedure discomfort—usually minimal, if any.

Stereotactic Core Needle Biopsy

Description

1. An x-ray–guided method for localizing and sampling nonpalpable lesions detected on mammography

with 90% to 95% sensitivity in detecting breast cancer.

2. Performed as an outpatient procedure with the patient lying prone on a special table using an automated biopsy gun with a vacuum system to draw tissue into a sampling chamber and rotate cutter to excise tissue. There may be a weight limit for this table.
3. After local anesthetic is administered, a needle is placed in the lesion with confirmation of its position on stereotactic x-ray views. Multiple samples are taken from different portions of the lesion. Allows harvesting of larger quantities of tissue with a single needle insertion. A tiny clip may be left in place at the end of the procedure to mark the area.
4. The procedure is quicker and less expensive than mammographically guided needle localization followed by surgical excisional biopsy and is an alternative to surgical excisional biopsy to make a diagnosis.

Nursing and Patient Care Considerations

1. Inform patient that it is a 1-hour outpatient procedure that requires no special preparation.
2. The patient should dress comfortably and will need to remain still during the procedure.
3. Complications may include minor bleeding, hematoma, and infection.
4. Explain that nonspecific, suspicious, or atypical findings may result in proceeding to excisional biopsy.
5. Remind patient that area in question will not be removed, only sampled.

Note: Many nonpalpable abnormalities that require breast biopsy are being identified because of increased use of screening mammography.

Excisional Biopsy

Description

1. Surgical removal of a palpable or nonpalpable lesion. A frozen section may be done for immediate tissue diagnosis.
2. Excisional biopsy or lumpectomy entails entire removal of a mass; incisional biopsy entails partial removal of a mass.
3. This outpatient procedure may be performed under local or general anesthesia.
4. Curvilinear incision is usually made directly over the mass, which is excised en bloc including a 1-cm grossly free margin of tissue.
5. Tumor ablation with insertion of a probe percutaneously that destroys cancer cells by freezing, heating, or with radiofrequency has been attempted; however, existing evidence is inadequate to recommend ablation as an alternative to surgical excision.

Nursing and Patient Care Considerations

1. Pressure dressing is placed, which can be removed in 24 to 48 hours.
2. Inform patient to watch for bleeding, hematoma, and signs of infection.
3. Recommend analgesics for discomfort and a support bra for comfort.
4. May take several days to get results, a stressful time for patients.

Needle Localization with Biopsy

Description

1. Performed when there is a nonpalpable mammographic finding.
2. Mammogram is used as a guide for placing a needle at the site of the breast change after injecting some local anesthetic.
3. A wire may be left in place for the surgeon, and dye may be injected to mark the site.
4. Excisional biopsy is then done (see above) removing the area around the tip of the wire.

Nursing and Patient Care Considerations

Inform patient that this may be a tedious procedure because she must remain immobile as the breast is compressed in the mammogram machine or stereotactic table and views are obtained.

Sentinel Lymph Node Biopsy

Description

1. A diagnostic surgical procedure utilizing selective lymph node sampling.
2. Pathologic study of the first (sentinel) axillary lymph node to receive drainage from a tumor; predicts the status of the remainder of the lymph nodes in the axilla.
3. Localization accomplished by injection of a blue dye and/or radioactive particles around a tumor to identify lymph nodes with afferent drainage.
4. The excised sentinel lymph nodes are subjected to routine pathologic examination and, possibly, immunohistochemical staining to detect micrometastasis.
5. The status of the sentinel lymph node is used to determine whether to proceed with full axillary dissection and/or determine treatment modalities.
6. If the sentinel lymph node tests negative, no further axillary surgery is indicated.
7. If test result is positive, further axillary dissection may be needed. However, in women undergoing breast-conserving surgery and having fewer than three involved lymph nodes, completion axillary lymph node dissection may be omitted per American Society of Clinical Oncology guidelines with no difference in overall survival.

EVIDENCE BASE Morrow, M. (2018). Management of the node-positive axilla in breast cancer in 2017: selecting the right option. *JAMA Oncology, 4*(2), 250–251.

Nursing and Patient Care Considerations

1. This is a reliable procedure, which is usually performed at the same time as definitive surgery—in conjunction with a breast-preserving procedure or mastectomy.
2. There is less morbidity and cost than with axillary dissection.

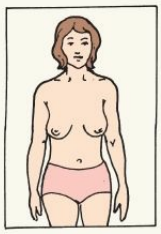
GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Patient Education Guidelines 23-1: Breast Self Exam

PATIENT EDUCATION GUIDELINES 23-1

Breast Self-Examination

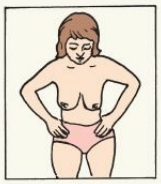
1. Look for changes.



Hands at side.
Compare for symmetry.
Look for changes in:
- shape
- color

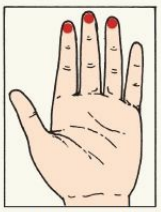
Check for:
- puckering
- dimpling
- skin changes
- nipple changes

Hands over head.
Check front and side view for:
- symmetry
- puckering
- dimpling

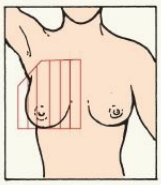


Hands on hips, press down, bend forward.
Check for:
- symmetry
- nipple direction
- general appearance

Lie down with a towel under right shoulder; raise right arm above the head.



Use the pads of the three middle fingers of the left hand.
Hold hand in bowed position.
Move fingers in dime-size circles.



Examine area from:
- underarm to lower bra line
- across to breast bone
- up to collar bone
- back to armpit

Use three levels of pressure:
- light
- medium
- firm

Examine entire area using vertical strip pattern.

2. Feel for changes.
3. Check your left breast with your right hand in the same way.
4. If you detect any changes, lumps, or knots, notify your health care provider immediately.

Surgery for Breast Cancer

Surgery for breast cancer may involve *mastectomy* or a *breast-preserving procedure*. The objective of breast-preserving procedures is a cosmetically acceptable breast after complete excision of the tumor. Research studies that compare breast conservation with mastectomy have demonstrated equivalent patient survival. Contraindications to breast conservation include multifocal disease; diffuse, extensive DCIS; inability to tolerate radiation therapy; and persistent positive margins. The evolving field of oncoplastic surgery uses techniques to allow the removal of large volumes of breast tissue while avoiding deformity. Although mastectomy rates have remained stable, risk-reducing contralateral prophylactic mastectomy has risen. See Table 23-1 for the surgical approach options that are available. The following discussion covers mastectomy and axillary node dissection.

Table 23-1 Types of Surgery for Breast Cancer

PROCEDURE	DESCRIPTION	INDICATIONS
Lumpectomy (excisional biopsy)	Removal of tumor and surrounding tissue	For diagnosis of an abnormal mammographic finding or palpable breast lump if needle biopsy not performed. Further surgery may be needed.
Quadrantectomy (partial mastectomy)	Removal of a breast quadrant that includes the tumor area and possibly overlying skin	Normal- to large-sized breasts. Usually done at the same time as axillary surgery.
Sentinel lymph node biopsy	Removal of only a few gatekeeper lymph nodes	Performed to predict status of lymph nodes—if negative for tumor, axillary dissection is not performed. May be done in conjunction with quadrantectomy or mastectomy.
Axillary dissection	Surgical removal of the axillary lymph nodes	Performed when lymph node is positive for tumor, mainly for prognosis, staging, and locoregional disease control.
Simple mastectomy*	Surgical removal of the entire breast	Large or multifocal tumors; women with very small breasts in whom local excision of tumor will be cosmetically unacceptable; ineligibility for radiation therapy; patient preference; prophylaxis.
Modified radical mastectomy*	Surgical removal of the entire breast and the axillary lymph nodes (simple mastectomy plus axillary dissection)	Positive lymph nodes; advanced disease.
Radical mastectomy*	Removal of entire breast, pectoral muscles, axillary nodes	Rarely done today—may be performed for advanced disease.

**Mastectomy may be followed by immediate or delayed reconstruction.*

Preoperative Management

See Chapter 7 for routine preoperative care. In addition:

1. The nature of the procedure is explained, along with expected postoperative care that includes drain care, location of the incision, and mobility of the arm.
2. Information is clarified about diagnosis and possibility of further therapy.
3. Measures are taken to recognize the extreme anxiety and fear that the patient, family, and significant others experience.
   a. Discuss patient's concerns and usual coping mechanisms.
   b. Explore support systems with patient.
   c. Discuss concerns regarding body image changes.
4. Evaluate the patient's overall medical condition to guide preoperative care, help determine how well the patient will tolerate surgery, and help prepare for complications that may occur postoperatively.

GERONTOLOGIC ALERT Assessment of preoperative mental status of the older patient will help determine if a cognitive change occurs postoperatively.

Potential Complications

1. Infection.
2. Hematoma, seroma.
3. Lymphedema.
4. Paresthesia, pain of axilla and arm.
5. Impaired mobility of arm.

Postoperative Management and Nursing Care

See Chapter 7 for routine postoperative care. In addition:

1. Dressing is removed and the wound is assessed for erythema, hematoma (fluid under incision), edema, tenderness, odor, and drainage. Report suspected hematoma promptly.
   a. Initial dressing may consist of gauze held in place by elastic, tape, or clear occlusive dressing wrap.
   b. Usually removed within 24 hours.
   c. Incision may remain open to air or elastic wrap may be replaced if patient prefers.
2. Suction drain from wound is maintained.
   a. May have 100 to 200 mL serous to serosanguineous drainage in the first 24 hours.
   b. Report if grossly bloody or excessive in amount.
3. Arm on affected side is observed for edema, erythema, and pain.
4. Patient teaching about drain care, exercises, and surgical outcome occurs.
5. Breast cancer surveillance of female relatives, especially sisters, daughters, and mother, is discussed.

NURSING ALERT Mastectomy patients may have an elastic wrap bandage that should fit snugly but not so tightly that it hinders respiration. It should fit comfortably and support unaffected breast.

Nursing Diagnoses

- Impaired Physical Mobility related to impaired movement of arm on operative side.
- Deficient Knowledge related to care of incision, drain, and arm.
- Ineffective Tissue Perfusion of affected arm related to lymphedema.
- Disturbed Body Image related to loss of breast (for mastectomy patient).
- Anxiety related to diagnosis of cancer.

- Sexual Dysfunction related to loss of breast and diagnosis of breast cancer.
- Compromised Family Coping related to diagnosis of cancer.

Nursing Interventions

In addition to routine postoperative interventions, provide the following care.

Mobilizing Affected Arm

1. Assess patient's ability to perform self-care and factors impeding performance.
2. Encourage wrist and elbow flexion and extension initially. Encourage use of arm for washing face, combing hair, applying lipstick, and brushing teeth. Encourage patient to gradually increase use of arm.
3. Encourage patient to avoid abduction initially to help prevent seroma formation.
4. Support arm in sling, if prescribed, to prevent abduction of the arm.
5. Instruct and provide patient with exercises to do when permitted (see Table 23-2).

Table 23-2 Exercises for the Rehabilitation of the Patient Following Mastectomy

EXERCISE	EQUIVALENT DAILY ACTIVITIES
1. Stand erect. • Lean forward at waist. • Allow arms to hang. • Swing arms from side to side together, then in opposite direction. • Next, swing arms from front to back together, then in opposite direction.	• Broom sweeping • Vacuum cleaning • Mopping floor • Pulling out and pushing in drawers • Weaving • Playing golf
2. Stand erect facing wall with palms flat against wall, arms extended. • Relax arms and shoulders and allow upper part of body to lean forward against hands. • Push away to original position; repeat.	• Pushing self out of bath tub • Kneading bread • Breaststroke—swimming • Sawing or cutting types of crafts
3. Stand erect facing wall with palms flat against wall. • Climb the wall with the fingers; descend, repeat.	• Raising windows • Washing windows • Hanging clothes on line • Reaching to an upper shelf
4. Stand erect and clasp hands at small of back; raise hands; lower; repeat. • Clasp hands back of neck; reach downward; upward; repeat.	• Fastening brassiere • Buttoning blouse or dress • Pulling up a dress zipper • Fastening beads • Washing the back
5. Toss a rope over a shower curtain rod. • Hold the ends of the rope (knotted) in each hand and alternately pull on each end. • Using a seesaw motion and with arms outstretched, slide the rope up and down over the rod.	• Drying the back with a bath towel • Raising and lowering a window blind • Closing and opening window drapes
6. Flex and extend each finger in turn.	• Sewing, knitting, crocheting • Typing, painting, playing piano or other musical instrument

Increasing Knowledge

1. Explain how wound will gradually change and that the newly healed wound may have less sensation because of severed nerves.

2. Instruct patient on signs of infection, hematoma, or seroma formation to be reported.
3. Teach patient to bathe incision gently and to blot carefully to dry, and later, with approval, massage the healed incision gently with cocoa butter to encourage circulation and increase skin elasticity.
4. Teach care of drains, if appropriate; empty contents, measure, and record.
5. Teach importance of BSE, mammograms, and regular follow-up visits.
6. Encourage discussion with health care provider about pregnancy after breast cancer, if indicated.

GERONTOLOGIC ALERT Signs and symptoms of infection may not be obvious in older patients. Assess patients for mental status changes or urinary incontinence.

Promoting Lymphatic Drainage

1. Instruct patient in potential problem of lymphedema of the arm, when lymph fluid collects in the arm. At particular risk are patients who undergo axillary node dissection in combination with radiation therapy to axilla. There is decreased risk when sentinel lymph node biopsy only is performed. Explain that lymphedema may occur years postoperatively. May present as arm heaviness, decreased flexibility, aching, or swelling.
2. Do not take blood pressure, draw blood, inject medications, or start intravenous lines in affected arm. Post sign over bed.
3. Elevate affected arm on pillows, above level of heart, and hand above elbow to promote gravity drainage of fluid.
4. Teach patient to massage affected arm, if prescribed, which will increase circulation and decrease edema. Treatment for severe lymphedema may also include the application of elastic bandages and/or intermittent pneumatic compression. Compressive sleeves and exercises may be recommended to prevent lymphedema.
5. Teach patient care of the affected arm to prevent lymphedema and infection.

PATIENT EDUCATION GUIDELINES 23-1

Prevention of Lymphedema

To reduce the risk of lymphedema of your arm after the removal of lymph nodes, follow these general guidelines to prevent infection and obstruction of blood and lymph fluid.

- Take care of your skin to prevent dryness, cracking, and irritation that may lead to infection.
- Keep your arm clean and cover any open areas.
- Take care of your fingernails to avoid ripped cuticles and nails.
- Avoid using a razor for underarm hair removal.
- Protect hands and fingers from injury while gardening, sewing, cooking, and other chores.
- Avoid constricting clothing around arms.

- Avoid having blood drawn or needles inserted into affected arm.
- Avoid having blood pressure taken on affected arm.
- Prevent insect bites and stings through use of repellent and protective clothing.
- For more information, refer to American Cancer Society (www.cancer.org).

EVIDENCE BASE American Cancer Society. (2018). Lymphedema. Available: *www.cancer.org/treatment/treatments-and-side-effects/physical-side-effects/lymphedema.html.*

Enhancing Body Image

1. Assess mastectomy patient's knowledge of prosthesis and reconstruction options and provide information, as needed.
2. Discuss patient's views on her altered body image.
3. Suggest clothing adjustments to camouflage loss of breast.
4. Assist patient to obtain a temporary prosthesis (may be provided by Reach to Recovery [see below]). First prosthesis should be light and soft to allow incision to heal. She may wear heavier type usually 4 to 8 weeks after surgeon's approval has been secured. Provide information regarding where to obtain permanent prosthesis and bras.
5. Encourage patient to discuss feelings with partner.
6. Encourage patient to allow herself to experience the grief process over the loss of her breast and to learn to cope with these feelings.

Reducing Anxiety

1. Familiarize patient with Reach to Recovery (*www.cancer.org*, then click on Support Programs), an American Cancer Society program that consists of volunteers who have had mastectomies or breast-preserving procedures and who make postoperative hospital visits to provide support and information. Clear first with patient's care provider.
2. Discuss patient's usual coping mechanisms.
3. Encourage and assist family to support patient.
4. Assist patient to maintain control by planning care with her and incorporating her usual routines.
5. Refer patient for postmastectomy support group, as needed and desired.
6. Offer list of community resources.
7. Remind patient that stress related to breast cancer and mastectomy may persist for a year or more and to seek help.
8. Include family in supportive interventions and measures to increase coping skills.

Maintaining Sexual Activity

1. Discuss effect of diagnosis and surgery on view of self as a woman.
2. Explore alternative means of sexual activity, such as changing position during intercourse, to decrease pressure on incision.
3. Encourage patient to discuss concerns with partner.
4. Assist patient and partner to look at incision when ready.

Facilitating Family Coping

1. Allow family members to acknowledge their feelings.
2. Approach family with warmth, respect, and support.
3. Acknowledge family strengths.
4. Involve family in care of patient.
5. Discuss stresses.
6. Direct family to community agencies, as indicated.

Community and Home Care Considerations

Because of short stays (1 to 2 days) after mastectomy, many patients can achieve the following benefits from home care:

1. Assess incision and drain tubes for proper healing and no signs of infection.
2. Teach patient drain tube and dressing care.
3. Support patient with adjustment back into home and community.
4. Monitor for lymphedema and reinforce teaching about arm care and exercises.
5. Goals of home care for these patients are to provide assessment of cardiovascular status and to ensure return of energy and proper healing.

TRANSITIONAL CARE ALERT Help identify those patients who may require longer hospitalizations and, possibly, a short stay in a subacute unit for rehabilitation to avoid readmission to the hospital. Factors that may be related to a delay in recovery include increased age, comorbid conditions, reduced nutritional status, infection, limited mobility, and limited support system or lack of presence of a caregiver.

Patient Education and Health Maintenance

1. Advise patient to call surgeon for signs of infection, increased pain, or edema of arm.
2. Make sure that patient knows schedule for follow-up with surgeon.
3. Provide resources for patient for ongoing information and support: The American Cancer Society (800-ACS-2345 or *www.cancer.org*) has numerous pages of information about surgery, nutrition and cancer, lymphedema, psychosocial issues, and other concerns.

4. Stress the importance of continued yearly mammogram.

Evaluation: Expected Outcomes

- Moves affected arm within prescribed limits.
- States care of incision, drains, and follow-up guidelines.
- No infection or swelling in affected arm.
- Expresses positive body image.
- Exhibits minimal anxiety.
- Reports satisfactory sexual activity and sexuality.
- Maintains a functional support system.

Breast Reconstruction After Mastectomy

Breast reconstruction (mammoplasty) may be performed at the same time as mastectomy (immediate) or as long after surgery as desired (delayed). Benefits include improved psychological coping because of improved body image and self-esteem. Cost is usually covered by insurance. Reconstruction selection is based on an assessment of cancer treatment, patient body type, smoking history, comorbidities, and patient concerns. An advantage of immediate reconstruction is a smaller scar through the use of a skin-sparing mastectomy. In general, the nipple–areolar complex is sacrificed with skin-sparing mastectomy. Nipple-sparring mastectomy may be an option for some women as well, especially those undergoing prophylactic mastectomy or those with a low nipple involvement rate. It appears to be a safe procedure for properly selected patients. Trials are warranted to determine the best incision and reconstruction methods. Reconstruction does not interfere with the detection of tumors.

NURSING ALERT Because breast reconstruction does not affect disease recurrence or survival, the expectations and desires of the patient are paramount in the decision-making process. Collaboration among members of the breast cancer team is essential.

Implants

Indicated for patients with inadequate breast tissue and skin of good quality.

Description

1. Uses prosthetic implants placed in pocket under the skin or pectoralis muscle. A variety of implants are available that contain saline, silicone gel, or a combination of both.
2. If opposite breast is ptotic (protruding downward), mastopexy may be necessary for symmetry.
3. A dermal matrix may be used at surgery to help provide a foundation for the tissue expander and/or implant.
4. Complications include capsular contracture resulting in firmness; may be painful and cause infection.
5. Tissue expanders may be necessary before implants are inserted.
    a. Inflatable envelope is placed under muscle or skin and is filled with saline when incision is healed (about 4 weeks).
    b. Saline is instilled every 1 to 3 weeks until the expander is beyond desired size.
    c. Later, expander is removed and a permanent implant is placed.
    d. Some types of expanders may be left in permanently.
6. Advantages of implant reconstruction over other methods: only one incision; less fibrosis.
7. Disadvantages may take months and may not be as cosmetically pleasing as other methods.

Nursing and Patient Care Considerations

1. Teach signs and symptoms of infection, hematoma, migration, and deflation.
2. Teach patient to massage breast to decrease capsule formation around implant.
3. Teach patient she may feel discomfort with expanders, if used.

Flap Grafts

Description

1. Transfer of skin, muscle, and subcutaneous tissue from another part of the body to the mastectomy site.
2. Types:
   a. Latissimus dorsi—skin, fat, and muscles of back between shoulder blades—are tunneled under the skin to front of chest. Usually, an implant is also needed.
   b. Transverse rectus abdominis myocutaneous flap—muscle, fat, skin, and blood supply are tunneled to breast area.
   c. Perforator flap reconstruction, that is, deep inferior epigastric perforator (DIEP) or superior gluteal artery perforator (SGAP), uses tissue as above without using muscle. Because of its complexity, offered by few breast centers.
3. Disadvantages include cost, slow process (done in stages), and increased morbidity.
4. Complications include flap loss, hematoma, infection, seroma, and abdominal hernia.

NURSING ALERT Smoking increases the risk of complications for all types of reconstruction. Patients who smoke should be made aware of increased rates of wound infections and healing complications.

Nursing and Patient Care Considerations

1. Assess flap and donor site for color, temperature, and wound drainage.
2. Control pain.
3. Provide support with bra or abdominal binder to maintain position of prosthesis.
4. Teach patient to perform BSE monthly and that she may have some asymmetry.

Nipple–Areolar Reconstruction

1. Usually done at a separate time from breast reconstruction.
2. Uses skin and fat from reconstructed breast for nipple and upper thigh for areola; tanning or tattoo done to obtain appropriate color.

Other Surgeries of the Breast

Reduction mammoplasty may be done for cosmetic purposes or to relieve uncomfortable symptoms. Augmentation mammoplasty is considered a cosmetic procedure.

Reduction Mammoplasty

Description

1. Removal of excess breast tissue, which also involves a reduction in skin and possible transposition of nipple–areolar complex.
2. Used for alleviation of symptoms that may include back and neck pain, muscle spasm, and grooving at the shoulders secondary to bra straps.
3. Complications include hematoma, infection, necrosis of skin flap, and nipple inversion.

Nursing and Patient Care Considerations

1. Explore reasons patient may desire surgery.
2. Discuss postoperative expectations with patient.
3. Nursing interventions are similar to those in patient undergoing reconstruction.

Augmentation Mammoplasty

Description

1. Enlarging of the breasts with the use of implants.
2. Implants may be made of silicone or saline. In most cases, this is a self-pay procedure if for cosmetic purpose.
3. Complications include hematoma, wound infection, diminished sensation of the nipple, and capsular contracture, resulting in firmness of the breast.
4. Breast implants are not associated with an increased incidence of breast cancer.

Nursing and Patient Care Considerations

1. Discuss patient's expectations preoperatively.
2. Nursing interventions are similar to those in the patient undergoing reconstruction with implants.

DISORDERS OF THE BREAST

See Standard of Care Guidelines 23-1, page 687.

STANDARD OF CARE GUIDELINES 23-1

Problems of the Breast

When caring for any patient undergoing evaluation, diagnostic testing, treatment, or counseling for a breast-related problem, ensure optimal outcome by adhering to the following guidelines:

- Explain the mammogram procedure or other diagnostic test and make sure patient knows when and how she will obtain results.
- Perform breast examination according to American Cancer Society guidelines.
- Inform health care provider and patient of any suspicious findings on breast examination—asymmetry of breasts, dimpling, skin changes, nipple discharge, fixed or hard mass.
- Inform health care provider and patient of abnormal mammogram or other test result and make sure that follow-up is arranged.

After Surgery for Breast Cancer

- Assess for evidence of bleeding from the incision or flaps, including increase in pain, and notify surgeon promptly for increased pain or bleeding.
- Assess drainage from suction drain for amount, color, and odor. Report if grossly bloody, purulent, or excessive in amount (may have 100 to 200 mL in the first 24 hours).
- Assess newly reconstructed breast flaps for viability by color, warmth, and wound drainage. Notify surgeon promptly for increased warmth, change in color, purulent or excessive drainage.
- Maintain proper protective positioning (avoid abduction to prevent edema) of arm and follow precautions for lymphedema.
- Assess patient's emotional response and provide support throughout the diagnostic and treatment process.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Fissure of the Nipple

A *fissure* is a type of ulcer that develops in the nipple of a nursing mother.

Etiology and Clinical Manifestations

1. May be caused by lack of preparation of nipples in the prenatal period.
2. Condition aggravated by sucking infant.
3. Nipple appears sore and irritated.
4. Nipple bleeds.
5. Infection may result.

Management and Nursing Interventions

1. Wash nipples with sterile saline solution.
2. Use artificial nipple for nursing.
3. If above does not initiate healing process, stop nursing and use breast pump.
4. Teach proper breastfeeding techniques to prevent fissures.
    a. Wash, dry, and lubricate nipples in prenatal period in preparation for nursing.
    b. Make sure infant's mouth covers areola.
    c. Keep nipple clean by washing and drying after each nursing period.
    d. Use lanolin cream to prevent cracking; must remove before breastfeeding.

Nipple Discharge

Nipple discharge may be serous, serosanguineous, bloody, purulent, or multicolored. It is commonly associated with benign conditions; rarely, malignancy is responsible. It may be spontaneous or nonspontaneous (occurs only when breast is compressed), and it is important to differentiate between the two.

Etiology and Clinical Manifestations

1. Galactorrhea—bilateral, nonspontaneous, multiple ducts, milky gray or green discharge usually seen in patients in child-bearing years.
   a. Commonly seen after pregnancy and can last for 1 to 2 years.
   b. May also be secondary to excessive breast manipulation, increased production of prolactin, medication, an endocrine anovulatory syndrome, or pituitary adenoma.
2. Mastitis—usually unilateral, purulent (see below).
3. Discharge containing blood—usually caused by intraductal papilloma (wart) or other benign lesion but, in rare cases, may be malignant.

Diagnostic Evaluation

1. Evaluate a spontaneous nipple discharge with clinical examination, test for occult blood, mammography, and/or ultrasonography. MRI is not usually helpful.
   a. Use of a Hemoccult card gently pressed against the nipple when expressing discharge will help determine if the discharge is bloody, which warrants further workup.
   b. May get prolactin level; if elevated, may indicate pituitary adenoma.
2. Nonspontaneous milky gray or green discharge generally is not of pathologic significance and may not require workup.

Management and Nursing Interventions

1. Nursing interventions are aimed at alleviating anxiety and providing support to patient undergoing diagnostic testing. Reassure woman that nipple discharge rarely indicates cancer.
2. Bromocriptine may be given to suppress galactorrhea.
3. Treat for mastitis if purulent (see below).
4. Surgery may be indicated to treat cause of bloody and some other discharges caused by breast lesions.
   a. Most commonly because of wartlike intraductal papilloma in one of larger collecting ducts at edge of areola. May be secondary to fibrocystic changes or duct ectasia.
   b. Excisional biopsy and histologic examination may be done to rule out cancer.
   c. Ductoscopy, an image-guided excision using direct visualization of the ductal system and an intraductal biopsy, is being investigated at some larger centers.
5. Pituitary surgery for excision of adenoma (see page 707).

2004

Acute Mastitis

Acute mastitis is inflammation of the breast secondary to infection. Breast infections may be lactational or nonlactational.

Pathophysiology and Etiology

1. Lactational infections usually occur at beginning of lactation in first-time, breastfeeding mothers. May also occur later in chronic lactation mastitis and central duct abscesses.
2. Milk stasis may lead to obstruction, followed by noninfectious inflammation, then infectious mastitis.
3. Source of infection may be from hands of patient, personnel caring for patient, baby's nose or throat, or blood-borne.
4. Nonlactational infections usually present with central subareolar inflammation.
5. Most common pathogens: *Staphylococcus aureus*, *Escherichia coli*, and *Streptococcus*.

Clinical Manifestations

1. Redness, warmth, edema; breast may feel doughy and tough. Fever may be present.
2. Patient may complain of dull pain in affected area and may have nipple discharge.
3. Complication is mammary abscess (see below).

Management and Nursing Interventions

1. Diagnosis is usually made by characteristic manifestations.
2. Antibiotics are given—10- to 14-day course of penicillinase-resistant antibiotic.
    a. Dicloxacillin—250 to 500 mg every 6 hours.
    b. Clindamycin—150 to 300 mg every 6 hours.
    c. Amoxicillin clavulanate 500 mg three times daily or 875 mg twice daily.
3. May have patient stop breastfeeding (controversial).
4. Apply heat to resolve tissue reaction; may cause increased milk production and worsen symptoms.
5. May apply cold to decrease tissue metabolism and milk production.
6. Have the patient wear firm breast support.
7. Encourage the breastfeeding patient to practice meticulous personal hygiene to prevent mastitis.
8. Consider lactation consult.

Mammary Abscess

Mammary abscess is a localized collection of pus in a cavity of breast tissue. About 3% of patients with mastitis may develop a breast abscess.

Etiology and Clinical Manifestations

1. May follow acute mastitis if untreated. Some patients may develop a chronic subareolar abscess thought to be caused by a plugging of major mammary ducts in the nipple with infection of obstructed secretions. This usually occurs in smokers.
2. Patient may have fever, chills, and malaise.
3. Affected area is sensitive and erythematous; may have palpable mass.
4. Pus may be expressed from nipple.

Management and Nursing Interventions

1. May perform needle aspiration if superficial mass.
2. Incision and drainage may be done, if deep.
3. A biopsy of the cavity wall may be done at time of incision and drainage to rule out breast carcinoma associated with abscess.
4. Administer antibiotics and analgesics, if ordered.
5. Apply hot, wet dressings to increase drainage and hasten resolution. Pack wound, as directed.
6. A diagnostic mammogram and sonogram may be ordered after resolution of the abscess to rule out cancer.

Fibrocystic Change/Breast Pain

Fibrocystic change is a general term that includes various changes in the breast, namely, fibrosis and cystic dilation of the ducts. May be present in up to 50% of women.

Pathophysiology and Etiology

1. Pathogenesis is not known but is related to the cyclic stimulation of the breast by estrogen and represents a change from the normal stimulation and regression pattern of this process.
2. Occurs usually in women between ages 35 and 50 and is a source of considerable discomfort in a sizable percentage of women.
3. Hormone replacement therapy (HRT) may be associated with fibrocystic changes in a woman who has never experienced this previously.

Clinical Manifestations

1. Increased generalized breast lumpiness or excessive nodularity with tenderness, pain, and breast swelling. Symptoms may decrease after menses.
2. Lumps or cysts—soft or firm; single or multiple; smooth, round, and movable. Cysts may enlarge and become tender and painful. There may be many cysts of different sizes; some may be palpable.
3. Possible nipple discharge—may be milky, yellow, or greenish.

Diagnostic Evaluation

1. Physical examination detects changes.
2. Mammography or ultrasound.
3. Aspiration—if a palpable, symptomatic mass exists or the cyst is complex.
4. Cytology of cyst fluid is not cost-effective and rarely of clinical value in fibrocystic breast changes.

Management

There is no satisfactory treatment and management is usually geared toward relief of symptoms.

Surgical Management

1. Needle aspiration and conservative medical follow-up if:
   a. The aspirate appears like normal cyst fluid and is not blood-stained.
   b. Cyst completely resolves after aspiration.
   c. No indication of an underlying neoplasm.
2. Surgical excision—indicated if a cyst keeps recurring after several aspirations or if a single solid discrete lump is present.

Medical Management

1. Sporadic discomfort may be relieved by OTC analgesics, including topical nonsteroidal anti-

inflammatory drugs (ie, diclofenac).

2. Bromocriptine, a dopamine agonist.
   a. May help with mastalgia by decreasing serum prolactin levels.
   b. Adverse effects include nausea, vomiting, headache, dizziness, and fatigue; used rarely because of intolerable adverse effects.
3. Contraceptives or supplemental progestins during the secretory phase of the menstrual cycle may help with pain control.
   a. Mastalgia that begins after initiating hormonal contraceptive pills may resolve after a few cycles.
   b. Switching to a lower estrogen/higher progesterone ratio may help.
4. Danazol, a synthetic androgen used for severe fibrocystic changes to decrease hormonal stimulation of the breast by suppressing gonadotropins.
   a. Adverse effects include a deepening of the voice, which may be permanent, menstrual irregularity, weight gain, depression, bloating, and acne.
   b. Tamoxifen is currently being investigated.

Other Measures

1. Diet modifications.
   a. Eliminating caffeine (coffee, tea, cola drinks, and chocolate) from the diet may help reduce symptoms in some women.
   b. Decreasing fat intake may improve swelling, tenderness, and nodularity.
2. Stopping tobacco use has been suggested to relieve symptoms.
3. Prophylactic lumpectomy—rarely indicated for intractable pain not relieved with medical therapy in women with multiple previous biopsies or biopsy evidence of a precancerous lesion.

Nursing Interventions and Patient Teaching

1. Suggest monthly BSE if the patient is interested—cysts may mask underlying cancer.
2. Reinforce patient's confidence in BSE by rechecking her findings.
3. Offer suggestions for alternative methods if BSE is difficult to do (ie, tender breasts).
4. Encourage patient to see health care provider regularly for examinations.
5. Recommend that patient wear a well-fitted support bra.
6. Offer emotional support for her anxiety and fear of cancer.
7. Reassure that discomfort is common to many women and that it is rarely the only presenting sign of cancer.

Benign Tumors of the Breast

Benign tumors of the breast are characterized clinically as benign lesions that are distinct and persistent over time. Approximately 90% of breast lumps are benign.

Pathophysiology and Etiology

1. Fibrocystic changes—solid lumps may be fatty or fibrous tissue or fluid-filled cysts (see above).
2. Galactocele—a milk-filled cyst.
3. Fibroadenoma—a benign breast tumor composed of epithelial and stromal components.
    a. Common in young women.
    b. A slight increase in the risk of breast cancer among women with fibroadenomas.
4. Other benign tumors include adenosis, intraductal papillomas, lipomas, and neurofibromatosis that may produce a palpable mass.

Clinical Manifestations

1. Gross cysts—may be tender or nontender. Consistency depends on pressure of fluid within cyst and breast tissue around them; may be soft and fluctuant or may feel like a solid tumor if dense.
2. Galactocele—firm, nontender mass.
3. Fibroadenoma—may be a firm, smooth, movable lump that is usually painless. Size does not usually fluctuate with menstrual cycle changes but tends to enlarge over time.

Diagnostic Evaluation

1. Physical examination, mammography, and ultrasound identify and characterize lesion.
2. Cyst aspiration—diagnostic aspiration is usually curative in a galactocele or breast cyst.
3. If a lump does not respond to cyst aspiration, excisional biopsy remains the "gold standard" to rule out cancer.

Management and Nursing Interventions

1. Nonsuspicious or indeterminate masses in young women may be observed through one or two menstrual cycles for resolution of the mass.
2. In general, any distinct and persistent solid lump should have biopsy and possibly excision.
3. Nursing care is directed toward support as woman goes through diagnostic process.

Disorders of the Male Breast

Disorders of the male breast include gynecomastia (benign) and malignant breast cancer.

Clinical Features

Gynecomastia

1. Overdevelopment of breast tissue, usually bilateral.
2. Common in infants, adolescents, and men older than age 50.
3. Usually results from hormonal alterations—idiopathic systemic disorders, such as endocrine disorders, disease of the liver, pituitary adenoma, and chronic renal failure; such drugs as cimetidine, thiazides, spironolactone, omeprazole, phenytoin, reserpine, nifedipine, and theophylline; such neoplasms as testicular tumors and in association with lung and prostate cancer (may be related to therapy).
4. Pubertal gynecomastia has an onset in boys ages 10 to 12 and generally regresses within 18 months. Need to rule out illicit drugs in teens. Marijuana, alcohol, amphetamines, heroin, LSD, and methadone can cause gynecomastia.
5. Asymptomatic and pubertal gynecomastia does not require further tests but should be reevaluated in 6 months. There is no evidence that links gynecomastia with male breast cancer.
6. Investigation is warranted if the drugs used by the patient do not explain the gynecomastia and the breast is tender or the diameter of the breast tissue is more than 4 cm.
7. Reduction subcutaneous nipple-sparring mammoplasty is considered for patients with long-standing gynecomastia for cosmetic and accompanying psychosocial reasons.

DRUG ALERT Question teenage boys presenting with gynecomastia about illicit drug use.

Breast Cancer

1. Resembles cancer of the breast in women.
2. Less than 1% of all breast cancers—incidence greatest in men in their 60s.
3. Carries poor prognosis because men may delay seeking treatment until disease is advanced.
4. Risk factors: family history (20% of men with breast cancer have a first-degree relative with the disease), estrogen exposure, occupation, and some genetic syndromes, such as Cowden and Klinefelter's. Men chronically exposed to hot environments, such as steel mills, have been shown to be at increased risk as well those employed in the soap and perfume industry and those exposed to petroleum and exhaust fumes.
5. There are no specific screening recommendations for men.
6. Nursing care and treatment is essentially the same as for postmenopausal female breast cancer, including tamoxifen, chemotherapy, and/or radiation therapy.

2011

Cancer of the Breast

Breast cancer is the most common cancer in women in the United States and is second only to lung cancer as a cause of cancer death.

EVIDENCE BASE National Comprehensive Cancer Network. (2017). *Clinical practice guidelines in oncology: Breast cancer. Version 4.2017.* Fort Washington, PA: Author. Available: *www.nccn.org.*

Pathophysiology and Etiology

1. Most breast cancer (85% to 90%) begins in the lining of the milk ducts, sometimes in the lobule. Eventually, it grows through the wall of the duct and into the fatty tissue. (See Table 23-3 for types of breast cancer.)
2. Family history accounts for approximately 7% of all breast cancers.
   a. Current genetic models attribute 5% to 10% of all breast cancer to dominantly inherited breast cancer susceptibility genes.
   b. Two breast/ovarian susceptibility genes have been identified as BRCA1 and BRCA2. Testing may be performed on those patients with an increased likelihood of breast and ovarian cancer based on personal and family history. The NCCN has outlined criteria for this testing. See their guidelines for these criteria. Women of Ashkenazi Jewish descent have an increased likelihood of BRCA mutations. Knowledge of a mutation can help patients make informed decisions to manage their risk for future breast cancers. It is important to have genetic counseling before the test because of its implications. Screening is not warranted for general population.
3. Present knowledge does not indicate that carcinogens play an important role in the development of breast cancer.

Table 23-3 Types of Breast Cancer

CELL TYPE	DESCRIPTION	INCIDENCE*	COMMENTS
In situ			
DCIS	Abnormal cells in duct	28% Frequently found in combination with invasive cancer	A noninvasive breast cancer; the majority found by mammogram
Invasive			
Ductal	Classified on basis of microscopic appearance as ductal or lobular	85%–90%	Characterized by stony hardness on palpation
Lobular	As above	5%–10%	Relatively uncommon; tends to be more infiltrative
Others			
Tubular Medullary Mucinous Papillary Sarcoma	Types frequently associated with above; cell type must dominate to be assigned.	<10% of all breast cancers	Axillary metastasis uncommon in tubular; medullary associated with fast growth rate and favorable prognosis
Inflammatory	Applies to distinctive inflamed appearance of skin; no consistent histologic type	1%–4%	Presents with erythema, warmth, tenderness, and edema; may be treated with chemotherapy or radiation therapy first
Paget disease of nipple	Usually associated with underlying intraductal or invasive carcinoma	2%	Presents as scaly, erythematous, periareolar eruption

**Percent greater than 100—infiltrating carcinoma frequently includes small areas containing other special types or a combination of in situ and infiltrating carcinoma is seen.*

DCIS, ductal carcinoma in situ.

Epidemiology of Breast Cancer

EVIDENCE BASE Siegel, R. L., Miller, K. D., & Jemal, A. (2018). Cancer statistics, 2018. *CA—A Cancer Journal for Clinicians, 67*, 7–30.

Incidence

1. The American Cancer Society estimates that 252,710 to 268,390 (2550 male) new cases of invasive breast cancer will be diagnosed in 2018 in the United States, with 41,070 to 41,400 deaths. This accounts for 30% of all new cancer diagnoses in women.
2. There are expected to be 63,410 to 63,960 cases of DCIS are expected in 2018.

Survival Rates

1. Five-year overall survival rates:

- Localized: 97%.
- Regional: 78.7%.
- Distant: 23.3%.

2. In the general population, the relative survival rate is lower among black women than white women.
3. Lymph node status is the most important prognostic indicator of disease-free survival.
4. Age, comorbidity, staging (tumor size, lymph node status, and distant metastasis), nuclear grade, histologic differentiation, possibly HER2 status, and treatment are important prognostic factors for

survival (see Table 23-4). These factors can be used to estimate overall 10-year survival.

5. There has been a decline in the death rate in the United States from breast cancer. This may be related to:
   a. Change in lifestyle such as diet.
   b. Early diagnosis—increased use and improvement in screening mammography.
   c. Improved treatment.

Table 23-4 Staging of Breast Cancer

STAGE	DESCRIPTION
0	Carcinoma in situ
I	Tumor 2 cm or less in greatest dimension; no axillary lymph node metastasis other than micrometastasis; no evidence of distant metastasis.
II	Tumor < 2 cm in greatest dimension but with one to three positive lymph nodes, a tumor 2 -5 cm with or without axillary lymph node metastasis, or a tumor >5 cm without spread to lymph nodes; no evidence of distant metastasis.
III	Any size tumor with four or more positive axillary lymph nodes or with direct extension to the chest wall or skin; inflammatory breast cancer; no evidence of distant metastasis.
IV	Any of the above plus distant metastasis (ie, liver, lungs, bone, brain).

Based on information from the National Cancer Institute and the American Joint Committee on Cancer (2010).

NURSING ALERT Black women are more likely than white women to be diagnosed with large tumors and distant-stage disease. This is true with black males as well. Learn about the demographics of your patient population.

Risk Factors

A woman's lifetime risk of developing breast cancer is 12.5% based on a life span of 80 years.

1. Major—female gender, increased age, a diagnosis of lobular carcinoma in situ, a prior history of breast or ovarian cancer, and family history (especially mother, sisters). Approximate twofold risk in women with affected sister or mother; this increases if more relatives were affected or if affected close relatives developed breast cancer before menopause.
2. Probable—nulliparity, older age at first live childbirth, late menopause, early menarche, benign proliferative breast disease, diagnosis of atypical ductal or lobular hyperplasia on biopsy, long-term use of estrogen replacement therapy that increases with duration of use, and previous exposure to chest wall irradiation.
3. Controversial—hormonal contraceptive use (estrogen and progestin may stimulate tumor growth with long-term use), multiple breast biopsies, decreased physical activity, alcohol use, obesity, and increased

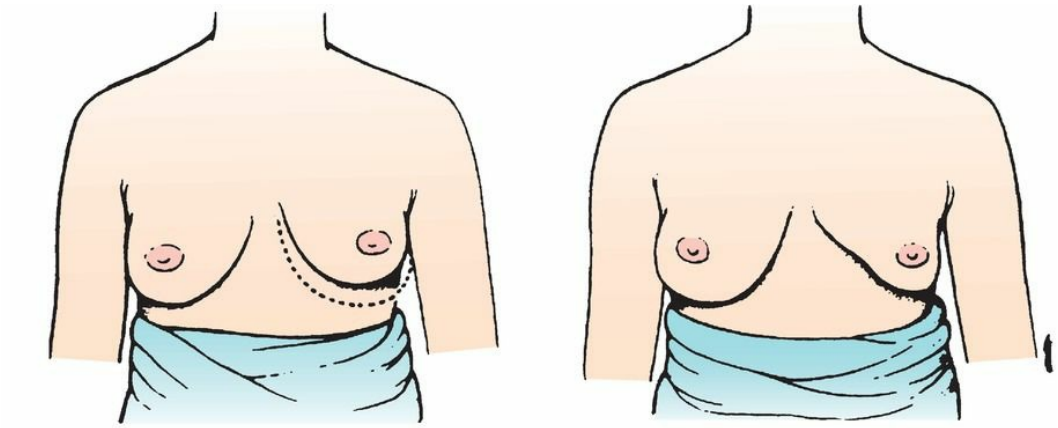
dietary fat intake.

4. Results of breast cancer prevention trials have shown a reduction in incidence of breast cancer in high-risk women treated with tamoxifen, exemestane, or raloxifene.

GERONTOLOGIC ALERT Age is the greatest single risk factor for the development of cancer. Cancer warning signals may be unheeded in older women, so thorough history-taking and physical examination are essential.

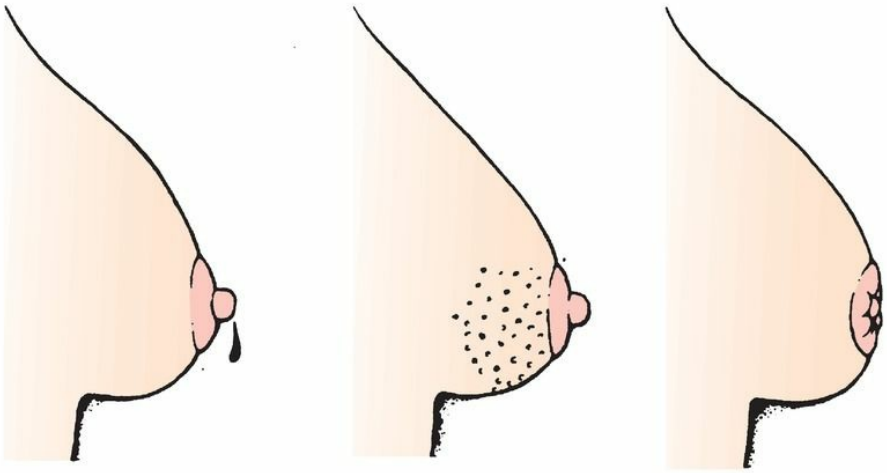
Clinical Manifestations

See Figure 23-1.



Elevation

Asymmetry

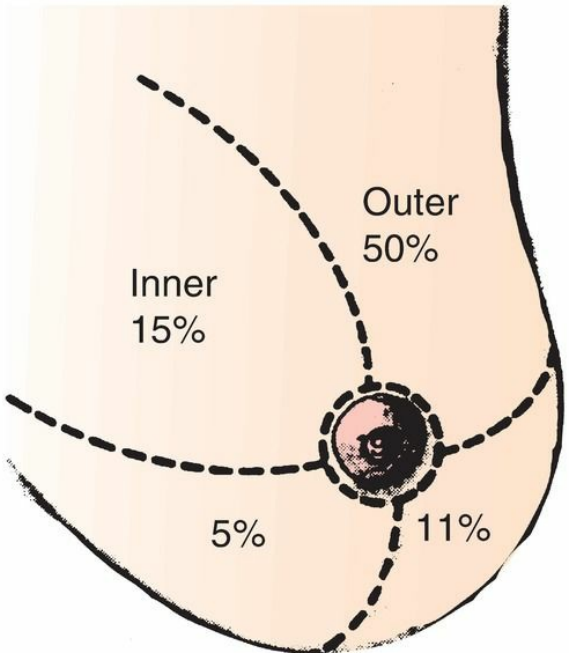


Bleeding

"Orange-peel" skin

Nipple retraction

A



B

Figure 23-1. (A) Signs of cancer of the breast. **(B)** Distribution of carcinomas in different areas of breast.

1. A firm lump or thickening in breast, usually painless; 50% located in upper outer quadrant of breast. Enlargement of axillary or supraclavicular lymph nodes may indicate metastasis.
2. Nipple discharge—spontaneous, may be bloody, clear, or serous.
3. Breast asymmetry—a change in the size or shape of the breast or abnormal contours. As woman changes positions, compare one breast to other.
4. Nipple retraction or scaliness, especially in Paget disease.
5. Late signs—pain, ulceration, edema, orange-peel skin (peau d'orange) from interference of lymphatic drainage.
6. Inflammatory breast cancer may present with erythema.
7. Many small invasive breast cancers as well as noninvasive breast cancer (DCIS) do not present with a palpable mass but are found on mammography.

NURSING ALERT Pain is not usually an early warning sign of breast cancer.

Diagnostic Evaluation

See page 679.

Management

Based on type and stage of breast cancer, receptors, and menopausal status. For women with localized invasive breast cancer, information from clinical trials indicates that treatment with a breast-preserving procedure has similar survival rates as mastectomy. Surgery for DCIS (noninvasive breast cancer) may involve only a lumpectomy, but mastectomy may be necessary for extensive disease. Treatment for DCIS is becoming more and more controversial with concern by some that this entity is being overtreated.

Surgery

See page 682 for a discussion of surgery for breast cancer.

Radiation Therapy

1. In conjunction with breast-preserving procedure as adjuvant (additional) therapy to decrease incidence of local recurrence for invasive breast cancer and DCIS. In the patient with DCIS, if it is thought that the individual risk is low, some patients may be treated by excision alone. May be used preoperatively to shrink a large tumor to operable size.
2. May be used after a mastectomy in patients with large tumors that involve the chest wall and/or many positive axillary lymph nodes; may delay reconstruction.

3. Absolute contraindications to a breast-preserving procedure include widespread disease, diffuse malignant-appearing microcalcifications on mammography, radiation therapy during pregnancy, and positive margins. Relative contraindications include active connective tissue disease, tumors greater than 5 cm in size, positive BRCA, and history of previous radiation therapy to the breast or chest wall.
4. Treatment may be individualized in pregnancy—that is, appropriate surgery followed by chemotherapy in the second or third trimester and delayed irradiation to preserve the breast.
5. May also be used to alleviate bone pain in metastatic breast cancer.
6. Radiation directed to breast, chest wall, and remaining lymph nodes.
    a. Usually five treatments per week for 6 or 7 weeks.
    b. A booster or second phase of treatment may be given.
    c. May include implants of radioactive material after external treatment completed.
7. Adverse effects include mild fatigue, sore throat, dry cough, nausea, and anorexia; later, skin will look and feel sunburned. Eventually, the breast may become firmer. Complications include increased arm edema, decreased arm mobility, pneumonitis, and brachial nerve damage. See page 122 for care of patient undergoing radiation therapy.
8. Accelerated partial breast irradiation through a balloon temporarily surgically implanted in the breast treats only the lumpectomy bed. Treatment is twice per day for 5 days. Early data suggest acceptable locoregional disease control with this approach; however, long-term follow-up studies are needed.
9. A one-time dose of radiation intraoperatively is also under investigation and shows promise. Both of these methods of partial breast irradiation should be performed only as part of a prospective trial. Whole breast radiotherapy remains the gold standard.

Chemotherapy

1. Major use is in adjuvant systemic treatment postoperatively; usually begins 4 weeks after surgery (stressful for patient who just finished major surgery).
2. Treatments are given every 2 to 4 weeks for 6 to 9 months. Because the drugs differ in their mechanisms of action, combinations of agents are used to treat cancer.
3. Main drugs used for breast cancer include doxorubicin, cyclophosphamide, paclitaxel, 5-fluorouracil (5-FU), gemcitabine, and methotrexate. For advanced cancer, docetaxel, vinorelbine, capecitabine, mitoxantrone, and fluorouracil by continuous infusion and oral forms of fluorouracil are used.
4. Indications for chemotherapy include:
    a. Large tumors, positive lymph nodes, premenopausal women, and poor prognostic factors. Currently, adjuvant chemotherapy and/or hormonal therapy are recommended for all patients with invasive breast cancers 1 cm wide or larger although the benefit in some patients may be relatively small.
    b. Patients who score high on gene assay as well as those tumors that are shown to be "triple negative"—ER/PR as well as HER2 negative.
    c. Data are insufficient to make definitive recommendations for patients older than 80 years.
5. Other agents that may be used include:

a. Trastuzumab—a member of the epithelial growth receptor family; increased survival when added to chemotherapy in metastatic breast cancer. Treatment is expensive; may be given to patients who express this gene (HER2).

6. Pertuzumab—another monoclonal antibody that may be used prior to surgery (neoadjuvant) in early-stage or locally advanced HER2 positive breast cancer patients.
   a. Bevacizumab—binds to vascular endothelial growth factor and blocks tumor blood vessel growth. Used in advanced breast cancer.
   b. Pamidronate, zoledronic acid, or denosumab may be added if bone metastasis present to help reduce pain. Patients should undergo dental exam prior to initiation of this therapy for preventive maintenance and to correct dental problems, as osteonecrosis of the jaw is more common in those with poor oral hygiene.
   c. Poly ADP ribose polymerase inhibitors, such as olaparib, are enzymes that help repair DNA and may be helpful in triple-negative cancers.
7. Adverse effects include bone marrow suppression, cardiotoxicity, nausea and vomiting, diarrhea, alopecia, weight gain or loss, fatigue, stomatitis, anxiety, depression, and premature menopause (see page 112 for nursing care of patient undergoing chemotherapy). Childbearing after treatment of invasive breast cancer does not increase rates of breast cancer recurrence or death.
8. Chemotherapy may also be used as primary treatment in inflammatory breast cancer and occasionally in large tumors.
9. Hope for the future is the development of specific targeted biologic therapies and more individualized treatment.

Endocrine Therapy

1. Selective estrogen receptor modulators, such as tamoxifen and raloxifene, bind estrogen receptors, thereby blocking effects of estrogen.
   a. Adjuvant systemic therapy after surgery.
   b. Benefits estrogen receptor–positive patients, regardless of menopausal status.
   c. Given for at least 5 years; oral administration once or twice per day.
   d. Adverse effects include hot flashes, irregular periods, vaginal irritation, nausea and vomiting, headaches, increased risk of endometrial cancer, and thromboembolic events.
   e. Women on tamoxifen should have an annual gynecologic assessment if uterus present.
2. Aromatase inhibitors, such as anastrozole, exemestane, and letrozole, block conversion of androgen, which is secreted by the adrenal glands, into estrogen. Large clinical trials report more favorable outcomes with aromatase inhibitors, and treatment has shifted from 5 years of tamoxifen therapy to initial treatment with an aromatase inhibitor in postmenopausal women.
   a. Anastrozole as well as fulvestrant, an estrogen receptor agonist, may be used as a second-line therapy after tamoxifen in patients whose cancer has returned or progressed.
   b. Aromatase inhibitors are ineffective in premenopausal women.

c. Adverse effects include hot flashes, vaginal dryness, musculoskeletal symptoms, osteoporosis, and increased rate of bone fracture. Therefore, women on aromatase inhibitors should have monitoring of bone health.

3. Hormones may be used in advanced disease. Remissions may last months to several years. Agents commonly used include:
   a. Estrogens, such as diethylstilbestrol or ethinyl estradiol, in high doses to suppress follicle-stimulating hormone (FSH) and luteinizing hormone and may decrease endogenous estrogen production.
   b. Progestins may decrease estrogen receptors.
   c. Androgens may suppress FSH and estrogen production.
   d. Aminoglutethimide suppresses estrogen production by blocking adrenal steroids; "medical adrenalectomy," especially useful for women with bone and soft tissue metastasis.
4. Corticosteroids suppress estrogen and progesterone secretion from the adrenals.

DRUG ALERT Traditionally, breast cancer survivors have not been considered candidates for estrogen. However, debates and studies continue to be conducted regarding the safety of estrogen in this population.

Bone Marrow Transplant

1. Autologous method after high-dose chemotherapy.
2. Clinical trials have shown it to be ineffective for breast cancer.

Oophorectomy

Removal of ovaries.

1. Treatment for recurrent or metastatic disease in estrogen receptor–positive premenopausal women.
2. Deprives tumor of primary estrogen source—remissions of 3 months to several years.
3. Medical ablation with tamoxifen has been compared to surgical oophorectomy in estrogen receptor–positive postmenopausal women and response rates are similar.
4. Surgical ablation is now considered second choice because of its increased risks.
5. The benefits of tamoxifen in combination with oophorectomy are the subject of ongoing research.

Adrenalectomy

Removal of adrenal glands to eliminate androgen production (which converts to estrogen).

1. Rarely done because of need for long-term steroid replacement therapy.
2. Remissions may last 6 months to several years.
3. Medical ablation with drugs being studied.

Complications

1. Metastasis—most common sites: lymph nodes, lung, bone, liver, and brain.
2. Signs and symptoms of metastasis may include bone pain, neurologic changes, weight loss, anemia, cough, shortness of breath, pleuritic pain, and vague chest discomfort.

Nursing Assessment

1. Assess general health status and underlying chronic illnesses that may have an impact on patient's response to treatment.
2. Identify what the patient and family need to know regarding breast cancer and its treatment and take measures to decrease their impact. Base education on patient and family needs.
3. Determine level of anxiety, fears, and concerns.
4. Identify coping ability and availability of support systems.

NURSING ALERT Evidence suggests that active lifestyle and achieving and maintaining an ideal body weight (20 to 25 body mass index) may lead to optimal breast cancer outcomes.

Nursing Diagnoses

Also see page 682 for breast surgery care and Chapter 8, Cancer nursing.

- Anxiety related to diagnosis of cancer.
- Deficient Knowledge related to disease process and treatment options.
- Ineffective Coping by patient or family related to diagnosis, prognosis, financial stress, or inadequate support.

Nursing Interventions

EVIDENCE BASE Greenlee, H., Dupont-Reyes, M., Balneaves, L., et al. (2017). Clinical practice guidelines on the evidence-based use of integrative therapies during and after breast cancer treatment. *CA-A Cancer Journal for Clinicians, 67*, 194–232.

Reducing Anxiety

1. Realize that diagnosis of breast cancer is a devastating emotional shock to patient. Support patient through the diagnostic process. Many women must make challenging decisions in a brief period of time. Some communities have developed nursing navigators as a way of assisting and supporting individuals through the process. Check if there is a nurse navigator in your community.

2. Interpret the results of each test in language patient can understand.
3. Stress the advances made in earlier diagnosis and treatment options.

Providing Information about Treatment

1. Involve patient in treatment planning.
2. Describe surgical procedures.
3. Prepare patient for the effects of chemotherapy; encourage patient to plan ahead for the common adverse effects of chemotherapy.
4. Educate patient about the effects of radiation therapy.
5. Teach patient about hormonal therapy. Patient may develop hot flashes with the start of hormonal therapy or with the discontinuation of HRT at the time of diagnosis of breast cancer (see Chapter 22 for information on menopausal symptoms). Measures that may help with symptoms of hot flashes include:
   a. Clonidine, belladonna/ergotamine/phenobarbital, anti-depressant medications.
   b. Various supplements and herbs have been used but have not been rigorously tested. Soy has been suggested, but there is no compelling evidence that phytoestrogens help menopausal symptoms. Indeed, concerns have been raised regarding stimulating breast cancer cell growth and, therefore, should not be used.
   c. Progesterone may be helpful, but the possible effect on breast cancer needs further study.

Strengthening Coping

1. Repeat information and speak in calm, clear manner.
2. Display empathy and acceptance of patient's emotions.
3. Explore coping mechanisms.
4. Evaluate where patient is in stages of acceptance.
5. Help patient identify and use support persons.
6. Obtain visit from support group member.
7. Refer for counseling, financial aid, and so forth.
8. Resources include American Cancer Society (800-ACS-2345 or *www.cancer.org*), National Cancer Institute (*www.cancer.gov*), National Alliance of Breast Cancer Organizations (*www.nabco.org*), and the Susan G. Komen Breast Cancer Foundation (*www.komen.org*).

Patient Education and Health Maintenance

1. Encourage patient to continue close follow-up and to report any new symptoms. Most women will be seen every 3 months for the first 2 years, every 6 months for the next 3 years, and once per year after 5 years.
2. Stress importance of continued yearly mammogram.
3. Inform patient that yearly laboratory work, bone scan, and chest x-ray may be performed when clinically indicated.

4. Suggest to patient that psychological intervention may be necessary for anxiety, depression, or sexual problems.

Evaluation: Expected Outcomes

- Verbalizes less anxiety.
- Verbalizes understanding of all treatment options and their adverse effects.
- Identifies appropriate coping mechanisms and support systems.

Pituitary Tumors

OVERVIEW AND ASSESSMENT

The Function of Hormones

The endocrine system and the nervous system maintain homeostasis. The endocrine glands produce hormones, chemical substances that are secreted into the bloodstream and that exert a stimulatory or inhibitory effect on target tissues or on glands. Hormones achieve their effect by binding with specific receptors located on the membrane on the target cell (eg, catecholamines) or by penetrating the cell membrane and forming a complex that influences cellular metabolism (eg, steroids). The target cell response may be reflected through the production and secretion of a second hormone or through a change in cell metabolism that alters the concentration of electrolytes or other substances in the bloodstream.

General Effects of Hormone Action

1. Regulate the overall metabolic rate and the storage, conversion, and release of energy.
2. Regulate fluid and electrolyte balance.
3. Initiate coping responses to stressors.
4. Regulate growth and development.
5. Regulate reproduction processes.

Regulation of Hormones

1. Hormone secretion is typically controlled through a negative feedback system.
    a. Fall in blood concentration of hormone leads to activation of the regulator endocrine gland and to release of its stimulator hormones.
    b. Elevations in blood concentration of target cell hormones or changes in blood composition resulting from target cell activity can cause inhibition of hormone secretion.
2. Endocrine disorders are manifested as states of hormone deficiency or hormone excess. The underlying pathophysiology may be expressed as:
    a. *Primary*—the secreting gland releases inappropriate hormone because of disease of the gland itself.
    b. *Secondary*—the secreting gland releases abnormal amounts of hormone because of disease in a regulator gland (eg, pituitary).
    c. *Tertiary*—the secreting gland releases inappropriate hormone because of hypothalamic dysfunction, resulting in abnormal stimulation by the pituitary.
3. Abnormal hormone concentrations may also be caused by hormone-producing tumors (adenomas) located at a remote site.

History

Patients with diseases of the endocrine system commonly report nonspecific complaints. Commonly, symptoms may reflect changes in general well-being, such as fatigue, weakness, weight change, appetite, sleep patterns, or emotional status. A thorough review of systems is necessary to detect changes in various body systems caused by an endocrine disorder (see Table 24-1).

Table 24-1 Clinical Manifestations of Endocrine Dysfunction

SIGN OR SYMPTOM	POSSIBLE CAUSES
Cardiovascular	
Tachycardia or tachyarrhythmia	• Hyperthyroidism • Pheochromocytoma • Adrenal insufficiency
Bradycardia	• Hypothyroidism
Orthostatic hypotension	• Adrenal insufficiency
Hypertension	• Pheochromocytoma • Hyperaldosteronism • Cushing syndrome • Hyperparathyroidism • Hypothyroidism
Heart failure	• Hyperthyroidism • Hypothyroidism • Cushing syndrome
Neurologic	
Fatigue	• Adrenal insufficiency • Hypothyroidism • Hyperparathyroidism
Nervousness, tremor	• Pheochromocytoma • Hyperthyroidism
Confusion, lethargy, or coma	• Diabetic ketoacidosis • Hypothyroidism • Syndrome of inappropriate antidiuretic hormone
Paresthesia	• Hypothyroidism • Hypoparathyroidism • Diabetes mellitus
Headache	• Acromegaly • Pituitary tumor • Pheochromocytoma
Psychosis	• Hyperaldosteronism • Hypothyroidism • Hyperthyroidism • Cushing syndrome • Adrenal insufficiency • Hyperparathyroidism
Chvostek sign, Trousseau sign	• Hypoparathyroidism
Increased reflexes	• Hyperthyroidism
Decreased reflexes	• Hypothyroidism
Peptic ulcer	• Cushing syndrome
Diarrhea	• Adrenal insufficiency
Constipation	• Hypothyroidism • Hyperparathyroidism • Pheochromocytoma
Weight loss	• Hyperthyroidism • Hyperparathyroidism • Pheochromocytoma
Hyperdefecation	• Hyperthyroidism
Abdominal pain	• Addisonian crisis • Hyperparathyroidism
Musculoskeletal	
Weakness	• Hyperthyroidism • Hypothyroidism • Cushing syndrome • Adrenal insufficiency • Hyperparathyroidism • Hypoparathyroidism • Hyperaldosteronism
Pathologic fractures	• Hyperparathyroidism
Joint pain	• Hypothyroidism • Acromegaly
Bone pain	• Hyperparathyroidism
Bone thickening	• Acromegaly
Urologic	
Polyuria	• Diabetes insipidus • Diabetes mellitus
Kidney stones	• Hyperparathyroidism • Acromegaly • Cushing syndrome
Integumentary	
Hirsutism	• Adrenal hyperfunction • Acromegaly
Hair loss	• Hypoparathyroidism • Hypothyroidism • Cushing syndrome
Sparse body hair	• Pituitary insufficiency • Adrenal insufficiency • Hypogonadism
Hyperpigmentation	• Addison disease • Hyperthyroidism • Ectopic corticotropin production
Profuse diaphoresis	• Hyperthyroidism • Pheochromocytoma
Thin skin	• Cushing syndrome
Coarse hair	• Hypothyroidism
Fine hair	• Hyperthyroidism
Edema	• Cushing syndrome
Reproductive	
Amenorrhea	• Hyperthyroidism • Hypogonadism • Cushing syndrome • Acromegaly • Pituitary tumor
Gynecomastia	• Hypogonadism • Pituitary tumor
Loss of libido, impotence	• Hypogonadism • Hypothyroidism • Adrenal insufficiency • Diabetes mellitus
Ophthalmic/Visual	
Exophthalmos	• Graves disease
Diplopia	• Graves disease • Pituitary tumor
Visual field deficit	• Pituitary tumor
Periorbital swelling	• Hypothyroidism • Graves disease
Body Habitus	
Round face, "buffalo hump"	• Cushing syndrome
Abnormally tall stature	• Prepubertal growth • Acromegaly

Physical Examination

Objective findings may be obvious and related to the patient's complaints or may be "silent signs" of which the patient is completely unaware. Thorough physical examination of all body systems, particularly the integumentary, cardiovascular, and neurologic systems, may reveal key findings for endocrine dysfunction (see Chapter 5).

Tests of Thyroid Function

Total Thyroxine

Description

1. This is a direct measurement of the concentration of total thyroxine (T_4) in the blood, using a radioimmunoassay technique.
2. It is an accurate index of thyroid function when T_4-binding globulin (TBG) is normal.
3. Low plasma-binding protein states (malnutrition, liver disease) may give low values.
4. High plasma-binding protein values (pregnancy, estrogen therapy) may give high values.
5. It can be used to diagnose hypofunction and hyperfunction of the thyroid and to guide and evaluate thyroid hormone replacement therapy.

Nursing and Patient Care Considerations

1. The test to monitor thyroid hormone therapy may be performed 6 to 8 weeks after dosage adjustment because of the time required for thyroid-stimulating hormone (TSH) to reflect the body's response to the new dose.
2. Interpretation of test results:
   a. Hypothyroidism—below normal.
   b. Hyperthyroidism—above normal.

Free Thyroxine

Description

1. Direct measurement of free T_4 concentration in the blood using a two-step radioimmunoassay method.
2. Accurate measure of thyroid function independent of the variable influence of thyroid-binding globulin levels.
3. Used to aid in the diagnosis of hyperthyroidism and hypothyroidism.
4. Used to monitor and guide thyroid hormone replacement therapy.

Nursing and Patient Care Considerations

1. Interpretation of test results:
   a. Hyperthyroidism—above normal.
   b. Hypothyroidism—below normal.
2. Results best interpreted in conjunction with TSH levels for diagnostic purposes.
3. Often used to monitor thyroid hormone replacement therapy, levels meaningful only after 6 to 8 weeks of therapy to evaluate adequacy of dosage because of long half-life of T_4.

Thyroid-Binding Globulin

Description

1. This measures the concentration of the carrier protein for T_4 in the blood.
2. Because most T_4 is protein bound, changes in TBG will influence values of T_4.
3. Helpful in distinguishing between true thyroid disease and T_4 test abnormalities caused by TBG excess or deficit.

Nursing and Patient Care Considerations

Determine if patient is taking estrogen or is pregnant, both of which can elevate TBG; results may be depressed by malnutrition or by liver disease.

Triiodothyronine

Description

1. Directly measures concentration of triiodothyronine (T_3) in the blood using a radioimmunoassay technique.
2. T_3 is less influenced by alterations in thyroid-binding proteins; it binds to albumin.
3. T_3 has a shorter half-life than T_4 and occurs in minute quantities in the active form.
4. Useful to rule out T_3 thyrotoxicosis, hyperthyroidism when T_4 is normal, and to evaluate effects of thyroid replacement therapy.

Nursing and Patient Care Considerations

1. T_3 can be transiently depressed in the acutely ill patient.
2. Interpretation of test results:
   a. Hypothyroidism—below normal.
   b. Hyperthyroidism—above normal.

T_3 Resin Uptake

Description

1. This is an indirect measure of thyroid function, based on the available protein-binding sites in a serum sample that can bind to radioactive T_3.
2. The radioactive T_3 is added to the serum sample in the test tube and will bind with available protein-binding sites. The unbound T_3 binds to resin for T_3 uptake, reflecting the amount of T_3 left over because of lack of binding sites.
3. Estrogen and pregnancy produce an increase in binding sites, thus causing a lowered T_3 resin uptake.

Nursing and Patient Care Considerations

1. Results may be altered if patient has been taking estrogens, androgens, salicylates, or phenytoin.
2. Interpretation of test results:

a. Hypothyroidism—below normal.
b. Hyperthyroidism—above normal.

Free Thyroid Index

Description

The free thyroid index is a laboratory estimate of free T_4 concentration with calculated adjustment for variations in patient's TBG concentration.

Nursing and Patient Care Considerations

Interpretation of test results:

1. Below normal—hypothyroidism.
2. Above normal—hyperthyroidism.

Thyrotropin, Thyroid-Stimulating Hormone

Description

1. Direct measure of TSH, the hormone secreted by the anterior pituitary gland that regulates the production and secretion of T_4 by the thyroid gland.
2. Third-generation TSH chemiluminometric assays are most commonly utilized.
3. Preferred test differentiates between thyroid disorders caused by disease of the thyroid gland itself and disorders caused by disease of the pituitary or hypothalamus. Also useful to detect early stages of hypothyroidism (subclinical hypothyroidism) and to monitor hormone replacement therapy (HRT). Patient must be on a stable dose of thyroxine for 6 to 8 weeks for TSH levels to accurately reflect adequacy of treatment.
4. Morning samples are preferred.

Nursing and Patient Care Considerations

1. Interpretation:
   a. In primary hypothyroidism, TSH levels are elevated.
   b. In secondary hypothyroidism (failure of the pituitary gland), TSH levels are low.
   c. In hyperthyroidism, TSH levels are low.

Thyrotropin-Releasing Hormone Stimulation Test

Description

1. The thyrotropin-releasing hormone (TRH) stimulation test evaluates the patency of the pituitary–hypothalamic axis. Once used primarily to distinguish between primary and central hypothyroidism (secondary or tertiary), this test is rarely used for that purpose with the advent of more sensitive TSH assays. Now, its primary use is to distinguish between secondary and tertiary hypothyroidism and evaluate acromegaly.

2. A baseline sample is drawn, then TRH is administered via intravenous (IV) injection and blood samples are drawn to determine TSH levels at 30, 90, and 120 minutes.

Nursing and Patient Care Considerations

1. Interpretation:
   a. Increased TSH should be seen within 30 minutes.
   b. No rise in secondary hypothyroidism.
   c. Blunted rise in hyperthyroidism.
   d. Delayed rise (90-minute sample) associated with tertiary hypothyroidism.
   e. Elevated growth hormone levels associated with acromegaly.
2. A subnormal response can occur in patients taking L-dopa or cortisol.

Thyroid Autoantibodies

Description

Used to detect selected autoantibodies associated with some thyroid diseases and the levels of those autoantibodies.

1. Thyroid-stimulating immunoglobulin (TSI)—autoantibodies that stimulate the TSH receptor on the thyroid gland, causing hyperfunction of the thyroid. Helpful in the diagnosis of Graves disease.
2. Thyroid peroxidase antibodies (TPO)—associated with Hashimoto thyroiditis and Graves disease.
3. Thyroglobulin antibodies—elevated with Hashimoto thyroiditis and Graves disease.

Tests of Parathyroid Function

Parathyroid Hormone

Description

1. Test is either an intact PTH (second-generation assay) or PTH 1-84 assay (third generation), which should be measured concurrently with serum calcium level.
2. Range of normal values may vary by laboratory and method.

Nursing and Patient Care Considerations

Elevated PTH in hyperparathyroidism; decreased PTH in hypoparathyroidism.

Serum Calcium, Total

Description

1. This is a direct measurement of protein-bound and "free" ionized calcium.
2. Ionized calcium fraction is the best indicator of changes in calcium metabolism.
3. Results can be affected by changes in serum albumin, the primary protein carrier.
4. Used to detect alterations in calcium metabolism caused by parathyroid disease or malignancy.

Nursing and Patient Care Considerations

1. Sample may be obtained from fasting patient and should be collected in tube with heparin as anticoagulant.
2. Test should be repeated to confirm parathyroid disease.
3. Elevations in serum calcium can be caused by dehydration, vitamin D intoxication, thiazide diuretics, immobilization, hyperthyroidism, or lithium therapy.
4. Low values may be seen in renal failure, chronic disease states, malabsorption syndrome, and vitamin D deficiency.
5. Interpretation of test results:
    a. Hyperparathyroidism, malignancy—elevated.
    b. Hypoparathyroidism—below normal.

Serum Calcium, Ionized

Description

1. Approximately 45% to 50% of total serum calcium is in biologically active ionized form.
2. This is the preferred method of testing changes in calcium metabolism caused by parathyroid disease, malignancy, or thyroid surgery.

Nursing and Patient Care Considerations

1. Sample should be collected in tube with heparin as anticoagulant.

2. Test should be repeated on three different occasions to confirm parathyroid disease.
    a. Hyperparathyroidism, malignancy—elevated.
    b. Hypoparathyroidism—below normal.

NURSING ALERT Tourniquet use during blood sample collection for calcium studies should be kept to a minimum. Prolonged constriction will cause migration of plasma proteins into the bloodstream locally; this results in spuriously high serum calcium values and pseudohypercalcemia.

Serum Phosphate

Description

1. Test measures the level of inorganic phosphorus in the blood.
2. Alteration in parathyroid function tends to have opposite effects on calcium and phosphorus metabolism.
3. Used to confirm metabolic abnormalities that affect calcium metabolism.

Nursing and Patient Care Considerations

Elevated in hypoparathyroidism; low values in hyperparathyroidism.

Tests of Adrenal Function

Plasma Cortisol

Description

1. This is a direct measure of the primary secretory product of the adrenal cortex by radioimmunoassay technique.
2. Serum concentration varies with circadian cycle, so normal values vary with time of day and stress level of patient (8:00 A.M. levels typically double that of 8:00 P.M. levels).
3. Useful as an initial step to assess adrenal dysfunction, but further workup is usually necessary.

Nursing and Patient Care Considerations

1. A fasting sample is preferred.
2. Blood samples should coincide with circadian rhythm with draw time indicated on laboratory slip.
3. Interpretation of test results:
   a. Decreased values seen in Addison disease, anterior pituitary hyposecretion, and secondary hypothyroidism.
   b. Increased values seen in hyperthyroidism, stress (eg, trauma, surgery), carcinoma, Cushing syndrome, hypersecretion of corticotropin by tumors (oat cell cancer), adrenal adenoma, and obesity.

Salivary Cortisol

Description

1. Because cortisol-binding globulin (CBG) is normally absent from saliva, it does not interfere with cortisol levels. Therefore, salivary cortisol can be more reliably measured without variation because of fluctuating CBG levels.

Nursing and Patient Care Considerations

1. A mouth swab is collected from patient in the evening and can be done at home after rinsing the mouth before brushing teeth.

Twenty-Four–Hour Urinary Free Cortisol Test

Description

1. Test measures cortisol production during a 24-hour period.
2. Useful to establish diagnosis of hypercortisolism.
3. Less influenced by diurnal variations in cortisol.

Nursing and Patient Care Considerations

1. Instruct patient in appropriate collection technique.
2. Collection jug should be kept on ice and sent to laboratory promptly when collection completed.

3. Interfering factors:
    a. Elevated values—pregnancy, hormonal contraceptives, spironolactone, and stress.
    b. Recent radioisotope scans can interfere with test results.

Dexamethasone Suppression Tests

Description

1. The dexamethasone suppression test (DST) is a valuable method to evaluate adrenal hyperfunction.
2. Adrenal production and secretion of cortisol is stimulated by adrenocorticotropic hormone (ACTH; corticotropin) from the pituitary gland.
3. Dexamethasone is a synthetic steroid effective in suppressing corticotropin secretion.
4. In a healthy patient, the administration of dexamethasone will inhibit corticotropin secretion and will cause cortisol levels to fall below normal.
5. Certain drugs (rifampin, phenytoin) increase metabolic clearance of dexamethasone and may contribute to false-positive test results.
6. Those on estrogen-containing drugs should stop 6 weeks prior to test, and this test is not reliable in pregnancy.

Nursing and Patient Care Considerations

Explain the procedure to patient.

1. Overnight low-dose (1 mg) DST (used primarily to identify those *without* Cushing syndrome).
    a. Administer dexamethasone 1 mg orally at 11:00 P.M.
    b. Draw cortisol level at 8:00 A.M. before patient rises.
    c. Expect suppressed cortisol levels (less than 5 mcg/dL). Test is highly sensitive when a 2-mg cutoff is used for diagnosis.
2. Forty-eight–hour low-dose (2 mg) DST.
    a. Patient is instructed to take 0.5 mg of dexamethasone every 6 hours for a 2-day period.
    b. Plasma cortisol sample is collected 9 hours after first dose is administered and again at 48 hours.
    c. It is essential that patient have clearly written instructions for compliance with dosing and blood sampling schedule for test to be valid.
3. High-dose overnight DST (helpful to distinguish Cushing disease from other forms of Cushing syndrome).
    a. Give patient dexamethasone 8 mg orally at 11:00 P.M.
    b. Draw cortisol level at 8:00 A.M. before patient rises.
    c. Suppressed cortisol levels (less than 50% of baseline value) indicative of patient with corticotropin-secreting pituitary adenoma (Cushing disease).
    d. Unsuppressed cortisol levels are associated with ectopic corticotropin secretion (malignancy) or adrenal tumors.

4. Encourage patient to take dexamethasone with milk because it may cause gastric irritation.

Adrenocorticotropic Stimulation Test

Description

1. ACTH stimulates the production and secretion of cortisol by the adrenal cortex.
2. Demonstrates the ability of the adrenal cortex to respond appropriately to ACTH.
3. This is an important test to evaluate adrenal insufficiency but may not distinguish primary insufficiency from secondary insufficiency.

Nursing and Patient Care Considerations

1. Obtain baseline cortisol level.
2. Administer 0.25 mg ACTH (cosyntropin IV or intramuscularly [IM]).
3. Collect cortisol levels at times ordered (usually at 30 and 60 minutes).
4. Interpretation of test results:
   a. Range of normal responses may vary; however, typically a rise in cortisol of double baseline value is considered normal.
   b. Diminished response—adrenal insufficiency with low cortisol values.

DRUG ALERT Infusion of cosyntropin can cause flushing or slight reduction in blood pressure (BP). Warn patients about these effects, monitor BP, and ensure safety.

Corticotropin-Releasing Hormone Stimulation Test

Description

1. Test measures responsiveness of the pituitary gland to corticotropin-releasing hormone (CRH)—a hypothalamic hormone that regulates pituitary secretion of ACTH.
2. Useful to differentiate the cause of excess cortisol secretion when ectopic source of ACTH is suspected.
3. In general, CRH will stimulate ACTH secretion in the pituitary but not in nonpituitary corticotropin-secreting tissues.

Nursing and Patient Care Considerations

1. Describe procedure to patient.
   a. Fasting patient is given CRH (1 mcg/kg or 100 mcg) via IV line.
   b. Catheters are advanced through the femoral veins to areas near the adrenal glands, so sampling can take place near ACTH secretion.
   c. Blood samples for ACTH test are collected at 5, 10, 15, 30, 45, 60, 90, and 120 minutes.
2. Normal response is a rise in ACTH to at least double the baseline value.

3. Interpretation of test results:
    a. Brisk rise in ACTH double baseline value—Cushing disease.
    b. No response in ACTH—corticotropin-independent Cushing syndrome (adrenal tumor) or ectopic source of corticotropin secretion (ectopic tumor).
    c. Test can produce false-negative response.

Urine Vanillylmandelic Acid and Metanephrine

Description

1. Direct measure of metabolites of catecholamines secreted by the adrenal medulla.
2. Metanephrine is a more reliable measure of catecholamine secretion.
3. Preferred method to diagnose pheochromocytoma, neuroblastoma, and other neural crest tumors.

Nursing and Patient Care Considerations

1. Obtain proper urine collection jug with hydrochloride preservative, and explain 24-hour urine collection to patient.
2. A wide range of medications and foods may alter test performed by some laboratories. Verify with the laboratory and health care provider the need to hold some medications, such as sympathomimetics and methyldopa, and such foods as coffee, tea, vanilla extract, and bananas before and during urine collection.
3. Interpretation—pheochromocytoma: vanillylmandelic acid greater than 10 mcg/mg of creatinine or greater than 10 mg/24 hours; metanephrine greater than 0.7 mcg/mg of creatinine or greater than 0.7 mg/24 hours.

Plasma Catecholamines

Description

Direct measure of circulating catecholamines using radioimmunoassay technique; more sensitive test than urine test, but more prone to false-positive results.

Nursing and Patient Care Considerations

1. Collect sample from IV catheter 20 to 30 minutes after venipuncture, if possible, to reduce the rise in catecholamine levels from pain and anxiety.
2. Collect the sample in a heparinized tube.
3. Interpretation—levels higher than 2,000 ng/L diagnostic for pheochromocytoma.

Clonidine Suppression Test

Description

1. Based on the principle that catecholamine production by pheochromocytomas is autonomous, as opposed to other causes of excess catecholamines, which are regulated by the sympathetic nervous system.
2. Clonidine, as a central alpha-adrenergic agonist, suppresses production of catecholamines.

3. Useful to differentiate pheochromocytoma from essential hypertension when test results are inconclusive.
4. Corticosteroids should be avoided prior to testing.

Nursing and Patient Care Considerations

1. Collect baseline catecholamine sample from IV catheter 20 to 30 minutes after venipuncture, if possible, to reduce the rise in catecholamine levels from pain and anxiety.
2. Give clonidine 0.3 mg orally.
3. After 3 hours, collect second catecholamine sample.
4. Interpretation—in patients without pheochromocytoma, a significant drop in catecholamines should be seen at 3 hours (less than 500 pg/mL or reduction of total catecholamines by 50%), whereas in patients with pheochromocytoma, no drop in catecholamines will be evident.

DRUG ALERT Warn patients not to rise quickly and monitor for orthostatic hypotension after clonidine administration.

Aldosterone (Urine or Blood)

Description

1. Direct measure, using radioimmunoassay technique, of aldosterone, a hormone secreted by the adrenal cortex that regulates renal control of sodium and potassium.
2. May be measured in the blood or in 24-hour urine collection specimen.
3. Urine test is more reliable because it is less influenced by short-term fluctuations in the bloodstream.
4. Useful to diagnose primary aldosteronism.

Nursing and Patient Care Considerations

1. Test results can be elevated by stress, strenuous exercise, upright posture, and medications such as diazoxide, hydralazine, and nitroprusside.
2. Test results may be decreased by excessive licorice ingestion and the medications, fludrocortisone and propranolol.

Tests of Pituitary Function

Serum Growth Hormone

Description

1. Direct radioimmunoassay measurement of human growth hormone (GH), secreted by the anterior pituitary gland; useful to diagnose acromegaly, gigantism, pituitary tumors, pituitary-related growth failure in children, or GH deficiency in adults.
2. Because GH secretion is episodic, single fasting samples may not be reliable to detect GH excess or deficiency.
3. These conditions are best evaluated by using a stimulation test (for deficiency states) or a suppression test (for hormone excess conditions).

Nursing and Patient Care Considerations

1. Blood sample is taken after an overnight fast (caloric intake will lower GH blood levels).
2. Patient should be restful and calm before blood sample collection.
3. Normal range: males—less than 5 ng/mL; females—less than 8 ng/mL.
4. May be elevated by the following medications: alcohol, L-dopa, hormonal contraceptives, alpha-antagonists, and beta-adrenergic blockers.

Serum Prolactin

Description

Direct radioimmunoassay measurement of prolactin, secreted by the anterior pituitary gland; helps diagnose pituitary tumors.

Nursing and Patient Care Considerations

1. Blood sample is taken after an overnight fast.
2. Normal values: men—1 to 20 ng/mL; women—1 to 25 ng/mL.
3. Values above 300 ng/mL highly suggestive of pituitary tumor.
4. Elevated values may be caused by exercise or by breast stimulation, such as from friction.
5. Medications that will elevate test results include phenothiazines, reserpine, estrogens, tricyclic antidepressants, methyldopa, antihypertensive medications, and selective serotonin reuptake inhibitors.

Adrenocorticotropic Hormone

Description

1. Direct measurement of ACTH concentration in the bloodstream by radioimmunoassay technique.
2. One measure of pituitary gland function useful to provide important information regarding adrenal gland dysfunction.

3. Useful to identify cause of adrenal abnormalities when compared with serum cortisol levels.

Nursing and Patient Care Considerations

1. Because ACTH is rapidly degraded, blood samples should be centrifuged and frozen promptly to avoid falsely low results.
2. High stress levels in patient can invalidate results.
3. Interpretation of test results:
   a. Elevated levels with elevated cortisol—Cushing disease or ectopic production of ACTH.
   b. Elevated levels with low cortisol—Addison disease.
   c. Low levels with elevated cortisol—adrenal tumor.
   d. Low levels with low cortisol—hypopituitarism.

Insulin Tolerance Test

Description

1. Dynamic test measures pituitary response to induced hypoglycemia, particularly GH secretion and ACTH-stimulated cortisol production by the adrenal gland.
2. Useful to diagnose functional hypopituitarism that is caused by pituitary disease or that appears after pituitary surgery.
3. Considered the "gold standard" for diagnosis of GH deficiency.

Nursing and Patient Care Considerations

1. After overnight fast, insulin 0.15 unit/kg (usual dose but may vary) body weight is given via IV line.
2. Blood samples are collected, usually at baseline, every 15 minutes after insulin dose.
3. The test is considered valid if blood glucose falls to half of baseline or less than 35 mg/dL.
4. Peak response is seen at 60 to 100 minutes.
5. For adrenal response, a rise in cortisol by a factor of at least 1.5 is necessary to show normal response.
6. GH deficiency is present if growth hormone levels fail to rise above 3 mcg/L.
7. This test is contraindicated in people with epilepsy or heart disease. In people with suspected adrenal insufficiency, ACTH stimulation test should be done first.
8. For people in whom the insulin tolerance test is contraindicated, other agents may be used, such as clonidine, arginine, glucagon, L-dopa, or GH-releasing hormone, to stimulate GH secretion.

NURSING ALERT Test should be performed with health care provider present. Dextrose 50% solution should be available at bedside to treat hypoglycemia, and test stopped if blood sugar falls below 35mg/dL.

Glucose Suppression Test

Description

Postprandial elevations of glucose inhibit the secretion of GH by the pituitary gland. Failure to suppress GH levels after ingestion of glucose suggests a GH-secreting tumor.

Nursing and Patient Care Considerations

1. Patient should fast for this test.
2. Seventy-five to hundred grams of concentrated glucose is administered by mouth.
3. Blood samples are collected at baseline, 30, and 60 minutes.
4. Interpretation of test results:
   a. GH levels less than 2 mcg/L are considered normal.
   b. GH levels that are not suppressed are suggestive of acromegaly.
5. Failure of GH suppression may also be caused by starvation or protein calorie restriction.
6. Patients may complain of nausea after ingesting Glucola.

Water Deprivation Test

Description

1. Functional test of the adequacy of posterior pituitary secretion of antidiuretic hormone (ADH) and its ability to concentrate urine and to maintain serum osmolality in the face of water deprivation.
2. Useful to determine the diagnosis and etiology of diabetes insipidus (DI).

Nursing and Patient Care Considerations

1. The test is begun by obtaining patient's weight, serum, and urine osmolality at time 0.
2. Patient weight, urine output volume, and osmolality are determined hourly.
3. Deprivation is continued until urine osmolality "plateaus," as evidenced by a change of less than 10% in urine osmolality between consecutive measurements and a 2% reduction in patient's body weight. At this time, samples are collected for serum sodium, osmolality, and vasopressin.
4. The test may be stopped if patient loses more than 3% of his or her body weight or if cardiac instability occurs.
5. If urine osmolality remains below that of serum (usually 300 mOsm/kg), the diagnosis of DI is confirmed and the second stage of the test, which distinguishes central and nephrogenic DI, is begun.
6. Artificial ADH (desmopressin acetate [DDAVP]) 2 mcg is given SubQ or IM to determine changes in urine osmolality at 30, 60, and 120 minutes in response to the injected hormone.
7. If the highest urine osmolality value obtained after injection is more than 50% higher than the preinjection value, DI is caused by pituitary failure. If the osmolality value is less than 50% of preinjection value, then DI is caused by renal disease.

NURSING ALERT Patients with suspected DI who undergo the water deprivation test must be monitored closely because dehydration may occur rapidly in people with severe disease.

Radiology and Imaging

Radioactive ^{131}I Uptake

Description

1. Measures thyroid uptake patterns of iodine as a whole or within specified areas of the gland. A solution of sodium iodide-131 (^{131}I) is administered orally to fasting patient.
2. After a prescribed interval, usually 24 hours, measurements of radioactive counts per minute are taken with a scintillator.
3. Normal thyroid will remove 15% to 50% of the iodine from the bloodstream.
4. Hyperthyroidism may result in the removal of as much as 90% of the iodine from the bloodstream (eg, Graves disease); it may also cause a low uptake with some forms of thyroiditis.
5. Hypothyroidism is reflected in low uptake.

Nursing and Patient Care Considerations

After the test, radioactive iodine is eliminated through urine. The following measures are recommended from 1 to 21 days (depending on dose given, most average 3 days):

1. Drink lots of fluids.
2. Flush toilet two to three times after use.
3. Avoid close contact with other—6 feet distance.
4. Avoid contact with infants, children, and pregnant women.
5. Do not share a bed.
6. Avoid public areas.
7. Do not share utensils and/or prepare foods for others.

Thyroid Scan

Description

1. Rapid imaging of thyroid tissue, particularly suspicious nodules, as contrast imaging agent is rapidly taken up by functioning tissue.
2. Useful to diagnose thyroid carcinoma.
3. Contrast media is usually administered via IV line.
    a. Technetium (^{99m}Tc) pertechnetate or ^{123}I is used for best images.
4. Images can be obtained from gamma counter within 20 to 60 minutes.

Nursing and Patient Care Considerations

1. May interfere with serum radioimmunoassay tests; contact laboratory to determine when blood test can be done.

2. Benign adenomas may be visualized as “hot” nodules, indicating increased uptake of iodine, or as “cold” nodules, indicating decreased uptake.
3. Malignant nodules usually take the form of “cold” nodules.
4. No specific measures need to be taken after the test.

GENERAL PROCEDURES AND TREATMENT MODALITIES

STANDARDS OF CARE GUIDELINES 24-1

Endocrine Disorders

When caring for a patient with an endocrine disorder, remember that important metabolic functions may be disrupted, such as fluid and electrolyte balance, glucose and protein metabolism, energy production, calcium ionization, blood pressure (BP) control, thermoregulation, cardiac contractility, intestinal peristalsis, and ability of the body to react to stress.

- Monitor closely for electrolyte imbalance—sodium, potassium, chloride, bicarbonate—by checking laboratory test results, changes in the electrocardiogram pattern, and signs of particular excess or deficit (see Chapter 21, page 605).
- Check fingerstick or serum glucose periodically for patients on corticosteroids or for patients with adrenal disease; watch for signs of hyperglycemia (polydipsia, polyphagia, polyuria, blurred vision) or hypoglycemia (nervousness, tremor, difficulty concentrating, lethargy).
- Monitor for hypocalcemia after thyroidectomy, parathyroidectomy, or with hypoparathyroidism by checking serum calcium and phosphorus levels; watch for muscular twitching, anxiety, apprehension, spasms, and tetany. Check Chvostek sign and Trousseau sign.
- Monitor vital signs for heart rate, BP, and presence of arrhythmias.
- Monitor temperature and respiratory rate changes in thyroid and adrenal disease.
- Monitor intake and output, weight changes, and edema.
- Maintain a calm, quiet environment and provide meticulous care to prevent infection or dehydration in patients with adrenal hypofunction or patients on corticosteroid replacement.
- After surgery, check for bleeding, signs of infection, changes in vital signs. Monitor respiratory status carefully after thyroidectomy.
- Report worsening condition or development of suspicious signs and symptoms promptly to prevent serious complications, such as myxedema coma, thyroid storm, hypocalcemic tetany, adrenal crisis.
- Provide support, and explain care slowly and repeatedly because patient may have mental slowness, confusion, or lethargy because of his or her condition. Ask patient to restate important information to verify understanding.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

See Standards of Care Guidelines 24-1, page 703.

Steroid Therapy

Steroid therapy is a treatment used in some endocrine disorders and in various other conditions. Steroids are hormones that affect metabolism and many body processes.

Classification of Steroids

(By major metabolic effects on the body.)

Mineralocorticoids

1. Concerned with sodium and water retention and potassium excretion.
2. Example—aldosterone and 11-desoxycorticosterone.

Glucocorticoids (Corticosteroids, Steroids)

1. Concerned with metabolic effects, including carbohydrate metabolism.
2. Example—cortisol.

Sex Hormones

1. Important when secreted in large amounts or when the growth of hormone-sensitive cancers is stimulated.
2. Examples:
   a. Androgens—testosterone.
   b. Estrogens—estradiol.
   c. Progestins—progesterone.

Effects of Glucocorticoids

1. Antagonize action of insulin; promote gluconeogenesis, which provides glucose.
2. Increase breakdown of protein (inhibit protein synthesis).
3. Increase breakdown of fatty acids.
4. Suppress inflammation, inhibit scar formation, block allergic responses.
5. Decrease number of circulating eosinophils and leukocytes; decrease size of lymphatic tissue.
6. Exert a permissive action (allow the full effects) on catecholamines.
7. Exert a permissive action on functioning of central nervous system (CNS).
8. Inhibit release of adrenocorticotropin.
9. In summary, glucocorticoids are necessary to resist noxious stimuli and environmental change.

Uses of Steroids

1. Physiologically—to correct deficiencies or malfunction of a particular endocrine organ or system (eg, Addison disease).
2. Diagnostically—to determine proper functioning of the endocrine system.

3. Pharmacologically—to treat the following:
    a. Asthma and obstructive lung disease.
    b. Acute rheumatic fever.
    c. Blood conditions, such as idiopathic thrombocytopenic purpura, leukemia, hemolytic anemia.
    d. Allergic conditions—allergic rhinitis, anaphylaxis (after epinephrine).
    e. Dermatologic problems—drug rashes, contact dermatitis, atopic dermatitis.
    f. Ocular diseases—conjunctivitis, uveitis.
    g. Connective tissue disorders—systemic lupus erythematosus, rheumatoid arthritis.
    h. GI problems—ulcerative colitis.
    i. Organ transplant recipients—as an immunosuppressive agent.
    j. Neurologic conditions—cerebral edema, multiple sclerosis.

Preparing the Patient to Receive Steroid Therapy

1. Determine contraindications/precautions for such therapy.
    a. Peptic ulcer.
    b. Diabetes mellitus.
    c. Viral infections.
2. Administer a tuberculin test, if indicated, before therapy because steroids may suppress response to the test.
3. Assess the patient's own level of steroid secretion, if possible.
4. Explain the nature of the therapy, what is required of the patient, how long therapy will last, adverse effects to watch for, and answer any questions.

Choice of Steroid and Method of Administration

1. May be given by various methods—orally, parenterally, sublingually, rectally, by inhalation, or by direct application to skin or mucous membrane.
2. Combinations of steroids with other drugs should be avoided.
3. To help avoid steroid adverse effects, alternate-day therapy may be used; dose is taken in the morning.
4. May be given in initial high doses, then reduced; if the patient has been taking steroids for several weeks, doses must be tapered gradually to prevent addisonian crisis.

Nursing Interventions

Preventing Infection

1. Steroids may affect the circulating blood, resulting in decreased eosinophils and lymphocytes, increased red cells, and increased incidence of thrombophlebitis and infection.
2. Encourage the patient to avoid crowds and the possibility of exposure to infection.
3. Encourage exercise to prevent venous stasis.

4. Be aware that signs of infection/inflammation may be masked—fever, redness, swelling.
5. Practice and encourage good handwashing technique and asepsis.

Preventing Nutritional and Metabolism Complications

1. Determine whether the patient needs assistance in dietary control. Steroids may cause weight gain and an increase in appetite.
2. Encourage a high-protein diet. Because steroids affect protein metabolism, there may be negative nitrogen balance.
3. Encourage the patient to take steroids with milk or with food. Because steroids increase secretion of gastric acid and have an inhibiting effect on secretion of mucus in the stomach, they may cause peptic ulcer.
4. Be on guard for early evidence of gastric hemorrhage, such as melena, blood in vomitus.
5. Check fasting blood glucose levels.
    a. Steroids precipitate gluconeogenesis and insulin antagonism, which results in hyperglycemia, glucosuria, decreased carbohydrate tolerance.
    b. Temporary insulin injections may be necessary.

Observing for Bone Complications

1. Be on the alert for the possibility of pathologic fractures. Stress safety measures to prevent injury.
    a. Steroids affect the musculoskeletal system, causing potassium depletion and muscular weakness.
    b. Steroids cause increased output of calcium and phosphorus, which may lead to osteoporosis.
2. Administer a diet high in calcium and protein.
3. Recommend activities of daily living (ADLs) and weight-bearing program; recommend normal range of motion and safe repositioning for those who are bedridden.
4. Obtain baseline DXA scan, if on long-term steroid use.

Avoiding Electrolyte Disturbance

1. Restrict sodium intake and increase potassium intake.
    a. Mineralocorticoids differ from other steroids, resulting in sodium retention and potassium depletion; edema, weight gain.
    b. Lemon juice is high in potassium and low in sodium.
    c. Avoid saline as a diluent in preparing injectable medications.
2. Check BP frequently, and weigh the patient daily.
3. Observe for edema.

Monitoring Behavioral Reactions

1. Watch for convulsive seizures (especially in children). Steroids may alter behavior patterns, increase excitability, and may affect the CNS.
2. Avoid overstimulating situations.

3. Recognize and report any mood that deviates from the usual behavior patterns.
4. Report unusual behavior, haunting dreams, withdrawal, or suicidal tendencies.

Preventing Stress Reactions

1. Recommend that the patient carry an identification card that indicates steroid therapy and name of health care provider.
2. Be aware that steroids affect the hypothalamic–pituitary–adrenal system, which affects the patient's ability to respond to stress.
3. Advise the patient to avoid extremes of temperature, infections, and upsetting situations.

Preventing Injury and Promoting Healing

1. Instruct the patient to avoid injury; stress safety precautions. Because steroids interfere with fibroblasts and granulation tissue, altered response to injury results in impaired growth and delayed healing.
2. Observe daily the healing process of wounds, particularly surgical wounds, to recognize the potential for wound dehiscence.

Patient Education and Health Maintenance

1. Teach patient that steroids are valuable and useful medications, but that if taken for longer than 2 weeks, they may produce certain adverse effects.
    a. Acceptable adverse effects may include weight gain (because of increased appetite and water retention), acne, headaches, fatigue, and increased urinary frequency.
    b. Unacceptable adverse effects that are to be reported to the health care provider include dizziness when rising from chair or bed (orthostatic hypotension indicative of adrenal insufficiency), nausea, vomiting, thirst, abdominal pain, or pain of any type.
    c. Additional reportable adverse effects include convulsive seizures, feelings of depression or nervousness, or development of an infection.
2. Advise patient that a fall or an automobile accident may precipitate adrenal failure. This requires an immediate injection of hydrocortisone phosphate.
3. Tell patients on long-term therapy that they should wear a MedicAlert bracelet and carry a kit with hydrocortisone, as prescribed.
4. Instruct patient to inform any physician, dentist, or nurse about steroid therapy.
5. Tell patient that regular follow-up visits to health care provider are required.

Care of the Patient Undergoing Fine Needle Aspiration Biopsy

EVIDENCE BASE Haugen, B. R., Alexander, E. K., Bible, K. C., et al. (2016). American Thyroid Association Management Guidelines for Adult Patients with Thyroid Nodules and Differentiated Thyroid Cancer: The American Thyroid Association Guidelines Task Force on Thyroid Nodules and Differentiated Thyroid Cancer. *Thyroid, 26*(1), 1–133.

Jonklaas, J., Bianco, A. C., Bauer, A. J., et al. (2014). Guidelines for the Treatment of Hypothyroidism: Prepared by the American Thyroid Association Task Force on Thyroid Hormone Replacement. *Thyroid, 24*(12), 1670–1751.

Fine needle aspiration (FNA) biopsy is a procedure by which tissue from within a thyroid nodule is removed to detect malignancy. This procedure can easily be performed on an outpatient basis and requires no special patient preparation. Complications are uncommon but may include hematoma, tracheal perforation, and infection.

Preparation and Procedure

1. No special patient preparation activities are necessary for this procedure.
2. The procedure is explained to patient, and consent is obtained.
3. Patient is positioned comfortably on an examination table in the supine position with the neck fully exposed.
4. A rolled towel or sheet is placed beneath the patient's shoulder to hyperextend the neck, allowing ease of access to the biopsy site.
5. The biopsy site area is cleaned with alcohol and/or an antibacterial cleaning agent.
6. One percent lidocaine may be injected intracutaneously for local anesthetic to promote patient comfort.
7. A 25-G needle is inserted into the thyroid nodule and manipulated by the physician until a small amount of bloody material is seen on the hub of the needle.
8. The needle is removed and attached to a syringe. The contents of the needle are expressed onto a clean glass slide. A second slide is placed on top of the first slide and then pulled apart quickly to create a thin smear.
9. The slides are placed in a fixative and transported to a cytologist for interpretation.

Postprocedure Management

1. The biopsy site may be dressed with an adhesive bandage or other small dressing.
2. Follow-up visit for patient should be arranged to discuss results.

Nursing Considerations

1. Prevent infection by making sure that biopsy area is prepped appropriately before procedure.
2. Employ comfort measures during procedure, as necessary.
3. Assure patient that most thyroid nodules are determined to be benign and that most thyroid malignancies have a high cure rate.
4. Advise patient that some soreness at the biopsy site should be expected for a brief time.
5. Make sure that patient follows up for results and definitive treatment.

Care of the Patient Undergoing Thyroidectomy

Thyroidectomy involves the partial or complete removal of the thyroid gland to treat thyroid tumors, hyperthyroidism, or hyperparathyroidism.

Types of Procedures

1. Thyroidectomy can be total (removal of the entire thyroid gland); subtotal (95% of gland removed)—to prevent damage to the parathyroid glands; and partial (one lobe or isthmus removed)—to treat nodular disease.
2. The parathyroid glands are usually spared to prevent hypocalcemia.
3. Indications for thyroidectomy include Graves disease refractory to ^{131}I therapy, large goiters, adenoma (thyroid cancer), and some nodules.

Preoperative Management

1. The patient must be euthyroid at time of surgery, so thioamides are administered to control hyperthyroidism.
2. Iodide is given to increase firmness of the thyroid gland and to reduce its vascularity and blood loss.
3. An attempt is made to counteract the effects of hypermetabolism by maintaining a restful and therapeutic environment and by providing a nutritious diet.
4. The patient is prepared for surgery physically and emotionally in the following ways:
    a. Make a special effort to ensure that patient has a good night's rest preceding surgery.
    b. Explain to patient that speaking is to be minimized immediately postoperatively and that oxygen may be administered to facilitate breathing.
    c. Explain that postoperatively, fluids may be given via IV line to maintain fluid, electrolyte, and nutritional needs; IV glucose may also be given in the hours before the administration of anesthetic agents.

Postoperative Management

1. The patient is monitored for bleeding and respiratory distress that indicates laryngeal edema, secondary to swelling in the area of surgery.
2. Signs of hypocalcemia are watched for—irritability, twitching, spasms of the hands and feet.
    a. Calcium levels are monitored. If in 48 hours level falls below 7 mg/100 mL (3 mEq), IV calcium (gluconate, lactate) replacement is given.
    b. IV calcium is used cautiously in patients who have renal disease or who are taking digoxin.
3. Thyroid function is monitored after surgery.

Complications

1. Hemorrhage, edema of the glottis, damage to laryngeal nerve.

2. Hypothyroidism following subtotal thyroidectomy occurs in 5% of patients in first postoperative year; increases at rate of 2% to 3% per year.
3. Hypoparathyroidism occurs in about 4% of patients and is usually mild and transient; requires calcium supplements via IV administration and orally when more severe.

Nursing Diagnoses

- Risk for Bleeding related to invasive procedure of the neck.
- Risk for Injury related to possible removal of parathyroid glands.

Nursing Interventions

Observing for Hemorrhage and Airway Edema

1. Administer humidified oxygen, as prescribed, to reduce irritation of airway and to prevent edema.
2. Move patient carefully; provide adequate support to the head so that no tension is placed on the sutures.
3. Place patient in semi-Fowler position, with the head elevated and supported by pillows; avoid flexion of the neck.
4. Monitor vital signs frequently, watching for tachycardia and hypotension that indicates hemorrhage (most likely between 12 and 24 hours postoperatively).
5. Observe for bleeding at sides and back of the neck, and anteriorly, when patient is in dorsal position.
6. Watch for repeated clearing of the throat or for complaint of smothering or difficulty swallowing, which may be early signs of hemorrhage.
7. Watch for irregular breathing, swelling of the neck, and choking—other signs pointing to the possibility of hemorrhage and tracheal compression.
8. Reinforce dressing, if indicated.
9. Be alert for voice changes, which may indicate damage to laryngeal nerve.
10. Keep a tracheostomy set in patient's room for 48 hours for emergency use.

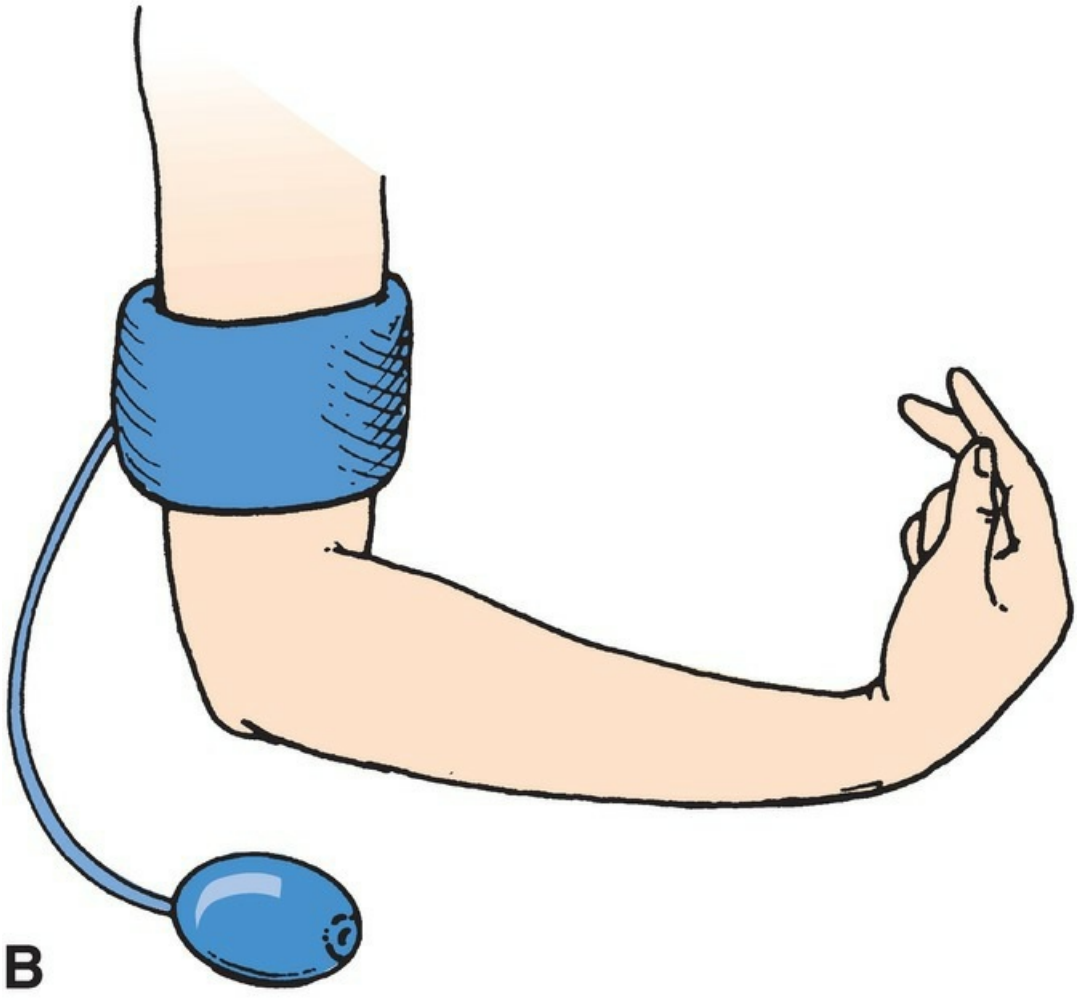
Preventing Tetany

1. Watch for the development of tetany caused by removal or disturbance of parathyroid glands through a progression of signs:
   a. Tingling of toes and fingers and around the mouth; apprehension.
   b. Positive Chvostek sign—spasm of facial muscles caused by tapping on the cheek over the facial nerve; causes a twitch of the lip or side of the face (see Figure 24-1A, page 706).
   c. Positive Trousseau sign—carpopedal spasm induced by occluding circulation in the arm or lower leg with a BP cuff (20 mm Hg above systolic pressure); within 3 minutes, flexion of the hands at the wrists and of the fingers at the metacarpophalangeal joints and extension of the fingers at the phalangeal joints or the feet are dorsiflexed at the ankles and the toes plantar flexed (see Figure 24-1B).
2. Be prepared to treat hypocalcemic tetany.

a. Position patient for optimal ventilation; remove pillow to prevent head from bending forward and compressing trachea.
b. Keep side rails padded and elevated, and position the patient to prevent injury if a seizure occurs; do not use restraints because they only aggravate the patient and may result in muscle strain or fractures.
c. Have equipment available to treat respiratory difficulties that includes airway suction equipment, tracheostomy, and cardiac arrest equipment.

3. Administer IV calcium, as directed.

A



B

Figure 24-1. (A) Chvostek sign. **(B)** Trousseau sign.

Patient Education and Health Maintenance

1. Teach patient about complications to look for if discharge occurs within a day or two of surgery.
2. Advise patient to rest at home and to prevent any strain on suture line, as directed by surgeon.
3. Advise nutritious diet; report difficulty swallowing.
4. Encourage follow-up for monitoring and thyroid hormone replacement after surgery.

Evaluation: Expected Outcomes

- No signs of hemorrhage or edema.
- No signs of hypocalcemia.

Care of the Patient Undergoing Adrenalectomy

Adrenalectomy may be unilateral or bilateral to treat adrenal tumors, Cushing syndrome, or hyperaldosteronism. It is accomplished through abdominal or flank incision. Careful manipulation of the gland is necessary—if surgery is indicated for pheochromocytoma—to prevent excessive release of epinephrine causing hypertensive crisis.

Preoperative Management

1. BP and fluid volume are optimized.
2. Surgical and nursing care is explained to patient. Patient is shown where adrenal glands lie on the top of the kidneys and where incision may be on the abdomen or loin area.
3. BP will be checked frequently before and after surgery, and glucocorticoids will be given to cover period of stress (surgery) because at least one adrenal gland will be removed.
4. Patient is prepared as for major abdominal surgery (see page 495).

Complications

Hemorrhage, adrenal crisis.

Postoperative Management

1. Usual postoperative care for abdominal surgery includes frequent check of vital signs; assessment for hemorrhage; turning, coughing, and deep breathing; early ambulation; slow progression of diet when bowel sounds return; and control of pain with scheduled opioid administration or patient-controlled analgesia (see page 1509).
2. IV hydrocortisone is given, as directed, to prevent adrenal crisis.
3. Nonstressful environment is maintained, rest is promoted, and meticulous care is given to protect patient from infection and from other complications that could cause adrenal crisis.
4. Serum sodium, potassium, and glucose are monitored for abnormality.
    a. Sodium and potassium may normalize, or potassium may become elevated (because of transient adrenal insufficiency after surgery).
    b. Electrolyte imbalances may persist for 4 to 18 months after surgery.
    c. Hypertension may persist for 3 to 6 months after surgery.
5. Hydrocortisone treatment causes glucose to rise and worsens control in patients with diabetes; may require additional treatment.

Nursing Diagnoses

- Risk for Infection related to nature of surgery.
- Readiness for Enhanced Knowledge about corticosteroid replacement.

Nursing Interventions

Ensuring Healing

1. Assess dressing for leakage initially, and after it has been changed, assess wound for signs of infection.
2. Perform dressing changes, wound care, and teach family how to do wound care at home.

Providing Patient Education

1. Teach patient with bilateral adrenalectomy that glucocorticoid and mineralocorticoid replacement is necessary for rest of life.
2. Administer additional doses IM in times of stress.
3. Administer oral glucocorticoids after unilateral adrenalectomy, and teach patient that this treatment will be needed for 6 months to 2 years after surgery until remaining adrenal gland can compensate.
4. Encourage wearing or carrying a medical alert tag containing this information at all times so that proper treatment can be instituted if patient becomes unconscious.
5. Encourage follow-up to monitor for signs of adrenal insufficiency.

Care of the Patient Undergoing Transsphenoidal Hypophysectomy

Procedure

1. Transsphenoidal approach to pituitary removal is carried out through the nasal cavity, sphenoid sinus, and into the sella turcica (see Figure 24-2).
2. Advantages over intracranial approach to hypophysectomy include:
   a. No need to shave the head.
   b. No visible scar.
   c. Low blood loss, less need for transfusions.
   d. Lower infection rate.
   e. Well tolerated by frail and older patients.
   f. Good visualization of tumor field.
3. Disadvantages include:
   a. Restricted field of surgery.
   b. Potential cerebrospinal fluid (CSF) leak.

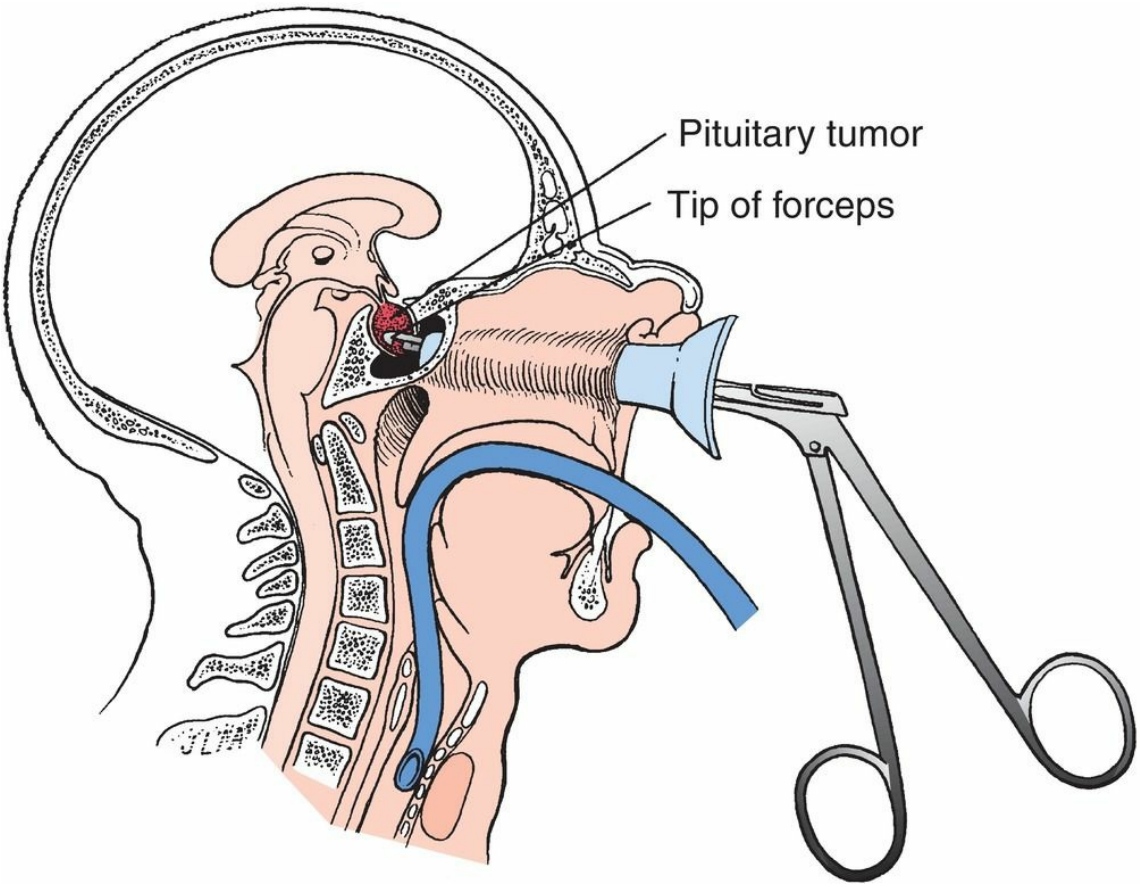


Figure 24-2. Transsphenoidal approach to the pituitary. A special nasal speculum is used to view the sinus cavity. After the dura is opened, the tumor is removed using microcurettes or other specially designed instruments.

Preoperative Management

1. Sinus infection is assessed and treated, if necessary.
2. Hydrocortisone may be given preoperatively because the source of ACTH is being removed.
3. The patient is prepared physically and emotionally for surgery.
    a. Deep-breathing exercises.
    b. Avoid coughing and sneezing postoperatively to prevent CSF leak.

Complications

1. CSF leak, meningitis.
2. Transient DI.
3. Syndrome of inappropriate antidiuretic hormone (SIADH).

Postoperative Management

1. Vital signs, visual acuity, and neurologic status are monitored.
2. Urine output and specific gravity and serum electrolytes and osmolality are monitored for development of DI or SIADH.
3. Drainage from nose is monitored for signs of infection or CSF leak (clear fluid).

Nursing Diagnoses

- Delayed Surgical Recovery related to potential complications.
- Risk for Infection secondary to invasive procedure.

Nursing Interventions

Protecting Against Complications

1. Monitor vital signs, visual acuity, and neurologic status frequently for signs of increasing intracranial pressure (see page 357).
2. Monitor fluid intake and output, and report any increase in output and decrease in specific gravity, which may indicate DI.
3. Report persistent clear fluid from nose and increasing headache; could signal CSF leak.
4. Teach patient signs of complications and to report them immediately and to follow up as scheduled.
5. Assess level of pain, and administer analgesic or supervise patient-controlled analgesia.

Preventing Infection

1. Observe for signs of infection. Check incision within inner aspect of upper lip for drainage or bleeding.
2. Note frequency of nasal dressing changes and character of drainage. Prepare patient for packing removal one to several days postoperatively.
3. Encourage the use of a humidifier to prevent drying from mouth breathing.

Evaluation: Expected Outcomes

- Vital signs stable, urine specific gravity 1.010, no clear drainage from nose.
- No purulent drainage noted.

DISORDERS OF THE THYROID GLAND

See additional online content: Nursing Care Plan 24-1

Nursing Care Plan 24-1

Care of the Patient with Hypothyroidism

You see Mrs. White in the clinic. She is a 45-year-old woman with a history of hypothyroidism, who has been treated with L-thyroxine 0.15 mg daily.

From your assessment and knowledge of hypothyroidism, develop your care plan.

Subjective data: Mrs. White tells you that she has been feeling tired lately and finds it hard to manage even the simplest chores around the house. She complains of constipation that gives her a feeling of fullness and affects her appetite. When asked about her medication, she states, "(Oh, I ran out of those a few months ago, and I never refilled the prescription. I was feeling fine, so I didn't see any need to keep taking medicine.)"

Objective data: Vital signs are temperature 98.2°F (36.8°C), pulse 58, blood pressure 100/60, respirations 12. On examination, you notice her skin is cool and dry to the touch. She is wearing a sweater even though it is a warm day outside. Bowel sounds are hypoactive. Knee jerk reflexes are sluggish.

Laboratory results: T_4-3.4 mcg/dL (normal range 5 to 12 mcg/dL), thyroid-stimulating hormone 25 μU/mL (normal range less than 7 μU/mL)

NURSING DIAGNOSIS

Constipation related to decreased bowel motility caused by hypofunction of the thyroid gland.

GOAL/EXPECTED OUTCOME

The patient will resume normal bowel function.

Nursing Intervention	Rationale	Evaluation: Actual Outcome
Encourage increased intake of fluids.	Promotes passage of soft stools.	Drinks 8–10 glasses of fluid per day.
Recommend foods high in fiber.	Increases bulk of stools and promotes more frequent bowel movements.	Identifies and consumes foods high in fiber.
Recommend that the patient monitor bowel function by recording frequency and consistency of stools.	Documents patient response to nursing interventions.	Reports bowel pattern has returned to normal.
Encourage increased mobility within patient's exercise tolerance.	Promotes evacuation of the bowel.	Gradually increases exercise.

NURSING DIAGNOSIS

Activity Intolerance related to reduced metabolic rate.

GOAL/EXPECTED OUTCOME

Exercise tolerance and participation in activities will increase.

Nursing Intervention	Rationale	Evaluation: Actual Outcome
Teach patient to space activities to promote rest and exercise as tolerated.	Promotes activity without overly stressing the patient.	Reports increased participation in activities of daily living.
Teach the patient to keep a record of physical activity, noting duration, intensity, and level of fatigue.	Promotes patient participation in care and promotes independence.	Provides reports of exercise tolerance and performance in daily activities.
Gradually increase level of activity as tolerated.	Demonstrates changes in patient activity tolerance.	Reports successful increases in activity tolerance.

NURSING DIAGNOSIS

Deficient Knowledge related to self-care needs for thyroid hormone replacement therapy.

GOAL/EXPECTED OUTCOME

Patient will demonstrate knowledge appropriate for self-care in thyroid replacement therapy.

Nursing Intervention	Rationale	Evaluation: Actual Outcome
Teach the patient about the nature of chronic hypothyroidism and the purpose of thyroid hormone replacement therapy.	Provides rationale for adherence to prescribed hormone replacement.	Describes reason for thyroid hormone replacement therapy and describes regimen correctly.
Describe effects of thyroid hormone medication to the patient.	Allows the patient to appreciate benefits of therapy from the standpoint of her current physical complaints.	States physiologic effects of thyroid hormone replacement therapy.
Describe signs and symptoms of underdosage and overdosage of medication. • Underdosage—fatigue, slow pulse, constipation • Overdosage—increased pulse or palpitations, sweating, difficulty sleeping, feeling jittery	Allows the patient to be an active participant in monitoring her therapy.	Identifies signs and symptoms indicative of overdosage and underdosage that should be reported to her health care provider promptly.

The thyroid gland affects the basal metabolic rate of all tissues, including the speed of chemical reactions, the volume of oxygen consumed, and the amount of heat produced. The stimulating effect is through the production and distribution of two hormones:

1. Levothyroxine (T_4)—contains four iodine atoms; maintains body's metabolism in a steady state; T_4 serves as a precursor of T_3.
2. Triiodothyronine (T_3)—contains three iodine atoms; approximately five times as potent as T_4; has a more rapid metabolic action and utilization than T_4 does. T_3 affects the protein synthesis and substrate by modifying gene transcription in most tissue.
3. Most conversion of T_4 to T_3 occurs at the cellular level in the periphery. Some T_3 is produced in the

thyroid gland.

Hypothyroidism

Hypothyroidism is a condition that arises from a deficiency in endogenous production of thyroid hormone in the bloodstream.

Pathophysiology and Etiology

1. Primary hypothyroidism is the most common form of this condition and is generally caused by:
   a. Autoimmune disease—chronic lymphocytic thyroiditis (also known as Hashimoto's thyroiditis).
   b. Postpartum thyroiditis.
   c. Use of radioactive iodine.
   d. Destruction, suppression, or removal of all or some of the thyroid tissue by thyroidectomy.
   e. Dietary iodide deficiency.
   f. Subacute granulomatous thyroiditis.
   g. Drug-induced iatrogenic hypothyroidism.
   h. Genetic causes.
2. Secondary hypothyroidism is caused when damage occurs to the hypothalamic–pituitary axis (ie, tumor, necrosis, head trauma, certain drugs, brain/pituitary irradiation).
3. Inadequate secretion of thyroid hormone leads to a general slowing of all physical and mental processes.
4. General depression of most cellular enzyme systems and oxidative processes occurs.
5. The metabolic activity of all cells of the body decreases, reducing oxygen consumption, decreasing oxidation of nutrients for energy, and producing less body heat.
6. The signs and symptoms of the disorder range from vague, nonspecific complaints that make diagnosis difficult to severe symptoms that may be life threatening if unrecognized and untreated.

Clinical Manifestations

1. Fatigue and lethargy, decreased energy, exhaustion.
2. Weight gain-despite possible decreased appetite.
3. Complaints of cold hands and feet, cold intolerant
4. Increased blood pressure, decreased pulse.
5. Reduced attention span; impaired short-term memory.
6. Constipation; decreased peristalsis.
7. Generalized appearance of "doughy" thick, puffy skin; subcutaneous swelling in the hands, feet, and eyelids.
8. Thinning hair; loss of the lateral one third of the eyebrow.
9. Dry skin.
10. Enlarged tongue.
11. Depression, other psychological problems.

12. Menorrhagia or amenorrhea; may have difficulty conceiving or may experience spontaneous abortion; decreased libido, erectile dysfunction.
13. Neurologic signs include polyneuropathy, cerebellar ataxia, muscle aches or weakness, clumsiness, prolonged deep tendon reflexes (especially ankle jerk).
14. Hyperlipoproteinemia and hypercholesterolemia.
15. Enlarged heart on chest x-ray.
16. Increased susceptibility to all hypnotic and sedative drugs and anesthetic agents.
17. Syndrome of subclinical hypothyroidism: state in which the patient is asymptomatic and the free T_4 level is within the normal range; however, the TSH level is elevated, suggesting impending thyroid gland failure. Therefore, many clinicians may elect to treat this condition as if the patient were symptomatic.

Diagnostic Evaluation

1. Low T_3 and T_4 levels.
2. Elevated TSH levels in primary hypothyroidism.
3. Elevation of serum cholesterol.
4. Electrocardiogram (ECG)—sinus bradycardia, low voltage of QRS complexes, and flat or inverted T waves.
5. Elevation of thyroid peroxidase antibodies and antithyroglobulin antibodies.

Management

Approach

1. Depends on severity of symptoms; may necessitate replacement therapy in mild cases or lifesaving support and treatment in severe hypothyroidism and myxedema coma.
2. As thyroid hormone levels gradually return to normal, the patient is monitored closely to prevent complications resulting from sudden increases in metabolic rate and oxygen requirements.

Restoration of Normal Metabolic State (Euthyroid)

1. Thyroid hormone: T_4, levothyroxine; T_3, liothyronine; T_3 and T_4 mixed. T_4 replacement therapy is typically the treatment of choice.
    a. In myxedema coma, a loading dose of levothyroxine is administered parenterally (until consciousness is restored) to restore T_4 level. Use of T_3 is controversial, may increase adverse cardiac events.
    b. Later, patient is continued on oral thyroid hormone therapy.
    c. With rapid administration of thyroid hormone, plasma T_4 levels may initiate adrenal insufficiency; hence, steroid therapy may be started.
    d. Mild symptoms in alert patient or asymptomatic cases (with abnormal laboratory results only) require only initiation of low-dose thyroid hormone given orally.
2. Monitoring to anticipate treatment effects.
    a. Diuresis, decreased puffiness.

b. Improved reflexes and muscle tone.

c. Accelerated pulse rate.

d. A slightly higher level of total serum T_4.

e. All signs of hypothyroidism should disappear in 3 to 12 weeks.

f. Decreasing TSH level.

g. Patients on T_4 can have an increase of dose every 4 to 6 weeks until TSH is therapeutic.

GERONTOLOGIC ALERT When starting thyroid hormone replacement, care must be taken with older patients and with those who have coronary ischemia disease, because of increased oxygen demands of the heart. It is preferable to start with much lower doses 25% to 50% lower than needed.

Complications

1. Myxedema coma—hypotension, unresponsiveness, bradycardia, hypoventilation, hyponatremia, (possibly) convulsions, hypothermia, cerebral hypoxia.
2. High mortality in myxedema coma.

Nursing Assessment

1. Obtain history of symptoms, medication program, and past history of thyroid disease, surgery, or treatment.
2. Perform multisystem assessment, including cardiac, respiratory, neurologic, and GI systems.

Nursing Diagnoses

- Decreased Cardiac Output related to decreased metabolic rate and decreased cardiac conduction.
- Constipation related to decreased bowel motility.
- Activity Intolerance related to reduced metabolic rate.

Nursing Interventions

Increasing Cardiac Output

1. Monitor vital signs frequently to detect changes in cardiovascular status and ability to respond to stress.
2. Monitor ECG tracings to detect arrhythmias and deterioration of cardiovascular status.
3. Prevent chilling to avoid increasing metabolic rate, which, in turn, places strain on the heart. Provide bed socks, bed jacket, warm environment.
4. Avoid rapid rewarming techniques (warmed IV fluids, hypothermia blanket) because the resulting increased oxygen requirements and peripheral vasodilation may worsen cardiac failure.
5. Administer fluids cautiously, even though hyponatremia is present.
6. Administer all prescribed drugs with caution before and after thyroid replacement begins.

a. Monitor the effects of sedatives, opioids, and anesthetics closely because patient is more sensitive to these agents.
b. After thyroid replacement is initiated, the thyroid hormones may increase the effects of digoxin (monitor pulse) and anticoagulants (watch for signs of bleeding).

7. Report occurrence of angina and be alert for signs and symptoms of myocardial infarction and cardiac failure.
8. Monitor arterial blood gas levels to assess cardiopulmonary function.

Promoting Normal Bowel Movements

1. Encourage too fluid intake of at least 64 ounces daily, unless contraindicated.
2. Recommend high-fiber food intake, including fresh or frozen fruit and vegetables lightly cooked, whole grains, and beans.
3. Advise patient to increase activity as tolerated and paying attention to the body's natural urge to evacuate the bowel.

Increasing Exercise Tolerance

1. Provide for uninterrupted rest periods between activities to assist with reconditioning.
2. Encourage exercise and walking goals based on patient's age and previous physical conditioning, in consultation with a physical therapist if required.
3. Recommend gradually increasing exercise and activity but stop if short of breath, chest pain, dizziness, or weakness. Report these symptoms if they do not resolve quickly with rest.

Patient Education and Health Maintenance

Instruct the patient about the following:

1. The need to receive lifelong thyroid hormone replacement therapy.
2. How and when to take medications.
3. Signs and symptoms of insufficient and excessive medication; reinforce teaching by providing written instructions.
4. The necessity of having blood evaluations periodically to determine thyroid levels.
5. Energy conservation techniques and the need to increase activity gradually.
6. Fluid intake and use of fiber to prevent constipation.
7. Control of dietary intake to limit calories and reduce weight.
8. Assist patient in identifying sources of information (see Box 24-1) and support available in the community such as local Office on Aging.

PITUITARY DISORDERS

- Pituitary Network Association: https://pituitary.org/Pituitary Foundation: https://www.pituitary.org.uk/

Evaluation: Expected Outcomes

- BP and pulse rate stable.
- Soft bowel movement without straining daily.
- Walking 15 minutes three times a day.

Hyperthyroidism

EVIDENCE BASE Ross D. S., Burch H. B., Cooper D. S., et al. (2016). American Thyroid Association Guidelines for Diagnosis and Management of Hyperthyroidism and Other Causes of Thyrotoxicosis. *Thyroid, 26*(10), 1343–1421.

Hyperthyroidism, a hypermetabolic condition, is characterized by excessive amounts of thyroid hormone in the bloodstream.

Pathophysiology and Etiology

1. More common in women than in men.
2. Graves disease (most prevalent)—diffuse hyperfunction of the thyroid gland with autoimmune etiology and associated with ophthalmopathy.
    a. TSI, an immunoglobulin found in the blood of patients with Graves disease, is capable of reacting with the receptor for TSH on the thyroid plasma membrane and of stimulating thyroid hormone production and secretion.
    b. Most common in younger women; may subside spontaneously.
3. Toxic nodular goiter (single or multiple)—more common preexisting goiter.
4. Toxic adenoma—present in 3% to 5% of thyrotoxicosis cases.
5. Hyperthyroidism is characterized by hypertrophy and hyperplasia of the thyroid gland, which is accompanied by increased vascularity and blood flow and enlargement of the gland.
6. Most of the clinical manifestations result from increased metabolic rate, excessive heat production, increased neuromuscular and cardiovascular activity, and hyperactivity of the sympathetic nervous system.
7. Hyperthyroidism ranges from a mild increase in metabolic rate to the severe hyperactivity known as thyrotoxicosis, thyroid storm, or thyroid crisis.
8. Hyperthyroidism can also be the result of ingestion of excessive amounts of thyroid hormone medication (factitious hyperthyroidism).

Clinical Manifestations

1. Nervousness, emotional lability, irritability, apprehension.
2. Difficulty sitting quietly; anxiety, hyperactivity.
3. Rapid pulse at rest and on exertion (ranges between 90 and 160); palpitations.
4. Heat intolerance; profuse perspiration; flushed skin (eg, hands may be warm, soft, moist).
5. Fine tremor of hands; change in bowel habits—constipation or diarrhea.
6. Increased appetite and progressive weight loss; frequent stools.
7. Muscle fatigability and weakness; amenorrhea.

8. Atrial fibrillation possible (cardiac decompensation common in older patients).
9. Exophthalmos, periorbital edema, chemosis, diplopia, proptosis suggestive of Graves disease.
10. Thyroid gland may be palpable, and a bruit may be auscultated over gland.
11. Course may be mild, characterized by remissions and exacerbations.
12. May progress to emaciation, extreme nervousness, delirium, disorientation, thyroid storm or crisis, and death.
13. Thyroid storm or crisis, an extreme form of hyperthyroidism, is characterized by hyperpyrexia, diarrhea, dehydration, tachycardia, arrhythmias, extreme irritation, delirium, coma, shock, and death if not adequately treated.
14. Thyroid storm may be precipitated by stress (surgery, infection) or inadequate preparation for surgery in a patient with known hyperthyroidism.

Diagnostic Evaluation

1. Elevated T_3 and T_4.
2. Elevated serum T_3 resin uptake and free thyroid index.
3. Low TSH levels.
4. Presence of TSI antibodies (if Graves disease is the cause).
5. ^{131}I uptake scan may be elevated or below normal depending on the underlying cause of the hyperthyroidism.

Management

Approach to Management

1. Treatment depends on causes, age of patient, severity of disease, and complications.
2. Remission of hyperthyroidism (Graves disease) occurs spontaneously within 1 to 2 years; however, relapse can be expected in half the patients. Antithyroid drugs, radiation, or surgery may be used for treatment.
3. Nodular toxic goiter—surgery or use of radioiodine is preferred.
4. Thyroid carcinoma—surgery or radiation is used.
5. Goal of therapy is to bring the metabolic rate to normal as soon as possible and to maintain it at this level.

Pharmacotherapy

1. Drugs that inhibit hormone formation:
   a. Thioamides—propylthiouracil and methimazole.
   b. Act by depressing the synthesis of thyroid hormone by inhibiting thyroid peroxidase.
   c. Propylthiouracil given in divided daily doses; methimazole may be given in a single daily dose.
   d. Duration of treatment is determined by clinical criteria.

i. Thyroid gland becomes smaller.

ii. Treatment continued until patient becomes clinically euthyroid; this varies from 3 months to 2 years; if euthyroidism cannot be maintained without therapy, then radiation or surgery is recommended.

iii. Therapy is withdrawn gradually to prevent exacerbation.

2. Drugs to control peripheral manifestations of hyperthyroidism:

a. Propranolol, a beta-adrenergic blocking agent.

i. Inhibits peripheral conversion of T_4 to T_3.

ii. Abolishes tachycardia, tremor, excess sweating, nervousness.

iii. Controls hyperthyroid symptoms until antithyroid drugs or radioiodine can take effect.

b. Glucocorticoids—decrease the peripheral conversion of T_4 to T_3, a more potent thyroid hormone.

Radioactive Iodine

1. Action—limits secretion of thyroid hormone by destroying thyroid tissue.
2. Dosage is calculated to help prevent hypothyroidism.
3. Chief advantage over thioamides is that a lasting remission can be achieved.
4. Chief disadvantage is that permanent hypothyroidism can be produced.

Surgery

1. Used for those with large goiters or for those for whom the use of radioiodine or thioamides is contraindicated.
2. Subtotal thyroidectomy involves removal of most of the thyroid gland (see page 705).

DRUG ALERT Observe the patient for evidence of iodine toxicity: swelling of buccal mucosa, excessive salivation, coryza, skin eruptions. If these occur, iodides are discontinued.

Emergency Management of Thyroid Storm

1. Inhibition of new hormone synthesis with thioamides (PTU and methimazole).
2. Inhibition of thyroid hormone release using a solution of potassium iodine.
3. Inhibition of peripheral effects of thyroid hormones with propranolol, corticosteroids, and propylthiouracil (PTU).
4. Treatment aimed at systemic effects of thyroid hormones and prevention of decompensation.
   a. Hyperthermia—cooling blanket, acetaminophen.
   b. Dehydration—administration of IV fluids and electrolytes.
5. Treatment of precipitating event.

Complications

1. Thioamide toxicity—agranulocytosis may occur suddenly.
2. Hypothyroidism if overtreated with antithyroid medication or if radiation treatment is used.
3. Radiation thyroiditis (a transient exacerbation of hyperthyroidism) may occur as a result of leakage of thyroid hormone into the circulation from damaged follicles.
4. Infiltrative ophthalmopathy.
    a. Occurs in 50% of patients with Graves disease.
    b. Features include exophthalmos, weakness of extraocular muscles, lid edema, lid lag.

Nursing Assessment

1. Obtain history of symptoms, family history of thyroid disease, medications, any recent physical stress, particularly infection.
2. Perform multisystem assessment that includes cardiac, respiratory, neurologic, and GI systems.
3. Closely monitor patient's temperature for thyroid storm.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to hypermetabolic state and fluid loss through diaphoresis.
- Risk for Impaired Skin Integrity related to diaphoresis, hyperpyrexia, restlessness, and rapid weight loss.
- Disturbed Thought Processes related to insomnia, decreased attention span, and irritability.
- Anxiety related to condition and concern about upcoming surgery/radioiodine treatment.

Nursing Interventions

Providing Adequate Nutrition

1. Determine patient's food and fluid preferences.
2. Provide high-calorie foods and fluids consistent with the patient's requirements.
3. Provide a quiet, calm environment at meals.
4. Restrict stimulants (tea, coffee, alcohol); explain rationale of requirements and restrictions to patient.
5. Encourage and permit patient to eat alone if embarrassed or if otherwise disturbed by voracious appetite.
6. Monitor IV infusion when prescribed to maintain fluid and electrolyte balance.
7. Monitor fluid and nutritional status by weighing patient daily and by keeping accurate intake and output records.
8. Monitor vital signs to detect changes in fluid volume status.
9. Assess skin turgor, mucous membranes, and neck veins for signs of increased or decreased fluid volume.

Maintaining Skin Integrity

1. Assess skin frequently to detect diaphoresis.

2. Bathe frequently with cool water; change linens when damp.
3. Avoid soap to prevent drying and apply lubricant skin lotions to pressure points.
4. Protect and relieve pressure from bony prominences while immobilized or while hypothermia blanket is used.

Promoting Normal Thought Processes

1. Explain procedures to patient in an unhurried, calm manner.
2. Limit visitors; avoid stimulating conversations or television programs.
3. Reduce stressors in the environment; reduce noise and lights.
4. Promote sleep and relaxation through use of prescribed medications, massage, and relaxation exercises.
5. Minimize disruption of patient's sleep or rest by clustering nursing activities.
6. Use safety measures to reduce risk of trauma or falls (padded side rails, bed in low position).

Relieving Anxiety

1. Encourage patient to verbalize concerns and fears about illness and treatment.
2. Support patient who is undergoing various diagnostic tests.
   a. Explain the purpose and requirements of each prescribed test.
   b. Explain results of tests if unclear to the patient or if questions arise.
3. Clear up misconceptions about treatment options.

Patient Education and Health Maintenance

1. Instruct patient as follows:
   a. When to take medications.
   b. Signs and symptoms of insufficient and excessive medication.
   c. Necessity of having blood evaluations periodically to determine thyroid levels.
   d. Signs of agranulocytosis (fever, sore throat, upper respiratory infection) or rash, fever, urticaria, or enlarged salivary glands caused by thioamide toxicity.
   e. Signs and symptoms of thyroid storm (ie, tachycardia, hyperpyrexia, extreme irritation) and predisposing factors to thyroid storm (ie, infection, surgery, stress, abrupt withdrawal of antithyroid medications and adrenergic blockers).
2. Reinforce teaching by providing written instructions as well.
3. Assist patient in identifying sources of information and support available in the community (see Box 24-1, page 709).

Evaluation: Expected Outcomes

- Food and fluid intake adequate, gaining weight.
- Skin cool, dry, and intact.
- Maintains concentration, follows conversation, and responds appropriately.

- Verbalizes concerns and questions about illness, treatment, and surgery.

Subacute Thyroiditis

Subacute thyroiditis is a self-limiting, painful inflammation of the thyroid gland, usually associated with viral infections.

Pathophysiology and Etiology

1. Affects younger women predominantly.
2. Acute inflammation results in sudden release of preformed T_3 and T_4, commonly causing symptoms of hyperthyroidism initially.
3. A clinical variant of this disorder, "silent thyroiditis," has been described as similar to subacute thyroiditis; however, the symptoms may be milder and, the thyroid gland is not painful.
4. Subacute thyroiditis has been associated with onset within 6 months of the postpartum period in women.

Clinical Manifestations

1. Pain, swelling, thyroid tenderness lasts several weeks or months and then disappears.
2. Sore throat.
3. Pain referred to the ear, making swallowing difficult and uncomfortable.
4. Fever, malaise, chills, fatigue, anorexia, and/or myalgia.
5. May develop clinical manifestations of hyperthyroidism (irritability, nervousness, insomnia, and weight loss) or hypothyroidism, depending on the point of time in the natural course of the disease when patient presents.

Diagnostic Evaluation

1. TSH level is low.
2. ^{131}I uptake is low.
3. Serum T_3 and T_4 levels are elevated.
4. Erythrocyte sedimentation rate is increased, usually greater than 50 m/hour.
5. C-reactive protein may also be elevated.

Management

1. Analgesics and mild sedatives.
2. The patient may be placed on beta-adrenergic blockers to reduce the symptoms of thyrotoxicosis.
3. Steroids may be administered for inflammation, pain, fever, and malaise.
4. Aspirin or nonsteroidal anti-inflammatory drugs may be used in mild cases to treat the symptoms of inflammation.

DRUG ALERT Aspirin should be avoided if the patient exhibits signs of hyperthyroidism because

it displaces thyroid hormone from its binding site and may increase the amount of free circulating hormone, resulting in exacerbation of the symptoms of hyperthyroidism.

Complications

In about 10% of patients, permanent hypothyroidism occurs and long-term T_4 therapy is needed.

Nursing Assessment

1. Assess for signs and symptoms of hyperthyroidism (see page 710).
2. Assess for level of discomfort.
3. Evaluate patient's coping skills regarding pain.

Nursing Diagnosis

- Pain related to inflammation of the thyroid gland.

Nursing Interventions

Reducing Pain

1. Administer or teach self-administration of pain relief medication, as prescribed.
2. Provide a restful environment and explain all tests and procedures to patient/family.
3. Assess for degree of pain relief.
4. Notify health care provider if pain relief medications are inadequate for acceptable pain control.

Patient Education and Health Maintenance

1. Explain all medications patient is to continue at home.
2. Reassure patient that subacute thyroiditis usually resolves spontaneously during weeks to months.
3. Teach patient signs and symptoms of hypothyroidism (ie, fatigue and lethargy, weight gain, cold intolerance) that may be experienced. These should be reported as inflammation of the gland subsides.
4. Assist patient in identifying sources of information and support available in the community (see Box 24-1, page 709).

Evaluation: Expected Outcomes

- Verbalizes acceptable pain relief.

Hashimoto Thyroiditis (Lymphocytic Thyroiditis)

Hashimoto thyroiditis is a chronic progressive disease of the thyroid gland caused by infiltration of lymphocytes; it results in progressive destruction of the parenchyma and hypothyroidism if untreated.

Pathophysiology and Etiology

1. Cause is unknown; believed to be an autoimmune disease, because of genetic susceptibility and environmental factors and perhaps related to Graves disease.
2. Ninety-five percent of cases occur in women in their 40s or 50s.
3. Possibly the most common cause of adult hypothyroidism.
4. Appears to be increasing in incidence.

Clinical Manifestations

1. Marked by a slowly developing, firm enlargement of the thyroid gland.
2. Usually no gross nodules.
3. Basal metabolic rate is usually low.
4. Periods of hyperthyroidism caused by large amounts of T_3 and T_4 being released into bloodstream.

Diagnostic Evaluation

1. T_3 and T_4 may be normal but usually become subnormal as the disease progresses.
2. TSH level is usually elevated.
3. Antithyroglobulin antibodies and antimicrosomal antibodies are virtually always present.
4. Normal or high concentration of thyroglobulin-binding protein.

Management

1. Thyroid medications to maintain a normal level of circulating thyroid hormone; this is done to suppress production of TSH, to prevent enlargement of the thyroid, and to maintain a euthyroid state.
2. Surgical resection of goiter if tracheal compression, cough, or hoarseness occurs.
3. Careful follow-up to detect and treat hypothyroidism.

Complications

1. Progressive hypothyroidism.
2. Without treatment, Hashimoto thyroiditis may progress from goiter and hypothyroidism to myxedema.

Nursing Assessment

1. Assess for signs and symptoms of hyperthyroidism and hypothyroidism.
2. Assess size of the thyroid gland and symptoms of compression— neck tightness, cough, hoarseness.

Nursing Diagnosis

- Anxiety related to enlargement of the neck/thyroid gland.

Nursing Interventions

Reducing Anxiety

1. Explain physiology of the disorder and the reason for enlarging gland. Show anatomic pictures of the thyroid gland, if possible.
2. Administer or teach self-administration of thyroid hormone to suppress stimulation on gland and possibly reduce size.
3. Reassure regarding slow progression of gland enlargement (during months) and the option of surgical resection, if necessary.
4. Suggest wearing loose-necked clothing, avoiding jewelry or scarves around the neck, and avoiding excessive neck flexion or hyperextension, which may aggravate feeling of compression.

Patient Education and Health Maintenance

1. Teach signs of tracheal compression that should be reported to health care provider as soon as possible—difficulty breathing, cough, hoarseness.
2. Explain outcome of hypothyroidism and necessity of taking thyroid hormones every day for life.
3. Explain the need for regular medical follow-up visits to monitor thyroid hormone and TSH levels.
4. Assist patient in identifying sources of information and support available in the community (see Box 24-1, page 709).

GERONTOLOGIC ALERT Careful and regular follow-up of older patients with Hashimoto thyroiditis is especially important because the progression to hypothyroidism is usually subtle in older people and is unlikely to be recognized promptly.

Evaluation: Expected Outcomes

- Verbalizes reduced anxiety, appears more relaxed, sleeps better.

Cancer of the Thyroid

Cancer of the thyroid is a malignant neoplasm of the gland.

Pathophysiology and Etiology

1. Incidence is more common with women. Usually diagnosed 30 to 50 years of age but also increasing with girls ages 15 to 19 years of age.
2. Exposure to radiation increases risk of thyroid carcinoma significantly. Exposure to Agent Orange also has been associated with higher risk.
3. Papillary and well-differentiated adenocarcinoma (most common, approximately 80%).
    a. Growth is slow, and spread is confined to lymph nodes that surround thyroid area.
    b. Cure rate is excellent after removal of involved areas.
4. Follicular (rapidly growing, widely metastasizing type, approximately 10%).
    a. Occurs predominantly in middle-aged and older persons.
    b. Brief encouraging response may occur with irradiation.
    c. Progression of disease is rapid; high mortality.
5. Parafollicular–medullary thyroid carcinoma.
    a. Rare, inheritable type of thyroid malignancy, which can be detected early by a radioimmunoassay for calcitonin.
6. Undifferentiated anaplastic carcinoma (approximately less than 3%).
    a. The most aggressive and lethal solid tumor found in humans.
    b. Least common of all thyroid cancers.
    c. Usually fatal within months of diagnosis.

Clinical Manifestations

1. On palpation of the thyroid, there may be a firm, irregular, fixed, painless mass or nodule.
2. The occurrence of signs and symptoms of hyperthyroidism is rare.

Diagnostic Evaluation

1. A thyroid uptake and scintigraphy using ^{99m}Tc will detect a “cold” nodule indicating a nonfunctional thyroid area.
2. Ultrasound-guided FNA biopsy for diagnostics.
3. Surgical exploration.

Management

1. Surgical removal is extensive, as required.
    a. Postoperative radiation therapy is commonly done to reduce chances of recurrence.
    b. Follow-up includes periodic ^{131}I uptake scan to detect evidence of recurrence along with following

other laboratory tests.

2. Thyroid replacement.
   a. Thyroid hormone is administered to suppress secretion of TSH.
   b. Such treatment is continued indefinitely and requires annual checkups.
3. For unresectable cancer, patient is referred for treatment with ^{131}I, chemotherapy, or radiation therapy.

Complications

1. Untreated thyroid carcinoma can be fatal.
2. Removal of the thyroid can disrupt the parathyroid function; calcium levels need to be monitored.

Nursing Assessment

1. Explore risk factors such as exposure to radiation and family history.
2. Explore patient's feelings and concerns regarding the diagnosis, treatment, and prognosis.

Nursing Diagnosis

- Anxiety related to concern about cancer, upcoming surgery.

Nursing Interventions

Also see "Care of the Patient Undergoing Thyroidectomy," page 705.

Allaying Anxiety

1. Provide all explanations in a simple, concise manner and repeat important information, as necessary, because anxiety may interfere with patient's processing of information.
2. Stress the positive aspects of treatment and high cure rate, as outlined by health care provider.
3. Encourage support by significant other, clergy, social worker, nursing staff, as available.

Patient Education and Health Maintenance

1. Instruct the patient on thyroid hormone replacement and follow-up blood tests.
2. Stress the need for periodic evaluation for recurrence of malignancy.
3. Supply additional information or suggest community resources dealing with cancer prevention and treatment.
4. Assist patient in identifying sources of information and support available in the community (see Box 24-1, page 709).

Evaluation: Expected Outcomes

- Discusses concerns with family, hospital, clergy.

DISORDERS OF THE PARATHYROID GLANDS

The *parathyroid glands* are small, pea-size glands embedded in the posterior section of the thyroid gland. Functions include the production, storage, and release of PTH in response to the serum level of ionized calcium. PTH increases serum calcium by decreasing elimination of calcium ions in the urine by the kidney, increasing absorption of calcium ions from the gut, and increasing bone contribution of calcium ions to the plasma.

Hyperparathyroidism

Hyperparathyroidism is hypersecretion of PTH.

Pathophysiology and Etiology

1. Disorder is most common among post-menopausal women older than age 50.
2. Primary hyperparathyroidism.
    a. Single parathyroid adenoma is the most common cause (approximately 85% of cases).
    b. Parathyroid hyperplasia accounts for approximately 14% of cases.
    c. Parathyroid carcinoma accounts for less than 1% of cases.
    d. May present asymptomatic, but can affect central nervous, cardiac, renal and gastrointestinal systems.
3. Secondary hyperparathyroidism.
    a. Primarily the result of chronic kidney disease and renal failure.
4. Excess secretion of PTH results in increased serum calcium levels (see Figure 24-3).

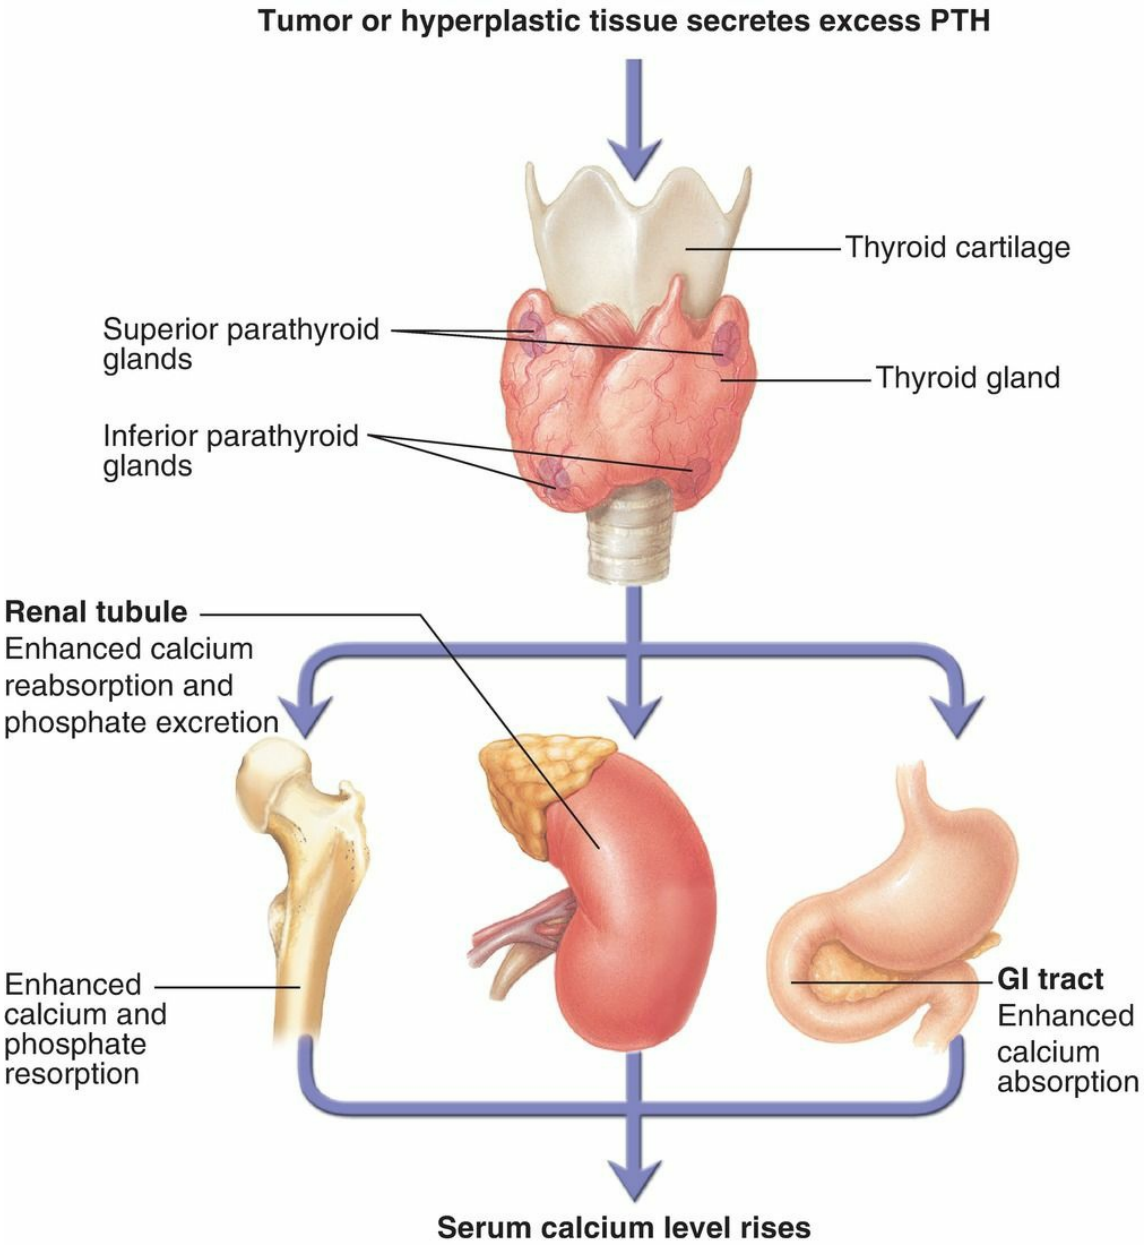

Figure 24-3. Pathogenesis of hyperparathyroidism. (Stewart, J.G. [2017]. *Anatomical Chart Company atlas of pathophysiology* [4th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Clinical Manifestations

1. May be asymptomatic with incidental elevated calcium and PTH.
2. Decalcification of bones.
    a. Skeletal pain, backache, pain on weight bearing, pathologic fractures, deformities, formation of bony cysts.
    b. Formation of bone tumors—overgrowth of osteoclasts.
    c. Formation of calcium-containing renal calculi.
3. Depression of neuromuscular function.

The patient may trip, drop objects, show general fatigue, lose memory for recent events, experience

a. emotional instability, have changes in level of consciousness, with stupor and coma.
b. Cardiac arrhythmias, hypertension, cardiac standstill, palpations, bradycarida, changes in PR and QT intervals on ECG, fatigue, irritability.

4. Other signs and symptoms
   a. Anorexia, nausea, constipation, polydipsia, polyuria, depression, acute pancreatitis, and proximal myopathy weakness.

Diagnostic Evaluation

1. Persistently elevated serum calcium (11 mg/100 mL); test is performed on at least two occasions to determine consistency of results and albumin level also obtained. If change in serum albumin or pH, ionized calcium is more accurate.
2. Exclusion of other causes of hypercalcemia—malignancy (usually bone or breast), vitamin D excess, multiple myeloma, sarcoidosis, milk-alkali syndrome, such drugs as thiazides, Cushing disease, hyperthyroidism.
3. PTH increased and alkaline phosphatase increased; phosphorus decreased.
4. 24-hour urine collection to evaluate kidney function
5. Skeletal changes are revealed by x-ray or dual-energy x-ray absorptiometry (DEXA) test.
6. Cine computed tomography (CT) will disclose parathyroid tumors more readily than x-ray.
7. Sestamibi scan is used to evaluate location of the tumor prior to surgery.

Management

Treatment of Hypercalcemia

1. Hydration with IV saline, loop diuretics such as furosemide and ethacrynic acid—to increase urinary excretion of calcium in patients not in renal failure.
2. Oral phosphate may be used as an antihypercalcemic agent.
3. In patients developing osteoporosis, pamidronate, calcitonin, or etidronate disodium are effective in treating hypercalcemia by inhibiting bone resorption.
4. Dietary calcium is restricted, and all drugs that might cause hypercalcemia (thiazides, lithium, vitamin A&D, canaglflozin, hormone therapy, antacids) may be discontinued.
5. Dialysis may be necessary in patients with resistant hypercalcemia or those with renal failure.
6. Digoxin is reduced because the patient with hypercalcemia is more sensitive to toxic effects of this drug.
7. Monitoring of daily serum calcium, blood urea nitrogen (BUN), potassium, and magnesium levels.
8. Removal of underlying cause.
9. Calcimimetics are a new class of medications that can decrease PTH secretion.

Treatment of Primary Hyperparathyroidism

Surgery for removal of abnormal parathyroid tissue.

Complications

1. Formation of renal calculi, calcification of kidney parenchyma, renal shutdown.
2. Ulceration of upper GI tract leading to hemorrhage and perforation.
3. Demineralization of bones, cysts, and fibrosis of marrow leads to fractures, especially of vertebral bodies and ribs.
4. Hypoparathyroidism after surgery.

Nursing Assessment

1. Obtain review of systems and perform multisystem examination to detect signs and symptoms of hyperparathyroidism.
2. Closely monitor patient's input and output and serum electrolytes, especially calcium level.
3. Monitor ECG to detect changes secondary to hypercalcemia. (During moderate elevations of serum calcium, QT interval is shortened; with extreme hypercalcemia, widening of the T wave is seen.)

Nursing Diagnoses

- Deficient Fluid Volume related to effects of elevated serum calcium levels.
- Impaired Urinary Elimination related to renal calculi and calcium deposits in the kidneys.
- Impaired Physical Mobility related to weakness, bone pain, and pathologic fractures.
- Anxiety related to surgery.

Nursing Interventions

Achieving Fluid and Electrolyte Balance

1. Monitor fluid intake and output.
2. Provide adequate hydration—administer water, glucose, and electrolytes orally or via IV line, as prescribed.
3. Prevent or promptly treat dehydration by reporting vomiting or other sources of fluid loss.
4. Help patient understand why and how to avoid dietary sources of calcium—dairy products, broccoli, calcium-containing antacids.

Promoting Urinary Elimination

1. Strain all urine to observe for calculi.
2. Increase fluid intake to 3,000 mL/day to maintain hydration and prevent precipitation of calcium and formation of calculi.
3. Instruct patient about dietary recommendations for restriction of calcium.
4. Observe for signs of urinary tract infection (UTI), hematuria, and renal colic.
5. Assess renal function through serum creatinine and BUN levels.

Increasing Physical Mobility

1. Assist patient in hygiene and activities if bone pain is severe or if patient experiences musculoskeletal weakness.
2. Protect patient from falls or injury.
3. Turn patient cautiously and handle extremities gently to avoid fractures.
4. Administer analgesia, as prescribed.
5. Assess level of pain and patient's response to analgesia.
6. Encourage patient to participate in mild exercise gradually as symptoms subside.
7. Instruct and demonstrate correct body mechanics to reduce strain, backache, and injury.

Relieving Anxiety

1. Encourage patient to verbalize fears and feelings about upcoming surgery.
2. Explain tests and procedures to patient.
3. Reassure patient about skeletal recovery.
   a. Bone pain diminishes fairly quickly.
   b. Fractures are treated by orthopedic procedures.
4. Prepare patient for surgery as for thyroidectomy (see page 705).

Patient Education and Health Maintenance

1. Instruct patient about calcium-reducing medications.
   a. Calcitonin is given subcutaneously—teach proper technique.
   b. Etidronate disodium—calcium-rich foods should be avoided within 2 hours of dose; therapeutic response may take 1 to 3 months.
   c. Pamidronate—monitor hypercalcemia-related parameters when treatment begins. Adequate intake of calcium and vitamin D is necessary to prevent hypocalcemia. Bisphosphonates should be used with caution in patients with active upper GI problems.
2. Teach signs and symptoms of tetany that patient may experience postoperatively and should report to health care provider (numbness and tingling in extremities or around mouth).
3. Assist patient in identifying sources of information and support available in the community (see Box 24-1, page 709).

Evaluation: Expected Outcomes

- Output equals intake, normal skin turgor, moist mucous membranes.
- No signs and symptoms of renal calculi or UTI; serum creatinine and BUN levels normal.
- Reports less bone and joint pain; uses correct body mechanics, avoid immobilization.
- Verbalizes concerns and fears about surgery; appears less anxious.

Hypoparathyroidism

Hypoparathyroidism results from a deficiency of PTH and is characterized by hypocalcemia and neuromuscular hyperexcitability.

Pathophysiology and Etiology

1. The most common cause is accidental removal or destruction of parathyroid tissue or its blood supply during thyroidectomy or radical neck dissection for malignancy.
2. Decrease in gland function (idiopathic hypoparathyroidism); may be autoimmune or familial in origin.
3. Malignancy or metastasis from a cancer to the parathyroid glands.
4. Resistance to PTH action.
5. With inadequate PTH secretion, there is decreased resorption of calcium from the renal tubules, decreased absorption of calcium in the GI tract, and decreased resorption of calcium from bone.
6. Blood calcium falls to a low level, causing symptoms of muscular hyperirritability, uncontrolled spasms, and hypocalcemic tetany.
7. In response to decreased serum calcium levels and lack of PTH, the serum phosphate level rises and phosphate excretion by the kidneys decreases.

Clinical Manifestations

1. Neuromuscular irritability: laryngeal spasm, bronchospasm, muscle cramps, paresthesias, seizures.
2. Tetany—general muscular hypertonia; attempts at voluntary movement result in tremors and spasmodic or uncoordinated movements; fingers assume classic tetanic position; Chvostek and Trousseau signs (see page 706).
3. Neurological signs and symptoms such as extrapyramidal signs, personality disturbances, irritability, parkinsonism, dystonic spasms.
4. Mental status changes: confusion, psychosis, fatigue, anxiety, poor memory.
5. Ectodermal changes: dry skin, brittle nails, course hair, atopic eczema, psoriasis.
6. Cardiac changes: ECG with prolong QT interval, congestive heart failure, cardiomyopathy.
7. Ophthalmologic changes: subcapsular cataracts, papilledema.

Diagnostic Evaluation

1. Decrease in serum calcium level to a low level (7.5 mg/100 mL or less).
2. Phosphorus level in blood is elevated.
3. May have concurrent hypomagnesemia and/or vitamin D deficiency.
4. Pseudohypocalcemia—total serum calcium level is low, but serum ionized calcium is normal. This is due to calcium binding to protein.
5. PTH levels are low in most cases; may be normal or elevated in pseudohypoparathyroidism.
6. In chronic hypoparathyroidism, bone density may be increased as seen on radiography.

Management

IV Calcium Administration

1. A syringe and an ampule of a calcium solution (calcium chloride, calcium gluceptate, calcium gluconate) are to be kept at the bedside at all times.
2. Most rapidly effective calcium solution is ionized calcium chloride (10%).
3. For rapid use to relieve severe tetany, infusion carried out every 10 minutes.
    a. All IV calcium preparations are administered slowly. It is highly irritating, stings, and causes thrombosis; patient experiences unpleasant burning flush of skin and tongue.
    b. Typical doses are as follows:
        i. Calcium chloride—500 mg to 1 g (5 to 10 mL) as indicated by serum calcium; administer at rate of less than 1 mL/minute of 10% solution.
        ii. Calcium gluconate—500 mg to 2 g (10 to 20 mL) at a rate of less than 0.5 mL/minute of a 10% solution.
        iii. Calcium gluceptate—1 to 2 g (5 to 10 mL) at a rate of less than 1 mL/minute.
4. A slow drip of IV saline containing calcium gluconate is given until control of tetany is ensured; then, IM or oral administration of calcium is prescribed.
5. Later, vitamin D is added to calcium intake—increases absorption of calcium and also induces a high level of calcium in the bloodstream. Thiazide diuretics may also be added because of their calcium-retaining effect on the kidney; doses of calcium and vitamin D may be lowered.
6. Administration of IV calcium seems to cause rapid relief of anxiety.

DRUG ALERT Too-rapid calcium administration may cause cardiac arrest.

Other Measures

1. Treat renal calculi.
2. Monitor patient for hypercalciuria.
3. Monitor blood calcium level periodically; variations in vitamin D may affect calcium levels.

Complications

1. Acute complications related to hypocalcemia include seizures, tetany, and mental disorders, all of which can be reversed with calcium therapy.
2. If onset of hypocalcemia is acute, the major concerns are laryngeal spasm, acute airway obstruction, and cardiovascular failure.
3. Long-term complications include subcapsular cataracts, calcification of the basal ganglia, and papilledema (caused by precipitation of calcium out of serum and deposition in tissue); shortening of the

fingers and toes; and bowing of the long bones (caused by inadequate PTH and additional genetic abnormalities). Of these complications, only papilledema is reversible.

Nursing Assessment

1. Perform multisystem assessment, focusing on neuromuscular system.
2. Closely monitor patient's input and output and serum electrolytes, especially calcium level.
3. Assess anxiety.

Nursing Diagnosis

- Risk for electrolyte imbalance related to impaired calcium regulation.

Nursing Interventions

Maintaining Normal Serum Calcium Levels

1. Assess neuromuscular status frequently in patients with hypoparathyroidism and in those at risk for hypocalcemia (patients in the immediate postoperative period after thyroidectomy, parathyroidectomy, radical neck dissection).
2. Check for Trousseau and Chvostek signs, and notify health care provider if test results are positive.
3. Assess respiratory status frequently in acute hypocalcemia and postoperatively.
4. Monitor serum calcium and phosphorus levels.
5. Promote high-calcium diet, if prescribed—dairy products; green, leafy vegetables.
6. Instruct the patient about signs and symptoms of hypo- and hypercalcemia that should be reported.
7. Use caution in administering other drugs to the patient with hypocalcemia.
    a. The hypocalcemic patient is sensitive to digoxin; as hypocalcemia is reversed, the patient may rapidly develop digoxin toxicity.
    b. Cimetidine interferes with normal parathyroid function, especially with renal failure, which increases the risk of hypocalcemia.

Patient Education and Health Maintenance

1. Explain to patient and family the function of PTH and the roles of vitamin D and calcium in maintaining good health.
2. Discuss the importance of each medication prescribed for the control of hypocalcemia including vitamin D, calcium, and thiazide diuretic.
    a. Take medications, as prescribed.
    b. Do not substitute with over-the-counter preparations without the advice and supervision of the health care provider.
3. Provide patient with a written list about hypercalcemia and hypocalcemia, and advise the patient to contact the health care provider immediately should signs of either condition develop.

4. Advise patient to wear a medical alert tag.
5. Explain the need for periodic medical follow-up for life.

Evaluation: Expected Outcome

- Verbalizes understanding of diet and medications; calcium level within normal limits.

DISORDERS OF THE ADRENAL GLANDS

The *adrenal medulla*, or inner portion of the gland, is not necessary to maintain life but enables a person to cope with stress. It secretes two hormones:

- *Epinephrine* (adrenalin) acts on alpha and beta receptors to increase contractility and excitability of heart muscle, leading to increased cardiac output; facilitates blood flow to muscles, brain, and viscera; enhances blood sugar by stimulating conversion of glycogen to glucose in the liver; and inhibits smooth muscle contraction.
- *Norepinephrine* (noradrenaline) acts primarily on alpha receptors to increase peripheral vascular resistance, leading to increases in diastolic and systolic BP.
    - The adrenal cortex, or outer portion of the gland, is essential to life. It secretes adrenocortical hormones—synthesized from cholesterol.

- *Glucocorticoids* (cortisone and hydrocortisone) enhance protein catabolism and inhibit protein synthesis; antagonize action of insulin and increase blood sugar; increase synthesis of glucose by the liver; influence defense mechanism of the body and its reaction to stress; and influence emotional reaction.
- *Mineralocorticoids* (aldosterone and desoxycorticosterone) regulate reabsorption of sodium; regulate excretion of potassium by renal tubules.
- *Adrenosterones* (adrenal androgens) exert minimal effect on sex characteristics and function.

Primary Aldosteronism

Primary aldosteronism refers to excessive secretion of aldosterone by the adrenal cortex.

Pathophysiology and Etiology

1. Excessive secretion of aldosterone results in the conservation of sodium and excretion of potassium primarily not only in the renal tubules but also in the sweat glands, salivary glands, and GI tract.
2. Caused primarily by a cortical adenoma, bilateral adrenal hyperplasia, or genetic–familial primary aldosteronism.
3. Secondary aldosteronism occurs in conjunction with heart failure, renal dysfunction, or cirrhosis of the liver.
4. Women constitute 70% of patients with aldosterone-secreting adenomas, and the incidence of primary aldosteronism is four times higher among African Americans than among the general population.

Clinical Manifestations

1. Hypertension (5% to 15% of cases of hypertension are a result of primary aldosteronism, which usually can be treated successfully by surgical removal of the adenoma).
2. A profound decline in blood levels of potassium (hypokalemia) and hydrogen ions (alkalosis) results in muscle weakness and inability of kidneys to acidify or concentrate urine, leading to excess volume of urine (polyuria).
3. A decline in hydrogen ions (alkalosis) results in tetany, paresthesia.
4. An elevation in blood sodium (hypernatremia) results in excessive thirst (polydipsia) and arterial hypertension.

Diagnostic Evaluation

1. Suspected in all hypertensive patients with spontaneous hypokalemia; also if hypokalemia develops concurrently with start of diuretics and remains after diuretics are discontinued.
2. The screening test of choice is the aldosterone/renin ratio, which is suggestive of primary aldosteronism if the ratio is greater than 20:1.
3. Salt loading may be used as a confirmatory test—ingestion of at least 200 mEq/day (approximately 12 g salt) for 4 days does not influence the serum potassium level without aldosteronism but will cause a decrease of serum potassium to less than 3.5 mEq/L in a patient with aldosteronism.
4. CT scanning to determine and localize cortical adenoma.

Management

1. Removal of adrenal tumor if the tumor is localized to one side—unilateral adrenalectomy.
2. If the cause is bilateral adrenal hyperplasia—spironolactone is used to treat both hypertension and potassium-depleted stages; therapy is needed 4 to 6 weeks before the full effect on BP is seen.
    a. Adverse effects include reduced testosterone in men (decreased libido, impotence, gynecomastia) and

GI discomfort.

   b. Amiloride may be used instead in sexually active men or in cases of GI intolerance.
   c. Sodium restriction is necessary—no saline infusions, low-sodium diet.
   d. Potassium supplementation is usually necessary, based on severity of deficit.
3. Addition of antihypertensive agent—thiazide diuretic such as triamterene.
4. Management of underlying causes of secondary aldosteronism.

Complications

Long-term effects of untreated hypertension—stroke, renal failure, heart failure.

Nursing Assessment

1. Obtain history of symptoms, such as muscle weakness, paresthesia, thirst, and polyuria.
2. Perform multisystem physical examination.
3. Evaluate BP.

Nursing Diagnosis

- Excess Fluid Volume related to sodium retention.

Nursing Interventions

Also see "Care of the Patient Undergoing Adrenalectomy," page 706.

Maintaining Normal Fluid and Sodium Balance

1. Monitor fluid intake and output, daily weight, ECG changes for hypokalemia.
2. Teach low-sodium diet, administration of potassium supplements, as ordered; evaluate serum sodium and potassium results.
3. Monitor BP; administer or teach self-administration of antihypertensives, as ordered.
4. Assess for dependent edema; encourage activity, frequent repositioning, and elevation of feet periodically.

Patient Education and Health Maintenance

1. Instruct patient about the nature of illness, the necessary treatment, and the need for continued medical care after discharge.
2. Instruct patient on the importance of following prescribed medical treatments.
   a. For medical management, patient must remain on spironolactone for life.
   b. Patient should report significant adverse effects that interfere with sexual performance and quality of life.
   c. Glucocorticoid administration may be temporary after subtotal or unilateral adrenalectomy, chronic for bilateral adrenalectomy; dose may need to be increased during times of illness or stress.
3. Teach patient and family members how to take BP readings, if indicated.

Evaluation: Expected Outcomes

- Intake equals urine output, daily weight stable.

Cushing Syndrome

Cushing syndrome is a condition in which the plasma cortisol levels are elevated, causing signs and symptoms of hypercortisolism.

Pathophysiology and Etiology

1. Is more common in women than in men.
2. The normal feedback mechanisms that control adrenocortical function are ineffective, resulting in secretion of adrenal cortical hormones despite adequate amounts of these hormones in the circulation.
3. The manifestations of Cushing syndrome are the result of excess hormones (glucocorticoids).
4. Excess of one hormone or all the hormones can occur; the predominant hormone secreted in excess (usually glucocorticoids) determines the predominant symptoms.
5. Pituitary Cushing syndrome (Cushing disease)—hyperplasia of both adrenal glands caused by overstimulation of the adrenal cortex by ACTH, usually from a pituitary adenoma or hyperplasia.
    a. Most common cause of Cushing syndrome.
    b. Affects mostly women between ages 20 and 40.
6. Adrenal Cushing syndrome.
        i. Associated with tumors of the adrenal cortex—adenoma or carcinoma.
7. Ectopic—results from autonomous ACTH secretion by extrapituitary neoplasms (such as lung).
8. Iatrogenic Cushing syndrome caused by exogenous glucocorticoid administration.

Clinical Manifestations

Manifestations Caused by Excess Glucocorticoids

1. Weight gain or obesity (see Figure 24-4).
2. Heavy trunk; thin extremities.
3. “Buffalo hump” (fat pad) in neck and supraclavicular area.
4. Rounded face (moon face); plethoric, oily.
5. Fragile and thin skin, striae and ecchymosis, acne.
6. Muscles wasted because of excessive catabolism.
7. Osteoporosis—characteristic kyphosis, backache.
8. Mental disturbances—mood changes, psychosis.
9. Increased susceptibility to infections.

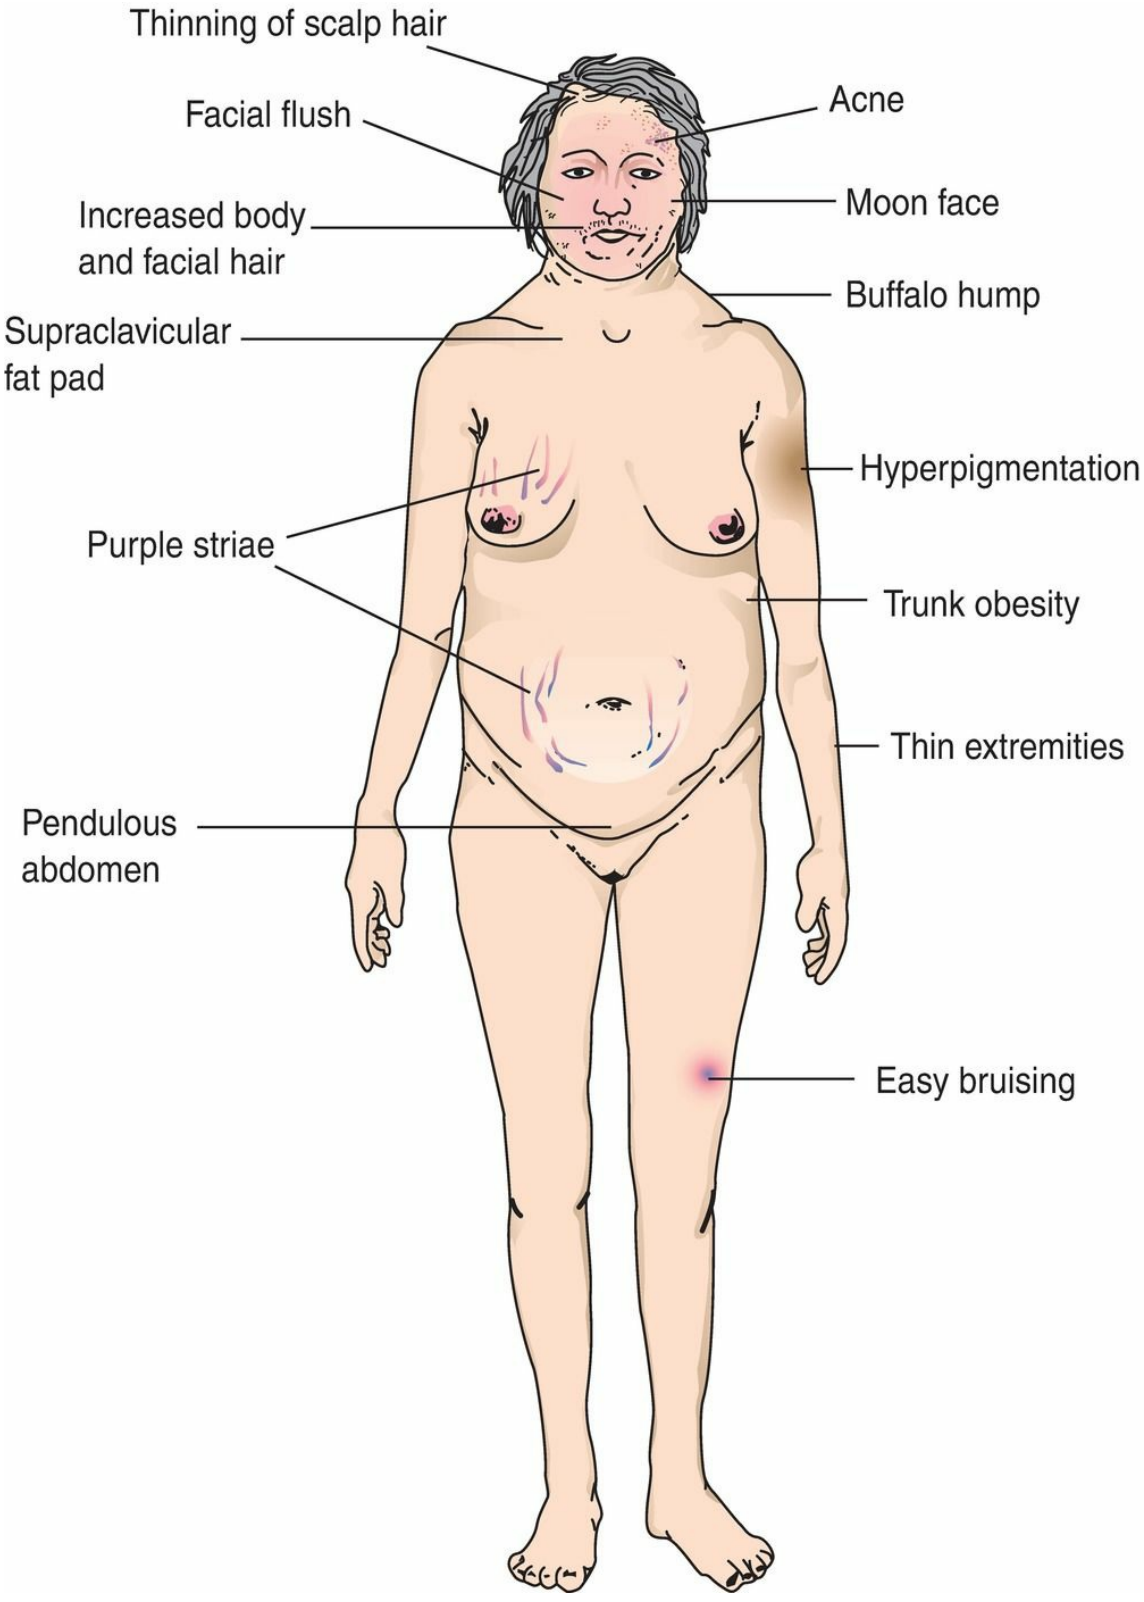

Figure 24-4. Clinical manifestations of Cushing syndrome. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical–surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Manifestations Caused by Excess Mineralocorticoids

1. Hypertension.
2. Hypernatremia, hypokalemia.
3. Weight gain.
4. Expanded blood volume.
5. Edema.

Manifestations Caused by Excess Androgens

1. Women experience virilism (masculinization).
    a. Hirsutism—excessive growth of hair on the face and midline of the trunk.
    b. Breasts—atrophy.
    c. Clitoris—enlargement.
    d. Voice—masculine.
    e. Loss of libido.
2. If exposed *in utero*—possible hermaphrodite.
3. Males—loss of libido.

Diagnostic Evaluation

1. Excessive plasma cortisol levels.
2. An increase in blood glucose levels and glucose intolerance.
3. Decreased serum potassium level.
4. Reduced eosinophils.
5. Elevated urinary 17-hydroxycorticoid and 17-ketogenic steroid levels.
6. Elevation of plasma ACTH in patients with pituitary tumors.
7. Low plasma ACTH levels with adrenal tumor.
8. Loss of diurnal variation of cortisol secretion.
9. X-rays of the skull may detect erosion of the sella turcica by a pituitary tumor.
10. Overnight DST or 48-hour low-dose DST, possibly with cortisol urinary excretion measurement.
11. Elevated levels of cortisol measured in saliva are significant.
12. CT scan, MRI, and ultrasonography detect location of tumor.

Management

Surgery and Radiation

Tumor (adrenal or pituitary) is removed or treated with irradiation.

1. An important development in the management of pituitary Cushing syndrome in adults is transsphenoidal adenomectomy or hypophysectomy (pituitary removal) (see page 707).
2. Transfrontal craniotomy may be necessary when pituitary tumor has enlarged beyond sella turcica (see page 361).

3. Hyperplasia of adrenals—bilateral adrenalectomy.

Replacement Therapy Postoperatively

1. Adrenalectomy patients require lifelong replacement therapy with the following:
   a. A glucocorticoid—cortisone.
   b. A mineralocorticoid—fludrocortisone.
2. After pituitary irradiation or hypophysectomy, patient may require adrenal replacement, plus thyroid, posterior pituitary, and gonadal replacement therapy.
3. After transsphenoidal adenomectomy, patient requires hydrocortisone replacement therapy for periods of 12 to 18 months and additional hormones if excessive loss of pituitary function has occurred.
4. Protein anabolic steroids may be given to facilitate protein replacement; potassium replacement is usually required.

Medical Treatment

1. If patients cannot undergo surgery, cortisol synthesis–inhibiting medications may be used.
   a. Mitotane, an agent toxic to the adrenal cortex (dichlorodiphenyltrichloroethane derivative)—known as medical adrenalectomy. Nausea, vomiting, diarrhea, somnolence, and depression may occur with use of this drug.
   b. Metyrapone to control steroid hypersecretion in patients who do not respond to mitotane therapy.
   c. Aminoglutethimide blocks cholesterol conversion to pregnenolone, effectively blocking cortisol production. Adverse effects include GI disturbances, somnolence, and skin rashes.

Complications

Possibility of recurrence in patients with adrenal carcinoma.

Nursing Assessment

1. Observe patient for signs and symptoms of Cushing disease.
2. Perform multisystem physical examination.
3. Monitor intake and output, daily weights, and serum electrolytes.

Nursing Diagnoses

- Impaired Skin Integrity related to altered healing, thin and fragile skin, and edema.
- Dressing, Grooming, Toileting Self-Care Deficit related to muscle wasting, osteoporosis, weakness, and fatigue.
- Disturbed Body Image related to altered physical appearance and emotional instability.
- Anxiety related to surgery.
- Delayed Surgical Recovery related to potential complications.

Nursing Interventions

Maintaining Skin Integrity

1. Assess skin frequently to detect reddened areas, breakdown or tearing of skin, excoriation, infection, or edema.
2. Handle skin and extremities gently to prevent trauma; protect from falls by use of side rails.
3. Avoid use of adhesive tape to reduce risk of trauma to skin on its removal.
4. Encourage patient to turn in bed frequently or to ambulate to reduce pressure on bony prominences and areas of edema.
5. Use meticulous skin care to reduce injury and breakdown.
6. Provide foods low in sodium to minimize edema formation.
7. Assess intake and output and daily weight to evaluate fluid retention.

Encouraging Active Participation in Self-Care

1. Assist patient with ambulation and hygiene when weak and fatigued.
2. Assist patient in planning schedule to permit exercise and rest.
3. Encourage patient to rest when fatigued.
4. Encourage gradual resumption of activities as patient gains strength.
5. Identify for patient the signs and symptoms indicating excessive exertion.
6. Instruct patient in correct body mechanics to avoid pain or injury during activities.
7. Use assistive devices during ambulation to prevent falls and fractures.
8. Encourage foods high in potassium (bananas, orange juice, tomatoes), and administer potassium supplement, as prescribed, to counteract weakness related to hypokalemia.

Strengthening Body Image

1. Encourage patient to verbalize concerns about illness, changes in appearance, and altered role functions.
2. Identify situations that are disturbing to patient, and explore with patient ways to avoid or modify those situations.
3. Be alert for evidence of depression; in some instances, this has progressed to suicide; alert health care provider of mood changes, sleep disturbance, change in activity level, change in appetite, or loss of interest in visitors or other experiences.
4. Refer for counseling, if indicated.
5. Explain to patient who has benign adenoma or hyperplasia that, with proper treatment, evidence of masculinization can be reversed.

Reducing Anxiety

1. Answer questions about surgery and encourage thorough discussion with health care provider if patient is not well informed.
2. Describe nursing care to expect in postoperative period.
3. Prepare the patient for abdominal surgery (see page 495) or hypophysectomy (see page 707) as indicated.

Providing Postoperative Care

1. Provide routine postoperative care for patient with abdominal surgery (see page 495) or hypophysectomy (see page 707).
2. Monitor closely for infection because glucocorticoid administration interferes with immune function; maintain sterile technique, clean environment, and good handwashing.
3. Monitor thyroid function tests and provide HRT, as ordered, after hypophysectomy.
4. Monitor fluid intake and output and urine specific gravity to detect DI caused by ADH deficiency after hypophysectomy.

Patient Education and Health Maintenance

1. Instruct patient on lifetime HRT and the need to follow up at regular intervals to determine if dosage is appropriate or to detect adverse effects.
2. Instruct patient in proper skin care and in the prompt reporting of trauma or infection for medical treatment.
3. Teach patient to monitor urine or blood glucose or to report for blood glucose tests, as directed, to detect hyperglycemia.
4. Help patient prevent hyperglycemia and obesity by teaching about a low-calorie, low-concentrated carbohydrate, and low-fat diet and to increase activity, as tolerated.
5. Encourage diet high in calcium (dairy products, broccoli) and weight-bearing activity to prevent osteoporosis caused by glucocorticoid replacement.
6. Assist patient in identifying sources of information and support available in the community (see Box 24-1, page 709).

Evaluation: Expected Outcomes

- Skin intact without evidence of breakdown, excoriation, infection, or trauma.
- Participates safely in ADLs.
- Verbalizes concerns about appearance, interacts well with visitors.
- Verbalizes understanding of surgery.
- Vital signs stable, pain controlled, no signs of infection.

Adrenocortical Insufficiency

Adrenocortical insufficiency occurs with inadequate secretion of the hormones of the adrenal cortex, primarily the glucocorticoids and mineralocorticoids.

Pathophysiology and Etiology

1. Primary adrenocortical insufficiency (Addison disease)—destruction and subsequent hypofunction of the adrenal cortex, usually caused by autoimmune process.
2. Secondary adrenocortical insufficiency—ACTH deficiency from pituitary disease or suppression of hypothalamic–pituitary axis by corticosteroid treatment for nonendocrine disorders causes atrophy of the adrenal cortex.
3. Inadequate aldosterone produces disturbances of sodium, potassium, and water metabolism.
4. Cortisol deficiency produces abnormal fat, protein, and carbohydrate metabolism; no cortisol during a period of stress can precipitate addisonian crisis, an exaggerated state of adrenal cortical insufficiency, and can lead to death.

Clinical Manifestations

1. Hyponatremia, hyperkalemia, and some have anemia.
2. Water loss, dehydration, and hypovolemia.
3. Muscular weakness, fatigue, weight loss.
4. GI problems—anorexia, nausea, vomiting, diarrhea, constipation, abdominal pain.
5. Hypotension, hypoglycemia, low basal metabolic rate, increased insulin sensitivity.
6. Mental changes—depression, irritability, anxiety, apprehension caused by hypoglycemia and hypovolemia.
7. Normal responses to stress lacking.
8. Hyperpigmentation.

Diagnostic Evaluation

1. Blood chemistry—decreased glucose and sodium; increased potassium, calcium, and BUN levels.
2. Increased lymphocytes on complete blood count.
3. Low fasting plasma cortisol levels; low aldosterone levels.
4. Twenty-four–hour urine studies—decreased 17-ketosteroid, 17-hydroxycorticoid, and 17-ketogenic steroid levels.
5. ACTH stimulation test—no rise or minimal rise in plasma cortisol and urinary 17-ketosteroid levels.

Management

1. Restoration of normal fluid and electrolyte balance: high-sodium, low-potassium diet and fluids.
2. Treatment of glucocorticoid deficiency with such agents as hydrocortisone or prednisone. Patients with

chronic obstructive pulmonary disease and heart failure may require preparations with low mineralocorticoid activity, such as methylprednisolone, to prevent fluid retention.

3. Mineralocorticoid deficiency is treated with fludrocortisone.
4. Cardiovascular support, if indicated.
5. Immediate treatment if addisonian (adrenal) crisis or circulatory collapse is imminent:
   a. IV sodium chloride solution to replace sodium ions.
   b. Hydrocortisone.
   c. Injection of circulatory stimulants, such as atropine sulfate, calcium chloride, epinephrine.
6. Diagnosis and treatment of underlying cause of adrenocortical insufficiency or addisonian crisis (eg, antibiotic therapy to treat infection if this is a factor in crisis).

NURSING ALERT Overtreatment may be manifested by hypertension, edema from sodium and water retention, and weakness caused by potassium loss.

Complications

1. Adrenal crisis—hypotension, nausea, vomiting, weakness, lethargy, fever, confusion, acute abdomen, and possibly coma.
2. May be precipitated by physiologic stress, such as surgery, infection, trauma, dehydration.

Nursing Assessment

1. Obtain recent or past history of corticosteroid therapy, including length of treatment, dosage, and compliance.
2. Review history for sources of stress, such as surgical procedures, infection, or development of other illness.
3. Perform thorough physical examination for manifestations of adrenocortical insufficiency or contributing factors.

Nursing Diagnoses

- Deficient Fluid Volume related to renal losses of sodium and water.
- Risk for Infection related to ineffective stress response.
- Activity Intolerance related to decreased cortisol production and fatigue.

Nursing Interventions

Achieving Normal Fluid and Electrolyte Balance

1. Assess fluid intake and output and serial daily weights.
2. Monitor vital signs frequently; a drop in BP may suggest an impending crisis.

3. Monitor results of serum sodium and potassium.
4. Assess skin turgor and mucous membranes for dehydration.
5. Encourage diet high in sodium and fluid content; administer or teach self-administration of potassium supplements, if prescribed.
6. Administer or teach self-administration of prescribed glucocorticoids and mineralocorticoids; document response.
7. Administer IV infusions of sodium, water, and glucose, as indicated.

Protecting Well-Being

1. Minimize stressful situations.
2. Protect patient from infection.
   a. Control patient's contacts so that infectious organisms are not transmitted.
   b. Protect patient from drafts, dampness, exposure to cold.
   c. Prevent overexertion.
   d. Use meticulous handwashing and sterile techniques.
3. Assess comfort and emotional status of patient.
   a. Control the temperature of the room to avoid sharp deviations in patient's temperature.
   b. Maintain a quiet, peaceful environment; avoid loud talking and noisy radios.
4. Observe and report early signs of addisonian crisis (sudden drop in BP, nausea and vomiting, fever).

Increasing Activity Tolerance

1. Assist the patient with ADLs.
2. Provide for periods of rest and activity to avoid overexertion.
3. Provide for high-calorie, high-protein diet.

Patient Education and Health Maintenance

1. Instruct patient about the necessity for long-term therapy for adrenocortical insufficiency and medical follow-up visits.
   a. Inform patient that therapy must be continued throughout his or her life.
   b. Emphasize the importance of taking more hormones when under stress.
   c. Suggest that patient carry an identification card that indicates the type of medication being taken and health care provider's telephone number.
2. Educate patient about manifestations of excessive use of medications and reportable symptoms.
3. Identify actions to take to avoid factors that may precipitate addisonian crisis (infection, extremes of temperature, trauma).
4. Assist patient in identifying sources of information and support available in the community (see Box 24-1, page 709).

Evaluation: Expected Outcomes

- Normal skin turgor, moist mucous membranes, stable vital signs.
- No signs of infection or stress.
- Completes daily activities with minimal assistance.

Pheochromocytoma

Pheochromocytoma is a catecholamine-secreting neoplasm associated with hyperfunction of the adrenal medulla. It may appear wherever chromaffin cells are located; however, most are found in the adrenal medulla.

Pathophysiology and Etiology

1. Pheochromocytoma can occur at any age but is most common between the ages of 30 and 60; it is uncommon in people older than age 65.
2. Most pheochromocytoma tumors are benign; 10% are malignant with metastasis into bone, liver, and lymph nodes.
3. 35% of extra-adrenal pheochromocytomas are malignant.
4. Tumors located in the adrenal medulla produce both increased epinephrine and norepinephrine; those located outside the adrenal gland tend to produce epinephrine only.
5. May occur as component of multiple endocrine neoplasia IIA, an autosomal dominant syndrome characterized by pheochromocytoma, thyroid cancer, and hyperparathyroidism.

Clinical Manifestations

1. Variation in signs and symptoms depends on the predominance of norepinephrine or epinephrine secretion and on whether secretion is continuous or intermittent.
2. Excess secretion of norepinephrine and epinephrine produces hypertension, hypermetabolism, and hyperglycemia.
3. Hypertension may be paroxysmal (intermittent) or persistent (chronic).
    a. Chronic form mimics essential hypertension; however, antihypertensives are not effective.
    b. Headaches and vision disturbances are common.
4. The hypermetabolic and hyperglycemic effects produce excessive perspiration, tremor, pallor or face flushing, nervousness, elevated blood glucose levels, polyuria, nausea, vomiting, diarrhea, abdominal pain, and paresthesia.
5. Emotional changes, including psychotic behavior, may occur.
6. Symptoms may be triggered by allergic reactions, physical exertion, emotional upset, or may occur without identifiable stimulus.

Diagnostic Evaluation

1. Metanephrine (metabolites of epinephrine and norepinephrine) are elevated in 24-hour urine specimen.
2. Epinephrine and norepinephrine in urine and blood are elevated while patient is symptomatic.
3. CT scan and magnetic resonance imaging (MRI) of the adrenal glands or of the entire abdomen are done to identify tumor.

Management

Medical Control of BP and Preparation for Surgery

1. Alpha-adrenergic blocking agents, such as phentolamine or phenoxybenzamine, inhibit the effects of catecholamines on BP.
    a. Effective control of BP and blood volume may take 1 or 2 weeks.
    b. Surgery is delayed until BP is controlled and blood volume has been expanded.
2. Catecholamine synthesis inhibitors, such as metyrosine, may be used preoperatively or for long-term management of inoperable tumors.
    a. Adverse effects include sedation and crystalluria.

Surgery

Unilateral or bilateral adrenalectomy or other tumor removal.

Complications

Metastasis of tumor.

Nursing Assessment

1. Obtain history of signs and symptoms patient has been experiencing.
2. Assess for predisposing factors that may be triggering signs and symptoms (ie, physical exertion, emotional upset, allergies).
3. Perform thorough physical examination to determine effects of hypertension.

Nursing Diagnoses

- Anxiety related to the systemic effects of epinephrine and norepinephrine.
- Ineffective Tissue Perfusion related to hypotension during the postoperative period.

Nursing Interventions

Reducing Anxiety

1. Remain with patient during acute episodes of hypertension.
2. Ensure bed rest and elevate the head of bed 45 degrees during severe hypertension.
3. Carry out tasks and procedures in calm, unhurried manner when with patient.
4. Instruct patient about use of relaxation exercises.
5. Reduce environmental stressors by providing calm, quiet environment. Restrict visitors.
6. Eliminate stimulants (coffee, tea, cola) from the diet.
7. Reduce events that precipitate episodes of severe hypertension—palpation of the tumor, physical exertion, emotional upset.
8. Administer sedatives, as prescribed, to promote relaxation and rest.
9. Monitor for orthostatic hypotension after administration of phentolamine.
10. Encourage oral fluids and maintain IV infusion preoperatively to ensure adequate volume expansion

going into surgery.

Maintaining Tissue Perfusion Postoperatively

1. Monitor vital signs, ECG, arterial BP, neurologic status, and urine output closely postoperatively.
2. Assess for and report complications of hypertension, hypotension, and hyperglycemia.
3. Maintain adequate hydration with IV infusion to prevent hypotension. (Because reduction of catecholamines immediately postoperatively causes vasodilation and enlargement of vascular space, hypotension may occur.)
4. Monitor intake and output and laboratory results for BUN, creatinine, and glucose levels.

Patient Education and Health Maintenance

1. Instruct patient how and when to take medications. Warn patients who take metyrosine of sedation and need to avoid taking other CNS depressants and participating in activities that require alertness; need to increase fluid intake to at least 2,000 mL/day to prevent renal calculi.
2. Inform patient regarding the need for continued follow-up for:
   a. Recurrence of pheochromocytoma.
   b. Assessment of any residual renal or cardiovascular injury related to preoperative hypertension.
   c. Documentation that catecholamine levels are normal 1 to 3 months postoperatively (by 24-hour urine test).
3. Help patient identify sources of information and support available in the community (see Box 24-1, page 709).

Evaluation: Expected Outcomes

- Reports less anxiety during hypertensive episodes.
- BP stable, adequate urine output.

DISORDERS OF THE PITUITARY GLAND

The pituitary gland (hypophysis) exerts prime control over the body's hormonal functions. It is located in the sella turcica at the base of the brain. Its function is regulated by the hypothalamus. The pituitary consists of two parts that are structurally and functionally separate: the anterior pituitary and the posterior pituitary. Hypothalamic control of the anterior pituitary is mediated by releasing factors secreted by the hypothalamus; the posterior pituitary is regulated through direct neural stimulation. See Table 24-2 for hormones of the pituitary gland.

Table 24-2 Hormones of the Pituitary Gland

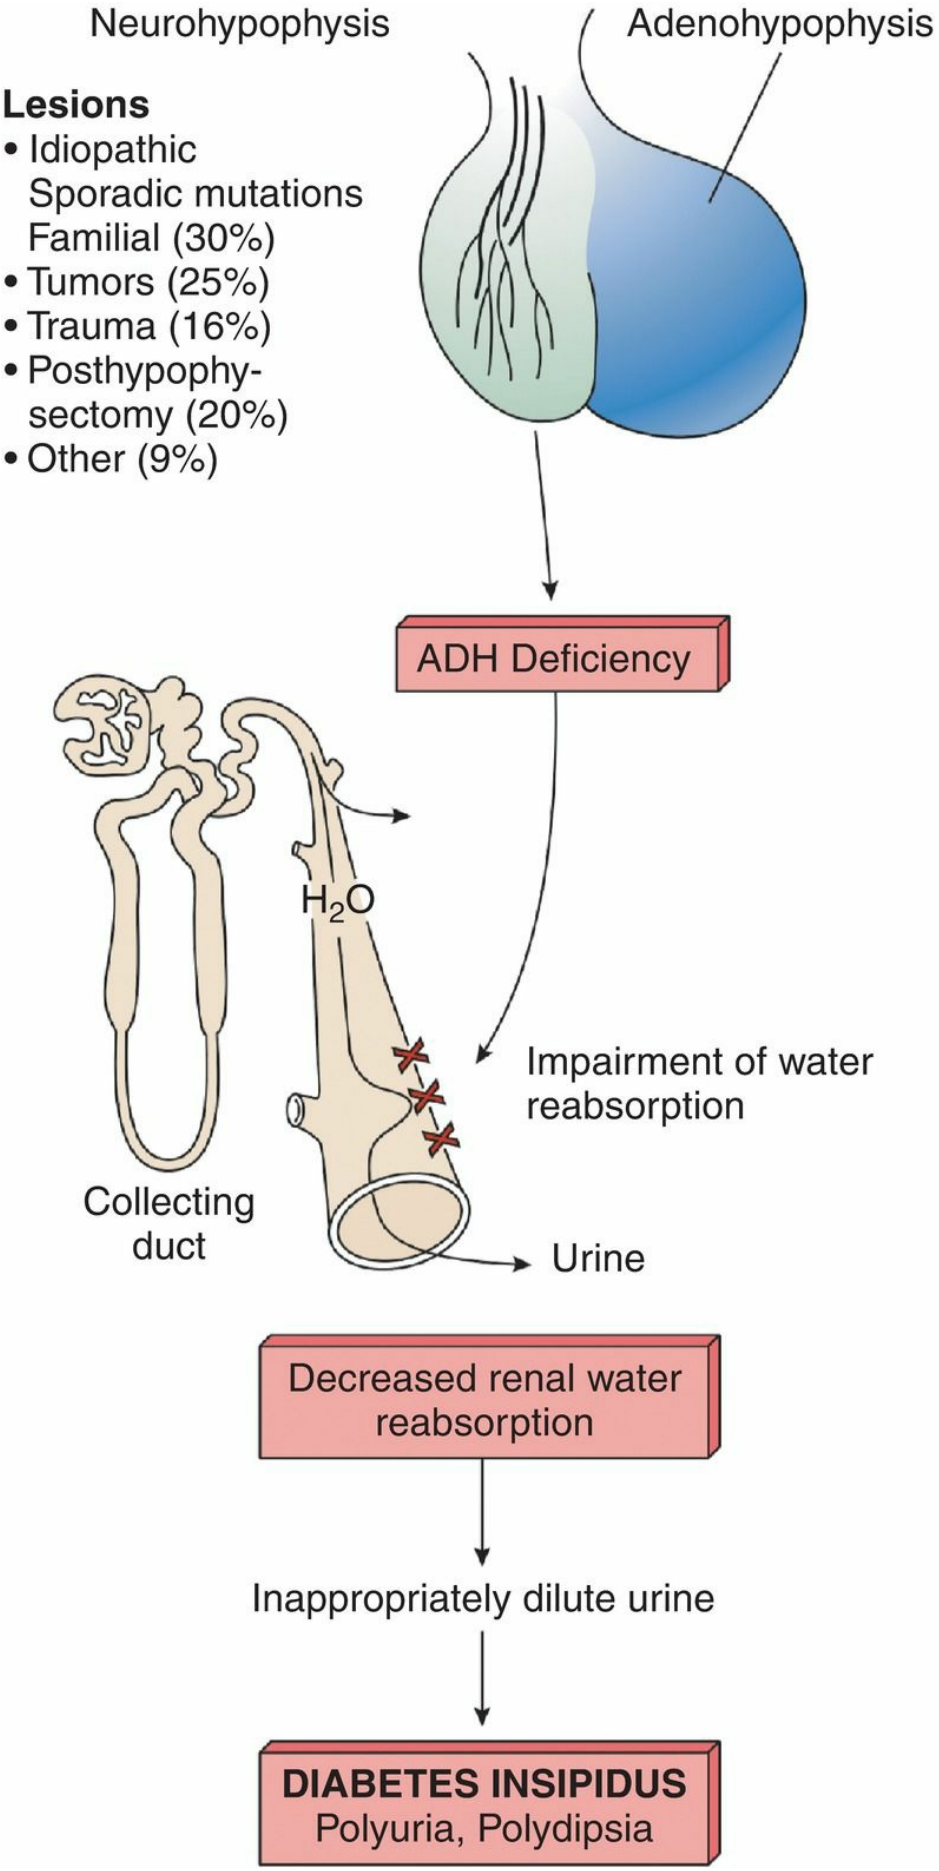
HORMONE	TARGET TISSUE
Anterior Pituitary	
Growth hormone	Multiple sites
Thyroid-stimulating hormone	Thyroid gland
Adrenocorticotropic hormone	Adrenal glands
Prolactin	Breasts
Luteinizing hormone	Ovaries, testes
Follicle-stimulating hormone	Ovaries, testes
Melanocyte-stimulating hormone	Melanocytes (skin)
Posterior Pituitary	
Oxytocin	Uterus, breasts
Antidiuretic hormone	Kidneys

Diabetes Insipidus

Diabetes insipidus (DI) is a disorder of water metabolism caused by deficiency of ADH, also called vasopressin, secreted by the posterior pituitary (central DI) or by inability of the kidneys to respond to ADH (nephrogenic DI).

Pathophysiology and Etiology

1. Primary: idiopathic.
2. Secondary: head trauma, neurosurgery, tumors (intracranial or metastatic), vascular disease (aneurysms, infarct), infection (meningitis, encephalitis).
3. Nephrogenic DI: long-standing renal disease, hypokalemia, some medications.
4. Deficiency of ADH results in decreased renal water reabsorption; it may be partial or complete (see Figure 24-5).
5. DI may be transient or permanent.



Neurohypophysis
Adenohypophysis
Lesions
• Idiopathic
Sporadic mutations
Familial (30%)
• Tumors (25%)
• Trauma (16%)
• Posthypophy-
sectomy (20%)
• Other (9%)
ADH Deficiency
H2O
Impairment of water
reabsorption
Collecting
duct
Urine
Decreased renal water
reabsorption
Inappropriately dilute urine
DIABETES INSIPIDUS
Polyuria, Polydipsia

Figure 24-5. The mechanisms of diabetes insipidus. (Rubin, R., & Strayer, D.S. [2011]. *Rubin's pathology: clinicopathologic foundations of medicine* [6th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Clinical Manifestations

1. Marked polyuria—daily output of greater than 3 L for adults, 2 L for children of dilute urine; corresponding to a urine osmolality of less than 250 mOsm/kg.
2. Polydipsia (intense thirst)—drinks 4 to 40 L of fluid daily; has craving for cold water.
3. High serum osmolality (above 295 mOsm) and high serum sodium level (greater than 142 mEq/L).

Diagnostic Evaluation

1. Serum osmolality—high; urine osmolality—low.
2. Water deprivation test determines central and nephrogenic DI.
3. Measurements of serum and urine ADH—decreased to absent.

Management

1. Administration of ADH or its derivative.
   a. DDAVP—vasopressin derivative administered intravenously, into the nose through a soft, flexible nasal tube, by nasal spray, or orally in tablet form. Potency varies by form of preparation (eg, IV form almost 10 times more potent than nasal spray).
      i. Duration of action 8 to 12 hours.
      ii. For patients who have some residual hypothalamic ADH (determined by low levels of circulating ADH).
      iii. Dosage may be reduced in older adults and in individuals with renal impairment.
   b. Chlorpropamide—potentiates action of vasopressin on renal concentrating mechanism.
   c. Tricyclic antidepressants and selective serotonin reuptake inhibitor antidepressants may potentiate the action of DDAVP.
   d. Carbamazepine—potentiates action of endogenous vasopressin (rarely used).
2. For patients with nephrogenic DI—chlorpropamide or thiazide diuretics may be of value. Reversible by discontinuing causative medication if cause is drug related.

Complications

1. If untreated, may result in death.
2. Overtreatment of DDAVP may cause hyponatremia and water intoxication.

GERONTOLOGIC ALERT Older patients are more sensitive to the effects of DDAVP, so make

sure that overdosage does not occur and watch for early signs of hyponatremia and water intoxication—drowsiness, confusion, headache, anuria, weight gain—to prevent seizures, coma, and death.

Nursing Assessment

1. Obtain complete health history to determine possible cause of DI.
2. Assess hydration status.

Nursing Diagnosis

- Risk for Deficient Fluid Volume related to disease process.

Nursing Interventions

Maintaining Adequate Fluid Volume

1. Measure fluid intake and output accurately.
2. Obtain daily weights.
3. Monitor hemodynamic status, as indicated, via frequent BP, heart rate, central venous pressure, and other measurements.
4. Provide patient with ample water to drink and administer IV fluids as indicated.
5. Monitor results of serum and urine osmolality and serum sodium tests.
6. Administer or teach self-administration of medication, as prescribed, and document patient response.

Patient Education and Health Maintenance

1. Inform patient that metabolic status must be monitored on a long-term basis because the severity of DI changes from time to time.
2. Advise patient to avoid limiting fluids to decrease urine output; thirst is a protective function.
3. Advise patient to wear a medical alert tag stating that the wearer has DI.
4. Teach patient to be alert for signs of dehydration—decreased weight, decreased urine output, increased thirst, dry skin and mucous membranes; and overhydration—increased weight and edema; report these to the health care provider.
5. Tell patient to consider eliminating coffee and tea from diet—may have an exaggerated diuretic effect.
6. Give written instruction on vasopressin administration. Have patient demonstrate intranasal and injection technique.

Evaluation: Expected Outcomes

- Fluid intake equals output, weight stable.

Pituitary Tumors

Pituitary tumors represent various cell types. Symptoms reflect tumor effects on target tissues or on local structures surrounding the pituitary gland.

Pathophysiology and Etiology

1. Multiple oncogene abnormalities are thought to be involved with pituitary tumorigenesis.
2. Typically, pituitary tumors are characterized by size and by what hormones, if any, are secreted.
   a. Size.
      i. Microadenoma—less than 10 mm wide.
      ii. Macroadenoma—greater than 10 mm wide.
   b. Functional status.
      i. Hormone secreting—exaggerated hormone activity; may secrete multiple hormones.
      ii. Nonsecreting—usually diminished hormone activity.
3. Malignancy in pituitary tumors is rare.

Clinical Manifestations

1. Mass effects—effects of tumor on surrounding structures.
   a. Nonspecific headache.
   b. Impairment of cranial nerves II, III, IV, and VI on testing because of bilateral hemianopsia, which results from pressure on the optic chiasm.
   c. Vision disturbances, such as visual field defects and diplopia.
2. Endocrine effects—effects of hormone imbalances caused by tumor (see Table 24-3).

Table 24-3 Clinical Manifestations Associated with Hormone Effects of Pituitary Tumors

HORMONE	HYPERPITUITARISM (INCREASED SECRETION)	HYPOPITUITARISM (DIMINISHED SECRETION)
Growth hormone	• Gigantism (child) • Acromegaly (adult)	• Shortness of stature (child) • Silent (adult)
Prolactin	• Infertility and galactorrhea (female)	• Postpartum lactation failure
Adrenocorticotropic hormone	• Cushing disease	• Adrenocortical insufficiency
Thyroid-stimulating hormone	• Hyperthyroidism	• Hypothyroidism
Luteinizing hormone and follicle-stimulating hormone	• Gonadal dysfunction	• Hypogonadism

Diagnostic Evaluation

1. MRI of the brain and sellar region; CT can also be done but is inferior.
2. Serum hormone levels to identify suspected abnormalities based on clinical evaluation.
3. Provocative testing to detect hormone secretion abnormalities of the pituitary, such as glucose tolerance test and DST.

Management

Hypophysectomy

1. Surgical removal of the pituitary; considered first line of treatment for pituitary adenomas.
2. Transsphenoidal hypophysectomy—direct approach through the sinus and nasal cavity to sella turcica (see page 707).
3. Frontal craniotomy—uncommon approach except where tumor occupies broad area (see page 361).

Other Methods of Pituitary Ablation

1. Cryogenic destruction or stereotaxic radiofrequency coagulation (may be used in conjunction with surgery or drug therapy).
2. Radiation therapy.
3. Drug therapy.
   a. Bromocriptine for prolactinomas and, in some instances, GH-secreting tumors is given daily.
   b. Cabergoline, a dopamine agonist, is administered twice per week for the treatment of acromegaly.
   c. Somatostatin analogues (octreotide, lanreotide) used in the treatment of acromegaly.
   d. GH antagonist (pegvisomant) used in the treatment of acromegaly.
   e. HRT for hypopituitarism.

Complications

1. Hypothyroidism and adrenocortical insufficiency after ablation, requiring hormone replacement.
2. Menstruation ceases and infertility occurs almost always after total or nearly total ablation.
3. Transient or permanent DI after surgery.
4. Without treatment—death or severe disability caused by stroke, blindness, or imbalances of ACTH, TSH, or ADH.

Nursing Assessment

1. Obtain history of signs and symptoms.
2. Perform thorough neurologic examination and general physical examination to identify signs of hormone deficiency or excess.
3. Assess patient's understanding of the management plan, coping with the diagnosis, and support from others.

Nursing Diagnoses

- Anxiety related to ablation treatment.
- Readiness for Enhanced Management of Therapeutic Regimen.

Nursing Interventions

Also see "Care of the Patient Undergoing Transsphenoidal Hypophysectomy," page 707.

Reducing Anxiety

1. Provide emotional support through the diagnostic process and answer questions about treatment options.
2. Prepare patient for surgery or other treatment by describing nursing care thoroughly.
3. Stress likelihood of positive outcome with ablation therapy.

Promoting Management of the Therapeutic Regimen

1. Teach patient the nature of hormonal deficiencies after treatment and the purpose of replacement therapy.
2. Instruct patient about the early signs and symptoms of cortisol or thyroid hormone deficiency or excess and the need to report them.
3. Describe and demonstrate the correct method of administering prescribed medications.
4. Encourage patient in assuming active role in self-care through information seeking and problem solving.

Patient Education and Health Maintenance

1. Advise patient on temporary limitations in activities.
2. Teach patient the need for frequent initial follow-up visits and lifelong medical management when on hormonal therapy.
3. If applicable, advise patient on the need for postsurgery radiation therapy and periodic follow-up MRI and visual field testing.
4. Teach patient to notify health care provider if signs of thyroid or cortisol imbalance become evident.
5. Advise patient to wear medical alert tag.
6. Help patient identify sources of information and support available in the community (see Box 24-1, page 709).

Evaluation: Expected Outcomes

- States rationale for treatment, asks appropriate questions.
- Demonstrates correct medication administration.

Metabolic Syndrome

OVERVIEW AND ASSESSMENT

EVIDENCE BASE Centers for Disease Control and Prevention (CDC). (2017) National Diabetes Statistics Report: Estimates of Diabetes and Its Burden in the United States, 2017. Available: *https://www.cdc.gov/diabetes/pdfs/data/statistics/national-diabetes-statistics-report.pdf.*

In 2015, diabetes mellitus (DM) was estimated to affect more than 30 million Americans. This is more than 9% of the US population and yet almost 24% of those with DM are unaware that they have it. Unfortunately, if current trends continue and in the absence of major lifestyle changes and an overhaul of our current health care delivery system, the number of Americans diagnosed with DM is expected to increase by 64% by 2025. This translates to roughly 1 in every 3 Americans.

It is thought that the factors contributing to the explosion of diabetes are an aging population, increased prevalence of type 2 diabetes mellitus in youth, growing numbers of ethnic minorities, and the increasing trend of obesity. In 2013-2014 the National Center for Health Statistics estimated that more than 70% of American adults were classified as being overweight or obese.

Additionally, the cost of caring for people with diabetes is staggering. In 2016, Rowley and colleagues found that, the United States spent over $407 billion on diabetes care alone. This is more than two times the health care costs of those without diabetes. By 2025, they estimate that the cost will exceed $560 billion.

Diabetes mellitus is the leading cause of blindness, kidney failure, and lower limb amputations. People with diabetes are two to four times more likely to be diagnosed with heart disease, three times more likely to have dental disease, and twice as more likely to suffer from depression.

This is a very serious disease with even more serious consequences. All nurses must stay current on the latest care recommendations. Screening for this disease is essential because early treatment leads to a reduction of morbidity and mortality.

Insulin Secretion and Function

1. Insulin is a hormone secreted by the beta cells of the islet of Langerhans in the pancreas.
2. Small amounts of insulin are released into the bloodstream in response to changes in blood glucose levels throughout the day (basal secretion).
3. Increased secretion or a bolus of insulin, released during meals, helps maintain euglycemia.
4. Through an internal feedback mechanism that involves the pancreas and the liver, circulating blood glucose levels are maintained at a normal range of 60 to 100 mg/dL.
5. Insulin is essential for the utilization of glucose for cellular metabolism as well as for the proper metabolism of protein and fat.
    a. Carbohydrate metabolism—insulin affects the conversion of glucose into glycogen for storage in the liver and skeletal muscles and allows for the immediate release and utilization of glucose by the cells.
    b. Protein metabolism—amino acid conversion occurs in the presence of insulin to replace muscle tissue or to provide needed glucose (gluconeogenesis).
    c. Fat metabolism—storage of fat in adipose tissue and conversion of fatty acids from excess glucose occurs only in the presence of insulin.
6. Glucose can be used in the endothelial and nerve cells without the aid of insulin.
7. Without insulin, plasma glucose concentration rises and glycosuria results.
    a. Absolute deficits in insulin result from decreased production of endogenous insulin by the beta cell of the pancreas.
    b. Relative deficits in insulin are caused by inadequate utilization of insulin by the cell.

Classification of Diabetes

EVIDENCE BASE American Association of Clinical Endocrinologists (AACE) and American College of Endocrinology (ACE). (2015). Clinical practice guidelines for developing a diabetes mellitus comprehensive care plan—2015. *Endocrine Practice, 21*(Suppl. 1).

American Diabetes Association (ADA). (2018). Standards of medical care in diabetes—2018. *Diabetes Care, 41*(Suppl. 1).

Type 1 Diabetes Mellitus

Type 1 diabetes mellitus (T1DM), formerly known as insulin-dependent diabetes mellitus or juvenile diabetes mellitus.

1. Little or no endogenous insulin, requiring injections of insulin to control diabetes, prevent ketoacidosis, and sustain life.
2. Only 5% to 10% of all people with diabetes have T1DM.
3. Etiology is not well understood: includes autoimmune, viral, and certain histocompatibility antigens as well as genetic components.
4. Clinical manifestation is abrupt with classic symptoms of polydipsia, polyphagia, polyuria, and weight loss.
5. Most commonly seen in patients under age 30 but can be seen in older adults.

Type 2 Diabetes Mellitus

Type 2 diabetes mellitus (T2DM), formerly known as non–insulin-dependent diabetes mellitus or adult-onset diabetes mellitus.

1. Caused by a combination of insulin resistance and relative insulin deficiency—some individuals have predominantly insulin resistance, whereas others have predominantly deficient insulin secretion, with little insulin resistance.
2. Approximately 90% to 95% of people with diabetes have T2DM.
3. Etiology: strong hereditary component, commonly associated with obesity.
4. Usual presentation is slow and typically insidious with symptoms of fatigue, weight loss, poor wound healing, and recurrent infection.
5. Found primarily in adults over age 30; however, it is now more frequently seen in younger adults and adolescents who are overweight.
6. People with this type of diabetes may be treated with insulin but are still referred to as having T2DM.

Gestational Diabetes Mellitus

Gestational diabetes mellitus (GDM) is defined as the onset of carbohydrate intolerance that initially presents during pregnancy and resolves upon delivery.

1. Affects approximately 2% to 10% of pregnancies; however, the new diagnostic criteria may yield that as many as 18% of pregnancies are affected by GDM.
2. Women with GDM have a 35% to 60% chance of developing T2DM diabetes in the next 10 to 20 years. They should be screened for diabetes 6 to 12 weeks postpartum and continue to have lifelong screening at least every 3 years.
3. GDM is associated with significant risk of maternal and fetal complications.
4. Because of the worldwide increases of both obesity and diabetes rates, both the AACE/ACE and the ADA recommend that all pregnant women with risk factors (Box 25-1) for T2DM be screened for the presence of T2DM at the initial prenatal visit using the standard diagnostic criteria. Women who screen positive in the 1st trimester should be classified as having preexisting pregestational diabetes, not GDM.
5. Pregnant women who screen negative for T2DM in the 1st trimester should then be screened for GDM at 24 to 28 weeks of gestation. AACE/ACE recommends using the one-step strategy; the American College of Obstetricians and Gynecologists (ACOG) supports using the two-step strategy and following the diagnostic criteria established by either Carpenter and Coustan or the National Diabetes Data Group. The ADA states that either screening method is appropriate (Box 25-1).

Diabetes Because of Other Causes

1. Genetic defects of insulin secretion and/or insulin action.
2. Pancreatic diseases (such as cystic fibrosis, pancreatitis, and pheochromocytoma).
3. Drug-induced (such as corticosteroids and medications used to treat HIV/AIDS).

Prediabetes

1. *Prediabetes* is an abnormality in glucose values intermediate between normal and overt diabetes.
2. Associated with obesity, dyslipidemia, and hypertension; prediabetes is a potent risk factor for developing T2DM and cardiovascular disease.
3. Every effort should be made to assist the patient with aggressive lifestyle modifications (diet, exercise, and weight loss) to prevent the progression from prediabetes to overt T2DM.
4. There are two forms of prediabetes, based on when glucose is elevated. Patients that simultaneously have both forms of prediabetes have a very high risk of developing T2DM.
    a. Impaired fasting glucose (IFG)—defined as having fasting blood glucose levels of 100 to 125 mg/dL.
    b. Impaired glucose tolerance (IGT)—defined as blood glucose measurement of 140 to 199 mg/dL using a 2-hour 75-g OGTT.

Laboratory Tests

EVIDENCE BASE AACE/ACE. (2015). Clinical practice guidelines for developing a diabetes mellitus comprehensive care plan—2015. *Endocrine Practice, 21*(Suppl. 1).

ADA. (2018). Standards of medical care in diabetes—2018. *Diabetes Care, 41*(Suppl. 1).

International Society for Pediatric and Adolescent Diabetes (ISPAD). (2014). Clinical practice guidelines 2014. *Pediatric Diabetes, 15*(Suppl. 20).

This section includes the laboratory tests used to diagnose and monitor short- and long-term glucose control as well as the recommended glucose treatment goals for different population groups. See Box 25-1 for details pertaining to the screening criteria for T2DM in nonpregnant adults, adolescents, children, and older adults.

BOX 25-1 Risk Factors and Screening for Type 2 Diabetes

ADULTS

Begin screening at any age if overweight (BMI ≥ 25 kg/m^2) *plus* any *one* of the following risk factors; otherwise begin screening all adults at age 45.

Screening should occur at least every 3 years.

- Family history of diabetes (first-degree relative).
- Sedentary lifestyle/habitual inactivity.
- Race/ethnicity (ie, black, Hispanic American, Native American, Alaskan American, and Pacific Islander).
- Previous diagnosis of prediabetes (IFG or IGT or A1C ≥ 5.7%).
- History of GDM.
- HTN ≥ 140/90 mm Hg.
- HDL cholesterol less than 35 mg/dL and/or triglyceride level greater than 250 mg/dL.
- History of insulin resistance (ie, polycystic ovary disease, acanthosis nigricans, severe obesity).
- History of cardiovascular disease.

CHILDREN

Begin screening at age 10 or onset of puberty (whichever first) and continuing at least every 3 years if:

Overweight (BMI greater than 85th percentile for age, gender, OR weight for height greater than 85th percentile, OR weight greater than 120% of ideal height) *plus* any *two* of the following risk factors:

- Family history of type 2 diabetes in first- or second-degree relative.
- Race/ethnicity (ie, Native American, black, Latino, Asian American, Pacific Islander).
- Signs of insulin resistance or conditions associated with insulin resistance (ie, acanthosis nigricans,

hypertension, dyslipidemia, PCOS, or small-for-gestational age birth weight).

- Maternal history of DM or GDM during child's gestation.

Blood Glucose

Description

1. Fasting blood sugar (FBS), drawn after at least an 8-hour fast, to evaluate circulating amounts of glucose.
2. Postprandial test, drawn usually 2 hours after a well-balanced meal, to evaluate glucose metabolism.
3. Random glucose, drawn at any time, without regard to the time of last caloric intake.

Nursing and Patient Care Considerations

1. For fasting glucose, make sure that patient has maintained 8-hour fast overnight; sips of water are allowed.
2. Advise patient to refrain from smoking before the glucose sampling because this affects the test results.
3. For postprandial glucose, advise patient that no additional food or caloric beverages should be consumed during the 2-hour interval.
4. For random blood glucose, note the time and content of the last meal.

Blood Glucose Values: Diagnostic Criteria and Treatment Goals

1. Diagnostic blood glucose values for diabetes mellitus all ages (ADA, AACE/ACE, and ISPAD):
   a. Fasting blood glucose ≥126 mg/dL, confirmed with a repeat test on another day.
   b. Random blood sugar (regardless of time of last caloric intake) ≥ 200 mg/dL *and* presence of classic symptoms of diabetes (polyuria, polydipsia, polyphagia, and weight loss). This test, when patients present symptomatic as described above, does not need to be repeated nor does the diagnosis need to be confirmed with another test.
   c. Fasting blood glucose result of 100 to 125 mg/dL is prediabetes (IFG) and demands close follow-up and repeat monitoring at least every 3 years.
2. Blood glucose treatment goals for many nonpregnant adults with diabetes mellitus:
   a. Premeal: 80 to 130 mg/dL (ADA) or less than 110 mg/dL (AACE/ACE).
   b. 1 to 2 hours postmeal: less than 180 mg/dL (ADA) or less than 140 mg/dL (AACE/ACE).
3. Blood glucose treatment goals for children and adolescents:
   a. Fasting and premeal: 70 to 145 mg/dL (ISPAD) or 90 to 130 mg/dL (ADA).
   b. Postmeal: 90 to 180 mg/dL (ISPAD).
   c. Bedtime: 120 to 180 mg/dL (ISPAD) or 90 to 150 mg/dL (ADA).
   d. Nocturnal (overnight): 80 to 162 mg/dL (ISPAD) or 90 to 150 mg/dL (ADA).
4. Blood glucose treatment goals for pregnant women with gestational diabetes (ADA and AACE/ACE):
   a. Premeal: ≤95 mg/dL.
   b. 1 hour postmeal: ≤140 mg/dL.

c. 2 hours postmeal: ≤120 mg/dL.

5. Blood glucose treatment goals for pregnant women with pre-existing diabetes:
   a. Premeal, bedtime: 60 to 99 mg/dL (AACE/ACE) or ≤95 mg/dL (ADA).
   b. 1 hour postmeal: 100 to 129 mg/dL (AACE/ACE) or ≤140 mg/dL (ADA).
   c. 2 hours postmeal: ≤120 mg/dL (ADA).
6. Blood glucose treatment goals for older adults (ADA):
   a. Healthy, few complications: 90 to 130 mg/dL fasting; 90 to 150 mg/dL bedtime.
   b. Complex with multiple coexisting chronic conditions: 90 to 150 mg/dL fasting; 100 to 180 mg/dL bedtime.
   c. Very complex/frail: 100 to 180 mg/dL fasting; 110 to 200 mg/dL bedtime.
7. Blood glucose treatment goals for hospitalized patients (critically and noncritically ill).
   a. 140 to 180 mg/dL (ADA and AACE/ACE).

NURSING ALERT Capillary blood glucose values obtained by fingerstick samples tend to be higher than values in venous samples. Diagnostic tests are always to be conducted in a laboratory using venous samples.

Oral Glucose Tolerance Test

Description

The *oral glucose tolerance test (OGTT)* evaluates insulin response to glucose loading. FBS is obtained before the ingestion of a glucose load and blood samples are drawn at timed intervals.

Nursing and Patient Care Considerations

1. Advise patient that for accuracy in results, certain instructions must be followed:
   a. Usual diet and exercise pattern must be followed for 3 days before OGTT.
   b. During OGTT, patient must refrain from smoking and remain seated.
   c. Hormonal contraceptives, salicylates, diuretics, phenytoin, and nicotinic acid can impair results and may be withheld before testing based on the advice of the health care provider.

Diagnostic Criteria Using the 75-g 2-hour OGTT (Nonpregnant Adults, Children, Adolescents)

1. ADA and AACE/ACE diagnostic OGTT values when screening for diabetes mellitus in children, adolescents, and nonpregnant adults:
   a. 200 mg/dL or higher at the 2-hour interval.
   b. 140 to 199 mg/dL at the 2-hour interval is prediabetes (IGT) and demands close follow-up and repeat monitoring at least every 3 years.
   c. See Box 25-2, page 733 for diagnostic criteria using OGTT for gestational Diabetes.

Glycated Hemoglobin (Glycohemoglobin, HbA_{1c}, A1c)

Description

Measures glycemic control over a 60- to 120-day period by measuring the irreversible reaction of glucose to hemoglobin through freely permeable erythrocytes during their 120-day life cycle. Currently used to screen for diabetes as well as to monitor control.

Nursing and Patient Care Considerations

1. No prior preparation, such as fasting or withholding insulin/medications, is necessary.
2. Test results can be affected by red blood cell disorders (eg, thalassemia, sickle cell anemia), room temperature, ionic charges, and ambient blood glucose values.
3. Many methods exist for performing the test, making it necessary to consult the laboratory for normal values.
4. Should be performed at least twice yearly in patients whose diabetes is stable and well controlled. Quarterly (every 3 months) testing is recommended for patients who have had treatment changes/adjustments or whose diabetes is not well controlled.

Diagnostic Criteria and Treatment Goals for A1c Values

1. ADA and AACE/ACE diagnostic A1c values when screening for diabetes mellitus in children, adolescents, and nonpregnant adults.
   a. 6.5% or higher (diagnosis should be confirmed with repeat A1c or a fasting glucose or OGTT).
   b. 5.7% to 6.4% (ADA) or 5.5% to 6.4% (AACE/ACE) is considered prediabetes and demands close follow-up and repeat monitoring at least every 3 years.
2. The joint position statement (2009) of the ADA, the American College of Cardiology Foundation, and the American Heart Association asserts that in general, the A1c goal for nonpregnant adults is less than 7%, but that this must be individualized based on life expectancy, duration of diabetes, history of hypoglycemia, presence of microvascular complications, and presence of cardiovascular disease.
3. The ISPAD and ADA treatment A1c goal for children and adolescents is less than 7.5% across all age groups.
4. The ADA and AACE/ACE treatment A1c goal of pregnant women with pre-existing type 1 or type 2 diabetes is less than 6% (if without excessive hypoglycemia).
5. Because GDM is diagnosed late in pregnancy, the A1c is not a reliable marker of control (3-month average) and the fructosamine assay (2- to 3-week average) may be more meaningful.

EVIDENCE BASE Skyler, J., Bergenstal, R., Bonow, R. O., et al. (2009). Intensive glycemic control and the prevention of cardiovascular events: Implications of the ACCORD, ADVANCE, and VA Diabetes trials: A position statement of the American Diabetes Association and a scientific statement of the

American College of Cardiology Foundation and the American Heart Association. *Diabetes Care, 32*(1), 187–192.

Fructosamine Assay

Description

Glycated protein with a much shorter half-life than glycated hemoglobin, reflecting control over a shorter period, approximately 14 to 21 days. May be advantageous in patients with hemoglobin variants that interfere with the accuracy of glycated hemoglobin tests.

Nursing and Patient Care Considerations

1. Note if patient has hypoalbuminemia or elevated globulins because test may not be reliable.
2. Should not be used as a diagnostic test for diabetes mellitus.
3. No special preparation or fasting is necessary.

C-Peptide Assay (Connecting Peptide Assay)

Description

Cleaved from the proinsulin molecule during its conversion to insulin, C-peptide acts as a marker for endogenous insulin production.

Nursing and Patient Care Considerations

1. Test can be performed after an overnight fast or after stimulation with Sustacal, intravenous (IV) glucose, or 1 mg of glucagon SubQ.
2. Absence of C-peptide indicates no beta cell function, reflecting possible T1DM or insulinopenia in T2DM.

Autoantibody Testing

Description

An *autoantibody* is an antibody (a type of protein) manufactured by the immune system that is directed against one or more of the individual's own proteins. Islet cell autoantibodies cause destruction to the pancreatic β-cells and are strongly associated with the development of T1DM. The appearance of autoantibodies to one or several of the autoantigens—GAD65, tyrosine phosphates (IA-2, IA-2β), ZnT8, or insulin—signals an autoimmune pathogenesis of β-cell destruction. The positivity of any of these autoantibodies in the presence of hyperglycemia is used to confirm the diagnosis of T1DM. Because T1DM affects such a small number of the population, screening is only recommended for 1st-degree family members of people diagnosed with T1DM. Generalized screening would be costly and therefore is not recommended.

Nursing and Patient Care Considerations

1. No special preparation or fasting is necessary.

2. Screen patients with T1DM for other autoimmune disorders such as hypothyroidism and celiac disease.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 25-1, 25-2

PROCEDURE GUIDELINES 25-1

Blood Glucose Monitoring Technique

NURSING ALERT Because of variation among glucose monitors, please refer to the operating instructions of the glucose monitoring device used in your facility.

EQUIPMENT

- Blood glucose meter
- Lancet/lancing device
- Test strip
- Alcohol wipe
- Disposable gloves
- 2“(Ã— 2)”œ gauze or clean tissue
- Cotton ball

PROCEDURE

Nursing Action	Rationale
1. Prepare the finger to be lanced by having the patient wash hands in warm water and soap. Dry thoroughly. For convenience, an alcohol wipe may be used to cleanse the finger. Alcohol must dry thoroughly before finger is lanced.	1. Washing in warm water will increase the blood flow to the finger and remove superficial contaminants that could cause erroneous readings. Alcohol is not needed when patient is testing at home. Alcohol not completely dry will yield inaccurate results.
2. Don disposable gloves.	2. Complies with Centers for Disease Control and Prevention standards for blood-borne pathogens.
3. Turn on the glucose meter. Prepare the meter by validating the proper calibration with the strips to be used. (This usually involves matching a code number on the strip bottle to the code registered on the meter.)	3. Errors in glucose readings can result from miscalibrated or improperly coded meters. (Some meters do not require calibration.)
4. The meter will indicate its readiness for testing blood glucose by message or symbol. Some meters require that the glucose test strip be inserted at this time.	
5. Prick the patient's finger lateral to the fingertip using lancet/lancing device, obtaining a drop of blood large enough to satisfy the requirements of the testing strips being used. Almost all glucose meters available today require very small amounts, ranging from 0.3 to 4 µL.	5. Avoids the most sensitive area of the fingertip. Most inaccurate readings of blood glucose result from insufficient blood samples.
6. Apply the blood carefully to the strip test area (varies by glucose meter model).	6. Some glucose meters require that the test area be covered completely for accurate results. Others use only a small drop of blood inserted at the side of the test strip.
7. Completing the test: a. The blood remains on the strip as the meter processes the result.	a. Processing time varies between meters, but will be programmed to display result at the appropriate time.
8. The lanced finger is covered with gauze or a tissue until bleeding subsides. If necessary, an adhesive bandage is then applied.	

Obtaining blood from a finger using a lancet device

Applying drop of blood to test strip

**Note: Standard precautions should be used throughout the procedure. All blood-contaminated items should be disposed of properly.*

PROCEDURE GUIDELINES 25-2

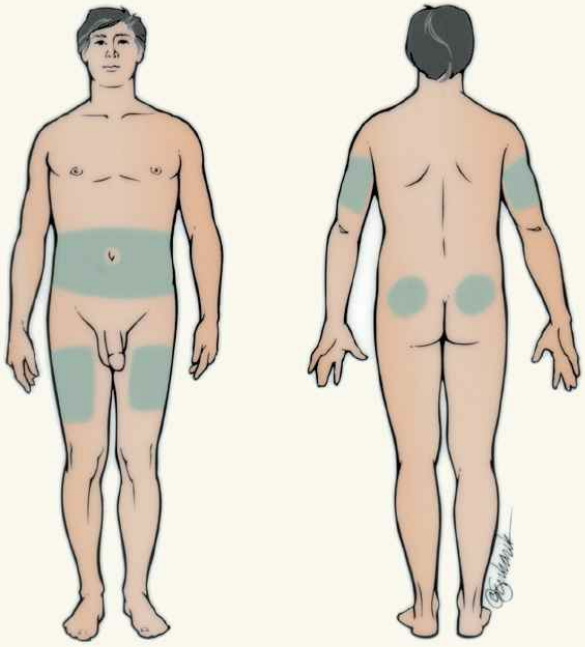
Teaching Self-Injection of Insulin and Other Injectable Diabetes Medications

EQUIPMENT

- Prescribed bottle of insulin or insulin pen or other injectable diabetes medication
- Disposable insulin syringe and needle or pen injection device and pen needle
- Cotton ball and alcohol or alcohol wipe (only in the institutionalized setting, not required for most patients at home)

PROCEDURE

Nursing Action	Rationale
To inject insulin using a syringe	
1. Give the patient the syringe containing the prescribed dose of insulin.	1. Demonstrate how to draw up the proper amount and explain that insulin is measured in "units."
2. Have the patient select a clean area of skin.	2. Preparation with alcohol is not necessary when administered at home, but if used must completely dry before injection to reduce pain.
3. Instruct the patient to hold the syringe as he or she would a pencil or a dart.	3. Helps to accurately target the injection site and reduces the risk of inadvertently depressing the plunger before the needle is in the skin.
4. Show the patient how to select an area of skin from the anterior thighs and form a skin fold by picking up subcutaneous tissue between the thumb and forefinger if the patient is thin. The skin fold should not be squeezed so tight that it would cause pain or blanching of the area.	4. Using a skin fold and injecting at a 45-degree angle is recommended for thin people; injecting at a 90-degree angle into taut skin is recommended for heavier people. Avoid pinching the skin tightly to avoid pain, bleeding, and trauma.
5. Select areas of upper arms, abdomen, and upper buttocks for injection after the patient becomes proficient with needle insertion (see figure).	5. The skin is loose and there is more subcutaneous fat in these areas. Systematic rotation of sites will keep the skin supple and favor uniform absorption of insulin. Use of the same body part for each time of day dosage will make absorption more consistent.



Rotate sites within each body part and use the same body part for the same injection time each day. Absorption is quicker from the abdomen and arms than the thighs and buttocks. Exercising a body part will hasten insulin absorption, so exercise should be consistent. From Smeltzer, S., & Bare, B. (2000). *Brunner and Suddarth's textbook of medical-surgical nursing* (9th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

Nursing Action	Rationale
6. Assist the patient to insert the needle with a quick thrust to the hub at a 45- to 90-degree angle to the skin surface.	6. The needle is inserted into deep subcutaneous tissue.
7. Inject the insulin slowly and then withdraw the needle from the skin.	7. The insulin is injected into the subcutaneous tissue, and the risk of bruising is reduced.
8. Instruct the patient to release the skin fold and dispose of the needle safely.	
To inject insulin/other DM medication using a pen device	
All non–insulin-injectable diabetes medications are only available in prefilled pen devices.	
1. Pen devices must be primed according to manufacturer's instructions before use. Once primed, the desired dose should be dialed.	1. Ensures no obstruction and clears any air in the needle.
2. Inserting the pen needle into the skin is the same procedure used for inserting a needle of a syringe and is described above.	2. 90-Degree angle for most individuals.
3. Once the needle is inserted into the skin up to the hub, the patient will administer the medication by pushing the thumb button at the end of the pen device.	
4. After completely pushing the thumb button, the patient will continue to hold the needle in place for a slow count of 10 before withdrawing the needle.	4. Unlike when using a syringe, the full dose takes longer to be fully dispensed from a pen device.
5. Remove the needle from the pen and dispose of it safely.	5. Leaving the needle attached to the pen will allow for air and possibly other contaminants to enter the cartridge or for the medication to leak out.
To load the syringe	
1. If insulin is in a suspension (NPH), gently rotate or roll the insulin bottle to mix well.	1. Vigorous shaking may result in air bubbles, so rotating or rolling is preferred.
2. Do not instruct the patient to wipe off the top of the vial with alcohol; instead, make sure that the vial is stored in its original carton and is kept clean.	2. Wiping with alcohol is not necessary as risk of infection is small.
3. Inject approximately the same volume of air into the insulin vial as the volume of insulin to be withdrawn.	3. Air is injected into the vial to keep its contents under slight positive pressure and to make it easier to withdraw the insulin.
4. If insulin pen device is being used, follow manufacturer's instructions for dialing the dosage and changing cartridges (if not using a prefilled pen device).	4. Most pen devices now available are prefilled and disposable, eliminating the need to change cartridges.
To fill a syringe with NPH and short-acting or rapid-acting insulin mixture	
1. Inject air equal to the number of units to be injected into each vial. Use the same sequence each time, for example, always NPH insulin first.	1. Creates positive pressure in vial so that insulin will be withdrawn from each vial without mixing.
2. After injecting air into the second vial, keep needle in vial and withdraw prescribed amount of that type of insulin, and then withdraw needle.	2. There is no real benefit to withdrawing either type of insulin first, as the risk of mixing insulins in the second vial is minimal. It is more important not to switch vials and draw up the wrong dose, so the sequence should always be the same.
3. Withdraw prescribed amount of insulin from the second vial.	3. Positive pressure already created in that vial will make withdrawal of insulin easy.

DRUG ALERT Lantus and Levemir insulins must never be mixed with any other insulin in the same syringe. Use of insulin pens eliminates the risk of combining insulin that should not be mixed together. When insulin pens are used in an institutional setting, they are for single-patient use only to prevent transmitting blood-borne infections.

Glucose Monitoring

EVIDENCE BASE AACE/ACE. (2016). Outpatient glucose monitoring consensus statement. *Endocrine Practice, 22*(2), 231–261.

ADA. (2018). Standards of medical care in diabetes—2018. *Diabetes Care, 41*(Suppl. 1).

Accurate determination of capillary blood glucose assists patients in the control and daily management of diabetes mellitus. Blood glucose monitoring helps evaluate effectiveness of medication, reflects glucose excursion after meals, assesses glucose response to exercise regimen, and assists in the evaluation of episodes of hypoglycemia and hyperglycemia to determine appropriate treatment.

Procedure

1. The most appropriate schedule for glucose monitoring is determined by the patient and health care provider.
   a. Medication regimens and meal timing are considered to set the most effective monitoring schedule.
   b. Scheduling of glucose tests should reflect cost-effectiveness for the patient. Glucose meter test strips may cost greater than $1 per strip. Medicare restricts frequency of testing to once a day for those not taking insulin and up to three times a day for those who are.
   c. Glucose monitoring is intensified during times of stress or illness or when changes in therapy are prescribed.
2. Patients with T2DM who are not being treated with insulin or other medications that increase the risk of hypoglycemia (ie, sulfonylureas) should be testing blood glucose using a structured format where information obtained is used to guide treatment.
3. Patients with T1DM as well as those with T2DM who are using a multiple-dose insulin regimen should test blood sugar at least three times a day. Those times should include before/after meals, at bedtime, and occasionally at 2:00 to 3:00 A.M.
4. Alternate-site testing has been recommended by some clinicians for patients who complain of painful fingers and for individuals such as musicians, who use their fingertips for occupational activities. However, testing in such sites as the forearm, palm, thigh, and calf have not proved as accurate as fingertip testing in most studies.
   a. If alternate site is used, the area should be rubbed until it is warm before testing.
   b. Do not use an alternate site when:
      i. Glucose levels are rapidly changing (postprandial, hypoglycemia, reaction to exercise/activity).
      ii. Accuracy is critical (hypoglycemia is suspected, before exercise, or before driving).
   c. Check with the glucometer manufacturer to see if it is approved for alternate-site testing.

5. Continuous glucose monitoring (CGM) is a supplemental tool for use in selected patients, such as those with TIDM experiencing frequent hypoglycemia episodes, severe hypoglycemia, and/or hypoglycemia unawareness. CGM measures glucose in the interstitial fluid. Ongoing advances in technology have rendered these readings highly reliable and correlate closely with plasma glucose.
    a. CGM systems currently available in the US will vary as to whether or not calibration is required by the user or as to whether or not confirmatory fingerstick testing is required to confirm CGM readings. As this technology continues to advance in accuracy, less input will be required by the user.
    b. CGM also detect changes in glucose patterns and will alert the user of potentially dangerous rises and falls. This enables the user to be proactive and avert harmful events.
    c. Current CGM are available for either a professional use (by experienced clinicians as a diagnostic tool) or for personal use (as either stand-alone devices or in an integrated insulin pump/CGM system).
6. In 2016, the FDA approved the 1st hybrid closed loop system (insulin delivery via an insulin pump that will adjust basal rates based on CGM data). It will not be long before a fully automated, closed loop system (bionic pancreas) will be available.

Insulin Therapy

EVIDENCE BASE AACE/ACE. (2018). Consensus statement by the AACE and ACE on the comprehensive type 2 diabetes management algorithm—2018 Executive Summary. *Endocrine Practice, 24*(1), 91–120.

ADA. (2018). Standards of medical care in diabetes—2018. *Diabetes Care, 41*(Suppl. 1).

Insulin therapy involves the subcutaneous injection of rapid-, short-, intermediate-, or long-acting insulin at various times to achieve the desired effect (see Table 25-1). Short-acting regular human insulin as well as some of the rapid-acting analogs can also be administered intravenously. As of this publication, there are 10 different types of insulin available in the United States. They are available in different concentrations (u-100, u-200, u-300, u-500) and premixed combinations. Most of the available insulin products are human insulin manufactured synthetically (analogs). Beef and pork insulins are no longer available in the United States.

Table 25-1 Insulin Products Available in the United States and Their Onset, Peak, Duration, Route, and Pregnancy Category

TYPE	ONSET	PEAK	DURATION	ROUTE
Rapid-Acting Analogs				
Insulin aspart (Fiasp)	<5 min	<1 hr	<3 hr	SQ, IV
Insulin aspart (Novolog)	<15 min	1–2 hr	3–4 hr	SQ, pump, IV
Insulin glulisine (Apidra)	<15 min	1–2 hr	3–4 hr	SQ, pump, IV
Insulin lispro (Humalog)	<15 min	1–2 hr	3–4 hr	SQ, pump
Afrezza human insulin	<15 to 30 min	53 min	2 hr	Inhaled
Short-Acting Human Insulin				
Humulin R	0.5–1 hr	2–4 hr	5–7 hr	SQ, IV
Novolin R	0.5–1 hr	2–4 hr	5–7 hr	SQ, IV
Intermediate-Acting Basal				
Insulin isophane susp. (NPH)	2–4 hr	4–10 hr	10–16 hr	SQ
Humulin N	2–4 hr	4–10 hr	10–16 hr	SQ
Novolin N				
Long-Acting Basal Analogs				
Insulin detemir (Levemir)	3–4 hr	None	6–24 hr	SQ
Insulin glargine (Lantus)	3–4 hr	None	<24 hr	SQ
Ultra–Long-Acting Basal Analogs				
Insulin glargine u-300 (Toujeo)	6 hr	None	>24 hr	SQ
Insulin degludec u-100 and u-200 (Tresiba)	30–90 min	None	>40 hr	SQ
Premixed Insulin				
Analog Preparations				
Novolog Mix 70/30 (aspart)	<15 min	2–4 hr	24 hr	SQ
Humalog Mix 75/25 (lispro)	<15 min	0½–1.5 hr	24 hr	SQ
Humalog Mix 50/50 (lispro)	<15 min	1 hr	16 hr	SQ
Ryzodeg 70/30 (degludec + aspart)	<15 min	72 min	>24 hr	SQ
NPH and Regular Suspensions				
Humulin 70/30	30 min	2–12 hr	24 hr	SQ
Novolin 70/30	30 min	2–12 hr	24 hr	SQ

Notes: No FDA-approved insulins derived from beef are available in the United States. They were discontinued in 1998 because of concerns about bovine spongiform encephalopathy (BSE; "mad cow disease").

Iletin II Regular (Pork), Iletin II NPH (Pork), Humulin Lente, and Humulin Ultralente were all discontinued by the manufacturer (Lilly) in 2005 because of reduced demand and high cost.

Exubera (inhaled insulin) was discontinued by Pfizer in late 2007 because of poor sales.

DRUG ALERT The following insulin types can be used during pregnancy (category B): human regular, human NPH, aspart, lispro, and detemir. All others, to include Afrezza inhaled insulin, remain category C and should not be used during pregnancy if other alternatives are available.

Self-Injection of Insulin

1. Teaching of self-injection of insulin should begin as soon as the need for insulin has been established.
2. Teach the patient and another family member or significant other.
3. Use written and verbal instructions and demonstration techniques.
4. Teach injection first because this is the patient's primary concern; then, teach loading the syringe.
5. Almost all insulin preparations are available in prefilled pen devices. These are much easier and safer for the patients to learn and use. It is recommended that pen devices be used whenever possible. These are most appropriate for patients with dexterity or vision limitation.

BOX 25-2 Screening and Diagnosing Parameters for Gestational Diabetes

ONE-STEP STRATEGY

WHEN: 24–28 weeks' gestation

HOW: 75-g 2-hr OGTT performed in the morning following 8-hr fast the night before

WHAT is diagnostic for GDM (any ONE of the results):

Fasting glucose: ≥92 mg/dL

1-hr interval: ≥180 mg/dL

2-hr interval: ≥153 mg/dL

TWO-STEP STRATEGY

WHEN: 24–28 weeks' gestation

HOW:

Step 1: nonfasting, 50-g glucose load test; PROCEED to Step 2 if 1-hr result: ≥135 mg/dL ***or*** ≥140 mg/dL (determined by the provider and patient risk factors).

Step 2: 100-g 3-hr OGTT performed in the morning following an 8-hr fast the night before.

WHAT is diagnostic for GDM (**2 positive results; choose 1 set of criteria to follow**):

GLUCOSE VALUE:	CARPENTER/ COUSTAN	NATIONAL DIABETES DATA GROUP
Fasting:	≥95 mg/dL	≥105 mg/dL
1-hr interval:	≥180 mg/dL	≥190 mg/dL
2-hr interval:	≥155 mg/dL	≥165 mg/dL
3-hr interval:	≥140 mg/dL	≥145 mg/dL

Community and Home Care Considerations

1. Assist the patient in deciding whether to reuse insulin syringe at home. The patient may decide to do so because of cost; however, reuse has become controversial because the newer, finer needles may become dull or bent after one or two injections, causing tearing of tissue, which can lead to lipodystrophy.
   a. Needles should not be reused if painful injection or irritated site results.
   b. Needle should be recapped by patient and stored in a clean place if it is going to be reused.
2. Assist the patient in obtaining the appropriate syringe size and needle length for injections.
   a. Determine if there are visual or dexterity issues that make a syringe with gradations farther apart more desirable.
   b. There is no medical reason to use needles greater than 8 mm in length, even in obese patients. Needle lengths of 4, 5, and 6 mm are reliable to deliver medication into the subcutaneous space. To prevent inadvertent intramuscular injection in patients who are thin, the needle can be inserted at a 45-degree angle (rather than at a 90-degree angle) and/or the skin should be folded prior to needle insertion.
   c. There are now insulin syringes available specifically for the use of u-500 regular insulin that are to be prescribed and dispensed with each vial of u-500 regular insulin. U-500 insulin is also now available in prefilled pen devices. Both the new u-500–specific syringes and the prefilled pens make the administration of this insulin much safer.

NURSING ALERT Using a u-100 syringe or tuberculin syringe to dose u-500 regular insulin is not safe and is not recommended.

---

3. Advise the patient that it is not necessary to use alcohol to wipe off the top of the vial or prepare the skin before injection. It has not proved to result in lower rate of infection and adds cost and time to the procedure. The patient should maintain good hygiene (handwashing using soap and water).
4. Instruct the patient to store insulin currently in use in a clean, secure place away from direct sunlight and heat. In-use insulin does not require refrigeration. Check manufacturer recommendations for when to discard insulin vials and pens; recommendations may vary from 10 to 56 days after initial use. All unopened vials/pens must be stored in the refrigerator until initial use.
5. Check manufacturer's recommendations before teaching the patient how to mix insulin; for example, the patient should know that insulin glargine and insulin detemir must never be mixed with any other insulin. Other manufacturers' Web sites containing recommendations are Aventis (*www.aventis.com*), Eli Lilly (*www.lilly.com*), and Novo Nordisk (*www.novonordisk.com*).
6. Avoid prefilling syringes if possible because manufacturers have no data on the stability of insulin stored in syringes for long periods. If prefilling is the only option, store in refrigerator or suggest an insulin pen injection device.

7. Help the patient develop a plan for the disposal of needles. There are no federal regulations for discarding needles used at home; however, needles and lancets can pose a risk for injury. The rules and regulations regarding sharps disposal are different in towns and counties around the country, so advise the patient to check with local sanitation or health departments.
    a. Sharps can be placed in a hard plastic or metal container with a tightly secured lid after use.
    b. More information on disposal can be obtained from the Environmental Protection Agency (*www.epa.gov/osw/nonhaz/industrial/medical/med-home.pdf*) or by contacting the Coalition for Safe Community Needle Disposal (800-643-1643 or *www.safeneedledisposal.org*).

Insulin Regimens

See Figure 25-1.

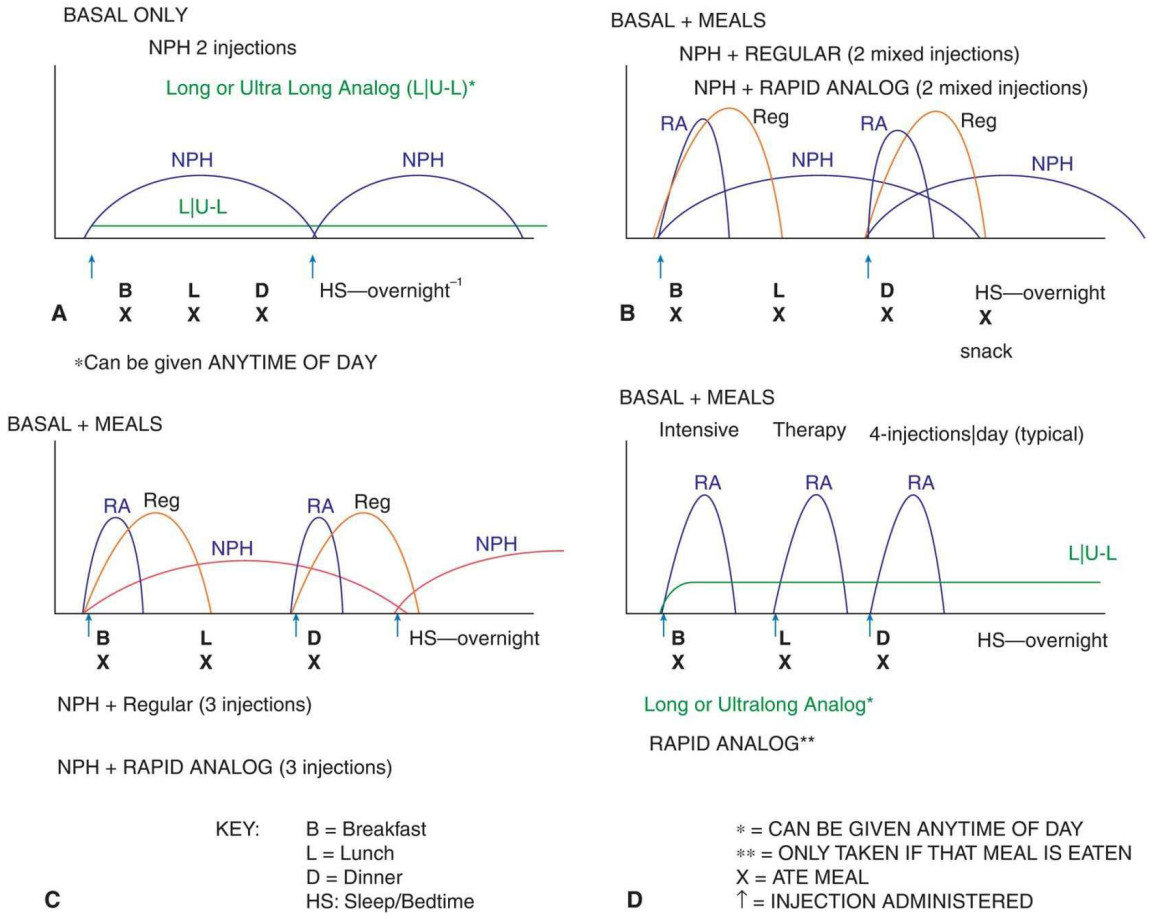

Figure 25-1. Insulin regimens.

Basal Insulin Only (Figure 25-1A)

1. Either NPH or long-acting analogs may be used as monotherapy only in T2DM as a supplement for better glucose control when patients are still capable of producing some exogenous insulin. Patients with T1DM will always require mealtime coverage in addition to basal insulin.
2. NPH is not used as frequently as a basal insulin because of the availability of the newer analog basal insulins that are more reliable, longer acting, and associated with less hypoglycemia. However, NPH is available without a prescription and may also be the most affordable option for some patients.
3. Basal insulin is traditionally administered at bedtime to assist with controlling early-morning hyperglycemia. Patients may take NPH in addition to a mealtime insulin before dinner and can be mixed in the same syringe. If NPH is taken before dinner, a snack before bed is usually necessary to prevent nocturnal hypoglycemia because of the onset of the peaking action several hours later. Bedtime dosing of NPH typically eliminates the need for a bedtime snack and will better address dawn phenomenon (elevated glucose values upon awakening the following morning).
4. The longer-acting insulin analogs typically allow for once-daily dosing and can be administered at various times of the day, and eating snacks between meals to prevent hypoglycemia is usually not required.
