Dedicated to the nurses who teach, educate, mentor, precept, and support new and future nurses. Whether you are a paid educator or a natural role model who assists with clinical training in addition to all your other duties, you are needed and appreciated. The art of nursing must be experienced and nurtured within students and recent graduates. Quality care is not gleaned from science alone. Our profession depends on all those who have followed in the footsteps of the Lady with the Lamp… to improve the health of individuals and the quality of health care.

PREFACE

The world's ever-changing technology and health care systems have challenged nurses more than ever over the past 10 years. I firmly believe, however, that to improve health we cannot forget the past. Fundamental tasks such as nursing assessment and documentation are more important than ever. Care of the patient from hospital to home and across all settings is essential to reduce cost and improve outcomes. Health care today must mirror the past, with the patient at center, in the home, or transitioning to home, in one's own family and community system, rather than as a mere cog in the wheel of a large health care system.

Following the publication of the *Lippincott Manual of Nursing Practice*, 10th edition, I moved my clinical practice into the home health arena, with the firm belief that this is where I could use my 40 years of nursing experience to make the greatest difference in people's health and quality of life. While I exclusively provide medical care in the home and assisted living facilities, I am active in coordination of care for the patient across settings. While a major focus is prevention of hospital admission, I am alert for care needs that become greater than even a highly skilled home health team can meet. When a patient is admitted, I stay involved to help with the transition to rehabilitation settings and back to home. When a patient at home needs more supervision or assistance with activities of daily living than can be provided, I assist with the transition to a long-term care setting. This is what nurses do, whatever the patient needs, and our skills can be used in all settings.

Now I present the 11th edition of the *Lippincott Manual of Nursing Practice* with that focus. This manual is meant to guide students and nurses across all care settings, to provide whatever the patient needs, according to established standards of practice, but not forgetting the caring interactions that nurses do so well.

ORGANIZATION

This new edition continues to follow a basic outline format for easy readability and access of information. The subheadings continue to follow a medical model—Pathophysiology and Etiology, Clinical Manifestations, Diagnostic Evaluation, Management, and Complications—and a nursing process model—Nursing Assessment, Nursing Diagnoses, Nursing Interventions, Community and Home Care Considerations, Patient Education and Health Maintenance, and Evaluation: Expected Outcomes. Medical model information is presented because nurses need to understand the medical disorder, diagnostic workup, and treatment that are the basis for nursing care. The nursing process section provides a practical overview of step- by-step nursing care for almost any patient scenario.

This edition is divided into five parts to present a comprehensive reference for all types of nursing care. Part One discusses the role of the nurse in the health care delivery system. It comprises chapters on Nursing Practice and the Nursing Process, Standards of Care and Ethical and Legal Issues, Health Promotion and Preventative Care, and Genetics and Health Applications.

Part Two encompasses medical–surgical nursing. General topics are presented in Unit I, including Adult Physical Assessment, Intravenous Therapy, Perioperative Nursing, Cancer Nursing, and Care of the Older Adult or Adult with Disability. Units II through XII deal with body system function and dysfunction and the various disorders seen in adult medical and surgical nursing.

Part Three covers Maternity and Neonatal Nursing. Chapters include Maternal and Fetal Health, Nursing Management during Labor and Delivery, Care of the Mother and Newborn during the Postpartum Period, and Complications of the Childbearing Experience. Chapters reflect the routine childbearing experience as well as frequently encountered high-risk situations and problems that may arise for the mother as well as the infant.

Part Four focuses on Pediatric Nursing. Chapters are divided into two units. One unit covers General Practice Considerations, comprising Pediatric Growth and Development, Pediatric Physical Assessment, Pediatric Primary Care, and Care of the Sick or Hospitalized Child. The other unit contains chapters based on body systems to describe the various disorders and corresponding nursing care seen in pediatric nursing.

Part Five discusses Psychiatric Nursing. Entries follow the *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition, classification of mental illness. Treatments and nursing management for each are discussed.

Sandra M. Nettina, MSN, ANP-BC

NEW TO THIS EDITION

New and Expanded Material

Information has been added to or extensively updated throughout chapters in these areas:

Chapter 1—new section on transitional care, the concept of ensuring coordination and continuity of care when a patient moves from one care setting to another.

Chapter 3—updated U.S. Preventive Services Task Force screening guidelines

Chapter 4—introduction of precision health care

Chapter 5—streamlined to highlight the most frequently used nursing assessment techniques

Chapter 6—IV therapy extensively updated

Chapter 8—survivorship care added

Chapter 10—extensive updating

Chapter 11—extensive updating

Chapter 12—extensive updating

Chapter 13—extensive updating

Chapter 15—extensive updating

Chapter 19—extensive updating

Chapter 20—eating disorders section expanded

Chapter 23—magnetic resonance imaging screening, hormonal treatment

Chapter 25—American Diabetic Association updates

Chapter 29—extensive updating

Chapter 34—extensive updating

Chapter 36-38—extensive updating with emphasis on improving outcomes

Chapter 42—expanded information

Chapter 45—new medications and treatment information

Chapter 46—new medications and treatment information

Chapter 47—risk factors for eustachian tube dysfunction

Chapter 53—extensive updating on pediatric immunodeficiency and other disorders

Chapter 57—reclassification of disorders according to DSM 5

You will find updated information on diagnostic tests and medical care for almost every entry. Nursing care has also been updated to reflect new treatments and best practice information.

Transitional Care

Added to this edition is the concept of transitional care, or ensuring coordination and continuity of care when a patient moves from one care setting to another, as in moving from an inpatient setting to home, or across health states such as from curative to palliative care or from pediatric care to adult care. The purpose is to

provide support during the transition and improve health outcomes. At every episode of transition, there are critical nursing assessment, intervention, and education opportunities to help facilitate the transition. In each chapter, we have included a new logo item, Transitional Care Alert, which highlights important nursing care in specific transitions.

Graphics

To streamline the book, we have removed Procedure Guidelines from the print edition. Important points from the procedures have been added to text, and Procedure Guidelines can be found in online editions. Many new figures, boxes, and tables have been added or updated.

It has been my pleasure preparing the 11th edition of the *Lippincott Manual of Nursing Practice* for you. I hope that it will serve you well in providing patient care across all settings.

Sandra M. Nettina, MSN, ANP-BC

ACKNOWLEDGMENTS

I would like to thank past and present reviewers and contributors and the entire Lippincott Williams & Wilkins team for their contribution to the *Lippincott Manual of Nursing Practice*, 11th edition. Lisa Marshall, developmental editor, has been instrumental in guiding and supporting me in this project. Lindsay Ries, editorial assistant, has been invaluable in directing the day-to-day logistics and activities behind the scenes. Bruce Hobart kept the chapters, and all of us involved, moving through production. Christine Nelson-Tuttle as my associate clinical editor provided complete oversight of the pediatric chapters and many other aspects of the project. Everyone involved has come to respect the enormity of the task and how each step affects the next. I am proud of our accomplishment.

PART ONE

NURSING PROCESS AND PRACTICE

1

Nursing Practice and the Nursing Process

Nursing Practice

Basic Concepts in Nursing Practice

Safe Nursing Care

The Nursing Process

Steps in the Nursing Process

Care Across Settings

Community and Home Health Concepts

Transitional Care

Home Health Practice

NURSING PRACTICE

Basic Concepts in Nursing Practice

Since Florence Nightingale developed the first model for nursing education in 1873, the role of the professional nurse and nursing scope of practice has evolved. Emphasis now is focused on evidence-based nursing care and preventive health practices. Understanding basic concepts in nursing practice, such as roles of nursing, theories of nursing, licensing, and legal issues, helps enhance performance.

Definition of Nursing

1. Nursing is an art and a science.
2. Earlier emphasis focused on care of the sick patient; now, the promotion of health is stressed.
3. American Nurses Association (ANA) definition (1980): Nursing is the diagnosis and treatment of the human response to actual and potential health problems.

Roles of Nursing

Whether in a hospital-based or community health care setting, nurses assume three basic roles:

1. Practitioner—involves actions that directly meet the health care and nursing needs of patients, families, and significant others; includes staff nurses at all rungs of the clinical ladder, advanced practice nurses, and community-based nurses.
2. Leader—involves actions, such as deciding, relating, influencing, and facilitating, that affect the actions of others and are directed toward goal determination and achievement; may be a formal nursing leadership role or an informal role periodically assumed by the nurse. Leadership roles may occur outside the typical nurse–patient relationship, in areas of advocacy in health policy where the focus is on improving the health of large populations of people.
3. Researcher—involves actions taken to implement studies to determine the actual effects of nursing care to further the scientific base of nursing; may include all nurses, not just academicians, nurse scientists, and graduate nursing students.

Theories of Nursing

1. Nursing theories help define nursing as a scientific discipline of its own.
2. The elements of nursing theories are uniform: nursing, patient, environment, and health—also known as the *paradigm* or *model* of nursing.
3. Nightingale was the first nursing theorist; she believed the purpose of nursing was to put the patient in the best condition for nature to restore or preserve health.
4. Theories range from broad to limited in scope.
    a. Grand nursing theories are the broadest and most abstract; they pertain to all nursing situations but are limited in directing or explaining nursing care.
    b. Middle-range nursing theories bridge grand theory with nursing practice; they can generate theoretical research and nursing practice strategies.
    c. Nursing practice theories (microrange) are limited in scope; they provide framework for nursing

interventions and predicted outcomes in specific nursing situations.

5. More recent nursing theorists include the following:
   a. Levine—nursing supports a patient's adaptation to change because of internal and external environmental stimuli.
   b. Orem—nurses assist the patient to meet universal, developmental, and health deviation self-care requisites.
   c. Roy—nurses manipulate stimuli to promote adaptation in four modes: physiologic, self-concept, role function, and interdependence relations.
   d. Leninger—model of transcultural nursing; nurses should provide culturally specific care.
   e. Pender—nurses promote healthy behavior through a preventive model of health care.
   f. Rogers—nurses promote harmonious interaction between the patient and environment to maximize health; both are four-dimensional energy fields.
6. In recent years, the priority of interprofessional care has resulted in many nursing research initiatives to utilize other health care theories not specifically designated as nursing theorists.

Nursing in the Health Care Delivery System

1. Technology, education, society values, demographics, and health care financing all have an impact on where and how nursing is practiced.
   a. As the population ages, chronic disease rates rise and health care utilization increases.
   b. Chronic diseases are responsible for 7 of 10 deaths each year, and treating people with chronic diseases accounts for 86% of health care costs in the United States.
   c. The World Economic Forum estimates that chronic diseases account for almost two thirds of all deaths worldwide—and 80% of these now occur in low- and middle-income countries. By 2030, more people in these countries will die from heart attacks and strokes than from infectious diseases.
2. Health promotion and prevention strategies such as immunizations, health education, and screening tests aimed at reducing the incidence of infectious disease, injuries, and chronic illness save health care dollars and improve well-being. Nurses are well prepared for implementing health promotion strategies.
3. A nursing faculty shortage may challenge the ability of nursing to meet the needs of the expanded patient population.
   a. US nursing schools turned away almost 70,000 qualified applicants from baccalaureate and graduate nursing programs in 2014 because of an insufficient number of faculty, clinical sites, classroom space, clinical preceptors, and budget constraints.
   b. Almost two thirds of the nursing schools report faculty shortages as a reason for not accepting all qualified applicants into baccalaureate programs.
4. Advanced practice nurses are utilized as primary care and acute care providers because of a shortage of physicians. The Institute of Medicine 2010 report "The Future of Nursing" called for removal of regulatory barriers so nurses could practice to the full extent of their education and scope of practice.

Advanced Practice Nursing

1. Registered professional nurses with advanced training, education, and certification are allowed to practice in expanded scope.
2. This includes nurse practitioners, nurse-midwives, nurse-anesthetists, and clinical nurse specialists.
3. Scope of practice and legislation vary by state.
    a. Clinical nurse specialists are included in advanced practice nurse (APN) legislation in at least 27 states (some of these include only psychiatric/mental health clinical nurse specialists).
    b. Nurse practitioners have some type of prescriptive authority in all 50 states and the District of Columbia.
    c. In most cases, nurse practitioners are now eligible for Medicare reimbursement across the United States at 85% of the physician fee schedule and are eligible for Medicaid reimbursement in most states.
    d. Many states give full practice authority to APNs through the board of nursing with no requirement for physician oversight or collaboration required.
4. Master's degree preparation is the current requirement for most APN roles; however, many certificate programs have trained APNs in the past 40 years. In addition, doctoral programs are becoming increasingly desired, with emphasis on the practice role of APNs.
5. In Canada and other countries, the growth of the number of APNs in practice has been slower than in the United States, except for midwives in many cases.

Licensing, Certification, and Continuing Education

1. Every professional registered nurse must be licensed through the state board of nursing in the United States to practice in that state or the College of Nursing to practice in a Canadian province.
2. Although the state primarily regulates and restricts practice, the framework for scope of practice actually depends on a four-tier hierarchy: (1) the ANA Scope and Standards for Nursing Practice, (2) the particular state Nurse Practice Act, (3) the facility policies and procedures where the nurse is practicing, and (4) the nurse with her or his individual self-determination and competencies. Indeed, it is the nurse's responsibility to maintain competency and practice within the appropriate scope.
3. Continuing education requirements vary depending on state laws, facility policies, and area of specialty practice and certification. Continuing education units can be obtained through a variety of professional nursing organizations and commercial educational services.
4. Many professional nursing organizations exist to provide education, certification, support, and communication among nurses; for more information, contact your state nurses' association, state board of nursing, or the ANA, 8515 Georgia Avenue, Suite 400, Silver Spring, MD 20910, 800-274-4ANA, *www.nursingworld.org* .
5. Nursing curriculum and the nursing role have expanded to meet the demands of an aging, chronically ill population, advanced technology in the acute care setting, and expanding preventive strategies and community-based care to promote a healthier population. A wide variety of certifications offered through

the American Nurses Credentialing Center (*www.nursecredentialing.org*) acknowledge advanced preparation of nurse practitioners, clinical nurse specialists, home health nurses, case management nurses, and many other specialties.

Management/Leadership in Nursing

1. There is a need to transform the health care workplace to better provide optimal health care to all patients. The transformation of health care will require nurses educated and actively using interprofessional collaborative processes, translation of knowledge, and motivation into the highest level of nursing care performance.
2. The Doctor of Nursing Practice (DNP) was introduced in 2005 to ensure that nursing can meet the demands of the changing health care system with the highest level of scientific knowledge and practice expertise.
    a. The American Association of Colleges of Nursing has proposed that the DNP replace the master's degree as preparation for advanced practice nursing; however, this is still up for debate.
    b. There are almost 300 DNP programs in the United States and more than 100 developments.
3. A recent addition to the certification arena is that of the clinical nurse leader, which has a master's degree requirement. It is defined as a nursing generalist whose role is to improve the quality of nursing care. The clinical nurse leader provides direction at the point of care, collaborates with the health care team, provides risk assessment, and implements quality improvement strategies based on evidence-based practice.
4. Challenges will exist in translating educational concepts in management and leadership into effective and relevant practices used by individuals in health care teams.

Safe Nursing Care

Patient Safety

1. Adequate nursing staffing is essential to reduce nurses' dissatisfaction, burnout, and high turnover rates, as well as reduce patient mortality. Studies have linked inadequate staffing to increased patient mortality.
   a. A recent retrospective observation study at a Magnet hospital identified an average patient exposed to three nursing shifts with below staffing resulted in 6% higher risk of mortality than patients with no below-target mortality.
   b. The American Nursing Association campaign, "Safe Nursing Saves Lives," advocates that hospitals set staffing levels on each unit based on patient acuity, number of patient, nursing skills, support staff, and technology (*http://www.nursingworld.org/MainMenuCategories/ThePracticeofProfessionalNursing/NurseStaffing*).

EVIDENCE BASE Lee, S., & Scott, L. (2018). Hospital nurses' work environment characteristics and patient safety outcomes: A literature review. *Western Journal of Nursing Research, 40*(1), 121–145.

---

2. The Institute of Medicine (IOM) of the National Academies has focused on deficient health care systems as the cause of medical errors that are preventable and result in more than 50% of adverse events and patient deaths. The IOM offers recommendations for improving systems and processes in health care organizations to ultimately improve patient safety. For more information, refer to the website *www.iom.edu* .
3. The Agency for Healthcare Research and Quality has compiled a wide array of patient safety literature as a resource for all types of health care providers and settings, available at *http://psnet.ahrq.gov/default.aspx* .
4. The Joint Commission is also committed to improving safety for patients in health care organizations. The National Patient Safety Goals were implemented in 2003 to help address specific concerns for patient safety by health care setting, including ambulatory care, long-term care, behavioral health care, home care, hospital, laboratory services, and office-based surgery. New goals are introduced yearly with suggested performance measures to meet the goals. These are available at *www.jointcommission.org/standards_information/npsgs.aspx* . See Box 1-1 for selected National Patient Safety Goals.

BOX 1-1 National Patient Safety Goals: Hospital Program

Use at least two patient identifiers when providing care, treatment, and services.

Ensure the correct patient gets the correct blood when they get a blood transfusion.

Report critical results of tests and diagnostic procedures on a timely basis.

Label all medications, medication containers, and other solutions on and off the sterile field in perioperative

and other procedural settings.

Reduce the likelihood of patient harm associated with the use of anticoagulant therapy.

Make improvements to ensure that alarms on medical equipment are heard and responded to in a timely manner.

Maintain and communicate accurate patient medication information.

Comply with either the current Centers for Disease Control and Prevention (CDC) hand hygiene guidelines or the current World Health Organization (WHO) hand hygiene guidelines.

Implement evidence-based practices to prevent health care–associated infections because of multidrug-resistant organisms in acute care hospitals.

Implement evidence-based practices to prevent central line–associated bloodstream infections.

Implement evidence-based practices for preventing surgical site infections.

Implement evidence-based practices to prevent indwelling catheter-associated urinary tract infections (CAUTI).

Identify patients at risk for suicide.

Conduct a preprocedure verification process.

Mark the procedure site.

A time-out is performed before the procedure.

---

*See *www.jointcommission.org/assets/1/6/NPSG_EPs_Scoring_HAP_20110706.pdf* for elements of performance.
https://www.jointcommission.org/standards_information/npsgs.aspx.

Personal Safety

1. Nurses may be at risk for personal harm in the workplace. The ANA has sponsored initiatives to improve nurses' personal safety. The Position Statement: Risk and Responsibility in Providing Nursing Care acknowledges that there may be limits to the personal risk a nurse can assume in providing care in any clinical setting.
2. The Centers for Disease Control and Prevention estimates that 380,000 health care workers are injured by needles and other sharps each year, increasing the risk of hepatitis B, hepatitis C, and human immunodeficiency virus. Nurses sustain the largest percentage of these injuries. The ANA's "Safe Needles, Save Lives" (*www.needlestick.org*) campaign was key in promoting the use of safety devices. Nurses and other health care workers are protected by the Needlestick Safety and Prevention Act (P.L. 106-430), which requires health care organizations to use needleless or shielded-needle devices, obtain input from clinical staff in the evaluation and selection of devices, educate staff on the use of safety devices, and have an exposure control plan.
3. The physical work environment, which includes patient-handling tasks such as manual lifting, transferring, and repositioning patients, can also place nurses at risk for musculoskeletal disorders such as back injuries and shoulder strains. The ANA's "Handle with Care" campaign (*www.nursingworld.org/handlewithcare*) aims to prevent such injuries and to promote safe patient handling through the use of technology and assistive patient-handling equipment and devices.

Culturally Competent Care

EVIDENCE BASE Darnell, L., & Hickson, S. (2015). Cultural competent patient-centered nursing care. *Nursing Clinics of North America, 50*(1), 99–108.

The changing demographics of the United States, Canada, the United Kingdom, and other countries bring a diverse array of individuals with varying cultures and beliefs into nursing practice. Nurses must provide culturally competent care by expanding their knowledge about different cultures. Cultural competence involves learning a new set of attitudes, behaviors, and skills to help the nurse provide care effectively in cross-cultural situations. See Box 1-2, Standards of Practice for Culturally Competent Nursing Care. The Transcultural Nursing Society (TCNS) was founded in 1975 by Madeleine Leininger with a focus on human caring. Culturally congruent and competent care results in improved health and well-being for people worldwide. TCNS offers a peer-reviewed evidence-based journal, educational courses, and many other resources to provide information about the values, beliefs, and traditions of various cultures (*www.tcns.org*). However, the nurse must always use caution and avoid generalizing and stereotyping patients. Culturally competent care begins with an individualized patient assessment, including the patient's own definition of health and expectations for care. Based on this assessment and application of a set of standards, the nurse can develop an individualized care plan.

BOX 1-2 Transcultural Nursing Standards of Practice

1. **Social Justice:** Professional nurses shall promote social justice for all. The applied principles of social justice guide decisions of nurses related to the patient, family, community, and other health care professionals. Nurses will develop leadership skills to advocate for socially just policies.
2. **Critical Reflection:** Nurses shall engage in critical reflection of their own values, beliefs, and cultural heritage to have an awareness of how these qualities and issues can impact culturally congruent nursing care.
3. **Transcultural Nursing Knowledge:** Nurses shall gain an understanding of the perspectives, traditions, values, practices, and family systems of culturally diverse individuals, families, communities, and populations for whom they care, as well as knowledge of the complex variables that affect the achievement of health and well-being.
4. **Cross-Cultural Practice:** Nurses shall use cross-cultural knowledge and culturally sensitive skills in implementing culturally congruent nursing care.
5. **Health Care Systems and Organizations:** Health care organizations should provide the structure and resources necessary to evaluate and meet the cultural and language needs of their diverse clients.
6. **Patient Advocacy and Empowerment:** Nurses shall recognize the effect of health care policies, delivery systems, and resources on their patient populations and shall empower and advocate for their patients as indicated. Nurses shall advocate for the inclusion of their patient's cultural beliefs and practices in all

dimensions of their health care when possible.

7. **Multicultural Workforce:** Nurses shall actively engage in the effort to ensure a multicultural workforce in health care settings. One measure to achieve a multicultural workforce is through strengthening of recruitment and retention effort in the hospital and academic setting.
8. **Education and Training:** Nurses shall be educationally prepared to promote and provide culturally congruent health care. Knowledge and skills necessary for ensuring that nursing care is culturally congruent shall be included in global health care agendas that mandate formal education and clinical training, as well as required ongoing, continuing education for all practicing nurses.
9. **Cross-Cultural Communication:** Nurses shall use culturally competent verbal and nonverbal communication skills to identify client's values, beliefs, practices, perceptions, and unique health care needs.
10. **Cross-Cultural Leadership:** Nurses shall have the ability to influence individuals, groups, and systems to achieve positive outcomes of culturally competent care for diverse populations.
11. **Policy Development:** Nurses shall have the knowledge and skills to work with public and private organizations, professional associations, and communities to establish policies and standards for comprehensive implementation and evaluation of culturally competent care.
12. **Evidence-Based Practice and Research:** Nurses shall base their practice on interventions that have been systematically tested and shown to be the most effective for the culturally diverse populations that they serve. In areas where there is a lack of evidence of efficacy, nurse researchers shall investigate and test interventions that may be the most effective in reducing the disparities in health outcomes.

THE NURSING PROCESS

The nursing process is a deliberate, problem-solving approach to meeting the health care and nursing needs of patients. It involves assessment (data collection), nursing diagnosis, planning, implementation, and evaluation, with subsequent modifications used as feedback mechanisms to promote the resolution of the nursing diagnoses. The process as a whole is cyclical, with the steps being interrelated, interdependent, and recurrent.

Steps in the Nursing Process

Assessment—systematic collection of data to determine the patient's health status and to identify any actual or potential health problems. (Analysis of data is included as part of the assessment. For those who wish to emphasize its importance, analysis may be identified as a separate step of the nursing process.)

Nursing diagnosis—identification of actual or potential health problems that are amenable to resolution by nursing actions.

Planning—development of goals and a care plan designed to assist the patient in resolving the nursing diagnoses.

Implementation—actualization of the care plan through nursing interventions or supervision of others to do the same.

Evaluation—determination of the patient's responses to the nursing interventions and of the extent to which the goals have been achieved.

Assessment

1. The nursing history.
    a. Subjective data obtained by interviewing the patient, family members, or significant other and reviewing past medical records.
    b. Provides the opportunity to convey interest, support, and understanding to the patient and to establish a rapport based on trust.
2. The physical examination.
    a. Objective data obtained to determine the patient's physical status, limitations, and assets.
    b. Should be done in a private, comfortable environment with efficiency and respect.

Nursing Diagnosis

EVIDENCE BASE Herdman, H., & Kamitsuru, S. (2018). *NANDA Nursing Diagnoses: Definitions and classifications, 2018–2020, 11th ed.* New York: Thieme.

---

1. The process of making a clinical judgment about experiences or responses to health problems or life processes, based on an individual, family, or community and done through patient assessment rather than picked from a list of medical diagnoses.
2. Used to determine the appropriate plan of care (ie, to select nursing interventions that will achieve desired outcomes).
3. Nursing diagnoses are based on the NANDA International taxonomy, which is a standardized nursing language that includes evidence-based definitions, defining characteristics, and etiologic factors.
    a. Nursing diagnoses continue to be developed and refined by NANDA International and the

University of Iowa Center for Nursing Classification and Clinical Effectiveness.

b. There are currently 235 nursing diagnoses grouped in 13 domains (see Box 1-3). Nursing diagnoses are listed throughout this book associated with medical diagnoses and other health conditions, but in reality, nursing diagnoses are formulated through individualized patient assessment.

Planning

See Nursing Care Plan 1-1 (page 7).

NURSING CARE PLAN 1-1

Example of a Nursing Care Plan

Mr. John Preston, a 52-year-old businessperson, was admitted with chest pain; rule out myocardial infarction. He had experienced substernal chest pain and weakness in his arms after having lunch with a business associate. The pain had lessened by the time he arrived at the hospital. The nursing history revealed that he had been hospitalized 5 months previously with the same complaints and had been told by his physician to go to the emergency department if the pain ever recurred. He had been placed on a low-fat diet and had stopped smoking. Physical examination revealed that Mr. Preston's vital signs were within normal limits. He stated that he had feared he was having a "heart attack" until his pain subsided and until he was told that his electrocardiogram was normal. He verbalized that he wanted to find out how he could prevent the attacks of pain in the future. The physician's orders on admission included activity as tolerated, low-cholesterol diet, and nitroglycerin 0.4 mg (1/500 g) sublingually as needed.

NURSING DIAGNOSIS

Acute Pain related to angina pectoris/rule out myocardial ischemia

GOAL

Short-term: Relief of pain.

Intermediate: Inclusion of healthy lifestyle measures that decrease myocardial ischemia.

Long-term: Compliance with therapeutic regimen.

Expected Outcomes	Nursing Intervention	Critical Time*	Actual Outcomes (Evaluation)
• Blood pressure (BP), pulse (P), and respiration (R) will remain within normal limits.	Monitor BP, P, R q4h.	24 h	• BP: stable at 116 to 122/72 to 84 • P: stable at 68 to 82 • R: stable at 16 to 20
• Patient will remain free from chest pain.	Assess frequency of chest pain and precipitating events.	24 h	• Denies chest pain; able to walk length of hall, eat meals, and visit with family and friends without chest discomfort.
• Will tolerate dietary regimen. • Will not experience chest pain after meals. • Will maintain normal bowel elimination. • Will have intake of 1,500 to 2,000 mL fluid/day.	Encourage food and fluid intake that promotes healthy nutrition, digestion, and elimination and that does not precipitate chest pain: light, regular meals; foods low in cholesterol; 1,500 to 2,000 mL fluid/day.	24 h	• Denies chest pain after meals; no constipation or diarrhea; fluid intake 1,700 to 2,100 mL/day.
• Will identify foods low in cholesterol and those foods that are to be avoided. • Will select well-balanced diet within prescribed restrictions.	Request consultation with dietitian. Reinforce diet teaching.	48 h	• Dietitian reviewed diet restrictions with patient and wife; wife counseled in meal planning. Patient selects and eats a balanced diet consisting of foods low in cholesterol.
• Will identify activities and exercises that could precipitate chest pain: those that require sudden bursts of activity and heavy effort. • Will identify emotionally stressful situations; will explain the necessity for alternating periods of activity with periods of rest.	Encourage alterations in activities and exercise that are necessary to prevent episodes of anginal pain.	48 h	• Patient and wife have identified activities and situations that should be avoided; patient and wife have studied their usual daily routine and have made plans to alter the routine to allow for rest periods; teenage son has volunteered to assist with strenuous home maintenance chores.
• Will describe action, use, and correct administration of nitroglycerin.	Teach about nitroglycerin regimen.	24 h	• Patient has accurately stated action, use, and dosage of nitroglycerin; demonstrated correct administration.

*These times have not been standardized but are individualized according to the patient's needs.

EVIDENCE BASE De Carvalho, E., Eduardo, A., Romanzini, A., Simao, T., Zamarioli, C., Garguio, D., & Herdman, T. (2018). Correspondence between NANDA international nursing diagnoses and outcomes as proposed by the nursing outcomes classification. *International Journal of Nursing Knowledge*, 29(1), 66–78.

1. Assign priorities to the nursing diagnoses. Highest priority is given to problems that are the most urgent and critical.
2. Establish goals or expected outcomes derived from the nursing diagnoses.

a. Specify short-term, intermediate, and long-term goals as established by nurse and patient together.
b. Goals should be specific, measurable, and patient-focused and should include a time frame.
c. The Nursing Outcomes Classification developed by the University of Iowa College of Nursing Center is a comprehensive, standardized nursing language of outcomes used to evaluate the effects of nursing interventions. Each of the approximately 490 outcomes includes a list of indicators and is linked to NANDA I nursing diagnoses.

3. Identify nursing interventions as appropriate for goal attainment.
   a. An intervention is defined as any treatment, based on clinical judgment and knowledge, that a nurse performs to enhance patient/client outcomes.
   b. Include independent nursing actions as well as collaborative interventions based on medical orders.
   c. Should be detailed to provide continuity of care.
   d. Nursing Interventions Classification (NIC) is a standardized language describing treatments performed by nurses in all settings and specialties. More than 550 NIC interventions have been developed through the University of Iowa College of Nursing. NIC is organized into 30 classifications and 7 domains and includes physiologic and psychosocial interventions as well as interventions for illness prevention and treatment. NIC interventions serve a role in documentation, possibly coding, and reimbursement for nursing care in the future.
4. Formulate the nursing care plan. The nursing care plan may be a component of the interdisciplinary/collaborative care plan for the patient.
   a. Include nursing diagnoses, expected outcomes, interventions, and a space for evaluation.
   b. May use a standardized care plan—check off appropriate data and fill in target dates for expected outcomes and frequency and other specifics of interventions.
   c. May use a protocol that gives specific sequential instructions for treating patients with a particular problem, including who is responsible and what specific actions should be taken in terms of assessment, planning, interventions, teaching, recognition of complications, evaluation, and documentation.
   d. May use a care path or clinical pathway (also called *care map* or *critical pathway*) in which the nurse as case manager is responsible for outcomes, length of stay, and use of equipment during the patient's illness; includes the patient's medical diagnosis, length of stay allowed by diagnostic-related group (DRG), expected outcomes, and key events that must occur for the patient to be discharged by that date. Key events are not as specific as nursing interventions but are categorized by day of stay and who is responsible (nurse, physician, other health team member, patient, family).
   e. May also use a computerized care plan that is based on assessment data and allows for the selection of nursing interventions and establishment of expected outcomes.
   f. Nursing concept maps are similar and may be used to plan and prioritize care.

Implementation

1. Coordinate activities of patient, family, significant others, nursing team members, and other health team

members.

2. Delegate specific nursing interventions to other members of the nursing team as appropriate.
    a. Consider the capabilities and limitations of the members of the nursing team.
    b. Supervise the performance of nursing interventions.
3. Record the patient's responses to nursing interventions precisely and concisely.

Evaluation

Determines the success of nursing care and the need to alter the care plan.

1. Collect assessment data.
2. Compare patient's actual outcomes to expected outcomes to determine to what extent goals have been achieved.
3. Include the patient, family, or significant other; nursing team members; and other health team members in the evaluation.
4. Identify alterations that need to be made in the goals and the nursing care plan.

Continuation of the Nursing Process

1. Continue all steps of the nursing process: assessment, nursing diagnosis, planning, implementation, and evaluation.
2. Continuous evaluation provides the means for maintaining the viability of the entire nursing process and for demonstrating accountability for the quality of nursing care rendered.

CARE ACROSS SETTINGS

Community and Home Health Concepts

The home care nurse functions in the home and community, outside the walls of health care facilities. The role is more independent, and the basic concepts of home health are different from hospital or outpatient nursing. With the emphasis on promoting patients quickly from the acute care settings to care in the home, descriptions and requirements for community health nurses have evolved. Theses nurses may work with one specific population based on care needs or developmental stages (wound care, pediatric patients) or care through all stages and nursing needs. Although some nurses focus on individual patients (and their families or support persons), some nurses focus on improving the overall health of an entire population of persons.

Roles and Duties of the Home Care Nurse

1. The home care nurse maintains a comprehensive knowledge base of the health of the patient.
2. The home care nurse performs an extensive evaluation of the patient's medical history, physical condition, psychosocial well-being, living environment, and support systems.
3. The home care nurse functions independently, recommending to the primary or specialty health care provider what services are needed in the home.
4. The home care nurse coordinates the services of other disciplines, such as physical therapy, occupational therapy, nutrition, and social work.
5. The home care nurse oversees the entire treatment plan and keeps the health care provider apprised of the patient's progress or lack of progress toward goals.
6. The home care nurse acts as a liaison between patient, family, caregivers, and the primary health care provider and other members of the health care team.
7. The home care nurse may function as supervisor of home health aides who provide direct daily care for the patient.
8. The home care nurse must honor the same patient rights as a health care facility.

Skills for Home Care Nursing

1. Good rapport building—to engage the patient, family, and caregivers in goal attainment.
2. Clear communication—to provide effective teaching to family and caregivers, to relate assessment information about the patient to the health care provider, and to share information with the home care team.
3. Flexibility—ability to care for a variety of patients in diverse home care settings with multiple health care conditions requiring nursing care.
4. Cultural competence—knowledge and appreciation of the cultural norms being practiced in the home. Cultural practices may affect family structure, communication, and decision-making in the home; health beliefs, nutrition, and alternative health practices; and spirituality and religious beliefs.
5. Accurate documentation—record keeping in home care is used for reimbursement of nursing services, accreditation and regulatory review, and communication among the home care team.

Reimbursement Issues

1. Skilled home health services are reimbursed by Medicare, Medicaid, and a variety of commercial insurances and managed care plans.
2. In recent years, many health care services have changed from reimbursement from volume-based reimbursement to more focus on outcomes.
3. Some patients are willing to pay out of pocket for additional services not covered by insurance because of the well-established value of home care services compared with more expensive hospital and nursing home services.
4. Services are reimbursed by Medicare Part A if they meet the following criteria:
    a. Need is documented in a face to face visit by a health care provider; plan of care must be signed by a physician.
    b. Services are intermittent or needed on a part-time basis.
    c. The patient is homebound.
    d. The services required are skilled (need to be provided by a licensed nurse, physical therapist, or speech therapist or by an occupational therapist, social worker, or home health aide along with the service of a nurse).
    e. The services requested are reasonable and medically necessary.
5. The home health nurse must evaluate the case and ensure that these criteria apply. This information must be documented so reimbursement will not be denied.

Transitional Care

Transitional care is the concept of ensuring coordination and continuity of care when a patient moves from one care setting to another. This may include between settings such as acute care hospital to skilled nursing facility or from an inpatient setting to home. It may also occur across levels of care within a setting such as from an intensive care unit to general medical unit or across health states such as from curative to palliative care or from pediatric care to adult care. The purpose is to provide support during the transition and improve health outcomes.

1. Patients experiencing a care transition experience a period of vulnerability that may contribute to high rate of health care services with potential adverse outcomes.
2. Transitional care services are a set of actions, essentially time-limited, which are added to usual care or primary care services that are designed to ensure health care continuity and best possible outcomes for at-risk populations.
3. At-risk individuals, particularly the elderly and those with chronic disease, may experience physical, emotional, and behavioral barriers to receiving optimal quality and safe care.
4. Transitional care services include logistical arrangements, education of the patient and family, and coordination among the health professionals.
5. Current transitional care programs are designed to reduce 30-day hospital readmission rates to save health care system dollars.

Home Health Practice

The nursing process is carried out in home care as it is in other nursing settings. Patient interactions are structured differently than in the hospital because the nurse will interact with the patient intermittently and in the intimate home environment. Many procedures and nursing interventions are implemented in a similar manner as other nursing settings, as outlined in the rest of this book. Major concerns of the home care nurse are patient teaching, infection control, and safety maintenance.

The Home Care Visit

1. The initial home care visit should be preceded by information gathering and an introductory phone call to the patient.
2. Extensive assessment is carried out at the first visit, including complete medical and psychosocial history, physical examination, home environment assessment, nutritional assessment, medication review, and current treatment plan review.
3. Once assessment (gathered from multiple sources) is complete, nursing diagnoses are formed. The plan of care must be adaptable to the specific home dynamics.
4. Outcome planning (goal setting) is done with the patient, family, and caregivers involved.
5. The plan is implemented over a prescribed time period (the certified period of service). Interventions may be:
    a. Cognitive—involves patient teaching.
    b. Psychosocial—reinforces coping mechanisms, supports caregivers, and reduces stress.
    c. Technical—entails procedures, such as wound care and catheter insertion.
6. Evaluation is ongoing at every visit and by follow-up phone calls to adjust and refine the care plan and frequency of service.
7. Recertification for continued service, discharge, or transfer (to a hospital or nursing home) ultimately occurs.

Patient Teaching

1. Patient teaching is directed toward the patient, family, caregivers, and involved significant others.
2. Patient teaching is usually considered skilled and is therefore reimbursable. Topics may include the following:
    a. Disease process, pathophysiology, and signs and symptoms to monitor treatment.
    b. Administration of injectable medication or complex regimen of oral medications.
    c. Diabetic management for a patient newly diagnosed with diabetes.
    d. Wound or ostomy care.
    e. Catheterization.
    f. Gastrostomy and enteral feedings.
    g. Management of peripheral or central intravenous catheters.

h. Use of adaptive devices for carrying out activities of daily living and ambulation.
i. Transfer techniques and body alignment.
j. Preparation and maintenance of therapeutic diet.

3. Barriers to learning should be evaluated and removed or compensated for.
   a. Environmental barriers, such as noise, poor lighting, and distractions.
   b. Personal barriers, such as sensory deficits, poor reading skills, and drowsiness.
4. The teaching plan should include the three domains of learning:
   a. Cognitive—sharing of facts and information.
   b. Affective—addressing the patient's feelings about the disease and treatment.
   c. Psychomotor—discussing performance of desired behavior or steps in a procedure.
5. Documentation of patient teaching should be specific and include the degree of patient competence of the procedure.
6. Patient teaching plans may include review of teaching started in the hospital and may take several sessions to implement successfully.
7. Patient teaching plans should include significant support persons (family or other persons important to the patient) who will assist the patient in obtaining or maintaining optimal health outcomes.

Infection Control

1. Nosocomial infection rates are much lower in home care, but patients are still at risk for infection because of weakened immune systems and the variability of a clean or sterile environment at home.
2. The nurse should assess and maintain a clean environment.
   a. Make sure that clean or sterile supplies are readily available when needed.
   b. Make sure that contaminated supplies are disposed of promptly and properly.
      i. Needles should be disposed of in a safe and secure container (usually kept in the home [until full]), which can be disposed of through the home health agency or the patient's pharmacy.
      ii. Supplies, such as dressings, gloves, and catheters, should be securely bagged and disposed of in small amounts through the regular trash collection at the patient's home. However, biohazardous waste disposal may be necessary in some cases.
3. The nurse should be aware of all methods of transmission of infection and implement and teach preventive practices.
4. The nurse must perform ongoing assessment for signs and symptoms of infection and teach the patient, family, and caregivers what to look for.
5. The nurse should be aware of community-acquired infections that may be prevalent in certain populations, such as tuberculosis, human immunodeficiency virus infection, hepatitis, and sexually transmitted diseases.
   a. Teach preventive practices.
   b. Encourage and institute screening programs.

c. Report infections according to the local public health department policy.

6. Encourage and provide vaccination for the patient and household contacts for influenza, pneumococcal pneumonia, hepatitis B, and others as appropriate.

NURSING ALERT Above all else, model and teach good hand-washing practice to everyone in the home.

Ensuring Safety

1. Continually assess safety in the home, particularly if the patient is very ill and the care plan is complex.
2. Assess for environmental safety issues—cluttered spaces, stairs, throw rugs, slippery floors, poor lighting.
3. Assess for the patient's personal safety issues—sensory deficits, weakness, problems with eating or swallowing.
4. Assess safety in the bathroom—handrails, bath mat, raised toilet seat, water temperature.
5. Assess safety in the kitchen—proper refrigeration of food, ability to shop for and cook meals, oven safety.
6. Be alert for abuse and neglect, especially of children, dependent elders, and women.
7. Check equipment for electrical and fire safety and that it is being used properly.
8. Be continually cognizant of your own safety—get directions, travel during daylight hours, wear seat belts, do not enter suspicious areas without an escort, be alert to your surroundings.

INTRODUCTION

Professional nurses occupy the front lines of the health care arena. So it is no surprise that nurses are members of the health care team patients trust most with their health and welfare. Along with this privilege, nurses carry equal duties of responsibility and accountability to follow ethical principles and standards of care integral to the profession. Continued efforts must be made from within the profession to systematically and deliberately apply evidence-based research data to daily practice, thereby increasing patient safety, improving outcomes, and reducing harm and adverse events. Transformation of the professional culture within the health care system gives nurses at the bedside the incentive to join in these efforts as full partners with colleagues in health care. Additional measures might include protocol implementation, preceptor performance review, peer review, continuing education, patient satisfaction surveys, and the implementation of risk management techniques. However, in certain instances, either despite or in the absence of such internal mechanisms, claims are made for an alleged injury or alleged malpractice liability. Although the vast majority of claims may be without merit, many professional nurses may have to cope with the unfamiliar legal system. Application of ethical principles and standards of care will be beneficial to prevent such situations. Therefore, it is preferable for the nursing profession to incorporate ethical and legal principles and protocols in daily practice to assure patient safety and excellent standards of patient care.

ETHICAL CORE CONCEPTS

Clinical ethics literature identifies four principles and values that are integral to the professional nurse's practice: the nurse's ethical duty to respect the patient's autonomy and to act with beneficence, nonmaleficence, and justice.

Respect for the Individual and Autonomy

1. Respect for the individual's autonomy incorporates principles of freedom of choice, self-determination, and privacy.
2. The professional nurse's duty is to view and treat each individual as an autonomous, self-determining person with the freedom to act in accordance with self-chosen, informed goals, as long as the action does not interfere or infringe on the autonomous action of another.
3. Numerous institutions and health care organizations have developed patient rights statements and policies that impact nursing care.
   a. The National League of Nursing (NLN) has developed an Education Competencies Model for all educational levels of nursing, which names the core values as caring, diversity, ethics, excellence, holism, integrity, and patient centeredness.
   b. The American Nurses Association (ANA) has developed and updated a Code of Ethics for Nurses, which states, "The nurse in all professional relationships practices with compassion with respect for the inherent dignity, worth, and uniqueness of every individual, unrestricted by considerations of social or economic status, personal attributes, or the nature of health problems."

EVIDENCE BASE National League of Nursing. (2015). *The NLN education competencies model.* New York, NY: Author.

American Nurses Association. (2015). *Code of ethics for nurses with interpretive statements (code for nurses).* Silver Spring, MD: Author.

Beneficence

The principle of beneficence affirms the inherent professional aspiration and duty to help promote the well-being of others and, often, is the primary motivating factor for those who choose a career in the health care profession. Health care professionals aspire to help people achieve a better life through an improved state of health.

Nonmaleficence

1. The principle of nonmaleficence complements beneficence and obligates the professional nurse not to harm the patient directly or with intent.
2. In the health care profession, this principle is often actualized with the complementary principle of beneficence because it is common for the nurse to cause pain or expose the patient to risk of harm when such actions are justified by the benefits of the procedures or treatments.
3. It is best to seek to promote a balance of potential risk-induced harms with benefits, with the basic guideline being to strive to maximize expected benefits and minimize possible harms. Therefore, nonmaleficence should be balanced with beneficence.

Justice

1. Justice, or fairness, relates to the distribution of services and resources.
2. As the health care dollar becomes increasingly scarce, justice seeks to allocate resources fairly and treat patients equally.
3. Dilemmas arise when resources are scarce and insufficient to meet the needs of everyone. How do we decide fairly who gets what in such situations?
4. One might consider whether it is just or fair for many people not to have funding or access to the most basic preventive care, whereas others have insurance coverage for expensive and long-term hospitalizations.
5. Along with respect for people and their autonomy, the complex principle of justice is a culturally accepted principle in countries such as the United States. Nonetheless, the application of justice is complex and often challenging.

ETHICAL DILEMMAS

Conflicting Ethical Principles

1. Ethical dilemmas arise when two or more ethical principles are in conflict.
2. Such dilemmas can best be addressed by applying principles on a case-by-case basis once all available data are gathered and analyzed.
3. Clinicians should network with their colleagues and consider establishing multidisciplinary ethics committees to provide guidance.

Ethics Committees

1. Ethics committees identify, examine, and promote resolution of ethical issues and dilemmas and strive to:
   a. Protect the patient's rights.
   b. Protect the staff and the organization.
   c. Review decisions regarding clinical standards of practice and policy development.
   d. Improve the quality of care and services.
   e. Serve as educational resources to staff.
   f. Build a consensus on ethical issues with other professional organizations.
2. Addressing and resolving ethical dilemmas is usually a challenging decision shared with the clinical staff.

Examples of Ethical Dilemmas and Possible Responses

Unsafe Nurse-to-Patient Ratio

1. A pattern of unsafe nurse-to-patient ratio can be caused by temporary or long-term staffing problems.
2. A series of actions to best resolve the problem may include the following:
    a. Address the unsafe situation verbally and in writing to the unit charge nurse with copies to the nursing supervisor.
    b. Work up the administrative chain of command as indicated.
    c. This will likely prompt action by the facility, such as creating an as-needed pool of nurses to call for such situations, hiring more staff, or, in the interim, securing contracts with outside nursing agencies and utilizing agency nursing personnel.
3. Tolerance by staff nurses employed under such circumstances will preclude appropriate resolution and will leave the nurse open to unsafe practice and unmet patient needs, potentially increasing the risk of liability.
4. Although the employer is liable for the acts of the employee performed within the scope of employment, the nurse will not be exonerated should a patient's care be compromised in a setting of an unsafe nurse-to-patient ratio.

Nonresponse by Physician

1. A patient arrives to the rehabilitation unit at 9 P.M. with numerous positive criteria for falling, including poor short-term memory, daily use of a diuretic, daily use of a sleep aid, a history of a fall within the preceding 2 months, and known vision impairment.
    a. Patient is oriented to time, place, and person, his new room, facility bed, and call light use.
    b. The nurse instructs patient to summon her if he needs to void or otherwise get out of bed, at least until he becomes familiar with his new environment.
    c. Upon returning to patient's room 10 minutes later, the nurse finds patient out of bed, arranging his clothes in his closet, standing in a pool of urine on the floor.
    d. The nurse weighs the risks and benefits of restraint use and determines whether alternatives are available. She calls the physician for a restraint order if patient continues to jeopardize his safety. The nurse intends to ask the physician for an order with clear specification of the least restrictive method of restraint, the duration, circumstances, frequency of monitoring, and reevaluation if it differs from facility policy. However, the physician does not return her calls.
    e. The nurse documents her initial assessment of the patient, her nursing diagnoses, the orientation to room and equipment provided to the patient, the circumstances wherein she found the patient out of bed, and her repeated messages for the physician and the lack of a return telephone call.
2. Again, a series of actions may resolve the problem or at least prevent injury to the patient. Address this situation with intermediate measures while waiting for the physician's return call:
    a. Raise side rails on the patient's bed.

b. Move patient to a room close to the nurse's station.
c. Place a sign on patient's room door and above the bed identifying him as being at risk for falling.
d. Place a sign above the bed instructing personnel to raise the bed's side rails fully before leaving patient's room.
e. Check on the patient frequently during the first 24 hours, reminding him of the call light, its use, and the need to call the nurse before getting out of bed.
f. If available, assign a patient care technician to stay with the patient.

3. Call the patient's family, advising them of your concern about the patient's safety, and discuss the issue of restraints with them. Discuss the risk for falling and prevention of fall-induced injury versus the restriction of the patient's freedom of movement about the room.
4. Document ongoing assessments of potential problems, calls to the physician, and discussions with family members.
5. Apply restraints according to the policy of the rehabilitation unit until an order is secured from the physician.
   a. Consult facility policy on restraint use.
   b. Secure an order from the physician for restraints to be used as needed, including specific criteria outlined in step 1d.
6. Reassess the patient's need for diuretic and sleep aid or sedative use. Discuss discontinuation of any unnecessary medications that increase the patient's degree of confusion or risk for falling, if possible.

Inappropriate Orders

1. A 74-year-old patient with a diagnosis of pneumonia is presently on a general medical ward for treatment and close monitoring. She is becoming increasingly anxious and dyspneic during your shift. Her heart rate is mildly increased. A house officer is summoned to evaluate this change in clinical status.
   a. The house officer, unfamiliar with the patient, spends 2 minutes reviewing the chart, quickly examines the patient, and orders a sedative to be administered stat and, as needed, every 4 hours.
   b. You tell the house officer that you heard decreased breath sounds in the left, lower lung and ask him to order some diagnostic tests, such as a chest x-ray and arterial blood gas analysis, and share your concern that administering a sedative to the patient may mask the underlying cause of the anxiety, lead to further respiratory compromise, and delay diagnosis and treatment of the underlying clinical problem. Nevertheless, he leaves the unit.
   c. Based on your evaluation of the situation, concerns about patient safety, and your role as patient advocate, you decide not to give the sedative ordered by the house officer.
2. Although you cannot automatically follow an order you think is unsafe, you cannot just ignore a medical order either.
   a. Document the scenario described above in the patient's chart, contact the resident on call, and notify your supervising nurse.
   b. If the resident on call agrees with the house officer's assessment, call the attending physician to

discuss your concerns, obtain appropriate stat orders, and notify the house officer and resident of the attending physician's orders and the actions taken.

c. Notify all involved medical and nursing personnel of the patient's status.

d. Document accurately, clearly, succinctly, and in a timely fashion.

3. Your actions reflect concern about the best interest of the patient, and although they may yield negative behaviors by the house officer or resident, it is more important to prevent potential harm to the patient.

LEGAL ASPECTS OF PROFESSIONAL NURSING PRACTICE

Accountability

1. Integral to the practice of any profession is the inherent need to be responsible for actions taken and for omissions.
2. The professional nurse must be proactive and take all appropriate measures to ensure that professional practice is not lacking, remiss, or deficient in any area or way.
3. Useful proactive measures include the following:
    a. Maintain familiarity of relevant, current facility policies, procedures, and regulations as they apply to the nurse's practice and specialty area.
    b. Provide for self-audit.
    c. Provide for peer review to assess reasonableness of care in a particular setting for a particular problem.
    d. Work with local nursing organizations to assure that local standards of practice are met.
    e. Examine the quality (accuracy and completeness) of documentation.
    f. Establish collegial working relationships with colleagues wherein honest constructive criticism and discussion are welcomed for the greater goal of quality patient care.
4. Local standards of practice normally align with those of nationally accepted standards.

Advocacy

The professional nurse has the duty to:

1. Promote what is best for the patient, as perceived by the patient and/or his surrogate.
2. Ensure that the patient's needs are met and a therapeutic environment is maintained.
3. Protect the patient's rights, including confidentiality and informed consent, among others.

Confidentiality

1. The patient's privacy is consistent with the Hippocratic Oath and with the law as part of the constitutional right to privacy.
2. Although the professional nurse should assure the patient of confidentiality, limits on this standard must be clarified and discussed with the patient at the earliest opportunity.
3. It is imperative to clearly understand the process of informed consent and the legal standard for disclosure of confidential patient information to others.
4. The Medical Record Confidentiality Act of 1995, a federal statute, is the primary federal law governing the use of health treatment and payment records. Several practical guidelines include the following:
   a. Respect the individual's right to privacy when requesting or responding to a request for a patient's medical records.
   b. Always require a signed medical authorization and consent form to release medical records and information to protect and respect patient–provider privilege statutes.
   c. Discuss confidentiality issues with the patient and establish consent. Address concerns or special requests for information not to be disclosed.
5. Based on the Health Insurance Portability and Accountability Act (HIPAA), the Department of Health and Human Services issued guidelines in 1996 to protect the confidentiality of individually identifiable health information. The rule:
   a. Limits the use and disclosure of certain individually identifiable health information.
   b. Gives patients the right to access their medical records.
   c. Restricts most disclosure of health information to the minimum needed for the intended purpose.
   d. Establishes safeguards and restrictions regarding the use and disclosure of records for certain public responsibilities, such as public health, law enforcement, and research.
   e. Provides for criminal or civil sanctions for improper uses or disclosures.
6. The exceptions or limits to confidentiality include situations in which society has judged that the need for information outweighs the principle of confidentiality. However, legal counsel should be consulted because these decisions are made on a case-by-case basis and broad generalizations cannot be assumed.
7. It may be appropriate to breach confidentiality on a limited basis in situations such as the following:
   a. If a patient reveals intent to harm him- or herself or another individual, it is imperative to protect the patient and third parties from such harm.
   b. A clinician employed by a company, school, military unit, or court has split allegiances, and the patient should be so advised at the appropriate time.
   c. Court orders, subpoenas, and summonses in some states may require the clinician to release records for review or testify in court. However, legal counsel should be consulted first to ensure that complying with these orders does not violate HIPAA.
   d. Most insurance companies, health maintenance organizations, and governmental payers require participants to sign a release of their records to the payers.

e. When a patient places his or her medical condition at issue, such as in personal injury cases, worker's compensation, or in various other cases of patients claiming injuries for which they are seeking compensation from any entity or organization.

f. Many states have laws requiring clinicians to report the incidence of certain diseases, deaths, and other vital statistics.

g. Criminal codes in many states require reporting gunshot wounds, incidents of rape, and incidents of child, spousal, or elder abuse if they have reasonable cause to suspect abuse.

Informed Consent

1. The doctrine of informed consent has become a fundamentally accepted principle governing the relationship between professional nurses and all other health care providers and patients.
2. Informed consent relates to the patient's right to accept or reject treatment by a nurse or any other health care provider and is a right of all legally competent adults or emancipated minors.
3. In the majority of circumstances, informed consent is obtained for medical or surgical procedures to be performed by physicians. Therefore, it is the duty of the physician to inform the patient of alternative treatments, the nature of the procedure, and benefits and potential risks. Oftentimes, especially when the patient is hospitalized, the nurse is required to witness the patient's signature before the procedure. It is prudent for the nurse to note witness to signature directly next to the patient's signature.
4. Emancipated minors are individuals who are under age 18 and married, are parents of their own children, or are self-sufficiently living away from the family domicile with parental consent.
5. In the case of a minor, informed consent would be obtained from the legal guardian.
6. In the case of individuals incapable of understanding medical treatment issues, informed consent must be obtained through a responsible person such as a guardian or surrogate.
7. The nurse has the duty to verify that the physician or other health care provider has explained each treatment or procedure in a language the patient (or the responsible person) can comprehend; has warned the patient of any material risks, dangers, or harms inherent in or collateral to the treatment; and has advised the patient of available alternatives. This enables the patient to make an intelligent and informed decision and choice about whether to undergo treatment.
8. The informed consent should be obtained before rendering the treatment or performance of the procedure. For more information on informed consent for patient's surgery, see Chapter 7 , page 86.
9. The nurse must document that the informed consent was obtained and that the patient demonstrated understanding of the information.
10. A witness signature is desirable and may be required by some health care institutions.

NURSING ALERT With the increasing cultural diversity of our patient population, it is prudent and ethically obligatory to obtain an interpreter for the patient if there is a reasonable chance that the patient will not understand explanations in the English language.

Scope of Practice, Licensure, and Certification

1. The professional nurse's scope of practice is defined and outlined by the State Board of Nursing that governs practice. The National Council of State Boards of Nursing and the NLN have developed standards that guide each State Board in the development of their licensure requirements and scope of practice rules.
2. Licensure is granted by an agency of state government and permits individuals accountable for the practice of professional nursing to engage in the practice of that profession while prohibiting all others from doing so legally.
3. Certification is provided by a nongovernmental association or agency and certifies that a person licensed to practice as a professional nurse has met certain predetermined standards described by that profession for specialty practice, thereby assuring the patient that a person has mastered a body of knowledge and acquired the skills in a particular specialty.
4. The mechanisms for achieving certification and maintaining a specialty certification vary by association and certifying body, such as a specified number of hours of clinical practice, continuing education, peer review, periodic self-assessment examination, or reexamination.
5. The American Nurses Credentialing Center is one certifying body that provides specialty certification (*www.nursecredentialing.org* or 800-284-2378). Credentialing protects the public by recognizing professional nurses who have successfully completed an approved course of study and achieved a level of specialized knowledge and skill to hold specialized positions.

Standards of Practice

General Principles

1. The practice of professional nursing has standards of practice setting minimum levels of acceptable performance for which its practitioners are accountable.
   a. The authority for the practice of nursing is based on a social contract that acknowledges rights and responsibilities, along with mechanisms for public accountability.
   b. These standards provide patients with a means of measuring the quality of care they receive.
2. Standards of practice were developed by the ANA and have been updated regularly to include general standards as well as standards for each nursing specialty. A copy can be purchased from the ANA publications office (*www.nursesbooks.org* or 800-637-0323).
   a. These standards describe what nursing is, what nurses do, and the responsibilities for which nurses are accountable.
   b. Professional nurses are to be guided by the generic standards applicable to all nurses in all areas of practice as well as by specialty area standards.
3. Various specialty groups have developed their own additional standards, but addressing these exceeds the scope of this chapter. The professional nurse needs to be familiar with all standards applicable to her or his own practice areas.
4. Standards and parameters also provide a source of legal protection for the practicing nurse.
   a. Standards and parameters typically consist of a simple, realistic series of steps that would be applicable given the same or similar clinical scenario.
   b. Standards and parameters should outline the minimum requirements for safe care and need to be updated as scientific knowledge changes.
5. A deviation from the protocol should be documented in the patient's chart with clear, concise statements of the nurse's decisions, actions, and reasons for the care provided, including any apparent deviation. This should be done at the time the care is rendered because passage of time may lead to a less than accurate recollection of the specific events.
6. Informal or volunteer practice must be consistent with the applicable standard of care. Documentation that the care rendered was the standard of practice within a community or state may afford the practitioner a degree of protection. Informal or volunteer care still needs to comply with the applicable standard of care.

Common Departures from the Standards of Nursing Care

Legal claims most commonly made against professional nurses include the following departures from appropriate care: failure to assess the patient properly or in a timely fashion, follow physician orders, follow appropriate nursing measures, communicate information about the patient, adhere to facility policy or procedure, document appropriate information in the medical record, administer medications as ordered, and follow physician's orders that should have been questioned or not followed, such as orders containing

medication dosage errors (see Box 2-1).

BOX 2-1 Common Legal Claims for Departure from Standards of Care

- Failure to monitor or observe a patient's clinical status adequately
- Failure to monitor or observe a change in a patient's clinical status
- Failure to communicate or document a significant change in a patient's condition to appropriate professional
- Failure to obtain a complete nursing history
- Failure to formulate or follow the nursing care plan
- Failure to perform a nursing treatment or procedure properly
- Failure to provide a safe environment and to protect the patient from avoidable injury
- Failure to implement a physician's, advanced practice nurse's, or physician assistant's order properly or in a timely fashion
- Failure to administer medications properly and in a timely fashion or to report and administer omitted doses appropriately
- Failure to observe a medication's action or adverse effect
- Failure to prevent infection
- Failure to obtain help for a patient not receiving proper care from a physician or other health care provider
- Failure to report that a patient is not receiving proper care from a physician or other health care provider
- Failure to use equipment properly
- Failure to evaluate or identify a patient at high risk for falling or to plan and implement a fall prevention program appropriate to the individual patient
- Failure to apply restraints when indicated and ordered
- Failure to apply restraints in a proper manner
- Using equipment that is known to be defective
- Failure to make prompt, accurate entries in a patient's medical record
- Altering a medical record without noting it as a correction with signature, date, and time of change
- Failure to adhere to facility policy or procedural guidelines
- Following medical orders that should not have been followed such as medication dosage errors
- Failure to act as a patient advocate, such as not questioning illegible or incomplete medical orders or not questioning discharge when a patient's clinical status warrants

Quality Assurance and Adverse Event Reduction

1. A quality assurance program creates and implements a systematic, deliberate, and ongoing mechanism for the evaluation and monitoring of professional nursing practice aimed at performance improvement and adverse event reduction. Many facilities follow the National Database of Nursing Quality Indicators program, implemented by the ANA. It is a database that is updated regularly to track progress in providing quality care in certain areas, including pressure ulcers, falls, hospital-acquired infections, and restraint prevalence.
2. In 2007, the U.S. Centers for Medicare and Medicaid Services announced that Medicare would be ending payments to facilities for the increased costs attributable to preventable, facility-acquired conditions, including pressure ulcers, catheter-associated urinary tract infections, vascular catheter–associated infections, coronary artery bypass graft–related mediastinitis, and injuries such as dislocations and fractures. More recently, payment will be withheld for patients readmitted within 30 days after hospital discharge for conditions such as heart failure and acute myocardial infarction. More than ever before, nurses delivering care at the front lines are critical partners in promoting quality care, preventing adverse events, and saving avoidable expenditure of health care dollars.
3. Integral to the creation of such a proactive program are the following key factors:
    a. Create an atmosphere of interprofessional collegiality.
    b. Develop and implement the consistent application of new policies and procedures for quick, easy, and, if possible, anonymous error reporting, with protection from disciplinary action.
    c. Support employees involved in serious errors, adopting a nonpunitive attitude.
    d. Acknowledge the need for system-wide improvement and for centralization of information. Doing so ensures maximal benefit to the patients of health care and to all disciplines involved in the delivery of care.
    e. Introduce scientifically valid quality and safety solutions universally throughout the health care system, allowing for sharing of successful strategies and measures and reward systems.
    f. These actions would promote the delivery of high-quality care, a sense of responsibility and accountability, as well as ongoing self- and peer-auditing, thus yielding greater trending, analysis, problem-solving, and system-wide refinements.
4. Consequently, the use of a quality assurance program effectively reduces the professional nurse's exposure to liability, identifies educational needs, and improves the documentation of the care provided.
5. The components of quality assurance include the following:
    a. Structure—focuses on the organization of patient care.
    b. Process—focuses on tests ordered and procedures performed.
    c. Outcome—focuses on the outcome, such as absence of complications, timely discharge, patient satisfaction, or mortality data.
6. Mechanisms to incorporate in quality assurance programs may include the following:
    a. Patient satisfaction surveys to assess nurse interactions and maintain open lines of communication

between the provider and the patient.

b. Peer review to recognize and reward care delivered, raise the expectations for higher standards of practice within a community, and discourage practice beyond the scope of legal authority.
c. Audit of clinical records to determine how well-established criteria were met by the care rendered.
d. Utilization review to evaluate the extent to which services or resources were used as measured against a standard.

Management of Liability

1. The sources of legal risk in a professional nurse's practice include patient care, procedures performed, quality of documentation, violation of confidentiality, among others.
2. Liability can be minimized by the application of risk management systems and activities, which are designed to recognize and intervene to reduce the risk of injury to patients and subsequent claims against professional nurses.
3. Risk management systems and activities are based on the premise that many injuries to patients are preventable.

Malpractice

1. Nursing malpractice refers to a negligent act of a professional nurse engaged in the practice of that profession.
2. Although negligence embraces all negligent acts, malpractice is a specific term referring to negligent conduct in the rendering of professional services.
3. There is no guaranteed way to avoid a medical malpractice suit short of avoiding practicing as a professional nurse. Even the best nurses have been named as defendants.
4. A diligent and reflective nurse can reduce the risks of malpractice by consistently incorporating the following four elements into her or his practice:
    a. Excellent communication skills, with consistent efforts to elicit and address the expectations and requests of the patient.
    b. Sincere compassion for each patient.
    c. Competent practice.
    d. Accurate and complete charting with notations of any deviations from the applicable standard of care with the specific reasons (eg, the patient refused chest radiograph because of personal time constraint) and, if applicable, the patient's noncompliance.
5. Generally, the professional nurse has the duty to:
    a. Exercise a degree of diligence and skill that is ordinarily exercised by other professional nurses in the same state and specialty of practice.
    b. Apply such knowledge with reasonable care.
    c. Keep up to date and informed of approved standards of care in general use.
    d. Exercise best judgment in rendering care to the patient.
6. Some states apply a geographic standard, referred to as a locality rule, which asserts that providers in remote rural areas may have less access to continuing education and various technology and equipment than their colleagues in urban areas. However, because communication and transportation continue to improve rapidly, the locality rule is becoming obsolete.

Burden of Proof for Malpractice

The plaintiff has the burden of proving four elements of malpractice, usually by means of expert testimony.

Duty

1. The plaintiff has a burden to prove that a nurse–patient relationship did, in fact, exist and, by virtue of that relationship, the nurse had the duty to exercise reasonable care when undertaking and providing treatment to the patient.
2. Limits and obligations of duty include the following:
    a. This duty exists only when there is a nurse–patient relationship.
    b. The professional nurse is not obligated to enter into a nurse–patient relationship with any individual.

c. Professional nurses generally have the right to decide to whom they will provide professional services and may request to be reassigned to another patient if the nurse–patient relationship is strained, the nurse feels unsafe, or the treatment plan is a gross violation of the nurse's ethical or religious values.

d. Nurses have limits on their rights to decide; however, they cannot refuse to treat a patient who has relied reasonably on the nurse's apparent willingness to treat all in need (eg, the emergency department in a general facility that advertises its emergency services) and may not abandon an established patient.

e. If a professional nurse wishes to terminate an established relationship with a patient, an alternative with an equivalent level of nursing services must be made available to the patient in a timely fashion.

NURSING ALERT The professional nurse must use caution when offering telephone advice for which there is no charge; there have been reported cases of patients successfully suing providers because they reasonably relied on the telephone advice of a nurse that caused them to delay seeking care and sustain permanent injuries as a result.

Breach of Duty

1. The plaintiff has the burden to establish that the professional nurse violated the applicable standard of care in treating the patient's condition.
2. The plaintiff must establish by way of expert professional nurse testimony that the "negligent" nurse failed to conform to the applicable standard of care or provided nursing care that fell below the level of care that would have been provided by a prudent and diligent nurse under the same circumstances.

Proximate Cause

1. The plaintiff has the burden of establishing a causal relationship between the breach in the standard of care and the patient's injuries.
2. If a breach in standard of care did not cause the alleged injuries, there is no proximate cause.

Damages

The plaintiff has the burden of establishing the existence of damages to the patient as a result of malpractice.

Malpractice Insurance

1. Malpractice insurance will not protect the professional nurse from charges of practicing outside the scope of practice if he or she is practicing outside the legal scope of practice permitted within the state.
2. It is critical that the nurse know the exact scope of practice permitted in his or her jurisdiction.
3. It is universally recommended that all professional nurses carry their own liability insurance coverage. This affords one's own legal representation and an attorney who will be looking out solely for the nurse's best interests. Such coverage is recommended over and above the legal coverage and representation afforded by the employer's coverage.

4. Coverage should be by occurrence, rather than claims-made terms. Occurrence policies cover the nurse whenever the occurrence of the care took place, even if the nurse is no longer employed at that location or the policy is not active at the time the claim is made.

Telephone Triage, Advice, and Counseling

1. The use of telephone triage, advice, and counseling has become increasingly prevalent as health care providers have attempted to meet and satisfy the health care needs of their patients, increase access to care, and improve continuity of care while limiting scheduled appointments to those truly requiring a patient–physician or other health care provider interaction.
2. Health care professionals who provide telephone services must keep in mind that they are legally accountable for gathering an accurate and complete history, application of appropriate protocols for diagnostic impressions, appropriate consultation with other health care providers, advice and counseling given, and facilitation of timely and appropriate access to treatment facilities or referral to specialists to those in need.
3. Internet and other means of electronic communication are becoming acceptable but present concerns for privacy.
4. A number of legal concepts of relevance to telephone triage are outlined in the next section.

Confidentiality

Just as in face-to-face interactions, all information exchanged during a telephone interaction is privileged and is to be used only in the context of the advice being sought, with the sole purpose of providing the most appropriate and timely care needed by the patient.

Implied Relationships

Even if the professional nurse providing telephone advice has never had face-to-face interaction with the patient, the telephone interaction itself will establish a formal and legally binding nurse–patient relationship, for which the practitioner will be accountable legally.

Information Retrieval

1. The professional nurse has the duty to provide advice and counsel in the context of all medical data available to the practice from within the patient's medical record.
2. Therefore, a rapid method for the retrieval of medical record data should be established and integrated into the telephone component of all practices.
3. Telephone advice must not be provided in a vacuum of knowledge about the patient's past history.
4. Because limited time will usually preclude the gathering of all data available in the medical record, advice rendered without the benefit of all known medical history is more subject to error.

Respondeat Superior

1. Employers are held accountable, legally responsible, and liable for all inappropriate advice provided by their employees and all damages that may result.
2. Therefore, employers must be responsible for educating and training employees and updating protocols.

Vicarious Liability

1. Although similar to the concept of respondeat superior, vicarious liability is a broader concept in that a professional nurse providing telephone advice or counseling may be viewed as a representative of the facility physician, practice group, or facility, thereby binding them legally for all acts of omission or commission and damages that result.
2. Thus, if telephone advice and counsel are rendered by an LPN, RN, or unlicensed personnel, the nurse, health care facility, or physicians in the practice may be viewed by a court as vicariously liable for inappropriate advice provided and all resulting damages to the patient.
3. This underscores the reasons for limiting this practice to well-trained nurses, physicians, and other health care providers and following carefully devised office protocols and standards.
4. The professional nurse must be encouraged to consult briefly with the in-office physician or other health care providers to reduce the possibility of advice that is not appropriate or is in error.

Negligent Supervisor

1. This concept relates to the failure of a supervising physician or other health care provider to provide the needed guidance and direction to the telephone advice nurse, despite a prevailing understanding, practice, or policy obligating this supervision.
2. This scenario usually overlaps with respondeat superior or vicarious liability.

Negligence

1. Any telephone assessment and advice rendered must be in accordance with the generally accepted standards and protocols.
2. Violation of the applicable standards of practice or care is considered to be negligent.
3. Evidence of standards of care is established by:
   a. Publications on the topic.
   b. Community practices.
   c. Generally accepted professional and evidence-based guidelines or treatises on the topic.

Abandonment

1. This concept becomes operational when a patient calls or comes in to report symptoms, seek advice, or request an on-site evaluation or treatment, and this communication is documented or otherwise established as fact, but the telephone advice nurse fails to follow through with the professional component of the interaction (advice).
2. However, unless an undesirable outcome with serious and permanent damages occurs due to the absence of follow-through by the telephone practitioner, it is doubtful that a legal claim could be brought successfully against the practitioner.

BOX 2-2 Components of Successful Telephone Practice

- Apply standardized protocols and guidelines for the most frequently reported chief complaints.

- Train nurses in proper history taking, protocol or guideline utilization, and documentation.
- Apply a computer-based approach to manage the telephone encounters to complement existing protocols and guidelines to improve the process and documentation of the encounter.
- Implement a quality assurance system to ensure a regular review of telephone logs.
- Discuss problem cases with telephone advice nurses and perform outcome surveys.
- Maintain a constant availability of physicians and other health care providers to provide consultative assistance to the telephone advice nurse as needed.
- Ensure an ongoing review and revision of protocols and policies to eliminate or improve on problematic policies and protocols.
- Schedule patients with serious problems as soon as possible.
- Ask and confirm that the patient understands and feels comfortable with the plan at the end of the telephone interaction.
- Invite the patient for an after-hours visit if he or she is uncomfortable with receiving home care instructions or with waiting until the next day to see the physician or other health care provider.
- Encourage patients to call back if their condition worsens or if they have additional questions.
- Advise patients to contact their health care provider the next day if the problem has not improved.
- Document succinctly the components of the telephone interaction, including the chief complaint, history of present illness, past medical history, allergies, home care or other instructions given, confirmation of the patient's understanding and comfort with the advice given, emergency precautions provided, and follow-up plans.

Successful Telephone Practice

1. Policies aimed at minimizing the risk of an untoward outcome resulting from telephone advice, triage, and counseling should be established in every practice.
2. Policies should include protocol use, telephone practitioner training and education, use of an established patient database, communication with a physician or other health care provider, and appropriate documentation of interaction.
3. See Box 2-2 for components of a successful telephone advice practice.
4. The telephone advice nurse must gather and document certain fundamental information from the patient seeking health care advice or treatment. Although the following list is presented, it is not intended to limit inquiry or imply that the list is exhaustive. The inquiry and documentation must minimally include the following:
    a. Date and time of the call.
    b. Caller information including the name of the patient, relationship to the patient, telephone number with area code, when and where the caller may be reached for return calls, and alternative telephone numbers with area code for backup.
    c. Chief complaint.
    d. History of present illness, with brief description of onset, symptoms, treatment used to date, effectiveness or lack thereof of measures attempted, and aggravating or alleviating factors.
    e. Whether the patient has had this problem before and, if so, when, diagnosis, and method of resolution.
    f. If female, last menstrual period, method of birth control, and follow-up to rule out pregnancy.
    g. Past medical history and other medical problems.
    h. Allergies.
    i. Likely differential diagnosis based on the established protocols and guidelines being utilized by the organization or facility.
    j. Impact of the problem on the caller or patient.
    k. Accessibility of alternative sources of health care.
    l. Nurse's perception of the patient's vulnerability.
    m. Nurse's perception of the patient's understanding and comfort with the plan of care and follow-up plans.

PATIENT EDUCATION GUIDELINES 3-1

Exercise Guidelines

Aerobic exercise provides a wide range of benefits including weight loss, muscle toning, endurance building, improved circulation, increased high-density lipoprotein (the "(good)" cholesterol), lowered risk of a heart attack, better controlled BP, and a sense of reduced tension and overall wellness. Aerobic exercise refers to any type of activity that uses oxygen to produce energy. The cardiovascular system is stimulated and fat is burned. Most people can do aerobic exercise of some kind, adjusting the intensity as necessary. Follow these guidelines to develop your own exercise program.

- Choose an activity that you enjoy, is convenient, and you are capable of; consider walking, bicycle riding, jogging, swimming, aerobics or step aerobics, sporting activities, or use of fitness equipment such as a rowing machine, stair stepper, or cross-country ski machine.
- Start out exercising 15 to 20 minutes at a time for the first week or two and then gradually increase the intensity and length of exercise time over several weeks to months.
- Include a 5- to 10-minute warm-up and cool-down period with each exercise session, doing stretching of major muscles, deep breathing, and light calisthenics.
- Exercise most days or a total of at least 150 minutes per week, but remember that some exercise is better than none.
- Exercise at 50% to 70% of your maximum heart rate for moderate intensity or 70% to 90% for high intensity, as tolerated.

CALCULATING TARGET HEART RATE

To get the most out of exercise, calculate your heart rate. First, subtract your age from 220. This is your maximum heart rate; do not exceed this rate while exercising to avoid strain on your heart.

If you are age 40, your maximum heart rate is 220 minus 40, or 180. Your target heart rate is 40% to 50% of maximum for low-intensity exercise, 50% to 70% of maximum for moderate-intensity exercise, or 70% to 90% of maximum for high-intensity exercise. So, if you want to exercise at moderate intensity, 60% of 180 is 108 (180 Ã— 0.6). Your target heart rate is 108. By taking your pulse several times during exercise, you can adjust your pace to stay close to your target heart rate and exercise optimally but safely.

TAKING YOUR PULSE

First take your resting pulse before you begin exercise, counting for 30 seconds and multiplying by 2.

To take your pulse during exercise, slow down and find the carotid pulse point in your neck. Place two or

three fingers on your trachea (windpipe) near the base of your neck and then move them over to the left or right about 2 to 3 inches until you feel the beating of your pulse. Press lightly so you do not cause an irregular heartbeat or interrupt circulation to your brain. Use a watch with a second hand to count the number of beats in 6 seconds. Now, multiply by 10 to get an estimate of your true 60-second pulse.

If you counted 10 beats in 6 seconds, your working heart rate is 100 (10 Ã— 10). As you continue to exercise, you can work a little harder to reach your target rate. If your working heart rate is 10 beats or more greater than your target rate, slow down your pace and check your pulse again in 5 to 10 minutes.

When you complete your exercise, your pulse should be no more than 15 beats above your resting pulse; if it is, continue your cool-down activity.

WHEN TO STOP

You should usually never stop exercising abruptly; you must allow the heart to slow down and the blood to redistribute appropriately.

You should slow down if you experience muscle cramps, shortness of breath, or fatigue. You should stop, however, if you experience chest pain, a cold sweat, dizziness, nausea or vomiting, heart palpitations, or fainting. Seek help and notify your health care provider immediately.

PATIENT EDUCATION GUIDELINES 3-2

Stress Management

Stress is a common phenomenon among most individuals today and can be related to job, relationship, financial, and other pressures. Known as the "(fight or flight)" reaction, the physiologic and emotional response to stress can lead to tension, anxiety, and a variety of health threats. Stress can be minimized by better coping with it and adapting to its causes. Follow this guide to better manage stress.

RECOGNIZE STRESS

- First, identify signs that you may be under stress (eg, irritability, tension, fatigue, insomnia, loss of interest in activities, feeling overwhelmed, or fighting with spouse and others).
- Next, try to identify the true cause of stress. For example, you may snap at your children for playing the stereo too loudly, but what is the underlying cause of your irritability?
- Examine areas of your job, family life, financial stability, and other roles and responsibilities that may be demanding or problematic.

DO SOMETHING ABOUT IT

- Try to manage stressful areas better—be assertive, negotiate, and say no if necessary. For example, confront the person with whom you are at odds and work out a mutual agreement, put the plan in writing, and try to stick to it.
- Make more time for yourself and important relationships. Say no to responsibilities that you do not

have time for and get help from a family member or friend, or hire a babysitter when necessary.

RELAX

When you enter a stressful situation or you feel tension rising, practice the following relaxation techniques; you will be able to think more clearly and function more effectively.

Relaxation Breathing

Concentrate on breathing slowly and deeply with eyes closed (if possible) for several minutes when you need a quick tension reducer or before beginning one of the other methods.

- Breathe in through your nose and mouth with face relaxed for a count of 1 and 2 and 3 and 4.
- Hold your breath for 4 seconds, without straining.
- Breathe out through your nose and pursed lips for a count of 6.
- Repeat two or three times, breathe naturally for about 30 seconds, then repeat one or more sequences.
- If you feel dizzy or tingling in your fingertips, you may be hyperventilating; slow down your breathing and do not breathe out so forcefully.

Progressive Muscle Relaxation

Because stress may cause you to subconsciously contract your muscles, in this exercise, you will alternately tense and relax your muscle groups one by one, until your entire body is in a state of relaxation.

- Assume a comfortable position, either sitting or reclining, and close your eyes.
- Start with your forehead and tense the muscles so you feel tightness or strain; hold this position for 5 to 10 seconds.
- Next, relax your forehead, noting the relief; concentrate on this for 10 to 15 seconds.
- Progress from head to toe with each muscle group, including your jaw, shoulders, arms, hands, abdomen, buttocks, legs, and feet (you can do both sides simultaneously).
- Note the feeling of total relaxation in your body once you have relieved tension from all your muscles.
- Complete the exercise by opening your eyes, taking a few deep breaths, stretching, and arising slowly.

Imagery

Imagery allows you to take a mental vacation by using your imagination and diverting your attention from stressful thoughts.

- Assume a comfortable position, breathe deeply, and close your eyes.
- Count backward from 5 and begin to imagine a pleasant place such as a beach or garden.
- Put yourself in that place by imagining it with all your senses (eg, hear the sound of waves washing up on the beach, feel the warm sun saturating your skin, or taste a tangy drink of lemonade).
- Stay in that place for about 5 minutes, imagining different images.
- Slowly let the images fade, breathe deeply, and count to 5 before opening your eyes.

Distraction

You can use many methods of distraction to block your concentration from anxiety and stressful matters.

Using your senses to listen to music, petting your dog, or reading can be relaxing.

- Choose activities that you enjoy—reading, watching television, listening to music, taking a walk, playing an instrument, knitting, doing a craft, or drawing or painting.
- Adjust the distraction method to your mood—if you are extremely tense, do not attempt a complex project or listen to loud, lively music. Rather, listen to quiet, soothing music or sketch a free-form design.
- Use a variety of methods—some reserved for longer periods of time and others that can be used on the spot when needed (eg, a portable tape player with headphones and your favorite music or a book of poetry).

If relaxation methods don't help and you are having difficulty coping with stress, contact a health care provider.

PAY ATTENTION TO CALORIES

- Eat the right amount of calories for you.
  - Think before you eat—do I need the calories?
  - Avoid oversized portions, use a smaller plate or bowl.
  - Cook more often at home, where you are in control of what is in your food.
  - When eating out, choose lower-calorie menu options, order a smaller portion, or share.
  - Stop eating when you are satisfied, not full.
  - Write down what you eat to keep track of how much you eat.
- Use food labels to make better choices.

For more information, go to *www.choosemyplate.gov*.

PATIENT EDUCATION GUIDELINES 3-4

Smoking Cessation

Cigarette smoking is the single most preventable cause of death and disability today. Smoking is related to about 30% of all cancer deaths, is the leading risk factor for coronary artery disease and emphysema, and has many other effects on health and hygiene. People who smoke tend to have more dental problems, premature aging of the skin, increased acid in the stomach, decreased exercise tolerance, loss of taste bud function, problems with pregnancy and fetal growth, more frequent respiratory infections, and bad breath.

Smoking cessation, however, will reverse most of these risks and allow you to breathe more easily and feel better.

PLAN TO QUIT

- Make a list of all the positive things and all the negative things about smoking; consider the short- and

long-term health risks on your list.

- Talk to your health care provider about the use of nicotine chewing gum, nasal spray, or skin patch to aid your stop-smoking program by reducing withdrawal symptoms and cravings for a cigarette. Oral medications that do not contain nicotine are also available by prescription.
- Talk to family and friends and form a support network of people who have quit smoking.
- Set a date to quit and don't make excuses.
- Stock up on low-calorie treats, such as raw vegetables, sugarless gum, popcorn, and sugar-free soft drinks, to enjoy when the urge to smoke hits.
- Remove ashtrays, cigarettes, matches, and lighters from your home, car, and office.

STICK WITH IT

- Avoid smoky environments, such as bars and coffee shops and the smoking section of restaurants.
- Restructure your routine to eliminate times you previously enjoyed a cigarette.
- Anticipate feeling irritable for several days to several weeks while quitting, and avoid stressful situations.
- Increase exercise, such as walking, biking, or sporting activities, to relieve tension, fill free time, and concentrate on healthy activity.
- Occupy your hands with modeling clay, knitting, doodling, or a craft project.
- Brush your teeth often to enjoy fresher breath.
- Reward yourself for not smoking.

TRY, TRY AGAIN

- If you start smoking again, do not be discouraged; many people are successful the second time around.
- Review and revise your plan and pick a new quit date.

For more information on smoking cessation, go to *www.healthfinder.gov*.

Principles of Health Promotion

Health promotion is defined as the actions taken to develop a high level of wellness and is accomplished by influencing individual behavior and the environment in which people live.

Levels of Prevention

1. Disease prevention is aimed at avoiding problems or minimizing problems once they occur.
   a. Primary prevention is the total prevention of a condition.
   b. Secondary prevention is the early recognition of a condition and the measures taken to speed recovery.
   c. Tertiary prevention is the care given to minimize the effects of the condition and prevent long-term complications.
2. Preventive care should involve assessment for people at risk for specific disorders.

Healthy People 2020

EVIDENCE BASE Office of Disease Prevention and Health Promotion, USDHHS. (2018). Healthy People 2020. Available: *www.healthypeople.gov*. Updated February 5, 2018.

---

1. Health promotion goes beyond prevention to help people manage their health and live longer and feel better.
2. Health promotion has become a priority since the U.S. Department of Health and Human Services (DHHS) initiated its Healthy People 2000 campaign in 1990.
3. For the Healthy People 2010 campaign, launched in 2000, 23% of the campaign's stated objectives were reached or exceeded, whereas 48% of the stated objectives were approached. The two major goals of Healthy People 2010 were to enhance life expectancy while improving quality of life and to reduce health disparities due to gender, race and ethnicity, income and education, disabilities, and other factors.
4. Healthy People 2020 consists of 42 topic areas with 1,200 objectives. Leading health indicators (LHIs) were chosen as a subset of objectives indicating priority health issues (see Box 3-1, page 21). At midcourse review, 4 (15.4%) LHIs had met or exceeded their target and 10 (38.5%) showed improvement.
5. The framework for Healthy People 2030 has been developed with the vision: A society in which all people achieve their full potential for health and well-being across the lifespan.

BOX 3-1 Healthy People 2020 Leading Health Indicators

- Persons with medical insurance
- Persons with a usual primary care provider

- Adults receiving colorectal cancer screening
- Adults with hypertension whose blood pressure (BP) is under control
- Persons with diagnosed diabetes with A1c > 9%
- Children receiving the recommended doses of vaccines
- Air Quality Index > 100
- Children exposed to secondhand smoke
- Injury deaths
- Homicides
- All infant deaths
- Total preterm live births
- Suicide
- Adolescents with a major depressive episode
- Adults meeting aerobic physical activity and muscle- strengthening requirements
- Obesity among adults
- Obesity among children and adolescents
- Mean daily intake of total vegetables
- Children, adolescents, and adults who visited the dentist
- Sexually active females receiving reproductive health services
- Knowledge of serostatus among human immunodeficiency virus (HIV)-positive persons
- Students graduating from high school 4 years after starting
- Adolescents using alcohol or illicit drugs
- Adult binge drinking
- Adult cigarette smoking
- Adolescent cigarette smoking

Nursing Role in Health Promotion

1. Nurses have played key roles in prevention in such areas as prenatal care, immunization programs, occupational health and safety, cardiac rehabilitation and education, and public health care and early intervention.
2. Nurses in all settings can meet health promotion needs of patients, whether their practice is in a hospital, a clinic, a patient's home, a health maintenance organization, a private office, or a community setting. Health promotion is primarily accomplished through patient education, an independent function of nursing.
3. Health promotion should occur through the life cycle, with topics focused on infancy, childhood, adolescence, adulthood, and older adults. Specific preventive services are evidence based and recommended by the United States Preventive Services Task Force (USPSTF) (*www.ahrq.gov/clinic/prevenix.htm*), the Canadian Task Force on Preventive Health Care (*www.canadiantaskforce.ca/index.html*), the National Institute for Health and Clinical Excellence (*www.nice.org.uk*) in the United Kingdom, as well as other agencies (see Table 3-1).

a. For infancy, teach parents about the importance of prenatal care, basic care of infants, breast-feeding, nutrition, and infant safety (see Chapter 42).

b. For childhood, stress the importance of immunizations, proper nutrition to enhance growth and development, and safety practices, such as use of car seats and seat belts, fire prevention, and poison-proofing the home (see Chapter 42).

c. For adolescence, focus on motor vehicle safety; avoidance of drug, alcohol, and tobacco use; sexual decision making and contraception; and prevention of suicide.

d. For adulthood, teach patients about nutrition, exercise, and stress management to help them feel better; also teach cancer-screening techniques, such as breast and testicular self-examination, and risk factor reduction for the leading causes of death—heart disease, stroke, cancer, and chronic lung disease.

e. For older adults, stress the topics of nutrition and exercise to help people live longer and stay fit, safety measures to help them compensate for decreasing mobility and sensory function, and ways to stay active and independent (see Chapter 9).

Table 3-1 Preventive Services Recommended by the USPSTF

The USPSTF recommends that clinicians discuss these preventive services with eligible patients and offer them as a priority. All these services have received an "A" (strongly recommended) or "B" (recommended) grade from the Task Force.

RECOMMENDATION	MEN	WOMEN	PREGNANT WOMEN	CHILDREN
Abdominal aortic aneurysm, screening (1)	✓			
Alcohol misuse screening and behavioral counseling interventions	✓	✓	✓	
Aspirin for the primary prevention of cardiovascular events (2)	✓	✓		
Asymptomatic bacteriuria in adults, screening (3)			✓	
BRCA-related cancer in women, screening (4)		✓		
Breast cancer, preventive medications (5)		✓		
Breast cancer, screening (6)		✓		
Breast-feeding, counseling (7)		✓	✓	
Cervical cancer, screening (8)		✓		
Chlamydial infection, screening (9)		✓	✓	
Colorectal cancer, screening (10)	✓	✓		
Congenital hypothyroidism, screening (11)				✓
Depression (adults), screening (12)	✓	✓		
Falls in older adults (13)	✓	✓		
Folic acid supplementation (14)		✓		
Gestational diabetes mellitus, screening (15)			✓	
Gonococcal ophthalmia, prophylactic medication (16)				✓
Gonorrhea, screening (17)		✓		
Hearing loss in newborns, screening (18)				✓
Hepatitis B virus in pregnant women, screening (19)			✓	
Hepatitis C virus in adults, screening (20)	✓	✓	✓	✓
High blood pressure in adults, screening	✓	✓		

RECOMMENDATION	MEN	WOMEN	PREGNANT WOMEN	CHILDREN
Human immunodeficiency virus (HIV), screening (21,22)	✓	✓	✓	✓
Iron deficiency anemia, prevention (23)				✓
Iron deficiency anemia, screening (24)			✓	
Lipid disorders in adults, screening (25)	✓	✓		
Lung cancer, screening (26)	✓	✓		
Major depressive disorder in children and adolescents, screening (27)				✓
Obesity in adults, screening (28)	✓	✓		
Obesity in children and adolescents, screening (29)				✓
Osteoporosis, screening (30)		✓		
Phenylketonuria, screening (31)				✓
Sexually transmitted infections, counseling (32)	✓	✓		
Sickle cell disease in newborns, screening (33)				✓
Skin cancer, counseling (34)	✓	✓	✓	✓
Syphilis infection in pregnant women, screening			✓	
Tobacco use in adults (35)	✓	✓	✓	
Tobacco use in children and adolescents (36)				✓
Visual impairment in children, screening (37)				✓

1. *One-time screening by ultrasonography in men aged 65 to 75 who have ever smoked.*
2. *When the potential harm of an increase in gastrointestinal hemorrhage is outweighed by a potential benefit of a reduction in myocardial infarctions (men aged 45 to 79 years) or in ischemic strokes (women aged 55 to 79 years).*
3. *Pregnant women at 12 to 16 weeks' gestation or at first prenatal visit, if later.*
4. *Refer women whose family history is associated with an increased risk for deleterious mutations in BRCA1 or BRCA2 genes for genetic counseling and evaluation for BRCA testing.*
5. *Engage in shared, informed decision making and offer to prescribe risk-reducing medications, if appropriate, to women aged ≥35 years without prior breast cancer diagnosis who are at increased risk.*
6. *Biennial screening mammography for women aged 50 to 74 years. Note: The Department of Health and Human Services, in implementing the Affordable Care Act, follows the 2002 USPSTF recommendation for screening mammography, with or without clinical breast examination, every 1 to 2 years for women aged 40 and older.*
7. *Interventions during pregnancy and after birth to promote and support breast-feeding.*
8. *Screen with cytology every 3 years (women aged 21 to 65) or co-test (cytology/HPV testing) every 5 years (women aged 30 to 65).*
9. *Sexually active women aged 24 or younger and other asymptomatic women at increased risk for infection. Asymptomatic pregnant women aged 24 and or younger and others at increased risk.*
10. *Adults aged 50 to 75 using fecal occult blood testing, sigmoidoscopy, or colonoscopy.*
11. *Newborns.*
12. *When staff-assisted depression care supports are in place to assure accurate diagnosis, effective treatment, and follow-up.*
13. *Provide intervention (exercise or physical therapy and/or vitamin D supplementation) to community-dwelling adults ≥65 years at increased risk for falls.*
14. *All women planning or capable of pregnancy take a daily supplement containing 0.4 to 0.8 mg (400 to 800 mcg) of folic acid.*
15. *Asymptomatic pregnant women after 24 weeks of gestation.*
16. *Newborns.*
17. *Sexually active women, including pregnant women aged 25 and younger, or at increased risk for infection.*
18. *Newborns.*
19. *Screen at first prenatal visit.*
20. *Persons at high risk for infection and adults born between 1945 and 1965.*
21. *All adolescents and adults aged 15 to 65 years and others who are at increased risk for HIV infection and all pregnant women.*
22. *Asymptomatic women of childbearing age; provide or refer women who screen positive to intervention services.*
23. *Routine iron supplementation for asymptomatic children aged 6 to 12 months who are at increased risk for iron deficiency anemia.*
24. *Routine screening in asymptomatic pregnant women.*
25. *Men aged 20 to 35 and women over age 20 who are at increased risk for coronary heart disease; all men aged 35 and older.*
26. *Asymptomatic adults aged 55 to 80 years who have a 30-pack-year smoking history and currently smoke or have quit smoking within the past 15 years.*
27. *Adolescents (aged 12 to 18) when systems are in place to ensure accurate diagnosis, psychotherapy, and follow-up.*
28. *Patients with a body mass index of 30 kg/m² or higher should be offered or referred to intensive, multicomponent behavioral interventions.*
29. *Screen children aged 6 years and older; offer or refer for intensive counseling and behavioral interventions.*
30. *Women aged 65 years and older and women under age 65 whose 10-year fracture risk is equal to or greater than that of a 65-year-old white woman without additional risk factors.*
31. *Newborns.*
32. *All sexually active adolescents and adults at increased risk for STIs.*
33. *Newborns.*
34. *Children, adolescents, and young adults aged 10 to 24 years.*
35. *Ask all adults about tobacco use and provide tobacco cessation interventions for those who use tobacco; provide augmented, pregnancy-tailored counseling for those pregnant women who smoke.*
36. *Provide interventions to prevent initiation of tobacco use in school-aged children and adolescents.*
37. *Screen children aged 3 to 5 years.*

Agency for Healthcare Research and Quality . (2014). The guide to clinical preventive services, 2014: Recommendations of the US Preventive Services Task Force . Author . Available:www.uspreventiveservicestaskforce.org/Page/Name/tools-and-resources-for-better-preventive-care.

Theories of Behavior Change

Lifestyle changes that promote wellness and reduce or prevent illness are often difficult to accomplish. Although education and support by nurses are key, lifestyle changes are ultimately up to the patient. Nurses should understand the concepts and processes related to behavior change to help direct interventions for successful outcomes in individual patients or groups.

Health Belief Model

The health belief model identifies perceptions that influence an individual's behavior. Nurses can inquire about a patient's perceptions in three areas to individualize education and interventions.

1. The first perception is susceptibility to and seriousness of disease or threat of illness. This most directly influences whether a person will take action.
2. The perceived benefit of taking action also affects behavior change.
3. Any perceived barriers to change may prevent or impede action.

Transtheoretical Model

The transtheoretical model of behavior change developed by Prochaska and DiClemente identifies six predictable stages of change. The stages may cycle back and forth several times before change is complete. Education and interventions can be aimed at moving the patient onto the next stage or back into the cycle if a lapse occurs.

1. Precontemplation—no intention to change; may deny that there is a problem; may blame others for any problems.
2. Contemplation—acknowledgment that there is a problem; willing to change but may be ambivalent or anxious about change.
3. Preparation—explores options; actively plans to change; may go public with intent.
4. Action—overtly making a change; substituting desired behavior for old behavior.
5. Maintenance—continuing the change; may devalue old behavior; lapse may occur.
6. Termination—takes on a new self-image; old behavior is no longer a threat.

Patient Teaching and Health Education

Health education is included in the American Nurses Association Standards of Care and is defined as an essential component of nursing care. It is directed toward promotion, maintenance, and restoration of health and toward adaptation to the residual effects of illness.

Learning Readiness

1. Assist the patient in physical readiness to learn by trying to alleviate physical distress that may distract the patient's attention and prevent effective learning.
2. Assess and promote the patient's emotional readiness to learn.
   a. Motivation to learn depends on acceptance of the illness or that illness is a threat, recognition of the need to learn, values related to social and cultural background, and a therapeutic regimen compatible with the patient's lifestyle.
   b. Promote motivation to learn by creating a warm, accepting, positive atmosphere; encouraging the patient to participate in the establishment of acceptable, realistic, and attainable learning goals; and providing constructive feedback about progress.
3. Assess and promote the patient's experiential readiness to learn.
   a. Determine what experiences the patient has had with health and illness, what success or failure the patient has had with learning, and what basic knowledge the patient has on related topics.
   b. Provide the patient with prerequisite knowledge necessary to begin the learning process.

Teaching Strategies

1. Patient education can occur at any time and in any setting; however, you must consider how conducive the environment is to learning, how much time you are able to schedule, and what other family members can attend the teaching session.
2. Use a variety of techniques that are appropriate to meet the needs of each individual.
   a. Lecture or explanation should include discussion or a question-and-answer session.
   b. Group discussion is effective for individuals with similar needs; participants commonly gain support, assistance, and encouragement from other members.
   c. Demonstration and practice should be used when skills need to be learned; ample time should be allowed for practice and return demonstration.
   d. Teaching aids include books, pamphlets, pictures, slides, videos, tapes, and models and should serve as supplements to verbal teaching. These can be obtained from government agencies, such as the Department of Health and Human Services, the Centers for Disease Control and Prevention, and the National Institutes of Health; nonprofit groups, such as the American Heart Association or the March of Dimes; various Internet health Web sites; or pharmaceutical and insurance companies.
   e. Reinforcement and follow-up sessions offer time for evaluation and additional teaching, if necessary, and can greatly increase the effectiveness of teaching.

3. Document patient teaching, including what was taught and how the patient responded; use standardized patient teaching checklists if available.

Health Literacy

1. Health literacy is the ability to read, understand, and act on health information.
2. Health literacy goes beyond ability to read; it encompasses the following processes:
   a. Being able to follow instructions on prescription bottles.
   b. Understanding follow-up and referral appointment information.
   c. Understanding consent forms.
   d. Reading and understanding informational brochures and other instructions.
   e. Being able to negotiate the complex health care system.
3. According to the Institute of Medicine's report "A Prescription to End Confusion," poor health literacy is a stronger predictor of a person's health than age, income, employment status, education level, or race.
4. Vulnerable groups include people over 65 years of age, minorities and immigrants, low-income populations, and people with chronic mental and physical conditions.
5. The majority of Americans read at an eighth-grade level, and 20% read at a fifth-grade level or below. Most health-related materials are written at a 10th-grade reading level.
6. Clear communication between patients and health care professionals is critical. Nurses can assess patient literacy skills, use level-appropriate language and written materials, and help patients ask the right questions. The Ask Me 3 program, designed by the Partnership for Clear Health Communication, encourages patients to ask and understand the answers to the following questions:
   a. What is my main problem?
   b. What do I need to do?
   c. Why is it important for me to do this?

Selected Areas of Health Promotion

Counsel patients about proper nutrition, smoking cessation, physical activity, relaxation, and sexual health to promote well-being.

Nutrition and Diet

EVIDENCE BASE U.S. Department of Health and Human Services and U.S. Department of Agriculture. (December 2015). 2015–2020 Dietary Guidelines for Americans (8th ed.). Available: *http://health.gov/dietaryguidelines/2015/guidelines.*

---

1. Poor diet and sedentary lifestyle are linked to cardiovascular disease, type 2 diabetes, hypertension, osteoporosis, and some cancers.
2. The U.S. DHHS and the U.S. Department of Agriculture recommend and update dietary guidelines every 5 years. These guidelines, combined with physical activity, should enhance the health of most individuals. For more information on these guidelines, see *www.dietaryguidelines.gov*.
3. The 2015–2020 guidelines recommend a healthy eating pattern that accounts for all foods and beverages within an appropriate calorie level.
4. A healthy eating pattern includes the following:
    a. A variety of vegetables from all subgroups—dark green, red and orange, legumes (beans and peas), starchy, and other.
    b. Fruits, especially whole fruits.
    c. Grains, at least half of which are whole grains.
    d. Fat-free or low-fat dairy, including milk, yogurt, cheese, and/or fortified soy beverages.
    e. A variety of protein foods, including seafood, lean meats and poultry, eggs, legumes (beans and peas), and nuts, seeds, and soy products.
    f. Oils.
5. A healthy eating pattern limits the following:
    a. Consume less than 10% of calories per day from added sugars.
    b. Consume less than 10% of calories per day from saturated fats.
    c. Consume less than 2,300 milligrams (mg) per day of sodium.
    d. If alcohol is consumed, it should be consumed in moderation—up to one drink per day for women and up to two drinks per day for men—and only by adults of legal drinking age.
6. Children and adults of all ages should also meet physical activity guidelines to maintain healthy body weight and reduce the risk of chronic disease.
7. Educate patients about the five basic food groups, optimum weight, calorie requirements, and ways to

increase fiber and decrease fat in the diet.

8. Teach patients to add fiber to the diet by choosing whole-grain breads and cereals; raw or minimally cooked fruits and vegetables (especially citrus fruits, squash, cabbage, lettuce and other greens, beans); and any nuts, skins, and seeds. Fiber can also be increased by adding several teaspoons of whole bran to meals each day or taking an over-the-counter fiber supplement, such as psyllium, as directed.
9. Encourage patients to keep food diaries and review them periodically to determine if other adjustments should be made.
10. If weight loss is desired, have the patient weigh in monthly, and review the diet and give praise or corrective advice at this visit. Many people, especially women, respond to group therapy that focuses on education, support, and expression of feelings related to overeating.

NURSING ALERT Encourage all patients to follow up closely with their health care providers if they are following any type of diet. Any diet that is unbalanced may require vitamin supplementation and alter biochemical processes such as cholesterol metabolism and fluid balance.

Smoking Prevention and Cessation

EVIDENCE BASE PDQ® Screening and Prevention Editorial Board. (2017). *PDQ Cigarette Smoking*. Bethesda, MD: National Cancer Institute. Available: *www.cancer.gov/about-cancer/causes-prevention/risk/tobacco/quit-smoking-hp-pdq*. Updated April 27, 2017.

---

1. Smoking is the leading cause of preventable deaths in the United States, with 480,000 deaths per year and many more living with a smoking-related illness such as cancer, heart disease, peripheral vascular disease, or chronic obstructive pulmonary disease (COPD).
2. Not smoking promotes health by increasing exercise tolerance, enhancing taste bud function, and avoiding facial wrinkles and bad breath. A 15% reduction all-cause mortality is seen in heavy smokers subjected to intensive clinical cessation interventions.
3. Smoking prevention education should begin during childhood and be stressed during adolescence, a time when peer modeling and confusion over self-image may lead to smoking.
4. Smoking cessation can be accomplished through an individualized, multidimensional program that includes the following:
   a. Information on the short- and long-term smoking effects.
   b. Behavioral therapy including practical behavior-modification techniques to help break the habit—gum chewing, snacking on carrot and celery sticks, or sucking on mints and hard candy to provide oral stimulation; working modeling clay, knitting, or other ways to provide tactile stimulation;

avoiding coffee shops, bars, or other situations that smokers frequent; delaying each cigarette and recording each cigarette in a log before it is smoked; and incentive plans such as saving money for each cigarette not smoked and rewarding oneself when a goal is reached.

c. Use of medications designed to reduce physical dependence and minimize withdrawal symptoms, including a long- (patch) or short-acting (gum, lozenge, inhaler or nasal spray) nicotine replacement product, varenicline, bupropion, or a combination of products. Nortriptyline and clonidine may also be prescribed.

d. Use of support groups, frequent reinforcement, and follow-up. Encourage additional attempts if relapse occurs.

e. There is not sufficient evidence to recommend the e-cigarette, hypnosis, acupuncture, or other alternative techniques.

5. Although the benefits of quitting are greater the earlier one quits, it is never too late to quit. Even quitting after the diagnosis of cancer improves prognosis and reduces the risk of a second cancer.
6. Many resources are available. For more information, call 1-800-QUIT-NOW or see *www.CDC.gov/tobacco*.

Exercise and Fitness

1. Regular exercise as part of a fitness program helps achieve optimal weight, control BP, increase high-density lipoprotein, lower risk of coronary artery disease, increase endurance, and improve the sense of well-being.
2. Long-term goals of regular exercise include decreased absenteeism from work, improved balance and reduced disability among older adults, decreased osteoporosis and fracture risk, and reduced health care costs.
3. Most health benefits occur with at least 150 minutes of physical activity a week, or 30 minutes of moderate-intensity physical activity (in addition to usual activity) most days of the week. Greater benefits can be obtained by increasing intensity and duration of activity.
   a. Children and adolescents should do 60 minutes of physical activity daily that is age appropriate and includes aerobic, muscle-strengthening, and bone-strengthening activities.
   b. For additional health benefits such as managing or losing weight, adults should increase their aerobic activity to 300 minutes (5 hours) of moderate-intensity or 150 minutes (2.5 hours) of vigorous-intensity aerobic activity weekly.
   c. Muscle-strengthening activities that involve all major muscle groups two or more days a week provide additional benefits.
   d. Older adults and those with disabilities should engage in physical activities as their conditions allow. Generally the benefits of physical activity outweigh potential risks.
4. Suggest walking, jogging, bicycling, swimming, water aerobics, and low-impact aerobic dancing as good low- to moderate-intensity exercise, performed three to five times per week for 45 minutes. Walking can be done safely and comfortably by most patients if the pace is adjusted to the individual's physical

condition. Use of weights is important for muscle strengthening throughout the life span.

   a. Exercise programs should include 5- to 10-minute warm-up and cool-down periods with stretching activities to prevent injuries.
   b. Full intensity and duration of exercise should be increased gradually over a period of several weeks to months.

5. Advise patients to stop if pain, shortness of breath, dizziness, palpitations, or excessive sweating is experienced.
6. Advise patients with cardiovascular, respiratory, and musculoskeletal disorders to check with their health care provider about specific guidelines or limitations for exercise.

GERONTOLOGIC ALERT Older adults who are at risk for falling should do exercise that maintains or improves balance.

NURSING ALERT Severe cases of COPD, osteoarthritis, or coronary disease are contraindications for unsupervised exercise; check with the patient's health care provider to see if a physical therapy or occupational therapy referral would be helpful.

Relaxation and Stress Management

1. *Stress* is a change in the environment that is perceived as a threat, challenge, or harm to the person's dynamic equilibrium. In times of stress, the sympathetic nervous system is activated to produce immediate changes of increased heart rate, peripheral vasoconstriction, and increased BP. This response is prolonged by adrenal stimulation and secretion of epinephrine and norepinephrine and is known as the "fight-or-flight" reaction.
2. A limited amount of stress can be a positive motivator to take action; however, excessive or prolonged stress can cause emotional discomfort, anxiety, possible panic, and illness.
3. Prolonged sympathetic–adrenal stimulation may lead to high BP, arteriosclerotic changes, and cardiovascular disease; stress has also been implicated in acute asthma attack, peptic ulcer disease, irritable bowel syndrome, migraine headaches, and other illnesses.
4. Stress management can help patients control illnesses, improve self-esteem, gain control, and enjoy life more fully.
5. Stress management involves the identification of physiologic and psychosocial stressors through assessment of the patient's education, finances, job, family, habits, activities, personal and family health history, and responsibilities. Positive and negative coping methods should also be identified.
6. Relaxation therapy is one of the first steps in stress management; it can be used to reduce anxiety brought

on by stress. Relaxation techniques include the following:

a. Relaxation breathing—the simplest technique that can be performed at any time. The patient breathes slowly and deeply until relaxation is achieved; however, this can lead to hyperventilation if done incorrectly.
b. Progressive muscle relaxation—relieves muscle tension related to stress. The patient alternately tenses and then relaxes muscle groups until the entire body feels relaxed.
c. Autogenic training—can help relieve pain and induce sleep. The patient replaces painful or unpleasant sensations with pleasant ones through self-suggestions; may require extensive coaching at first.
d. Imagery—uses imagination and concentration to take a "mental vacation." The patient imagines a peaceful, pleasant scene involving multiple senses. It can last as long as the patient chooses.
e. Distraction—uses the patient's own interests and activities to divert attention from pain or anxiety and includes listening to music, watching television, reading, singing, knitting, coloring, doing crafts or projects, or physical activities.

7. To assist patients with relaxation therapy, follow these steps:
   a. Review the techniques and encourage a trial with several techniques of the patient's choice.
   b. Teach the chosen technique and coach the patient until effective use of the technique is demonstrated.
   c. Suggest that the patient practice relaxation techniques for 20 minutes per day to feel more relaxed and to be prepared to use them confidently when stress increases.
   d. Encourage the patient to combine techniques such as relaxation breathing before and after imagery or progressive muscle relaxation along with autogenic training to achieve better results.
8. Additional steps in stress management include dealing with the stressors or problem areas and increasing coping behaviors.
   a. Help the patient to recognize specific stressors and determine if they can be altered. Then develop a plan for managing that stressor, such as changing jobs, postponing an extra class, hiring a babysitter once per week, talking to the neighbor about a problem, or getting up 1 hour earlier to exercise.
   b. Teach the patient to avoid negative coping behaviors, such as smoking, drinking, using drugs, overeating, cursing, and using abusive behavior toward others. Teach positive coping mechanisms, such as continued use of relaxation techniques and fostering of support systems—family, friends, church groups, social groups, or professional support groups.

Sexual Health

1. Because sexuality is inherent to every person and sexual functioning is a basic physiologic need of human beings, nurses can help patients gain knowledge, validate normalcy, prepare for changes in sexuality throughout the life cycle, and prevent harm gained through sexual activity.
2. Education about sexuality should begin with school-age children, increase during adolescence, and continue through adulthood.

3. Topics to cover include the following:
    a. Relationships, responsibilities, communication.
    b. Normal reproduction—the menstrual cycle, ovulation, fertilization, sperm production.
    c. Prevention of unwanted pregnancy (approximately 1 million teen pregnancies occur in the United States each year) and sexually transmitted diseases (STDs).
4. The Centers for Disease Control and Prevention estimates that there are approximately 19 million new STD infections each year, which cost the U.S. health care system $16.4 billion annually and cost individuals even more in terms of acute and long-term health consequences.
    a. The number of cases of gonorrhea is declining and the number of cases of chlamydia is increasing (probably due to increased screening), but still only about half of people at risk for STDs are screened.
    b. Chlamydia, gonorrhea, and syphilis are reportable to state and local health departments; however, other STDs such as human papillomavirus (HPV) and herpes simplex virus are prevalent and cause chronic effects. Complications of STDs include pelvic inflammatory disease, infertility, serious vital organ damage in the case of tertiary syphilis, cervical cancer in the case of HPV, and increased risk of contracting HIV.
    c. Nurses are in a key position to teach prevention through abstinence and barrier protection, identify cases through screening for earlier treatment, and reduce the burden of these serious and often chronic diseases.
5. Use and refer patients to such resources as the American Sexual Health Association (*www.ashastd.org*) and Centers for Disease Control and Prevention Health Topics A to Z: (*www.cdc.gov/health/default.htm*).

Genetics and Health Applications

Human Genetics

Underlying Principles

Clinical Application

Genetic Disorders

Precision Health Care

Genetic Counseling

HUMAN GENETICS

Human genetics, as it pertains to health care, is the study of the etiology, pathogenesis, and natural history of human conditions that are influenced by genetic factors. Genetic factors extend beyond the limited view of solely distinct genetic syndromes to encompass influences on health, the occurrence of complex disorders, individual biologic responses to illness, potential treatment and medical management approaches, and strategies for prevention or cure.

This tremendous realization is apparent through the accomplishments of initiatives such as the Human Genome Project. This 15-year international collaborative effort was completed in 2003. One significant goal of the Human Genome Project was to identify the approximately 25,000 human genes. These advances and the associated knowledge will continue to affect the delivery of health care and nursing practice significantly. Genetic evaluations, screening, testing, guided treatment, family counseling, and related legal, ethical, and psychosocial issues are increasingly becoming daily practice for many nurses.

The impact of genetics on nursing is significant. In 1997, the American Nurses Association (ANA) officially recognized genetics as a nursing specialty. This effort was spearheaded by the International Society of Nurses in Genetics (ISONG), which also initiated credentialing for the Advanced Practice Nurse in Genetics and the Genetics Clinical Nurse. ANA and ISONG have collaborated in the establishment of a scope and standards of practice for nurses in genetics practice. Essential Nursing Competencies and Curricula Guidelines for Genetics and Genomics were finalized in 2006 with Outcome Indicators established in 2008. The 2nd edition was published in 2009, "Essentials of Genetic and Genomic Nursing: Competencies, Curricula Guidelines, and Outcome Indicators." They reflect the minimal genetic and genomic competencies for every nurse regardless of academic preparation, practice setting, role, or specialty. In 2012, the ANA and ISONG published "Essential Genetic and Genomic Competencies for Nurses with Graduate Degrees." A copy of both of these documents is available through the ANA Web site (*www.nursingworld.org/genetics*).

The purpose of this chapter is to provide the nurse with practical information, resources, representative examples, and professional considerations critical to integration of genetics knowledge into nursing practice.

Underlying Principles

Readers are encouraged to use the Talking Glossary of Genetic Terms available through the National Human Genome Research Institute to supplement the terms provided here. This glossary can be found at *www.genome.gov/glossary*.

Cell: The Basic Unit of Biology

1. Cytoplasm—contains functional structures important to cellular functioning, including mitochondria, which contain extranuclear deoxyribonucleic acid (DNA) important to mitochondrial functioning.
2. Nucleus—contains 46 chromosomes in each somatic (body) cell or 23 chromosomes in each germ cell (egg or sperm) (see Figure 4-1, page 28).

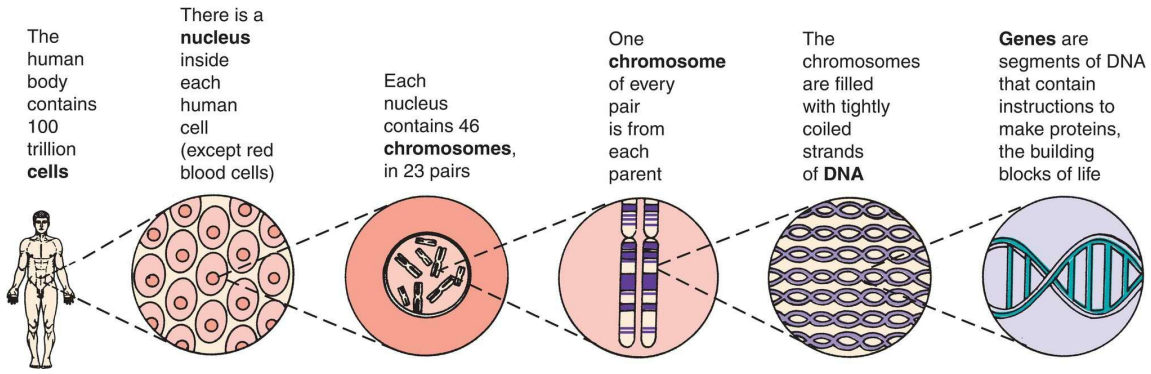

Figure 4-1. Cells, chromosomes, DNA, and genes.

Chromosomes

1. Each somatic cell with a nucleus has 22 pairs of autosomes (the same in both sexes) and 1 pair of sex chromosomes.
2. Females have two X sex chromosomes; males have one Y sex chromosome and one X sex chromosome.
3. Normally, at conception, each individual receives one copy of each chromosome from the maternal egg cell (1 genome, also called haploid) and one copy of each chromosome from the paternal sperm cell (1 genome), for a total of 46 chromosomes (2 genomes, also called diploid).
4. *Karyotype* is the term used to define the chromosomal complement of an individual (eg, 46, XY), as is determined by laboratory chromosome analysis.
5. Each chromosome contains a different number of genes, with a range of approximately 300 to 3,000 genes.

Genes

1. The basic unit of inherited information.
2. Each copy of the human genome in the nucleus has about 20,000 genes. Cells also have some nonnuclear genes located within the mitochondria within the cytoplasm.

3. Alternate forms of a gene are termed *alleles*.
4. For each gene, an individual receives one allele from each parent and thus has two alleles for each gene on the autosomes and also on the X chromosomes in females.
5. Males have only one X chromosome and, therefore, have only one allele for all genes on the X chromosome; they are hemizygous for all X-linked genes.
6. At any autosomal locus, or gene site, an individual can have two identical alleles (homozygous) for that locus or can have two different alleles (heterozygous) at a particular locus.
7. *Genotype* refers to the constitution of the genetic material of an individual; for practical purposes, it is commonly used to refer to a particular base or bases in the DNA, for example, the gene for sickle cell disease, the gene for cystic fibrosis, or the gene for familial polyposis.
8. *Phenotype* refers to the physical or biochemical characteristics an individual manifests regarding expression of the presence of a particular feature, or set of features, associated with a particular gene.
9. Each gene is composed of a unique sequence of DNA bases.

DNA: Nuclear and Mitochondrial

1. Human DNA is a double-stranded helical structure comprised of four different bases, the sequence of which codes for the assembly of amino acids to make a protein—for example, an enzyme. These proteins are important for the following reasons:
   a. For body characteristics such as eye color.
   b. For biochemical processes such as the gene for the enzyme that digests phenylalanine.
   c. For body structure such as a collagen gene important to connective tissue and bone formation.
   d. For cellular functioning such as genes associated with the cell cycle.
2. The four DNA bases are adenine, guanine, cytosine, and thymine (A, G, C, and T).
3. A change, or mutation, in the coding sequence, such as a duplicated or deleted region, or even a change in only one base, can alter the production or functioning of the gene or gene product, thus affecting cellular processes, growth, and development.
4. DNA analysis can be done on almost any body tissue (blood, muscle, skin) using molecular techniques (not visible under a microscope) for mutation analysis of a specific gene with a known sequence or for DNA linkage of genetic markers associated with a particular gene.

Normal Cell Division

1. Mitosis occurs in all somatic cells, which, under normal circumstances, results in the formation of cells identical to the original cell with the same 46 chromosomes.
2. Meiosis, or reduction division, occurs in the germ cell line, resulting in gametes (egg and sperm cells) with only 23 chromosomes, one representative of each chromosome pair.
3. During the process of meiosis, parental homologous chromosomes (from the same pair) pair and undergo exchanges of genetic material, resulting in recombinations of alleles on a chromosome and thus variation in individuals from generation to generation.

CLINICAL APPLICATION

Genetic Disorders

Presentations warranting genetic consideration include intellectual disability, birth defects, biochemical or metabolic disorders, structural abnormalities, multiple miscarriages, and family history of the same or related disorder.

Examples of disorders that result from abnormalities of chromosomes or genes or that are, at least in part, influenced by genetic factors are described in Table 4-1.

Table 4-1 Selected Genetic Disorders

DISORDER AND INCIDENCE	CHARACTERISTICS	ETIOLOGY AND RECURRENCE RISKS	CONSIDERATIONS AND COMMENTS
Chromosomal Disorders			
Autosomal			
Down syndrome (Trisomy 21) 1 in 700 neonates; incidence increases with advanced maternal age (eg, risk at maternal age 25 is 1 in 1,350; at age 35, 1 in 384; at age 45, 1 in 28)	Brachycephaly: oblique palpebral fissures; epicanthal folds; Brushfield spots; flat nasal bridge; protruding tongue; small, low-set ears; clinodactyly; simian crease; congenital heart defects; hypotonia; intellectual disability; growth retardation; dry, scaly skin; increased risk for childhood leukemia and early-onset Alzheimer disease	• Extra copy of number 21 chromosome (total of three copies). • 94% of cases are trisomy (karyotype 47, +21) for three distinct number 21 chromosomes because of nondisjunction (failure of chromosomal separation during meiosis); recurrence risk 1%, plus maternal age–related risk if older than age 35. • 4% of cases have a translocation—the extra number 21 is attached to another chromosome, usually a number 13 or number 14; half of these translocations are new occurrences, and the other half are inherited from a parent. • 2% of cases are mosaic—affected individual has two different cell lines, one with the normal number of chromosomes and the other cell line trisomic for the number 21 chromosome; because of a postconception error in chromosomal division during mitosis.	• Recurrence risk for parents of affected are dependent on one or more of the following: chromosomal type of disorder, maternal age, parental karyotype, family history, and sex of transmitting parent and other chromosome involved (if translocation). • May demonstrate nuchal thickening prenatally on ultrasound examination. • Associated with moderate intellectual disability. • No phenotypic differences between trisomy Down syndrome and translocation Down syndrome. • Chromosome analysis should be performed on all persons with Down syndrome. • Prenatal maternal serum screening can adjust risk for the pregnancy. See page 1458 for nursing care.
Trisomy 13 (Patau syndrome) 1 in 5,000 live births	Holoprosencephaly; cleft lip or palate, or both; abnormal helices; cardiac defects; rocker-bottom feet; overlapping positioning of fingers; seizures; severe intellectual disability	• Extra number 13 chromosome (total of three copies): Either trisomy form, because of nondisjunction, with less than a 1% recurrence risk, or translocation form, with recurrence risk less than that of translocation Down syndrome and dependent on other factors, including chromosomes involved.	• 44% die within the first month; 18% survive first year of life.
Trisomy 18 (Edwards syndrome) 1 in 6,000 live births	Small for gestational age (may be detected prenatally); feeble fetal activity; weak cry; prominent occiput; low-set, malformed ears; short palpebral fissures; small oral opening; overlapping positioning of fingers (fifth digit over fourth, index over third); nail hypoplasia, short hallux; cardiac defects; inguinal or umbilical hernia; cryptorchidism in males; severe intellectual disability	• Extra number 18 chromosome (total of three copies): Majority due to nondisjunction resulting in three distinct chromosome 18s with less than 1% recurrence risk.	• Most trisomy 18 conceptions miscarry; 90% die within first year of life.

Sex Chromosome			
Klinefelter syndrome 1 in 700 males; 47, XXY abnormality in 90%; other 10% have more than two X chromosomes in addition to the Y chromosome or have mosaicism (about 20%)	Body habitus may be tall, slim, and underweight; long limbs; gynecomastia; small testes; inadequate virilization; azoospermia or low sperm count; cognitive defects; behavioral problems	• Because of nondisjunction during meiosis, except for cases of mosaicism, which are due to mitotic nondisjunction.	• No distinguishing features prenatally. • Diagnosis may not be suspected or pursued before puberty. • Diagnosis in childhood is beneficial in planning for testosterone replacement therapy, in addition to accurate understanding of learning or behavioral problems. • Tend to be delayed in onset of speech, have difficulty in expressive language, may be relatively immature, may have history of recurrent respiratory infections.
Turner syndrome (45, X) 1 in 2,500 female births	Webbing of neck and short stature; lymphedema of hands and feet as neonate; congenital cardiac defects (especially coarctation of the aorta); low posterior hairline; cubitus valgus; widely spaced nipples; underdeveloped breasts; immature internal genitalia (eg, streak ovaries); primary amenorrhea; learning disabilities	• About 50% because of a nondisjunctional error during meiosis (karyotype 45, X); 20% are mosaic because of nondisjunction during mitosis; 30% have two X chromosomes, but one is functionally inadequate (eg, because of presence of abnormal gene); generally a sporadic occurrence.	• Webbing of neck and short stature may be detected prenatally by ultrasound. • Early diagnosis enhances optimal health care management (eg, planning for administration of growth hormone therapy, estrogen replacement). • Psychosocial implications associated with short stature, delayed onset of puberty. • Infertility associated with ovarian dysgenesis; oocyte donation and adoption are generally the only options for having children. See page 1461.
Microdeletion/Microduplication			
Fragile X syndrome 1 in 3,600 males; 1 in 4,000 females	Motor delays; hypotonia; speech delay and language difficulty; hyperactivity; classic features including long face, prominent ears, and macroorchidism manifest around puberty; autism (about 7% of males); intellectual disability in most males; learning disabilities in most affected females	• Mutation in the FMR-1 gene, represented as a large DNA expansion of a normally present trinucleotide. • Carrier mother of an affected male has a 50% risk for future affected males and 50% chance of transmitting the FMR-1 X chromosome to a daughter who would be a carrier, may be unaffected, or manifest features associated with the fragile X syndrome and has a 50% chance of transmitting that gene to future offspring.	• Expansion of DNA in the region of the gene that houses a CpG island results in methylation of the DNA resulting in the gene being "shut down," and the protein normally made by the gene is not made resulting in the phenotype. Testing involves DNA analysis to characterize the size of the DNA expansion. Testing for methylation status of the DNA increases sensitivity. • Phenotypic expression of this gene in males and females is variable; genetic mechanisms determining expression of this gene are very complicated. • Fragile X should be considered in the differential diagnosis of any male with intellectual disability who is undiagnosed; it is the most common intellectual disability in males.

Microdeletion/Microduplication			
Prader-Willi syndrome Estimated incidence 1 in 15,000	Hypotonia and poor sucking ability in infancy; almond-shaped palpebral fissures; small stature; small, slow growth of hands or feet; small penis, cryptorchidism; insatiable appetite, behavioral problems developing in childhood; below-normal intelligence or intellectual disability	• Cytogenetic microdeletion in chromosome 15q11 to 13 identified in 50% to 70% of cases; deletion associated with paternally inherited number 15 chromosome. • Generally sporadic occurrence; empiric recurrence risk 1.6%.	• Consider diagnosis in infants presenting with hypotonia and sucking problems where etiology is unknown. • Associated with lack of a functioning paternal gene at this locus; presents clinical evidence for the necessity of two functioning genes, both a maternal and paternal contribution. • Another distinct entity, termed *Angelman syndrome*, is associated with a deletion of the maternal contribution in this same cytogenetic region; it is also associated with mental deficiency but with a different phenotypic presentation.
Mendelian Disorders—Single Gene			
Autosomal Dominant			
Achondroplasia 1 in 10,000 live births Increased incidence associated with advanced paternal age (>40)	Megalocephaly; small foramen magnum and short cranial base with early sphenooccipital closure; prominent forehead; low nasal bridge; midfacial hypoplasia; small stature; short extremities; lumbar lordosis; short tubular bones; incomplete extension at the elbow; normal intelligence	• Autosomal dominant inheritance; 80% to 90% are due to a new mutation and neither parent is affected. • An affected parent has a 50% risk to transmit the gene to each child.	• Hydrocephalus can be a complication of achondroplasia and may be masked by megalocephaly. • Risk for apnea secondary to cervical spinal cord and lower brain stem compression because of alterations in shape of cervical vertebral bodies; respiratory problems are also a risk because of the small chest and upper airway obstruction. • Can be diagnosed prenatally by ultrasound.
Osteogenesis imperfecta (Type 1) 1 in 15,000 live births	Blue sclerae; fractures (variable number); deafness may occur	• Defect in the procollagen gene associated with decreased synthesis of a constituent chain important to collagen structure. • Can occur as a new mutation in that gene or can be inherited from a parent who has a 50% recurrence risk to transmit the gene; most severe cases represent a sporadic occurrence within a family.	• There are at least four general classifications of osteogenesis imperfecta, each with varying clinical severity, presentation, and pattern of genetic transmission. • Treatment with calcitonin and fluoride may be beneficial in reducing the number of fractures.
Breast and breast/ovarian cancer syndrome Accounts for 5% to 10% of breast cancer	Breast cancer (usually, but not exclusively, early-age onset, premenopausal); ovarian cancer	• Mutation in the BRCA1 or BRCA2 gene; poses increased susceptibility (not certainty) for breast (31% to 78%) and/or ovarian (3% to 54%) cancer.	• Studies have also noted increased risk for prostate cancer and colon cancer in some families; also an association between male breast cancer and BRCA2 mutations. • Individuals from Ashkenazi Jewish ancestry are at increased risk for mutations in BRCA1 and BRCA2.

Autosomal Dominant			
Familial adenomatous polyposis (FAP) Accounts for about 1% of colon cancer	Associated with multiple adenomatous colorectal polyps (classic: >100; atypical: <100), desmoid tumors, other GI polyps, jaw cysts; family history of polyps or colorectal cancer; polyps progress to cancer; polyps can be present in childhood	• Mutations in the APC gene (a tumor suppressor gene). The majority of APC mutations result in a truncated protein. • Mutations in the MUTYH gene (a DNA repair gene). The majority of mutations in MUTYH result in an amino acid change.	• Genetic testing (protein truncation testing is available). If mutation is identified in affected person, relatives can be tested for the same finding. Relatives at risk, whether by family history or by genetic testing, should start cancer screening by age 18, if not earlier, if there are symptoms or as a baseline. Screening includes colonoscopy and ophthalmologic examination.
Autosomal Recessive			
Sickle cell disease 1 in 400 live births of African Americans	Physically normal in appearance at birth; hemolytic anemia and the occurrence of acute exacerbations (crises), resulting in increased susceptibility to infection and vascular occlusive episodes	• Point mutation in the beta globin gene resulting in an altered gene product; red blood cells susceptible to sickling at times of low-oxygen tension. • Parents of an affected individual are both unaffected carriers of one abnormal copy of the beta globin gene (sickle cell trait); together have a 25% risk for recurrence in any offspring.	• 1 in 10 African Americans is a carrier of the beta globin gene mutation; population screening is indicated for these individuals. • Unaffected siblings of an affected individual have two-thirds, or 67%, risk to have the sickle cell trait and should be screened. • See page 1376 for nursing care. • Prenatal testing is available through DNA analysis from specimen obtained during chorionic villus sampling or amniocentesis.
Cystic fibrosis (CF) 1 in 2,500 live births (predominantly white)	Phenotypically normal at birth; may present with meconium ileus (10%) as neonate or later with persistent cough, recurrent respiratory problems, gastrointestinal complaints, malnutrition, abdominal pain, or infertility	• Mutation in the CF transmembrane conduction regulator gene on chromosome 7 results in an abnormality of a protein integral to the cell membrane. • Healthy parents of an affected individual are both considered obligate carriers of one copy of the abnormal CF gene; thus, together, they have a 25% recurrence risk with each conception.	• 1 in 25 White from Northern European ancestry; 1 in 58 Hispanic White; and 1 in 61 African Americans is a carrier of a CF gene mutation. • Many different mutations have been identified within the CF gene, the most common of which is Delta-F508, which accounts for about 70% of CF mutations. CF screening can identify about 85% of all CF mutations, but the rate of detection varies by ancestry (94% in Ashkenazi Jewish population; 88% in non-Hispanic Whites; 72% in Hispanic Whites; 64% in African Americans; and 49% in Asian Americans). • "General population" screening is recommended by the American College of Obstetrics and Gynecology. • DNA analysis of the CF gene is advised for affected individuals and relatives of persons with CF. • See page 1191 for nursing care.

Autosomal Recessive			
Tay-Sachs disease 1 in 3,600 Ashkenazi Jews	Normal at birth; progressive neurodegenerative manifestations, including loss of developmental milestones and lack of central nervous system maturation; cherry-red spot on macula	• Mutation in the gene for hexosaminidase A, an enzyme important to cellular metabolic processes, results in accumulation of metabolic by-products within the cell (especially brain), impairing functioning and causing the neurodegenerative effects. • Parents of an affected individual are both considered unaffected obligate carriers of one copy of the Tay-Sachs disease gene; together, they have a 25% risk of recurrence in their offspring.	• About 1 in 25 Ashkenazi Jews is a carrier of the Tay-Sachs gene; about 1 in 17 French Canadians is a carrier of an abnormal Tay-Sachs gene (different mutation from that of the Jewish ancestry); persons of these ancestries should be screened. • No treatment available; results in death in childhood. • Prenatal and preimplantation testing are available.
X-Linked Recessive			
Duchenne muscular dystrophy (DMD) 1 in 3,500 males	Phenotypically normal at birth; dramatically elevated creatinine kinase level (detectable as early as age 2 days); hypertrophy of the calves; history of tendency to trip and fall (at about age 3); Gowers sign (tendency to push off oneself when getting up from a sitting position)	• DNA mutation, generally a deletion, detectable in 70% of affected males. • Carrier females have a 25% risk, with each pregnancy, to have an affected male, a 25% risk to have a carrier female, a 25% chance to have a healthy male, and a 25% chance to have a healthy noncarrier female.	• 1 in 1,750 females is a carrier of the DMD gene. • In the case of an isolated affected male, the mother has a two-thirds statistical risk that she is a carrier of the DMD gene and a one-third chance that her affected son developed as the result of a new mutation in that gene (she is not a carrier). • DNA testing is recommended for affected males; once type of gene mutation is known in that family, prenatal diagnosis and evaluation of potential female carriers can be carried out. • DNA analysis may provide clues as to expected clinical severity.
Hemophilia A 1 in 5,000 males	Phenotypically normal at birth; bleeding tendency (ranging from frequent spontaneous bleeds associated with the severe form to bleeding only after trauma associated with the mild form)	• Deficiency of Factor VIII (antihemophilic factor) because of abnormality in this gene located on the X chromosome. • Carrier females have a 25% risk, with each pregnancy, to have an affected son, a 25% risk to have a carrier daughter, and a 25% chance each to have a healthy unaffected daughter or son. • Mates of affected males should be tested for carrier status. If the female is not a carrier, the affected male will not have any affected children.	• Frequency of carrier females is about 1 in 3,500. • The severe form occurs in about 48% of cases. • Moderate cases account for 31%. • The mild form accounts for 21% of cases. • See page 1384 for nursing care.

X-Linked Recessive			
Glucose-6-phosphate dehydrogenase (G6PD) Frequency varies by ancestry (ie, 11% to 12% of male live births of African American origin and 60% to 70% of Kurdish Jewish origin)	Phenotypically normal at birth; many remain asymptomatic throughout life; may manifest acute hemolysis associated with exposure to outside factors (eg, certain medications)	• Abnormality of the G6PD gene on the X chromosome. • Carrier females have a 25% risk, with each pregnancy, to have an affected male and 25% risk to have a carrier female.	• Be aware of drugs, such as antimalarial drugs or sulfonamides, or chemicals, such as phenylhydrazine (used in silvering mirrors, photography, soldering), associated with hemolysis in G6PD-deficient individuals.
Multifactorial Disorders			
Neural tube defects 1 in 1,000 live births	Abnormalities of neural tube closure, ranging from anencephaly to myelomeningocele to spina bifida occulta	• Probably several genetic factors may predispose certain individuals or families to susceptibility, but certain environmental (eg, prolonged hyperthermia or folate deficiency) and other unknown factors play an additive rule in surpassing an arbitrary threshold, placing the developing fetus at risk. • Recurrence risk for isolated neural tube defects range between 1% and 5%.	• Recurrence risk for isolated neural tube defects is dependent on the severity of the defect (ie, a defect in the neurulation [the cranial end of the neural tube] vs. cannulation [the development of the caudal end]) and if there is a positive family history. • Maternal screening can be performed prenatally (after 14 weeks' gestation) through alpha-fetoprotein levels in maternal serum. • Can be associated with chromosomal or genetic disorders.
Cleft lip and/or cleft palate 1 in 1,000 live births	Unilateral or bilateral; cleft lip and cleft palate may occur together or in isolation	• Failure of migration and fusion of the maxillary processes during embryogenesis. • Recurrence risk for first-degree relatives of a person with an isolated cleft lip or cleft palate ranges between 2% and 6%.	• Clefting can occur as an isolated congenital abnormality or be one component of a syndrome, genetic defect, or chromosome abnormality, the latter three of which are associated with a recurrence risk specific to that disorder. • Recurrence for isolated cleft lip or palate is dependent on the type of cleft, the sex of the affected individual, and the family history. See page 1271.

Classification of Genetic Alterations

Chromosomal

1. The entire chromosome or only part can be affected. This is usually associated with birth defects and intellectual disability because there are extra or missing copies of all genes associated with the involved chromosome.
   a. Numerical—abnormal number of chromosomes because of nondisjunction (error in chromosomal separation during cell division). Examples are Down and Klinefelter syndromes.
   b. Structural—abnormality involving deletions, additions, or translocations (rearrangements) of parts of chromosomes. Examples are Prader-Willi and Angelman syndromes.
2. May involve autosomes or sex chromosomes.

Single Gene or Pair of Genes

1. Manifestations are specific to cells, organs, or body systems affected by that gene.
2. Autosomal dominant—presence of a single copy of an abnormal gene results in phenotypic expression.
   a. These genes may involve proteins of a structural nature such as collagen. Affected individuals are

usually of normal intelligence.

b. Can be inherited from one parent, whose physical manifestations can vary, depending on the specific disorder and the gene's penetrance and expressivity (eg, neurofibromatosis).

c. Can arise as a result of a new mutation in that gene in the affected individual.

d. An individual with an autosomal dominant gene has a 50% chance of transmitting that gene to all offspring.

3. Autosomal recessive—requires that both alleles at a gene locus be abnormal for an individual to be affected.

a. These genes are frequently important to biochemical functions, such as the breakdown of phenylalanine. Depending on the gene and the nature of the mutation, affected individuals may be of normal intelligence or have intellectual disability.

b. Generally, two healthy parents of an affected child are considered obligate carriers (unaffected) of one copy of the abnormal gene.

c. Such a carrier couple has a 25% chance, with each pregnancy, to have an affected child, a 50% chance for the child to be an unaffected carrier, and a 25% chance for the child to be an unaffected noncarrier.

4. X-linked recessive—because of one or more abnormal genes on the X chromosome.

a. These genes may be important to structure or biochemical function. Depending on the gene and the nature of the mutation, affected individuals may be of normal intelligence or have intellectual disability.

b. Recessively inherited, in most cases, meaning that two abnormal genes are required to be affected. However, only one abnormal gene needs to be present for a male to be affected because males are hemizygous for all X-linked genes, as in Duchenne muscular dystrophy.

c. Females are typically only carriers of X-linked recessive disorders because the presence of a corresponding normal gene on the other X chromosome in a female produces enough gene products for normal functioning. Carrier females can be affected to varying degrees in certain circumstances. Incidence of females affected with X-linked recessive conditions is possible and usually have an affected father and a carrier mother.

d. A carrier female has a 25% chance, with each pregnancy, to have an affected son, a 25% chance to have a carrier daughter, a 25% chance to have an unaffected son, and a 25% chance to have an unaffected noncarrier daughter.

e. A male with an abnormal X-linked gene who has children with a noncarrier female will transmit that gene to all of his daughters, who will be carriers of that gene (usually unaffected); none of his sons will inherit his abnormal X-linked gene because they receive his Y chromosome.

5. X-linked dominant—relatively rare.

a. Mutations in these genes are usually lethal to male conceptions, as in Rett syndrome.

b. Depending on the gene and the nature of the mutation, affected females may be of normal intelligence or have intellectual disability. An example is incontinentia pigmenti.

6. Mitochondrial—genes whose DNA is within the mitochondria, which are located in the cytoplasm, not in the nucleus and therefore do not follow Mendelian laws of inheritance.
    a. Many of these genes are associated with respiratory functions within mitochondria and thus affect energy capacity of cells. Disorders may be manifested by diminished strength in the involved tissue or myopathy.
    b. Essentially are maternally inherited because the egg cell contains the cytoplasmic material that is involved in the zygote; the sperm cell contributes mainly only nuclear DNA.
    c. Varying phenotypes, depending on the number and distribution of abnormal mitochondrial genes.
    d. Males and females can have mitochondrial conditions, but males transmit few, if any, mitochondrial genes to their offspring.

Multifactorial

1. Caused by multiple genetic factors in addition to other nongenetic influences (eg, environmental).
2. Because of the genetic components, affected individuals or close relatives are at an increased risk, compared with the general population, to have an affected child or develop the condition themselves.
3. Elimination of known nongenetic risk factors or proactive treatment regimen in some conditions can reduce risk for occurrence (eg, diet modification to manage hypercholesterolemia, cessation of smoking to reduce risk of cancer, or weight control and exercise to prevent type 2 diabetes in susceptible individuals).

Precision Health Care

Precision health care is the tailoring of health care to the individual patient. Data informing the health care provider to enable precision health care to a patient include information about their lifestyle, environment, and genetic makeup (ie, genetic variations drive a lot of the variability in how patients respond to medications) or the genetic makeup of their diseased cells (ie, using information on gene expression in cancer cells to prognosticate and select targeted therapies). This is a rapidly evolving area of health care on which genomics is having a huge impact. The National Institutes of Health website provides a timely resource for information about the Precision Medicine Initiative at *www.nih.gov/research-training/allofus-research-program*.

Genetic Counseling

Genetic counseling is a communication process that deals with human problems associated with the occurrence or recurrence of a genetic disorder in a family or individual at increased risk for a condition that has a genetic component because of factors such as ancestral background or the results of screening tests. For these individuals or families, specific concern exists about risk associated with a certain problem or because of the relationship to someone who is affected (the proband). Several steps occur in the genetic evaluation, including obtaining and reviewing the medical history and records of the affected, eliciting the family history with special attention to factors pertinent to the diagnosis in the proband, evaluating and examining the affected (if available and indicated), ordering appropriate tests and interpreting results, and then meeting with the person seeking the consultation and/or the proband.

Goals of Genetic Counseling

Assist the patient and proband to:

1. Comprehend the medical facts, including the diagnosis, the possible course of the disorder, and the available management.
2. Understand the inheritance of the disorder, susceptibility to a condition, and the risk of recurrence in specified relatives.
3. Understand the options for dealing with the risk of recurrence.
4. Choose a course of action that seems appropriate to the individuals involved; consider their risk, family goals, and religious beliefs and act in accordance with that decision.
5. Make the best possible adjustment to the disorder.
6. Understand the individual risks and the types of testing available and assist with interpretation and follow-up of test results.

Identify People in Need of Genetic Assessment and Counseling

1. Parents of a child with a birth defect, intellectual disability, or known or possible genetic disorder.
2. Any individual with a genetic or potentially genetic disorder.
3. People with a family history of intellectual disability, birth defects, genetic disorder, or condition that tends to run in the family.
4. Pregnant women who will be age 35 or older at the time of delivery.
5. Couples of ancestral/ethnic origin known to be at an increased risk for a specific genetic disorder.
6. Couples who have experienced two or more miscarriages.
7. Pregnant women who have an elevated or low maternal serum screening test result such as alpha-fetoprotein (AFP).
8. Women who have been exposed to drugs or infections during pregnancy.
9. Couples who are related to each other.
10. Couples who are identified as carriers of autosomal recessive conditions through screening.

11. People who are concerned about the risk for a genetic disorder.

Genetic Screening, Testing, and Research

Screening

1. Screening is the level of testing offered to large populations (eg, neonate) or to high-risk segments of the population at increased risk of being carriers (such as individuals from African ancestry, Ashkenazi Jewish ancestry, and Mediterranean ancestry) to identify individuals with a genetic disorder, increased risk for abnormality, or carriers of a genetic disorder.
2. Criteria include that the test itself must be reliable, appropriate to the designated population, and cost-effective and that the condition being tested must be treatable or that early identification will enhance quality of life.
3. Neonate screening varies among facilities and states; however, all states and facilities test for a minimum of 30 conditions including phenylketonuria, hypothyroidism, sickle cell disease, and galactosemia, with most states testing for up to 50 or more conditions.
4. Prenatal screening includes multiple-marker screening that uses maternal serum to test AFP level alone or the triple screen (includes measurement of maternal serum AFP, beta-human chorionic gonadotropin, and estriol). A fourth protein, inhibin-A, measured by some laboratories, is called the quadruple screen. These tests are typically conducted after 14 weeks' gestation and can identify pregnancies at increased risk for neural tube defects (NTD), Down syndrome, trisomy 13 (Patau syndrome), and trisomy 18 (Edwards syndrome).

EVIDENCE BASE National Newborn Screening and Genetic Resource Center. (2018). Resources on newborn screening including the national newborn screening status reports. Available: *http://genes-r-us.uthscsa.edu* .

Testing

1. Biochemical testing is done on body tissue or fluid to measure enzyme levels and activity.
2. DNA testing is done on blood or tissue samples to look for a gene mutation or to study DNA linkage.
3. Chromosomal testing is done on nucleated cells (usually white blood cells) or other tissue for detection of various conditions, such as extra, missing, deleted, duplicated, or rearranged chromosomes.

Prenatal Testing

1. Chorionic villus sampling—for chromosomal and DNA testing; done at 9 to 12 weeks' gestation.
2. Amniocentesis—for chromosomal, biochemical, and DNA testing as early as 11 to 13 weeks' gestation (early amniocentesis); AFP measures can be done starting at 14 weeks' gestation.
3. Ultrasound—for dating pregnancy and assessing fetal structures, placenta, amniotic fluid, and nuchal translucency.

4. Acetylcholinesterase—for testing amniotic fluid for suspected NTD.
5. Fetoscopy—for obtaining fetal blood samples or visualizing details of fetal structures; done during the second trimester.
6. Percutaneous umbilical blood sampling—for obtaining fetal blood; done during second trimester.

Preimplantation Diagnosis

1. Requires *in vitro* fertilization so that embryos can form in the laboratory. One or two cells are removed from the embryo and sent for genetic testing. Only embryos lacking the genetic composition for disease are placed into the womb for further development.
2. Useful if the embryo is at an increased risk for a specific genetic condition, for example, an autosomal/X-linked recessive, autosomal/X-linked dominant, or chromosomal condition.

Research

1. Testing is performed to further understand the genetics of a disorder, biochemical process, or individual response to therapies.
2. Genetic research is *not* clinical testing and may have no clinical value to the patient's case.
3. There is ongoing and extensive research on cancer susceptibility genes, genetic abnormalities present in different cancer types, and genes related to therapeutic response to medications.

Additional Genetic Testing Consideration

DNA banking—extraction and storage of one's DNA from blood through a qualified genetics laboratory; requires informed consent, proper collection, and prompt handling.

Nursing Roles and Responsibilities

1. Recognize or suspect genetic disorders by their physical characteristics and clinical manifestations.
2. Demonstrate an understanding of the relationship of genetics and genomics to health, prevention, screening, diagnostics, prognostics, selection of treatment, and monitoring of treatment effectiveness.
3. Create a genetic pedigree (diagram of the family history), including cause of death and any genetically linked ailments (see Figure 4-2).

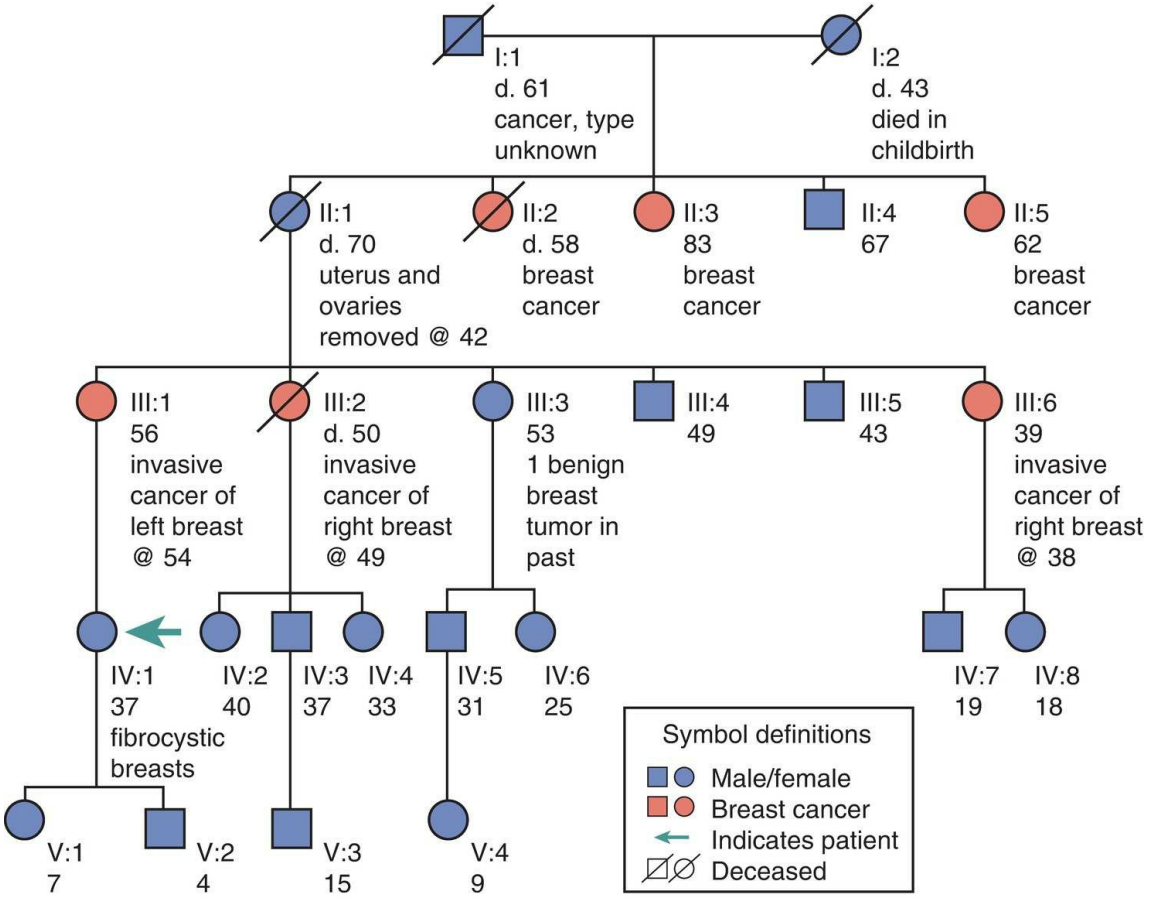

Figure 4-2. Genetic pedigree of a patient with breast cancer. Maternal side only is shown; however, both maternal and paternal sides are assessed. Genetic risk may run through either side.

4. Explain those aspects of diagnosis, prognosis, and treatment that affect the patient and family. Relate information that parents, affected or at-risk individuals, and caregivers need to know to plan for the care of the patient.
5. Clear up misconceptions and allay feelings of guilt.
6. Assist with the diagnostic process by exploring medical and family history information, using physical assessment skills, procuring samples for testing, and developing a plan of care that incorporates genetic and genomic assessment information.
7. Enhance and reinforce self-image and self-worth of parents, child, or the individual at risk for or presenting with a genetic condition.
8. Advocate for clients' access to genetic/genomic services and resources, including support groups.
9. Refer and prepare family for genetic counseling.
    a. Inform that prenatal testing does not mean termination of pregnancy (eg, it may confirm that the fetus is not affected, thus eliminating worry throughout pregnancy, although the determination of an abnormality is also a possibility).
    b. Encourage parents and patient to allow adequate time to deliberate on a course of action (eg, they should not rush into a test without full knowledge of what the results can and can't tell, nor should

they rush to make future reproductive decisions such as tubal ligation because in a few years, they may want more children).

c. Remain nonjudgmental.

10. Check with the state (eg, state health department) or with the Centers for Disease Control and Prevention (*www.cdc.gov*) for information and resources regarding neonatal testing required and state regulations on genetic testing and research.
11. Recognize that there are many ethical, legal, psychosocial, and professional issues associated with obtaining, using, and storing genetic information.
    a. Be aware of associated professional responsibilities, including informed consent, documentation in medical records, medical releases, and individual privacy of information.
    b. Refer to federal legislation (Genetic Information Nondiscrimination Act of 2008 and Health Insurance Portability and Accountability Act, 1997) that deals with protection from genetic discrimination in medical insurance; individual state legislation; genetics professional societies (see below); and the World Health Organization document on ethical considerations in genetic testing and services.

PART TWO

MEDICAL-SURGICAL NURSING

UNIT I General Health Considerations

5

Adult Physical Assessment

The Patient History

General Principles

Interviewing Techniques

Components

Ending the History

Physical Examination

General Principles

Approaching the Patient

Techniques of Examination and Assessment

THE PATIENT HISTORY

General Principles

1. The first steps in caring for a patient are to establish a relationship and gather information.
2. In all patient encounters, the assessment process begins with thorough and accurate history taking, thorough review of the patient record, interviewing the patient, and obtaining information from other individuals.
3. Use good communication skills, to elicit comprehensive health history and establish rapport with the patient simultaneously.

Interviewing Techniques

1. Provide privacy in as quiet a place as possible and see that the patient is comfortable.
2. Begin the interview with a courteous greeting and an introduction. Address the patient as *Mr.*, *Mrs.*, or *Ms.* and shake hands if appropriate. Explain who you are and the reason for your presence.
3. Make sure that facial expressions, body movements, and tone of voice are pleasant, unhurried, and nonjudgmental and that they convey the attitude of a sensitive listener so the patient will feel free to express thoughts and feelings.
4. Use open-ended questions and avoid narrowing the discussion or reassuring the patient prematurely (before you have adequate information about the problem). This only cuts off discussion; the patient may then be unwilling to expand on a problem causing concern.
5. Be alert for cues or suggestions by the patient that may require you to explore more by asking more pointed questions.
6. Guide the interview so the necessary information is obtained in a timely manner. Controlling a rambling patient is often difficult, but, with practice, it can be done without jeopardizing the quality of the nurse–patient relationship.

Components

Identifying Information

1. Supply date and time of the interview. Review data about the patient if already in the record or obtain patient's name, address, telephone number, race, ethnicity, religion, birth date, and age.
2. Obtain name of referring practitioner, insurance data, and name and contact information of informant(s) other than the patient. Note reliability of an informant if necessary.
3. Explain the reasons why the information is needed to help put the patient at ease.

Chief Complaint

1. Obtain a brief statement of the patient's primary problem or concern in the patient's own words, including the duration of the complaint, for example, "hacking cough × 3 weeks."
2. Purpose is to allow the patient to describe his or her own problems and expectations with little or no direction from the interviewer and to identify the overriding problem for which the patient is seeking help (there may be numerous complaints).
3. To obtain information, ask the patient a direct question, such as "For what reason have you come to the facility?" or "What is your primary health concern at this time?"
    a. Avoid confusing questions, such as "What brings you here?" ("The bus.") or "Why are you here?" ("That's what I came to find out.")
    b. Ask how long the concern or problem has been present, for example, whether it has been hours, days, or weeks. If necessary, establish the time of onset precisely by offering such clues as "Did you feel this way a month (6 months or 2 years) ago?"
4. Write down what the patient says using quotation marks to identify patient's words.

History of Present Illness

1. Obtain a detailed chronological picture, beginning with the time the patient was last well (or, in the case of a problem with an acute onset, the patient's condition just before the onset of the problem) and ending with a description of the patient's current condition.
2. If there is more than one important problem, describe each in a separate, chronologically organized paragraph in the written history of present illness.
3. Investigate the chief complaint by eliciting more information through the use of the mnemonic "OLD CARTS":
    a. **O**nset (setting, circumstances, rapidity, or manner in which it began).
    b. **L**ocation (exact place where the symptom is felt, radiation pattern).
    c. **D**uration (how long; if intermittent, the frequency and duration of each episode).
    d. **C**haracter/course (nature or quality of the symptom, such as sharp pain, interference with activity, how it has changed or evolved over time; ask to describe a typical episode).
    e. **A**ggravating/associated factors (medications, rest, activity, diet; associated nausea, fever, and other

symptoms).

   f. **R**elieving factors (lying down, having bowel movement).

   g. **T**reatments tried (pharmacologic and nonpharmacologic methods attempted and their outcomes).

   h. **S**everity (the quantity of the symptom; eg, how severe on scale of 1 to 10).

4. Alternately, use the mnemonic PQRST: **p**rovocative/palliative factors, **q**uality/quantity, **r**egion/radiation, **s**everity, **t**iming.
5. Obtain OLD CARTS data for all the major problems associated with the present illness, as applicable.
6. Clarify the chronology of the illness by asking questions and summarizing the history of present illness for the patient to comment on.

Past Medical History

1. Determine the background health status of the patient, including present status, recent health conditions, and past health conditions, that will serve as a basis for nursing care planning for holistic patient care.
2. General health and lifestyle patterns—sleeping pattern; diet; stability of weight; usual exercise and activities; use of tobacco, alcohol, illicit drugs.
3. Childhood illnesses, such as infectious diseases (if applicable).
4. Immunizations—childhood vaccines; adult vaccines including hepatitis, human papillomavirus, influenza, tetanus, herpes zoster, and pneumococcal vaccines.
5. Operations—surgical procedure, indication, approximate date, any complications.
6. Previous hospitalizations—facility, approximate date, diagnosis, treatment.
7. Injuries—approximate date, treatment, outcome.
8. Major acute and chronic illnesses (any serious or prolonged illnesses not requiring hospitalization)—dates, symptoms, course, treatment.
9. Medications—prescription drugs from all providers (including ophthalmologist and dentist); nonprescription drugs including vitamins, supplements, and herbal products; include dosage, length of use, and adherence.
10. Allergies—environmental allergies, food allergies, drug reactions; give type of reaction (hives, rhinitis, local reaction, angioedema, anaphylaxis).
11. Obstetric history (may appear in review of systems).
    a. Pregnancies, miscarriages, abortions.
    b. Describe course of pregnancy, labor, and delivery; date, place of delivery.
12. Psychiatric history (may appear in review of systems)—treatment by a mental health provider, diagnosis, date, medications.

Family History

1. Purpose is to present a picture of the patient's family health, including that of grandparents, parents, brothers, sisters, aunts, and uncles because some diseases show a familial tendency or are hereditary.

2. Include age and health status (or age at and cause of death) of maternal and paternal grandparents, parents, and siblings.
3. History, in immediate and close relatives, of heart disease, hypertension, stroke, diabetes, gout, kidney disease or stones, thyroid disease, pulmonary disease, blood problems, cancer (types), epilepsy, mental illness, arthritis, alcoholism, obesity.
4. Genetic disorders, such as hemophilia or sickle cell disease.
5. Age and health status of spouse and children.

Review of Systems

1. Purpose is to obtain detailed information about the current state of the patient and significant past symptoms, or lack of symptoms, patient may have experienced related to a particular body system.
2. May give clues to diagnosis of multisystem disorders or progression of a disorder to other areas.
3. Include subjective information about what the patient feels or sees with regard to the major systems of the body.
    a. General constitutional symptoms—fever, chills, night sweats, malaise, fatigability, recent weight loss or gain.
    b. Skin—rash, itching, change in pigmentation or texture, sweating, hair growth and distribution, condition of nails, skin care habits, protection from sun.
    c. Skeletal—problems of joints, muscles, or bones including pain, stiffness, deformity, restriction of motion, swelling, redness, heat, cramping.
    d. Head—headaches, dizziness, syncope, head injuries.
    e. Eyes—vision, pain, diplopia, photophobia, blind spots, itching, burning, discharge, glaucoma, cataracts, glasses or contact lenses worn, date of last eye appointment.
    f. Ears—hearing acuity, earache, discharge, tinnitus, vertigo, history of tubes or infection.
    g. Nose—sense of smell, frequency of colds, obstruction, epistaxis, postnasal discharge, sinus pain or therapy, use of nose drops or sprays (type and frequency).
    h. Teeth—pain; bleeding, swollen or receding gums; recent abscesses, extractions; dentures; dental hygiene practices, last dental examination.
    i. Mouth and tongue—soreness of tongue or buccal mucosa, ulcers, swelling.
    j. Throat—sore throat, tonsillitis, hoarseness, dysphagia.
    k. Neck—pain, stiffness, swelling, enlarged glands or lymph nodes.
    l. Endocrine—goiter, thyroid tenderness, tolerance to heat and cold, changes in skin pigmentation, libido, polyuria, polydipsia, polyphagia, hormone therapy, unexplained weight change.
    m. Respiratory—pain in the chest with breathing, dyspnea, wheezing, cough, sputum, hemoptysis, risk factors, and testing for tuberculosis.
    n. Cardiovascular—chest pain, palpitations, dyspnea, orthopnea (note number of pillows required for sleeping), history of heart murmur, edema, cyanosis, claudication, varicose veins, exercise tolerance, blood pressure (if known), history of blood clots.

o. Hematologic—anemia, tendency to bruise or bleed, any known abnormalities of blood cells.
p. Lymph nodes—enlargement, tenderness, drainage.
q. Gastrointestinal—appetite, food intolerance, belching, heartburn, nausea, vomiting, hematemesis, bowel habits, diarrhea, constipation, flatulence, stool characteristics, hemorrhoids, jaundice, use of laxatives or antacids, history of ulcers or other conditions, previous diagnostic tests such as colonoscopy.
r. Urinary—dysuria, pain, urgency, frequency, hematuria, nocturia, oliguria, hesitancy, dribbling, decrease in size or force of stream, passage of stones, incontinence.
s. Male reproductive—puberty onset, sexual activity, use of condoms, libido, sexual dysfunction, history of sexually transmitted diseases (STDs).
t. Female reproductive—pattern and characteristics of menses, libido, sexual activity, pregnancies, methods of contraception, STD protection.
u. Breasts—pain, tenderness, discharge, lumps, mammograms, breast self-examination.
v. Neurologic—loss of consciousness, seizures, confusion, memory, cognitive function, incoordination, weakness, numbness, paresthesia, tremors.
w. Psychiatric—how patient views self, mood, sadness, depression, anxiety, irritability, obsessive thoughts, compulsions, suicidal or homicidal thoughts, hallucinations.

Personal and Social History

1. Explore the patient's family structure and habits to identify resources an individual has to aid in coping with the situation and determine what health promotion activities may improve health.
2. Determine personal status—birthplace, education, position in the family, education level, job status, satisfaction with life situations, personal concerns.
3. Identify habits and lifestyle patterns.
    a. Sleeping pattern, number of hours of sleep, difficulty sleeping.
    b. Exercise, activities, recreation, hobbies.
    c. Nutrition and eating habits (diet recall for a typical day).
    d. Alcohol—frequency, amount, type; CAGE questionnaire—positive response may indicate problem drinking:
        i. Have you ever thought you should **C**ut down on your drinking?
        ii. Have you ever been **A**nnoyed by criticism of your drinking?
        iii. Have you ever felt **G**uilty about your drinking?
        iv. Do you drink in the morning (ie, an **E**ye-opener)?
    e. Caffeine—type and amount per day.
    f. Illicit drugs (illegal or improperly used prescription or over-the-counter medications).
    g. Tobacco—past and present use, type (cigarettes, cigars, chewing, snuff), pack, years.
    h. Sexual habits (can be part of genitourinary history)—relationships, frequency, satisfaction, number of

partners in past year and lifetime, STD and pregnancy prevention.

4. Home conditions.
    a. Marital status, nature of family relationships.
    b. Financial—source of income, health insurance.
    c. Living arrangements, type of housing.
    d. Involvement with agencies (name, caseworker).
    e. History of abuse—physical, intimate partner, sexual.
5. Environmental exposure—through work or other activities, including exposure to stress, noise, chemicals, pollution.
6. Culture—important in coping and health practices.
7. Religion/faith—may affect some treatment decisions.

Ending the History

When you have completed the history, it is often helpful to say, "Is there anything else you would like to tell me?" or "What additional concerns do you have?" This allows the patient to end the history by saying what is on his or her mind and what concerns the patient most.

PHYSICAL EXAMINATION

General Principles

1. Conduct a complete or partial physical examination following a careful comprehensive or problem-related history.
2. Make sure the exam takes place in a quiet, well-lit room with consideration for patient privacy and comfort.

Approaching the Patient

1. When possible, begin with the patient in a sitting position so both the front and back can be examined.
2. Completely expose the part to be examined, but drape the rest of the body appropriately.
3. Conduct the examination systematically from head to foot so as not to miss observing any system or body part.
4. While examining each region, consider the underlying anatomic structures, their function, and possible abnormalities.
5. Because the body is bilaterally symmetric for the most part, compare findings on one side with those on the other.
6. Explain all procedures to the patient while the examination is being conducted to avoid alarming or worrying the patient and to encourage cooperation.

Techniques of Examination and Assessment

Use the following techniques of examination, as appropriate, for eliciting findings.

Inspection

1. Begin on your first encounter with the patient to observe behavior and physical appearance in a systematic manner.
2. Use your eyes to inspect each part of the body with the appropriate light and exposure for characteristics such as symmetry, color, enlargement or swelling, and deformity.

Palpation

1. Use your fingertips or palms to touch the region or body part just observed for temperature, texture, tenderness, and moisture in a systematic manner.
2. With experience, you will be able to determine abnormal consistency and pinpoint tender areas.

Percussion

1. By setting underlying tissues in motion, percussion helps in determining the density of the underlying tissue and whether it is air-filled, fluid-filled, or solid.
2. Audible sounds and palpable vibrations are produced, which you can distinguish as five basic notes of percussion, differing in sound, pitch, duration, and intensity (see Table 5-1).
3. To perform percussion, follow these steps:
    a. Hyperextend the middle finger of your left hand, pressing the distal portion and joint firmly against the surface to be percussed.
        i. Other fingers touching the surface will damp the sound.
        ii. Be consistent in the degree of firmness exerted by the hyperextended finger as you move it from area to area or the sound will vary.
    b. Cock the right hand at the wrist, flex the middle finger upward, and place the forearm close to the surface to be percussed. The right hand and forearm should be as relaxed as possible.
    c. With a quick, sharp, relaxed wrist motion, strike the extended left middle finger with the flexed right middle finger, using the tip of the finger, not the pad. Aim at the end of the extended left middle finger (just behind the nail bed) where the greatest pressure is exerted on the surface to be percussed.
    d. Lift the right middle finger rapidly to avoid damping the vibrations.
    e. The movement is at the wrist, not at the finger, elbow, or shoulder; use the lightest touch capable of producing a clear sound.

Table 5-1 Five Basic Notes Produced by Percussion

	RELATIVE INTENSITY	RELATIVE PITCH	RELATIVE DURATION	EXAMPLE LOCATION
Flatness	Soft	High	Short	Thigh
Dullness	Medium	Medium	Medium	Liver
Resonance	Loud	Low	Long	Normal lung
Hyperresonance	Very loud	Lower	Longer	Emphysematous lung
Tymphany	Loud	High*	*	Gastric air bubble

Distinguished mainly by its musical timbre.

Adapted from Bickley, L. S. (2016). Bates' guide to physical examination and history taking (12th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

Auscultation

1. You will use a stethoscope to augment your sense of hearing. Earpieces should be comfortable, the length of the tubing should be 10 to 15 inches (25 to 38 cm), and the head should have a diaphragm and a bell.
2. Use the bell to detect low-pitched sounds such as certain heart murmurs.
3. Use the diaphragm for high-frequency sounds such as breath sounds.
4. Try to minimize extraneous sounds produced by clothing, hair, and movement of the head of the stethoscope.

Adult Physical Assessment

EQUIPMENT

- Cotton applicator stick
- Flashlight
- Oto-ophthalmoscope
- Reflex hammer
- Safety pin
- Sphygmomanometer
- Stethoscope
- Thermometer
- Tongue blade
- Tuning fork
- Additional items may include disposable loves and lubricant for rectal examination and a speculum for examination of female pelvis.

Technique	Findings
VITAL SIGNS	
Important: Many major therapeutic decisions are based on the vital signs; therefore, accuracy is essential.	
Temperature	
Oral, axillary, and temporal artery (forehead) temperature are measured routinely as a substitute for core body temperature. Tympanic membrane (ear) readings are considered inaccurate.	Temperature—may vary with the time of day and method used (axillary slightly lower). 98.6°F (37°C) is considered normal oral temperature, but range is 96.4 (35.8) to 99.1 (37.3).
A rectal temperature is the most accurate but may be contraindicated with some rectal problems and cardiac arrhythmias.	Rectal temperature is higher than oral by 0.7°F to 0.9°F (0.4°C to 0.5°C).
Pulse	
Palpate the radial pulse and count for at least 30 seconds.	Pulse—Normal adult pulse is 60 to 80 beats/minute; regular in rhythm. Elasticity of the arterial walls, blood volume, and mechanical action of the heart muscle are some of the factors that affect the strength of the pulse wave, which normally is full and strong.
If the pulse is irregular, count for a full minute and note the number of irregular beats per minute.	
Note whether the beat of the pulse against your finger is strong or weak, bounding or thready.	
Respiration	
Count the number of respirations for 15 seconds and multiply by 4. Count longer for better accuracy if abnormality detected.	Respiration—Normally 16 to 20 respirations per minute.
Note rhythm and depth of breathing.	
Blood pressure	
Measure the blood pressure (BP) in both arms. Document the patient's position.	Normal BP is less than 120/80 mm Hg.
Palpate the systolic pressure before using the stethoscope to detect an auscultatory gap.*	A difference of 5 to 10 mm Hg between arms is common.
Apply the cuff firmly; if it is too loose, it will give a falsely high reading.	Systolic pressure in lower extremities is usually 10 mm Hg higher than reading in upper extremities.
Use an appropriate-sized cuff: a pediatric cuff for children; a large cuff or a leg cuff for obese people.	Going from a recumbent to a standing position can cause the systolic pressure to fall 10 to 15 mm Hg and the diastolic pressure to rise slightly (by 5 mm Hg).
The cuff should be approximately 1 inch (2.5 cm) above the antecubital fossa.	

HEIGHT, WEIGHT, AND WAIST CIRCUMFERENCE

Determine the patient's height and weight. Use a measuring device rather than asking the patient for recent measurements.	Height and weight can be used to determine body mass index.
Determine waist circumference by using tape measure just above the umbilicus at the narrowest point.	Waist circumference is an independent risk factor for cardiovascular disease. Normal is ≤40 inches (102 cm) for men and ≤35 inches (88 cm) for women.

**Auscultatory gap:*

1. *The first sound of blood in the artery is usually followed by continuous sound until nothing is audible with the stethoscope.*
2. *Occasionally, the sound is not continuous and there is a gap after the first sound, after which the sound of blood in the vessel is heard again.*
3. *If one uses only the auscultatory method and pumps the cuff up until the sound is no longer heard, it is possible, when there is a gap in the sound or when the sound is not continuous, to get a falsely low systolic reading.*

Technique	Findings
GENERAL APPEARANCE Begin observation on first contact with the patient; continue throughout the interview systematically.	
Inspection	
Observe for: race, gender, general physical development, nutritional state, mental alertness, affect, evidence of pain, restlessness, body position, clothes, apparent age, hygiene, grooming. Use smell and hearing as well as sight.	Careful observation of the general state of the individual provides many clues about a person's body image, how he or she behaves, and also some idea of how well or ill he or she is.

SKIN

Examine the skin as you proceed through each body system.

Inspection	
Observe for: skin color, pigmentation, lesions (distribution, type, configuration, size), jaundice, cyanosis, scars, superficial vascularity, hydration, edema, color of mucous membranes, hair distribution, nails.	"Normal" varies considerably depending on racial or ethnic background, exposure to sun, complexion, and pigmentation tendencies (such as freckles). Nails are present and smooth and cared for in some way.
Palpation	
Examine skin for temperature, texture, elasticity, turgor, and superficial tenderness.	The skin is normally warm, slightly moist, and smooth and returns quickly to its original shape when picked up between two fingers and released. There is a characteristic hair distribution over the body associated with gender and normal physiologic function.

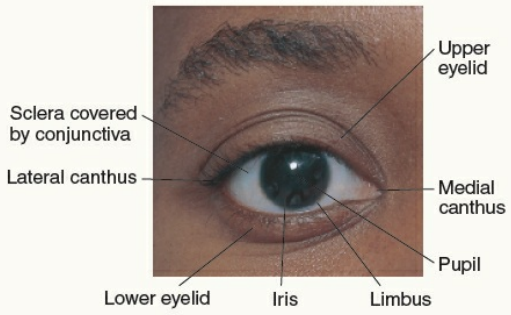
HEAD

Inspection	
Observe for: symmetry of face, configuration of skull, hair color and distribution, scalp.	Normally, the skull and face are symmetric, with distribution of hair varying from person to person. (However, determine by history if there has been any change.)
Palpation	
Examine: hair texture, masses, swelling or tenderness of scalp, configuration of skull.	The scalp should be free of flaking, with no signs of nits (small, white louse eggs), lesions, deformities, or tenderness.

EYES AND VISION

Equipment

- Snellen chart for visual acuity (see page 433)
- Ophthalmoscope for advanced examination



Bickley, L. (2016). *Bates' guide to physical examination and history taking* (12th ed.) Philadelphia: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

Inspection

1. Globes (eyeballs)—for protrusion.	
2. Palpebral fissures (oval opening between the upper and lower eyelids)—for width and symmetry.	2. Palpebral fissures—appear equal when eyes open. Normally, upper lid covers small portion of iris and lower lid margin is just below the junction of cornea and sclera (limbus). Ptosis—drooping of the upper eyelid.
3. Lid margins—for scaling, secretions, erythema, position of lashes.	3. Lid margins—are clear; the lacrimal duct openings (puncta) are evident at the nasal ends of the upper and lower lids. Eyelashes—normally are evenly distributed and turn outward.
4. Bulbar and palpebral conjunctivae—for congestion and color. Bulbar conjunctiva—membranous covering of the sclera (contains blood vessels). Palpebral conjunctiva—membranous covering of the inside of the upper and lower lids (contains blood vessels).	4. Bulbar conjunctiva—normally, transparent blood vessels may become dilated and produce the characteristic "bloodshot" eye. Palpebral conjunctivae—are pink and clear. Conjunctivitis—inflammation of the conjunctival surfaces.
5. Sclerae and iris—for color.	5. Sclerae—should be white and clear.
6. Pupils—for size, shape, symmetry, reaction to light and accommodation (ability of the lens to adjust to objects at varying distances).	6. Pupils—normally constrict with increasing light and accommodation. Pupils are normally round and can range in size from very small ("pinpoint") to large (occupying the entire space of the iris).
7. Eye movement—extraocular movements, nystagmus, convergence. (Nystagmus: rapid, lateral, horizontal, or rotary movement of the eye; convergence: ability of the eye to turn in and focus on a very close object.) (See neurologic system, page 65.)	7. Extraocular movement—movement of the eyes in conjugate fashion. (Six muscles control the movement of the eye.) Eyes normally move in conjugate fashion, except when converging on an object that is moving closer. Nystagmus—may be seen briefly on lateral movement as a result of eye fatigue; however, vertical nystagmus or prolonged nystagmus should be evaluated. Convergence—fails when double vision occurs, usually 4 to 6 inches (10 to 15 cm) from the nose.
8. Gross visual fields—by confrontation. (See neurologic system, page 65.)	8. Peripheral vision—is full (medially and laterally, superiorly and inferiorly) in both eyes.
9. Visual acuity—check with a Snellen chart (with and without glasses).	9. Normal vision—20/20. Myopia—nearsightedness. Hyperopia—farsightedness.

Palpation

1. Determine the strength of the upper lids by attempting to open closed lids against resistance.	1. The examiner should not be able to open the lids when the patient is squeezing them shut.
2. Palpate globes through closed lids for tenderness and tension.	2. Globes normally are not tender when palpated.

Fundoscopic examination

Advanced assessment technique, which visualizes the cornea, lens, and retina for abnormalities.

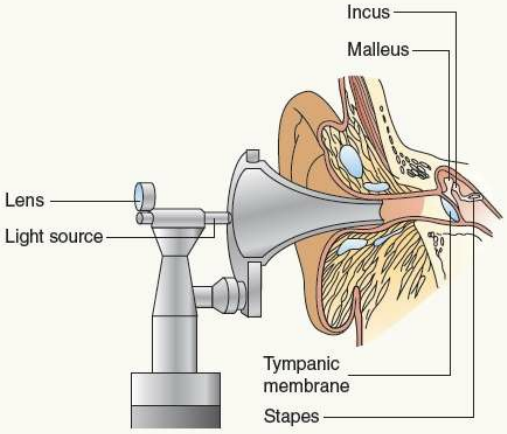
EARS AND HEARING

Equipment

- Tuning fork
- Otoscope

To examine with otoscope

1. Hold the helix of the ear and gently pull the pinna upward and back toward the occiput to straighten the external canal.
2. Gently insert the lighted otoscope, using an earpiece that is a comfortable size for the patient.
3. Once the otoscope is in place, put your eye up to the eyepiece and examine the external canal.



Inspection

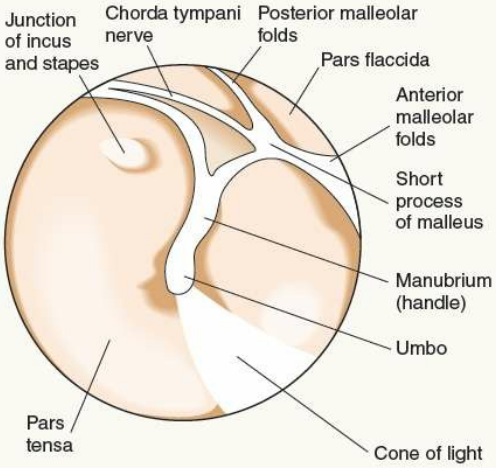
1. Pinna—examine for size, shape, color, symmetry, placement on the head, lesions, and masses.
2. External canal—examine with the otoscope for discharge, impacted cerumen, inflammation, masses, or foreign bodies.
3. Tympanic membrane—examine for color, luster, shape, position, transparency, integrity, and scarring.
4. Landmarks—note cone of light, umbo, handle and short process of the malleus, pars flaccida, and pars tensa. Gently move the otoscope to observe the entire drum. (Cerumen may obscure visualization of the drum.)

Palpation

Pinna—examine for tenderness, consistency of cartilage, swelling.

2. External canal—is normally clear with perhaps minimal cerumen.

3. Tympanic membrane and landmarks.

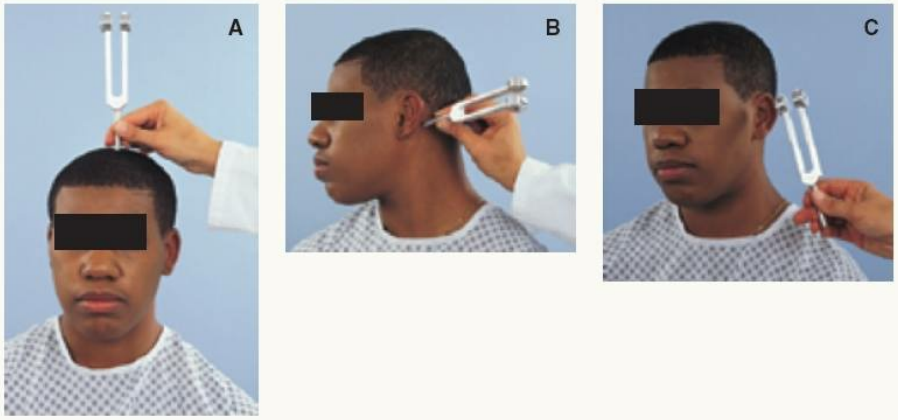


Right ear drum

Smeltzer, S., & Bare, B. (2006). *Brunner and Suddarth's textbook of medical-surgical nursing* (11th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

Mechanical tests

1. Test each ear for gross hearing acuity using a whispered word or a watch. Cover the ear not being tested.	1. A person with normal hearing can hear a whispered word from approximately 15 feet (4.5 m) and a watch from 1 foot (30 cm). The patient should hear the sound equally well in both ears; that is, there is no lateralization.
2. Weber test—test for lateralization of vibration. Tap the tuning fork against a hard surface to make it vibrate. Then, place the tuning fork in the center of the scalp near the forehead **(A)**. (Also see Chapter 17.)	2. Sound should be heard equally in both ears.
3. Rinne test—compares air and bone conduction. a. Place the vibrating tuning fork on the mastoid process behind the ear and have the patient tell you when the vibration stops **(B)**. b. Then, quickly hold the buzzing end of the tuning fork near the ear canal and ask if patient can hear it **(C)**.	3. Sound should be heard after vibration can no longer be felt; that is, air conduction is greater than bone conduction. Lateralization and conduction findings are altered by damage to the cranial nerve VIII and damage to the ossicles in the middle ear.



A-C. Weber, J., & Kelley, J. (2009). *Health assessment in nursing* (4th ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photographs by Barbara Proud.

NOSE AND SINUSES

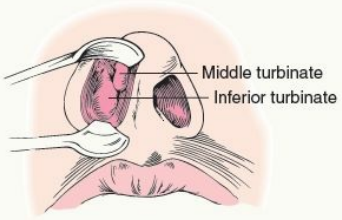
Equipment

- Otoscope
- Nasal speculum

Inspection

1. Observe for general deformity.	1. External features vary but are generally symmetrical.
2. With nasal speculum (otoscope, if speculum is unavailable), examine for:	
a. Nasal septum (position and perforation)	Nasal septum—is normally straight and not perforated.
b. Discharge (anteriorly and posteriorly)	Discharge—none should be present.
c. Nasal obstruction and airway patency	Airways—are patent.
d. Mucous membranes for color	Mucous membranes—are normally pink.

e. Turbinates for color and swelling



Weber, J., & Kelley, J. (2003). *Health assessment in nursing* (2nd ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

Turbinates—three bony projections on each lateral wall of the nasal cavity covered with well-vascularized, mucous-secreting membranes. They warm the air going into the lungs and may become swollen and pale with colds and allergies.

Tenderness of sinuses may indicate sinusitis. (Weber, J., & Kelley, J. [2006]. *Health assessment in nursing* [3rd ed.]. Philadelphia, PA: Lippincott Williams & Wilkins. Photographs by Barbara Proud.)

Palpation

Sinuses (frontal and maxillary)—for tenderness.

Frontal—direct manual pressure upward toward the wall of the sinus. Avoid pressure on eyes.

Maxillary—with thumbs, direct pressure upward over lower edge of maxillary bones.

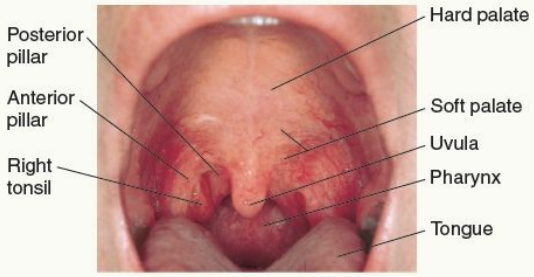
MOUTH

Equipment

- Flashlight
- Tongue blade
- Gloves
- Gauze sponges

Inspection

1. Observe lips for color, moisture, pigment, masses, ulcerations, fissures.



Smeltzer, S., & Bare, B. (2000). *Brunner and Suddarth's textbook of medical-surgical nursing* (9th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

2. Use tongue blade and penlight to examine:
   a. Teeth—number, arrangement, general condition.
   b. Gums—for color, texture, discharge, swelling, retraction.
   c. Buccal mucosa—for discoloration, vesicles, ulcers, masses.
   d. Pharynx—for inflammation, exudate, masses.

Teeth—an adult normally has 32 teeth.

Gums—commonly recede in adults. Bleeding is fairly common and may result from trauma, gingival disease, or systemic problems (less common).

Buccal mucosa and pharynx are pink to reddish brown with some color variation.

e. Tongue (protruded)—for size, color, thickness, lesions, moisture, symmetry, deviations from midline, fasciculations.

Tongue—is normally midline and covered with papillae, which vary in size from the tip of the tongue to the back. (The circumvallate papillae are large and posterior.)

f. Salivary glands—for patency.

i. Parotid glands

Parotid glands—open in the buccal pouch at the level of the upper teeth halfway back.

ii. Sublingual and submaxillary glands

Sublingual and submaxillary glands—open underneath the tongue.

g. Uvula—for symmetry when patient says "ah."

Uvula—should be midline.

h. Tonsils—for size, ulceration, exudates, inflammation.

Lingual tonsils—can often be seen on the posterior portion of the tongue.

i. Breath—for odor.

Odor of breath—may indicate dental caries.

j. Voice—for hoarseness.

Palpation

1. Examine the oral cavity with a gloved hand for masses and ulceration. Palpate beneath the tongue and laterally explore the floor of the mouth.
2. Grasp the tongue with a gauze sponge to retract it; inspect the sides and undersurface of the tongue and the floor of the mouth.

1. Entire oral cavity should be pink and without ulcers, deep-red color, lesions, palpable masses, or swelling. An indurated mass raises the suspicion of malignancy.

Weber, J., & Kelley, J. (2006). *Health assessment in nursing* (3rd ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

NECK

Equipment

- Stethoscope

Inspection

1. Inspect all areas of the neck anteriorly and posteriorly for muscular symmetry, masses, unusual swelling or pulsations, and range of motion.

1. Range of motion—normally, the chin can touch the anterior chest, and the head can be extended at least 45 degrees from the vertical position and can be rotated 90 degrees from midline to side.

2. Thyroid—ask the patient to swallow and observe for movement of an enlarged thyroid gland at the suprasternal notch.

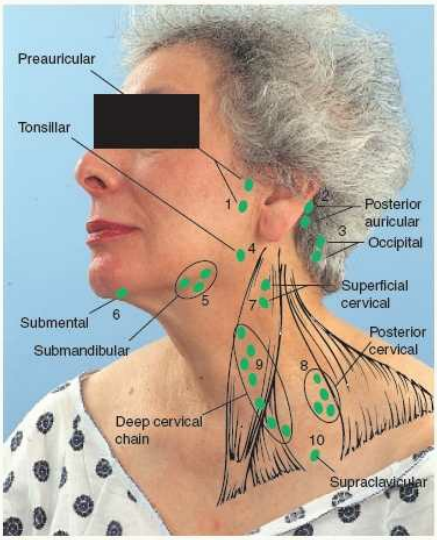
2. Thyroid—is not usually visible, except in extremely thin people.

3. Muscular strength.
   a. Cervical muscles—have the patient turn his chin forcefully against your hand.
   b. Trapezius muscles—exert pressure on the patient's shoulders while he or she shrugs the shoulders.

3. Strength—see "Findings, cranial nerve XI," page 67.

Palpation

1. Palpate the 10 areas for cervical lymph nodes as shown here.



Timby, B. K., & Smith, N. E. (2017). *Introductory medical-surgical nursing* (12th ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

1. Cervical nodes—in the adult, the cervical lymph nodes are not normally palpable unless the patient is very thin, in which case the nodes are felt as small, freely movable masses. Tender nodes suggest inflammation; hard, fixed nodes suggest malignancy.

2. Trachea—palpate at the sternal notch. Place one finger along the side of the trachea and note the space between it and the sternomastoid. Compare to the other side.
3. Thyroid—palpate for size, symmetry, and consistency.
   a. Stand behind the patient and have him flex the neck slightly to relax the muscles.
   b. Place the fingertips of both hands on either side of the trachea just below the cricoid cartilage. Have the patient swallow and feel for any glandular tissue rising under your fingertips.
   c. Palpate the area over the trachea for the isthmus and laterally for the right and left lobes.
   d. Note any enlargement, nodules, masses, or consistency.

2. Trachea—should be midline. Spaces measured by fingers should be symmetrical. Tracheal deviation may be caused by neck mass or problems within the chest.
3. If the thyroid is palpable, it is normally smooth, without nodules, masses, or irregularities. Enlargement, asymmetry, or nodules require further evaluation.

Weber, J., & Kelley, J. (2006). *Health assessment in nursing* (3rd ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

4. Carotid arteries
   a. Palpate the carotids one side at a time.
   b. The carotids lie anterolaterally in the neck—avoid palpating the carotid sinuses at the level of the thyroid cartilage just below the angle of the jaw because this may cause slowing of heart rate.
   c. Note the symmetry of pulsations, strength, and amplitude, as well as any abnormal thrill.

4. A thrill (humming-like vibration) usually indicates arterial narrowing.

Auscultation

1. Use the diaphragm of the stethoscope to listen for bruits (murmur-like sound) over the carotid arteries.

1. A bruit may indicate arterial narrowing with turbulent blood flow. A cardiac murmur may also be referred to the carotid arteries.

LYMPH NODES

1. Lymph nodes are normally nonpalpable or felt as small, nontender, freely moveable masses.

Inspection

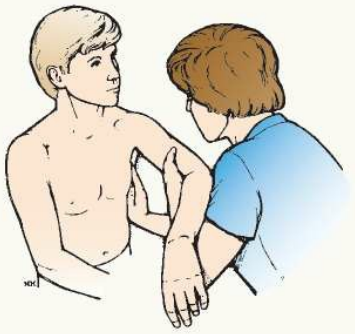
Additional lymph nodes are examined when the region of the body is examined; for example, the inguinal nodes are inspected when the abdomen is examined. Observe size and shape.

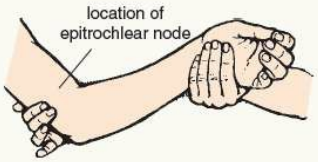
Lymph nodes are usually not visible unless enlarged or inflamed.

Palpation

1. Supraclavicular and infraclavicular nodes (usually palpated during neck or chest exam). Palpate for size, shape, mobility, consistency, tenderness, and warmth.
2. Axillary nodes (usually done during breast exam).
   a. Examine the patient while patient is sitting.
   b. Place the patient's arm at his side and examine the apex of the patient's axilla. (Use the fingers of your right hand to examine the left axilla and vice versa.)
   c. Rotate the examining hand so the fingers can palpate the anterior and posterior axillary fossae pressing against the chest wall. Press against the humerus bone in the axilla to examine the lateral fossa for nodes. Conclude the axillary examination by moving the fingers from the apex of the axilla downward in the midline along the chest wall.

1. Supraclavicular and infraclavicular nodes—not normally palpable. Enlargement may indicate a thoracic problem.
2. Axillary nodes—normally nonpalpable. Enlargement may occur with a breast or arm problem.





3. Inguinal nodes—are located in the groin and are usually examined when the abdomen is examined.
4. Epitrochlear nodes—are palpated just above the medial epicondyle, between the biceps and triceps muscles.

3. Inguinal nodes—a few may be felt. Enlargement and acute tenderness may indicate a genital or lower extremity problem.
4. Epitrochlear nodes—not normally palpable. Enlargement may indicate an arm or systemic problem.

BREASTS (MALE AND FEMALE)

Female breast

Inspection

(With the patient sitting, arms relaxed at sides.)

1. Inspect the areolae and nipples for position, pigmentation, inversion, discharge, crusting, and masses. Extra, or supernumerary, nipples may occur normally, most commonly in the anterior axillary region or just below the normal breasts.
   1. The *nipples* should be at the same level and protrude slightly. An *inverted nipple* (one that turns inward), if present since puberty, may be normal.

      A *supernumerary nipple* usually consists of a nipple and a small areola and may be mistaken for a mole.
2. Examine the breast tissue for size, shape, color, symmetry, surface, contour, skin characteristics, and level of breasts. Note any retraction or dimpling of the skin.
   2. Breast size—in the female, it is not uncommon to find a difference in the size of the two breasts. Normal asymmetry has usually been present since puberty and is not a recent phenomenon.
3. Ask the patient to elevate her hands over her head; repeat the observation.
   3. If there is a mass attached to the pectoral muscles, contracting the muscles will cause retraction of the breast tissue.
4. Have the patient press her hands to her hips; repeat the observation.

Palpation

(This is best done with the patient in a recumbent position.)

1. The patient with pendulous breasts should be given a pillow to place under the ipsilateral scapula of the breast being palpated, so the tissue is distributed more evenly over the chest wall.
2. The arm on the side of the breast being palpated should be raised above the patient's head.

3. Palpate one breast at a time, beginning with the "asymptomatic" breast if the patient complains of symptoms.
   3. This allows the examiner to palpate the "normal" breast first and then compare the "symptomatic" breast to it.
4. To palpate, use the palmar aspects of the fingers in a rotating motion, compressing the breast tissue against the chest wall. Don't forget to include the "tail" of the breast tissue, which extends into the axillary region in the upper outer quadrant of the breast.
   4. Breast texture—varies according to the amount of subcutaneous tissue present.
      a. In young females, tissue is fairly soft and homogeneous; in postmenopausal women, tissue may feel nodular or stringy.
      b. Consistency also varies with menstrual cycle, being more nodular and edematous just prior to menstruation.
5. Note skin texture, moisture, temperature, or masses.
   5. Masses—If a mass is palpated, its location, size, shape, consistency, mobility, and associated tenderness are reported.
6. Gently squeeze the nipple and note any expressible discharge.
   6. Discharge—In the normal nonpregnant or nonlactating female, there is usually no nipple discharge.
7. Repeat the examination on the opposite breast and compare findings.

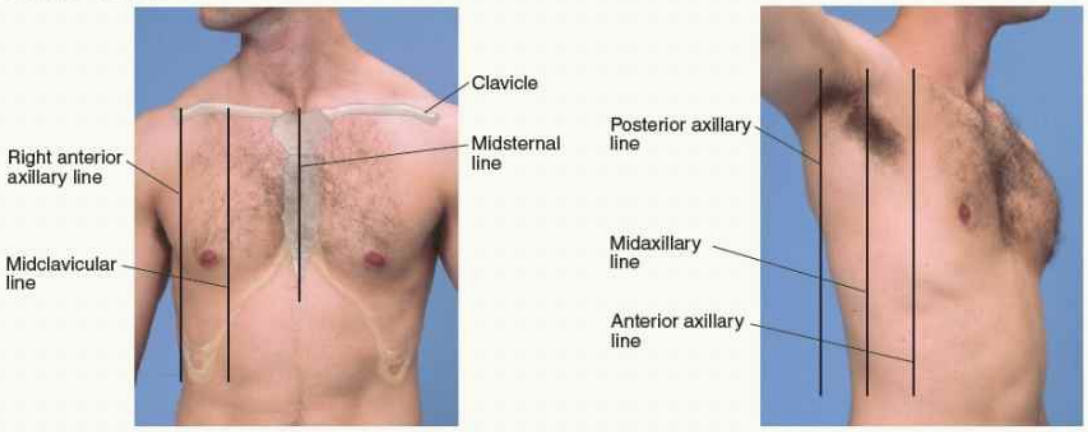
Male breast

Examination of the male breast can be brief but may be important.

1. Observe the nipple and areola for ulceration, nodules, swelling, or discharge.
   1. There should be no discharge.
2. Palpate the areola for nodules and tenderness.
   2. Enlargement of glandular tissue is gynecomastia, related to hormone imbalance.
3. Palpate axillary lymph nodes (see page 52).

THORAX AND LUNGS

Use anatomic landmarks to perform and document assessment of the thorax, keeping in mind the underlying structures of the lungs and heart.



Bickley, L. (2008). *Bates' guide to physical examination and history taking* (10th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

Posterior thorax and lungs

Begin the examination with the patient seated; examine posterior chest and lungs.

Inspection

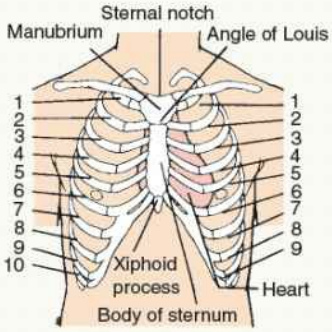
1. Inspect the spine for mobility and any structural deformity.
2. Observe the symmetry of the posterior chest and the posture and mobility of the thorax on respiration. Note any bulges or retractions of the costal interspaces on respiration or any impairment of respiratory movement.
3. Note the anteroposterior diameter in relation to the lateral diameter of the chest.

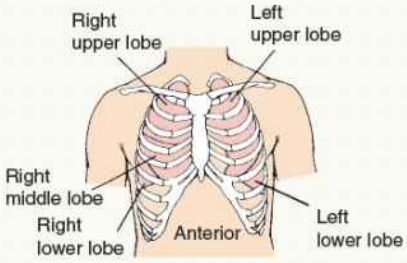
2. The thorax is normally symmetric; it moves easily and without impairment on respiration. There are no bulges or retractions of the intercostal spaces, which may indicate respiratory distress.
3. The anteroposterior diameter of the thorax in relation to the lateral diameter is approximately 1:2.

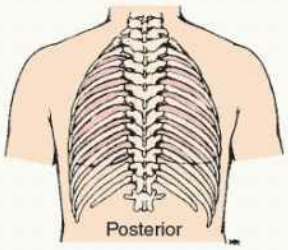
Palpation

1. Palpate the posterior chest with the patient sitting; identify areas of tenderness, masses, and inflammation.
2. Palpate the ribs and costal margins for symmetry, mobility, and tenderness and the spine for tenderness and vertebral position.
3. To assess respiratory expansion, place thumbs at the level of the 10th vertebra. With hands held parallel to the 10th ribs as they grasp the lateral rib cage, ask the patient to inhale deeply. Observe the movement of the thumbs while feeling the range and observe the symmetry of the hands.

2. On palpation, there should be no tenderness; chest movement should be symmetric and without lag or impairment. Tenderness may indicate musculoskeletal strain, fracture, or other problems.





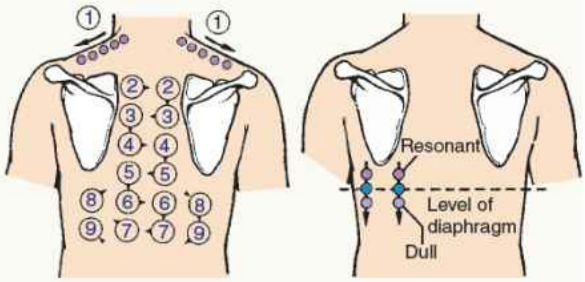


4. To elicit tactile *fremitus* (palpable vibrations transmitted through the bronchopulmonary system on speaking). a. Ask the patient to say "99"; palpate and compare symmetric areas of the lungs with the ball of one hand. Begin at the upper lobes and move downward. b. Note any areas of increased or decreased fremitus. c. If fremitus is faint, ask the patient to speak louder and in a deeper voice.	4. Posteriorly, fremitus is generally equal throughout the lung fields. It may be increased near the large bronchi because of consolidation of tissue resulting from pneumonia. It may be decreased or absent anteriorly and posteriorly when vocal loudness is decreased, when posture is not erect, or when excessive tissue or underlying structures are present or in cases of pneumothorax and other pathology.

Percussion

As with palpation, the posterior chest is optimally percussed with the patient sitting.

1. Percuss symmetric areas, comparing sides.	1. Percussion normally reveals resonance over symmetric areas of the lung. Percussion sound may be altered by poor posture or the presence of excessive tissue.
2. Begin across the top of each shoulder and proceed down between the scapulae and then under the scapulae, both medially and laterally in the axillary lines.	
3. Note and localize any abnormal percussion sound.	3. Dullness may indicate mass or consolidation because of pneumonia.
4. For diaphragmatic excursion, percuss by placing the pleximeter (stationary) finger parallel to the approximate level of the diaphragm below the right scapula. (See diagram on the right.) a. Ask the patient to inhale deeply and hold his breath; percuss downward to the point of dullness. Mark this point. b. Let the patient breathe normally, and then, ask patient to exhale deeply; percuss upward from the mark to the point of resonance. c. Mark this point and measure between the two marks—normally 2 to 2½ inches (5 to 6 cm). d. Repeat this procedure on the opposite side of the chest.	4. The lower border of the lungs is approximately at the level of the 10th thoracic spinous process on normal respiration. Unilateral abnormality of decreased excursion may indicate pleural effusion, atelectasis, or paralysis of one side of the diaphragm.



Auscultation

Aids in assessing airflow through the lungs, the presence of fluid or mucus, and the condition of the surrounding pleural space.

1. Have the patient sit erect.*
2. With a stethoscope, listen to the lungs as the patient breathes more deeply than normally with the mouth open. (Let the patient pause, as needed, to avoid hyperventilation.)
3. Place the stethoscope in the same areas on the chest wall as those percussed, and listen to a complete inspiration and expiration in each area.
4. Compare symmetric areas methodically from the apex to the lung bases.

On auscultation, breath sounds vary according to proximity of the large bronchi.

- They are louder and coarser near the large bronchi and over the anterior.
- They are softer and much finer (vesicular) at the periphery over the alveolae.

Breath sounds also vary in duration with inspiration and expiration. Sounds may normally decrease in obese individuals.

**Note: If the patient is unable to sit without assistance for examination of the posterior chest and lungs, position him or her first on one side and then on the other as you examine the lung fields.*

Technique	Findings
THORAX AND LUNGS (*Continued*)	
5. It should be possible to distinguish three types of normal breath sounds as indicated in the following table.	5. Pathology will alter the normal bronchial, bronchovesicular, and vesicular breath sounds. Adventitious sounds include crackles, wheezes, and rhonchi.

Breath Sounds	Duration of Inspiration and Expiration	Pitch of Expiration	Intensity of Expiration	Normal Location
Vesicular	Inspiration > Expiration	Low	Soft	Most of lungs
Bronchovesicular	Inspiration = Expiration	Medium	Medium	Near the main stem bronchi (below the clavicles and between the scapulae, especially on the right)
Bronchial or tubular	Expiration > Inspiration	High	Usually loud	Over the trachea

Adapted from Bickley, L. S. (2008). Bates' guide to physical examination and history taking (10th ed.). Philadelphia: Lippincott Williams & Wilkins.

Anterior Thorax and Lungs

The patient should be recumbent with his or her arms at sides and slightly abducted.

Inspection

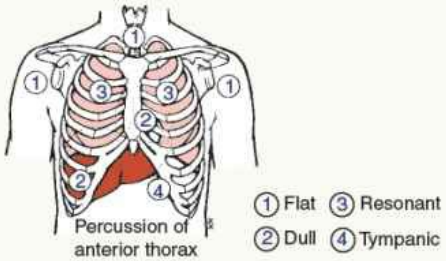
1. Inspect the chest for any structural deformity.
2. Note the width of the costal angle.
   2. The angle at the tip of the sternum is determined by the right and left rib margins at the xiphoid process. Normally, the angle is less than 90 degrees.
3. Observe the rate and rhythm of breathing, any bulging or retraction of intercostal spaces on respiration, and use of accessory muscles of respiration (sternocleidomastoid and trapezius on inspiration and abdominal muscles on expiration).
   3. There are no bulges or retractions of the intercostal spaces.
4. Note any asymmetry of chest wall movement on respiration.
   4. The thorax is normally symmetric and moves easily without impairment on respiration.

Palpation

1. To assess expansion, place your hands along the costal margins and note symmetry and degree of expansion as the patient inhales deeply.
   1. Hands should separate slightly on inspiration.
2. Palpate for tactile fremitus with the ball of the hand anteriorly and laterally. (Underlying structures [heart, liver] may damp, or decrease, fremitus.)
   2. Vibration should be felt somewhat symmetrical. It may be necessary to displace the female breast gently.

Percussion

1. With patient's arms resting comfortably at sides, percuss the anterior and lateral chest. Begin just below the clavicles and percuss downward from one interspace to the next, comparing the sound from the interspace on one side with that of the contralateral interspace.
   1. Resonance is heard over most of the lungs.
2. Displace the female breast so breast tissue does not damp the vibration. Continue downward, noting the intercostal space where hepatic dullness is percussed on the right and cardiac dullness on the left.
   2. A tympanic sound is produced over the gastric air bubble on the left somewhat lower than the point of liver dullness on the right.
3. Note the effect of underlying structures.
   3. Percussion over heart will produce a dull sound. The upper border of the liver will be percussed on the right side, producing a dull note.



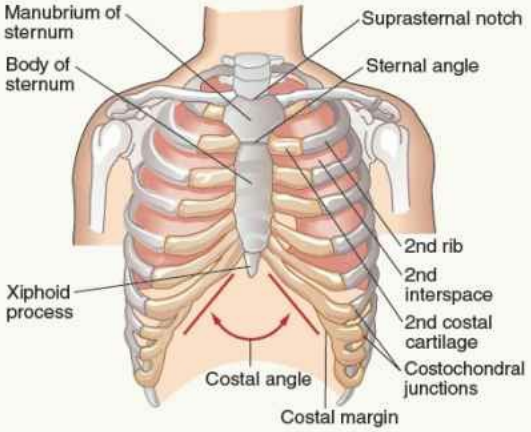
Percussion of anterior thorax

Auscultation

Listen to the chest anteriorly and laterally for the distribution of resonance and any abnormal or adventitious sounds.

HEART

1. Landmarks in relation to the sternum and the ribs are used during examination to yield the most information about function of the heart and its valves.
   a. In locating the intercostal spaces, begin by identifying the angle of Louis, which is felt as a slight ridge approximately 1 inch (2.5 cm) below the sternal notch, where the manubrium and the body of the sternum are joined.
   b. The 2nd ribs extend to the right and left of this angle.
   c. Once the 2nd rib is located, palpate downward and obliquely away from the sternum to identify the remaining ribs and intercostal spaces.



Inspection

1. Inspect the precordium for any bulging, heaving, or thrusting.
   1. Normally, there are no bulges or heaves; these indicate pathology.
2. Look for the apical impulse in the 5th or 6th intercostal space at or just medial to the midclavicular line.
   2. An apical impulse may or may not be observable.
3. Note any other pulsations. Tangential lighting is most helpful in detecting pulsations.
   3. There should be no other pulsations.

Palpation

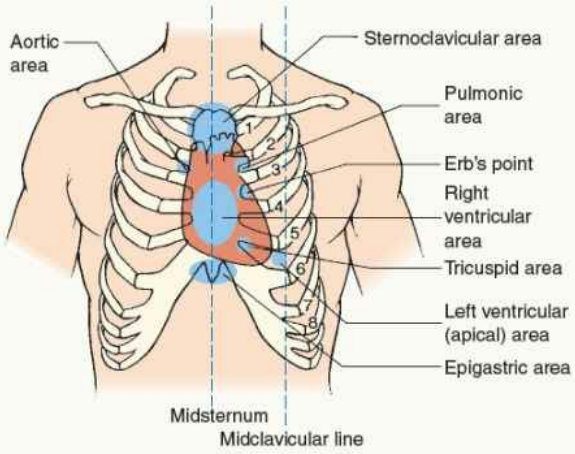
1. Use the ball of the hand to detect vibrations, or "thrills," which may be caused by murmurs. (Use the fingertips or palmar surface to detect pulsations.)
   1. There should be no thrills or other pulsations. (Thrills are vibrations caused by turbulence of blood moving through valves that are transmitted through the skin, which feels similar to a purring cat.)
2. Proceed methodically through the examination so no area is omitted. Palpate for thrills and pulsations in each area (aortic, pulmonic, tricuspid, mitral).
   a. Begin in the aortic area (2nd right intercostal space, close to the sternum) and proceed to the pulmonic area (2nd left intercostal space) and then downward to the apex of the heart. (The mitral area is considered the apex of the heart.)
   b. In the tricuspid area, use the palm of the hand to detect any heaving or thrusting of the precordium (tricuspid area—5th intercostal space next to the sternum).
      Ordinarily, no heaving of the ventricle is felt except, possibly, in the pregnant female.
   c. In the mitral area (5th intercostal space, at or just medial to the midclavicular line), palpate for the apical beat; identify the point of maximal impulse (PMI) and note its size and force.
      The apical pulse should be felt approximately in the 5th intercostal space, at or just medial to the midclavicular line. In a young, thin person, it is a sharp, quick impulse no larger than the intercostal space. In an older person, the impulse may be less sharp and quick. An apical impulse displaced laterally may indicate left ventricular hypertrophy.

Percussion

1. Outline the heart border or area of cardiac dullness.
   a. The left border generally does not extend beyond 4, 7, and 10 cm left of the midsternal line in the 4th, 5th, and 6th intercostal spaces, respectively.
   b. The right border usually lies under the sternum.
2. Percuss outward from the sternum with the stationary finger parallel to the intercostal space until dullness is no longer heard. Measure the distance from the midsternal line in centimeters.

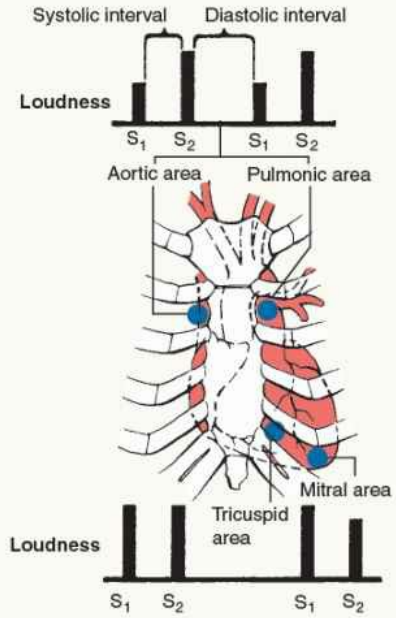
Auscultation

1. Place the stethoscope in the pulmonic or aortic area.
2. Begin by identifying the first (S_1) and second (S_2) heart sounds.
   a. S_1 is caused by the closing of the tricuspid and mitral valves.
   b. S_2 results from the closing of the aortic and pulmonic valves.



Smeltzer, S., & Bare, B. (2000). *Brunner and Suddarth's textbook of medical-surgical nursing* (9th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

2. The two sounds are separated by a short systolic interval; each pair of sounds is separated from the next pair by a longer, diastolic interval. Normally, two sounds are heard—"lub, dub."
   – In the aortic and pulmonic areas, S_2 is usually louder than S_1. In this way, each of the paired sounds can be distinguished from the other.
   – In the tricuspid area, S_1 and S_2 are of almost equal intensity and, in the mitral area, S_1 is often slightly louder than S_2.



3. Once the heart sounds are identified, count the rate and note the rhythm as discussed under vital signs. If there is an irregularity, try to determine if there is any pattern to the irregularity in relation to the intervals, heart sounds, or respirations.
4. Once rate and rhythm are determined, listen in each of the four areas and at Erb's point (3rd left interspace, close to the sternum) systematically, first with the diaphragm (detects higher-pitched sounds) and then with the bell (detects lower-pitched sounds). In each area, listen to S_1 and then to S_2 for intensity and splitting.

3. Normally, the heart sounds are regular, with a rate of 60 to 80 beats/minute (in the adult). In the athlete or jogger, the resting pulse may be between 40 and 60 beats/minute.

4. An extra "woosh" sound between S_1 and S_2 indicates systolic murmur; between S_2 and S_1 indicates a diastolic murmur. Note the area of its greatest intensity (aortic, pulmonic, mitral, tricuspid). An extra sound of short duration usually indicates an S_3 or S_4 gallop. Occasionally, there may be a splitting of S_2 in the pulmonic area. This is normal. Splitting of S_2 (two contiguous sounds are heard instead of one) is best heard at the end of inspiration, when right ventricular stroke volume is sufficiently increased to delay closure of the pulmonic valve *slightly* behind closure of the aortic valve.

PERIPHERAL CIRCULATION

Jugular veins

Evaluation of jugular venous distention is most useful in patients with suspected compromise of cardiac function.

Inspection

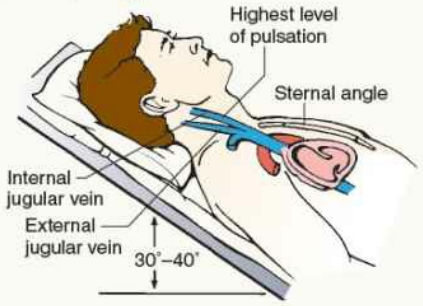
1. Inspect neck for internal jugular venous pulsations.

1. Jugular venous pulsations can be distinguished from carotid pulsations by the following chart:

Internal Jugular Pulsations	Carotid Pulsations
Rarely palpable	Palpable
Soft, undulating quality, usually with two or three outward components (a, c, and v waves)	A more vigorous thrust with a single outward component
Pulsation eliminated by light pressure on the vein just above the sternal end of the clavicle	Pulsation not eliminated
Level of pulsation barely descends with inspiration	Pulsation not affected by inspiration
Pulsations vary with position	Pulsations are unchanged by position

From Bickley, L. S. (2008). Bates' guide to physical examination and history taking (10th ed.). Philadelphia: Lippincott Williams & Wilkins.

2. Note the highest point at which pulsations are seen and measure the vertical line between the point and the sternal angle. With the head raised 30 degrees, the internal jugular venous pulsations should not be visible more than 1 inch (2.5 cm) above the sternal angle. Increased level of internal jugular pulsations indicates right heart failure.



Morton, P. G., & Fontaine, D. K. (2017). *Critical care nursing* (11th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

Extremities

Inspection

1. Observe skin over extremities for color, hair distribution, pallor, rubor, and swelling.

1. Extremities should be symmetrically even in color, warmth, and moisture, without swelling. Swelling of feet may occur after prolonged standing or sitting but will disappear when extremity is elevated (dependent edema).

2. Inspect for any visible vessels.

2. Faint veins may be visible, but tortuous and bulging veins may be abnormal.

Palpation

1. Note the temperature of the skin over extremities, comparing one side to the other.
2. Palpate pulses (radial, femoral, posterior tibial, dorsalis pedis), comparing symmetry from side to side.

1. Temperature varies but should not be very warm or very cool.
2. Absence of peripheral pulses indicates peripheral vascular disease.

Left: Bickley, L. (2016). Bates' *guide to physical examination and history taking* (12th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.
Right: Rosdahl, C. B., & Kowalski, M. T. (2016). *Textbook of basic nursing* (11th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

Weber, J., & Kelley, J. (2006). *Health assessment in nursing* (3rd ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

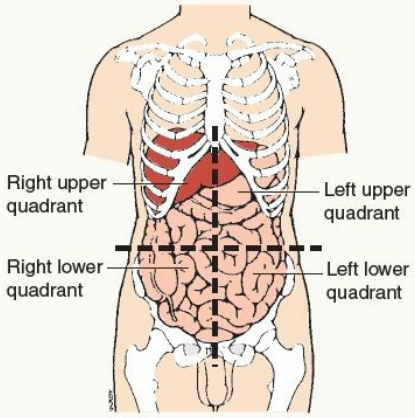
3. Palpate the skin over the tibia for edema by squeezing the skin for 30 to 60 seconds. Run the pads of your fingers over the area pressed and note indentation. If indentation is noted, repeat the procedure, moving up the extremity, and note the point at which no more swelling is present.

Weber, J., & Kelley, J. (2006). *Health assessment in nursing* (3rd ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

3. Edema is usually graded from trace to 3+ or 4+ pitting. Trace is a slight indentation that disappears in a short time. Grade 3+ or 4+ is deep pitting that does not disappear readily. At best, these are subjective measurements, which are tried and confirmed through practice and comparison of findings with associates.

ABDOMEN

1. Make sure the patient has an empty bladder and is lying comfortably with arms at sides. Bend the knees to help relax the abdominal muscles if necessary.
2. Expose the abdomen fully. Make sure your hands and the stethoscope diaphragm are warm.
3. Be methodical in visualizing the underlying organs as you inspect, auscultate, percuss, and palpate each quadrant or region of the abdomen.



Inspection

1. Observe the general contour of the abdomen (flat, protuberant, scaphoid, or concave; local bulges). Also, note symmetry, visible peristalsis, and aortic pulsations.
2. Check the umbilicus for contour or hernia and the skin for rashes, striae, and scars.

1. The abdomen may or may not have any scars and should be flat or slightly rounded in the nonobese person. Slight pulsation may be noted.

Auscultation

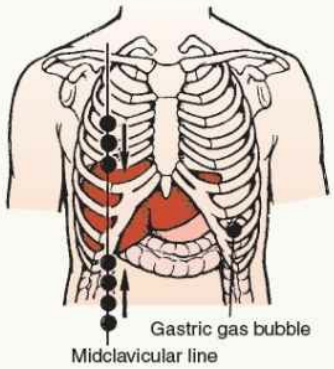
1. This is done before percussion and palpation because palpation may alter the character of bowel sounds.
2. Note the frequency and character of bowel sounds (pitch, duration).
3. Listen over the aorta, renal arteries (upper quadrants), and iliac arteries (lower quadrants) for bruits.

2. Anywhere from 5 to 35 bowel sounds per minute. May have familiar sound of "growling."
3. Bruits indicate arterial narrowing.

Percussion

1. Percussion provides a general orientation to the abdomen.
2. Proceed methodically from quadrant to quadrant, noting tympany and dullness.
3. In the right upper quadrant (RUQ) in the midclavicular line, percuss the borders of the liver.
   a. Begin at a point of tympany in the midclavicular line of the right lower quadrant (RLQ) and percuss upward to the point of dullness (the lower liver border); mark the point.
   b. Percuss downward from the point of lung resonance above the RUQ to the point of dullness (the upper border of the liver); mark the point.
   c. Measure in centimeters the distance between the two marks in the midclavicular line (the liver span).
   d. Tympany of the gastric air bubble can be percussed in the left upper quadrant over the anterior lower border of the rib cage.

2. Tympany usually predominates, possibly with scattered areas of dullness because of fluid and feces.
3. Percussion of the liver should help guide subsequent palpation. The liver border in the midclavicular line should normally range from 2½ to 4½ inches (6 to 11 cm).



4. Assess for an enlarged spleen by percussing the lowest interspace of the right anterior axillary line (should be tympanic). Ask the patient to take a deep breath and repeat (should still be tympanic).

4. Change in percussion note to dullness on inspiration indicates an enlarged spleen.

Palpation

1. Perform light palpation in an organized manner to detect any muscular resistance (guarding), tenderness, or superficial organs or masses.
2. Perform deep palpation to determine location, size, shape, consistency, tenderness, pulsations, and mobility of underlying organs and masses.
3. Move slowly and gently from one quadrant to the next to relax and reassure the patient.
4. Use two hands if the abdomen is obese or muscular, with one hand on top of the other. The upper hand exerts pressure downward, whereas the lower hand feels the abdomen.

1. Tenderness and involuntary guarding indicate peritoneal inflammation.
2. Rebound tenderness (pain on quick withdrawal of the fingers following palpation) suggests peritoneal irritation, as in acute appendicitis.
3. Palpate painful areas last.

Liver

1. Palpate the liver by placing the left hand under the patient's lower right rib cage and the right hand on the abdomen below the level of liver dullness. Press gently inward and upward with your fingertips while the patient takes a deep breath.	1. A normal liver edge may be palpable as a smooth, sharp, regular surface. An enlarged liver will be palpable and may be tender, hard, or irregular.

Spleen

1. Place your left hand around and under the patient's left lower rib cage and press your right hand below the left costal margin inward toward the spleen while the patient takes a deep breath.	1. A normal spleen is usually not palpable. Be sure to start low enough so as not to miss the border of an enlarged spleen.

Kidney

1. Next, palpate for the left and right kidneys.	1. The kidney is usually felt only in people with very relaxed abdominal muscles (the very young, the aged, and multiparous women). The right kidney is slightly lower than the left.
2. Place the left hand under the patient's back between the rib cage and the iliac crest.	
3. Support the patient while you palpate the abdomen with the right palmar surface of the fingers facing the left side of the body.	
4. Palpate by bringing the left and right hands together as much as possible slightly below the level of the umbilicus on the right and left.	
5. If the kidney is felt, describe its size and shape and note any tenderness.	5. The kidney is felt as a solid, firm, smooth elastic mass.
6. Costal vertebral angle tenderness is palpated with the patient sitting, usually during the examination of the posterior chest. Locate the costal vertebral angle in the flank region and strike firmly with the ulnar surface of your hand. Note any tenderness over the area.	6. There should be no costal vertebral angle tenderness. If found may indicate kidney infection.

Aorta

1. Palpate for the aorta with the thumb and index finger.	1. The aorta is soft and pulsatile.
2. Press deeply in the epigastric region (roughly in the midline) and feel with the fingers for pulsations, as well as for the contour of the aorta.	

Other Findings

1. Palpation of the RLQ may reveal the part of the bowel called the *cecum*.	1. The cecum will be soft.
2. The sigmoid colon may be palpated in the lower left quadrant.	2. The sigmoid colon is ropelike and vertical and, if filled with feces, may be quite firm.
3. The inguinal and femoral areas should be palpated bilaterally for lymph nodes.	3. Often, small inguinal nodes are present; they are nontender, freely movable, and firm.

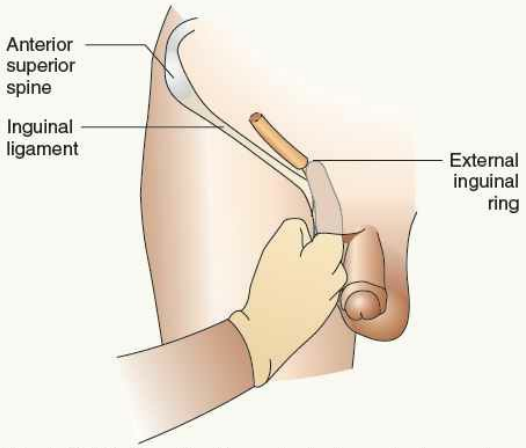
MALE GENITALIA AND HERNIAS

This part of the examination requires wearing gloves and is best done with the patient standing. (A hernia is the protrusion of a portion of the intestine through an abnormal opening.)

Inspection

1. With the groin and genitalia exposed, inspect the pubic hair distribution and the skin of the penis.	
2. Retract the foreskin, if present.	2. The foreskin of the penis, if present, should be easily retractable.

3. Observe the glans penis and the urethral meatus. Note any ulcers, masses, or scars.	3. The skin of the glans penis is smooth, without ulceration.
4. Note the location of the urethral meatus and any discharge.	4. The urethral meatus normally is located ventrally on the end of the penis. Normally, there is no discharge from the urethra.
5. Observe the skin of the scrotum for ulcers, masses, redness, or swelling. Note size, contour, and symmetry. Lift the scrotum to inspect the posterior surface.	5. The scrotum descends approximately 1½ inches (4 cm) in the adult; the left side is often larger than the right side.
6. Inspect the inguinal areas and groin for bulges (with and without the patient bearing down, as though having a bowel movement).	
Palpation	
1. Palpate any lesions, nodules, or masses, noting tenderness, contour, size, and induration. Palpate the shaft of the penis for any induration (firmness in relation to surrounding tissues).	1. There should be no nodules or tenderness.
2. Palpate each testis and epididymis separately between the thumb and first two fingers, noting size, shape, consistency, and undue tenderness (pressure on the testis normally produces pain).	2. The testes are usually rubbery and of approximately equal size. The epididymis is located posterolaterally on each testis and is most easily palpable on the superior portion of the testis.
3. Palpate the spermatic cord, including the vas deferens within the cord, from the testis to the inguinal ring.	3. There should be no nodules or tenderness.
4. Palpate for inguinal hernias, using the left hand to examine the patient's left side and the right hand to examine the patient's right side. a. Insert the right index finger laterally, invaginating the scrotal sac to the external inguinal ring. b. If the external ring is large enough, insert the finger along the inguinal canal toward the internal ring and ask the patient to strain down, noting any mass that touches the finger.	4. Normally, there is no palpable herniating mass in the inguinal area.
5. Palpate the anterior thigh for a herniating mass in the femoral canal. Ask the patient to strain down. (The femoral canal is not palpable; it is a potential opening in the anterior thigh, medial to the femoral artery below the inguinal ligament.)	5. Ordinarily, there is no palpable mass in the femoral area.



Bickley, L. (2003). *Bates' guide to physical examination and history taking* (8th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

FEMALE GENITALIA

Wearing gloves, observe the external genitalia for abnormalities such as lesions, discharge, or bulging of the vagina. Gently separate the labia to continue visual inspection, noting any tenderness.

RECTUM

Equipment

- Glove
- Lubricant

Position patient on left side with knees drawn up toward chest and drape so that buttocks are exposed. Men may also stand and bend over the edge of the exam table with toes pointed inward. Women may be examined in lithotomy position at the end of a pelvic examination. (Change gloves to prevent cross-contamination.)

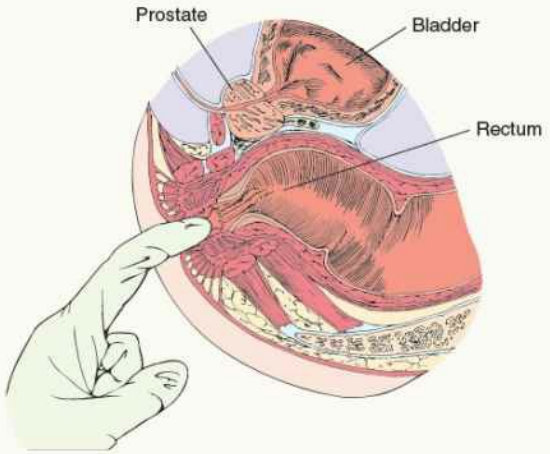
Inspection

Spread the buttocks and inspect the anus, perianal region, and sacral region for inflammation, nodules, scars, lesions, ulcerations, or rashes. Ask the patient to bear down; note any bulges.

In males and females, the perianal and sacrococcygeal areas are dry, with varying amounts of hair covering them. Anal and perianal lesions include hemorrhoids, abscesses, skin tags, and sexually transmitted genital lesions.

Palpation

1. Palpate any abnormal area noted on inspection.
2. Lubricate the index finger of the gloved hand. Rest the finger over the anus as the patient bears down, and as the sphincter relaxes, insert your finger slowly into the rectum.



Weber, J., & Kelley, J. (2006). *Health assessment in nursing* (3rd ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

3. Note sphincter tone, any nodules or masses, or tenderness.
3. The anal canal is approximately 1 inch (2.5 cm) long; it is bordered by the external and internal anal sphincters, which are normally firm and smooth.
4. Insert the finger further and palpate the walls of the rectum laterally and posteriorly while rotating your index finger. Note irregularities, masses, nodules, tenderness.
4. The wall of the rectum in males and females is smooth and moist.
5. Anteriorly, palpate the two lateral lobes of the prostate gland in males and its median sulcus for irregularities, nodules, swelling, or tenderness.
5. The male prostate gland is approximately 1 inch (2.5 cm) long, smooth, regular, nonmovable, nontender, and rubbery.
6. If possible, palpate the superior portion of the lateral lobe, where the seminal vesicles are located. Note induration, swelling, or tenderness.
6. The seminal vesicles are generally not palpable unless swollen.
7. Just above the prostate anteriorly, the rectum lies adjacent to the peritoneal cavity. If possible, palpate this region for peritoneal masses and tenderness.
7. No masses or tenderness should be palpable.
8. In the female, anteriorly, the cervix, and perhaps a retroverted uterus, may be felt.
8. Anteriorly, the cervix is round and smooth.
9. Continue to insert the finger as far as possible and have the patient bear down so more of the bowel can be palpated.
10. Gently withdraw your finger. Any fecal material on the glove should be tested for occult blood.
10. There is normally no occult blood in the stools.

MUSCULOSKELETAL SYSTEM

General approach

1. Examine the muscles and joints, keeping in mind the structure and functions of each.
2. Observe and palpate joints and muscles for symmetry and examine each joint individually as indicated.
3. The examination is performed with the joints both at rest and in motion, moving through a full range of motion; joints and supporting muscles and tissues are noted.

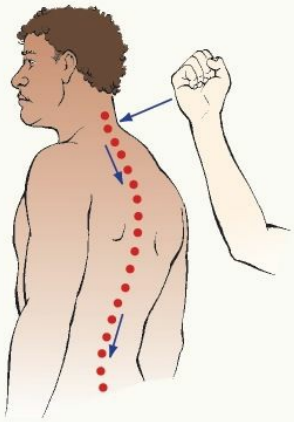
Inspection

1. Inspect the upper and lower extremities for size, symmetry, deformity, and muscle mass.
2. Inspect the joints for range of motion (in degrees), enlargement, redness.
3. Note gait and posture; observe the spine for range of motion, lateral curvature, or any abnormal curvature.
4. Observe the patient for signs of pain during the examination.

Palpation

1. Palpate the joints of the upper and lower extremities and the neck and back for tenderness, swelling, warmth, any bony overgrowth or deformity, and range of motion.
2. Hold the palm of your hand over the joint as it moves, or move the joint through the fullest range of motion and note any crepitation (crackling feeling within the joint).
3. Palpate the muscles for size, tone, strength, any contractures, and tenderness.
4. Palpate the spine for bony deformities and crepitation. Gently tap the spine with the ulnar surface of your fist from the cervical to the lumbar region and note any pain or tenderness.

3. Joints should move freely without resistance or pain.



NEUROLOGIC SYSTEM

Equipment

- Safety pin
- Cotton
- Tuning fork
- Reflex hammer
- Flashlight
- Tongue blade
- Vision screener
- Cloves, coffee, or other scented items

The screening neurologic exam or any of its components can be performed with the patient in either the sitting or supine position and may be incorporated into examination of other regions of the body. Rather than using palpation, percussion, and auscultation, the examiner uses inspection and special testing to assess the components of mental status, cranial nerves, cerebellar function, motor function, sensation, and deep tendon reflexes.

Mental status

1. Determine level of consciousness by speaking the patient's name loudly and gently shaking the patient, if necessary.
   1. Normally, the individual is alert, knows who he or she is and where he or she lives, and can tell you the date.
2. The patient's ability to remember is also evaluated as the history is taken; ask for his or her past medical history (long-term memory) and dietary habits: "What did you eat for breakfast?" (intermediate memory).
   2. The patient remembers recent and past events consistently and willingly admits forgetting something. Older adults often have much better long-term memory than recent memory.
3. Cognition and ideational content are evaluated throughout the history by what the patient says and by his or her articulateness, consistency, and reliability in reporting events.
   3. There is no evidence of delusions or hallucinations.
4. Affect or mood is evaluated by observing the patient's verbal and nonverbal behavior in response to questions asked, sudden noises, and interruptions. For example, does the patient laugh or smile when talking about normally sad events, or is he or she easily startled by unexpected noises?
   4. Mood should be appropriate to the content of the conversation.

Cranial nerves (CN)

1. Test the olfactory nerve (first CN) by occluding one nostril and having the patient (with eyes closed) identify a common substance by smell; repeat on the opposite side.
   1. The patient should be able to identify common smells such as cinnamon and coffee.
2. Evaluate the optic nerve (second CN) by testing visual acuity via a Snellen chart and testing visual fields.
   a. Have the patient cover right eye with the right hand. (You cover your left eye with your left hand.)
   b. Stand approximately 2 feet (60 cm) from the patient and have him or her fix gaze on your nose.
   c. Bring two wagging fingers in from the periphery (in a plane equidistant from the patient and you) in all quadrants of the visual field and ask the patient to tell you when he or she sees your wagging fingers.
   2. Normal vision (with glasses or contact lenses) is at or near 20/20. Assuming your visual fields are grossly normal, the patient and you should see the wagging fingers approximately simultaneously. (The patient's peripheral vision should approximate the examiner's.)

3. Test the oculomotor (3rd CN), trochlear (4th CN), and abducens (6th CN) together. They control the movements of the extraocular muscles of the eye—the superior and inferior oblique and the medial and lateral rectus muscles. The oculomotor nerve also controls pupillary constriction.
   a. Hold your index finger approximately 1 foot (30 cm) from the patient's nose. Ask the patient to hold head steady.
   b. Ask the patient to follow your finger with his or her eyes.
   c. Move your finger to the right as far as the patient's eye moves. Before bringing your finger back to the center, move it up and then down so that the patient glances up and peripherally and then down and peripherally.
   d. Repeat the test, moving your finger to the left.
4. Test the trigeminal nerve (5th CN). which controls muscles of mastication and has a sensory component that controls sensations of the face.
   a. Test the motor component by having the patient clench teeth while palpating the temporal and masseter muscles of the jaws with both hands.
      a. Muscle strength in the face should be present and should be symmetric.
   b. Test the sensory component by having the patient close eyes and touch one side of the face then the other (forehead, cheek, chin). (Always demonstrate to the patient how you are testing sensation—to avoid startling the patient and to encourage cooperation.)
      b. Sensation should be present and symmetrical.
5. Test the facial nerve (7th CN) by observing facial expression and symmetry of facial movement. Ask the patient to frown, close eyes, and smile.
   5. The facial muscles should look symmetric when the patient frowns, closes eyes, and smiles. Notice particularly the symmetry of the nasolabial folds.

6. Evaluate the acoustic nerve (8th CN) cochlear branch by testing hearing (see page 48) and vestibular branch by performing the Romberg test for equilibrium. Have the patient stand erect with eyes closed and feet close together.	6. Slight swaying may occur, but the patient should not fall. (Stand close to the patient so you can assist if he or she begins to fall.)
7. Test the glossopharyngeal (9th CN) and vagus nerve (10th CN) together (they both have a motor portion innervating the pharynx). a. Ask the patient to say "ah" and observe the movement of the uvula and palate (10th CN). b. Gently use a tongue blade to check the presence of the gag reflex (9th CN).	a. The palate and uvula should move symmetrically without deviation. b. The gag reflex should be present, and there should be no difficulty in swallowing.
8. Evaluate the spinal accessory nerve (11th CN), which mediates the sternocleidomastoid and upper portion of the trapezius muscles. a. Ask the patient to turn head to the side against resistance while you apply pressure to the jaw. b. Palpate the sternocleidomastoid muscle on the opposite side. c. Have the patient shrug shoulders while you place your hands on his or her shoulders and apply slight pressure.	8. Neck and shoulder muscle strength should be symmetric.
9. Evaluate the hypoglossal nerve (12th CN), which innervates muscles of the tongue by noting articulation and by having the patient stick out the tongue, noting any deviation or asymmetry.	9. The patient should speak clearly and tongue should be symmetric and should not deviate.
Cerebellar function	
1. Observe posture and gait.	
2. Ask the patient to walk forward (and then backward) in a straight line.	2. The patient should be able to perform all the tests described with smooth, even movement and without losing balance.
3. To test for muscle coordination in the lower extremities, have the patient run the right heel down the left shin and vice versa.	
4. To test coordination in upper extremities, have the patient close eyes and touch the nose with the index finger (starting position: arms outstretched) first left, then right, in rapid succession.	4. The normal person can do this with rapid, smooth movements without undershooting or overshooting the target.
Motor function	
1. Evaluate muscle mass, tone, strength, and any abnormal movements (tics, fasciculations, twitching). May be done with musculoskeletal exam.	Normally, abnormal movements are not present either at rest or with movement.
a. Test muscle tone by noting the resistance the muscle offers to movement on passive motion.	a. Generally, there is slight resistance to passive movement of muscles as opposed to flaccidity (no resistance) or rigidity (increased muscle tone).
b. Test muscle strength by asking the patient to actively resist your movement to flex or extend their various muscle groups. Grade muscle strength as follows: 0 = no muscle contraction, 1 = faint muscle contraction, 2 = active movement of body part with gravity eliminated, 3 = active movement against gravity, 4 = active movement against gravity and some resistance, 5 = active movement against full resistance without fatigue.	b. Strength will vary from person to person, but 5 on a scale of 0 to 5 is considered normal. It should be equal bilaterally.

Sensory function

1. Test sensitivity to light touch (cotton), pain (pinprick), vibration (tuning fork), and discrimination. Compare both sides of the body.
   a. Ask the patient to close eyes. Brush the skin with a piece of cotton (on the back of hands, forearms, upper arms, dorsal portion of foot laterally and medially, and along the tibia and thigh laterally and medially). Ask the patient to indicate when he or she feels the cotton and to compare the sensation bilaterally.
   b. Use a safety pin; touch the skin as lightly as possible to elicit a sharp sensation. (Alternately, temperature discrimination can be tested.)
   c. Test vibration sense by placing a vibrating tuning fork on a distal interphalangeal joint of the finger, then of the great toe, and ask if they feel vibration. If they are unable to feel vibration, move proximally to the next bony prominence. (Alternately, position sense can be tested by moving a toe up or down.)
   d. Test discrimination (which also depends on an intact cortex) by placing a small object such as a paper clip in the hand (stereognosis), using the blunt end of a pen to draw a number in the palm (graphesthesia), or using an open paper clip to touch the skin with 1 or 2 points alternately (two-point discrimination).

   a. Patient should feel light touch bilaterally.

   b. Pain should be felt bilaterally, or warm and cold can be differentiated.

   c. The patient should be able to detect vibration or position if there is no peripheral neuropathy. (If the patient is unsure if they can feel vibration, touch the fork to stop vibration and ask the patient to tell you when it stops).

   d. The patient should be able to identify object, number, or one- or two-point stimulation.

Deep tendon reflexes

1. Make sure the patient is relaxed and extremity is supported for all reflex testing. If the patient is not relaxed and you cannot elicit reflexes, have the patient grasp hands and contract arm muscles to relax the lower extremities or tap feet on the floor to relax the upper extremities.
2. Test biceps reflex by striking indirectly.
   a. Place your right thumb on the patient's right biceps tendon (located in the antecubital fossa) with the patient's arm slightly flexed.
   b. Strike your thumb with the pointed end of the hammer head. Hold the hammer loosely so it pivots in your hand when it is moved with a wrist action.
   c. Strike your thumb with the least amount of pressure needed to elicit the reflex.
3. Test the triceps tendon by using the pointed end of the hammer.

1. Amplitude of the reflex may vary for different tendons bu is equal bilaterally.

   c. The forearm may move, and your thumb should feel the tendon jerk.

a. Have the patient hang arm freely while you support it with your nondominant hand or rest the slightly flexed arm in the patient's lap.
b. With the elbow flexed, strike the tendon directly, using the pointed end of the hammer.

4. Test the brachioradialis tendon by striking the forearm with the flat end of the hammer about 1 inch (2.5 cm) above the wrist over the radius.
5. Test the quadriceps reflex by having the patient sit with legs hanging over the edge of the table or lay down while you support the legs at the knee (slightly bent), and strike the tendon with the pointed end of the hammer just above the patella.

b. The forearm should move slightly.

4. There should be slight flexion and supination of the forearm.

Bickley, L. (2016). *Bates' guide to physical examination and history taking* (12th ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

6. Test the Achilles reflex by supporting the foot in dorsiflexed position and tapping the Achilles tendon with the flat end of the hammer.

Lynn, P. (2010). *Taylor's Clinical Nursing Skills* (3rd ed.). Philadelphia, PA: Lippincott Williams & Wilkins. Photograph by Barbara Proud.

6. The foot should move downward into your hand.

7. Stroke the sole of the patient's foot with a flat object such as a tongue blade to test the plantar reflex.

7. Toes normally flex. Dorsiflexion of the great toe and fanning of the other toes is known as a positive Babinski response and indicates a central nervous system problem.

Intravenous Therapy

General Considerations

Goals

Physiologic Assimilation of Infusion Solutions

Types of Intravenous Medication Administration

IV "Push" (Bolus)

Intermittent Infusions

Continuous Infusion

Use of Infusion Control Devices

Vascular Access Device Selection

Nursing Role in Intravenous Therapy

Initiating an IV Line

Vascular Access Maintenance and Removal

Evaluation, Documentation, Patient Education, and Quality Improvement

Complications of IV Therapy

GENERAL CONSIDERATIONS

Goals

The goals of intravenous (IV) therapy are to:

1. Provide hydration and/or correction of electrolyte imbalances in the patient who cannot maintain an adequate oral intake.
2. Administer safe and effective infusions of medications by using the appropriate vascular access.
3. Administer blood components and/or blood products.
4. Provide for invasive patient hemodynamic monitoring.
5. Provide nutrition while resting the GI tract.

Physiologic Assimilation of Infusion Solutions

Principles

1. Tissue cells (such as epithelial cells) are surrounded by a semipermeable membrane.
2. Cell membrane permeability refers to the ability of the cellular membrane to allow substances such as water to pass freely, whereas charged ions, such as sodium, cannot cross the membrane and are trapped on one side.
3. Osmotic pressure is the "pulling" pressure demonstrated when water moves through the semipermeable membrane of tissue cells from an area of weaker concentration to stronger concentration of solute (eg, sodium ions and blood glucose). The end result is dilution and equilibration between the intracellular and extracellular compartments.
4. Total body water (TBW), depending slightly on age, gender, and race, comprise 45% to 60% of a person's weight. Total body water is the sum of intracellular fluid (about 2/3 TBW) and extracellular fluid volume (about 1/3 TBW). Extracellular fluid volume (EFV) is a composition of interstitial fluid (about 2/3 of EFV) and intravascular volume (about 1/3 of EFV).
5. Extracellular compartment fluids primarily include plasma and interstitial fluid.

Types of Intravenous Fluids

Intravenous fluids include colloids and crystalloids. See Table 6-1.

Table 6-1 Composition of Selected Intravenous Solutions

SOLUTION	TONICITY	NA^+ (MEQ/L)	K^+ (MEQ/L)	CL^- (MEQ/L)	CA^{++} (MEQ/L)	BUFFER	PH
Lactated Ringer (LR)*	Isotonic	130	4	109	3	28 lactate	6.5
0.9% normal saline (NS)	Isotonic	154	0	154	0	0	—
D5W	Isotonic	0	0	0	0	0	4.5
D5LR	Slightly hypertonic	130	4	109	3	28 lactate	5
D5NS	Hypertonic	154	0	154	0	0	4
3% NS	Hypertonic	513	0	513	0	0	—
0.45% NS	Hypotonic	77	—	7	—	0	5.3
5% D and 0.45% NS†	Slightly hypertonic	77	—	77	—	0	4

**Lactate converts to bicarbonate in the liver.*

†5% dextrose metabolizes rapidly in the blood and, in reality, produces minimal osmotic effects.

DW, dextrose in water; NS, normal saline.

1. Colloid solutions contain large proteins or molecules that cannot pass through the cellular semipermeable membrane. Colloids increase intravascular volume by drawing fluid into the intravascular space via oncotic pressure. Common natural colloids include red blood cells, plasma, and albumin. Common synthetic colloids include dextran and hetastarch.
2. Crystalloid fluid contains electrolytes but lack large proteins and molecules. Crystalloid fluid is capable of passing through a semipermeable membrane. Classified according to their "tonicity," crystalloids are isotonic, hypotonic, or hypertonic solutions.

Isotonic

A solution that exerts the same osmotic pressure as that found in plasma. This fluid will distribute evenly

between the intravascular and intracellular space. This type of fluid is typically administered to replace extracellular fluid losses to expand intravascular volume.

1. 0.9% sodium chloride solution (normal saline, NS).
2. Lactated Ringer solution (LR).
3. Dextrose 5% in water (D_5W).

Hypotonic

A solution that exerts less osmotic pressure than that of blood plasma. Administration of this fluid generally causes dilution of plasma solute concentration and forces water to move into cells to reestablish intracellular and extracellular equilibrium; cells will then rehydrate.

1. 0.45% sodium chloride solution (half NS).
2. 0.33% sodium chloride solution (one-third NS).

Hypertonic

A solution that exerts a higher osmotic pressure than that of blood plasma. Administration of this fluid increases the solute concentration of plasma, drawing water out of the cells and into the extracellular compartment to restore osmotic equilibrium; cells will then shrink.

1. D_5W in lactated Ringer solution (D_5LR).
2. D_5W in normal saline solution.
3. D_5W in 0.45% (half normal) saline solution (only slightly hypertonic because dextrose is rapidly metabolized and renders only temporary osmotic pressure).
4. Dextrose 10% in water ($D_{10}W$).
5. Dextrose 20% in water ($D_{20}W$).
6. 3% or 5% sodium chloride solution.
7. Hyperalimentation solutions.

Uses and Precautions with Common Types of Infusions

See Table 6-2, for signs and symptoms of water excess or deficit.

Table 6-2 Signs and Symptoms of Water Excess or Deficit

SITE	WATER EXCESS	WATER DEFICIT
Central nervous system	• Muscle twitching • Hyperactive tendon reflexes • Convulsions • Increased intracranial pressure, coma	• Sleepiness • Apathy • Restlessness • Weakness • Delirium • Coma
Cardiovascular	• Elevated venous pressure • Increased cardiac output • High pulse pressure • Heart gallop • Rales, pulmonary edema	• Tachycardia • Orthostatic hypotension, hypotension • Flat neck veins • Cool, clammy skin
Gastrointestinal	• Anorexia, nausea, and vomiting • Edema of stomach, colon, and mesentery	• Anorexia • Thirst • Silent ileus
Tissues	• Increased salivation, tears • Watery diarrhea • Subcutaneous pitting edema	• Decreased saliva and tears • Dry, sticky mucous membranes • Red, swollen tongue • Flushed skin • Decreased skin turgor • Sunken eyes
Other	• None	• Decreased temperature

1. D_5W.
    a. Used to replace water (hypotonic fluid) losses, supply some caloric intake, or administer as carrying solution for numerous medications.
    b. Should be used cautiously in patients with water intoxication (hyponatremia, syndrome of inappropriate antidiuretic hormone release).
    c. Should not be used as concurrent solution infusion with blood or blood components.
2. Normal saline solution (0.9% NS or NaCl).
    a. Commonly used resuscitative crystalloid used to replace isotonic fluid losses, administer with blood components, or treat patients in hemodynamic shock.
    b. Should be used cautiously in patients with isotonic volume excess such as heart or renal failure patients; monitor for hyperchloremic acidosis with resuscitation uses.
    c. Inexpensive.

3. Lactated Ringer solution (LR).
    a. Commonly used resuscitative crystalloid used to replace fluid losses, replenish specific electrolyte losses, and moderate metabolic acidosis.
    b. Use cautiously in patients with liver failure.
4. Hypertonic saline solution (3% NS or NaCl).
    a. Acts as a plasma volume expander by increasing the movement of intracellular and interstitial water into the intravascular space.
    b. Risk of hypernatremia and requires careful monitoring, particularly of patient's neurologic status.

TYPES OF INTRAVENOUS MEDICATION ADMINISTRATION

There are three intravenous routes of administration: bolus or "IV push," intermittent infusion, and continuous infusion.

IV "Push" (Bolus)

IV "push" (or *IV bolus*) refers to the administration of a medication from a syringe directly into an ongoing IV infusion or may be given directly into a vein by way of an intermittent access device (saline or heparin lock).

Indications

1. When a rapid concentration of a medication in the patient's bloodstream is needed (eg, cardiopulmonary resuscitative procedures).
2. When quicker response from a medication is required (eg, furosemide or digoxin).
3. To administer "loading" doses of a drug that will be continued by way of infusion (eg, heparin, pain medications).
4. To reduce patient discomfort by limiting the need for intramuscular injections.
5. To avoid incompatibility problems that may occur when several medications are mixed in one bottle/bag.
6. To deliver medications or solutions to patients unable to take them orally (eg, unresponsive patients) or intramuscularly (eg, coagulation disorder).
7. Cost-effective method—no need for extra tubing or syringe pump.

Precautions and Recommendations

1. Before medication administration, review order and confirm patient identification and allergies. Be familiar with facility policies and guidelines regarding how, where, and by whom IV push medications or solutions can be given.
2. Use aseptic technique when preparing and administering IV push medications and accessing the vascular device.
3. Determine the correct (safest) rate of administration. Consult the pharmacy or pharmaceutical text. Most medications are given slowly (rarely in less than 1 minute); sometimes as long as 30 minutes is required. Too rapid administration may result in serious adverse effects.
4. Dilute the drug as indicated by manufacturer or pharmacy references with the appropriate dilutant. Many medications are irritating to veins and require sufficient dilution. Caution during this process because of the associated increased risk for medication errors and contamination of sterile IV medications or solutions.
5. If withdrawing IV push medications from a glass ampule, use a filter needle or straw unless the specific drug precludes their use. Unless the medication or solution is prepared at the patient's bedside for immediate administration without any break in the process, appropriately label all nurse-prepared syringes of IV push medications or solutions.
6. Perform an appropriate assessment of the patient. This includes an evaluation of the prescribed therapy for the patient's age and clinical condition, rights of medication administration (right patient, medication name, dose, route, time), and reason for medication or solution treatment. Assess the vascular site and ensure patency of the IV line by aspirating for positive blood return and encountering no resistance when manually flushing the vascular access device. Ascertain the dwell time of the catheter. For infusion of

vesicants, a catheter placement of 24 hours or less is advisable.

7. If your facility uses barcode technology, scan your identification (ID) badge, the patient's ID bracelet, and the medication's barcode.
8. If IV push is to be given with an ongoing IV infusion or to follow another IV push medication, check pharmacy for possible incompatibility. It is always wise to flush the IV tubing or cannula with saline before and after administration of a drug.
9. Use a needleless connector that is closest to the patient to allow the medication or solution to reach the central circulation as soon as possible with a minimal amount of flushing. Needleless connectors protect health care providers by eliminating the need for needles and subsequent needlestick injuries when attaching syringes and/or administration sets to the vascular access device.
10. Monitor the patient's reaction to the medication during and after administration.
    a. Be alert for major adverse effects, such as anaphylaxis, respiratory distress, tachycardia, bradycardia, or seizures. If this occurs, stop the medication and notify the health care provider. Institute emergency procedures as necessary.
    b. Assess for minor adverse effects, such as nausea, flushing, skin rash, or confusion. If this occurs, stop medication and notify the health care provider.

NURSING ALERT Unless its use would result in a clinically significant delay and potential patient harm (eg, medication administration during cardiopulmonary resuscitation), barcode scanning or similar technology is recommended immediately prior to medication or solution administration as an effective error reduction strategy.

---

11. Monitor the vascular access site for any signs of infiltration or extravasation.

Intermittent Infusions

Intermittent intravenous infusions are a medication or solution administered over a set period of time at prescribed intervals. An intermittent infusion may be given through an intermittent access device (saline lock) or "piggybacked" to a continuous IV infusion as a secondary medication.

Intermittent Access Device (Saline Lock)

1. This intermittent infusion device permits the administration of periodic IV medications and solution without continuous fluid administration.
2. Needleless connectors protect health care providers by eliminating the need for needles and subsequent needlestick injuries when attaching syringes and/or administrations sets to the vascular access device.
3. Prepare for medication or solution administration by confirming patient and order as required by facility procedure and perform appropriate hand hygiene.
4. Provide patient education regarding medication or solution. Encourage patient to report any discomfort at the IV site including pain, burning sensation, or swelling noted.
5. Maintain aseptic technique throughout the procedure.
6. Ensure patency of saline lock with normal saline flush prior to administration of medication or solution. Do not force if resistance is felt.
7. When administering the medication or solution, use a timer with a second hand to inject according to facility policy and manufacturer recommendations. Use a push–pause method to inject the medication.
8. After administration of the medication or solution, flush the saline lock with normal saline at the same rate as the medication administration to ensure that all medication remaining in the saline lock or extension tubing is administered at the appropriate rate and to prevent future contact incompatibilities.
9. Observe for expected therapeutic effect and potential adverse effects.

NURSING ALERT Medication errors are often a result of calculation errors, drug preparation errors, human errors, and transcription inaccuracy. Unusual dosages or unfamiliar medication or solutions should always be confirmed with the health care provider and pharmacist before administration. Ultimately, the nurse is accountable for the medication or solutions administered.

Secondary Medication Administration ("Piggyback")

1. Means of administering a medication or solution by way of an established primary infusion line.
2. Needleless connectors protect health care providers by eliminating the need for needles and subsequent needlestick injuries when attaching syringes and/or administration sets to the vascular access device.
3. Prepare for medication or solution administration by confirming patient and order as required by facility procedure and perform appropriate hand hygiene.

4. Provide patient education regarding medication or solution. Encourage patient to report any discomfort at the IV site including pain, burning sensation, or swelling noted.
5. Maintain aseptic technique throughout the procedure.
6. Prime the secondary tubing and use the extension hook.
    a. If using gravity infusion, hang the secondary medication higher than the primary IV solution bag. Use the roller clamp or flow regulators to calculate infusion rate.
    b. If using an electronic infusion device, set an appropriate rate.
7. When a backcheck valve is present on the primary tubing, it:
    a. Permits the primary infusion to flow after the medication has been administered.
    b. Prevents air from entering the system.
    c. Prevents secondary fluid from "running dry."
    d. Permits less mixing of primary fluid with secondary solution.
8. Always select the assess port closest to the insertion site of the vascular access device.
9. Use of an electronic infusion device or flow regulator will permit rate changes between primary and secondary infusions.
10. Never administer a solution or medication through a continuous IV line that is infusing blood, blood products, heparin IV, insulin IV, cytotoxic medications, or parenteral nutrition solutions.
11. A volume-controlled intermittent set is a device attached below the primary infusion to regulate the secondary medication or solution. These devices are used most often for children, older adults, or critically ill patients where fluid volume is a concern.

Continuous Infusion

Continuous infusion is the IV infusion of a medication or solution over several hours to days. Use of an electronic infusion device with dose-error technology is recommended.

1. Prepare for medication or solution administration by confirming patient and order as required by facility procedure and perform appropriate hand hygiene.
2. Provide patient education regarding medication or solution. Encourage patient to report any discomfort at the IV site including pain, burning sensation, or swelling noted.
3. Maintain aseptic technique throughout the procedure.

Use of Infusion Control Devices

Infusion control devices allow for the infusion of large and small volumes of IV solution or medication with accuracy over a determined time period at prescribed intervals, reducing the risk of rapid infusion. Use of infusion control devices should be based on the needs and factors of the patient, type of vascular access device, and health care setting. Electronic infusion devices with dose-error reduction systems are preferred. The nurse must be competent in the use of all available equipment.

Types

Manual Control Flow Regulator

1. Delivers a prescribed fluid volume per hour.
2. To be used for lower-risk infusions.
3. Nonautomated and requires manual adjustment of a regulator clamp to administer correct flow rate.

Electronic Infusion Devices

1. Deliver a prescribed fluid volume per hour.
2. Often, incorporate dose-error reduction technologies to minimize adverse patient situations.
3. Divided into large-volume and small-volume devices.
4. Indicated for continuous infusions of chemotherapy, hyperalimentation, fluid and electrolytes in patients at risk for fluid overload, infant and pediatric therapies, and most medications.
5. Some electronic infusion devices are designed to be used at a patient's bedside, whereas other, called ambulatory infusion pumps, are designed to be portable or wearable.

Blood and Fluid Warmers

Used when attempting to avoid or treat hypothermia, during cardiopulmonary bypass, when the patient is known to have cold agglutinins, or during replacement of large blood volumes.

Power Injectors

1. Used to deliver specific amounts of contrast media at a specified rate/time during radiological diagnostic procedures. Radiological contrast media are to be considered vesicant solutions with the potential to cause severe tissue injury in the setting of infiltration/extravasation.
2. Vascular access device must be able to withstand pressure of 300 psi or greater to be compatible with power injectors.

Nursing Responsibilities

1. Continuous or intermittent infusions must be monitored by the nurse to ensure accurate delivery.
2. Follow the manufacturer's instructions carefully when using administration tubing sets or inserting tubing into an electronic infusion device.
3. Eliminate all air from the administration tubing set before connecting it to the patient's vascular access

device.

4. Continue to check the patient regularly for complications, such as infiltration or infection, and not rely solely on the electronic infusion device pressure alarms.
5. Ensure that infusion therapy is initiated, changed, or discontinued based upon the order of the prescribing health care provider.
6. Explain the purpose of the device and the alarm system to the patient and/or caregivers. Added machines in the room can evoke greater anxiety in the patient and family.
7. For rapid administration of solutions and blood or blood products, avoid using needleless connectors. Instead connect directly to the hub of the vascular access device because needleless connectors can greatly reduce flow rates.
8. Adhere to all manufacturers' guidelines regarding product use.

Vascular Access Device Selection

Selecting the appropriate vascular access device is based on the needs of the patient, particularly the prescribed therapy and duration of therapy, as well as characteristics of the patient including age, comorbidities, and vascular characteristics.

Short Peripheral Catheters

1. These catheters are inserted into the dorsal and ventral surfaces of the upper extremities, including the metacarpal, cephalic, basilic, and median veins.
2. These catheters are intended for short-term therapy—typically less than 6 days.
3. The smallest gauge short peripheral catheter that can accommodate the prescribed therapies and patient's needs should be selected.
4. Therapies not appropriate for short peripheral catheters include continuous vesicant therapy, parenteral nutrition, and infusions with a pH less than 5 or greater than 9 or with an osmolality greater than 600 mOsm/L.

Midline Catheters

1. These catheters are inserted into the basilic, cephalic, or median cubital veins and extend 3 to 8 inches (7.5 to 20 cm) up the arm with the proximal tip resting in the upper arm just distal to the axillary arch.
2. Per manufacturing guidelines, may need to be routinely replaced every 28 to 30 days.
3. They are considered deep peripheral and not appropriate for continuous vesicant therapy such as hyperosmolar solutions, parenteral nutrition, and some antibiotics, such as erythromycin and nafcillin, as well as infusions with a pH less than 5 or greater than 9 or with an osmolality greater than 600 mOsm/L.
4. Avoid use in patients with a history of thrombosis, hypercoagulability, and decreased venous flow or in the setting of vein preservation such as with end-stage renal disease.
5. Ultrasound guidance is recommended to decrease the risks of cannulation failure, arterial puncture, hematoma, and pulmonary complications.

NURSING ALERT Avoid placing vascular access devices in the veins of an upper extremity on the same side as a previous breast surgery with axillary lymph node dissection, after radiation therapy to that side, in the setting of lymphedema, or in an extremity affected by cerebrovascular accident, because risk is greater for infectious and thrombotic complication.

Central Venous Access Devices

Indications

1. Physiologic instability of the patient and/or complexity of infusion therapies.

2. Continuous vesicant or irritant therapy, chemotherapy, or parenteral nutrition medication.
3. Invasive hemodynamic monitoring.
4. History of difficult peripheral venous access because of extensive previous IV therapy, surgery, or previous tissue damage where vascular site selection is limited or the use of ultrasound guidance has failed.
5. Long-term IV therapy—weeks, months, or years.

Types

See Figure 6-1.

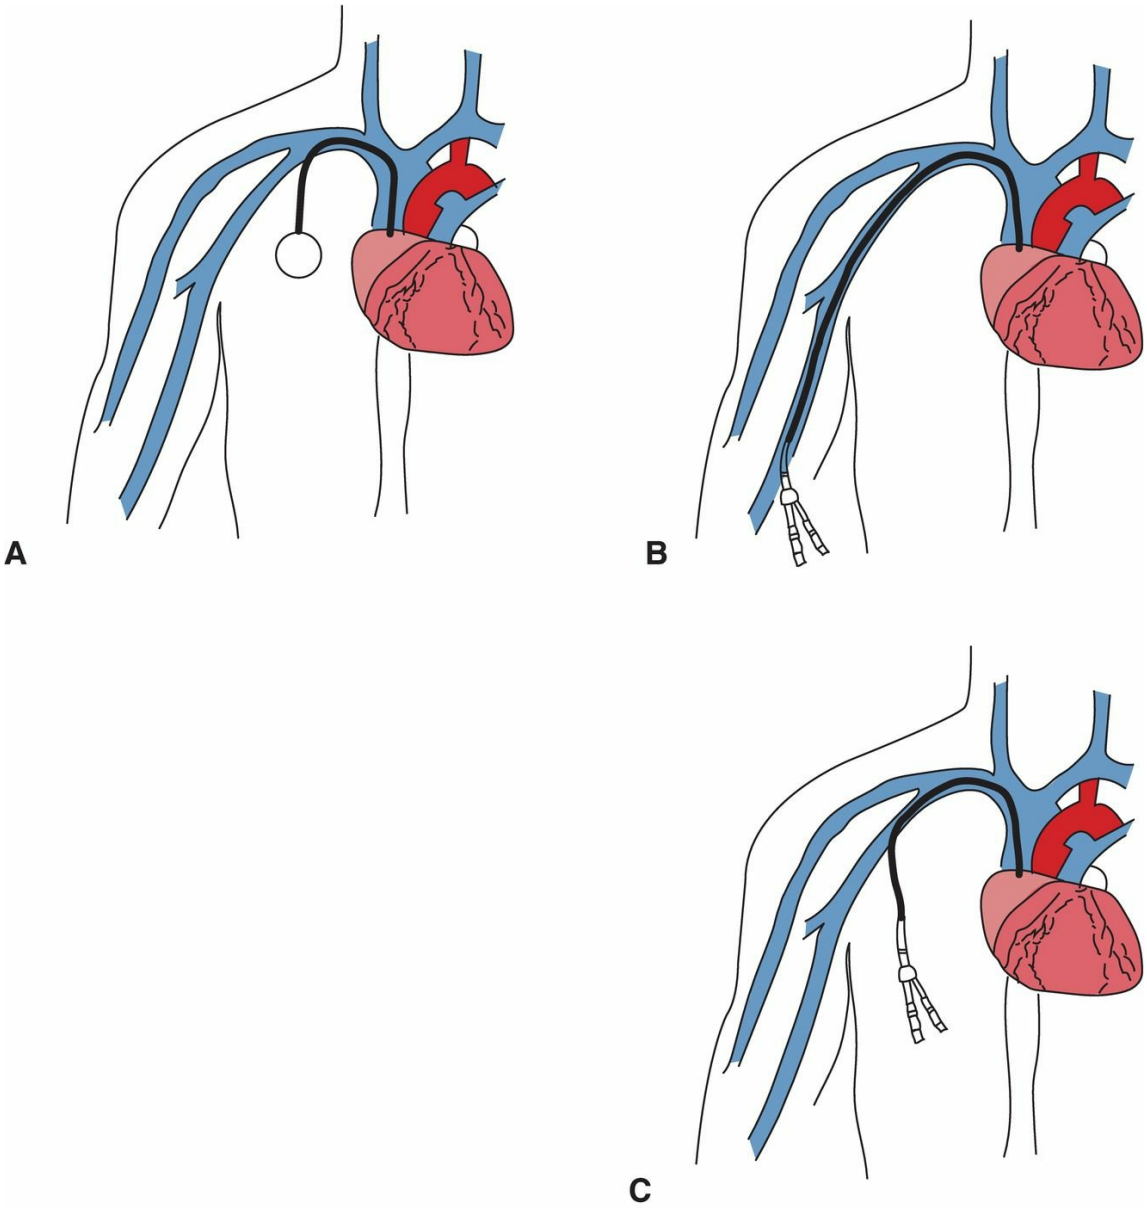

Figure 6-1. Types of central venous catheters for long-term venous access. **(A)** Implantable venous access port. **(B)** Peripherally inserted central catheter (PICC). **(C)** Tunneled central venous catheter.

1. Central catheter—nontunneled; commonly called *percutaneous*.
   a. Has one to four lumens.
   b. Dwell time usually less than 1 month.
   c. May be inserted in femoral, jugular, or subclavian veins. To minimize the risk of catheter-related infections and thrombotic complications in adult patients, the subclavian vein is preferred. However, in patients with advanced kidney disease, the subclavian site to prevent subclavian stenosis and preserve the site for hemodialysis.
   d. Ultrasound guidance is recommended to decrease the risks of cannulation failure, arterial puncture, hematoma, and pulmonary complications.

NURSING ALERT Prior to the initiation of medication or solution therapy, ensure the appropriate placement of all central vascular catheters radiographically or by other imaging technology.

2. Central catheter—tunneled.
    a. A tunneled catheter is inserted into a central vein (usually the subclavian, then the superior vena cava) and subcutaneously tunneled to an exit site approximately 4 inches (10 cm) from the insertion site.
    b. A Dacron cuff is located approximately ¾ to 1 inch (2 to 3 cm) from the exit site, providing a barrier against microorganisms.
    c. Examples of the tunneled catheters in current use are Hickman™, Broviac™, and Groshong™.
3. Peripheral inserted central catheter (PICC).
    a. Inserted in basilic, median cubital, brachial, or cephalic veins in adult patients; additional sites are available in neonate and pediatric patients.
    b. PICCs placed in the median cubital vein tend to follow the cephalic vein to central placement. Observe carefully for pain and tenderness because the cephalic vein is smaller than the basilic.
    c. Used in patients in acute, long-term, and home care settings.
    d. May be inserted by nurses with special training or interventional radiologists.
    e. PICC tip placement must be located in superior vena cava (verified by x-ray). Tip placement in subclavian or innominate vein contraindicated for hyperosmolar solutions (hyperalimentation).
    f. Ultrasound guidance is recommended for placement to improve first-attempt success and decrease adverse events.
    g. PICC insertion site and hub should be covered by a transparent dressing.
    h. Extension tubing must be clamped when no solution is being infused. Tape it securely to the patient's arm.
    i. Measure upper arm circumference before and after insertion and as clinically indicated to assess for edema and possible infiltration/extravasation or deep vein thrombosis. Take this measurement 10 cm above the antecubital fossa. Positive pressure flushing will keep PICC from clotting.
4. Central implanted vascular device.
    a. A subcutaneous pocket is formed and a reservoir is placed; a catheter is attached to the reservoir and tunneled subcutaneously and inserted into a central vein (usually, the catheter tip is in the superior vena cava). This device cannot be seen exteriorly.
    b. Central implanted vascular devices are typically used in patients who require intermittent long-term infusion therapy such as with chemotherapy.
    c. Examples of implanted devices in current use include the Port-A-Cath™, Mediport™, Infuse-A-Port™, Bard Port systems, and Groshong Port™.

NURSING ALERT If central catheters are placed too deeply and extend into the right atrium, an irregular heartbeat may result. Monitor heart rhythm and notify the health care provider immediately.

EVIDENCE BASE Infusion Nursing Society (INS). (2016). Infusion therapy standards of practice nursing standards of practice. *Journal of Infusion Nursing*, *349*(1S).

Alternative Infusion Devices

1. Intraspinal access devices
    a. Access devices placed in the epidural, intrathecal, or ventricular spaces.
    b. Anticipate intraspinal infusion administration that requires pain management, chemotherapies, or spasticity control.
    c. Administer only preservative-free medications or solutions.
2. Intraosseous (IO) access devices
    a. Access devices placed in the marrow of the bone.
    b. Anticipate intraosseous infusion for emergent and nonemergent use in patients with limited or no vascular access.
3. Subcutaneous access devices
    a. Anticipate subcutaneous access for administration of isotonic solutions for treatment of mild to moderate dehydration or continuous opioid administration.
    b. Use hyaluronidase to facilitate the dispersion and absorption of medications or solutions in adults and pediatric patients.

NURSING ROLE IN INTRAVENOUS THERAPY

Initiating an IV Line

Intravenous therapy is an invasive procedure and should be ordered only when necessary. Nurses must be familiar with the procedure as well as the equipment involved in initiating an IV to provide effective therapy and prevent complications. See Standards of Care Guidelines 6-1, page 76.

See additional online content: Procedure Guidelines 6-1–6-4.

PROCEDURE GUIDELINES 6-1

Venipuncture Using Needle or Catheter

EQUIPMENT

- Tourniquet (nonlatex preferred)
- Personal protective equipment
- Antiseptic swab (chlorhexidine, alcohol, iodine, povidone-iodine)
- Sterile gauze (to absorb blood spillage or in case of unsuccessful attempt)

If continuous infusion:

- IV solution
- IV tubing
- Infusion device

If intermittent access device:

- Extension set or leur lock port
- Prepackaged normal saline solution flush
- Tape
- Transparent IV dressing or other dressing supplies
- Covered armboard (if necessary) or other joint stabilization device
- Desired cannula
    - Catheter (Teflon, silastic polyurethane, or polyvinyl chloride) in chosen bore size (gauges 14 to 25)
    - Winged ("(butterfly)") needle

Note: Aseptic nontouch technique should be used when performing a venipuncture. Thorough hand washing is required before handling sterile supplies and initiating venipuncture.
Note: When obtaining blood samples from a peripheral vein, best practice is to perform a separate venipuncture using a new straight-line needle rather than aspirating from an existing peripheral IV catheter. Research has documented a significant increase in the incidence of hemolysis when blood is drawn through a peripheral IV catheter as compared to when blood is drawn with a needle.

PROCEDURE

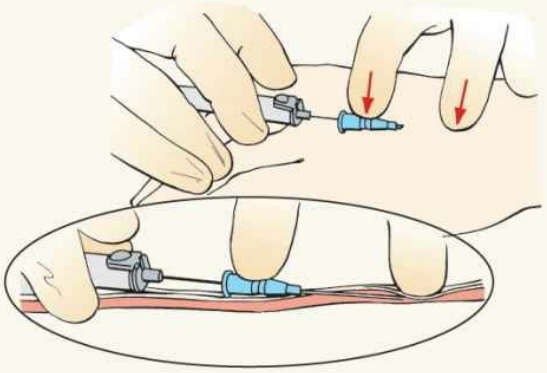
Nursing Action	Rationale
Preparatory phase	
1. Confirm order and indication for the procedure. Confirm patient identify and explain the procedure to the patient. Ascertain whether the patient is left or right handed.	1. Helps alleviate anxiety about the procedure. Start the infusion in the nondominant arm, if possible.
2. Review the patient's medical record for allergies to antiseptic, adhesive, and latex. Use an alternate product if necessary.	2. Ensures patient's safety and eliminates exposure to an allergen.
3. Prime all IV and winged-needle tubing (clear the tubing of air with fluid from infusion tubing by attaching a needle, or by irrigating the needle with saline in a sterile syringe).	3. Prevents infusion of air and potential air embolus.
4. Apply necessary personal protective equipment.	4. Complies with CDC requirements to minimize passing of blood-borne pathogens between the patient and nurse.
5. Select a site for insertion. See the discussion on site selection.	
6. Apply a tourniquet 2–6 inches (5–15 cm) above the desired insertion site and ascertain satisfactory distention of the vein. Distal pulses should remain palpable.	6. The vein must be visible or palpable before venipuncture is attempted. The tourniquet should not be applied too tightly so it does not interfere with arterial blood flow.
7. Have the patient open and close fist several times.	7. Increases blood supply in the area. Further techniques to aid in vein distention. A tourniquet may not be necessary on greatly distended veins.
8. Remove the tourniquet. Limit tourniquet time to less than 1 minute.	8. Prevents trauma to the arm from extended application of the tourniquet. It can be reapplied later.
9. Clip the hair if site is obscured and clean as follows:	9. Reduce the number of skin microorganisms and minimizes risk of infection.
a. Consider use of local anesthetic agents. Administer per facility guidelines and manufacturer recommendations.	a. Minimizes pain experienced by the patient while obtaining vascular access.
b. Cleanse the skin with a chlorhexidine solution.	b. Chlorhexidine is the preferred solution.
c. If chlorhexidine is contraindicated, clean skin with alcohol first, using the swab in a circular motion outward from the site for at least 30 seconds; then povidone-iodine swab for 1 minute, working from the center of the proposed site to the periphery until a circle of 2–4 inches (5–10 cm) has been disinfected.	c. Alcohol should be used as part of a two-step process, but may be used alone if the patient is allergic to iodine.If a 1%–2% iodine solution is used, it should be used before alcohol for 30–60 seconds and allowed to dry.
d. Allow the area to air-dry.	d. Drying allows for additional disinfection.
10. Reapply a tourniquet.	10. Facilitates catheter insertion.
11. Have visualization technology such as near-infrared light technology or ultrasound available as needed.	11. Assists in locating viable peripheral venous access sites in patients with difficulty venous access.

Nursing Action	Rationale
Performance phase: catheter insertion	
1. Remove the needle guard. Hold the cannula between your dominant thumb and index finger.	
2. Hold the patient's arm so your nondominant thumb is positioned approximately 2 inches (5 cm) from the site. Exert traction on the skin in the direction of your hand.	2. Stabilizes the vein and facilitates successful cannulation.
3. Insert the needle, bevel up, through the skin at a 10–30-degree angle. Use a slow, continuous motion.	3. Bevel-up position allows for the smallest and sharpest point of the needle to enter the vein first. Satisfactory penetration is evidenced by a sudden decrease in resistance and by the appearance of blood coming back into catheter.
4. When the vein is entered, lower the catheter to skin level.	4. Prevents puncturing the vessel wall.
5. When inserting, always hold the catheter by the clear plastic flashback chamber and not by the colored hub.	
6. Advance the catheter approximately ¼–½ inches (0.5–1.5 cm) into the vein.	6. Ensures entry into the vein.
7. Pull back on needle to separate needle from catheter about ¼ inch and advance the catheter into the vein. Activate the device's safety mechanisms following the manufacturer's instructions for use.	7. Pulling back on the needle prevents inadvertent puncture of the vein and provides stability of catheter for insertion.

KEY DECISION POINT If resistance is met while attempting to thread the catheter, do not force it. Resistance is a sign the catheter is not positioned well within the lumen of the vein, and attempts to advance the catheter further against resistance may cause vein damage. If the catheter does not freely advance, you may attach IV tubing or a heparin lock and flush, attempting to float the catheter into the vein. If resistance is still met, release the tourniquet and carefully remove the needle and the catheter.

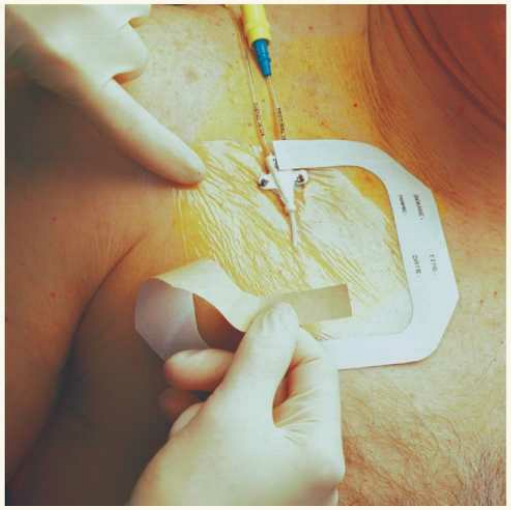
NURSING ALERT Never reinsert a stylet back into a catheter once it has been removed. You may puncture or sever the catheter.

8. Once the catheter is positioned within the vein, apply pressure on the vein beyond the catheter tip with your little finger (see illustration); release the tourniquet and slowly remove the needle while holding the catheter hub in place.	8. Reduces blood leakage while removing the needle and connecting tubing to the infusion set.



Finger palpation of dorsal venous arch, applying pressure above cannula.

Nursing Action	Rationale
9. If a continuous infusion, attach the primed administration set to the hub of the catheter and adjust the infusion flow at the prescribed rate.	
10. If an intermittent access device, attach leur lock port and extension set, taking care to maintain sterility of the set. Flush with normal saline to confirm patency.	
11. Secure and anchor the cannula with a stabilization device. Apply sterile transparent dressing to the site or use dressing according to facility protocol (see illustration).	11. Transparent dressing secures the IV catheter and prevents infection.
12. Loop tubing and tape to dressing or arm.	12. Prevents tension on the IV catheter itself.



Transparent IV dressing. (Courtesy of 3M Health Care.)

13. Apply a stabilization device or site protection device per facility policy.	13. Further secures and protects site placement in difficult areas or in restless patients.
14. Label the strip of tape with an arrow indicating the path of the catheter, size of catheter, date, time of insertion, and your initials. Affix the tape to the dressing. Prepare a similar label with each dressing change.	14. Labeling the dressing is dictated by facility policy. Such a practice provides information useful in determining the next dressing change and the capability of the needle to accommodate various types of infusion.
15. Document the procedure.	15. Communicates relevant information to health care providers.

EVIDENCE BASE Infusion Nursing Society (INS). (2016). Infusion therapy standards of practice nursing standards of practice. *Journal of Infusion Nursing, 349*(1S).

PROCEDURE GUIDELINES 6-2

Accessing Intermittent Access Device (Saline Lock)

A saline lock is an intermittent infusion reservoir that permits administration of periodic IV medications and solution without continuous fluid administration. The reservoir indicated here includes the extension set, access valve, and catheter.

EQUIPMENT

- Antiseptic swabs (usuallyalcohol)
- Prefilled syringe with normal saline solution
- Preflushed extension set if converting IV line to existing cannula in vein

- Tape
- Personal protective equipment
- Disinfectant-containing end cap as requested by facility procedures, if applicable

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Perform hand hygiene.	1. Minimizes possibility of infection.
2. Confirm order and indication for the procedure. Confirm patient identify and explain the procedure to the patient.	2. Helps alleviate anxiety about the procedure.
3. Apply necessary personal protective equipment. Put on gloves.	3. Complies with CDC requirements to minimize passing of blood-borne pathogens between the patient and nurse.
Performance phase	
1. Clean the port of the saline lock with alcohol. Unclamp the clamp if necessary. Attach a normal saline syringe onto the port and aspirate slightly.	1. Use either a syringe directly to the leur lock or blunt-end syringe to access the port. This equipment avoids accidental needle sticks. If a small-gauge catheter does not show a positive blood return, monitor the site carefully.
2. Inject normal saline solution slowly to flush the reservoir of saline solution and blood.	2. Assess for resistance, which may mean that the catheter is blocked or not functioning properly.
3. Check with the patient to ensure that he or she has no pain on flushing.	3. May indicate a clot or infiltration.
4. Check for swelling at the needle site when flushing.	4. May indicate a clot or infiltration.
5. Attach medication-filled syringe or medication tubing and administer the drug, at the prescribed rate.	
6. After drug or solution administration, attach the saline syringe and flush the reservoir slowly. Remove the syringe while still pushing the plunger of the syringe to ensure positive pressure.	6. Prevents blood clotting in the IV cannula. It is recommended that flush is equivalent to two times the volume of the catheter and any add-on devices.
Follow-up phase	
1. If used by facility procedures, apply a new disinfectant-containing end cap on the injection cap.	
2. Maintain patency of saline lock by flushing it every 8–12 hours, regardless of use.	2. If resistance is met, the device should not be flushed. Attempt to remove the occlusion via aspiration. If unable to restore patency, remove the IV device.
3. Needleless connectors should be changed no more frequently than every 72 hours or according to the manufacturer's recommendations. IV administration set for intermittent therapy should be changed according to facility policy. The tubing should only be used for the same medication.	3. Limits the potential infection risks.

EVIDENCE BASE Infusion Nursing Society (INS). (2016). Infusion therapy standards of practice nursing standards of practice. *Journal of Infusion Nursing, 349*(1S).

PROCEDURE GUIDELINES 6-3

Setting Up a Secondary IV line

EQUIPMENT

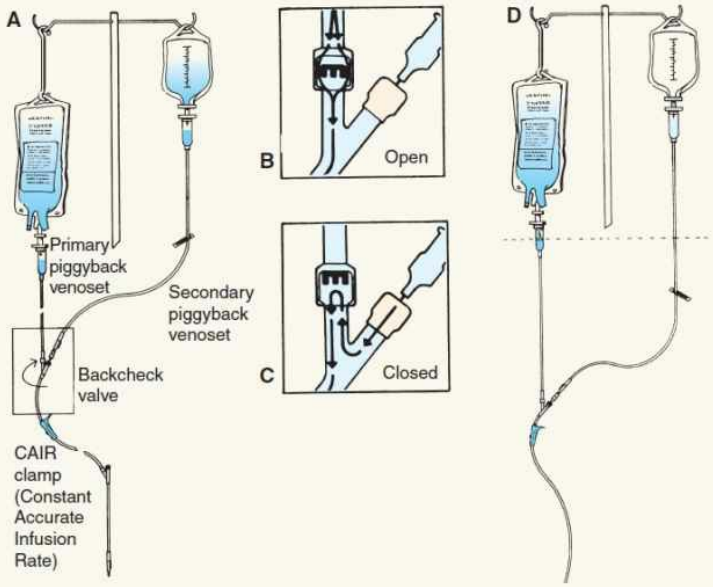
- Personal protective equipment
- Antiseptic pads
- Prefilled normal saline solution syringe
- Sterile infusion set (primary)
- Sterile infusion set (secondary)

- Prescribed IV medication or solution
- Needleless adapter
- IV pole
- Extension hook as needed
- Infusion device

PROCEDURE

Follow the procedure of the manufacturer of the secondary line, "(piggyback,)" infusion set being used. In general, most procedures are similar to the following:

Nursing Action	Rationale
Preparatory phase	
1. Perform hand hygiene.	1. Minimizes possibility of infection.
2. Confirm order and indication for the procedure. Confirm patient identify and explain the procedure to the patient.	2. Helps alleviate anxiety about the procedure.
3. Apply necessary personal protective equipment. Put on gloves.	3. Complies with CDC requirements to minimize passing of blood-borne pathogens between the patient and nurse.
4. Set up the primary infusion set; this may have a check valve (see part **A** in illustration).	4. The primary set should be functioning effectively before the secondary (piggyback) set can be attached. This check valve prevents the flow from the primary line during infusion and returns it after infusion.
5. Lower the primary flask on the IV pole; usually, an extension hook accompanies the set.	5. Permits the check valve to function.
Performance phase	
1. Use an alcohol swab to carefully clean the injection site.	1. Usually, this is a Y-connection on the primary site.
2. Attach secondary tubing to primary tubing—preferably with a needle-free adapter—at entry port.	
3. Lower secondary solution, open clamp, and allow infusate from primary solution to prime secondary tubing. Close clamp.	3. Clears the secondary tubing of air and prevents any loss of medication from the secondary line.



"Piggyback" IV. **(A)** On the left is the primary infusion flask. Note the use of an extension hook (hanging from the IV pole) to suspend the primary flask. The back check valve is seen more clearly in **(B)** and **(C)**. The secondary "piggyback" source is seen on the right. **(B)** Open check valve. Fluid from primary source flows down on either side of movable disc. Fluid from secondary source is closed off with clamp (not visible). **(C)** Closed check valve. Note that the fluid source from the secondary flask (where pressure is greater because the flask source is higher) is forcing the movable disc upward, thereby closing off fluid from the primary source. **(D)** When the last of the fluid from the secondary source reaches the level of the fluid in the primary set drip chamber (as indicated by a broken line), hydrostatic pressure between both sets will equalize. This releases the check valve; flow will shift from the secondary to the primary source. (Adapted from Abbott Laboratories.)

Nursing Action	Rationale
4. Hang secondary solution higher than primary solution. Open roller clamp (see part **D** in illustration).	
5. Program pump or controller for rate of infusion for secondary medication.	5. Ensures medication administration over the appropriate time period.
Follow-up phase	
1. Change IV administration tubing according to your facility's guidelines.	1. Minimizes risk of infection.

EVIDENCE BASE Infusion Nursing Society (INS). (2016). Infusion therapy standards of practice nursing standards of practice. *Journal of Infusion Nursing, 349*(1S).

PROCEDURE GUIDELINES 6-4

Accessing an Implanted Port

Implanted ports are becoming increasingly popular for patients with diseases such as cancer, sickle cell anemia, or cystic fibrosis to administer medications and continuous or intermittent IV fluids.

EQUIPMENT

- Personal protective equipment
- Sterile gloves
- Sterile drape
- Two prefilled 10-mL syringes filled with normal saline solution
- Noncoring needle
- Antiseptic pads
- Antiseptic swabs
- Sterile, semipermeable transparent dressing
- Stabilization device

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Perform hand hygiene.	1. Minimizes possibility of infection.
2. Confirm order and indication for the procedure. Confirm patient identify and explain the procedure to the patient.	2. Helps alleviate anxiety about the procedure.
3. Apply necessary personal protective equipment. Put on gloves.	3. Complies with CDC requirements to minimize passing of blood-borne pathogens between the patient and nurse.
Performance phase	
1. Position the patient for comfort with head turned away from the implanted port or apply a mask to the patient.	1. Assists in preventing contamination and subsequent infection.
2. Assess the skin surrounding the port for signs of infection or thrombosis. Palpate the port—feel the septum.	2. Ensures placement and patency.
3. Establish sterile field.	3. Prevents contamination of the port and subsequent infections.
4. Select the appropriate noncoring needle—gauge and length.	
5. Attach an extension set with needless adaptor to the noncoring needle. Flush noncoring needle and extension with normal saline solution, leaving one of the 10-mL syringes attached, being careful not to touch the needle with unsterile gloves or fingers.	5. Priming of the needle is essential to prevent infusion of air and ensure patency.
6. Clean site by scrubbing with a chlorhexidine scrub povidone-iodine swabs. Apply with outward concentric circles beginning at the intended insertion site. Allow to dry.	6. Prevents the introduction of organisms into the central line.
7. Hold the noncoring needle with your dominant hand and stabilize the port with the nondominant hand—again locating septum.	
8. With a firm, steady motion, insert the needle perpendicular to the skin through the septum of the port.	
9. Aspirate. If unable to aspirate, flush the port with saline solution and try to aspirate blood again. Have the patient change positions slightly, raise his arms, cough, or perform Valsalva maneuver to increase thoracic pressure and increase yield for blood return.	9. By aspirating first, you withdraw saline solution that has been in the port.
10. After aspirating blood, flush with 10 mL normal saline solution.	10. The presence of blood confirms correct needle placement in the port.
11. If still no blood return, report findings to the health care provider.	11. May order a radiologic study or urokinase declotting procedure.
12. When placement of the needle is confirmed, attach the IV line.	

Nursing Action	Rationale
Follow-up phase	
1. Secure the noncoring needle and tubing with a stabilization device. Apply a sterile semipermeable transparent dressing over the insertion site.	
2. Maintain patency by flushing according to your facility's guidelines. Change the needle every 7 days, or per facility policy.	1–2. Maintains potency and prevents infection.
3. Instruct the patient to have the port flushed monthly when not in use and notify the health care provider of any problems.	

EVIDENCE BASE Infusion Nursing Society (INS). (2016). Infusion therapy standards of practice nursing standards of practice. *Journal of Infusion Nursing, 349*(1S).

STANDARDS OF CARE GUIDELINES 6-1

IV Therapy

To prevent adverse effects of IV therapy, perform the following assessments and procedures:

- Before starting IV therapy, consider the indication for intravenous therapy including duration of therapy, type of infusion, condition of veins, and medical condition of the patient to assist in choosing IV site and type of catheter.
- Ensure competence in initiating the type of IV therapy to be utilized and familiarity with facility policy and procedure before initiating therapy.
- After initiation of IV therapy, monitor the patient frequently for:
    - Signs of infiltration or sluggish flow.
    - Signs of phlebitis or infection.
    - Correct solution, medication, volume, and rate.
    - Dwell time of catheter and need to be replaced.
    - Condition of catheter dressing and frequency of change.
    - Fluid and electrolyte balance.
    - Signs of fluid overload or dehydration.
    - Patient satisfaction with mode of therapy.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Selecting a Vein

1. Verify the order for IV therapy and explain the procedure to the patient.
2. Select a vein suitable for venipuncture.
    a. Back of hand—metacarpal veins (see Figure 6-2A). Avoid digital veins, if possible.
        i. Advantages: Veins in location are easily visualized and palpated. Selection of this site permits arm movement. Should successive venipuncture be needed, another location higher up the arm may be utilized.
        ii. Disadvantages: Caution when selecting this site in the older adult because of thin skin and inadequate tissue often occurring in this area. When possible, select the nondominant hand.
    b. Forearm—basilic (along the ulnar side of the forearm) or cephalic (along the radial side of the forearm) vein (see Figure 6-2B).
        i. Advantages: These are larger veins that allow for more rapid infusion. Hand can be used freely.
        ii. Disadvantages:
    c. Inner aspect of elbow, antecubital fossa—intermediate median basilic and intermediate median cephalic; used for relatively short-term infusion.
        i. Advantages: Well supported by subcutaneous tissue preventing vein mobility; deeper and more tolerant to caustic substances.
        ii. Disadvantages: Prevents bending of arm; median basilic and cephalic veins are not

recommended for chemotherapy because of the potential for extravasation and poor healing, resulting in impaired joint movement; should be reserved for intermediate- or long-term indwelling catheters.

NURSING ALERT Avoid selecting areas of flexion for placement of intravascular access. Areas of flexion are at an increased risk for adverse events because of the superficial presentation of arteries and nerves and are more likely to result in infiltration/extravasation, thrombophlebitis, arterial puncture, and nerve injury.

---

d. Lower extremities—great saphenous vein at the ankle, superficial dorsal plexus, dorsal venous arch, or medial marginal vein of the foot.
    i. Advantages: The lower division of the great saphenous vein is frequently used in infants and toddlers.
    ii. Disadvantages: May require explicit orders from the health care provider because thrombosis occurs more frequently than in veins of the upper extremities; irregular absorption may occur due to the increased number of valves present in the lower extremities causing infusions to potentially pool.

NURSING ALERT Selection of lower extremity sites for venipuncture in patients with diabetes or peripheral vascular disease is not recommended because of the increased risk of phlebitis, thrombosis, infection, and potential for poor healing.

---

3. Be prepared to use central veins in the following cases:
    a. When medications and infusions are hypertonic or highly irritating, requiring rapid, high-volume dilution to prevent systemic reactions and local venous damage (eg, chemotherapy and hyperalimentation).
    b. When peripheral blood flow is diminished (eg, shock) or when peripheral vessels are not accessible (eg, obese patients).
    c. When hemodynamic monitoring is desired.
    d. When moderate- or long-term fluid therapy is expected.

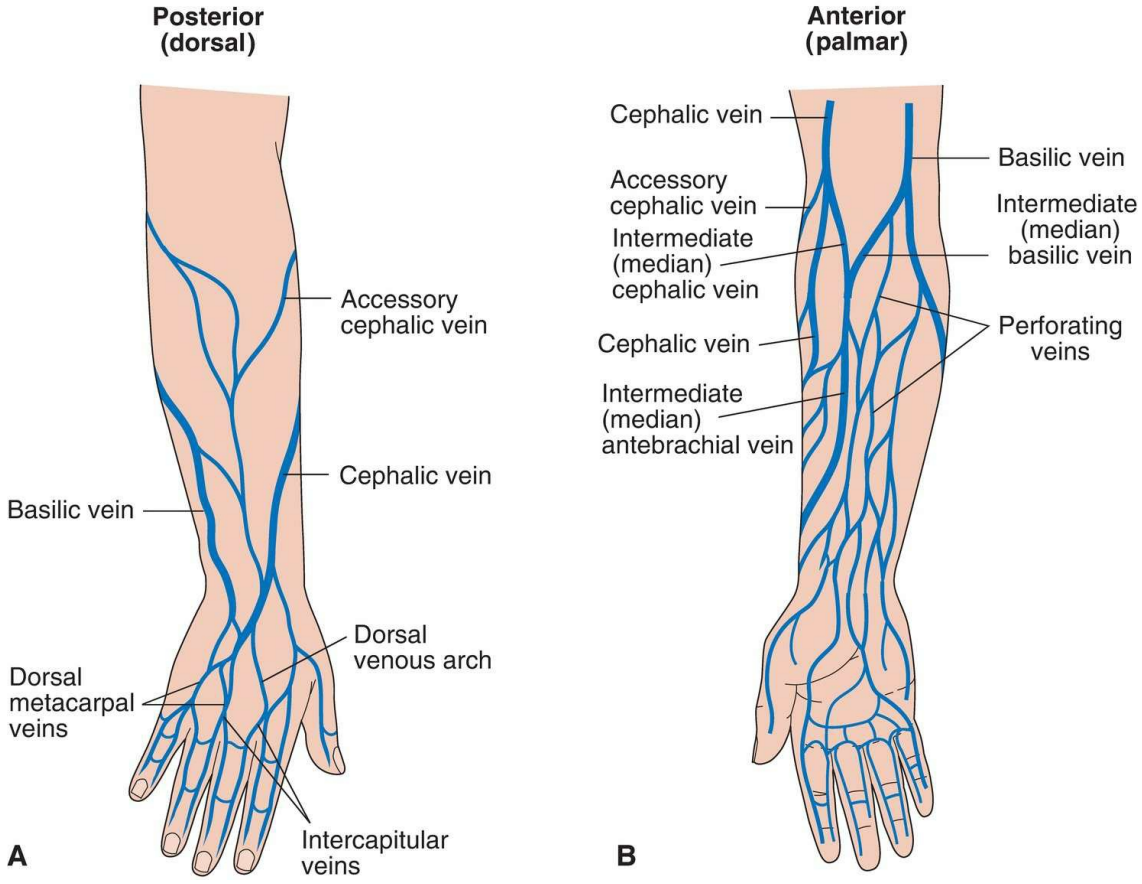


Figure 6-2. **(A)**Superficial veins, dorsal aspect of the hand. **(B)**Superficial veins, forearm. (Smeltzer, S., and Bare, B. [2000]. Brunner and Suddarth's textbook of medical-surgical nursing [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

NURSING ALERT Ultrasound-guided vascular access as compared to cannulation by anatomic landmarks and/or acoustic Doppler is significantly safer for the patient and improves efficiency and effectiveness of the clinician.

Methods of Distending a Vein

1. Apply a tourniquet (soft nonlatex) at least 2 to 6 inches (5 to 15 cm) above the planned insertion site, fastening it with a slipknot or hemostat, in a manner to impede venous flow but allowing for arterial circulation. Alternately apply a blood pressure cuff (keep pressure just below systolic pressure).
2. Apply manual compression above the site where the cannula is to be inserted.
3. Position the extremity lower than the level of the heart, having the patient open and close his or her fist, and lightly stoke the vein downward.
4. Lightly tap the vein site; this is to be done gently so the vein is not injured.
5. Apply warmth to site by using a warm dry towel or heat pack.

Selecting Needle or Catheter

1. Use the smallest gauge catheter suitable for the type and location of the infusion to minimize trauma to the vein.
2. Refer to Table 6-3, Types of Short Peripheral Cannulas, to assist in selecting the most appropriate catheter type. If a blood transfusion is to be given, use a larger-bore catheter, preferably 18G or larger.
3. Consider local anesthetic agents to minimize pain while obtaining vascular access.
   a. Agents include topical vapocoolant sprays, topical transdermal agents, intradermal lidocaine, and pressure-accelerated lidocaine.
   b. May cause collapse of desired veins, allergic reactions, and increase cost of the procedure.
   c. Warm compresses can mitigate the vasoconstrictive effects of local anesthetics.
4. Do not leave steel-winged devices in place; they are for single-dose administration only.
5. Use catheters manufactured with protective devices to guard against needlestick injuries (see Figure 6-3).

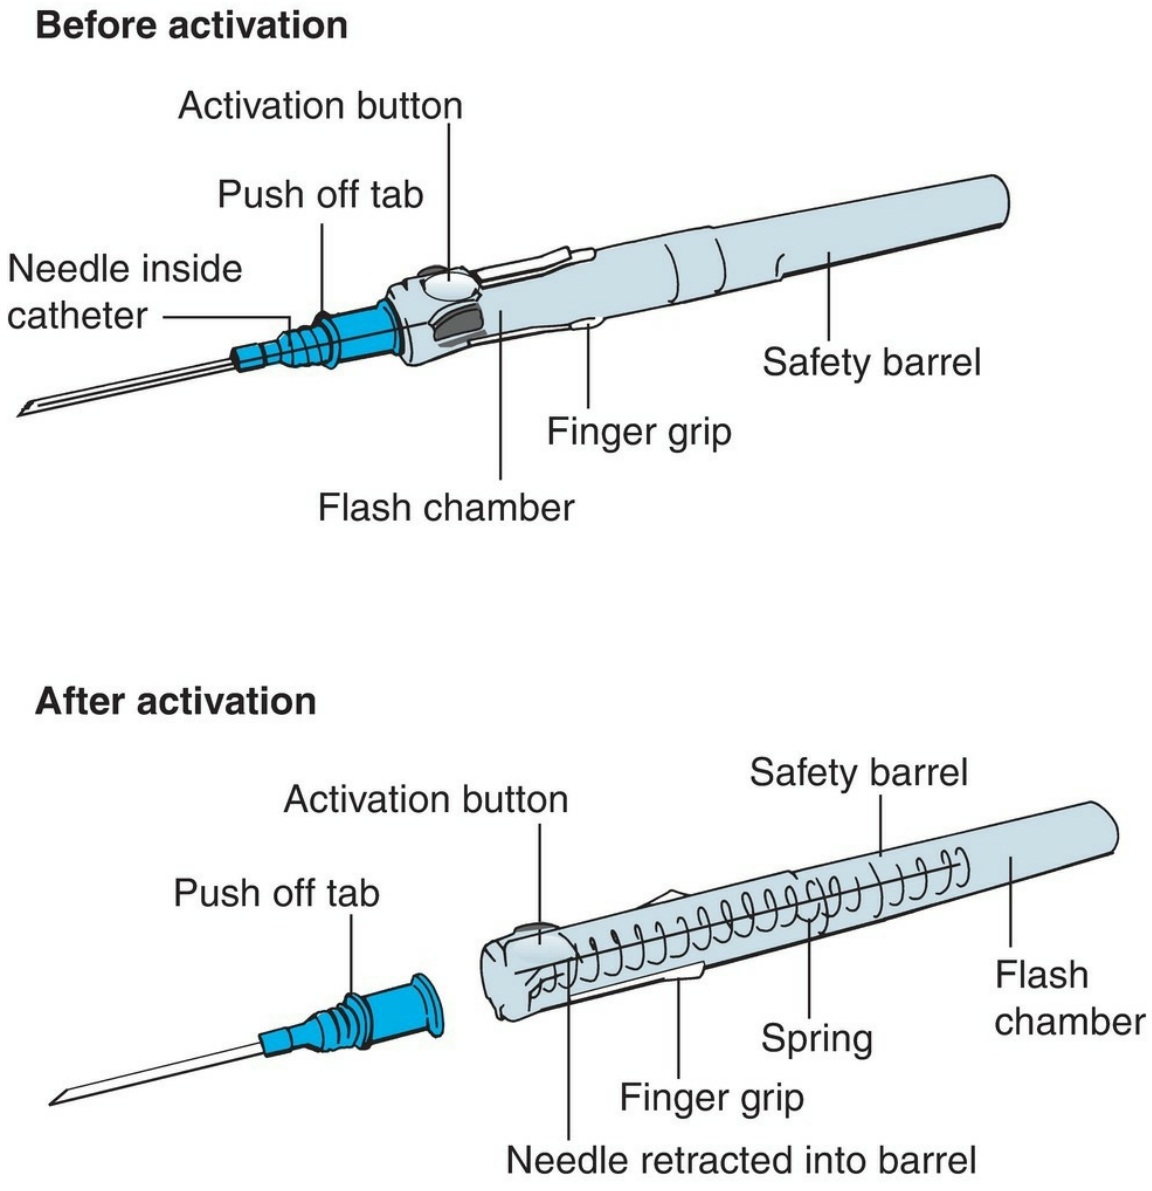

Figure 6-3. The activation button is pressed after the catheter is in the vein so that the needle will retract into the safety barrel while catheter remains in the vein.

Table 6-3 Types of Short Peripheral Cannulas

CANNULA TYPE	PURPOSE	APPROXIMATE MAXIMUM FLOW RATE WITH GRAVITY	VOLUMES
24 gauge Yellow/lime	Infants; pediatric patients; older adults; patient with difficult venous access	23 mL/min	Small
22 gauge Blue	Infants; pediatric patients; older adults; small veins	22–50 mL/min	Small
20 gauge Pink	Adult; most infusion therapies; commonly used	55–80 mL/min	Medium
18 gauge Green	Fluid replacement; blood transfusion; for use with a contrast-based radiographic study; commonly used	100–120 mL/min	Large
16 gauge Gray	Rapid fluid replacement; blood transfusion	150–240 mL/min	Large
14 gauge Orange/brown	Rapid fluid replacement; blood transfusion	250–300 mL/min	Extra large
Medial (blue) and proximal (white) lumen of triple-lumen catheter 18 gauge	Fluid replacement; blood transfusion; medication administration	26 mL/min	Large
Distal (brown) lumen of the triple-lumen catheter 16 gauge	Fluid replacement; blood transfusion; medication administration; hemodynamic monitoring	52 mL/min	Large

Cleaning the Infusion Site

EVIDENCE BASE Infusion Nursing Society (INS). (2016). Infusion therapy standards of practice nursing standards of practice. *Journal of Infusion Nursing*, *349*(1S).

1. If skin is dirty, clean the infusion site thoroughly with soap and rinse.
2. Clean the IV site with an effective topical antiseptic according to facility protocol.
   a. The preferred skin antiseptic is chlorhexidine solution used in an outward, circular scrubbing manner following manufacturer's instructions. Allow to dry completely.
   b. Caution with chlorhexidine in premature infants and infants under 2 months of age because of increased risks of skin irritation and chemical burns.
   c. Alcohol swabs, povidone–iodine, or tincture of iodine may be used in the same outward circular scrubbing manner where chlorhexidine is contraindicated. Allow to dry completely.

DRUG ALERT Iodine solutions may cause allergic reactions in some patients. The patient should be assessed for iodine allergies before use.

Use of Stabilization Devices

Stabilizing vascular access devices can prevent unintentional dislodgement and adverse complications. Do not rely on vascular access device dressings such as a transparent semipermeable membrane or gauze as a means for stabilization.

Infusion Tubing

1. Drip chambers.
    a. A "microdrip" system delivers 60 drops/mL and is used when small volumes are being delivered (eg, less than 50 mL/hour); this reduces the risk of clotting the IV line because of slow infusion rates.
    b. The "macrodrip" system delivers 10, 15, or 20 drops/mL and is used to deliver solution in large quantities or at fast rates.
2. Vented tubing should be used with standard glass bottles; this permits air to enter the vacuum in the bottle and displace solution as it flows out. Nonvented tubing should be used for IV bags and glass bottles that have a built-in air vent.
3. Filters help minimize the risk of contamination from certain microorganisms and particulate matter.
    a. Filters are found "in line" on conventional IV, blood, and parental nutrition tubing and are preferred because they reduce the risks of contamination. An additional filter is needed for mannitol and may be needed for other solutions based on facility protocol.
    b. "Add-on" filters should be located as close to the insertion site as possible and be changed with administration set changes.
4. Most electronic infusion pumps require specialized tubing to fit their particular pumping chamber. Need for such a device should be determined before initiating infusion therapy.
    a. If added tubing length is required (especially for children and restless patients), extension tubing is available; this should be added at the time of IV setup.
    b. Secondary administration tubing sets are used for administration of intermittent, "piggyback," medications that are connected to the port closest to the drip chamber.
    c. Special-coated tubing, designed to prevent leaching of polyvinyl chloride, is used for delivering medications, such as nitroglycerin, paclitaxel, and cyclosporine.
    d. Add-on devices such as single- and multilumen extension sets, extension loops, needleless connectors, inline filters, manual flow-control devices, and stopcocks should be used only when clinically indicated. Use systems that minimize the manipulation and reduce multiple components to limit potential contamination and change with each new administration set.
5. Administration tubing set change—label with date, time opened, and initials.
    a. Primary and secondary continuous tubing administration sets used for medications and solutions other than lipids, blood, or blood products should be changed no more frequently than every 96 hours but at least every 7 days.
    b. Intermittent tubing administration sets should be changed every 24 hours.
    c. Tubing administration sets used for parenteral nutrition solutions should be replaced every 24 hours or with each new container.

d. Tubing administration sets used for intravenous fat emulsions should be replaced every 12 hours or with each new container.
e. Tubing administration sets used for blood or blood products should be changed every 2–4 units of blood or every 4 hours.

Adjusting Rate of Flow

The health care provider prescribes the flow rate. The nurse is responsible for regulating and maintaining the proper rate. When initiating an infusion, consider using smart pumps with dose-error reduction software as an effective error-reducing strategy.

Patient Determining Factors

When determining flow rates, consider patient factors such as age, acuity and severity of the illness/injury, type of therapy, dosing considerations, and health care setting.

1. Age—fluids should be administered slowly in the very young and elderly.
2. Condition—a patient in hypovolemic shock requires greater amounts of fluids, whereas the patient with heart or renal failure should receive fluids judiciously.
3. Tolerance to solutions—fluids containing medications causing potential allergic reactions or intense vascular irritation (eg, potassium chloride) should be well diluted or given slowly.
4. Prescribed fluid composition—efficacy of some drugs is based on speed of infusion (eg, antibiotics); rate for other solutions is titrated to the patient's response to them (eg, dopamine, nitroprusside, heparin).

System Determining Factors

1. Gauge of IV catheter.
2. Pressure gradient—the difference between two levels in a fluid system.
3. Friction—the interaction between fluid molecules and surfaces of inner wall of tubing.
4. Diameter and length of tubing.
5. Height of column of fluid.
6. Characteristics of fluid.
   a. Viscosity.
   b. Temperature—refrigerated fluids may cause diminished flow and vessel spasm; bring fluid to room temperature before infusion.
7. Vein trauma, clots, plugging of vents, venous spasm, and vasoconstriction.
8. Flow-control clamp derangement.
   a. Some clamps may slip and loosen, resulting in a rapid, or "runaway," infusion. Many tubings now have safety clamps to prevent this rapid infusion.
   b. Plastic tubing may distort, causing "creep" or "cold flow"—the inside diameter of tubing will continue to change long after clamp is tightened or relaxed.
   c. Marked stretching of tubing may cause distortions of tubing and render clamp ineffective (may occur

when patient turns over and pulls on a short tubing).

9. If there is any question about the rate of fluid administration, check with the health care provider.

GERONTOLOGIC ALERT Be aware that veins are more likely to roll within the loose tissue beneath the skin, collapse, and become irritated in older adults. Also, fluid overload may be more pronounced, making IV therapy more difficult and potentially dangerous.

Calculation of Flow Rate

1. Most infusion rates are given at a certain volume per hour.
2. Delivery of the prescribed volume is determined by calculating necessary drops per minute to deliver the volume.
3. Drops per milliliter will vary with commercial parenteral sets (eg, 10, 15, 20, or 60 drops/mL). Check manufacturer's instructions. Most macrodrip sets delivers 10 to 20 drops/mL and microdrip sets 60 drops/mL.
4. Calculate the infusion rate using the following formula:

$$\text{Drop/minute} = \frac{\text{total volume} \times \text{infused drops/mL}}{\text{total time for infusion in minutes}}$$

Example: Infuse 150 mL of D_5W in 1 hour (set indicates 10 drops/mL)

$$\frac{150 \times 10}{60 \text{ minutes}} = 25 \text{ drops/minute}$$

5. The nurse hanging a new IV solution should write the date, time, and her or his initials on the container label.

NURSING ALERT To avoid leaks, never write directly on the IV bag. Do not use magic markers because they are absorbed into the plastic bag and possibly into the solution. Write on the label or tape using a regular pen.

Vascular Access Maintenance and Removal

Maintaining Patency

Flush vascular access device with normal saline and aspirate blood prior to each infusion to assess catheter function as well as after each infusion to clear the infused medicine from the catheter lumen and to prevent potential contact of incompatible medicines. Flushing intermittent peripheral catheters with normal saline is equivalent to flushing with heparin in maintaining catheter patency and complication rates. Flush volume of 10 mL may remove fibrin deposits, drug precipitate, and other debris from the lumen to ensure patency. See Box 6-1.

BOX 6-1 Flushing Intravenous Access

1. Locked vascular access devices must be flushed before and after medication or solution administration.
2. Flushing with prefilled syringes is preferred over nurse-filled syringes. Do not use intravenous solution containers (bags or bottles) as a "flush" bag.
3. Flush all vascular access devices with preservative-free 0.9% sodium chloride (NS). If bacteriostatic 0.9% sodium chloride is used, limit volume to less than 30 mL per 24-hour period to reduce potential toxic effects of benzyl alcohol, the preservative used. However, facilities should have an established standardized locking solution for each patient population that should be used.
4. Use a push–pause method to inject the medication. Do not force if resistance is met, rather evaluate for patency or complications of the vascular access.
5. Recommendation is to flush at least two times the volume of the catheter and add-on devices, usually 10 mL. An adequate flush volume removes debris, fibrin deposits, and medication/solution in the catheter and port reservoir to reduce the risk of clotting and infection.

Assess vascular access frequently for signs of infiltration, infection, phlebitis, and other complications.

Removal of Vascular Access Device

1. Assess vascular access daily as part of the patient's overall plan of care, with the goal of removal as soon as possible.
2. Realize that vascular access devices should be removed with any signs and symptoms of complications, however working in coordination with the health care team to avoid delays in medically necessary treatments.
3. In the event of infiltration/extravasation of a short peripheral or midline catheter, stop the infusion immediately, detach all administration sets, and determine if a vesicant extravasation has taken place before removing the vascular access device.

Evaluation, Documentation, Patient Education, and Quality Improvement

Documentation and Patient Education

1. Documentation must contain accurate, factual, and complete information regarding the initial and ongoing assessment, nursing diagnosis or problems, interventions, and patient's response to those interventions.
2. Documentation specific to intravenous therapy should include, but is not limited to, the following:
    a. Date and time of cannula insertion.
    b. Site and preparation of insertion.
    c. Number of cannulation attempts.
    d. Size and type of inserted cannula.
    e. Dressing.
    f. Tolerance of the procedure.
    g. Monitoring of the site.
    h. Date and time of cannula removal.
    i. Identification and management of complications.
3. The clinician is responsible for educating the patient and/or caregiver about intravenous therapies. This education should include such topics as the plan of care, purpose and/or goals of treatment, intravascular device-related care, and potential complications. The teaching methods and any learning materials provided should be sensitive to the preferred learning style of the patient considering such factors as developmental and cognitive level, health literacy, cultural influences, or readiness to learn.

Evaluation and Quality Improvement

1. Quality improvement programs include the surveillance, aggregation, analysis, and reporting of intravenous-related patient quality indicators.
2. Adverse events must be recognized and documented to minimize health care–associated infections related to intravenous therapy.
3. Clinician practice, processes, and/or systems should be evaluated to identify areas for improvement.

Complications of IV Therapy

GERONTOLOGIC ALERT Providing intravascular therapy for special populations including older adult patient requires competency in the clinical management of such populations and understanding of anatomic and physiologic differences, safety considerations, implications for vascular access device management, and infusion administration. Older adults have more fragile peripheral veins and surrounding tissue and may be at risk for circulatory overload.

Infiltration/Extravasation

Cause

1. Dislodgment of the IV cannula from the vein. Infiltration is the unintentional infusion of nonvesicant medications or solutions into the surrounding tissue; whereas, extravasation is the unintentional infusion of a vesicant into the surrounding tissues.

Clinical Manifestations

1. Discomfort or pain, depending on nature of solution.
2. Swelling, blanching, and coolness of surrounding skin and tissues.
3. Fluid flowing more slowly or ceasing.
4. Absence of blood backflow in IV catheter and tubing.

Preventive Measures

1. Select the most appropriate vascular access device and insertion site.
2. Make sure that the IV and distal tubing are secured sufficiently with tape to prevent movement.
3. Splint the patient's arm or hand as necessary.
4. Assess the vascular access device for functionality routinely and prior to use.

Nursing Interventions

1. Stop infusion immediately and remove the IV needle or catheter.
2. In the event of infiltration/extravasation of a short peripheral or midline catheter, stop the infusion immediately and detach all administration sets. Remove the vascular access device, however if extravasation has occurred, aspirate from the catheter hub prior to catheter removal to remove as much of the medication or solution from the catheter lumen and subcutaneous tissue as possible.
3. If a vasoconstrictor agent (eg, norepinephrine bitartrate, dopamine), vesicant (various chemotherapy agents, potassium chloride, etc.), or irritant (determined by facility) has extravasated, initiate emergency local treatment as directed to limit the potential damage to subcutaneous tissue by the medication or solution. Serious tissue injury, necrosis, and sloughing may result if actions are not taken.

4. To localize the medication or solution in the tissues and reduce inflammation, apply dry, cold compresses to the area; or to to increase blood flow and disperse the medication, apply dry compresses, per facility protocol.
5. Document assessments and interventions.

Phlebitis

Causes

1. Injury to the vein that occurs during venipuncture or caused from prolonged needle or catheter use or using too large of a catheter for the selected vein.
2. Poor aseptic technique.
3. Irritation to vein because of rapid infusions or irritating solutions (eg, hypertonic glucose solutions, cytotoxic agents, strong acids or alkalis, potassium, antibiotics, and others); smaller veins are more susceptible.
4. Clot formation at the end of the needle or catheter because of slow infusion rates or inadequate hemodilution of medications or solutions.
5. More commonly seen with synthetic polyurethane catheters than synthetic silicone catheters or steel needles.

Clinical Manifestations

1. Pain and tenderness to palpation at intravenous site that will progress to extending along the path of the cannula and vein.
2. Redness, swelling, warmth, induration, or purulence at intravenous site; the vein may appear as a red streak above the insertion site.
3. Palpable venous cord.

Preventive Measures

1. Routinely assess the vascular access site with a standardized tool for signs and symptoms of phlebitis.
2. Anchor the needle or catheter securely at the insertion site.
3. Use large veins for irritating fluid because of higher blood flow, which rapidly dilutes the irritant.
4. Sufficiently dilute irritating agents before infusion.

Nursing Interventions

1. Apply warm compresses to stimulate circulation and promote absorption, counteracting venoconstriction caused by phlebitis.
2. Elevate the extremity.
3. Consider removal of the vascular access device.
4. Consider other pharmacologic interventions such as analgesics, anti-inflammatory agents, or corticosteroids as necessary.

5. Document assessments and interventions.
6. Participate in facility quality improvement activities regarding phlebitis occurrence rates. One formula that can be used is:

$$\frac{\text{Number of phlebitis incidents}}{\text{Total number of IV peripheral catheters}} \times 100 = \%\ \text{peripheral phlebitis}$$

EVIDENCE BASE Infusion Nursing Society (INS). (2016). Infusion therapy standards of practice. *Journal of Infusion Nursing*, *39*(1S).

Catheter-Associated Bloodstream Infections

Causes

1. Underlying thrombophlebitis increases risk 18-fold.
2. Contaminated equipment or infused solutions (see Figure 6-4).
3. Prolonged placement of an IV device (catheter or needle, tubing, solution container).
4. Nonsterile IV insertion or dressing change.
5. Cross-contamination by the patient with other infected areas of the body.
6. A critically ill or immunosuppressed patient is at greatest risk of bacteremia.

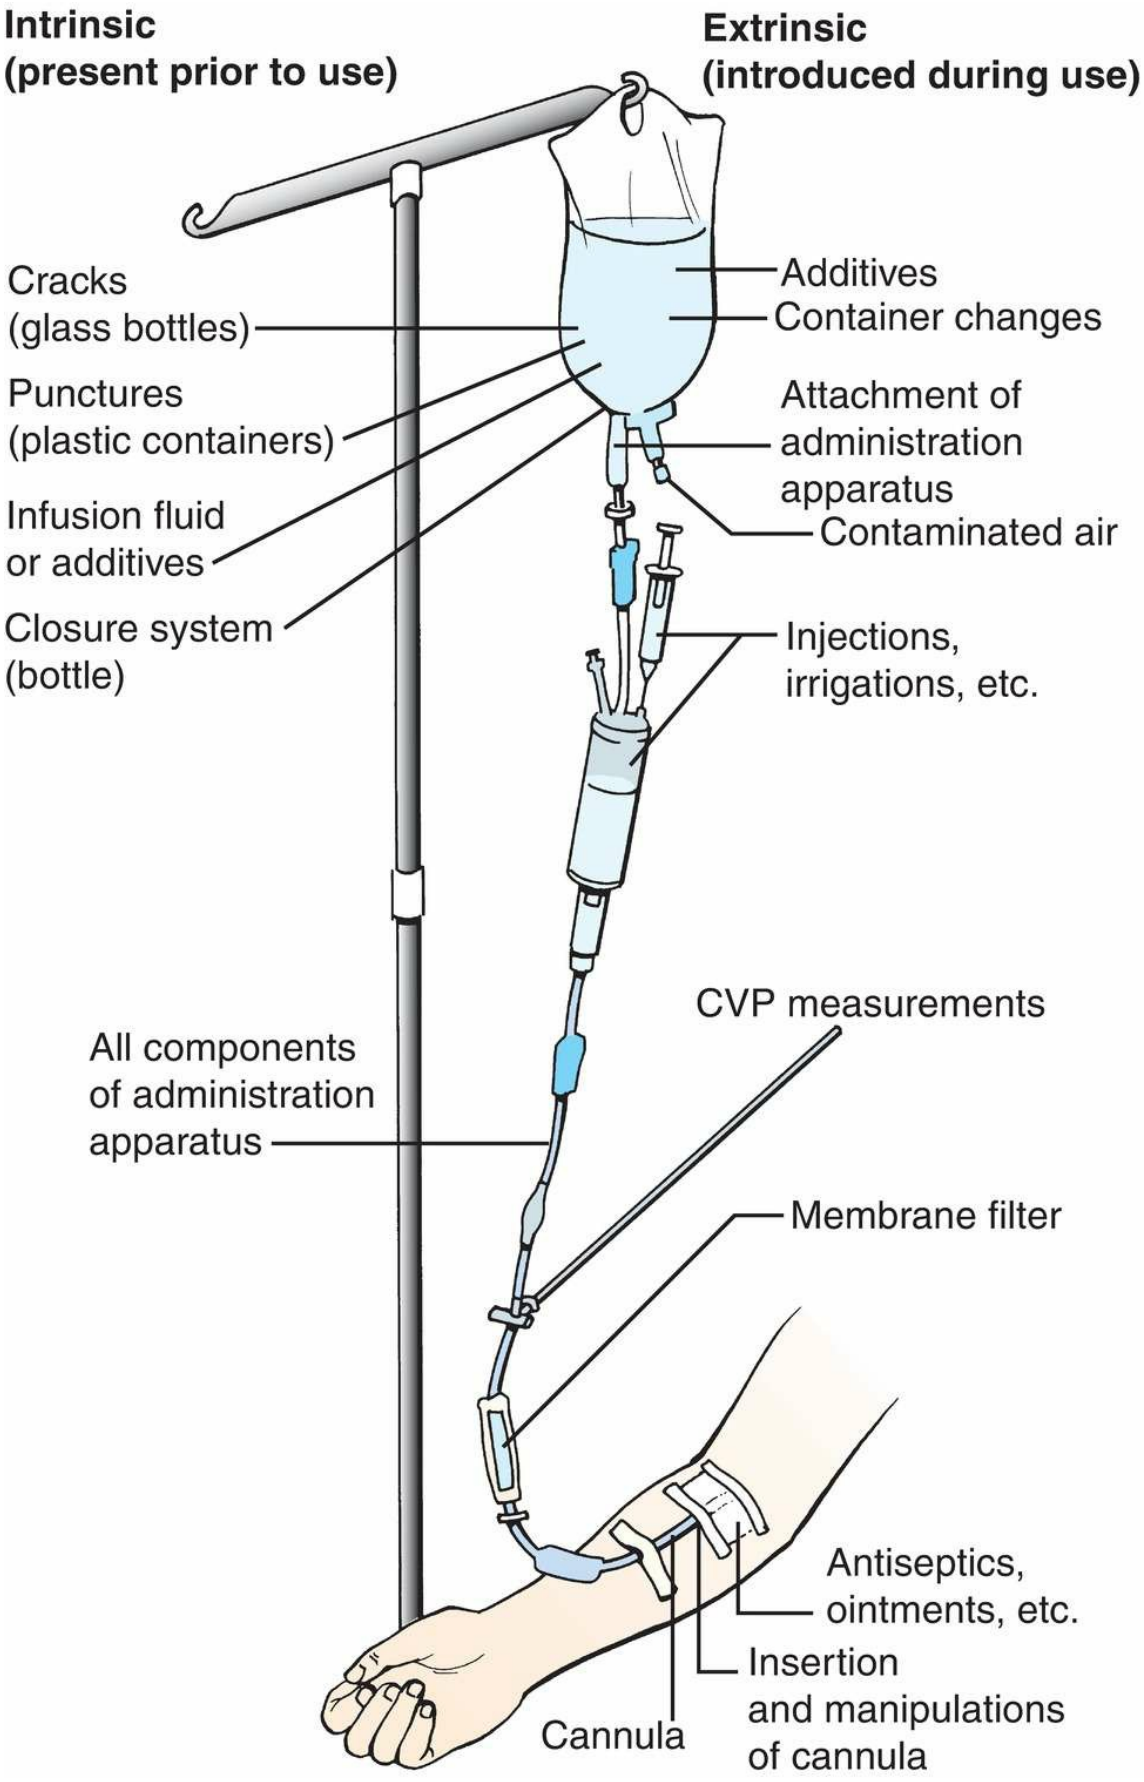

Figure 6-4. Potential mechanisms for contamination of IV infusion systems.

Clinical Manifestations

1. Possible signs of local infection at vascular access insertion site (eg, redness, pain, edema, foul drainage).
2. Elevated temperature, chills.
3. Nausea, vomiting.
4. Elevated white blood cell (WBC) count.
5. Malaise, increased pulse.
6. Backache, headache.
7. May progress to septic shock with profound hypotension.

Preventive Measures

1. Follow the same measures as outlined for thrombophlebitis.
2. Strict adherence to hand hygiene and the use of aseptic techniques with maximal barrier precautions during insertion and dressing changes remain the most important measure for the prevention of catheter-associated bloodstream infections.
3. Ensure appropriate cleaning products are used to cleanse the skin prior to insertion of the cannula. Chlorhexidine is preferred and has been shown to reduce the rate of infections.

TRANSITIONAL CARE ALERT Hand hygiene, personal protective equipment, and safe injection practices using aseptic technique form the basis of standard precautions. Appropriate infection control measures are essential in preventing complications and ensuring the delivery of efficient, high-quality care across care settings, and ultimately so the patient can remain at home.

---

4. Choose appropriate sites for catheter insertion.
5. Replacing intravenous catheters when clinically indicated, rather than routine replacement every 72 to 96 hours, demonstrates no increased patient risk of thrombophlebitis or infection. An exception to this is when adherence to aseptic technique cannot be assured (eg, insertion during a medical emergency) at which time, the catheter should be replaced as soon as possible but no longer than 48 hours after insertion.
6. Use antimicrobial-impregnated central venous catheters where the expected dwell time is greater than 5 days or in patients with high risk of infections such as neutropenic, burn, or critically ill patients.
7. Change catheter administration sets at appropriate intervals. Continuous IV administration sets should be changed every 96 hours when the medications or solutions do not contain lipids, blood, or blood products. When the catheter administration sets contain lipids, blood, or blood products, the catheter administration set should be changed every 24 hours. Intermittent IV administration sets including secondary sets and add-on devices should be changed no more frequently than at 72- to 96-hour intervals.

8. Do not allow medications and solutions to hang longer than 24 hours. Lipid-containing solutions should be completed within 24 hours of hanging the solution. Lipid emulsions should be completed within 6 to 12 hours of hanging the solution. Blood or other blood products should be completed within 4 hours of hanging the solution. Maintain integrity of the infusion system at all times.
9. Ensure proper vascular access site assessment and care. Change the IV dressing on a routine basis and immediately if it becomes damp, loosened, or soiled.
    a. Gauze dressing that prevents visualization of the site should be changed every 48 hours.
    b. Transparent semipermeable dressing should be changed every 7 days.
10. Use passive disinfection caps containing disinfecting agents (eg, isopropyl alcohol), which result in reduced intraluminal microbial contamination and decreases the rates of catheter-associated bloodstream infection.
11. Ensure removal of catheters when no longer essential.

NURSING ALERT When accessing the port of a vascular access device, vigorously scrub—not wipe—the hub of the catheter for 15 seconds with alcohol or clorhexidine solution.

Nursing Interventions

1. Discontinue infusion and consider removal of vascular access device. A peripheral venous device with signs and symptoms of infection and erythema extending at least 1 cm from the insertion site, induration, exudate, and fever with no other source of infectious process should be removed. Collaboration with the health care team is needed to determine whether a central venous access device can be salvaged or necessitates removal.
2. If purulent exudate is present, obtain a sample for culture and gram staining.
3. With removal of the vascular access device, cut off the tip of the catheter with sterile scissors; place in a dry, sterile container; and immediately send it to the laboratory for culture and gram staining.
4. Assess for and provide necessary measures to maintain patient's stability.
5. Start appropriate antibiotic therapy immediately after receiving orders and obtaining all additional specimens for culture and gram staining.
6. Document assessments and interventions.

Circulatory Overload

Cause

1. Delivery of excessive amounts of IV fluid (greater risk exists for older patients, infants, or patients with cardiac or renal insufficiency).

Clinical Manifestations

1. Increased BP and pulse.
2. Increased CVP, venous distention (engorged jugular veins).
3. Headache, anxiety.
4. Shortness of breath, tachypnea, coughing.
5. Pulmonary crackles.
6. Chest pain (if history of coronary artery disease).

Preventive Measures

1. Assess patient for existing heart or kidney condition. Be particularly vigilant in the high-risk patient.
2. Closely monitor the infusion flow rate, and use electronic infusion devices in patients at greater risk.
3. Keep accurate intake and output records.
4. Splint the arm or hand if the IV flow rate fluctuates too widely with movement.

Nursing InterventionsIf circulatory overload is suspected, notify health care provider, sit patient up for easier breathing, and anticipate reduced IV infusion rate and additional medication therapy.Monitor closely for worsening clinical condition.

Air Embolism

Causes

1. A greater risk exists in central venous lines, when air enters catheter during tubing changes (air sucked in during inspiration because of negative intrathoracic pressure).
2. Air in tubing delivered by IV push or infused by infusion pump.

Clinical Manifestations

1. Sudden onset of dyspnea, breathlessness, elevated respiratory rate.
2. Chest pain, hypotension, elevated heart rates.
3. Altered mental status, altered speech.
4. Changes in facial appearance, paralysis.

Preventive Measures

1. Clear all air from tubing before infusion to patient.
2. Change solution containers before they run empty.
3. Ensure that all connections are secure. Use Luer-lock connections or administration sets with air-eliminating filters unless contraindicated.
4. Use appropriate technique with removal of central venous access devices.
5. When removing a central venous access device, place the patient in supine or Trendelenburg position unless contraindicated so that the insertion site is at or below the level of the heart.
6. Instruct the patient to bear down (Valsalva maneuver) during catheter withdrawal unless contraindicated.

Nursing Interventions

1. Immediately prevent additional air from entering the bloodstream by closing, kinking, clamping, or covering the existing vascular access device or insertion site with an air-occlusive dressing.
2. Immediately turn the patient on left side and lower the head of the bed; in this position, air will become trapped in the right side of the heart.
3. Notify the health care provider immediately.
4. Administer oxygen as needed and support the medical stability of the patient.
5. Document assessments and interventions.

Mechanical Failure (Sluggish Flow or Occlusion)

Causes

1. Malposition of the catheter including the cannula lying against the side of the vein, cutting off fluid flow or infiltration of the catheter.
2. Clot at the end of the catheter or needle.
3. External mechanical causes such as inking of the tubing or catheter, clogged filter, or needless connector.

Clinical Manifestations

1. Inability to withdraw blood or sluggish blood return.
2. Sluggish IV flow or frequent occlusion alarms on electronic infusion devices.
3. Signs of infiltration/extravasation.

Preventive Measures

1. Asses the functionality of the vascular access device routinely.
2. Use appropriate flushing procedures.
3. Secure the IV well with tape and an armboard, if necessary.

Nursing Interventions

1. Assess for mechanical causes of occlusion.
2. Reposition the catheter by pulling back on the cannula slightly because it may be lying against the vein wall valve or bifurcation.
3. Reposition the patient's extremity in which the vascular access device is placed.
4. Lower the solution container to below the level of patient's heart and observe for blood backflow.
5. If using an electronic infusion device, assess its functionality.
6. Consider the need for a catheter-clearing agent or thrombolytic agent in collaboration with the health care team.
7. Consider the need to remove the vascular access device.

Hemorrhage

Causes

1. Loose connection of tubing or injection port.
2. Inadvertent removal of peripheral or central catheter.
3. Anticoagulant therapy.

Clinical Manifestations

1. Oozing or trickling of blood from IV site or catheter.
2. Hematoma.

Preventive Measures

1. Cap all central lines with Luer-lock adapters and connect Luer-lock tubing to the cap—not directly to the line.
2. Secure catheters. Use transparent dressing when possible for peripheral and central catheters. Tape the remaining catheter lumens and tubing in a loop so tension is not directly on the catheter.
3. Keep pressure on sites where catheters have been removed—a minimum of 10 minutes for a patient taking anticoagulants.

Venous Thrombosis

Causes

1. Infusion of irritating solutions.
2. Infection along catheter may preclude this syndrome.
3. Fibrin sheath formation with eventual clot formation around the catheter. (This clot will eventually occlude the vein.)
4. Patient factors including a medical history of a hypercoagulable state (eg, cancer, diabetes, or end-stage renal failure), history of deep vein thrombosis, surgical or trauma patients, critical care patients, and extremes of age.
5. Stasis of blood in the intravenous catheter.

Clinical Manifestations

1. Swelling and pain in the area of catheter or in the extremity proximal to the insertion site.
2. Slowing of IV infusion or inability to draw blood from the central line.
3. Palpable lump in the cannulated vessel.

Preventive Measures

1. Select appropriate vascular access device and site location.
2. Ensure proper dilution of irritating substances.
3. Ensure proper placement of vascular access device.
4. Institute nonpharmacological strategies for thrombosis prevention if possible such as early patient

mobility and adequate hydration.

5. Prophylaxis with anticoagulant therapies as ordered by the health care team.

Nursing Interventions

1. If venous thrombosis is suspected, notify health care provider, anticipate evaluation and therapeutic anticoagulant dose, and support the patient.

PATIENT EDUCATION GUIDELINES 7-1

Outpatient Postanesthesia and Postsurgery Instructions and Information

- Although you will be awake and alert in the recovery room, small amounts of anesthetic will remain in your body for at least 24 hours and you may feel tired and sleepy for the remainder of the day. Once you are home, take it easy and rest as much as possible. It is advisable to have someone with you at home for the remainder of the day.
- Eat lightly for the first 12 to 24 hours, then resume a well-balanced, normal diet. Drink plenty of fluids. Alcoholic beverages are to be avoided for 24 hours after your anesthesia or IV sedation.
- Nausea or vomiting may occur in the first 24 hours. Lie down on your side and breathe deeply. Prolonged nausea, vomiting, or pain should be reported to your surgeon.
- Ask your surgeon or anesthesiologist when you can resume your daily medications after surgery.
- Your surgeon will discuss your postsurgery instructions with you and prescribe medication for you as indicated. You will also receive additional instructions specific to your surgical procedure before leaving the facility.
- Your family will be waiting for you in the facility's waiting room area near the outpatient surgery department. Your surgeon will speak to them in this area before your discharge.
- Do not operate a motor vehicle or any mechanical or electrical equipment for 24 hours after your anesthesia.
- Do not make any important decisions or sign legal documents for 24 hours after your anesthesia.

Introduction

Perioperative nursing is a term used to describe the nursing care provided during the total surgical experience of the patient: preoperative, intraoperative, and postoperative.

Preoperative phase—from the time the decision is made for surgical intervention to the transfer of the patient to the operating room.

Intraoperative phase—from the time the patient is received in the operating room until admitted to the postanesthesia care unit (PACU).

Postoperative phase—from the time of admission to the PACU to the follow-up evaluation.

An *anesthesia care provider* is a professional who can administer and monitor anesthesia during a surgical procedure; he or she may be a licensed physician board certified in anesthesia (anesthesiologist) or a certified registered nurse anesthetist.

Types of surgery include the following:

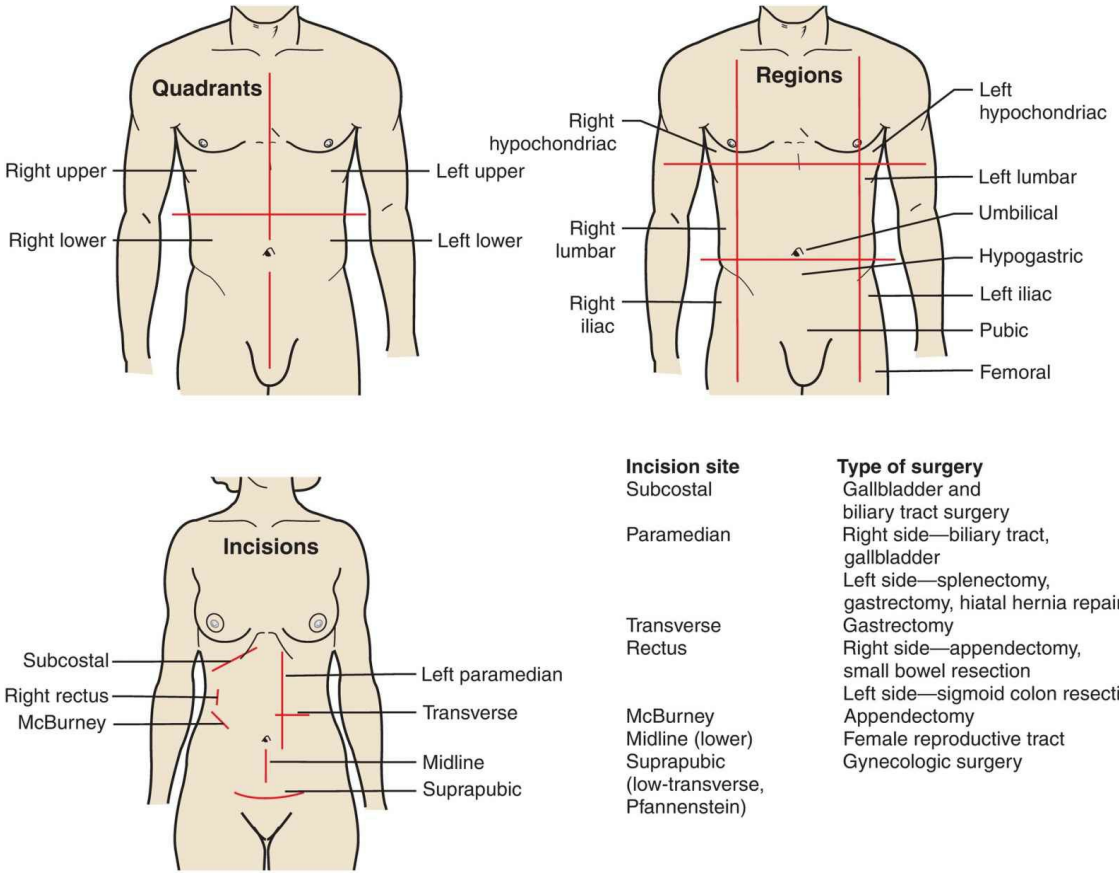
Elective—The scheduled time for surgery is at the convenience of the patient; failure to have surgery is not catastrophic (eg, superficial cyst).

Required—The condition requires surgery within a few weeks (eg, cataract).

Urgent—Necessitates surgery as soon as possible but may be delayed for a short amount of time (eg, internal fixation of fracture).

Emergent—The situation requires immediate surgical attention without delay (eg, intestinal obstruction). This must be done to save life or limb or functional capacity.

Common abdominal incisions are pictured in Figure 7-1.



Incision site	Type of surgery
Subcostal	Gallbladder and biliary tract surgery
Paramedian	Right side—biliary tract, gallbladder Left side—splenectomy, gastrectomy, hiatal hernia repair
Transverse	Gastrectomy
Rectus	Right side—appendectomy, small bowel resection Left side—sigmoid colon resection
McBurney	Appendectomy
Midline (lower)	Female reproductive tract
Suprapubic (low-transverse, Pfannenstein)	Gynecologic surgery

Figure 7-1. Regions and incisions of the abdomen.

Perioperative Safety

The safety and welfare of patients during surgical intervention is a primary concern. Patients entering the perioperative settings are at risk for infection, impaired skin integrity, altered body temperature, fluid volume deficit, and injury related to positioning and chemical, electrical, and physical hazards.

The Surgical Care Improvement Project (SCIP), National Safety Goals for Surgery, and Enhanced Recovery After Surgery (ERAS) programs have resulted in major improvements in clinical outcomes. Care protocols are developed based on evidence of best practice. Examples include practices as apparent as proper identification and early mobilization, as well as proper antibiotic use, minimally invasive surgery, and multimodal approaches to resolving issues.

EVIDENCE BASE The Joint Commission. (2018). Hospital: 2018 National Patient Safety Goals. Available: *www.jointcommission.org/hap_2017_npsgs.*

The Joint Commission. (2018). Surgical Care Improvement Project. Available: *www.jointcommission.org/surgical_care_improvement_project.*

Surgical Care Improvement Project

1. The Surgical Care Improvement Project (SCIP), a national quality partnership interested in improving surgical care by significantly reducing surgical complications, is a coalition of health care organizations that has developed evidence-based interventions that have proven effective.
   a. The goal is to reduce surgical complications by 25%.
   b. Implementing nursing interventions at the earliest stage possible of a developing complication is also of utmost importance.
2. SCIP measures that have been shown to be effective include the following:
   a. Prophylactic antibiotic received within 1 hour prior to surgical incision.
   b. Prophylactic antibiotic discontinued within 24 hours after surgery end time.
   c. Cardiac surgery patients with controlled postoperative serum glucose.
   d. Surgery patients with appropriate hair removal.
   e. Urinary catheter removed on postoperative day 1 or postoperative day 2 with day of surgery being day 0.
   f. Patients continue beta-blockers on day of surgery.
   g. Appropriate venous thromboembolism prophylaxis and treatment.

National Patient Safety Goals

1. Prevent infection—use hand cleaning guidelines from the Centers for Disease Control and Prevention or the World Health Organization.

a. Use proven guidelines to prevent infections that are difficult to treat.
b. Use proven guidelines to prevent infection of the blood from central lines.
c. Use proven guidelines to prevent infection after surgery.
d. Use proven guidelines to prevent infections of the urinary tract caused by catheters.

2. Prevent mistakes in surgery—make sure the correct surgery is done on the correct patient at the correct place on the patient's body.
    a. Mark the correct place on the patient's body where the surgery is to be done.
    b. Pause before surgery to make sure a mistake is not being made.

Enhanced Recovery after Surgery

Multimodal perioperative care pathways designed to achieve early recovery after surgical procedures by maintaining preoperative organ function and reducing the profound stress response following surgery.

Ambulatory Surgery

Ambulatory surgery (same-day surgery, outpatient surgery) is a common occurrence for certain types of procedures. The office nurse is in a key position to assess patient status, plan the perioperative experience, and monitor, instruct, and evaluate the patient.

Advantages

1. Reduced cost to the facility and insuring and governmental agencies.
2. Reduced psychological stress to the patient.
3. Less incidence of hospital-acquired infection.
4. Less time lost from work by the patient and minimal disruption of the patient's activities and family life.

Disadvantages

1. Less time to assess the patient and perform preoperative teaching.
2. Less time to establish rapport between the patient and health care personnel.
3. Less opportunity to assess for late postoperative complications. (This responsibility is primarily with the patient, although telephone and home care follow-up is possible.)

Patient Selection

Criteria for selection include the following:

1. Surgery of short duration (varies by procedure and facility).
2. Noninfected conditions.
3. Type of operation in which postoperative complications are predictably low.
4. Age usually not a factor, although too risky in a premature neonate.
5. Examples of commonly performed procedures but not limited to:
    a. Ear–nose–throat (tonsillectomy, adenoidectomy)
    b. Gynecology (diagnostic laparoscopy, tubal ligation, dilation and curettage).
    c. Orthopedics (arthroscopy, fracture, or tendon repair).
    d. Oral surgery (wisdom teeth extraction, dental restorations).
    e. Urology (circumcision, cystoscopy, vasectomy).
    f. Ophthalmology (cataract).
    g. Plastic surgery (mammary implants, reduction mammoplasty, liposuction, blepharoplasty, face-lift).
    h. General surgery (laparoscopic hernia repair, laparoscopic cholecystectomy, biopsy, cyst removal).

Nursing Management

Initial Assessment

1. Develop a nursing history for the outpatient; this may be initiated in the health care provider's office.

The history should include the patient's physical and psychological status. You will also inquire about allergies, tobacco, alcohol, and drug use; disabilities or limitations; current medications (including over-the-counter drugs, vitamins, supplements, and herbal products); current health conditions (focus should be on cardiovascular and respiratory problems, diabetes, and renal impairments); and any past surgeries and/or problems with anesthesia.

2. Ensure availability of a signed and witnessed informed consent that includes correct surgical procedure and site.
3. Explain any additional laboratory studies needed and state why.
4. Begin health education with the following instructions:
    a. Notify the health care provider and surgical unit immediately if you get a cold, have a fever, or have any illness before the date of surgery.
    b. Arrive at the specified time.
    c. Restrict food and fluid before surgery according to facility protocol to prevent aspiration of gastric contents. Based on scientific evidence, the American Society of Anesthesiologists has issued guidelines for elective procedures recommending the following:
        i. Clear liquids—minimum fasting of 2 hours.
        ii. Breast milk—minimum fasting of 4 hours.
        iii. Infant formula—minimum fasting of 6 hours.
        iv. Nonhuman milk—minimum fasting of 6 hours.
        v. Light meal—minimum fasting of 6 hours.
    d. Do not wear makeup or nail polish.
    e. Wear comfortable, loose clothing and low-heeled shoes.
    f. Leave valuables or jewelry at home.
    g. Brush your teeth in morning and rinse but do not swallow any liquid.
    h. Shower the night before or day of the surgery.
    i. Follow the health care provider's instructions for taking medications, including over-the-counter medications and supplements.
    j. Have a responsible adult accompany you and drive you home; have someone stay with you for 24 hours after the surgery.

EVIDENCE BASE American Society of Anesthesiologists Committee on Standards and Practice Parameters. (2017). Practice guidelines for preoperative fasting and the use of pharmacologic agents to reduce the risk of pulmonary aspiration: An updated report. *Anesthesiology*, *126*(3), 376–393.

NURSING ALERT Minimum fasting times must be followed to reduce the risk of aspiration, but patients are often instructed to fast after midnight because schedule changes the morning of surgery are possible due to cancellations, which can cause surgery time to be moved forward. Be aware that prolonged fasting before surgery may result in undue thirst, hunger, irritability, headache, and possibly dehydration, hypovolemia, and hypoglycemia.

Preoperative Preparation

1. Conduct a nursing assessment, focusing on cardiovascular and respiratory status. Determine if patient is diabetic and, if so, follow glucose control measures. Obtain baseline vital signs, including an oxygen saturation level and current pain score.
2. Review the patient's chart for witnessed and informed consent, laterality (right or left, if applicable), lab work, and history and physical.
3. Verify correct patient, correct site, and correct procedure. Consider "time out" and SCIP measures, including marking of incision.
4. Make sure the patient has followed food and fluid restrictions, has removed all jewelry and dentures, and is appropriately dressed for surgery.
5. Perform medication reconciliation. Certain home meds may be taken, especially beta-blockers. Check with health care provider and have patient take with a sip of water.
6. Inform anesthesia provider if patient is taking any herbal supplements.
7. Administer preprocedural medication, if applicable.

Postoperative Care

1. Check vital signs, including oxygen saturation, temperature, and pain score.
2. Administer oxygen, if necessary.
3. Change the patient's position and progress activity—head of bed elevated, dangling, and walking. Watch for dizziness or nausea.
4. Ascertain, using the following criteria, that the patient has recovered adequately to be discharged:
   a. Vital signs stable and returned to preoperative level.
   b. Stands without excessive dizziness and able to walk short distances.
   c. Pain score within tolerable level (usually less than 3 required).
   d. Able to drink fluids.
   e. Oriented to time, place, and person.
   f. No evidence of respiratory distress.
   g. Has the services of a responsible adult who can escort the patient home and remain with patient.
   h. Understands postoperative instructions and takes an instruction sheet home.

Informed Consent (Operative Permit)

Informed consent (operative permit) is the process of informing the patient about the surgical procedure, that is, risks and possible complications of surgery and anesthesia. Consent is obtained by the surgeon. This is a legal requirement. Hospitals usually have a standard operative permit form approved by the hospital's legal department.

Purposes

1. To ensure that the patient understands the nature of the treatment, including potential complications and alternative treatment or procedures.
2. To indicate that the patient's decision was made without pressure.
3. To protect the patient against unauthorized procedures and to ensure that the procedure is performed on the correct body part.
4. To protect the surgeon and facility against legal action by a patient who claims that an unauthorized procedure was performed.

Adolescent Patient and Informed Consent

1. An emancipated minor is usually recognized as one who is not subject to parental control. Regulations vary by jurisdiction but generally include:
   a. Married minor.
   b. Those in military service.
   c. Minor who has a child.
2. Most states have statutes regarding treatment of minors.
3. Standards for informed consent are the same as for adults.

Procedures Requiring Informed Consent and Time Out

1. Any surgical procedures whether major or minor.
2. Entrance into a body cavity, such as colonoscopy, paracentesis, bronchoscopy, cystoscopy, or lumbar puncture.
3. Radiologic procedures, particularly if a contrast material is required (such as myelogram, magnetic resonance imaging with contrast, angiography).
4. All procedures requiring any type of anesthesia, which includes cardioversion.

Obtaining Informed Consent

1. Before signing an informed consent document, the patient should:
   a. Be told in clear and simple terms by the surgeon what is to be done, the risks and benefits, as well as any alternatives to the surgery or procedure. The anesthesia care provider will explain the anesthesia plan and possible risks and complications.
   b. Have a general idea of what to expect in the early and late postoperative periods.

c. Have a general idea of the time involved from surgery to recovery.
d. Have an opportunity to ask any questions may be necessary.
e. Sign a separate form for each procedure or operation may be necessary.

2. Written permission is required by law and a witness may be required according to facility policy.
3. Signature is obtained with the patient's complete understanding of what is to occur; it is obtained before the patient receives sedation and is secured without pressure or duress.
4. For a minor (or a patient who is unconscious or irresponsible), permission is required from a responsible family member—parent, legal guardian, or court-appointed guardian.
5. For a married emancipated minor, permission from the spouse is acceptable when the patient is declared incapable.
6. If the patient is unable to write, an "X" is acceptable.
7. In an emergency, permission by way of telephone is acceptable with two witnesses.

Surgical Risk Factors and Preventive Strategies

Obesity

Danger

1. Increases the difficulty involved in the technical aspects of performing surgery; risk for wound dehiscence is greater.
2. Increases the likelihood of infection because of compromised tissue perfusion.
3. Increases the potential for postoperative pneumonia and other pulmonary complications because obese patients chronically hypoventilate.
4. Increases demands on the heart, leading to cardiovascular compromise.
5. Increases the risk for airway complications.
6. Alters the response to many drugs and anesthetics.
7. Decreases the likelihood of early ambulation.

Therapeutic Approach

1. Encourage weight reduction if time permits.
2. Anticipate postoperative obesity-related complications.
3. Be extremely vigilant for respiratory complications.
4. Carefully splint abdominal incisions when moving or coughing.
5. Be aware that some drugs should be dosed according to ideal body weight versus actual weight (owing to fat content) to prevent toxicity, including digoxin, lidocaine, aminoglycoside antibiotics, and theophylline.
6. Be aware that obese patients require higher doses of antibiotics to achieve effective tissue levels.
7. Avoid intramuscular (IM) injections in morbidly obese individuals (IV or subcutaneous routes preferred).
8. Never attempt to move an impaired patient without assistance or without using proper body mechanics.
9. Obtain a dietary consultation early in the patient's postoperative course.

Poor Nutrition

Danger

1. Greatly impairs wound healing (especially protein and calorie deficits and a negative nitrogen balance).
2. Increases the risk of infection.

Therapeutic Approach

1. Any recent (within 4 to 6 weeks) weight loss of 10% of the patient's normal body weight or decreased serum albumin should alert the health care staff to poor nutritional status and the need to investigate as to the cause of the weight loss.
2. Attempt to improve nutritional status before and after surgery. Unless contraindicated, provide a diet

high in proteins, calories, and vitamins (especially vitamins C and A); this may require enteral and parenteral feeding.

3. Review a serum prealbumin level to determine recent nutritional status.
4. Recommend repair of dental caries and proper mouth hygiene to prevent infection.

Fluid and Electrolyte Imbalance

Danger

Can have adverse effects in terms of general anesthesia and the anticipated volume losses associated with surgery, causing shock and cardiac dysrhythmias.

NURSING ALERT Patients undergoing major abdominal operations (such as colectomies and aortic repairs) often experience a massive fluid shift into tissues around the operative site in the form of edema (as much as 1 L or more may be lost from circulation). Watch for the fluid shift to reverse (from tissue to circulation) around the 3rd postoperative day. Patients with heart disease may develop failure because of the excess fluid "load."

Therapeutic Approach

1. Assess the patient's fluid and electrolyte status.
2. Rehydrate the patient parenterally and orally as prescribed.
3. Monitor for evidence of electrolyte imbalance, especially Na^+, K^+, Mg^{++}, and Ca^{++}.
4. Be aware of expected drainage amounts and composition; report excess and abnormalities.
5. Monitor the patient's intake and output; be sure to include all body fluid losses.

Aging

Danger

1. Potential for injury is greater in older people.
2. Be aware that the cumulative effect of medications is greater in the older patient.
3. Medications in the usual dosages, such as morphine, may cause confusion, disorientation, and respiratory depression.

Therapeutic Approach

1. Consider using lesser medication doses for desired effect.
2. Anticipate problems from chronic disorders such as anemia, obesity, diabetes, and hypoproteinemia.
3. Adjust nutritional intake to conform to higher protein and vitamin needs.
4. When possible, cater to their set patterns in older patients, such as sleeping and eating.

Presence of Cardiovascular Disease

Danger

1. May compound the stress of anesthesia and the operative procedure.
2. May result in impaired oxygenation, cardiac rhythm, cardiac output, and circulation.
3. May also produce cardiac decompensation, sudden arrhythmia, thromboembolism, acute myocardial infarction (MI), or cardiac arrest.
4. Holding cardiac medications, particularly beta-blockers, may have negative impact on cardiac status.

Therapeutic Approach

1. Frequently assess heart rate and blood pressure (BP) and hemodynamic status and cardiac rhythm, if indicated.
2. Avoid fluid overload (oral, parenteral, blood products) because of possible MI, angina, heart failure, and pulmonary edema.
3. In compliance with SCIP measures, make sure the patient has not held beta-blocker prior to surgery. Administer with a sip of water.
4. Prevent prolonged immobilization, which results in venous stasis. Monitor for potential deep vein thrombosis (DVT) or pulmonary embolus.
5. Encourage position changes but avoid sudden exertion.
6. Use antiembolism stockings and/or sequential compression device intraoperatively and postoperatively.
7. Note evidence of hypoxia and initiate therapy.

EVIDENCE BASE American Society of PeriAnesthesia Nurses. (2017). *2017–2018 perianesthesia nursing: Standards, practice recommendations, and interpretive statements*. Cherry Hill, NJ: Author.

Presence of Diabetes Mellitus

Danger

1. Hypoglycemia may result from food and fluid restrictions and anesthesia.
2. Hyperglycemia and ketoacidosis may be potentiated by increased catecholamines and glucocorticoids because of surgical stress.
3. Chronic hyperglycemia results in poor wound healing and susceptibility to infection.
4. Research has shown that surgical patients have better outcomes when glucose levels are well controlled throughout the surgical process.

Therapeutic Approach

1. Recognize the signs and symptoms of ketoacidosis and hypoglycemia, which can threaten an otherwise

uneventful surgical experience. Dehydration also threatens renal function.

2. Monitor blood glucose and be prepared to administer insulin, as directed, or treat hypoglycemia.
3. Confirm what medications the patient has taken and what has been held. Facility protocol and provider preference vary, but the goal is to prevent hypoglycemia. If the patient is NPO (nothing by mouth), oral agents are usually withheld and insulin may be ordered at 75% of the usual dose.
4. Reassure the diabetic patient that when the disease is controlled, the surgical risk is no greater than it is for the nondiabetic patient.

DRUG ALERT Rare reports of lactic acidosis have raised concerns about the use of metformin in the perioperative period. Metformin is usually held 48 hours before surgery and restarted when full food and fluid intake has restarted and normal renal function has been confirmed.

Presence of Alcoholism

Danger

The additional problem of malnutrition may be present in the presurgical patient with alcoholism. The patient may also have an increased tolerance to anesthetics.

Therapeutic Approach

1. Note that the risk of surgery is greater for the patient who has chronic alcoholism.
2. Anticipate the acute withdrawal syndrome within 72 hours of the last alcoholic drink.

Presence of Pulmonary and Upper Respiratory Disease

Danger

1. Chronic pulmonary illness may contribute to hypoventilation, leading to pneumonia and atelectasis.
2. Surgery may be contraindicated in the patient who has an upper respiratory infection because of the possible advance of infection to pneumonia and sepsis.
3. Sleep apnea in the perioperative patient provides a great risk to anesthesia and must be noted and assessed prior to surgery.

Therapeutic Approach

1. Patients with chronic pulmonary problems, such as emphysema or bronchiectasis, should be evaluated and treated prior to surgery to optimize pulmonary function with bronchodilators, corticosteroids, and conscientious mouth care, along with a reduction in weight and smoking and methods to control secretions.
2. Patients with obstructive sleep apnea should be evaluated by an anesthesia provider prior to surgery. General anesthesia should be avoided if possible. Patients should bring continuous positive airway

pressure (CPAP) machines to the hospital for use postanesthesia.

3. Opioids should be used cautiously to prevent hypoventilation. Patient-controlled analgesia is preferred.
4. Oxygen should be administered to prevent hypoxemia (low liter flow in chronic obstructive pulmonary disease).

Concurrent or Prior Pharmacotherapy

Danger

Hazards exist when certain medications are given concomitantly with others (eg, interaction of some drugs with anesthetics can lead to hypotension and circulatory collapse). This also includes the use of many herbal substances. Although herbs are natural products, they can interact with other medications used in surgery.

Therapeutic Approach

1. An awareness of drug therapy is essential.
2. Notify the health care provider and anesthesia provider if the patient is taking any of the following drugs:
   a. Certain antibiotics.
   b. Antidepressants, particularly monoamine oxidase inhibitors, and St. John's wort, an herbal product.
   c. Phenothiazines.
   d. Diuretics, particularly thiazides.
   e. Corticosteroids.
   f. Anticoagulants, such as warfarin or heparin, or medications or herbals that may affect coagulation, such as aspirin, feverfew, Ginkgo biloba, nonsteroidal anti-inflammatory drugs, ticlopidine, and clopidogrel.

PREOPERATIVE CARE

Patient Education

Patient education is a vital component of the surgical experience. Preoperative patient education may be offered through conversation, discussion, the use of audiovisual aids, demonstrations, and return demonstrations. It is designed to help the patient understand the surgical experience to minimize anxiety and promote full recovery from surgery and anesthesia. The educational program may be initiated before hospitalization by the physician, nurse practitioner or office nurse, or other designated personnel. This is particularly important for patients who are admitted the day of surgery or who are to undergo outpatient surgical procedures. The perioperative nurse can assess the patient's knowledge base and use this information in developing an IPOC (interdisciplinary plan of care), for an uneventful perioperative course.

Teaching Strategies

Obtain a Database

1. Determine what the patient already knows or wants to know. This can be accomplished by reading the patient's chart, interviewing the patient, and communicating with the health care provider, family, and other members of the health care team.
2. Ascertain the patient's psychosocial adjustment to impending surgery.
3. Determine cultural or religious health beliefs and practices that may have an impact on the patient's surgical experience, such as refusal of blood transfusions, burial of amputated limbs within 24 hours, or special healing rituals.

Plan and Implement Teaching Program

1. Begin at the patient's level of understanding and proceed from there.
2. Plan a presentation, or series of presentations, for an individual patient or a group of patients.
3. Include family members and significant others in the teaching process.
4. Encourage active participation of patients in their care and recovery.
5. Demonstrate essential techniques; provide the opportunity for patient practice and return demonstration.
6. Provide time for and encourage the patient to ask questions and express concerns; make every effort to answer all questions truthfully and in basic agreement with the overall therapeutic plan.
7. Provide general information and assess the patient's level of interest in or reaction to it.
    a. Explain the details of preoperative preparation and provide a tour of the area and view the equipment when possible.
    b. Offer general information on the surgery. Explain that the health care provider is the primary resource person.
    c. Notify the patient when surgery is scheduled (if known) and approximately how long it will take; explain that afterward the patient will go to the PACU. Emphasize that delays may be attributed to many factors other than a problem developing with this patient (eg, previous case in the operating room may have taken longer than expected or an emergency case has been given priority).

d. Let the patient know that his or her family will be kept informed and that they will be told where to wait and when they can see the patient; note visiting hours.
e. Explain how a procedure or test may feel during or afterward.
f. Describe the PACU and what personnel and equipment the patient may expect to see and hear (specially trained personnel, monitoring equipment, tubing for various functions, and a moderate amount of activity by nurses and health care providers).
g. Stress the importance of active participation in postoperative recovery.

8. Use other resource people: health care providers, therapists, chaplain, and interpreters.
9. Document what has been taught or discussed as well as the patient's reaction and level of understanding.
10. Discuss with the patient the anticipated postoperative course (eg, length of stay, immediate postoperative activity, follow-up visit with the surgeon).

Use Audiovisual Aids if Available

1. Videotapes or computer programs are effective in giving basic information to a single patient or group of patients. Many facilities provide a television channel dedicated to patient instruction.
2. Booklets, brochures, and models, if available, are helpful.
3. Demonstrate any equipment that will be specific for the particular patient. Examples:
   a. Drains and drainage bags.
   b. Monitoring equipment.
   c. Side rails.
   d. Incentive spirometer.
   e. Sequential compression device.

General Instructions

Preoperatively, the patient will be instructed in the following postoperative activities. This will allow a chance for practice and familiarity.

Incentive Spirometry

Preoperatively, the patient uses a spirometer to measure deep breaths (inspired air) while exerting maximum effort. The preoperative measurement becomes the goal to be achieved as soon as possible after the operation.

1. Postoperatively, the patient is encouraged to use the incentive spirometer about 10 to 12 times per hour.
2. Deep inhalations expand alveoli, which prevents atelectasis and other pulmonary complications.
3. There is less pain with inspiratory concentration than with expiratory concentration such as with coughing.

Coughing

Coughing promotes the removal of chest secretions. Instruct the patient to:

1. Interlace fingers and place hands over the proposed incision site; this will act as a splint during coughing and not harm the incision.

2. Lean forward slightly while sitting in bed.
3. Breathe, using the diaphragm.
4. Inhale fully with the mouth slightly open.
5. Let out three or four sharp "hacks."
6. With the mouth open, take in a deep breath and quickly give one or two strong coughs.
7. Secretions should be readily cleared from the chest to prevent respiratory complications (pneumonia, obstruction).

NURSING ALERT Incentive spirometry, deep breathing, and coughing, as well as certain position changes, may be contraindicated after some surgeries (eg, craniotomy and eye or ear surgery).

Turning

Changing positions from back to side-lying (and vice versa) stimulates circulation, encourages deeper breathing, and relieves pressure areas.

1. Help the patient to move onto his or her side if assistance is needed.
2. Place the uppermost leg in a more flexed position than that of the lower leg, and place a pillow comfortably between the legs.
3. Make sure that the patient is turned from one side to the back and onto the other side every 2 hours.

Foot and Leg Exercises

Moving the legs improves circulation and muscle tone.

1. Have the patient lie supine; instruct the patient to bend a knee and raise the foot—hold it a few seconds, and lower it to the bed. Alternately, have the patient do ankle pumps by flexing and pointing feet 20 times.
2. Repeat above about five times with one leg and then with the other. Repeat the set five times every 3 to 5 hours.
3. Then, have the patient lie on one side and exercise the legs by pretending to pedal a bicycle.
4. Suggest the following foot exercise: trace a complete circle with the great toe.

Evaluation of Teaching Program

1. Observe the patient for correct demonstration of expected postoperative behaviors, such as foot and leg exercises and special breathing techniques.
2. Ask pertinent questions to determine the patient's level of understanding.
3. Reinforce information when necessary.

Preparation for Surgery

EVIDENCE BASE Mehta, J. A., Sable, S. A., & Nagral, S. (2015). Updated recommendations for control of surgical site infection. *Annals of Surgery*, *261*(3), e65.

World Health Organization. (2016). *Global guidelines on the prevention of surgical site infections*. Geneva: Author.

Skin Antisepsis

1. Human skin normally harbors transient and resident bacterial flora, some of which are pathogenic. Skin cannot be sterilized without destroying skin cells.
2. The attributes of an appropriate surgical skin antiseptic require the ability to significantly reduce microorganisms, provide broad-spectrum activity, be fast acting, and have a persistent effect.
   a. Preoperative bathing with chlorhexidine reduces pathogenic organisms on the skin. Using multiple showers or showers immediately before coming to the operating room substantially reduces skin organisms.
   b. Cleansing with a bactericidal-impregnated sponge just before operation will provide additional reduction in skin bacteria.
3. The Centers for Disease Control and Prevention recommends that hair not be removed near the operative site unless it will interfere with surgery. The skin is easily injured during shaving that often results in a higher rate of postoperative wound infection.
4. If required, hair removal should be done by clipping, not shaving, and should be performed within 2 hours of surgery. Scissors may be used to remove hair greater than 3 mm in length.
5. For head surgery, obtain specific instructions from the surgeon concerning the extent of shaving.

Gastrointestinal Tract

1. Preparation of the bowel is imperative for patients undergoing intestinal surgery because escaping bacteria can invade adjacent tissues and cause sepsis.
   a. Cathartics and enemas remove gross collections of stool (eg, GoLYTELY).
   b. Oral antimicrobial agents (eg, neomycin, erythromycin) suppress the colon's potent microflora.
   c. Enemas "until clear" are generally not necessary. If ordered, they are given the night before surgery. Notify the health care provider if the enemas never return clear.
2. Solid food is withheld from the patient for 6 hours before surgery. Patients having morning surgery are kept NPO overnight. Clear fluids (water) may be given up to 4 hours before surgery depending on facility protocols.

Genitourinary Tract

A medicated douche may be prescribed preoperatively if the patient is to have a gynecologic or urologic operation.

Preoperative Medication

1. Administration of systemic prophylactic perioperative antibiotics is among one of the most important steps in preventing surgical site infection, which are the most common and costly type of hospital-acquired infections. It is estimated that 60% are preventable through evidence-based protocols.
2. Redosing of antibiotics during long procedures and when there is excessive blood loss, and discontinuation within 24 hours after surgery end time (48 hours for cardiac surgeries) is recommended.

DRUG ALERT *Antibiotics should be administered just before surgery—preferably 1 hour (2 hours for vancomycin and fluoroquinolones) before an incision is made—to be effective when bacterial contamination is expected.*

---

3. There is a risk, however, of an increase in *Clostridium difficile* diarrheal infections because of antibiotic use.

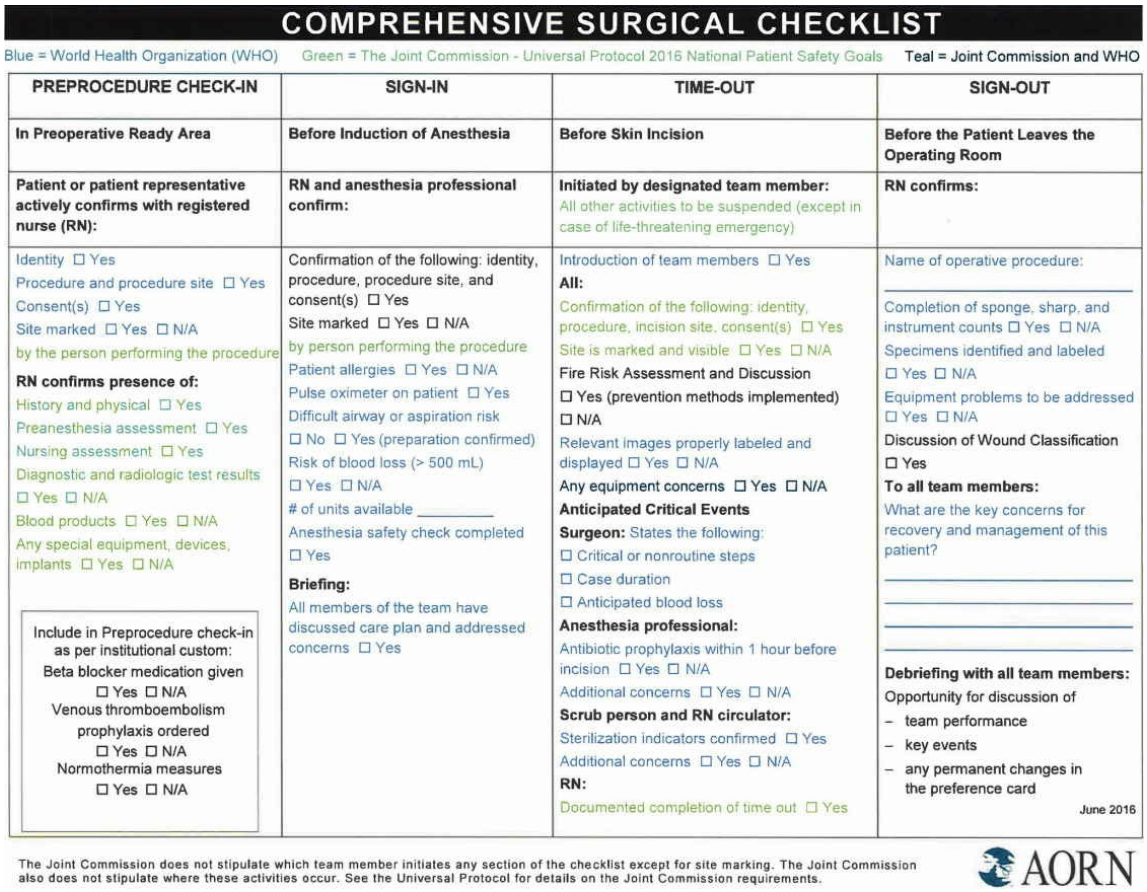
Administering "On-Call" Medications

1. Have the medication ready and administer it as soon as the call is received from the operating room.
2. Proceed with the remaining preparation activities.
3. Indicate on the chart or preoperative checklist the time when the medication was administered and by whom.

Admitting the Patient to Surgery

Final Checklist

The Comprehensive Surgical Checklist from Association of periOperative Registered Nurses (AORN) combines the World Health Organization and the Joint Commission measures for patient preparedness. It may be customized for use in any setting or may be used in addition to a facility's specific checklist that the nurse is also responsible for (see Figure 7-2).



COMPREHENSIVE SURGICAL CHECKLIST

Blue = World Health Organization (WHO) Green = The Joint Commission - Universal Protocol 2016 National Patient Safety Goals Teal = Joint Commission and WHO

PREPROCEDURE CHECK-IN	SIGN-IN	TIME-OUT	SIGN-OUT
In Preoperative Ready Area	**Before Induction of Anesthesia**	**Before Skin Incision**	**Before the Patient Leaves the Operating Room**
Patient or patient representative actively confirms with registered nurse (RN):	**RN and anesthesia professional confirm:**	**Initiated by designated team member:** All other activities to be suspended (except in case of life-threatening emergency)	**RN confirms:**
Identity ☐ Yes Procedure and procedure site ☐ Yes Consent(s) ☐ Yes Site marked ☐ Yes ☐ N/A by the person performing the procedure **RN confirms presence of:** History and physical ☐ Yes Preanesthesia assessment ☐ Yes Nursing assessment ☐ Yes Diagnostic and radiologic test results ☐ Yes ☐ N/A Blood products ☐ Yes ☐ N/A Any special equipment, devices, implants ☐ Yes ☐ N/A Include in Preprocedure check-in as per institutional custom: Beta blocker medication given ☐ Yes ☐ N/A Venous thromboembolism prophylaxis ordered ☐ Yes ☐ N/A Normothermia measures ☐ Yes ☐ N/A	Confirmation of the following: identity, procedure, procedure site, and consent(s) ☐ Yes Site marked ☐ Yes ☐ N/A by person performing the procedure Patient allergies ☐ Yes ☐ N/A Pulse oximeter on patient ☐ Yes Difficult airway or aspiration risk ☐ No ☐ Yes (preparation confirmed) Risk of blood loss (> 500 mL) ☐ Yes ☐ N/A # of units available _____ Anesthesia safety check completed ☐ Yes **Briefing:** All members of the team have discussed care plan and addressed concerns ☐ Yes	Introduction of team members ☐ Yes **All:** Confirmation of the following: identity, procedure, incision site, consent(s) ☐ Yes Site is marked and visible ☐ Yes ☐ N/A Fire Risk Assessment and Discussion ☐ Yes (prevention methods implemented) ☐ N/A Relevant images properly labeled and displayed ☐ Yes ☐ N/A Any equipment concerns ☐ Yes ☐ N/A **Anticipated Critical Events** **Surgeon:** States the following: ☐ Critical or nonroutine steps ☐ Case duration ☐ Anticipated blood loss **Anesthesia professional:** Antibiotic prophylaxis within 1 hour before incision ☐ Yes ☐ N/A Additional concerns ☐ Yes ☐ N/A **Scrub person and RN circulator:** Sterilization indicators confirmed ☐ Yes Additional concerns ☐ Yes ☐ N/A **RN:** Documented completion of time out ☐ Yes	Name of operative procedure: _____ Completion of sponge, sharp, and instrument counts ☐ Yes ☐ N/A Specimens identified and labeled ☐ Yes ☐ N/A Equipment problems to be addressed ☐ Yes ☐ N/A Discussion of Wound Classification ☐ Yes **To all team members:** What are the key concerns for recovery and management of this patient? _____ _____ _____ _____ **Debriefing with all team members:** Opportunity for discussion of – team performance – key events – any permanent changes in the preference card June 2016

The Joint Commission does not stipulate which team member initiates any section of the checklist except for site marking. The Joint Commission also does not stipulate where these activities occur. See the Universal Protocol for details on the Joint Commission requirements.

AORN

Figure 7-2. Comprehensive surgical checklist. (Reprinted with permission from AORN.org. Copyright © 2016, AORN, Inc, 2170 S. Parker Road, Suite 400, Denver, CO 80231. All rights reserved. www.aorn.org/guidelines/clinical-resources/tool-kits/correct-site-surgery-tool-kit/aorn-comprehensive-surgical-checklist.)

Identification and Verification

This includes verbal identification by the perioperative nurse while checking the identification band on the patient's wrist and written documentation (such as the chart) of the patient's identity, the procedure to be performed (laterality, if indicated), the specific surgical site marked by the surgeon with indelible ink, the surgeon, and the type of anesthesia. These are all patient safety goals as outlined by the Joint Commission.

Review of Patient Record

Check for inclusion of the fact sheet; allergies; history and physical; completed preoperative checklist; laboratory values, including most recent results, pregnancy test, if applicable; electrocardiogram (ECG) and chest x-rays, if necessary; preoperative medications; and other preoperative orders by either the surgeon or anesthesia care provider.

Consent Form

All nurses involved with patient care in the preoperative setting should be aware of the individual state laws regarding informed consent and the specific facility policy. Obtaining informed consent is the responsibility of the surgeon performing the specific procedure. Consent forms should state the procedure, various risks, and alternatives to surgery, if any. It is a nursing responsibility to make sure the consent form has been obtained with the patient or guardian's signature and that it is in the chart.

Patient Preparedness

1. NPO status.
2. Proper attire (clean gown and hair covering) and clean linen.
3. Skin preparation, if ordered.
4. IV line started with correct gauge needle.
5. Dentures or plates removed.
6. Jewelry, piercings, contact lenses, and glasses removed and secured in a locked area or given to a family member.
7. Allow the patient to void.

Transporting the Patient to the Operating Room

1. Adhere to the principle of maintaining the comfort and safety of the patient.
2. Accompany operating room attendants to the patient's bedside for introduction and proper identification.
3. Assist in transferring the patient from bed to stretcher (unless the bed goes to the operating room floor).
4. Complete the chart and preoperative checklist; include laboratory reports and x-rays as required by facility policy or the health care provider's directive.
5. Make sure that the patient arrives in the operating room at the proper time.

The Patient's Family

1. Direct the patient's family to the proper waiting room where magazines, television, and beverages may be available.
2. Tell the family that the surgeon will probably contact them there after surgery to inform them about the operation.
3. Inform the family that a long interval of waiting does not mean the patient is in the operating room the whole time; anesthesia preparation and induction take time, and after surgery, the patient is taken to the PACU.

4. Tell the family what to expect postoperatively when they see the patient—tubes, monitoring equipment, and blood transfusion, suctioning, and oxygen equipment.

INTRAOPERATIVE CARE

NURSING ALERT Nursing competencies for intraoperative care include ACLS/PALS, moderate sedation, intralipid protocol, recognition of signs and symptoms of toxicity including cardiac arrhythmias and seizures, pharmacology of local anesthetic agents, and neurovascular/neurological checks. Nurses should be familiar with each type of block performed, its therapeutic effects, associated side effects, possible adverse reactions associated with the specific block performed, and any indicated emergency interventions. These competencies are necessary to ensure the patient's optimal safety during the perioperative patient experience.

Anesthesia and Related Complications

The goals of anesthesia are to provide analgesia, sedation, and muscle relaxation appropriate for the type of operative procedure as well as to control the autonomic nervous system.

Common Anesthetic Techniques

Moderate Sedation

EVIDENCE BASE Association of periOperative Registered Nurses. (2017). *Recommended practice for managing the patient receiving moderate sedation/analgesia*. Denver, CO: Author.

---

1. A specific level of sedation that allows patients to tolerate unpleasant procedures by reducing the level of anxiety and discomfort, previously known as conscious sedation.
2. The patient achieves a depressed level of consciousness (LOC) and altered perception of pain while retaining the ability to respond appropriately to verbal and tactile stimuli.
3. Cardiopulmonary function and protective airway reflexes are maintained by the patient.
4. Knowledge of expected outcomes is essential. These outcomes include, but are not limited to:
   a. Maintenance of consciousness.
   b. Maintenance of protective reflexes.
   c. Alteration of pain perception.
   d. Enhanced cooperation.
5. Adequate preoperative preparation of the patient will facilitate achieving the desired effects.
6. Nurses caring for patients receiving moderate sedation should be specially trained in the agents used for moderate sedation, such as midazolam and fentanyl, and should be skilled in advanced life support. Many facilities have strict regulations and training requirements for staff handling such patients.
7. Nurses working in this setting should also be aware of the regulations from the board of nursing in the state they are practicing concerning the care of patients receiving anesthesia and should be compliant with state advisory opinions, declaratory rules, and other regulations that direct the practice of the registered nurse.
8. Patients who are not candidates for conscious sedation and require more complex sedation should be managed by anesthesia care providers.

Monitored Anesthesia Care

1. Light to deep sedation that is monitored by an anesthesia care provider.
2. The patient is asleep but arousable.
3. The patient is not intubated.

4. The patient may receive local anesthesia and oxygen, is monitored, and receives sedation and analgesia. Midazolam, fentanyl, alfentanil, and propofol are frequently used in monitored anesthesia care procedures.

General Anesthesia

1. A reversible state consisting of complete loss of consciousness. Protective reflexes are lost.
2. With the loss of protective reflexes, the patient's airway needs to be maintained. This can be done by endotracheal intubation or insertion of a laryngeal mask airway (LMA).
    a. For certain, short, and uncomplicated surgeries (eg, myringotomies), the insertion of a breathing tube may not be necessary, and the airway is maintained manually with a jaw thrust/chin-lift.
    b. Endotracheal (ET) intubation is facilitated by the use of a laryngoscope. The ET tube is inserted into the trachea and passed through the vocal cords. A cuff is then inflated, thus ensuring a secure airway where no secretions from the oral cavity can enter the lungs.
    c. LMA does not require a laryngoscope for insertion and is inserted only to the entrance of the trachea. Although LMA does not provide a totally protected airway, it is noninvasive and more gentle on the tissue.
3. General anesthesia consists of three phases: induction, maintenance, and emergence.
4. Induction can be accomplished either by parenteral or inhalation route. Common agents for IV induction are propofol and phenobarbital. In addition to the induction agent, a potent analgesic is also often added (eg, fentanyl) to potentiate the induction agent as well as provide analgesia. Patients can also reach an unconscious state by inhaling a potent, short-acting volatile gas, such as sevoflurane. Once the patient is asleep, and if the surgical procedure so requires, a muscle relaxant is given and the ET tube is inserted.
5. Maintenance is accomplished through a continuous delivery of the inhalation agent, or an IV infusion of an agent, such as propofol, to maintain an unconscious state. Intermittent doses of an analgesic are given as needed as well as intermittent doses of a muscle relaxant for longer surgeries.
6. Emergence occurs at the end of the surgery when the continuous delivery of either the gas or the IV infusion is stopped and the patient slowly returns to a conscious state. If muscle relaxants are still in effect, they can be reversed with neostigmine to allow for adequate muscle strength and return of spontaneous ventilations. A nerve stimulator can be used to assess if adequate muscle control has returned before extubation of the trachea.

NURSING ALERT During emergence, the patient is very sensitive to any stimuli. Keep noise levels to a minimum, and refrain from manipulating the patient during this stage.

Regional Anesthesia

1. Anesthesia block is achieved by injecting a local anesthetic, such as lidocaine or bupivacaine, in close proximity to appropriate nerves. It may be spinal, epidural, or peripheral block.

2. Nursing responsibilities include being familiar with the drug used and maximum dose that can be given, knowing signs and symptoms of toxicity, and maintaining a comfortable environment for the conscious patient.
3. *Spinal anesthesia* is the injection of a local anesthetic into the lumbar intrathecal space. The anesthetic blocks conduction in spinal nerve roots and dorsal ganglia, thereby causing paralysis and analgesia below the level of injection.
4. *Epidural anesthesia* involves injecting local anesthetic into the epidural space. Results are similar to spinal analgesia but with a slower onset.
    a. Often, a catheter is inserted for continuous infusion of the anesthetic to the epidural space.
    b. The catheter may be left in place to provide postoperative analgesia as well.
5. *Peripheral nerve block* is achieved by injecting a local anesthetic into a bundle of nerves (eg, axillary plexus) or into a single nerve to achieve anesthesia to a specific part of the body (eg, hand or single finger).

Intraoperative Complications

1. Hypoventilation and hypoxemia—because of inadequate ventilatory support.
2. Oral trauma (broken teeth, oropharyngeal or laryngeal trauma)—because of difficult ET intubation.
3. Hypotension—because of preoperative hypovolemia or untoward reactions to anesthetic agents.
4. Cardiac dysrhythmia—because of preexisting cardiovascular compromise, electrolyte imbalance, or untoward reactions to anesthetic agents.
5. Hypothermia—because of exposure to a cool ambient operating room environment and loss of normal thermoregulation capability from anesthetic agents.
6. Peripheral nerve damage—because of improper positioning of the patient (eg, full weight on an arm) or use of restraints.
7. Malignant hyperthermia.
    a. This is a rare reaction to anesthetic inhalants (notably sevoflurane, enflurane, isoflurane, and desflurane) and the muscle relaxant succinylcholine.
    b. Caused by abnormal and excessive intracellular accumulations of calcium with resulting hypermetabolism, increased muscle contraction, and elevated body temperature.
    c. Treatment consists of discontinuing the inhalant anesthetic, administering IV dantrolene, and applying cooling techniques (eg, cooling blanket, iced saline lavages).
8. Local anesthesia systemic toxicity (LAST)
    a. This is an adverse outcome that occurs when the serum level of local anesthesia increases to an unsafe level.
    b. It is important for the nurse to recognize signs and symptoms. CNS symptoms usually present first (patient has metallic taste, numbness of the tongue and lips, tinnitus, confusion, agitation, and seizures) followed by cardiac symptoms.
    c. Lipid emulsion (20%) therapy must be administered intravenously bolus 100 mL over 2 to 3 minutes for >70 kg patient and bolus 1.5 mL/kg for >70 kg patient. Learn more about LAST protocol at

www.lipidrescue.org.

EVIDENCE BASE Fencl, J. L. (2015). Local anesthetic systemic toxicity: Perioperative implications. *AORN Journal*, *101*(6), 697–700.

NURSING ALERT Recognize malignant hyperthermia immediately so that inhalant anesthesia can be discontinued and treatment measures started, to prevent seizures and other adverse effects.

POSTOPERATIVE CARE

Postanesthesia Care Unit

To ensure continuity of care from the intraoperative phase to the immediate postoperative phase, the circulating nurse or anesthesia care provider gives a thorough report to the PACU nurse. See Standards of Care Guidelines 7-1 (page 94). This report should include the following:

1. Type of surgery performed and any intraoperative complications.
2. Type of anesthesia (eg, general, local, sedation).
3. Drains and type of dressings.
4. Presence of ET tube or type of oxygen to be administered (eg, nasal cannula, T piece).
5. Types of lines and locations (eg, peripheral IV, central line, arterial line).
6. Catheters or tubes, such as a urinary catheter or T tube.
7. Administration of blood, colloids, and fluids and electrolytes.
8. Drug allergies and pertinent medical history.
9. Preexisting medical conditions.
10. Intraoperative course, including any complications or instability in the patient's vital signs.

STANDARDS OF CARE GUIDELINES 7-1

PACU Care

Postanesthesia care unit (PACU) care is geared toward recognizing the signs of distress and anticipating and preventing postoperative difficulties. Carefully monitor the patient coming out of general anesthesia until:

- Vital signs are stable and are within normal range.
- The patient has no signs of respiratory distress and can maintain his or her own airway.
- Reflexes have returned to normal.
- Pain is under control and at a tolerable level for the patient.
- The patient is responsive and oriented to time and place.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Initial Nursing Assessment

Before receiving the patient, note the proper functioning of monitoring and suctioning devices, oxygen therapy equipment, and all other equipment. The following initial assessment is made by the nurse in the PACU:

1. Verify the patient's identity, the operative procedure, and the surgeon who performed the procedure.
2. Obtain vital signs, including pulse oximetry and temperature.

3. Evaluate airway status, noting any stridor or snoring respirations. Capnography may be used to assess adequate oxygenation as well.
4. Evaluate respiratory status, including rate and effort, and auscultate breath sounds.
5. Assess circulatory status, noting skin color, peripheral pulses, and ECG monitor.
6. Observe LOC and orientation to time and place.
7. Evaluate condition of surgical dressings and drains, and check IV lines and infusing fluids and/or IV medications. Initial surgical dressing is usually maintained for 48 hours.
8. Determine patient's pain level using a 1 to 10 scale.
9. Review the health care provider's orders.

NURSING ALERT It is important for the nurse to be able to communicate in the patient's language to provide an accurate assessment. An interpreter must be obtained when necessary.

Initial Nursing Diagnoses

- Ineffective Airway Clearance related to effects of anesthesia.
- Impaired Gas Exchange related to ventilation–perfusion imbalance.
- Risk for unstable glucose level related to uncontrolled diabetes and stress of surgery.
- Ineffective Tissue Perfusion (Cardiopulmonary) related to hypotension postoperatively.
- Risk for Imbalanced Body Temperature related to medications, sedation, and cool environment.
- Risk for Deficient Fluid Volume related to blood loss, food and fluid deprivation, vomiting, and indwelling tubes.
- Acute Pain related to surgical incision and tissue trauma.
- Impaired Skin Integrity related to invasive procedure, immobilization, and altered metabolic and circulatory state.
- Risk for Injury related to sensory dysfunction and physical environment.
- Disturbed Sensory Perception related to effects of medications and anesthesia.

Initial Nursing Interventions

Maintaining a Patent Airway

1. Closely monitor the patient arriving with an oral or nasal airway in place until fully awake.
2. Monitor for return of cough and gag reflex. When the patient is awake and able to protect his or her own airway, the oral or nasal airway can be discontinued.
3. Early initiation of CPAP in the PACU is beneficial for patients exhibiting hypoxemia, apnea, and frequent severe airway obstruction because of obstructive sleep apnea.

Maintaining Adequate Respiratory Function

1. Encourage the patient to take deep breaths to aerate the lungs fully and prevent atelectasis; use an incentive spirometer to aid in this function.
2. Assess lung fields frequently through auscultation.
3. Periodically evaluate the patient's LOC—response to name or command. *Note:* Alterations in cerebral function may suggest impaired oxygen delivery.
4. Administer humidified oxygen to reduce irritation of airways and facilitate secretion removal.

Maintaining Glycemic Control

1. Check serum glucose on arrival to PACU and monitor as indicated.
2. For patients who are diabetic, administer insulin and follow protocols to keep serum glucose levels between 120 and 160 mg/dL. Studies show that normalizing blood glucose for the first 2 to 3 days postoperatively reduces the incidence of deep wound infections comparable to that in nondiabetic patients.

Promoting Tissue Perfusion

1. Monitor vital signs (BP, pulse, respiratory rate, and oxygen saturation) according to protocol, normally every 15 minutes while in the PACU. Monitor ECG tracing for arrhythmias.
   a. Report variations in BP, heart rate, respiratory rate, and cardiac arrhythmias.
   b. Evaluate pulse pressure to determine status of perfusion. (A narrowing pulse pressure indicates impending shock.)
2. Monitor intake and output closely.
3. Recognize the variety of factors that may alter circulating blood volume, such as blood loss during surgery and fluid shifts after surgery.
   a. Recognize early symptoms of shock or hemorrhage: cool extremities, decreased urine output (less than 30 mL/hour), slow capillary refill (greater than 3 seconds), decreased BP, narrowing pulse pressure, and increased heart rate.
4. Intervene to improve tissue perfusion.
   a. Initiate oxygen therapy or increase fraction of inspired oxygen of existing oxygen delivery system.
   b. Increase parenteral fluid infusion, as prescribed.
   c. Place the patient in the shock position with his or her feet elevated (unless contraindicated).
   d. See Chapter 35 for more detailed consideration of shock.

Stabilizing Thermoregulatory Status

1. Monitor temperature every 15 minutes and be alert for development of both hypothermia and hyperthermia.
2. Report a temperature more than 101.5°F (38.6°C) or less than 95°F (35°C).
3. Monitor for postanesthesia shivering that, although common in hypothermic patients, may also occur in normothermic patients, especially those who received inhalants during anesthesia. It represents a heat-gain mechanism, which drastically increases oxygen demand.

4. Provide warm blankets for patients feeling cold.
5. Provide active warming with forced warm air for hypothermic patients.

Maintaining Adequate Fluid Volume

1. Administer IV, as ordered.
2. Monitor intake and output.
3. Monitor electrolytes and recognize evidence of imbalance, such as nausea, vomiting, and weakness.
4. Evaluate mental status and skin color and turgor.
5. Recognize signs of fluid imbalance.
   a. Hypovolemia—decreased BP, decreased urine output, decreased central venous pressure (CVP), and increased pulse.
   b. Hypervolemia—increased BP; changes in lung sounds, such as crackles in the bases; changes in heart sounds (eg, S_3 gallop); and increased CVP.
6. Evaluate IV sites to detect early infiltration. Restart lines immediately to maintain fluid volume.

Promoting Comfort

1. Assess pain by observing behavioral and physiologic manifestations (change in vital signs may be a result of pain); have the patient rate pain on a scale of 1 to 10.
2. Administer analgesics and document efficacy.
3. Position the patient to maximize comfort.

Minimizing Complications of Skin Impairment

1. Perform handwashing before and after contact with the patient.
2. Inspect dressings routinely and reinforce them, if necessary.
3. Record the amount and type of wound drainage (see "Wound management," page 103).
4. Turn the patient frequently and maintain good body alignment.

Maintaining Safety

1. Keep the side rails up until the patient is fully awake.
2. Protect the extremity into which IV fluids are running so that the needle will not become accidentally dislodged.
3. Avoid nerve damage and muscle strain by properly supporting and padding pressure areas.
4. Be aware that patients who have received regional anesthesia may not be able to complain of an injury, such as the pricking of an open safety pin or a clamp that is exerting pressure.
5. Check the dressing for constriction.
6. Determine the return of motor control following regional anesthesia—indicated by how the patient responds to a request to move a body part.

Minimizing Sensory Deficits

1. Know that the ability to hear returns more quickly than other senses as the patient emerges from anesthesia.
2. Avoid saying anything in the patient's presence that may be disturbing; the patient may appear to be sleeping but still consciously hears what is being said.
3. Explain procedures and activities at the patient's level of understanding.
4. Minimize the patient's exposure to emergency treatment of nearby patients by drawing the curtains and lowering your voice and noise levels.
5. Treat the patient as a person who needs as much attention as the equipment and monitoring devices.
6. Respect the patient's feeling of sensory deprivation and overstimulation; make adjustments to minimize this fluctuation of stimuli.
7. Demonstrate concern for and an understanding of the patient and anticipate his or her needs and feelings.
8. Tell the patient repeatedly that the surgery is over and that he or she is in the PACU.

Evaluation: Expected Outcomes

- Absence of respiratory distress.
- Lung sounds clear to auscultation.
- Glucose less than 160 mg/dL.
- Vital signs stable and within preoperative ranges.
- Body temperature more than 95°F (35°C) and less than 101.5°F (38.6°C).
- IV infusion patent; urine output 50 to 60 mL/hour.
- Adequate pain control.
- Wound/dressing intact without excessive drainage.
- Side rails up; positioned carefully; moving extremities appropriately.
- Quiet, reassuring environment maintained.

Transferring the Patient from the PACU

Each facility may have an individual checklist or scoring guide used to determine a patient's readiness for transfer. The above evaluation criteria must be met before transfer.

Transfer Responsibilities

1. Relay appropriate information to the unit nurse regarding the patient's condition. Use an approved method of communication such as SBAR (situation, background, assessment, and recommendations). Point out significant needs, vital signs (trends and most recent set), fluid therapy, incision and dressing requirements, intake needs, urine output, and color and amount of any drainage.
2. Physically assist in the transfer of the patient.
3. Orient the patient to the room, attending nurse, call light, and therapeutic devices.

Postoperative Discomforts

Most patients experience some discomforts postoperatively. These are usually related to the general anesthetic and the surgical procedure. The most common discomforts are nausea, vomiting, restlessness, sleeplessness, thirst, constipation, flatulence, and pain.

Postoperative Nausea and Vomiting (PONV)

Causes

1. Occurs in many postoperative patients.
2. Most commonly related to inhalation anesthetics (nitrous oxide) and opioid use.
3. Can result from an accumulation of fluid or food in the stomach before peristalsis returns.
4. May occur as a result of abdominal distention, which follows manipulation of abdominal organs.

Preventive Measures

EVIDENCE BASE American Society of PeriAnesthesia Nurses. (2017). *2017–2018 perianesthesia nursing standards and practice recommendations*. Cherry Hill, NJ: Author.

---

1. Insert a nasogastric (NG) tube intraoperatively for operations on the GI tract to prevent abdominal distention, which triggers vomiting.
2. Evaluate patient preoperatively for risk factors for PONV, such as being female, being a nonsmoker, and having a history of motion sickness.

Nursing Interventions

1. Encourage the patient to breathe deeply to facilitate elimination of anesthetic.
2. Support the wound during retching and vomiting; turn the patient's head to the side to prevent aspiration.
3. Discard vomitus and refresh the patient—provide mouthwash and clean linens.
4. Provide small sips of a carbonated beverage such as ginger ale, if tolerated or permitted.
5. Report excessive or prolonged vomiting so the cause may be investigated.
6. Maintain an accurate intake and output record and replace fluids as ordered.
7. Detect the presence of abdominal distention or hiccups, suggesting gastric retention.
8. Administer antiemetic agents such as ondansetron or promethazine as directed; be aware that some of these drugs may potentiate the hypotensive effects of opioids.

DRUG ALERT Suspect idiosyncratic response to a drug if vomiting is worse when a medication is given (but diminishes thereafter).

Thirst

Causes

1. Inhibition of secretions by medication with atropine.
2. Fluid lost by way of perspiration, blood loss, and dehydration because of NPO status.

Preventive Measures

Unfortunately, postoperative thirst is a common and troublesome symptom that is usually unavoidable due to anesthesia. The immediate implementation of nursing interventions is most helpful.

Nursing Interventions

1. Administer fluids parenterally or orally, if tolerated and permitted.
2. Offer ice chips.
3. Apply a moistened gauze square over lips occasionally to humidify inspired air.
4. Allow the patient to rinse mouth with mouthwash.

Constipation and Gas Cramps

Causes

1. Trauma and manipulation of the bowel during surgery as well as opioid use.
2. More serious causes: peritonitis or abscess.

Preventive Measures

1. Encourage early ambulation to aid in promoting peristalsis.
2. Provide adequate fluid intake to promote soft stools and hydration.
3. Advocate proper diet to promote peristalsis.
4. Encourage the early use of nonopioid analgesia because many opiates increase the risk of constipation.
5. Assess bowel sounds frequently.

Nursing Interventions

1. Ask the patient about any usual remedy for constipation and try it, if appropriate.
2. Insert a gloved, lubricated finger and break up the fecal impaction manually, if necessary.
3. Administer an oil retention enema (180 to 200 mL), if prescribed, to help soften the fecal mass and facilitate evacuation.
4. Administer a return flow enema (if prescribed) or a rectal tube to decrease painful flatulence.

5. Administer GI stimulants, laxatives, suppositories, and stool softeners, as prescribed.

Postoperative Pain

Pain is a subjective symptom, in which the patient exhibits a feeling of distress; stimulation of, or trauma to, certain nerve endings cause pain. Pain is one of the earliest symptoms that the patient expresses on return to consciousness. Maximal postoperative pain occurs directly after surgery and usually diminishes significantly by 48 hours.

Clinical Manifestations

1. Autonomic.
    a. Elevation of BP.
    b. Increase in heart and pulse rate.
    c. Rapid and irregular respiration.
    d. Increase in perspiration.
2. Skeletal muscle.
    a. Increase in muscle tension or activity.
3. Psychological.
    a. Increase in irritability.
    b. Increase in apprehension.
    c. Increase in anxiety.
    d. Attention focused on pain.
    e. Complaints of pain.
4. The patient's reaction depends on:
    a. Previous experience.
    b. Anxiety or tension.
    c. State of health.
    d. Ability to be distracted.
    e. Meaning that pain has for the patient.

Preventive Measures

1. Reduce anxiety because of anticipation of pain.
2. Teach patient about pain management.
3. Review analgesics with patient and reassure that pain relief will be available quickly.
4. Establish a trusting relationship and spend time with patient.

Nursing Interventions

Use Basic Comfort Measures

1. Provide therapeutic environment—proper temperature and humidity, ventilation, and visitors.

2. Massage patient's back and pressure points with soothing strokes—move patient gently and with prewarning.
3. Offer diversional activities, soft music, or favorite television program.
4. Provide for fluid needs by giving a cool drink; offer a bed pan.
5. Investigate possible causes of pain, such as bandage or adhesive that is too tight, full bladder, a cast that is too snug, or elevated temperature indicating inflammation or infection.
6. Instruct the patient to splint the wound when moving.
7. Keep bedding clean, dry, and free from wrinkles and debris.

Recognize the Power of Suggestion

1. Provide reassurance that the discomfort is temporary and that the medication will aid in pain reduction.
2. Clarify patient's fears regarding the perceived significance of pain.
3. Assist patient in maintaining a positive, hopeful attitude.

Assist in Relaxation Techniques

Imagery, meditation, controlled breathing, self-hypnosis or suggestion (autogenic training), and progressive relaxation.

Apply Cutaneous Counterstimulation

1. Vibration—a vigorous form of massage that is applied to a nonoperative site. It lessens the patient's perception of pain. (Avoid applying this to the calf because it may dislodge a thrombus.)
2. Heat or cold—apply to the operative or nonoperative site as prescribed. This works best for well-localized pain. Cold has more advantages than heat and fewer unwanted adverse effects (eg, burns). Heat works well with muscle spasm.

Give Analgesics as Prescribed in a Timely Manner

1. Instruct the patient to request an analgesic before the pain becomes severe.
2. If pain occurs consistently and predictably throughout a 24-hour period, analgesics should be given around the clock—avoiding the usual "demand cycle" of dosing that sets up eventual dependency and provides less adequate pain relief.
3. Administer prescribed medication to the patient before anticipated activities and painful procedures (eg, dressing changes).
4. Monitor for possible adverse effects of analgesic therapy (eg, respiratory depression, hypotension, nausea, skin rash). Administer naloxone to relieve significant opioid-induced respiratory depression.
5. Assess and document the efficacy of analgesic therapy.

Pharmacologic Management

Oral and Parenteral Analgesia

1. Surgical patients are commonly prescribed a parenteral analgesic for 2 to 4 days or until the incisional

pain abates. At that time, an oral analgesic, opioid, or nonopioid will be prescribed.

2. Although the health care provider is responsible for prescribing the appropriate medication, it is the nurse's responsibility to make sure the drug is given safely and assessed for efficacy.

NURSING ALERT The patient who remains sedated because of analgesia is at risk for complications such as aspiration, respiratory depression, atelectasis, hypotension, falls, and poor postoperative course.

DRUG ALERT Opioid "potentiators," such as hydroxyzine, may further sedate the patient.

Patient-Controlled Analgesia (PCA)

1. Benefits.
   a. Bypasses the delays inherent in traditional analgesic administration (the "demand cycle").
   b. Medication is administered by IV, producing more rapid pain relief and greater consistency in patient response.
   c. The patient retains control over pain relief (added placebo and relaxation effects).
   d. Decreased nursing time in frequent delivery of analgesics.
2. Contraindications.
   a. Generally, patients younger than age 10 or 11 (depends on the weight of the child and facility policy).
   b. Patients with cognitive impairment (delirium, dementia, mental illness, hemodynamic or respiratory impairment).
3. A portable PCA device delivers a preset dosage of opioid (usually morphine). An adjustable "lockout interval" controls the frequency of dose administration, preventing another dose from being delivered prematurely. An example of PCA settings might be a dose of 1 mg morphine with a lockout interval of 6 minutes (total possible dose is 10 mg/hour).
4. Patient pushes a button to activate the device.
5. Instruction about PCA should occur preoperatively; some patients fear being overdosed by the machine and require reassurance.

Epidural Analgesia

1. Requires injections of opioids into the epidural space by way of a catheter inserted by an anesthesiologist under aseptic conditions (see Figure 7-3).
2. Benefit: provides for longer periods of analgesia.
3. Disadvantages.

a. The epidural catheter's proximity to the spinal nerves and spinal canal, along with its potential for catheter migration, makes correct injection technique and close patient assessment imperative.

b. Adverse effects include generalized pruritus (common), nausea, urinary retention, respiratory depression, hypotension, motor block, and sensory or sympathetic block. These adverse effects are related to the opioid used (usually, a preservative-free morphine or fentanyl) and catheter position.

4. Strict sterile technique is necessary when inserting the epidural catheter.
5. Opioid-related adverse effects are reversed with naloxone.
6. The nurse ensures proper integrity of the catheter and dressing.

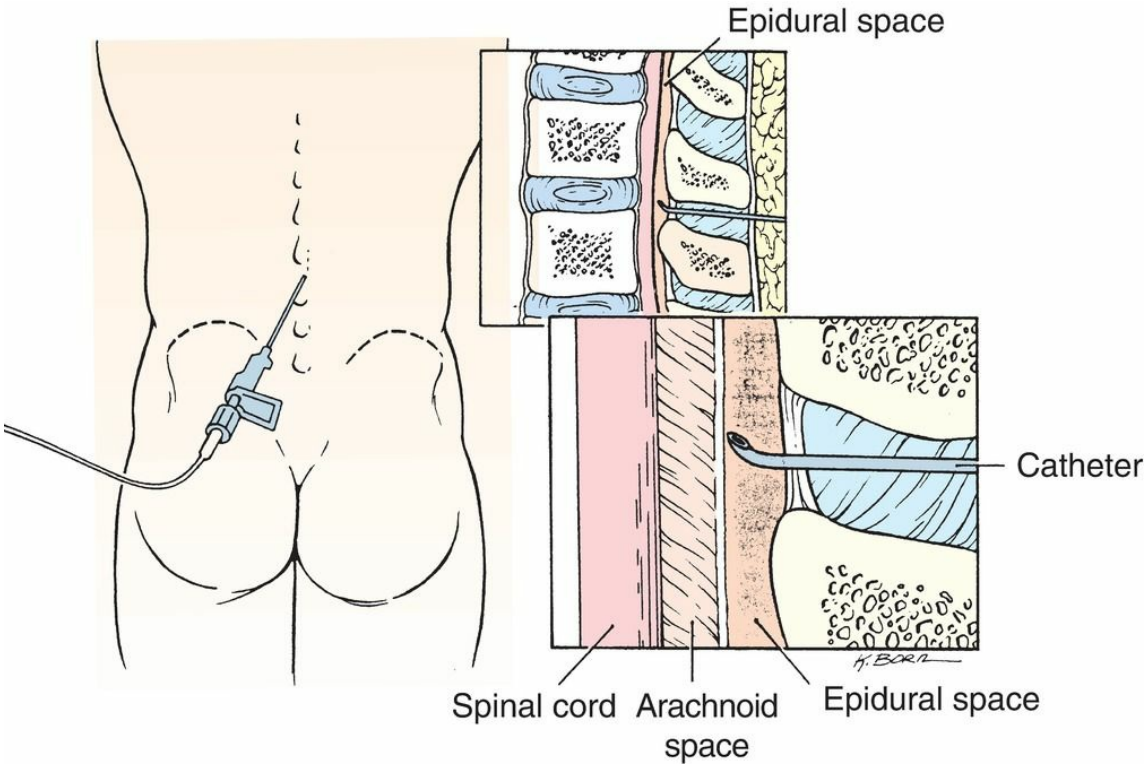


Figure 7-3. Epidural catheter placement.

Postoperative Complications

Postoperative complications are a risk inherent in surgical procedures. They may interfere with the expected outcome of the surgery and may extend the patient's hospitalization and convalescence. The nurse plays a critical role in attempting to prevent complications and in recognizing their signs and symptoms immediately.

NURSING ALERT Notify the surgeon if there is any deviation from the normal expected outcomes postoperatively.

Shock

Shock is a response of the body to decreased tissue perfusion, culminating, eventually, in cellular hypoxia and death. (See Chapter 35 for classification and emergency management of shock.)

Preventive Measures

1. Have blood available if there is any indication that it may be needed.
2. Accurately measure any blood loss and monitor all fluid intake and output.
3. Anticipate the progression of symptoms on earliest manifestation.
4. Monitor vital signs per facility protocol until they are stable.
5. Assess vital sign deviations; evaluate BP in relation to other physiologic parameters of shock and the patient's premorbid values. Orthostatic pulse and BP are important indicators of hypovolemic shock.
6. Prevent infection (eg, indwelling catheter care, wound care, pulmonary care) to minimize the risk of septic shock.

Hemorrhage

Hemorrhage is the escape of blood from a ruptured blood vessel. Hemorrhage from an arterial vessel may be bright red in color and come in spurts, whereas blood from a vein is dark red and comes in a steady flow. Hemorrhage may be external or internal (concealed).

Clinical Manifestations

1. Apprehension; restlessness; thirst; cold, moist, pale skin; and circumoral pallor.
2. Pulse increases, respirations become rapid and deep ("air hunger"), and temperature drops.
3. With progression of hemorrhage:
    a. Decrease in cardiac output and narrowed pulse pressure.
    b. Rapidly decreasing BP, as well as hematocrit and hemoglobin (if hypovolemic shock is due to hemorrhage).

Nursing Interventions and Management

1. Treat the patient as described for shock (see Chapter 35).

2. Inspect the wound as a possible site of bleeding. Apply pressure dressing over an external bleeding site.
3. Increase the IV fluid infusion rate and administer blood as directed and as soon as possible.
4. Administer 100% oxygen.

NURSING ALERT Numerous, rapid blood transfusions may induce coagulopathy and prolonged bleeding time. The patient should be monitored closely for signs of increased bleeding tendencies after transfusions.

Deep Vein Thrombosis

DVT occurs in pelvic veins or in the deep veins of the lower extremities in postoperative patients. The incidence of DVT varies between 10% and 40% depending on the complexity of the surgery or the severity of the underlying illness. DVT is most common after hip surgery, followed by retropubic prostatectomy and general thoracic or abdominal surgery. Venous thrombi located above the knee are considered the major source of pulmonary emboli.

Causes

1. Injury to the intimal layer of the vein wall.
2. Venous stasis.
3. Hypercoagulopathy and polycythemia.
4. High risks include obesity, prolonged immobility, cancer, smoking, estrogen use, advancing age, varicose veins, dehydration, splenectomy, and orthopedic procedures.

Clinical Manifestations

1. Most patients with DVT are asymptomatic.
2. Pain or cramp in the calf or thigh, progressing to painful swelling of the entire leg.
3. Slight fever, chills, and perspiration.
4. Marked tenderness over the anteromedial surface of the thigh.
5. Intravascular clotting without marked inflammation may develop, leading to phlebothrombosis.
6. Circulation distal to the DVT may be compromised if sufficient swelling is present.

Preventive Measures and Management

1. Hydrate patient adequately postoperatively to prevent hemoconcentration.
2. Encourage leg exercises and ambulate patient as soon as permitted by surgeon.
3. Avoid restricting devices, such as tight straps, that can constrict and impair circulation.
4. Avoid rubbing or massaging calves and thighs.
5. Instruct the patient to avoid standing or sitting in one place for prolonged periods and crossing legs when seated.

6. Refrain from inserting IV catheters into legs or feet of adults.
7. Assess distal peripheral pulses, capillary refill, and sensation of lower extremities.
8. Check for positive Homans sign—calf pain on dorsiflexion of the foot, present in nearly 30% of DVT patients.
9. Prevent the use of bed rolls or knee gatches in patients at risk because there is danger of constricting the vessels under the knee.
10. Initiate anticoagulant therapy IV, subcutaneously, or orally as prescribed.
11. Prevent swelling and stagnation of venous blood by applying appropriately fitting compression stockings or wrapping the legs from the toes to the groin with compression bandage.
12. Apply external pneumatic compression intraoperatively to patients at highest risk of DVT. Pneumatic compression can reduce the risk of DVT by 30% to 50% (see Figure 7-4).
13. Mechanical prophylaxis by having the patient perform foot pumps also provides an alternative to chemical agents in the prevention of thromboembolic disease. The use of foot pumps is safe and patient compliance may be enhanced.

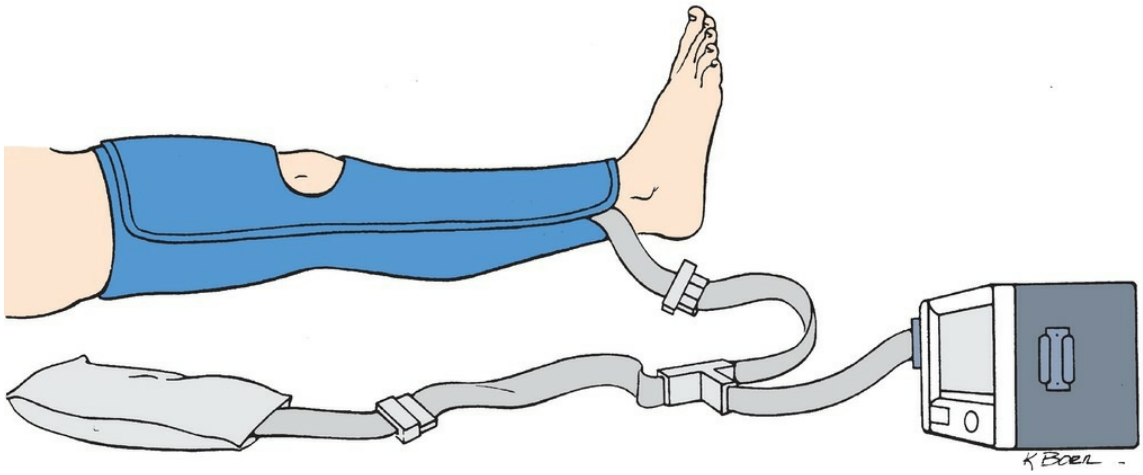

Figure 7-4. Pneumatic compression. Pressures of 35 to 20 mm Hg are sequentially applied from the ankle to the thigh, producing an increase in blood flow velocity and improved venous clearing.

Pulmonary Complications

Causes and Clinical Manifestations

1. Atelectasis.
   a. Incomplete expansion of the lung or portion of it occurring within 48 hours of surgery.
   b. Attributed to the absence of periodic deep breaths.
   c. A mucus plug closes a bronchiole, causing the alveoli distal to the plug to collapse.
   d. Symptoms are typically absent but may include mild to severe tachypnea, tachycardia, cough, fever, hypotension, and decreased breath sounds and chest expansion of the affected side.
2. Aspiration.

a. Caused by the inhalation of food, gastric contents, water, or blood into the tracheobronchial system.
b. Anesthetic agents and opioids depress the central nervous system, causing inhibition of gag or cough reflexes.
c. NG tube insertion renders upper and lower esophageal sphincters partially incompetent.
d. Gross aspiration has 50% mortality.
e. Symptoms depend on the severity of aspiration and may be silent or become evident within minutes, including tachypnea, dyspnea, cough, bronchospasm, wheezing, rhonchi, crackles, hypoxia, and frothy sputum.

3. Pneumonia.
   a. An inflammatory response in which cellular material replaces alveolar gas.
   b. In the postoperative patient, most commonly caused by gram-negative bacilli because of impaired oropharyngeal defense mechanisms.
   c. Predisposing factors include atelectasis, upper respiratory infection, copious secretions, aspiration, dehydration, prolonged intubation or tracheostomy, history of smoking, and impaired normal host defenses (cough reflex, mucociliary system, alveolar macrophage activity).
   d. Symptoms include dyspnea, tachypnea, pleuritic chest pain, fever, chills, hemoptysis, cough (rusty or purulent sputum), and decreased breath sounds over the involved area.

Preventive Measures

1. Report evidence of upper respiratory infection to the surgeon.
2. Suction nasopharyngeal or bronchial secretions if the patient cannot clear his or her own airway.
3. Use proper patient positioning to prevent regurgitation and aspiration.
4. Recognize the predisposing causes of pulmonary complications:
   a. Infections—mouth, nose, sinuses, and throat.
   b. Aspiration of vomitus.
   c. History of heavy smoking and chronic pulmonary disease.
   d. Obesity.
5. Avoid oversedation.

Nursing Interventions and Management

1. Monitor the patient's progress carefully on a daily basis to detect early signs and symptoms of respiratory difficulties.
   a. Slight temperature, pulse, and respiration elevations.
   b. Apprehension and restlessness or a decreased LOC.
   c. Complaints of chest pain, signs of dyspnea, or cough.
2. Promote full aeration of the lungs.
   a. Turn the patient frequently.
   b. Encourage the patient to take 10 deep breaths hourly, holding each breath to a count of five and

exhaling.

c. Use a spirometer or other device that encourages the patient to ventilate more effectively.
d. Assist the patient in coughing in an effort to bring up mucus secretions. Have patient splint chest or abdominal wound to minimize discomfort associated with deep breathing and coughing.
e. Encourage and assist the patient to ambulate as early as the health care provider will allow.

3. Initiate specific measures for particular pulmonary problems.
   a. Provide cool mist or heated nebulizer for the patient exhibiting signs of bronchitis or thick secretions.
   b. Encourage the patient to take fluids to help "liquefy" secretions and facilitate expectoration (in pneumonia).
   c. Elevate the head of the bed and ensure proper administration of prescribed oxygen.
   d. Prevent abdominal distention—NG tube insertion may be necessary.
   e. Administer prescribed antibiotics for pulmonary infections.

Pulmonary Embolism

Causes

1. Pulmonary embolism (PE) is caused by the obstruction of one or more pulmonary arterioles by an embolus originating somewhere in the venous system or in the right side of the heart.
2. Postoperatively, the majority of emboli develop in the pelvic or iliofemoral veins before becoming dislodged and traveling to the lungs.

Clinical Manifestations

1. Sharp, stabbing pains in the chest.
2. Anxiousness and cyanosis.
3. Pupillary dilation and profuse perspiration.
4. Rapid and irregular pulse becoming imperceptible—leads rapidly to death.
5. Dyspnea, tachypnea, and hypoxemia.
6. Pleural friction rub (occasionally).

Nursing Interventions and Management

1. Administer oxygen with the patient in an upright sitting position (if possible).
2. Reassure and calm the patient.
3. Monitor vital signs, ECG, and arterial blood gases.
4. Treat for shock or heart failure, as needed.
5. Give analgesics or sedatives, as directed, to control pain or apprehension.
6. Prepare for anticoagulation or thrombolytic therapy or surgical intervention. Management depends on the severity of the PE.

NURSING ALERT Massive PE is life-threatening and requires immediate intervention to maintain the patient's cardiorespiratory status.

Urinary Retention

Causes

1. Occurs postoperatively, especially after operations of the rectum, anus, vagina, or lower abdomen.
2. Often seen in patients having epidural or spinal anesthesia.
3. Caused by spasm of the bladder sphincter.
4. More common in male patients because of inherent increases in urethral resistance to urine flow.
5. Can lead to urinary tract infection and possibly renal failure.

Clinical Manifestations

1. Inability to void or voiding small amounts at frequent intervals.
2. Palpable bladder.
3. Lower abdominal discomfort.

Preventive Measures and Management

1. Help patient to sit or stand (if permissible) because many patients are unable to void while lying in bed.
2. Provide patient with privacy.
3. Run tap water—frequently, the sound or sight of running water relaxes spasm of bladder sphincter.
4. Use warmth to relax sphincters (eg, a sitz bath or warm compresses).
5. Notify health care provider if the patient does not urinate regularly after surgery.
6. Administer antispasmodic as directed to reduce painful bladder spasm.
7. Catheterize only when all other measures are unsuccessful. SCIP recommends removing an indwelling catheter within 24 hours. Use of bladder scanner can reduce the need for catheterization by checking for residual urine noninvasively.

NURSING ALERT Recognize that when a patient voids small amounts (30 to 60 mL every 15 to 30 minutes), this may be a sign of an overdistended bladder with "overflow" of urine.

Intestinal Obstruction

Intestinal obstructions result in a partial or complete impairment to the forward flow of intestinal contents. Most obstructions occur in the small bowel, especially at its narrowest point—the ileum. (See page 515 for a full discussion of intestinal obstruction.)

Preventive Measures and Management

1. Monitor for adequate bowel sound return after surgery. Assess bowel sounds and the degree of abdominal distention (may need to measure abdominal girth); document these findings every shift.
2. Monitor and document characteristics of emesis and NG drainage.
3. Relieve abdominal distention by passing a nasoenteric suction tube as ordered.
4. Replace fluid and electrolytes.
5. Monitor fluid, electrolyte (especially potassium and sodium), and acid–base status.
6. Administer opioids judiciously because these medications may further suppress peristalsis.
7. Prepare the patient for surgical intervention if the obstruction continues unresolved.
8. Closely monitor the patient for signs of shock.
9. Provide frequent reassurance to the patient; use nontraditional methods to promote comfort (touch, relaxation, imagery).

Wound Infection

Wound infections are the second most common health care–related infection. The infection may be limited to the surgical site (60% to 80%) or may affect the patient systemically.

Causes

1. Exposed tissues during long operations, operations on contaminated structures, gross obesity, old age, chronic hypoxemia, and malnutrition are directly related to an increased infection rate.
2. The patient's own flora is most commonly implicated in wound infections (*Staphylococcus aureus*).
3. Other common culprits in wound infection include *Escherichia coli*, *Klebsiella*, *Enterobacter*, and *Proteus*.
4. Wound infections typically present 5 to 7 days postoperatively.
5. Factors affecting the extent of infection include:
    a. Type, virulence, and quantity of contaminating microorganisms.
    b. Presence of foreign bodies or devitalized tissue.
    c. Location and nature of the wound.
    d. Amount of dead space or presence of hematoma.
    e. Immune response of the patient.
    f. Presence of adequate blood supply to wound.
    g. Presurgical condition of the patient (eg, age, alcoholism, diabetes, malnutrition).

Clinical Manifestations

1. Redness, excessive swelling, tenderness, and warmth.
2. Red streaks in the skin near the wound.
3. Pus or other discharge from the wound.
4. Tender, enlarged lymph nodes in the axillary region or groin closest to the wound.

5. Foul smell from the wound.
6. Generalized body chills or fever.
7. Elevated temperature and pulse.
8. Increasing pain from the incision site.

GERONTOLOGIC ALERT Older adults do not readily produce an inflammatory response to infection, so they may not present with fever, redness, and swelling. Increasing pain, fatigue, anorexia, and mental status changes are signs of infection in older patients.

NURSING ALERT Mild, transient fevers appear postoperatively as a result of tissue necrosis, hematoma, or cauterization. Higher sustained fevers arise with the following four most common postoperative complications: atelectasis (within the first 48 hours), wound infections (in 5 to 7 days), urinary infections (in 5 to 8 days), and thrombophlebitis (in 7 to 14 days).

Preventive Measures and Management

1. Preoperative.
   a. Encourage the patient to achieve an optimal nutritional level. Enteral or parenteral alimentation may be ordered preoperatively to reduce hypoproteinemia with weight loss.
   b. Reduce preoperative hospitalization to a minimum to avoid acquiring nosocomial infections.
2. Operative.
   a. Follow strict sterile technique throughout the operative procedure.
   b. When a wound has exudate, fibrin, desiccated fat, or nonviable skin, it is not approximated by primary closure but through secondary (delayed) closure.
3. Postoperative.
   a. Keep dressings intact, reinforcing if necessary, until prescribed otherwise.
   b. Use strict sterile technique when dressings are changed.
   c. Monitor and document the amount, type, and location of drainage. Ensure that all drains are working properly. (See Table 7-1 for expected drainage amounts from common types of drains and tubes.)
4. Postoperative care of an infected wound.
   a. The surgeon removes one or more stitches, separates the wound edges, and looks for infection using a hemostat as a probe.
   b. A culture is taken and sent to the laboratory for bacterial analysis.
   c. Wound irrigation may be done; have an aseptic syringe and saline available.

d. A drain may be inserted or the wound may be packed with sterile gauze.

e. Antibiotics are prescribed.

f. Wet-to-dry dressings may be applied (see page 103).

g. If deep infection is suspected, the patient may be taken back to the operating room.

Table 7-1 Expected Drainage from Tubes and Catheters and Catheters

DEVICE	SUBSTANCE	DAILY DRAINAGE
• Foley catheter • Ileal conduit • Suprapubic catheter	Urine	500–700 mL/24 hr first 48 hr; then 1,500–2,500 mL/24 hr
• Gastrostomy tube	Gastric contents	Up to 1,500 mL/24 hr
• Chest tube	Blood, pleural fluid, air	Varies: 500–1,000 mL first 24 hr
• Ileostomy	Small bowel contents	Up to 4,000 mL in first 24 hr; then <500 mL/24 hr
• Miller-Abbott tube	Intestinal contents	Up to 3,000 mL/24 hr
• NG tube	Gastric contents	Up to 1,500 mL/24 hr
• T tube	Bile	500 mL/24 hr

Wound Dehiscence and Evisceration

Causes

1. Commonly occurs between the 5th and 8th day postoperatively when the incision has weakest tensile strength; greatest strength is found between the 1st and 3rd postoperative day.
2. Chiefly associated with abdominal surgery.
3. This catastrophe is commonly related to:
   a. Inadequate sutures or excessively tight closures (the latter compromises blood supply).
   b. Hematomas and seromas.
   c. Infections.
   d. Excessive coughing, hiccups, retching, and distention.
   e. Poor nutrition and immunosuppression.
   f. Uremia and diabetes mellitus.
   g. Steroid use.

Preventive Measures

1. Apply an abdominal binder for heavy or elderly patients or those with weak or pendulous abdominal walls.
2. Encourage the patient to splint the incision while coughing.
3. Monitor for and relieve abdominal distention.
4. Encourage proper nutrition with emphasis on adequate amounts of protein and vitamin C.

Clinical Manifestations

1. Dehiscence is indicated by a sudden discharge of serosanguineous fluid from the wound.
2. Patient complains that something suddenly "gave way" in the wound.
3. In an intestinal wound, the edges of the wound may part and the intestines may gradually push out. Observe for drainage of peritoneal fluid on dressing (clear or serosanguineous fluid).

Nursing Interventions and Management

1. Stay with patient and have someone notify the surgeon immediately.
2. If the intestines are exposed, cover with sterile, moist saline dressings.
3. Monitor vital signs and watch for shock.
4. Keep patient on absolute bed rest.
5. Instruct the patient to bend the knees, with head of the bed elevated in semi-Fowler position to relieve abdominal tension.
6. Assure patient that the wound will be properly cared for; attempt to keep patient calm and relaxed.
7. Prepare patient for surgery and repair of the wound.

Psychological Disturbances

Depression

1. Cause—perceived loss of health or stamina, pain, altered body image, various drugs, and anxiety about an uncertain future.
2. Clinical manifestations—withdrawal, restlessness, insomnia, nonadherence to therapeutic regimens, tearfulness, and expressions of hopelessness.
3. Nursing interventions and management.
    a. Clarify misconceptions about surgery and its future implications.
    b. Listen to, reassure, and support the patient.
    c. If appropriate, introduce the patient to representatives of ostomy, mastectomy, or amputee support groups.
    d. Involve the patient's family and support people in care; psychiatric consultation is obtained for severe depression.

Delirium

1. Cause—prolonged anesthesia, cardiopulmonary bypass, drug reactions, sepsis, alcoholism (delirium tremens), electrolyte imbalances, and other metabolic disorders.
2. Clinical manifestations—disorientation, hallucinations, perceptual distortions, paranoid delusions, reversed day–night pattern, agitation, and insomnia; delirium tremens often appears within 72 hours of last alcoholic drink and may include autonomic overactivity—tachycardia, dilated pupils, diaphoresis, and fever.
3. Nursing interventions and management.

a. Assist with the assessment and treatment of the underlying cause (restore fluid and electrolyte balance, discontinue the offending drug).
b. Reorient the patient to environment and time.
c. Keep surroundings calm.
d. Explain in detail every procedure done to the patient.
e. Sedate the patient, as ordered, to reduce agitation, prevent exhaustion, and promote sleep. Assess for oversedation.
f. Allow extended periods of uninterrupted sleep.
g. Reassure family members with clear explanations of the patient's aberrant behavior.
h. Have contact with the patient as much as possible; apply restraints to the patient only as a last resort if safety is in question and if ordered by the health care provider.

WOUND CARE

See additional online content: Procedure Guidelines 7-1 and 7-2.

PROCEDURE GUIDELINES 7-1

Changing Surgical Dressings

GENERAL CONSIDERATIONS

1. The procedure of changing dressings, then examining and cleaning the wound, uses the principles of sterility.

2. The initial dressing change is usually done by the surgeon, especially for craniotomy, orthopedic, or thoracotomy procedures; subsequent dressing changes are the nurse's responsibility.

EQUIPMENT

Sterile

- Gloves
- Scissors, forceps (disposable packs available)
- Appropriate dressing materials
- Sterile saline solution
- Cotton-tipped swabs
- Culture tubes (if infection suspected)
- For draining a wound: add extra gauze and packing material, absorbent pads, and an irrigation set

Unsterile

- Gloves
- Plastic bag for discarded dressings
- Tape, proper size and type
- Pads to protect the patient's bed
- Gown for the nurse if the wound is purulent or infected

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Inform the patient of dressing change. Explain the procedure and have the patient lie in bed.	1. Enhances cooperation.
2. Avoid changing dressings near mealtime.	2. May affect appetite.
3. Ensure privacy by drawing the curtains or closing the door; expose the dressing site.	3. May reduce anxiety.
4. Respect the patient's modesty and prevent the patient from being chilled.	4–5. For protection of the patient.
5. Wash your hands thoroughly.	
6. Place dressing supplies on a clean, flat surface (overbed table).	6. Increases efficiency.
7. If linen protection is needed, place a clean towel or plastic bag under part of the body where the wound is located.	
8. Cut (or tear) off pieces of tape to be used in dressing change.	8. Having all supplies ready to use increases efficiency.
9. Place a disposable bag nearby to collect soiled dressings.	
10. Determine how many and what types of dressings are necessary. Open each dressing by peeling apart the edges of the package (maintain the sterility of the dressing). Leave each dressing within the open package.	10. Prepare enough supplies, but take care not to waste dressings.
Removing old dressing	
1. Put on gloves.	1. Unsterile gloves are sufficient if care is used not to touch wound.
2. Loosen all tape and gently pull tape ends toward the wound. It helps to hold skin taut with one hand while carefully peeling up an edge of the tape with the other hand.	2. This process is less painful and less disturbing to the healing process (avoids pulling the wound edges apart and traumatizing sensitive skin).
3. Remove old dressings, one layer at a time, and place them in a disposable bag.	3. Hasty removal of dressing can cause trauma to the wound and dislodge existing drains.
4. Removal of adherent dressings may be facilitated by moistening dressing with sterile saline solution.	4. This process is less painful and less traumatic to the delicate healing tissues.

Nursing Action	Rationale
Obtaining a wound culture	
1. Use sterile technique.	1. Prevents contamination of a clean wound or culture media, or to prevent further contamination of a "dirty" wound.
2. Open the sterile package of gloves; open the package containing the sterile syringe and needle; open the package containing a cotton-tipped culture swab. Keep all products within their sterile open packages until use.	2. Preparation for sterile procedure.
3. Put on sterile gloves.	
4. Aspirate a generous amount of drainage liquid into the syringe; inject it into an anaerobic tube. If liquid material is unobtainable, swab the desired area with a cotton-tipped culture swab, attempting to get maximum saturation.	4. It is important to collect culture specimen before wound is cleaned. The swab is the more common approach to wound cultures.
5. Make sure that specimen is properly labeled and sent to the laboratory for study.	
Cleansing the simple surgical wound	
1. Use sterile technique.	
2. Open the package of sterile gloves; open the sterile cleaning supplies (cotton-tipped applicators, sterile gauze sponges, sterile solution cup, sterile saline solution).	2. Preparation for sterile procedure. Pour a sterile solution (preferably saline) into the solution cup before putting on sterile gloves.
3. Put on sterile gloves.	
4. Clean along the wound edges using a small circular motion from one end of the incision to the other; be sure to clean each side of the wound separately. Repeat the process using another moistened gauze or swab until the entire incision is clean. Do not scrub back and forth across the incision line.	4. Prevents contamination and mechanical trauma of wound.
5. Sterile saline solution is the cleansing agent of choice. Topical antiseptics (ie, povidone-iodine, chlorhexidine) may be used on intact skin surrounding the wound but should never be used within the wound.	5. Most of the antiseptic agents are caustic to tissues and impair healing. The old saying "Never put anything in a wound that you couldn't put in your eye" is a truthful one.
6. Repeat the same process with the drain site. Always clean the drain site separately from the primary incision site.	6. Reduces the risk of cross-contamination.
7. Discard used cleaning supplies in the disposable bag.	7. This will be incinerated later.
8. Pat the incision site and drain the site dry with a sterile dressing sponge.	8. Prepares the wound for final dressing.
Dressing the wound	
1. Maintain sterile technique with the use of sterile gloves.	
2. After the wound is dry, apply the appropriate dressing, taking into consideration the nature of wound.	
3. Tape dressing, using only the amount of tape required for secure attachment of dressing. Applying a "skin prep" on site to be taped can facilitate fixation and reduce irritation.	3. Excessive use of tape can cause irritation and trauma to intact skin.
4. When dressing the drain site:	
a. Use a premade drain pad (can be prepared by making a 2-inch [5-cm] slit, with sterile scissors, in 4 × 4 inches gauze pad).	a. The slit allows gauze to fit around the drainage tube.

Nursing Action	Rationale
b. Gently slip the sponge around the drain; repeat the process with the second drain sponge, placing it at a right angle to the other pad (see accompanying figure).	b. Placement of the drain sponges in this manner allows for circumferential coverage of the drain site.
 *Dressing the drainage tube insertion site.* Make sure that one pad is placed at a right angle to the second sponge so the slits are going in different directions. If drainage is heavy, a sterile absorbent pad or extra gauze may be placed over all.	
5. When dressing an excessively draining wound:	
a. Consider the need for extra dressings and packing material.	a. More dressing materials are needed to absorb excess fluid.
b. Use Montgomery straps if frequent dressing changes are required	b. Frequent dressing changes can damage surrounding, intact skin owing to the frequent application and removal of tape.
 Montgomery straps alleviate the problem.	
c. Excessively draining wounds may be "pouched," much like an ostomy bag.	c. Protects surrounding skin, saves nursing time, and facilitates accurate assessment of drainage.
d. Protect skin surrounding wound from copious or irritating drainage (such as gastrointestinal drainage) by applying some type of skin barrier.	d. Maintaining the cleanliness and integrity of surrounding tissue is essential for successful overall wound healing.
Follow-up care	
1. Assess the patient's tolerance to the procedure and help make the patient more comfortable.	
2. Discard the disposable items according to facility protocol and clean equipment that is to be reused.	2. Prevents transmission of pathogenic organisms.
3. Wash your hands.	
4. Record the nature of the procedure and the condition of the wound as well as patient reaction.	4. For continuity of care.

PROCEDURE GUIDELINES 7-2

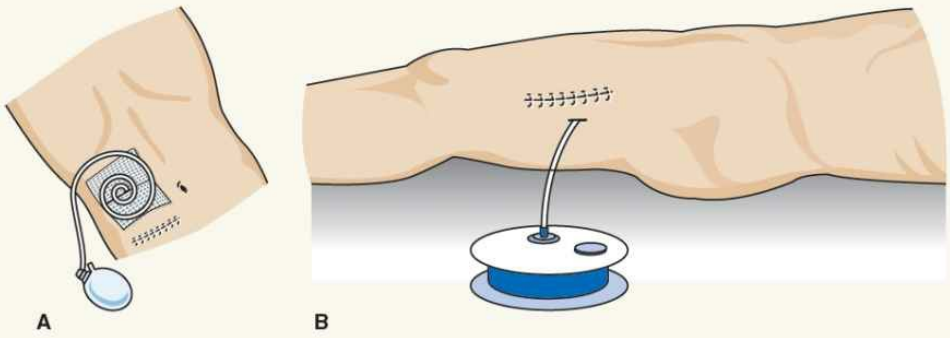
Changing Surgical Dressings

EQUIPMENT

- A calibrated collection container
- Nonsterile gloves

PROCEDURE

Nursing Action	Rationale
1. When the evacuator is full (200 to 800 mL, depending on size of evacuator), it is time to empty it. A good rule is to empty every 8 hr, or more frequently, if necessary.	1. Negative pressure is dissipated as the evacuator fills.
2. Carefully remove the plug, maintaining its sterility.	2. Minimizes risk of wound infection.
3. Empty the contents of the evacuator into the calibrated container.	3. Measures drainage.
4. Place the evacuator on a flat surface.	4. Permits adequate compression.
5. Clean the opening and the plug with an alcohol sponge.	5. Maintains cleanliness of outlet.
6. Compress the evacuator completely (see accompanying figure).	6. Removes air.



Types of surgical drains: **(A)** Jackson-Pratt; **(B)** Hemovac. Catheters drain the incision after surgery. Drainage is drawn into the portable wound suction unit.

7. Replace the plug while the evacuator is compressed.	7. Reestablishes negative pressure (suction).
8. As the evacuator expands, a negative pressure of approximately 45 mm Hg is produced.	8. Any fluid and blood in tissues is sucked into the evacuator. Negative pressure is not great enough to suck the soft tissues into the holes of the drainage catheter.
9. Check system for proper operation.	9. Look for fluid entering the system; if none, look for disconnections.
10. Secure an evacuator to the patient's dressing; if the patient is ambulatory, it may be fastened to the patient's clothing.	10. Permits the patient to move without disturbing closed suction.
11. Make sure that the drainage catheters are positioned off the incisional site.	11. Minimizes the trauma and contamination of wound.
12. Wash your hands thoroughly.	12. Prevents cross-contamination with other patients and staff.
13. Record the character and amount of drainage.	13. Evaluates fluid balance.

KEY DECISION POINT If no drainage is observed, ensure that catheter is positioned within the wound and there are no kinks in the drain tubing. Report lack of drainage, which may signal time for removal of drain, which acts as a portal for possible wound infection.

Wounds and Wound Healing

A *wound* is a disruption in the continuity and regulatory processes of tissue cells; *wound healing* is the restoration of that continuity. Wound healing, however, may not restore normal cellular function.

Wound Classification

Mechanism of Injury

1. Incised wounds—made by a clean cut of a sharp instrument, such as a surgical incision with a scalpel.
2. Contused wounds—made by blunt force that typically does not break the skin but causes considerable tissue damage with bruising and swelling.
3. Lacerated wounds—made by an object that tears tissues, producing jagged, irregular edges; examples include glass, jagged wire, and blunt knife.
4. Puncture wounds—made by a pointed instrument, such as an ice pick, bullet, or nail.

Degree of Contamination

1. Clean—an aseptically made wound, as in surgery, that does not enter the alimentary, respiratory, or genitourinary tracts.
2. Clean-contaminated—an aseptically made wound that enters the respiratory, alimentary, or genitourinary tracts. These wounds have slightly higher probability of wound infection than do clean wounds.
3. Contaminated—wounds exposed to excessive amounts of bacteria. These wounds may be open (avulsive) and accidentally made or may be the result of surgical operations in which there are major breaks in sterile techniques or gross spillage from the gastrointestinal tract.
4. Infected—a wound that retains devitalized tissue or involves preoperatively existing infection or perforated viscera. Such wounds are often left open to drain.

Physiology of Wound Healing

The phases of wound healing—inflammation, reconstruction (proliferation), and maturation (remodeling)—involve continuous and overlapping processes.

Inflammatory Phase (Lasts 1 to 5 Days)

1. Vascular and cellular responses are immediately initiated when tissue is cut or injured.
2. Transient vasoconstriction occurs immediately at the site of injury, lasting 5 to 10 minutes, along with the deposition of a fibrinoplatelet clot to help control bleeding.
3. Subsequent dilation of small venules occurs; antibodies, plasma proteins, plasma fluids, leukocytes, and red blood cells leave the microcirculation to permeate the general area of injury, causing edema, redness, warmth, and pain.
4. Localized vasodilation is the result of direct action by histamine, serotonin, and prostaglandins.
5. Polymorphic leukocytes (neutrophils) and monocytes enter the wound to engage in destruction and

ingestion of wound debris. Monocytes predominate during this phase.

6. Basal cells at the wound edges undergo mitosis; resultant daughter cells enlarge, flatten, and creep across the wound surface to eventually approximate the wound edges.

Proliferative Phase (Lasts 2 to 20 Days)

1. Fibroblasts (connective tissue cells) multiply and migrate along fibrin strands that are thought to serve as a matrix.
2. Endothelial budding occurs on nearby blood vessels, forming new capillaries that penetrate and nourish the injured tissue.
3. The combination of budding capillaries and proliferating fibroblasts is called *granulation tissue*.
4. Active collagen synthesis by fibroblasts begins by the 5th to 7th day, and the wound gains tensile strength.
5. By 3 weeks, the skin obtains 30% of its preinjury tensile strength, intestinal tissue about 65%, and fascia 20%.

Remodeling Phase (21 Days to Months or Years)

1. Scar tissue is composed primarily of collagen and ground substance (mucopolysaccharide, glycoproteins, electrolytes, and water).
2. From the start of collagen synthesis, collagen fibers undergo a process of lysis and regeneration. The collagen fibers become more organized, aligning more closely to each other and increasing in tensile strength.
3. The overall bulk and form of the scar continue to change once maturation has started.
4. Typically, collagen production drops off; however, if collagen production greatly exceeds collagen lysis, keloid (greatly hypertrophied, deforming scar tissue) will form.
5. Normal maturation of the wound is clinically observed as an initial red, raised, hard immature scar that molds into a flat, soft, and pale mature scar.
6. The scar tissue will never achieve greater than 80% of its preinjury tensile strength.

Types of Wound Healing

(See Figure 7-5.)

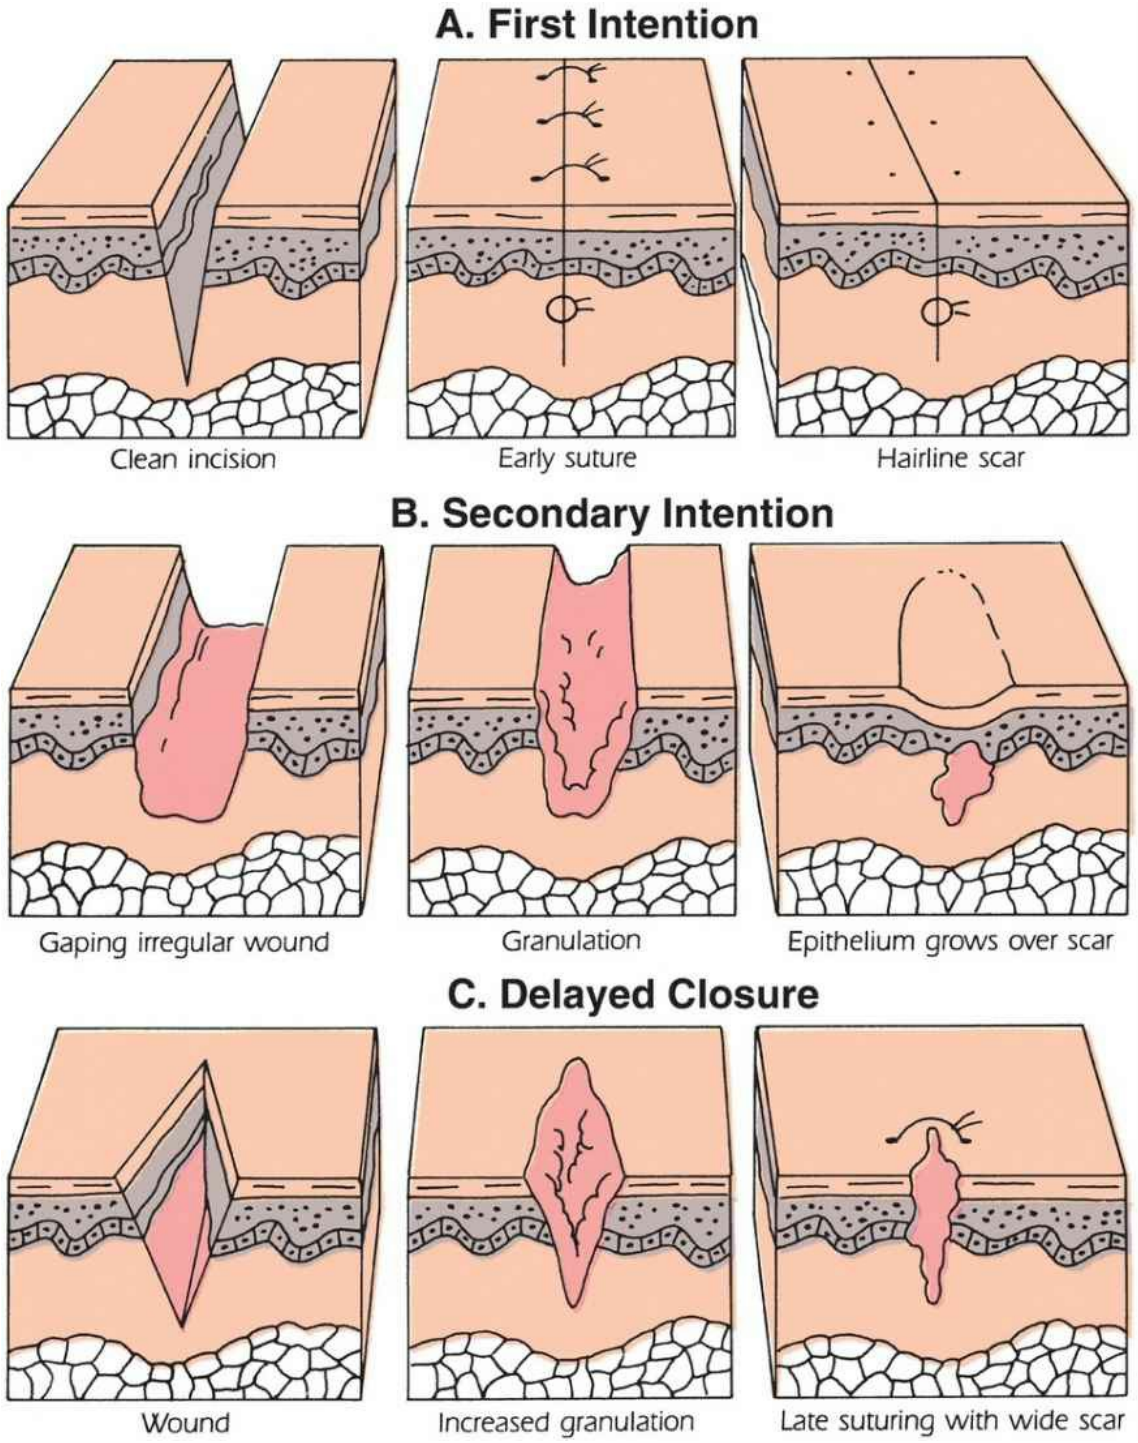


Figure 7-5. Classification of wound healing. (A) First intention: A clean incision is made with primary closure; there is minimal scarring. **(B)** Second intention: The wound is left open so that granulation can occur; a large scar results.**(C)** Delayed closure: The wound is initially left open and later closed when there is no further evidence of infection. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

First Intention Healing (Primary Closure)

1. Wounds are made sterile by minor debridement and irrigation, with a minimum of tissue damage and tissue reaction; wound edges are properly approximated with sutures.
2. Granulation tissue is not visible and scar formation is typically minimal (keloid may still form in susceptible people).

Secondary Intention Healing (Granulation)

1. Wounds are left open to heal spontaneously or are surgically closed at a later date; they need not be infected.
2. Examples in which wounds may heal by secondary intention include burns, traumatic injuries, ulcers, and suppurative infected wounds.
3. The cavity of the wound fills with a red, soft, sensitive tissue (granulation tissue), which bleeds easily. A scar (cicatrix) eventually forms.
4. In infected wounds, drainage may be accomplished by the use of special dressings and drains. Healing is thus improved.
5. In wounds that are later sutured, the two opposing granulation surfaces are brought together.
6. Secondary intention healing produces a deeper, wider scar.

Wound Management

Many factors promote wound healing, such as adequate nutrition, cleanliness, rest, and position, along with the patient's underlying psychological and physiologic state. Of added importance is the application of appropriate dressings and drains.

Dressings

Purpose of Dressings

1. To protect the wound from mechanical injury.
2. To splint or immobilize the wound.
3. To absorb drainage.
4. To prevent contamination from bodily discharges (feces, urine).
5. To promote hemostasis, as in pressure dressings.
6. To debride the wound by combining capillary action and the entwining of necrotic tissue within its mesh.
7. To inhibit or kill microorganisms by using dressings with antiseptic or antimicrobial properties.
8. To provide a physiologic environment conducive to healing.
9. To provide mental and physical comfort for the patient.
10. To encourage healing by applying localized subatmospheric pressure at site of wound as in negative pressure dressings.

Advantages of Not Using Dressings

When the initial dressing on a clean, dry, and intact incision is removed, it is often not replaced; this may occur within 24 hours after surgery.

1. Permits better visualization of the wound.
2. Eliminates conditions necessary for growth of organisms (warmth, moisture, and darkness).
3. Minimizes adhesive tape reaction.
4. Aids bathing.

Types of Dressings

1. Dry dressings.
    a. Used primarily for wounds closing by primary intention.
    b. Offers good wound protection, absorption of drainage, and aesthetics for the patient and provides pressure, if needed, for hemostasis.
    c. Disadvantage—they adhere to the wound surface when drainage dries. (Removal can cause pain and disruption of granulation tissue.)
2. Wet-to-dry dressings.
    a. These are useful for infected wounds that must be debrided and closed by secondary intention.

b. Gauze saturated with sterile saline (preferred) or an antimicrobial solution is packed into the wound, eliminating dead space.
c. The wet dressings are then covered by dry dressings (gauze sponges or absorbent pads).
d. As drying occurs, wound debris and necrotic tissue are absorbed into the gauze dressing by capillary action.
e. The dressing is changed when it becomes dry (or just before). If there is excessive necrotic debris on the dressing, more frequent dressing changes are required.

3. Wet-to-wet dressings.
   a. Used on clean open wounds or on granulating surfaces. Sterile saline or an antimicrobial agent may be used to saturate the dressings.
   b. Provides a more physiologic environment (warmth, moisture), which can enhance the local healing processes as well as ensure greater patient comfort. Thick exudate is more easily removed.
   c. Disadvantage—surrounding tissues can become macerated, there is an increased risk for infection, and bed linens become damp.

Types of Surgical Dressing Supplies

1. Hydrophobic occlusive (petroleum gauze).
   a. This is an impermeable, nonadhering dressing that protects wounds from air- and moisture-borne contamination.
   b. It is used around chest tubes and any fistula or stoma that drains digestive juices.
   c. It is relatively nonabsorptive.
2. Hydrophilic permeable (oil-based gauze, Telfa pads).
   a. Allows drainage to penetrate the dressing but remains somewhat nonadhering.
   b. For wounds with light to moderate exudate.
   c. Oil-based gauze used on abraded and open ulcerated or granulating wounds.
   d. May also be used to pack "caverns and sinuses" of large open wounds.
   e. Telfa pads are generally reserved for simple, closed, stable wounds.
3. Dressing sponges (general-use gauze sponges).
   a. Gauze sponges come in various sizes (most commonly 2″ × 2″, 4″ × 4″) and may be used for simple dry dressings, wet-to-dry dressings, or wet-to-wet dressings. Gauze allows for better absorption of drainage and necrotic wound debris.
4. All-absorbent combined dressing.
   a. Large (5″ × 9″, 8″ × 10″) cotton-filled dressing that is typically used as an "overdressing," covering gauze or hydrophilic dressings for added wound protection, stabilization of dressings, and drainage absorption.
   b. May also be used unaccompanied over intact surgical wounds.
5. High-bulk gauze bandage ("fluffs")—primarily used for packing large wounds that are undergoing

healing by secondary intention.

6. Drain sponge—a gauze sponge with a premade slit, which makes the dressing highly suitable for drain sites and tracheostomy sites.
7. Transparent film dressing.
   a. Highly elastic dressing, adjusts exceptionally well to body contours. It is permeable to oxygen and water vapor but generally impermeable to liquids and bacteria.
   b. Controversies (related to incidence of infection) have reduced its use.
   c. Most common indications include covering arterial and venous catheter sites as well as protecting vulnerable skin exposed to shearing forces.
   d. Commonly used for surgical wounds over gauze dressing to replace tape.
8. Silver-impregnated dressing.
   a. Highly effective for difficult-to-heal wounds. They are available in many sizes and should be placed directly on the wound without any topical ointment.
   b. These may replace need for wet-to-dry or wet-to-wet dressings.
9. Negative pressure wound therapy—promotes healing by applying a vacuum through a special sealed dressing.
   a. Evacuates wound fluid, stimulates granulation tissue, and decreases bacterial colonization.
   b. Contraindicated on patients with active bleeding or taking anticoagulants.
   c. NPWT has different interface materials, safety features, and recommended applications by manufacturers. The use is dependent on wound type, provider's preference for gauze or foam packing, and product available.

Drains

Purpose of Drains

1. Drains are placed in wounds only when abnormal fluid collections are present or expected to decrease pooling of body fluids in wound.
2. Drains are usually placed in compartments (eg, joints and pleural space) that are intolerant to fluid accumulation and have large blood supply (eg, neck and kidney), in areas of large superficial tissue dissection (eg, the breast), or in infected wounds.
3. Collection of body fluids in wounds can be harmful in the following ways:
   a. Provides culture media for bacterial growth.
   b. Causes increased pressure at surgical site, interfering with blood flow to area.
   c. Causes pressure on adjacent areas.
   d. Causes local tissue irritation and necrosis (because of fluids such as bile, pus, pancreatic juice, and urine).

Wound Drainage

1. Drains are commonly made of latex, polyvinyl chloride, or silicone and placed within either wounds or body cavities.
2. Drains placed within wounds are typically attached to portable (or, rarely, wall) suction with a collection container.
    a. Examples include the Hemovac, Jackson-Pratt, and Surgivac drainage systems.
3. Drains may also be used postoperatively to form hollow connections from internal organs to the outside to drain a body fluid, such as the T tube (bile drainage), nephrostomy, gastrostomy, jejunostomy, and cecostomy tubes.
4. Drains create a portal for entry and exit of infectious microorganisms; therefore, the risk of infection exists.
5. Drains within wounds are removed when the amount of drainage decreases over a period of days or, rarely, weeks.
6. Body fluid drains are often left in for longer periods of time.
    a. Careful handling of these drains and collection bags is essential.
    b. Accidental early removal may result in caustic drainage leaking within the tissues.
    c. The risk is reduced within 7 to 10 days when a wall of fibrous tissue has been formed.
7. The amount of drainage varies with the procedure. Drains are commonly not needed on some surgical procedures (eg, appendectomy, cholecystectomy, abdominal hysterectomy), which usually have minimal wound drainage.

NURSING ALERT The greatest amount of drainage is expected during the first 24 hours; closely monitor dressing and drains.

Nursing Process Overview

EVIDENCE BASE Leaper, D., & Edmiston, C. (2017). World Health Organization: global guidelines for the prevention of surgical site infection. *Journal of Hospital Infection*, *95*(2), 135–136.

Nursing Assessment

The wound should be assessed every 15 minutes while the patient is in the PACU. Thereafter, the frequency of wound assessment is determined by the nature of the wound, the degree of drainage, and the facility protocol. Assessment and documentation of the wound's status should occur at least every shift until the patient is discharged.

Determine the following, which will affect wound healing:

1. What type of surgery did the patient have?
2. Was hemostasis in the operating room effective?
3. Has the patient received blood to sustain an adequate hematocrit (and promote perfusion to wound)?
4. What is the patient's age?
5. What is the nutritional status? What was it preoperatively?
    a. Is current intake of protein and vitamin C adequate?
    b. Is the patient obese or cachectic?
6. What underlying medical conditions does the patient have, and what medications is he or she taking that could affect wound healing (eg, diabetes mellitus, steroids)?
7. How long has the patient been hospitalized preoperatively? (Longer preoperative facility stays can increase complications.)
8. How is the wound held together?
    a. Staples, nylon sutures, adhesive strips, tension sutures, surgical skin glue.
    b. If the wound is left open, how is it being treated? Is granulation tissue present?
9. Are drains in place? What kind? How many?
    a. Is portable suction being used?
    b. Is the amount of drainage consistent with the nature of surgery?
10. What kinds of dressings are being used?
    a. Are they saturated?
    b. Is the amount and type of drainage consistent with nature of the surgery?
11. How does the wound appear?
    a. Is there evidence of edema, irritation, inflammation?
    b. Are the wound edges well approximated?

c. Is the wound clean and dry?

12. How does the patient appear?
    a. Are there signs of wound pain or discomfort?
    b. Is fever or elevated white blood cell count present?
    c. Does the patient express concern about the wound and potential disfigurement?
13. Does the patient understand the purpose of wound therapies, and can he or she or his or her family effectively carry out discharge instructions about wound care?

Nursing Diagnoses

- Risk for Infection related to surgical wound.
- Impaired Tissue Integrity related to surgical wound.
- Acute Pain related to wound dressing procedures.

Nursing Interventions

Preventing Infection

1. Prior to the first dressing change (usually performed by the surgeon), reinforce the dressing when saturated.
2. Gather supplies (dressings, tape, scissors, sterile saline solution, cotton swabs, extra gauze and culture materials if indicated).
3. Explain procedure to the patient. Provide privacy and comfort by premedicating for pain.
4. Wash your hands thoroughly and don gloves. Ensure strict aseptic technique during dressing changes.
5. Remove the old dressings and assess the wound. Loosen all tapes gently. Place dressings in disposable bag. Assess the wound for future documentation noting any redness, swelling, exudate, warmth, bleeding, swelling, or discoloration.
6. Culture the wound if necessary, using sterile technique. Wear sterile gloves. Dab the wound using the culture swab attempting saturation. Place it in the tube. Prepare and label this specimen and send to the lab.
7. Using sterile gloves, clean around the wound edges with saline moist gauze. Do not go over the area with the same gauze. Repeat as necessary with a fresh gauze until all the areas are clean.
8. Dress the wound with sterile gauze and secure with tape. Use minimal amount of tape to assure adhesive.
9. Discard contaminated items, ensure the patient's comfort, and document the procedure.

Enhancing Tissue Integrity Through Healing

1. Assess the patient's nutritional intake; consult with the patient's health care provider if supplemental nutritional intake is required.
2. Minimize strain on the incision site:
    a. Use appropriate tape, bandages, and binders.

b. Have the patient splint abdominal and chest incision when coughing.
c. Instruct the patient in proper way to get out of bed while minimizing incision strain (eg, for abdominal incision, have the patient turn on one side and push self up with the dependent elbow and the opposite hand).

3. Assess and accurately document the condition of the incision site each shift.

Relieving Pain

1. Give the patient prescribed medication before painful dressing changes.
2. Continue to assess for pain at incision site.
3. Consider nonpharmacologic pain relief, such as use of music therapy, relaxation exercises, and acupressure, as indicated.

Patient Education

Before discharge, instruct the patient and family on techniques and rationale for wound care.

1. Report immediately to the health care provider if the following signs of infection occur:
   a. Redness, marked swelling, tenderness, and increased warmth around wound.
   b. Pus or unusual discharge and foul odor from wound.
   c. Red streaks in the skin near wound.
   d. Chills or fever (over 100°F [37.8°C]).
2. Follow the directives of the health care provider regarding activity allowances.
3. Keep the wound clean (the patient may shower unless contraindicated by the health care provider; avoid tub bathing until sutures or staples are removed); never vigorously rub near the suture line; pat dry.
   a. Sutures that have been placed need to be removed or may be absorbable. Gently cleanse one to two times daily. Dab dry.
   b. Staples if used will need to be removed after 7 to 14 days. Keep the site clean and dry.
   c. Skin glue, which may be used, allows for good approximation of tissue. Keep the wound clean, and remove glue with medical adhesive removing wipes according to your doctor's instruction.
4. Contact your health care provider for follow-up appointment.
5. Report to the health care provider if after 2 months the incision site continues to be red, thick, and painful to pressure (probable beginning of keloid formation).

Evaluation: Expected Outcomes

- No signs of infection.
- Wound edges well approximated without gaping.
- Pain at level 1 or 2.

POSTOPERATIVE DISCHARGE INSTRUCTIONS

It is of primary importance that the nurse makes sure that the patient has been given specific and individualized discharge instructions. These should be written by a provider and reinforced verbally by the nurse. A provider telephone contact should be included as well as information regarding follow-up care and appointments. The instructions should be signed by the patient, provider, and nurse, and a copy becomes part of the patient's chart. Forms and procedures for discharge instructions may vary per facility.

Patient Education

Rest and Activity

1. It is common to feel tired and frustrated about not being able to do all the things you want; this is normal.
2. Plan regular naps and quiet activities, gradually increasing your exercise over the following weeks.
3. When you begin to exercise more, start by taking a short walk two or three times per day. Consult your health care provider if more specific exercises are required.
4. Climbing stairs in your home may be surprisingly tiring at first. If you have difficulty with this activity, try going upstairs backward ("scooching") on your "bottom" until your strength has returned.
5. Consult your health care provider to determine the appropriate time to return to work.

Eating

1. Follow dietary instructions provided at the facility before your discharge.
2. Your appetite may be limited or you may feel bloated after meals; this problem should lessen as you become more active. (Some prescribed medications can cause this.) If symptoms persist, consult your health care provider.
3. Eat small, regular meals and make them as nourishing as possible to promote wound healing.

Sleeping

1. If sleeping is difficult because of wound discomfort, try taking your pain medication at bedtime.
2. Attempt to get sufficient sleep to aid in your recovery.

Wound Healing

1. Your wound will go through several stages of healing. After initial pain at the site, the wound may feel tingling, itchy, numb, or tight (a slight pulling sensation) as healing occurs.
2. Do not pull off any scabs because they protect the delicate new tissues underneath. They will fall off without any help when ready. Change the dressing according to the surgeon's instructions.

Bowels

1. Irregular bowel habits can result from changes in activity and diet or the use of some drugs.
2. Avoid straining because it can intensify discomfort in some wounds; instead, use a rocking motion while trying to pass stool.
3. Drink plenty of fluids and increase the fiber in your diet through fruits, vegetables, and grains, as tolerated.
4. It may be helpful to take a mild laxative. Consult your health care provider if you have any questions.

Bathing and Showering

1. You may get your wound wet 3 days after your operation if the initial dressing has already been changed (unless otherwise advised).
2. Showering is preferable because it allows for thorough rinsing of the wound.
3. If you are feeling too weak, place a plastic or metal chair in the shower so you can be seated during showering.
4. Be sure to dry your wound thoroughly with a clean towel and dress it as instructed before discharge.

Clothing

1. Avoid tight belts and underwear and other clothes with seams that may rub against the wound.
2. Wear loose clothing for comfort and to reduce mechanical trauma to wound.

Driving

1. Ask your health care provider when you may resume driving. Safe driving may be affected by your pain medication. In addition, any violent jarring from an accident may disrupt your wound.

Bending and Lifting

1. How much bending, stretching, and lifting you are allowed depends on the location and nature of your surgery.
2. Typically, for most major surgeries, you should avoid lifting anything heavier than 5 pound for 4 to 8 weeks.
3. It is ideal to obtain home assistance for the first 2 to 3 weeks after discharge.

OVERVIEW AND ASSESSMENT

Cancer is a large group of malignant diseases characterized by a lack of controlled growth and the ability to spread to distant sites.

The malignant cell is able to invade the surrounding tissue and regional lymph nodes. Primary cancer usually has a predictable natural history and pattern of spread.

Metastasis is the secondary growth of the primary cancer in another organ. The cancer cell migrates through a series of steps to another area of the body. Metastasis begins with local invasion followed by detachment of cancer cells that disseminate via the lymphatics and blood vessels and eventually establish a secondary tumor in another area of the body. Lymph nodes are often the first site of distant spread (see Figure 8-1).

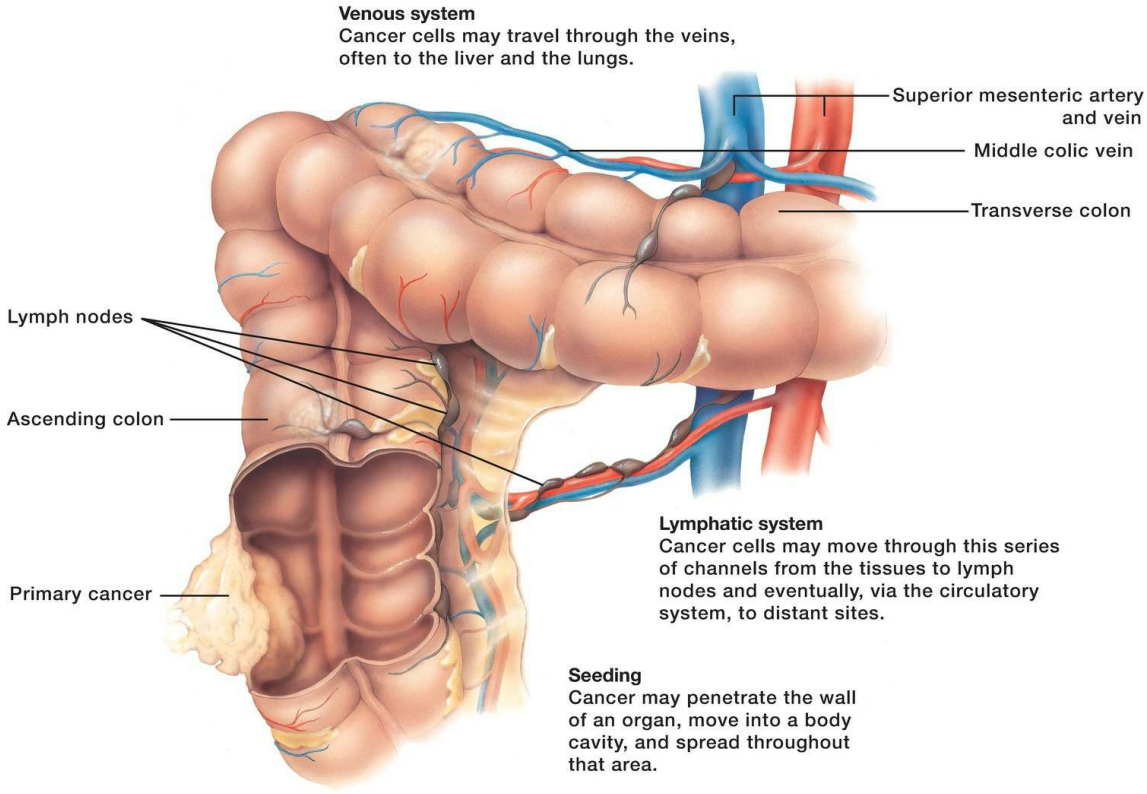

Figure 8-1. How cancer spreads. Cancer cells may invade nearby tissues or metastasize (spread) to other organs. Cancer cells may move to other tissues by any or all of three routes: venous, lymphatic, or seeding. (Springhouse. [2001]. *Anatomical chart company atlas of pathophysiology* [1st ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

---

1. According to the American Cancer Society (ACS), there will be 1,735,350 predicted new diagnoses of invasive cancer diagnosed in the United States in 2018. This does not include basal and squamous cell skin cancers as well as noninvasive cancers or DCIS (ductal carcinoma *in situ*).
2. According to the International Agency for Research on Cancer, there were 14.7 million new cancer cases in 2016 worldwide. This number is expected to rise as developing countries adopt Western lifestyles such as smoking and lack of exercise.
3. Although the death rate continues to decline, cancer is the second leading, under heart disease, cause of death in the United States, with 729, 000 predicted for 2018.
4. There are multiple factors that can lead to the development of cancer.
    a. Spontaneous transformation of the cell where no causative agent is identified.
    b. Exposure to a chemical or other carcinogen.
    c. Genetic mutations or alterations.
    d. Exposure to virus.
5. Age is the most outstanding risk factor for cancer.
    a. Cancer incidence increases progressively with age.
    b. Approximately 87% of people diagnosed with cancer are over age 50.
    c. Prostate, lung and bronchus, and colorectal cancers account for 32% of all cases in men. For women, the three most commonly diagnosed cancers are breast, lung and bronchus, and colorectal, representing one half of all cases; breast cancer alone is expected to account for 30% all new cancer diagnoses in women.
6. Forty two percent of all cancers in the United States are related to lifestyle habits (eg, smoking, alcohol consumption, diet, physical activity) and environmental carcinogens.
    a. Tobacco is the single greatest cause of cancer-related deaths and is attributed to more than 480,000 deaths annually from various cancers and 42,000 from secondhand smoke.
    b. Excessive alcohol intake is associated with cancers of the mouth, larynx, throat, esophagus, and liver, especially when combined with smoking. In addition, regular consumption of alcohol is associated with an increased risk of breast cancer. This may be due to alcohol-induced increases in circulating

estrogens.

c. Being overweight or obese is clearly linked with an increased risk of many cancers, including cancers of the breast (in postmenopausal women), colon and rectum, endometrium, esophagus, kidney, and pancreas. Overweight and obesity may also be associated with increased risk of gallbladder, liver, cervical, and ovarian cancer, non-Hodgkin lymphoma, and multiple myeloma.

d. Exposure to carcinogens, such as asbestos, benzene, and radiation, increases the risk of developing certain types of cancer.

e. Solar ultraviolet radiation exposure is related to an increased risk of skin cancers.

7. There is a hereditary predisposition to specific forms of cancers that have been linked to certain events within a gene (eg, BRCA1 and BRCA2 in breast cancer; MLH1, MSH2, and MSH6 in colon cancer).
8. Infections and viruses are associated with an increased risk of certain forms of cancer.
   a. Human papillomavirus (HPV)—cervical cancer, anal cancers, upper airway cancers.
   b. Epstein-Barr virus—lymphoma, nasopharyngeal cancers, gastric cancer, Kaposi sarcoma.
   c. Cytomegalovirus—Kaposi sarcoma, colon cancer.
   d. Human immunodeficiency virus (HIV)—Kaposi sarcoma, lymphoma.
   e. Human T-lymphocyte virus—T-cell lymphoma/leukemia.
   f. Hepatitis B and C—hepatocellular cancer.
   g. *Helicobacter pylori*—gastric lymphoma (possibly).
9. Five-year survival rates are increasing with improved therapy and earlier detection.
10. Ongoing genetic research is searching for the ability to correct and modify hereditary susceptibility.
11. Patterns of incidence and death rates vary with sex, age, race, and geographic location (see Table 8-1).

Table 8-1 Leading New Cancer Cases and Deaths: 2018 Estimates

ESTIMATED NEW CASES*		ESTIMATED DEATHS	
MALE	**FEMALE**	**MALE**	**FEMALE**
Prostate 164,690 (19%)	Breast 266.120 (30%)	Lung and bronchus 83,550 (27%)	Lung and bronchus 70,500 (25%)
Lung and bronchus 121,680 (14%)	Lung and bronchus 112,350 (12%)	Colon and rectum 27,390 (9%)	Breast 40,920 (14%)
Colon and rectum 75,610 (8%)	Colon and rectum 64,640 (8%)	Prostate 29,430 (8%)	Colon and rectum 23,240 (8%)
Urinary bladder 62,380 (7%)	Uterine corpus 63,230 (7%)	Pancreas 23,020 (7%)	Pancreas 21,310 (7%)
Melanoma of the skin 55,150 (6%)	Thyroid 40,900 (5%)	Liver and intrahepatic bile duct 20,540 (6%)	Ovary 14,070 (5%)
Kidney and renal pelvis 42,680 (5%)	Melanoma of the skin 36,120 (4%)	Leukemia 14,270 (4%)	Uterine corpus 11,350 (4%)
Non-Hodgkin lymphoma 41,730 (5%)	Non-Hodgkin lymphoma 32,950 (4%)	Esophagus 12,850 (4%)	Leukemia 10,100 (4%)
Leukemia 35,030 (4%)	Leukemia 27,270 (3%)	Urinary bladder 12,520 (4%)	Liver and intrahepatic bile duct 9,660 (3%)
Oral cavity and pharynx 37,160 (4%)	Pancreas 26,240 (3%)	Non-Hodgkin lymphoma 11,510 (4%)	Non-Hodgkin lymphoma 8,400 (3%)
Liver and hepatic bile duct 30,610 (3%)	Kidney and renal pelvis 22,660 (3%)	Kidney and renal pelvis 10,010 (3%)	Brain and other nervous system 7,340 (3%)
All sites 856,370 (100%)	All sites 878,980 (100%)	All sites 323,630 (100%)	All sites 286,010 (100%)

**Excludes basal and squamous cell skin cancers and in situ carcinoma except urinary bladder.*

Nutrition, Physical Activity, and Cancer

EVIDENCE BASE American Cancer Society. (2017). American Cancer Society guidelines on nutrition and physical activity for cancer prevention: Reducing the risk of cancer with healthy food choices and physical activity. Available: *www.cancer.org/healthy/eat-healthy-get-active/acs-guidelines-nutrition-physical-activiy-cancer-prevention/guidlelines.*

U.S. Department of Health and Human Services and U.S. Department of Agriculture. (2015). 2015—2020 dietary guidelines for Americans (8th ed.). Available: *http://health.gov/dietaryguidelines/2015/guidelines.*

1. Lifestyle does influence the risk of cancer. Among nonsmokers, dietary choices and physical activity are the most important modifiable risks of cancer. The ACS and the U.S. Department of Health and Human Services have established guidelines on nutrition and physical activity to promote optimal health and prevent cancer.
2. Achieve and maintain a healthy weight.
    a. Be as lean as possible throughout life without being underweight.
    b. Avoid excessive weight gain at all ages.
    c. Limit the consumption of high-calorie foods and beverages.
3. Adopt a physically active lifestyle.
    a. Adults should engage in 150 minutes of moderate intensity or 75 minutes of vigorous activity each week, preferably spread throughout the week.
    b. Children and adolescents should engage in 60 minutes/day of moderate to vigorous physical activity each day, with vigorous intensity activity at least 3 days a week.
    c. Limit sedentary behavior such as sitting, lying down, and watching TV and other forms of screen-based entertainment.
    d. Doing any intentional physical activity above usual activities can have many health benefits.
4. Consume a healthy diet, with emphasis on plant sources.
    a. Choose foods and drinks in amounts that help achieve and maintain a healthy weight.
    b. Eat at least 2½ cups of vegetables and fruits daily.
    c. Choose whole grains over processed (refined) grains.
    d. Limit intake of processed and red meats.
    e. Limit alcoholic beverages to no more than 2 drinks per day for men and 1 drink per day for women.
5. ACS recommendations for community action:
    a. Increase access to healthful foods in schools, worksites, and communities.
    b. Changes in public policy and community environment that help individuals make smart food choices and portion sizes to help maintain a healthy weight.

c. Provide safe, enjoyable spaces for physical activity in schools.
d. Provide for safe, physically active transportation (such as biking and walking) and recreation in communities.

Detection and Prevention

Primary prevention and secondary prevention are effective measures in decreasing mortality and morbidity of many cancers. Most cancers, however, are diagnosed after reported symptoms. The ACS recommends specific primary and secondary prevention measures to reduce an individual's risk of cancer death.

Primary Prevention

The assessment or reduction of risk factors before the disease occurs:

1. Make appropriate lifestyle changes.
2. Stop smoking.
3. Limit alcohol intake.
4. Eat a healthy diet as outlined above.
5. Be physically active: maintain a healthy weight and follow exercise guidelines outlined above.
6. Avoid sun exposure, especially during the hours of 10 A.M. and 4 P.M., and cover exposed skin with sunscreen with a skin protection factor of 15 or higher.
7. Those at high risk for certain cancers should consider genetic counseling and testing.
8. Chemoprevention—the use of natural or synthetic substances to reduce the risk of developing cancer.
   a. Aspirin—can decrease the risk of colorectal cancer.
   b. Tamoxifen and raloxifene—can reduce the risk of breast cancer in women who are at high risk by nearly 50%.
   c. Finasteride—may reduce the risk of prostate cancer.
   d. COX-2 inhibitors—may reduce the risk of colorectal cancer.
   e. Metformin—may decrease the risk of breast, colon, and possibly other cancers.
   f. Statins—may reduce the risk of prostate, lung, colorectal, and breast cancers.
9. Vaccinations—HPV causes most cervical, vulvar, vaginal, anal, and oropharyngeal cancers in women and most oropharyngeal, anal, and penile cancers in men. These could be prevented by HPV vaccinations. The Advisory Committee on Immunization Practices in conjunction with the Centers for Disease Control and Prevention has established guidelines on the use of this vaccine.
   a. Routine HPV vaccination is recommended for males and females ages 11 to 13 in two doses; may begin as early as age 9.
   b. For persons initiating vaccination on or after their 15th birthday, 3 doses are recommended.
   c. HPV vaccination is not currently recommended for persons over age 27.
   d. Screening for cervical cancer should continue in both vaccinated and unvaccinated women according to current ACS early detection guidelines.

EVIDENCE BASE The Advisory Committee on Immunization Practices. (2018). *General recommendations on immunizations*. Available: *www.cdc.gov/vaccines/pubs/ACIP-list.htm.*

Secondary Prevention

EVIDENCE BASE Smith, R., Andrews, K. et al. (2016). Cancer screening in the United States, 2017: A review of current American Cancer Society guidelines and current issues in cancer screening. *CA_Cancer journal for Clinicians*, *67*, 100–121.

---

1. The goal of screening is early detection to improve overall outcome and survival. Performing routine screening tests should be based on whether these tests are adequate to detect a potentially curable cancer in an otherwise asymptomatic person and are also cost-effective.
2. Screening should be based on an individual's age, sex, family history of cancer, ethnic group or race, previous iatrogenic factors (prior radiation therapy or drugs such as DES), and history of exposure to environmental carcinogens. See Table 8-2 for ACS recommendations for screening.

Table 8-2 ACS Recommendations for the Early Detection of Cancer in Average-Risk, Asymptomatic Individuals

CANCER SITE	POPULATION	TEST OR PROCEDURE	FREQUENCY
Breast	Women, ages 40–54 yr	Mammography	Women should undergo regular screening mammography starting at age 45 yr; women aged 45 to 54 yr should be screened annually; women should have the opportunity to begin annual screening between ages 40 and 44 yr
	Women, aged >55 yr	Mammography	Women aged ≥55 should transition to biennial screening or have the opportunity to continue screening annually; women should continue screening mammography as long as their overall health is good and they have a life expectancy of ≥10 yr
Cervix	Women, ages 21–29 yr	Pap test	Cervical cancer screening should begin at age 21 yr; for women ages 21–29 yr, screening should be done every 3 yr with conventional or liquid-based Pap tests; for women ages 30–65 yr, screening should be done every 5 yr with both the HPV test and the Pap test (preferred) or every 3 yr with the Pap test alone (acceptable); women aged >65 yr who have had ≥3 consecutive negative Pap tests or ≥2 consecutive negative HPV and Pap tests within the last 10 yr, with the most recent test occurring in the last 5 yr, and women who have had a total hysterectomy (for a benign condition) should stop cervical cancer screening; women at any age should not be screened annually by any screening method.
	Women, ages 30–65 yr	Pap test and HPV DNA test	
	Women, ages 66+	Pap test and HPV DNA test	
	Women who have had a total hysterectomy	Pap test and HPV DNA test	
Colorectal	Men and women, ages ≥50 yr, for all tests listed	Guaiac-based fecal occult blood test (gFOBT) with at least 50% test sensitivity for cancer, or fecal immunochemical test (FIT) with at least 50% test sensitivity for cancer, or	Annual: Testing stool sampled from regular bowel movements with adherence to manufacturer's recommendation for collection techniques and number of samples is recommended; "throw in the toilet bowl" FOBTs are also not recommended; compared with guaiac-based tests for the detection of occult blood, immunochemical tests are more patient friendly and are likely to be equal or better in sensitivity and specificity; there is no justification for repeating FOBT in response to an initial positive finding; patients should be referred to colonoscopy
		Multitarget stool DNA test, or	Every 3 yr, per manufacturer's recommendation
		Flexible sigmoidoscopy (FSIG), or	Every 5 yr. FSIG can be performed alone, or consideration can be given to combining FSIG performed every 5 yr with a highly sensitive gFOBT or FIT performed annually.
		DCBE, or	Every 5 yr.
		Colonoscopy	Every 10 yr.
		CT colonography	Every 5 yr.
Endometrial	Women, at menopause		At the time of menopause, women at average risk should be informed about the risks and symptoms of endometrial cancer and strongly encouraged to report any unexpected bleeding or spotting to their physicians.
Lung	Current or former smokers ages 55–74 yr in good health with at least a 30-pack-year history	Low-dose helical CT (LDCT)	Clinicians with access to high-volume, high-quality lung cancer screening, and treatment centers should initiate a discussion about annual lung cancer screening with apparently healthy patients ages 55–74 yr who have at least a 30-pack-year smoking history and who currently smoke or have quit within the past 15 yr; a process of informed and shared decision-making with a clinician related to the potential benefits, limitations, and harms associated with screening for lung cancer with LDCT should occur before any decision is made to initiate annual lung cancer screening; smoking cessation counseling remains a high priority for clinical attention in discussions with current smokers, who should be informed of their continuing risk of lung cancer; screening should not be viewed as an alternative to smoking cessation.
Prostate	Men, ages ≥50 yr	DRE and PSA	Men who have at least a 10-yr life expectancy should have an opportunity to make an informed decision with their health care provider about whether to be screened for prostate cancer, after receiving information about the potential benefits, risks, and uncertainties associated with prostate cancer screening. Prostate cancer screening should not occur without an informed decision-making process.

ACS, American Cancer Society; BSE, breast self-examination; CBE, clinical breast examination; CT, computed tomography; DCBE, double-contrast barium enema; DRE, digital rectal examination; FOBT, fecal occult blood test; FIT, fecal immunochemical test; FSIG, flexible sigmoidoscopy; gFOBT, guaiac-based toilet bowl FOBT tests; HPV, human papillomavirus; Pap, Papanicolaou; PSA, prostate-specific antigen.

Diagnostic Evaluation

1. Complete medical history and physical examination, radiographic evaluation based on the affected body system, laboratory evaluation, and biopsy.
2. Biopsy of tumor site to determine pathologic diagnosis. Biopsy results are used to determine the histology and/or grade of a tumor, which is a prerequisite for planning definitive therapy. Additional cellular and genetic features are also used to form a final diagnosis and guide treatment.
    a. Fine-needle aspiration (FNA)—technique in which cells are aspirated from the tumor using a needle and syringe. FNA cannot distinguish invasive from noninvasive malignancy. Negative results do not rule out malignancy. However, it is inexpensive, causes little discomfort, and can be performed in an outpatient or office setting.
    b. Needle core—needle biopsies are performed with a large-bore needle. This technique retrieves a small piece of intact tumor tissue, which yields enough tissue to adequately diagnose most tumor types. It is highly accurate and can be performed in an office or outpatient setting.
    c. Open biopsy—may be required for some lesions to determine a definitive diagnosis. This is done in the operating room, is more expensive, and requires a longer period of recovery. The biopsy may be incisional, sampling only part of the tumor, or excisional, removing the total tumor.
3. Classification of tumor type is based on tissue and cellular staining. Differences in cytoplasmic and nuclear staining distinguish one cell type from another and identify their stage of differentiation. The grade of the tumor (rating of 1 to 4) is based on how well differentiated the tissue or cells appear or how closely tumor cell resemble normal cells. The higher the grade, the less differentiated it is, which is associated with poorer prognosis.
4. Flow cytometry testing of tumor tissue determines the deoxyribonucleic acid (DNA) content and indicates potential risk of recurrence.
5. Special stains are performed to determine specific markers or proteins that may help guide treatment (ie, estrogen and progesterone receptors for breast cancer).
6. Laboratory tests—including complete blood count (CBC) with differential; platelet count; and blood chemistries, including liver function tests, blood urea nitrogen (BUN), and creatinine—are done to determine baseline values.
    a. Further testing depends on cancer diagnosis.
7. Blood markers (carcinoembryonic antigen, PSA, CA 15-3, CA 125) may be appropriate to follow response to therapy.
8. Imaging procedures—chest x-ray, nuclear medicine scan, CT scanning, magnetic resonance imaging (MRI), and positron-emission tomography (PET) are used to determine evidence or extent of metastasis.

Staging

Staging is necessary at the time of diagnosis to determine the extent of disease (local vs. metastatic), to determine prognosis, and to guide proper management.

1. The American Joint Committee on Cancer (AJCC) has developed a simple classification system that can be applied to all tumor types. It is a numeric assessment of tumor size (T), presence or absence of

regional lymph node involvement (N), and presence or absence of distant metastasis (M) (see Box 8-1).

2. No standard evaluation exists for all cancers. Workup depends on the patient, tumor type, symptoms, and medical knowledge of the natural history of that cancer.

BOX 8-1 AJCC Classification System of Tumors

T—primary tumor

Tx—primary cannot be evaluated

T0—no evidence of primary tumor

Tis—carcinoma *in situ*

T1, T2, T3, T4—increasing size and/or local extent of primary tumor

N—presence or absence or regional lymph node involvement

Nx—regional lymph nodes are unable to be assessed

N0—no regional lymph node involvement

N1, N2, N3—increasing involvement of regional lymph nodes

M—absence or presence of distant metastasis

Mx—unable to assess

M0—absence of distant metastasis

M1—presence of distant metastasis

PROCEDURES AND TREATMENT

The method of treatment depends on the type of malignancy, the specific histologic cell type, stage, presence of metastasis, and condition of the patient. It is important to have ongoing discussions with the patient regarding the goals of therapy and whether those goals are achievable. The four modalities of treatment are surgery, chemotherapy/hormonal therapy, radiation therapy, and biologic therapy or a combination of these modalities. Many clinical trials are available to evaluate the effectiveness of a new drug or other therapy. Refer patients who are interested in clinical trials to CancerTrials at *https://www.cancer.gov/about-cancer/treatment/clinical-trials*.

Surgical Management

Surgical management may be curative to remove all or a portion of the primary tumor, it may be the only treatment a patient requires or it may be used in conjunction with other modalities, or it may be used in the palliative setting to alleviate symptoms.

Types of Surgical Procedures

The role of surgery can be divided into several approaches: preventive, primary surgery, cytoreductive, salvage treatment, palliative treatment, and reconstructive.

1. Preventive/prophylactic surgery—removal of lesions that, if left in the body, are at risk of developing into cancer; for example, resection of polyps in the rectum or mastectomy in women who are at high risk.
2. Primary surgery—complete surgical removal of a malignant tumor and may include regional lymph nodes and neighboring structures. This can be performed laparoscopically in some cases.
3. Cytoreductive surgery—partial removal of bulk of disease. This is performed when the spread of tumor precludes the removal of all disease. In some cases, this approach improves survival when used in combination with chemotherapy (ie, ovarian cancer).
4. Salvage treatment—use of an extensive surgical approach to treat a local recurrence.
5. Palliative treatment—attempts to relieve the complications of cancer (eg, obstruction of the GI tract, pain produced by tumor extension into surrounding nerves).
6. Reconstructive/rehabilitative surgery—repair of defects from previous radical surgical resection; can be performed early (breast reconstruction) or delayed (head and neck surgery).

Chemotherapy

Chemotherapy is the use of antineoplastic drugs given systemically that may promote tumor cell destruction by interfering with cellular function and reproduction.

Principles of Chemotherapy Administration

1. The intent of chemotherapy is to destroy as many tumor cells as possible with minimal effect on healthy cells.
2. Cancer cells depend on the same mechanisms for cell division as normal cells. Damage to those mechanisms leads to cell death.
3. Chemotherapy is utilized in different clinical settings:
    a. Adjuvant chemotherapy is the use of systemic treatment following surgery and/or radiation therapy. Adjuvant therapy is given to patients who have no evidence of residual disease but who are at high risk for relapse. The justifications for adjuvant chemotherapy are the high recurrence rate after surgery for apparently localized tumors, the inability to identify cured patients at the time of surgery, and the failure of therapy to cure these patients after recurrence of disease.
    b. Neoadjuvant chemotherapy is the use of systemic treatment prior to primary surgery or radiation. The goal is to shrink or downstage the primary tumor to improve the effectiveness of surgery as well as control/eradicate microscopic cancer cells. For example, patients with large breast tumors can preserve the breast and undergo lumpectomy instead of mastectomy. The goal of therapy is to decrease the amount of tissue that needs to be removed as well as to attempt to maximize cure potential.
    c. High-dose/intensive therapy is the administration of high doses of chemotherapy, usually in association with growth factor support before bone marrow transplant/stem cell rescue.
    d. Palliative chemotherapy is used when a cure is not possible to control the cancer and minimize side effects from the disease.
4. Chemotherapeutic agents can be effective on any stage of the cell life cycle. This is the reproductive process ion both normal and malignant cells. The cell cycle is divided into five stages:
    a. G0 (gap 0) resting phase: Cells are not dividing in this stage and, for the most part, are refractory to chemotherapy.
    b. G1 (gap one) postmitotic phase: Ribonucleic acid (RNA) and proteins (enzymes for DNA synthesis) are manufactured.
    c. S (synthesis) phase: DNA is replicated in preparation for cell division.
    d. G2 (gap two) premitotic phase: This is a short period; protein and RNA synthesis occurs, and the mitotic spindle apparatus is formed.
    e. M (mitosis) phase: In an extremely short period, the cell divides into two identical daughter cells.
5. Routes of administration
    a. Oral

b. Subcutaneous
c. Intravenous (IV) push (bolus) or infusion over a specified period
d. Intramuscular
e. Intrathecal/intraventricular—given by injection via an Ommaya reservoir or by lumbar puncture
f. Intra-arterial
g. Intraperitoneal cavity
h. Intravesical—into uterus or bladder
i. Topical

6. Most drug dosage is based on surface area (mg/m^2) in both adults and children. Some agents are based on AUC (area under the curve), which refers to the amount of drug exposure over time or the total drug concentration in plasma over a period of time.
7. Most chemotherapeutic agents have dose-limiting toxicities that require nursing interventions (see Table 8-3, pages 114 to 117). Chemotherapy predictably affects normal, rapidly growing cells (eg, bone marrow, GI tract lining, hair follicles). It is imperative that these toxicities be recognized early by the nurse. Patient education is very important to minimize hospital admission and readmissions.

Table 8-3 Frequently Used Chemotherapeutic Agents

CLASSIFICATION	MEDICATION NAME	ROUTE OF ADMINISTRATION	COMMON THERAPEUTIC USES	COMMON TOXICITIES	NURSING CONSIDERATIONS
Alkylating Agents	Altretamine	PO	Ovarian cancer	Nausea, vomiting, peripheral neuropathy, myelosuppression	Do not open capsules
	Cyclophosphamide	IV or PO	Lymphomas, leukemias, and a variety of solid tumors	Nausea, vomiting, diarrhea, myelosuppression, alopecia, lethargy, hemorrhagic cystitis	Ensure adequate hydration (2–3 L /d). Have patients void frequently to avoid hemorrhagic cystitis
	Busulfan	IV or PO	Chronic myelocytic leukemia, bone marrow transplantation	Pulmonary fibrosis, hypertension, tachycardia, myelosuppression, alopecia, skin pigmentation	Instruct patients to take on an empty stomach to decrease nausea/vomiting. Monitor blood counts
	Carboplatin	IV or IP	Ovarian cancer	Myelosuppression particularly platelets, alopecia, hypersensitivity reaction	Have emergency medications available for possible hypersensitivity reactions
	Chlorambucil	PO	Chronic lymphocytic leukemia, Hodgkin disease	Myelosuppression, nausea, vomiting, skin reactions, seizures	Contraindications in patients with a history of seizures
	Cisplatin	IV	Ovarian, testicular, bladder, cervical, non–small cell lung cancer, esophageal	Nausea, vomiting, myelosuppression, nephrotoxicity, hypersensitivity reactions, low electrolytes	Monitor renal function and electrolytes. Have emergency medications available for possible hypersensitivity reactions
	Dacarbazine	IV or IM	Malignant melanoma, Hodgkin lymphoma, sarcomas	Nausea, vomiting, myelosuppression, alopecia, rash	Irritant—may cause tissue necrosis if extravasated
	Ifosfamide	IV	Testicular, lymphoma, sarcomas, ovarian, bone	Hemorrhagic cystitis, nausea, vomiting, myelosuppression, confusion, encephalopathy	Always given in conjunction with mesna to decrease risk of hemorrhagic cystitis
	Melphalan	IV or PO	Multiple myeloma, ovarian, malignant melanoma	Myelosuppression, nausea, vomiting	Vesicant—Avoid extravasation
	Oxaliplatin	IV	Colorectal cancers	Nephrotoxicity, hypersensitivity reactions, peripheral neuropathy, nausea, vomiting, myelosuppression	Monitor for peripheral neuropathy. Instruct patients to avoid consuming cold beverages for 3–4 d to avoid laryngopharyngeal dysaesthesias
	Temozolomide	PO	Glioblastoma, astrocytoma, melanoma	Myelosuppression, nausea, vomiting, headache, photosensitivity	Contraindicated in patients with sensitivity to dacarbazine. Instruct patients to avoid sun exposure for several days
	Thiotepa	IV, IM, SC, IT	Breast, ovarian, bladder, lymphomas, bone marrow transplantation	Myelosuppression, nausea, vomiting, rash, fever	
Antibiotics	Bleomycin	IV, SC, IM	Head and neck cancers, cervical, lymphomas, testicular, Hodgkin's	Skin reaction, pulmonary fibrosis, fever, allergic reaction, alopecia, stomatitis	Administer a test dose in patient with lymphoma as they seem to have a higher incidence of allergic reactions
	Dactinomycin	IV	Ewing sarcoma, Wilms tumor, testicular	Myelosuppression, nausea, vomiting, alopecia, venoocclusive disease of the liver, skin rash, and fever	Vesicant—avoid extravasation
	Daunorubicin	IV	Leukemias	Myelosuppression, nausea, vomiting, alopecia, cardiomyopathy, red urine, radiation recall	Vesicant—avoid extravasation. Monitor cardiac function
	Doxorubicin	IV	Breast, ovarian, prostate, thyroid, lung, head and neck cancers, leukemia	Cardiomyopathy, alopecia, red urine, radiation recall, nausea, vomiting, red urine	Vesicant—avoid extravasation 550 mg/m² lifetime dose
	Doxorubicin liposomal	IV	Ovarian, breast, AIDS-related sarcoma	Myelosuppression, nausea, vomiting, mucositis, diarrhea, alopecia, radiation recall	Similar to Adriamycin, less cardiotoxic
	Epirubicin	IV	Breast cancer	Myelosuppression, nausea, vomiting, alopecia, heart failure, radiation recall, red urine	Vesicant—avoid extravasation
	Mitomycin	IV	Pancreatic, stomach, colon, lung, bladder, esophageal	Delayed myelosuppression, nausea, vomiting, alopecia, mucositis, renal and pulmonary dysfunction	Vesicant—avoid extravasation
	Mitoxantrone	IV	Prostate acute myelocytic leukemia	Myelosuppression, tachycardia, mucositis, nausea, vomiting, alopecia	May turn urine blue-green
Camptothecins	Irinotecan	IV	Colorectal	Diarrhea, myelosuppression	Monitor for severe diarrhea that may require delays or dose reduction
	Topotecan	IV	Ovarian, cervical, small cell lung cancer	Myelosuppression, alopecia, diarrhea, headache, fatigue	
Plant alkaloids (vinca alkaloids)	Vinblastine	IV	Hodgkin lymphoma, Kaposi sarcoma, testicular, bladder, prostate, renal cell	Myelosuppression, alopecia, peripheral neuropathy, bone pain	Vesicant—avoid extravasation
	Vincristine	IV	Hodgkin lymphoma, acute lymphoblastic leukemia, bladder, ovarian, renal cell neuroblastoma, multiple myeloma, testicular	Constipation, nausea, vomiting, alopecia, bone pain	Vesicant—avoid extravasation; monitor for severe constipation
	Vinorelbine	IV	Non–small cell lung, breast, cervical, ovarian cancer	Alopecia, diarrhea, nausea, neuropathy	Distal neuropathies, extravasation, and necrosis; should consider central access
	Etoposide	IV or PO	Small cell lung, testicular cancer	Myelosuppression, nausea, alopecia, mucositis	Monitor renal function
	Teniposide	IV	Childhood acute lymphocytic leukemia, adult neuroblastoma	Myelosuppression, nausea, vomiting, diarrhea, alopecia	Can cause hypersensitivity reactions
Antimetabolites	Azacitidine	SC, IV	MDS	Myelosuppression, nausea, vomiting, elevated serum creatinine	Administration should occur within 1 hr of reconstitution
	Methotrexate	IV, IM, IT, or PO	Lymphoma, acute lymphoblastic leukemia, breast, bladder, sarcoma	Mucositis, diarrhea, myelosuppression, acute renal failure, pneumonitis	High doses require concomitant use of leucovorin and IV fluids
	Cytarabine	IV, SC, IT, IM	Hodgkin and non-Hodgkin lymphoma, acute myelogenous leukemia, acute lymphoblastic leukemia	Nausea, vomiting, myelosuppression, cerebellar ataxia, lethargy	Side effects are dose dependent; higher doses are associated with profound myelosuppression, GI toxicity, and neurotoxicity
	5-Fluorouracil	IV or topical	Breast, colorectal, anal, gastroesophageal, hepatocellular, pancreatic, head and neck cancer	Nausea, vomiting, diarrhea, mucositis, myelosuppression, neurotoxicity, photosensitivity	Instruct patients to avoid sun exposure, use auriscreen. Leucovorin may be used concomitantly
	6-Mercaptopurine	PO	Acute lymphoblastic leukemia	Myelosuppression, nausea, vomiting, diarrhea, hepatotoxicity	Instruct patients to take on an empty stomach
	Thioguanine	PO	Acute myelogenous leukemia, acute lymphoblastic leukemia	Myelosuppression, nausea, vomiting, mucositis, diarrhea, hepatotoxicity	Instruct patients to take on an empty stomach
	Fludarabine	IV or PO	Chronic lymphocytic leukemia, non-Hodgkin lymphoma	Myelosuppression, mild nausea, vomiting, fever, interstitial pneumonitis	Monitor pulmonary function tests
	Pemetrexed	IV	Non–small cell lung cancer	Myelosuppression, renal, and liver toxicities	Must be given with folic acid starting 1 wk prior to infusion
	Gemcitabine	IV	Pancreatic, non–small cell lung, breast, bladder, ovarian, sarcoma, Hodgkin lymphoma	Nausea, vomiting, myelosuppression, flulike syndrome, fever	Warn patients of flulike symptoms that can occur the day following treatment
Taxanes	Paclitaxel	IV	Breast, ovarian, non–small cell lung, bladder, esophagus, cervical, gastric, head and neck sarcoma	Myelosuppression, peripheral neuropathy, myalgias, alopecia, fatigue	Observe closely for hypersensitivity reaction; premedication required with dexamethasone, diphenhydramine, and H2 blocker requires non-PVC IV tubing
	Docetaxel	IV	Breast, gastric, head and neck, prostate, non–small cell lung, ovarian cancer	Myelosuppression, edema, alopecia, nail changes, peripheral neuropathy	Treatment with dexamethasone prior to and for 2 d after can minimize edema
	Ixabepilone	IV	Breast cancer	Myelosuppression, fatigue, neuropathy, nausea, vomiting, diarrhea, myalgias	Observe closely for hypersensitivity reaction; premedication required with dexamethasone, diphenhydramine, and H2 blocker requires non-PVC IV tubing
Miscellaneous	Asparaginase	IM	ALL	Anaphylaxis, nausea, vomiting, hypercalcemia, fever, renal toxicity	Observe closely for anaphylaxis
	Hydroxyurea	PO	CML, myeloma	Myelosuppression, nausea, vomiting, fever	Do not open capsules
	Eribulin	IV	Breast cancer	Neutropenia, peripheral neuropathy	Not compatible with D5W
	Ixabepilone	IV	Breast cancer	Peripheral neuropathy, myelosuppression, fatigue	Avoid St. John's wort. Monitor for hypersensitivity reaction

IM, intramuscular; IP, intraperitoneal; IT, intrathecal; IV, intravenous; PO, by mouth; SQ, subcutaneous.

Chemotherapy Administration Safety Standards

EVIDENCE BASE Oncology Nursing Society. (2014). *Chemotherapy and biotherapy guidelines and recommendations for practice* (4th ed.). Pittsburgh, PA: Author.

1. Specialized education, preparation, and training of the oncology nurse who administers chemotherapy and biotherapy are essential and ensure a safe level of care for patients. The Oncology Nursing Society (ONS) offers the ONS/Oncology Nursing Credentialing Center (ONCC) Chemotherapy Biotherapy Certificate Course and provides up-to-date resources. See Standard of Care Guidelines 8-1 (page 113)

for a checklist of the competency required by ONS.

2. The American Society of Clinical Oncology's (ASCO) quality oncology practice initiative certification program requires that hospitals, infusion centers, and physician practices comply with safety standards for chemotherapy administration.
3. Check with your hospital/institutional policy on handling and administering antineoplastic drugs.
4. Cytotoxic drugs are considered hazardous to health care workers. A safe level of occupational exposure is unknown. It is important to adhere to practices to minimize occupational exposure.

STANDARD OF CARE GUIDELINES 8-1

Administering IV Chemotherapy

ONS Chemotherapy Administration Competency Evaluation

Prior to Administration

1. Coordinates time of administration with pharmacy and others as needed.
2. Verifies signed consent for treatment.
3. Verifies laboratory values are within acceptable range and reports to the provider as needed.
4. Performs independent double check of original orders with a second RN for accuracy of
    a. Protocol or regimen
    b. Agents
    c. Calculated body surface area
    d. Patient dose
    e. Schedule
    f. Route.
5. Verifies that patient education, premedication, prehydration, and other preparations are completed.

Administration

1. Compares original order to dispensed drug label at the bedside with another RN.
2. Verifies patient identification.
3. Applies gloves and gown and uses safe handling precautions.
4. Verifies adequacy of venous access and appropriate IV site selection.
5. Checks patency of IV and flushes with 5 to 10 mL normal saline.
6. Demonstrates safe administration
    a. Pushes through side arm or at hub closest to the patient, checks patency every 2 to 5 mL.
    b. Verifies appropriate rate of administration.
7. Demonstrates appropriate monitoring/observation for specific acute drug effects.
8. Verbalizes appropriate action in the event of extravasation.
9. Verbalizes appropriate action in the event of hypersensitivity reaction.

After Administration

1. Flushes line with enough fluid to clear IV tubing of drug.
2. Removes peripheral IV device or flushes/maintains vascular access device.
3. Disposes of chemotherapy waste according to policy.
4. Documents medications, education, and patient response.
5. Communicates posttreatment considerations to the patient, caregivers, and appropriate personnel.

Guidelines for Personal Protective Equipment

1. Gloves—wear two pairs of disposable gloves that are powder-free and have been tested for use with hazardous drugs. Avoid latex drugs because of potential latex sensitivity. Remove outer glove first, turning them inside out to prevent contaminated outer surfaces from touching the inner gloves. Remove the inner gloves last after discarding all contaminated items. Do not reuse gloves.
2. Gowns—wear a disposable, lint-free gown made of low-permeability fabric. The gown should have a solid front, long sleeves, tight cuffs, and back closure. The inner glove should be worn under the gown cuff and the outer glove should extend over the gown to protect the skin. Gown and gloves are meant for single use only.
3. Respirators—wear a National Institute for Occupational Health and Safety–approved respirator mask when there is a risk of aerosol exposure such as when administering chemotherapy or cleaning a spill. Surgical masks do not provide adequate protection.
4. Eye and face protection—wear a face shield and/or mask that provides splash protection whenever there is a possibility of splashing.
5. Wear personal protective equipment whenever there is a risk of chemotherapy being released into the environment such as preparation or mixing of chemotherapy, spiking/priming IV tubing, administering the drug, and when handling body fluids or chemotherapy spills.

Personal Safety to Minimize Exposure

1. Prepare cytotoxic drugs in a vertical laminar flow hood.
2. Wash hands before donning PPE and change gloves after each use, tear, puncture, or medication spill or after every 60 minutes of wear. Wash hands after removing PPE.
3. Vent vials with filter needle to equalize the internal pressure or use negative-pressure techniques.
4. Wrap gauze or alcohol pads around the neck of ampules when opening to decrease droplet contamination.
5. Wrap gauze or alcohol pads around injection sites when removing syringes or needles from IV injection ports.
6. Use puncture- and leak-proof containers for noncapped, nonclipped needles.
7. Prime all IV tubing with normal saline or other compatible solution to reduce exposure.
8. Use syringes and IV tubing with Luer locks (which have a locking device to hold needle firmly in place).
9. Label all syringes and IV tubing containing chemotherapeutic agents as hazardous material.
10. Place an absorbent pad directly under the injection site to absorb any accidental spillage.

11. Do not eat, drink, or chew gum while preparing or handling chemotherapy agents.
12. Keep all food and drink away from preparation area.
13. Avoid hand-to-mouth or hand-to-eye contact while handling chemotherapeutic agents or body fluids of the patient receiving chemotherapy.
14. If any contact with the skin occurs, immediately wash the area thoroughly with soap and water.
15. If contact is made with the eye, immediately flush the eye with water and seek medical attention.
16. Spill kits should be available in all areas where chemotherapy is stored, prepared, and administered.

Safe Disposal of Antineoplastic Agents, Body Fluids, and Excreta

1. Discard gloves and gown into a leak-proof container, which should be marked as contaminated or hazardous waste.
2. Use puncture- and leak-proof containers for needles and other sharp or breakable objects.
3. Linens contaminated with chemotherapy or excreta from patients who have received chemotherapy within 48 hours should be contained in specially marked hazardous waste bags.
4. Wear nonsterile nitrile gloves for disposing of body excreta and handling soiled linens within 48 hours of chemotherapy administration.
5. In the home, wear gloves when handling bed linens or clothing contaminated with chemotherapy or patient excreta within 48 hours of chemotherapy administration. Place linens in a separate, washable pillow case. Wash separately in hot water and regular detergent.

DRUG ALERT It is imperative that the nurse be alert for immediate complications that patients may experience during or shortly after cytotoxic therapy.

Extravasation

1. Occurs when the vesicant chemotherapy leaks out of the blood vessel and into the surrounding tissue resulting in:
   a. Blistering, begins within 3 to 5 days.
   b. Peeling and sloughing of skin, begins within 2 weeks.
   c. Tissue necrosis, usually in 2 to 3 weeks.
   d. Damage to tendons, nerves and joints.
   e. Functional and sensory impairment of the area.
   f. Disfigurement.
   g. Loss of limb.
2. Steps to take if extravasation is suspected:
   a. STOP infusion of the vesicant.
   b. Disconnect the IV tubing from the IV device. DO NOT remove the IV device or port needle.

c. Attempt to aspirate residual vesicant from the IV using a small syringe.

d. Remove the IV or port needle.

e. Assess the site of extravasation.

f. Assess symptoms experienced by the patient.

g. Notify the patient's provider.

h. Initiate appropriate management measures in accordance with type of agent (see Table 8-4).

Table 8-4 Management of Chemotherapy Extravasation

CHEMOTHERAPEUTIC AGENT	ANTIDOTE	NURSING INTERVENTION
Anthracyclines (doxorubicin, epirubicin, daunorubicin)	Dexrazoxane	Apply ice, but remove at least 15 min before dexrazoxane. Dose of dexrazoxane is based on body surface area and should be administered IV in an area other than the extravasation site, opposite arm: Day 1: 1,000 mg/m^2 Day 2: 1,000 mg/m^2 Day 3: 500 mg/m^2
Alkylating agents (nitrogen mustard, cisplatin)	Sodium thiosulfate	Prepare ⅙ molar solution and inject 2 mL for each milligram of chemotherapy suspected to have extravasated. Inject solution subcutaneously in the site using a 25G needle (change the needle with each injection). Apply ice for 6–12 hr following sodium thiosulfate injection.
Vinca alkaloids (vincristine, vinblastine, vinorelbine)	Hyaluronidase	Inject 1 mL of hyaluronidase locally as five separate injections subcutaneously into the extravasated area. Apply moderate heat for 15–20 min at least four times daily for the first 24–48 hr to disperse drug and minimize pain.
Taxanes (paclitaxel, docetaxel)	No known antidote	Apply ice for 15–20 min at least four times daily for the first 24 hr.
Antibiotics	None	Apply ice for 15–20 min at least four times daily for the first 24 hr.

Chemotherapy Follow-Up

1. Document drug dosage, site, and any occurrence of extravasation, including estimated amount of drug.
2. Observe regularly after administration for pain, erythema, induration, and necrosis, and notify the appropriate health care provider as indicated.
3. Monitor for other adverse effects of infusion.
   a. Patient may describe sensations of pain or pressure within the vessel, originating near the venipuncture site or extending 3 to 5 inches (7.5 to 12.5 cm) along the vein.
   b. Discoloration or red streak following the line of the vein (called a flare reaction, common with doxorubicin) or darkening of the vein (with 5-fluorouracil).
   c. Itching, urticaria, muscle cramps, or pressure in the arm, caused by irritation of surrounding subcutaneous tissue.

Adverse Effects of Chemotherapy

All chemotherapy drugs have adverse effects. Adverse effects are exacerbated if the patient is elderly, has comorbid conditions, or has impaired renal or hepatic function.

Adverse effects of chemotherapy are graded on a scale of 0 to 5, with 0 being no toxicity and 5 resulting in death. Scoring of adverse effects will determine if a delay in therapy is necessary, dose modification is necessary, or cessation of therapy must occur.

Alopecia

1. Most chemotherapeutic agents cause some degree of alopecia. This is dependent on the drug dose, half-life of drug, and duration of therapy.
2. Most commonly occurs on the scalp but can occur anywhere on the body.
3. Usually begins 1 to 3 weeks after administration of chemotherapy. Regrowth takes about 3 to 5 months.
4. Emotionally difficult for patients. Encourage patients to verbalize their feelings.
5. The use of scalp hypothermia and tourniquets is highly controversial.

Anorexia

1. Chemotherapy changes the reproduction of taste buds.
2. Absent or altered taste can lead to a decreased food intake.
3. Concurrent renal or hepatic disease can increase anorexia.

Diarrhea

1. Defined as loose or watery stool. If left untreated, can lead to severe dehydration, electrolyte imbalances, hospitalizations, and treatment delays.
2. Cause is multifactorial, but up to 90% of all patients receiving chemotherapy can experience diarrhea.

Fatigue

The cause of fatigue is generally unknown but can be related to anemia, weight loss, altered sleep patterns, and emotional stress.

Nausea and Vomiting

1. Caused by the stimulation of the vagus nerve by serotonin released by cells in the upper GI tract.
2. Incidence depends on the particular chemotherapeutic agent and dosage.
3. Patterns of nausea and vomiting:
    a. Anticipatory—conditioned response from repeated association between therapy and vomiting; can be prevented with adequate antiemetic control.
    b. Acute—occurs 0 to 24 hours after chemotherapy administration.
    c. Delayed—can occur 1 to 6 days after chemotherapy administration; nausea is often worse than vomiting.

Mucositis

1. Caused by the destruction of the oral mucosa, causing an inflammatory response.
2. Initially presents as a burning sensation with no changes in the mucosa and progresses to significant breakdown, erythema, and pain of the oral mucosa.
3. Consistent oral hygiene is important to avoid infection.

Neutropenia

1. Defined as an absolute neutrophil count (ANC) of 1,500/mm^3 or less.
2. Primary dose-limiting toxicity of chemotherapy.
3. Risk of infection is greatest with an ANC less than 500/mm^3.
4. Caused by suppression of the stem cell.
5. Usually occurs 7 to 14 days after administration of chemotherapy but depends on the agent used.
6. Can be prolonged.
7. Patients should be taught to avoid infection through proper handwashing and hygiene and avoiding those with illness. Eliminating raw meats, seafood, eggs, or unwashed vegetables is also recommended.
8. Patients need to be monitored and treated promptly for fever or other signs of infection.
9. Can be prevented with the use of growth factors (eg, granulocyte colony-stimulating factor [CSF], pegfilgrastim).

Anemia

1. Caused by suppression of the stem cell or interference with cell proliferation pathways.
2. May require red blood cell transfusion or injection of erythropoietin or darbepoetin.

Thrombocytopenia

1. Caused by suppression of megakaryocytes.
2. Incidence depends on the agent being used.
3. Risk of bleeding is present when platelet count falls below 50,000/mm^3.
4. Risk is high when count falls below 20,000/mm^3.
5. Risk is critical when count falls below 10,000/mm^3.
6. Patient should be taught to avoid injury (eg, no razors), vaginal douches, rectal suppositories, and dental floss during the period of thrombocytopenia.
7. May require platelet transfusions if count drops below 20,000/mm^3.

Hypersensitivity Reactions

1. Nearly all of the available chemotherapeutic agents can produce hypersensitivity reactions (HSRs) in at least an occasional patient, and some cause reactions in 5% or more of patients receiving the drug. There are several agents (L-asparaginase, paclitaxel, docetaxel, teniposide, and carboplatin) for which HSRs are frequent enough to be a major form of treatment-limiting toxicity.
2. The mechanism is unknown for most of the chemotherapeutic agents.
3. Signs and symptoms include hives, pruritus, back pain, shortness of breath, hypotension, and anaphylaxis.
4. All unexpected drug reactions should be reported to the manufacturer.

Nursing Assessment

Skin and Mucous Membranes

1. Inspect for pain, swelling with inflammation or phlebitis, necrosis, or ulceration.
2. Inspect for skin rash and characteristics (eg, whether pruritus is general or local).
3. Assess areas of erythema and associated tenderness or pruritus. Instruct the patient to avoid irritation to skin, sun exposure, or irritating soaps.
4. Assess changes in skin pigmentation.
5. Note reports of photosensitivity and tearing of the eyes.
6. Assess condition of gums, teeth, buccal mucosa, and tongue.
    a. Determine whether any taste changes have occurred.
    b. Check for evidence of stomatitis, erythematous areas, ulceration, infection, or pain on swallowing.
    c. Determine whether the patient has any complaints of pain or burning of the oral mucosa or on swallowing.

GI System

1. Assess for frequency, timing of onset, duration, and severity of nausea and vomiting episodes before and after chemotherapy.
    a. Usually occurs from 0 to 24 hours after chemotherapy but may be delayed. Anticipatory vomiting may occur after first course of therapy. Can be initiated by various cues, including thoughts, smell, or even sight of the medical personnel.
2. Observe for alterations in hydration and electrolyte balance.
3. Assess for diarrhea or constipation.
    a. Ascertain any changes in bowel patterns.
    b. Discuss the consistency of stools.
    c. Consider the frequency and duration of diarrhea (the number of stools each day for the number of days).
    d. Evaluate dietary changes or use of medications such as opioids or 5-HT3 blockers that have had an impact on diarrhea or constipation.
4. Assess for anorexia.
    a. Discuss taste changes and changes in food preferences.
    b. Ask about daily food intake and normal eating patterns.
5. Assess for jaundice, right upper quadrant abdominal pain, changes in the stool or urine, and elevated liver function tests that indicate hepatotoxicity.
6. Monitor liver function tests and total bilirubin.

Hematopoietic System

NURSING ALERT Fever greater than 101°F (38.3°C) in a patient with an ANC less than

500/mm^3 is an emergency requiring immediate administration of antibiotics.

---

1. Assess for neutropenia—ANC less than 500/mm^3.
   a. Assess for any signs of infection (pulmonary, integumentary, central nervous system, GI, and urinary).
   b. Auscultate lungs for adventitious breath sounds.
   c. Assess for productive cough or shortness of breath.
   d. Assess for urinary frequency, urgency, pain, or odor.
   e. Monitor for elevation of temperature above 101°F (38.3°C) and chills.
2. Assess for thrombocytopenia—platelet count less than 50,000/mm^3 (mild risk of bleeding); less than 20,000/mm^3 (high risk of bleeding).
   a. Assess skin and oral mucous membranes for petechiae and bruises on extremities.
   b. Assess for signs of bleeding (including nose, urinary, rectal, or hemoptysis).
   c. Assess for blood in stools, urine, or emesis.
   d. Assess for signs and symptoms of intracranial bleeding if platelet count is less than 20,000/mm^3; monitor for changes in level of responsiveness, vital signs, and pupillary reaction.
3. Assess for anemia.
   a. Assess skin color, turgor, and capillary refill.
   b. Ascertain whether patient has experienced dyspnea on exertion, fatigue, weakness, palpitations, or vertigo. Advise rest periods as needed.

Respiratory and Cardiovascular Systems

1. Assess lung sounds.
2. Assess for pulmonary fibrosis, evidenced by a dry, nonproductive cough with increasing dyspnea. Patients at risk include those over age 60, smokers, those receiving or having had pulmonary radiation, those receiving a cumulative dose of bleomycin, or those with any pre-existing lung disease.
3. Assess for signs and symptoms of heart failure or irregular apical or radial pulses.
4. Verify baseline cardiac studies (eg, electrocardiogram, multiple-gated acquisition scan/ejection fraction) before administering cardiotoxic chemotherapy such as doxorubicin.

Neuromuscular System

1. Determine whether the patient is having difficulty with fine motor activities, such as zipping pants, tying shoes, or buttoning a shirt.
2. Determine the presence of paresthesia (tingling, numbness) of fingers or toes.
3. Evaluate deep tendon reflexes.
4. Evaluate the patient for weakness, ataxia, or slapping gait.
5. Determine impact on activities of daily living and discuss changes.

6. Discuss symptoms of urinary retention or constipation.
7. Assess for ringing in ears or decreased hearing acuity.

Genitourinary System

1. Monitor urine output.
2. Assess for urinary frequency, urgency, or hesitancy.
3. Evaluate changes in odor, color, or clarity of urine sample.
4. Assess for hematuria, oliguria, or anuria.
5. Monitor BUN and creatinine.

Nursing Diagnoses

- Risk for Infection related to neutropenia.
- Risk for Bleeding related to thrombocytopenia.
- Fatigue related to anemia.
- Imbalanced Nutrition: Less Than Body Requirements related to adverse effects of therapy.
- Impaired Oral Mucous Membranes related to stomatitis.
- Ineffective Protection and risk for hypersensitivity reaction related to chemotherapy.
- Disturbed Body Image related to alopecia and weight loss.

Nursing Interventions

Preventing Infection

1. Monitor vital signs every 4 hours; report occurrence of fever greater than 101˚F (38.3˚C) and chills.
2. Provide patient education.
    a. Instruct patient to report signs and symptoms of infection:
        i. Fever greater than 101˚F (38.3˚C) and/or chills.
        ii. Mouth lesions, swelling, or redness.
        iii. Redness, pain, or tenderness at rectum.
        iv. Change in bowel habits.
        v. Areas of redness, swelling, induration, or pain on skin surface.
        vi. Pain or burning when urinating or odor from urine.
        vii. Cough or shortness of breath.
    b. Reinforce good personal hygiene habits (routine bathing [preferably a shower], clean hair, nails, and mouth care).
    c. Avoid contact with people who have a transmittable illness.
    d. Encourage deep breathing and coughing to decrease pulmonary stasis.
3. Avoid performing invasive procedures—rectal temperatures, enemas, or insertion of indwelling urinary catheters.

4. Monitor white blood cell (WBC) count and differential.
5. Be aware that hematologic nadirs (lowest level) generally occur within 7 to 14 days after drug administration. Length of myelosuppression depends on specific drug. Institution of further therapy usually depends on an adequate WBC count and ANC.
6. Calculate ANC to determine the number of neutrophils capable of fighting an infection by:

   Total WBC count × (% polys + % bands) = ANC
   Example: 700 × (10% + 5%) = 105.

   Interpretation: 105 of the 700 WBCs are neutrophils and capable of fighting an infection (indicates severe neutropenia).
7. Administer prophylactic antibiotics, as prescribed (if WBC count is less than 500).
8. Administer growth factors, as prescribed: subcutaneous (SC) filgrastim 5 mcg/kg starting 24 hours after chemotherapy for 5 to 10 days for neutropenia prophylaxis or pegfilgrastim 6 mg SC for a single dose 24 hours after chemotherapy. Should also be administered with subsequent courses of chemotherapy to hasten neutrophil maturity.

Preventing Bleeding

1. Avoid invasive procedures when platelet count is less than 50,000/mm^3, including IM injections, suppositories, enemas, and insertion of indwelling urinary catheters.
2. Apply pressure on injection sites for 5 minutes.
3. Monitor platelet count; administer platelets as prescribed.
4. Monitor and test all urine, stools, and emesis for blood.
5. Provide patient education.
   a. Instruct patient to avoid straight-edge razors, nail clippers, and vaginal or rectal suppositories.
   b. Avoid intercourse when platelet count is less than 50,000/mm^3.
   c. Encourage patient to blow his or her nose gently.
   d. Avoid dental work or other invasive procedures while thrombocytopenic.
   e. Avoid the use of nonsteroidal anti-inflammatory drugs (NSAIDs), aspirin, and aspirin-containing products.

Minimizing Fatigue

1. Monitor blood counts (hemoglobin and hematocrit).
2. Administer blood products as prescribed.
3. Administer growth factors as prescribed, such as erythropoietin or darbepoetin.
4. Provide patient education and counseling.
   a. Information about fatigue.
   b. Reassurance that treatment-related fatigue does not mean your cancer is worse.
   c. Why fatigue and shortness of breath may occur.
   d. Suggestions for ways to cope with fatigue.

i. Encourage aerobic and strength-training exercise. Balance activity and rest.

ii. Plan frequent rest periods between daily activities; take naps that do not interrupt nighttime sleep.

iii. Set priorities and delegate tasks to others.

e. Stress management.

f. Explain that blood transfusions, if given, are a part of therapy and not necessarily an indication of a setback.

g. Observe skin color.

h. Monitor nutritional status.

TRANSITIONAL CARE ALERT Oncology patients are very complex. The most common admission diagnosis includes chemotherapy-related side effects, infectious causes, anemia, and dehydration. Prevention is a key responsibility of the nurse in any setting. Prior to discharge, a coordinated effort between social work, case management, and the medical and nursing teams is critical to prevent readmissions. This includes discharge education, adherence to medications, and attention to outpatient follow-up appointments.

Promoting Nutrition

EVIDENCE BASE National Comprehensive Cancer Network. (2017). *Clinical practice guidelines in oncology: Version 2.2017 Antiemesis*. Available: *www.nccn.org.*

---

1. Prevention of nausea/vomiting is the goal. Administer antiemetics before chemotherapy and on a routine schedule (not as needed).
2. Be aware that antiemetic combinations are more effective than single agents.
3. For highly emetogenic chemotherapy regimens greater than 90% frequency of emesis:
   a. Serotonin (5-HT3) antagonist.
      i. Ondansetron, 16 to 24 mg PO or 8 to 12 mg (maximum 32 mg) IV day 1, then 8 mg PO tid for 2 to 3 days or
      ii. Granisetron, 2 mg PO or 1 mg PO bid or 0.01 mg/kg (maximum 1 mg) IV day 1, then daily for 2 to 3 days or
      iii. Dolasetron, 100 mg PO, then daily for 2 to 3 days or
      iv. Palonosetron, 0.25 mg IV day 1, and
   b. Corticosteroid—dexamethasone, 12 mg PO or IV day 1, then 8 mg PO or IV days 2 to 4.

c. Neurokinin 1 agonist.
    i. Aprepitant, 125 mg PO day 1, then 80 mg PO daily days 2 and 3 or
    ii. Fosaprepitant, 150 mg IV day 1 only, or
    iii. Rolapitant 180 mg PO once.
d. Include an as-needed antiemetic, such as metoclopramide, prochlorperazine, dexamethasone, or lorazepam.

4. For moderately emetogenic regimens:
    a. Premedicate with aprepitant, 125 mg PO (for selected high-risk patients); dexamethasone, 12 mg PO or IV and a 5-HT3 antagonist, such as palonosetron, 0.25 mg IV, or ondansetron, 16 to 24 mg PO or 8 to 12 mg; or ± lorazepam, 0.5 to 2 mg either PO or IV or sublingual every 4 to 6 hours prn.
    b. On days 2 to 4: aprepitant, 80 mg PO on days 2 and 3 (if used on day 1); dexamethasone, 8 mg IV or PO daily plus a 5-HT3 agonist, such as ondansetron, PO bid; granisetron, 1 to 2 mg PO or 1 mg PO bid; or dolasetron, 100 mg PO
    c. Include an as-needed antiemetic, such as prochlorperazine or lorazepam.
5. For low emetogenic regimens:
    a. Dexamethasone, 12 mg PO or IV daily, or
    b. Prochlorperazine, 10 mg PO or IV every 4 to 6 hours or 15 mg spansule PO every 8 to 12 hours, or
    c. Metoclopramide, either 20 to 40 mg PO every 4 to 6 hours or 1 to 2 mg/kg IV every 3 to 4 hours; ± diphenhydramine, 25 to 50 mg PO or IV every 4 to 6 hours; or ± lorazepam, 0.5 to 2 mg PO or IV every 4 to 6 hours.
6. Extrapyramidal reactions occur frequently in patients under age 30 and over age 65. Treat dystonic reactions with diphenhydramine; treat restlessness with lorazepam.
7. Consider alternative measures for relief of anticipatory nausea, such as relaxation therapy, imagery, acupuncture, and distraction.
8. Encourage small, frequent meals appealing to patient preferences, but including high calories and proteins. Provide a high-protein supplement as needed.
9. Discourage smoking and alcoholic beverages, which may irritate mucous membranes.
10. Encourage fluid intake to prevent constipation.
11. Monitor intake and output, including emesis.
12. Consult dietitian about patient's food preferences, intolerances, and individual dietary interventions.
13. Recognize that the patient may have alterations in taste perception, such as a keener taste of bitterness and loss of ability to detect sweet tastes.

Minimizing Stomatitis

1. Report signs of infection—erythematous areas, white patches, ulcers.
2. Encourage good oral hygiene.
    a. Soft nylon-bristled toothbrush, brush two to three times daily, rinse frequently.

b. Floss once daily.

3. Encourage the use of oral agents to promote cleansing, debridement, and comfort. Mouthwashes with more than 25% alcohol should be avoided.
4. Assess the need for antifungal, antibacterial, or antiviral therapy (each infection has a different appearance).
5. Administer local oral therapy, such as combinations with viscous lidocaine, for symptomatic control and maintenance of calorie intake.

Preventing and Managing Hypersensitivity Reactions

1. Be alert for signs of allergic reactions such as pruritus, urticaria, and difficulty breathing as well as back pain. The situation may worsen suddenly to hypotension and anaphylaxis.
2. Stop the medication or infusion immediately, notify the health care provider, and monitor the patient closely. Treatment is supportive and dependent on type of reaction and its severity.
   a. Do not administer the agent again if there was a severe reaction resulting in significant hypotension.
   b. Premedicate the patient with antihistamine or corticosteroid, as directed, if there is a history of moderate reaction.

Strengthening Coping for Altered Body Image

1. Reassure patient that hair will grow back; however, it may grow back a different texture or different color.
2. Suggest wearing a turban, wig, or headscarf, preferably purchased before hair loss occurs. Many insurance companies will pay for a wig with a prescription.
3. Encourage patient to stay on therapeutic program.
4. Be honest with patient.

Patient Education and Health Maintenance

1. Make sure patient uses good hygiene, knows the symptoms of infection to report, and avoids crowds and people with infection while neutropenic.
2. Advise patient to avoid using a razor blade to shave, contact sports, manipulation of sharp articles, use of a hard-bristle toothbrush, and passage of hard stool to prevent bleeding while thrombocytopenic.
3. Advise women to report symptoms of vaginal infection because of opportunistic fungal or viral infection.
4. Encourage patient participation in plan for chemotherapy and to set realistic goals for work and activities.
5. Assure patient that changes in menses, libido, and sexual function are usually temporary during therapy.

Evaluation: Expected Outcomes

- Afebrile, no signs of infection.
- No bruising or bleeding noted; stool and urine heme test negative.

- Denies shortness of breath or severe fatigue.
- Tolerates small, frequent meals following antiemetic.
- No oral lesions or pain on swallowing.
- No urticaria, shortness of breath, or change in vital signs.
- Wears turban and expresses feelings about body image.

Radiation Therapy

Radiation therapy is the use of high-energy x-rays or other radiation particles to treat malignant diseases. Radiation with sufficient energy to disrupt atomic structures by ejecting orbital electrons is called ionizing radiation. The goal of radiation is to deliver a precisely measured dose of irradiation to a defined tumor volume with minimal damage to surrounding healthy tissue. This results in eradication of tumor, high quality of life, and prolongation of survival and allows for effective palliation or prevention of symptoms of cancer, with minimal morbidity. Over the past 20 years, advances have been made in imaging and treatment delivery, allowing for improved targeting and increased sparing of normal tissues.

General Considerations

1. Different irradiation doses are required for tumor control, depending on tumor type and the number of cells present. Varying radiation doses can be delivered to specific portions of the tumor (periphery vs. central portion) or to the tumor bed in cases in which all gross tumor has been surgically removed.
2. Treatment portals must adequately cover all treatment volumes plus a margin.

Goals of Therapy

1. Curative—when there is a probability of long-term survival after adequate therapy, some adverse effects of therapy, although undesirable, may be acceptable.
2. Palliative—when there is no hope of survival for extended periods, radiation can be used to palliate symptoms, primarily pain. Lower doses of irradiation (75% to 80% of curative dose) can control the tumor and palliate symptoms without excessive toxicity.

Principles of Therapy

1. Radiosensitivity is the sensitivity of cells, tissues, or tumors to radiation. Rapidly dividing cells are most sensitive.
2. Radioresistance is the lack of tumor response to radiation because of tumor characteristics (slow growing, less responsive), tumor cell proliferation, and circulation. Radiation is most effective during the mitotic stage of the cell cycle.
3. Radioresistant tumors: Many tumors are resistant to radiation, such as squamous cell, ovarian, soft tissue sarcoma, and gliomas. Many other tumors can become resistant after a period of time. Normal radioresistant tissues include mature bone, cartilage, liver, thyroid, muscle, brain, and spinal cord.
4. Role of oxygen: The presence of oxygen enhances radiation. Without oxygen, chemical damage to DNA may be repaired. Giving multiple, daily doses allows reoxygenation and enhances radiosensitivity. The dose should allow for repair of normal tissues.
5. Tissue tolerance dose is the amount of radiation that a healthy cell can receive and still function. This is what limits the dose of radiation one can receive.
6. Tumor size is a major factor in response to radiation therapy. Smaller tumors are more responsive than larger tumors.

Types of Radiation Therapy

There are generally two types of ionizing radiation: teletherapy and brachytherapy and several ways in which it is delivered.

1. Teletherapy is most commonly delivered through a linear accelerator machine. And there are a number of techniques used to administer teletherapy.
    a. Intraoperative radiation therapy—given during surgery for tumors that are not completely operable or are at high risk for recurrence. Examples include gynecological malignancies and colorectal cancers.
    b. Stereotactic radiation (radiosurgery)—used for brain tumors where the radiation beam is delivered precisely to the tumor itself sparing surrounding healthy brain tissue. This can be administered through gamma knife technology. The patient's head is placed into a frame that is secured to the cranium with screws. Scanning technology allows for precise and accurate delivery of radiation.
    c. Intensity-modulated radiation therapy (IMRT)—uses radiation beams of varying intensities to deliver different doses of radiation to small areas of tissue at the same time. This is used most commonly in brain, head, and neck tumors and lung tumors.
    d. Image-guided radiation therapy—uses repeated imaging scans (obtained via CT, MRI, or PET) during treatment to identify changes in a tumor's size and location because of treatment and to allow the position of the patient or the planned radiation dose to be adjusted, as needed. Repeated imaging can increase the accuracy of radiation treatment and may allow reductions in the planned volume of tissue to be treated, thereby decreasing the total radiation dose to normal tissue.
    e. Tomotherapy—type of image-guided IMRT. A tomotherapy machine is a hybrid between a CT imaging scanner and an external beam radiation therapy machine. Tomotherapy machines can capture CT images of the patient's tumor immediately before each treatment, to allow for precise tumor targeting and sparing of normal tissue.
2. Brachytherapy uses seeds, wires, or catheters to deliver radiation directly to or adjacent to the tumor bed. This technique delivers less radiation to adjacent normal tissue, but it requires direct tumor access. It may be temporary or permanent. The permanent type remains in place with gradual decay. The implant procedure is performed under local or general anesthesia and is typically used for breast and prostate cancers.
    a. Intracavitary therapy utilizes radioactive material that is inserted into a cavity such as the vagina, as in cancer of the uterine cervix.
    b. Other forms of brachytherapy are systemic irradiation (parenteral or IV), oral ^{131}I for thyroid cancer, or intraperitoneal radiation.

Chemical and Thermal Modifiers of Radiation

1. Radiosensitization is the use of medications to enhance the sensitivity of the tumor cells.
2. Radioprotectors increase therapeutic ratio by promoting repair of normal tissues.
3. Hyperthermia is combined with radiation. Uses a variety of sources (ultrasound, microwaves) and produces a greater effect than radiation alone. It is usually applied locally or regionally immediately after

radiation.

Units for Measuring Radiation Exposure or Absorption

1. Centigray (cGy) is a unit of radiation dose absorbed by the body equal to one hundredth of a gray; formerly called a rad (eg, 1 cGy equals 1 rad). Gray (Gy) is the unit of absorbed radiation dose equal to 100 rad.
2. Hyperfractionated radiation therapy is the division of the total radiation dose into smaller daily doses. Administering fractions allows treatment of tumor cells while giving healthy cells time to repair themselves.

Nature and Indications for Use

Used alone or in combination with surgery or chemotherapy, depending on the stage of disease and goal of therapy.

1. Adjuvant radiation therapy—used in combination with other treatment modalities, such as chemotherapy or surgery, when a high risk of local recurrence or large primary tumor exists.
2. Curative radiation therapy—used in anatomically limited tumors (retina, optic nerve, certain brain tumors, skin, oral cavity). Course is usually longer and the dose higher.
3. Palliative—for treatment of symptoms.
    a. Provides excellent pain control for bone metastasis.
    b. Used to relieve obstruction.
    c. Relief of neurologic dysfunction for brain metastasis.
    d. Given in short, intensive courses.

Treatment Planning

1. Evaluation of tumor extent (staging), including diagnostic studies before treatment.
2. Define the goal of therapy (cure or palliation).
3. Select appropriate treatment modalities (irradiation alone or combined with surgery, chemotherapy, or both).
4. Treatment planning is known as simulation. This is the process of aiming and defining radiation beams to meet the goals of prescribed therapy.
    a. Simulation is used to accurately identify target volumes and sensitive structures. CT simulation allows for accurate three-dimensional treatment planning of target volume and anatomy of critical normal structures.
    b. Treatment aids (eg, shielding blocks, molds, masks, immobilization devices, compensators) are extremely important in treatment planning and delivery of optimal dose distribution. Repositioning and immobilization devices are critical for accurate treatment.
    c. Lead blocks are made to shape the beam and protect normal tissues.
    d. Skin markings are applied to define the target and portal. These are generally replaced later by permanent tattoos.

5. Usual schedule is Monday through Friday.
6. Actual therapy lasts minutes. Most time is spent on positioning.
7. Determine optimal dose of irradiation and volume to be treated, according to anatomic location, histologic type, stage, potential regional nodal involvement (and other tumor characteristics), and normal structures in the region.

Complications

Complications depend on the site of radiation therapy, type of radiation therapy (brachytherapy or teletherapy), total radiation dose, daily fractionated doses, and overall health of the patient. Adverse effects are predictable, depending on the normal organs and tissues involved in the field.

Acute Adverse Effects

1. Fatigue and malaise.
2. Skin: may develop a reaction as soon as 2 weeks into the course of treatment.
   a. Erythema—may range from mild to severe.
   b. Dry desquamation—shedding of the skin.
   c. Moist desquamation—shedding of the skin to reveal moist, edematous skin underneath. Areas having folds, such as the axilla, under the breasts, groin and gluteal fold, are at an increased risk because of increased warmth and moisture.
   d. Folliculitis—infection of the hair follicles, which may result in pustule formation.
3. GI effects: nausea and vomiting, diarrhea, and esophagitis.
4. Oral effects: changes in taste, mucositis, dryness, and xerostomia (dryness of mouth from lack of normal secretions).
5. Pulmonary effects: dyspnea, productive cough, and radiation pneumonitis (usually occurs 1 to 3 months after radiation to the lung).
6. Renal and bladder effects: cystitis and urethritis.
7. Cardiovascular effects: damage to vasculature of organs and thrombosis (heart is relatively radioresistant).
8. Recall reactions: acute skin and mucosal reactions when concurrent or past chemotherapy (doxorubicin, dactinomycin).
9. Bone marrow suppression: more common with pelvic or large bone radiation.

Chronic Adverse Effects

After 6 months with variability in time of expression:

1. Skin effects: fibrosis, telangiectasia, permanent darkening of the skin, and atrophy.
2. GI effects: fibrosis, adhesions, obstruction, ulceration, and strictures.
3. Oral effects: permanent xerostomia, permanent taste alterations, and dental caries.
4. Pulmonary effects: fibrosis.
5. Renal and bladder effects: radiation nephritis and fibrosis.

6. Second primary cancer: patients who have received combined radiation and chemotherapy with alkylating agents have a rare risk of developing acute leukemia.

Nursing Assessment

1. Assess skin and mucous membranes for adverse effects of radiation.
2. Assess GI, respiratory, and renal function for signs of adverse effects.
3. Assess patient's understanding of treatment and emotional status.

Nursing Diagnoses

- Risk for Impaired Skin Integrity related to radiation effects.
- Ineffective Protection related to brachytherapy.

Nursing Interventions

Maintaining Optimal Skin Care

1. Inform the patient that some skin reaction can be expected but that it varies from patient to patient. Examples include dry erythema, dry desquamation, wet desquamation, epilation, and tanning.
2. Do not apply lotions, ointments, or cosmetics to the site of radiation unless prescribed.
3. Discourage vigorous rubbing, friction, or scratching because this can destroy skin cells. Apply ointments as instructed by health professionals.
4. Avoid wearing tight-fitting clothing over the treatment field; prevent irritation by not using rough fabric such as wool and corduroy.
5. Take precautions against exposing the radiation field to sunlight and extremes in temperature.
6. Do not apply adhesive or other tape to the skin.
7. Avoid shaving the skin in the treatment field.
8. Use lukewarm water only and mild soap when bathing.

Ensuring Protection from Radiation

1. To avoid exposure to radiation while the patient is receiving therapy, consider the following:
    a. Time—exposure to radiation is directly proportional to the time spent within a specific distance to the source.
    b. Distance—amount of radiation reaching a given area decreases as resistance increases.
    c. Shield—sheet of absorbing material placed between the radiation source and the nurse decreases the amount of radiation exposure.
2. Individual monitoring devices should be worn by personnel exposed to radiation or radioactive material.
3. Take appropriate measures associated with sealed sources of radiation implanted within a patient (sealed internal radiation).
    a. Follow directives on precaution sheet that is placed on the charts of all patients receiving radiotherapy.

b. Do not remain within 3 feet (1 m) of the patient any longer than required to give essential care.

4. Know that the casing material absorbs all alpha radiation and most beta radiation but that a hazard concerning gamma radiation may exist.
5. Do not linger longer than necessary in giving patient care, even though all precautions are followed.
6. Be alert for implants that may have become loosened (those inserted in cavities that have access to the exterior); for example, check the emesis basin following mouth care for a patient with an oral implant.
7. Notify the radiation therapist of any implant that has moved out of position.
8. Use long-handled forceps or tongs and hold at arm's length when picking up any dislodged radium needle, seeds, or tubes. Never pick up a radioactive source with your hands.
9. Do not discard dressings or linens unless you are sure that no radioactive source is present.
10. After the patient is discharged from the facility, it is a good policy for the radiologist to check the room with a radiograph or survey meter to be certain that all radioactive materials have been removed.
11. Continue radiation precautions when a patient has a permanent implant, until the radiologist declares precautions unnecessary.

Evaluation: Expected Outcomes

- Skin without breakdown or signs of infection.
- Radiation precautions maintained.

Biologic Therapy

Biologic therapy is targeted cancer treatment. It has emerged as an important modality of cancer treatment and one where intensive research is actively being conducted. The goal is to produce antitumor effects through the action of natural host defense mechanisms. It is capable of altering the immune system with either stimulatory or suppressive effects. The underlying principle is that the primary function of the immune system is to detect and eliminate substances that are recognized as "nonself." This represents the most promising new cancer treatment approach since the development of chemotherapy.

Types of Immunotherapy

Cytokines

Cytokines are soluble proteins produced by mononuclear cells of the immune system (usually the lymphocytes and monocytes) that have regulatory actions on other cells in the immune system. Cytokines produced by lymphocytes are referred to as *lymphokines*, and cytokines produced by monocytes are referred to as *monokines*.

1. Examples of cytokines include interleukins, interferons, CSFs, and tumor necrosis factor.
2. Many other biologic agents are currently under investigation.

Antibody Therapy

Monoclonal antibodies work on cancer cells in the same way natural antibodies work, by identifying and binding to the target cells. They then alert other cells in the immune system to the presence of the cancer cells.

1. Promotes targeting cells through antibody–antigen response.
2. Monoclonal antibodies may be used alone or in combination with chemotherapy.
3. Examples of monoclonal antibodies include:
    a. Rituximab—a murine/human chimeric monoclonal antibody specific for the CD20 surface marker on B cells. It is approved for the treatment of relapsed or refractory low-grade/follicular non-Hodgkin lymphoma.
    b. Ibritumomab—combines the targeting power of monoclonal antibodies with the cell-damaging ability of localized radiation. It is developed to recognize and attach to substances on the surface of certain cells and deliver cytotoxic radiation directly to the cancerous cells.
    c. Trastuzumab—a recombinant DNA–derived humanized monoclonal antibody that selectively binds with high affinity in a cell-based assay to the extracellular domain of the human epidermal growth factor receptor 2 protein (HER2). It is approved for the treatment of patients with early stage and advanced metastatic breast cancer whose tumors overexpress the HER2 protein.
    d. Cetuximab—binds to extracellular EGRF resulting in inhibition of cell growth and induction of apoptosis.
    e. Bevacizumab—binds to and inhibits the activity of human VEGF to its receptors blocking proliferation and formation of new blood vessels that supply tumor cells.

f. Panitumumab—inhibits the binding of ligand to the EGFR receptor resulting in inhibition of cell growth.
g. Alemtuzumab—recognizes the CD52 antigen expressed on malignant and normal B lymphocytes. It has come to be used therapeutically in B-cell malignancies.

4. Potential adverse effects of monoclonal antibodies include dyspnea and mild wheezing, fever and chills, headache, rash, nausea and vomiting, tachycardia, bleeding, and allergic reactions.

Other Types of Immunotherapy

1. Virus immunotherapy—uses viruses to deliberately infect the cancer cell, which in turn triggers an immune response against the infected cancer cell.
2. Immune checkpoint inhibitors—these drugs block tumor cells from inactivating T cells. This allows the T cell to remain active and fight the tumor cells. Examples include nivolumab and pembrolizumab.

Nursing Assessment

1. Review patient's record or obtain history from the patient to determine site of cancer, previous cancer therapies, current medications, and other medical conditions.
2. Assess current cardiovascular and respiratory status.
3. Assess patient's understanding of immunotherapy and associated toxicities.
4. Assess for common side effects of immune system stimulation, including fever, chills, body aches, nausea, vomiting, and fatigue, as well as serious and potentially life-threatening adverse reactions, including dyspnea, wheezing, tachycardia, bleeding, hypotension, and anaphylaxis.

Nursing Diagnoses

- Hyperthermia as an adverse effect of immunotherapy.
- Ineffective Tissue Perfusion related to capillary permeability leak syndrome (third spacing of fluid) caused by immunotherapy.

Nursing Interventions

Controlling Hyperthermia

1. Discuss the overall goal of immunotherapy, expected adverse effects, and the method of administration.
2. Instruct the patient to report fever, chills, diarrhea, nausea and vomiting, itching, or weight gain.
3. Administer or advise self-administration of antipyretics, such as acetaminophen for fever.
4. Emphasize that adverse effects are temporary and will usually cease within 1 week after treatment ends.

Maintaining Tissue Perfusion

1. Monitor vital signs at least every 4 hours for hypotension, tachycardia, tachypnea, and fever.
   a. Instruct the patient to remain in bed if blood pressure is low.
   b. Monitor apical heart rate.

2. Assess respirations for rate and depth, and auscultate breath sounds for evidence of pulmonary edema.
3. Assess for signs of restlessness, apprehension, discomfort, or cyanosis, which may indicate respiratory distress.
4. Administer oxygen as prescribed.
5. Maintain patent IV line and administer serum albumin as prescribed.
6. Check extremities for warmth, color, and capillary refill.

Evaluation: Expected Outcomes

- Relief of fever after medication.
- Blood pressure stable and lungs clear.

SPECIAL CONSIDERATIONS IN CANCER CARE

Pain Management

Pain related to cancer may be caused by direct tumor infiltration of bones, nerves, viscera, or soft tissue, as well as by therapeutic measures (surgery, radiation). Pain is the most common symptom associated with cancer and has a negative impact on a patient's functional status and quality of life. Cancer pain can be controlled with medication in 80% to 95% of patients, and there is increasing evidence that survival is linked to pain management. See Appendix D, page 1508 for more information on pain management.

Oncologic Emergencies

Oncologic emergencies are a group of life-threatening metabolic syndromes or abnormalities associated with cancer and/or cancer treatment.

Septic Shock

Septic shock is a systemic disease associated with the presence and persistence of pathogenic microorganisms or their toxins in the blood. It is characterized by hemodynamic instability, abnormal coagulation, and altered metabolism.

Risk Factors

1. Neutropenia, ANC less than 500.
2. Patients who are neutropenic longer than 7 days most susceptible.
3. Patients with HIV and concomitant neutropenia.
4. Prolonged hospitalization.
5. Older patients.
6. Patients with comorbid conditions, such as diabetes and pulmonary diseases.

Clinical Manifestations

1. Fever greater than 100.5°F (38.3°C).
2. Warm, flushed, dry skin.
3. Hypotension.
4. Tachycardia.
5. Tachypnea.
6. Decreased level of consciousness.
7. Patients will not have the usual symptoms of infection because of the lack of neutrophils. For example, skin infections may manifest as subtle rash or erythema. Urinary tract infections may be asymptomatic and patients with lung infections may be without pulmonary infiltrates.

Diagnostic Evaluation

1. Vital signs.
2. Culture—blood, urine, stool, sputum, central and peripheral IV lines, and any open wounds to determine source and type of infection.
3. Chest x-ray—to detect underlying pneumonia.
4. CT scans as necessary.
5. Arterial blood gas analysis—decreased pH reflects acidosis.
6. BUN and creatinine—elevated because of decreased circulating blood volume.
7. CBC with differential—elevated WBC count with shift to left.

Management

1. Antibiotics are started immediately; broad-spectrum antibiotics are given until organism is identified.
2. IV fluids and plasma expanders are used to restore circulating volume.
3. CSFs are administered to increase ANC.
4. Vasopressors are administered to support blood pressure.
5. Oxygen is administered, as needed, to prevent tissue hypoxia.
6. Vital signs, respiratory status, urine output, and any signs of bleeding are monitored carefully.
7. Complications, such as renal failure, respiratory failure, cardiac failure, metabolic acidosis, and disseminated intravascular coagulation, are treated aggressively.

Spinal Cord Compression

Spinal cord compression (SCC) is the result of tumor compression on the dural sac. This can result in neurologic impairment or permanent loss of function if not treated immediately.

Incidence

1. Affects 5% of all terminal cancer patients in the last 2 years of their lives with less than a 6-month median survival from diagnosis.
2. Lung, breast, and prostate cancer account for 15% to 20% of all cases.
3. Multiple myeloma, non-Hodgkin lymphoma, and renal carcinoma account for 5% to 10% of cases.

Clinical Manifestations

1. Cervical spine.
    a. Vertigo.
    b. Radicular pain in neck and back of head that is aggravated by neck flexion.
    c. Upper extremity weakness.
    d. Sensory loss in area of weakness (ie, paresthesia, numbness).
    e. Abnormal deep tendon reflexes.
    f. Gastric hypersecretion and paralytic ileus.
2. Thoracic spine.
    a. Local or radicular pain (or both).
    b. Lower extremity weakness.
    c. Sensory loss below the level of the lesion.
    d. Band of hyperesthesia at dermatome of tumor site.
    e. Impaired bladder or bowel control.
3. Lumbar spine.
    a. Local or radicular pain (or both).
    b. Lower extremity weakness and paralysis.

c. Atrophy of lower extremity muscles.

d. Sensory loss below level of the lesion.

e. Urinary symptoms (hesitancy, retention), constipation, or bowel incontinence.

4. Weakness and unsteadiness may be noted before changes in motor function. (Progression is usually rapid with foot drop and impaired ambulation. Urgent investigation and treatment are crucial to minimize the risk of paraplegia. The degree of weakness and ability to walk at presentation are important clinical predictors of outcome.)
5. Changes in sensation—paresthesia, numbness, tingling. (Severity usually mirrors the severity of motor weakness.)

NURSING ALERT Any abnormal neurologic symptoms in a patient with cancer should be considered an SCC until proven otherwise.

Diagnostic Evaluation

1. Neurologic examination—early diagnosis is important.
2. X-ray of the painful site—may be abnormal; can be used as an initial screen for complaints of back pain.
3. Bone scan—more sensitive to bony metastasis than x-ray to detect abnormal vertebral bodies.
4. MRI—most useful in detecting spinal cord lesions. The entire spine can be viewed. Immediately indicated if radiculopathy or myelopathy is present or x-rays are abnormal.

Management

1. Treatment is usually palliative because it is associated with metastatic disease.
2. Treatment goals are to relieve pain, minimize complications, and preserve or restore neurologic function.
3. Corticosteroids are the initial treatment until more definitive treatment can be instituted, reduce inflammation and swelling at site, increase neurologic function, and relieve pain.
   a. A loading dose of dexamethasone is usually given followed by tapering doses over a period of weeks.
   b. Steroids must be tapered and not abruptly discontinued.
   c. Monitor patient's glucose levels during dexamethasone treatment because it can cause hyperglycemia.
4. Radiation therapy to the tumor on spinal column is the most common treatment. Radiation is effective with 70% of patients having improvement in pain and function.
5. Surgery is considered when tumors are not radiosensitive or located in an area that has been previously radiated. It is also indicated for spinal instability.

Complications

1. Respiratory impairment, including pneumonia and atelectasis.
2. Mobility impairment, foot drop, skin impairment, and postural hypotension.

3. Sensory losses creating safety concerns.
4. Bladder or bowel dysfunction.

Patient Education

1. Facilitate referral to home care services for nursing assessment, nursing intervention, and rehabilitation for residual deficits.
2. Facilitate referral to appropriate outpatient services, including physical therapy, occupational therapy, and psychosocial support.
3. Provide instruction about safety issues for residual sensory deficits (eg, test bath water temperature, careful use of extreme hot or cold).

Hypercalcemia

Hypercalcemia is an elevated serum calcium level above 11 mg/dL. It results when bone resorption exceeds both bone formation and the ability of the kidneys to excrete extracellular calcium released from the bones.

Incidence

1. The most common life-threatening disorder associated with malignancy; occurs in 20% to 30% of patients at some point in their illness.
2. Occurs most commonly in patients with carcinoma of the lung, breast, and renal cells; multiple myeloma; and adult lymphomas.
3. Can occur with or without skeletal metastasis, but more than 80% of patients do have bony disease.
4. Associated with a poor prognosis.

Clinical Manifestations

1. Signs and symptoms may vary, depending on the severity, and may be nonspecific and insidious.
   a. Early symptoms include anorexia, weakness, polyuria, polydipsia, and fatigue.
   b. Late symptoms include apathy, irritability, profound muscle weakness, nausea, vomiting, constipation, pruritus, lethargy, and confusion.
2. A rapid and life-threatening increase in calcium may cause dehydration, renal failure, coma, and death.

Diagnostic Evaluation

1. Serum calcium level greater than 11 mg/dL in adults, but ionized calcium of greater than 1.29 mmol/L is the most reliable test.
2. Electrolyte levels, BUN, and creatinine are obtained to determine hydration status and renal function.
3. ECG may show shortening of the QT interval and prolongation of the PR interval.

Management

1. Management includes treating the primary malignancy with chemotherapy, surgery, or radiation.
2. Acute, symptomatic hypercalcemia should be treated as an emergency.
3. Hydration and diuresis—IV normal saline (0.9% NaCl) is the initial treatment for patients with acute

hypercalcemia and clinical symptoms to dilute the calcium and promote its renal excretion. Diuresis is induced with furosemide. (Thiazide diuretics aggravate hypercalcemia and should be avoided.)

4. Pharmacotherapy includes:
    a. Bisphosphonates—primary drug therapy, administered IV; pamidronate or zoledronic acid inhibits osteoclast resorption in the bone.
    b. Calcitonin—used in combination with glucocorticoids and inhibits bone resorption. It has a rapid onset but a short duration of action. Used most commonly in patients with multiple myeloma. It should not be used for longer than 72 hours.
    c. Denosumab—a monoclonal antibody that should be used in the setting of hypercalcemia at least 7 days after bisphosphonates.

Nursing Interventions

1. Prevent and detect hypercalcemia early.
    a. Recognize patients at risk and monitor for signs and symptoms, such as nausea and vomiting, constipation, lethargy, and anorexia.
    b. Emphasize importance of mobility to minimize bone demineralization and constipation.
    c. Instruct patient on the importance of adequate hydration.
2. Administer normal saline infusions as prescribed.
3. Administer medications as prescribed.
4. Maintain accurate intake and output; observe for oliguria or anuria.
5. Take vital signs every 4 hours, especially apical pulse and blood pressure.
6. Monitor electrolyte values and renal function.
7. Assess mental status.
8. Assess cardiorespiratory status for signs of fluid overload.

Superior Vena Cava Syndrome

Superior vena cava syndrome (SVCS) is obstruction and thrombosis of the superior vena cava caused by direct compression by a tumor or an enlarged lymph node, resulting in impaired venous drainage of the head, neck, arms, and thorax.

Incidence

1. Eighty percent to 95% of patients with SVCS are cancer patients.
2. Eighty percent of cases arise from advanced lung cancer, specifically small cell lung cancers, and 15% from lymphoma.
3. Other malignancies associated with SVCS are thymoma and breast cancer.

Clinical Manifestations

1. Signs and symptoms may vary, depending on the degree of obstruction and how rapidly the obstruction occurs.

2. A rapid onset of SVCS is dramatic and potentially life threatening and requires immediate intervention.
3. Facial edema is found in 80% of cases and is the most common initial finding.
4. Early symptoms include progressive dyspnea, cough, feeling of fullness in the head, difficulty buttoning shirt collar (Stoke sign), dysphagia and hoarseness, and chest pain.
5. Cyanosis and edema of the head and upper extremities may be apparent. Collateral circulation with dilated chest wall veins may be visible.
6. Late symptoms include respiratory distress, headache, vision disturbances, dizziness and syncope, lethargy, irritability, and mental status changes.
7. Pleural effusion on chest x-ray may also be seen.

Diagnostic Evaluation

1. CT scan is the most common imaging technique used to diagnose SVC syndrome.

Management

1. Radiation therapy and corticosteroids are the gold standard of treatment for SVCS to reduce tumor size and relieve pressure. Most patients experience a relief of symptoms within the first 4 days of therapy.
2. Chemotherapy may be used in conjunction with radiation. Specific chemotherapeutic agents depend on the tumor type.
3. Surgery is rarely used because of the associated high morbidity and mortality risks.
4. Percutaneous stent placement—an expandable stent may be placed inside the superior vena cava to keep it patent. Anticoagulants are also used in conjunction.
5. Thrombolytic and anticoagulant therapy may be used if a thrombus is suspected or to prevent the formation of a thrombus; must be used within the first 7 days to be effective.
6. Oxygen is given for relief of dyspnea and maintenance of tissue oxygenation.
7. Analgesics and tranquilizers are used for discomfort and anxiety.

Nursing Interventions

1. Administer oxygen, as prescribed, to relieve hypoxia.
2. Place patient in Fowler position—facilitates gravity drainage and reduces facial edema.
3. Limit patient's activity and provide a quiet environment.
4. Reassure patient that cyanotic color and facial edema will subside with treatment.

Psychosocial Components of Care

Nursing Assessment

1. Assess lifestyle before illness. How did patient solve other problems?
2. Assess for signs of anxiety and coexistence of depression: agitation and restlessness, sleep disturbances, excessive autonomic activity, weight gain or loss, mood changes.
3. What activities of daily living can patient perform?
4. What changes in lifestyle have resulted from cancer and its treatment?
5. Determine patient's perception of the disease and treatment.
6. Evaluate available social support; who is the most significant other?
7. Ask patient if any complementary or alternative medicine (CAM) modalities are being utilized for cancer treatment. Be aware that many patients seek herbal and other remedies despite lack of scientific evidence of any benefit. Encourage patient and family to discuss CAM use with health care provider to ensure safety.
8. Try to gain a sense of emotional strengths and potential problem areas. Ask if patient and family have a plan for end-of-life care as appropriate.

Nursing Diagnoses

- Anxiety related to complex disease process, treatment options, and prognosis.
- Ineffective Coping related to life-altering disease process.
- Fear of Death and dying.

Nursing Interventions

Reducing Anxiety

1. Establish and sustain an unhurried approach to give the patient time to organize fears, thoughts, and feelings.
2. Allow patient to share feelings about having cancer.
3. Reflect and amplify insights and judgments; try to reduce anxiety through reflection and reorientation.
4. Recognize feelings of losing control.
5. Discuss methods of stress reduction (imagery, relaxation).
6. Discuss the positive aspects of treatment.
7. Encourage expression of positive emotions—emphasis on living in the here and now, greater appreciation of life.
8. Reinforce effective coping behaviors.
9. Encourage patient to join a support group. Refer to local chapter of the ACS, call 1-800-ACS-2345 or visit *www.cancer.org*.
10. Remain available as problems arise. Give patient telephone numbers of people to call when needed.

11. Initiate referrals for additional rehabilitation and psychosocial services as appropriate.

Promoting Effective Coping

1. Encourage patient and family members to enroll in cancer education program.
2. Encourage patient to learn everything about treatment plan because this promotes a sense of control.
3. Provide expert physical care and teach patient about care.
4. Assist patient in strengthening support system (family, friends, visitors, health care staff and volunteers, support groups)—strengthens self-esteem through the experience of feeling accepted and valued.
5. Help patient readjust expectations and goals to promote ongoing adjustment.
6. Support patient in coping mechanisms chosen.

Allaying Fear of Death and Dying

1. Educate patient and family about prognosis and end-of-life choices, as outlined by patient's health care provider. Be direct, stating the statistics but stressing the positive aspects of the situation.
2. Assess and respect patient's beliefs.
3. Help patient and family agree on goals.
4. Facilitate emotional support for patient.
5. Provide bereavement support to survivors.

Evaluation: Expected Outcomes

- Discusses feelings; practices stress reduction.
- Patient and family attend cancer education program.
- Asks questions about prognosis and sets goals for care.

Survivorship

With earlier diagnosis and better treatment, more and more patients are surviving and living beyond cancer. Recent estimates show that as of 2016, the number of cancer survivors has surpassed 16 million. This expected continual increase in cancer survivors has put a strain on the health care delivery system. Primary care providers and oncologists have not been able to keep up with the growing number of patients who have completed their therapy.

The oversight of a health care provider is important as patient's transition from active cancer care to survivorship. Sadly, many needs of cancer survivors are not being met. In 1986, the National Coalition for Cancer Survivors was created to address these issues. Nearly two decades later, accredited cancer centers are now required to have survivorship programs. Nurses are uniquely positioned to help transform care survivorship care and improve the quality of care and patient outcomes.

Principles of Survivorship Care

1. Survivorship care is the process of learning how to live through cancer and beyond.
2. The goals cancer survivorship programs as recommended by the ASCO include the following:
    a. Prevention of recurrent and new cancers.
    b. Surveillance for cancer spread or recurrence.
    c. Assessment of late medical and psychological effects of therapy.
    d. Adherence and interventions for consequences for cancer and its treatment.
    e. Coordination between specialist and other health care providers.
3. There are different models of survivorship programs. Most include a transition visit at the end of treatment. During this visit, current symptoms are addressed and patients are provided a survivorship care plan and education to include prevention of recurrent and new cancers, surveillance and late effects, health promotion, and a follow-up plan.
4. These visits are often conducted by physicians and/or nurse practitioners. Nurses, however, have a pivotal role in survivorship programs. As patients often receive care from each of the treatment disciplines (medical oncology, surgical oncology, radiation oncology), nurses have the skills to integrate, coordinate care, and serve as the patient advocate. Nurses possess the skills and knowledge to educate and manage treatment-related side effects.

Management and Nursing Interventions

1. Realize that patients themselves have a difficult time adjusting to life after cancer treatment. They are often challenged with long-term side effects, both physical and psychological.
2. Provide education regarding the symptoms of recurrence, identification of late side effects, and an adoption of healthy lifestyle changes.
3. Ensure the patient has a knowledgeable provider that specifically addresses survivorship needs, and coordinate referrals to specialists as needed.

Palliative Care

Palliative cancer care is the integration of therapies that address the multiple issues that cause cancer patients and their families suffering. It is the care of the whole person along the illness trajectory, not just the end of life, to promote quality of life and relieve suffering. Palliative care comprises the management of pain, as well as other physical, psychological, and spiritual problems, and may be integrated into anticancer treatment and life-prolonging therapy. The hospice model of palliative care provides intensive end-of-life care, bereavement services, and support of the family after death of a loved one. Although palliative care is appropriate for many cancer patients, it is not limited to cancer; many neurologic, cardiac, pulmonary, and other types of disorders call for palliative care in their more severe or advanced forms.

There are facility- and community-based programs as well as inpatient facilities and home care services (including hospice). Care of patients with advanced illness, such as cancer, and dealing with death and dying is an integral part of oncology nursing. Palliative care has been added to most medical and nursing schools across the country in recent years.

Principles of Palliative Care

1. Palliative care is an interdisciplinary team approach, including experts from medicine, nursing, social work, the clergy, and nutrition. This team approach is needed to make the necessary assessments and to institute appropriate interventions.
2. The essential components of palliative care are relief of symptom distress, improved quality of life, opening of communication on a regular basis with patients to provide appropriate care on their terms, and psychosocial support for patients and families.
3. The goal is to provide comfort and maintain the highest possible quality of life for as long as possible.
4. The traditional focus of palliative care is not on death but on a compassionate, specialized care for the living. It is based on a comprehensive understanding of patient suffering and focuses on providing effective pain and symptom management to seriously ill patients while improving quality of life.

End-of-Life Care

- Hospice and palliative care provide care during progressive illness, but hospice eligibility begins only when a patient has a life expectancy of 6 months or less. In contrast, palliative care begins when the patient has been diagnosed with a life-limiting illness. It recognizes that the goals of care may change, but the focus is always on quality of life.
- Unfortunately, hospice is equated with care of the dying, causing it to be underutilized; thus, many patients only live a few days to a week after contacting hospice.
- It has been shown that early referral to palliative care and hospice not only improves patient's symptoms and quality of life but also improves survival.
- Hospice care and palliative care offer end-of-life care, which can be achieved by:

  a. Enhancing physical well-being through effective symptom management: pain, nausea, vomiting,

constipation, sleeplessness.

b. Enhancing psychological well-being through management of anxiety, depression, fear, denial, and hopelessness. Rather, happiness, enjoyment, and leisure are promoted.

c. Enhancing social well-being by addressing financial burden, caregiver burden, roles and relationships, affection and sexual function, and concerns about appearance.

d. Enhancing spiritual well-being through minimization of suffering and instead focusing on religious beliefs, hope, and meaning.

Management and Nursing Interventions

1. Provide pain relief, symptom control (dyspnea, nausea, constipation, anxiety, agitation), and prevention of complications.
2. Encourage patient and family to exceed their current situation.
   a. Encourage patient and family to pursue enjoyable activities.
   b. Assist patient and family to focus on present and past joys.
   c. Share positive and hope-inspiring stories.
3. Facilitate participation in religious or spiritual activities.
4. Encourage families to minimize social isolation.
5. Provide private time for relationships.
6. Discuss end-of-life issues early in patient's treatment plan.
7. Encourage patients to express their preferences about end of life in the form of a legal document.
   a. Advance directives, such as medical orders for life-sustaining treatment or health care proxy and durable power of attorney, allow for the refusal of further treatment or authorize a family member or friend to make decisions for the patient (see page 159).
   b. After discussion with the patient and family, the primary care provider in an inpatient setting can write orders based on the directives such as "do not resuscitate."
8. Make referrals for respite care, counseling, pastoral care, and bereavement services, as needed.
9. Assist patients and families with decisions for withholding or withdrawing life-sustaining therapies and transfer in and out of inpatient settings by explaining such therapies and clarifying how they fit with the goals of care.
10. Promote ethical practice by organizing interdisciplinary rounds on patients with end-of-life care issues, setting up a partnership in care with family members, collaborating with other nurses who have been through similar situations, and consulting with the ethics committee within your facility.

NURSING ALERT It is important for health care professionals to have open and frank discussions with patients about their preferences regarding end-of-life care. This discussion should not occur during a life-threatening event when patients and families are stressed and feel rushed to make a decision.

OVERVIEW AND ASSESSMENT

A comprehensive geriatric evaluation (CGE) is essential to understand the holistic health needs of older adults. The CGE is performed by an interdisciplinary team, which typically includes a geriatric nurse, geriatrician, and social worker. Other members of the team may include a pharmacist, physical therapist, occupational therapist, and dietitian. The Hartford Institute for Geriatric Nursing provides many tools for assessment of older adults on their website (*www.consultgerirn.org/resources*).

Normal Changes of Aging

There are a number of normal age-related changes that occur in all major systems of the body. These may present at different times for different people. It is important to be able to differentiate between normal and abnormal changes in older adults and to educate patients and families about these differences.

Vision

Characteristics

1. Decreased visual acuity.
2. Decreased visual fields, resulting in decreased peripheral vision.
3. Decreased dark adaptation.
4. Elevated minimal threshold of light perception.
5. Presbyopia (farsightedness) because of decreased visual accommodation from loss of lens elasticity.
6. Decreased color discrimination because of the yellowing of the lens; short wavelength colors, such as blues and greens, are more difficult to see.
7. Increased sensitivity to glare.
8. Decreased depth perception.
9. Decreased tear production.
10. Be aware that patients with decreased vision can experience feelings of depression or anxiety.

Assessment Findings

1. Arcus senilis—deposits of lipid around the eye, seen as a white circle around the iris; causes no vision impairments.
2. Cataracts—clouding of the normally clear lens of the eye. (This results in lens thickening and decreased permeability; noted on examination with an ophthalmoscope; fuzziness of vision, like looking through wax paper. Cataracts cause blurring, sensitivity to light, and/or double vision.)
3. Macular degeneration—because of damage to macula that results in loss of central vision. (Objects seem blurred or distorted or are not seen.)
4. Glaucoma—increased intraocular pressure with tonometer testing. (Results in blurring, colored "halos" around lights, pain or redness of eyes, loss of peripheral vision.)
5. Smaller pupil size.
6. Complaints of decreased ability to read, discomfort from light, changes in depth perception, falls, collisions, difficulty handling small objects, difficulty with activities of daily living (ADLs), and tunnel vision.
7. Dry, red eyes.
8. Vitreous floaters, which are lightning flashes in the visual field.

Nursing Considerations and Teaching Points

1. Make sure objects are in the patient's visual field, and do not move objects around.
2. Use large lettering to label medications and any distributed written information.
3. Allow the person more time to focus and adjust to the environment.
4. Avoid glare—may help to wear sunglasses.
5. Use nightlights to help with dark adaptation problems.
6. Use red and yellow to stimulate vision.
7. Mark the edges of stairs and curbs to help with depth perception problems.
8. Use microspiral telescopes or magnifying glasses and high-intensity lighting.
9. Encourage yearly eye examination and/or refer for examination if vision changes worsen (flashing lights in fields or "veil over the eye").
10. Encourage use of isotonic eyedrops as needed for dry eyes.
11. Encourage use of low vision aids, such as magnifying lens, light filtering lens, telescopic lenses, or electronic devices.
12. If patient reports depression or anxiety, refer patient for further evaluation of symptoms.
13. Refer patients to the following resources for vision impairments:

- Prevent Blindness America
  800-331-2020
  www.preventblindness.org
- American Foundation for the Blind
  800-232-5463
  www.afb.org

  800-242-8666
  www.acb.org
- National Institutes of Health Low Vision & Blindness Educational Resources
  http://health.nih.gov/topic/LowVisionBlindness

Hearing

Characteristics

1. Approximately 30% to 50% of people older than age 65 have significant hearing loss.
2. Two major types of hearing disorders are common in the older population.
   a. Sensorineural—progressive, irreversible bilateral loss of high-tone perception often associated with aging. This results in difficulty with discriminating sounds. Sound waves reach the inner ear but are not properly transmitted to the brain.
   b. Conduction deafness—results from blockage or impairment of the mechanical movement in the outer or middle ear (also a pathologic condition). Sound waves are not conducted to the inner ear, resulting in sounds that are muffled.

3. Hearing loss in older adults is usually a combined problem. The majority of the loss is due to auditory nerve changes or deterioration of the structures of the ear. There may also be nerve damage beyond the ear. Presbycusis and central deafness can result in permanent hearing loss; conduction deafness is reversible.
4. Usual progression from high-tone or high-frequency loss to a general loss of both high and low tones.
5. Consonants (higher-pitched sounds) are not heard well.
6. Hearing loss increases with age and is greater in men.
7. Increase in the sound threshold (ie, greater sound needed to stimulate the older adult).
8. Decreased speech discrimination, especially with background noise.
9. Cerumen impaction, the most common cause of conductive hearing loss, is reversible.

Assessment Findings

1. Increased volume of patient's own speech.
2. Turning of head toward speaker.
3. Requests of a speaker to repeat.
4. Inappropriate answers, but otherwise cognitively intact.
5. The person may withdraw, demonstrate a short attention span, and become frustrated, angry, and depressed.
6. Lack of response to a loud noise.

Nursing Considerations and Teaching Points

1. Be aware that hearing loss can impact the safety and quality of life for older adults in many ways. For example, the older adult may not hear instructions, alerting signals, telephones, or oncoming traffic. Hearing loss can contribute to social isolation and lower self-esteem.
2. Suggest hearing testing with an audiologist for further evaluation and consideration of an assistive device.
3. Face the person directly so he can lip-read.
4. Use gestures and objects to help with verbal communication.
5. Touch the person to get his or her attention before talking.
6. Speak into the patient's "good ear."
7. *Do not shout*. Shouting increases the tone of the voice, and older adults are unable to hear these high tones. Try speaking in a deeper or lower tone of voice.
8. Speak slowly and clearly.
9. Suggest amplifiers on telephones and alarms.
10. Allow the person more time to answer your questions.
11. Evaluate the person's ear canals regularly and assist with cerumen removal. Cerumen removal is facilitated by:
    a. Use of ceruminolytic agents, such as carbamide peroxide, 10 drops in the affected ear twice per day for 5 days, followed by flushing the ear with warm water via a 50-mL irrigation syringe or an

electronic irrigation device.

b. Careful use of an ear spoon to mechanically remove cerumen.

12. Refer patients to the following organizations:

- American Speech–Language–Hearing Association: *www.asha.org*
- HearingLoss.com: *www.hearingloss.com*
- National Institute on Deafness and Other Communication Disorders: *www.nidcd.nih.gov/health/hearing/pages/older.aspx*

Smell

Characteristics

1. Changes in smell (olfaction) are due to nasal sinus disease preventing odors from reaching smell receptors, a decrease in nerve fibers, chronic injury from infections, or bleeding.
2. Discrimination of fruity odors seems to persist the longest.
3. Generally, olfaction decreases in men more than in women.

Assessment Findings

1. Inability to notice unpleasant odors, such as fire, body odor, or excessive perfume.
2. Decreased appetite.

Nursing Considerations and Teaching Points

1. Age-related changes can impact safety and quality of life. For example, an older individual may not be able to recognize the smell of smoke or gas.
2. The inability to smell food may cause a decrease in the consumption of nutritious food.
   a. At mealtimes, name food items and give the person time to think of the smell/taste of the food.
   b. Suggest use of stronger spices and flavorings to stimulate sense of smell.

Taste

Characteristics

1. Taste buds decrease with age, especially in men. People over age 60 have lost half of their taste buds. By age 80, only one sixth of the taste buds remain.
2. Taste buds are lost from the front to the back (ie, sweet and salty tastes are lost first, whereas bitter and sour tastes remain longer).

Assessment Findings

1. Complaints that food has no taste.
2. Excessive use of sugar and salt.
3. Inability to identify foods.
4. Decrease in appetite and weight loss.

5. Decreased pleasure from food.

Nursing Considerations and Teaching Points

1. Age-related changes can impact safety. For example, the older individual may not be able to detect spoiled food.
2. Serve food attractively, and separate different types of foods.
3. Vary the texture of foods.
4. Encourage good oral hygiene.
5. Season food.

Kinesthetic Sense

Characteristics

1. With age, the receptors in the joints and muscles that tell us where we are in space lose their ability to function. Therefore, there is a change in balance.
2. Walking with shorter step length, less leg lift, a wider base, and a tendency to lean forward.
3. With age, less ability to stop a fall from occurring.

Assessment Findings

1. Alterations in posture, ability to transfer, and gait.
2. Complaint of dizziness.

Nursing Considerations and Teaching Points

1. Position items within reach.
2. Give person more time to move.
3. Take precautions to prevent falls.
4. Suggest physical therapy with balance training after periods of prolonged immobility.

Cardiovascular

Characteristics

1. With age, the valves of the heart become thick and rigid as a result of sclerosis and fibrosis, compounding any cardiac disease already present.
2. Blood vessels also become thick and rigid, resulting in elevated blood pressure, which is present in half of the US population over age 65.
3. Maximum heart rate and aerobic capacity decrease with age.
4. Slower response to stress. Once the pulse rate is elevated, it takes longer to return to baseline.
5. Decline in maximum oxygen consumption.
6. About 50% of older adults have an abnormal resting electrocardiogram.
7. Subtle changes in artery walls result in a less flexible vasculature.

8. Decreased baroreceptor sensitivity.

Assessment Findings

1. High blood pressure (BP) over age 60 requiring treatment is greater than or equal to 150/90 mm Hg and greater than or equal to 140/90 for adults with diabetes and kidney disease.
2. Prolonged tachycardia may occur following stress.

EVIDENCE BASE James, P. A., Oparil, S., Carter, B. L., et al. (2014). Evidence-based guideline for the management of high blood pressure in adults. Report from the panel members appointed to the Eighth Joint National Committee (JNC 8). *JAMA, 311*(5), 507–520.

Nursing Considerations and Teaching Points

1. Encourage regular BP evaluation as well as lifestyle modifications and medication adherence, if indicated, for hypertension.
2. Check for postural BP changes to detect orthostatic hypotension and prevent falls. Instruct patients to rise slowly from lying to sitting to standing.
3. Encourage longer cooldown period after exercise to return to baseline cardiac function.
4. Encourage moderate physical activity: walking, biking, or swimming for 30 minutes five times per week (150 minutes per week), in addition to muscle strengthening exercises two times a week.

Pulmonary

Characteristics

1. With age, there is a weakening of the intercostal respiratory muscles, and the elastic recoil of the chest wall diminishes.
2. There is no change in total lung capacity; however, residual volume and functional residual capacity increase.
3. Partial pressure of oxygen decreases with age because of ventilation–perfusion mismatches. However, older adults are not hypoxic without coexistent disease.
4. There is a decrease in the mucus transport/ciliary system. Therefore, there is decreased clearance of mucus and foreign bodies, including bacteria.

Assessment Findings

1. Prolonged cough, inability to raise secretions.
2. Increased frequency of respiratory infections.

Nursing Considerations and Teaching Points

1. Older adults who are undergoing surgical treatment should engage in deep breathing exercises.

2. Teach measures to prevent pulmonary infections—avoid crowds during cold and flu season, wash hands frequently, and report early signs of infection.
3. Avoid smoking and exposure to secondhand smoke.
4. Encourage annual flu vaccine and pneumonia vaccine at age 65 or as needed.

Immunologic

Characteristics

1. The function of T-cell lymphocytes, such as cell-mediated immunity, declines with age because of involution and atrophy of the thymus gland.
2. Decreased T-cell helper activity; increased T-cell suppressor activity.
3. Declining B-cell function as a result of T-cell changes.

Assessment Findings

1. More frequent infections.
2. Increased incidence of many types of cancer.

Nursing Considerations and Teaching Points

1. Teach older adults that they are at increased risk of infection, cancer, and autoimmune disease; therefore, routine follow-up and screening are essential.
2. Encourage healthy lifestyle practices to maintain optimal health.

Neurologic

Characteristics

1. There is gradual loss in the number of neurons with age, but no major change in neurotransmitter levels.
2. Some brain tissue atrophy is normal and does not relate to cognitive impairment.
3. Decrease in muscle tone, motor speed, and nerve conduction velocity.
4. Decrease in gait speed of 1.6% per year after age 63; decreased step length, stride length, and arm swing.

Assessment Findings

1. Decreased position and vibration sense.
2. Diminished reflexes, possible absent ankle jerks.
3. Complaint of falls and impaired balance.
4. Wide-based gait with decreased arm swing.

Nursing Considerations and Teaching Points

1. Because gait, strength, and sensory changes, it is essential to teach older adults fall-prevention techniques.
2. Teach environmental safety techniques, including nonslip surfaces, securely fastened handrails, sufficient

light, glare-free lights, avoidance of low-lying objects, chairs of the proper height with armrests, skidproof strips or mats in the tub or shower, toilet and tub grab bars, elevated toilet seats.

3. Refer for home safety evaluations, which may be available through state and local health departments. A home safety checklist can be obtained from the National Safety Council at *www.nsc.org*.

TRANSITIONAL CARE ALERT Using Electronic Health Care Records can help reduce hospital readmissions and improve outcomes for older adults. When nurses worked with IT departments to design input data such as evidence-based assessment tools and decision support tools, several nurse sensitive quality measures improved. An expert decision support system developed by nurses was embedded within the nursing admission assessment identified older adults who needed postacute care, which reduced hospital readmission rates.

EVIDENCE BASE Bowles, K. H., Hanlon, A., Holland, D., Potashnik, S. L., & Topaz, M. (2014). Impact of discharge planning decision support on time to readmission among older adult medical patients. *Professional Case Management, 19*(1), 29–38.

Musculoskeletal

Characteristics

1. Declining muscle mass and endurance with age, although deconditioning may be an associated factor.
2. Decreased bone density, less so in men than in women.
3. Decreased thickness and resiliency of cartilage, with a resulting increase in the stiffness of joints.
4. Bone resorption exceeds bone formation, resulting in a decline in bone density.
5. Injuries to the cartilage accumulate with age.

Assessment Findings

1. Muscle atrophy.
2. Increased incidence of fractures.
3. Complaint of joint stiffness in absence of arthritis.
4. Decreased bone density (less than 2.5 standard deviations below normal).

Nursing Considerations and Teaching Points

1. Early intervention to encourage regular exercise (including weight-bearing exercise and resistance training) in older adults is important to prevent exacerbation of these normal changes.
2. Encourage increased intake of calcium and vitamin D and decreased alcohol and nicotine use.

Community and Home Care Considerations

1. Encourage older adults to engage in 30 minutes of moderate physical activity, including walking, biking, or swimming, at least five times per week, in addition to muscle strengthening exercises at least two times a week.
2. For older adults who will be exercising at less than 80% of the maximum heart rate (220 – age), stress testing before starting an exercise program is not needed.
3. To help with adherence to the exercise program, older adults should be encouraged to exercise at a set time, to relieve pain before exercising, and to do an activity they enjoy. Provide positive reinforcement for those who do exercise, and continually reinforce the benefits of exercise (increased bone strength, cardiovascular fitness, decreased risks of falls, overall sense of well-being).

Endocrine

Characteristics

1. Decreased secretion of trophic hormones from the pituitary gland.
2. Blunted growth hormone release during stress.
3. Elevated vasopressin (antidiuretic hormone); exaggerated response to osmotic challenge.
4. Elevated levels of follicle-stimulating hormone and luteinizing hormone because of reduced end-organ response.
5. Decreased insulin secretion after meals; this may be a function of weight or genetic factors.

Assessment Findings

Usually asymptomatic.

Nursing Considerations and Teaching Points

1. Encourage routine screening for elevated blood glucose—both fasting and postprandial.
2. Provide education about a well-balanced diet.

Reproductive

Characteristics

1. In women, menopause leads to decreases in the size of the ovaries and hormone production. This results in uterine involution, vaginal atrophy, and loss of breast mass.
2. With age, there is increased risk in females of cystocele, rectocele, and uterine prolapse.
3. In men, testosterone production and secretion decrease with age. However, serum levels may be in the low-normal range through age 80.

Assessment Findings

1. Vaginal dryness, painful intercourse.
2. Atrophic vaginitis.

3. Urinary incontinence.

Nursing Considerations and Teaching Points

1. Suggest the use of additional lubrication during sexual intercourse.
2. Advise sexually active older men that spermatogenesis may continue into advanced age.
3. Address risks and benefits of time-limited hormone replacement therapy for symptomatic relief related to menopause.
4. Refer patient for further evaluation for urinary incontinence

Renal and Body Composition

Characteristics

1. Increased body fat and decreased lean muscle mass, even when weight remains stable.
2. Decreased renal function, measured by the glomerular filtration rate, or creatinine clearance.
3. Despite reduced total body creatinine because of decreased muscle mass in the older adult, serum creatinine often remains within normal range. This is because of decreased elimination of creatinine by the kidneys.
4. About 10% decline in creatinine clearance per decade after age 40; however, relatively unchanged serum creatinine.

Assessment Findings

1. Usually asymptomatic.
2. Increased incidence of anemia.

Nursing Considerations and Teaching Points

1. Be aware that although serum creatinine may be within normal range, creatinine clearance may be decreased. To obtain an accurate creatinine clearance in an older adult, the following formula may be used: (140 – age) (weight [kg])/(72)(serum creatinine [mg/dL]).
2. Drugs that are cleared through the kidneys may be given in decreased dosage. Adverse effects and toxicity must be closely monitored.
3. Consider the advantages and disadvantages of drug management for anemia associated with renal disease.

Skin

Characteristics

1. Thinning of all three layers of the skin—epidermis, dermis, and subcutaneous tissue—leads to greater fragility of the skin and decreased ability of the skin to function as a barrier to external factors.
2. Fewer melanocytes and decreased tanning.
3. Less efficient thermoregulation of heat because of fewer sweat glands.

4. Drier skin because the decreased number of sebaceous glands results in reduced oil production.
5. Other changes in aging skin include reduced sensory input, decreased elasticity, and impaired cell-related immune response.

Assessment Finding

1. Dry, irritated skin.

Nursing Considerations and Teaching Points

1. Excessive use of soap, which can be drying to the skin, should be avoided.
2. Careful skin evaluation and lubrication are necessary to prevent fissures and breakdown.
3. Heat regulation needs to be controlled by proper clothing and avoidance of extreme temperatures.
4. Avoid direct application of extreme hot or cold to skin because damage may occur without feeling it.
5. Encourage use of sunscreen during all outdoor activities.

Community and Home Care Considerations

Xerosis (dry skin) is a common problem for older adults. Treatment should include:

1. Drinking 2,000 mL of liquid daily.
2. Total body immersion in warm water (90°F to 105°F [32.2°C to 40.6°C]) for 10 minutes.
3. Use of nonperfumed soap without hexachlorophene.
4. Application of emollient, particularly those with alpha-hydroxy acids, after bathing and at bedtime.

Hematopoietic

Characteristics

1. Unchanged number of stem cells of all three cell lines; however, bone marrow cellularity is decreased by 33% during adult life.
2. Declining marrow activity, especially in response to stress, such as with blood loss or infection.

Assessment Finding

Asymptomatic.

Nursing Considerations and Teaching Points

1. Anemia and granulocytopenia are not normal consequences of aging and should be investigated.
2. Teach patients that there is no need to take oral iron unless there is an actual documented decrease in iron levels.
3. Encourage oral B_{12} and folate replacement to manage associated anemias.

Altered Presentation of Disease

Characteristics

1. In part because of the physiologic changes that occur with aging, the manifestations of illness in the older

patient are less dramatic than in younger patients.

2. Most older adults have at least one chronic condition. These coexisting conditions can complicate the evaluation of new symptoms.
3. Some risk factors make it more likely that they will present with an altered presentation of disease: over age 85, multiple comorbid conditions, taking over five medications, and having cognitive or functional impairment.

EVIDENCE BASE Smith, C. M., Cotter, V. T. (2016). Age-related changes in health. In M. Boltz, E. Capezuti, T. Fulmer, & D. Zwicker (Eds.), *Evidence-based geriatric nursing protocols for best practice* (5th ed., pp. 23–41). New York, NY: Springer Publishing Company.

Assessment Findings

1. The classic indicators of disease are usually absent or disorders present atypically (see Table 9-1).
2. Older people are less likely to report new symptoms but, rather, attribute them to aging or existing conditions. Many older adults minimize symptoms because of fears of hospitalization or health care costs.

Table 9-1 Atypical Presentation of Disorders in the Older Adult

DISORDER	ATYPICAL PRESENTATION
Acute intestinal infection	• Abdominal pain may be absent. • May present with acute confusional state, leukocytosis, and acidosis
Appendicitis	• Pain may be diffuse, not localized in the right lower quadrant.
Biliary disease	• Confusion, declining function, and other nonspecific symptom • Abnormal liver function tests may be only sign.
Heart failure	• Initially, may have change in mental status and fatigue
Hyperthyroidism	• Apathy, palpitations, weight loss, weakness
Hypothyroidism	• Presents with weight loss
Myocardial infarction	• Chest pain may be absent. • May present with syncope, dyspnea, vomiting, or confusion
Perforated ulcer	• Rigidity may be absent until late.
Pneumonia	• May present with confusion • Fever and cough may be absent
Pulmonary embolism	• May present with change in mental status • May not have fever, leukocytosis, or tachycardia
Septicemia	• May be afebrile
Systemic lupus erythematosus	• Pneumonitis, subcutaneous nodules, and discoid lesions are more common. • Malar rash, Raynaud phenomenon, and nephritis are less common.
Urinary tract infection	• Confusion

Nursing Considerations and Teaching Points

1. Have a high index of suspicion for underlying illness if the older adult presents with an acute change in cognition, behavior, or function.

Functional Assessment

Functional assessment is the measurement of a patient's ability to complete functional tasks and fulfill social roles, specifically addressing a patient's ability to complete tasks ranging from simple self-care to higher-level activities. It provides the nurse with objective data to help determine the older adult's needs and plan interventions. Across the United States, there is an imperative to reduce hospital readmissions. Many programs have been successful. A common feature in most of the programs is the need to complete a functional assessment

Purpose

1. Functional assessment is essential in the care of the older adult because it:
    a. Offers a systematic approach to assessing older adults for deficits that commonly go undetected.
    b. Helps the nurse to identify problems and utilize appropriate resources.
    c. Provides a way to assess progress and decline over time.
    d. Helps the nurse evaluate the safety of the patient's ability to live alone.
2. Functional status includes the evaluation of sensory changes, ability to complete ADLs and instrumental ADLs, gait and balance problems, and elimination.

Instruments to Measure Functional Ability

1. Functional status may be assessed by several methods: self-report, direct observation, or family report. Direct observation is the method of choice, when possible.
2. The instrument chosen should be based on the specific goal or purpose for the evaluation. For example, if the focus is on basic self-care and mobility, the Barthel index should be used. See page 161 for reference (Mahoney & Barthel).
3. The Katz Index for Activities of Daily Living and Instrumental Activities of Daily Living is another rating scale for measuring functional ability. Use this scale to determine level of independence of the older adult and repeat periodically to compare level of functioning over time. See page 161 for reference (Katz, et al.).
4. Performance measures, such as the Tinetti Gait and Balance measure or the Chair Rise test, can be used to evaluate higher-level functioning. Consult with a physical therapist.

Psychosocial Assessment

Altered Mental Status

1. Assessment of mental status to detect altered cognition involves examination of memory, perception, communication, orientation, calculation, comprehension, problem solving, thought processes, language, executive function, visual–spatial abilities, abstraction, attention, aphasia, and apraxia.
2. Assessment can be facilitated by use of cognitive screening tools. A commonly utilized instrument is the Mini-Mental State Examination (MMSE), a 30-point cognitive screening instrument that assesses orientation to time and place, registration and recall, calculation, language skills, and visual–spatial abilities.
3. The total possible score is 30. A score of 24 to 30 suggests intact cognitive function; 20 to 23, mild cognitive impairment; 16 to 19, moderate cognitive impairment; and 15 or less, severe cognitive impairment. The MMSE can help to follow the patient's cognition over time and assess for acute and/or chronic changes.
4. Although success on scales such as this has been associated with language abilities, education, and socioeconomic status, this scale continues to be used as an appropriate screening tool for abnormal cognitive function.
5. Another cognitive screening instrument is the Mini-Cog examination, which is composed of a three-item recall and the clock drawing test (CDT). The Mini-Cog can be administered under 3 minutes, does not appear to be affected by the patient's education or language abilities, and has been successfully used to screen for dementia across a variety of clinical settings. The Mini-Cog can be administered as follows:
   a. Tell the patient to listen carefully and remember and repeat three unrelated words.
   b. Tell the patient to draw the face of a clock including numbers and hands to read a specific time. The CDT is considered normal if all numbers are present in the correct sequence and position and the hands display the requested time.
   c. Ask the patient to repeat the three previously stated words.
   d. Unsuccessful recall of all three items suggests dementia. Successful recall of all three items suggests intact cognition. An abnormal CDT with one to two errors on recall suggests dementia. A normal CDT with one error on recall suggests no dementia.
6. Assessment of altered mental status or behavior may elicit criteria that lead to a diagnosis of dementia. It is essential to differentiate dementia from delirium (which is treatable and reversible).
7. *Delirium* is a change in mental status that is abrupt in onset and is commonly because of an underlying medical condition, such as infection, electrolyte imbalance, medication intolerance or toxicity, cardiac decompensation, or hypoxia.
   a. Occurs early, and the behavior is variable hour to hour. May be superimposed upon dementia making identification difficult.
   b. Clouded, altered, or fluctuating level of consciousness (lethargic to hypervigilant), short attention span, and disturbed sleep–wake cycle. Hallucinations (sensory experiences without a stimulus) are

common.

c. Reversible with treatment of the underlying cause; however, individuals with an unrecognized and prolonged episode of delirium may not return to their previous cognitive baseline.

d. Underrecognized and is associated with morbidity and mortality among older adults.

8. *Dementia* has a gradual onset. Behavior is usually consistent, and disorientation occurs late. Consciousness is not clouded, attention span is generally not reduced, and day–night reversal of sleep–wake cycles can occur rather than hour-to-hour variation. Delusions (fixed false beliefs) are more common than hallucinations.

Social Activities and Support

1. Social support for older adults is generally instrumental, informational, or emotional. The social environment is important with regard to recovery of acute medical problems and management of chronic illness.
2. Elicit information by asking such questions as:
   a. How often do you socialize with others?
   b. With whom do you socialize?
   c. What type of activities do you enjoy?
   d. Do you enjoy socializing?
   e. Who can you call for help?
   f. Do you know of any church or community groups you can call for help?

Emotional and Affective Status

Characteristics

1. Depression may occur for the first time in older age and has been related to the many changes that occur with aging:
   a. The independence of one's children.
   b. Adjusting to new routines associated with retirement.
   c. The loss of roles, income, spouse, friends, family, home, pets, functional ability, health, and ability to participate in leisure activities such as reading.
   d. Ageist messages from society supporting and encouraging the value of youth.
2. Depression may also be associated with underlying illnesses, such as Alzheimer disease, Parkinson disease, and stroke, and by medications, such as antihypertensives (beta-blockers), antiarthritics, and antianxiety agents.
3. Depression is usually difficult to identify in the older adult because the presentation is different than in younger people. Obtain the following information to assess for depression:
   a. Complaints of insomnia, weight loss, anorexia, and constipation (vegetative symptoms).
   b. Presence of anhedonia (lack of joy in usually pleasurable activities).

c. Decrease in concentration, memory, and decision-making (pseudodementia syndrome).
d. Other somatic complaints, such as decreased appetite, musculoskeletal aches and pains, chest pain, and fatigue.
e. History of chronic illness or other health problems.
f. Current medications.

4. Evaluate depression using the Geriatric Depression Scale as a screening tool for older adults without or with mild cognitive impairment. The Cornell Scale for Depression in Dementia can be used as a screening tool for older adults with dementia.
5. Suicide is sometimes associated with depression, with suicides being especially high in older white men. Assess for suicide risk.
6. Pain is underdetected and may be undertreated in older adults and can contribute to depressive symptoms. Assess pain by asking and observing the patient, and provide appropriate measures to make patient more comfortable.

Nursing and Patient Care Considerations

1. Treatment of depression should be given to older adults and includes medications, psychotherapy, and, in some cases, electroconvulsive therapy.
2. Complement other therapeutic measures by providing opportunities to increase the patient's self-esteem.
   a. Encourage participation in meaningful activities.
   b. Promote the patient's positive self-image.
   c. Help the patient develop a sense of mastery.
   d. Encourage reminiscence of meaningful past events.
3. Help patient identify and use social supports.
4. For behavioral problems (agitation, combative behavior, or irritability) consider options such as aromatherapy, music therapy, pet therapy, relaxation techniques, massage, or physical activity.

Motivation in Older Adults

Characteristics

1. Motivation is an important variable in the older adult's ability to recover from any disabling event and the ability to maintain his or her highest level of wellness.
2. Understanding individual motivational factors for engaging in health promotion activities like exercise is an approach that can improve adherence. It is possible to evaluate a patient's motivation to comply with a given treatment plan and adopt interventions to help to improve the older adult's motivation.
3. Factors that influence motivation in an older adult include:
   a. Needs such as hunger.
   b. Past experiences, specifically with health care providers.
   c. Negative attitudes toward aging.

   d. Self-efficacy expectations or the belief in one's ability to perform a specific activity.
   e. Outcome expectations or the belief that if a specific activity is performed there will be an expected outcome.
   f. The cost of performing a specific activity in terms of time, money, pain, fatigue, or fear.
   g. Internal factors, such as sensory changes, cognitive status, resilience and adverse drug effects.
   h. External factors, such as social norms (particularly if those norms conflict with treatment) and the influence of social supports.
4. Problems in motivation because of age-related differences include:
   a. A shift from achievement motivation to conservative motivation.
   b. Establishment of meaningful rewards for older people, because of losses.
   c. Greater significance placed on the meaning of a task; it must be meaningful to the older person.
   d. Evidence that older adults do not do well on tasks if they are asked to do them rapidly, under a time limit, or in a stressful situation.
   e. Increased importance placed on the cost of participating in an activity; fear of failing can be expressed either as increased anxiety or decreased willingness to take risks.
5. The Motivation Wheel (see Figure 9-1) can be used to evaluate motivation in the older adult.
   a. Motivation is influenced by beliefs about physical and emotional benefits, mastery experiences, individualized care, social support, the environment, goals, physical sensations, and new activities.
   b. Motivation can be increased by strengthening beliefs about potential benefits, providing opportunities for mastery, identifying individualized care approaches and goals, using social supports, accessing supportive environments, decreasing unpleasant sensations, and trying new activities.

Figure 9-1. The wheel that moves.

Nursing and Patient Care Considerations

1. Strategies to improve motivation include:
    a. Establish whose motives are being discussed. Involve the patient, family, and health care providers in setting patient-centered goals.
    b. Explore with patient any indication of fear or other unpleasant sensation associated with the activity, such as pain or fatigue, and implement interventions to decrease these unpleasant sensations.
    c. Evaluate the spokes of the wheel to consider the many factors that influence motivation and implement interventions as appropriate.
    d. Encourage patient to verbally express emotional factors associated with the activity.
    e. Examine the setting for the desired behavior to occur. Is the environment too stressful, too dark, or too noisy?
    f. Attempt to use role models. Older adult role models can change ageist attitudes and stimulate patients to perform the desired behavior.
    g. Set small goals to be met either daily or each shift. This provides frequent rewards.
    h. Do not be afraid to use yourself. Research has indicated that being nice, demonstrating caring, using humor, verbal encouragement, and support, can all help motivate the older adult.

2. Educate the older adult about the benefits of the activity, whether these are physical or psychological.

EVIDENCE BASE Smaerup, M., Gronvall, E., Larsen, S. B., et al. (2017). Exercise gaming: a motivational approach for older adults with vestibular dysfunction. *Disability and Rehabilitation: Assistive Technology, 12*(2), 137–144.

HEALTH MAINTENANCE

EVIDENCE BASE United States Preventive Services Task Force. (2017). The guide to clinical preventive services: Recommendations of the U.S Preventive Services Task Force. Available: *https://www.uspreventiveservicestaskforce.org/Page/Name/recommendations*.

Primary Prevention

The goal of health promotion and disease prevention is to add more quality years to life. There are three levels of health promotion and disease prevention.

Primary prevention is the prevention of disease before it occurs. Primary prevention can be broken down into counseling, immunizations, and chemoprophylaxis.

Counseling

1. Encourage smoking cessation.
    a. Approximately 8% of people in the United States age 65 and older are smokers.
    b. Tobacco use has been linked to heart disease; peripheral vascular disease; cerebrovascular disease; chronic obstructive pulmonary disease; cancer such as lung, bladder, and esophageal malignancies; and numerous other health problems that decrease quality of life or cause premature death.
    c. Although much damage has been done to the lungs and blood vessels by many years of smoking, older adults can still benefit from smoking cessation by increasing quality of life.
    d. The US Preventive Service Task Force recommends the "5-A" behavioral counseling framework as a useful strategy for engaging patients in smoking cessation discussions: (1) Ask about tobacco use; (2) Advise to quit through clear personalized messages; (3) Assess willingness to quit; (4) Assist to quit; and (5) Arrange follow-up and support.
2. Encourage physical activity.
    a. It has been stated that 75% of older Americans are inactive.
    b. It has been recommended that older adults participate in regular physical activity for 30 minutes, 5 days a week, especially aerobic activities that promote cardiovascular fitness, such as walking, cycling, or swimming.
    c. Refer to a physical, occupational, or rehabilitation therapist. An individualized exercise prescription should be developed and cleared with the health care provider.
3. Identify alcohol abuse in older adults.
    a. The consequences of alcoholism include liver disease, gastrointestinal (GI) bleeding, and motor vehicle accidents.
    b. Question older adults about drug or alcohol abuse. Although current street drug use is less common, prescription drug abuse may be occurring or alcohol may be used for pain.
    c. Recognize the signs and symptoms of alcohol abuse in older adults (see Box 9-1).
    d. Refer for counseling.
4. Evaluate and counsel on dental health.
    a. Dental problems in older adults include missing teeth, ill-fitting dentures, periodontal disease, and tooth decay.
    b. Dental problems commonly lead to poor eating habits, apathy, and fatigue.
    c. Regular dental care should be encouraged to improve nutrition and the quality of life.

BOX 9-1 Signs of Alcohol Abuse in Older Adults

- Difficulty with gait and balance.
- Acute change in cognition.
- Frequent falls or accidents.
- Change in drinking patterns.
- Poor nutritional intake.
- Poor hygiene and self-care.
- Lack of physical exercise.

Immunizations

EVIDENCE BASE Centers for Disease Control and Prevention. (2016). *Advisory Committee for Immunization Practices (ACIP) recommendations*. Atlanta, GA: CDC. Available: *www.cdc.gov/vaccines/pubs/ACIP-list.htm#pcv.*

1. Pneumococcal pneumonia is a significant cause of mortality and morbidity in older adults.
   a. There are two vaccines that prevent pneumococcal disease: pneumococcal conjugate vaccine (PCV13) and pneumococcal polysaccharide vaccine (PPSV23). The CDC recommends that two pneumococcal vaccines be given to all people age 65 or over. A dose of PCV13 should be given first, followed by a dose of PPSV23 at least 1 year later. Individuals who have been previously vaccinated with PPSV23 should receive a dose of PCV13 at least 1 year following their most recent dose of PPSV23.
   b. The above vaccination schedule is also recommended for individuals aged 19 to 64 who smoke or who have functional or structural asplenia or immunocompromising conditions.
2. Influenza may cause significant complications in older adults. Annual influenza vaccination is recommended for all people over age 6 months without contraindications (eg, egg allergy).
   a. The intranasal live-attenuated influenza vaccine has not been approved for individuals 50 years of age or older.
   b. Several antiviral agents are effective against influenza. These agents can be effective in ameliorating symptoms if given within 48 hours of onset of illness.
3. Tetanus–diphtheria (Td) immunization is an important but frequently forgotten component of health maintenance, especially in older adults.
   a. The mortality rate of tetanus exceeds 50% in those over age 65.
   b. Combined tetanus–diphtheria boosters should be given every 10 years; no age for discontinuation has been stated.
   c. Because of an increase in pertussis cases, a single dose of acellular pertussis is also recommended as a

component (Tdap) for adults aged 65 years and older who anticipate having close contact with an infant less than 12 months of age and who previously have not received Tdap. Tdap can be administered regardless of interval since the last tetanus booster.

   d. For those with no history of immunization or unknown immunization status, a primary series should be initiated, consisting of two doses of tetanus–diphtheria vaccine at least 4 weeks apart, followed by a third dose 6 to 12 months later.

4. A single dose of the herpes zoster vaccine is recommended for older adults to prevent the dermatologic reoccurrence of varicella and the possible painful sequela known as postherpetic neuralgia.
   a. Age is the most important factor in the development of herpes zoster, with a large increase beginning between age 50 and 60, and about 50% of people experience herpes zoster by age 85.

Chemoprophylaxis

1. The risk and benefits of oral anticoagulation therapy should be considered for older adults at risk of cardiovascular disease, particularly stroke. The United States Preventive Services Task Force (USPSTF) strongly recommends that clinicians discuss aspirin therapy with patients at risk for coronary heart disease.
   a. Contraindicated if patient is at risk for GI bleeding.
   b. Should be discussed with older adults with regard to prevention of deep vein thrombosis, nonvalvular atrial fibrillation, cardiomyopathy, valvular heart disease, mechanical prosthetic heart valves, and acute myocardial infarction.
2. Calcium, vitamin D, and other agents, such as selective estrogen receptor modulators or bisphosphonates, may be considered for those at risk for osteoporosis.

Secondary Prevention

Secondary prevention is the detection of disease in an early stage for best treatment outcomes, such as cancers, cardiovascular disease, osteoporosis, and tuberculosis.

Screening Recommendations

EVIDENCE BASE United States Preventive Services Task Force. (2016). The guide to clinical preventive services: Recommendations of the U.S Preventive Services Task Force. Available: *www.uspreventiveservicestaskforce.org/index.html*.

Age alone is not a criterion as to when to stop screening. Rather, the patient and health care provider should discuss values, expectations, functional status, and quality of life. A guide to shared decision-making for cancer screening is available at the USPSTF website at *www.uspreventiveservicestaskforce.org/3rduspstf/shared/sharedba.htm*.

The USPSTF has made the following recommendations for cancer screenings for older adults:

1. The precise age at which to discontinue screening mammography is uncertain. No clinical trials have been conducted on women over age 74. Furthermore, although older women face a higher probability of developing breast cancer, they also have a greater chance of dying from other causes.
2. Regarding cervical cancer, it is appropriate for older women to discontinue cervical cancer screening after age 65 only if they have had adequate recent screening with normal results and are not at high risk for cervical cancer.
3. The age to discontinue colorectal cancer screening has not been determined; however, the USPSTF recommends against routine colorectal cancer screening in adults ages 75 to 85, unless there are conditions that support screening for these individuals.
4. The USPSTF states that there is insufficient evidence to recommend for or against screening for prostate cancer. Older men and men with other significant medical conditions who have a life expectancy of fewer than 10 years are unlikely to benefit from the prostate-specific antigen test and digital rectal examination.

Tertiary Prevention

Tertiary prevention addresses the treatment of established disease to avoid complications and death. The major areas of focus for the older adult are preventing the complications of immobility and rehabilitation

Preventing Complications of Immobility

Positioning

1. The goal of frequent position changes is to prevent contractures, stimulate circulation and prevent pressure sores, prevent thrombophlebitis and pulmonary embolism, promote lung expansion and prevent pneumonia, and decrease edema of the extremities. Changing position from lying to sitting several times per day can help prevent changes in the cardiovascular system, which is known as *deconditioning*.
2. The recommendation is to change body position at least every 2 hours and, preferably, more frequently in patients who have no spontaneous movement.

EVIDENCE BASE Lozano-Montoya, I., Velez-Diaz-Pallares, M., Abraha, I., et al. (2016). Nonpharmacologic interventions to prevent pressure ulcers in older patients: An overview of systematic reviews (Software ENgine for the Assessment and optimization of drug and non-drug Therapy in Older peRsons [SENATOR] definition of Optimal evidence-based Non-drug Therapies in Older People [ONTOP] Series). *Journal of the American Medical Directors Association, 17* (4), 370.e1–370.e10.

Proper Body Alignment

1. Dorsal or supine position
   a. The head is in line with the spine, both laterally and anteroposteriorly.
   b. The trunk is positioned, so flexion of the hips is minimized to prevent hip contracture.
   c. The arms are flexed at the elbow with the hands resting against the lateral abdomen.
   d. The legs are extended in a neutral position with the toes pointed toward the ceiling.
   e. The heels are suspended in a space between the mattress and the footboard to prevent heel pressure.
   f. Trochanter rolls are placed under the greater trochanters in the hip joint areas.
2. Sidelying or lateral position
   a. The head is in line with the spine.
   b. The body is in alignment and is not twisted.
   c. The uppermost hip joint is slightly forward and supported by a pillow in a position of slight abduction.
   d. A pillow supports the arm, which is flexed at both the elbow and shoulder joints.
3. Prone position
   a. The head is turned laterally and is in alignment with the rest of the body.

b. The arms are abducted and externally rotated at the shoulder joint; the elbows are flexed.
c. A small, flat support is placed under the pelvis, extending from the level of the umbilicus to the upper third of the thigh.
d. The lower extremities remain in a neutral position.
e. The toes are suspended over the edge of the mattress.

Therapeutic Exercise

1. It has been reported that there is a daily loss of 1% to 1.5% of initial strength in an immobilized older adult.
2. The goals of therapeutic exercise are to develop and retrain deficient muscles, to restore as much normal movement as possible to prevent deformity, to stimulate the functions of various organs and body systems, to build strength and endurance, and to promote relaxation.
3. Perform passive range-of-motion (ROM) exercise.
   a. Carried out without assistance from the patient.
   b. The purpose is to retain as much joint ROM as possible and to maintain circulation.
   c. Move the joint smoothly through its full ROM (see Box 9-2, pages 141 to 144). Do not push beyond the point of pain.
4. Perform active assistive ROM.
   a. Carried out by the patient with the encouragement and/or assistance of the nurse.
   b. The purpose is to encourage normal muscle function.
   c. Support the distal part and encourage the patient to take the joint actively through its ROM.
   d. Give only the amount of assistance necessary to accomplish the action.
5. Encourage active ROM.
   a. Accomplished by the patient without assistance.
   b. The purpose is to increase muscle strength.
   c. When possible, active exercise should be done against gravity.
   d. Encourage the patient to move the joint through the full ROM without assistance.
   e. Make sure that the patient does not substitute another joint movement for the one intended.
   f. Other active forms of exercise include turning from side to side, turning from back to abdomen, and moving up and down in bed.
6. Assist with resistive exercise.
   a. Carried out by the patient working against resistance produced by either manual or mechanical means.
   b. The purpose is to increase muscle strength.
   c. Encourage the patient to move the joint through its ROM while you or someone else provides slight resistance at first and then progressively increases resistance.
   d. Weights may be used and are attached at the distal point of the involved joint.

e. The movements should be done smoothly.

7. Teach isometric or muscle-setting exercise.
   a. Involve alternately contracting and relaxing a muscle while keeping the part in a fixed position; performed by the patient.
   b. The purpose is to maintain strength when a joint is immobilized.
   c. Teach the patient to contract or tighten the muscle as much as possible without moving the joint.
   d. The patient holds the position for several seconds and then relaxes.

Geriatric Rehabilitation and Restorative Care

Characteristics

1. The primary goal is restoring the older adult to maximum functional level.
2. Multidisciplinary service involving input from the primary care provider; nursing personnel; physical, occupational, speech, and recreational therapists; social worker; psychologist; and dietitian.
3. Rehabilitation and restorative nursing involves developing a rehabilitation philosophy of care.
   a. Patients are encouraged, and allowed sufficient time, to perform as much of their personal care as possible.
   b. Goals are set *with* the patient rather than *for* the patient.
   c. Prevention of further impairment is imperative.
   d. Focus on skin and wound care, regaining or maintaining bowel and bladder function, independent medication use, good nutritional status, psychosocial support, an appropriate activity–rest balance, and patient and family education.

EVIDENCE BASE Resnick, B., Galik, E., Wells, C., et al. (2015). Optimizing physical activity

among older adults post trauma: Overcoming system and patient challenges. *International Journal of Orthopedic and Trauma Nursing, 19*(4), 194–206.

Nursing and Patient Care Considerations

1. Impaired cognitive function may have an impact on the quality of rehabilitation.
    a. Assess for physical problems that may exacerbate cognitive dysfunction (eg, infection, adverse drug effects, metabolic or circulatory problems, or fatigue).
    b. Provide innovative measures to encourage ambulation, active ROM, and increased function; provide frequent verbal cues and large-print reminders; focus on basic self-care abilities and activities that are consistent with the individual's past life experiences.
    c. Implement appropriate safety measures, such as bed side rails, proper lighting, appropriate staffing, and avoidance of chemical and physical restraints.
2. Disability has a tremendous impact on patient's body image and requires an adjustment by patient. Be aware of the stages of psychological reaction the patient may undergo.
    a. Period of confusion, disorganization, and denial.
    b. Period of depression or anxiety and grief.
    c. Period of adaptation and adjustment.
3. Interventions in rehabilitation nursing include:
    a. Provide an atmosphere of acceptance.
    b. Identify and encourage positive coping patterns.
    c. Encourage socialization and participation in group activities.
    d. Give positive reinforcement and feedback about progress.
    e. Involve families as much as possible.
4. Use suggested interventions to motivate older adult to engage in functional activities and exercise.

Community and Home Care Considerations

1. Family or significant other caring for the older adult at home can have a major impact on the rehabilitation process.
    a. Assist family or significant other to face the reality of the patient's disability and to set appropriate and achievable goals.
    b. Involve family or significant other in the decision-making and in the patient's care for them to develop and practice the skills necessary for the patient to reach rehabilitation goals.
    c. Help extend and enlarge family's or significant other's skills by teaching problem solving, treatment needs of the patient, ways to communicate to health care providers, and the use of community resources.
    d. Assess the level of caregiver fatigue or burnout (see Box 9-3).
2. For the older adult living independently:

a. Encourage adherence to a regular exercise program, which includes aerobic exercise, stretching, and strength training to maintain optimal function.
b. The Centers for Disease Control and Prevention recommends that all adults should accumulate at least 150 minutes of moderate-intensity physical activity (walking, biking, swimming, etc.) per week and strength training (heavy gardening, yoga, lifting weights, resistance exercises) at least 2 days a week.
c. Older adults can meet the physical activity recommendations with the following sample schedule:
    i. Aerobic exercise: brisk walking 5 days per week for at least 30 minutes.
    ii. Flexibility: stretch every day.
    iii. Strength training: do strength-building activities 2 to 3 days per week that involve all major muscle groups.
d. For further information on exercise for older adults living independently, see *www.cdc.gov/physicalactivity/everyone/guidelines/olderadults.html*.

BOX 9-3 Caregiver Strain Index

Instructions given to the caregiver: I am going to read a list of things that other people have found to be difficult in caring for patients after they come home from the hospital. Would you tell me whether any of these apply to you? (Give the examples.)

Score one point for "yes" and zero for "no"

1. Sleep is disturbed (eg, because is in and out of bed or wanders around at night).
2. It is inconvenient (eg, because helping takes so much time or it is a long drive over to help).
3. It is a physical strain (eg, because of lifting in and out of a chair).
4. It is confining (eg, because helping restricts free time or cannot visit).
5. There have been family adjustments (eg, because helping has disrupted routine or there has been no privacy).
6. There have been changes in personal plans (eg, had to turn down a job or could not go on vacation).
7. There have been other demands on my time (eg, from other family members).
8. There have been emotional adjustments (eg, because of severe arguments).
9. Some behavior is upsetting (eg, incontinence; has trouble remembering things; accuses others of taking things).
10. It is upsetting to find that has changed so much from before (eg, is a different person from before).
11. There have been work adjustments (eg, because of having to take time off).
12. It is a financial strain.
13. It has been completely overwhelming (eg, because of worry about or concerns about how to continue to manage).

Scoring: Total score of 7 or more suggests a greater level of stress.

Robinson, B. C. (1983). Validation of a caregiver strain index. Journal of Gerontology, 38(3), 344–348. ©1983 The Gerontological Society of America.

SPECIAL HEALTH PROBLEMS OF THE OLDER ADULT

Altered Response to Medication

Adults over age 65 consume 30% to 40% of all prescription drugs and over-the-counter drugs. Age-related changes predispose older adults to problems with adverse drug effects.

Pathophysiology and Etiology

1. Drug absorption is affected by such age-related changes as:
   a. Decreased gastric acid.
   b. Decreased GI motility.
   c. Decreased gastric blood flow.
   d. Changes in GI villi.
   e. Decreased blood flow and body temperature in rectum.
2. Drug distribution is affected by:
   a. Decreased body size.
   b. Decreased water content in the body.
   c. Increased total body fat.
   d. Drugs distributed in water have a higher concentration in older adults (eg, gentamicin).
   e. Drugs distributed in fat have a wider distribution and less intense but prolonged effect (eg, phenobarbital).
3. Drug metabolism in the older adult:
   a. Is altered by a decrease in liver size, blood flow, enzyme activity, and protein synthesis.
   b. Requires more time than in younger adults. Therefore, there is increased drug activity time in drugs that are metabolized in the liver (eg, propranolol, theophylline).
4. Excretion of drugs is altered in older adults because of the following renal changes:
   a. Decreased renal tubular function and blood flow.
   b. This causes a decrease in renal filtration and an increase in blood levels of drugs that are excreted through the kidneys (eg, cimetidine).

DRUG ALERT Drugs that may have severe adverse effects in elderly patients include anticholinergics (antihistamines, tricyclic antidepressants, drugs for treating urinary incontinence), nonsteroidal anti-inflammatory drugs (NSAIDs), any drug with a long half-life, and drugs with action on the central nervous system (CNS).

Nursing Assessment

1. Drug toxicities in older adults are different than they are in younger people.
2. Fewer symptoms may be identified, and they may develop slower; however, the reactions may be more

pronounced and further advanced once they do present.

3. Behavioral and cognitive adverse effects are more common in older adults because the blood–brain barrier becomes less effective; the first reaction to a drug is confusion.
4. Many potential adverse drug effects are not identified because they are attributed to old age; fatigue, dementia, anorexia, or indigestion as adverse drug effects may not be reported.
5. Allergic reactions to drugs increase with age because of a greater likelihood of earlier exposure.

Nursing and Patient Care Considerations

1. Maintain awareness that the older adult is at greater risk for adverse drug reactions.
    a. This risk increases from 6% when two drugs are taken to 50% when five different drugs are taken and to 100% when eight or more drugs are taken.
2. Assess patient's ability to follow medication regimen by evaluation of:
    a. Cognition.
    b. Ability to read drug labels.
    c. Hand and muscle coordination.
    d. Swallowing difficulty.
    e. Lifestyle patterns, specifically smoking and alcohol use.
    f. Cultural beliefs toward medication.
    g. Ability to afford medication.
    h. Caregiver involvement in medication administration; assess caregiver if indicated.
3. Identify problems in the use of medications, such as:
    a. Lack of knowledge about drugs.
    b. Multiple medications and difficult administration techniques.
    c. Caregiver misunderstanding of medication use.
4. Appropriate interventions for safe drug use include:
    a. Obtain a complete drug history.
    b. Reinforce verbal instructions with written instructions using large-print and simple wording. If necessary, use color-coding rather than drug names.
    c. Write what the drug is used for and what the adverse effects can be.
    d. Make sure patient or caregiver can open the medication container.
    e. Arrange medication schedules to coincide with regular activity, such as eating (if appropriate for that drug). Simplify the drug regimen as much as possible.
    f. If necessary, arrange a check-off system using a chart to ensure adherence or weekly pill box.
    g. If possible, visibly evaluate all medications in the home, or ask patient to bring all medications for evaluation.
    h. Encourage patient to check expirations dates and discard all old or unneeded medications.
    i. Encourage patient to store medications in original containers in a dry, dark place.

j. Encourage patient to avoid over-the-counter (OTC) medication without checking with the primary care provider before use.

k. Encourage patient to report adverse drug effects.

l. Work with prescribing caregiver and patient to maintain a medication regimen that follows the principles for geriatric drug use; start dosages low and go slow, use only necessary medications, titrate the dose to patient response, simplify the regimen, and have frequent reevaluations of the medication regimen.

Community and Home Care Considerations

1. Ask the patient or family to bring in all the patient's medications for clinic or office visits or whenever the patient goes to a facility to obtain an accurate medication history.
2. Ask the patient what vitamins, minerals, herbal supplements, and other OTC products are being used. Many patients do not consider these medications and will not readily supply the information unless specifically asked.
3. Alert patients and family members that many "natural" products sold over the counter still may cause adverse reactions and toxicity as well as interactions with other drugs.
4. Warn patients and families that many complementary and alternative medicine (CAM) therapies do not have proven effectiveness despite advertisements. CAM should be used as an adjunct to conventional therapy, and the patient should notify all health care providers of supplements and therapies being used.

Altered Nutritional Status

EVIDENCE BASE Bowles, K. H., Dykes, P., & Demiris, G. (2015). The use of health information technology to improve care and outcomes for older adults. *Research in Gerontological Nursing, 8*(1), 5–10.

There is growing evidence that a balanced diet along with other health promotion behavior contribute to longevity. However, normal age-related changes, behavioral changes, and pathologic conditions may lead to malnutrition in the older adult.

Pathophysiology and Etiology

1. Changes in the oral cavity, including loss of teeth, diminished saliva production, and difficulty with mastication, may cause decreased food intake.
2. A decrease in gastric secretion with reduced pepsin hinders protein digestion and iron, vitamin B_{12}, calcium, and folic acid absorption; there are no significant changes in the small or large bowel.
3. Sensory changes involving taste and smell cause anorexia.
4. Psychosocial factors including changes in living situation, widowhood, depression, loneliness, decreased choice of food for institutionalized older adults, need to adhere to special diets, socioeconomic status, and ability to obtain and prepare food all impact what is eaten.
5. Alcohol use interferes with the absorption of B-complex vitamins. Additionally, alcohol is high in calories and low in nutritional value.
6. Medications can alter nutrition by directly decreasing absorption and utilization of nutrients. Indirectly, medications can result in anorexia, xerostomia, dysgeusia, and early satiety.
7. Dysphagia, which commonly occurs after stroke, intubation, or head and neck surgery, or is related to Parkinson disease and dementia, may cause decreased food intake.
8. With age, there is a decrease in energy needs because of a decrease in muscle mass (total caloric need decreases by 30%).

Nursing Assessment

1. Be alert for patients who complain of difficulty swallowing and difficulty managing saliva. Watch for coughing after swallowing, sounding “wet” after eating, and pocketing food in the cheeks.
2. Assess for absent or diminished gag reflex.
3. Assess for a 10% weight loss over 6 months (marasmus) or weight loss along with low serum albumin levels (kwashiorkor), which are signs of protein-energy malnutrition.
4. Determine if cholesterol level is below 130 mg/dL, which also may indicate malnourishment.

Nursing and Patient Care Considerations

1. Educate older adult and family or significant other about basic nutritional requirements and on overcoming barriers that interfere with optimal nutrition.
    a. The Required Dietary Allowances for healthy older adults are the same as that for younger adults, with three exceptions: decreased caloric intake, decreased protein intake (1 g/kg), and decreased iron requirements for postmenopausal women.
2. Encourage good mouth care.
3. Encourage patients to avoid alcohol if possible; refer for counseling if necessary and compensate for the nutritional consequences of alcohol abuse with liquid supplements, B vitamins.
4. Review all prescription and OTC medications with patients, and evaluate the influence of these on nutritional status.
5. If food procurement, preparation, and enjoyment are a problem, identify community resources to offer assistance in obtaining food and community meals.
6. In large facility settings, environmental factors may influence food enjoyment. Encourage socialization when eating, and try to minimize the negative effects of disruptive people and/or settings. Try to improve aesthetics.
7. To compensate for age-related changes in taste and smell, encourage use of low-sodium food additives.
8. Encourage proper body position (eg, sitting upright during mealtimes) and staying up for 30 minutes after eating to help with digestion.
9. If possible, encourage five to six small meals per day rather than three large meals.
10. If appropriate, encourage family to bring in favorite foods for patient.
11. Position food on the plate so that if there is visual neglect, or impairment, patient is best able to see the food served.
12. Identify patients with dysphagia and obtain a referral to a speech therapist.
    a. Work with the speech therapist and primary health care provider to determine what consistency of food is safe for patient to swallow. If patient is unable to swallow, thin liquids, slushes, puddings, or applesauce should be given to ensure adequate hydration.
    b. Use good compensatory techniques if indicated. These include sitting upright, tucking and turning the head, placing the food on the unaffected side of the tongue, swallowing twice to clear the pharyngeal tract, tucking the chin to the chest, and bringing the tongue up and back and holding the breath to swallow.
    c. Write out swallowing instructions for patient and family and educate family regarding the importance of maintaining these precautions.

Community and Home Care Considerations

1. Encourage the older adult at home to eat a well-balanced diet to maintain an optimal nutritional state.
2. Suggest vitamin preparations with the fewest number of minerals and vitamins needed to prevent

interactions and avoid megadoses.

3. Advise taking calcium carbonate, iron, and zinc at least 2 hours apart and taking vitamins at the same time daily.
4. Advise taking iron on an empty stomach and taking fat-soluble vitamins (A, D, E, and K) with food.
5. Educate about different types of calcium preparations:
    a. Calcium carbonate is more difficult to absorb on an empty stomach; it needs an acidic environment to enhance absorption. The percent of calcium absorbed decreases as the calcium load increases; therefore, calcium carbonate absorption is greatest in doses of 500 mg or less, with food.
    b. Because calcium citrate is highly soluble in acid, it is better absorbed on an empty stomach. The citrate form does not need gastric acid for absorption.
    c. Calcium lactate can be absorbed at various pHs and does not need to be taken with food for absorption.

Urinary Incontinence

EVIDENCE BASE Dowling-Castronovo, A., & Broadway, C. (2016). Urinary incontinence. In M. Bolts, E. Capezuti, T. Fulmer, & D. Zwicker (Eds.), *Evidence-based geriatric nursing protocols for best practice* (5th ed., pp. 343–349). New York, NY: Springer Publishing Company.

Approximately 13 million Americans suffer from urinary incontinence. Approximately 35% of older adults admitted to an acute care hospital will develop urinary incontinence. The prevalence increases significantly for older adults living in nursing homes; it is estimated that up to 90% of residents in nursing homes are incontinent of urine.

Pathophysiology and Etiology

1. There are five basic types of urinary incontinence:
   a. Stress—an involuntary loss of urine with increases in intra-abdominal pressure. Usually caused from weakness and laxity of pelvic floor musculature or bladder outlet weakness.
   b. Urge—involves leakage of urine because of inability to delay voiding after sensation of bladder fullness is perceived. This is associated with detrusor hyperactivity, CNS disorders, or local genitourinary conditions.
   c. Overflow—because of a leakage of urine resulting from mechanical forces on an overdistended bladder. This results from mechanical obstruction or hypomobility of the detrusor muscle.
   d. Mixed—symptoms of both stress and urge incontinence secondary to both an overactive detrusor and pelvic floor/urethral incompetence.
   e. Functional—involves urinary leakage associated with inability to get to the toilet because of cognitive and/or physical functioning.

Nursing Assessment

Because of the prevalence and increased incidence of incontinence in older adults, it is imperative that nurses include urine function in their assessments.

1. Identify reversible causes of incontinence using the DRIP acronym:
   D—Delirium, especially new-onset delirium.
   R—Restricted mobility, retention.
   I—Infection (especially sudden-onset cystitis), inflammation (such as atrophic vaginitis or urethritis), impaction (fecal).
   P—Polyuria (from poorly controlled diabetes or diuretic treatment), pharmaceuticals (including psychotropics, anticholinergics, alpha-agonists, beta-agonists, calcium channel blockers, opioids, alpha-antagonists, and alcohol).

2. Evaluate lower urinary tract function.
    a. Stress maneuvers are evaluated by asking the patient, with a full bladder, to cough three times while standing. Observe for urine leakage.
    b. Check for postvoid residual by inserting a 12- or 14-French straight catheter a few minutes after the patient voids or use a portable ultrasound bladder scanner to measure postvoid urine residual.
    c. Evaluate bladder filling by leaving the straight catheter in place and using a 50-mL syringe to fill the bladder with sterile water. Hold the syringe about 6 inch (15 cm) above the pubic symphysis. Continue to fill the bladder in 25-mL increments until the patient feels the urge to void. Observe for involuntary bladder contractions. These contractions are detected by continuous upward movement of the column of fluid in the absence of abdominal straining.

Nursing and Patient Care Considerations

1. For stress or urge incontinence, teach Kegel (pelvic muscle) exercises.
    a. Teach the patient to first practice stopping the stream of urine while voiding to identify proper contraction of the pubococcygeal muscle; contraction will result in stopping flow, and relaxation allows flow.
    b. Once proper contraction is verified, advise patient to practice contraction of the muscle for 3 seconds and then relaxation of the muscle for 3 seconds in sets of 15 three times per day.
    c. The exercise can be practiced anywhere at any time because it involves contraction of an internal muscle; encourage patient to try them sitting, standing, and lying down. The abdomen should be relaxed, and no movement should be visible by doing Kegel exercises.
2. Assist with biofeedback that involves the use of bladder, rectal, or vaginal pressure recordings to train patients to contract pelvic floor muscles and relax the abdomen.
3. Institute a behavioral training program, using bladder records, biofeedback, and pelvic floor exercises for patients with stress or urge incontinence.
4. Institute other interventions such as:
    a. Bladder retraining—progressive lengthening or shortening of voiding intervals to restore the normal pattern of voiding; this is useful after period of immobility or catheterization.
    b. Scheduled toileting—using a fixed toileting schedule to prevent wetting episodes for patients with urge or functional incontinence.
    c. Habit training—involves using a variable toileting schedule based on patient's pattern of voiding; also incorporates positive reinforcement.
    d. Prompted voiding—includes regular prompts to void every 1 to 2 hours with positive reinforcement.
    e. Appropriate use of incontinence aids, such as pads or diapers.
    f. Judicious use of medications to help control urge incontinence. These include oxybutynin and tolterodine, among others. Contraindicated in urinary or gastric retention, myasthenia gravis, and uncontrolled glaucoma. Monitor carefully for anticholinergic effects—dry mouth, heat intolerance, urine retention, constipation, drowsiness, dry eyes, blurred vision.

Urine Retention

EVIDENCE BASE Park, J. & Palmer, M. H. (2015). Factors associated with incomplete bladder emptying in older women with overactive bladder symptoms. *Journal of the American Geriatrics Society, **63*** (7), 1426–1431.

Urine retention is a common problem in the older adult, commonly related to a neurologic or other underlying condition.

Pathophysiology and Etiology

1. Frequently encountered in the acute care setting, postcatheterization, after stroke, in diabetics because of atonic neuropathic bladder, because of fecal impaction, and in males with prostatic enlargement.
2. The patient with urine retention may void small amounts or may be incontinent continuously because of overflow of urine.
3. Patients with urine retention will usually have incontinence during the night.
4. Urine retention may also be caused or aggravated by drugs with anticholinergic properties, such as levodopa or tricyclic antidepressants, especially amitriptyline. Other commonly prescribed drugs, such as alpha-agonists, beta-agonists, and calcium channel blockers, can cause urinary retention.

GERONTOLOGIC ALERT Urine retention may cause urinary tract infection, which can lead to poor outcomes for older adult.

Nursing Assessment

1. Take a complete history and perform a physical examination to rule out causes of urine retention.
2. Understand and identify the risk factors for urinary retention.
3. Monitor for a distended bladder and perform postvoid catheterization; there is no consensus of the upper or lower limits of a postvoid residual. However, residual of greater than 100 mL of urine is often used as a sign of urine retention.

Nursing and Patient Care Considerations

1. Remove fecal impaction to help patient regain bladder function.
2. If prostatic disease is suspected, appropriate referral is necessary.
3. Encourage male to use the standing position and female to use the sitting position to facilitate urinary flow; provide privacy.

4. Teach “double voiding.” Finish voiding and then reposition oneself to void again. Also teach Credé method: have the patient massage the area of the abdomen directly over the bladder to “milk” the bladder to express any residual urine.
5. Evaluate medication regimen and discuss with health care provider the necessity or substitution of offending medication.
6. If no underlying condition is suspected, attempt intermittent catheterizations every 8 hours, in combination with regular voiding attempts by patient. If there is no response in 2 weeks (ie, no decrease in postvoid residuals), referral to a urologist may be necessary for medical management of the urine retention.

Fecal Incontinence

Fecal incontinence is an inability to voluntarily control the passage of gas or feces. It occurs in an estimated 15% of women and 6% to 10% of men who live in the community and in an estimated 45% of older adults who live in nursing homes.

EVIDENCE BASE Any, U. U., Vaughan, C. P., Burgio, K. L., et al. (2016). Shared risk factors for constipation, fecal incontinence, and combined symptoms in older U.S. adults. *Journal of the American Geriatrics Society, **64*** (11), e183–e188.

Pathophysiology and Etiology

1. Fecal continence depends on normal rectal and anal sensation, rectal reservoir capacity, and internal and external sphincter mechanisms.
2. In institutionalized older adults, fecal impaction is a primary cause of fecal incontinence because of stool leaking around a fecal mass.
3. In noninstitutionalized older adults, fecal incontinence is commonly associated with dysfunction of one of the anorectal continence mechanisms, such as impaired contractile strength of the sphincters and lower rectal volume capacity. Stroke and spinal cord injuries cause loss of sensation in the rectal area.
4. Sometimes, functional or cognitive impairment and depression may inhibit motivation and the ability to remain continent.
5. Commonly, no cause can be determined for the fecal loss, and it is believed that the incontinence may be due to a degenerative injury to the pudendal nerve.

Nursing Assessment

1. Assess overall function, cognition, and affect.
2. Assess baseline bowel status through health history or observation.
3. Assess severity and frequency of symptoms, including quantity of fecal incontinence.
4. Perform a rectal examination to check for impaction or decreased rectal sphincter tone.
5. If the fecal incontinence is diarrheal in nature, stool evaluation for leukocytes, culture and sensitivity, ova and parasites, and *Clostridium difficile* may be indicated.

Nursing and Patient Care Considerations

1. Increase dietary fiber in an attempt to add bulk to the stool to stimulate regular defecation, if there is no infection and no impaction present.
2. Try antidiarrheals such as loperamide, as directed, for managing diarrhea.
3. Try to set up a regular bowel evacuation pattern once an impaction is detected and removed. This includes regular toileting times, set preferably after breakfast, and increased fluid and fiber intake. Use

laxatives only as a last resort.

4. In bedbound patients, increased fiber in the diet is contraindicated. These patients may require a bisacodyl suppository or an enema to help with rectal evacuation two to three times per week.
5. Treat those with neurogenic fecal incontinence, such as patients with spinal cord injuries and poststroke, to induce fecal evacuation at regularly scheduled times.
6. Administer glycerin or bisacodyl suppository two to three times per week before breakfast (to use the normal gastrocolic reflex that starts after the first meal of the day) to help induce a complete rectal evacuation and decrease stool incontinence.

Community and Home Care Considerations

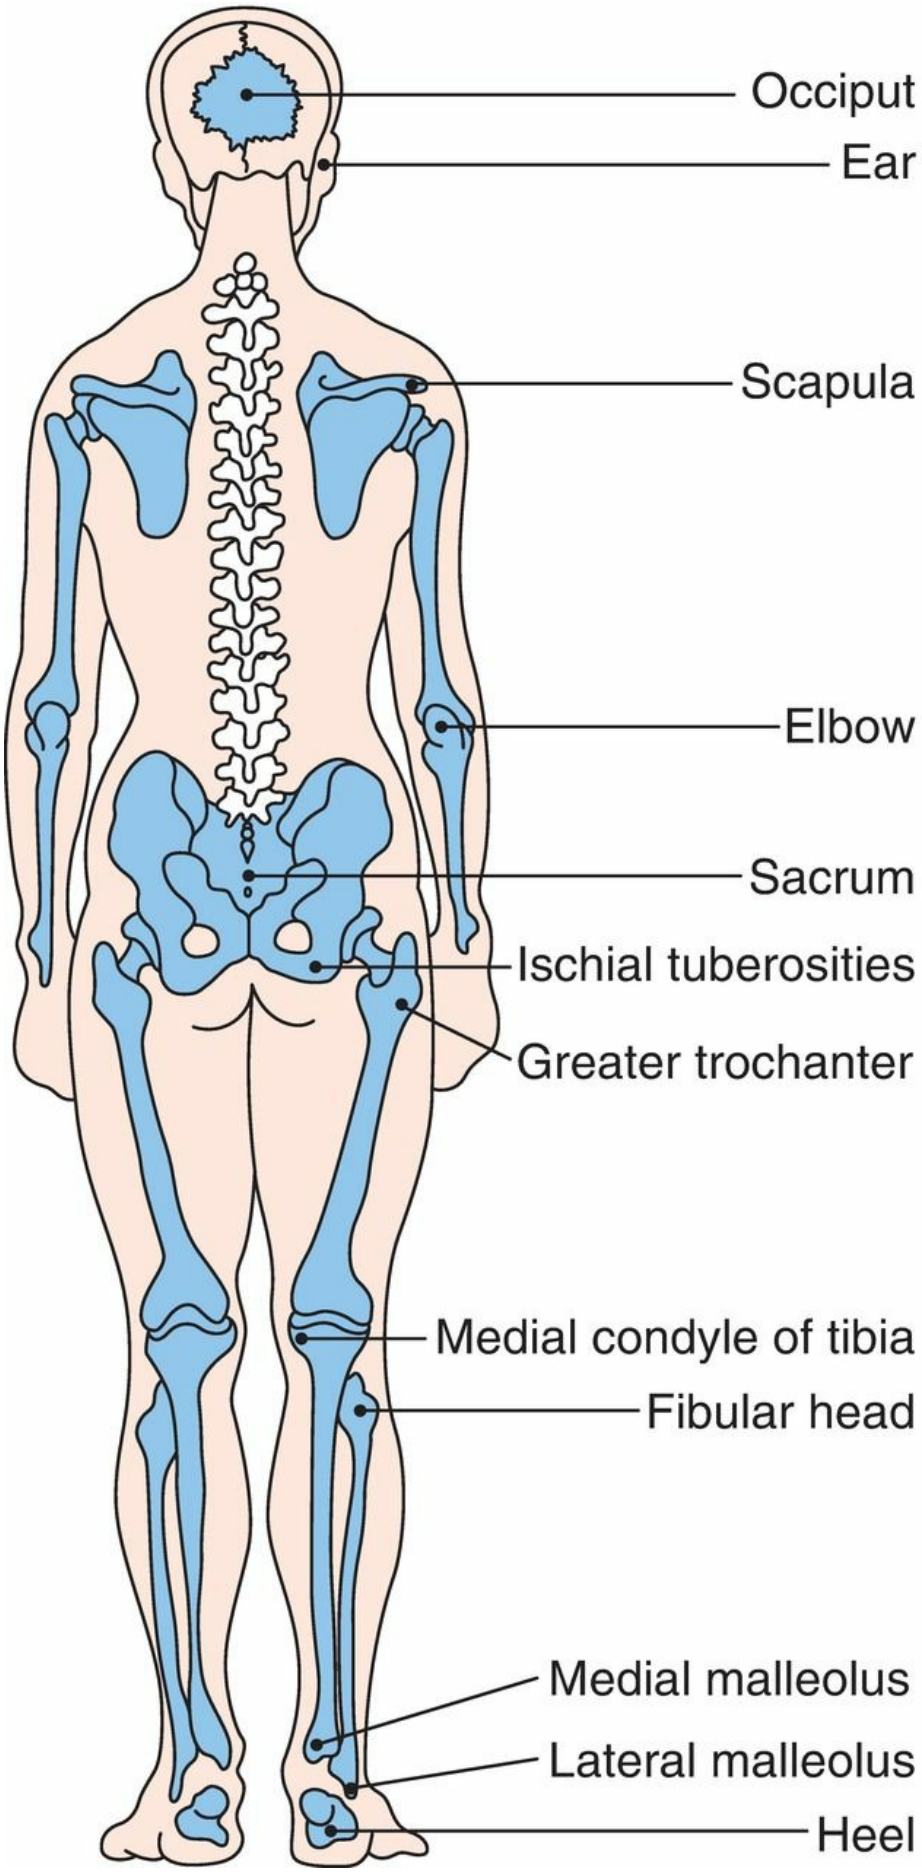
1. Explain to patient and family that it is not necessary to have bowel movements every day.
2. Advise avoidance of laxatives, which may induce diarrhea.
3. Encourage fibrous foods that stimulate the bowel to be eaten daily, preferably at breakfast, such as stewed prunes, citrus fruits, and bran cereals. Make sure that help is available to toilet patient when the urge to defecate is felt.
4. Recommend a home remedy to maintain regular bowel movements: 3 tbsp applesauce, 2 tbsp bran, and 1 tbsp prune juice mixed, refrigerated, and given at least 1 tbsp each morning.

Pressure Ulcers

EVIDENCE BASE Ayello, E. A., & Sibbald, R. G. (2016). Nursing standard of practice protocol: Pressure ulcer prevention & skin tear prevention. In M. Boltz, E. Capezuti, T. Fulmer, & D. Zwicker (Eds.), *Evidence-based geriatric nursing protocols for best practice* (5th ed.). New York, NY: Springer Publishing Company.

Haesler, E. (Ed.), National Pressure Ulcer Advisory Panel, European Pressure Ulcer Advisory Panel and Pan Pacific Pressure Injury Alliance. (2014). *Prevention and Treatment of Pressure Ulcers: Quick Reference Guide*. Osborne Park, Western Australia: Cambridge Media.

Pressure ulcers (decubitus ulcers) are localized ulcerations of the skin or deeper structures. They most commonly result from prolonged periods of bed rest in acute- or long-term care facilities; however, they can develop within hours in the compromised individual (see Figure 9-2).



Occiput

Figure 9-2. Areas susceptible to pressure ulcers. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

Factors in the Development of Pressure Ulcers

1. Pressure of 70 mm Hg applied for longer than 2 hours can produce tissue destruction; healing cannot occur without relieving the pressure.
2. Friction contributes to pressure ulcer development by causing abrasion of the stratum corneum.
3. Shearing force, produced by sliding of adjacent surfaces, is particularly important in the partial sitting position. This force ruptures capillaries over the sacrum.
4. Moisture on the skin results in maceration of the epithelium.

Risk Factors for Pressure Ulcers

1. Bowel or bladder incontinence.
2. Malnourishment or significant weight loss.
3. Edema, anemia, hypoxia, or hypotension.
4. Neurologic impairment or immobility.
5. Altered mental status, including delirium or dementia.

Nursing Assessment

1. Assess for risk factors for pressure ulcer development and alter those factors, if possible.
2. Assess skin of the older adult frequently for the development of pressure ulcers. The Braden Scale for Predicting Pressure Sore Risk is one of the most commonly used instruments for predicting the development of pressure ulcers (*www.bradenscale.com*). The Braden Scale assesses pressure ulcer risk in six areas: sensory perception, skin moisture, activity, mobility, nutrition, and friction/shear.
3. Stage the ulcer so appropriate treatment can be started. The National Pressure Ulcer Advisory Panel advocates the following staging system (see Figure 9-3).
    a. Stage I—intact skin with nonblanchable redness of a localized area, usually over a bony prominence.
    b. Stage II—partial thickness loss of dermis presenting as a shallow open ulcer with a red–pink wound bed, without slough; may also present as an intact or open/ruptured serum-filled blister.
    c. Stage III—full-thickness tissue loss, with subcutaneous fat that may be visible but bone, tendon, or muscle is not exposed; may include undermining and tunneling. Slough may be present but does not obscure the depth of tissue loss.
    d. Stage IV—full-thickness tissue loss with exposed bone, tendon, or muscle; slough or eschar may be present on some parts of the wound bed; often includes undermining and tunneling.
    e. Unstageable—full-thickness tissue loss in which the base of the ulcer is covered by slough and/or

eschar in the wound bed.

f. Suspected deep tissue injury—a localized area of intact skin or blood-filled blister, maroon or purple in color, caused by damage of the underlying soft tissue from shear or pressure.

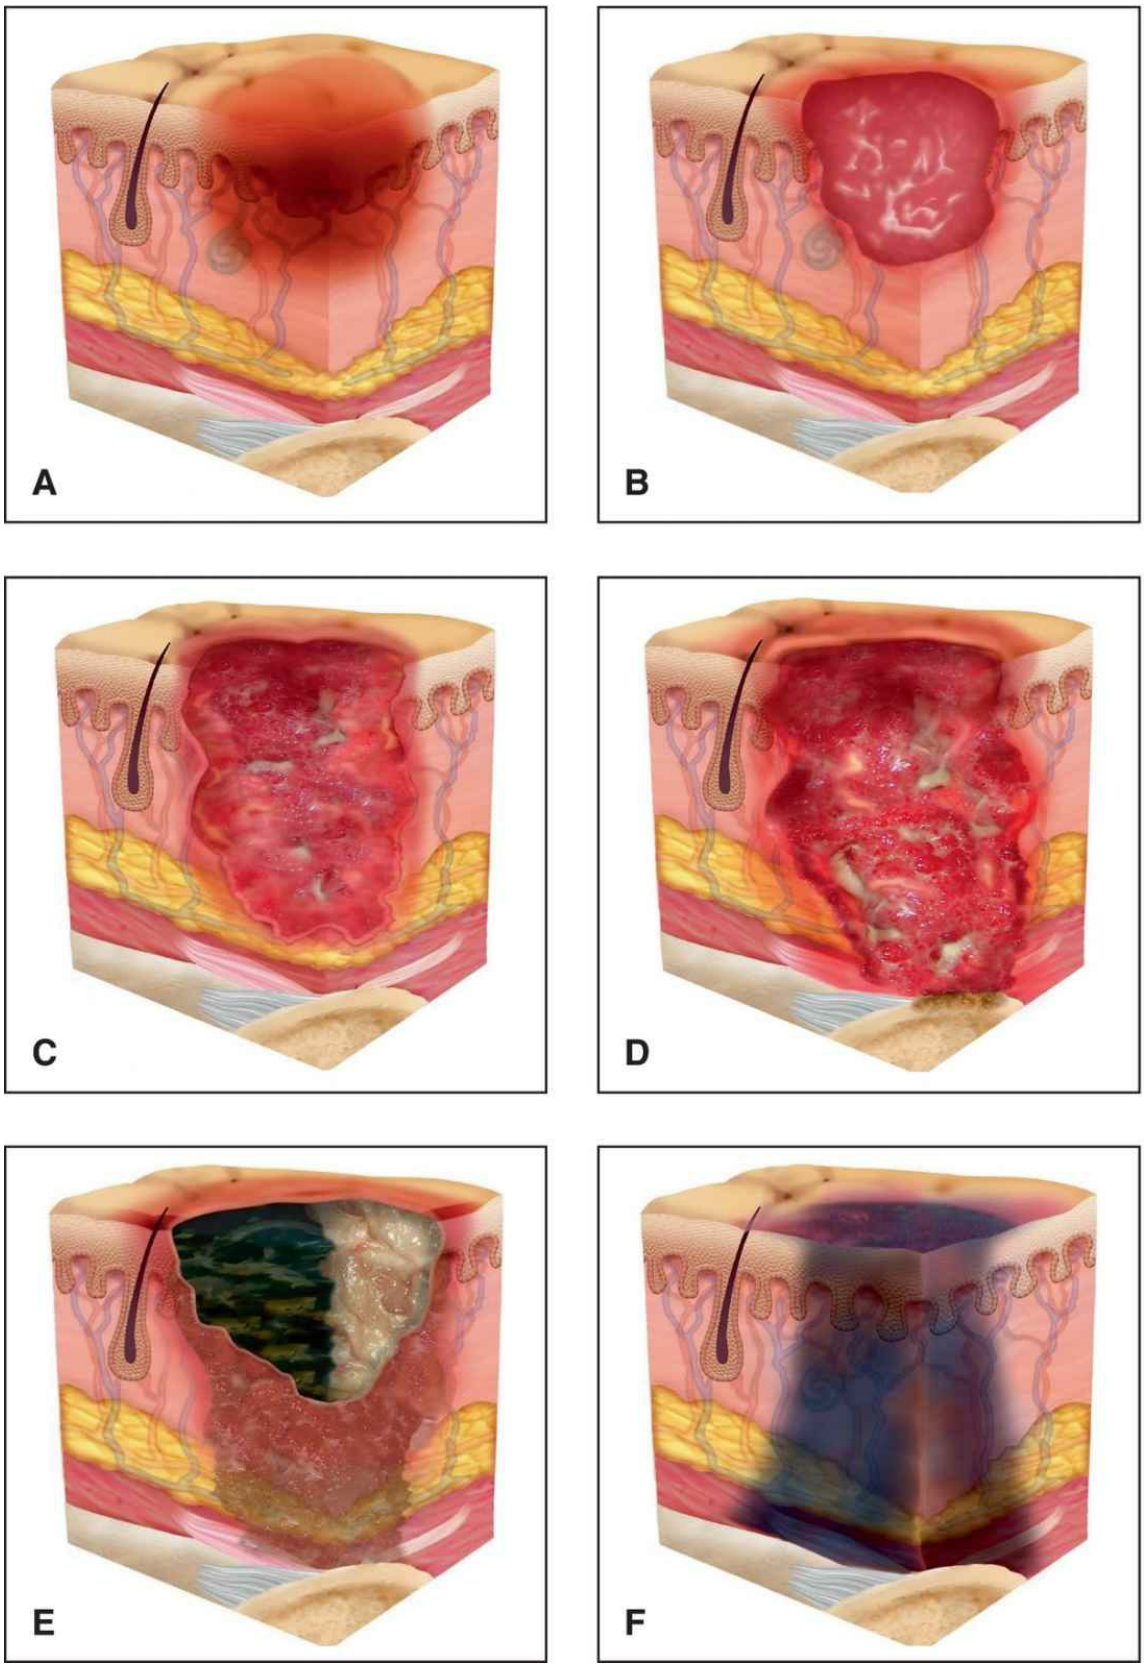

Figure 9-3. International NPUAP/EPUAP pressure injury stages. **(A)** Stage I—nonblanchable erythema. **(B)** Stage II—partial thickness skin loss with exposed dermis. **(C)** Stage III—full-thickness skin loss. **(D)** Stage IV—full-thickness skin and tissue loss. **(E)** Unstageable pressure injury—obscured full thickness skin and tissue loss. **(F)** Deep tissue pressure injury—persistent

non-blanchable deep red, maroon, or purple discoloration. (2016 NPUAP Pressure Injury Staging Illustrations from http://www.npuap.org/resources/educational-and-clinical-resources/pressure-injury-staging-illustrations/. Used with permission of the National Pressure Ulcer Advisory Panel March 2018. © NPUAP.)

Nursing and Patient Care Considerations

Prevent Pressure Ulcer Development

1. Provide meticulous care and positioning for immobile patients.
    a. Inspect skin several times daily.
    b. Wash skin with mild soap, rinse, and pat dry with a soft towel.
    c. Lubricate skin with a bland lotion to keep skin soft and pliable.
    d. Avoid poorly ventilated mattress that is covered with plastic or impermeable material.
    e. Employ bowel and bladder programs to prevent incontinence.
    f. Encourage ambulation and exercise.
    g. Promote nutritious diet with optimal protein, vitamins, and iron.
2. Teach older adult and family or significant other the importance of good nutrition, hydration, activity, positioning, and avoidance of pressure, shearing, friction, and moisture.

Relieve the Pressure

1. Avoid elevation of head of bed greater than 30 degrees.
2. Reposition every 2 hours.
3. Use special devices to cushion specific areas (especially bony areas), such as flotation rings, lamb's wool or fleece pads, convoluted foam mattresses, booties, or elbow pads. Lift heels off the bed in bedbound patients. Do not use donut devices.
4. Use an alternating-pressure mattress or air-fluidized bed for patients at high risk to prevent or treat pressure ulcers.
5. Provide for activity and ambulation as much as possible.
6. Advise frequent shifting of weight and occasional raising of buttocks off chair while sitting.

Clean and Debride the Wound

1. Use normal saline for cleaning and disinfecting wounds.
2. Apply wet-to-dry dressings or enzyme ointments for debridement as directed or assist with surgical debridement.

Treat Local Infection

1. Avoid obtaining wound cultures because open wounds are always colonized with bacteria, unless there is evidence of systemic infection or progressive local infection such as cellulitis.
2. Apply topical antibiotics to locally infected pressure ulcer as prescribed.

Cover the Wound

1. Cover the wound with a protective dressing as this minimizes disruption of migrating fibroblasts and epithelial cells and results in a moist, nutrient-rich environment for healing to occur.
   a. Polyurethane thin film dressings can be used for superficial low-exudate wounds. They are air and water permeable but do not absorb exudate.
   b. Hydrocolloids can provide padding to wounds but can lead to maceration; they are not oxygen permeable.
   c. Polyurethane foam/membrane dressings absorb exudate and are oxygen permeable.
   d. Hydrogel dressings are multilayered and include properties of both hydrocolloids and polyurethane (see Table 9-2 for comparison of selected occlusive dressings).

Table 9-2 Comparison of Selected Occlusive Dressing

DRESSING TYPE	EXAMPLES	APPROPRIATE USE	ADVANTAGES	DISADVANTAGES
Absorption	Debrisan Hydrophilic Beads	• Stage II–V ulcer with drainage	• Absorbs drainage and deodorizes wound	• Need to change dressing 1–2 times daily
Hydrocolloid	DuoDerm	• Stage I–II ulcer	• Provides padding • Easy to apply • Water impermeable • No skin excoriation	• Poor absorptive capacity • Poor oxygen exchange • Messy residue • Pressure areas possible
Polyurethane	OpSite, Tegaderm	• Nondraining wounds	• Transparent • Self-adhesive • Oxygen permeable	• No absorptive capacity • May cause excoriation • Difficult to apply
Polyurethane membrane	Mitraflex	• Skin tears • Tape burns • Blisters • Stage II ulcers • Low-moderate exudate wounds	• Good absorptive ability • Good oxygen exchange • Water impermeable • May debride	• May cause excoriation
Polyurethane foam	Epi-Lock	• Skin tears • Tape burns • Blisters • Stage II ulcers • Low to moderate exudate wounds	• Good absorptive ability • Good oxygen exchange • Water impermeable • May debride • No skin excoriation	• Nonadhesive
Hydrogel	Vigilon, Biofilm	• Stage I–III	• No skin excoriation • Transparent • Some ability to absorb drainage • Easy to apply	• Difficult to apply • Nonadherent
Debriding enzyme	Elase, Travase	• Stage III–IV	• Acts against devitalized tissue • Not appropriate for hard, dry eschar	• May damage healthy tissue

Osteoporosis

Osteoporosis is a condition in which the bone matrix is lost, thereby weakening the bones and making them more susceptible to fracture. Bone mineral density is 2.5 standard deviations below the peak bone density for young adults (T score –2.5). Decrease in bone density of 1.5 to 2.5 below young adult is termed *osteopenia* (T score –1.5 to –2.5). It is the most age-related metabolic bone disorder.

Pathophysiology and Etiology

1. The rate of bone resorption increases over the rate of bone formation, causing loss of bone mass.
2. Calcium and phosphate salts are lost, creating porous, brittle bones.
3. Occurs most commonly in postmenopausal women but may also occur in men.
4. Other factors include:
    a. Age.
    b. Inactivity.
    c. Chronic illness.
    d. Medications, such as corticosteroids, excessive thyroid replacement, cyclosporine.
    e. Calcium and vitamin D deficiency.
    f. Family history.
    g. Smoking and alcohol use.
    h. Diet—caffeine has been linked as a risk factor.
    i. Race—whites and Asians have higher-risk incidence.
    j. Body type—small frame/short stature, low body fat.

Clinical Manifestations

1. Asymptomatic until later stages.
2. Fracture after minor trauma may be first indication. Most frequent fractures associated with osteoporosis include fractures of the distal radius, vertebral bodies, proximal humerus, pelvis, and proximal femur (hip).
3. May have vague complaints related to aging process (stiffness, pain, weakness).
4. Estrogen deficiency may be noted.

Diagnostic Evaluation

1. X-rays show changes only after 30% to 60% loss of bone.
2. Dual-energy x-ray absorptiometry (DEXA) scanning shows decreased bone mineral density (T score –2.5 or worse).
3. Serum and urine calcium levels are normal.
4. Serum bone matrix Gla protein (a marker for bone turnover) is elevated.
5. Bone biopsy shows thin, porous, otherwise normal bone.

Management

Management is primarily preventive.

1. Identify patients at risk for fractures.
2. Reduce modifiable risk factors through improved diet, smoking cessation, decreased alcohol consumption, and other healthy lifestyle choices.
3. Adequate intake of calcium—1.2 g/day—may be preventive.
4. Adequate intake of vitamin D.
    a. Vitamin D plays a major role in calcium absorption and bone health. With age, there is decreased ability to take in vitamin D through the skin; therefore, replacement is recommended.
    b. Food sources are milk products, egg yolks, fish, and liver; however, dietary intake of vitamin D is limited.
    c. Vitamin D can be manufactured in the skin through sunlight exposure; however, this may be limited by cloud cover, latitude, season and skin cancer prevention methods that limit exposure.
    d. Recommended daily allowance for adults age 70 and over is 800 international units.
5. Weight-bearing exercise (eg, walking) throughout life.
6. Hormone replacement therapy is no longer recommended for osteoporosis prevention or treatment because the risks outweigh the benefits.
7. Raloxifene, an estrogen receptor agonist, is an alternative to estrogen. Not as effective as estrogen, but does show some benefit in preserving bone density. No increase in risk of breast cancer.
8. Calcitonin administered by nasal spray may help prevent spinal fracture. Adverse effect is nasal burning and a runny nose.
9. Bisphosphonates, such as risedronate, alendronate, and ibandronate, bind to and inhibit osteoclast action, remain active on bone resorptive surfaces for 3 weeks, and do not impede normal bone formation.
    a. Associated with improved bone density and decreased hip and spinal fracture rate.
    b. They must be taken with fluid but not food, and patient must remain upright for 30 minutes after taking pill to prevent esophagitis.
    c. Long-acting injectables such as zoledronic acid and teriparatide are protective for women at high risk for fractures and helpful in increasing bone mass in men who are on long-term glucocorticoid therapy.
10. Parathyroid hormone teriparatide utility is limited because it requires daily subcutaneous injections.
11. Prevention of falls in older adults helps to prevent fractures.

EVIDENCE BASE Cosman, F., de Beur, S. J., LeBoff, M. S., et al. (2014). Prevention and treatment of osteoporosis. *Osteoporosis International, 25*, 2359.

Complications

1. Fractures.
2. Progressive kyphosis, loss of height (see Figure 9-4).
3. Chronic back pain from compression fracture.

Figure 9-4. Progressive kyphosis in osteoporosis. (Anatomical Chart Company.)

Nursing Assessment

1. Obtain history of risk factors for osteoporosis, fractures, and other musculoskeletal disease.
2. Assess risk for falls and fractures—sensory or motor problems, improper footwear, lack of knowledge of safety precautions, and so forth. See Table 9-3, for assessment factors and interventions.

Table 9-3 Assessment Factors and Interventions to Decrease Risk of Falls

KNOWN RISK FACTORS	SPECIFIC INTERVENTIONS TO DECREASE INDIVIDUAL RISK
History of falls	• Identify the patient as being at risk for falls: May use sticker on chart or door, inform families and other care providers of increased risk.
Fear of falling	• Encourage patient to verbalize feeling. • Strengthen self-efficacy related to transfers and ambulation by providing verbal encouragement about capabilities and ability to perform safely.
Bowel and bladder incontinence	• Set up regular voiding schedule (every 2 hr or as appropriate based on patient need). • Monitor bowel function and encourage sufficient fluids and fiber (eight 8-oz glasses daily and 24 g of fiber). • Utilize laxatives as appropriate.
Cognitive impairment	• Evaluate patient for reversible causes of cognitive impairment or delirium and eliminate causes as relevant. Monitor patient with cognitive impairment at least hourly with relocation of the patient such that nursing staff can observe and monitor regularly. • Encourage family member to hire staff or stay with patient continuously. • Utilize monitoring devices if available (ie, bed/chair or exit alarms) rather than restraint.
Mood	• Encourage verbalization of feeling. • Evaluate patient's ability to concentrate and learn new information. • Encourage participation in daily activities. • Utilize alternative interventions, such as massage, aromatherapy, pet and plant therapy, and music or exercise.
Dizziness	• Monitor lying, sitting, and standing blood pressures and continually evaluate for factors contributing to dizziness. • Encourage adequate fluid intake (eight 8-oz glasses daily). • Set up environment to avoid movements that result in dizziness or vertigo. • Decrease or avoid alcohol use.
Functional impairment, immobility, impaired gait	• Encourage participation in personal care activities at highest level (ie, if possible encourage ambulation to bathroom rather than use of bed pan). • Refer to physical and occupational therapy as appropriate. • Facilitate adherence to exercise program when indicated. • Maintain safe and appropriate use of assistive device.
Medications	• Review medications with primary health care provider and determine need for each medication. • Make sure that medications are being used at lowest possible dosages to obtain desired result.
Medical problems	• Work with primary health care provider to augment management of primary medical problem, such as Parkinson disease, heart failure, or anemia.
Environment	• Remove furniture if patient cannot be seated with feet reaching the floor. • Remove clutter. • Make sure furniture and any assistive devices used are in good condition. • Make sure lighting is adequate. • Make sure safety bars are available in the bathroom.

Nursing Diagnosis

Chronic Pain related to vertebral compression fractures in late stages of osteoporosis

Nursing Interventions

Reducing Pain

1. Administer opioid analgesics, as ordered, for acute exacerbations of pain.
2. Encourage replacement with nonopioid pain relievers as soon as possible to avoid drowsiness, possible

addiction.

3. Assist with putting on back brace and ensure proper fit. Encourage use as much as possible, especially while ambulatory.
4. Encourage compliance with physical therapy appointments and practicing exercises at home to increase muscle strength surrounding bones and to relieve pain.

GERONTOLOGIC ALERT Be alert for alcohol use combined with other CNS depressants in older adults. With advanced age, there is a reduction in lean body mass, an increase in body fat, a decrease in water content, and a decrease in the gastric alcohol dehydrogenase enzyme. This results in an increase in the blood alcohol level in older individuals compared to younger individuals per unit of alcohol consumed, especially in women. Alcohol use, particularly when combined with opioids or sedative hypnotics, is commonly associated with falls in these individuals.

Patient Education and Health Maintenance

1. Encourage exercise for all age groups. Teach the value of walking daily throughout life to provide stress required for strong bone remodeling.
2. Provide dietary education in relation to adequate daily intake of calcium (1,200 mg). Calcium can be obtained through milk and dairy products, vegetables, and supplements. Anyone with a history of urinary tract calculi should consult with health care provider before increasing calcium intake.
3. Encourage use of combined calcium and vitamin D replacement. Avoid massive doses of vitamin D, however, because this may be harmful.
4. Encourage young women at risk to maximize bone mass through nutrition and exercise.
5. Suggest that perimenopausal women confer with their health care provider about the need for calcium supplements and estrogen therapy.
6. Alert patients to resources such as the National Osteoporosis Foundation (*www.nof.org*).

Community and Home Care Consideration

EVIDENCE BASE U.S. Preventive Services Task Force. (2015). Final Update Summary: Osteoporosis: Screening. Available: *www.uspreventiveservicestaskforce.org/Page/Document/UpdateSummaryFinal/osteoporosis-screening?ds=1&s=osteoporosis.*

---

1. Encourage screening according to the USPSTF guidelines for all women over age 65 and women over age 60 at increased risk through DEXA of the femoral neck, with rescreening at approximately 2-year

intervals.

2. Identify women at high risk for osteoporotic fractures in the community—frail, older white or Asian women with poor dietary intake of dairy products and little exposure to sun—and provide education and safety measures to prevent falls and fracture.
3. Make sure that diet contains maximal calcium. Teach family and caregivers how to read labels, encourage dairy products, and add powdered milk to foods as possible. Use skim milk if cholesterol and fat intake is a consideration.
4. Make sure that supplements and other medications are being taken properly.
    a. Patient teaching is critical in dosing of bisphosphonates to prevent esophagitis. Patient must take this upon waking with 6 to 8 oz of water, at least 30 minutes before ingesting first food of the day, and must remain upright for 30 minutes after taking the medication. Weekly or monthly dosing increases compliance.
    b. Calcitonin nasal spray dose is one spray in one nostril once per day; alternate nostrils each day.
5. Teach strategies to prevent falls. Assess home for hazards (eg, scatter rugs, slippery floors, extension cords, inadequate lighting).
6. Obtain physical and occupational therapy consultations, as needed, to encourage use of walking aids when balance is poor and to improve muscle strength.

Evaluation: Expected Outcomes

- Pain tolerable with nonopioid analgesics; no new fractures.
- Received screening and understands prevention measures.

Alzheimer Disease

The most common form of dementia is characterized by progressive impairment in memory, cognitive function, language, judgment, perception, and learned motor skills. Ultimately, patients cannot perform self-care activities and become dependent on caregivers.

Pathophysiology and Etiology

1. Gross pathophysiologic changes in the brain include cortical atrophy most prominent in the frontal and temporal lobes, enlarged ventricles, and atrophy of the hippocampus.
2. Microscopically, changes occur in the proteins of the nerve cells of the cerebral cortex and lead to accumulation of neurofibrillary tangles composed of the tau protein and neuritic plaques composed of the amyloid protein (deposits of protein and altered cell structures on the interneuronal junctions) and granulovascular degeneration. There is loss of cholinergic nerve cells, which are important in memory, function, and cognition.
3. Biochemically, neurotransmitter systems are impaired.
4. The cause is unknown, but advanced age, female gender, family history of AD, and head trauma with a loss of consciousness are risk factors. Indeed, research has identified four specific genes involved in predisposition to Alzheimer's. Genes on chromosomes 1, 14, and 21 have been implicated in the causation of early-onset Alzheimer disease, whereas the #4 allele of the apolipoprotein gene on chromosome 19 appears to be associated with the development of Alzheimer disease after age 65.
5. Viruses, environmental toxins, cerebrovascular disease, and educational level may also play a role.

Clinical Manifestations

1. Disease onset is subtle and insidious. Initially, a gradual decline of cognitive function from a previously higher level may be noticed. Short-term memory impairment and problems with executive functioning (planning and organizing) is commonly the first characteristic in earliest stages of the disease. Patients are forgetful and have difficulty learning and retaining new information. In addition to memory impairment, at least one of the following functional deficits is present:
   a. Language disturbance (aphasia, may be receptive, expressive or both).
   b. Visual processing and recognition difficulty (agnosia).
   c. Inability to perform skilled motor activities, such as dressing and walking (apraxia).
   d. Poor abstract reasoning and concentration.
2. Patients may have difficulty planning meals, managing finances, using a telephone, or driving without getting lost. Other classic signs include personality changes, such as irritability and suspiciousness, personal neglect of appearance, and disorientation to time and place.
3. The following clinical manifestations are typical in the middle stage of Alzheimer disease:
   a. Repetitive actions (perseveration).
   b. Nocturnal restlessness.

c. Apraxia (impaired ability to perform purposeful activity).
d. Aphasia (impaired ability to speak).
e. Agraphia (inability to write).

4. With disease progression, signs of frontal lobe dysfunction appear, including loss of social inhibitions and loss of spontaneity. Delusions, hallucinations, aggression, and wandering behavior often occur in the middle and late stages.
5. Patients in the advanced stage of Alzheimer disease require total care. Symptoms may include:
   a. Urinary and fecal incontinence.
   b. Emaciation.
   c. Resistance to care
   d. Inability to walk.
   e. Decreased responsiveness to verbal and physical stimulation.
   f. Difficulty swallowing (dysphagia).

Diagnostic Evaluation

1. Detailed patient history with corroboration by an informed source to determine cognitive and behavioral changes, their duration, and symptoms that may be indicative of other medical or psychiatric illnesses.
2. Noncontrast computed tomography (CT) scan to rule out other neurologic conditions, such as a stroke or tumor. Magnetic resonance imaging and single-photon emission CT may be used.
3. Neuropsychological evaluation, including some form of mental status assessment, to identify specific areas of impaired mental functioning in contrast to areas of intact functioning.
4. Laboratory tests include complete blood count, sedimentation rate, chemistry panel, thyroid-stimulating hormone, test for syphilis, urinalysis, serum B_{12}, folate level, and test for human immunodeficiency virus to rule out infectious or metabolic disorders.
5. Commercial assays for cerebrospinal fluid tau protein and beta-amyloid are available, but their use is limited. Genetic testing is available, but its use is controversial. Three disease genes and one gene indicating susceptibility have been identified.

Management

1. Primary goals of treatment for Alzheimer disease are to optimize functional abilities and improve quality of life by enhancing mood, cognition, and behavior. No curative treatment exists. Treatment includes pharmacologic and nonpharmacologic approaches.
2. Cholinesterase inhibitors were the first treatment for cognitive impairment of Alzheimer disease. These drugs improve cholinergic neurotransmission to help delay decline in cognition and function over time. There is also evidence that cholinesterase inhibitors may be helpful in decreasing agitated behaviors common in dementia.
   a. Donepezil is widely used in mild to moderate cases because it can be given once daily and is well tolerated; starting at 5 mg at bedtime and increased to 10 mg after 4 to 6 weeks. In patients with

moderate to severe Alzheimer disease, the dose of Donepezil may be increased to 23 mg daily; however, there is an increased risk of adverse gastrointestinal side effects at this higher dose. Donepezil has also been shown to be beneficial in individuals with severe dementia.

b. Galantamine is given with food in dosage of 4 to 12 mg twice per day. Should be restarted at 4 mg bid if interrupted for several days. Dose should be reduced in cases of renal or hepatic impairment. Razadyne ER is an extended-release formula that can be given in once-daily dosing with dose ranges from 8 to 24 mg/day.

c. Rivastigmine is given 1.5 mg twice per day with meals and increased up to 6 to 12 mg/day. Rivastigmine is also available in an oral solution and a patch form. Use of the Rivastigmine patch is associated with fewer gastrointestinal side effects than oral use.

DRUG ALERT Cholinesterase inhibitors were initially aimed at improving memory and cognition. These drugs, however, seem to have an important impact on the behavioral changes that occur in patients with cognitive impairment. Specifically, research studies have demonstrated that use of cholinesterase inhibitors improves the apathy, disinhibition, pacing, and hallucinations commonly noted in dementia. Be alert for drug interactions with NSAIDs, succinylcholine-type muscle relaxants, cholinergic and anticholinergic agents, drugs that slow the heart, and other drugs that are metabolized by the hepatic CYP2D6 or CYP3A4 pathways.

---

1. Memantine, an N-methyl D-aspartate-receptor antagonist, is approved for moderate to severe Alzheimer disease. The immediate release dosage is 10 mg bid, and the extended-release dosage begins at 7 mg once a day and is gradually increased to a maximum dose of Memantine XR 28 mg once a day. The drug can be used with a cholinesterase inhibitor because it works by regulating the neurotransmitter, glutamate.
2. Studies indicate that other drugs, such as estrogen and NSAIDs, have not proven helpful in treatment and prevention of Alzheimer disease.
3. Patients with depressive symptoms should be considered for antidepressant therapy.
4. Nonpharmacologic treatments used to optimize cognition and behavior include environmental manipulation that decreases stimulation, pet therapy, aromatherapy, massage, music therapy, and exercise.
5. If nonpharmacologic approaches have been applied consistently and have failed to adequately reduce the frequency and severity of behavioral symptoms that have the potential to cause harm to the patient or others, then the introduction of medications such as antipsychotics, benzodiazepines, anticonvulsants, antidepressants, and sedatives may be appropriate but will still need to be carefully and routinely monitored over time.
   a. The risk and potential benefits of any medication must be discussed with the patient (when appropriate) and/or the patient's family/decision maker.
   b. The minimum amount of a medication should be used for the shortest time possible.

DRUG ALERT Be aware that no medications are specifically approved by the FDA to treat the neuropsychiatric and behavioral symptoms of individuals with dementia. Antipsychotics have been linked to higher risk of death among older adults with dementia. This led the FDA to issue a black box warning for antipsychotic use in dementia.

Complications

1. Increased incidence of functional decline.
2. Injury because of lack of insight, hallucinations, and confusion.
3. Malnutrition because of inattention to mealtimes and hunger or lack of ability to prepare meals or feed self.

Nursing Assessment

1. Perform cognitive assessment for orientation, insight, abstract thinking, concentration, memory, and verbal ability.
2. Assess for changes in behavior and ability to perform ADLs.
3. Evaluate nutrition and hydration; check weight, skin turgor, and meal habits.
4. Assess motor ability, strength, muscle tone, and flexibility.

Nursing Diagnoses

- Disturbed Thought Processes related to physiologic disease process.
- Risk for Injury because of loss of cognitive abilities.
- Insomnia Secondary to disease process.
- Caregiver Role Strain related to physical needs and behavioral manifestations of the disease process.

Nursing Interventions

Improving Cognitive Response

1. Simplify the environment: reduce noise and social interaction to a level tolerable for the patient.
2. Maintain a predictable, structured routine, decrease the number of choices available to the patient, use pictures to identify activities, and use structured group activities.
3. Encourage active participation in care as tolerated and provide positive feedback for tasks that are accomplished.
4. Provide opportunities for physical activity alternating with rest periods.
5. Avoid confrontations and arguments. Follow the patient's direction and individualize care as much as possible.
6. Maintain consistency in interactions and introduce new people slowly.

Preventing Injury

1. Avoid restraints, but maintain observation of the patient as necessary.
2. Provide for adequate lighting to avoid misinterpretation of the environment.
3. Remove unneeded furniture and equipment from the room.
4. Provide medical alert identification such as bracelet.
5. Make sure patient has nonslip shoes or slippers that are easy to put on.
6. Encourage use of assistive safety devices, such as handrails and shower chairs.
7. Ensure physical activity as tolerated and ROM exercises to maintain mobility.

Ensuring Adequate Rest

1. Attempt to limit the use of medications that act on the CNS, such as anxiolytics and antipsychotics; however, if used, monitor for clinical response and potential adverse effects, including increased confusion, excess sedation, parkinsonism, extrapyramidal symptoms, and cardiovascular events.
2. Provide periods of physical exercise to expend energy.
3. Support normal sleep habits and bedtime rituals.
   a. Keep regular bedtime.
   b. Have patient change into pajamas at bedtime.
   c. Allow desired bedtime activity, such as snack, warm noncaffeinated beverage, listening to music, or prayer.
4. Maintain quiet, relaxing environment to avoid confusion and agitation.

Supporting Caregiver

1. Encourage caregiver to discuss feelings.
2. Encourage caregiver to maintain own health and emotional well-being.
3. Stress the need for relaxation time or respite care.
4. Assist the caregiver in finding resources, such as community or church groups, social service programs, or facility-based support groups.
5. Assess caregiver's stress and refer for counseling.
6. Support decision to place patient in a long-term care facility.

Community and Home Care Considerations

1. Encourage regular medical checkups with attention to health maintenance every 3 to 6 months to provide ongoing medical surveillance of patient and stamina of caregivers. Include influenza vaccine and ensure that patient has had pneumococcal pneumonia vaccine.
2. Discuss advance directives for patients and discuss long-term placement options in anticipation of future needs to help family members adjust and plan arrangements.
3. Encourage patients to be involved in social and intellectual activities as long as possible, such as family events, exercise, and recreational activities and sharing the newspaper and other forms of media.

4. Assist caregivers to modify the home environment for safety, and advise families of safety hazards such as wandering and driving a car. Encourage use of door locks, electronic wander-alert guards, and registration with the "Safe Return" program through the Alzheimer's Association or local police department.
5. Remind family members of possible dangers around the house as patient becomes less responsible for behavior. Encourage caregivers to reduce the temperature of the hot water heater, remove dials from stove and other electrical appliances, remove matches and lighters, and safely store away tools and other potentially dangerous items.

Patient Education and Health Maintenance

1. Encourage activities that provide physical exercise and repetitive movement but that require little thought, such as dancing, painting, doing laundry, or vacuuming.
2. Teach patient and family to eliminate stimulants, such as caffeine, and maintain good nutrition.
3. Discuss with the family the need to organize finances and to make advanced directive decisions and guardianship arrangements before they are needed to allow the patient input into the process.
4. OTC products, such as ginkgo biloba, have gained popularity; however, their clinical benefits have not been demonstrated to be better than placebo in well-designed randomized clinical trials. Although high doses of vitamin E (2,000 international units) have shown to delay nursing home placement by a few months, there is no evidence of cognitive improvements, and doses higher than 400 international units have been associated with bleeding and cardiovascular events. Families should be encouraged to discuss their use with the health care provider and not abandon conventional treatment.
5. For additional information, refer families to:
   Alzheimer's Association: *www.alz.org*.
   Alzheimer's Disease Education and Referral Center: *www.nia.nih.gov/Alzheimers*.

Evaluation: Expected Outcomes

- Participates in ADL without agitation or resistance.
- Remains free from injury.
- Sleeps 6 to 8 hours a night with a 1-hour rest period twice per day.
- Caregiver reports using support systems and community resources.

LEGAL AND ETHICAL CONSIDERATIONS

Restraint Use

Since the Nursing Home Reform Act took effect in October 1990, long-term care facilities throughout the United States have been required to follow guidelines emphasizing individualized, less restrictive care for residents.

The goal should be to minimize restraint use. This is a challenge, yet there are many nursing strategies that can be implemented to help reduce restraint use. And, although most nurses cite the rationale for placing a restraint on a patient is for patient safety, there is little evidence that patient safety or a reduction in injuries is actually achieved.

There are many alternative approaches to care as well as how to minimize risks associated with falls, as outlined at *https://consultgeri.org/geriatric-topics/physical-restraints* and *https://consultgeri.org/try-this/dementia/issue-d1* and *https://consultgeri.org/patient-symptoms/pulling-out-tubes*.

Guidelines

1. The following are the federal requirements for the use of restraints based on the 1987 Omnibus Budget Reconciliation Act.
2. These guidelines must be met in any long-term care facility that participates in Medicare or Medicaid. However, these guidelines are useful for health care providers working with older adults in all settings.
    a. The resident has the right to be free from any physical restraints imposed or psychoactive drug administered for purposes of discipline or convenience and not required to treat the resident's medical symptoms.
    b. Physical restraints are any manual method of physical or mechanical device, material, or equipment attached or adjacent to the resident's body that the person cannot remove easily, which restricts freedom of movement or access to one's body (includes leg and arm restraints, hand mitts, soft ties or vest, wheelchair safety bars, and geriatric chairs).
    c. There must be a trial of less restrictive measures unless the physical restraint is necessary to provide life-saving treatment.
    d. The resident or legal representative must consent to the use of restraints.
    e. Residents who are restrained should be released, exercised, toileted, and checked for skin redness every 2 hours.
    f. The need for restraints should be re-evaluated periodically.
    g. The specific facility will have to develop policies and procedures for the appropriate use of restraints and psychoactive drugs.
    h. Primary health care providers will have to write appropriate orders for restraints and psychoactive drugs.
3. The most frequently reported reason for nurses' use of restraints is to prevent patients from harming themselves or others. Specifically, they are used to prevent falls and prevent removal of catheters or IV lines.

4. Multiple studies have found that restraints actually increase incidence of falls, can result in patient strangulation, can increase patient confusion, can cause pressure ulcers and nosocomial infections, can decrease functional ability, and can result in social isolation.
5. In regard to the patient's personal and social integrity, restraints have resulted in emotional responses of anger, fear, resistance, humiliation, demoralization, discomfort, resignation, and denial.

Alternative Interventions Instead of Restraints

1. Evaluate those patients who are considered to be in need of a restraint. Evaluation should include physical function and cognitive status (see page 136), elimination history, history of falls, vision impairment, BP (specifically evaluating for orthostatic hypotension), and medication use.
2. Attempt to correct any problems identified in the evaluation, such as vision impairment or unsafe gait.
3. Use the evaluation to determine patients at high risk of falling (eg, those with confusion, orthostatic hypotension, multiple medication regimens, and altered gait).
4. Use interventions as alternatives to restraints as outlined in Box 9-4.

BOX 9-4 Techniques to Prevent Falls as Alternative to Restraints

FOR ALL PATIENTS

- Familiarize patient with environment (ie, identify call light or bell to ring, label the bathroom, kitchen, closet).
- Have patient demonstrate ways to obtain help if needed.
- Place bed in low position with brakes locked if possible, or mattress on the floor.
- Make sure that footwear is fitted and nonslip and is used properly.
- Determine appropriate use of side rails based on cognitive and functional status.
- Utilize nightlight.
- Keep floor surfaces clean and dry.
- Keep room uncluttered and make sure that furniture is in optimal condition.
- Make sure patient knows where personal possessions are and can safely access them.
- Ensure adequate handrails in bathroom (commode, shower, and tub), room, and hallway.
- Establish a care plan to maintain bowel and bladder function.
- Evaluate effects of medications that increase the patient's risk of falling.
- Encourage participation in functional activities and exercise at patient's highest possible level and refer to physical therapy as appropriate.
- Monitor patient regularly and encourage safe activities.

FOR PATIENTS AT HIGH RISK FOR FALLING WHEN WALKING INDEPENDENTLY

- Use specially designed chairs that make independent transfer difficult.
- Use a chair alarm and bed alarm when the patient cannot be visually supervised.

- Institute physical therapy and increased exercise activities to help strengthen muscles and improve function.
- For the patient who interferes with treatment, evaluate the need for invasive treatments. When such treatments are essential, use mittens or gloves rather than restraints.
- For the patient who wanders, provide an exercise program or establish a bounded environment in which the person can ambulate freely.
- For aggressive and agitated patients, be aware that restraints may only make the behavior worse. Provide a low-stimulus environment, consistent caregivers, and appropriate medications to help control the agitation. Music therapy has also been shown to decrease aggressive behavior.

Advance Directives

The 1990 Patient Self-Determination Act, which requires that patients be asked about the existence of advanced directives at the time of enrollment into a health care facility, has increased awareness of older adults' rights to determine their own care. Based on the ethical principle of autonomy (a person's privilege of self-rule), advance directives provide a clear and detailed expression of a person's wishes for care. Providing an older adult with the opportunity to discuss their end-of-life plans is helpful. A four-step process includes initiating a discussion, facilitating the discussion, completing the document, and updating.

Durable power of attorney is now called *health care proxy*. It involves the designation of another person to make health care decisions for an incapacitated person. Many states have official documents that can be downloaded from their websites with detailed information about advanced directives and health care proxy.

EVIDENCE BASE Farber-Post, M., Boltz, M. (2016). Advance care planning. In M. Boltz, E. Capezuti, T. Fulmer, & D. Zwicker (Eds.), *Evidence-based geriatric nursing protocols for best practice* (5th ed., pp. 691–701). New York, NY: Springer Publishing Co.

Types of Advance Directives

Living Wills

1. Living wills were the first and most widespread type of advance directive.
2. They were proposed as a mechanism for refusing "heroic" or unwanted medical intervention for the dying person.
3. They allow a person to state in writing that certain life-sustaining treatments should be withdrawn or withheld when that person is dying and unable to directly communicate his or her wishes.
4. Living wills only allow for the refusal of further treatment. They are not precise in terms of directives and focus only on the patient who is clearly terminally ill.

Health Care Proxy

1. This document appoints a proxy to act on behalf of another person, provides guidance for the proxy, and endures even when the maker is incapacitated.
2. This is always a written document.
3. The document states the preferences and perhaps even the values of its maker. It outlines the types of decisions the person would want to have made on his behalf.
4. Because no health care proxy document can cover all situations, the document should name a person who has the task of ensuring that the patient's wishes are honored. The proxy has the responsibility to interpret the document and extrapolate its contents to situations not specifically covered.

Medical Orders for Life Sustaining Treatment (MOLST)

1. Many states are beginning to implement a standard health care provider order form that indicates patient choices for a variety of life-sustaining treatment and is used across health care facilities.
2. MOLST (also known as Physician Orders for Life Sustaining Treatment—POLST) is important for patients with serious health conditions who:
    a. Want to avoid or receive any or all life-sustaining treatment.
    b. Are residents of long-term care facilities.
    c. Might die within a year.
3. Completion of the MOLST begins with a conversation or a series of conversations between the patient, patient's health care agent or surrogate, primary care provider, and specialist care provider.
4. The health care provider should help delineate the patient's goals for care, review possible treatment options on the entire MOLST form, and facilitate informed medical decision-making.
5. The completed form can then also be used as a medical order across health care settings, from emergency personnel responding to the patient at home and to the staff of an intensive care unit.

Nursing and Patient Care Considerations

1. Under the Patient Self-Determination Act, all patients who enter a Medicare- or Medicaid-certified facility, nursing home, or home health agency must:
    a. Be provided with information about the state's laws and the facility's policies regarding advance directive.
    b. Be asked if they have advance directives.
    c. Have their advance directives placed in their medical record.
2. Education of patients and families is essential in helping them to understand the difference between living wills, MOLST, or health care proxy and determining which document best suits their needs.
3. Patients and families need to be educated about what is involved in undergoing various life-sustaining procedures so they can make a decision regarding their future treatment.
4. Patients need to be informed that they can have more than one advance directive. That is, if a patient has a living will but is not terminally ill, encourage the patient to obtain a health care proxy to ensure that health care wishes will be met in any situation.

Community and Home Care Considerations

1. Information about completing advance directives can be obtained by contacting the National Palliative Care and Hospice Organization at *www.caringinfo.org*.
2. Instruct older adults that they will be allowed to record their wishes about various types of medical treatments, and let them appoint a proxy for if and when they are unable to make those decisions on their own.

Advocacy for Persons with Disabilities

There are an estimated 54 million Americans, not all of whom are older adults, with disabilities. Disability may strike any age group, ethnic or racial origin, and socioeconomic group. Nurses must not only provide skilled physical care to reduce complications and enhance the rehabilitation potential of disabled persons, they must also act as advocates to help these individuals transcend their disabilities to be as independent, functional, and self-actualized as possible. The United States Surgeon General's Call to Action to Improve the Health and Wellness of Persons with Disability requests that all health care providers do the following:

- Give each patient the information necessary to live a long and healthy life.
- Listen and respond to the patient's health concerns.
- Communicate clearly and directly.
- Take the time needed to meet the patient's health care needs.

Definition of Disability

1. A disability can be viewed as any restriction or lack of ability to perform activities in a manner that is normal for most people.
2. The Americans with Disabilities Act (1990) defines a disability as a physical or mental impairment that substantially limits one or more major life activities. A person can also be disabled if there is a record of such an impairment or is regarded as having such an impairment.
3. Handicap is an outdated term; there should be no reason for an individual with a disability to be handicapped. A handicap is a disadvantage resulting from an impairment that limits or prevents fulfillment of a role.

Disability Laws

1. There were many laws enacted in the United States in the 20th century to provide funding for health care, education, and vocational rehabilitation.
    a. Initial laws were limited and focused on groups, such as wounded soldiers, injured workers, and veterans.
    b. The Social Security Act of 1935 broadened vocational rehabilitation to cover civilians and gave rehabilitation a permanent legislative basis.
    c. Medicare and Medicaid were created in 1965 as an amendment to the Social Security Act to provide health insurance and benefits to individuals based on age, presence of disability, and low income. Medical and nursing care are covered.
2. The Rehabilitation Act of 1973 was the first federal law in the United States to protect persons with a disability from discrimination.
    a. This law focused on access to public buildings and transportation, discrimination in the workplace, and independent living situations.
    b. However, this law only applied to facilities and programs supported by the federal government and

did not affect the private sector.

3. The Americans with Disabilities Act of 1990 amended previous legislation and made it illegal to discriminate against individuals with disabilities in the private sector as well as the public sector. Areas of focus are:
   a. Employers with 15 or more employees must provide qualified individuals with disabilities an equal opportunity to benefit from employment, including the hiring, training, promotion, and other privileges of employment. Employers are required to provide reasonable accommodations for the known physical or mental limitations of otherwise qualified individuals, so long as accommodations do not cause undue hardship to the employer.
   b. All state and local government institutions are required to provide equal opportunities for individuals with disabilities to take part in all programs, services, and activities, regardless of federal funding status.
   c. Public accommodations, which calls for the removal of barriers in public places that may be owned by private entities, such as restaurants, shops, hotels, and private schools. In addition, courses and examinations related to educational programs must be provided in a manner accessible to all despite obstacles such as hearing, vision, or speech limitations.
   d. Telecommunication relay services are required in all areas to allow those with hearing and speech limitations to communicate with others through a third party.

Problems for Persons with Disabilities

1. Psychosocial adaptation to a disability is an ongoing process that progresses through stages: shock, denial, depression, ambivalence, and adaptation. It may become stalled at one or more stages and not reach adaptation.
2. Caregiver and family strain because of loss of income, hopelessness, and physical and mental exhaustion from taking over roles and responsibilities from the person with a disability may impede successful rehabilitation.
3. Despite laws, persons with disabilities are still discriminated against when applying for jobs and educational programs. To get around the laws, employers and educational systems may list multiple physical requirements of a job or program that are meant to discourage disabled persons from applying or that would prompt failure, even though these physical requirements may have nothing to do with the actual job.
4. In addition to physical barriers at workplaces and educational institutions, persons with disabilities must overcome tremendous attitude barriers. Once a disability is known, stereotyping and prejudice may overshadow a person's potential.

Nursing Interventions for Advocacy

1. Become familiar with Medicare and Medicaid regulations and coverage in the United States and assist patients with the medical forms.
   a. Medicare is available to individuals with a disability after 2 continuous years of disability with

inability to work. Medicare is provided through the federal government and is not driven by income level.

   b. Medicare does cover health care provider visits, hospitalizations, and medications, but does not cover some durable medical equipment.

   c. Eligibility for Medicaid is based on income level and how many persons are in the household and is controlled by the state and local government. This may cover very-low-income people with disabilities.

2. Help individuals in the United States understand the eligibility for Social Security disability income if their medical condition lasts for 1 year or longer and they are unable to perform substantial employment. The individual must have worked within the last 5 years and have adequate employment credits.
3. Become aware of social services in your geographic area, both through government and charitable programs, such as public transportation that will transport individuals who use wheelchairs to medical appointments.
4. Assist patients in obtaining prescription drugs through discounted and free programs that may be available through pharmaceutical companies to those who do not have limited prescription coverage. Contact pharmaceutical companies directly or *www.ppaRx.com* Partnership for Pharmaceutical Assistance) for eligibility requirements and applications.
5. If your facility is not fully accessible for persons with disabilities, advocate for structural changes that allow access.
6. When providing care for a person with a disability, always ask if you can assist and allow the individual to direct your assistance. Most individuals with disabilities know what works for them and what causes the least amount of discomfort.
7. Be aware that an individual with an acquired disability goes through an adjustment phase that can be compared with bereavement. Allow the individual time and respect for where they are in the process. Denial can last a year or more and they must be supported, not pushed, to move on in the process.
8. Be aware of your own biases and attitudes toward individuals with a disability. Refrain from stereotyping. Also be aware that not all disabilities are visible (eg, mental illness or impairment from a head injury). Treat all persons with respect and understanding.
9. Encourage sensitivity training in your facility for all employees to ensure compassionate care and polite interactions with all individuals with a disability.
10. Utilize the following resources for additional information and support:

PROCEDURE GUIDELINES 10-1

Assisting with Arterial Puncture for Blood Gas Analysis

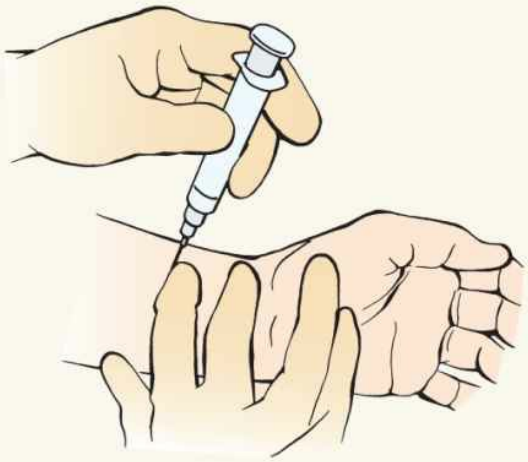
EQUIPMENT

- Commercially available blood gas kit or
- 2- or 3-mL syringe
- 23G or 25G needle
- 0.5 mL sodium heparin (1:1,000)
- Stopper or cap
- Sterile germicide
- Cup or plastic bag with crushed ice
- Gloves
- Goggles
- Rolled towel or washcloth

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Record the patient's inspired oxygen concentration.	1. Changes in inspired oxygen concentration alter the change in PaO_2. Degree of hypoxemia cannot be assessed without knowing the inspired oxygen concentration.
2. Take the patient's temperature.	2. May be considered when results are evaluated. Hyperthermia and hypothermia influence oxygen release from hemoglobin.
If not using a commercially available blood gas kit:	
3. Heparinize the 2-mL syringe.	
a. Withdraw heparin into the syringe to wet the plunger and fill dead space in the needle.	a. Coats the interior of the syringe with heparin to prevent blood from clotting.
b. Hold syringe in an upright position and expel excess heparin and air bubbles.	b. Air in the syringe may affect measurement of PaO_2; heparin in the syringe may affect measurement of the pH. Heparin left in the syringe can decrease the pH.
Performance phase (by health care provider, nurse or respiratory therapist with special instruction)	
1. Verify correct patient; perform hand hygiene.	1. Reduces risk of infection.
2. Put on gloves and goggles.	2. Blood and body fluid precautions.
3. Palpate the radial, brachial, or femoral artery.	3. The radial artery of the nondominant side is the preferred site of puncture but is contraindicated if a fistula or shunt for dialysis exists. Arterial puncture is performed on areas where a good pulse is palpable.
4. If puncturing the radial artery, perform the Allen test.	4. The Allen test is a simple method for assessing collateral circulation in the hand. Ensures circulation if radial artery thrombosis occurs.
In the conscious patient:	
a. Obliterate the radial and ulnar pulses simultaneously by pressing on both blood vessels at the wrist.	a. Impedes arterial blood flow into the hand
b. Ask the patient to clench and unclench fist until blanching of the skin occurs.	b. Forces blood from the hand.
c. Release pressure on ulnar artery (while still compressing radial artery). Watch for return of skin color within 15 sec.	c. Documents that ulnar artery alone is capable of supplying blood to the hand because radial artery is still occluded.
KEY DECISION POINT If skin color does not return following the Allen test, the ulnar artery does not have sufficient blood flow to supply the entire hand. If the radial artery is compromised while obtaining arterial blood gas, circulation to the entire hand could be compromised. Make note of this and pick an alternate arterial site.	
In the unconscious patient:	
a. Obliterate the radial and ulnar pulses simultaneously at the wrist.	
b. Elevate the patient's hand above the heart and squeeze or compress hand until blanching occurs.	b. Drains blood from the hand passively in a patient who cannot cooperate by clenching the fist.
c. Lower the patient's hand while still compressing the radial artery (release pressure on ulnar artery) and watch for return of skin color.	

Nursing Action	Rationale
5. For the radial site, turn palm up and mildly hyperextend the wrist, placing a small towel roll under the patient's wrist.	5. Makes the artery more accessible. The wrist should be stabilized to allow for better control of the needle.
6. Feel along the course of the radial artery and palpate for maximum pulsation with the middle and index fingers. Prepare the skin with an antiseptic; allow to dry completely.	6. Disinfecting the arterial site reduces the risk of infection.
7. The needle is at a 45-degree angle to the skin surface (see accompanying figure) and is advanced into the artery with the bevel facing upward.	7. The arterial pressure will cause the syringe to be filled within a few seconds.



Technique of arterial puncture for blood gas analysis.

8. The needle is slowly advanced until arterial blood appears in the syringe barrel.	8. Significant bleeding can occur because of pressure in the artery.
9. After 1 mL of blood is obtained, withdraw the needle and apply firm pressure over the puncture with a sterile gauze pad.	9. Proper closure of the needle prevents room air from mixing with the blood specimen.
10. Remove air bubbles from syringe and needle. Use safety syringe system for closure.	10. Icing the syringe will prevent a clinically significant loss of oxygen.
11. Place the capped syringe in the container of ice. Label as per facility policy.	11. Firm pressure on the puncture site prevents further bleeding and hematoma formation.
12. Maintain firm pressure on the puncture site for 5 min. If the patient is on anticoagulant medication, apply direct pressure over puncture site for 10–15 min and then apply a firm pressure dressing only after hemostasis has been achieved.	12. All connections must be tight to avoid disconnection and rapid blood loss. The arterial line also allows for direct blood pressure (BP) monitoring in the critically ill patient.
13. For patients requiring serial monitoring of arterial blood, an arterial catheter (connected to a flush solution of heparinized saline) is inserted into the radial or femoral artery.	
Follow-up phase	
1. Send the labeled, iced specimen to the laboratory immediately.	1. Blood gas analysis should be done as soon as possible because PaO_2 and pH can change rapidly.
2. Palpate the pulse (distal to the puncture site), inspect the puncture site, and assess for cold hand, numbness, tingling, or discoloration.	2. Hematoma and arterial thrombosis are complications following this procedure.
3. Change ventilator settings, inspired oxygen concentration, or type and setting of respiratory therapy equipment, if indicated by the results.	3. The PaO_2 results will determine whether to maintain, increase, or decrease the FiO_2. The PaO_2 and pH results will detect if any changes are needed in tidal volume or rate of patient's ventilator.

PROCEDURE GUIDELINES 10-2

Assisting the Patient Undergoing

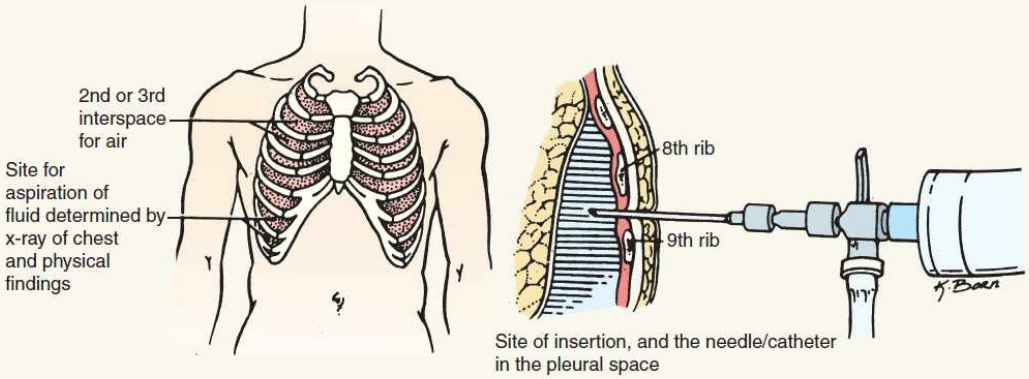
EQUIPMENT

- Thoracentesis tray (if available) or

- 5-, 20-, 50-mL syringes
- Needles: 22G, 26G, or 16G (3 inches long)
- Three-way stopcock and tubing
- Hemostat
- Biopsy needle
- Germicide solution
- Local anesthetic (such as lidocaine 1%)
- Sterile gauze pads (4 inches Ã— 4 inches and 2 inches Ã— 2 inches)
- Sterile towels and drape
- Sterile specimen containers
- Sterile gloves
- Overhead table and chair

PROCEDURE

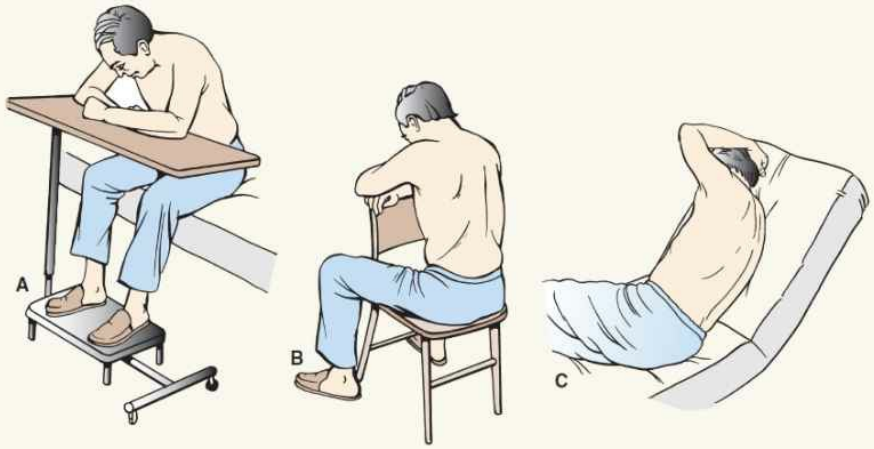
Nursing Action	Rationale
Preparatory phase	
1. Determine in advance if chest x-ray or other tests have been prescribed and completed. These should be available at the bedside.	1. Localization of pleural fluid is accomplished by physical examination, chest x-ray, ultrasound localization, or fluoroscopic localization.



Technique of thoracentesis.

2. Check if consent form has been explained and signed.	2. Invasive procedure requires informed consent.
3. Determine if the patient is allergic to the local anesthetic agent to be used. Give sedation, if prescribed.	3. Prevents allergic reaction; eases pain and anxiety.
4. Inform the patient about the procedure and indicate how the patient can be helpful. Explain: a. The nature of the procedure. b. The importance of remaining immobile and of not talking or coughing. c. Pressure sensations to be experienced. d. That no discomfort is anticipated after the procedure.	4. An explanation helps orient the patient to the procedure, assists with coping, and provides an opportunity to ask questions and verbalize anxiety.
5. Assist the patient to obtain comfortable position with adequate supports. If possible, place the patient upright (see accompanying figure) and help the patient maintain this position during the procedure.	5. The upright position ensures that the diaphragm is most dependent and facilitates the removal of fluid that usually localizes at the base of the chest. A comfortable position helps the patient to relax.

Nursing Action	Rationale



Positioning the patient for a thoracentesis. The nurse assists the patient to one of three positions and offers comfort and support throughout the procedure. **(A)** Sitting on the edge of the bed with head and arms on and over the bed table. **(B)** Straddling a chair with arms and head resting on the back of the chair. **(C)** Lying on unaffected side with the bed elevated 30 to 45 degrees.

Performance phase

1. Expose the site to be aspirated. If fluid is in the pleural cavity, the thoracentesis site is determined by study of the chest x-ray and physical findings, with attention to the site of maximal dullness on percussion. If air is in the pleural cavity, the thoracentesis site is usually in the second or third intercostal space in the midclavicular line.	1. Fluid usually settles in the lower pleural cavity. Air rises in the thorax because the density of air is much less than the density of liquid.
2. Perform hand hygiene and put on personal protective equipment.	2. Protects the patient and nurse.
3. Support and reassure the patient during the procedure. a. Prepare the patient for sensations of cold from skin germicide and for pressure and sting from infiltration of local anesthetic agent. b. Encourage the patient to refrain from coughing, talking, or moving. c. Be prepared to monitor the patient's condition throughout the procedure.	3. Sudden and unexpected movement by the patient can cause trauma to the visceral pleura with resultant trauma to the lung. A local anesthetic inhibits nerve conduction and is used to prevent pain during the procedure.
4. The procedure is done under aseptic conditions. After the skin is cleaned, the health care provider slowly injects a local anesthetic with a small-gauge needle into the intercostal space.	4. An intradermal wheal is raised slowly; rapid intradermal injection causes pain. The parietal pleura is very sensitive and should be well infiltrated with anesthetic before the thoracentesis needle is passed through it.
5. Ultrasound or direct physical examination is used to guide needle placement.	5. Prevents pneumothorax.

Nursing Action	Rationale
6. The thoracentesis needle is advanced with the syringe attached. When the pleural space is reached, suction may be applied with the syringe.	
a. A 20- or 50-mL syringe with a three-way adapter (stopcock) is attached to the needle. (One end of the adapter is attached to the needle and the other to the tubing leading to a receptacle that receives the fluid being aspirated.)	a. When a larger quantity of fluid is withdrawn, a three-way adapter serves to keep air from entering the pleural cavity. The amount of fluid removed depends on clinical status of the patient and absence of complications during the procedure.
b. If a considerable quantity of fluid is to be removed, the needle is held in place on the chest wall with a small hemostat.	b. The hemostat steadies the needle on the chest wall and prevents too deep a penetration of pleural space. Sudden pleuritic pain or shoulder pain may indicate that the visceral or diaphragmatic pleura are being irritated by the needle point.
c. A pleural biopsy may be performed.	
7. After the needle is withdrawn, pressure is applied over the puncture site and a small sterile dressing is fixed in place.	7. Prevents air entry into pleural space.
Follow-up phase	
1. Place the patient on bed rest. A chest x-ray is usually obtained after thoracentesis.	1. Chest x-ray verifies that there is no pneumothorax.
2. Record vital signs every 15 min for 1 hr.	2. Assesses for complications.
3. Administer oxygen, as directed, if the patient has cardiorespiratory disease.	3. Pulmonary gas exchange may worsen after thoracentesis in patients with cardiorespiratory disease.
4. Record the total amount of fluid withdrawn and the nature of the fluid, its color, and viscosity. If prescribed, prepare samples of fluid for laboratory evaluation (usually bacteriology, cell count and differential, determinations of protein, glucose, lactate dehydrogenase, specific gravity). A small amount of heparin may be needed for several of the specimen containers to prevent coagulation. A specimen container with preservative may be needed if a pleural biopsy is obtained.	4. The fluid may be clear, serous, bloody, or purulent. Analysis may aid in diagnosis and treatment.
5. Evaluate the patient at intervals for increasing respirations, faintness, vertigo, tightness in the chest, uncontrollable cough, blood-tinged mucus, and rapid pulse and signs of hypoxemia.	5. Pneumothorax, tension pneumothorax, hemothorax, subcutaneous emphysema, or pyogenic infection may result from a thoracentesis.
6. Encourage deep breaths.	6. Promotes lung expansion.

Respiratory Function

The major function of the pulmonary system (lungs and pulmonary circulation) is to deliver oxygen (O_2) to cells and remove carbon dioxide (CO_2) from the cells (gas exchange). The adequacy of oxygenation and ventilation is measured by partial pressure of arterial oxygen (PaO_2) and partial pressure of arterial carbon dioxide ($PaCO_2$). The pulmonary system also functions as a blood reservoir for the left ventricle when it is needed to boost cardiac output, as a protector for the systemic circulation by filtering debris/particles, and as a provider of metabolic functions such as surfactant production and endocrine functions.

Terminology

1. Alveolus—air sac where gas exchange takes place.
2. Apex—top portion of the upper lobes of the lungs.
3. Base—bottom portion of the lower lobes of the lungs, located just above the diaphragm.
4. Bronchoconstriction—constriction of smooth muscle surrounding bronchioles.
5. Bronchus—large airways; lung divides into right and left bronchi.
6. Carina-a ridge at the base of the trachea that separates the right and left mainstem bronchi.
7. Cilia—hairlike projections on the tracheobronchial epithelium, which aid in the movement of secretions and removal of debris.
8. Compliance—ability of the lungs to distend and change in volume relative to an applied change in pressure (eg, emphysema—lungs very compliant; fibrosis—lungs noncompliant or stiff).
9. Dead space—ventilation that does not participate in gas exchange; also known as wasted ventilation when there is adequate ventilation but no perfusion, as in pulmonary embolus or pulmonary vascular bed occlusion. Normal dead space is 150 mL.
10. Diaphragm—primary muscle used for respiration; located just below the lung bases; it separates the chest and abdominal cavities.
11. Diffusion (of gas)—movement of gas from area of higher to lower concentration.
12. Dyspnea—subjective sensation of breathlessness associated with discomfort, often caused by a dissociation between motor command and mechanical response of the respiratory system as in:
    a. Respiratory muscle abnormalities (hyperinflation and airflow limitation from chronic obstructive pulmonary disease [COPD]). Abnormal ventilatory impedance (narrowing airways and respiratory impedance from COPD or asthma).
    b. Abnormal breathing patterns (severe exercise, pulmonary congestion or edema, recurrent pulmonary emboli).
    c. Arterial blood gas (ABG) abnormalities (hypoxemia, hypercarbia).
13. Hemoptysis—the expectoration of blood or of blood-stained sputum from the larynx, trachea, bronchi, or lungs.
14. Hypoxemia—PaO_2 less than normal, which may or may not cause symptoms. (Normal PaO_2 is 80 to 100 mm Hg on room air.)

15. Hypoxia—insufficient oxygenation at the cellular level because of an imbalance in oxygen delivery and oxygen consumption. (Usually causes symptoms reflecting decreased oxygen reaching the brain and heart.)
16. Mediastinum—compartment between lungs containing lymph and vascular tissue that separates left from right lung.
17. Orthopnea—shortness of breath when in reclining position.
18. Paroxysmal nocturnal dyspnea—sudden shortness of breath associated with sleeping in recumbent position.
19. Perfusion—blood flow, carrying oxygen and CO_2 that passes by alveoli.
20. Pleura—serous membrane enclosing the lung; composed of visceral pleura, covering all lung surfaces, and parietal pleura, covering chest wall and mediastinal structures, between which exists a potential space.
21. Pulmonary circulation—network of vessels that supply oxygenated blood to and remove CO_2-laden blood from the lungs.
22. Pulmonary hypertension—an increase in pressure in the pulmonary arteries, pulmonary vein, or pulmonary capillaries.
23. Respiration—inhalation and exhalation; at the cellular level, a process involving uptake of oxygen and removal of CO_2 and other products of oxidation.
24. Shunt—adequate perfusion without ventilation, with deoxygenated blood conducted into the systemic circulation, as in pulmonary edema, atelectasis, pneumonia, and COPD.
25. Surfactant—lipid–protein complex secreted by alveolar cells that reduces surface tension of pulmonary fluids and aids in elasticity of pulmonary tissue. Plays a role in the barrier against the entry of pathogens.
26. Ventilation—is the process by which oxygen and CO_2 are transported to and from the lungs.
27. Ventilation–perfusion (V/Q) imbalance or mismatch—imbalance of ventilation and perfusion; a cause for hypoxemia. V/Q mismatch can be due to:
    a. Blood perfusing an area of the lung where ventilation is reduced or absent.
    b. Ventilation of parts of the lung that is not perfused.

Subjective Data

Explore symptoms retrieved from the patient's description of an event through characterization and history taking to help anticipate needs and plan care. Encourages the patient to give a full description of the onset, the course, and the character of the problem and any factors that aggravate or relieve it.

Dyspnea

EVIDENCE BASE Chen, Y., Coxson, H., & Reid, W. D. (2016). Reliability and validity of the brief fatigue inventory and dyspnea inventory in people with chronic obstructive pulmonary disease. *Journal of Pain and Symptom Management*, *52*(2), 298–304.

---

1. Characteristics—Is the dyspnea acute or chronic? Has it occurred suddenly or gradually? Is more than one pillow required to sleep? Is the dyspnea progressive, recurrent, or paroxysmal? Walking how far leads to shortness of breath? How does it compare to the patient's baseline level of dyspnea? Ask patient to rate dyspnea on a scale of 1 to 10, with 1 being no dyspnea and 10 being the worst imaginable. What relieves and what aggravates the dyspnea?
2. Associated factors—Is there a cough associated with the dyspnea and is it productive? What activities precipitate the shortness of breath? Does it seem to be worse when upset? Is it influenced by the time of day, seasons, and/or certain environments? Does it occur at rest or with exertion? Any fever, chills, night sweats, ankle/leg swelling? Any change in body weight?
3. History—Is there a patient history or family history of chronic lung disease, cardiac or neuromuscular disease, cancer, problems with blood clotting, or immunocompromise? What is the smoking history?
4. Significance—Sudden dyspnea could indicate pulmonary embolus, pneumothorax, myocardial infarction (MI), acute heart failure, or acute respiratory failure. In a postsurgical or postpartum patient, dyspnea may indicate pulmonary embolus or edema. Orthopnea can be indicative of heart disease or COPD. If dyspnea is associated with a wheeze, consider asthma, COPD, heart failure, or upper airway obstruction. When dyspnea occurs in combination with fatigue, pulmonary hypertension may exist. Metabolic disorders, psychiatric conditions, and neuromuscular disorders may also contribute to dyspnea.

Chest Pain

1. Characteristics—Is the pain sharp, dull, stabbing, or aching? Is it intermittent or persistent? Is the pain localized or does it radiate? If it radiates, where? How intense is the pain? Are there factors that alleviate or aggravate the pain, such as position or activity?
2. Associated factors—What effect do inspiration and expiration have on the pain? What other symptoms accompany the chest pain? Is there diaphoresis, shortness of breath, or nausea?
3. History—Is there a smoking history or environmental exposure? Has the pain ever been experienced before? What was the cause? Is there a preexisting pulmonary or cardiac diagnosis? Has there been recent

trauma?

4. Significance—Chest pain related to pulmonary causes is usually felt on the side where pathology arises, but it can be referred. Dull persistent pain may indicate carcinoma of the lung, whereas sharp, stabbing pain usually arises from the pleura. Dyspnea with pleuritic chest pain indicates clinically significant pulmonary embolism.

Cough

EVIDENCE BASE Irwin, R., French, C., Lewis, Z. S., et al. (2014). Overview of the management of cough: Chest guideline and expert panel report. *Chest*, *146*(4), 885–889.

---

1. Characteristics—Is the cough dry, hacking, loose, barky, wheezy, or more like clearing the throat? Is it strong or weak? How frequent is it? Is it worse at night or at any time of day? Does the intensity change on days off from work? Is there seasonal variation? Is it aggravated by food intake or exertion? Is it alleviated by any medication? How long has it been going on?
2. Associated factors—Is the cough productive? If so, what is the consistency, amount, color, and odor of the sputum? Is there hemoptysis? How does sputum compare to the patient's baseline? Is it associated with shortness of breath, pain, or nausea?
3. History—Is there a smoking history? Is the smoking current or in the past? Has there been any environmental or occupational exposure to dust, fumes, or gases that could lead to cough? Are there past pulmonary diagnoses, asthma, rhinitis, allergy, or exposure to allergens, such as pollen, house dust mites, animal dander, birds, mold or fungi, cockroach waste, and irritants (smoke, odors, perfumes, cleaning products, exhaust, pollution, cold air)? Has there been prolonged exposure to dampness, chemical sanitizers, cobalt or other hard metals, beryllium, asbestos, dusts from coal, wood, or grains? Does the patient have a history of acid reflux, postnasal drip or use an angiotensin-converting enzyme inhibitor with a common adverse effect of cough? Has there been a concurrent voice change? Has the patient recently traveled outside the country? Can the patient identify any specific triggers? Is the patient immunocompromised?
4. Significance—A dry, irritative cough may indicate viral respiratory tract infection. A cough at night should alert to potential left-sided heart failure, asthma, or postnasal drip worsening at night. A morning cough with sputum might be bronchitis. A cough that is less severe on days off from work may be related to occupational or environmental exposures. A patient with severe or changing cough should be evaluated for bronchogenic carcinoma. Consider bacterial pneumonia if sputum is rusty and lung tumor if it is pink-tinged. A profuse pink frothy sputum could be indicative of pulmonary edema. A cough associated with food intake could indicate problems with aspiration. A dry cough may be associated with pulmonary fibrosis. History of recent travel may be associated with infection from a source not commonly identified in the United States.

Hemoptysis

1. Characteristics—Is the blood from the lungs? It could be from the GI system (hematemesis) or upper airway (epistaxis). Is it bright red and frothy? How much? Is onset associated with certain circumstances or activities? Was the onset sudden, and is it intermittent or continuous?
2. Associated factors—Was there an initial sensation of tickling in the throat? Was there a salty taste or burning or bubbling sensation in the chest? Has there been shortness of breath, chest pain, or difficulty with exertion?
3. History—Was there any recent chest trauma or respiratory treatment (chest percussion)? Does the patient have an upper respiratory infection, sinusitis, or recent epistaxis? Has the patient used cocaine or other illicit drugs?
4. Significance—Hemoptysis can be linked to pulmonary infection, pulmonary edema, COPD, lung carcinoma, abnormalities of the heart or blood vessels, pulmonary artery or vein abnormalities, or pulmonary emboli and infarction. Small amounts of blood-tinged sputum may be from the upper respiratory tract, and regurgitation of blood comes from a GI bleed.

Objective Data

The process in which data relating to the patient's problem are obtained through direct physical examination, including observation, palpation, percussion, auscultation; laboratory analysis; radiologic and other studies.

EVIDENCE BASE Heuer, A., & Scanlan, C. (2017). *Wilkins clinical assessment in respiratory care* (8th ed.). St. Louis, Mo: Mosby.

Key Observations

1. What is the respiratory rate, depth, and pattern? Are accessory muscles being used? Is the patient breathing through the mouth or pursing lips during exhalation? Is sputum being expectorated, and what is its appearance and odor?
2. Is there an increase in the anterior to posterior chest diameter, suggesting air trapping?
3. Is there obvious orthopnea or splinting?
4. Is there clubbing of the fingers, associated with bronchiectasis, lung abscess, empyema, cystic fibrosis, pulmonary neoplasms, and various other disorders?
5. Is there central cyanosis indicating possible hypoxemia or cardiac disease? Are mucous membranes and nail beds pink?
6. Are there signs of tracheal deviation, as seen with pneumothorax?
7. Are the jugular veins distended? Is there peripheral edema or other signs of cardiac dysfunction?
8. Does palpation of the chest cause pain? Is chest expansion symmetrical? Any change in tactile fremitus or egophony?
9. Is percussion of lung fields resonant bilaterally? Is diaphragmatic excursion equal bilaterally?
10. Are breath sounds present and equal bilaterally? Are the lung fields clear or are there rhonchi, wheezing, crackles, stridor, or pleural friction rub? Does auscultation reveal egophony, bronchophony, or whispered pectoriloquy?

Laboratory Studies

Arterial Blood Gas Analysis

Description

1. An ABG is a laboratory test that measures (PaO_2) oxygen tension, ($PaCO_2$) carbon dioxide tension, acidity (pH), oxyhemoglobin saturation SaO_2, and bicarbonate (HCO_3). This provides a means of assessing the adequacy of ventilation.
2. Allows assessment of body's acid–base (pH) status, indicating if acidosis or alkalosis is present, whether acidosis or alkalosis is respiratory or metabolic in origin, and whether it is compensated or uncompensated.
3. Used for diagnostic evaluation and evaluation of response to clinical interventions (oxygen therapy, mechanical ventilation, noninvasive ventilation, etc.).

Nursing and Patient Care Considerations

1. Blood can be obtained from any artery but is usually drawn from the radial, brachial, or femoral site. It can be drawn directly by percutaneous needle puncture or accessed by way of indwelling arterial catheter. Determine facility policy for qualifications for ABG sampling and site of arterial puncture.
2. If the radial artery is used, an Allen test must be performed before the puncture to determine if collateral circulation is present.
3. Arterial puncture should not be performed through a lesion, through or distal to a surgical shunt, or in area where peripheral vascular disease or infection is present.
4. Absolute contraindications include an abnormal modified Allen test, severe peripheral vascular disease of the artery being sampled, active Raynaud syndrome, and local infection at the arterial site.
5. Coagulopathy or medium- to high-dose anticoagulation therapy may be a relative contraindication for arterial puncture.
6. Results may be affected by recent changes in oxygen therapy, suctioning, or positioning.
7. Interpret ABG values by looking at trends for the patient as well as the following normal values:
   a. PaO_2—partial pressure of arterial oxygen (80 to 100 mm Hg).
   b. $PaCO_2$—partial pressure of arterial carbon dioxide (35 to 45 mm Hg).
   c. SaO_2—arterial oxygen saturation (greater than 95%).
   d. pH—hydrogen ion concentration or degree of acid–base balance (7.35 to 7.45).
   e. (HCO_3^-)—bicarbonate primarily a metabolic buffer (22 to 26 mEq/L).

Sputum Examination

Description

1. Sputum may be obtained for evaluation of gross appearance, microscopic examination, Gram stain, culture and sensitivity, acid-fast bacillus, and cytology.

a. The direct smear shows presence of white blood cells and intracellular (pathogenic) bacteria and extracellular (mostly nonpathogenic) bacteria.
b. Gram stain shows whether bacteria is gram-positive or gram-negative and can be used to guide therapy until culture and sensitivity results are available.
c. The sputum culture is used to identify presence of specific pathogens; sensitivity determines drug efficacy and serves as a guide for drug treatment (ie, choice of antibiotic).
d. Acid-fast smears detect presence of pathogens such as *Mycobacterium tuberculosis*.
e. Cytology identifies abnormal and possibly malignant cells.

Nursing and Patient Care Considerations

1. Patients receiving antibiotics, steroids, and immunosuppressive agents for a prolonged time may have periodic sputum examinations because these agents may give rise to opportunistic pulmonary infections.
2. It is important that the sputum be collected correctly and that the specimen be sent to a laboratory immediately. Allowing it to stand in a warm room will result in overgrowth of organisms, making identification of pathogen difficult; this also alters cell morphology. A series of three early morning specimens is needed for acid-fast bacillus examination. Cytology samples should be collected in container with fixative solution.
3. Sputum can be obtained by various methods:
    a. Deep breathing and coughing.
        i. An early morning specimen obtained prior to eating or drinking yields best sample of deep pulmonary secretions from all lung fields.
        ii. Have patient clear nose and throat and rinse mouth with plain water—to decrease contamination by oral and upper respiratory flora.
        iii. Position patient upright or in high Fowler's unless contraindicated. Instruct patient to take several deep breaths, exhale, and perform a series of short coughs.
        iv. Have patient cough deeply and expectorate the sputum into a sterile container.
        v. If patient is unable to produce specimen, increasing oral fluid intake may be useful (unless on fluid restriction).
    b. Induction through use of ultrasonic or hypertonic saline nebulization.
        i. Patient inhales mist through mouth slowly and deeply for 10 to 20 minutes.
        ii. Nebulization increases the moisture content of air going to lower tract; particles will condense on tracheobronchial tree and aid in expectoration.
    c. Suctioning—aspiration of secretions via mechanical means; must be used with caution because it may cause bleeding, cardiac dysrhythmias, and increased intracranial pressure.
        i. Tracheal, through endotracheal (ET) or tracheostomy tube.
        ii. Nasotracheal (NT), through nose and into back of throat or trachea.
    d. Bronchoscopy with bronchoalveolar lavage, in which 60 to 100 mL, is instilled and aspirated from various lung segments. Sedation and/or anesthesia is required.

e. Gastric aspiration (rarely necessary since advent of ultrasonic nebulizer).
    i. Nasogastric (NG) tube is inserted into the stomach, approximately 50 mL sterile water is instilled, and swallowed pulmonary secretions are siphoned out.
    ii. Useful only for culture of tubercle bacilli, not for direct examination.
    iii. Must be done as soon as patient wakes up in the morning
f. Transtracheal aspiration involves passing a needle and then a catheter through a percutaneous puncture of the cricothyroid membrane. Transtracheal aspiration bypasses the oropharynx and avoids specimen contamination by mouth flora.

4. Generally, a sputum sample of 15 mL is adequate for laboratory testing.

Pleural Fluid Analysis

Description

1. Pleural fluid is continuously produced and reabsorbed, with a thin layer normally in the pleural space. Abnormal pleural fluid accumulation (effusion) occurs in diseases of the pleura, heart, or lymphatics. The pleural fluid is studied, with other tests, to determine the underlying cause.
2. Obtained by aspiration (thoracentesis) or by tube thoracotomy. See Figure 10-1.
3. The fluid is examined for cancerous cells, cellular makeup, chemical content, and microorganisms.
4. Pleural cavity contains 10 to 20 mL clear yellow (serous) fluid that lubricates the surfaces of the pleura, the thin membrane that lines the chest cavity and surrounds the lungs. A pleural effusion is an abnormal collection of this fluid.
5. The test is performed to determine the cause of a pleural effusion and to relieve associated shortness of breath.

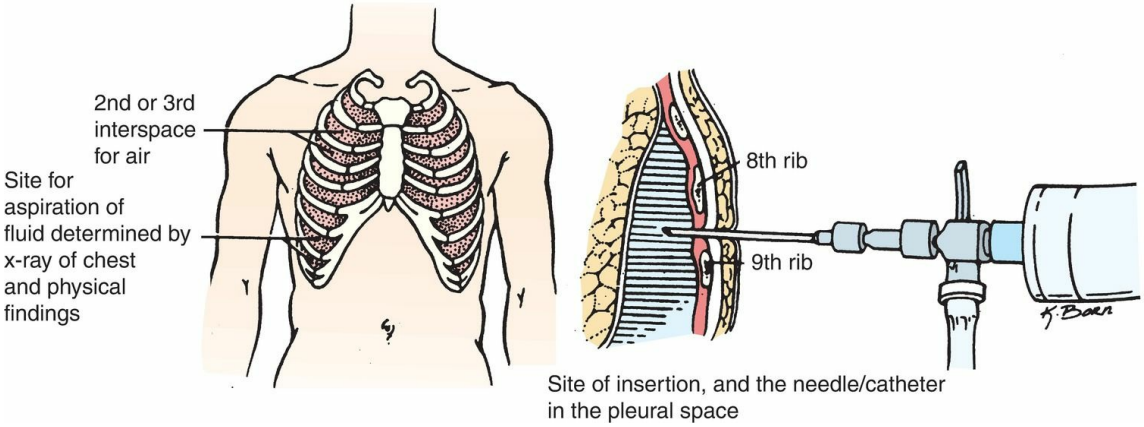


Figure 10-1. Thoracentesis for removal of pleural effusion and pleural fluid analysis.

Nursing and Patient Care Considerations

1. If done at bedside, prepare the patient by assisting to a supported upright position with lateral and posterior thorax of particular side exposed or in side-lying position with head of bed elevated 30 to 45

degrees and arm overhead. Support the patient through the process.

2. Observe and record total amount of fluid withdrawn, nature of fluid, and its color and viscosity.
3. Prepare sample of fluid and ensure transport to the laboratory.
4. A chest x-ray may be done before or after the fluid is withdrawn.
5. Patient should not cough, breathe deeply, or move while fluid is being withdrawn.
6. Instruct patient to inform provider immediately if sharp chest pain or shortness of breath occurs.

Radiology and Imaging

Chest X-Ray

Description

1. Normal pulmonary tissue is radiolucent and appears black on film. Thus, densities produced by tumors, foreign bodies, and infiltrates can be detected as lighter or white images.
2. Commonly, two views—posterior–anterior and lateral—are obtained.
3. This test shows the position of normal structures, displacement, and presence of abnormal shadows. It may reveal pathology in the lungs in the absence of symptoms.

Nursing and Patient Care Considerations

1. Should be taken upright if patient's condition permits. Assist technician at bedside in preparing patient for portable chest x-ray.
2. Encourage patient to take deep breath, hold breath, and remain still as x-ray is taken.
3. Make sure that all jewelry, electrocardiogram (ECG) or monitor leads, and metal objects (including metal-containing transdermal patches) in x-ray field are removed so as not to interfere with film.
4. Consider the contraindication of x-rays for pregnant patients.

Computed Tomography Scan

Description

1. Cross-sectional x-rays of the lungs are taken from many different angles and processed through a computer to create three-dimensional images. This three-dimensional imaging provides more complete diagnostic information than the two-dimensional x-ray.
2. It may be used to define pulmonary nodules and pulmonary abnormalities or to demonstrate mediastinal abnormalities and hilar adenopathy.

Nursing and Patient Care Considerations

1. Describe test to patient and family, including that table will slide into doughnut-shaped scanner and patient must lie still during test. The test usually takes about 30 minutes but may take longer.
2. Be alert to allergies to iodine or other radiographic contrast media that might be used during testing.
3. For scans performed with contrast, informed consent and IV access required. Patient should take nothing by mouth (NPO) for 4 hours prior to scan. Blood urea nitrogen and creatinine should be evaluated 24 to 48 hours before test or according to facility protocol.
4. Hydrate patient well to facilitate excretion of contrast, if used.
5. Check regarding weight limit of equipment prior to scanning bariatric patients.
6. Consider the contraindication of radiologic studies for the pregnant patient, especially computed tomography (CT) scans with contrast media.

Magnetic Resonance Imaging

Description

1. Noninvasive procedure that uses a powerful magnetic field, radio waves, and a computer to produce detailed pictures of the organs, soft tissue, bone, and other internal structures.
2. Provides contrast between various soft tissues and is performed to:
   a. Assess abnormal growths, including cancer of the lungs or other tissues inadequately assessed with other imaging modalities.
   b. Determine stage of cancer, including tumor size, extent, and degree to which cancer has spread.
   c. Visualize lymph nodes and blood vessels.
   d. Assess disorders of the vertebrae, ribs, and sternum.
3. Traditional radiographic contrast media are not used but gadolinium injection or ingestion may be necessary, depending on patient's medical history and anatomy to be imaged.
4. It is helpful to synchronize the magnetic resonance imaging (MRI) picture to the ECG in thoracic studies.
5. The hazards of MRI during pregnancy are unknown, although ionizing radiation (x-ray) is not used during MRI.

Nursing and Patient Care Considerations

1. Explain procedure to patient and assess ability to remain still in a closed space; sedation may be necessary if the patient is claustrophobic. The test takes approximately 1 hour.
2. Evaluate patient for contraindications to MRI: implanted devices, such as implanted defibrillators that may malfunction; cochlear implants; or metallic surgical clips used on brain aneurysms.
3. Devices that may interfere with the exam or potentially pose a risk include artificial heart valves, implanted drug infusion ports, infusion catheters, intrauterine devices, pacemakers and neurostimulators, metallic implants such as prosthetic valves or joints, and metal pins, screws, plates, or surgical staples.
4. Make sure that all jewelry, ECG or monitor leads, hearing aids, pins/hairpins, removable dental work, and metal objects (including metal-containing transdermal patches) are removed.
5. Kidney disease and sickle cell anemia may contraindicate MRI with contrast material.
6. Check with MRI technician about the use of equipment, such as ventilator or mechanical IV pump, in MRI room.
7. Earplugs may be used to muffle loud thumping and humming noises during imaging.
8. Evaluate the patient for claustrophobia, and teach relaxation techniques to use during test or advocate for use of open MRI. Be ready to administer sedation, if necessary.
9. Check regarding size capacity of equipment prior to scanning bariatric patients.
10. It is recommended that nursing mothers not breastfeed for 36 to 48 hours after MRI with contrast.

Positron Emission Tomography Scan

Description

1. Physiologic images are obtained, based on the detection of radiation from the emission of positrons. Positrons are tiny particles emitted from a radioactive isotope–administered IV to the patient. Radioactivity localizes in the area(s) being scanned and is detected by positron emission tomography (PET). Different colors or degrees of brightness on a PET image represent different levels of tissue or organ function.
2. Radioisotope is administered 30 to 90 minutes prior to scan via IV or inhalation.
3. Distinguishes between benign and malignant lung nodules.

Nursing and Patient Care Considerations

1. Describe test to patient and family, including that table will slide into doughnut-shaped scanner and patient must lie still during test. The test usually takes 30 to 45 minutes.
2. Isotope has a short half-life and is not considered a radiologic hazard.
3. Encourage fluids to facilitate excretion of isotope.
4. Consider the contraindication of radiologic studies for the pregnant or breastfeeding patient.
5. Test results may be inaccurate for diabetic patients or for patients who have eaten within a few hours prior to the scan if blood glucose or insulin levels are not normal.

Pulmonary Angiography

Description

1. An imaging method used to study pulmonary vessels and pulmonary circulation.
2. For visualization, radiopaque medium is injected by way of a catheter in the main pulmonary artery rapidly into the vasculature of the lungs. Films are then taken in rapid succession after injection.
3. It is considered the "gold standard" for diagnosis of pulmonary embolus, but spiral CT scanning can also be effectively used.

Nursing and Patient Care Considerations

1. Determine whether patient is allergic to radiographic contrast media, describe the procedure, and obtain informed consent.
2. Patient may be kept NPO for 4 to 8 hours prior to procedure.
3. Instruct patient that injection of dye may cause flushing, cough, and a warm sensation.
4. Pulse, blood pressure (BP), and respirations are monitored during the procedure.
5. After the procedure, make sure pressure is maintained over access site and monitor pulse rate, BP, and circulation distal to the injection site.
6. Patient may be advised to keep extremity straight for up to 12 hours after the procedure.
7. Necessity of test should be carefully evaluated in patients with bleeding disorders and pregnant women.

Ventilation–Perfusion Scan

Description

1. A pair of nuclear scan tests using inhaled and injected radioisotopes to measure breathing (ventilation) and blood flow (perfusion) in all areas of the lungs. The two tests may be performed either separately or together.
2. Perfusion scan is done after injection of a radioactive isotope. It measures blood perfusion through the lungs and evaluates lung function on a regional basis.
3. Ventilation scan is done after inhalation of radioactive gas (eg, xenon with O_2), which diffuses throughout the lungs. It indicates how well air reaches all parts of the lung.
4. Usually performed to detect pulmonary embolus. Also useful in evaluating advanced pulmonary disease (COPD), detecting abnormal circulation (shunts) in the pulmonary blood vessels, evaluating lung function, and identifying fibrosis.
5. Is also referred to as *V/Q scan* because the initials are used in mathematical equations that calculate air and blood flow.

Nursing and Patient Care Considerations

1. Determine if patient is allergic to radiographic dye before V/Q scan.
2. Explain the procedure to patient and encourage cooperation with inhalation and brief episodes of breath holding.
3. Contraindicated in patients with primary pulmonary hypertension.
4. False positives may occur in patients with vasculitis, mitral stenosis, and pulmonary hypertension and when tumors obstruct a pulmonary artery with airway involvement, fatty tissues, and presence of parasites.
5. False negatives are associated with partially occluded vessels.

Other Diagnostic Tests

Bronchoscopy

EVIDENCE BASE Paradis, T., Dixon, J., & Tieu, B. (2016). The role of bronchoscopy in the diagnosis of airway disease. *Journal of Thoracic Disease*, *8*(12), 3826–3837.

Description

1. The direct inspection and observation of the upper and lower respiratory tract through fiberoptic (flexible) or rigid bronchoscope as a means of diagnosing and managing inflammatory, infectious, and malignant diseases of the airway and lungs including airway injury and obstruction by a foreign body tumor or mass.
2. Flexible fiberoptic bronchoscopy allows for more patient comfort and better visualization of smaller airways, including nasal passages. It is usually performed using local anesthesia with or without moderate sedation. Fluoroscopy may be needed to facilitate specimen collection. Used for therapeutic and diagnostic procedures such as:
   a. Bronchoalveolar lavage.
   b. Endobronchial or transbronchial biopsies.
   c. Cytologic wash or brush.
   d. Transbronchial needle aspiration.
   e. Endobronchial ultrasound.
   f. Autofluorescence bronchoscopy.
   g. Balloon dilation.
   h. Endobronchial laser ablation.
   i. Electrocautery.
   j. Photodynamic therapy.
   k. Brachytherapy.
   l. Some types of stent placement.
3. Rigid bronchoscopy, often requires general anesthesia with adequate sedation and muscle relaxants, may be combined with flexible bronchoscopy for better access to distal airways. Diagnostic and therapeutic indications include:
   a. Bleeding or hemorrhage into the airway.
   b. Foreign body extraction.
   c. Deeper biopsy specimen collection than can be obtained fiberoptically.
   d. Dilation of tracheal or bronchial strictures.

e. Relief of airway obstruction.

f. Insertion of stents.

g. Tracheobronchial laser therapy or other mechanical tumor ablation.

Nursing and Patient Care Considerations

1. Check that an informed consent form has been signed and that risks and benefits have been explained to the patient.
2. Make sure that IV access is present and patent.
3. Absolute contraindications include uncorrectable coagulopathy, severe refractory hypoxemia, unstable hemodynamic status, facial trauma, and unstable cervical spine. Patients with increased risk are those with MI within past 6 weeks, head injuries susceptible to increased intracranial pressures (ICP), and known or suspected pregnancy (because of possible radiation exposure).
4. Review and follow facility policy and procedure for anesthesia and sedation.
5. Administer prescribed medication to reduce secretions, block the vasovagal reflex and gag reflex, and relieve anxiety. Give encouragement and nursing support.
6. Restrict fluid and food, as ordered, before procedure to reduce risk of aspiration when reflexes are blocked. Patient may be kept NPO for 4 hours prior to flexible bronchoscopy with minimal sedation; if deeper sedation is used, patient's time on NPO is extended.
7. Remove dentures, contact lenses, and other prostheses.
8. After the procedure:
   a. Monitor cardiac rhythm and rate, BP, and level of consciousness (LOC).
   b. Monitor respiratory effort and rate.
   c. Monitor oximetry.
   d. Withhold ice chips and fluids until patient demonstrates gag reflex.
   e. Monitor patient's perceptions of pain, discomfort, and dyspnea.
9. Promptly report cyanosis, hypoventilation, hypotension, tachycardia or dysrhythmia, hemoptysis, dyspnea, and decreased breath sounds.
10. Provide outpatients with specific instructions regarding signs and symptoms of complications and what to do if they arise.

NURSING ALERT After bronchoscopy, be alert for complications, such as pneumothorax, dysrhythmias, laryngospasm, and bronchospasm.

Lung Biopsy

Description

1. Procedures used for obtaining histologic material from the lung to aid in diagnosis include:
    a. Transbronchial biopsy—biopsy forceps inserted through bronchoscope and specimen of lung tissue obtained.
    b. Transthoracic needle aspiration biopsy—specimen obtained through needle aspiration under fluoroscopic guidance.
    c. Open lung biopsy—specimen obtained through small anterior thoracotomy; used in making a diagnosis when other biopsy methods have not been effective or are not possible.

Nursing and Patient Care Considerations

1. Obtain permission for consent, if required.
2. Observe for possible complications, including pneumothorax, hemorrhage (hemoptysis), and bacterial contamination of pleural space.
3. A chest x-ray should be done 1 hour after transbronchial biopsy to exclude pneumothorax.
4. See "Bronchoscopy" (page 167) or "Thoracic Surgeries" (page 184) for postprocedure care.

Pulmonary Function Tests

EVIDENCE BASE Cheung, H., & Cheung, L. (2015). Coaching patients during pulmonary function testing. A practical guide. *Canadian Journal of Respiratory Therapy*, *51*(3), 65–68.

Description

1. Pulmonary function tests (PFTs) are used to detect and measure abnormalities in respiratory function and quantify severity of various lung diseases. Such tests include measurements of lung volumes, ventilatory function, diffusing capacity, gas exchange, lung compliance, airway resistance, and distribution of gases in the lung.
2. Ventilatory studies (spirometry) are the most common group of tests.
    a. Requires electronic spirometer, water spirometer, or wedge spirometer that plots volume against time (timed vital capacity).
    b. Patient is asked to take as deep a breath as possible and then to exhale into spirometer as completely and either slowly or as forcefully as possible, depending on the type of test.
    c. Results are compared with normals for patient's age, height, and sex (see Table 10-1).
    d. A reduction in the vital capacity, inspiratory capacity, and total lung capacity may indicate a restrictive form of lung disease (disease because of increased lung stiffness).
    e. An increase in functional reserve capacity, total lung capacity, and reduction in flow rates usually indicate an obstructive flow because of bronchial obstruction or loss of lung elastic recoil.
3. Lung volumes are determined by asking the patient to inhale a known concentration of inert gas, such as helium or 100% oxygen, and measuring concentration of inert gas or nitrogen in exhaled air (dilution

method) or by plethysmography.

a. Yields thoracic volume (total lung capacity, plus any unventilated blebs or bullae).

b. An increased residual volume is found in air trapping because of obstructive lung disease.

c. A reduction in several parameters usually indicates a restrictive form of lung disease or chest wall abnormality.

4. Diffusing capacity measures lung surface effective for the transfer of gas in the lung by having patient inhale gas containing known low concentration of carbon monoxide and measuring carbon monoxide concentration in exhaled air. Difference between inhaled and exhaled concentrations is related directly to uptake of carbon monoxide across alveolar–capillary membrane. Diffusing capacity is reduced in interstitial lung disease, emphysema, pneumonectomy, pulmonary embolus, and anemia.

Table 10-1 Pulmonary Function Tests

TERM	SYMBOL	DESCRIPTION	REMARKS
Vital capacity	VC	Maximum volume of air exhaled after a maximum inspiration	• VC < 10–15 mL/kg suggests need for mechanical ventilation • VC > 10–15 mL/kg suggests ability to wean
Forced vital capacity	FVC	Total volume of air a patient is able to exhale for the total duration of the test during maximal effort	• Reduced in obstructive disease (COPD) because of air trapping and restrictive disease • Reflects airflow in large airways
Forced expiratory volume in 1 sec	FEV_1	Volume of air exhaled in the first second of the performance of the FVC	• Reduced in obstructive disease (COPD) because of air trapping • Reflects airflow in large airways
Ratio of FEV_1/FVC	FEV_1/FVC	FEV_1 expressed as a percentage of the FVC The percentage of FVC expired in 1 sec	• Decreased in obstructive disease • Normal in restrictive disease
Forced midexpiratory flow	$FEF_{25\%–75\%}$	Average flow during the middle half of the FVC	• Reflects airflow in small airways • Smokers may have change in this test before other symptoms develop
Peak expiratory flow rate	PEFR	Most rapid flow during a forced expiration after a maximum inspiration	• Used to measure response to bronchodilators, airflow obstruction in patients with asthma
Maximal voluntary volume	MVV	Volume of air expired in a specified period (12 sec) during repetitive maximal effort	• An important factor in exercise tolerance • Decreases in neuromuscular diseases

Nursing and Patient Care Considerations

1. Instruct the patient in correct technique for completing PFTs; coach the patient through test, if needed. Appropriate interpretation requires adequate patient cooperation and effort and accurate equipment. Instruct patient not to use oral or inhaled bronchodilator (eg, albuterol), caffeine, or tobacco at least 4 to 6 hours before the test (longer for long-acting bronchodilators).
2. Used with caution in patients with hemoptysis of unknown origin; pneumothorax; unstable cardiovascular status; recent MI or pulmonary embolus; thoracic, abdominal, or cerebral aneurysm; or recent eye, thoracic, or abdominal surgery.
3. Using a noseclip for all spirometric maneuvers is strongly recommended.
4. Although forced expiratory volume in the first second of a forced vital capacity is the "gold standard" for diagnosing airway obstruction, there is no single cutoff value separating normal from abnormal. This determination is based more on trending of individual results.

Pulse Oximetry

Description

1. Noninvasively provides an estimate of arterial oxyhemoglobin saturation by using selected wavelengths of light to determine the saturation of oxyhemoglobin. Oximeters function by passing a light beam through a vascular bed, such as the finger or earlobe, to determine the amount of light absorbed by oxygenated (red) and deoxygenated (blue) blood.
2. Calculates the amount of arterial blood that is saturated with oxygen (SaO_2) and displays this as a percentage.
3. Provides indication only of oxygenation, not ventilation.
4. Indications include:
   a. Monitor adequacy of oxygen saturation; quantify response to therapy.
   b. Monitor unstable patient who may experience sudden changes in blood oxygen level.
   c. Evaluation of need for home oxygen therapy.
   d. Determine supplemental oxygen needs at rest, with exercise, and during sleep.
   e. Need to follow the trend and need to decrease number of ABG sample drawn.
5. The oxyhemoglobin dissociation curve allows for correlation between SaO_2 and PaO_2 (see Figure 10-2).
   a. Increased body temperature, acidosis, and increased phosphates (2,3-DPG) cause a shift in the curve to the right, thus increasing the ability of hemoglobin to release oxygen to the tissues.
   b. Decreased temperature, decreased 2,3-DPG, and alkalosis cause a shift to the left, causing hemoglobin to hold on to the oxygen, reducing the amount of oxygen being released to the tissues.
6. Increased bilirubin, increased carboxyhemoglobin, low perfusion, or SaO_2 less than 80% may alter light absorption and interfere with results.

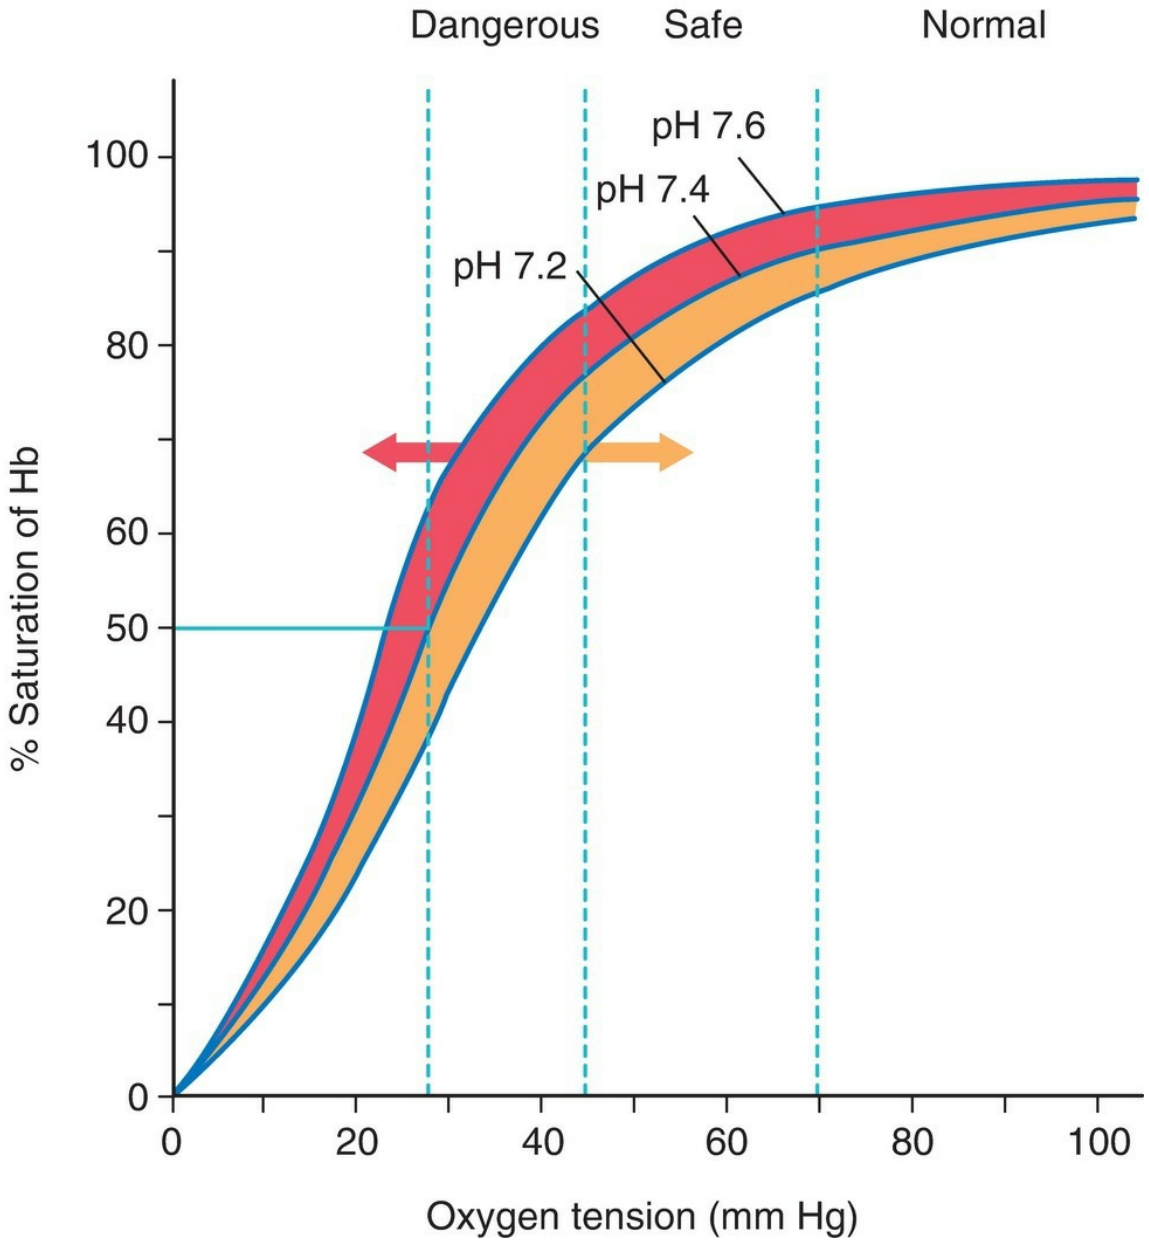

Figure 10-2. The oxyhemoglobin dissociation curve shows the relation between the partial pressure of oxygen and the oxygen saturation. At pressures greater than 60 mm Hg, the curve is essentially flat with blood oxygen content not changing with increases in the oxygen partial pressure. As oxygen partial pressures decrease in the slope of the curve, the oxygen is unloaded to peripheral tissue as the hemoglobin's affinity decreases. The curve is shifted to the right by an increase in temperature, 2,3-DPG, or $PaCO_2$, or a decrease in pH and to the left by the opposite of these conditions.

NURSING ALERT There is a potential error in SaO_2 readings of ±2% that can increase to greater than 2% if the patient's SpO_2 drops below 80%. Oximeters rely on differences in light absorption to determine SaO_2. At lower saturations, oxygenated hemoglobin appears bluer in color and is less easily

distinguished from deoxygenated hemoglobin. ABG analysis should be used in this situation.

Nursing and Patient Care Considerations

1. Assess patient's hemoglobin. SaO_2 may not correlate well with PaO_2 if hemoglobin is not within normal limits.
2. Remove patient's nail polish because it can affect the ability of the sensor to correctly determine oxygen saturation, particularly polish with blue or dark colors.
3. Correlate oximetry with ABG values and then use for single reading or trending of oxygenation (does not monitor $PaCO_2$).
4. Display heart rate should correlate with patient's heart rate.
5. To improve quality of signal, hold finger dependent and motionless (motion may alter results) and cover finger sensor to occlude ambient light.
6. Assess site of oximetry monitoring for perfusion on a regular basis because pressure ulcer may occur from prolonged application of probe. Rotate probe every 2 hours.
7. Device limitations include motion artifact, abnormal hemoglobins (carboxyhemoglobin and methemoglobin), intravenous (IV) dye, exposure of probe to ambient light, low perfusion states, skin pigmentation, nail polish or nail coverings, and nail deformities such as severe clubbing.
8. Document inspired oxygen or supplemental oxygen and type of oxygen delivery device.
9. Accuracy can be affected by decreased peripheral perfusion, ambient light, IV dyes, nail polish, deeply pigmented skin, cold extremities, hypothermia, patients in sickle cell crisis, jaundice, severe anemia, and use of antibiotics such as sulfas.
10. In patients with COPD, oxygen saturation levels may remain unchanged, even though CO_2 levels may be rising as the patient becomes acidotic. Pulse oximetry will not detect this deterioration.
11. Contraindicated for monitoring patients who have high levels of arterial carboxyhemoglobin, such as fire victims.

Capnometry/Capnography

Description

1. Used to noninvasively determine and monitor end-tidal carbon dioxide ($ETCO_2$)—the amount of CO_2 that is expired with each breath—via colorimetric indicator.
2. $ETCO_2$ is displayed as a capnogram (a waveform that may be time-based or volume-based and a numeric reading).
3. Normally, 2 to 5 mm Hg less than $PaCO_2$ in adults, with the difference being greater in the presence of lung disease, or increase in dead space, and can be used as an indirect estimate of V/Q mismatching for the lung.
4. Indicated for monitoring severity of pulmonary disease and monitoring response to therapy; evaluating efficacy of mechanical ventilatory support; monitoring adequacy of pulmonary, systemic, and coronary

blood flow; and assessing metabolic rate and/or alveolar ventilation.

5. A standard in anesthesia care, it is being increasingly used in the critical care setting as well as in emergency care via pocket-sized models.

Nursing and Patient Care Considerations

1. Draw ABGs initially to correlate $ETCO_2$ with $PaCO_2$ and to establish the gradient between $PaCO_2$ and $ETCO_2$.
2. Accuracy of measurement can be affected by alterations in breathing pattern or tidal volume (V_T), breathing frequency, presence of freon from metered-dose inhalers, contamination of the system by secretions or condensate, low cardiac output, use of antacids or carbonated beverages, and leaks around tracheal tube cuffs or uncuffed tubes.
3. Does not evaluate pH or oxygenation.
4. Effective for confirming ET tube placement and for monitoring CO_2 in patients who tend to retain CO_2 (eg, COPD).
5. Not a reliable method for determining inadvertent pulmonary placement of gastric tubes.
6. Clean and disinfect sensors and monitors as per manufacturer's instructions.

Exhaled Breath Condensate

EVIDENCE BASE Konstaninidi, E., Lappa, A., Tzortzi, A., & Panagiotis, B. (2015). Exhaled breath condensate: Technical and diagnostic aspects. *The Scientific World Journal*, *2015*, 435160.

Description

1. Emerging as a source for determining biomarkers of lung disease mainly from the lower respiratory tract. Exhaled breath condensate (EBC) is a matrix of exhaled particles and droplets in which biomarkers may be identified, such as:
   a. Volatile (acetic acid, formic acid, ammonia) and nonvolatile compounds.
   b. Very-low- and low-molecular-weight compounds.
   c. Polypeptides.
   d. Proteins.
   e. Nucleic acids.
   f. Lipid mediators.
   g. Inorganic molecules.
   h. Organic molecules.
   i. Redox relevant molecules.
   j. pH relevant molecules.

k. Cytokines and chemokines.

2. Currently, there is no gold standard—either invasively or noninvasively—for determining absolute concentrations with which EBC can be easily compared.
3. The pH of EBC depends on disease state, ranging from 3.5 to 9.0, which can affect the reactivity and stability of other biomarkers being assayed.

Nursing and Patient Care Considerations

1. Collect condensate sample. Collection methods vary, depending on specific biomarkers to be analyzed. Ten minutes of tidal breathing yields 1 to 2 mm of sample; smaller sample sizes may be adequate for analysis of only one or two biomarkers.
2. Be aware that lower airway condensate may be contaminated by particles from oral and retropharyngeal mucosa.
3. Saliva trapping systems may be used with drooling patients to reduce salivary contamination.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 10-3–10-24.

PROCEDURE GUIDELINES 10-3

Endotracheal Intubation

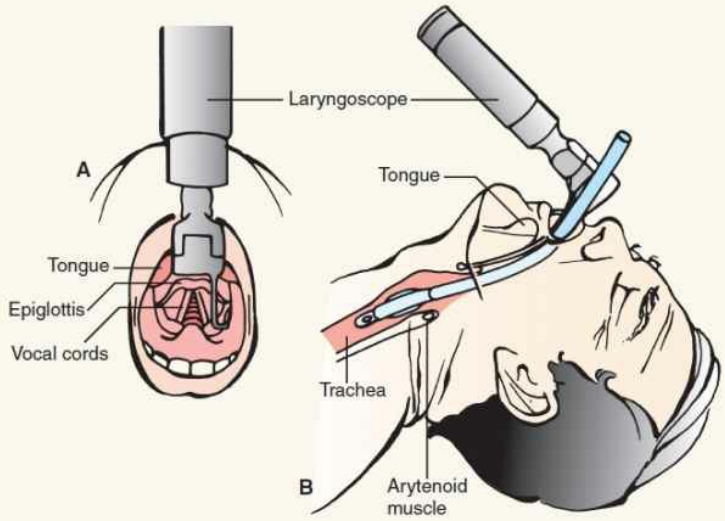
EQUIPMENT

- Laryngoscope with curved or straight blade and working light source (check batteries and bulb regularly)
- Endotracheal (ET) tube with low-pressure cuff and adapter to connect tube to ventilator or resuscitation bag
- Stylet to guide the ET tube
- Oral airway (assorted sizes) or bite block to keep patient from biting into and occluding the ET tube
- Adhesive tape or tube fixation system
- Sterile anesthetic lubricant jelly (water-soluble)
- 10-mL syringe
- Suction source
- Suction catheter and tonsil suction
- Resuscitation bag and mask connected to oxygen source
- Sterile towel
- Gloves
- Face shield
- End tidal CO2 detector

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Assess the patient's heart rate, level of consciousness, and respiratory status.	1. Provides a baseline to estimate the patient's tolerance of the procedure.
2. Remove the patient's dental bridgework and plates.	2. May interfere with insertion. Will not be able to remove easily from the patient once intubated.
3. Remove the headboard from the bed (optional).	3. Provides room to stand behind patient's head.
4. Prepare equipment.	
a. Ensure function of resuscitation bag with mask and suction.	a. The patient may require ventilatory assistance during procedure. Suction should be functional because gagging and emesis may occur during procedure.
b. Assemble the laryngoscope. Make sure the light bulb is tightly attached and functional.	
c. Select an ET tube of the appropriate size (7–9 mm for the average adult).	
d. Place the ET tube on a sterile towel.	d. Although the tube will pass through the contaminated mouth or nose, the airway below the vocal cords is sterile, and efforts must be made to prevent iatrogenic contamination of the distal end of the tube and cuff. The proximal end of the tube may be handled because it will reside in the upper airway.
e. Inflate the cuff to make sure it assumes a symmetrical shape and holds volume without leakage. Then deflate maximally.	e. Malfunction of the cuff must be determined before tube placement occurs.
f. Lubricate the distal end of the tube liberally with the sterile anesthetic water-soluble jelly.	f. Aids in insertion.
g. Have stylet available for oral intubation (user preference, although rarely used).	g. Stiffens the soft tube, allowing it to be more easily directed into the trachea. Nasal intubation does not employ use of the stylet.
5. Aspirate the stomach contents if an NG tube is in place.	5. Reduces risk of aspiration.
6. If time allows, inform the patient of the impending inability to talk and discuss alternative means of communication.	6. To alleviate fear.
7. If the patient is confused, consider requesting an order for soft wrist restraints.	7. Restraint of the confused patient may be necessary to promote patient safety and maintain sterile technique.
Performance phase	
1. Put on gloves and face shield.	1. Prevents contact with patient's oral secretions.
2. During oral intubation if cervical spine is not injured, place patient's head in a "sniffing" position (raise head with folded towel to extend at the junction of the neck and thorax and flexed at the junction of the spine and skull).	2. Upper airway is open maximally in this position.
3. Spray the back of the patient's throat with anesthetic spray.	3. Will decrease gagging.
4. Ventilate and oxygenate the patient with the resuscitation bag and mask before intubation.	4. Preoxygenation decreases the likelihood of cardiac dysrhythmias or respiratory distress secondary to hypoxemia.

Nursing Action	Rationale
5. Assist with intubation as needed. Anticipate the following steps:	
a. The handle of the laryngoscope is held in the left hand and the patient's mouth is held open with the right hand by placing crossed fingers on the teeth.	a. Leverage is improved by crossing the thumb and index fingers when opening the patient's mouth (scissor-twist technique).
b. The blade of the laryngoscope is inserted along the right side of the tongue, pushing the tongue to the left, and the right thumb and index finger are used to pull patient's lower lip away from lower teeth.	b. Rolling the lip away from teeth prevents injury by being caught between the teeth and the blade.
c. The laryngoscope is lifted forward (toward opposite corner) to expose the epiglottis.	c. This stretches the hypoepiglottis ligament, folding the epiglottis upward and exposing the glottis.
d. The laryngoscope is lifted upward and forward at a 45-degree angle to expose the glottis and visualize vocal cords.	d. This stretches the hypoepiglottis ligament, folding the epiglottis upward and exposing the glottis.
e. As the epiglottis is lifted forward (toward ceiling), the vertical opening of the larynx between the vocal cords will come into view (see accompanying figure).	e. The shoulder and arm are used to lift the epiglottis rather than the wrist.



Endotracheal intubation. **(A)** The primary glottic landmarks for tracheal intubation as visualized with proper placement of the laryngoscope. **(B)** Positioning the ET tube.

f. Once the vocal cords are visualized, the tube is inserted into the right corner of the mouth and passed while keeping vocal cords in constant view.	f. Care is taken not to insert the tube into the esophagus; the esophageal mucosa is pink, and the opening is horizontal rather than vertical.
g. The tube is gently pushed through the triangular space formed by the vocal cords and back wall of trachea.	g. Care is taken not to cause trauma to the vocal cords. If the vocal cords are in spasm (closed), waiting a few seconds may relieve spasm and allow passage of the tube.
h. Insertion is stopped just after the tube cuff has disappeared from view beyond the cords.	h. Advancing the tube further may lead to its entry into a mainstem bronchus (usually the right bronchus) causing collapse of the unventilated lung.
i. The laryngoscope is withdrawn while holding ET tube in place.	i. Prevents displacement.

Nursing Action	Rationale
6. Disassemble mask from resuscitation bag, attach bag to ET tube, and ventilate the patient.	6. Relieves hypoxia during the procedure.
7. Inflate the cuff with the minimal amount of air required to occlude the trachea.	7. Listen over the cuff area with a stethoscope. Occlusion occurs when no air leak is heard during ventilator inspiration or compression of the resuscitation bag.
8. Insert a bite block if necessary.	8. Keeps the patient from biting down on the tube and obstructing the airway.
9. Use a capnometer.	9. Confirms consistent exhalation of CO_2.
10. Ascertain expansion of both sides of the chest by observation and auscultation of breath sounds.	10. Observation and auscultation help in determining that tube remains in position and has not slipped into the right mainstem bronchus.
11. Auscultate over epigastrium.	11. Confirms no air movement in stomach.
12. Record distance from proximal end of tube to the point where the tube reaches the teeth.	12. Allows for detection of any later change in tube position.
13. Secure the tube to the patient's face with adhesive tape or apply a commercially available ET tube stabilization device.	13. The tube must be fixed securely to ensure that it will not be dislodged. Dislodgement of a tube with an inflated cuff may result in damage to the vocal cords.
Follow-up phase	
1. Obtain a chest x-ray.	1. Verifies tube placement and expansion of both lungs.
2. Record tube type, depth of insertion and size, cuff pressure, and patient tolerance of the procedure.	2. For future reference.
3. Auscultate breath sounds every 2 hr or if signs and symptoms of respiratory distress occur. Assess ABGs after intubation if requested by the health care provider.	3. Respiratory distress may be sign of tube displacement. If the cuff is above the vocal cords, extubation may occur with coughing. If the tube is touching the carina, paroxysmal coughing will occur. If the tube slips into a mainstem bronchus, collapse of the unventilated lung may occur.
4. Measure cuff pressure with manometer; adjust pressure. Make adjustment in tube placement on the basis of the chest x-ray results.	4. The tube may be advanced or removed several centimeters for proper placement based on the chest x-ray results.

EVIDENCE BASE Johnson, A., & Seltis, L.M. (2017). *Critical care nursing certification: Preparation, review and practice exam* (7th ed.). New York, NY: McGraw-Hill.

American Society of Anesthesiologists. (2013). Practice guidelines for management of the difficult airway: An updated report by the American society of anesthesiologists task force on management of the difficult airway. *Anesthesiology, 118*(2), 251–270.

PROCEDURE GUIDELINES 10-4

Assisting with Tracheostomy Insertion

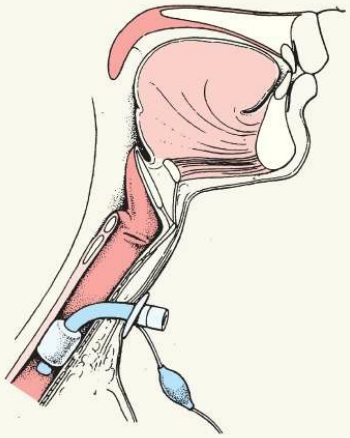
EQUIPMENT

- Tracheostomy tube (sizes 6 to 9 mm for most adults)
- Sterile instruments: hemostat, scalpel and blade, forceps, suture material, scissors
- Sterile gown and drapes, gloves
- Cap and face shield
- Antiseptic prep solution
- Gauze pads
- Shave prep kit
- Sedation
- Local anesthetic and syringe
- Resuscitation bag and mask with oxygen source
- Suction source and catheters
- Syringe for cuff inflation

- Respiratory support available for posttracheostomy (mechanical ventilation, tracheal oxygen mask, CPAP, T-piece)

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain the procedure to the patient. Discuss a communication system with the patient.	1. Apprehension about inability to talk is usually a major concern of the tracheostomized patient.
2. Obtain consent for operative procedure.	2. Required.
3. Shave neck region.	3. Hair and beard may harbor microorganisms. If the beard is to be removed, inform the patient or family.
4. Assemble equipment. Using aseptic technique, inflate tracheostomy cuff and evaluate for symmetry and volume leakage. Deflate maximally.	4. Ensure that the cuff is functional before tube insertion.
5. Position the patient (in a supine position with head extended and a support under the shoulders).	5. This position brings the trachea forward.
6. Obtain an order for and apply soft wrist restraints if the patient is confused.	6. Restraint of the confused patient may be necessary to ensure patient safety and preservation of aseptic technique.
7. Give medication, if ordered.	7. Sedation or local anesthetic may be used to decrease pain and anxiety.
8. Position the light source.	
Performance phase	
1. Assist with antiseptic prep, gowning and gloving, and sterile draping.	1. Reduces the risk of infection.
2. Put on face shield.	2. Spraying of blood or airway secretions may occur during this procedure.



Tracheostomy tube placement.

Nursing Action	Rationale
3. During procedure, monitor the patient's vital signs, suction as necessary, give medication as prescribed, and be prepared to administer emergency care.	3. Bradycardia may result from vagal stimulation because of tracheal manipulation or hypoxemia. Hypoxemia may also cause cardiac irritability.
4. Immediately after the tube is inserted, inflate the cuff. The chest should be auscultated for the presence of bilateral breath sounds.	4. Ensures ventilation of both lungs.
5. Secure the tracheostomy tube with twill tapes or other securing device and apply dressing.	5. Prevents accidental extubation.
6. Apply appropriate respiratory assistive device (mechanical ventilation, tracheostomy, oxygen mask, CPAP, T-piece adapter).	6. Relieves hypoxia.
7. Check the tracheostomy tube cuff pressure.	7. Excessive cuff pressure may cause tracheal damage.
8. "Tie sutures" or "stay sutures" of silk may have been placed through either side of the tracheal cartilage at the incision and brought out through the wound. Each is to be taped to the skin at a 45-degree angle laterally to the sternum.	8. Should the tracheostomy tube become dislodged, the stay sutures may be grasped and used to spread the tracheal cartilage apart, facilitating placement of the new tube.
Follow-up phase	
1. Assess vital signs and breath sounds; note tube size used, physician performing procedure, and type, dose, and route of medications given.	1. Provides baseline.
2. Obtain chest x-ray.	2. Documents proper tube placement.
3. Assess and document condition of stoma for bleeding, swelling, or subcutaneous air. Monitor and inform the health care provider of an increase in bleeding or swelling.	3. Some bleeding around the stoma site is not unusual for the first few hours, but increased bleeding, swelling, or crepitus in the subcutaneous tissue could indicate complications.
KEY DECISION POINT When positive pressure respiratory assistive devices are used (mechanical ventilation, CPAP) before the wound is healed, air may be forced into the subcutaneous fat layer. This can be seen as enlargement of the neck and facial tissues and felt as crepitus or "crackling" when the skin is depressed. Report immediately, assess for respiratory distress and be prepared to provide manual ventilation if condition worsens.	
4. Clean the site aseptically when necessary but do not change tracheostomy ties for first 24 hr.	4. Dried blood and other debris around the surgical site may increase risk of infection.
NURSING ALERT Accidental dislodgement of the tube could result when the ties are loose, and tube reinsertion through the as-yet-unformed stoma may be difficult or impossible to accomplish.	
5. An extra tube, obturator, and hemostat should be kept at the bedside. In the event of tube dislodgement, reinsertion of a new tube may be necessary.	5. The hemostat will open the airway and allow ventilation in the spontaneously breathing patient. Avoid inserting the tube horizontally because the tube may be forced against the back wall of the trachea.
6. For emergency tube insertion, place the patient in the same position as insertion, then: a. Spread the wound with a hemostat or stay sutures. b. Insert replacement tube (containing the obturator) at an angle. c. Point cannula downward and insert the tube maximally. d. Remove the obturator.	
EVIDENCE BASE Johnson, A., & Seltis, L.M. (2017). *Critical care nursing certification: Preparation, review and practice exam* (7th ed.). New York, NY: McGraw-Hill.	

PROCEDURE GUIDELINES 10-5

Artificial Airway Cuff Maintenance

EQUIPMENT

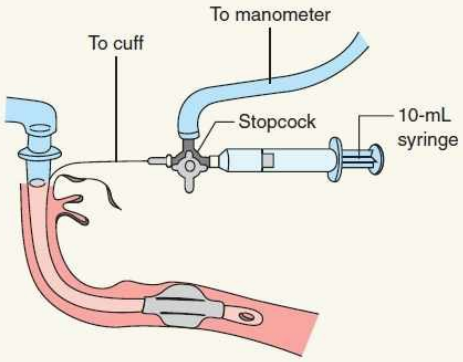
- Suction catheter
- Tonsil suction

- Suction source
- 10-mL syringe
- Pressure manometer (mercury or aneroid)
- Handheld resuscitation bag with reservoir, connected to 100% O_2 at 10 to 15 L/minute
- Face shield

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain the procedure to the patient.	1. Decreases the patient's anxiety and promotes cooperation.
2. Put on the face shield.	2. Spraying of secretions may occur.
Performance phase	
Deflating the cuff	
1. Suction the trachea, then the oral and nasal pharynx. Replace the catheter with a second sterile suction catheter.	1. Removes secretions collected above the cuff, which could be aspirated into the lungs when the cuff is deflated. Do not reenter the trachea with the same catheter used for suctioning the mouth.
2. Deflate the cuff slowly.	2. The small test balloon at the end of the tubing remains inflated as long as the cuff at the distal end of the tube is inflated. A vacuum within the syringe is sensed when no more air can be aspirated.
3. (Concomitant with step 2.) Have the patient cough or manually inflate the lungs with the resuscitation bag. Be ready to receive secretions in a tissue or aspirate with tonsil suction.	3. Positive pressure in the airways may help force secretions upward and prevent aspiration of secretions.
4. Suction through the tracheostomy or ET tube.	4. Secretions that may have been present above the inflated cuff and around the exterior tube have now seeped downward. Coughing reflex may be stimulated, helping to mobilize secretions.
5. Provide adequate ventilation while the cuff is deflated.	
a. If the patient does not require assisted ventilation, maintain humidified oxygen, as directed.	
b. If the patient requires assisted ventilation, provide manual ventilation via a resuscitation bag. Leave cuff deflated for as long as the tube repositioning requires; then reinflate.	b. Monitor the patient closely for tolerance. Loss of tidal volume or PEEP may promote hypoxemia and hypocarbia. Cuff should not be deflated for more than 30–45 sec.
Inflating a cuff	
1. No leak technique.	1. Air leakage will be heard when the intra-airway pressure is most positive (maximum peak airway pressure) on patient's chest under tracheostomy site.
a. Attach air-filled syringe to cuff injection port.	
b. Slowly inject air until no air escapes from the patient's lungs around the cuff.	
c. Note amount of air injected to provide a seal.	
2. Minimal leak technique (for mechanical ventilation).	2. Inflates cuff at lowest possible pressure while still maintaining an adequate seal. Prevents tracheal necrosis from excessive or prolonged cuff pressure.
a. Attach air-filled syringe to cuff injection port.	
b. Slowly inject air until no leak is heard at maximum peak airway pressure.	
c. Slowly remove air from cuff until a small air leak is heard at maximum peak airway pressure.	c. Adjustment in V_T setting may be necessary to compensate for the leak.
d. Note amount of air injected.	

Nursing Action	Rationale
3. Measurement of minimal occluding volume (see accompanying figure).	
a. Inject sufficient air into the manometer tubing to raise the dial reading 1 cm H_2O above the zero reading.	a. This "pressurizes" the tubing and prevents loss of air from the cuff to the tubing when the reading is taken.
b. Insert male port of three-way stopcock into cuff injection port. One female port of stopcock holds the air-filled syringe, and one port holds the pressure manometer.	



Airway cuff pressure is measured by opening stopcock to the cuff and manometer. Air is injected into the cuff by opening the stopcock to the syringe and cuff.

c. Inject air into cuff until desired intracuff pressure is reached at maximum peak airway pressure.	c. Aneroid manometer measures cuff pressure in cm H_2O: A pressure of 20–25 cm H_2O is desired. Mercury manometer pressure should be 15–20 mm Hg. Pressure greater than upper limit may cause compression of tracheal vessels, resulting in decreased blood flow to tissue. Pressure less than lower limit may allow aspiration of gastric or oral secretions.
d. Note amount of air needed to achieve the desired intracuff pressure.	
e. Remove the stopcock from the injection port.	e. Most injection ports have self-sealing valves. If not, a cap or closed stopcock may be left in the injection port (clamping of the inflation tubing is discouraged because it may result in cracking or kinking of the line permanently).
Monitoring cuff pressure	
1. While the cuff is inflated, monitor cuff pressure every 4 hr. Maintain cuff pressure between 20 and 25 mm Hg or 25 and 35 cm H_2O.	1. Excessive pressure will decrease blood flow to the tissue, resulting in tracheal necrosis. Insufficient cuff pressure predisposes to aspiration.
2. Document the amount of air required to maintain cuff pressure at this level.	2. Establishes a baseline for evaluation of change in pressure.
Inability to maintain a seal	
1. Assess the degree of leakage and length of time elapsed because cuff volume was replenished.	1. If an inflated cuff leaks air within 10 min, assessment is necessary. Possibilities may be: a. Cuff positioned above the vocal cords (direct visualization necessary for repositioning). b. Incompetence of self-sealing valve on injection port. c. Tracheal dilation (requiring larger size tube). d. Cuff may be ruptured, requiring a new tube.

Nursing Action	Rationale
2. Inflate the cuff to desired level.	
3. Disconnect syringe (and manometer, if used).	
4. Assess for leakage.	
5. If leakage recurs, place three-way stopcock between syringe and injection port, inflate cuff, and close stopcock. Remove syringe (and manometer, if used) leaving closed stopcock in injection port.	5. Closed stopcock left in injection port acts as "plug" if self-sealing valve is incompetent.
6. If air leak persists, tube repositioning or replacement may be necessary. Consult with appropriate personnel.	
Follow-up phase	
1. Note and record amount of air used for adequate seal, intracuff pressure, and inability to achieve seal.	1. Documents interventions necessary to reintubate or change tracheostomy tube to obtain a desired seal.
2. While the cuff is inflated, assess cuff pressure every 4 hr. The cuff pressure manometer is useful for this.	2. Leakage of air from the cuff or cuff injection port may occur. Assess the inflation status and adjust as needed.

EVIDENCE BASE Johnson, A., & Seltis, L. M. (2017). *Critical care nursing certification: Preparation, review and practice exam* (7th ed.). New York, NY: McGraw-Hill.

PROCEDURE GUIDELINES 10-6

Tracheostomy Care (Routine)

EQUIPMENT

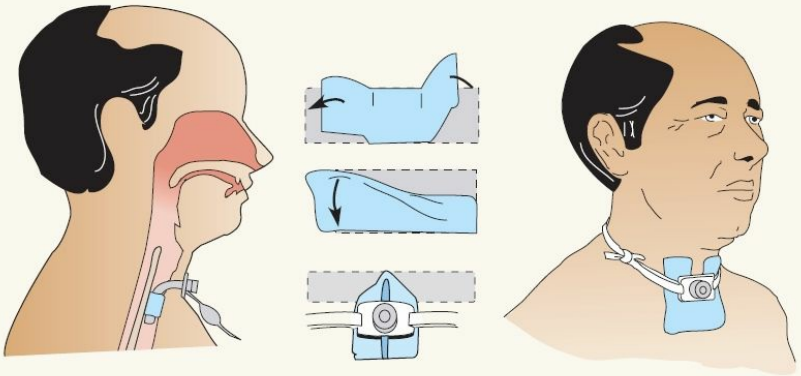
- Assemble the following equipment or obtain a prepackaged tracheostomy care kit:
- Sterile towel
- Sterile gauze pads (10)
- Sterile cotton swabs
- Sterile gloves
- Hydrogen peroxide
- Sterile water
- Antiseptic solution and ointment (optional)
- Tracheostomy tie tapes or commercially available tracheostomy securing device
- Face shield

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Assess the condition of the stoma before tracheostomy care (redness, swelling, character of secretions, presence of purulence, or bleeding).	1. The presence of skin breakdown or infection must be monitored. Culture of the site may be warranted by appearance of these signs.
2. Examine the neck for subcutaneous crepitus.	2. Indicates air leak into subcutaneous tissue.
3. Suction the trachea and pharynx thoroughly before tracheostomy care.	3. Removal of secretions before tracheostomy care keeps the area clean longer.
4. Explain the procedure to the patient.	4. Allays anxiety.
5. Wash hands thoroughly.	5. Reduces risk of infection.
Performance phase	
1. Assemble equipment:	
a. Assemble equipment: ACE sterile towel.	a. Provides sterile field.
b. Open four gauze pads and pour hydrogen peroxide on them.	b. For removal of mucus and crust, which promotes bacterial growth.
c. Open two gauze pads and pour antiseptic solution on them.	c. May be applied to fresh stoma or infected stoma. Not necessary for clean, healed stoma.
d. Open two gauze pads; keep dry.	
e. Open two gauze pads and pour sterile water on them.	
f. Place tracheostomy tube tapes on field.	
g. Put on face shield and sterile gloves.	g. Face shield prevents secretions from getting into the nurse's eyes. Sterile gloves prevent contamination of the wound by nurse's hands and also protect the nurse's hands from infection.
2. Clean the external end of the tracheostomy tube with two gauze pads with hydrogen peroxide; discard pads.	2. Designate the hand you clean with as contaminated and reserve the other hand as sterile for handling sterile equipment.
3. Unlock and remove inner cannula, if present.	3. Many tracheostomies do not have an inner cannula.
4. If disposable inner cannula is used, replace with new cannula (with your clean hand), touching only external portion, and lock it securely in place.	4. To avoid contamination of inner portion.
5. If inner cannula is reusable, remove it with your contaminated hand and clean it in hydrogen peroxide solution, using brush or pipe cleaners with your sterile hand. When clean, drop it into sterile saline solution and agitate it to rinse thoroughly with your sterile hand. Tap it gently to dry it and replace it with your sterile hand.	5. Because cannula is dirty when you remove it, use your contaminated hand. It is considered sterile once you clean it, so handle it with your sterile hand.
6. Clean the stoma area every 4–8 hr with cotton tipped syringes or gauze pads soaked with saline in a semicircular motion inward to outward. Dried secretions can be loosened with diluted hydrogen peroxide.	6. Hydrogen peroxide may help loosen dry, crusted secretions.

Nursing Action	Rationale
7. Loosen and remove crust with sterile cotton swabs.	
8. Repeat step 6 using the sterile water-soaked gauze pads.	8. Ensures that all hydrogen peroxide is removed.
9. Repeat step 6 using dry pads.	9. Ensures dryness of the area. Wetness promotes infection and irritation.
10. (optional) An infected wound may be cleaned with gauze saturated with an antiseptic solution, then dried. A thin layer of antibiotic ointment may be applied to the stoma with a cotton swab.	10. May help clear wound infection.
11. Change the tracheostomy securement device when soiled and as per facility policy:	
a. To avoid accidental dislodgement one person should hold the tube, whereas a second person performs the tie exchange.	a. Stabilization of the tube helps prevent accidental dislodgement and keeps irritation and coughing because of tube manipulation at a minimum.
b. Remove old securement device carefully.	
c. Grasp slit end of clean tape and pull it through opening on side of the tracheostomy tube.	
d. Pull other end of tape securely through the slit end of the tape.	
e. Repeat on the other side.	
f. Tie the tapes at the side of the neck in a square knot. Alternate knot from side to side each time tapes are changed, or secure the securement device, Velcro ties, etc.	f. Prevents irritation and rotates pressure site.
g. Ties should be tight enough to keep tube securely in the stoma but loose enough to permit two fingers to fit between the tapes and the neck.	g. Excessive tightness of tapes will compress jugular veins, decrease blood circulation to the skin under the tape, and result in discomfort for the patient.
12. Place a gauze pad between the stoma site and the tracheostomy tube per facility policy (see accompanying figure).	12. Gauze absorbs secretions and prevents irritation of peristomal tissue; however, it may promote infection if moisture builds up.
Follow-up phase	
1. Document procedure performance, observations of stoma (irritation, redness, edema, subcutaneous air), and character of secretions (color, purulence). Report changes in stoma appearance or secretions.	1. Provides a baseline.
2. Clean the fresh stoma every4–8 hr or more frequently if indicated by accumulation of secretions. Ties should be changed every 24 hr, or more frequently if soiled or wet, and then according to facility policy.	2. The area must be kept clean and dry to prevent infection or irritation of tissues.

Nursing Action	Rationale



Placement of tracheostomy tube ties and elective gauze pad.

Morris, L., Whitmer, A., & McIntosh, E. (2013). Tracheostomy care and complications in the intensive care unit. *Critical Care Nurse, 33*(5)18–30.

PROCEDURE GUIDELINES 10-7

Insertion of a Tracheostomy Button

EQUIPMENT

- Appropriate-size tracheostomy button kit (includes cannula, solid closure plug, spacers, universal adapter)
- Water-soluble lubricant
- Syringe for deflation of tracheostomy cuff
- Replacement of tracheostomy tube
- Flashlight
- Gloves

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Assess whether the patient meets the criteria for use of a tracheostomy button. Criteria include able to be adequately oxygenated with nasal cannula or face mask; able to swallow and protect the airway; able to cough up secretions; and a noninfected, nonirritated tracheal stoma.	1. If the patient does not meet these criteria, use of tracheostomy tube as airway must be continued.
2. Determine vital signs, LOC, SaO_2, or ABG.	2. Provides baseline for future assessment.
Performance phase	
1. Elevate the head of the bed 45 degrees, suction the airway, deflate the tracheostomy tube cuff, and remove the tube.	1. Protects against aspiration.
2. Determine the distance from anterior tracheal wall to the outer edge of the stoma (skin surface) using a probe with a right-angle bend (contained in the kit).	
3. Insert the angled end of the probe into the stoma, pull gently until the probe touches the anterior wall, and then mark the probe at the outer edge of the stoma (skin surface).	
4. Compare the length of the tracheostomy button cannula with this measurement. If the cannula is too long, it can be sized to fit by adding spacers included in the kit.	4. Spacer rings can be slipped over the cannula to size it for individualized patient requirements.
5. Coat the cannula with a water-soluble lubricant. Ask the patient to relax and take several deep breaths. Insert the cannula into the stoma.	5. The cannula should pass easily into the stoma. If insertion is difficult, recheck cannula size. Several sizes are available.
6. Insert the closure plug into the cannula. Ties may be used to hold the button in place until the stoma closes around the button.	6. A slight snap will be heard as the plug enters the cannula. The plug causes the proximal end of the cannula to flare, holding it in place.
7. Remove the button two times per week, clean with antibacterial soap, rinse with sterile water, and replace it.	7. Periodic removal helps to keep tissue from granulating into the distal portion of the cannula.
Follow-up phase	
1. Observe immediate patient response and obtain SaO_2 or ABGs after insertion. Report changes.	1. Use of the button increases dead space, which may increase work of breathing or cause a decrease in SaO_2.
2. Determine ability of patient to cough out secretions and swallow with button in place.	2. Confirms the patient will not retain secretions or be at risk for aspiration with use of this device.

EVIDENCE BASE Ahrens, T., Prentice, D., & Kleinpell, R. (2010). *Critical care nursing certification: Preparation, review and practice exam* (6th ed.). New York, NY: McGraw-Hill.

PROCEDURE GUIDELINES 10-8

Nasotracheal Suctioning

EQUIPMENT

- Assemble the following equipment or obtain a prepackaged kit:
- Disposable suction catheter (preferably soft rubber)
- Sterile towel
- Sterile disposable gloves
- Sterile water
- Water-soluble lubricant jelly
- Suction source at −80 to −120 mm Hg
- Resuscitation bag with face mask. Connect 100% O2 source with flow of 10 L/minute
- Oximeter

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Auscultate breath sounds, and monitor heart rate, oxygen saturation, respiratory rate, color, ease of respirations. If the patient is on monitor, continue monitoring heart rate or arterial BP.	1. Baseline assessment is important because suctioning may cause hypoxemia, resulting in tachycardia and increased BP, and later causing cardiac ectopy, bradycardia, hypotension, and cyanosis. Vagal stimulation may result in bradycardia.
KEY DECISION POINT Discontinue the suctioning and apply oxygen if heart rate decreases by 20 beats/minute or increases by 40 beats/minute, if BP increases, or if cardiac dysrhythmia is noted.	
2. Make sure that the suction apparatus is functional. Place suction tubing within easy reach.	2. Ensures functionality before beginning the procedure.
3. Inform and instruct the patient about the procedure. a. At a certain interval, the patient will be requested to cough to open the lung passage so the catheter will go into the lungs and not into the stomach. The patient will also be encouraged to try not to swallow because this will also cause the catheter to enter the stomach. b. The postoperative patient can splint the wound to make the coughing produced by NT suctioning less painful.	3. A thorough explanation will decrease patient anxiety and promote patient cooperation.
4. Place the patient in a semi-Fowler's or sitting position, if possible.	4. Upright position eases breathing and helps mobilize secretions.
NURSING ALERT Avoid suctioning immediately after feeding to reduce the risk of vomiting and possible aspiration.	
5. Monitor oxygen saturation via oximetry and heart rate during suctioning.	5. Detects hypoxia during the procedure.
Performance phase	
1. Open the sterile pack containing flexible suction catheter. Maintain inside of the package as sterile, and arrange equipment after donning sterile gloves.	1. Catheter entering trachea should not be contaminated.
2. Aseptically glove both hands. Designate one hand (usually the dominant one) as "sterile" and the other hand as "contaminated."	2. The "contaminated" hand must also be gloved to protect the nurse from organisms in the sputum.
3. Grasp the sterile catheter with the sterile hand.	
4. Lubricate catheter with the water-soluble jelly and pass the catheter into the nostril and back into the pharynx.	4. Lubricate adequately and proceed carefully to prevent trauma to tissue that may bleed easily.
NURSING ALERT If obstruction is met while passing the catheter through the nose and nasopharynx, do not force the catheter. Remove it and try the other nostril.	

Nursing Action	Rationale
5. Pass the catheter into the trachea. To do this, ask the patient to cough or say "ahh." If the patient is incapable of either, try to advance the catheter on inspiration. Asking the patient to stick out tongue, or hold tongue extended with a gauze pad, may also help to open the airway.	5. These maneuvers may aid in opening the glottis and allowing passage of the catheter into the trachea.

KEY DECISION POINT To evaluate proper placement of the suction catheter in the trachea, listen at the catheter end for air or feel for air movement against the cheek. An increase in intensity of breath sounds or more air movement against cheek indicates nearness to the larynx. Gagging or sudden lessening of sound means the catheter is in the hypopharynx. Draw back and advance again. The presence of the catheter in the trachea is indicated by:

- Sudden paroxysms of coughing.
- Movement of air through the catheter.
- Vigorous bubbling of air when the distal end of the suction catheter is placed in a cup of sterile water.
- Inability of the patient to speak.

If three attempts to place the catheter are unsuccessful, request assistance. If a protracted amount of time is needed to position the catheter in the trachea, stop and oxygenate the patient with face mask or the resuscitation bag-mask unit at intervals.

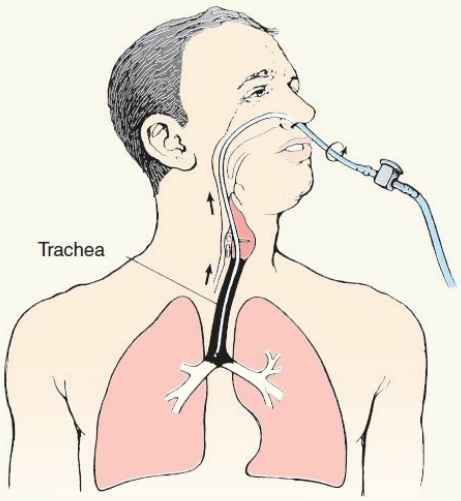
6. Specific positioning of catheter for deep bronchial suctioning a. For left bronchial suctioning, turn the patient's head to the extreme right, chin up. b. For right bronchial suctioning, turn the patient's head to the extreme left, chin up. *Note:* The value of turning the head as an aid to entering the right or left mainstem bronchi is not accepted by all clinicians.	6. Turning the patient's head to one side elevates the bronchial passage on the opposite side, making catheter insertion easier. Suctioning of a particular lung segment may be of value in patients with unilateral pneumonia, atelectasis, or collapse.
7. Never apply suction until catheter is in the trachea. Once the correct position is ascertained, apply suction and gently rotate catheter while pulling it slightly upward. Do not remove catheter from the trachea.	7. Because entry into the trachea is often difficult, less change in arterial oxygen may be caused by leaving the catheter in the trachea than by repeated insertion attempts.
8. Disconnect the catheter from the suctioning source after 5–10 sec. Apply oxygen by placing a face mask over the patient's nose, mouth, and catheter, and instruct the patient to breathe deeply.	8. Allows for reoxygenation during the procedure.
9. Reconnect the suction source. Repeat as necessary.	9. More than one suction attempt may be necessary to remove secretions; however, hypoxemia and trauma to the tissues may result from multiple suction attempts.

NURSING ALERT No more than three to four suction passes should be made per suction episode.

10. During the last suction pass, remove the catheter completely while applying suction and rotating the catheter gently. Apply oxygen when the catheter is removed.	10. Removes secretions in the proximal airway.

NURSING ALERT Never leave the catheter in the trachea after the suction procedure is concluded because the epiglottis is splinted open and aspiration may occur.

Nursing Action	Rationale



Placement of nasotracheal catheter for suctioning the tracheobronchial tree.

Follow-up phase	
1. Dispose of disposable equipment.	1. Infection control.
2. Auscultate breath sounds. Measure heart rate, BP, respiratory rate, and oxygen saturation. Record the patient's tolerance of procedure, type and amount of secretions removed, and complications.	2. Assesses for hypoxemia, trauma, or other complications.
3. Report any patient intolerance of procedure (changes in vital signs, bleeding, laryngospasm, upper airway noise).	3. For possible adjustment on future suctioning attempts.

EVIDENCE BASE American Association for Respiratory Care. (2010). Clinical practice guidelines. Endotracheal suctioning of mechanically ventilated patients with artificial airways. *Respiratory Care, 55*(6), 758–764.

PROCEDURE GUIDELINES 10-9

Sterile Tracheobronchial Suction by Way of Tracheostomy or Endotracheal Tube (Spontaneous or Mechanical Ventilation)

EQUIPMENT

- Assemble the following equipment or obtain a prepackaged suctioning kit:
- Sterile suction catheters—No. 14 or 16 (adult), No. 8 or 10 (child). The outer diameter of the suction catheter should be no greater than one-half the inner diameter of the artificial airway.
- Two sterile gloves
- Sterile towel
- Suction source at 80 to 120 mm Hg (pressure varies neonatal to adult)
- Sterile water
- Resuscitation bag with a reservoir connected to 100% oxygen source (if patient is on positive end-expiratory pressure [PEEP] or continuous positive airway pressure [CPAP], add PEEP valve to exhalation valve on resuscitation bag in an amount equal to that on the ventilator or CPAP device)

- Normal saline solution (in syringe or single-dose packet)—optional
- Sterile cup for water
- Sterile water-soluble lubricant jelly
- Face shield

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Monitor heart rate and oxygen saturation and auscultate breath sounds. If the patient is monitored, continuously monitor heart rate and arterial BP. If ABG are done routinely, know baseline values.	1. Baseline assessment is important because suctioning may cause hypoxemia, initially resulting in tachycardia and increased BP, progressing to cardiac ectopy, bradycardia, hypotension, and cyanosis. Vagal stimulation may result in bradycardia.
2. Explain the procedure to the patient.	2. Thorough explanation lessens patient's anxiety and promotes cooperation.
NURSING ALERT Instruct postoperative patients how to "splint" surgical incisions because coughing will be induced during the procedure.	
3. Assemble equipment. Check function of suction and manual resuscitation bag connected to 100% O_2 source.	3. Make sure that all equipment is functional before sterile technique is instituted to prevent interruption once the procedure is begun. Use of 100% O_2 will help to prevent hypoxemia.
4. Wash hands thoroughly. Put on face shield.	4. Reduces risk of infection transmission for patient and nurse.
5. If the patient is on mechanical ventilation, test to make sure disconnection of ventilator attachment may be made with one hand.	5. If unable to disconnect and reconnect ventilator tubing with nonsterile hand, will need a second person for assistance.
Performance phase	
1. Open suction catheter package and place on flat work surface and set up a sterile field.	1. Sterile field contains suction catheter, gloves, lubricant for catheter, and sterile water/saline for rinsing catheter.
2. Put on sterile gloves. Designate one hand as contaminated for disconnecting, bagging, and working the suction control. Usually the dominant hand is kept sterile and will be used to thread the suction catheter.	2. The hand designated as sterile must remain uncontaminated so organisms are not introduced into the lungs. The contaminated hand must also be gloved to prevent sputum from contacting the nurse's hand, possibly resulting in an infection of the nurse.
3. Use the sterile hand to remove carefully the suction catheter from the package, curling the catheter around the gloved fingers.	
4. Connect suction source to the suction fitting of the catheter with the contaminated hand.	
5. Using the contaminated hand, disconnect the patient from the ventilator, CPAP device, or other oxygen source.	5. Using one hand prevents contamination of hand used for suctioning. If closed-circuit suction catheter is being used, the patient will not need to be disconnected from the ventilator and PEEP is maintained.
6. Ventilate and oxygenate the patient with the resuscitator bag, compressing firmly and as completely as possible approximately four to five times (try to approximate the patient's tidal volume). This procedure is called "bagging" the patient. In the spontaneously breathing patient, coordinate manual ventilations with the patient's own inspiratory effort.	6. Ventilation before suctioning helps prevent hypoxemia. When possible, two nurses or a nurse and a respiratory therapist work as a team to suction. Attempting to ventilate against the patient's own respiratory efforts may result in high airway pressures, predisposing the patient to barotrauma (lung injury because of pressure).

Nursing Action	Rationale
7. Gently insert suction catheter as far as possible into the artificial airway without applying suction. Most patients will cough when the catheter touches the carina.	7. Suctioning on insertion would unnecessarily decrease oxygen in the airway.
8. Withdraw the catheter ¾ inch to 1 inch (2–3 cm) and apply suction. Quickly rotate the catheter while it is being withdrawn.	8. Failure to withdraw and rotate catheter may result in damage to tracheal mucosa. Release suction if a pulling sensation is felt.
KEY DECISION POINT Limit suction time to no more than 10 sec to avoid hypoxemia. Discontinue if heart rate decreases by 20 beats/minute (because of vagal stimulation) or increases by 40 beats/minute, or if cardiac ectopy is observed (signs of hypoxemia).	
9. Bag patient between suction passes with approximately four to five manual ventilations.	9. The oxygen removed by suctioning must be replenished before suctioning is attempted again to reduce hypoxemia.
10. Rinse catheter between suction passes by inserting tip in cup of sterile water/saline and applying suction. *Note:* Evidence does not support the use of saline installation.	10. Prevents obstruction of catheter.
EVIDENCE BASE Caparros, A., & Forbes, A. (2015). Mechanical ventilation and the role of saline instillation in suctioning adult intensive care unit patients: An evidence-based practice review. *Dimensions of Critical Care Nursing, 33*(4), 246–253.	
11. Continue making suction passes, bagging the patient between passes, until the airways are clear of accumulated secretions. Limit insertions of suction catheter to as few as needed (do not exceed four passes per suction episode).	11. Repeated suctioning of a patient in a short time interval predisposes to hypoxemia, as well as being tiring and potentially traumatic to tissue.
12. Give the patient four to five "sigh" breaths with the bag.	12. Sighing is accomplished by depressing the bag slowly and completely with two hands to deliver ~1½ times the normal tidal volume to the patient, allowing for maximal lung expansion and prevention of atelectasis.
13. Return the patient to the ventilator or apply CPAP or other oxygen-delivery device.	
14. Suction oral secretions from the oropharynx above the artificial airway cuff.	14. Prevents possible aspiration if the cuff becomes deflated.
15. Remove suction catheter from tubing and remove gloves, folding catheter into glove in dominant hand. Dispose of equipment.	15. Controls infection.
Follow-up phase	
1. Note change in vital signs or patient's intolerance to the procedure. Record amount and consistency of secretions.	1. Evaluates and documents the effectiveness of procedure and patient response.
2. Assess need for further suctioning at least every 2 hr, or more frequently if secretions are copious.	2. Copious secretions can impair oxygenation.
EVIDENCE BASE Lucchini, A., Zanella, A., Bellani, G., et al. (2011). Tracheal secretion management in the mechanically ventilated patient: Comparison of standard assessment and an acoustic secretion detector. *Respiratory Care, 56*(5), 596–603.	

PROCEDURE GUIDELINES 10-10

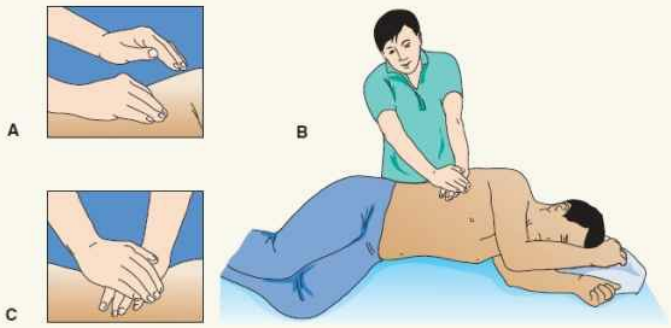
Percussion (Clapping) and Vibration

EQUIPMENT

- Pillows
- Sputum cup
- Tilt table
- Paper tissues
- Emesis basin

PROCEDURE

Nursing Action	Rationale
Performance phase	
1. Instruct the patient to use diaphragmatic breathing.	1. Diaphragmatic breathing helps the patient relax and helps widen airways.
2. Position the patient in prescribed postural drainage positions (see page 235). The spine should be straight to promote rib cage expansion.	



Percussion and vibration. **(A)** Proper hand positioning for percussion. **(B)** Proper hand positioning for vibration. Note that the wrists and elbows are kept stiff and the vibrating motion is produced by the shoulder muscles. **(C)** Proper hand position for vibration.

3. Percuss (or clap) with cupped hands over the chest wall for 5 min over each segment for cystic fibrosis (or 1–2 min for other conditions). Work from:	3. Helps dislodge mucus plugs and mobilize secretions toward the main bronchi and trachea. The air trapped between the operator's hand and chest wall will produce a characteristic hollow sound that resembles the sound of horses trotting.
a. The lower ribs to shoulders in the back.	
b. The lower ribs to top of chest in the front.	
4. Avoid clapping over the spine, liver, kidneys, spleen, breast, scapula, clavicle, or sternum.	4. Percussion over these areas may cause injuries to the spine or internal organs.
5. Instruct the patient to inhale slowly and deeply. Vibrate the chest wall as the patient exhales slowly through pursed lips.	5. Sets up a vibration that carries through the chest wall and helps free the mucus.
a. Place one hand on top of the other over affected area or place one hand on each side of the rib cage.	
b. Tense the muscles of the hands and arms while applying moderate pressure downward and vibrate hands and arms.	b. This maneuver is performed in the direction in which the ribs move on expiration.
c. Relieve pressure on the thorax as the patient inhales.	
d. Encourage the patient to cough, using abdominal muscles, after three or four vibrations.	d. Contracting the abdominal muscles while coughing increases cough effectiveness. Coughing aids in the movement and expulsion of secretions.
6. Allow the patient to rest several minutes.	
7. Listen with a stethoscope for changes in breath sounds.	7. The improvement of crackles and rhonchi indicates movement of air around mucus in the bronchi.
8. Repeat the percussion and vibration cycle according to the patient's tolerance and clinical response, usually 15–30 min.	
	Note: Percussion and vibration are considered to have limited research-based evidence of benefit versus risk.

EVIDENCE BASE Pathmanathan, N., Beaumont, N., & Gratrix, A. (2015). Respiratory physiotherapy in the critical care unit. *British Journal of Anesthesia, 15*(1), 20–25.

PROCEDURE GUIDELINES 10-11

Administering Nebulizer Therapy (Sidestream Jet Nebulizer)

EQUIPMENT

- Air compressor
- Connection tubing
- Nebulizer

- Medication and saline solution

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Auscultate breath sounds, monitor the heart rate before and after the treatment for patients using bronchodilator drugs.	1. Bronchodilators may cause tachycardia, palpitations, dizziness, nausea, or nervousness.
2. Verify correct patient. Explain the procedure to the patient. This therapy depends on patient effort.	2. Proper explanation of the procedure helps to ensure the patient's cooperation and effectiveness of the treatment.
3. Place the patient in a comfortable sitting or a semi-Fowler position.	3. Diaphragmatic excursion and lung compliance are greater in this position. This ensures maximal distribution and deposition of aerosolized particles to basilar areas of the lungs.
Performance phase	
1. Add the prescribed amount of medication and saline to the nebulizer. Connect the tubing to the compressor and set the flow at 6–8 L/minute.	1. A fine mist from the device should be visible.
2. Instruct the patient to exhale.	2. Readies the lungs for a deep inspiration.
3. Tell the patient to take in a deep breath from the mouthpiece, hold breath briefly, then exhale.	3. Encourages optimal dispersion of the medication. Nose clips are sometimes used if the patient has difficulty breathing only through the mouth.
4. Observe expansion of chest to ascertain that patient is taking deep breaths.	4. Ensures that medication is deposited below the level of the oropharynx.
5. Instruct the patient to breathe slowly and deeply until all the medication is nebulized.	5. Medication will usually be nebulized within 15 min at a flow of 6–8 L/minute.
6. On completion of the treatment, encourage the patient to cough after several deep breaths.	6. The medication may dilate airways, facilitating expectoration of secretions.
Follow-up phase	
1. Record medication used and description of secretions.	
2. Disassemble and clean nebulizer after each use. Keep this equipment in the patient's room. The equipment is changed according to facility policy.	2. Each patient has own breathing circuit (nebulizer, tubing, and mouthpiece). Through proper cleaning, sterilization, and storage of equipment, organisms can be prevented from entering the lungs.

EVIDENCE BASE Hess, D. (2016). *Delivery of inhaled medications in adults.* UpToDate. Available: https://www-uptodate-com/contents/delivery-of-inhaled-medications-in-adults.

PROCEDURE GUIDELINES 10-12

Administering Oxygen by Nasal Cannula

EQUIPMENT

- Oxygen source
- Plastic nasal cannula with connecting tubing (disposable)
- Humidifier filled with sterile water
- Flowmeter
- No smoking signs

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Verify correct patient. Determine current vital signs, LOC, and most recent ABG.	1. Provides a baseline for future assessment. Nasal cannula oxygen administration is often used for patients prone to CO_2 retention. Oxygen may depress the hypoxic drive of these patients (evidenced by a decreased respiratory rate, altered mental status, and further $PaCO_2$ elevation).
2. Assess risk of CO_2 retention with oxygen administration.	2. If $PaCO_2$ is decreased or normal, the patient is not experiencing CO_2 retention and can use oxygen without fear of the above consequences.
3. Show the nasal cannula to the patient and explain the procedure.	3. To allay anxiety and enlist cooperation.
Performance phase	
1. Make sure the humidifier is filled to the appropriate mark.	1. Humidification may not be ordered if the flow rate is <4 L/ minute.
2. Attach the connecting tube from the nasal cannula to the humidifier outlet.	
3. Set the flow rate at the prescribed liters per minute. Feel to determine if oxygen is flowing through the tips of the cannula.	3. Because a nasal cannula is a low-flow/high-flow system (patient's tidal volume supplies part of the inspired gas), oxygen concentration will vary, depending on the patient's respiratory rate and tidal volume. Approximate oxygen concentrations delivered are: 1L = 24% – 25% 2L = 27% – 29% 3L = 30% – 33% 4L = 33% – 37% 5L = 36% – 41% 6L = 39% – 45%
4. Place the tips of the cannula in the patient's nose and adjust straps around ears for snug, comfortable fit.	4. Prevents slipping out of place or creating pressure point and possible skin breakdown behind ears and across cheeks. Areas of contact may be padded to prevent pressure points.

Administering oxygen by nasal cannula.Patient's inspiration consists of a mixture of supplemental oxygen supplied via the nasal cannula and room air. Oxygen concentration is variable and depends on the patient's tidal volume and ventilator pattern.

Nursing Action	Rationale
Follow-up phase	
1. Record flow rate used and immediate patient response.	1. Note the patient's tolerance of treatment. Report any intolerance noted.
2. Assess the patient's condition, ABG or SaO_2, and the functioning of equipment at regular intervals.	2. Depression of hypoxic drive is most likely to occur within the first hours of oxygen use. Monitoring of SaO_2 with oximetry can be substituted for ABG if the patient is not retaining CO_2.
3. Determine patient comfort with oxygen use.	

NURSING ALERT Avoid use of petroleum jelly to lubricate nares because it is flammable and may clog openings of cannula. Use saline spray or water-based gel.

EVIDENCE BASE Bailey, P. (2016). *Continuous oxygen delivery systems for infants, children, and adults.* UpToDate. Available: https://www.uptodate-com/contents/continous-oxygen-delivery-systems-for-infants-adults-children

PROCEDURE GUIDELINES 10-13

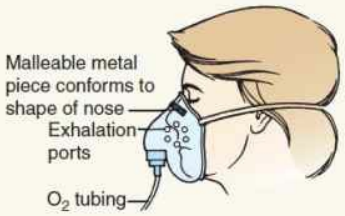
Administering Oxygen by Simple Face Mask with or without Aerosol

EQUIPMENT

- Oxygen source
- Humidifier bottle with distilled water, if high humidity is desired for simple face mask
- Simple face mask or plastic aerosol mask
- Large-bore tubing for aerosol or small-bore tubing for simple face mask
- Flowmeter
- Nebulizer for aerosol
- Humidifier heating element

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Verify correct patient. Determine current vital signs, LOC, and SaO_2 or ABG, if patient is at risk for CO_2 retention.	1. Because the nebulizer face mask is a low-flow system (patient's tidal volume may supply part of inspired gas), oxygen concentration will vary depending on the patient's respiratory rate and rhythm. Oxygen delivery may be inadequate for tachypneic patients (flow does not meet peak inspiratory demand) or excessive for patients with slow respirations.
2. Assess viscosity and volume of sputum produced.	2. Aerosol is given to assist in mobilizing retained secretions.
3. Show the mask to the patient and explain the procedure.	3. Allays fear and enlists cooperation.
Performance phase	
1. Make sure the humidifier or nebulizer is filled to the appropriate mark.	1. If the humidifier bottle is not sufficiently full, less moisture will be delivered.
2. Attach the large-bore tubing from the mask to the humidifier in the heating element, if used.	
3. Set desired oxygen concentration and plug in the heating element, if used. If the patient is tachypneic and concentration of 50% oxygen or greater is desired, two humidifiers and flowmeters should be yoked together.	3. The inspired oxygen concentration is determined by the humidifier setting. Usual concentrations are 35%–50%. The aerosol mask is a low-flow system. Yoking two humidifiers together doubles humidifier flow but does not change the inspired oxygen concentration.
4. Adjust the flow rate until the desired mist is produced (usually 10–12 L/minute).	4. Ensures that the patient is receiving flow sufficient to meet inspiratory demand and maintains a constant, accurate concentration of oxygen.
5. Apply the mask to the patient's face and adjust the straps so the mask fits securely. Dry face around mask every 2 hr.	5. Prevents straps from slipping out of place, but not too tightly to prevent skin breakdown because of pressure and moisture.
6. Drain the tubing frequently by emptying condensate into a separate receptacle, not into the humidifier. If a heating element is used, the tubing will have to be drained more often.	6. The tubing must be kept free of condensate. Condensate allowed to accumulate in the delivery tube will block flow and alter oxygen concentration. If condensate is emptied into the humidifier, bacteria may be aerosolized into the lungs.
7. If a heating element is used, check the temperature. The humidifier bottle should be warm, not hot, to the touch.	7. Excessive temperatures can cause airway burns; patients with elevated temperature should be humidified with an unheated device.



Simple face mask. Oxygen concentration varies with patient's tidal volume and respiratory rate.

Follow-up phase	
1. Record FiO_2 and immediate patient response. Note the patient's tolerance of treatment. Notify the health care provider if intolerance occurs.	1. Documentation to guide therapy.
2. Assess the patient's condition and the functioning of equipment at regular intervals.	2. Change in mental status, diaphoresis, changes in blood pressure, and increasing heart and respiratory rates may indicate a need for change in therapy.

Nursing Action	Rationale
3. If the patient's condition changes, assess SaO_2 or ABG.	3. If the patient has a high minute ventilation or V_E, flow from the mask may not be sufficient to meet inspiratory needs without pulling in room air. Room air will dilute the oxygen provided and lower the inspired oxygen concentration, resulting in hypoxemia. A change in mask or delivery system may be indicated.
4. Record changes in volume and tenacity of sputum produced.	4. Indicates effectiveness of humidification.

EVIDENCE BASE American Association of Respiratory Care. (2002). Clinical practice guideline. Oxygen therapy for adults in the acute care facility, 2002 revision and update. *Respiratory Care, 47*(6), 717–720. Bailey, P. (2016). *Continuous oxygen delivery systems for infants, children, and adults*. Available: UpToDate. https://www.uptodate-com/contents/continous-oxygen-delivery-systems-for-infants-adults-children

PROCEDURE GUIDELINES 10-14

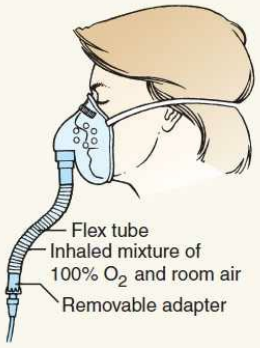
Administering Oxygen by Venturi Mask (High Air Flow Oxygen Entrainment System)

EQUIPMENT

- Oxygen source
- Flowmeter
- Venturi mask for correct concentration (24%, 28%, 31%, 35%, 40%, 50%) or correct concentration adapter if interchangeable color-coded adapters are used
- If high humidity desired
- Compressed air source and flowmeter
- Humidifier with distilled water
- Large-bore tubing

PROCEDURE

Nursing Action	Rationale
1. Verify correct patient. Determine current vital signs, LOC, and most recent ABG.	1. Provides a baseline for future assessment. Venturi masks are used for patients prone to CO_2 retention. Oxygen may depress the hypoxic drive of these patients (evidenced by a decreased respiratory rate, altered mental status, and further $PaCO_2$ elevation).
2. Assess risk of CO_2 retention with oxygen administration.	2. Risk is greater if the patient is experiencing an exacerbation of illness.
3. Show the Venturi mask to the patient and explain the procedure.	3. Allays fear and enlists patient cooperation.
Performance phase	
1. Connect the mask by lightweight tubing to the oxygen source.	
2. Turn on the oxygen flowmeter and adjust to the prescribed rate (usually indicated on the mask). Check to see that oxygen is flowing out the vent holes in the mask.	2. To ensure the correct air/oxygen mix, oxygen must be set at the prescribed flow rate. Prescribed flow rates differ for different oxygen concentrations. Usually this information is printed on the mask or interchangeable color-coded source.
3. Place Venturi mask over the patient's nose and mouth and under the chin. Adjust elastic strap.	3. Prevents strap and mask from slipping out of place, but not too tightly to prevent pressure on skin.
4. Check to make sure holes for air entry are not obstructed by the patient's bedding.	4. Proper mask function depends on mixing of sufficient amount of air and oxygen.
5. If aerosol nebulizer used: a. Connect the humidifier to a compressed air source. b. Attach large-bore tubing to the humidifier and connect the tubing to the fitting for high humidity at the base of the Venturi mask.	5. When a Venturi mask is used with aerosol, an oxygen source is required. The compressed air source provides air for the air/oxygen mix. Excessive oxygen would be inspired if both tubings were connected to an oxygen source.



Venturi mask. Constant high concentrations of oxygen can be delivered.

Nursing Action	Rationale
Follow-up phase	
1. Record flow rate used and immediate patient response. Note the patient's tolerance of treatment. Report if intolerance occurs.	1. Depression of hypoxic drive is most likely to occur within the first hours of oxygen use.
KEY DECISION POINT If CO_2 retention is present, assess ABG every 30 minutes for 1 to 2 hours or until the PaO_2 is >50 mm Hg and the $PaCO_2$ is no longer increasing. Monitor for change in pH. A modest (5 to 10 mm Hg) increase in $PaCO_2$ may occur after initiation therapy; however, a decreasing pH indicates failure of compensatory mechanisms. Report if the pH decreases below the initial assessment value. Mechanical ventilation may be required.	
2. Determine patient comfort with oxygen use.	2. Venturi masks are best tolerated for relatively short periods because of their size and appearance. They also must be removed for eating and drinking. With improvement in patient condition, a nasal cannula may often be substituted.

EVIDENCE BASE American Association of Respiratory Care. (2002). Clinical practice guideline. Oxygen therapy for adults in the acute care facility, 2002 revision and update. *Respiratory Care, 47*(6), 717–720.

PROCEDURE GUIDELINES 10-15

Administering Oxygen by Partial Rebreathing or Nonrebreathing Mask

EQUIPMENT

- Oxygen source
- Plastic face mask with reservoir bag and tubing
- Humidifier with distilled water
- Flowmeter

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Verify correct patient. Determine current vital signs and LOC.	1. Provides a baseline for evaluating patient response. Typically used for short-term support of patients who require a high inspired oxygen concentration.
2. Determine most recent SaO_2 or ABG.	2. Allows objective evaluation of patient response.
3. Show the mask to the patient and explain the procedure.	3. Allays fear and enlists patient cooperation.
Performance phase	
1. Attach tubing to flowmeter.	
2. Flush the reservoir bag with oxygen to inflate the bag and adjust flowmeter to 6–10 L/minute.	2. Bag serves as a reservoir, holding oxygen for patient inspiration.
3. Place the mask on the patient's face and adjust strap so that it fits snugly.	3. Ensures that there is an airtight seal between the mask and the patient's face for optimal performance.
4. Adjust liter flow so the rebreathing bag will not collapse during the inspiratory cycle, even during deep inspiration.	4. With a well-fitting rebreathing bag adjusted so the patient's inhalation does not deflate the bag, inspired oxygen concentration of 60%–90% can be achieved. Some patients may require flow rates higher than 10 L/minute to ensure that the bag does not collapse on inspiration.
5. Stay with the patient for a time to make the patient comfortable and observe reactions.	
6. Remove mask periodically (if the patient's condition permits) to dry the face around the mask. Apply water-based lotion to skin and massage face around the mask.	6. Reduces moisture accumulation under the mask. Massage of the face stimulates circulation and reduces pressure over the area.
	Partial rebreathing mask. 100% oxygen fills bag, but concentration delivered varies with respiration. Nonrebreathing mask is similar with the addition of a one-way valve that prevents expired air from entering bag and one-way flaps over exhalation ports.	
Follow-up phase	
1. Record flow rate and immediate patient response. Note the patient's tolerance of treatment. Report if intolerance occurs. Observe the patient for change of condition.	1. Change in mental status, diaphoresis, change in BP, and increasing heart and respiratory rates may indicate need for change in therapy.
2. Assess equipment for malfunctioning and low water level in humidifier.	2. For optimal performance.

NURSING ALERT Monitor functioning of mask to ensure that side ports of mask do not get blocked. This could lead to patient inability to exhale and may lead to suffocation.

EVIDENCE BASE Hess, D., MacIntyre, N., Mishoe, S., et al. (2012). *Respiratory care: Principles and practice* (2nd ed.). Sudbury, MA: Jones & Bartlett.

PROCEDURE GUIDELINES 10-16

Administering Oxygen by Continuous Positive Airway Pressure Mask

EQUIPMENT

- O2 blender
- Flowmeter
- Continuous positive airway pressure (CPAP) mask
- Valve for prescribed PEEP (2.5, 5, 7.5, 10 cm H2O)

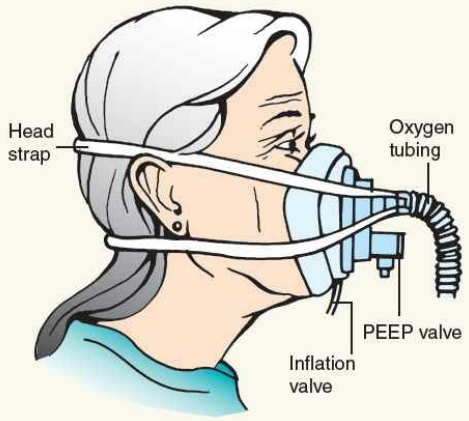
- Nebulizer with distilled water
- Large-bore tubing
- NG tube (if ordered)
- Sealing pad to accommodate NG tube

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Verify correct patient. Assess the patient's LOC and gag reflex.	1. CPAP mask may lead to aspiration unless the patient is breathing spontaneously and is able to protect the airway.
2. Determine current ABGs.	2. Documents that patient meets criteria for use of this mask (normal or increased $PaCO_2$ and provides baseline to evaluate whether therapy results in CO_2 retention).

NURSING ALERT CPAP is used when patients have not responded to attempts to increase PaO_2 with other types of masks.

3. Show the mask to the patient and explain the procedure.	3. Allays fear and enlists patient cooperation.
4. Insert NG tube if ordered. (May be used for some patients at risk for aspiration.)	4. With CPAP, the patient may swallow air, causing gastric distention or emesis. Prophylactic NG suction diminishes this risk.
Performance phase	
1. Set desired concentration of O_2 blender and adjust flow rate so it is sufficient to meet the patient's inspiratory demand.	1. O_2 blenders are devices that mix air and O_2 using a proportioning valve. Concentrations of 21%–100% may be delivered, depending on the model. Because the patient will be receiving all minute ventilation from this "closed system," it is essential that the flow rate be adequate to meet changes in the patient's breathing pattern.



Administering oxygen by face mask with continuous positive airway pressure (CPAP).

2. Place the mask on the patient's face, adjust the head strap, and inflate the mask cushion to ensure a tight seal.	2. To maintain CPAP, an airtight seal is required. Head straps and the inflatable cushion help to ensure that difficult areas, such as the nose and chin, are sealed with greater comfort to the patient.
3. Organize care to remove the mask as infrequently as possible.	3. If mask is removed (for coughing, suctioning, bathing), CPAP is not maintained and inspired O_2 concentrations drop.

Nursing Action	Rationale
Follow-up phase	
1. Assess ABGs, hemodynamic status, and LOC frequently.	1. Provides objective documentation of patient response. CPAP may increase work of breathing, resulting in patient tiring and inability to maintain ventilation without intubation. CPAP may also decrease venous return, resulting in decreased cardiac output.
2. Immediately report any increase in $PaCO_2$.	2. An increase in $PaCO_2$ suggests hypoventilation, resulting from tiring of the patient or inadequate alveolar ventilation. Need for intubation and mechanical ventilation should be evaluated.
3. Assess patency of NG tube, if used, at frequent intervals.	3. May become obstructed, causing gastric distention.
4. Assess patient comfort and functioning of the equipment frequently.	4. Tight fit of the mask may predispose to skin breakdown. System may develop leaks, resulting in air escaping between the patient's face and mask.
5. Record patient response. With improvement, O_2 therapy without positive airway pressure can be substituted. With deterioration, intubation and mechanical ventilation may be required. Note the patient's tolerance of treatment. Report if intolerance occurs.	5. Face mask CPAP is usually continued only for short periods (72 hr) because of patient tiring and the necessity to remove mask for suctioning and coughing.
Note: CPAP may be used as a therapy for sleep apnea during the time the patient sleeps. A nasal CPAP mask is typically used.

PROCEDURE GUIDELINES 10-17

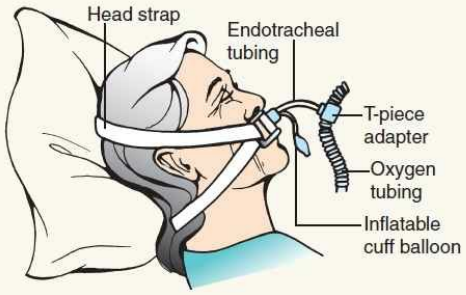
Administering Oxygen by Way of Endotracheal and Tracheostomy Tubes with a T-Piece (Briggs) Adapter

EQUIPMENT

- Oxygen
- O2 blender
- Flowmeter
- Nebulizer with sterile water (heating element may be used as described in aerosol masks)
- Large-bore tubing
- T-piece and reservoir tubing

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Verify correct patient. Assess the patient's SaO_2, hemodynamic status, and LOC frequently. If patient condition changes, assess ABGs.	1. Provides baseline to assess response.
2. Assess viscosity and volume of sputum produced.	2. Aerosol is given to assist in mobilizing retained secretions.
3. Show the T-tube to the patient and explain the procedure.	3. Allays fear and enlists patient cooperation.
Performance phase	
1. Make sure the humidifier is filled to the appropriate mark.	1. If humidifier is not sufficiently full, less aerosol will be delivered.
2. Attach the large-bore tubing from the T-tube to the humidifier outlet.	
3. Set desired O_2 concentration of O_2 blender or humidifier bottle and plug in heating element, if used.	3. O_2 blenders are devices that mix air and O_2 using a proportioning valve. Concentrations of 21%–100% may be delivered at flows of 2–100 L/minute, depending on the model. Used when precise control is required.
4. Adjust the flow rate until the desired mist is produced and meets the patient's inspiratory demand.	4. The aerosol mist in the reservoir tubing attached to the T-tube should not be completely withdrawn on patient inspiration. If mist is withdrawn (does not extend from reservoir tubing) on inspiration, room air may be inspired and O_2 concentration decreased.
5. Drain the tubing frequently by emptying condensate into a separate receptacle, not into the humidifier. If a heating element is used, the tubing will have to be drained more often.	5. The tubing must be kept free of condensate. Condensate allowed to accumulate in the delivery tube will block flow and alter O_2 concentration. If condensate is emptied into the humidifier, bacteria may be aerosolized into the lungs.
6. If a heating element is used, check the temperature. The humidifier bottle should be warm, not hot, to the touch.	6. Excessive temperatures can cause airway burns; patients with elevated temperatures will be better humidified with an unheated device.



Administering oxygen via endotracheal tube with a T-piece adapter. A T-piece adapter is attached to the endotracheal tube and large-bore tubing, which serves as a source of oxygen and humidity.

Nursing Action	Rationale
Follow-up phase	
1. Record FiO_2 and immediate patient response. Assess functioning of equipment and patient's condition at regular intervals. Note the patient's tolerance of treatment. Report if intolerance occurs.	1. Change in mental status, diaphoresis, perspiration, changes in BP, and increasing heart and respiratory rates may indicate intolerance and need to change therapy.
2. If the patient's condition changes, assess SaO_2 or ABGs and vital signs. Note changes suggesting increased work of breathing (diaphoresis, intercostal muscle retraction).	2. If the patient is being weaned, return to the ventilator if changes suggesting inability to tolerate spontaneous ventilation occur. (See Weaning the Patient from Mechanical Ventilation, pages 258–260.)
3. Record changes in volume and tenacity of sputum produced.	3. Indicates effectiveness of humidification therapy.

EVIDENCE BASE Wiegand, D. J., & Carlson, K. K. (2010). *AACN procedure manual for critical care* (6th ed.). Philadelphia: Elsevier Saunders.

PROCEDURE GUIDELINES 10-18

Administering Oxygen by Manual Resuscitation Bag

EQUIPMENT

- O2 source
- Resuscitation bag and mask
- Reservoir tubing or reservoir bag
- O2 connecting tubing
- Nipple adapter to attach flowmeter to connecting tubing
- Flowmeter
- Gloves
- Face shield

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. In cardiopulmonary arrest:	
a. Follow steps to establish that a cardiopulmonary arrest has occurred.	a. The steps are established unresponsiveness; call for help; position the patient on a firm, flat surface; open the mouth and remove vomitus or debris, if visible; assess presence of respirations with the airway open; if apneic, ventilate; palpate the carotid pulse; if absent, deliver chest compressions.
b. Use caution not to injure or increase injury to the cervical spine when opening the airway.	b. If cervical spine injury is a potential, the modified jaw thrust should be used. In other situations, the head-tilt or chin-lift method can be used. These maneuvers lift the tongue off the back of the throat and, in some situations, may be all that is needed to restore breathing.
2. In suctioning or transport situation, assess patient's heart rate, level of consciousness (LOC), and respiratory status.	2. Provides a baseline to stimulate patient's tolerance of procedure.
Performance phase	
1. Attach connecting tubing from flowmeter and nipple adapter to resuscitation bag.	1. A humidifier bottle is not used because the high flow rates of oxygen required would force water into the tubing and clog it.
2. Turn flowmeter to "flush" position.	2. A high flow rate or "flush" position is necessary to meet the minute ventilation of the patient.
3. Attach reservoir tubing or reservoir bag to resuscitation bag.	3. A high inspired O_2 concentration is required. Without a reservoir, inspired O_2 concentration will be low (28%–56%) because inspired gas will be air/O_2 mix. With a reservoir, manual resuscitation bags can achieve a FiO_2 of >96% at a flow rate of 15 L/minute.
4. Put on face shield and gloves.	4. Body fluid precautions.
Cardiopulmonary arrest	
1. If respirations are absent after the airway is open, insert an oropharyngeal airway and ventilate twice with slow, full breaths of 1–1½ sec each. Allow 2 sec between breaths.	1. The airway helps prevent obstruction from prolapse of the tongue in an unconscious patient. If ventilation is difficult, confirm that airway is unobstructed.
2. Breaths will have to be quickly interposed between cardiac compressions. If the patient needs only respiratory assistance, watch for chest expansion and listen with the stethoscope to ensure adequate ventilation.	2. Squeeze resuscitation bag with sufficient force and at the rate necessary to maintain adequate minute ventilation.
3. A rate of ~10–12 breaths/minute is used.	3. Continue squeezing bag at appropriate intervals until CPR is no longer required.
Preoxygenation and suctioning	
1. If hyperinflation is being used with suctioning, ventilate the patient before and after each suctioning pass (including after the last suction pass).	1. Hyperinflation before suctioning helps prevent hypoxemia. Hyperinflation after suctioning replaces O_2 removed during the procedure and helps to prevent atelectasis. The larger tidal volumes may also assist in mobilizing secretions and promote surfactant secretion.

Nursing Action	Rationale
Transport	
1. If hyperinflation is used in transport, suction patient before disconnection for transport; monitor heart and respiratory rates and LOC during procedure.	1. Establishes a patent airway before the patient is moved. Provides information for assessing tolerance of transport.
2. Ventilate at rate of 12–15 breaths/minute.	
Follow-up phase	
1. In cardiopulmonary arrest, verify return of spontaneous pulse and respirations. Initiate further support as needed.	1. Establishes the patient's need for definitive therapy (drugs, defibrillation, intensive care).
2. In suctioning or transport, return to previous support. Note patient tolerance of procedure.	2. Note SaO_2, heart rate, rate and ease of respirations, arterial BP (if monitored), LOC. Report if intolerance occurs.

NURSING ALERT Make sure that a good seal is maintained between face and mask so volume delivered through compression of bag is not lost.

NURSING ALERT Airways are not appropriate in conscious patients or patients with a gag reflex because stimulation of the oropharynx could cause vomiting and aspiration. Short nasal pumps can be used in conscious patients with a gag reflex.

EVIDENCE BASE American Heart Association. (2015). Highlights from 2015 American Heart Association Guidelines update for cardiopulmonary resuscitation and emergency cardiovascular care. *Circulation, 132*(18, Suppl 2).

PROCEDURE GUIDELINES 10-19

Managing the Patient Requiring Mechanical Ventilation

EQUIPMENT

- Artificial airway (endotracheal [ET] tube or tracheostomy)
- Manual self-inflating resuscitation bag
- Pulse oximetry
- Suction equipment
- Mechanical ventilator
- Ventilation circuitry
- Humidifier
- See manufacturer's directions for specific machine.

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Obtain baseline samples for blood gas determinations (pH, PaO_2, $PaCo_2$, HCO_3^-) and chest x-ray.	1. Baseline measurements serve as a guide in determining progress of therapy.
2. Give a brief explanation to the patient and family.	2. Allays fear and enlists cooperation. Emphasize that mechanical ventilation is a temporary measure. The patient should be prepared psychologically for weaning at the time the ventilator is first used.
3. Premedicate as needed.	3. Promotes cooperation through mild sedation.
4. Establish the airway by means of a cuffed ET or tracheostomy tube (see pages 212–216).	4. A closed system between the ventilator and patient's lower airway is necessary for positive pressure ventilation.
5. Prepare the ventilator. (Respiratory therapist does this in many facilities.)	5. Have all equipment and settings in place before applying to patient.
a. Set up desired circuitry.	
b. Connect oxygen and compressed air source.	
c. Turn on power.	
d. Set V_T (usually 6–8 mL/kg body weight [Morton]).	d. Adjusted according to pH and $PaCO_2$.
e. Set oxygen concentration.	e. Adjusted according to PaO_2.
f. Set ventilator sensitivity.	
g. Set rate at 12–14 breaths/minute (variable).	g. This setting approximates normal ventilation. These machines' settings are subject to change according to the patient's condition and response and the ventilator type being used.
h. Set inspiratory–expiratory (I:E) times (varies depending on the ventilator). Adjust flow rate (velocity of gas flow during inspiration). Usually set at 40–60 L/minute. Depends on rate and V_T.	h. The slower the flow, the lower the peak airway pressure will result from set volume delivery. This results in lower intrathoracic pressure and less impedance of venous return. However, a flow that is too low for the rate selected may result in inverse I:E ratios.
i. Select mode of ventilation.	
j. Check machine function—measure V_T, rate, I:E ratio, analyze oxygen, check all alarms.	j. Ensures safe function.
Performance phase	
1. Couple the patient's airway to the ventilator.	1. Make sure all connections are secure. Prevent ventilator tubing from "pulling" on artificial airway, possibly resulting in tube dislodgement or tracheal damage.
2. Assess patient for adequate chest movement and rate. Note peak airway pressure and PEEP.	2. Ensures proper function of equipment.

Nursing Action	Rationale
3. Set airway pressure alarms according to patient's baseline:	
a. High-pressure alarm	a. High airway pressure is set at 10–15 cm H_2O above peak inspiratory pressure. An alarm sounds if airway pressure selected is exceeded. Alarm activation indicates decreased lung compliance (worsening pulmonary disease); decreased lung volume (such as pneumothorax, tension pneumothorax, hemothorax, pleural effusion); increased airway resistance (secretions, coughing, bronchospasm, breathing out of phase with the ventilator); loss of patency of airway (mucus plug, airway spasm, biting, or kinking of tube).
b. Low-pressure alarm	b. Low airway pressure alarm set at 5–10 cm H_2O below peak inspiratory pressure. Alarm activation indicates inability to build up airway pressure because of disconnection or leak, and changing compliance and resistance.
4. Assess frequently for change in respiratory status by evaluation of ABGs, pulse oximetry, spontaneous respiratory rate, use of accessory muscles, breath sounds, and vital signs. Other means of assessing are through the use of exhaled carbon dioxide (see "Capnography," page 210, or "Oxygen saturation monitoring," page 209). If change is noted, notify health care provider.	4. Guides therapy.
5. Monitor and troubleshoot alarm conditions. Ensure appropriate ventilation at all times.	5. Priority is ventilation and oxygenation of the patient. In alarm conditions that cannot be immediately corrected, disconnect the patient from mechanical ventilation and manually ventilate with resuscitation bag.
6. Check for secure stabilization of artificial airway.	6. Reduces risk of inadvertent extubation.
7. Positioning:	
a. Turn the patient from side to side every 2 hr, or more frequently if possible. Consider kinetic therapy as early intervention to improve outcome.	a. Repositioning may improve secretion clearance and reduce atelectasis. For patients on long-term ventilation, this may result in sleep deprivation. Follow a turning schedule best suited to a particular patient's condition.
b. Lateral turns are desirable; from right semiprone to left semiprone.	
c. Make the patient to sit upright at regular intervals, if possible.	c. Upright posture increases lung compliance.
d. Consider prone positioning to improve oxygenation.	d. Prone positioning has been shown to have some beneficial effects or the improvement of oxygenation in certain populations, such as patients with ARDS.
NURSING ALERT For patients in severe compromised respiratory state or who are unstable hemodynamically, consider use of specialty bed with kinetic therapy.	
8. Carry out passive range-of-motion exercises of all extremities for patients unable to do so.	8. Prevents contractures.
9. Assess for need of suctioning at least every 2 hr.	9. Patients with artificial airways on mechanical ventilation are unable to clear secretions on their own. Suctioning may help to clear secretions and stimulate the cough reflex.

Nursing Action	Rationale
10. Assess respiratory effort and breath sounds every 2 hr in all lobes bilaterally.	
a. Determine whether breath sounds are present or absent, normal or abnormal, and whether a change has occurred.	a. Auscultation of the chest is a means of assessing airway patency and ventilatory distribution. It also confirms the proper placement of the ET or tracheostomy tube.
11. Humidification:	
a. Check the water level in the humidification reservoir to ensure that the patient is never ventilated with dry gas.	a. Humidity may improve secretion mobilization.
b. Empty the water that condenses in the delivery and exhalation tubing into a separate receptacle, not into the humidifier. Always wash hands before and after emptying fluid from ventilator circuitry. Humidification may also be achieved using a moisture enhancer.	b. Water condensing in the inspiratory tubing may cause increased resistance to gas flow. This may result in increased peak airway pressures. Warm, moist tubing is a perfect breeding area for bacteria. If this water is allowed to enter the humidifier, bacteria may be aerosolized into the lungs. Emptying the tubing also prevents introduction of water into the patient's airways.
12. Assess airway pressures at frequent intervals.	12. May indicate changes in compliance or onset of conditions that may cause airway pressure to increase or decrease.
13. Measure delivered V_T and analyze oxygen concentration every 4 hr or more frequently, if indicated. (Respiratory therapist performs this in most facilities.)	13. Ensures that patient is receiving the appropriate ventilatory assistance.
14. Monitor cardiovascular function. Assess for abnormalities.	14. Determines patient's response to therapy and possible adverse effects.
a. Monitor pulse rate and arterial BP; intra-arterial pressure monitoring may be carried out.	a. Arterial catheterization for intra-arterial pressure monitoring also provides access for ABG samples.
b. Use pulmonary artery catheter to monitor pulmonary capillary wedge pressure (PCWP), mixed venous oxygen saturation (SvO_2), and cardiac output (CO).	b. Intermittent and continuous positive pressure ventilation may increase the PAP and decrease cardiac output.
15. Provide mouth care every 1–4 hr and assess for development of pressure areas from ET tubes.	15. For comfort and reduced risk of infection.
16. Monitor for systemic signs and symptoms of pulmonary infection (pulmonary physical examination findings, increased heart rate, increased temperature, increased count).	16. Risk of infection increases with artificial airways.
17. Evaluate need for sedation or muscle relaxants.	17. Sedatives may be prescribed to decrease anxiety or to relax the patient to prevent "competing" with the ventilator. At times, pharmacologically induced paralysis may be necessary to permit mechanical ventilation.
DRUG ALERT Never administer paralyzing agents until the patient is intubated and on mechanical ventilation. Sedatives should be prescribed in conjunction with paralyzing agents because the patient may not be able to move but can still have awareness of his or her surroundings and inability to move.	
18. Use "ventilator bundle" protocol, as directed, to prevent ventilator-associated complications.	18. Reduces the risk of aspiration, peptic ulcer, and deep vein prophylaxis; reduces sedation that may interfere with assessment.
a. Elevate the head of the bed to between 30 and 45 degrees.	
b. Daily "sedative interruption" and daily assessment of readiness to extubate.	
c. Peptic ulcer disease prophylaxis.	
d. Deep vein thrombosis prophylaxis (unless contraindicated).	

Nursing Action	Rationale
19. Report intake and output precisely and obtain an accurate daily weight to monitor fluid balance.	19. Positive fluid balance resulting in increase in body weight and interstitial pulmonary edema is a frequent problem in patients requiring mechanical ventilation. Prevention requires early recognition of fluid accumulation. An average adult who is dependent on parenteral nutrition can be expected to lose ½ pound (0.25 kg) per day; therefore, constant body weight indicates fluid retention.
20. Monitor nutritional status. (Patients with ET tubes are to receive nothing by mouth [the tube splints the epiglottis open] but patients with tracheostomy tubes may take food by mouth if otherwise capable.) a. Weigh patient daily at same time. b. Assess serum prealbumin level as directed. c. Obtain nutritional consult with prolonged therapy.	20. Patients on mechanical ventilation require inflation of artificial airway cuffs at all times. Enteral or parenteral nourishment is usually employed (see page 219) to prevent rapid weight loss and malnutrition.
21. Monitor for GI bleeding. a. Test all stools and gastric drainage for occult blood (if part of facility protocol).	21. Mechanically ventilated patients are at risk for development of stress ulcers, resulting in occult or frank GI bleeding.
22. Provide psychological support and assist with communication needs of patient with an artificial airway. a. Use alternate means of communication. b. Orient frequently to environment and function of mechanical ventilator. c. Ensure that the patient has adequate rest and sleep.	22. Mechanical ventilation may result in sleep deprivation and loss of touch with surroundings and reality, as well as inability to talk.
Follow-up phase	
1. Maintain a flow sheet to record ventilation patterns, ABGs, pertinent laboratory results, fluid balance, weight, vital signs, and other clinical assessments. Notify appropriate health care provider of changes in the patient's condition.	1. Establishes means of assessing for effectiveness and progress of treatment.
2. Change ventilator circuitry per facility protocol; assess ventilator's function every 4 hr or more frequently if problem occurs.	2. Prevents contamination of lower airways.

PROCEDURE GUIDELINES 10-20

Weaning the Patient from Mechanical Ventilation

EQUIPMENT

- Varies according to technique used
- CPAP adapter
- Synchronized intermittent mandatory ventilation (SIMV) (set up in addition to ventilator or incorporated in ventilator and circuitry)
- Pressure support
- Briggs T piece (rarely used)

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. For weaning to be successful, the patient must be physiologically capable of maintaining spontaneous respirations. Assessments must ensure that: a. The underlying disease process is significantly reversed, as evidenced by pulmonary examination, ABGs wnl, chest x-ray. b. The patient can mechanically perform ventilation. Should be able to generate a negative inspiratory pressure <−20 cm H_2O; have a vital capacity of >10 mL/kg; have a resting minute ventilation <10 L/minute, and be able to double this; have a spontaneous respiratory rate of <25 breaths/minute, without significant tachycardia; be normotensive; have optimal hemoglobin for condition; and have adequate nutritional status.	1. Provides baseline; ensures that patient is capable of having adequate neuromuscular control to provide adequate ventilation.
2. Assess for other factors that may cause respiratory insufficiency. a. Acid–base abnormality b. Nutritional depletion c. Electrolyte abnormality d. Fever e. Abnormal fluid balance f. Hyperglycemia g. Infection h. Pain i. Sleep deprivation j. Decreased LOC	2. Weaning is difficult when these conditions are present.
3. Assess psychological readiness for weaning.	3. Patient must be physically and psychologically ready for weaning.
4. Explain the procedure and that weaning is not always successful on the initial attempt.	4. Explaining procedure to patient will decrease patient anxiety and promote cooperation. The patient should not be discouraged if weaning is unsuccessful on the first attempt.
5. Prepare appropriate equipment.	
6. Position the patient in sitting or semi-Fowler's position.	6. Increases lung compliance, decreases work of breathing.
7. Pick optimal time of day, preferably early morning.	7. The patient should be rested.
8. Perform bronchial hygiene as needed (postural drainage, suctioning) before weaning attempt.	8. The patient should be in best pulmonary condition for weaning to be successful.
Performance phase	
CPAP weaning (preferred)	
1. Discontinue mechanical ventilation and apply CPAP adapter.	1. The patient breathes on own with 2.5–5 cm H_2O CPAP. *Note: Briggs T piece may be used instead of CPAP; however, CPAP is preferable to prevent atelectasis during the weaning process.*

Nursing Action	Rationale
2. Monitor the patient for factors indicating need for reinstitution of mechanical ventilation. a. BP increase or decrease >20 mm Hg systolic or 10 mm Hg diastolic b. Heart rate increase of 20 beats/minute or >110 c. Respiratory rate increase >10 breaths/minute or rate >30 d. V_T <250–300 mL (in adults) e. Appearance of new cardiac ectopy or increase in baseline ectopy f. PaO_2 <60, $PaCO_2$ >55, or pH <7.35 (may accept lower PaO_2 and pH, and higher $PaCO_2$ in patients with COPD)	2. Indicates intolerance of weaning procedure. Stay with the patient during weaning time to decrease patient anxiety and monitor for tolerance of procedure.
3. Increase time off ventilator with each weaning attempt as the patient's condition indicates. Evaluate for toleration before moving to the next increment.	3. The patient will progress as he or she becomes mentally and physically able to perform adequate spontaneous ventilation.
4. Institute other techniques helpful in encouraging weaning. a. Mental stimulation b. Biofeedback c. Participation in care d. Provision of rewards e. Contact with successfully weaned patients	4. Provides motivation and positive feedback.
5. When patient tolerates 40–60 min of continuous weaning, weaning increments can increase rapidly.	
6. When the patient can maintain spontaneous ventilation throughout day, begin night weaning.	
SIMV weaning	
1. Set ventilator to SIMV mode.	
2. Set rate interval.	2. Determines the time interval between machine-delivered breaths, during which the patient will breathe on own.
3. If gas for the patient's spontaneous breath is delivered via a demand valve regulator, ensure that machine sensitivity is at maximum setting.	3. Aids in decreasing work of breathing necessary to open demand valve.
4. Evaluate for tolerance of procedure. Monitor for factors indicating need for increase or decrease of mandatory respiratory rate (see step 2 above). In rapid weaning, changes may be made approximately every 20–30 min.	4. If the patient does not tolerate the procedure, the $PaCO_2$ will rise and pH will fall.
5. If $PaCO_2$ and pH levels remain stable, then continue to decrease mandatory rate as patient tolerates.	5. May be done as frequently as every 20–30 min with ABG monitoring, pulse oximetry, documentation of successful weaning.
Pressure support	
1. The amount of pressure support (cm H_2O) provided to the airway is progressively decreased over time, allowing the patient to increase role in supporting own spontaneous ventilation.	1. May be beneficial adjunct to SIMV weaning. 2. Overcomes resistance associated with ET tubes demand valves

Nursing Action	Rationale
Follow-up phase	
1. Record at each weaning interval: heart rate, BP, respiratory rate, FiO_2, ABG, pulse oximetry value, respiratory and ventilator rate (if SIMV), or length of time off ventilator (if CPAP weaning). *Note:* It is not within the scope of this manual to establish criteria for the use of one weaning modality as opposed to another.	1. Provides record of procedure and assessment of progress.

PROCEDURE GUIDELINES 10-21

Extubation

EQUIPMENT

- Tonsil suction (surgical suction instrument)
- 10-mL syringe
- Resuscitation bag and mask with oxygen flow
- Face mask connected to large-bore tubing, humidifier, and oxygen source
- Suction catheter
- Suction source
- Gloves
- Face shield

PROCEDURE

Nursing Action	Rationale
Preparatory phrase	
1. Monitor heart rate, lung expansion, and breath sounds before extubation. Record tidal volume (V_T), vital capacity (VC), negative inspiratory pressure (NIP).	1. V_T, VC, and NIF are measured to assess respiratory muscle function and adequacy of ventilation.
2. Assess the patient for other signs of adequate muscle strength. a. Instruct the patient to tightly squeeze the index and middle fingers of your hand. Resistance to removal of your fingers from the patient's grasp must be demonstrated. b. Ask the patient to lift head from the pillow and hold for 2–3 sec.	2. Adequate muscle strength is necessary to ensure muscle strength for spontaneous breathing and coughing.
NURSING ALERT Keep in mind that patient's underlying problems must be improved or resolved before extubation is considered. Patient should also be free from infection and malnutrition.	
3. Obtain orders for extubation and postextubation oxygen therapy.	3. Do not attempt extubation until postextubation oxygen therapy is available and functioning at the bedside.
4. Explain the procedure to the patient: a. Artificial airway will be removed. b. Suctioning will occur before extubation. c. Deep breath should be taken on command. d. Instruction will be given to cough after extubation.	4. Increases patient cooperation.
5. Prepare necessary equipment. Have ready for use tonsil suction, suction catheter, 10-mL syringe, bag-mask unit, and oxygen by way of face mask.	
6. Place the patient in sitting or semi-Fowler's position (unless contraindicated).	6 Increases lung compliance and decreases work of breathing. Facilitates coughing.
Performance phase	
1. Put on face shield and gloves.	1. Spraying of airway secretions may occur.
2. Loosen tape or ET tube-securing device.	2. So that tube can be removed more easily when ready.
3. Suction ET tube, then suction oropharyngeal airway above the ET cuff as thoroughly as possible.	3. To reduce secretions above and within the tube. Secretions not cleared from above the cuff will be aspirated when the cuff is deflated.
4. Extubate the patient: a. Ask the patient to take as deep a breath as possible (if the patient is not following commands, give a deep breath with the resuscitation bag). b. At peak inspiration, deflate the cuff completely and pull the tube out in the direction of the curve (out and downward).	a. At peak inspiration, the trachea and vocal cords will dilate, allowing a less traumatic tube removal.
5. Once the tube is fully removed, ask the patient to cough or exhale forcefully to remove secretions. Then suction the back of the patient's airway with the tonsil suction.	5. Frequently, old blood is seen in the secretions of newly extubated patients. Monitor for the appearance of bright red blood because of trauma occurring during extubation.

Nursing Action	Rationale
6. Apply oxygen therapy as ordered.	
7. Evaluate immediately for any signs of respiratory distress, stridor (high-pitched crowing sounds), or decreased air flow. If the patient develops any of these problems, attempt to ventilate the patient with the resuscitation bag and mask and prepare for reintubation. (Nebulized treatments may be ordered to avoid having to reintubate the patient.)	7. Evaluates for laryngospasm or edema at the cuff site, resulting in obstruction of the airway.
Follow-up phase	
1. Note patient tolerance of procedure, upper and lower airway sounds postextubation, description of secretions.	1. Establishes a baseline to assess improvement/development of complications.
2. Observe the patient closely postextubation for any signs and symptoms of airway obstruction or respiratory insufficiency.	2. Tracheal or laryngeal edema may develop up to 24 hr postextubation.
3. Observe character of voice and signs of blood in sputum.	3. Hoarseness is a common postextubation complaint. Observe for worsening hoarseness or vocal cord paralysis.
4. Provide supplemental oxygen and humidification using face mask.	

EVIDENCE BASE American Association for Respiratory Care. (2007). Clinical practice guidelines. Removal of endotracheal tube. *Respiratory Care*, *52*(3), 81–93.

PROCEDURE GUIDELINES 10-22

Assisting the Patient Using an Incentive Spirometer

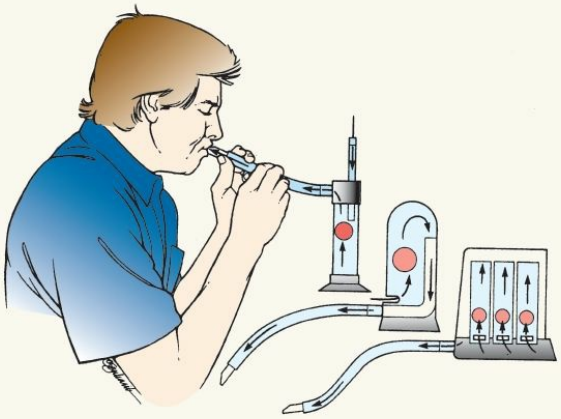
EQUIPMENT

According to the type of device used

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Measure the patient's normal tidal volume (V_T) and auscultate the chest, preferably preprocedure/treatment and/or preoperatively.	1. Establishes the patient's baseline.
2. Explain the procedure and its purpose to the patient. The device provides measurement and feedback related to breathing effectiveness and mimics the natural sigh and yawn, thus keeping the lungs clear.	2. Optimal results are achieved when the patient is given pretreatment or preoperative instruction.
3. Place the patient in a comfortable sitting, semi-Fowler's, or upright position.	3. Diaphragmatic excursion is greater in this position; however, if the patient is medically unable to be in this position, the exercise may be done in any position.
4. For the postoperative patient, try as much as possible to avoid discomfort. Try to coordinate treatment with administration of pain relief medications. Instruct and assist the patient with splinting of incision.	4. Incentive spirometry is most successful when pain is controlled.
Performance phase	
1. Set the incentive spirometer V_T indicator at the desired goal the patient is to reach or exceed (500 mL is often used to start). The V_T is set according to the manufacturer's instructions.	1. The initial V_T may be prescribed, but the purpose of the device is to establish a baseline V_T and provide incentive to achieve greater volumes progressively.
2. Demonstrate the technique to the patient. a. Instruct the patient to exhale fully. b. Tell the patient to take in a slow, easy, deep breath from the mouthpiece.	2. To increase understanding and effectiveness. *Note:* Nose clips are sometimes used if the patient has difficulty breathing only through mouth. This will ensure full credit for each breath measured.
3. When the desired goal is reached (lungs fully inflated), ask the patient to continue the inspiratory effort for 3 sec, even though the patient may not actually be drawing in more air.	3. Sustaining the inspiratory effort helps to open closed alveoli. For the postoperative patient, hypoventilation can result in atelectasis within the first hour.
4. Instruct the patient to remove the mouthpiece, relax, and passively exhale; patient should take several normal breaths before attempting another one with the incentive spirometer.	4. Usually one incentive breath per minute minimizes patient fatigue. No more than four to five maneuvers should be performed per minute to minimize hypocarbia.
5. Continue to monitor the patient's spirometer breaths, periodically increasing the V_T as the patient tolerates.	5. Increases lung expansion.
6. At the conclusion of the treatment, encourage the patient to cough after a deep breath.	6. The deep lung inflation may loosen secretions and enable the patient to expectorate them.
7. Instruct the patient to take 10 sustained maximal inspiratory maneuvers per hour and note the volume on the spirometer.	7. A total of 10 sustained maximal inspiratory maneuvers per hour during waking hours is a typical order. A counter on the incentive spirometer indicates the number of breaths the patient has taken.

Nursing Action	Rationale
Performance phase	



Flow incentive spirometer.Patients are instructed to inhale briskly to elevate the balls and to keep them floating as long as possible. The volume inhaled is estimated and variable.

Follow-up phase	
1. Auscultate the chest. Chart any improvement or variation, the volume attained, effectiveness of cough, description of any secretions expectorated.	1. Notes the effectiveness and patient tolerance of the treatment for continuity of care.
2. Record effectiveness and frequency of use of incentive spirometer.	

EVIDENCE BASE Restrepo, R., Wettstein, R., Wittnebel, L., et al. (2011). AARC clinical practice guideline: Incentive spirometry: 2011. *Respiratory Care*, *56*(10), 1600–1604.

PROCEDURE GUIDELINES 10-23

Assisting with Chest Tube Insertion

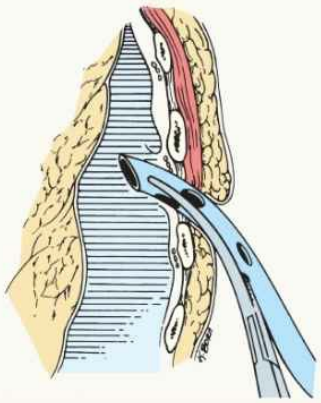
EQUIPMENT

- Tube thoracostomy tray
- Syringes
- Needles/trocar
- Basins/skin germicide
- Sponges
- Scalpel, sterile drape, and gloves
- Two large clamps
- Suture material
- Local anesthetic
- Chest tube (appropriate size); connector
- Cap, mask, gloves, gown, drapes
- Chest drainage system—connecting tubes and tubing, collection bottles or commercial system, vacuum pump (if required)
- Sterile water

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Assess patient for pneumothorax, hemothorax, presence of respiratory distress.	
2. Obtain a chest x-ray. Other means of localization of pleural fluid include ultrasound or fluoroscopic localization.	2. Evaluates extent of lung collapse or amount of bleeding in pleural space.
3. Ensure that informed consent has been obtained.	3. Invasive procedures require written consent.
4. Verify right patient and right location/procedure.	
5. Premedicate if indicated.	5. Sedation may be required if patient is restless.
6. Assemble drainage system.	
7. Reassure the patient and explain the steps of the procedure. Tell the patient to expect a needle prick and a sensation of slight pressure during infiltration anesthesia.	7. Allays fear and enlists patient cooperation. The patient can cope by remaining immobile and doing relaxed breathing during tube insertion.
8. Position the patient as for an intercostal nerve block or according to health care provider preference.	8. The tube insertion site depends on the substance to be drained, the patient's mobility, and the presence of coexisting conditions.
Performance phase	
Needle or intracath technique	
1. Using universal precautions, the skin is prepared, anesthetized, and draped, using local anesthetic with a short 25G needle and using aseptic technique. A larger needle is used to infiltrate the subcutaneous tissue, intercostal muscles, and parietal pleura.	1. The area is anesthetized to make tube insertion and manipulation relatively painless. Use of universal precautions and aseptic technique prevent contamination of chest tube, which will be entering a sterile cavity. Patient may feel pressure while tube is inserted.
2. An exploratory needle is inserted.	2. Punctures the pleura and determines the presence of air or blood in the pleural cavity.
3. The catheter is inserted through the needle into the pleural space. The needle is removed, and the catheter is pushed several centimeters into the pleural space.	
4. The catheter is taped to the skin; may be sutured to the chest wall and covered with a dressing.	4. Prevents it from being dislodged out of the chest during patient movement or lung expansion.
5. The catheter is attached to a connector/tubing and attached to a drainage system (underwater-seal or commercial system) and all connections taped.	5. All connections are taped to prevent disconnection. The chest tube clamp is removed once the chest tube is attached to the system.
Performance phase	
Trocar technique for chest tube insertion	
Using universal precautions and aseptic technique, a trocar catheter is used for the insertion of a large-bore tube for removal of a moderate to large amount of air leak or for the evacuation of serous effusion.	
1. A small incision is made over the prepared, anesthetized site. Blunt dissection (with a hemostat) through the muscle planes in the interspace to the parietal pleura is performed.	1. Admits the diameter of the chest tube.
2. The trocar is directed into the pleural space, the cannula is removed, and a chest tube is inserted into the pleural space and connected to a drainage system.	2. There is a trocar catheter available equipped with an indwelling pointed rod for ease of insertion.

Nursing Action	Rationale
Hemostat technique using a large-bore chest tube Using universal precautions and aseptic technique, a large-bore chest tube is used to drain blood or thick effusions from the pleural space.	
1. Using universal precautions, aseptic technique, and after skin preparation and anesthetic infiltration, an incision is made through the skin and subcutaneous tissue.	1. The skin incision is usually made one interspace below proposed site of penetration of the intercostal muscles and pleura.
2. A curved hemostat is inserted into the pleural cavity, and the tissue is spread with the clamp.	2. Makes a tissue tract for the chest tube.
3. The tract is explored with an examining finger.	3. Digital examination helps confirm the presence of the tract and penetration of the pleural cavity.
4. The tube is held by the hemostat and directed through the opening up over the ribs and into the pleural cavity.	
5. The clamp is withdrawn, and the chest tube is connected to a chest drainage system.	5. The chest tube has multiple openings at the proximal end for drainage of air or blood.
6. The tube is sutured in place and covered with a sterile dressing.	6. Prevents dislodgment.
7. Catheter is attached to a connector/tube and to the system. All connections are taped.	7. Clamps are removed from the chest tube once connected to the drainage system. Chest tubes open to air at the time of insertion will result in a pneumothorax.



Chest tube (tube thoracostomy) inserted via hemostat technique.

Follow-up phase	
1. Observe the drainage system for blood and air. Observe for fluctuation in the tube on respiration. (See page 274.)	1. If a hemothorax is draining through a thoracostomy tube into a bottle containing sterile normal saline, the blood is available for autotransfusion.
2. Secure a follow-up chest x-ray.	2. To confirm correct chest tube placement and reexpansion of the lung.
3. Assess for bleeding, infection, leakage of air and fluid around the tube.	3. With too rapid removal of fluid, a vasovagal response may occur with resulting hypotension. Continued use of petroleum gauzes or ointment can irritate the skin.
4. Maintain integrity of the chest drainage system.	4. Chest tube malposition is the most common complication.

PROCEDURE GUIDELINES 10-24

Managing the Patient with Water-Seal Chest Drainage

EQUIPMENT

- Closed chest drainage system
- Holder for drainage system (if needed) connector for emergency use
- Vacuum motor
- Sterile connector for emergency use (ie, sterile water)

PROCEDURE

Nursing Action	Rationale
Performance phase	
1. Attach the chest tube from the pleural space (the patient) to the collecting/drainage tubing and water-seal drainage system. Add sterile water to water-seal chambers, as needed. Adjust suction until bubbling is seen or set gauge as directed. Keep drainage system below level of chest.	1. Water-seal drainage provides for the escape of air and fluid into a drainage bottle. The water acts as a seal and keeps the air from being drawn back into the pleural space. Vigorous bubbling is not indicated.
2. Check the tube connections periodically. Tape, if necessary. a. The tube should be as straight as possible and coiled below level of chest without dependent loops. b. Do not let the patient lie on collecting/tubing drainage.	2. Tube connections are checked to ensure tight fit, patency of the tubes, and to prevent backflow of drainage or air.
3. Mark the original fluid level with tape on the outside of the drainage system. Mark hourly and daily increments (date and time) at the drainage level.	3. This marking will show the amount of fluid loss and how fast fluid is collecting in the drainage bottle. It serves as a basis for blood replacement, if the fluid is blood. Grossly bloody drainage will appear in the bottle in the immediate postoperative period and, if excessive, may necessitate reoperation. Drainage usually declines progressively after the first 24 hr.
4. Assess the patient's clinical status at least once per shift. Observe and report immediately signs of rapid, shallow breathing, cyanosis, pressure in the chest, subcutaneous emphysema, or symptoms of hemorrhage.	4. Removal of 1,000–1,200 mL of pleural fluid at one time can result in hypotension and rebound pleural effusion. Report to physician immediately. More frequent monitoring is required at the initiation of therapy and when warranted by patient's condition. Many clinical conditions may cause these signs and symptoms, including tension pneumothorax, mediastinal shift, hemorrhage, severe incisional pain, pulmonary embolus, and cardiac tamponade. Surgical intervention may be necessary.
5. Make sure the tubing does not loop or interfere with the movements of the patient.	5. Fluid collecting in the dependent segment of the tubing will decrease the negative pressure applied to the catheter. Kinking, looping, or pressure on the drainage tubing can produce back pressure, thus possibly forcing drainage back into the pleural space or impeding drainage from the pleural space.
6. Encourage the patient to assume a position of comfort. Encourage good body alignment. When the patient is in a lateral position, place a rolled towel under the tubing to protect it from the weight of the patient's body. Encourage the patient to change position frequently.	6. The patient's position should be changed frequently to promote drainage and body kept in good alignment to prevent postural deformity and contractures. Proper positioning helps breathing and promotes better air exchange. Pain medication may be indicated to enhance comfort and deep breathing.
7. Put the arm and shoulder of the affected side through ROM exercises several times daily. Some pain medication may be necessary.	7. Exercise helps to avoid ankylosis of the shoulder and assists in lessening postoperative pain and discomfort.

Nursing Action	Rationale
8. Make sure there is fluctuation ("tidaling") of the fluid level in the drainage system.	8. Fluctuation of the water level in the tube shows that there is effective communication between the pleural space and the drainage system; provides a valuable indication of the patency of the drainage system and is a gauge of intrapleural pressure.
9. Fluctuations of fluid in the tubing will stop when: a. The lung has reexpanded. b. The tubing is obstructed by blood clots or fibrin. c. A dependent loop develops.	9. Leaking and trapping of air in the pleural space can result in tension pneumothorax.
10. Watch for leaks of air in the drainage system as indicated by constant bubbling in the water-seal bottle. a. Report excessive bubbling in the water-seal change immediately.	10. Air leak prevents proper drainage and expansion of the lung.
11. Encourage the patient to breathe deeply and cough at frequent intervals. If there are signs of incisional pain, adequate pain medication is indicated.	11. Deep breathing and coughing help to raise the intrapleural pressure, which allows emptying of any accumulation in the pleural space and removes secretions from the tracheobronchial tree so the lung expands.
12. If the patient has to be transported to another area, place the drainage system below the chest level (as close to the floor as possible).	12. The drainage apparatus must be kept at a level lower than the patient's chest to prevent backflow of fluid into the pleural space.
13. If the tube becomes disconnected, cut off the contaminated tips of the chest tube and tubing, insert a sterile connector in the chest tube and tubing, and reattach to the drainage system. Otherwise, do not clamp the chest tube during transport.	13. Clamping may result in tension pneumothorax.
14. When assisting with removal of the tube: a. Administer pain medication 30 min before removal of chest tube. b. Instruct the patient to perform a gentle Valsalva maneuver or to breathe quietly. c. The chest tube is clamped and removed. d. Simultaneously, a small bandage is applied and made airtight with petroleum gauze covered by a 4 inches × 4 inches gauze and thoroughly covered and sealed with tape.	14. The chest tube is removed as directed when the lung is reexpanded (usually 24 hr to several days). Signs of reinflation include little or no drainage, absence of air leak, no noted respiratory distress, no fluctuations in fluid in water-seal chamber, no residual air or fluid in chest x-ray. During the tube removal, avoid a large sudden inspiratory effort, which may produce a pneumothorax.
Follow-up phase	
1. Monitor the patient's pulmonary status for signs and symptoms of decompensation. Observe insertion site for signs of infection and changes in drainage.	1. Patient could have reformation of pneumothorax after removal as well as infection at injection site.

EVIDENCE BASE Bauman, M., & Handley, C. (2010). Chest-tube care: The more you know, the easier it gets. *American Nurse Today, 6*(9), 27–32.

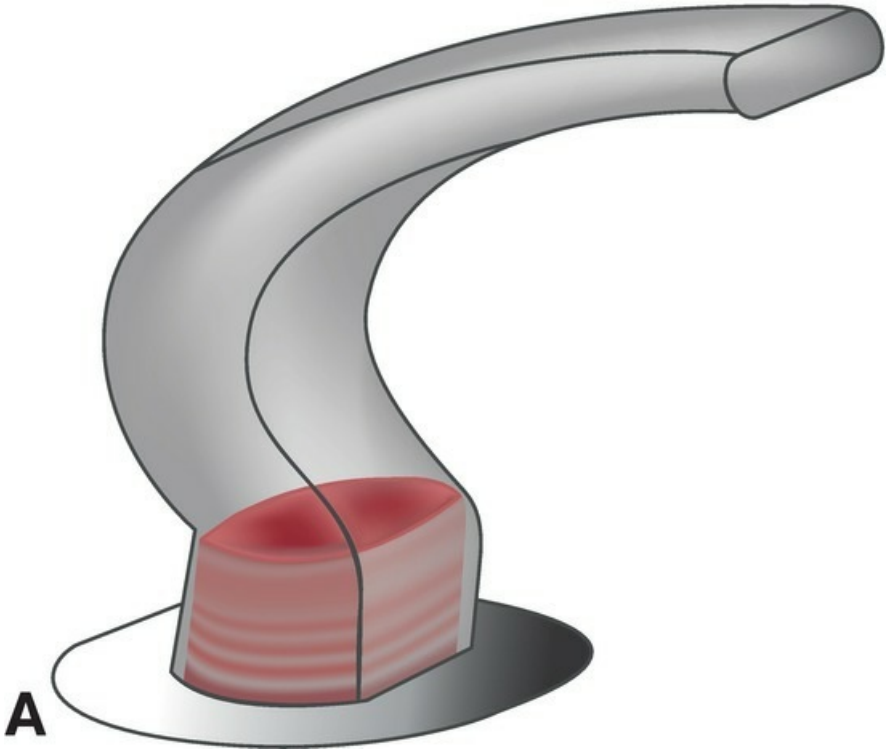
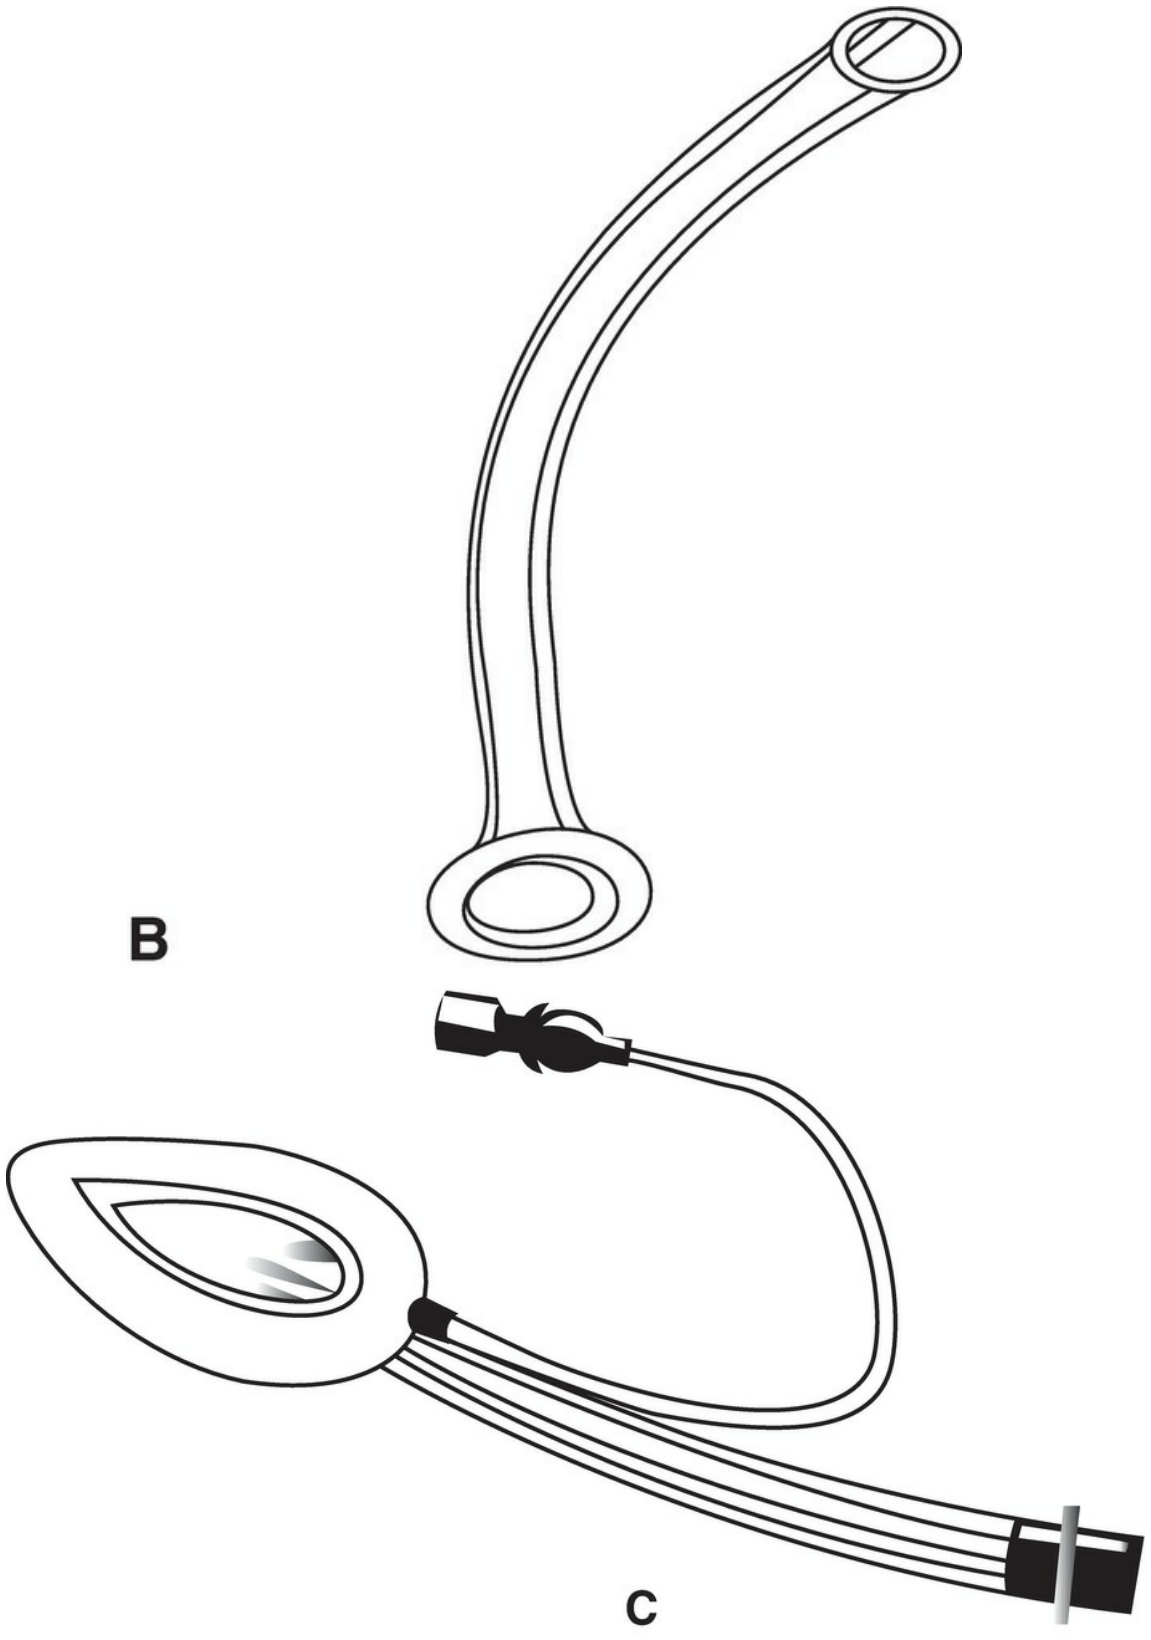
Artificial Airway Management

EVIDENCE BASE Burns, S. (2014). *AACN essentials of critical care nursing* (3rd ed.). New York, NY: McGraw Hill.

Airway management may be indicated in patients with loss of consciousness, facial or oral trauma, aspiration, tumor, infection, copious respiratory secretions, respiratory distress, and the need for mechanical ventilation. See Figure 10-3.





B
C

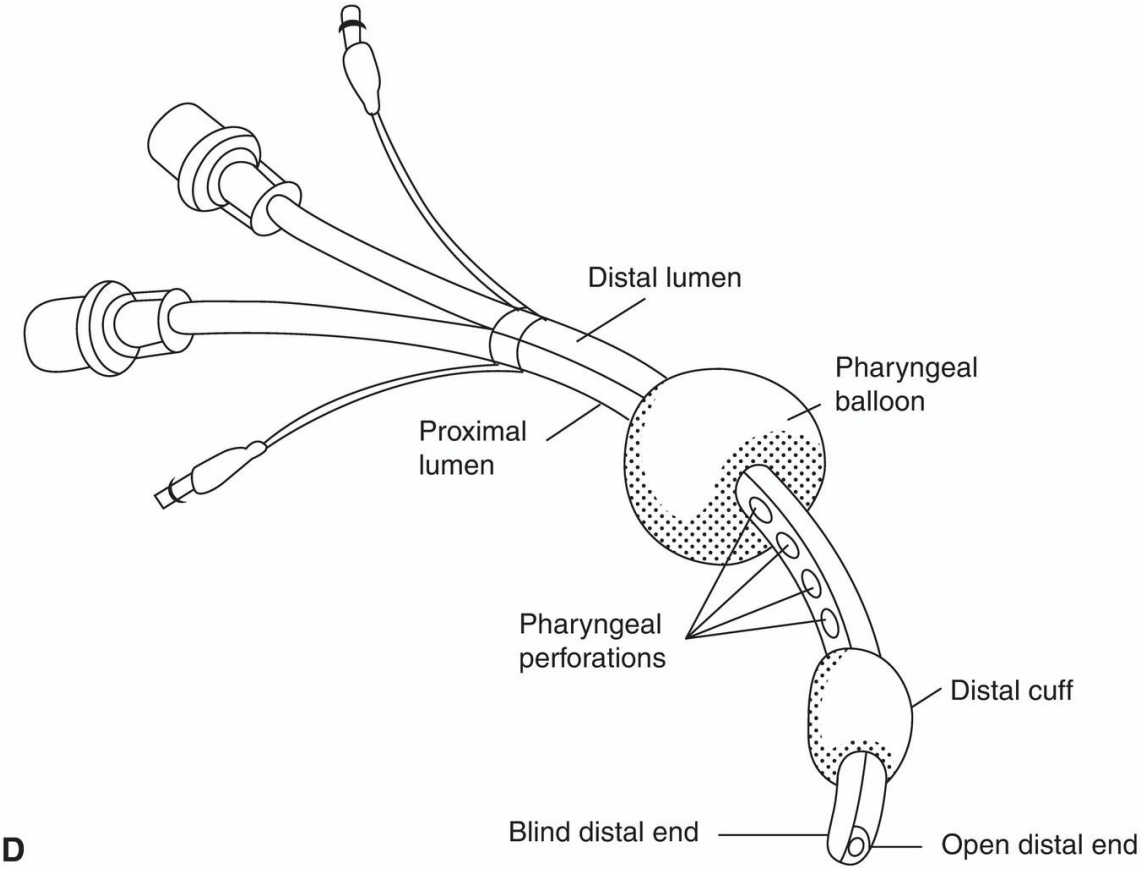


Figure 10-3. Types of airways: **(A)** oropharyngeal airway, **(B)** nasopharyngeal airway (nasal trumpet), **(C)** laryngeal mask airway, **(D)** combined tub.

Types of Airways

1. Oropharyngeal airway—curved plastic device inserted through the mouth and positioned in the posterior pharynx to move tongue away from palate and open the airway.
   a. Usually for short-term use in the unconscious patient or may be used along with an oral ET tube.
   b. Not used if recent oral trauma, surgery, or if loose teeth are present.
   c. Does not protect against aspiration.
   d. Not recommended for use in alert patients because the device may trigger the gag reflex and induce vomiting
2. Nasopharyngeal airway (nasal trumpet)—soft rubber or plastic tube hollow inserted through nose into posterior pharynx.
   a. Facilitates frequent nasopharyngeal suctioning.
   b. Useful in the semiconscious patient as an adjunct to help maintain airway patency
   c. Use extreme caution with patients on anticoagulants or bleeding disorders.
   d. Select size that is slightly smaller than diameter of nostril and slightly longer than distance from tip of nose to earlobe.
   e. Check nasal mucosa for irritation or ulceration, and clean airway with hydrogen peroxide and water.

3. Laryngeal mask airway—composed of a tube with a cuffed masklike projection at the distal end; inserted through the mouth into the pharynx; seals the larynx and leaves distal opening of tube just above glottis.
    a. Easier placement than ET tube because visualization of vocal cords is not necessary.
    b. Provides ventilation and oxygenation comparable to that achieved with an ET tube.
    c. Cannot prevent aspiration because it does not separate the GI tract from the respiratory tract.
    d. May cause laryngospasm and bronchospasm.
    e. Greater likelihood of misplacement.
4. Combitube—double-lumen tube with pharyngeal lumen and tracheoesophageal lumen; pharyngeal lumen has blocked distal end and perforations at pharyngeal level; tracheoesophageal lumen has open upper and lower end; large oropharyngeal balloon serves to seal mouth and nose; distal cuff seals the esophagus or trachea.
    a. Very seldom used in the hospital setting because of complications.
5. Endotracheal tube—flexible tube inserted through the mouth or nose and into the trachea beyond the vocal cords that acts as an artificial airway. Preferred method for trauma, medical emergencies, short-term complex patient.
    a. Maintains a patent airway.
    b. Allows for deep tracheal suction and removal of secretions.
    c. Permits mechanical ventilation.
    d. Inflated balloon seals off trachea so aspiration from the GI tract cannot occur.
    e. Generally easy to insert in an emergency, but maintaining placement is more difficult so this is not for long-term use.
6. Tracheostomy tube—firm, curved artificial airway inserted directly into the trachea at the level of the second or third tracheal ring through a surgically made incision.
    a. Permits mechanical ventilation and facilitates secretion removal.
    b. Can be for long-term use.
    c. Bypasses upper airway defenses, increasing susceptibility to infection.
    d. Allows the patient to eat and swallow.

NURSING ALERT Position patient on side and suction oral cavity frequently to prevent aspiration of oral secretions or vomitus when an oral airway is in place.

NURSING ALERT Nasopharyngeal airways may obstruct sinus drainage and produce acute sinusitis. Be alert to fever and facial pain.

Endotracheal Tube Insertion

1. Orotracheal insertion is technically easier because it is done under direct visualization with a laryngoscope. Disadvantages are increased oral secretions, decreased patient comfort, difficulty with tube stabilization, and inability of patient to use lip movement as a communication means.
2. NT insertion may be more comfortable to the patient and is easier to stabilize. Disadvantages are that blind insertion is required; possible development of pressure necrosis of the nasal airway, sinusitis, and otitis media.
3. Tube types vary according to length and inner diameter, type of cuff, and number of lumens.
   a. Usual sizes for adults are 6.0, 7.0, 8.0, and 9.0 mm.
   b. Most cuffs are high volume, low pressure, with self-sealing inflation valves, or the cuff may be of foam rubber.
   c. Most tubes have a single lumen; however, dual-lumen tubes may be used to ventilate each lung independently (see Figure 10-4).
4. May be contraindicated when glottis is obscured by vomitus, bleeding, foreign body, or trauma or cervical spine injury or deformity.

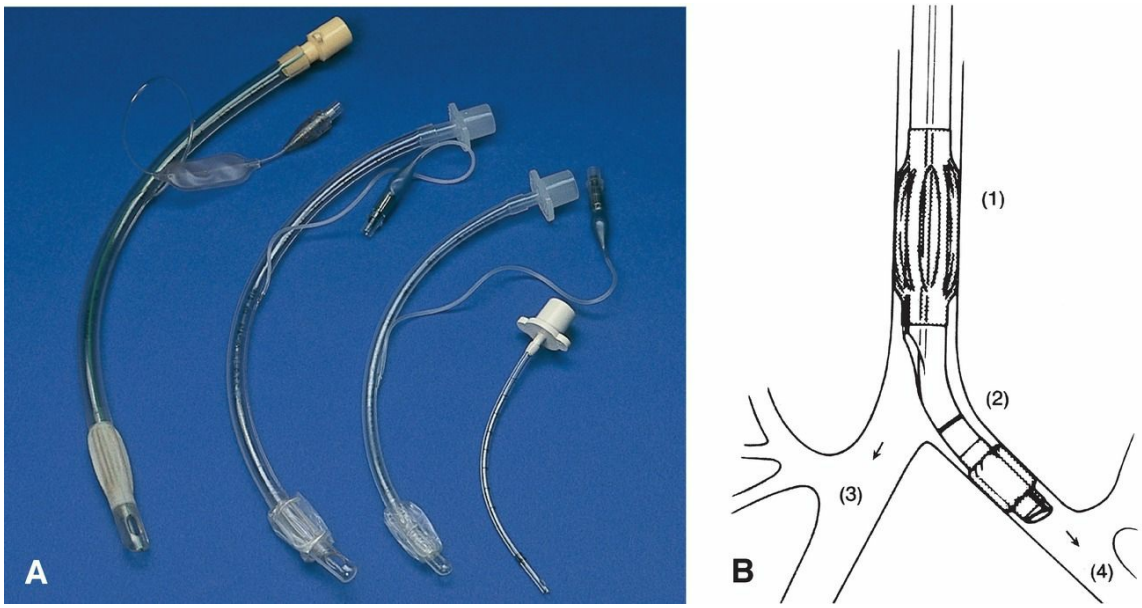

Figure 10-4. (A) Endotracheal tubes: single-lumen and double-lumen endotracheal tube. When the double-lumen tube is used **(B)**, two cuffs are inflated. One cuff (*1*) is positioned in the trachea and the second cuff (*2*) in the left mainstem bronchus. After inflation, air flows through an opening below the tracheal cuff (*3*) to the right lung and through an opening below the bronchial cuff (*4*) to the left lung. This permits differential ventilation of both lungs, lavage of one lung, or selective inflation of either lung during thoracic surgery. (Republished with permission of John Wiley and Sons, Inc., from *Anesthesia for thoracic procedures*, Marshall, B, E., Longnecker, D. E., & Fairley, H. B. [Eds.], Blackwell Scientific, 1988.)

Tracheostomy Tube Insertion

1. Tube types vary according to presence of inner cannula and presence and type of cuff (see Figure 10-5).
   a. Tubes with high-volume, low-pressure cuffs with self-sealing inflation valves; with or without inner cannula.
   b. Fenestrated tube.
   c. Foam-filled cuffs.
   d. Speaking tracheostomy tube.
   e. Tracheal button or Passy-Muir valve.
   f. Silver tube (rarely used).
2. Vary according to length and inner diameter in millimeters. Usual sizes for an adult are 5.0, 6.0, 7.0, and 8.0.
3. Tracheostomy is usually planned, either as an adjunct to therapy for respiratory dysfunction or for longer-term airway management when ET intubation has been used for more than 14 days.
4. May be done at the bedside in an emergency when other means of creating an airway have failed.

Cuffless: nonfenestrated (left) and fenestrated (right). Tracheostomy plug to allow breathing through upper airway is also shown.

Cuffed: fenestrated (left) and nonfenestrated (right) with inner cannula and obturator for insertion. Percutaneous tracheostomy inducer (bottom).

Speaking valve.

Figure 10-5. Types of tracheostomy tubes. (© 2018 Medtronic. All rights reserved. Used with the permission of Medtronic.)

Indications for Endotracheal or Tracheostomy Tube Insertion

1. Acute respiratory failure, central nervous system (CNS) depression, neuromuscular disease, pulmonary disease, chest wall injury.
2. Upper airway obstruction (tumor, inflammation, foreign body, laryngeal spasm).
3. Anticipated upper airway obstruction from edema or soft tissue swelling because of head and neck trauma, some postoperative head and neck procedures involving the airway, facial or airway burns, decreased LOC.
4. Need for airway protection (vomiting, bleeding, or altered mental status).
5. Aspiration prophylaxis.
6. Fracture of cervical vertebrae with spinal cord injury; requiring ventilatory assistance.

Complications of Endotracheal or Tracheostomy Tube Insertion

1. Laryngeal or tracheal injury.
    a. Sore throat, hoarse voice.
    b. Glottic edema.
    c. Trauma (damage to teeth or mucous membranes, perforation or laceration of pharynx, larynx, or trachea).
    d. Aspiration.
    e. Laryngospasm, bronchospasm.
    f. Ulceration or necrosis of tracheal mucosa.
    g. Vocal cord ulceration, granuloma, or polyps.
    h. Vocal cord paralysis.
    i. Postextubation tracheal stenosis.
    j. Tracheal dilation.
    k. Formation of tracheal–esophageal fistula.
    l. Formation of tracheal–arterial fistula.
    m. Innominate artery erosion.
2. Pulmonary infection and sepsis.
3. Dependence on artificial airway.

Nursing Care for Patients with Artificial Airways

General Care Measures

1. Handwashing and application of application of alcohol gel should be followed before and after all procedures.
2. Ensure adequate ventilation and oxygenation through the use of supplemental oxygen or mechanical ventilation as indicated.
3. Assess breath sounds every 2 hours. Note evidence of ineffective secretion clearance (rhonchi, crackles), which suggests need for suctioning.
4. Provide adequate humidity when the natural humidifying pathway of the oropharynx is bypassed.
5. Provide adequate suctioning of oral secretions to prevent aspiration and decrease oral microbial colonization.
6. Use clean technique when inserting an oral or nasopharyngeal airway, and take it out and clean it with hydrogen peroxide and rinse with water at least every 8 hours.
7. Perform oral care every 2 to 4 hours with soft toothbrush or swabs and prepackaged oral care kits. Frequent oral care will aid in prevention of ventilator-associated pneumonia. The patient's lips should be kept moisturized to prevent them from becoming sore and cracked.
8. Ensure that aseptic technique is maintained when inserting an ET or tracheostomy tube. The artificial

airway bypasses the upper airway, and the lower airways are sterile below the level of the vocal cords.

9. Elevate the patient to a semi-Fowler's or sitting position, when possible; these positions result in improved lung compliance. The patient's position, however, should be changed at least every 2 hours to ensure ventilation of all lung segments and prevent secretion stagnation and atelectasis. Position changes are also necessary to avoid skin breakdown.
10. If an oral or nasopharyngeal airway is used, turn patient's head to the side to reduce the risk of aspiration (because there is no cuff to seal off the lower airway).

Nutritional Considerations

1. Consciousness is usually impaired in patient with an oropharyngeal airway, so oral feeding is contraindicated.
2. To enhance comfort, remove a nasopharyngeal airway in the conscious patient during mealtimes.
3. Recognize that an ET tube holds the epiglottis open. Therefore, only the inflated cuff prevents the aspiration of oropharyngeal contents into the lungs. The patient must not receive oral feeding. Administer enteral tube feedings or parenteral feedings, as ordered.
4. Administer oral feedings to a conscious patient with a tracheostomy, usually with the cuff inflated. The inflated cuff prevents aspiration of food contents into the lungs but causes the tracheal wall to bulge into the esophageal lumen and may make swallowing more difficult. Patients who are not on mechanical ventilation and are awake, alert, and able to protect the airway are candidates for eating with the cuff deflated. Utilize a speech therapist to evaluate the patient's ability to eat.
5. Patients should receive thickened rather than regular liquids; this will assist in effective swallowing.

NURSING ALERT Consider the patient's nutritional needs early in the process of intubation so nutritional status does not decline further. It is difficult to wean patients who have compromised nutritional status.

Cuff Maintenance

1. ET tube cuffs should be inflated continuously and deflated only during intubation, extubation, and tube repositioning.
2. Tracheostomy tube cuffs also should be inflated continuously in patients on mechanical ventilation or continuous positive airway pressure (CPAP).
3. Tracheostomized patients who are breathing spontaneously may have the cuff inflated continuously (in the patient with decreased LOC without ability to fully protect airway), deflated continuously, or inflated only for feeding if the patient is at risk of aspiration.
4. Monitor cuff pressure every 4 hours.

External Tube Site Care

1. Secure an ET tube so it cannot be disrupted by the weight of ventilator or oxygen tubing or by patient movement.
   a. Use strips of adhesive tape or Velcro straps wrapped around the tube and secured to tape on patient's cheeks or around the back of patient's head.
   b. Replace when soiled or insecure or when repositioning of tube is necessary.
   c. Position tubing so traction is not applied to ET tube.
2. Perform tracheostomy site care at least every 8 hours using 0.9%NS, and change tracheostomy ties when soiled and according to facility policy.
   a. Make sure ventilator or oxygen tubing is supported so traction is not applied to the tracheostomy tube.
3. Have available at all times at the patient's bedside a replacement ET tube in the same size as patient is using, resuscitation bag, oxygen source, and mask to ventilate the patient in the event of accidental tube removal. Anticipate your course of action in such an event.
   a. ET tube—know location and assembly of reintubation equipment including replacement ET tube. Know how to contact someone immediately for reintubation.
   b. Tracheostomy—have extra tracheostomy tube, obturator, and hemostats at bedside. Be aware of reinsertion technique, if facility policy permits, or know how to contact someone immediately for reinserting the tube.

NURSING ALERT In the event of accidental ET or tracheostomy tube removal, use a bag/mask resuscitation device to ventilate the patient by mouth while covering tracheostomy stoma. However, if the patient has complete upper airway obstruction, a gaping stoma, or a laryngectomy, mouth-to-stoma ventilation must be performed.

Psychologic Considerations

1. Assist patient to deal with psychological aspects related to artificial airway.
2. Recognize that patient is usually apprehensive, particularly about choking, inability to communicate verbally, inability to remove secretions, uncomfortable suctioning, difficulty in breathing, or mechanical failure.
3. Explain the function of the equipment carefully.
4. Inform patient and family that speaking will not be possible while the tube is in place, unless using a tracheostomy tube with a deflated cuff, a fenestrated tube, a Passy-Muir speaking valve, or a speaking tracheostomy tube.
   a. A Passy-Muir valve is a speaking valve that fits over the end of the tracheostomy tube. Air that is inhaled is exhaled through the vocal cords and out through the mouth, allowing speech.
5. Develop with patient the best method of communication (eg, sign language, lip reading [alphabet,

picture, writing boards]).

a. Patients with tracheostomy tubes or nasal ET tubes may effectively use orally operated electrolarynx devices.

b. Devise a means for patient to get the nurse's attention when someone is not immediately available at the bedside, such as call bell, soft-touch call bell hand-operated bell, or rattle.

6. Anticipate some of patient's questions by discussing "Is it permanent?" "Will it hurt to breathe?" "Will someone be with me?"

7. If appropriate, advise patient that as condition improves, a tracheostomy button may be used to plug the tracheostomy site. A tracheostomy button is a rigid, closed cannula that is placed into the tracheostomy stoma after removal of a cuffed or uncuffed tracheostomy tube. When in proper position, the button does not extend into the tracheal lumen. The outer edge of the button is at the skin surface and the inner edge is at the anterior tracheal wall.

NURSING ALERT With the use of artificial airways, remember the patient may use a call bell, but he or she will not be able to communicate verbally (unless device is used to allow speech).

Community and Home Care Considerations

1. Teach patient and/or caregiver procedure. Patient will need to use stationary mirror to visualize tracheostomy and perform procedure.
2. Suctioning patient in the home: whenever possible, patient and/or caregiver should be taught to perform procedure. Patient should use controlled cough and other secretion-clearance techniques.
3. Preoxygenation and hyperinflation before suctioning may not be routinely indicated for all patients cared for in the home. Preoxygenation and hyperinflation are based on patient need and clinical status.
4. Normal saline should not be instilled unless clinically indicated (eg, to stimulate cough).
5. Clean technique and clean examination gloves are used. At the end of suctioning, the catheter or tonsil tip should be flushed by suctioning recently boiled and cooled, or distilled, water to rinse away mucus, followed by suctioning air through the apparatus. The outer surface may be wiped with alcohol or hydrogen peroxide. The catheter and tonsil tip should be air-dried and stored in a clean, dry place. Generally, suction catheters should be discarded after 24 hours. Tonsil tips may be boiled and reused.
6. Care of tracheostomy stoma: clean with half-strength hydrogen peroxide (diluted with sterile water) and wipe with sterile water or sterile saline.

Mobilization of Secretions

The goal of airway clearance techniques is to improve clearance of airway secretions, thereby decreasing obstruction of the airways. This serves to improve ventilation and gas exchange. Patients with respiratory disorders, neuromuscular disorders, or CNS disorders, such as loss of consciousness that may impair respiratory function, typically require help with mobilization and removal of secretions. Increased amount and viscosity of secretions and/or inability to clear secretions through the normal cough mechanism may lead to pooling of secretions in lower airways. Pooling of secretions leads to infection and inadequate gas exchange. Secretions should be removed by coughing or, when necessary, by suctioning. However, routine suctioning should be avoided. Auscultation and visual inspection of the patient should be used to determine the need for suctioning. Secretions can be mobilized through the chest physical therapy measures of postural drainage, directed cough, positive expiratory pressure (PEP), high-frequency oscillation (oral devices such as Flutter or Acapella device, or chest devices such as the Vest) mucus clearance devices, autogenic drainage, intrapulmonary vibration, percussion and vibration, and other secretion-clearance measures.

Nasotracheal Suctioning

1. Intended to remove accumulated secretions or other materials that cannot be moved by the patient's spontaneous cough or less-invasive procedures. Suctioning of the tracheobronchial tree in a patient without an artificial airway can be accomplished by inserting a sterile suction catheter lubricated with water-soluble jelly through the nares into the nasal passage, down through the oropharynx, past the glottis, and into the trachea.
2. NT suction is a blind, high-risk procedure with uncertain outcome. Complications include mechanical trauma, hypoxia, dysrhythmias, bradycardia, increased BP, vomiting, increased ICP, and misdirection of catheter.
3. Contraindications include:
    a. Bleeding disorders, such as disseminated intravascular coagulation, thrombocytopenia, leukemia.
    b. Laryngeal edema, laryngeal spasm.
    c. Esophageal varices.
    d. Tracheal surgery.
    e. Gastric surgery with high anastomosis.
    f. Myocardial infarction.
    g. Occluded nasal passages or nasal bleeding.
    h. Epiglottitis.
    i. Head, facial, or neck injury.
4. May cause trauma to the nasal passages.
    a. Do not attempt to force the catheter if resistance is met.
    b. Report if significant bleeding occurs.
5. Insert a nasal airway if repeated suctioning is necessary to protect the nasal passages from trauma.

6. Be alert for signs of laryngeal edema because of irritation and trauma.
    a. Stop if suctioning becomes difficult or if the patient develops new upper airway noise or obstruction.
    b. Duration of the suctioning should be limited to less than 15 seconds.

NURSING ALERT NT suctioning should not be routinely performed. Only indicated when other methods to remove secretions from airway have failed.

Suctioning Through an Endotracheal or Tracheostomy Tube

1. Ineffective coughing may cause secretion collection in the artificial airway or tracheobronchial tree, resulting in narrowing of the airway, respiratory insufficiency, and stasis of secretions.
2. Assess the need for suctioning at least every 2 hours through auscultation of the chest.
3. Ventilation with a manual resuscitation bag will facilitate auscultation and may stimulate coughing, decreasing the need for suctioning.
4. Maintain sterile technique while suctioning.
5. Administer supplemental 100% oxygen through the mechanical ventilator or manual resuscitation bag before, after, and between suctioning passes to prevent hypoxemia.
6. Closed-system suctioning may be done with the suction catheter contained in the mechanical ventilator tubing. Ventilator disconnection is not necessary so positive end-expiratory pressure (PEEP) is maintained, sterility is maintained, risk of exposure to body fluids is eliminated, and time is saved. However, studies have not demonstrated that closed-system suctioning is more effective when compared to open suctioning in actually removing secretions.

Community and Home Care Considerations

1. Encourage patient to use directed cough or other airway clearance technique prior to suctioning. Auscultate the lungs to assess need for suctioning.
2. Teach caregivers to suction in the home situation using a clean technique, rather than sterile. Wash hands well before suctioning.
3. Put on fresh examination gloves for suctioning, and reuse catheter after rinsing it in warm water.
4. Be aware that appropriate and aggressive airway clearance will assist in preventing pulmonary complications, thus lessening the need for hospitalization.
5. Hazards and complications are the same for the home care patient as they are for a hospitalized patient.

Chest Physical Therapy

EVIDENCE BASE Pathmanathan, N., Beaumont, N., & Gratrix, A. (2015). Respiratory

physiotherapy in the critical care unit. *British Journal of Anesthesia*, *15*(1), 20–25.Strickland, S. L., Rubin, B. K., Drescher, G. S., et al. (2013). AARC clinical practice guideline: Effectiveness of nonpharmacologic airway clearance therapies in hospitalized patients. *Respiratory Care*, *58*(12), 2187–2193.

Breathing Exercises

1. Techniques used to compensate for respiratory deficits and conserve energy by increasing efficiency of breathing. Have patient breathe in through the nose and out through the mouth at a ratio of 1:2.
2. The overall purposes for doing breathing exercises are:
   a. To relax muscles, relieve anxiety, and improve control of breathing.
   b. To eliminate useless, uncoordinated patterns of respiratory muscle activity.
   c. To slow the respiratory rate.
   d. To decrease the work of breathing.
   e. To improve efficiency and strength of respiratory muscles.
   f. To improve ventilation and oxygen saturation during exercise.
3. Diaphragmatic abdominal breathing is used primarily to strengthen the diaphragm, which is the main muscle of respiration. It also aids in decreasing the use of accessory muscles and allows for better control over the breathing pattern, especially during stressful situations and increased physical demands.
4. Pursed-lip breathing is used primarily to slow the respiratory rate and assist in emptying the lungs of retained CO_2. This technique is always helpful to patients, but especially when they feel extreme dyspnea because of exertion.
5. Breathing exercises are most helpful to patients when practiced and used on a regular basis.

NURSING ALERT For patients with severe COPD, evidence does not support the use of diaphragmatic breathing because this type of breathing may result in hyperinflation as a result of increased dyspnea and fatigue.

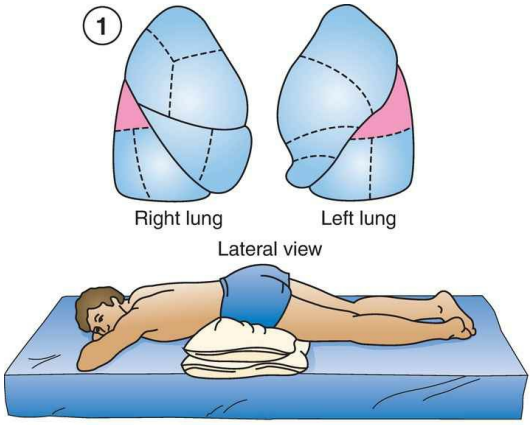
Percussion and Vibration

1. Postural drainage uses gravity and, possibly, external manipulation of the thorax to improve mobilization of bronchial secretions, to enhance matching of ventilation and perfusion, and to normalize functional residual capacity.
2. Indicated for difficulty with secretion clearance, evidence of retained secretions, and lung conditions that cause increased production of secretions such as bronchiectasis, cystic fibrosis, chronic bronchitis, and emphysema.
3. Contraindicated in undrained lung abscess, lung tumors, pneumothorax, diseases of the chest wall, lung hemorrhage, painful chest conditions, tuberculosis, severe osteoporosis, increased ICP, uncontrolled hypertension, and gross hemoptysis.

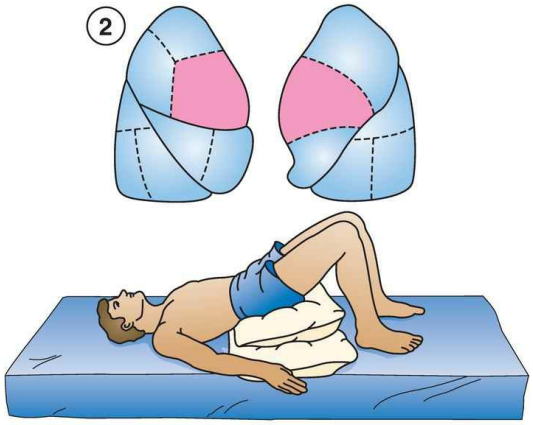
4. Percussion is movement done by "clapping" the chest wall in a rhythmic fashion with cupped hands or a mechanical device directly over the lung segments to be drained. The wrists are alternately flexed and extended so the chest is cupped or clapped in a painless manner. A mechanical percussor may be used to prevent repetitive motion injury. Research is mixed on the benefit of this technique.
5. Vibration is the technique of applying manual compression with oscillations or tremors to the chest wall during the exhalation phase of respiration. Research is mixed on the benefit of this technique.

Postural Drainage

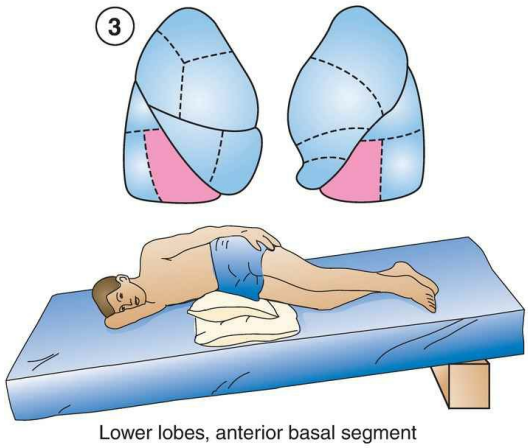
1. Gravity-assisted positions, deep breathing, chest clapping, shaking or vibration to assist in the removal of bronchial secretions from affected lung segments to central airways (see Figure 10-6).
2. The patient is positioned so the diseased areas are in a near vertical position, and gravity is used to assist drainage of the specific segments.
3. The positions assumed are determined by the location, severity, and duration of mucus obstruction.
4. The exercises are usually performed two to four times daily, before meals and at bedtime. Each position is held for 3 to 15 minutes.
5. The procedure should be discontinued if tachycardia, palpitations, dyspnea, or chest pain occurs. These symptoms may indicate hypoxemia. Discontinue if hemoptysis occurs.
6. Contraindications include increased ICP, unstable head or neck injury, active hemorrhage with hemodynamic instability or gross hemoptysis, recent spinal surgery or injury, empyema, bronchopleural fistula, rib fracture, flail chest, and uncontrolled hypertension.
7. Bronchodilators, mucolytic agents, water, or saline may be nebulized and inhaled, or an inhaled bronchodilator may be used before postural drainage and chest percussion to reduce bronchospasm, decrease thickness of mucus and sputum, and combat edema of the bronchial walls, thereby enhancing secretion removal.
8. Perform secretion-clearance procedures before eating or a minimum of 1 hour after eating.
9. Make sure patient is comfortable before the procedure starts and as comfortable as possible while he or she assumes each position.
10. Auscultate the chest to determine the areas of needed drainage.
11. Encourage the patient to deep-breathe and cough after spending the allotted time in each position (normally 3 to 15 minutes).
12. Encourage diaphragmatic breathing throughout postural drainage; this helps widen airways so secretions can be drained.



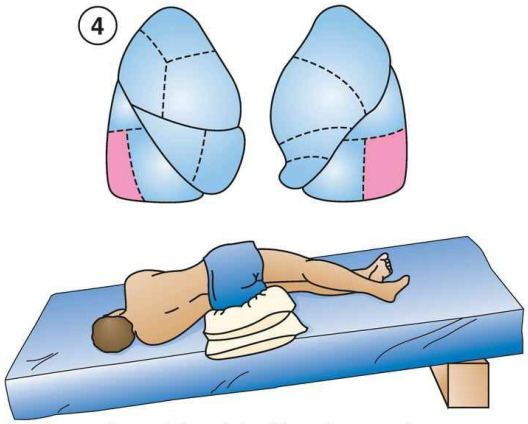
Lower lobes, superior segments



Upper lobes, anterior segment



Lower lobes, anterior basal segment



Lower lobes, lateral basal segment

Figure 10-6. Postural drainage positions. Anatomic segments of the lung with four postural drainage positions. The numbers relate the position to the corresponding anatomic segment of the lung. (Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

NURSING ALERT Postural drainage and chest percussion may result in hypoxia and should only be used if secretions are believed to be present.

Forced Expiratory Technique

1. Used to enhance effects of a spontaneous cough and compensate for physical limitations. Used for secretion clearance, atelectasis, prophylaxis against postoperative pulmonary complications, routine bronchial hygiene for cystic fibrosis, bronchiectasis, and chronic bronchitis and to obtain sputum specimen for diagnostic analysis.
2. Procedure includes a forced expiratory technique of two to three "huffs" (forced expirations), from mid- to low-lung volume, with glottis open, followed by a period of relaxed, controlled diaphragmatic breathing. Explain to the patient that to huff cough is the same maneuver that fogs eyeglasses. The forced expiration can be augmented by brisk adduction of the upper arms to self-compress the thorax.
3. Contraindications include increased ICP or known intracranial aneurysm, as well as acute or unstable head, neck, or spinal injury.

Manually Assisted Cough

The external application of mechanical pressure to the epigastric region coordinated with forced exhalation. This procedure may improve cough efficiency in those individuals with neuromuscular weakness or structural defects of the abdominal wall.

Positive Expiratory Pressure

1. Positive back pressure is created in the airways when the patient breathes in and out 5 to 20 times through a flow resistor or fixed orifice device.
2. During prolonged exhalation against positive pressure, peripheral airways are stabilized while air is pushed through collateral pathways (pores of Kohn and canals of Lambert) into distal lung units past retained secretions.
3. Expiratory airflow moves secretions to larger airways to be removed by coughing.
4. The pressure generated can be monitored and adjusted with a manometer (usually ranges from 10 to 20 cm H_2O).
5. Active exhalation with an inspiratory-to-expiratory (I:E) ratio of 1:3 or 1:4 is suggested.
6. The cycle is repeated until secretions are expelled, usually within 20 minutes or less if patient tires.

Autogenic Drainage

1. Controlled breathing used at three lung volumes, beginning at low-lung volume to unstick mucus, moving to midlung volume to collect mucus, and then to high-lung volume to expel mucus.
2. This method may be difficult for some patients to learn and to perform independently.
3. Can be performed in a seated position.

Flutter Mucus Clearance Device

1. Provides PEP and high-frequency oscillations at the airway opening. Provides approximately 10 cm H_2O positive airway pressure.
2. The flutter valve is a pipe-shaped device with an inner cone and bowl loosely supporting a steel ball. The bowl containing the steel ball is covered by a perforated cap.
3. Indications include atelectasis, bronchitis, bronchiectasis, cystic fibrosis, and other conditions producing retained secretions.
4. Mucus clearance is based on:
   a. Vibration of the airways, which loosens mucus from airway walls.
   b. Intermittent increase in endobronchial pressure that keeps airways open.
   c. Acceleration of expiratory airflow to facilitate upward movement of mucus.
5. Contraindications include pneumothorax and right-sided heart failure.
6. Directions:
   a. Patient should be seated upright with chin tilted slightly upward to further open airway.
   b. Instruct patient to inhale slowly to three fourths of normal breath.
   c. Place flutter in mouth with lips firmly sealed around stem or mouthpiece.
   d. Position flutter at horizontal level or raise bulb end up to 30 degrees for greater force.
   e. Instruct patient to hold breath for 2 to 3 seconds.
   f. Exhale through flutter at moderately fast rate, keeping cheeks stiff. Urge to cough should be suppressed.
   g. Repeat for 5 to 10 more breaths.
7. Have patient perform same technique with one to two forced exhalations to generate mucus elimination and huff coughs as needed.
8. Generally used for 10 to 20 breaths with device followed by several directed coughs, repeating series four to six times or for 10 to 20 minutes up to four times daily.
9. Clean flutter device every other day by disassembling and using a liquid soap and tap water. Disinfect regularly by soaking cleaned disassembled parts in one part alcohol to three parts tap water for 1 minute; rinse, wipe, reassemble, and store.

Acapella Vibratory Positive Expiratory Pressure Device

1. Enhances movement of secretions to larger airways, prevents collapse of airways, and facilitates filling of collapsed alveoli.

2. Airway vibration provides percussive effect, disengages mucus from airway walls, causes pulsation of mucus toward larger airways, and reduces viscoelasticity of mucus.
3. Select color-coded device: green for expiratory flow ≥15 L/minute, blue for less than 15 L/minute.
4. Place mask tightly and comfortably over patient's mouth and nose (or seal lips tight around mouthpiece if mask not used). Patient may sit, stand, or recline.
5. Instruct patient to perform diaphragmatic breathing, inhale to near-total lung volume, and exhale actively but not forcefully through device fully. Set resistance to achieve I:E ratio of 1:3 to 1:4. Use inline manometer to select expiratory pressure of 10 to 20 cm H_2O.
6. Use every 1 to 6 hours, according to response.
7. Assessment: improving breath sounds, patient's report of improved dyspnea, improved chest x-ray, improved oxygenation.
8. Acapella Choice can be disassembled for cleaning in dishwasher, boiled, or autoclaved.

AeroPEP Valved Holding Chamber

1. Combines aerosol therapy from a metered-dose inhaler with a fixed orifice resister PEP therapy.
2. Place disposable mouthpiece over AeroPEP mouthpiece and attach manometer. Instruct patient to seal lips tightly around mouthpiece.
3. Although performing diaphragmatic breathing, inhale fully.
4. Exhale actively and fully to achieve PEP of 10 to 20 cm H_2O. Set AeroPEP between 0 and 6 at desired pressure on manometer.
5. Repeat for up to 20 minutes four times daily or as clinically indicated.

Intrapulmonary Percussive Ventilation or Percussionaire

1. Therapy is delivered by a percussionator, which delivers minibursts of air into the lungs at a rate of 100 to 300 per minute. Process includes delivery of a dense aerosol mist through a mouthpiece. The treatment lasts about 20 minutes.
2. Patient uses in sitting or recumbent position.
3. Instill nebulizer bowl with 20 mL of saline or aqueous water and prescribed bronchodilator.
4. Clinician or patient programs percussive cycle by holding down a button for 5 to 10 seconds for percussive inspiratory cycle and releasing to expectorate or pause during therapy.
5. Seal lips around mouthpiece with "pucker" to minimize cheek flapping.
6. Observe chest for percussive shaking.
7. Use twice daily for approximately 20 minutes with increased frequency as needed.

Mechanical Insufflation–Exsufflation

1. Assists in secretion clearance by applying positive pressure to the airway and then rapidly shifting to negative pressure by way of a face mask, mouthpiece, ET tube, or tracheostomy tube to increase cough effectiveness.

2. Used in patients with impaired cough who are unable to clear secretions.

Electrical Stimulation of the Expiratory Muscles

Electrical stimulation of the abdominal muscles to increase cough effectiveness. An advantage is that presence of a caregiver is not required.

The Vest Airway Clearance System

1. Enhances secretion clearance through high-frequency chest wall oscillation. High-frequency compression pulses are applied to the chest wall by way of an air pulse delivery system and inflatable vest.
2. Variable-frequency large-volume air pulse delivery system attached to inflatable vest. Pressure pulses that fill the vest and vibrate the chest wall are controlled by a foot pedal. Pulse frequency ranges from 5 to 25 Hz and pressure in the vest ranges from 28 to 39 mm Hg.
3. A foot or hand control starts and stops pulsations.
4. Treatment length usually 10 to 30 minutes. Therapy should include a break at least every 10 minutes for directed cough. Use twice daily, with increased frequency as needed.

Community and Home Care Considerations

1. Nebulizer tubing and mouthpiece can be reused at home repeatedly. Recommend thorough rinsing with warm water after each use, shake off excess water, and let air-dry.
2. Twice-weekly cleaning should include washing with liquid soap and hot water, followed by 30-minute soak in one part white vinegar and two parts tap water, and then rinsing with tap water, air-drying, and storing in a clean, dry place.

Administering Oxygen Therapy

EVIDENCE BASE Singh, L. T., Sharara, R., Leap, J., & Singh, A. (2016). Management of respiratory failure. *Critical Care Nursing Quarterly*, 39(2), 94–109.

Oxygen is an odorless, tasteless, colorless, transparent gas that is slightly heavier than air. It is used to treat or prevent symptoms and manifestations of hypoxia. Oxygen can be dispensed from a cylinder, piped-in system, liquid oxygen reservoir, or oxygen concentrator. It may be administered by nasal cannula, transtracheal catheter, nasal cannula with reservoir devices, or various types of face masks, including CPAP mask. It may also be applied directly to the ET or tracheal tube by way of a mechanical ventilator, T-piece, or manual resuscitation bag. The method selected depends on the required concentration of oxygen, desired variability in delivered oxygen concentration (none, minimal, moderate), and required ventilatory assistance (mechanical ventilator, spontaneous breathing).

Methods of Oxygen Administration

1. Nasal cannula—nasal prongs that deliver low or high flow of oxygen.
   a. Requires nose breathing.
   b. Cannot deliver oxygen concentrations much higher than 40%.
2. Simple face mask—mask that delivers moderate oxygen flow to nose and mouth. Delivers oxygen concentrations of 40% to 60%.
3. Venturi mask—mask with device that mixes air and oxygen to deliver constant oxygen concentration.
   a. Total gas flow at the patient's face must meet or exceed peak inspiratory flow rate. When other mask outputs do not meet inspiratory flow rate of patient, room air (drawn through mask side holes) mixes with the gas mixture provided by the face mask, lowering the inspired oxygen concentration.
   b. Venturi mask mixes a fixed flow of oxygen with a high but variable flow of air to produce a constant oxygen concentration. Oxygen enters by way of a jet (restricted opening) at a high velocity. Room air also enters and mixes with oxygen at this site. The higher the velocity (smaller the opening), the more room air is drawn into the mask.
   c. Mask output ranges from approximately 30% to 50% oxygen.
   d. Virtually eliminates rebreathing of CO_2. Excess gas leaves through openings in the mask, carrying with it the expired CO_2.
4. Partial rebreather mask—has an inflatable bag that stores 100% oxygen.
   a. On inspiration, the patient inhales from the mask and bag; on expiration, the bag refills with oxygen and expired gases exit through perforations on both sides of the mask and some enters bag (see Figure 10-7A).
   b. High concentrations of oxygen (50% to 75%) can be delivered.

c. Often used to conserve oxygen supply during patient transport.

5. Nonrebreathing mask (see Figure 10-7B)—has an inflatable bag to store 100% oxygen and a one-way valve between the bag and mask to prevent exhaled air from entering the bag.
   a. Has one-way valves covering one or both of the exhalation ports to prevent entry of room air on inspiration.
   b. Has a flap or spring-loaded valves to permit entry of room air should the oxygen source fail or patient needs exceed the available oxygen flow.
   c. Optimally, all the patient's inspiratory volume will be provided by the mask/reservoir, allowing delivery of nearly 100% oxygen.
6. Transtracheal catheter—accomplished by way of a small (8 French) catheter inserted between the second and third tracheal cartilage.
   a. Does not interfere with talking, drinking, or eating and can be concealed under a shirt or blouse.
   b. Oxygen delivery is more efficient because all oxygen enters the lungs.
   c. Requires surgical procedure with temporary stent until tract is healed.
7. Continuous Positive Airway Pressure mask—used to provide expiratory and inspiratory positive airway pressure in a manner similar to PEEP and does not require ET intubation.
   a. Has an inflatable cushion and head strap designed to tightly seal the mask against the face. See Figure 10-8.
   b. A PEEP valve is incorporated into the exhalation port to maintain positive pressure on exhalation.
   c. High inspiratory flow rates are needed to maintain positive pressure on inspiration.
8. Bilevel positive airway pressure (BiPAP) mask—a combination of inspiratory and expiratory pulmonary artery pressure (PAP) often used to avoid intubation and mechanical ventilation.
   a. Preset pressure to be delivered during inspiration and preset pressure to be maintained during expiration.
   b. Mask with airtight seal is used, similar to CPAP.
9. T-piece (Briggs) adapter—used to administer oxygen to patient with ET or tracheostomy tube who is breathing spontaneously.
   a. High concentration of aerosol and oxygen delivered through wide-bore tubing.
   b. Expired gases exit through open reservoir tubing.
10. Manual resuscitation bag—delivers high concentration of oxygen to patient with insufficient inspiratory effort.
    a. With mask, uses upper airway by delivering oxygen to mouth and nose of patient.
    b. Without mask, adapter fits on ET or tracheostomy tube.
    c. Usually used in cardiopulmonary arrest, hyperinflation during suctioning, or transport of ventilator-dependent patients.

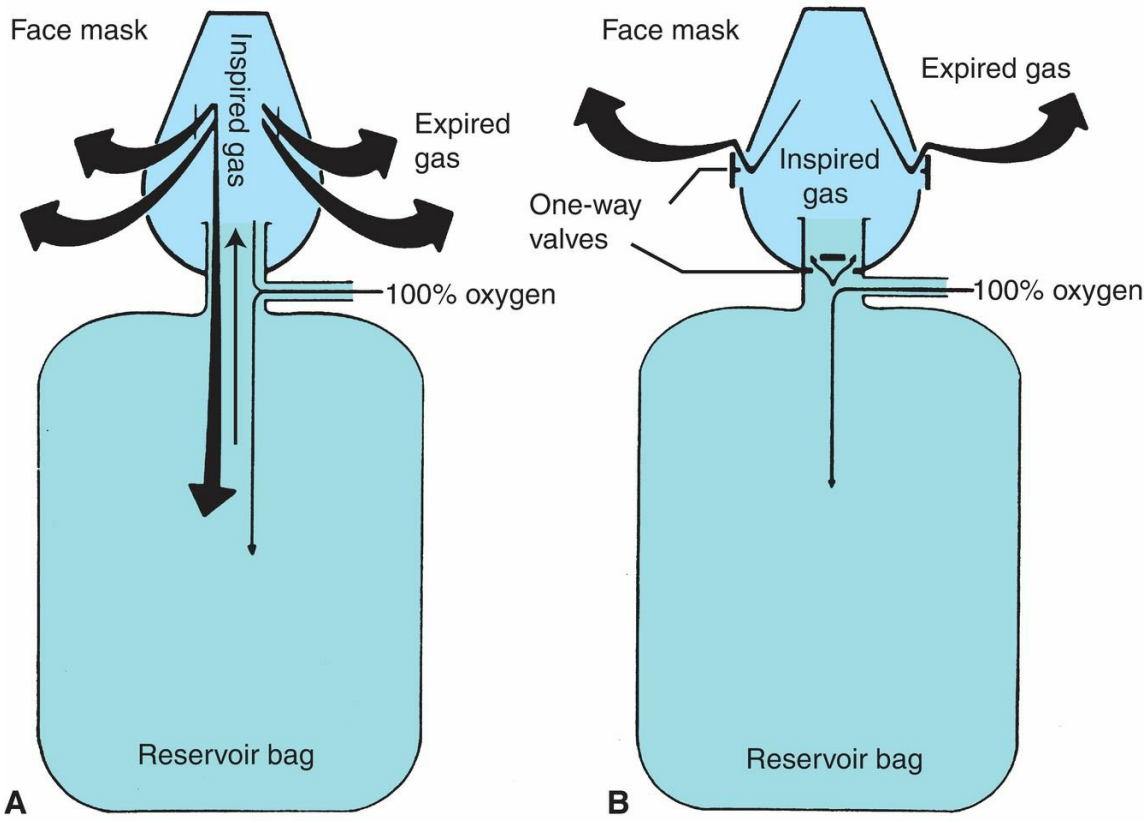


Figure 10-7. (A) Airflow diagram with partial rebreathing mask. **(B)** Airflow diagram with nonrebreathing mask. *Arrows* indicate direction of flow.

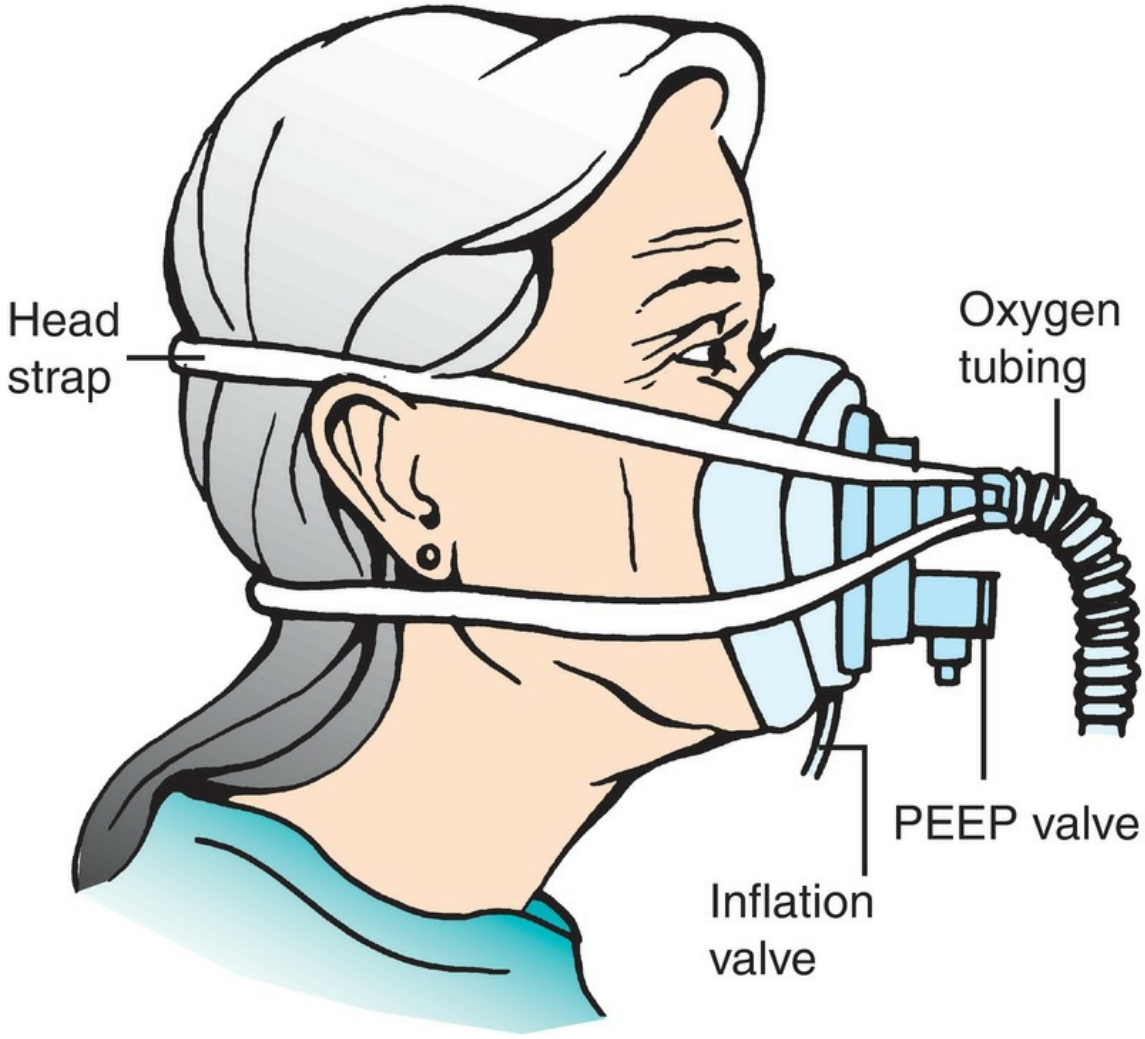

Figure 10-8. CPAP mask with airtight seal.

Nursing Assessment and Interventions

1. Assess need for oxygen by observing for symptoms of hypoxia:
   a. Tachypnea.
   b. SaO_2 less than 88%.
   c. Tachycardia or dysrhythmias (premature ventricular contractions).
   d. A change in LOC (symptoms of decreased cerebral oxygenation are irritability, confusion, lethargy, and coma, if untreated).
   e. Cyanosis occurs as a late sign ($PaO_2 \leq 45$ mm Hg).
   f. Labored respirations indicate severe respiratory distress.
   g. Myocardial stress—increase in heart rate and stroke volume (cardiac output) is the primary mechanism for compensation for hypoxemia or hypoxia; pupils dilate with hypoxia.
2. Obtain ABG values and assess the patient's current oxygenation, ventilation, and acid–base status.
3. Administer oxygen in the appropriate concentration and device.

Low concentration (24% to 28%)—may be appropriate for patients prone to retain CO_2 (COPD,

a. drug overdose), who are dependent on hypoxemia (hypoxic drive) to maintain respiration. If hypoxemia is suddenly reversed, hypoxic drive may be lost and respiratory depression and, possibly, respiratory arrest may occur. Monitor $PaCO_2$ levels.

b. High concentration (≥30%)—appropriate in patients not predisposed to CO_2 retention.

c. Ensure proper use and fit of oxygen delivery device-cannula or mask, with oxygen flow rate according to manufacturer's instructions.

4. Monitor response by oximetry and/or ABG sampling.
5. Increase or decrease the inspired oxygen concentration, as appropriate.

NURSING ALERT Success of any PAP device depends on patient compliance, which can be improved by proper education, proper mask fit, and frequent follow-up care.

NURSING ALERT All Joint Commission–accredited hospitals must be smoke free; however, other facilities and homes where oxygen is used may allow smoking. Make sure that no smoking is permitted where oxygen is used.

Community and Home Care Considerations

1. Indications for supplemental oxygen based on Medicare reimbursement guidelines:
   a. Documented hypoxemia: In adults: PaO_2 = 55 torr or SaO_2 ≤ 88% when breathing room air, or PaO_2 56 to 59 torr or SaO_2 ≤ 89% in association with cor pulmonale, heart failure, or polycythemia with hematocrit greater than 56%.
   b. Some patients may not qualify for oxygen therapy at rest but will qualify for oxygen during ambulation, exercise, or sleep. Oxygen therapy is indicated during these specific activities when SaO_2 is demonstrated to fall to ≤88%.
   c. Determine oxygen prescription for rest, exercise, and sleep, and instruct patient and caregiver to follow these flow rates.
2. Precautions in the home:
   a. In COPD with presence of CO_2 retention (generally because of chronic hypoxemia), oxygen administration at higher levels may lead to increased $PaCO_2$ level and decreased respiratory drive.
   b. Fire hazard is increased in presence of higher than normal oxygen concentrations. Instruct patient and caregiver of home oxygen precautions:
      i. Post no smoking signs. Instruct on avoidance of cigarettes within 6 feet of oxygen.
      ii. Avoid potential electrical sparks around oxygen (shave with blade razor instead of electric razor;

keep away from heat sources).

iii. Keep oxygen at least 6 feet (1.8 m) from any source of flame.

c. Power failure may lead to inadequate oxygen supply when an oxygen concentrator is used without backup tank.

d. Oxygen tanks must be secured in stand to prevent falling over.

e. Improper use of liquid oxygen (touching liquid) may result in burns.

3. Oxygen delivered by way of tracheostomy collar or T tube should be humidified.
4. Oxygen concentrators extract oxygen from ambient air and should deliver oxygen at concentrations of 85% or greater at up to 4 L/minute.
5. Liquid oxygen is provided in large reservoir canisters with smaller portable units that can be transfilled by patient or caregiver. Liquid oxygen evaporates from canister when not in use.
6. Compressed gas may be supplied in large cylinders (G or H cylinders) or smaller cylinders (D or E cylinders) with wheels for easier movement.
7. All oxygen delivery equipment should be checked at least once daily by patient or caregiver, including function of equipment, prescribed flow rates, remaining liquid or compressed gas content, and backup supply.

Mechanical Ventilation

EVIDENCE BASE Singh, L. T., Sharara, R., Leap, J., & Singh, A. (2016). Management of respiratory failure. *Critical Care Nursing Quarterly*, *39*(2), 94–109.

Burns, S. (2014). *AACN critical care nursing* (3rd ed.). New York, NY: McGraw-Hill.

The mechanical ventilator device functions as a substitute for the bellows action of the thoracic cage and diaphragm. The mechanical ventilator can maintain ventilation automatically for prolonged periods. It is indicated when the patient is unable to maintain safe levels of oxygen or CO_2 by spontaneous breathing even with the assistance of other oxygen delivery devices.

Clinical Indications

Mechanical Failure of Ventilation

1. Neuromuscular disease.
2. CNS disease.
3. CNS depression (drug intoxication, respiratory depressants, cardiac arrest).
4. Inefficiency of thoracic cage in generating pressure gradients necessary for ventilation (chest injury, thoracic malformation).
5. When ventilatory support is needed postoperatively.

Disorders of Pulmonary Gas Exchange

1. Acute respiratory failure.
2. Chronic respiratory failure.
3. Left-sided heart failure.
4. Pulmonary diseases resulting in diffusion abnormality.
5. Pulmonary diseases resulting in V/Q mismatch.
6. Acute lung injury.

Underlying Principles

1. Variables that control ventilation and oxygenation include:
    a. Ventilator rate—adjusted by rate setting.
    b. V_T—volume of gas required for one breath (mL/kg).
    c. Fraction of inspired oxygen concentration (FiO_2)—set on ventilator and measured with an oxygen analyzer.
    d. Ventilator dead space—circuitry (tubing) common to inhalation and exhalation; tubing is calibrated.

e. PEEP—set within the ventilator or with the use of external PEEP devices; measured at the proximal airway.

2. CO_2 elimination is controlled by V_T, rate, and dead space.
3. Oxygen tension is controlled by oxygen concentration and PEEP (also by rate and V_T).
4. In most cases, the duration of inspiration should not exceed exhalation.
5. The inspired gas must be warmed and humidified to prevent thickening of secretions and decrease in body temperature. Sterile or distilled water is warmed and humidified by way of a heated humidifier.

Types of Ventilators

Negative Pressure Ventilators

1. Applies negative pressure around the chest wall. This causes intra-airway pressure to become negative, thus drawing air into the lungs through the patient's nose and mouth.
2. No artificial airway is necessary; patient must be able to control and protect own airway.
3. Indicated for selected patients with respiratory neuromuscular problems or as adjunct to weaning from positive pressure ventilation.
4. Examples are the iron lung and cuirass (shell unit) ventilator.

Positive Pressure Ventilators

During mechanical inspiration, air is actively delivered to the patient's lungs under positive pressure. Exhalation is passive. Requires use of a cuffed artificial airway.

1. Pressure cycled.
   a. Delivers selected gas pressure during inspiratory phase.
   b. Volume delivered depends on lung compliance and resistance.
   c. Use of volume-based alarms is recommended because any obstruction between the machine and lungs that allows a buildup of pressure in the ventilator circuitry will cause the ventilator to cycle, but the patient will receive no volume.
   d. Exhaled tidal volume is the variable to monitor closely.
2. Volume limited.
   a. Designated volume of air is delivered with each breath regardless of resistance and compliance. Usual starting volume is 6 to 8 mL/kg.
   b. Delivers the predetermined volume regardless of changing lung compliance (although airway pressures will increase as compliance decreases). Airway pressures vary from patient to patient and from breath to breath.
   c. Pressure-limiting valves, which prevent excessive pressure buildup within the patient-ventilator system, are used. Without this valve, pressure could increase indefinitely and pulmonary barotrauma could result. Usually equipped with a system that alarms when selected pressure limit is exceeded. Pressure-limited settings terminate inspiration when reached.

Modes of Operation

Controlled Ventilation

1. Patient receives a predetermined number and volume of breaths/minute.
2. Provides a fixed level of ventilation, but will not cycle or have gas available in circuitry to respond to patient's own inspiratory efforts. This typically increases work of breathing for patients attempting to breathe spontaneously.
3. Generally used for patients who are unable to initiate spontaneous breaths.

Assist/Control

1. Inspiratory cycle of ventilator is activated by the patient's voluntary inspiratory effort and delivers a preset full volume.
2. Ventilator also cycles at a rate predetermined by the operator. Should the patient not initiate a spontaneous breath, or breathe so weakly that the ventilator cannot function as an assistor, this mandatory baseline rate will provide a minimum respiratory rate.
3. Indicated for patients who are breathing spontaneously, but who have the potential to lose their respiratory drive or muscular control of ventilation. In this mode, the patient's work of breathing is greatly reduced.

Synchronized Intermittent Mandatory Ventilation (SIMV)

1. Allows patient to breathe at his or her own rate and volume spontaneously through the ventilator circuitry.
2. Periodically, at a preselected time, a mandatory breath is delivered. The ventilator delivers the mandatory breath in synchrony with the patient's inspiratory effort.
3. If no inspiratory effort is delivered, the ventilator will deliver a mandatory breath at a scheduled time.
4. Gas provided for spontaneous breathing flows continuously through the ventilator.
5. Ensures that a predetermined number of breaths at a selected V_T are delivered each minute.
6. Indicated for patients who are breathing spontaneously, but at a V_T and/or rate less than adequate for their needs. Allows the patient to do some of the work of breathing.

Pressure Support

1. Augments inspiration to a spontaneously breathing patient.
2. Maintains a set positive pressure during spontaneous inspiration.
3. The patient ventilates spontaneously, establishing own rate, V_T, and inspiratory time.
4. Pressure support may be used independently as a ventilatory mode or used in conjunction with CPAP or synchronized intermittent mandatory ventilation.

Positive Pressure Ventilation Techniques

Positive End-Expiratory Pressure

1. Maneuver by which pressure during mechanical ventilation is maintained above atmospheric at end of exhalation, resulting in an increased functional residual capacity. Airway pressure is therefore positive throughout the entire ventilatory cycle.
2. Purpose of PEEP is to increase functional residual capacity (or the amount of air left in the lungs at the end of expiration). This aids in:
    a. Increasing the surface area of gas exchange.
    b. Preventing collapse of alveolar units and development of atelectasis.
    c. Decreasing intrapulmonary shunt.
    d. Improving lung compliance.
    e. Improving oxygenation.
    f. Recruiting alveolar units that are totally or partially collapsed.
3. Benefits:
    a. Because a greater surface area for diffusion is available and shunting is reduced, it is often possible to use a lower FiO_2 than otherwise would be required to obtain adequate arterial oxygen levels. This reduces the risk of oxygen toxicity in conditions such as acute respiratory distress syndrome (ARDS).
    b. Positive intra-airway pressure may be helpful in reducing the transudation of fluid from the pulmonary capillaries in situations where capillary pressure is increased (ie, left-sided heart failure).
    c. Increased lung compliance resulting in decreased work of breathing.
4. Hazards:
    a. Because the intrathoracic pressure is increased by PEEP, venous return is impeded. This may result in:
        i. Decreased cardiac output and decreased oxygen delivery to the tissues (especially noted in hypovolemic patients).
        ii. Decreased renal perfusion.
        iii. Increased intracranial pressure.
        iv. Hepatic congestion.
    b. The decreased venous return may cause antidiuretic hormone formation to be stimulated, resulting in decreased urine output.
5. Precautions:
    a. Monitor frequently for signs and symptoms of respiratory distress—shortness of breath, dyspnea, tachycardia, chest pain.
    b. Monitor frequently for signs and symptoms of pneumothorax (increased PAP, increased size of hemothorax, uneven chest wall movement, hyperresonant percussion, distant or absent breath sounds).
    c. Monitor for signs of decreased venous return (decreased BP, decreased cardiac output, decreased urine output, peripheral edema).
    d. Abrupt discontinuance of PEEP is not recommended. The patient should not be without PEEP for

longer than 15 seconds. The manual resuscitation bag used for ventilation during suction procedure or patient transport should be equipped with a PEEP device. In-line suctioning may also be used so that PEEP can be maintained.

e. Intrapulmonary blood vessel pressure may increase with compression of the vessels by increased intra-airway pressure. Therefore, central venous pressure (CVP), PAP, and pulmonary capillary wedge pressure may be increased. The clinician must bear this in mind when determining the clinical significance of these pressures.

Continuous Positive Airway Pressure

1. Assists the spontaneously breathing patient to improve oxygenation by elevating the end-expiratory pressure in the lungs throughout the respiratory cycle.
2. May be delivered through ventilator circuitry when ventilator rate is at "0" or may be delivered through a separate CPAP circuitry that does not require the ventilator.
3. Indicated for patients who are capable of maintaining an adequate V_T, but who have pathology preventing maintenance of adequate levels of tissue oxygenation or for sleep apnea.
4. CPAP has the same benefits, hazards, and precautions noted with PEEP. Mean airway pressures may be lower because of lack of mechanical ventilation breaths. This results in less risk of barotrauma and impedance of venous return.

Newer Modes of Ventilation

Inverse Ratio Ventilation

1. I:E ratio is greater than 1, in which inspiration is longer than expiration.
2. Potentially used in patients who are in acute severe hypoxemic respiratory failure. Oxygenation is thought to be improved.
3. Very uncomfortable for patients; need to be heavily sedated.
4. Pressure-controlled inverse ratio ventilation—used in ARDS and acute lung injury.
5. Pressure-regulated volume control ventilator mode is a volume-targeted mode used in acute respiratory failure that combines the advantages of the decelerating inspiratory flow pattern of a pressure-control mode with the ease of use of a volume-control (VC) mode.

Airway Pressure Release Ventilation

1. Ventilator cycles between two different levels of CPAP.
2. The baseline airway pressure is the upper CPAP level and the pressure is intermittently released.
3. Uses a short expiratory time.
4. Used in severe ARDS/acute lung injury.

Noninvasive Positive Pressure Ventilation

1. Uses a nasal or face mask or nasal pillows. Delivers air through a volume- or pressure-controlled ventilator.

2. Used primarily in the past for patients with chronic respiratory failure associated with neuromuscular disease. Now is being used successfully during acute exacerbations. Some patients are able to avoid invasive intubation. Other indications include acute or chronic respiratory distress, acute pulmonary edema, pneumonia, COPD exacerbation, weaning, and postextubation respiratory decompensation.
3. Can be used in the home setting. Equipment is portable and relatively easy to use.
4. Eliminates the need for intubation; preserves normal swallowing, speech, and the cough mechanism.
5. May include BiPAP, which is essentially pressure support with CPAP. The system has a rate setting as well as inspiratory and expiratory pressure setting.

High-Frequency Ventilation

1. Uses very small V_T (dead space ventilation) and high frequency (rates greater than 100/minute).
2. Gas exchange occurs through various mechanisms, not the same as conventional ventilation (convection).
3. Types include:
   a. High-frequency oscillatory ventilation.
   b. High-frequency jet ventilation.
4. Theory is that there is decreased barotrauma by having small V_T and that oxygenation is improved by constant flow of gases.
5. Successful with infant respiratory distress syndrome, much less successful with adult pulmonary complications.

Nursing Assessment and Interventions

1. Monitor for complications:
   a. Airway aspiration, decreased clearance of secretions, ventilator-acquired pneumonia, tracheal damage, and laryngeal edema.
   b. Impaired gas exchange.
   c. Ineffective breathing pattern.
   d. ET tube kinking, cuff failure, mainstem intubation.
   e. Sinusitis.
   f. Pulmonary infection.
   g. Barotrauma (pneumothorax, tension pneumothorax, subcutaneous emphysema, pneumomediastinum).
   h. Decreased cardiac output.
   i. Atelectasis.
   j. Alteration in GI function (stress ulcers, gastric distention, paralytic ileus).
   k. Alteration in renal function.
   l. Alteration in cognitive–perceptual status.
2. Suction the patient as indicated.

a. When secretions can be seen or sounds resulting from secretions are heard with or without the use of a stethoscope.
   b. After chest physiotherapy.
   c. After bronchodilator treatments.
   d. Increased peak airway pressure in mechanically ventilated patients that is not due to the artificial airway or ventilator tube kinking, the patient biting the tube, the patient coughing or struggling against the ventilator, or a pneumothorax.
3. Provide routine care for patient on mechanical ventilator, including good oral care and repositioning to prevent ventilator-associated pneumonia. Provide humidity to help mobilize secretions.
4. Assist with the weaning process, when indicated (patient gradually assumes responsibility for regulating and performing own ventilations).
   a. Patient must have acceptable ABG values, no evidence of acute pulmonary pathology, and must be hemodynamically stable.
   b. Obtain serial ABGs and/or oximetry readings, as indicated.
   c. Monitor very closely for change in pulse and BP, anxiety, and increased rate of respirations.
   d. The patient is awake and cooperative and displays optimal respiratory drive.
5. Once weaning is successful, extubate and provide alternate means of oxygen.
6. Extubation will be considered when the pulmonary function parameters of V_T, VC, and negative inspiratory pressure are adequate, indicating strong respiratory muscle function.

Community and Home Care Considerations

Patients may require mechanical ventilation at home to replace or assist normal breathing. Ventilator support in the home is used to keep patient clinically stable and to maintain life.

1. Candidates for home ventilation are those patients who are unable to wean from mechanical ventilation and/or have disease progression requiring ventilator support. Candidates for home mechanical ventilator support:
   a. Have a secure artificial airway (tracheostomy tube).
   b. Have FiO_2 requirement ≤40%.
   c. Are medically stable.
   d. Are able to maintain adequate ventilation on standard ventilator settings.
2. Patients may choose not to receive home ventilation. Examples of inappropriate candidates for home ventilation include patients who:
   a. Have a FiO_2 ≥ 40%.
   b. Use PEEP greater than 10 cm H_2O.
   c. Require continuous invasive monitoring.
   d. Lack a mature tracheostomy.
   e. Lack able, willing, appropriate caregivers, and/or caregiver respite.

f. Lack adequate financial resources for care in home.

g. Lack adequate physical facilities:

   i. Inadequate heat, electricity, sanitation.

   ii. Presence of fire, health, or safety hazards.

3. For patients on mechanical ventilation in the home, a contract and relationship with a home medical equipment company and home nursing agency must be developed to provide:

   a. Care of ventilator-dependent patient.

   b. Provision and maintenance of equipment.

   c. Timely provision of disposable supplies.

   d. Ongoing monitoring of patient and equipment.

   e. Training of patient, caregivers, and clinical staff on proper management of ventilated patient and use and troubleshooting of equipment.

4. Equipment required:

   a. Appropriate ventilator with alarms (disconnect and high pressure).

   b. Power source.

   c. Humidification system.

   d. Manual resuscitation bag with tracheostomy adapter.

   e. Suction equipment.

   f. Replacement tracheostomy tubes.

   g. Supplemental oxygen, as medically indicated.

   h. Communication method for patient.

   i. Backup charged battery to run ventilator during power failures.

5. Lay caregiver training and return demonstration must include the following:

   a. Proper setup, use, troubleshooting, maintenance, and cleaning and infection control of equipment and supplies.

   b. Appropriate patient assessment and management of abnormalities, including cardiopulmonary resuscitation, response to emergencies, and power and equipment failure.

6. Potential complications include:

   a. Patient deterioration, decannulation, and need for emergency services.

   b. Equipment failure and malfunction.

   c. Psychosocial complications, including depression, anxiety, and/or loss of resources (caregiver, financial, detrimental change in family structure or coping capacity).

7. Communication is essential with local emergency medical services (fire, police, rescue) and utility (telephone, electric) companies from whom the patient would need immediate and additional assistance in event of emergency (eg, power failure, fire).

Thoracic Surgeries

Thoracic surgeries (see Table 10-2) are operative procedures performed to aid in the diagnosis and treatment of certain pulmonary conditions and when performing surgery that compromises the integrity of the thoracic cavity. Procedures include thoracotomy, video-assisted thoracoscopy, decortication, lung volume reduction surgery, lobectomy (see Figure 10-9, page 185), pneumonectomy, segmental resection, and wedge resection. These procedures may or may not require chest drainage immediately after surgery.

Table 10-2 Thoracic Surgery Types

TYPE	DESCRIPTION	INDICATIONS
Exploratory thoracotomy	*Internal view of lung* • Usually posterolateral parascapular but could be anterior incision • Chest tubes after procedure	May be used to confirm carcinoma or for chest trauma (to detect source of bleeding)
Lobectomy	*One-lobe removal* • Thoracotomy incision at site of lobe removal • Chest tubes after procedure	Used when pathology is limited to one area of lung: bronchogenic carcinoma, giant emphysematous blebs or bullae, benign tumors, metastatic malignant tumors, bronchiectasis, and fungal infections
Pneumonectomy	*Removal of an entire lung* • Posterolateral or anterolateral thoracotomy incision • Sometimes there is a rib resection • Normally no chest drains or tubes because fluid accumulation in empty space is desirable	Performed chiefly for carcinoma but may be used for lung abscesses, bronchiectasis, or extensive tuberculosis. *Note: Right lung is more vascular than left; may cause more physiologic problems if removed*
Segmentectomy (segmental resection)	• *Removal of one or more lung segments.* Segments function as individual units	Used when pathology is localized (such as in bronchiectasis) and when the patient has preexisting cardiopulmonary compromise
Wedge resection	*Removal of small, localized lesion that occupies only part of a segment.* • Incision made without regard to segments • Chest tubes after procedure	Performed for random lung biopsy and small peripheral nodules Considered when less invasive tests have failed to establish a diagnosis May be used as a therapeutic procedure
Thoracoscopy	*Direct visualization of pleura with thoracoscope via an intercostal incision* • Medical under sedation or local anesthesia; allows for visualization and biopsy • Video-assisted thoracoscopic surgery (VATS) under general anesthesia; multiple puncture sites and video screen allow for visualization and manipulation of the pleura, mediastinum, and lung parenchyma	VATS may be used for lung biopsy, lobectomy, resection of nodules, repair of fistulas
Decortication	*Removal or stripping of thick fibrous membrane from visceral pleura* • Use of chest tube drainage system postoperatively	Empyema unresponsive to conservative management
Thoracotomy not involving lungs	• Incision into the thoracic cavity for surgical procedures on other structures	Used for hiatal hernia repair, open-heart surgery, esophageal surgery, tracheal resection, aortic aneurysm repair
Lung volume reduction surgery (LVRS)	• Involves reducing lung volume by multiple wedge excisions or VATS	Performed in advanced bullous emphysema, α^1-antitrypsin emphysema

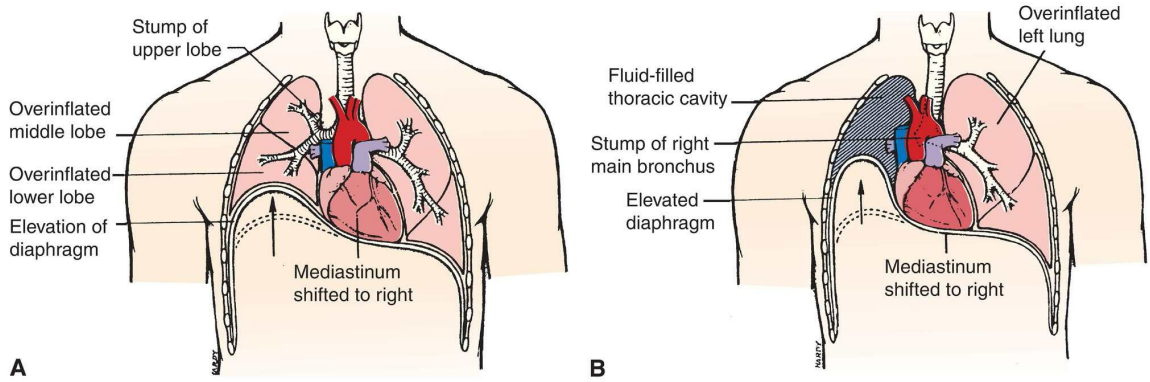

Figure 10-9. Operative procedures. **(A)** Lobectomy.**(B)**Pneumonectomy.

NURSING ALERT Meticulous attention must be given to the preoperative and postoperative care of patients undergoing thoracic surgery. These operations are wide in scope and represent a major stress on the cardiorespiratory system.

Preoperative Management

Goal is to maximize respiratory function to improve the outcome postoperatively and reduce risk of complications.

1. Encourage the patient to stop smoking to restore bronchial ciliary action and to reduce the amount of sputum, and likelihood of postoperative atelectasis, by decreasing secretions and increasing oxygen saturation.
2. Teach an effective coughing technique.
   a. Sit upright with knees flexed and body bending slightly forward (or lie on side with hips and knees flexed if unable to sit up).
   b. Splint the incision with hands or folded towel.
   c. Take three short breaths, followed by a deep inspiration, inhaling slowly and evenly through the nose.
   d. Contract abdominal muscles and cough twice forcefully with mouth open and tongue out.
   e. Alternate technique—huffing and coughing—is less painful. Take a deep diaphragmatic breath and exhale forcefully against hand; exhale in a quick, distinct pant, or "huff."
3. Humidify the air to loosen secretions.
4. Administer bronchodilators to reduce bronchospasm.
5. Administer antimicrobials for infection.
6. Encourage deep breathing with the use of incentive spirometer to prevent atelectasis postoperatively.
7. Teach diaphragmatic breathing.
8. Carry out chest physical therapy and postural drainage to reduce pooling of lung secretions (see page 176).

9. Evaluate cardiopulmonary status for risk and prevention of complication.
10. Encourage activity to improve exercise tolerance.
11. Diagnostic studies may include PFT, chest x-ray, ECG, ABGs, serum electrolytes, CBC, and coagulation studies.
12. Administer medications and limit sodium and fluid to improve heart failure, if indicated.
13. Correct anemia, dehydration, and hypoproteinemia with IV infusions, tube feedings, and blood transfusions as indicated.
14. Give prophylactic anticoagulant, as prescribed, to reduce perioperative incidence of deep vein thrombosis and pulmonary embolism.
15. Provide teaching and counseling.
    a. Orient the patient to events that will occur in the postoperative period—coughing and deep breathing, suctioning, chest tube and drainage system, oxygen therapy, ventilator therapy, pain control, leg exercises, and range-of-motion (ROM) exercises for affected shoulder.
16. Make sure that patient fully understands surgery and is emotionally prepared for it; verify that informed consent has been obtained.

Postoperative Management

1. Use mechanical ventilator and/or supplemental oxygen until respiratory function and cardiovascular status stabilize. Assist with weaning and extubation.
2. Auscultate chest, monitor vital signs, monitor ECG, and assess respiratory rate and depth frequently. Arterial line, CVP, and pulmonary artery catheter are usually used.
3. Monitor ABG values and/or SaO_2 frequently.
4. Monitor and manage chest drainage system to drain fluid, blood, clots, and air from the pleura after surgery (see page 188). Chest drainage is usually not used after pneumonectomy because it is desirable that the pleural space fills with an effusion, which eventually obliterates the space.

Complications

1. Hypoxia—assess for restlessness, tachycardia, tachypnea, and elevated BP.
2. Postoperative bleeding—monitor for restlessness, anxiety, pallor, tachycardia, and hypotension.
3. Pneumonia; atelectasis—monitor for fever, chest pain, dyspnea, changes in lung sounds on auscultation.
4. Bronchopleural fistula from disruption of a bronchial suture or staple; bronchial stump leak.
    a. Observe for sudden onset of respiratory distress or cough productive of serosanguineous fluid.
    b. Position with the operative side down.
    c. Prepare for immediate chest tube insertion and/or surgical intervention.
5. Cardiac dysrhythmias (usually occurring 3rd to 4th postoperative day); MI or heart failure.

Nursing Diagnoses

- Ineffective breathing pattern related to thoracic surgery.
- Risk for deficient fluid volume related to chest drainage and blood loss.
- Acute pain related to wound closure and presence of drainage tubes in the chest.
- Impaired physical mobility of affected shoulder and arm related to wound closure and the presence of drainage tubes in the chest.

Nursing Interventions

Maintaining Adequate Breathing Pattern

1. Monitor rate, rhythm, depth, and effort of respirations.
2. Auscultate chest for adequacy of air movement to detect bronchospasm, consolidation.
3. Monitor pulse oximetry and obtain ABG analysis and pulmonary function measurements as ordered.
4. Monitor LOC and inspiratory effort closely to begin weaning from ventilator as soon as possible.
5. Suction, as needed, using meticulous aseptic technique.
6. Elevate the head of the bed 30 to 40 degrees when patient is oriented and BP is stabilized to improve movement of diaphragm and alleviate dyspnea.
7. Encourage coughing and deep-breathing exercises and use of an incentive spirometer to prevent bronchospasm, retained secretions, atelectasis, and pneumonia.
8. Provide optimal pain relief to promote deep breathing, turning, and coughing.

NURSING ALERT Tracheobronchial secretions are present in excessive amounts in postthoracotomy patients because of trauma to the tracheobronchial tree during operation, diminished lung ventilation, and diminished cough reflex.

NURSING ALERT Look for changes in color and consistency of suctioned sputum. Colorless, fluid sputum is not unusual; opacification or coloring of sputum may mean dehydration or infection.

Stabilizing Hemodynamic Status

1. Evaluate BP, pulse, and respiration every 15 minutes or more frequently as indicated; extend the time intervals according to the patient's clinical status.
2. Monitor heart rate and rhythm by way of auscultation and continuous ECG because dysrhythmias are frequently seen following thoracic surgery.
3. Monitor CVP for prompt recognition of hypovolemia and for effectiveness of fluid replacement.
4. Monitor cardiac output and pulmonary artery systolic, diastolic, and wedge pressures. Watch for subtle changes, especially in the patient with underlying cardiovascular disease.

5. Assess chest tube drainage for amount and character of fluid.
    a. Chest drainage should progressively decrease after first 12 hours.
    b. Prepare for blood replacement and possible reoperation to achieve hemostasis if bleeding persists.
    c. Chest tube drainage in excess of 1,000 to 1,200 mL per 24-hour period should be reported to the health care provider for follow-up.
    d. Chest drainage greater than 200 mL in the first hour, development of subcutaneous emphysema, or any signs and symptoms of respiratory distress should be reported to the health care provider immediately.
6. Maintain intake and output record, including chest tube drainage.
7. Monitor infusions of blood and parenteral fluids closely because the patient is at risk for fluid overload if portion of pulmonary vascular system has been reduced.

Achieving Adequate Pain Control

1. Perform comprehensive pain assessment including onset, location, duration, characteristics, precipitating factors, and response to interventions.
2. Provide appropriate pain relief—pain limits chest excursions, thereby decreasing ventilation. Severity of pain varies with type of incision and with the patient's reaction to and ability to cope with pain. Usually, a posterolateral incision is the most painful.
3. Give opioids (usually by continuous IV infusion or by epidural catheter by way of patient-controlled analgesia pump) for pain relief, as prescribed, to permit patient to breathe more deeply and cough more effectively. To avoid respiratory and CNS depression, do not give too much opioid; patient should be alert enough to cough.
4. Assist with intercostal nerve block or cryoanalgesia (intercostal nerve freezing) for pain control as ordered.
5. Position for comfort and optimal ventilation (head of bed elevated 15 to 30 degrees); this also helps residual air to rise in upper portion of pleural space where it can be removed by the chest tube.
    a. Patients with limited respiratory reserve may not be able to turn on unoperated side because this may limit ventilation of the operated side.
    b. Vary the position from horizontal to semi-erect to prevent retention of secretions in the dependent portion of the lungs.
6. Encourage splinting of incision with pillow, folded towel, or hands, while turning, changing position, or coughing.
7. Teach relaxation (nonpharmacologic) techniques, such as progressive muscle relaxation and imagery, to help reduce pain.

NURSING ALERT Evaluate for signs of hypoxia thoroughly when anxiety, restlessness, and agitation of new onset are noted before administering as-needed sedatives.

Increasing Mobility of Affected Shoulder

1. Begin ROM exercise of arm and shoulder on affected side immediately to prevent ankylosis of the shoulder ("frozen" shoulder).
2. Perform exercises at time of maximal pain relief.
3. Encourage patient to actively perform exercises three to four times per day, taking care not to disrupt chest tube or invasive lines (ie, IV).

Patient Education and Health Maintenance

1. Advise that there will be some intercostal pain for several weeks, which can be relieved by local heat and oral analgesia. Many patients experience intercostal pain up to 1 year following surgery.
2. Advise that weakness and fatigability are common during the first 3 weeks after a thoracotomy, but exercise tolerance will improve with conditioning.
3. Suggest alternating walking and other activities with frequent short rest periods. Walk at a moderate pace and gradually extend walking time and distance.
4. Encourage continuing deep-breathing exercises for several weeks after surgery to attain full expansion of residual lung tissue.
5. Instruct on maintaining good body alignment to ensure full lung expansion.
6. Advise that chest muscles may be weaker than normal for 3 to 6 months after surgery. Patient must avoid lifting more than 10 pound (4.5 kg) until complete healing has taken place.
7. Any activity that causes undue fatigue, increased shortness of breath, or chest pain should be stopped immediately.
8. Because all or part of one lung has been removed, warn patient to avoid respiratory irritants (smoke, fumes, and high level of air pollution).
    a. Avoid irritants that may cause coughing spasms.
    b. Sit in nonsmoking areas in public places.
9. Encourage patient to receive an annual influenza vaccine and obtain a pneumococcal pneumonia vaccine.
10. Encourage patient to keep follow-up visits.
11. Instruct patient to prevent respiratory infections by frequent handwashing and avoiding others with respiratory infections.

Evaluation: Expected Outcomes

- Respirations with normal range, adequate depth; lungs clear; ABG values and SaO_2 within normal limits.
- BP, CVP, and pulse within normal limits for individual.
- Coughs and turns independently; reports relief of pain.
- Performs active ROM of affected arm and shoulder; reports improved exercise tolerance.

Chest Drainage

Chest drainage is the insertion of a tube into the pleural space to evacuate air or fluid and/or help regain negative pressure. Whenever the chest is opened, there is loss of negative pressure in the pleural space, which can result in collapse of the lung. The collection of air, fluid, or other substances in the thoracic cavity can compromise cardiopulmonary function and cause collapse of the lung.

It is necessary to keep the pleural space evacuated postoperatively and to maintain negative pressure within this potential space. Therefore, during or immediately after thoracic surgery, chest tubes/catheters are positioned strategically in the pleural space, sutured to the skin, and connected to a drainage apparatus to remove the residual air and fluid from the pleural or mediastinal space. This assists in the reexpansion of remaining lung tissue.

Chest drainage can also be used to treat spontaneous pneumothorax or hemothorax/pneumothorax caused by trauma (see Table 10-3). Sites for chest tube placement are:

Table 10-3 Indications for Chest Tube Use

INDICATION	ACCUMULATING SUBSTANCE
Pneumothorax	Air
Hemothorax	Blood
Pleural effusion	Fluid
Chylothorax	Lymphatic fluid
Empyema	Pus

1. For pneumothorax (air)—second or third interspace along midclavicular or anterior axillary line.
2. For hemothorax (fluid)—sixth or seventh lateral interspace in the midaxillary line.

Principles of Chest Drainage

1. Many types of commercial chest drainage systems are in use, most of which use the water-seal principle. The chest tube/catheter and collecting tubing is attached to a chest drainage system using a one-way valve principle. Water acts as a seal and permits air and fluid to drain from the chest. However, air cannot reenter the chest cavity.
2. Chest drainage can be categorized into three types of mechanical systems (see Figure 10-10). There are numerous types of chest drainage units available including dry suction systems.

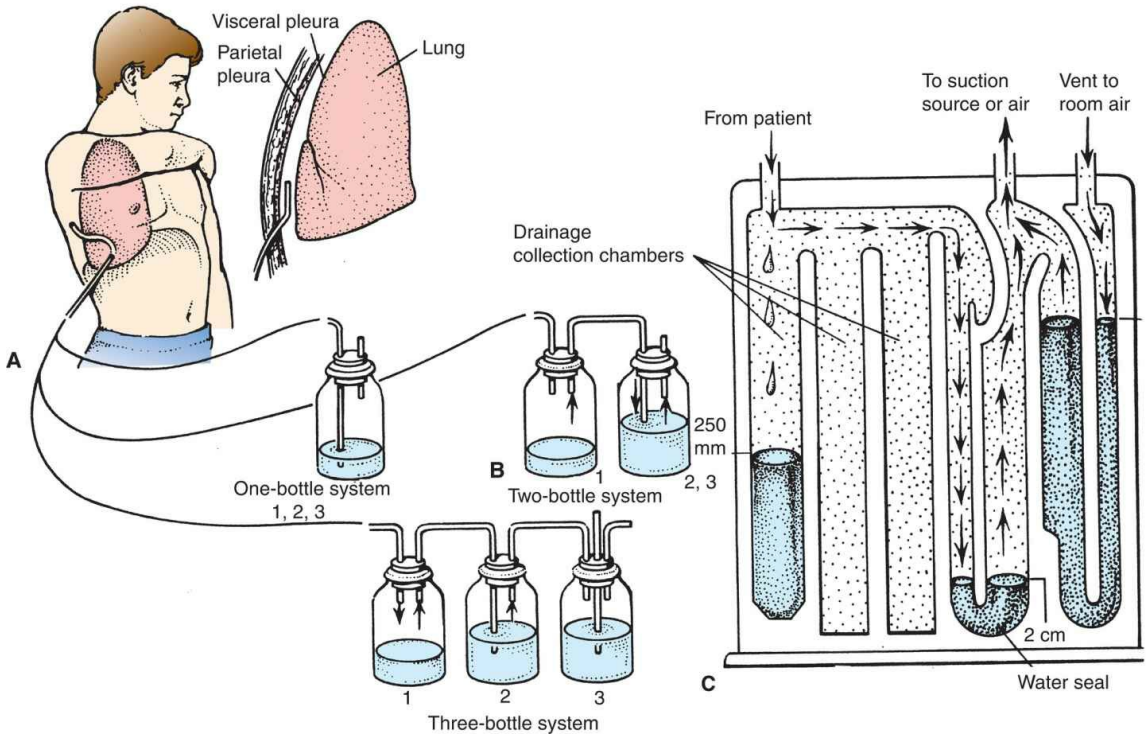

Figure 10-10. Chest drainage systems. **(A)** Strategic placement of a chest catheter in the pleural space. **(B)** Three types of mechanical drainage systems. **(C)** A Pleur-evac operating system: (*1*) the collection chamber, (*2*) the water seal chamber, and (*3*) the suction control chamber. The Pleur-evac is a single unit with all three bottles identified as chambers.

One-Bottle Water-Seal System

1. The end of the collecting tube is covered by a layer of water, which permits drainage of air and fluid from the pleural space, but does not allow air to move back into the chest. Functionally, drainage depends on gravity, on the mechanics of respiration, and, if desired, on suction by the addition of controlled vacuum.
2. The tube from the patient extends approximately 1 inch (2.5 cm) below the level of the water in the container. There is a vent for the escape of any air that may be leaking from the lung. The water level fluctuates as the patient breathes; it goes up when the patient inhales and down when the patient exhales.
3. At the end of the drainage tube, bubbling may or may not be visible. Bubbling can mean either persistent leakage of air from the lung or other tissues or a leak in the system.

Two-Bottle Water-Seal System

1. The two-bottle system consists of the same water-seal chamber, plus a fluid-collection bottle.
2. Drainage is similar to that of a single unit, except that when pleural fluid drains, the underwater-seal system is not affected by the volume of the drainage.
3. Effective drainage depends on gravity or on the amount of suction added to the system. When vacuum (suction) is added to the system from a vacuum source, such as wall suction, the connection is made at the vent stem of the underwater-seal bottle.
4. The amount of suction applied to the system is regulated by the wall gauge.

Three-Bottle Water-Seal System

1. The three-bottle system is similar in all respects to the two-bottle system, except for the addition of a third bottle to control the amount of suction applied. Recent research has shown that suction may actually prolong an air leak by pulling air through the opening that would otherwise heal on its own.
2. The amount of suction is determined by the depth to which the tip of the venting glass tube is submerged in the water and level of water in the suction chamber or setting of a dial—depending on the system in use.
3. In the three-bottle system (as in the other two systems), drainage depends on gravity or the amount of suction applied. The mechanical suction motor or wall suction creates and maintains a negative pressure throughout the entire closed drainage system.
4. The manometer bottle regulates the amount of negative pressure transmitted back to the patient from the suction/vacuum device. This is accomplished through the use of a water or dry system that down-regulates the suction/vacuum applied.
5. In the commercially available systems, the three bottles are contained in one unit and identified as "chambers" (see Figure 10-10C). The principles remain the same for the commercially available products as they do for the glass bottle system.
6. First chamber acts as the collection chamber and receives fluid and air from the chest cavity through the collecting tube attached to the chest tube.
7. Second chamber acts as the water-seal chamber with 2 cm of water acting as a one-way valve, allowing drainage out but preventing backflow of air or fluid into the patient.
8. Third chamber applies controlled suction. The amount of suction is regulated by the volume of water (usually 20 cm) in the chamber, not the amount of suction or bubbling with a water system. In a dry suction control system no water is used, no bubbling occurs, and a restrictive device or regulator is used to dial the desired negative pressure (up to 40 cm suction).

NURSING ALERT When the motor or the wall vacuum is turned off, the drainage system should be open to the atmosphere so that intrapleural air can escape from the system. This can be done by detaching the tubing from the suction port to provide a vent.

Nursing and Patient Care Considerations

1. Assist with chest tube insertion.
2. Assess patient's pain at insertion site and give medication appropriately. If patient is in pain, chest excursion and lung inflation will be hampered. Medicate for pain as needed. Assess for effectiveness and respiratory depression.
3. Maintain chest tubes to provide drainage and enhance lung reinflation. Ensure the tubing does not loop, kink, or restrict movements of the patient.

4. Maintain integrity of insertion site, observing for drainage, redness, impaired healing, and subcutaneous emphysema.
5. Make sure there is fluctuation of the fluid level in the drainage container ("tidaling"). Fluctuation will stop if a dependent loop develops or the tubing is obstructed by blood clots or fibrin and when the lung is reexpanded.

NURSING ALERT Clamping of chest tubes is not recommended because of the increased danger of tension pneumothorax from rapid accumulation of air in the pleural space. Clamp only momentarily to change the drainage system. Check for leaks to assess the patient's tolerance for removal of the chest tube (perhaps up to 24 hours).

NURSING ALERT Milking and stripping of chest tubes to maintain patency are not recommended. This practice has been found to cause significant increases in intrapleural pressures and damage to the pleural tissue. New chest tubes contain a nonthrombogenic coating, thus decreasing the potential for clotting. If it is necessary to help the drainage move through the tubing, apply a gentle squeeze-and-release motion to small segments of the chest tube between your fingers.

PROCEDURE GUIDELINES 11-1

Tuberculin Skin Test

EQUIPMENT

- Purified protein derivative (PPD) tuberculin antigen intermediate strength
- Tuberculin syringe
- 5/8 inches, 27G steel needle with engineered sharps safety mechanism
- Alcohol pad
- Gloves recommended but not required as the risk of exposure to blood is minimal with intradermal injection.

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Administer symptom screening questionnaire.	1. Any positive response should raise the index of suspicion for TB and merits investigation regardless of the test result.
2. Determine if the patient has ever had Bacille Calmette-Guérin (BCG) vaccine, recent viral disease, immunosuppression by disease, drugs, or corticosteroids.	2. Any of these may cause false readings. Previous BCG vaccine or the other factors should not preclude PPD testing, but will be considered with the result.
3. Do not give PPD to person who has had a positive test or TB in the past.	3. Chest x-ray as indicated for screening and symptom review.
Performance phase	
1. Draw up PPD-tuberculin into tuberculin syringe.	1. Follow the manufacturer's directions. Each 0.1-mL dose should contain 5 tuberculin units (TU) of PPD-tuberculin. Use the antigen immediately to avoid absorption onto the plastic/glass syringe.
2. Put on gloves.	2. Follow standard infection control precautions.
3. Clean the skin of the inner aspect of forearm with alcohol. Allow to dry.	3. Alcohol must dry for antisepsis.
4. Stretch the skin taut.	
5. Hold the tuberculin syringe as near parallel to the skin as possible (10-degree angle) so the hub of the needle touches it as the needle is introduced, bevel up.	5. Reduces the needle angle at the skin surface and facilitates the injection of tuberculin just beneath the surface of the skin.
6. Inject the tuberculin into the superficial layer of the skin to form a wheal 6–10 mm in diameter. Activate engineered sharps safety mechanism.	6. If no wheal appears (because the injection was made too deep), inject again at another site at least 2 inches (5 cm) away.
7. Immediately place disposable needle and syringe into puncture-resistant sharps container.	
Follow-up phase	
To read the test	
1. Read the test within 48–72 hours.	1. Tuberculin skin tests are tests of delayed hypersensitivity.
2. Have a good light available. Flex the patient's forearm slightly at the elbow.	2. Relieves tension on the skin.
3. Inspect for the presence of induration; inspect from a side view against the light; inspect by direct light.	3. Induration refers to hardening or thickening of tissues.
4. Palpate: Lightly rub the finger across the injection site from the area of normal skin to the area of induration. Outline the diameter of induration.	4. Erythema (redness) without induration is generally considered to be of no significance.
5. Measure the maximum transverse diameter of induration (not erythema) in millimeters with a flexible ruler.	5. The full extent of induration is important for interpretation.
Interpretation	

Nursing Action	Rationale
1. Induration of 5 mm or more in diameter indicates positive reaction and need for treatment for latent TB infection in high-risk groups.	1. High-risk groups include the following: a. People with HIV. b. People who have had recent contact with active TB. c. People who have fibrotic changes on chest x-ray, consistent with healed TB. d. People with organ transplants or other causes of immunosuppression (including therapy with ≥15 mg of prednisone daily ≥1 month) or taking TNF-α antagonists.
2. Induration of 10 mm or more in diameter indicates a positive reaction and need for treatment of latent TB infection in persons at risk.	2. Persons at risk include the following: a. People with medical conditions, such as substance abuse, diabetes mellitus, silicosis, head and neck cancer, leukemia, end-stage renal disease, gastrectomy, intestinal bypass, and prolonged corticosteroid therapy. b. Recent arrivals (<5 years) from high-prevalence countries. c. Residents and employees of long-term care facilities and other congregate settings. d. Children younger than age 4; adolescents exposed to adults in high-risk categories. e. Injection drug users. f. Mycobacteriology laboratory personnel. g. All people who do not meet above criteria but who have other risk factors for TB, such as homelessness, alcoholism, malnutrition, and health care workers.
3. Induration of 15 mm in persons with no known risk factors for TB may be considered for treatment.	3. Targeted skin testing programs should be conducted among risk groups only to avoid false positives.

NURSING ALERT False-positive reaction may occur in people infected with mycobacteria other than *M. tuberculosis*, vaccination with BCG, or inaccurate testing. False-negative reactions may occur in people with HIV infection or anergy (inability to react to skin tests because of weakened immune system), recent (6 to 8 weeks of exposure) or very old TB infection (many years), very young age (less than 6 months), overwhelming miliary or pulmonary TB, recent measles or other viral infections, recent live virus vaccinations (measles and smallpox), and those receiving corticosteroids or immunosuppressive drugs.

Respiratory Failure

Respiratory failure is a failure of the one or both of the respiratory system's gas exchange systems: oxygenation (hypoxemia respiratory failure) and carbon dioxide elimination (hypercapnic respiratory failure).

Hypoxemic respiratory failure (type I) is characterized by arterial oxygen (PaO_2) level below 60 mm Hg (hypoxemia) with a normal (40 mm Hg) or low arterial carbon dioxide level ($PaCO_2$). It is the most common form of respiratory failure, usually associated with acute diseases of the lung generally involving fluid collection or collapse of alveolar units. Examples include cardiogenic or noncardiogenic pulmonary edema, pneumonia, and pulmonary hemorrhage.

Hypercapnic respiratory failure (type II) is characterized by an arterial carbon dioxide ($PaCO_2$) level of greater than 50 mm Hg. Hypoxemia is common while breathing room air. The pH depends on the bicarbonate level, which, in turn, is dependent on the duration and degree of hypercapnia.

Respiratory failure may be further classified as acute, chronic, or both. Acute respiratory failure is characterized by life-threatening abnormalities in arterial blood gases (ABGs) and acid–base levels, whereas chronic respiratory failure abnormalities may be less dramatic and more insidious.

Classification

Acute Respiratory Failure

1. Characterized by hypoxemia (PaO_2 less than 60 mm Hg) or hypercapnia ($PaCO_2$ greater than 50 mm Hg) and acidosis (pH less than 7.35).
2. Occurs rapidly, usually in minutes to hours or days.

Chronic Respiratory Failure

1. Characterized by hypoxemia and/or hypercapnia with a normal pH (7.35 to 7.45).
2. Occurs over a period of days, months, or years, allowing activation of compensatory mechanisms, including renal bicarbonate retention (normal, approximately 22 to 26 mEq/L) with normalization of pH (or only slightly decreased, approximately 7.30 to 7.34).

Combined Acute and Chronic Respiratory Failure

1. Characterized by an abrupt increase in the degree of hypoxemia and/or hypercapnia in patients with preexisting chronic respiratory failure.
2. May occur during or following acute upper respiratory infection, pneumonia, exacerbation, or without obvious cause.
3. Extent of deterioration is best assessed by comparing the patient's present ABG levels with previous ABG levels (patient baseline).

Pathophysiology and Etiology

Hypoxemic Respiratory Failure

Characterized by a decrease in PaO_2 and normal or decreased $PaCO_2$.

1. The primary problem is inability to adequately oxygenate blood, resulting in hypoxemia, because of an abnormality in one or more parts of the respiratory system, central nervous system (CNS), respiratory muscles, or chest wall.
2. Hypoxemia occurs because damage to the alveolar–capillary membrane causes leakage of fluid into the interstitial space or into the alveoli and slows or prevents movement of oxygen from the alveoli to the pulmonary capillary blood.
   a. Damage is either widespread (eg, acute respiratory distress syndrome [ARDS]) or relatively localized (eg, lobar pneumonia), resulting in decreased or absent ventilation in affected areas of the lung.
   b. Consequences are severe ventilation–perfusion mismatch and shunt (perfusion without ventilation).
3. Hypocapnia may result from hypoxemia and decreased pulmonary compliance or stiffness because of fluid within the lung.
   a. Change in compliance reflexively stimulates the increased ventilation.
   b. Ventilation is also increased as a response to hypoxemia.
4. Ultimately, if treatment is unsuccessful, $PaCO_2$ will increase and the patient will experience both an increase in $PaCO_2$ and a decrease in PaO_2.
5. Etiology includes the following:
   a. Cardiogenic or noncardiogenic pulmonary edema, pneumonia, and pulmonary hemorrhage.
   b. ARDS. The four main causes of ARDS are aspiration, pneumonia, sepsis, and trauma. However, there are numerous other causes of lung injury including pancreatitis, smoke inhalation, and near drowning.
   c. Hypercapnic respiratory failure: drug overdose, neuromuscular disease, chest wall abnormalities, asthma, and chronic obstructive pulmonary disease (COPD).

Ventilatory Failure without Underlying Lung Disease

Characterized by a decrease in PaO_2 that is proportional to the increase in $PaCO_2$ and a decrease in pH.

1. The primary problem is insufficient respiratory center stimulation or insufficient chest wall movement, resulting in alveolar hypoventilation.
2. Hypercapnia occurs because impaired neuromuscular function or chest wall expansion limits the amount of carbon dioxide removed from the lungs.
   a. The primary problem is not the lungs. The patient's minute ventilation (tidal volume [V_T] × respiratory rate) is insufficient to allow normal alveolar gas exchange.
3. Carbon dioxide (CO_2) not excreted by the lungs combines with water (H_2O) to form carbonic acid (H_2CO_3). This predisposes to acidosis and a fall in pH.
4. Hypoxemia occurs as a consequence of inadequate ventilation and hypercapnia. When $PaCO_2$ rises, PaO_2 falls unless supplemental oxygen is used.
5. Etiology includes the following:

a. Insufficient respiratory center activity (drug intoxication, eg, opioid overdose, oversedation, general anesthesia; vascular disorders, such as cerebral vascular insufficiency, brain tumor; trauma, such as head injury, increased intracranial pressure).

b. Insufficient chest wall function (neuromuscular disease, such as Guillain-Barré syndrome, myasthenia gravis, amyotrophic lateral sclerosis, poliomyelitis; chest wall trauma resulting in multiple fractures; spinal cord trauma; kyphoscoliosis).

Ventilatory Failure with Intrinsic Lung Disease

Characterized by a decrease in PaO_2, increase in $PaCO_2$, and decrease in pH.

1. The primary problem is acute exacerbation or chronic progression of previously existing lung disease, resulting in CO_2 retention.
2. Hypercapnia occurs because of damage to the lung parenchyma primarily caused by chronic airway obstruction (chronic bronchitis, emphysema, or severe asthma). This limits the amount of CO_2 removed by the lungs because the lungs are hyperinflated and poorly perfused.
3. The CO_2 not excreted by the lungs combines with H_2O to form H_2CO_3. This predisposes to acidosis with a fall in pH.
4. Hypoxemia occurs due to hypoventilation and hypercapnia. In addition, damage to the lung parenchyma and/or airway obstruction limits the amount of oxygen that enters the pulmonary capillary blood.
5. Etiology includes the following:
   a. COPD, chronic bronchitis, emphysema.
   b. Severe asthma.
   c. Cystic fibrosis.

Clinical Manifestations

1. Hypoxemia—restlessness, agitation, dyspnea, disorientation, confusion, delirium, loss of consciousness.
2. Hypercapnia—headache, somnolence, dizziness, confusion.
3. Tachypnea initially; when no longer able to compensate, bradypnea.
4. Accessory muscle use.
5. Asynchronous respirations.

NURSING ALERT Obtain ABG levels whenever the history or signs and symptoms suggest that the patient is at risk for developing respiratory failure. Initial and subsequent values should be recorded, so comparisons can be made over time. The need for ABG analysis can be decreased by continuous oximetry monitoring of oxygen saturation (SpO_2). Correlate oximeter values with ABG values and then use oximeter for trending. Be aware that oximetry does not measure $PaCO_2$ and pH, important determinants of respiratory acidosis.

Diagnostic Evaluation

1. ABG analysis—shows changes in PaO_2, $PaCO_2$, pH, and possibly HCO_3 from patient's normal levels or PaO_2 less than 60 mm Hg, $PaCO_2$ greater than 50 mm Hg, and pH less than 7.35.
2. Pulse oximetry—decreasing SpO_2 (less than 90%).
3. End-tidal CO_2 monitoring—elevated (greater than 40 mm Hg or greater than 5 mm Hg above $PaCO_2$).
4. Complete blood count, serum electrolytes, chest x-ray, urinalysis, electrocardiogram (ECG), and blood and sputum cultures—to aid in determination of underlying cause and patient's condition.

Management

Hypoxemia is the major acute concern impacting organ function. Once corrected with stable ventilation and hemodynamics, identification and correction of underlying causes is essential and used to direct treatment.

1. Oxygen therapy to correct hypoxemia.
2. Turn patient regularly and mobilize when clinically stable to improve ventilation and oxygenation. When appropriate, early ambulation of the patient.
3. Bronchodilators and possibly corticosteroids to reduce bronchospasm and inflammation.
4. Diuretics for pulmonary vascular congestion or pulmonary edema.
5. Ventilatory support using mechanical ventilation or noninvasive positive pressure ventilation using a face mask.

NURSING ALERT Unless mechanically ventilated, high-flow oxygen in COPD patients with CO_2 retention is contraindicated because it may cause depression of the respiratory center drive. In this population, the drive to breathe may be hypoxemia.

Complications

1. Oxygen toxicity if prolonged high FiO_2 required (≥0.80 for ≥3 days).
2. Barotrauma from mechanical ventilation intervention—damage to alveoli causing extra-alveolar air, primarily caused by the use of nonphysiologic tidal volumes (greater than 8 mL/kg predicted body weight).

Nursing Assessment

See Standards of Care Guidelines 11-1.

1. Note objective signs suggesting increased work of breathing that include some combination of the following: tachypnea, pronounced use of sternocleidomastoid muscles, tracheal tugging, nasal flaring, sternal retractions (or intercostal muscle retraction) recruitment of abdominal muscles during exhalation, and diaphoresis. Patient may also complain of dyspnea ("can't catch my breath," "my breathing is hard," etc.).

2. Assess breath sounds.
    a. Diminished or absent sounds may suggest inability to ventilate the lungs sufficiently to prevent atelectasis. Decreased breath sounds may be common in moderate to severe COPD.
    b. Crackles may indicate ineffective airway clearance and fluid in the lungs.
    c. Wheezing indicates narrowed airways and bronchospasm.
    d. Rhonchi and crackles suggest ineffective secretion clearance.
3. Assess level of consciousness (LOC) and ability to tolerate increased work of breathing.
    a. Confusion and lethargy.
    b. Rapid shallow breathing, abdominal paradox (inward movement of abdominal wall during inspiration), and accessory muscle retractions suggest inability to maintain adequate minute ventilation.
4. Assess for signs of hypoxemia and hypercapnia.
5. Analyze ABG and compare with previous values.
    a. If the patient cannot maintain a minute ventilation sufficient to prevent CO_2 retention, pH will fall.
    b. Mechanical ventilation or noninvasive ventilation may be needed if pH falls to 7.30 or below.
6. Determine vital capacity (VC) and respiratory rate, and compare with values indicating the need for mechanical ventilation:
    a. VC less than 15 mL/kg.
    b. Respiratory rate greater than 30 breaths/minute.
    c. Negative inspiratory force less than −30 cm H_2O.
    d. Refractory hypoxemia.
7. Determine hemodynamic status through assessment of blood pressure (BP), heart rate, pulmonary wedge pressure, cardiac output, and SvO_2, and compare with previous values. If patient is on mechanical ventilation with positive end-expiratory pressure (PEEP), venous return may be limited, resulting in decreased cardiac output.

STANDARDS OF CARE GUIDELINES 11-1

Respiratory Compromise

When caring for patients at risk for respiratory compromise, consider the following assessments and interventions:

- Monitor closely and document complete assessments. Evaluate closely for any changes in clinical assessments.
- Perform thorough systematic assessment, including mental status, vital signs, respiratory status, and cardiovascular status.
- Evaluate for signs of hypoxia when anxiety, restlessness, confusion, or aggression of new onset are noted. Do not administer sedatives unless hypoxia has been ruled out by performing respiratory assessment.

- Notify appropriate health care provider of significant findings of hypoxia: SpO_2 < 92%, cyanosis, circumoral pallor, rapid and shallow respirations, abnormal breath sounds, change in behavior or level of consciousness (LOC). Request assessment and intervention by health care provider, as indicated.
- Use extreme caution in administering sedatives and opioids to patients at risk for respiratory compromise.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Nursing Diagnoses

- Impaired Gas Exchange related to inadequate respiratory center activity, chest wall movement, airway obstruction, and/or fluid in the lungs.
- Ineffective Airway Clearance related to increased, tenacious, and/or retained secretions.

Nursing Interventions

Improving Gas Exchange

1. Administer oxygen to maintain PaO_2 of 60 mm Hg or SaO_2 greater than 90% using devices that provide increased oxygen concentrations (aerosol mask, partial rebreathing mask, nonrebreathing mask, noninvasive positive pressure ventilation, or mechanical ventilation).
2. Administer diuretics and, as indicated, antibiotics and/or cardiac medications as ordered for underlying disorder.
3. Monitor fluid balance by intake and output measurement, daily weight, and direct measurement of pulmonary capillary wedge pressure to detect hypovolemia or hypervolemia.
4. Provide measures to prevent hypoventilation and atelectasis, and promote chest expansion and secretion clearance, such as incentive spirometer, nebulization, head of bed elevated 30 degrees, turn frequently, out of bed when clinically stable.
5. Monitor adequacy of alveolar ventilation by frequent measurement of SpO_2, ABG levels, respiratory rate, and forced vital capacity (FVC).
6. Compare monitored values with criteria indicating the need for mechanical ventilation (see above in Nursing Assessment section). Report and prepare to assist with noninvasive ventilation or intubation and initiation of mechanical ventilation, if indicated.

Maintaining Airway Clearance

1. Where indicated, administer medications to increase alveolar ventilation—bronchodilators to reduce bronchospasm and corticosteroids to reduce airway inflammation.
2. Teach slow, pursed-lip breathing to reduce dyspnea and improve oxygen saturation. Secretion clearance

techniques may be considered for retained secretions.

3. Promote effective cough with positioning, deep breathing, and bronchodilators if ordered. If cough effort is poor and/or ineffective for mucus clearance, suction patient, if needed, to assist with removal of secretions.
4. If the patient becomes increasingly lethargic, cannot cough or expectorate secretions, and cannot cooperate with therapy, or if pH falls below 7.30, despite the use of the above therapy, report and prepare to assist with intubation and initiation of mechanical ventilation.

Patient Education and Health Maintenance

1. Instruct patient with preexisting pulmonary disease to seek early intervention for infections to prevent acute respiratory failure, pneumonia, and exacerbations.
2. Teach patient about medication regimen.
   a. Return demonstrate proper technique for inhaler use.
   b. Actions, dosage, and timing of medications.
   c. Monitoring for adverse effects of oral corticosteroids to report to health care provider: weight gain because of fluid retention and/or increased appetite, hyperglycemia, mood changes, insomnia, bruising, fragile skin, and vision changes because of cataracts or glaucoma.

Community and Home Care Considerations

1. Encourage patients at risk, especially older adults and those with preexisting lung disease, to get pneumococcal pneumonia and annual influenza vaccination.
2. All adults aged 65 years and older should receive the 13-valent pneumococcal conjugate vaccine (PCV13), in addition to the 23-valent pneumococcal polysaccharide vaccine (PPSV23). PCV13 is recommended for all adults aged 65 years and older who were not previously vaccinated with it, followed by PPSV23 12 months later.
3. Encourage annual immunization for influenza in persons 6 months and older.
4. Intranasal live attenuated vaccine is an alternative for people ages 5 to 49 without chronic conditions, human immunodeficiency virus (HIV), or asthma.

EVIDENCE BASE Center for Disease Control and Prevention. (2016). Prevention and control of seasonal influenza with vaccines: Recommendations of the Advisory Committee on Immunization Practices —United States, 2016–17 Influenza Season. *MMWR, 65*(5), 1–54.

Kobayashi, M., Bennett, N. M., Gierke, R., Almendares, O., Moore, M. R., Whitney, C. G., & Pilishvili, T. (2015). Intervals between PCV13 and PPSV23 vaccines: Recommendations of the Advisory Committee on Immunization Practices (ACIP). *MMWR*, *64* (34), 944–947.

Evaluation: Expected Outcomes

- ABG values within patient's normal limits.
- Decreased secretions; lungs clear.

Acute Respiratory Distress Syndrome

ARDS or acute *lung injury* results from acute insult at the level of the alveoli leading to severe hypoxemia and decreased pulmonary compliance. Hallmarks of ARDS include a risk factor for ARDS (eg, sepsis, trauma, pancreatitis), severe hypoxemia with the need for high FiO_2, decreased lung compliance, bilateral pulmonary infiltrates, and absence of cardiogenic pulmonary edema. Mortality is 55% and improves with early intervention.

Pathophysiology and Etiology

1. Pulmonary and/or nonpulmonary insult to the alveolar–capillary membrane causing protein-rich fluid leakage into interstitial and alveolar spaces, resulting in edema.
    a. Inflammation in the interstitium and alveolar space promotes atelectasis and lung damage.
    b. This is associated with severe hypoxemia and reduced pulmonary compliance.
    c. Fibroproliferative state is often accompanied by capillary thrombosis, lung fibrosis, and neovascularization follows.
2. Diffuse alveolar damage with ventilation–perfusion (V/Q) mismatch caused by shunting of blood (see Figure 11-1).
3. Mechanisms are unclear. Acute lung injury includes both pulmonary capillary endothelium and alveolar epithelium. Etiologies are numerous and can be pulmonary or nonpulmonary. Predisposing factors include (but are not limited to):
    a. Infections, including sepsis, pneumonia (usually bacterial or aspiration).
    b. Shock (any cause), trauma, pulmonary contusion, near drowning, direct or indirect lung injury, burns, pancreatitis.
    c. Inhaled agents—smoke, high concentration of oxygen, corrosive substances.
    d. Major surgery including coronary artery bypass graft, fat emboli, lung or bone marrow transplantation, transfusion of blood products, reperfusion pulmonary edema.

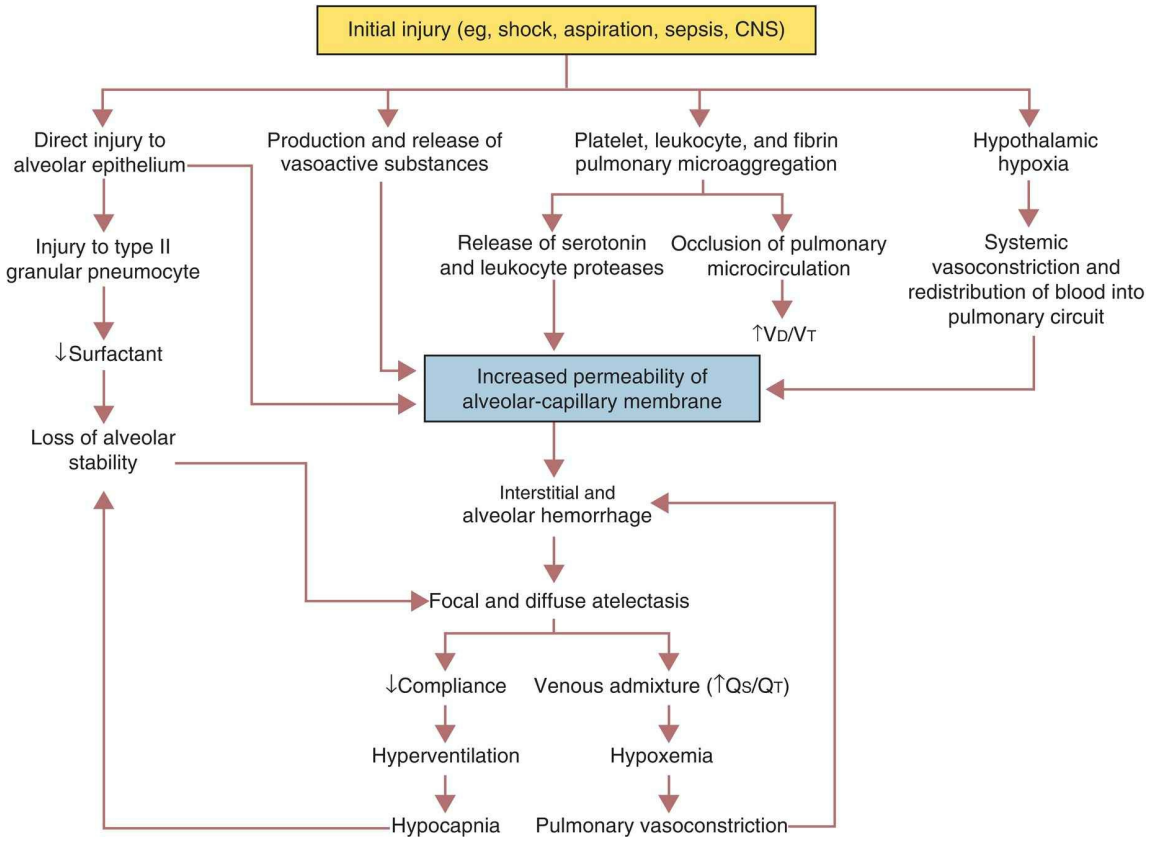

Figure 11-1. Pathogenesis of ARDS.

Clinical Manifestations

1. Acute onset of severe dyspnea, tachypnea, tachycardia, use of accessory muscles, cyanosis.
2. Increasing requirements of oxygen therapy. Hypoxemia refractory to supplemental oxygen therapy.
3. Scattered crackles and rhonchi heard on auscultation.
4. Decreased pulmonary compliance, evidenced by increasing pressure required to ventilate patient on mechanical ventilator.

Diagnostic Evaluation

1. Diagnosis is based on clinical, hemodynamic, and oxygen criteria. The hallmark signs for ARDS include acute-onset, severe hypoxemia, despite increasing oxygen therapy, and chest x-ray exhibiting bilateral infiltrates.
2. Pulmonary artery catheter readings show pulmonary artery wedge pressure greater than 18 mm Hg, absence of left atrial hypertension, and no clinical signs of heart failure.

Management

1. Current ARDS treatment is primarily supportive. The underlying cause for ARDS should be determined so appropriate treatment can be initiated.
2. Mechanical ventilation is nearly always required to decrease work of breathing and improve oxygenation.

a. Low V_T by mechanical ventilation (6 mL/kg of predicted body weight) reduces mortality compared to high-volume ventilation.
b. Protective ventilation (ie, maximum inspiratory pressure of less than 35 cm) should be instituted.
c. PEEP should be used to improve PaO_2 (keeps the alveoli open, thereby improving gas exchange). Therefore, a lower oxygen concentration (FiO_2) may be used to maintain satisfactory oxygenation.

3. Fluid management must be maintained. The patient may be hypovolemic because of the movement of fluid into the interstitium of the lung. Pulmonary artery catheter monitoring and inotropic medication can be helpful.
4. Medications are aimed at treating the underlying cause. Corticosteroids are used infrequently because of controversial benefits.
5. Adequate nutrition should be initiated early and maintained.

NURSING ALERT The treatment for ARDS is aimed at maximizing clinical stability and managing symptoms, but the underlying cause must be treated or ARDS will not resolve. Supportive measures assist the patient while the underlying cause is being treated.

Complications

1. Infections, such as pneumonia, sepsis.
2. Respiratory complications, such as pulmonary emboli, barotrauma, oxygen toxicity, subcutaneous emphysema, or pulmonary fibrosis.
3. GI complications, such as stress ulcer, ileus, pancreatitis.
4. Cardiac complications, such as decreased cardiac output and dysrhythmias.
5. Renal failure, disseminated intravascular coagulation.
6. Multiorgan failure and sepsis, which may result in death.
7. Cognitive impairment.

Nursing Interventions

Care is similar to patient with respiratory failure (page 191) and pulmonary edema (page 304). Also see "Mechanical Ventilation" section, page 181.

Acute Bronchitis

Acute bronchitis is an inflammation of the airways resulting from infection (viral, bacterial) or an irritant (smoke, gastric acid). The inflammation causes airway narrowing and congestion, with increase in secretions.

Pathophysiology and Etiology

1. Primarily viral etiology, such as rhinovirus, respiratory syncytial virus (RSV), and influenza.
2. Bacterial etiology more common in people with underlying pulmonary disease.
3. Exposure to irritants may be acute or chronic.
4. Airways become inflamed, narrowed, and congested with increased mucus production.

Clinical Manifestations

1. Dry cough, which may become productive with clear to purulent sputum.
2. Rhinorrhea, sore throat, and nasal congestion may precede and accompany lower respiratory tract symptoms.
3. Occasional pleuritic chest pain and fever.
4. Diffuse rhonchi and crackles and occasional wheezing heard on auscultation.

Diagnostic Evaluation

1. Chest x-ray—no evidence of infiltrates or consolidation.
2. Sputum Gram stain and culture have limited value.
3. Spirometry to determine FVC, forced expiratory volume in 1 second (FEV_1), and FEV_1/FVC ratio, which may indicate underlying airflow limitation as found in COPD (chronic bronchitis +/or emphysema).

Management

1. Antibiotic therapy is normally avoided due to predominantly viral cause of infection. If bacterial infection is present or strongly suspected, or for patients with underlying COPD, antibiotics are usually prescribed based on community resistance patterns and patient history and physical examination.
2. Hydration and humidification.
3. Secretion clearance interventions for retained or excess mucus (may include controlled cough, positive expiratory pressure [PEP] valve therapy, chest physical therapy) and mobilization.
4. Bronchodilators for bronchospasm, secretion clearance, and treatment of airflow obstruction if present.
5. Symptom management for cough and fever.
6. Management of irritants through acid reflux therapy, smoking cessation, and use of air filter.

Nursing Assessment

1. Obtain history of respiratory infection, course, and length of symptoms.

2. Assess severity of cough and characteristics of sputum production.
3. Auscultate chest for diffuse rhonchi and crackles as opposed to localized crackles usually heard with pneumonia.
4. Obtain medical history including COPD, GERD, smoking history, and exposure to irritants.

Nursing Diagnosis

- Ineffective Airway Clearance related to sputum production.

Nursing Interventions

Establishing Effective Airway Clearance

1. Supportive care with symptom management is usually first line in otherwise healthy patients. For those with bacterial infections and/or underlying COPD, administer or teach self-administration of antibiotics, as ordered.
2. Encourage mobilization of secretions through patient mobilization and, possibly, hydration, effective cough technique, and, if needed, the use of secretion clearance devices such as PEP and, possibly, chest physical therapy. Educate patient that beverages with caffeine or alcohol do not promote hydration.
3. If ordered, administer or teach self-administration of inhaled bronchodilators to reduce bronchospasm and enhance secretion clearance.
4. Caution patients on the use of over-the-counter cough suppressants, antihistamines, and decongestants that may cause drying and retention of secretions. Cough preparations containing the mucolytic guaifenesin may be appropriate.

Patient Education and Health Maintenance

1. Instruct patient about medication regimen, including the completion of the full course of antibiotics, if prescribed, and the effects of food or alcohol on the absorption of the selected medications. If patient is not being treated with antibiotics, reassure patient that full recovery without antibiotic treatment occurs in most cases, but to advise health care provider if symptoms do not improve.
2. Encourage patient to seek medical attention for shortness of breath, severe fatigue, and worsening condition.
3. Advise patient that a dry cough may persist after bronchitis because of irritation of the airways. A bedside humidifier and avoidance of dry environments may help. Humidifiers must be cleaned frequently to avoid growth of mold.
4. Encourage patient to discuss complementary and alternative therapies with health care provider. When questioned, some people use garlic as an antimicrobial. Other herbs that many believe to be helpful for asthma and bronchitis are echinacea, eucalyptus, and thyme; however, there are no definitive studies that show benefit. Because herbal products and supplements are not standardized, and may be mixed with other ingredients, safety and effectiveness cannot be ensured.

Evaluation: Expected Outcomes

- Coughs up clear secretions effectively.

Pneumonia

Pneumonia is an inflammatory process, involving the terminal airways and alveoli of the lung, caused by infectious agents (see Table 11-1, pages 196–198). It may be classified according to its causative agent.

Table 11-1 Commonly Encountered Pneumonias

TYPE	ORGANISM RESPONSIBLE	MANIFESTATIONS	CLINICAL FEATURES	TREATMENT*	COMPLICATIONS
Bacterial					
Streptococcal pneumonia (pneumococcal pneumonia) (60% of community-acquired pneumonia)	• *Streptococcus pneumoniae*	• May be history of previous respiratory infection • Sudden onset, with shaking and chills • Rapidly rising fever; tachypnea • Cough, with expectoration of rusty or green (purulent) sputum • Pleuritic pain aggravated by cough • Chest dull to percussion; crackles, bronchial breath sounds **GERONTOLOGIC ALERT** Confusion and/or increase in respiratory rate may be only presenting feature in older patient.	• Usually involves one or more lobes • Chest x-ray shows consolidation of affected areas • Common community-acquired pneumonia as well as seen in nursing home residents, alcoholics, smokers, those with chronic obstructive pulmonary disease (COPD), IV drug use, early human immunodeficiency virus (HIV), endobronchial obstruction	• Penicillin nonresistant: MIC < 2 mg/mL • Penicillin G, amoxicillin • Penicillin resistant: MIC > 2 mg/mL • Agents chosen on the basis of susceptibility, including cefotaxime, ceftriaxone, fluoroquinolone	• Shock • Pleural effusion • Superinfections • Pericarditis • Otitis media
Staphylococcal pneumonia	• *Staphylococcus aureus*	• Commonly, history of viral infection, especially influenza • Insidious development of cough, with expectoration of yellow, blood-streaked mucus • Onset may be sudden if patient is outpatient • Fever, pleuritic chest pain, progressive dyspnea • Pulse varies; may be slow in proportion to temperature	• Commonly seen in facility setting; during influenza epidemics; in IV drug abuse; and COPD, smokers, bronchiectasis • These infections commonly lead to necrosis and destruction of lung tissue • Treatment must be vigorous and prolonged owing to disease's tendency to destroy the lungs • Organism may develop rapid drug resistance • Prolonged convalescence usual	• Methicillin susceptible: antistaph penicillins, cefazolin, clindamycin • Methicillin resistant: vancomycin or TM-SMX for methicillin-resistant *S. aureus*	• Effusion/pneumothorax • Lung abscess • Empyema • Meningitis
Pneumonia because of gram-negative enteric bacilli	• *Klebsiella* species, *Pseudomonas* organisms, *Escherichia coli*, *Serratia*, *Proteus* species	• Sudden onset with fever, chills, dyspnea • Pleuritic chest pain and production of purulent sputum	• Infection usually occurs from aspiration of pharyngeal flora into bronchioles. • Seen in persons with severe illness; among the more common causes of hospital-acquired pneumonia	• Enterobacteriaceae: third-generation cephalosporin, carbapenem (drug of choice if extended-spectrum beta-lactamase producer) beta-lactam/beta-lactamase inhibitor, fluoroquinolone • *Pseudomonas aeruginosa*: antipseudomonal beta-lactam *plus* ciprofloxacin or levofloxacin or aminoglycoside, aminoglycoside *plus* ciprofloxacin or levofloxacin	• Early necrosis of lung tissue with rapid abscess formation • High mortality
Legionella species	• *Legionella pneumophila*	• High fever, chills, cough, chest pain, tachypnea • Respiratory distress	• Peak incidence in people over age 50 who are cigarette smokers and have underlying diseases that increase susceptibility to infection or who have been on a cruise ship in the past 2 wk	• Fluoroquinolone, azithromycin, doxycycline	• Respiratory failure
Haemophilus influenza pneumonia *Moraxella catarrhalis* pneumonia	• *H. influenzae* • *M. catarrhalis*	• Abrupt onset of coughing, fever, chills, tachypnea	• Common in smokers and former smokers • May affect healthy young adults • X-ray may show consolidation • Often seen in early HIV and may be first indication of endobronchial tumor	• Non–beta-lactam-producing organisms: amoxicillin, fluoroquinolones, doxycycline, azithromycin, clarithromycin • Beta-lactam–producing organisms: second- or third-generation cephalosporins, amoxicillin clavulanate, fluoroquinolones, doxycycline, azithromycin, clarithromycin	• High mortality in patients with underlying disease (cancer, COPD) • Pleural effusion common
Atypical and Nonbacterial					
Mycoplasma or chlamydial pneumonia (*Legionella pneumoniae* may also be included in this category)	• *Mycoplasma pneumoniae*, *Chlamydia trachomatis*, or *L. pneumophila*	• Gradual onset; severe headache; irritating hacking cough producing scanty, mucoid sputum • Anorexia; malaise • Fever; nasal congestion; sore throat	• Occurs most commonly in children and young adults, as well as in older adults in community or hospital setting • Rise in serum complement-fixing antibodies to the organism • More common in COPD and in smokers	• For mycoplasma or *Chlamydophila pneumoniae*: macrolides, fluoroquinolones • For *Legionella*: fluoroquinolones, azithromycin, doxycycline	• Persisting cough, meningoencephalitis, polyneuritis, monoarticular arthritis, pericarditis, myocarditis • Chlamydial pneumonia has been implicated in cardiac atheromatous lesions in some patients
Viral pneumonia	• Influenza viruses • Parainfluenza viruses • Respiratory syncytial viruses • Rhinoviruses • Adenovirus • Varicella, rubella, rubeola, herpes simplex, cytomegalovirus, Epstein-Barr virus	• Cough • Constitutional symptoms may be pronounced (severe headache, anorexia, fever, and myalgia)	• In majority of patients, influenza begins as an acute coryza and myalgias; others have bronchitis and pleurisy, whereas still others develop GI symptoms • Risk of developing influenza related to crowding and close contact with groups	• Treat symptomatically • Prophylactic vaccination recommended for high-risk persons (over age 65; chronic cardiac or pulmonary disease, diabetes, and other metabolic disorders) • For influenza virus: oseltamivir, zanamivir	• Persons with underlying disease have increased risk of complications, primary influenzal pneumonia, and secondary bacterial pneumonia • Bacterial superinfection • Pericarditis • Endocarditis
Pneumocystis jiroveci pneumonia (PCP)	• *P. jiroveci*	• Insidious onset • Increasing dyspnea and nonproductive cough • Tachypnea; progresses rapidly to intercostal retraction, nasal flaring, and cyanosis • Lowering of arterial oxygen tension • Chest x-ray will reveal diffuse, bilateral interstitial pneumonia	• Usually seen in host whose resistance is compromised; most common opportunistic infection in AIDS in the United States • Organism invades the lungs of patients who have suppressed immune system (from AIDS, cancer, leukemia) or after immunosuppressive therapy for cancer, organ transplant, or collagen disease • Frequently associated with concurrent infection by viruses (cytomegalovirus), bacteria, and fungi	• TMP-SMX; dapsone with trimethoprim, clindamycin with primaquine • Pentamidine methanesulfonate	• Patients are critically ill • Prognosis guarded because it is usually a complication of a severe underlying disorder
Fungal pneumonia	• *Aspergillus fumigatus*	• Fever, productive cough, chest pain, hemoptysis • Chest x-ray reveals a broad range of abnormalities from infiltration to consolidation, cavitation, and empyema	• Neutropenic individual most susceptible • May develop Aspergillus as a superinfection • Often seen in late HIV disease	• Amphotericin B; itraconazole	• High mortality rate • Invades blood vessels and destroys lung tissue by direct invasion and vascular infarction

** Patients with CAP should be treated a minimum of 5 days and should be afebrile for 48 to 72 hours and clinically stable before discontinuing antibiotics.*

Pathophysiology and Etiology

1. Community-acquired pneumonia (CAP) is a common infectious disease often caused by the bacteria *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis*, as well as the viruses rhinovirus and influenza.
2. Development of CAP may be due to a defect in host defenses, exposure to a virulent microorganism, or an overwhelming exposure. An organism gains access to the lungs through aspiration of oropharyngeal contents, by inhalation of respiratory secretions from infected individuals, via the bloodstream, or from direct spread to the lungs as a result of surgery or trauma.
3. Risk factors include altered mental status, smoking, alcohol use, hypoxemia, toxic inhalations, pulmonary edema, uremia, malnutrition, bronchial obstruction, advanced age, immunosuppression, heart disease, underlying lung disease (cystic fibrosis, bronchiectasis, COPD, ciliary dysfunction, lung cancer), viral respiratory infection, and history of pneumonia.

a. Immunocompromised patients include those receiving corticosteroids, immunosuppressants, chemotherapy, or radiotherapy; those with cancer, HIV infection, acquired immunodeficiency syndrome (AIDS), and alcoholism; those who are intravenous (IV) drug users; and those undergoing organ transplantation.

b. These people have an increased risk of developing overwhelming infection. Infectious agents include aerobic and anaerobic gram-negative bacilli, *Staphylococcus*, *Nocardia*, fungi, *Candida*, viruses such as cytomegalovirus, *Pneumocystis jiroveci*, reactivation of tuberculosis (TB), and others.

4. When bacterial pneumonia occurs in a healthy person, it may be preceded by a viral illness.
5. Other predisposing factors include conditions interfering with normal secretion clearance of the lung, such as tumor, general anesthesia, postoperative immobility; depression of the CNS from drugs, neurologic disorders, alcohol; and intubation.
6. Pneumonia may be divided into three groups:
   a. Community acquired, because of several organisms.
      i. "Typical" organisms include *Streptococcus pneumoniae* (most common organism), *Haemophilus influenzae*, *Staphylococcus aureus*, *Moraxella catarrhalis*, anaerobes, and aerobic gram-negative bacteria, and rhinovirus and influenza virus.
      ii. Atypical pneumonia may be caused by *Legionella* species, *Mycobacterium pneumoniae*, and *Chlamydophila pneumoniae*.
   b. Health care–associated pneumonia, also known as hospital or nursing home acquired (nosocomial), due primarily to gram-negative bacilli and staphylococci. HCAP includes patients who have recently been hospitalized within 90 days of the infection, resided in a nursing home or long-term care facility, or received parenteral antimicrobial therapy, chemotherapy, or wound care within 30 days of pneumonia.
   c. Pneumonia in the immunocompromised person.
7. People older than age 65 have a high rate of mortality, even with appropriate antimicrobial therapy.

NURSING ALERT Recurring pneumonia commonly indicates underlying disease, such as cancer of the lung, multiple myeloma, bronchiectasis, or COPD.

Clinical Manifestations

For most common forms of bacterial pneumonia:

1. Typical bacterial CAP typically presents with fever, dyspnea, fatigue, and productive cough and often with pleuritic chest pain.
2. Pleuritic chest pain may be aggravated by respiration/coughing.
3. Dyspnea and tachypnea use of accessory muscles of respiration and fatigue.
4. Tachycardia may be present.

Diagnostic Evaluation

1. Chest x-ray shows a discernible infiltrate and presence/extent of pulmonary disease, typically consolidation.
2. Gram stain and culture and sensitivity of sputum are reliable and diagnostic if performed on a well-collected specimen without saliva contamination (excess squamous epithelial cells are present if saliva contamination) and if a predominant organism is present.
    a. Many patients, especially elderly persons, are not able to produce an adequate suitable sputum sample.
    b. Endobronchial specimens should be obtained from intubated patients.
    c. CAP is often diagnosed presumptively, without culture, but should be investigated for specific pathogens that would significantly alter standard management decisions, based on sputum culture (Gram stain typically shows few or no predominant organisms in atypical CAP).
3. Indications for sputum culture include:
    a. All patients requiring intubation and mechanical ventilation.
    b. Nonventilator patients with risk factors for *Pseudomonas aeruginosa* or other multidrug-resistant gram-negative enteric pathogen infection, including severe COPD, use of chronic oral corticosteroids, and those with active alcohol abuse.
    c. Nonventilator patients with risk factors for *Staphylococcus aureus*, including end-stage renal disease, receiving hemodialysis, history of injection drug use, cavitary pulmonary infiltrates, and acute postinfluenza pneumonia.
4. Pretreatment blood samples for culture to detect bacteremia should be obtained from patients with admission to intensive care unit, cavitary lesion on chest x-ray, leukopenia, active alcohol abuse, chronic severe liver disease, asplenia, positive pneumococcal urinary antigen test, or pleural effusion.
5. Immunologic tests may be ordered to detect microbial antigens in serum, sputum, and urine.
6. Severity-of-illness scores, such as the CURB-65 criteria (confusion, uremia, respiratory rate, low BP, age 65 or greater), or pneumonia severity index can be used to identify patients with CAP who may be candidates for outpatient treatment.

Management

1. Antimicrobial therapy—depends on empiric recommendations and/or laboratory identification of causative organism and sensitivity to specific antimicrobials.
2. Oxygen therapy, if patient has inadequate gas exchange.
3. Patients with hypoxemia or respiratory distress who are refractory to oxygen should receive a cautious trial of noninvasive ventilation unless they require immediate intubation because of severe hypoxemia or acute respiratory failure.
4. Low V_T ventilation (6 mL/kg ideal body weight) for diffuse bilateral pneumonia or ARDS.
5. Early mobilization when clinically stable reduces length of facility stay.

6. Assess influenza and pneumococcal vaccination status, and if not currently vaccinated or status uncertain, perform prior to hospital discharge.
7. Advise and assist with smoking cessation in currently smoking patients.
8. Respiratory hygiene measures, including the use of hand hygiene and masks or tissues for patients with cough, should be used in outpatient settings and EDs to reduce the spread of respiratory infections.

Complications

1. Pleural effusion.
2. Sustained hypotension and shock, especially in gram-negative bacterial disease, particularly in older patients.
3. Empyema.
4. Superinfection: pericarditis, bacteremia, and meningitis.
5. Delirium—considered a medical emergency.
6. Atelectasis—because of mucus plugs.
7. Delayed resolution.

Nursing Assessment

1. Take a careful history to help establish etiologic diagnosis. Local epidemiology and patient travel history, history of exposures, and local or national outbreaks may help in pneumonia identification.
    a. History of recent respiratory illness, complete medical history, and social history including risk factors for pneumonia.
    b. Presence of purulent sputum, increased amount of sputum, fever, chills, pleuritic pain, dyspnea, and tachypnea.
    c. Any pattern of family illness.
    d. Medications (including recent antibiotics) and allergies.
2. Observe for dyspnea, excess fatigue, change in mental status, anxiety, or respiratory distress.
3. Auscultate for crackles overlying affected region and for bronchial breath sounds when consolidation (filling of airspaces with exudate) is present.

Nursing Diagnoses

- Impaired Gas Exchange related to decreased ventilation secondary to inflammation and infection involving distal airspaces.
- Ineffective Airway Clearance related to excessive tracheobronchial secretions.
- Acute Pain related to inflammatory process, infection, and dyspnea.
- Risk for Injury secondary to complications.

Nursing Interventions

Improving Gas Exchange

1. Observe for dyspnea, hypoxia, cyanosis, and confusion, indicating worsening condition.
2. Follow ABG levels/SpO_2 to determine oxygen need and response to oxygen therapy.
3. Administer oxygen at concentration to maintain PaO_2/SpO_2 at acceptable level. Hypoxemia may be due to abnormal V/Q mismatch with shunt in affected lung segments.
4. Use caution with high concentrations of oxygen in patients with COPD, particularly with evidence of CO_2 retention; use of high oxygen concentrations may worsen alveolar ventilation in some patients by depressing the patient's only remaining ventilatory drive. If high concentrations of oxygen are given, monitor alertness and PaO_2 and $PaCO_2$ levels for signs of CO_2 retention.
5. Place patient in an upright position as tolerated to obtain greater lung expansion and improve aeration. Frequent turning and increased activity (up in chair, ambulate as tolerated) should be employed if clinically stable.

Enhancing Airway Clearance

1. If ordered, obtain freshly expectorated sputum for Gram stain and culture initially prior to antibiotic treatment. Early morning specimens are preferable for subsequent specimens. Instruct the patient as follows:
   a. Perform oral care and rinse mouth with water to minimize contamination by normal flora.
   b. Breathe deeply several times.
   c. Cough deeply and expectorate raised sputum into sterile container.
2. Auscultate the chest for crackles and rhonchi. Encourage patient to deep breath and cough to reduce retained secretions that interfere with gas exchange. Suction as necessary.
3. Encourage increased fluid intake, unless contraindicated, to replace fluid losses caused by fever, diaphoresis, dehydration, and tachypnea.
4. Humidify oxygen over 4 L/minute to reduce dryness of mucus membranes.
5. Employ PEP device use, huff cough, and possibly chest wall percussion and postural drainage, when appropriate, to loosen and mobilize secretions.
6. When clinically stable, mobilize patient to improve ventilation and secretion clearance and reduce risk of atelectasis and worsening pneumonia.

Relieving Pleuritic Pain

1. Place patient in a comfortable position (semi-Fowler's) for resting and breathing; encourage frequent change of position to prevent pooling of secretions in lungs and atelectasis.
2. Demonstrate how to splint the chest while coughing.
3. Avoid suppressing a productive cough.
4. Administer prescribed nonsedating analgesic agent to relieve pain.
5. Use comfort measures to improve symptom control.
6. Encourage modified bed rest during febrile period.
7. Watch for abdominal distention or ileus, which may be due to swallowing of air during intervals of severe

dyspnea. Insert a nasogastric (NG) or rectal tube, as directed.

GERONTOLOGIC ALERT Sedatives, opioids, and cough suppressants should be used cautiously in older patients because of their tendency to suppress cough and gag reflexes and respiratory drive. Also, provide or encourage frequent oral care for pneumonia prevention.

Monitoring for Complications

1. Be aware that fatal complications may develop during the early period of antimicrobial treatment.
2. Monitor temperature, pulse, respiration, BP, oximetry, mentation, and for evidence of dyspnea at regular intervals to assess the patient's response to therapy.
3. Auscultate lungs and heart. Heart murmurs or friction rub may indicate acute bacterial endocarditis, pericarditis, or myocarditis.
4. Employ special nursing surveillance for patients with:
   a. Alcoholism, COPD, and immunosuppression—these people as well as older patients may have little or no fever.
   b. Chronic bronchitis—it may be difficult to detect subtle changes in condition because the patient may have seriously compromised pulmonary function and regular mucus production.
   c. Epilepsy—pneumonia may result from aspiration after a seizure.
   d. Delirium—may be caused by hypoxia, meningitis, and alcohol withdrawal.
5. Assess these patients for unusual behavior, alterations in mental status, stupor, and heart failure.
6. Assess for resistant fever or return of fever, potentially suggesting bacterial resistance to antibiotics.

NURSING ALERT Delirium causes and treatment must be identified to control symptoms and prevent exhaustion and cardiac failure. Prepare for lumbar puncture, if indicated, to rule out meningitis, which may be lethal. Mild sedation should be considered with caution.

Patient Education and Health Maintenance

1. Advise patient to complete entire course of antibiotics.
2. Advise patient that fatigue and weakness may persist after pneumonia.
3. Once clinically stable, encourage gradual increase in activities to improve ventilation and reduce hazards of immobility.
4. Encourage breathing exercises to clear lungs and promote full expansion and function.
5. Explain that a chest x-ray is usually taken 4 to 6 weeks after recovery to evaluate lungs for clearing and detect any tumor or underlying cause.

6. Advise smoking cessation. Cigarette smoke destroys tracheobronchial cilial action, which is the first line of defense of lungs, also irritates mucosa of bronchi, and inhibits function of alveolar scavenger cells (macrophages).
7. Advise the patient to keep up natural resistance with good nutrition, adequate rest, and physical activity, when tolerated. One episode of pneumonia may make the patient susceptible to recurring respiratory infections.
8. Instruct patient to avoid fatigue, sudden extremes in temperature, and excessive alcohol intake, which lower resistance to pneumonia.
9. Assess for and facilitate vaccination with pneumococcal and influenza vaccines (see pages 193 to 194). Influenza vaccine is associated with reduced hospitalizations for pneumonia, influenza, and death in community-dwelling older adults.
10. Advise avoidance of contact with people with upper respiratory infections for several months after pneumonia resolves.
11. Respiratory and hand hygiene includes frequent handwashing, especially after contact with others.

Evaluation: Expected Outcomes

- Cyanosis and dyspnea reduced; ABG levels and SaO_2 improved.
- Coughs effectively; absence of crackles.
- Appears more comfortable; free of pain.
- Fever controlled; no signs of resistant infection.

Aspiration Pneumonia

Aspiration is the inhalation of oropharyngeal secretions and/or stomach contents into the lower airways. It may lead to acute pneumonia.

Pathophysiology and Etiology

1. Loss of protective airway reflexes (swallowing, cough) may be caused by altered state of consciousness, alcohol or drug overdose, seizures, stroke, head trauma, general anesthesia, intercranial mass or lesion, during resuscitation procedures, seriously ill or debilitated patients, and abnormalities of gag and swallowing reflexes.
2. Other conditions and risk factors associated with aspiration include the following:
   a. Esophageal strictures and diverticula, head and neck neoplasms, tracheoesophageal fistula, and gastroesophageal reflux.
   b. Multiple sclerosis, dementia, Parkinson disease, myasthenia gravis, and pseudobulbar palsy.
   c. Intubation, tracheostomy, endoscopy, and bronchoscopy.
   d. Obstetric patients—from general anesthesia, lithotomy position, delayed emptying of the stomach from enlarged uterus, and labor contractions.
   e. Gastrointestinal conditions—hiatal hernia, intestinal obstruction, abdominal distention, nasogastric or feeding tube, and gastric or postpyloric tube feedings.
   f. Prolonged vomiting or recumbent position.
3. Effects of aspiration depend on volume and character of aspirated material.
   a. Gastric acid causes a chemical pneumonitis.
   b. Bacteria from the oropharynx causes aspiration pneumonia.
   c. Oil (mineral oil or vegetable oil) causes exogenous lipoid pneumonia.
   d. Foreign body may cause an acute respiratory emergency and may predispose the patient to bacterial pneumonia.
   e. Many cases of pneumonia result from aspiration of pathogens from the oral cavity or nasopharynx caused by *Streptococcus pneumoniae*, *Haemophilus influenza*, *Staphylococcus aureus*, and gram-negative bacteria. These bacteria are relatively virulent so that only a small inoculum is required to result in a pneumonia. The aspiration episode may be subtle.

GERONTOLOGIC ALERT Oropharyngeal dysphagia has been found in the majority of elderly patients (mean age, 84 years).

Clinical Manifestations

1. Tachycardia and fever.

2. Dyspnea, cough, and tachypnea.
3. Hypoxemia and cyanosis.
4. Decreased breath sounds, rales, pleural friction rub, and dullness to percussion overconsolidation.
5. Purulent sputum.

Diagnostic Evaluation

1. Chest x-ray may be normal initially; with time, shows consolidation and other abnormalities.

Management

1. Clearing the obstructed airway.
    a. If foreign body is visible, it may be removed manually.
    b. Suction trachea/ET tube—to remove particulate matter.
    c. Optimize secretion clearance and manage hypoxia with supplemental oxygen.
2. Antimicrobial therapy or specific therapy depending on material aspirated.
3. Laryngoscopy/bronchoscopy may be performed for aspiration of solid material.
4. Oxygen therapy and assisted ventilation if adequate oxygenation cannot be maintained.
5. Fluid volume replacement and correction of acidosis for correction of hypotension and shock.

Complications

1. Lung abscess and empyema.
2. Necrotizing pneumonia.
3. ARDS.

Nursing Assessment

1. Assess for airway obstruction and hypoxemia.
2. Assess for development of fever, foul-smelling sputum, and congestion.
3. Assess LOC, gag reflex, swallowing ability, and other risk factors for aspiration.

Nursing Diagnoses

- Impaired Gas Exchange related to decreased ventilation secondary to inflammation and infection involving distal airspaces.
- Ineffective Airway Clearance related to excessive tracheobronchial secretions.
- Acute Pain related to inflammatory process and dyspnea.
- Risk for Injury secondary to complications.

(See pages 196 to 201 for nursing interventions.)

Additional Nursing Interventions

1. Carefully monitor patients at risk for aspiration.
2. Elevate head of bed for debilitated patients, for those receiving tube feedings, and for those at risk for aspiration.
3. For patients with feeding tubes, make sure tube is positioned properly and tube is patent.
   a. Give tube feedings slowly, with head of bed elevated. Check for residual volume.
   b. Check position of tube in the stomach before feeding.
   c. Check seal of cuff of tracheostomy or ET tube before feeding.
4. Keep the patient in a fasting state before anesthesia (at least 8 hours).
5. Feed patients with impaired swallowing slowly, and make sure that no food is retained in the mouth after feeding.

NURSING ALERT Morbidity and mortality rates of aspiration pneumonia remain high even with optimum treatment. Prevention is the key to the problem.

Pulmonary Embolism

Pulmonary embolism (PE) refers to the obstruction of one or more pulmonary arteries by a thrombus (or thrombi) usually originating in the deep veins of the legs, the right side of the heart, or, rarely, an upper extremity, which becomes dislodged and is carried to the pulmonary vasculature.

Acute PE is a common form of venous thromboembolism (VTE) leading to V/Q mismatch, increase in pulmonary vascular resistance, pulmonary artery pressure, right heart workload and heart failure, decrease in cardiac output, and shock. Pulmonary infarction refers to necrosis of lung tissue because of reduction in blood supply.

Pathophysiology and Etiology

1. Obstruction, either partial or full, of pulmonary arteries, which causes decrease or absent blood flow; therefore, there is ventilation but no perfusion (V/Q mismatch).
2. Hemodynamic consequences:
   a. Increased pulmonary vascular resistance.
   b. Increased pulmonary artery pressure (PAP).
   c. Increased right-sided heart workload to maintain pulmonary blood flow.
   d. Right-sided heart failure.
   e. Decreased cardiac output.
   f. Decreased BP.
   g. Shock.
   h. Risk of hypoxemia.
3. Pulmonary emboli can vary in size and seriousness of consequences.
4. Predisposing factors include the following:
   a. Stasis and prolonged immobilization.
   b. Concurrent phlebitis.
   c. Heart failure and stroke.
   d. Injury to vessel wall.
   e. Coagulation disorders and hypercoagulable state.
   f. Malignancy.
   g. Advancing age, estrogen therapy, and oral contraceptives.
   h. Fracture of long bones.
   i. Obesity.

NURSING ALERT Be aware of high-risk patients for pulmonary embolism—immobilization, trauma to the pelvis (especially surgical) and lower extremities (especially hip fracture), obesity, history of

thromboembolic disease, varicose veins, pregnancy, heart failure, myocardial infarction (MI), malignant disease, postoperative patients, and older patients.

Clinical Manifestations

1. Rapid onset of dyspnea at rest, pleuritic chest pain, cough, syncope, delirium, apprehension, tachypnea, diaphoresis, and hemoptysis. Onset may be prolonged and presentation more subtle if obstruction is partial.
2. Chest pain with apprehension and a sense of impending doom occur when most of the pulmonary artery is obstructed.
3. Tachycardia, rales, fever, hypotension, cyanosis, heart gallop, and loud pulmonic component of S_2 (split S_2).
4. Calf or thigh pain, edema, erythema, tenderness, or palpable cord (signs suggestive of deep vein thrombosis).

NURSING ALERT Have a high index of suspicion for pulmonary embolus if there is a subtle or significant deterioration in the patient's condition and unexplained cardiovascular and pulmonary findings.

Diagnostic Evaluation

1. Thoracic imaging: V/Q scan (possibly using single-photon emission computed tomography) or helical contrast-enhanced computed tomography (CT).
2. Pulmonary angiography if noninvasive testing is inconclusive or not candidate for noninvasive testing. Contrast studies should be avoided in persons who are pregnant or have advanced renal failure.
3. D-Dimer assay for low to intermediate probability of pulmonary embolism.
4. ABG levels—decreased PaO_2 is usually found, because of perfusion abnormality of the lung.
5. Chest x-ray—normal or possible wedge-shaped infiltrate.

Management

Emergency Management

For massive pulmonary embolism, the goal is to stabilize cardiorespiratory status.

NURSING ALERT Massive pulmonary embolism is a medical emergency; the patient's condition tends to deteriorate rapidly. There may be a profound decrease in cardiac output, with an accompanying increase in right ventricular pressure.

1. Oxygen is administered to relieve hypoxemia, respiratory distress, and cyanosis and to dilate pulmonary vasculature.
2. An infusion is started to open an IV route for drugs and fluids.
3. Vasopressors, inotropic agents such as dopamine, and antiarrhythmic agents may be indicated to support circulation if the patient is unstable.
4. ECG is monitored continuously for findings suggestive of right-sided heart failure, which may have a rapid onset. Changes may include sinus tachycardia, Q waves, late T-wave inversion, S wave in lead I, right bundle-branch block, right axis deviation, atrial fibrillation, and T-wave changes.
5. Small doses of IV morphine may be given to relieve anxiety, alleviate chest discomfort (which improves ventilation), and ease adaptation to mechanical ventilator, if this is necessary.
6. Pulmonary angiography, thoracic imaging, hemodynamic measurements, ABG analysis, and other studies are carried out.

Subsequent Management: Anticoagulation and Thrombolysis

1. Anticoagulant therapy includes subcutaneous low molecular weight heparin (LMWH), IV or subcutaneous unfractionated heparin (UFH) with monitoring, unmonitored weight-based subcutaneous UFH, or subcutaneous fondaparinux.
2. Anticoagulants stop further thrombus formation and extend the clotting time of the blood; they do not dissolve clots.
    a. UFH is given as IV loading dose usually followed by continuous pump or drip infusion or given intermittently every 4 to 6 hours.
    b. Dosage adjusted to maintain the partial thromboplastin time (PTT) at 1½ to 2 times the pretreatment value (if the value was normal).
    c. Protamine sulfate may be given to neutralize heparin in the event of severe bleeding.
3. Oral anticoagulation with warfarin is usually used for follow-up anticoagulant therapy after heparin therapy has been established and interrupts the coagulation mechanism by interfering with the vitamin K–dependent synthesis of prothrombin and factors VII, IX, and X.
    a. Dosage is controlled by monitoring serial tests of international normalized ratio (INR), achieving 2.0 to 3.0 as the norm.
    b. Fresh frozen plasma (FFP) should be given for emergent reversal of INR greater than 9 (2 units FFP for patients with low to moderate risk of bleeding, 4 units for those with high risk).
    c. Vitamin K may be given orally when INR is greater than 5, in addition to holding doses of coumadin, or by slow IV infusion for significant bleeding.
4. Thrombolytic (fibrinolytic) agents, such as streptokinase, may be used in patients with massive pulmonary embolism.
    a. Effective in lysing recently formed thrombi.
    b. Improved circulatory and hemodynamic status.
    c. Administered IV in a loading dose followed by constant infusion.

5. Newer clot-specific thrombolytics (tissue plasminogen activator, streptokinase activator complex, single-chain urokinase) are preferred.
   a. Activate plasminogen only within thrombus itself rather than systematically.
   b. Minimize occurrence of generalized fibrinolysis and subsequent bleeding.
6. Absolute contraindications to fibrinolytics include any prior intracranial hemorrhage, known structural intracranial cerebrovascular disease such as artriovenous malformation, known intracranial neoplasm, ischemic stroke within 3 months, suspected aortic dissection, bleeding, recent surgery of spinal canal or brain, and recent closed head or facial trauma. Caution should be the used in patients greater than 75 years, current use of anticoagulation, pregnancy, no compressible vascular punctures, traumatic or prolonged cardiopulmonary resuscitation, recent internal bleeding, history of severe hypertension, current systolic BP greater than 180 or diastolic BP greater than 110, dementia, remote ischemic stroke, and major surgery within 3 weeks.
7. Graduated compression stockings with 30 to 40 mm Hg compression, knee-high, and sized to fit help dilate deep veins and decrease swelling and venous ulcers that can develop due to postthrombosis syndrome and reduce risk of recurrent DVT and PE.

GERONTOLOGIC ALERT Consider the patient's age and INR level in dosing of anticoagulation therapy. Older patients will usually need a decreased dosing regimen.

Surgical Intervention

1. When anticoagulation and thrombolysis are contraindicated or patient has recurrent embolization or develops serious complications from drug therapy.
2. Placement of transvenously inserted intraluminal filter in inferior vena cava to prevent migration of emboli (see Figure 11-2); inserted through femoral or jugular vein by way of catheter.
3. Embolectomy (removal of pulmonary embolic obstruction), either by open surgical embolectomy or catheter embolectomy with fragmentation.

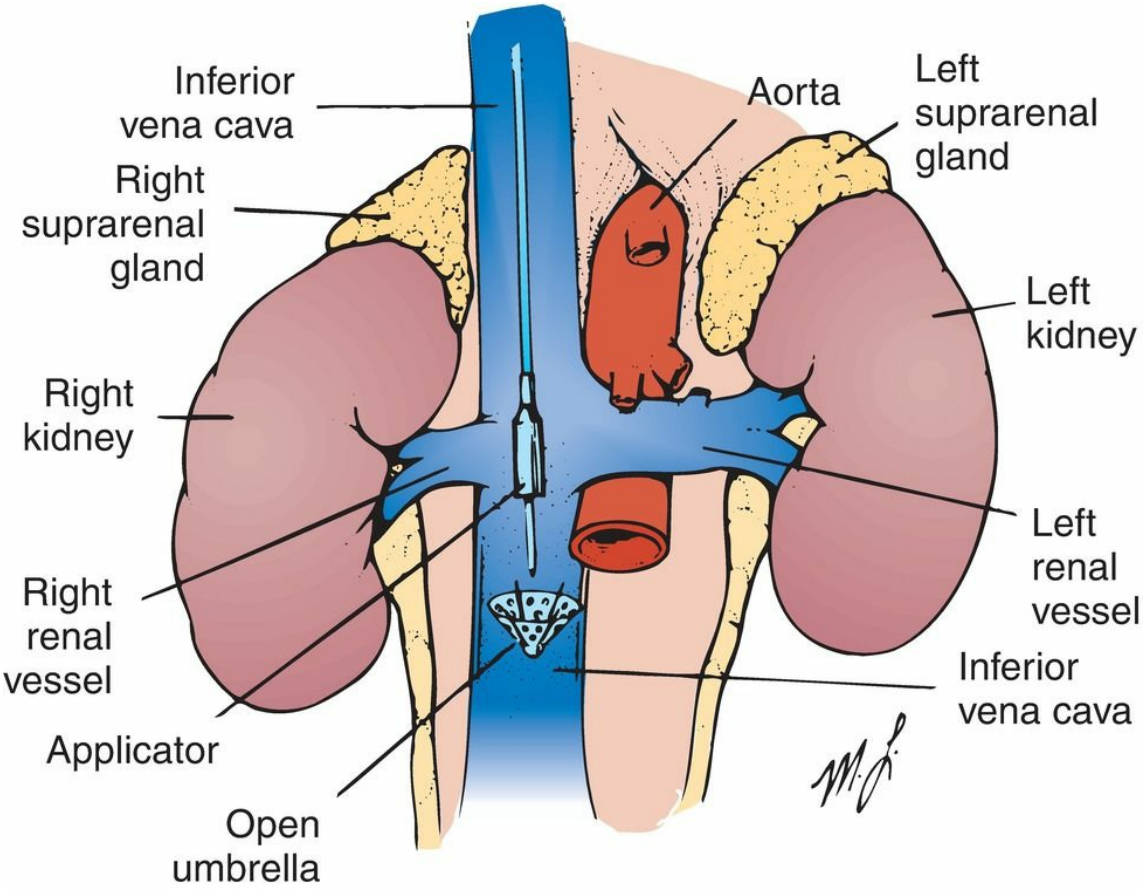

Figure 11-2. Insertion of umbrella filter in inferior vena cava to prevent pulmonary embolism. Filter (compressed within an applicator catheter) is inserted through an incision in the right internal jugular vein. The applicator is withdrawn when the filter fixes itself to the wall of the inferior vena cava after ejection from the applicator.

EVIDENCE BASE Poterucha, T. J., Bergmark, B., Aranki, S., et al. (2015). Surgical pulmonary embolectomy. *Circulation, 132*, 1146–1151.

Complications

1. Bleeding as a result of treatment.
2. Respiratory failure.
3. Chronic thromboembolic pulmonary hypertension (CTEPH) and cor pulmonale.

Nursing Assessment

1. Take nursing history with emphasis on onset and severity of dyspnea and nature of chest pain, as well as PMH for contraindications to thrombolytic therapy.
2. Examine the patient's legs carefully. Assess for swelling of the leg, duskiness, warmth, pain on pressure

over gastrocnemius muscle, and pain on dorsiflexion of the foot (positive Homans sign), which indicate thrombophlebitis as source.

3. Monitor respiratory rate—may be accelerated out of proportion to degree of fever and tachycardia.
   a. Observe rate of inspiration to expiration.
   b. Percuss for resonance or dullness.
   c. Auscultate for friction rub, crackles, rhonchi, and wheezing.
4. Auscultate heart; listen for splitting of second heart sound.
5. Evaluate results of INR for patients on anticoagulants and report results that are outside of therapeutic range promptly; anticipate a dosage change.

Nursing Diagnoses

- Ineffective Breathing Pattern related to acute increase in alveolar dead airspace and possible changes in lung mechanics from embolism.
- Ineffective Tissue Perfusion (Pulmonary) related to decreased blood circulation.
- Acute Pain (pleuritic) related to congestion, possible pleural effusion, and possible lung infarction.
- Anxiety related to dyspnea, pain, and seriousness of condition.
- Risk for Injury related to altered hemodynamic factors and anticoagulant therapy.

Nursing Interventions

Correcting Breathing Pattern

1. Assess for hypoxia, dyspnea, headache, restlessness, apprehension, pallor, cyanosis, and behavioral changes.
2. Monitor vital signs, ECG, oximetry, and ABG levels for adequacy of oxygenation.
3. Monitor patient's response to IV fluids/vasopressors.
4. Monitor oxygen therapy—used to relieve hypoxemia.
5. Prepare patient for assisted ventilation when hypoxemia does not respond to supplemental oxygen. Hypoxemia is due to ventilation/perfusion mismatch.

Improving Tissue Perfusion

1. Closely monitor for shock—decreasing BP, tachycardia, and cool, clammy skin.
2. Monitor prescribed medications given to preserve right-sided heart filling pressure and increase BP.
3. Maintain patient on bed rest during acute phase to reduce oxygen demands and risk of bleeding.
4. Monitor urinary output hourly because there may be reduced renal perfusion and decreased glomerular filtration.
5. Provide antiembolism compression stockings with 30 to 40 mm Hg of compression.

Relieving Pain

1. Watch patient for signs of discomfort and pain.

2. Ascertain if pain worsens with deep breathing and coughing; auscultate for friction rub.
3. Give morphine, as prescribed, and monitor for pain relief and signs of respiratory depression.
4. Position with head of bed slightly elevated (unless contraindicated by shock) and with chest splinted for deep breathing and coughing.
5. Evaluate patient thoroughly for signs of hypoxia when anxiety, restlessness, and agitation of new onset are noted, before administering as-needed sedatives. Consider calling health care provider when these signs are present, especially if accompanied by cyanotic nail beds, circumoral pallor or cyanosis, and increased respiratory rate.

Reducing Anxiety

1. Correct dyspnea and relieve physical discomfort.
2. Explain diagnostic procedures and the patient's role; correct misconceptions.
3. Listen to the patient's concerns; attentive listening relieves anxiety and reduces emotional distress.
4. Speak calmly and slowly.
5. Do everything possible to enhance the patient's sense of control.

Intervening for Complications

1. Be alert for bleeding—related to anticoagulant or thrombolytic therapy. Major bleeding may occur from GI tract, brain, lungs, nose, and genitourinary (GU) tract.
2. Perform stool guaiac test to detect occult blood loss.
3. Monitor platelet count to detect heparin-induced thrombocytopenia.
4. Minimize risk of bleeding by performing essential ABG analysis on upper extremities; apply digital compression at puncture site for 30 minutes; apply pressure dressing to previously involved sites; check site for oozing.
5. Maintain patient on strict bed rest during thrombolytic therapy; avoid unnecessary handling.
6. Discontinue infusion in the event of uncontrolled bleeding.
7. Notify health care provider on call immediately for change in LOC or sensation or ability to follow commands, move limbs, or respond to questions with clear articulation. Intracranial bleed may necessitate discontinuation of anticoagulation promptly to avert massive neurologic catastrophe.
8. Be alert for shock from low cardiac output secondary to resistance to right-sided heart outflow or to myocardial dysfunction because of ischemia.
    a. Assess for skin color changes, particularly nail beds, lips, earlobes, and mucous membranes.
    b. Monitor BP, pulse, and SpO_2.
    c. Measure urine output.
    d. Monitor IV infusion of vasopressor or other prescribed agents.

TRANSITIONAL CARE ALERT Follow-up nursing care involves anticoagulant management and early identification of complications to prevent readmission. Patients presenting with unexplained dyspnea, exercise intolerance, or clinical evidence of right-sided heart failure should be evaluated for CTEPH with echocardiogram 6 weeks after an acute PE to screen for persistent pulmonary hypertension. Risk factors for CTEPH include multiple episodes of PE, larger perfusion defect, younger age, female gender, and genetic propensity.

Patient Education and Health Maintenance

1. Advise patient of the possible need to continue taking anticoagulant therapy for 6 weeks up to an indefinite period as well as safety considerations and drug and food interactions with anticoagulants.
2. Train regarding food and drug interactions if taking warfarin.
3. Teach about signs of bleeding, especially of the gums and nose, bruising, and blood in urine and stools.
4. For patients on anticoagulants, instruct to use soft toothbrush, avoid shaving with blade razor (use electric razor instead), and avoid aspirin-containing products. Notify health care provider of bleeding or increased bruising.
5. Warn against taking medications unless approved by health care provider because many drugs interact with anticoagulants.
6. Instruct patient to tell dentist about taking an anticoagulant.
7. Warn against inactivity for prolonged periods or sitting with legs crossed to prevent recurrence.
8. Warn against sports/activities that may cause trauma or injury to legs and predispose to a thrombus.
9. Encourage wearing a MedicAlert bracelet, identifying patient as anticoagulant user.
10. Instruct patient to lose weight, if applicable; obesity is a risk factor.
11. Discuss contraceptive methods with patient, if applicable; females with history of pulmonary embolus are advised against taking hormonal contraceptives.

Evaluation: Expected Outcomes

- Verbalizes less shortness of breath.
- Vital signs stable; adequate urinary output.
- Reports freedom from pain.
- Appears more relaxed; sleeping at long intervals.
- Progresses without major bleeding or other complications.

Tuberculosis

Tuberculosis (*TB*) is an infectious disease caused by bacteria (*Mycobacterium tuberculosis*). It is usually spread from person to person through droplet aerosolization (droplet nuclei). It usually infects the lung but can occur at virtually any site in the body.

Pathophysiology and Etiology

Transmission

1. The term *Mycobacterium* is descriptive of a bacterium that resembles a fungus. The organisms multiply at varying rates and are characterized as acid-fast aerobic organisms that can be killed by heat, sunshine, and ultraviolet light.
2. TB is an airborne disease transmitted by droplet nuclei, usually from within the respiratory tract of an infected person who exhales them during coughing, talking, sneezing, or singing.
3. When a susceptible person inhales the droplet-containing air, the organism is carried into the lung to the pulmonary alveoli.
    a. About 2½ to 12 weeks after initial TB infection, TB testing (purified protein derivative [PPD] or quantiFERON blood test) is positive; however, most people who become infected do not develop clinical illness because the body's immune system brings the infection under control.
    b. Some bacilli remain viable in the body for years, such as with LTBI. Persons with LTBI have no symptoms and are not infectious.
4. Persons at increased risk for TB include close contacts of persons with active TB; persons travelling from Africa, Asia, Eastern Europe, Latin America, and Russia; residents of high-risk congregate settings (correctional facilities, long-term care facilities, and homeless shelters); health care workers exposed to high-risk patients; and infants and children or adolescents exposed to high-risk adults.
5. Of concern in controlling TB in the United States is the prevalence of infection among foreign-born persons residing in the United States, delays in detecting and reporting pulmonary TB, and deficiencies in identifying and screening close contacts and persons with LTBI who are at risk for progression to active TB. The population at risk for progression include the following:
    a. Those who are HIV positive.
    b. Those who have acquired TB infection within last 2 years.
    c. Children younger than age 4.
    d. Those with already immunocompromised conditions such as silicosis; diabetes mellitus; chronic renal failure; leukemia, lymphoma, and carcinoma of the head, neck, or lung; 10% or more below ideal body weight; prolonged corticosteroid use; use of tumor necrosis factor–alpha (TNF-α) antagonists; organ transplant; intestinal bypass or gastrectomy; and history of untreated or inadequately treated TB.

Pathology

1. The bacilli of TB infect the lung, forming a tubercle (lesion).

2. The tubercle:
    a. May heal, leaving scar tissue.
    b. May continue as a granuloma, then heal, or be reactivated.
    c. May eventually proceed to necrosis, liquefaction, sloughing, and cavitation.
3. The initial lesion may disseminate tubercle bacilli by extension to adjacent tissues, by way of the bloodstream, the lymphatic system, or through the bronchi.
4. Extrapulmonary TB occurs more commonly in children and immunocompromised individuals and can involve lymph nodes, bones, joints, pleural space, pericardium, CNS, GI tract, GU tissue, and the peritoneum.

Clinical Manifestations

Patient may be asymptomatic or may have insidious symptoms that may be ignored.

1. Constitutional symptoms.
    a. Fatigue, anorexia, weight loss, low-grade fever, and night sweats.
    b. Some patients have acute febrile illness, chills, and flulike symptoms.
2. Pulmonary signs and symptoms.
    a. Cough (insidious onset) progressing in frequency and producing mucoid or mucopurulent sputum and hemoptysis.
    b. Chest pain and dyspnea (suggest extensive involvement).
3. Extrapulmonary TB: pain, inflammation, and dysfunction in any of the tissues infected.

Diagnostic Evaluation

1. Testing for suspected TB infection includes sputum smear evaluated by microscopy for acid-fast bacilli (AFB) following Center for Disease Control and Prevention guidelines. Three sputum specimens are collected 8 to 24 hours apart with one being an early morning specimen.
    a. Results of sputum sample are needed to drive decisions regarding the discontinuation of isolation precautions for patients with suspected TB in health care settings.
    b. For patients with a diagnosis of TB, decisions regarding discontinuation of precautions should be based on sputum smear (ie, three consecutive negative smears) and other clinical criteria.
    c. In patients unable to produce sputum, induction with hypertonic saline should be attempted.
2. Sputum culture—a positive culture for *M. tuberculosis* confirms a diagnosis of active TB infection and can detect drug-resistant strains.
3. Chest x-ray to determine the presence and extent of disease.
4. Tuberculin skin test (PPD or Mantoux test)—inoculation of tuberculin purified protein derivative into the intradermal layer of the inner aspect of the forearm. It is used to detect *M. tuberculosis* infection, past or present, active or inactive (latent).
    a. Skin reaction is observed 48 to 72 hours after injecting 0.1 mL of PPD intradermally. Inspect and

palpate for induration and measure the maximum transverse diameter.

b. An induration of 5 or more millimeters is considered positive in HIV-infected persons, recent contact of a person with TB disease, persons with chest x-ray changes consistent with prior TB, organ recipients, and persons immunosuppressed for other reasons.

c. An induration of 10 or more millimeters is considered positive in recent immigrants (less than 5 years) from high-prevalence countries, injection drug users, those exposed to high-risk congregate settings, mycobacteriology laboratory personnel, other clinical conditions considered high risk, children less than 4 years of age, infants, children, and adolescents exposed to adults in high-risk categories.

d. An induration of 15 or more millimeters is considered positive in any person, including persons with no known risk factors for TB. However, targeted skin testing programs should only be conducted among high-risk groups.

5. QuantiFERON TB Gold blood assay for *Mycobacterium tuberculosis* may serve as an alternative to PPD, but does not distinguish between active and latent TB.

a. Unaffected by past exposure to BCG vaccine.

b. Negative tests should be interpreted with caution in the immunocompromised, those at high risk for TB, and children.

EVIDENCE BASE Centers for Disease Control and Prevention. (2016). Tuberculin skin testing. Available: *www.cdc.gov/tb/publications/factsheets/testing/skintesting.htm.*

NURSING ALERT Cavitation on chest x-ray, positive sputum AFB smear, and ongoing cough increase the risk of infection transmission.

Management

See Table 11-2.

Table 11-2 Recommended Drugs for the Initial Treatment of Tuberculosis in Adults

DRUG	DOSAGE FORMS	DAILY DOSE	TWICE-WEEKLY DOSE	THRICE-WEEKLY DOSE	MAJOR ADVERSE EFFECTS
Isoniazid	• Tablets: 50 mg, 100 mg, 300 mg • Syrup: 50 mg/5 mL • Vials: 1 g	5 mg/kg PO or IM (maximum 300 mg)	15 mg/kg (maximum 900 mg) (can also be given once per week)	15 mg/kg (maximum 900 mg)	Paresthesias, nausea, vomiting, elevated liver transaminases peripheral neuropathy, hepatitis, hypersensitivity, hepatotoxicity, seizures, irritability, lack of concentration, lupuslike syndrome
Rifampin	• Capsules: 150 mg, 300 mg • Syrup: formulated from capsules, 10 mg/mL	10 mg/kg PO (maximum 600 mg)	10 mg/kg (maximum 600 mg)	10 mg/kg (maximum 600 mg)	Red-orange discoloration of body fluids, nausea, vomiting, anorexia, hepatitis, elevated liver transaminases, febrile reaction, purpura (rare), pruritus and rash, caution regarding drug interactions
Pyrazinamide	• Tablets: 500 mg	20 to 25 mg/kg PO	40 to 50 mg/kg	30 to 40 mg/kg (maximum 3 g)	Anorexia, rash, urticaria, nausea, vomiting, hepatotoxicity, hyperuricemia, arthralgias, acute gouty arthritis
Ethambutol	• Tablets: 100 mg, 400 mg	15 to 20 mg/kg	240 to 250 mg/kg	25 to 35 mg/kg	Optic neuritis (decreased red-green color discrimination, decreased visual acuity), peripheral neuritis, joint pain, anorexia, nausea, vomiting, skin rash

1. In patients with active TB, a combination of drugs to which the organisms are susceptible is given to destroy viable bacilli as rapidly as possible and to protect against the emergence of drug-resistant organisms.
2. Current recommended regimen of uncomplicated, previously untreated pulmonary TB is an initial phase of 2 months of bactericidal drugs, including isoniazid (INH), rifampin, pyrazinamide (PZA), and ethambutol (EMB). This regimen should be followed until the results of drug susceptibility studies are available, unless there is little possibility of drug resistance.
    a. If drug susceptibility results are known and organism is fully susceptible, EMB does not need to be included.
    b. For children whose visual acuity cannot be monitored, EMB is not normally recommended except with increased likelihood of INH resistance or if the child has upper lobe infiltration and/or cavity formation.
    c. Because of increasing frequency of global streptomycin resistance, streptomycin is not considered interchangeable with EMB unless organism is known to be susceptible to streptomycin.
    d. PZA may be withheld in patients with severe liver disease, gout, and, possibly, pregnancy.
    e. Adverse effects, including liver injury, have been noted with rifampin and pyrazinamide in a once-daily or twice-weekly combination; therefore, this combination is not recommended for the treatment of latent TB infection.
3. Follow with 4 months of isoniazid and rifampin. Six months of therapy is usually effective for killing the three populations of bacilli: those rapidly dividing, those slowly dividing, and those only intermittently dividing.
4. Sputum smears may be obtained every 2 weeks until they are negative; sputum cultures do not become negative for 3 to 5 months.
5. Rifabutin is used as a substitute for rifampin if the organism is susceptible to rifabutin and for patients taking medications that may interact with rifampin.

6. Second-line drugs—such as cycloserine, ethionamide, streptomycin, amikacin, kanamycin, capreomycin, para-aminosalicylic acid, and some fluoroquinolones—are used in patients with resistance, for retreatment, and in those with intolerance to other agents. Patients taking these drugs should be monitored by health care providers experienced in their use.
7. Extensively drug-resistant tuberculosis (XDR TB) is a relatively rare type of multidrug-resistant tuberculosis resistant to almost all oral drugs used to treat TB, including isoniazid, rifampin, fluoroquinolones, and at least one of the three injectable drugs (ie, amikacin, kanamycin, or capreomycin). XDR TB is of special concern for persons with HIV infection and/or immunocompromised persons because of increased risk of infection and mortality.
8. For people with suspected LTBI, treatment should begin after active TB has been ruled out (see Table 11-3). The usual treatment regimen for LTBI is isoniazid 300 mg PO daily for 9 months. To prevent neurotoxicity, pyridoxine 25 to 50 mg daily is also recommended.

Table 11-3 Drug Therapy for Latent Tuberculosis Infection

DRUG	DURATION (MONTHS)	INTERVAL	MINIMUM DOSES
Isoniazid	9	Daily	270
		Twice weekly	76
Isoniazid	6	Daily	180
		Twice weekly	52
Rifampin	4	Daily	120
Rifampin/ pyrazinamide	Generally should not be offered for treatment of LTBI	—	—

Adapted from Centers for Disease Control and Prevention. (2016). Treatment options for latent tuberculosis infection (LTBI) . Available: www.cdc.gov/tb/publications/factsheets/treatment/LTBItreatmentoptions.htm.

DRUG ALERT Adverse reactions to anti-TB drugs may be significant. Monitor liver function tests and instruct patients to seek immediate medical attention if signs or symptoms of hepatitis occur (nausea, emesis, anorexia, jaundice, dark urine, light grey or clay colored stool, and/or abdominal pain).

EVIDENCE BASE Centers for Disease Control and Prevention. (2016). Treatment Options for Latent Tuberculosis Infection (LTBI). Available: *www.cdc.gov/tb/publications/factsheets/treatment/LTBItreatmentoptions.htm.*

Complications

1. Pleural effusion.

2. TB pneumonia.
3. Other organ involvement with TB.
4. Serious reactions to drug therapy.

Nursing Assessment

1. Obtain history of exposure to TB.
2. Assess for symptoms of active disease—productive cough, night sweats, afternoon temperature elevation, unintentional weight loss, and pleuritic chest pain.
3. Auscultate lungs for crackles.
4. During drug therapy, assess for liver dysfunction.
    a. Question the patient about loss of appetite, fatigue, joint pain, fever, tenderness in liver region, clay-colored stools, dark urine, and vision changes.
    b. Monitor for fever, right upper quadrant abdominal tenderness, nausea, vomiting, rash, and persistent paresthesia of hands and feet.
    c. Monitor results of periodic liver function studies.

Nursing Diagnoses

- Ineffective Breathing Pattern related to pulmonary infection and potential for long-term scarring with decreased lung capacity.
- Risk for infection of staff and other patients related to nature of the disease and patient's symptoms.
- Imbalanced Nutrition: Less Than Body Requirements related to poor appetite, fatigue, and productive cough.
- Noncompliance related to lack of motivation particularly in LTBI and long-term treatment associated with health risk to patient, close contacts, and public health.

Nursing Interventions

Improving Breathing Pattern

1. Administer and teach self-administration of medications as ordered.
2. Encourage rest and avoidance of exertion if acutely ill.
3. Monitor breath sounds, respiratory rate, sputum production, dyspnea, and urine and stool color.
4. Provide supplemental oxygen as ordered.

Preventing Transmission of Infection

1. Be aware that TB is transmitted by respiratory droplets.
2. Provide care for hospitalized patient in a negative pressure room to prevent respiratory droplets from escaping when door is opened.
3. Enforce rule that all staff and visitors use well-fitted standard N-95 particulate masks for contact with patient.

4. Use high-efficiency particulate masks, such as high-efficiency particulate air (HEPA) filter masks or positive air pressure respirators, for high-risk procedures, including suctioning, bronchoscopy, or pentamidine treatments.
5. Use standard precautions for additional protection: gowns and gloves for direct contact with patient, linens or articles in room, and meticulous hand hygiene.
6. Educate the patient to control spread of infection through secretions.
   a. Cover mouth and nose with double-ply tissue when coughing or sneezing. Do not sneeze into bare hand.
   b. Wash hands after coughing or sneezing.
   c. Dispose of tissues promptly into closed plastic bag.
   d. Limit contact with others while infectious.

Improving Nutritional Status

1. Explain the importance of eating a nutritious diet to promote healing and improve defense against infection.
2. Provide small, frequent meals and liquid supplements during symptomatic period.
3. Monitor weight.
4. Administer vitamin supplements, as ordered, particularly pyridoxine (vitamin B_6), to prevent peripheral neuropathy in patients taking INH.

Improving Compliance

1. Educate the patient about the etiology, transmission, and effects of TB. Stress the importance of continuing to take medicine for the prescribed time because bacilli multiply slowly and thus can only be eradicated over a long period.
2. Review adverse effects of the drug therapy (see page 207). Question the patient specifically about common toxicities of drugs being used and emphasize immediate reporting should these occur.
3. Participate in observation of medication taking, weekly pill counts, or other programs designed to increase compliance with treatment for TB.

NURSING ALERT Patient compliance remains a major problem in eradicating TB. Directly observed therapy (DOT) can be helpful (taking medication in an observed setting) and is especially critical for patients with drug-resistant TB, HIV-infected patients, a history of non-adherence to treatment, and those on intermittent treatment regimens (ie, two or three times weekly). Coordinate with case manager, local health department, and home health agency to ensure needed follow-up.

Community and Home Care Considerations

1. Improve ventilation in the home by opening windows in room of affected person and keeping bedroom

door closed as much as possible.

2. Instruct patient to cover mouth with fresh tissue when coughing or sneezing and to dispose of tissues promptly in plastic bags.
3. Discuss TB testing of people residing with patient.
4. Investigate living conditions, availability of transportation, financial status, alcohol and drug abuse, and motivation, which may affect compliance with follow-up and treatment. Initiate referrals to a social worker for interventions in these areas.
5. Report new cases of TB to local or state public health department for screening of close contacts and monitoring.

Patient Education and Health Maintenance

1. Review possible complications: hemorrhage, pleurisy, and symptoms of recurrence (persistent cough, fever, or hemoptysis).
2. Instruct patient on avoidance of job-related exposure to excessive amounts of silicone (working in foundry, rock quarry, sand blasting), which increases risk of reactivation.
3. Encourage patient to report at specified intervals for bacteriologic (smear) examination of sputum to monitor therapeutic response and compliance.
4. Instruct patient in basic hygiene practices and investigate living conditions. Crowded, poorly ventilated conditions contribute to development and spread of TB.
5. Encourage regular symptom screening. Follow-up chest x-ray is recommended if an individual with LTBI chooses not to be treated. A single posteroanterior chest x-ray annually for 2 years is sufficient. Any individual with a history of positive TB test who develops symptoms suggestive of TB (fever, night sweats, weight loss, productive cough, or hemoptysis) should be screened with chest x-ray as part of the clinical evaluation for possible recurrent TB disease.
6. Instruct patient on prophylaxis with INH for people with LTBI or for children or patients infected with HIV who are close household contacts of patients with active TB because these individuals are at high risk of becoming infected.
7. Educate asymptomatic people about PPD testing and treatment of latent TB for positive results, based on risk grouping.

Evaluation: Expected Outcomes

- Afebrile; dyspnea relieved.
- Standard precautions observed; disposes of respiratory secretions properly.
- Maintains body weight.
- Takes medications as prescribed.

Pleurisy

Pleurisy or *pleuritis* is inflammation of the parietal and visceral pleura of the lung.

Pathophysiology and Etiology

1. Inflammation may occur in the course of pulmonary infectious, vascular, or neoplastic disorders:
    a. Pneumonia (bacterial, viral), TB, abscess, and some upper respiratory infections.
    b. Pulmonary embolism or infarction.
    c. Lung cancer.
2. Inflammation of the pleura stimulates nerve endings, causing pain.
3. Additional fluid may develop in pleural space, causing pleural effusion.

Clinical Manifestations

1. Chest pain—becomes severe, sharp, and knifelike on inspiration (pleuritic pain).
    a. May become minimal or absent when breath is held.
    b. May be localized or radiate to the shoulder or abdomen.
2. Intercostal tenderness on palpation.
3. Pleural friction rub—grating or leathery sounds heard in both phases of respiration; heard low in the axilla or over the lung base posteriorly; may be heard for only a day or so.
4. Evidence of infection: fever, malaise, and increased white blood cell count.

Diagnostic Evaluation

1. Chest x-ray may show pleural thickening.
2. Sputum examination may indicate infectious organism.
3. Examination of pleural fluid obtained by thoracentesis for smear and culture.
4. Pleural biopsy may be necessary to rule out other conditions.

Management

1. Treatment for the underlying primary disease (pneumonia, infarction); inflammation usually resolves when the primary disease subsides.
2. Pain relief, using pharmacologic and nonpharmacologic methods.
3. Intercostal nerve block may be necessary when pain causes hypoventilation.

Complications

1. Severe pleural effusion.
2. Atelectasis because of shallow breathing to avoid pain.

Nursing Assessment

1. Assess patient's level of pain.
2. Evaluate for pleural effusion (dyspnea, decreased breath sound, and dullness to percussion on affected side).
3. Auscultate lungs for pleural friction rub.

Nursing Diagnosis

- Ineffective Breathing Pattern related to stabbing chest pain.

Nursing Interventions

Easing Painful Respiration

1. Assist patient to find comfortable position that will promote aeration; lying on affected side decreases stretching of the pleura and, therefore, the pain decreases.
2. Instruct patient in splinting chest while taking a deep breath or coughing.
3. Administer or teach self-administration of pain medications, as ordered.
4. Employ nonpharmacologic interventions for pain relief, such as application of heat, muscle relaxation, and imagery.
5. Assist with intercostal nerve block if indicated.
6. Evaluate patient for signs of hypoxia (with SpO_2 or ABG) when anxiety, restlessness, and agitation of new onset are noted, before administering as-needed sedatives. Consider evaluation by a health care provider when these signs are present, especially if accompanied by cyanotic nail beds, circumoral pallor, and increased respiratory rate.

Patient Education and Health Maintenance

1. Instruct patient to seek early intervention for pulmonary diseases so pleurisy can be avoided.
2. Reassure and encourage patience because pain will subside.
3. Advise patient on reporting shortness of breath, which could indicate pleural effusion.

Evaluation: Expected Outcomes

- Respirations deep without pain.

Pleural Effusion

Pleural effusion refers to a collection of fluid in the pleural space. It is almost always secondary to other diseases.

Pathophysiology and Etiology

1. May be either transudative or exudative.
2. Transudative effusions occur primarily in noninflammatory conditions such as congestive heart failure; it is an accumulation of low-protein, low-cell-count fluid.
3. Exudative effusions occur in an area of inflammation caused by pneumonia, TB, or malignancy; it is an accumulation of high-protein fluid.
4. Occurs as a complication of:
    a. Disseminated cancer (particularly lung and breast) and lymphoma.
    b. Pleuropulmonary infections (pneumonia).
    c. Heart failure, cirrhosis, and nephrosis.
    d. Other conditions—sarcoidosis, lupus, and peritoneal dialysis.
    e. Medications such as procainamide, hydralazine, quinidine, nitrofurantoin, dantrolene, methysergide, procarbazine, and methotrexate.

Clinical Manifestations

1. Dyspnea, pleuritic chest pain, and cough.
2. Dullness or flatness to percussion (over areas of fluid) with decreased or absent breath sounds.

Diagnostic Evaluation

1. Chest x-ray or ultrasound detects the presence of fluid.
2. Thoracentesis—biochemical, bacteriologic, and cytologic studies of pleural fluid indicate cause.

Management

General

1. Transudative effusions are normally managed by treating the underlying cause (congestive heart failure, fluid overload) with diuretics and other medications; however, thoracentesis may be necessary for refractory effusion.
2. Thoracentesis is done to remove fluid that is impeding lung expansion and relieve dyspnea.
    a. Chest x-ray, ultrasound, or fluoroscopy may assist in localization.
    b. Repeated thoracentesis may be necessary until underlying cause is resolved, as fluid redevelops.

For Malignant Effusions

1. Video-assisted thoracoscopy, chest tube drainage, radiation, and/or chemotherapy.

2. In malignant conditions, pleurodesis may be required. Thoracentesis may provide only transient benefits because effusion may reaccumulate within a few days.
3. Pleurodesis—production of adhesions between the parietal and visceral pleura accomplished by tube thoracostomy, pleural space drainage, and intrapleural instillation of a sclerosing agent (tetracycline, doxycycline, or minocycline).
    a. Drug introduced through tube into pleural space; tube clamped.
    b. Patient is assisted into various positions for 3 to 5 minutes each to allow drug to spread to all pleural surfaces.
    c. Tube is unclamped, when directed, and chest drainage is facilitated for 24 hours or longer.
    d. Resulting pleural irritation, inflammation, and fibrosis cause adhesion of the visceral and parietal surfaces when they are brought together by the negative pressure caused by chest suction.

Complications

1. Large effusion could lead to respiratory failure.

Nursing Assessment

1. Obtain history of previous pulmonary condition.
2. Assess patient for dyspnea, tachypnea, and signs of fluid overload.
3. Auscultate and percuss lungs for abnormalities.

Nursing Diagnosis

- Ineffective Breathing Pattern related to collection of fluid in pleural space.

Nursing Interventions

Maintaining Normal Breathing Pattern

1. Institute treatments to resolve the underlying cause, as ordered.
2. Assist with thoracentesis, if indicated (may be done at bedside or in interventional radiology suite).
3. Maintain chest drainage, as needed (see page 187).
4. Provide care after pleurodesis.
    a. Monitor for excessive pain from the sclerosing agent, which may cause hypoventilation.
    b. Administer prescribed analgesic.
    c. Report uncontrolled pain, which may necessitate intrapleural lidocaine instillation.
    d. Administer oxygen as indicated by dyspnea and hypoxemia.
    e. Observe patient's breathing pattern, oxygen saturation, and other vital signs for evidence of improvement or deterioration.

Patient Education and Health Maintenance

1. Instruct patient to seek early intervention for unusual shortness of breath, along with signs of worsening heart or lung disease.

Evaluation: Expected Outcomes

- Reports absence of shortness of breath.

Lung Abscess

A *lung abscess* is a localized, pus-containing, necrotic lesion in the lung characterized by cavity formation.

Pathophysiology and Etiology

1. Most commonly occurs due to aspiration of vomitus or infected material from upper respiratory tract.
2. Secondary causes include:
    a. Aspiration of foreign body into the lung.
    b. Pulmonary embolus.
    c. Trauma.
    d. TB and necrotizing pneumonia.
    e. Bronchial obstruction (usually a tumor) causes obstruction to bronchus, leading to infection distal to the growth.
3. The right lung is involved more frequently than the left because of dependent position of the right bronchus, the less acute angle that the right main bronchus forms within the trachea, and its larger size.
4. In the initial stages, the cavity in the lung may communicate with the bronchus.
5. Eventually, the cavity becomes surrounded or encapsulated by a wall of fibrous tissue, except at one or two points where the necrotic process extends until it reaches the lumen of some bronchus or pleural space and establishes a communication with the respiratory tract, the pleural cavity (bronchopleural fistula), or both.
6. The organisms typically seen are *Klebsiella pneumoniae* and *Staphylococcus aureus*.

Clinical Manifestations

1. Cough, fever, and malaise from segmental pneumonitis and atelectasis.
2. Headache, anemia, weight loss, dyspnea, and weakness.
3. Pleuritic chest pain from extension of suppurative pneumonitis to pleural surface.
4. Production of mucopurulent sputum, usually foul-smelling; blood streaking common; may become profuse after abscess ruptures into bronchial tree.
5. The chest may be dull to percussion, with decreased or absent breath sounds and intermittent pleural friction rub.

Diagnostic Evaluation

1. Chest x-ray to help diagnose and locate lesion.
2. Chest CT to locate and identify if lesion is singular or multiple areas of involvement.
3. Direct bronchoscopic visualization to exclude possibility of tumor or foreign body; bronchial washings and brush biopsy may be done for cytopathologic study.
4. Sputum culture and sensitivity tests to determine causative organisms and antimicrobial sensitivity.

Management

1. Administration of appropriate antimicrobial agent, usually by IV route, until clinical condition improves, and then oral administration.
2. Percutaneous drainage by interventional radiology.
3. Bronchoscopy to drain abscess is controversial.
4. Surgical intervention only if patient fails to respond to medical management, sustains a hemorrhage, or has a suspected tumor.
5. Nutritional management is usually a high-calorie, high-protein diet.

Complications

1. Hemoptysis from erosion of a vessel.
2. Empyema and bronchopleural fistula.
3. Entrapment of the lung.
4. Hemoptysis.
5. Further expansion of abscess.
6. Lung necrosis.

Nursing Assessment

1. Examine the oral cavity because poor condition of teeth and gums increases the number of anaerobes in the oral cavity and could be a source for infection. Promote frequent oral care.
2. Perform chest examination for abnormalities.
3. Monitor temperature to evaluate effectiveness of therapy.

Nursing Diagnoses

- Ineffective Breathing Pattern related to the presence of suppurative lung disease.
- Acute or Chronic Pain related to infection.
- Imbalanced Nutrition: Less Than Body Requirements related to catabolic state from chronic infection.

Nursing Interventions

Minimizing Respiratory Dysfunction

1. Monitor patient's response to antimicrobial therapy by vital signs, energy level, and appetite.
2. Evaluate patient thoroughly for signs of hypoxia, including SpO_2, when anxiety, restlessness, and agitation of new onset are noted before administering as-needed sedatives. Notify health care provider for evaluation when these signs are present, especially if accompanied by cyanotic nail beds, circumoral pallor, and increased respiratory rate.
3. Perform postural drainage as directed (positions to be assumed depend on location of abscess) and encourage coughing and breathing exercises.

a. Measure and record the volume of sputum to follow patient's clinical course (may be of limited use because of patient swallowing of sputum).

b. Give adequate fluids to enhance liquefying of secretions.

Attaining Comfort

1. Use nursing measures to combat generalized discomfort: oral hygiene, positions of comfort, and relaxing massage.
2. Encourage rest and limitation of physical activity during febrile periods.
3. Monitor chest tube functioning.
4. Administer analgesics as directed. Use caution with opioids that might depress respirations.

Improving Nutritional Status

1. Provide a high-protein, high-calorie diet.
2. Offer liquid supplements for additional nutritional support when anorexia limits patient's intake. Monitor weight weekly.
3. Obtain nutritional consult and consider medication side effects causing anorexia.

Patient Education and Health Maintenance

1. Teach the patient that an extended course of antimicrobial therapy (4 to 8 weeks) is usually necessary; mixed infections are common and may require multiple antibiotics.
2. Encourage patient to have periodontal care, especially in the presence of gingival lesions.
3. Stress importance of follow-up x-rays to monitor abscess cavity closure.
4. Remind family that patient may aspirate if weakness, confusion, alcoholism, seizures, and swallowing difficulties are present. Train in aspiration precautions.
5. Encourage patient to assume responsibility for attaining and maintaining an optimal state of health through a planned program of nutrition, rest, and exercise.

Evaluation: Expected Outcomes

- Respirations unlabored; temperature in normal range; less purulent sputum expectorated.
- Appears more comfortable; verbalizes less pain.
- Eats better; weight stable.

Cancer of the Lung (Bronchogenic Carcinoma)

Bronchogenic carcinoma is the most common cause of cancer deaths worldwide. It is classified according to cell type:

- Non–small cell lung cancer (NSCLC) (80%) includes epidermoid (squamous cell) carcinoma, adenocarcinoma, and bronchoalveolar carcinoma. This requires careful staging that will determine prognosis and treatment. Surgery may be an option for stage I-II and offers that best chance of survival but is only appropriate for approximately 20% to 25% of patients.
- Small cell lung cancer (about 20%) is almost always metastatic and is commonly treated with combination chemotherapy. The overall 5-year survival rate is low because of initial presentation with locally advanced or metastatic disease. Approximately 65% to 80% of patients present with unresectable disease.

Pathophysiology and Etiology

Predisposing Factors

1. Cigarette, pipe, cigar smoking, and secondhand smoke exposure—amount, frequency, and duration of smoking have positive relationship to cancer of the lung.
2. Occupational exposure to radon, asbestos, air pollution, polycyclic aromatic hydrocarbons (from incomplete combustion of carbon-based fuels, such as wood, coal, diesel, fat, tobacco, incense, or tar), arsenic, chromium, nickel, iron, radioactive substances, isopropyl oil, and petroleum oil mists alone or in combination with tobacco smoke.
3. History of lung cancer.
4. Age greater than 65 years.

NURSING ALERT Suspect lung cancer in patients who belong to a susceptible, high-risk group and who have repeated unresolved respiratory infections. The National Cancer Institute has found that low-dose spiral chest CT provides a decided benefit in screening and management of lung cancer.

Staging and Classification

1. Staging refers to anatomic extent of tumor, lymph node involvement, atelectasis, bronchus involvement, and metastatic spread, including malignant pleural effusions. Classification refers to criteria that classify pathologic type of lung cancer.
2. Staging done by the tumor, node, metastasis staging system for NSCLC is an internationally accepted system used to determine the disease stage and extent of disease and is used to guide management (particularly surgical) and determine prognosis.
   a. Imaging including chest CT and PET scan.

b. Pathology including biopsy (mediastinoscopy, tissue).

3. The International Association for the Study of Lung Cancer (IASLC) has developed a classification system using standardized criteria and terminology for the pathologic diagnosis of lung cancer in small biopsies and cytology. NSCLC can be further classified into a more specific type, such as adenocarcinoma or squamous cell carcinoma, based on this system. This classification system is important because 70% of lung cancer patients present with advanced stages that are potentially unresectable.

EVIDENCE BASE Nicholson, A. G., Chansky, K., Crowley, J., et al. (2016). The International Association for the Study of Lung Cancer Lung Cancer Staging Project: Proposals for the revision of the clinical and pathologic staging of small cell lung cancer in the forthcoming eighth edition of the TNM Classification for Lung Cancer. *Journal of Thoracic Oncology, 11*(3), 300–311.

Clinical Manifestations

Symptoms are related to size and location of tumor, extent of spread, and involvement of other structures.

1. Cough, especially a new type or changing cough, results from bronchial irritation.
2. Dyspnea and wheezing (suggests partial bronchial obstruction).
3. Chest pain (poorly localized and aching).
4. Excessive sputum production and repeated upper respiratory infections.
5. Hemoptysis.
6. Malaise, fever, weight loss, fatigue, and anorexia.
7. Paraneoplastic syndrome—metabolic or neurologic disturbances related to the secretion of substances by the neoplasm.
8. Symptoms of metastasis—bone pain; abdominal discomfort, nausea, and vomiting from liver involvement; pancytopenia from bone marrow involvement; and headache from CNS metastasis.
9. Usual sites of metastasis—lymph nodes, bones, liver, and CNS.

Diagnostic Evaluation

1. Abnormal findings seen on chest x-ray are typically followed with chest CT. If suggestive of possible cancer, a needle biopsy or bronchoscopy is typically performed to establish diagnosis, followed by a positron emission tomography (PET) scan for staging and consideration of surgical options.
2. CT scan of the chest and abdomen and whole-body PET scan are indicated in most candidates for surgical resection.
3. Cytologic examination of sputum/chest fluids for malignant cells for pleural effusion.
4. Fiberoptic bronchoscopy for observation of location and extent of tumor and for biopsy or surgery.
5. PET scan—sensitive in detecting small nodules and metastatic lesions.

6. Lymph node biopsy; mediastinoscopy to establish lymphatic spread; to plan treatment.
7. Pulmonary function tests (PFTs)—to determine if patient will have adequate pulmonary reserve to withstand surgical procedure.
8. Laboratory testing, including complete blood count, metabolic panel, calcium level, and liver function tests.

Management

Treatment depends on the cell type, the stage of disease, and the physiologic status of the patient. It includes a multidisciplinary approach that may be used separately or in combination, including surgical resection, radiation, chemotherapy, and biotherapy.

Complications

1. Hypercoagulable state.
2. Complications of treatment including pancytopenia, rash, and hair loss.
3. Superior vena cava syndrome—oncologic complication caused by obstruction of major blood vessels draining the head, neck, and upper torso.
4. Pleural effusion and pulmonary scarring.
5. Infectious complications, especially upper respiratory infections.
6. Brain metastasis.
7. With advanced lung cancer—massive hemoptysis, central airway obstruction, malignant pleural effusion, venous thrombosis, spinal cord compression, hypercalcemia, and SIADH.

Nursing Assessment

1. Determine onset and duration of coughing, sputum production (purulent vs. bloody), and degree of dyspnea. Auscultate breath sounds. Observe symmetry of the chest during respirations.
2. Take anthropometric measurements: weigh patient, review laboratory tests, and conduct appraisal of 24-hour food intake.
3. Ask about pain, including location, intensity, and factors influencing pain.
4. Monitor vital signs including oximetry.

Nursing Diagnoses

- Ineffective Breathing Pattern related to obstructive and restrictive respiratory processes associated with lung cancer.
- Imbalanced Nutrition: Less Than Body Requirements related to hypermetabolic state, taste aversion, and anorexia secondary to radiotherapy/chemotherapy.
- Acute or Chronic Pain related to tumor effects, invasion of adjacent structures, and toxicities associated with radiotherapy/chemotherapy.
- Anxiety and/or depression related to treatment-related side effects, uncertain outcome, and fear of

recurrence.

Nursing Interventions

See also Chapter 8, page 107, for interventions related to cancer treatment.

Improving Breathing Patterns

1. Teach breathing retraining exercises to increase diaphragmatic excursion with resultant reduction in work of breathing.
2. Give prescribed treatment for productive cough (expectorant, antimicrobial agent) and mobilize patient, as tolerated, to potentially control thickened or retained secretions and subsequent dyspnea.
3. Augment the patient's ability to cough effectively.
   a. Splint chest manually with hands.
   b. Instruct patient to inspire fully and cough two to three times in one exhalation.
   c. Provide humidifier/vaporizer to provide moisture to loosen secretions.
4. Support patient undergoing removal of pleural fluid (by thoracentesis or tube thoracostomy) and instillation of sclerosing agent to obliterate pleural space and prevent fluid recurrence.
5. Administer oxygen by way of nasal cannula as prescribed.
6. Encourage energy conservation through pacing of activities and sitting for tasks.
7. Allow patient to sleep in a reclining chair or with head of bed elevated if severely dyspneic.
8. Recognize the anxiety associated with dyspnea; teach relaxation techniques.

Improving Nutritional Status

1. Emphasize that nutrition is an important part of the treatment of lung cancer.
   a. Encourage small amounts of high-calorie, high-protein foods frequently, rather than three daily meals.
   b. Ensure adequate protein intake—milk, eggs, chicken, fowl, fish, cheese, and oral nutritional supplements if patient cannot tolerate meats or other protein sources.
2. Administer or encourage prescribed vitamin supplement to avoid deficiency states, glossitis, and cheilosis.
3. Change consistency of diet to soft or liquid if patient has esophagitis from radiation therapy.
4. Give enteral or total parenteral nutrition for malnourished patient who is unable or unwilling to eat.
5. Obtain nutritional consultation.

Controlling Pain

1. Take thorough history of pain; assess presence/absence of support system.
2. Administer prescribed drug, usually starting with nonsteroidal anti-inflammatory drugs (NSAIDs) and progressing to adjuvant analgesic and short- and long-acting opioids.
   a. Administer regularly to control pain.

b. Titrate to achieve pain control.

3. Consider alternative methods, such as cognitive and behavioral training, biofeedback, and relaxation, to increase patient's sense of control. Mind–body modalities (meditation, hypnosis, relaxation techniques, cognitive–behavioral therapy, biofeedback, and guided imagery) and massage therapy may be helpful for mood disorders and chronic pain. Acupuncture may improve pain control.
4. Evaluate problems of insomnia, depression, anxiety, and so forth that may be contributing to patient's pain.
5. Initiate bowel training program because constipation is an adverse effect of some analgesic/opioid agents.
6. Facilitate referral to pain clinic/specialist if pain becomes refractory (unyielding) to usual methods of control.
7. Radiation therapy may be used to treat pain caused by bone metastasis.

Minimizing Anxiety

1. Realize that shock, disbelief, denial, anger, and depression are all normal reactions to the diagnosis of lung cancer.
2. Try to have the patient express concerns; share these concerns with health professionals. Link patient and family with cancer support groups.
3. Encourage the patient to communicate feelings to significant people in his or her life.
4. Prepare patient physically, emotionally, and intellectually for prescribed therapeutic program.
5. Expect some feelings of anxiety and depression to recur during illness.
6. Encourage the patient to keep active and remain in the mainstream. Continue with usual activities (work, recreation, sexual) as much as possible.
7. Administer antidepressants that may be used to treat depression; however, therapeutic effect is delayed 3 to 4 weeks.

Patient Education and Health Maintenance

1. Teach patient to use NSAIDs or other prescribed medication, as necessary, for pain without being overly concerned about addiction.
2. Help the patient realize that not every ache and pain is caused by lung cancer; some patients do not experience pain.
3. Radiation therapy may be used for pain control if tumor has spread to bone, control of hemoptysis, bronchial obstruction, or brain metastasis.
4. Advise the patient to report new or persistent pain; it may be due to some other cause such as arthritis.
5. Suggest talking to a social worker about financial assistance or other services that may be needed.
6. For additional information, contact the American Cancer Society, 1-800-ACS-2345, *www.cancer.org*; National Comprehensive Cancer Network, *www.nccn.org*.
7. Facilitate referral to cancer support group or mental health professional.
8. Support patient and family to make decisions regarding long-term care, possibly pulmonary

rehabilitation.

Evaluation: Expected Outcomes

- Performs self-care without dyspnea.
- Eats small meals four to five times per day; weight stable.
- Reports pain decreased from level 6 to level 2 or a level that patient reports as tolerable for completing activities of daily living (ADLs) when treated with medication.
- Verbalizes emotions and concerns associated with cancer diagnosis; practices relaxation techniques.

CHRONIC DISORDERS

See additional online content: Patient Education Guidelines 11-1.

PATIENT EDUCATION GUIDELINES 11-1

Chronic Obstructive Pulmonary Disease

There are two types of chronic obstructive pulmonary disease (COPD), chronic bronchitis and emphysema, which may occur together or separately. Chronic bronchitis is diagnosed when there is a chronic cough with phlegm (sputum) for at least 3 months over a period of 2 years. With emphysema, there is a loss of elasticity of the lung tissue, leading to trapped air. Both result in inflammation of the airways, trapping air in the lung. Smoking is the leading cause.

CONTROLLING SYMPTOMS

Cough and Phlegm

- Use inhalers on a regular basis as prescribed:
- Short-acting bronchodilators, such as albuterol, albuterol with ipratropium combination, levalbuteral to open up the airways and improve shortness of breath.
- Long-acting bronchodilators (tiotropium, salmeterol, fluticasone and salmeterol, formoterol, mometasone and formoterol long-acting anticholinergics, long-acting beta agonists, l, etc.) have the strongest benefit to control COPD.
- Inhaled corticosteroids to reduce swelling inside airways (inflammation) and shortness of breath in patients with asthma comorbidity (inhaled corticosteroids) and/or frequent exacerbations.
- Avoid irritants to the lungs, such as cigarette smoke, dust, smog, strong odors, burning biomass fuels indoors, and other irritants.
- Report worsening breathlessness and/or change in color, amount, or thickness of phlegm mucus that could indicate an infection.
- Try to avoid risk of respiratory infections by regular frequent hand hygiene, limiting contact with people during cold and flu season. Get the pneumonia vaccine, as indicated, and yearly influenza vaccine and wash hands; use effective, frequently hand hygiene.
- Drink water and fluids high in nutrients (8 to 10 glasses per day or as directed by your health care provider) to keep phlegm thin; remain well hydrated.

Shortness of Breath

- Practice "(pursed-lip breathing)" by breathing in through the nose for a count of two and out through pursed lips (like you are whistling), with a long, slow expiration for a count of four.
- Position yourself for better breathing by leaning forward while sitting with elbows on table or resting

on knees.

- Use relaxation techniques, such as listening to soft relaxing music, imagining you are in place you enjoy a quiet, peaceful place, or having someone give you a massage.
- If prescribed, use oxygen, as directed, especially while performing such activities as bathing, dressing, eating, and walking.

Fatigue

- Do not stop doing physical activity; instead, learn how to manage by planning activities to conserve energy.
- Start with an exercise program that is easy and progress slowly to increase your activity.
- Talk to your health care provider about joining a pulmonary rehabilitation program.
- Eat a well-balanced, nutritious diet. Consider small, frequent meals.
- Sleep with head elevated using several pillows or in a reclining chair to reduce shortness of breath and increase rest.
- If awakened by cough, sit up, sip fluid, and use inhaler to try to clear lungs of phlegm mucus.
- Avoid overuse of short-acting bronchodilators. Discuss poor control of breathlessness with your health care provider. Long-acting inhalers provide the strongest benefit when used regularly.

Poor Appetite

- Compensate by eating six or more small meals and snacks per day rather than two or three large meals.
- Eat slowly; plan at least 30 minutes per meal.
- Unless otherwise directed, try a high-protein, moderate-fat, lower-carbohydrate diet of sufficient calories to cover the increased work of breathing.
- Consider a high-calorie, high-protein foods such as nuts, milk shakes, avocado, or high calorie liquid supplements drink if you do not feel like eating and are underweight.

Bronchiectasis

Bronchiectasis is a chronic inflammation and dilatation of the bronchi caused by immune defects, cystic fibrosis, aspiration, and lung infections.

Pathophysiology and Etiology

1. May be a complication of respiratory infections including pneumonia, mycobacterium, and other organisms leading to damage to the bronchial wall, and buildup of thick sputum, causing obstruction.
2. Causes chronic coughing and excess mucus production, which is often purulent.
3. May involve a single lobe or segment or one or both lungs more diffusely.
4. As the condition progresses, there may be atelectasis and fibrosis, which lead to respiratory insufficiency.
5. Other causes include pulmonary infections; obstruction of bronchi; aspiration of foreign bodies, vomitus, chemicals, or material from upper respiratory tract; cilial dysmotility syndrome; alpha$_1$-antitrypsin deficiency; and immunodeficiency.

Clinical Manifestations

1. Persistent cough with production of increased amounts of sputum that may be purulent.
2. Intermittent hemoptysis; dyspnea.
3. Recurrent fever and pulmonary infections.
4. Crackles and rhonchi heard over involved lobes.
5. Finger clubbing.

Diagnostic Evaluation

Early diagnosis is essential to prevent complications.

1. High-resolution CT is necessary for diagnosis of bronchiectasis.
2. Chest x-ray may reveal areas of atelectasis with widespread dilation of bronchi.
3. Sputum examination may detect offending pathogens.
4. PFT to evaluate airflow obstruction and impairment.

Management

The goal is to prevent progression of the disease, thereby improving symptoms, limiting exacerbations, decreasing complications, and reducing morbidity and mortality.

1. Infection controlled by:
    a. Smoking cessation.
    b. Prompt antimicrobial treatment of exacerbations of infection.
    c. Immunization against potential pulmonary pathogens (influenza and pneumococcal vaccine).
2. Secretion clearance techniques may be helpful, such as postural drainage, devices that provide PEP and/or oscillations to lung walls including PEP valve, flutter valve, Acapella device, vest therapy, and,

possibly, percussion and vibration or other methods.

3. Bronchodilators for bronchodilation and improved secretion clearance.
4. Mobilization and exercise such as in a pulmonary rehabilitation program.
5. Early management of acute exacerbations, including antibiotics, corticosteroids, and oxygen for hypoxemia. Severe exacerbation is normally managed with hospitalization, IV antibiotics, bronchodilators, and secretion clearance.
6. Surgical resection (segmental resection) when conservative management fails.

Complications

1. Progressive excess mucus production or suppuration.
2. Hemoptysis, major pulmonary hemorrhage.
3. COPD, emphysema, chronic respiratory failure, pulmonary hypertension, cor pulmonale.

Nursing Assessment

1. Obtain history regarding amount and characteristics of sputum produced, including hemoptysis.
2. Auscultate lungs for diffuse rhonchi and crackles.

Nursing Diagnosis

- Ineffective Secretion Clearance related to tenacious and copious secretions.

Nursing Interventions

Maintaining Airway Clearance

1. Encourage use of secretion clearance therapy techniques to empty the bronchi of accumulated secretions (see page 165).
    a. Assist with postural drainage positioning for involved lung segments to drain the bronchiectatic areas by gravity, thus reducing the degree of infection and symptoms. Contraindicated with increased intracranial pressure, uncontrolled hypertension, recent face or head surgery.
    b. Vibratory vest therapy and PEP devices (such as PEP valve, flutter valve, Acapella device) for enhanced secretion clearance.
    c. Chest percussion and vibration may be used to assist in mobilizing secretions (use after bronchodilators and before meals). Contraindicated with osteoporosis, known rib or vertebral fractures.
    d. Encourage effective coughing to help clear secretions.
2. Encourage increased mobilization and intake of fluids to reduce viscosity of sputum and make expectoration easier.
3. Consider vaporizer to provide humidification and keep secretions thin.

Patient Education and Health Maintenance

1. Instruct the patient to avoid smoking, noxious fumes, dust, smoke, and other pulmonary irritants.
2. Teach the patient to monitor sputum. Report if untoward change in quantity or character occurs.
3. Instruct the patient and family about importance of pulmonary drainage.
    a. Teach drainage exercises, use of secretion clearance device(s), and chest physical therapy techniques.
    b. Encourage AM postural drainage to address nocturnal accumulation of secretions.
    c. Encourage patient to engage in physical activity throughout the day to help mobilize mucus.
4. Encourage regular oral hygiene and dental care.
5. Emphasize the importance of influenza and pneumococcal immunizations and prompt evaluation of treatment of respiratory infections.

Evaluation: Expected Outcomes

- Decreased sputum and pulmonary infections; lungs clear after chest physical therapy.

Chronic Obstructive Pulmonary Disease

EVIDENCE BASE Global Strategy for the Diagnosis, Management and Prevention of COPD. (2018). Global Initiative for Chronic Obstructive Lung Disease (GOLD) 2018. Available: *http://goldcopd.org.*

Chronic obstructive pulmonary disease (*COPD*) is a common, preventable, and treatable disease characterized by persistent respiratory symptoms and airflow limitation because of airway and/or alveolar abnormalities usually caused by significant exposure to noxious particles or gases, which cause an abnormal inflammatory response in the airways. Airflow limitation is not fully reversible. Emphysema or destruction of the gas-exchanging surfaces of the lungs describes one component of COPD. Chronic bronchitis is another component occurring in some patients. Asthma is not considered part of COPD because of reversibility seen on spirometry (see Chapter 28).

Pathophysiology and Etiology

1. Irritants from cigarette smoke and pollutants deposited in the lower respiratory tract cause inflammation and a cellular response that leads to alveolar wall destruction causing hyperinflation of the terminal bronchioles (emphysema) and increased size and number of mucus glands in bronchiole walls, which increases mucus production (chronic bronchitis). See Figure 11-3.
   a. In chronic bronchitis, the diameter of the bronchiole lumen is reduced, cilia are damaged, and mucus obstructs the bronchioles.
   b. In emphysema, hyperinflation causes trapped air to remain in the terminal bronchioles and alveoli, reducing oxygenation.
2. Risk factors for COPD include the following:
   a. Cigarette smoking (primary risk factor).
   b. Environmental air pollution
   c. Indoor air pollution from heating and cooking with biomass (energy sources from organic material).
   d. Host factors including genetic predisposition, abnormal lung development, and accelerated aging.
3. $Alpha_1$-antitrypsin deficiency is a genetically determined cause of emphysema and liver disease. $Alpha_1$-antitrypsin is the most common protease inhibitor in the blood and inhibits neutrophil elastase, an elastin and basement membrane–degrading protease released by neutrophils. When alveolar structures are left unprotected from exposure to elastase, progressive destruction of elastin tissues results in the development of emphysema.

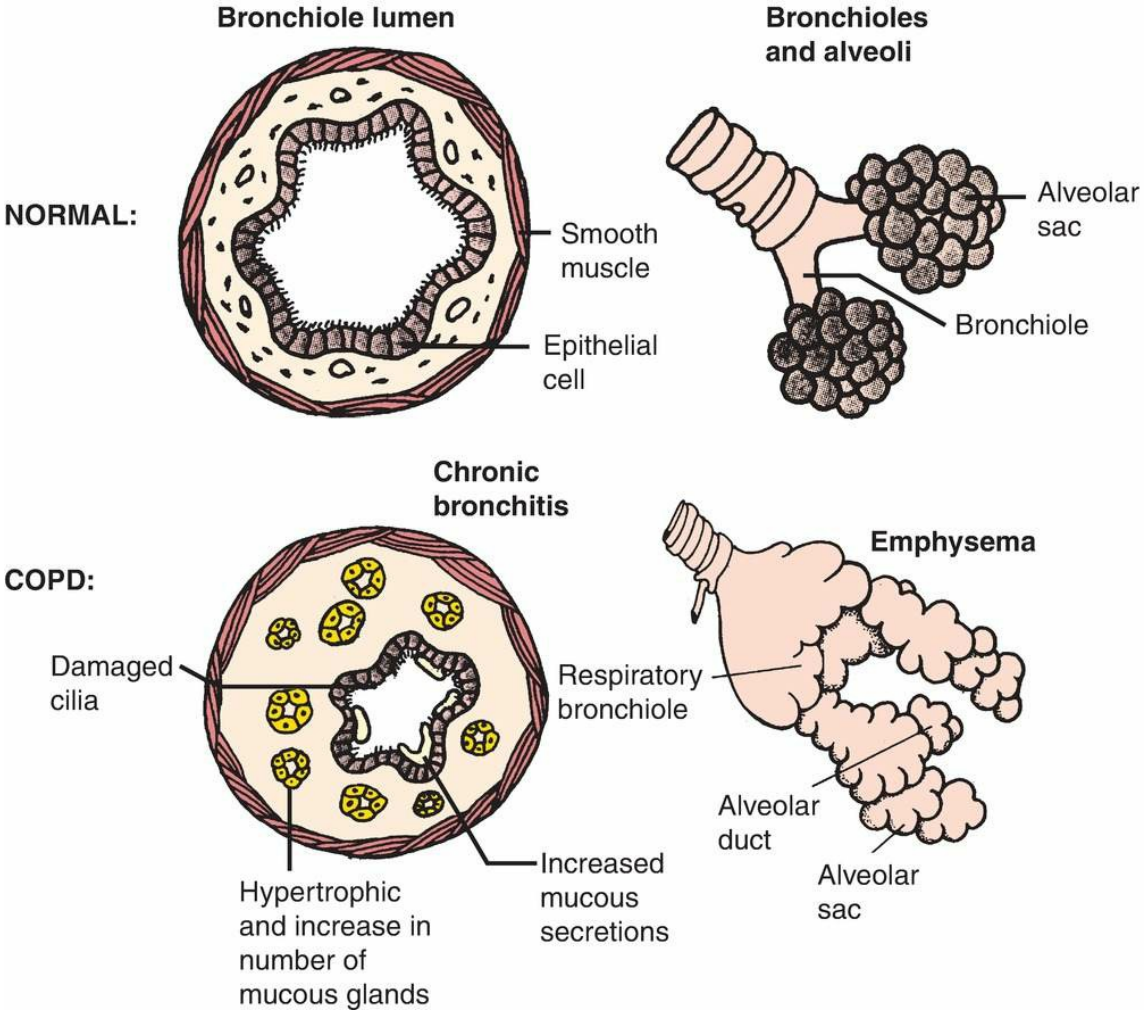

Figure 11-3. Airway changes in chronic obstructive pulmonary disease compared with normal.

Clinical Manifestations

Chronic Bronchitis and Emphysema

Usually insidious, gradual in onset, and steadily progressive.

1. Dyspnea (particularly with stairs or inclines) and decreased exercise tolerance occur in all cases. Skeletal muscle dysfunction is common.
2. Cough, which may be productive. Chronic bronchitis is characterized by cough and increased sputum production for at least 3 months during 2 consecutive years.
3. Increased anteroposterior diameter of the chest (barrel chest) because of air trapping, causing hyperinflation and diaphragmatic flattening in emphysema.
4. Wheezing, decreased breath sounds, and chest tightness may be present.

Exacerbation of COPD

Episodic and often recurrent, contributing to disease worsening because of increased inflammatory airway response.

1. Acute change in the patient's baseline dyspnea, cough, and sputum amount and color, which requires a change in treatment (typically oral steroids and/or antibiotics).
2. Triggers may include viral and/or bacterial infection or environmental pollutants or irritants. One third of exacerbations have no identifiable cause.
3. Exacerbations are associated with increased hyperinflation and air trapping with decreased expiratory flow contributing to worsening dyspnea as well as worsening ventilation/perfusion abnormalities, which may lead to hypoxemia.
4. Because exacerbations have increased risk of mortality and morbidity and decreased quality of life, prevention and early detection and management are important.

Diagnostic Evaluation

1. Spirometry or PFTs are necessary to accurately diagnose COPD. Airflow obstruction based on spirometry or pulmonary function including a postbronchodilator FEV_1/FVC of less than 70% of predicted for age, height, and gender. FEV_1 percent predicted is used to stage severity of COPD.
   a. Stage I (mild)—$FEV_1/FVC < 0.7$; $FEV_1 \geq 80\%$ predicted.
   b. Stage II (moderate)—$FEV_1/FVC < 0.7$; FEV_1 50% to 80% predicted.
   c. Stage III (severe)—$FEV_1/FVC < 0.7$; FEV_1 30% to 50% predicted.
   d. Stage IV (very severe)—$FEV_1/FVC < 0.7$; $FEV_1 < 30\%$ predicted, or $FEV_1 < 50\%$ predicted plus chronic respiratory failure.
2. The GOLD COPD guidelines also emphasize exacerbation history and COPD Assessment Test (CAT) and modified Medical Research Council Dyspnea Scale (mMRC) scores to further characterize COPD.
3. ABG or oximetry can be used to detect hypoxemia (SaO_2 or SpO_2 less than 92%). ABG can additionally detect respiratory failure (PaO_2 less than 60 mm Hg with or without PCO_2 greater than 50 mm Hg on room air).
4. Chest x-ray—for diagnosis of pneumonia and pneumothorax.
5. $Alpha_1$-antitrypsin assay is useful in identifying genetically determined deficiency in emphysema (helpful when COPD occurs at young age or nonsmoker).

Management

The goals of COPD management are to relieve symptoms, prevent disease progression, reduce mortality, improve exercise tolerance, improve health status/quality of life, and prevent and treat complications and exacerbations. The goal of acute care is to improve airflow obstruction. Treatment regimens are based on severity.

1. Smoking cessation is essential to reduce disease progression and improve survival.
2. Inhaled bronchodilators (see Table 11-4, pages 216–220) reduce dyspnea and bronchospasm and improve secretion clearance; these are delivered by metered-dose inhalers (MDIs), dry powder inhalers, or nebulizer devices. One or more long-acting agents are normally used for daily control, with short-acting "rescue" agents used as needed prior to exertion or when symptoms worsen.

a. Anticholinergics such as tiotropium (a long-acting agent) and ipratropium (a short-acting agent).
b. Short-acting beta-adrenergic agonists such as albuterol and levalbuterol.
c. Long-acting beta-adrenergic agonists such as salmeterol, formoterol, and arformoterol.

3. Methylxanthines, such as theophylline, are oral bronchodilators, but are not considered first-line treatment because of suboptimal effectiveness, side effects, and drug interactions.
4. Inhaled corticosteroids are recommended for patients with symptomatic COPD with FEV_1 that is less than 50% of the predicted value and repeated exacerbations and asthma COPD overlap syndrome (ACOS).
5. Oral corticosteroids are used in acute exacerbations for anti-inflammatory effect and may also be given an IV line in severe cases. Long-term treatment with systemic corticosteroids is not recommended due to significant adverse effects (see page 702).
6. For retained secretions, mobilizing the patient, bronchodilators, and for some, use of chest physical therapy, including postural drainage for secretion clearance, and breathing retraining, may be used for improved ventilation and control of dyspnea.
7. Supplemental oxygen therapy for patients with hypoxemia. Use caution in increasing oxygen flow rates in patients with CO_2 retention.
8. Pulmonary rehabilitation to improve function, strength, symptom control, disease self-management techniques, independence, mood, and quality of life and reduce health care utilization.
9. Antimicrobial agents for pneumonia, exacerbations, or bronchitis suspected or known to be because of bacterial infections.
10. Lung volume reduction surgery is a potential option for treatment of upper lobe emphysema in patients with poor exercise capacity.
11. Influenza (annual) and pneumococcal vaccination.
12. Lung transplantation may be considered for people with advanced COPD.
13. Self-management strategies such as prevention and management of exacerbations. Disease self-management strategies include the use of action plans, frequent hand hygiene, physical activity, and regular medical follow-up.
14. Treatment for $alpha_1$-antitrypsin deficiency:
    a. Regular IV infusions (normally every week) of human $alpha_1$-antitrypsin as replacement therapy to correct the antiprotease imbalance in the lungs.
    b. Smoking cessation.
    c. Lung transplantation may be considered.

Table 11-4 Commonly Used Pulmonary Drugs

DRUGS/ADMINISTRATION	PHARMACOLOGIC EFFECTS	INDICATIONS	ADVERSE EFFECTS	NURSING CONSIDERATIONS
Bronchodilators				
Albuterol (metered-dose inhaler [MDI], nebulized solution, oral)	• Short-acting sympathomimetic (beta$_2$-adrenergic agonist) with highly selective beta$_2$ activity	• MDI, nebulized liquid: rapid relief of bronchospasm; acute exacerbation—works within 3 to 5 min • Oral (rarely used): Maintenance therapy for bronchospasm, works within 30 min	• Throat irritation, URI symptoms, cough, tremor, dizziness, nervousness, tachycardia, headache, nausea, tremors, hypokalemia, tachyphylaxis • Continuous nebulization may cause hypokalemia	• Observe inhalation by patient to be certain that correct technique is used. • Caution patient not to exceed prescribed dose. Adverse effects may be associated with excessive use. Does not reduce inflammation. • HFA MDIs must be primed for four puffs before initial use and after not using for long periods.
Levalbuterol (HFA and nebulized solution)	• Short-acting sympathomimetic with selective beta$_2$ activity	• Treatment and prevention of bronchospasm	• Tachycardia, hypertension, nervousness	• Administered every 4 to 6 hr.
Salmeterol xinafoate (dry powder inhaler [DPI])	• Selectively stimulates beta-2 adrenergic receptors, relaxing airway smooth muscle; long-acting	• Maintenance therapy for asthma, COPD, exercise-induced bronchospasm; long-acting (12 hr)	• Headache, throat irritation, nasal congestion, rhinitis, palpitations, tachycardia, tremor, hypertension, bronchospasm • Possible increased risk of asthma-related deaths	• Observe inhalation by patient to make sure that correct technique is used. • Instruct patient that it is not for immediate relief of bronchospasm and dyspnea. • Maximum dose two puffs every 12 hr.
Formoterol (DPI)	• Selectively stimulates beta-2 adrenergic receptors, relaxing airway smooth muscle; long-acting	• Treatment and prevention of bronchospasm; long-acting	• URI, dyspepsia, chest pain, back pain, fever, diarrhea, nausea, vomiting, dry mouth, dizziness, insomnia, nervousness, tremor, palpitations, bronchospasm; possible increased risk of asthma-related deaths	• Train patient for proper use of aerolizer. • Instruct patient that it is not for immediate relief of bronchospasm and dyspnea. • Administer twice daily or 15 min before exercise.
Indacaterol (DPI)	• Selectively stimulates beta-2 adrenergic receptors, relaxing airway smooth muscle; long-acting	• Treatment and prevention of bronchospasm; long-acting	• Cough, throat irritation, headache, tremor, palpitations	• Once-daily dosing.
Arformoterol (nebulized solution)	• Selectively stimulates beta-2 adrenergic receptors, relaxing airway smooth muscle	• Maintenance therapy for COPD; long-acting	• Pain, chest pain, back pain, diarrhea, sinusitis, leg cramps, dyspnea, rash, flulike symptoms, bronchospasm • Possible increased risk of asthma-related deaths	• Not indicated for acute bronchospasm.
Ipratropium bromide (MDI, nebulized liquid)	• Anticholinergic	• Maintenance therapy for COPD, asthma, bronchospasm • Acts within 15 min	• Bronchitis, dyspnea, URI, cough, COPD exacerbation, nausea, dry mouth, flulike symptoms Rare: Can cause blurring of vision if sprayed into the eyes (atropine derivative) • Voice hoarseness • Urinary retention	• Instruct patient to use spacer device with MDI or close lips around inhaler mouthpiece; close eyes during inhalation.
Tiotropium (DPI)	• Long-acting anticholinergic	• Maintenance therapy for COPD	• Dry mouth, pharyngitis, constipation, increased heart rate, blurred vision, urinary retention, URI symptoms, chest pain, UTI, dyspepsia, rhinitis, abdominal pain, angioedema	• Not indicated for acute bronchospasm. • Eye discomfort and visual changes require prompt ophthalmology evaluation.
Aclidinium bromide (dry powder inhaler)	• Long-acting anticholinergic	• Maintenance therapy for COPD	• Urinary retention • Increased intraocular pressures • Headache, URI, cough	• Acute dyspnea, avoid in severe allergies to milk proteins. • Rash, hives, facial swelling, itching.
Aminophylline (IV injection)	• Methylxanthine compound—relaxes smooth muscle by increasing level of cyclic adenosine monophosphate	• Acute exacerbation of asthma or bronchitis	• CNS: irritability, restlessness, insomnia • CV: palpitations, tachycardia, hypotension • GI: nausea, vomiting, diarrhea	• Too rapid administration can cause hypotension, extra systoles, and muscle tremors. Administer at prescribed rate with an IV infusion pump. • Requires monitoring of blood levels, associated with frequent drug interactions.
Theophylline preparations (oral)	• Methylxanthine compound—relaxes muscle by increasing cyclic adenosine monophosphate	• Mild bronchodilator, maintenance therapy for bronchospasm, asthma, COPD maintenance	• CNS: irritability, restlessness, insomnia, seizures in toxic ranges • CV: palpitations, tachycardia, hypotension • GI: nausea, vomiting, diarrhea	• Teach patients to take at equal intervals throughout the day. • To decrease GI irritation, take with milk or crackers. • Monitor theophylline blood level periodically as directed to ensure therapeutic range and prevent toxicity. • Be alert for drug interactions.
Albuterol + ipratropium combination (MDI nebulized solution)	• Sympathomimetic with selective beta$_2$ and anticholinergic activity	• Fast-acting and maintenance therapy for bronchospasm; exacerbation of COPD	• See albuterol and ipratropium	• See albuterol and ipratropium. • One puff of Combivent equals one puff of albuterol and one puff of ipratropium.
Tiotropium bromide and olodaterol	• Long-acting selective beta$_2$ and anticholinergic activity	• Long-acting control of COPD	• See tiotropium and formoterol	• See tiotropium and formoterol.
Umeclidinium	• Long-acting anticholinergic activity	• Long-acting control of COPD	• Nasal and throat irritation, URI, cough, muscle aches urinary retention	• Bronchospasm. • Narrow-angle glaucoma closure.
Umeclidinium and vilanterol	• Long-acting selective beta$_2$ and anticholinergic activity	• Long-acting control of COPD	• Increase in heart rate, BP, EKG changes, hyperglycemia • Nasal and throat irritation, URI, cough, muscle aches urinary retention	• See salmeterol and umeclidinium.
Fluticasone furoate and vilanterol trifenatate	• See fluticasone and vilanterol	• See fluticasone and vilanterol	• See fluticasone and vilanterol	• See fluticasone and vilanterol.
Prednisone, prednisolone (IV injection, oral preparation)	• Potent anti-inflammatory activity	• Acute exacerbation of asthma or bronchitis (IV preparation) • Acute exacerbation (oral preparation) of asthma or COPD	• CNS: depression, euphoria, mood changes, insomnia • GI: gastric irritation, peptic ulcer • Metabolic: hypernatremia, hypokalemia, hyperglycemia, water retention, and weight gain • Long-term, high-dose: adrenal insufficiency, osteoporosis, muscle weakness, cataracts, glaucoma, fragile and easily bruised skin, immunosuppression	• Long-term use: Do not stop abruptly because of adrenal suppression. • Take oral form with food. • Usually given as taper from higher dose to lowest possible dose that achieves desired effect. Alternatively, short course may be recommended. Long-term use should be avoided if possible. • Advise patient of possible increased appetite and weight gain risk; advise to eat small, frequent meals high in protein, fruits, and vegetables, and low in simple carbohydrates.
Beclomethasone (MDI)	• Synthetic corticosteroid with potent anti-inflammatory activity; effective only by inhalation • Not effective in acute attack; must be used for 2 to 4 wk to show effectiveness	• Asthma • Severe COPD with frequent exacerbations	• Oral candidiasis, dysphonia, cough, pharyngitis, bronchospasm, headache, sinusitis, URI, rhinitis, pain, back pain, bronchospasm • May experience skin bruising in high doses	• Bronchospasm, glaucoma, cataracts, osteoporosis. • Not used with status asthmaticus or acute asthma episodes • Use a spacer device with MDI. • Gargle, rinse, and spit after use to prevent oral candidiasis.
Mometasone (DPI)	• Anti-inflammatory steroid; effective only by inhalation • Not effective in acute attack; must be used for up to 2 to 4 wk to show effectiveness	• Asthma maintenance • COPD (severe COPD with frequent exacerbations)	• Oral candidiasis, dysphonia • Risk for systemic adverse effects associated with oral steroids is low • May experience skin bruising in high doses • Headache, rhinitis, URI, sinusitis, bronchospasm	• Use water gargle, rinse, and spit after use to prevent oral yeast growth.
Ciclesonide (MDI)	• Anti-inflammatory steroid; effective only by inhalation • Not effective in acute attack; must be used for up to 2 to 4 wk to show effectiveness	• Asthma maintenance	• Oral candidiasis, dysphonia • Risk for systemic adverse effects associated with oral steroids is low • May experience skin bruising in high doses • Headache, rhinitis, URI, sinusitis, bronchospasm	• Use water gargle, rinse, and spit after use to prevent oral yeast growth; avoid eyes.
Fluticasone (MDI, DPI)	• Anti-inflammatory steroid; effective only by inhalation • Not effective in acute attack; must be used for 2 to 4 wk to show effectiveness	• Asthma • COPD (severe COPD with frequent exacerbations)	• Oral candidiasis, dysphonia • Risk for systemic adverse effects associated with oral steroids is low • May experience skin bruising in high doses • URI, headache, sinusitis, bronchospasm	• Longer acting. • Use a spacer device with MDI; use water gargle, rinse, and spit after use to prevent oral candidiasis.
Budesonide (DPI, nebulized liquid)	• Anti-inflammatory steroid; effective only by inhalation • Not effective in acute attack; must be used for 2 to 4 wk to show effectiveness	• Asthma • COPD (severe COPD with frequent exacerbations)	• Oral candidiasis • Risk for systemic adverse effects associated with oral steroids is low • May experience skin bruising in high doses • Nasopharyngitis, rhinitis, nausea, bronchospasm	• Longer acting. • Use water gargle, rinse, and spit after use to prevent oral candidiasis.
Fluticasone and salmeterol (MDI, DPI)	• Combination inhaled corticosteroid and long-acting beta-agonist bronchodilator	• Asthma maintenance • COPD maintenance • Maintenance therapy for controlled bronchospasm	• See fluticasone and salmeterol	• See fluticasone and salmeterol.
Budesonide and formoterol (MDI)	• Combination inhaled corticosteroid and long-acting beta agonist	• Asthma maintenance • COPD maintenance	• See budesonide and formoterol	• See budesonide and formoterol.
Mometasone and formoterol (MDI)	• Combination inhaled corticosteroid and long-acting beta agonist	• Asthma maintenance • COPD maintenance	• See mometasone and formoterol	• See mometasone and formoterol
Mast Cell Stabilizers				
Cromolyn (solution for inhalation, powder used with special inhaler)	• Inhibits activation of a variety of inflammatory cells associated with asthma, prevents bronchospasm • Not effective in acute attack; must be used for 2 to 4 wk to show effectiveness	• Maintenance therapy for asthma	• Cough, bronchospasm	• Should not be used with status asthmaticus or acute asthma episodes. May be given in combination with bronchodilator if administration causes bronchospasm.
Leukotriene Receptor Antagonists				
Zafirlukast	• Blocks leukotriene receptors	• Prophylaxis and chronic treatment of mild to moderate asthma for persons older than age 4	• Potential drug interactions, particularly warfarin, cisapride • Headache, infection, nausea, diarrhea	• Will not reverse acute bronchospasm.
Zileuton	• Blocks leukotriene receptors	• Prophylaxis and chronic treatment of mild to moderate asthma for persons older than age 12	• Potential drug interactions • Headache, sinusitis, nausea	• Will not reverse acute bronchospasm.
Montelukast	• Blocks leukotriene receptors	• Prophylaxis and chronic treatment of mild to moderate asthma for persons older than age 5 • Exercise-induced bronchospasm	• Potential drug interactions, particularly phenobarbital, amiodarone • Headache, flu, abdominal pain	• Will not reverse acute bronchospasm.
Antifibrotics				
Nintedanib	• Treatment of idiopathic pulmonary fibrosis, binds to multiple tyrosine kinases, inhibiting intracellular signaling of fibroblasts	• Reduce progression of idiopathic pulmonary fibrosis	• Diarrhea, nausea, abdominal pain, vomiting, decreased appetite, headache, weight loss	Arterial thromboembolism, MI, HTN, GI perforation, bleeding Monitor LFTs at baseline, monthly × 6 months, and then every 3 months thereafter.
Pirfenidone	• Treatment of idiopathic pulmonary fibrosis, mechanism unknown	• Reduce progression of idiopathic pulmonary fibrosis	• Nausea, rash, abdominal pain, URI, diarrhea, fatigue • Photosensitivity: patient must wear sunscreen when outdoors	Angioedema Agranulocytosis Monitor LFTs at baseline, monthly × 6 months, and then every 3 months thereafter.
Other				
Roflumilast	• Inhibits phosphodiesterase type 4 leading to increased intracellular cAMP	• Chronic bronchitis and frequent exacerbations	• Diarrhea, weight loss, nausea, headache, suicidality	
Omalizumab	• Inhibits IgE binding to mast cells and basophils, decreasing mediator release	• Asthma prophylaxis, aeroallergen associated	• Injection site reaction, viral infection, URI, sinusitis, anaphylaxis	

DRUG ALERT Long-acting inhaled bronchodilators are the gold standard of COPD management because of their effectiveness and safety.

DRUG ALERT High-dose or long-term prednisone therapy is associated with significant side effects including hypertension, edema, muscle weakness, increased risk of cataracts and glaucoma, weight gain, hyperglycemia, depression, insomnia, gastric and esophageal ulcer, osteoporosis, skin frailty, and bruising. Ensure that a plan is implemented for tapering steroid dose after an exacerbation, prescription is written, instructions are communicated to patient and family, and follow-up can be scheduled with health care provider.

Complications

1. Respiratory failure.
2. Pneumonia, overwhelming respiratory infection.
3. Right-sided heart failure, pulmonary hypertension, dysrhythmias.
4. Depression, anxiety disorder.
5. Skeletal muscle dysfunction.

Nursing Assessment

1. Determine smoking pack per year history, exposure history, positive family history of respiratory disease, onset and triggers of dyspnea.
2. Determine level of dyspnea, how it compares to patient's baseline.
3. Note amount, color, and consistency of sputum.
4. Inspect for use of accessory muscles during respiration and use of abdominal muscles during exhalation; note increase of anteroposterior diameter of the chest.
5. Auscultate for decreased/absent breath sounds, crackles, decreased heart sounds.
6. Determine oxygen saturation, pulse, and respiratory rate at rest and with activity.

Nursing Diagnoses

- Ineffective Breathing Pattern related to chronic airflow limitation.
- Ineffective Airway Clearance related to bronchoconstriction, increased mucus production, ineffective cough, possible pulmonary infection, immobility, and weakness.
- Risk for Infection related to compromised pulmonary function, retained secretions, and compromised defense mechanisms.
- Impaired Gas Exchange related to chronic airflow obstruction and V/Q abnormalities because of

destruction of alveolar–capillary membrane.

- Imbalanced Nutrition: Less Than Body Requirements related to increased work of breathing, hyperinflation, drug effect on body mass index (less than 21 or greater than 30), and skeletal muscle dysfunction.
- Activity Intolerance related to airflow limitation, dynamic hyperinflation, resulting in shortness of breath and fatigue, skeletal muscle dysfunction.
- Disturbed Sleep Pattern related to hypoxemia and hypercapnia, dyspnea, cough, and wheezing.
- Ineffective Coping related to the stress of living with chronic disease, loss of independence, depression, anxiety disorder, panic of breathlessness.

NURSING ALERT If disease is moderately advanced, issues of an advance directive and resuscitation status need to be addressed. Although effective treatment and prevention and management of exacerbations and comorbidities often stabilize disease, COPD is progressive. It is better to have these discussions with the patient before a crisis situation.

Nursing Interventions

Improving Airway Clearance

1. Eliminate pulmonary irritants, particularly cigarette smoking.
   a. Cessation of smoking is a top priority, improving survival, slowing progression of COPD, and reducing pulmonary irritation, sputum production, and cough.
   b. Keep patient's room as free from pulmonary irritants as possible.
2. Administer bronchodilators to improve dyspnea, reduce hyperinflation at rest and with activity, control bronchospasm and dyspnea, and assist with raising sputum.
   a. Train, teach back, and monitor patient's inhaler technique.
   b. Assess for adverse effects—tremors, tachycardia, cardiac dysrhythmias, CNS stimulation, hypertension.
   c. Auscultate the chest after administration of aerosol bronchodilators to assess for improvement of aeration and reduction of adventitious breath sounds.
   d. Observe if patient has reduction in dyspnea.
   e. Monitor serum theophylline level, as ordered, to ensure therapeutic level and prevent toxicity.
3. Use controlled coughing (see page 177).
4. Mobilize the patient when stable. Use pursed-lip breathing, controlled cough, and possibly postural drainage positions to aid in clearance of secretions, particularly if secretions are tenacious, excessive, and/or mucopurulent (see page 176).
5. Keep secretions thin.
   a. Encourage fluid intake within level of cardiac reserve.

b. If appropriate, give continuous aerosolized sterile water or nebulized normal saline to humidify bronchial tree and liquefy sputum.

Improving Breathing Pattern

1. Teach and supervise breathing retraining exercises to improve dyspnea and decrease work of breathing (see page 176). Use pursed-lip breathing at intervals and during periods of dyspnea especially associated with activity and/or panic to reduce hyperinflation, control rate and depth of respiration, and improve respiratory muscle coordination. Pursed-lip breathing should be practiced for 10 breaths four times daily before meals and before sleep. Inspiratory-to-expiratory ratio should be 1:≥2. Evidence for effectiveness of diaphragmatic breathing is less robust, particularly given flattened diaphragm in COPD.
2. Discuss and demonstrate relaxation exercises to reduce stress, tension, and anxiety.
3. Encourage patient to assume position of comfort to decrease dyspnea. Positions might include leaning the trunk forward with arms supported on a fixed object, sleeping with two or three pillows, or sitting upright.

Controlling Infection

1. Recognize early manifestations of respiratory infection—increased dyspnea; change in color, amount, and character of sputum including purulence; cough; wheeze; and possibly irritability and low-grade fever. Promptly report findings to physician for possible workup and treatment.
2. If ordered, obtain sputum for Gram stain and culture and sensitivity.
3. Administer prescribed antimicrobials to control bacterial infections in the bronchial tree, thus clearing the airways. Administer bronchodilators to improve ventilation.

Improving Gas Exchange

1. Monitor for hypoxemia with a typical goal of SaO_2 or SpO_2 of 92% to 93%. Watch for and report excessive somnolence, restlessness, anxiety, headaches, irritability or confusion, central cyanosis, and dyspnea at rest, which is caused by acute respiratory insufficiency and may signal respiratory failure.
2. Review ABG levels; document for evaluation and comparisons by clinical team.
3. Give supplemental oxygen, as ordered, to correct hypoxemia in a controlled manner. Monitor and minimize CO_2 retention. Patients that experience CO_2 retention may need lower oxygen flow rates.
4. Be prepared to assist with noninvasive ventilation *or* intubation and mechanical ventilation if acute respiratory failure and significant CO_2 retention occur.

NURSING ALERT Normally, CO_2 levels in the blood provide a stimulus for respiration. However, in some patients with COPD, chronically elevated CO_2 may impair this mechanism and low oxygen levels may act as stimulus for respiration. Giving a high flow rate or percent of supplemental oxygen to people who retain CO_2 may suppress the hypoxic drive, leading to worsening hypoventilation, respiratory depression and decompensation, and the development of a worsening respiratory acidosis.

Improving Nutrition

1. Take nutritional history, weight, and height and calculate BMI. Patients are at risk for cachexia (survival is decreased with BMI less than 21) and obesity because of poor nutritional intake, work of breathing, and inactivity.
2. Encourage frequent, small meals if patient is dyspneic and/or underweight; even a small increase in abdominal contents may press on the diaphragm and impede breathing and decrease interest in eating. Encourage snacking on nutritious, calorie-appropriate, and high-protein snacks, such as nuts, avocados, and dairy if tolerated.
3. Offer liquid nutritional supplements, if needed, to improve nutrient intake and provide appropriate calorie intake.
4. Encourage foods high in potassium (including bananas, dried fruits, dates, figs, orange juice, grape juice, milk, peaches, potatoes, tomatoes), and monitor for low potassium, which may occur with COPD, corticosteroid use, and diuretic use.
5. Restrict sodium, as directed, if fluid retention is a problem or comorbidity of CHF, HTN, or heart disease.
6. Avoid foods producing gas and abdominal distention and/or discomfort.
7. Employ good oral hygiene before meals to sharpen taste sensations.
8. Avoid hurrying and encourage pursed-lip breathing between bites if patient is short of breath; rest after meals.
9. Give supplemental oxygen while patient is eating to relieve dyspnea if ordered.
10. Monitor body weight and evaluate body mass index.

Increasing Activity Tolerance

1. Reemphasize the importance of exercise and physical conditioning programs (may reverse skeletal muscle dysfunction, improve dyspnea, improve muscle utilization of oxygen, and improve independence). This is part of pulmonary rehabilitation and may be included as part of physical therapy.
   a. Discuss walking, stationary bicycling, swimming, and "sit and be fit"-type videos.
   b. Encourage use of portable lightweight oxygen system for ambulation for patients with hypoxemia.
2. Encourage patient to carry out regular exercise program 3 to 7 days per week to increase physical endurance, but to discuss with physician before beginning program.
3. Train patient in energy conservation techniques and pacing of activities.

Improving Sleep Patterns

1. Use nocturnal oxygen therapy, when ordered.
2. Avoid the use of high-dose sedatives and hypnotics that may cause respiratory depression.
3. Administer long- or short-acting inhaled anticholinergics, as directed (have been found to improve nocturnal respiratory symptoms in COPD).

4. Sleep with head of bed elevated based on patient's preference to improve pulmonary mechanics.

Enhancing Coping

1. Recognize signs of depression and anxiety disorders or use validated questionnaires to screen for mood disorders, which are common and often undiagnosed and untreated in COPD. Contributing factors include persistent dyspnea, fatigue, loss of independence, personal identity, social isolation, and quality of life that may make the patient irritable, apprehensive, anxious, and depressed, with feelings of helplessness and hopelessness.
2. Assess the patient for thoughts of suicide or self-harm and intentions. Communicate any positive findings promptly to the patient's MD, social worker, and appropriate resources, if needed.
3. Demonstrate a sincere, supportive, and open approach to the patient.
   a. Be a good listener and show that you care.
   b. Be sensitive to patient's fears, anxiety, and depression; provide emotional support.
   c. Provide patient with control of as many aspects of care as possible.
4. Administer antidepressants and antianxiety agents as directed, but avoid oversedation.
5. Support and encourage the patient to discuss concerns about disease, symptoms, and impact on the patient.
6. Be aware that dyspnea, fatigue, and altered self-image may lead to discomfort with sexuality and intimacy in patients with COPD. Encourage discussion of concerns and fears, and discuss adaptations and clarify misunderstandings. Encourage patient to use a bronchodilator and secretion clearance techniques before sexual activity, plan for sexual relations at time of day when patient has highest level of energy, use supplemental oxygen, if needed, and consider alternative displays of affection to loved one.
7. Support patient and spouse/family members. Refer to local or national support groups (American Lung Association: *www.lungusa.org* 1-800-LUNGUSA).

Community and Home Care Considerations

1. Help to relax and pace activities. Obtain occupational therapy consult to help employ work simplification techniques, such as sitting for tasks, pacing activities, and using dressing aids (grabber, sock aid, long-handled shoe horn), shower bench, and handheld shower head.
2. Encourage enrollment in a pulmonary rehabilitation program where available and Better Breathers club or other support group found through the American Association for Cardiovascular and Pulmonary Rehabilitation at (312) 321-5146 or *www.aacvpr.org*. Components of pulmonary rehabilitation include supervised exercise training, breathing retraining techniques, proper use of medications and inhalers, secretion clearance techniques, prevention and management of respiratory infection, panic control, controlling dyspnea with ADLs and stair climbing, control of pulmonary irritants, monitored and supervised exercise, proper use of oxygen systems, and group support.
3. Suggest vocational counseling to help patient maintain gainful employment within physical limits for as long as possible.
4. Warn patient to avoid excessive fatigue, which is a factor in producing respiratory distress. Advise to

adjust activities per individual fatigue patterns.

5. Advise in strategies and mechanisms to cope with emotional stress and mood disorders. Stress may trigger worsening dyspnea and panic. Teach coping strategies, such as pursed-lip breathing, relaxation techniques, meditation, and guided imagery.
6. Stress that progression of worsening lung function may be slowed through smoking cessation and prevention of exacerbations. Long-term ongoing medical follow-up is a key aspect of disease self-management.
7. For patients who use oxygen or who are hypoxic, coordinate with oxygen supplier and patient to promote safe adherence to oxygen prescription and use of appropriate oxygen system so patient can maintain activities and control hypoxemia.
8. Use community resources, such as Meals on Wheels or a home care aide, if energy level is low.

Patient Education and Health Maintenance

General Education

1. Give the patient a clear explanation of the disease, what to expect, and how to treat and live with it. Reinforce by frequent explanations, reading material, demonstrations, and question-and-answer sessions.
2. Review with the patient the objectives of treatment and nursing management.
3. Work with the patient to set goals (eg, stair climbing, return to work).
4. Encourage patient involvement in disease self-management techniques, such as identification and prompt reporting of respiratory infection or respiratory deterioration and physical activity. Encourage patient to have open communication, partnership, and regular follow-up with primary care provider.

Avoid Exposure to Respiratory Irritants

1. Advise patient to stop smoking and avoid exposure to secondhand smoke. Offer strategies to promote long-term cessation including the use of medications, support groups, and counseling.
2. Advise patient to avoid exposure to indoor and outdoor pulmonary irritants and particulates, including dust, smog, and other respiratory irritants.
3. Advise patient to keep entire house well ventilated.
4. Warn patient to avoid extremely hot/cold weather if exposure causes bronchospasm and dyspnea. Use a scarf over the nose and mouth and drink warm beverages in cold weather.
5. Stay indoors and exercise indoors with air conditioning when air pollution level is high.
6. Shower with warm (*not hot*) water to avoid excess exposure to steam.
7. If sensitive to dry air, instruct patient to humidify indoor air in winter; maintain 30% to 50% humidity for optimal mucociliary function. Clean and dry humidifier frequently to avoid mold and bacterial growth
8. If the patient is sensitive to dust, pollen, and other particles, consider the use of a HEPA air cleaner to remove particles from air. Advise regular replacement.

Improve Airflow

1. Teach the proper technique for inhalation of medication to maximize aerosol deposition in the bronchial tree. See page 806 for patient education on inhaler use.
   a. Use spacer device if unable to use MDI effectively.
   b. If using a dried powder inhaler, instruct in proper use according to manufacturer's instructions. Spacer devices are not necessary.
2. MDIs with HFA propellants require priming (spray four puffs of medication before first use and if not used for several days). Rinse plastic cartridge holder well daily and air-dry to prevent blockage.
3. Inhalers have built-in courters. Advise patient to refill inhaler well in advance of running out of medication.

DRUG ALERT To prevent oral candidiasis with use of inhaled corticosteroids, instruct patient on use of a spacer device and to rinse mouth after use.

Evaluation: Expected Outcomes

- Coughs up secretions easily; decreased wheezing and crackles.
- Reports less dyspnea; effectively using pursed-lip breathing.
- No fever or change in sputum.
- ABG levels and/or SpO_2 improved.
- Tolerates small, frequent meals; weight stable.
- Reports walking longer distances without tiring.
- Sleeping in 4- to 6-hour intervals; uses low-flow oxygen at night as prescribed.
- Demonstrates more effective coping; expresses feelings; seeks support group.

Cor Pulmonale

Pulmonary heart disease (*cor pulmonale*) is typically due to right heart strain caused by excessively high pressures in pulmonary circulation. This alteration in the structure or function of the right ventricle results from disease of lung structure or function or its vasculature, such as pulmonary hypertension (except when this alteration results from disease of the left side of the heart or from congenital heart disease). It is heart disease caused by lung disease.

Pathophysiology and Etiology

1. Chronic lung disease or alteration of the pulmonary vasculature causes increased pressure in pulmonary circuit producing strain on the right ventricle, leading to right-sided heart failure.
2. Often chronic (associated with right ventricular hypertrophy), but may develop acutely because of pulmonary embolism and, less commonly, ARDS associated with right ventricular dilatation.
3. May develop due to pulmonary vasoconstriction because of alveolar hypoxia or acidosis and anatomic compromise of the pulmonary vascular bed.
4. Causes include:
    a. Pulmonary vascular disease (acute or chronic).
    b. Idiopathic pulmonary hypertension.
    c. Underlying lung disease such as COPD, cystic fibrosis, interstitial lung disease.
    d. Polycythemia vera, sickle cell disease, macroglobulinemia.
    e. Significant kyphoscoliosis.
    f. Obstructive sleep apnea.

Clinical Manifestations

1. Fatigue, tachypnea, exertional dyspnea, and cough.
2. Anterior chest pain and hemoptysis.
3. Distended jugular veins, peripheral edema (often associated with hypercapnia), and possible cyanosis.
4. In advanced stages, right upper abdominal discomfort, jaundice, and syncope with exertion.
5. Split second heart sound on auscultation of the chest.

Diagnostic Evaluation

1. Chest x-ray shows right-sided heart enlargement and enlargement of central pulmonary arteries.
2. ECG changes are consistent with right-sided heart hypertrophy and/or right heart strain.
3. Echocardiogram shows right-sided heart enlargement.
4. Right heart catheter examination to confirm diagnosis and evaluate for pulmonary hypertension and underlying disease.
5. ABG levels—decreased PaO_2 and pH and increased $PaCO_2$.
6. PFTs to confirm underlying lung disease such as obstruction.

7. V/Q scanning or chest CT if history and physical examination suggest pulmonary thromboembolism as the cause or if other diagnostic tests do not suggest other etiologies. If interstitial lung disease is suspected, chest CT will aid in diagnosis.
8. Hematocrit for polycythemia, serum alpha$_1$-antitrypsin if deficiency is suspected, antinuclear antibody level for collagen vascular disease, such as scleroderma, coagulation studies to evaluate hypercoagulability states.

Management

The goal is the treatment of underlying lung disease and management of heart disease.

1. In cases of hypoxemia, supplemental oxygen to improve oxygen delivery to peripheral tissues, thus decreasing cardiac work and lessening sympathetic vasoconstriction. Liter flow individualized during activities, rest, and sleep.
2. Targeted therapy such as prostacyclin analogues and endothelin receptor antagonists may be used in primary pulmonary hypertension (PPH).
   a. Epoprostenol, treprostinil, and iloprost are prostacyclin (PGI2) analogues and have potent vasodilatory properties. Epoprostenol and treprostinil are administered via the IV route and iloprost is inhaled.
   b. Bosentan is a mixed endothelin-A and endothelin-B receptor antagonist indicated for pulmonary arterial hypertension, including PPH. In clinical trials, bosentan improved exercise capacity, decreased rate of clinical deterioration, and improved hemodynamics.
   c. The PDE5 inhibitors sildenafil and tadalafil promote selective smooth muscle relaxation in lung vasculature. Their use in secondary pulmonary hypertension, such as in patients with COPD, is unclear.
3. The use of the cardiac glycoside digoxin is somewhat controversial; it can improve RV function but must be used with caution and should be avoided during acute hypoxia.
4. Oral anticoagulants in underlying thromboembolic event or primary PAH.
5. Diuretics are used if RV filling volume is markedly elevated and to manage peripheral edema.
   a. Used cautiously because of hemodynamic adverse effects with excessive volume depletion.
   b. Can lead to a decline in cardiac output as well as hypokalemic metabolic alkalosis.
6. Vasodilators including calcium channel blockers, particularly oral sustained-release nifedipine and diltiazem, can lower pulmonary pressures, although these agents appear more effective in primary rather than secondary pulmonary hypertension.
7. Bronchodilators to improve lung function.
8. Mechanical ventilation, if patient in respiratory failure.
9. Sodium restriction to reduce edema.

Complications

1. Respiratory failure.

2. Dysrhythmias.

Nursing Assessment

1. Determine if patient has long-standing history of lung disease.
2. Assess degree of dyspnea, fatigue, and hypoxemia.
3. Inspect for jugular vein distention and peripheral edema.

Nursing Diagnoses

- Impaired Gas Exchange related to excess fluid in lungs and increased pulmonary vascular resistance.
- Excess Fluid Volume related to right-sided heart failure.

Nursing Interventions

Improving Gas Exchange

1. Monitor ABG values and/or oxygen saturation as a guide in assessing adequacy of ventilation.
2. Use continuous low-flow oxygen as directed to reduce pulmonary artery pressure.
3. Avoid CNS depressants (opioids, hypnotics). They have depressant action on respiratory centers and mask symptoms of hypercapnia.
4. Monitor for signs of respiratory infection because infection causes CO_2 retention and hypoxemia.

Attaining Fluid Balance

1. Watch alterations in electrolyte levels, especially potassium, which can lead to disturbances of cardiac rhythm.
2. Employ ECG monitoring when necessary and monitor closely for dysrhythmias.
3. Limit physical activity until improvement is seen.
4. Restrict sodium intake based on evidence of fluid retention.

Patient Education and Health Maintenance

1. Emphasize the importance of stopping cigarette smoking; cigarette smoking is a major cause of pulmonary heart disease.
    a. Ask patient about smoking habits.
    b. Inform patient of risks of smoking and benefits to be gained when smoking is stopped.
    c. Discuss the use of behavior modification techniques and smoking cessation aids.
2. Teach patient to recognize and treat infections immediately.
3. Advise patient to avoid environments with poor air quality, have good ventilation, but keep windows closed and use air conditioning, if necessary.
4. Explain to patient and family that restlessness, depression, and poor sleeping as well as irritable and angry behavior may be characteristic; patient should improve with rise in oxygen and fall in CO_2 levels.
5. Explain the use of supplemental oxygen, which will reduce further workload on the right side of the

heart.

Evaluation: Expected Outcomes

- Less dyspneic; ABG levels improved, oxygen saturation.
- Edema reduced; no dysrhythmias.

INTERSTITIAL LUNG DISEASE (PULMONARY FIBROSIS)

Interstitial lung disease (*ILD*) is a general term that refers to a variety of chronic lung disorders, such as *idiopathic pulmonary fibrosis*, *sarcoidosis*, *asbestosis*, *silicosis*, *scleroderma*, *hypersensitivity pneumonitis*, and *coal worker's pneumoconiosis* (*CWP*). There are estimated to be 130 types of interstitial lung disease; only about one third have known causes. Causes include abnormal immune response or abnormal healing in response to a variety of causes, including connective tissue diseases, occupational and environmental exposure, drugs and poisons, radiation, and infections. The most common ILD is idiopathic pulmonary fibrosis.

Overview

Unknown etiology such as idiopathic pulmonary fibrosis.

1. Connective tissue diseases including scleroderma, rheumatoid arthritis, Sjogren syndrome, systemic lupus erythematosus (SLE), polymyositis, dermatomyositis, and mixed connective tissue disease. Sarcoidosis is considered a multisystem disorder, although it may resemble a connective tissue disorder.
2. Hypersensitivity pneumonitis (acute or chronic) may be due to repeated inhalation of certain fungal, bacterial, animal protein, or reactive antigens from occupational or environmental exposure. Susceptible persons develop immune reactions leading to pulmonary inflammation and possible scarring.
3. Occupational exposure may include asbestosis (increased risk for lung cancer), silicosis, and CWP.
4. Environmental exposure may include:
    a. Hard metal disease (cobalt, tungsten, carbide).
    b. Gas, fumes, vapors, and aerosols.
    c. Poison exposure.
    d. Cancer drugs (nitrofurantoin, methotrexate, busulfan, bleomycin).
    e. Anti-inflammatory drugs (aspirin, gold, penicillamine).
    f. Cardiac drugs (amiodarone).
    g. IV use of heroin, methadone, propoxyphene, and talc used in IV drug abuse.
    h. Exposure to radiation.
    i. Infections.
5. Chronic changes include lung tissue damage, inflammation of alveoli with scarring, and fibrosis and stiffening of the interstitium tissue.
6. The damage limits oxygen transport through scarred alveolar–capillary membranes into the bloodstream.

Presentation

Additional information follows on idiopathic pulmonary fibrosis, interstitial lung disease because of sarcoidosis and other connective tissue diseases, and occupational lung diseases. A generalized nursing process appears on pages 227 to 228.

1. The most prevalent symptom is dyspnea, particularly with exercise, along with dry cough and fatigue.
2. Bibasilar crackles are heard on auscultation.
3. Connective tissue diseases may be associated with joint pain and swelling, rash, dry eyes, and dry mouth.
4. Symptoms may vary in severity and the course of the disease may be unpredictable.

Idiopathic Pulmonary Fibrosis

EVIDENCE BASE Raghu, G., Rochwerg, B., Zhang, Y. et al. (2015). An official ATS/ERS/JRS/ALAT clinical practice guideline: Treatment of idiopathic pulmonary fibrosis. An update of the 2011 clinical practice guideline. *American Journal of Respiratory Critical Care Medicine, 192*(2), e3–e19.

Pathophysiology and Etiology

1. *Idiopathic pulmonary fibrosis* is a chronic, progressive fibrosing interstitial pneumonia of unknown cause, occurring primarily in older adults and limited to the lungs. It is characterized by progressive worsening of dyspnea and lung function and associated with a poor prognosis.
2. Lung function may worsen gradually or more rapidly, worsen due to acute exacerbation of IPF or remain stable based on pulmonary function testing (usually measurement of FVC and/or diffusion capacity of oxygen or DLCO) or findings on chest CAT scan.
3. Incidence is approximately 7 to 16 cases per 100,000 people, although this number is believed to be much higher than reported.
4. It is generally diagnosed between ages 50 and 70 with increased incidence with age.

Clinical Manifestations

1. Dyspnea and hypoxemia are common with exertion and may be present at rest.
2. Chronic, dry cough.
3. Breath sounds commonly include bibasilar inspiratory crackles.
4. Finger clubbing may be present.
5. Patients may have pulmonary hypertension and gastroesophageal reflux disorder.
6. History of smoking is common.

Diagnostic Evaluation

1. A multidisciplinary diagnosis that includes pulmonology, radiology and pathology is recommended. Exclusion of other causes of interstitial lung disease is important.
2. High-resolution chest CT shows usual interstitial pneumonia, basilar honeycombing, traction bronchiectasis with predominant subpleural reticular distribution, and absence of other features that would be inconsistent with IPF.
3. PFTs show decreased FVC with decreased diffusion capacity.
4. ABG may show low arterial oxygen level.
5. Exercise test shows hypoxemia.
6. Chest x-ray may demonstrate patchy, nonuniform infiltrates, ground-glass pattern, reticular nodular pattern, and small lung volume.

7. Right-sided heart catheterization may be performed if pulmonary hypertension is suspected or if elevated PA pressures seen on echocardiogram.

Management

1. Two medications (pirfenidone and nintedanib) have been found to reduce loss of lung function.
2. Other agents such as prednisone, azathioprine, *N*-acetylcysteine, and warfarin do not provide clinical benefit when used specifically to treat IPF. They may be used for other non-IPF disorders or appropriate comorbidities.
3. Several promising clinical trials are developing. Patients should be informed of the National Institutes of Health registry of clinical trials at *www.clinicaltrials.gov*. The database includes information about a trial's purpose, who may participate, locations, and study contacts.
4. Supportive measures include oxygen for hypoxemia and pulmonary hypertension.
5. Options for cough include management of comorbidities (GERD, rhinitis, asthma), cough lozenges, and possibly prednisone (controversial).
6. Treatment of dyspnea includes pulmonary rehabilitation, which also works to improve endurance.
7. Lung transplantation may offer improved symptoms, function, and survival for some patients.

Sarcoidosis and Other Connective Tissue Diseases

For comprehensive management of connective tissue disorders, see Chapter 30.

General Considerations

1. *Sarcoidosis* is an inflammatory, multisystem disorder of unknown cause that affects the connective tissue and lungs.
   a. Granulomatous disease in which clumps of inflammatory epithelial cells (nodules) occur in many organs, primarily in lungs.
   b. Nodules in the lungs can lead to narrowing of the airways, inflammation, and fibrosis of lung tissue.
   c. Other tissues including the skin, eyes, nose, muscles, heart, liver, spleen, bowel, kidney, testes, nerves, lymph nodes, and brain.
2. Rheumatoid arthritis is an inflammatory connective tissue disorder that causes interstitial lung disease because of pleural inflammation in about 20% of cases, mostly females between ages 50 and 60.
3. SLE is a multisystem autoimmune disease that causes pleural inflammation and pneumonitis.
4. Scleroderma is a connective tissue disorder that causes hardening of the skin and fibrotic changes, resulting in interstitial fibrosis.
5. Ankylosing spondylitis is a seronegative arthropathy causing back pain and possible pulmonary manifestations.

Occupational Lung Diseases

Pathophysiology and Etiology

1. *Asbestosis*: Asbestos fibers are inhaled and enter alveoli, which, in time, are obliterated by fibrous tissue that surrounds the asbestos particles.
   a. Fibrous pleural thickening and pleural plaque formation produce restrictive lung disease, decrease in lung volume, diminished gas transfer, and hypoxemia with subsequent development of cor pulmonale.
   b. Found in workers involved in manufacture, cutting, and demolition of asbestos-containing materials; there are more than 4,000 known sources of asbestos fiber (asbestos mining and manufacturing, construction, roofing, demolition work, brake linings, floor tiles, paints, plastics, shipyards, insulation).
2. *Silicosis*: When silica particles (which have fibrogenic properties) are inhaled, nodular lesions are produced throughout the lungs. These nodules undergo fibrosis, enlarge, and fuse.
   a. Dense masses form in the upper portion of the lungs; restrictive and obstructive lung disease results.
   b. Exposure to silica dust is encountered in almost any form of mining because the earth's crust is composed of silica and silicates (gold, coal, tin, copper mining); also stone cutting, quarrying, manufacture of abrasives, ceramics, pottery, and foundry work.
3. *CWP* ("black lung") is a variety of respiratory diseases found in coal workers in which there is an accumulation of coal dust in the lungs, causing a tissue reaction in its presence.
   a. Dusts (coal, kaolin, mica, silica) are inhaled and deposited in the alveoli and respiratory bronchioles.
   b. There is an increase of macrophages that engulf the particles and transport them to terminal bronchioles.
   c. When normal clearance mechanisms can no longer handle the excessive dust load, the respiratory bronchioles and alveoli become clogged with coal dust, dying macrophages, and fibroblasts, which lead to the formation of the coal macule, the primary lesion of CWP.
   d. As macules enlarge, there is dilation of the weakening bronchiole, with subsequent development of focal or centrilobular emphysema.
4. Hypersensitivity pneumonitis is considered a disease of exposures to various agents including mold and birds (feathers and related products such as down). Diagnosis can be difficult and requires good history taking about exposure to potential occupational and environmental antigens and detailed home and work history.
   a. Effects of inhaling organic dust (moldy hay, mushroom compost, malt, moldy maple bark, pigeon or parrot droppings, feathers, microwave popcorn fumes, hot tub exposure, or contaminated grain), noxious particles, gases, or fumes. Development of disease depends on composition of inhaled substance, its antigenic (precipitating an immune response) or irritating properties, the dose inhaled, the length of time inhaled, and the host's response.
   b. Exposure to inorganic dusts stimulates pulmonary interstitial fibroblasts, resulting in pulmonary

interstitial fibrosis.

c. Acute symptoms of fever, cough, and chills may occur 4 to 12 hours after exposure and recur with repeated exposure. Chronic disease develops years later.

d. Noxious fumes may cause acute injury to alveolar wall with increasing capillary permeability and pulmonary edema.

NURSING ALERT Asbestosis is strongly associated with bronchogenic cancer and mesotheliomas of the pleura and peritoneal surfaces. Smoking increases the risk of lung cancer 50 to 100 times.

Clinical Manifestations

Occupational lung diseases may develop slowly (over 20 to 30 years) and may be asymptomatic in the early stages.

1. Chronic cough; productive in silicosis and CWP.
2. Dyspnea on exertion; progressive and irreversible in asbestosis and CWP.
3. Susceptibility to lower respiratory tract infections.
4. Bibasilar crackles in asbestosis.
5. Expectoration of varying amounts of black fluid in CWP.

Diagnostic Evaluation

1. Chest x-ray—nodules of upper lobes in silicosis and CWP; diffuse parenchymal fibrosis, especially of lower lobes, in asbestosis.
2. High-resolution chest CT to evaluate and characterize fibrosis.
3. PFTs primarily show restrictive pattern.
4. Bronchoscopy with lavage to identify specific exposure.
5. Lung tissue biopsy may be needed to rule out other disorders.

Management

1. Pulmonary rehabilitation may be considered for patients with chronic, disabling symptoms.
2. For hypersensitivity pneumonitis, anti-inflammatory medications may be recommended if the condition is worsening, including prednisone and possibly azathioprine, mycophenolate, or cyclophosphamide.
3. For most other occupational lung diseases, there is no specific treatment; exposure is eliminated and the patient is treated symptomatically.
4. Silicosis is associated with high risk of TB; patients should receive evaluation and appropriate treatment for TB.
5. Smoking cessation measures for people who have been exposed to asbestos to decrease risk of lung cancer.

6. Keep asbestos worker under cancer surveillance; watch for changing cough, hemoptysis, weight loss, and melena.
7. Bronchodilators may be of some benefit if any degree of airway obstruction is present.

Complications

1. Respiratory failure.
2. Lung cancer in asbestosis.
3. Hypoxemia.

Nursing Care of the Patient with Interstitial Lung Disease

Nursing Assessment

1. Obtain occupational and environmental exposure history. Determine length and degree of exposure.
2. Obtain full medical history and family history for connective tissue disorders.
3. Obtain medication history and allergies.
4. Obtain history of smoking, respiratory infections, and other chronic lung disease.
5. Evaluate symptoms and functional capacity, and auscultate lungs for crackles.

Nursing Diagnoses

- Ineffective Breathing Pattern related to fibrotic lung tissue causing restriction.
- Impaired Gas Exchange related to fibrotic lung tissue and secretions.

Nursing Interventions

Improving Breathing Pattern

1. Administer oxygen therapy, as required.
2. If ordered, administer or teach self-administration of bronchodilators.
3. Encourage smoking cessation.

Promoting Gas Exchange

1. Encourage mobilization of secretions through hydration and breathing and coughing exercises.
2. Advise patient on pacing activities to prevent excess dyspnea or fatigue.

Patient Education and Health Maintenance

1. Provide information about the importance of smoking cessation as well as methods and resources for smoking cessation.
2. Instruct patient in health maintenance, such as adequate nutrition and exercise and immunizations, so additional medical problems can be avoided.
3. Encourage participation in pulmonary rehabilitation.
4. Advise patient that compensation may be obtained for impairment related to occupational lung disease through the Worker's Compensation Act.
5. Provide information to healthy workers on prevention of occupational lung disease.
    a. Enclose toxic substances to reduce their concentration in the air.
    b. Employ engineering controls to reduce exposure.
    c. Monitor air samples.
    d. Use standards established by NIOSH and USDPH to eliminate exposure to asbestos and other pulmonary toxins. These may include the use of appropriate masks, respirators, and hoods depending

on the toxin.

Evaluation: Expected Outcomes

- Reports less dyspnea.
- Reports improved quality of life.

TRANSITIONAL CARE ALERT Patients and family members require clear understanding of their diagnosis, treatment options, and expectations regarding the course of the disease. Those with hypoxemia require linkage with durable medical equipment companies to provide both stationary oxygen concentrators and lightweight portable oxygen that supports ambulation and independence. Once oxygen needs are determined, the patient should be trained in monitoring SpO_2 and goals of therapy. Patients and family members require linkage to community organizations for support.

TRAUMATIC DISORDERS

Pneumothorax

A *pneumothorax* is air in the pleural space occurring spontaneously or from trauma (see Figure 11-4). In patients with chest trauma, it is usually the result of a laceration to the lung parenchyma, tracheobronchial tree, or esophagus. The patient's clinical status depends on the rate of air leakage and size of wound. Pneumothorax is classified as:

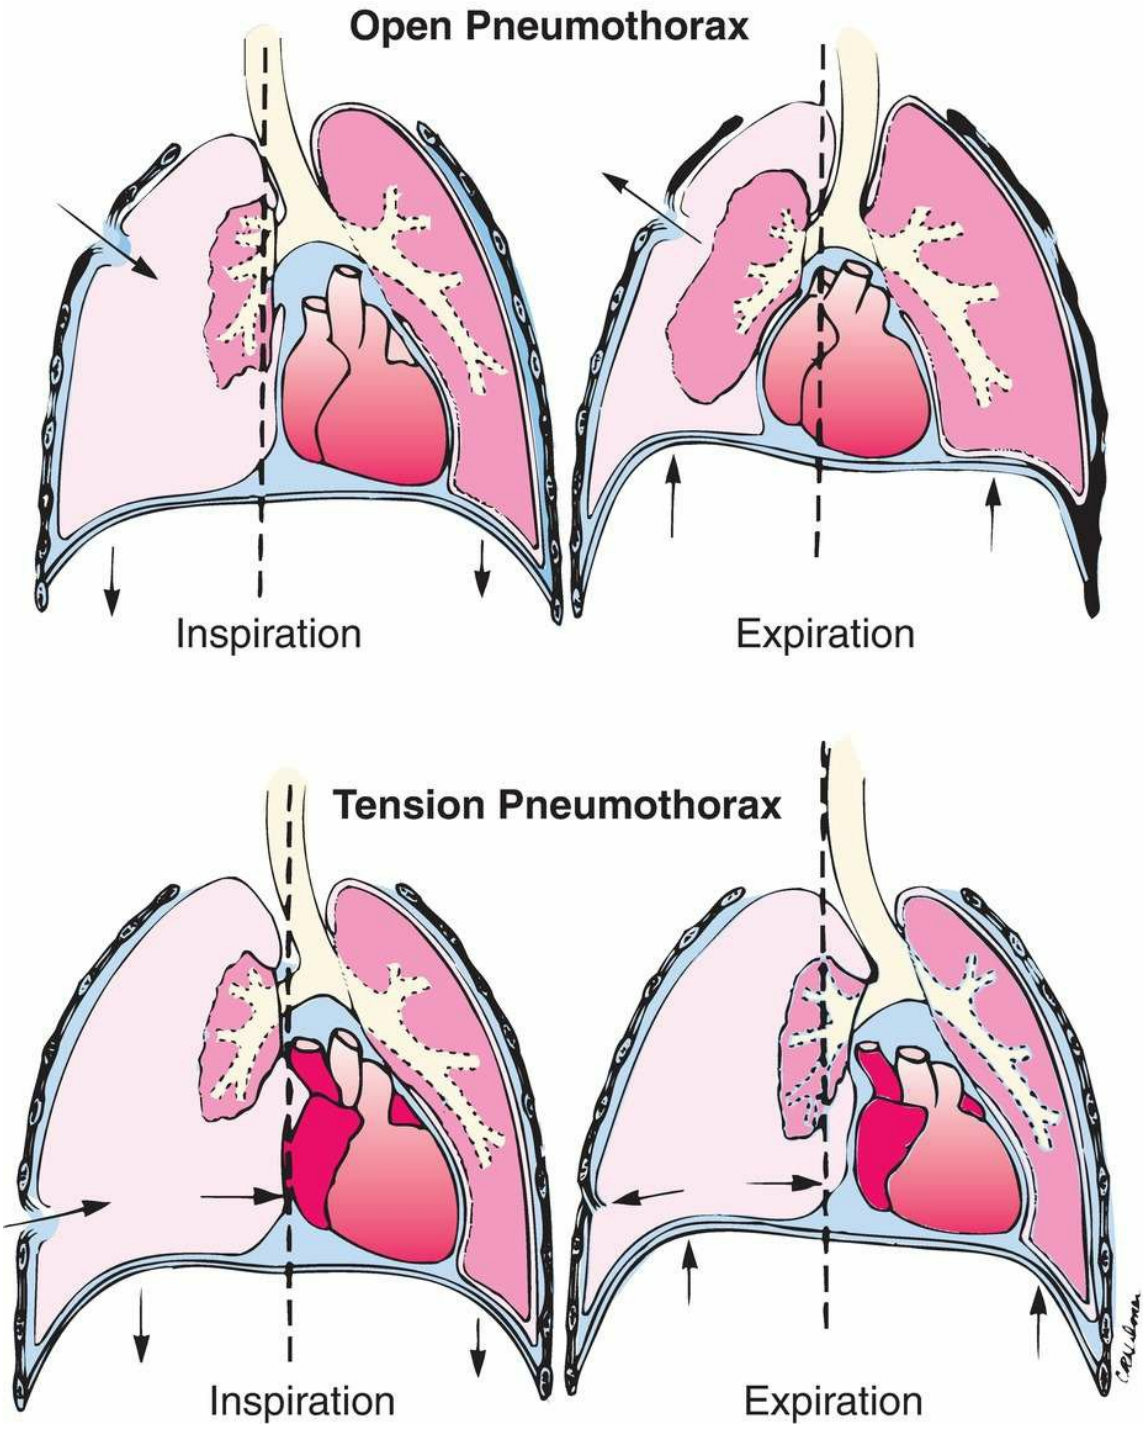

Figure 11-4. Open pneumothorax and tension pneumothorax. In open pneumothorax, air enters the chest during inspiration and exits during expiration. There may be slight inflation of the

affected lung because of a decrease in pressure as air moves out of the chest. In tension pneumothorax, air can enter but not leave the chest. As the pressure in the chest increases, the heart and great vessels are compressed and the mediastinal structures are shifted toward the opposite side of the chest. The trachea is pushed from its normal midline position toward the opposite side of the chest, and the unaffected lung is compressed.

Spontaneous pneumothorax—sudden onset of air in the pleural space with deflation of the affected lung in the absence of trauma.

Tension pneumothorax—buildup of air under pressure in the pleural space resulting in interference with filling of both the heart and lungs.

Open pneumothorax (sucking wound of the chest)—implies an opening in the chest wall large enough to allow air to pass freely in and out of thoracic cavity with each attempted respiration.

Pathophysiology and Etiology

1. When there is a large, open hole in the chest wall, the patient will have a "steal" in ventilation of the other lung.
2. A portion of the V_T will move back and forth through the hole in the chest wall, rather than the trachea as it normally does.
3. Spontaneous pneumothorax is usually due to rupture of a subpleural bleb.
   a. May occur secondary to chronic respiratory diseases or idiopathically.
   b. May occur in healthy people, particularly in thin, white males and those with family history of pneumothorax.

Clinical Manifestations

1. Moderate to very severe dyspnea and often severe chest discomfort radiating to the back.
2. Hyperresonance and diminished breath sounds on the affected side.
3. Reduced mobility of affected half of the thorax.
4. Tracheal deviation away from the affected side in tension pneumothorax.
5. Clinical picture of open or tension pneumothorax is one of air hunger, agitation, hypotension, and cyanosis.

Diagnostic Evaluation

- Chest x-ray confirms the presence of air in the pleural space.

Management

Spontaneous Pneumothorax

1. Observe and allow for spontaneous resolution for less than 50% pneumothorax in otherwise healthy person.

2. Needle aspiration or chest tube if greater than 50% pneumothorax.
3. Pleurodesis may be done to prevent recurrence. Chemical pleurodesis uses various solutions inserted through chest tube to irritate and thereby cause adhesion of parietal and visceral pleura. Surgical pleurodesis uses mechanical irritation to achieve adhesion, with possible removal of parietal pleura.
4. Thoracotomy to remove apical blebs in some cases.

Tension Pneumothorax

1. Immediate decompression to prevent cardiovascular collapse by chest tube insertion to let air escape.
2. Chest tube drainage with underwater seal suction to allow for full lung expansion and healing.

Open Pneumothorax

1. Close the chest wound immediately to restore adequate ventilation and respiration.
    a. Patient is instructed to inhale and exhale gently against a closed glottis (Valsalva maneuver) as a pressure dressing (petroleum gauze secured with elastic adhesive) is applied.
    b. This maneuver helps to expand collapsed lung.
2. Chest tube is inserted and water seal drainage set up to permit evacuation of fluid/air and produce reexpansion of the lung.
3. Surgical intervention may be necessary to repair trauma.

Complications

1. Acute respiratory failure.
2. Cardiovascular collapse with tension pneumothorax.

Nursing Assessment

1. Obtain history for chronic respiratory disease, trauma, and onset of symptoms.
2. Inspect the chest for reduced mobility and tracheal deviation.
3. Auscultate the chest for diminished breath sounds and percuss for hyperresonance.

Nursing Diagnoses

- Ineffective Breathing Pattern related to air in the pleural space.
- Impaired Gas Exchange related to atelectasis and collapse of the lung.

Nursing Interventions

Achieving Effective Breathing Pattern

1. Provide emergency care as indicated.
    a. Apply petroleum gauze to sucking chest wound (see “Management”).
    b. Assist with emergency thoracentesis or thoracostomy.
    c. Be prepared to perform cardiopulmonary resuscitation or administer medications if cardiovascular

collapse occurs.

2. Maintain patent airway; suction as needed.
3. Position patient upright if condition permits to allow greater chest expansion.
4. Maintain patency of chest tubes.
5. Assist patient to splint chest while turning or coughing and administer pain medications, as needed.

Resolving Impaired Gas Exchange

1. Encourage patient in the use of incentive spirometer.
2. Monitor oximetry and ABG levels to determine oxygenation.
3. Provide oxygen as needed.

Patient Education and Health Maintenance

1. Instruct patient to continue use of the incentive spirometer at home.
2. For patients with spontaneous pneumothorax, there is an increased risk for recurrence; therefore, encourage these patients to report sudden dyspnea immediately.

Evaluation: Expected Outcomes

- Breath sounds equal bilaterally; less dyspneic.
- ABG levels improved.

Chest Injuries

Chest injuries are potentially life-threatening because of immediate disturbances of cardiorespiratory physiology and hemorrhage and later developments of infection, damaged lung, and thoracic cage. Traumatic chest injuries include *rib fracture or contusion*, *hemothorax*, *flail chest*, *pulmonary contusion*, and *cardiac tamponade or contusion*. Patients with chest trauma may have injuries to multiple organ systems. The patient should be examined for intra-abdominal injuries, which must be treated aggressively.

Pathophysiology and Clinical Manifestations

Rib Fracture

1. Most common chest injury may be severe if several ribs are fractured, especially unstable fractures or in the presence of other morbidities.
2. May interfere with ventilation and may lacerate the underlying lung.
3. Causes pain at fracture site; painful, shallow respirations; and localized tenderness and crepitus (crackling) over fracture site.

Hemothorax

1. Blood in pleural space as a result of penetrating or blunt chest trauma.
2. Accompanies a high percentage of chest injuries.
3. Can result in hidden blood loss and increased risk of empyema.
4. Patient may be asymptomatic, dyspneic, hypoxemic, hypotensive, apprehensive, or in shock.
5. Diminished or absent breath sounds of the affected side, tracheal deviation to the unaffected side.

Flail Chest

1. Loss of stability of chest wall as a result of multiple rib fractures or combined rib and sternum fractures.
    a. When this occurs, one portion of the chest has lost its bony connection to the rest of the rib cage.
    b. During respiration, the detached part of the chest will be pulled in on inspiration and moved outward on expiration (paradoxical movement).
2. Normal mechanics of breathing are impaired to a degree that seriously jeopardizes ventilation, causing dyspnea, hypoxemia, cyanosis, and risk of acute respiratory failure.
3. Generally associated with other serious chest injuries: lung contusion, lung laceration, and diffuse alveolar damage. Also associated with tracheal damage, ARDS, and pneumonia.

Pulmonary Contusion

1. Injury of the lung parenchyma that results in leakage of blood and edema fluid into the alveolar and interstitial spaces of the lung. May occur with rib fracture or chest trauma.
2. May not be fully developed for 24 to 72 hours.
3. Signs and symptoms include:
    a. Tachypnea, tachycardia, and hypoxemia.

b. Crackles on auscultation.
c. Pleuritic chest pain.
d. Secretions may be copious.
e. Cough—constant, loose, rattling.

Cardiac Tamponade

1. Compression of the heart as a result of accumulation of fluid within the pericardial space.
2. Caused by penetrating injuries, metastasis, cardiac rupture, cardiac surgery, pericarditis, and other disorders.
3. Signs and symptoms include:
   a. Tachycardia.
   b. Muffled heart sounds.
   c. Falling BP.
   d. Distended jugular veins, elevated central venous pressure (CVP).
   e. Pulsus paradoxus (audible BP fluctuation with respiration).
   f. Dyspnea, cyanosis, shock.

NURSING ALERT A rapidly developing tamponade interferes with ventricular filling and causes impairment of circulation. Thus, there is a reduced cardiac output and poor venous return to the heart. Cardiac collapse can result. In the patient with hypovolemia caused by associated injuries, the CVP may not rise, thus masking the signs of cardiac tamponade.

Management and Nursing Interventions

The goal is to restore normal cardiorespiratory function as quickly as possible. This is accomplished by performing effective resuscitation if required while simultaneously assessing the patient, restoring chest wall integrity when possible, and reexpanding the lung. The order of priority is determined by the clinical status of the patient.

Rib Fracture

1. Give analgesics (usually nonopioid) to assist in effective coughing and deep breathing.
2. Encourage deep breathing with slow, full inspiration; give local support to injured area by splinting with pillow or hands.
3. Assist with intercostal nerve block to relieve pain so coughing and deep breathing may be accomplished. An intercostal nerve block is the injection of a local anesthetic into the area around the intercostal nerves to relieve pain temporarily after rib fractures, chest wall injury, or thoracotomy.
4. For multiple rib fractures, epidural anesthesia may be used.

Hemothorax

1. Assist with chest tube insertion and set up drainage system for complete and continuous removal of blood and air.
   a. Auscultate lungs and monitor for relief of dyspnea.
   b. Monitor amount of blood loss in drainage.
2. Assist with thoracentesis to aspirate blood from pleural space, if being done before a chest tube insertion.
3. Replace volume with IV fluids or blood products.
4. Trauma patients with pulmonary contusion and flail chest should receive adequate IV fluids to maintain adequate tissue perfusion. Once adequately resuscitated, unnecessary fluid administration should be meticulously avoided. A pulmonary artery catheter may be useful to avoid fluid overload.
5. The use of optimal analgesia and chest physiotherapy should be applied to minimize the likelihood of respiratory failure and ensuing ventilatory support.
6. Patients may require noninvasive positive pressure ventilation or mechanical ventilation with PEEP.
7. Steroids should not be used in therapy for pulmonary contusion.
8. Diuretics may be used in the setting of hydrostatic fluid overload as evidenced by elevated pulmonary capillary wedge pressures in hemodynamically stable patients or in the setting of known concurrent heart failure.

Flail Chest

1. Analgesia for pain management. Thoracic epidural analgesia may be used for some patients to relieve pain and improve ventilation.
2. Stabilize cardiopulmonary status. If respiratory compromise or failure is present, prepare for immediate ET intubation and mechanical ventilation—treats underlying pulmonary contusion and serves to stabilize the thoracic cage for healing of fractures, improves alveolar ventilation, and restores thoracic cage stability and intrathoracic volume by decreasing work of breathing.
3. Prepare for operative stabilization of chest wall in select patients. Surgical fixation may be considered in severe unilateral flail chest or in patients requiring mechanical ventilation when thoracotomy is otherwise required.

Pulmonary Contusion

For moderate lung contusion:

1. Employ mechanical ventilation to keep lungs inflated.
2. Administer diuretics for pulmonary edema.
3. Use PAP monitoring.
4. Monitor for development of pneumonia, ARDS.

Cardiac Tamponade

For penetrating injuries:

1. Assist with pericardiocentesis (see page 255) to provide emergency relief and improve hemodynamic function until surgery can be undertaken.
2. Prepare for emergency thoracotomy to control bleeding and to repair cardiac injury.

Additional Responsibilities

1. Secure and support the airway as indicated. ET intubation or tracheostomy may be needed.
2. Assist with noninvasive continuous positive airway pressure (CPAP) or mechanical ventilation to help to clear tracheobronchial tree, help the patient breathe with less effort, and reduce paradoxical motion.
3. Secure one or more IV lines for fluid replacement and obtain blood for baseline studies, such as hemoglobin level and hematocrit.
4. Monitor serial CVP readings to prevent hypovolemia and circulatory overload.
5. Monitor ABG/SpO_2 results to determine requirements for supplemental oxygen and mechanical ventilation.
6. Obtain urinary output hourly to evaluate tissue perfusion.
7. Continue to monitor thoracic drainage to provide information about rate of blood loss, whether bleeding has stopped, and whether surgical intervention is necessary.
8. Institute ECG monitoring for early detection and treatment of cardiac dysrhythmias (dysrhythmias are a frequent cause of death in chest trauma).
9. Maintain ongoing surveillance for complications:
    a. Aspiration.
    b. Atelectasis.
    c. Pneumonia.
    d. Mediastinal/subcutaneous emphysema.
    e. ARDS.
    f. Respiratory failure.

Patient Education and Health Maintenance

1. Instruct patient in splinting techniques.
2. Make sure patient is aware of importance of seat belt use to reduce serious chest injuries caused by automobile accidents.
3. Teach patient to report signs of complications—increasing dyspnea, fever, and cough.

OVERVIEW AND ASSESSMENT

Common Manifestations of Heart Disease

In patients with cardiac disease, chest pain is the most common manifestation and is the second most common chief complaint presenting to emergency departments. Heart disease may also be characterized by shortness of breath, palpitations, weakness, fatigue, dizziness, syncope, diaphoresis, edema or swelling, or GI complaints.

NURSING ALERT Older, diabetic, and female patients may not present with typical symptoms of acute coronary syndrome (ACS). Consider the diagnosis of ACS in these patients when they present with other complaints, such as back pain, nausea, fatigue, dyspnea, light-headedness, cold sweats, jaw pain, and right arm pain (without chest pain).

Chest Pain

Characterization

1. How does the patient describe chest pain? Is it mild or severe, transient or constant? What activity or other factors make it worse, or better? Can it be characterized as tightness, discomfort, fullness, pressure-like, crushing, or searing? Does it radiate to the jaw, neck, back, or arm (particularly left)?
2. Assess chest pain systematically. See Box 12-1. Most pain management scales (visual analogues or numerical scales) are fast and easy to use but can only be used to measure the intensity of the pain; these scales do not measure the other essential elements for describing chest pain. In your assessment, ascertain the character and quality of the pain; location and radiation of the pain; factors that precipitate, aggravate, or relieve the pain; the duration of the pain; and any associated symptoms.
3. Use one of two popular and similar assessment mnemonics—OLDCARTS or the PQRST assessment (see Chapter 5 , page 41) to evaluate chest pain.

BOX 12-1 Chest Pain Assessment Tips

Consider all chest pain and associated symptoms to be signs of myocardial ischemia (angina pectoris or MI) until it is ruled out.

The severity of the chest pain does not correlate with the cause of the pain. Indigestion and vague symptoms in a female patient, for example, may indicate myocardial ischemia or infarction. Diabetic and older patients may present with noncardiac symptoms that, with further testing, are found to be related to ischemia.

The patient's perception of pain should also be considered, including such factors as gender, response to pain, cultural beliefs, and level of stress.

Location of perceived pain may be misleading. Referred pain occurs with many diseases—that is, pain is perceived by the patient to be in one area, but its source is actually located in another area.

The patient may present with one problem but have multiple coexisting problems. Older patients, for example, may have several health problems in addition to the reason for the present visit. Likewise, patients who delay seeking medical attention sometimes present with multisystem problems.

The patient may experience no symptoms at all.

Significance

1. Ischemia caused by an increase in demand for coronary blood flow and oxygen delivery, which exceeds available blood supply, may result from coronary artery disease (CAD) or a decreased supply without an increased demand because of coronary artery spasm or thrombus.
2. Pain that is brought on by exertion and relieved by rest suggests angina pectoris or psychogenic pain. Psychogenic pain differs from angina in that it is usually associated with other symptoms, such as headache, back pain, stomach pain, and hyperventilation. Angina is usually caused by three Es: exercise, emotion, and eating.
3. Chest pain that worsens on deep inspiration or cough is suggestive of pleural, pericardial, or chest wall type pain.
4. Chest wall tenderness and pain on inspiration are suggestive of costochondritis.
5. Chest pain that is relieved by leaning forward and aggravated by lying down suggests pericarditis.
6. Sudden onset of chest pain accompanied by dyspnea is suggestive of pulmonary emboli or pneumothorax.
7. Dissecting aortic aneurysm is likely in the hypertensive patient who complains of a sudden onset of tearing, ripping pain.
8. If the patient reports chest pain while eating, this suggests angina or esophageal spasm or biliary (cholecystitis), pancreatic (pancreatitis), or gastric disease (gastroesophageal reflux disease or ulcers).
9. A panic attack may imitate a heart attack but is more common in younger individuals and in women more than in men.

Shortness of Breath (Dyspnea)

Characterization

1. What precipitates or relieves dyspnea?
2. How many pillows does patient sleep with at night?
3. How far can patient walk or how many flights of stairs can patient climb before becoming dyspneic?
4. Determine the type of dyspnea.
   a. Exertional—breathlessness on moderate exertion that is relieved by rest.
   b. Paroxysmal nocturnal—sudden dyspnea at night; awakens patient with feeling of suffocation; sitting up relieves breathlessness.
   c. Orthopnea—shortness of breath when lying down. Patient must keep head elevated with more than one pillow to minimize dyspnea.

Significance

1. Exertional dyspnea occurs as a result of an elevated pulmonary artery pressure (PAP) because of left ventricular dysfunction.
2. Paroxysmal (nocturnal) dyspnea, also known as cardiac asthma, is precipitated by stimuli that aggravate previously existing pulmonary congestion, resulting in shortness of breath that generally occurs at night and usually awakens the patient.
3. Orthopnea (dyspnea in the supine position) is caused by alterations in gravitational forces resulting in an elevation in pulmonary venous pressure and PAP. These, in turn, increase the pulmonary closing volume and reduce vital capacity. Orthopnea indicates advanced heart failure.

NURSING ALERT Patients with cardiac dyspnea tend to take short, shallow breaths, and patients with pulmonary dyspnea will likely breathe slower and deeper.

Palpitations

Characterization

1. Does patient feel heart pounding, fluttering, beating too fast, or skipping beats?
2. Does patient experience dizziness, pain, or dyspnea with palpitations?
3. What brings on this sensation?
4. How long does it last?
5. What does patient do to relieve these sensations?

Significance

1. Pounding, jumping, fluttering sensations occur in the chest because of a change in the patient's heart rate or rhythm or an increase in the force of its contraction.
2. Palpitations can occur as a result of cardiac arrhythmia as well as many other cardiac and noncardiac conditions.
3. Palpitations can be a manifestation of anxiety and panic disorders.
4. Palpitations can be intermittent, sustained and regular, or irregular.
5. Palpitations are most significant if dizziness and difficulty breathing occur simultaneously.
6. Palpitations that have a gradual onset and terminate in a pounding heartbeat may indicate sinus tachycardia.
7. Palpitations may be caused by noncardiac causes, such as thyrotoxicosis, hypoglycemia, pheochromocytoma, and fever.
8. Certain substances, such as tobacco, coffee, tea, unregulated synthetic cannabinoid, and alcohol, as well as certain drugs, including epinephrine, ephedrine, aminophylline, and atropine, may also precipitate arrhythmias and palpitations.

Weakness and Fatigue

Characterization

1. What activities can you perform without becoming tired?
2. What activities cause you to become tired, weak, or fatigued?
3. Is the fatigue relieved by rest?
4. Is leg weakness accompanied by pain or swelling?

Significance

1. Fatigue can be produced by low cardiac output (CO) because of right- or left-sided heart failure. The heart can't provide sufficient blood to meet the increased metabolic needs of cells.
2. As heart disease advances, fatigue is precipitated by less effort.
3. Weakness or tiring of the legs may be caused by peripheral arterial or venous disease.
4. Weakness and tiredness may be related to electrolyte imbalances, such as hypokalemia, hyperkalemia, hypercalcemia, hypernatremia, hyponatremia, hypophosphatemia, and hypermagnesemia.
5. Other disorders, such as chronic fatigue syndrome, multiple sclerosis, fibromyalgia, influenza, and Lyme disease, may also cause weakness and fatigue.

Dizziness and Syncope

Characterization

1. Is the dizziness characterized as light-headedness, feeling faint, off balance, vertigo, or spinning?
    a. How long does the dizziness last and what relieves it?
2. How many episodes of syncope or near syncope have been experienced?
3. Did a hot room, hunger, sudden position change, defecation, or pressure on your neck precipitate the episode?

Significance

1. Patients who experience anxiety attacks and hyperventilation syndrome frequently experience faintness and dizziness.
2. Patients who suffer repeated bouts of unconsciousness may be experiencing seizures rather than syncope.
3. Syncope can be a result of hypoglycemia, anemia, or hemorrhage.
4. Vasovagal (vasodepressor or neurocardiogenic) syncope can be precipitated by a hot or crowded environment, alcohol, extreme fatigue, severe pain, hunger, prolonged standing, and emotional or stressful situations. Vasovagal syncope is caused by temporary slowing of the heart and reduction of brain perfusion.
5. Orthostatic or postural hypotension, another cause of dizziness, occurs when the patient stands up suddenly.
6. Cardiac syncope results from a sudden reduction in CO because of bradyarrhythmias and/or

tachyarrhythmias.

7. Cerebrovascular disease such as carotid stenosis can cause dizziness and syncope because of reduced cerebral blood flow.

Nursing History

History of Present Illness

1. The patient's history is the single most important aspect in evaluating chest discomfort. The quality, location, duration, and modifying (ie, aggravating and relieving) factors are essential to making a correct diagnosis.
2. How long has the patient been ill? What has the course of the illness been, including current management? Obtain a characterization and review of systems (see Chapter 5).

Past Medical History

Medical and Surgical History

1. Assess childhood and adult illnesses, hospitalizations, accidents, and injuries.
    a. Does the patient have hypertension, diabetes mellitus, hyperlipidemia, chronic obstructive pulmonary disease (COPD), or other chronic illnesses (bleeding disorders or acquired immunodeficiency syndrome)? These may increase the risk of cardiac disease or aggravate disease.
    b. Review the patient's past illnesses and hospitalizations: trauma to the chest (possible myocardial contusion), sore throat and dental extractions (possible endocarditis), rheumatic fever (valvular dysfunction, endocarditis), and thromboembolism (MI, pulmonary embolism).

Review of Allergies

1. Ask if the patient is allergic to any drugs, foods, environmental agents, or animals and what reaction occurred.
    a. Allergies to penicillin or other commonly used emergency drugs, such as lidocaine or morphine, may influence the choice of drug treatments, if needed.
    b. Allergies to shellfish indicate iodine allergy; many contrast dyes used in radiologic procedures contain iodine.
    c. Does the patient have allergies to aspirin or nonsteroidal anti-inflammatory drugs, such as naproxen and ibuprofen? (An upset stomach or indigestion from aspirin is not an allergy—rather, it is sensitivity; the patient may still be able to take an enteric-coated aspirin.)

Medications

1. Assess the patient's prescription drugs, if any. Many cardiac drugs must be tapered to prevent a "rebound effect," whereas other drugs affect heart rate and may cause orthostatic hypotension. Estrogen preparations may lead to thromboembolism.
2. Assess the patient's use of over-the-counter medications, which may cause an increase in heart rate and blood pressure.
3. Assess the patient's use of herbal preparations, vitamin and mineral supplements, and other alternative or complementary therapies. Herbal preparations can interact with other drugs and anesthesia and interfere

with normal blood clotting.

Family History

1. Note the ages and health status of patient's family members (parents, grandparents, siblings, and other blood relatives).
2. A family history of CAD, MI, sudden death, hypertension, hyperlipidemia, hypercholesterolemia, or diabetes could place the patient at an increased risk for heart disease.

Personal and Social History

1. Assess the patient's health habits, such as alcohol or drug use (cocaine may cause MI), tobacco use, nutrition, obesity, pattern of recurrent weight gain after dieting, occupation, stress, sleeping patterns, and physical activity (sedentary lifestyle) (see Chapter 5 for additional information).
2. Many lifestyle choices increase the risk of acute and chronic cardiovascular disease.

Physical Examination

General Appearance

1. Is the patient awake and alert or lethargic, stuporous, or comatose?
2. Does the patient appear to be in acute distress, for example, clenching the chest (Levine sign)? Focus the physical assessment on what is essential when examining a patient in acute distress.
3. Observe the patient's general build (eg, thin, emaciated, or obese) and skin color (eg, pink, pale, ruddy, flushed, or cyanotic).
4. Assess the patient for shortness of breath and distention of jugular veins.

Vital Signs

1. Obtain temperature and note route.
2. Determine heart rate and rhythm.
   a. Assess pulse rate and rhythm using the radial artery.
   b. Time for 1 full minute; note regularity.
   c. Compare apical and radial heart rate (pulse deficit).
   d. Rhythm should be noted as regular, regularly irregular, or irregularly irregular.
3. Monitor blood pressure.
   a. Blood pressure can be measured indirectly using a sphygmomanometer and a stethoscope and electronic devices (dynamo) or directly by way of an arterial catheter. Be sure to use the right cuff size. Small cuff will result in overestimated BP.
   b. Avoid taking blood pressure in an arm with an arteriovenous shunt or fistula or on the same side as a mastectomy site or any type of lymphedema.
   c. If possible, take pressure in both arms and note differences (5 to 10 mm Hg difference is normal). Differences of more than 10 mm Hg may indicate subclavian steal syndrome or dissecting aortic aneurysm.
   d. Determine pulse pressure (systolic pressure minus diastolic pressure), which reflects stroke volume, ejection velocity, and systemic resistance and is a noninvasive indicator of CO (30 to 40 mm Hg, normal; less than 30 mm Hg, decreased CO).
   e. Note presence of pulsus alternans—loud sounds alternate with soft sounds with each auscultatory beat (hallmark of left-sided heart failure).
   f. Note presence of pulsus paradoxus—abnormal fall in blood pressure more than 10 mm Hg during inspirations (cardinal sign of cardiac tamponade).
4. Assess for orthostatic hypotension.
   a. Orthostatic hypotension occurs when a patient's blood pressure drops 15 to 20 mm Hg or more (with or without an increase in heart rate of at least 20 beats/minute) when rising from a supine to sitting or standing position.

b. Autonomic compensatory factors for upright posture are inadequate because of volume depletion; bed rest; drugs, such as beta-or alpha-adrenergic blockers; or neurologic disease; prompt hypotension occurs with assumption of the upright position.

c. Note changes in heart rate and blood pressure in at least two of three positions: lying, sitting, and standing; allow at least 3 minutes between position changes before obtaining rate and pressure.

DRUG ALERT Note that patients taking beta-adrenergic blockers may not exhibit a compensatory increase in heart rate when changing to upright position.

NURSING ALERT Vital signs are dependent on age, gender, weight, exercise tolerance, and medical conditions, so note patient's baseline for future comparison.

Head, Neck, and Skin

1. Examination of the head includes assessment of facial characteristics and facial expressions and color of skin and eyes, any of which can reveal underlying cardiac disease.
   a. Earlobe creases in a patient younger than age 45 may indicate a genetic tendency toward CAD.
   b. Facial color: look for a malar flush, cyanotic lips, or slightly jaundiced skin (rheumatic heart disease).
   c. de Musset sign (head bobbing with each heartbeat) may indicate severe aortic insufficiency.
   d. Facial edema may be noted with constrictive pericarditis and associated tricuspid valve disease.
2. Examine the neck for jugular venous pulse. Jugular vein distention is characteristic of heart failure and other cardiovascular disorders, such as constrictive pericarditis, tricuspid stenosis, and obstruction of the superior vena cava.
3. Examine the skin for temperature, diaphoresis, cyanosis, pallor, and jaundice.
   a. Warm, dry skin indicates adequate CO; cool, clammy skin indicates compensatory vasoconstriction because of low CO.
   b. Cyanosis may be central (noted on the tongue, buccal mucosa, and lips) because of bronchiectasis, COPD, heart failure, lung cancer, pneumothorax, polycythemia vera, pulmonary edema, pulmonary emboli, shock, and sleep apnea or peripheral (noted on distal aspects of extremities, tip of the nose, and earlobes) because of chronic arteriosclerotic occlusive disease, Buerger disease, deep vein thrombosis (DVT), heart failure, acute peripheral occlusions, and Raynaud disease and cold exposure.
   c. Jaundice may be a sign of right-sided heart failure or chronic hemolysis from prosthetic heart valve.
   d. Xanthelasmas are yellow plaque (fatty deposits) evident on the skin, commonly seen along the nasal side of one or both eyelids, palms, and tendons. Xanthelasmas are associated with hyperlipidemia and CAD and may occur normally in the absence of hyperlipidemia.

e. Pallor indicates decreased peripheral oxyhemoglobin or decreased total oxyhemoglobin. Onset may be sudden or gradual and extent may be generalized (most apparent on the face, conjunctiva, oral mucosa, and nail beds) or local (seen only in the affected limb).

Chest

See page 54.

Extremities

1. Inspect nail beds for color, splinter hemorrhages, clubbing, and capillary refill.
   a. Color—pale nail beds may be indicative of anemia, whereas cyanosis may be indicative of decreased oxygenation.
   b. Splinter hemorrhages are thin brown lines in nail bed and are associated with endocarditis. Janeway lesions (nontender, small erythematous, or hemorrhagic macular or nodular lesions on the palm and soles) are indicative of infective endocarditis.
   c. Clubbing (swollen nail base and loss of normal angle) is associated with chronic pulmonary or cardiovascular disease.
   d. Capillary refill indicates an estimate of the rate of peripheral blood low.
2. Inspect and palpate for edema—if pitting edema, describe degree of edema in terms of depth of pitting that occurs with slight pressure: 1+ or mild, 0 to ¼ inch (0 to 0.6 cm); 2+ or moderate, ½ inch (1.3 cm); and 3+ to 4+ or severe, ¾ to 1 inch (2 to 2.5 cm).
3. Inspect hands and feet for tenderness. Tender nodes (Osler nodes) may be associated with infective endocarditis.
4. Palpate arterial pulses (see page 59).

Laboratory Studies

Cardiovascular function and disease are evaluated by blood tests that indirectly monitor heart function and structural damage.

Enzymes and Isoenzymes

The diagnostic utilization of cardiac markers has evolved dramatically over the past 50 years. When myocardial tissue is damaged (eg, because of MI), cellular injury results in the release of intracellular enzymes and proteins (cardiac enzymes, isoenzymes, and biochemical markers) into the bloodstream, which, in turn, causes elevated peripheral blood enzyme levels (see Table 12-1).

Table 12-1 Cardiac Markers—Normal Values, Rise, Peak, Advantages, and Disadvantages

ENZYME	RISE (HR)	PEAK (HR)	NORMALIZATION	ADVANTAGES	DISADVANTAGES
CK	3–12	10–36	3–4 d	• Rises fairly early	• Lacks cardiac specificity • Increases only after severe damage
CK-MB	3–8	9–30	2–3 d	• Can detect reinfarction • Low cost	• Lacks cardiac specificity • False-positive results • Increases only after severe damage
CK Isoforms	2–6	6–12	1 d	• Highly sensitive in early stages of AMI	• Elevates slowly • Lacks cardiac specificity • False-positive results
TnT	3–12	12–96	5–14 d	• Cardiac specific and sensitivity in late AMI	• Low sensitivity in early AMI • Inability to diagnose subsequent myocardial infarction (MI)
TnI	3–12	12–24	5–10 d	• Cardiac specific and sensitivity in late AMI	• Low sensitivity in early AMI • Inability to diagnose subsequent MIs
Myoglobin	1–4	6–12	1 d	• Extremely sensitive • Shows in blood before CK-MB	• Low cardiac specificity • Not beneficial in late AMIs • False-positive results

1. The troponin complex is located on the thin filament of the contractile apparatus of striated and skeletal muscle and consists of three subunits: troponin C (TnC), troponin T (TnT), and troponin I (TnI). In the presence of myocardial damage, the troponin complex on the myofibril breaks down, and the subunits of troponin are slowly released into the bloodstream.
    a. TnC is not sensitive or specific for myocardial injury.
    b. TnT has a sensitivity of approximately 50% within 4 hours of the onset of chest pain, but increases to approximately 75% sensitivity after 6 hours of onset and approximately 100% sensitivity in 12 hours. However, its specificity for myocardial injury is lower.
    c. TnI has been found to be the most sensitive and specific for myocardial injury. It has little sensitivity within 4 hours of the onset of chest pain, but increases to 96% sensitivity after 6 hours of the onset of symptoms.
    d. Troponins are the preferred test for the diagnosis of acute myocardial infarction (AMI).
2. High sensitivity troponin (hs-cTnT and hs-cTnI) testing detects troponins at much lower levels, increasing sensitivity and reducing diagnostic time. Also detects circulating troponins in stable CAD in the absence of myocardial necrosis. Potentially can be used to monitor therapeutic response in patients with CAD.
3. Creatine kinase (CK) has a 98% sensitivity for AMI 72 hours after infarction. CK is a catalyst for energy

production and is found in the brain, myocardium, and skeletal muscle. CK is sensitive but not specific for myocardial injury.

4. CK isoenzymes are more specific than CK. Three CK isoenzymes have been identified: CK-MM, CK-MB, and CK-BB, with only CK-MB related to the heart. The specificity of CK-MB is greater than 85% and in some cases as high as 100%, but false positives do occur. Two types of CK-MB assays (CK-MB mass and CK-MB activity) are presently used.
   a. CK-MB mass assays are found to be more sensitive than CK-MB activity assays.
   b. CK-MB mass increases about 3 hours after onset of chest pain, whereas CK-MB activity requires another hour to elevate.
   c. CK-MB index is the ratio of CK-MB to the total CK and is considered abnormal when it exceeds 3% to 5%.
   d. CK-MB is no longer recommended for most patients being evaluated for an ACS.
5. Eventually, electrophoresis further breaks down CK-MB into its isoforms or subforms ($CK\text{-}MB_1$ and $CK\text{-}MB_2$). Normally, the ratio of $CK\text{-}MB_2$ to $CK\text{-}MB_1$ is 1:1. In myocardial injury, the $CK\text{-}MB_2/MB_1$ ratio increases to greater than 1.5 within 1 to 1½ hours. CK-MB isoforms have 56% sensitivity for patients presenting within 4 hours of the onset of symptoms.
6. Myoglobin is a small, oxygen-binding protein found in cardiac and skeletal muscles and is rapidly released into the bloodstream. Myoglobin is sensitive very early after injury, but has poor sensitivity over time and can generate many false-positive results. When myoglobin levels are assessed with CK-MB results, sensitivity increases (as high as 96%), but specificity can drop to as low as 81%.
   a. Myoglobin is directly related to muscle mass and is affected by age (levels increase with age), race (blacks have higher levels), gender (women have higher levels), and physical activity.
   b. Myoglobins can be elevated in the presence of reinfarction, skeletal muscle or neuromuscular disorders, trauma, severe burns, electrical shock, alcohol withdrawal delirium, metabolic disorders, systemic lupus erythematosus, strenuous exercise, renal failure, IM injections, cardiac bypass surgery, seizures, and heart failure.

Other Biochemical Markers

1. Homocysteine is a toxic by-product of the metabolism of the amino acid methionine into cysteine. Homocysteine exerts a direct cytotoxic effect on the endothelium of blood vessels by blocking the production of nitrous oxide, resulting in decreased pliability of vessels and development of atherosclerotic plaque. Increased homocysteine levels ultimately result in atherosclerosis, CAD, MI, stroke, thromboembolism, and peripheral vascular disease.
   a. Hyperhomocysteinemia (increased homocysteine levels) is related to gender (male), advanced age, smoking, hypertension, elevated cholesterol, decreased folate, decreased levels of vitamin B_6 and B_{12}, and lack of exercise.
   b. Homocysteine can also be elevated in the presence of other diseases, drug use, and caffeine intake.
2. B-type natriuretic peptide (BNP) is synthesized in the ventricular myocardium and released as a response

to increased wall stress. BNP is used for diagnosis and prognosis of suspected heart failure. Plasma levels of BNP increase in the presence of left ventricular systolic and diastolic dysfunction, particularly in the presence of decompensating heart failure.

   a. An increased BNP level identifies patients at the highest risk of developing sudden cardiac death and those who are in need of heart transplant. It is also associated with heart failure readmissions.
   b. BNP is considered a useful marker of myocardial function and is used to guide therapy.

3. C-reactive protein (CRP) is an inflammatory marker that may be an important risk factor for atherosclerosis and ischemic heart disease. CRP is produced by the liver in response to systemic cytokinesis. Elevated CRP is associated with AMI, stroke, and the progression of peripheral vascular disease. However, it can also be elevated with any inflammatory process. In addition to revealing events associated with CAD, CRP can also be used to identify patients at risk for developing CAD.
4. Lipoprotein(a) is a molecule that is similar to low-density lipoprotein cholesterol (LDL-C). It increases cholesterol deposits in the arterial wall, enhances oxidation of LDL-C, and inhibits fibrinolysis, resulting in the formation of atherosclerotic plaque and thrombosis. Treatment of elevated lipoprotein(a) is suggested only for patients with a history of premature vascular disease without other risk factors.
5. Factor I, or fibrinogen, is directly linked to increased cardiovascular risk. It is involved in the coagulation cascade (converting fibrinogen to fibrin by thrombin), stimulates smooth muscle cell migration and proliferation, and promotes platelet aggregation, which increases blood viscosity.
6. D-dimer may be done to evaluate for aortic dissection when chest pain is present. It is a degradation product of cross-linked fibrin and reflects activation of the extrinsic pathway of the coagulation cascade by tissue factor exposed in the aortic media by the intimal tear. It is also used to evaluate for the presence of thrombus or embolus (see page 323).

NURSING ALERT When measured at first contact or during the hospital stay, the natriuretic peptides are strong predictors of both short- and long-term mortality in patients with STEMI and UA/NSTEMI.

Nursing and Patient Care Considerations

1. A single set of negative cardiac biomarkers is not sufficient to rule out myocardial infarction. Make sure that enzymes are drawn in a serial pattern, usually on admission and every 3 to 6 hours until three samples are obtained; enzyme activity is then correlated with the extent of heart muscle damage.
2. Maintain standard precautions while obtaining blood specimens and properly dispose of all equipment.
3. Advise patient that results of blood tests will be interpreted based on time and within the context of risk factors and other diagnostic tests.

NURSING ALERT Greater peaks in enzyme activity and the length of time an enzyme remains at its peak level are correlated with serious damage to the heart muscle and, thus, a poorer prognosis.

Radiology and Imaging

Chest X-Ray

Chest x-rays can be used to assess heart size, contour, and position and may also reveal cardiac and pericardial calcification as well as physiologic alterations in pulmonary circulation. For further description and nursing considerations, see page 166.

Myocardial Imaging

Description

With the use of radionuclides and scintillation cameras, radionuclide angiograms can be used to assess left ventricular performance.

1. Thallium 201 is a radionuclide (an unstable atom that produces a small amount of energy) that behaves like potassium in the body and is distributed throughout the myocardium in proportion to blood flow.
   a. Negative result of "cold spot" imaging with thallium 201 rules out MI.
   b. A positive result, on the other hand, is inconclusive because it cannot differentiate between old and new infarction or areas of ischemia versus infarction.
2. Technetium-99m–labeled sestamibi is a myocardial perfusion marker used to assess cell membrane and mitochondrial integrity and to reveal myocardial perfusion.
   a. Sestamibi is not taken up by acute or chronic infarct tissue, and the amount of uptake of the radionuclide by other tissue correlates with the size of the infarction, the amount of CK released in the blood, and the postinfarction left ventricular ejection fraction (LVEF).
   b. "Hot spot" or positive imaging with technetium-99m is used when diagnosis of MI is unclear.
3. Radionuclide ventriculogram with technetium-99m is used to evaluate valve structure and ventricular function.
   a. Contrast medium is injected through a catheter, opacifying the ventricular cavity to enable measuring of right and LVEF.
   b. Also distinguishes regional from global ventricular wall motion and allows subjective analysis of cardiac anatomy to detect intracardiac shunts as well as valvular or congenital abnormalities.
   c. Complications include arrhythmias, intramyocardial or pericardial injection of contrast medium, and, possibly, development of emboli because of injection of air or a thrombosis through the catheter.
4. Dual single-photon emission computed tomography with simultaneous imaging using two isotopes improves the accuracy of assessing the infarcted area. The overlap of two isotopes may reflect the presence of salvaged myocardium adjacent to necrotic tissue.

Nursing and Patient Care Considerations

1. Advise patient that a radionuclide will be injected through a central venous, Swan-Ganz, or IV catheter or into an antecubital vein.
2. Reassure patient that the radionuclide will not cause radiation injury or affect heart function.

3. Explain to patient that hot flashes and nausea or vomiting may occur. A test dose will be administered before the dose required for contrast to assess patient's tolerance of radionuclide.
4. Results of the study will be discussed by the patient's health care provider after the study is interpreted by the radiologist.

Treadmill Stress Testing

Description

1. In treadmill stress testing, the patient walks a treadmill or rides a stationary bicycle until reaching a target heart rate, typically 70% to 80% of the maximum predicted heart rate. Treadmill stress testing has 70% sensitivity and specificity among the general population.
2. Indications for stress testing have been adapted from the American Heart Association (AHA) and the American College of Cardiology (see Box 12-2).
3. Reasons for terminating a stress test include:
   a. ST-segment elevations of 2 mm or more.
   b. 20 mm Hg drop in systolic blood pressure.
   c. Drop in heart rate or the development of heart block.
   d. Progressively increasing angina.
   e. ST-segment depression of 2 mm or greater.
   f. Three or more premature ventricular contractions (PVCs).
   g. Supraventricular arrhythmias.
   h. Severe hypertension.
   i. ST-segment depression at baseline that progresses during the test.
   j. Claudication.
   k. Fatigue, dyspnea, or feelings of light-headedness.
   l. Equipment malfunction.
   m. Sustained ventricular tachycardia.
4. Complications of stress testing include supraventricular tachyarrhythmias, bradycardias, heart failure, hypotension, ventricular ectopy (because of ventricular tachycardia), ventricular fibrillation, stroke, MI, and death.
5. Contraindications for performing a stress test include:
   a. AMI within 2 days.
   b. Unstable coronary syndrome.
   c. Wolff-Parkinson-White syndrome.
   d. Uncontrolled arrhythmias.
   e. High-degree atrioventricular (AV) blocks.
   f. Acute myocarditis.

g. Acute pericarditis.

h. Severe aortic stenosis.

i. Uncontrolled hypertension.

j. Acute aortic dissection.

k. Acute pulmonary embolism or pulmonary infarct.

BOX 12-2 Indications for Stress Test

CLASS I INDICATIONS

(*Clear indications for stress testing*)

- Suspected or proven coronary artery disease (CAD).
- Male patients who present with atypical chest pain.
- Evaluation of functional capacity and assessment of prognosis in patients with CAD.
- Patients with exercise-related palpitations, dizziness, or syncope.
- Evaluation of recurrent exercise-induced arrhythmias.

CLASS II INDICATIONS

(*Stress testing may be indicated*)

- Evaluation of typical or atypical symptoms in women.
- Evaluation of variant angina.
- Evaluation of patients who are on digoxin preparations or who have a right bundle-branch block.

CLASS III INDICATIONS

(*Stress testing is probably not necessary*)

- Young or middle-age asymptomatic patients who have no risk factors for CAD.
- Young or middle-age asymptomatic patients who present with noncardiac chest pain.
- Evaluation of patients for CAD who have complete left bundle-branch block.
- Evaluation of patients for CAD who have preexcitation syndrome.

Nursing and Patient Care Considerations

1. Explain to patient how the procedure will be done and screen for contraindications.
2. Advise patient to abstain from eating, smoking, and consuming caffeine for 2 hours before the test.
3. Inform patient that monitoring will occur throughout the test for signs of complications.
4. Advise patient to inform you of how he or she is feeling during the test.
5. Monitor patient throughout testing for color, respirations, ECG changes, and blood pressure.

Echocardiography (Ultrasound Cardiography)

Description

1. *Echocardiography* is used to visualize and assess cardiac function, structure, and hemodynamic abnormalities. It is the most commonly used noninvasive cardiac imaging tool.
2. It records high-frequency sound vibrations that are sent into the heart through the chest wall. The cardiac structures return the echoes derived from the ultrasound. The motions of the echoes are traced on an oscilloscope and recorded on film, CD, or DVD.
3. Clinical usefulness includes demonstration of valvular and other structural deformities, detection of pericardial effusion, evaluation of prosthetic valve function, and diagnosis of cardiac tumors of asymmetric thickening of interventricular septum, cardiomegaly (heart enlargement), clots, vegetations on valves, and wall motion abnormalities.
4. Types include two-dimensional (2-D), M-mode, and Doppler mode. The methods are complementary and are commonly used in conjunction.
    a. 2-D echocardiography—provides a wider view of the heart and its structures because it involves a planar ultrasound beam.
    b. M-mode—utilizes a single ultrasound beam and provides a narrow segmental view.
    c. Doppler mode—evaluates pressures and blood flow across the valves; also assesses for atrial and ventricular septal defects.

Nursing and Patient Care Considerations

1. Advise patient that traditional echocardiography is noninvasive and that no preparation is necessary.
2. Position patient on left side, if tolerated, to bring the heart closer to the chest wall. Assist patient to clean the chest of transducer gel after the test.

Transesophageal Echocardiography

Description

1. In *transesophageal echocardiography* (*TEE*), an ultrasound transmitter located at the end of a catheter is passed through the esophagus to the stomach, where flexion of the tip permits imaging of the heart through the stomach wall and the diaphragm, thus allowing clearer and more accurate diagnostic evaluation. It is particularly useful in evaluating valvular disease.
2. As the catheter is slowly withdrawn, views of cardiac structures are obtained at several levels in various 2-D planes.
3. TEE can be used for continuous monitoring of cardiac and noncardiac patients during surgery.
4. Atrial fibrillation is the most common indication for performing a TEE, used to evaluate for thromboembolism.

Nursing and Patient Care Considerations

1. Explain procedure to patient and provide written information, if possible.
2. This is an invasive procedure; patient will require mild sedation and must be kept on nothing-by-mouth

status (NPO) for a specified time—usually 4 to 6 hours—before the procedure.

3. The entire procedure takes less than 30 minutes.
4. Results of the study will be discussed with patient by the patient's health care provider after it is interpreted by the radiologist.

Stress Echocardiography

Description

1. *Stress (treadmill) echocardiography* has been found to have better sensitivity and specificity than treadmill stress testing alone.
2. Stress echocardiography is used to evaluate changes in wall motion when the patient is at rest and under stress.
3. Stress echocardiography can be coupled with pharmacologic stress testing. Myocardial perfusion imaging with dobutamine, adenosine, and dipyridamole is an alternative for patients who cannot exercise because of degenerative joint disease, physical deconditioning, neurologic disorders, COPD, or peripheral vascular disease.

Nursing and Patient Care Considerations

1. Explain procedure to patient and provide written information, if possible.
2. Withhold caffeine-containing products for 24 hours before adenosine and dipyridamole stress testing.
3. Discuss with cardiologist which medications should be withheld before test.
4. Maintain NPO status before testing for 2 hours or according to facility policy.
5. Establish a patent IV access.
6. Results of the study will be discussed with patient by the patient's health care provider after fully interpreted.

DRUG ALERT Theophylline-containing products should be discontinued 48 to 72 hours before an adenosine or dipyridamole stress test. Patients receiving oral dipyridamole should not be given IV adenosine because of potential for precipitating severe heart block. If possible, beta-adrenergic blockers should be withheld for 48 to 72 hours before a dobutamine stress test.

Cardiac MRI

Magnetic resonance imaging (*MRI*) is used to evaluate diseased heart muscle. Currently, three techniques are being used. Resting MRI can assess end-diastolic wall thickness and contractile function. Dobutamine MRI is used to evaluate contractile reserve. Contrast-enhanced MRI allows for the visualization of the *in vivo* regions of microvascular obstruction. The extent of microvascular obstruction determines the magnitude of myocardial scarring. Once determined, the extent of microvascular obstruction is a strong predictor of

myocardial remodeling and outcome after revascularization. It may eventually replace cardiac catheterization. Safety has been demonstrated in patients with permanent pacemakers and implantable cardioverter–defibrillators. For further description and nursing considerations, see page 166.

Phlebography (Venography)

Description

An x-ray visualization of the vascular tree after the injection of a contrast medium to detect venous occlusion.

Nursing and Patient Care Considerations

1. Inform patient that an intense burning sensation in the vessel where the solution is injected may be experienced. This will last for only a few seconds.
2. Note evidence of allergic reaction to the contrast medium; this may occur as soon as the contrast medium is injected, or it may occur after the test.
   a. Perspiring, dyspnea, nausea, and vomiting.
   b. Rapid heart rate and numbness of extremities.
   c. Hives.
3. Advise patient to notify health care provider of signs of allergic reaction.
4. Observe injection site for redness, swelling, bleeding, and thrombosis.

Positron Emission Tomography

Description

1. Considered the most sensitive modality for detecting hibernating viable myocardium and predicting left ventricular recovery after coronary revascularization.
2. F-FDG, a glucose analog that is transported into cells through glucose membrane transporter, is injected. It does not undergo any further metabolism (unlike glucose) and essentially is trapped within the cell.
3. Trapped F-FDG accumulates and becomes an index of cellular glucose utilization signifying ongoing cellular metabolism. Reduced FDG uptake (reduced or absent glucose metabolism) signifies myocardial scar. Also see page 167.
4. Used to determine blood flow to the heart muscle and viability of areas with decreased function because of previous MI.
5. Allows for the differentiation of nonfunctioning heart muscle from heart muscle that would benefit from a procedure.

Nursing and Patient Care Considerations

1. Inform patient not to eat for 4 hours prior to the scan.
2. Check blood glucose prior to test for diabetic patients; if greater than 200, may need to reschedule test.
3. Encourage patient to drink water following the scan to assist excretion of contrast medium.

Other Diagnostic Tests

Electrocardiogram

Basic Principles

1. Despite its limited sensitivity and specificity, the 12-lead ECG is still the standard for the evaluation of myocardial ischemia.
2. Electrical activity is generated by the cells of the heart as ions are exchanged across cell membranes.
3. Electrodes that are capable of conducting electrical activity from the heart to the ECG machine are placed at strategic positions on the extremities and chest precordium (see Figure 12-1).
4. The electrical energy sensed is then converted to a graphic display by the ECG machine. This display is referred to as the ECG.
5. Each ECG lead consists of a positive and negative pole; each lead also has an axis that represents the direction in which current flows.
6. Each lead takes a different view of the heart; therefore, the tracing will be different with each view obtained.
7. The direction in which electrical current flows determines how the waveform will appear.
8. There are three sets of leads:
   a. Standard limb or bipolar leads (I, II, III) utilize three electrodes; these leads form a triangle known as Einthoven triangle.
   b. Augmented unipolar leads (AVR, AVL, AVF).
   c. Precordial unipolar leads (V_1, V_2, V_3, V_4, V_5, V_6).
9. A heart contraction is represented on the ECG graph paper by the designated P wave, QRS complex, and T waves.
   a. The P wave is the first positive deflection and represents atrial depolarization or atrial contraction.
   b. The PR interval represents the time it takes for the electrical impulse to travel from the sinoatrial node to the AV node and down the bundle of His to the right and left bundle branches.
   c. The Q wave is the first negative deflection after the P wave; the R wave is the first positive deflection after the P wave.
   d. The S wave is the negative deflection after the R wave.
   e. The QRS waveform is generally regarded as a unit and represents ventricular depolarization. Atrial repolarization (relaxation) occurs during the QRS complex, but cannot be seen.
   f. The T wave follows the S wave and is joined to the QRS complex by the ST segment. The ST segment represents ventricular repolarization or relaxation. The point that represents the end of the QRS complex and the beginning of the ST segment is known as the J point.
   g. The T wave represents the return of ions to the appropriate side of the cell membrane. This signifies relaxation of the muscle fibers and is referred to as *repolarization* of the ventricles.
   h. The QT interval is the time between the Q wave and the T wave; it represents ventricular

depolarization (contraction) and repolarization (relaxation).

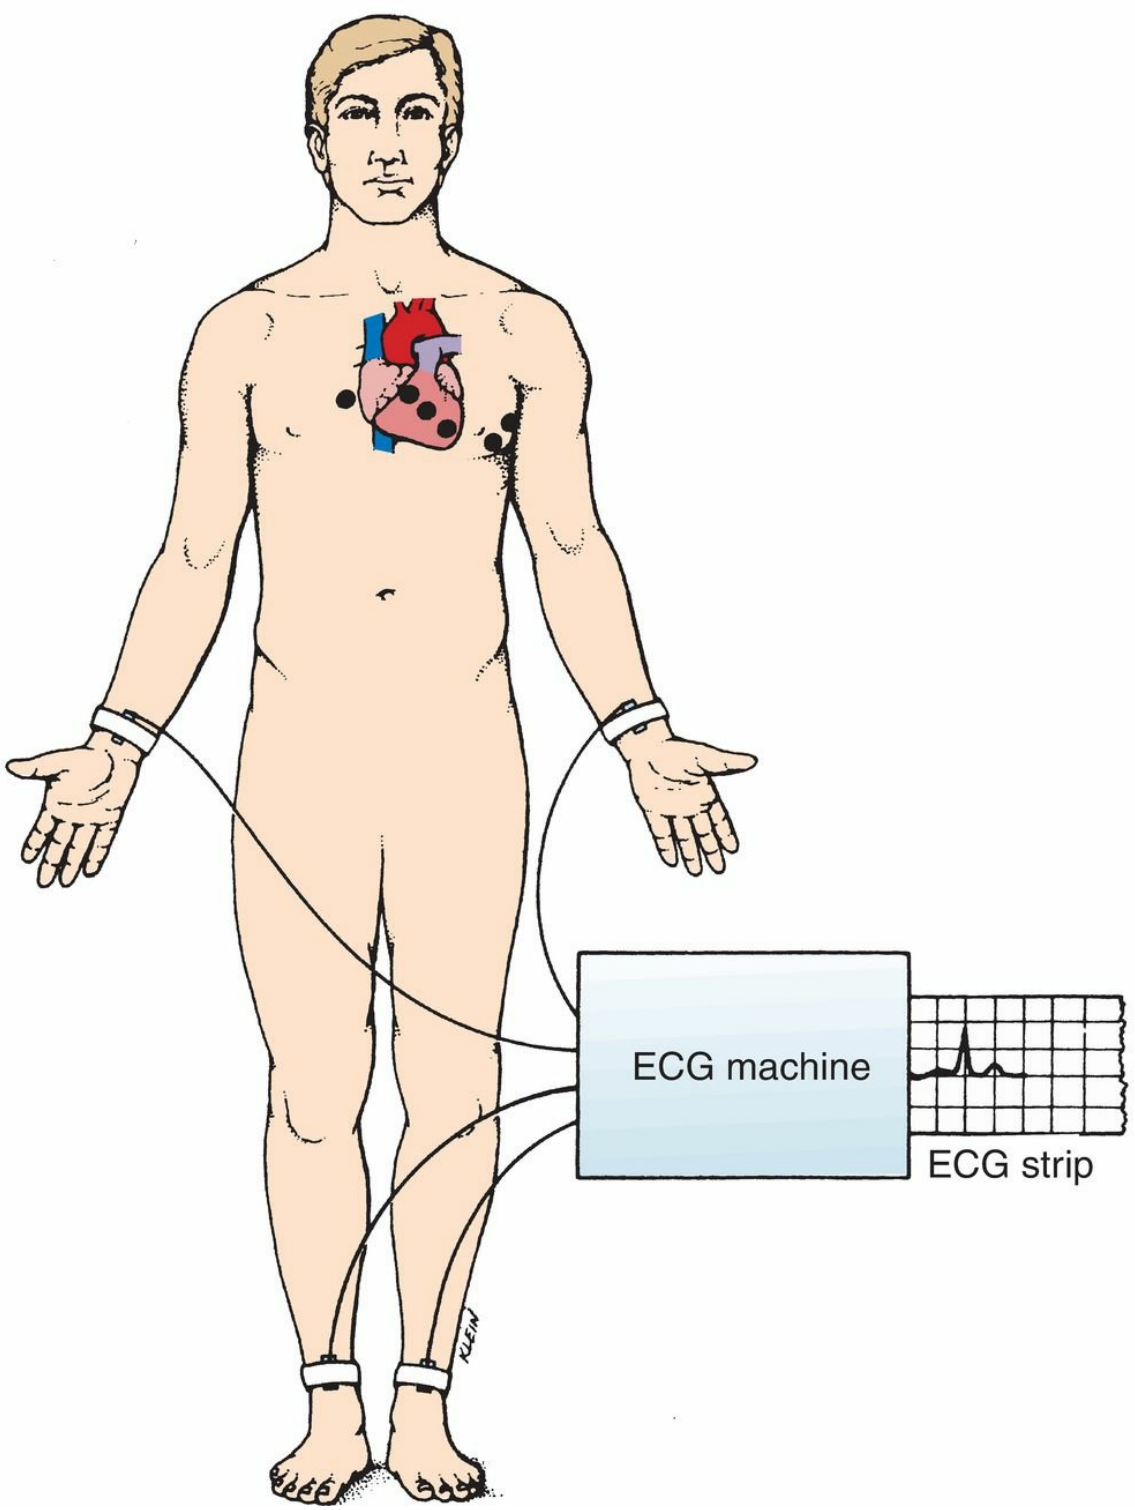

Figure 12-1. Transmission of the heart's impulse to a graphic display by ECG machine. The electrodes, which conduct electrical activity from the heart to the ECG machine, are placed at strategic positions on the extremities and chest precordium.

Indications

1. The ECG is a useful tool in the diagnosis of conditions that may cause aberrations in the electrical activity of the heart. Examples of these conditions include:

a. MI and other types of CAD such as angina.
b. Cardiac dysrhythmias.
c. Cardiac enlargement.
d. Electrolyte disturbances (calcium, potassium, magnesium, and phosphorous).
e. Inflammatory diseases of the heart.
f. Effects on the heart by drugs, such as antiarrhythmics and tricyclic antidepressants.

2. Despite its many advantages, however, the ECG also has several shortcomings:
   a. Fifty percent of all patients with AMI have no ECG changes.
   b. A patient may have a normal ECG, present pain-free, and still have significant risk for myocardial ischemia.
   c. Several disease processes can mimic that of an AMI, including left bundle-branch blocks, ventricular paced rhythms, and left ventricular hypertrophy.

ECG Leads and Normal Waveform Interpretation

See Figure 12-2.

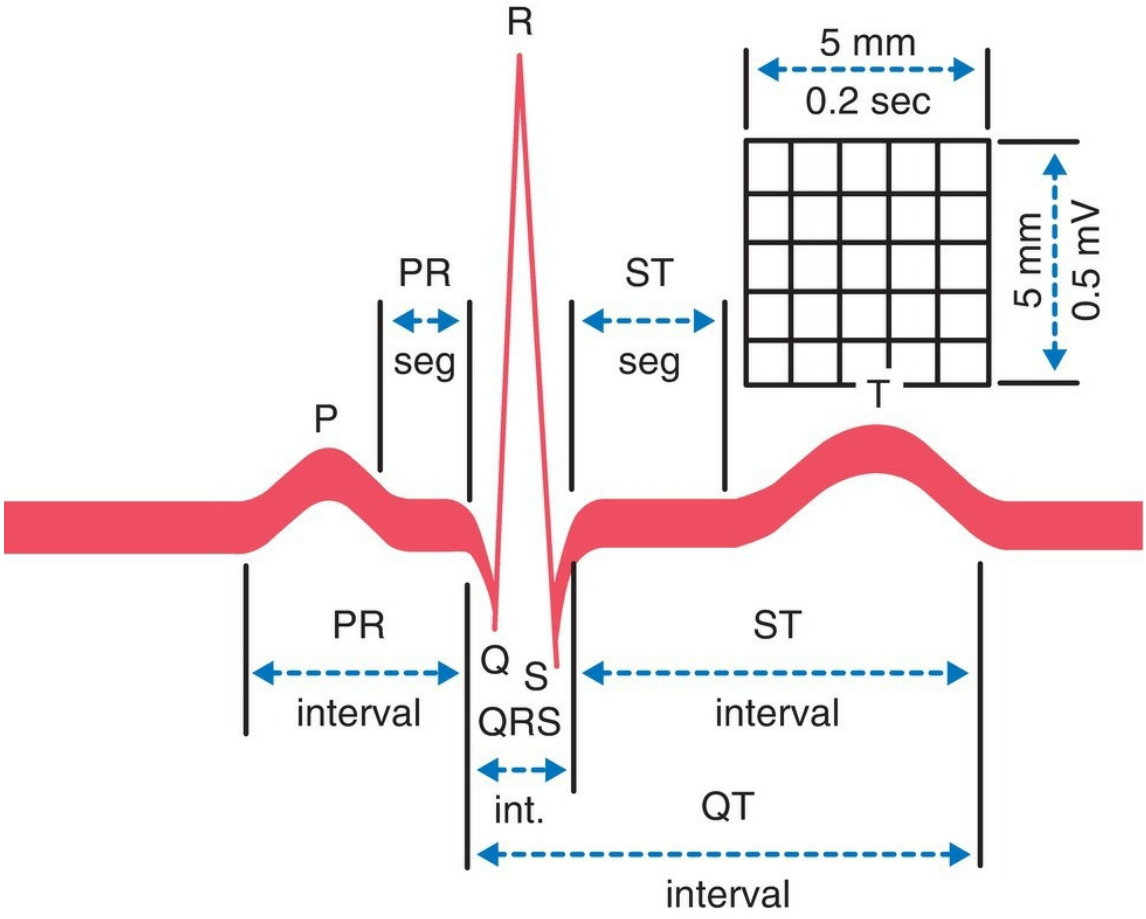

Figure 12-2. Waveform analysis.

1. The normal amplitude of the P wave is 3 mm or less; the normal duration of the P wave is 0.04 to 0.11

second. P waves that exceed these measurements are considered to deviate from normal.

2. The PR interval is measured from the upstroke of the P wave to the QR junction and is normally between 0.12 and 0.20 second. There is a built-in delay in time at the AV node to allow for adequate ventricular filling to maintain normal stroke volume.
3. The QRS complex contains separate waves and segments, which should be evaluated separately. Normal QRS complex should be between 0.06 and 0.10 second.
   a. The Q wave, or first downward stroke after the P wave, is usually less than 3 mm in depth. A Q wave of significant deflection is not normally present in the healthy heart. A pathologic Q wave usually indicates a completed MI.
   b. The R wave is the first positive deflection after the P wave, normally 5 to 10 mm in height. Increases and decreases in amplitude become significant in certain disease states. Ventricular hypertrophy produces very high R waves because the hypertrophied muscle requires a stronger electrical current to depolarize.
4. The ST segment begins at the end of the S wave, the first negative deflection after the R wave, and terminates at the upstroke of the T wave.
5. The T wave represents the repolarization of myocardial fibers or provides the resting state of myocardial work; the T wave should always be present.
   a. Normally, the T wave should not exceed a 5-mm amplitude in all leads except the precordial (V_1 to V_6) leads, where it may be as high as 10 mm.
6. The P, Q, R, S, and T waves all appear differently depending on which lead you are viewing.

Nursing and Patient Care Considerations

1. Perform ECG or begin continuous ECG monitoring as indicated.
   a. Provide privacy and ask patient to undress, exposing the chest, wrists, and ankles. Assist with draping as appropriate. Remove large jewelry or metal from upper body to avoid interference.
   b. Place leads on the chest and extremities as labeled, using self-adhesive electrodes or water-soluble gel or other conductive material.
   c. Instruct patient to lie still, avoiding movement, coughing, or talking, while ECG is recording to avoid artifact.
   d. Make sure ECG machine is plugged in and grounded a-nd operate according to manufacturer's directions.
   e. If continuous cardiac monitoring is being done, advise patient on the parameters of mobility as movement may trigger alarms and false readings.
2. Interpret the rhythm strip (see Figure 12-3). Develop a systematic approach to assist in accurate interpretation.
   a. Determine the rhythm—is it regular, irregular, regularly irregular, or irregularly irregular? Use calipers, count blocks between QRS complexes, or measure the distance between R waves to determine regularity.

b. Determine the rate—is it fast, slow, or normal?

   i. A gross determination of rate can be accomplished by counting the number of QRS complexes within a 6-second time interval (use the superior margin of ECG paper) and multiplying the complexes by a factor of 10.

   Note: This method is accurate only for rhythms that are occurring at normal intervals and should not be used for determining rate in irregular rhythms. Irregular rhythms are always counted for 1 full minute for accuracy.

   ii. Another means of obtaining rate is to divide the number of large 5-square blocks between each two QRS complexes into 300. Five large 5-square blocks represent 1 minute on the ECG paper. For example, in Figure 12-3, the number of large square blocks between complexes no. 5 and no. 6 equals 5, and 300 divided by 5 equals 60, or a rate of 60.

c. Evaluate the P wave—are P waves present? Is there a P for every QRS complex? If there is not a P for every QRS, do the P waves have a normal configuration?

d. Measure and evaluate the PR interval.

e. Evaluate the QRS complex—measure the QRS complex and examine its configuration.

f. Evaluate the ST segment—an elevated ST segment heralds a pattern of injury and usually occurs as an initial change in acute MI. ST depression occurs in ischemic states. Calcium and potassium changes also affect the ST segment.

g. Evaluate the T wave—are T waves present? Do all T waves have a normal shape? Could a P wave be hidden in the T wave, indicating a junctional rhythm or third-degree heart block? Is it positively or negatively deflected (inverted T waves indicate ischemia) or peaked (indicative of hyperkalemia)?

h. Evaluate the QT interval—should be less than one half the R-R interval. Prolonged QT interval may indicate digoxin toxicity, long-term quinidine or procainamide therapy, or hypomagnesemia.

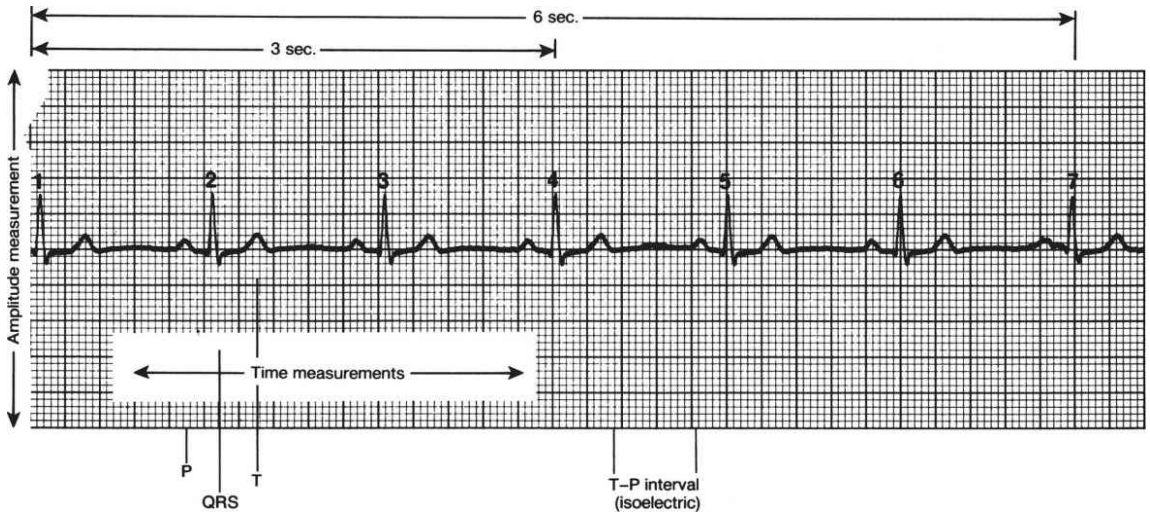

Figure 12-3. Lead II shows normal sinus rhythm on ECG paper.

See Chapter 13 for common cardiac dysrhythmias.

Angiography

Description

1. Invasive imaging procedure that enables visualization of blood vessels for their patency of blood flow versus blockage through the insertion of a catheter into an artery or vein followed by injection of contrast dye.
2. Various types include coronary, aortic, renal, peripheral, cerebral, and pulmonary angiography, lymphangiogram, ventriculography, and fluorescein angiography.
3. Provide information that may direct assessment and management of cardiovascular and cerebrovascular disease, peripheral blockage (arterial and venous), aneurysms, arterial and venous malformations, thrombosis (deep vein or pulmonary embolus), and fistulae, guide mapping prior to interventional procedures, and diagnose internal bleeding.

Nursing and Patient Care Considerations

Preprocedure

1. Question patient for known allergies, particularly to iodine (shellfish). If so, notify health care provider, who may want to prepare patient with oral corticosteroids and diphenhydramine before the study.
2. Make sure there is a signed consent and that patient/family questions have been answered.
3. Make sure fasting guidelines have been followed, varying from NPO to liquid or light diet. Follow facility policy; should be in accordance with American Society of Anesthesiologists guidelines (minimum fasting 6 hours from light meal, 2 hours from clear liquids) to minimize risk of pulmonary aspiration should emesis occur.
4. Make sure laboratory testing has been ordered and results have been reviewed, including blood urea nitrogen (BUN) and creatinine, to evaluate kidney function for ability to clear contrast dye; hemoglobin/hematocrit, platelet count, and coagulation values, to ensure clotting and anticoagulation baseline; white blood cell (WBC) count, to rule out infection that may be exacerbated by invasive procedure; electrolytes; pregnancy test (in female of child-bearing age); and blood type and screen, in case blood transfusion is necessary.
5. Make sure baseline ECG is on file.
6. Ensure IV patency for medication administration.
7. Make sure patient has voided.
8. Administer premedication, if ordered.

Postprocedure

1. Record vital signs according to facility policy and stability of patient.
2. Check for bleeding or hematoma formation at insertion site.
3. Check distal extremity for normal color and intact pulses.
4. Patient may complain of discomfort in the groin or other site depending on route by which contrast

medium was administered. Check for bed rest/activity progression and special fluid instructions. Encourage fluids/hydration to ensure clearance of contrast dye.

5. Provide patient with discharge instructions, including follow-up care, medications, and driving and activity restrictions.

Diagnostic Electrophysiology Studies

Description

Electrophysiology studies (EPS) are a complex invasive procedure in which flexible catheters (with 2 to 10 electrodes) are placed percutaneously in the right or left femoral vein, the subclavian vein, the internal jugular vein, or the median cephalic veins. EPS assesses pacing thresholds and measures conduction intervals in the high right atrium, the right ventricular apex, the right ventricular outflow tract, the coronary sinuses, the bundle of His, and, occasionally, the left ventricle. The test is followed by programmed stimulation protocols to evaluate the heart's conduction system.

Indications for EPS

1. Definite indications for EPS include:
   a. Sustained ventricular tachycardia.
   b. Cardiac arrest in the absence of AMI, antiarrhythmic drug toxicity, or electrolyte imbalance.
   c. Syncope of uncertain origin (for which noncardiac causes have been ruled out).
   d. Wide QRS tachycardia of uncertain etiology.
   e. To evaluate the effectiveness of a device for the detection and electrical termination of tachycardias (pacemakers or implanted defibrillators).
   f. Symptomatic Wolff-Parkinson-White syndrome.
   g. Frequent symptomatic regular supraventricular tachycardia unresponsive to medications.
2. Possible indications for EPS include:
   a. Asymptomatic Wolff-Parkinson-White syndrome.
   b. Post–myocardial infarction.
   c. Nonsustained ventricular tachycardia.
   d. Cardiomyopathy.
   e. Frequent ventricular ectopy.
   f. Supraventricular tachycardia.
3. Contraindications for EPS include:
   a. Asymptomatic sinus bradycardia.
   b. Asymptomatic bundle-branch blocks.
   c. Palpitation.
   d. Atrial fibrillation or flutter.
   e. Third-degree AV blocks.

f. Second-degree Mobitz type II AV blocks.

Nursing and Patient Care Considerations

1. Anticoagulants (warfarin) should be discontinued at least 3 days before EPS.
2. Discuss with health care provider which cardiac medications should be discontinued and when they should be discontinued.
3. Instruct patient to fast for at least 6 hours before the study.
4. Ensure laboratory tests are sent; may include BUN and creatinine, to evaluate kidney function for ability to clear contrast dye; hemoglobin/hematocrit, platelet count and coagulation values to ensure clotting and anticoagulation baseline; WBC count, to rule out infection that may be exacerbated by invasive procedure; electrolytes; blood type and screen, in case blood transfusion is necessary; and pregnancy test in females of child-bearing age.
5. Place electrodes for a 12-lead ECG, which will be recorded during the procedure.
6. Discuss with patient any feelings about the procedure and his or her physical condition. Patients frequently experience anxiety, fear of loss of control, denial, depression, and uncertainty.
7. Explain the procedure, its purpose, and the preparation involved.
8. Inform patient that pain medication and conscious sedation will be used during the procedure.
9. Postprocedure care includes:
   a. Keeping extremity used for IV straight, restraining if necessary.
   b. Monitoring patient's groin for bleeding or hematoma formation.
   c. Monitoring vital signs as ordered.
   d. Providing emotional support to patient and family.

Cardiac Catheterization

Description

1. *Cardiac catheterization* is a diagnostic procedure in which a catheter is introduced into the heart and blood vessels to provide physiologic data to guide treatment; measure cardiovascular hemodynamics; acquire radiographic images of coronary arteries, cardiac chambers, and aorta; collect blood from various chambers for analysis; and evaluate pulmonary blood flow and shunts.
2. The radial approach is becoming the preferred access site especially when there is peripheral vascular disease or morbid obesity. The femoral vein is another frequently used site. The catheter is directed up the aorta and into the coronary vasculature to visualize coronary anatomy (right or left) and measure hemodynamics. In rare instances of aortic disease, a transseptal approach may be used.
3. Right-sided heart catheterization—right side of the heart is accessed to evaluate pulmonary shunts, cardiac anomalies, and valvular disease. A radiopaque catheter is passed from the femoral vein and through the inferior vena cava or from the basilic vein and through the superior vena cava into the right atrium, right ventricle, and pulmonary vasculature under direct visualization with a fluoroscope.
   a. Right atrium and right ventricle pressures are measured; blood samples are taken for hematocrit and

oxygen saturation.

   b. After entering the right atrium, the catheter is then passed through the tricuspid valve and similar tests are performed on blood within the right ventricle.
   c. Finally, the catheter is passed through the pulmonic valve, and as far as possible beyond that point, capillary samples are obtained, capillary wedge pressure is recorded, and CO can be determined.
   d. Complications include cardiac dysrhythmias, venous spasm, thrombophlebitis, infection at insertion site, cardiac perforation, and cardiac tamponade.

4. Left-sided heart catheterization—primarily done to diagnose coronary artery disease; usually done by retrograde approach by advancing the catheter up the aorta into the coronary anatomy.
   a. Retrograde approach—catheter may be introduced percutaneously by puncture of the femoral artery or by direct radial or brachial approach and advanced under fluoroscopic control into the ascending aorta and into the left ventricle.
   b. Transseptal approach—catheter is passed from the right femoral vein (percutaneously or by saphenous vein cut down) upward into the right atrium. A long needle is passed up through the catheter and is used to puncture the septum separating the right and left atria; needle is withdrawn and the catheter is advanced under fluoroscopic control into the left ventricle.
   c. The catheter tip is placed at the coronary sinus, and contrast medium is injected directly into one or both of the coronary arteries to evaluate patency.
   d. Gives hemodynamic data—permits flow and pressure measurements of left side of the heart.
   e. Usually performed to evaluate the patency of coronary arteries and function of the left ventricular muscle and mitral and aortic valves; may also be done to evaluate patients before surgery.
   f. Ventriculography—study of the left ventricle; catheter is passed into the left ventricle, and dye is injected with a rapid, uniform rate via an injector machine to measure ejection fraction or function of the left ventricle.
   g. Complications of left-sided heart catheterization and implications for nursing assessment include dysrhythmias (ventricular fibrillation), syncope, vasospasm, pericardial tamponade, MI, pulmonary edema, allergic reaction to contrast medium, perforation of great vessels of the heart, systemic embolization (stroke, MI), loss of pulse distal to arteriotomy, and possible ischemia of the lower arm and hand.

5. Angiography is usually combined with heart catheterization for coronary artery visualization.
6. Contraindications for cardiac catheterization include uncontrolled ventricular irritability, electrolyte imbalance, medication toxicity (digitalis), uncontrolled heart failure, renal failure, recent stroke (within past 3 months), active GI bleeding, active infection, uncontrolled hypertension, patient's refusal, and pregnancy. Some of these conditions can be reversed or improved prior to catheterization.

Nursing and Patient Care Considerations

Preprocedure

1. Question patient for known allergies, particularly iodine (shellfish), and make health care provider aware

so that premedication with corticosteroid and antihistamine may be considered.

2. Make sure that there is a signed consent form and that patient and family questions have been answered.
3. Make sure that fasting guidelines have been followed, varying from NPO to liquid or light diet. Follow facility policy; should be in accordance with American Society of Anesthesiologists guidelines (minimum fasting 6 hours from light meal, 2 hours from clear liquids).
4. Make sure laboratory testing has been ordered and results reviewed (see page 242). Make sure baseline ECG is on file.
5. Ensure IV patency for administration of medications.
6. Mark distal pulses.
7. Explain to patient that he or she will be lying on an examination table for a prolonged period and may experience certain sensations:
   a. Occasional thudding sensations in the chest—from extrasystoles, particularly when the catheter is manipulated in ventricular chambers.
   b. Strong desire to cough, which may occur during contrast medium injection into right side of heart during angiography.
   c. Transient feeling of hot flashes or nausea as the contrast medium is injected.
8. Evaluate patient's emotional status before catheterization, dispel myths, and provide factual information.
9. Have patient void before the procedure.
10. Allow for premedication (if any) to take effect prior to procedure.

Postprocedure

1. Record vital signs according to facility protocol and patient's condition.
2. Check for bleeding or hematoma formation at insertion site.
3. Check distal extremity for normal color and intact pulses, and evaluate complaints of pain, numbness, or tingling sensation to determine signs of arterial insufficiency.
4. Assess for complaints of chest pain and respond immediately.
5. Follow activity restriction/progression directions, which are based on coagulation status and whether a vascular closure method was employed.
6. Evaluate complaints of back, thigh, or groin pain (may indicate retroperitoneal bleeding).
7. Obtain postprocedure ECG and labs according to facility protocol.
8. Be alert for signs and symptoms of vagal reaction (nausea, diaphoresis, hypotension, bradycardia); treat as directed with atropine and fluids.
9. Assess neurologic status if receiving IIB/IIIA platelet inhibitors or thrombolytics according to facility protocol.
10. Provide discharge instructions, including follow-up care, medications, driving and activity restrictions, and the need to report any pain or above-listed problems.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 12-1–12-8.

PROCEDURE GUIDELINES 12-1

Manual Central Venous Pressure (CVP) Monitoring

EQUIPMENT

- Venous pressure tray
- Cutdown tray or percutaneous catheter insertion tray with introducer
- Infusion solution/infusion set with CVP manometer (electronic CVP monitoring does not use a manometer) or attached to semirigid pressure tubing
- IV pole
- Arm board (for antecubital insertion)
- Sterile dressing and tape
- Gowns, masks, caps, and sterile gloves
- Heparin flush system and pressure bag (if transducer to be used)
- ECG monitor
- Carpenter's level (for establishing zero point)
- Transducer and transducer cable

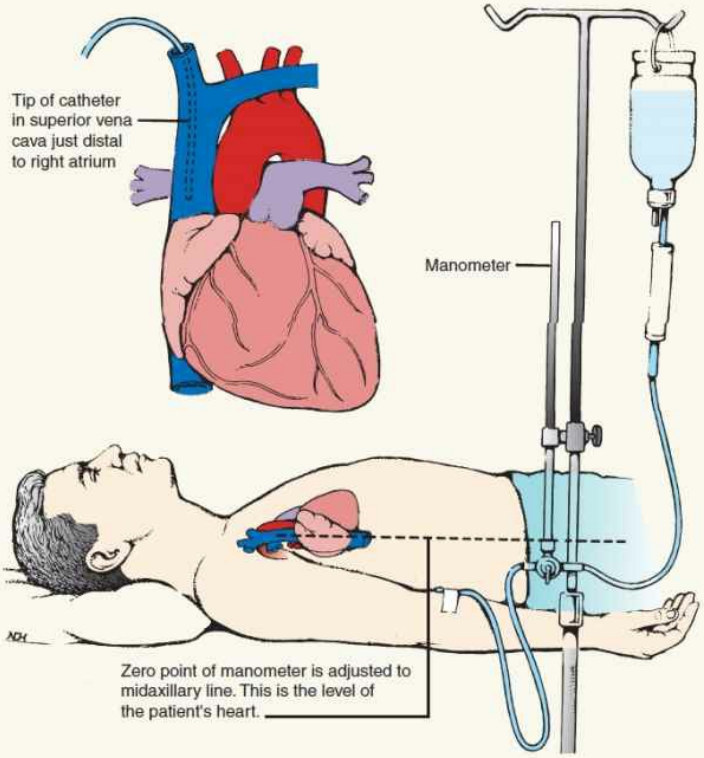
PROCEDURE

NURSING ALERT A CVP line is a potential source of septicemia.

PROCEDURE

Nursing Action	Rationale
Preparatory phase (by nurse)	
1. Assemble equipment according to the manufacturer's directions. Evaluate the patient's prothrombin time, partial thromboplastin time, and complete blood count.	1. Assesses for coagulopathies or anemia.
2. Explain the procedure to the patient and ensure that informed consent is obtained.	2. Allays anxiety and enlists cooperation. Procedure is similar to an IV, and the patient may move in bed as desired after passage of catheter.
a. Explain to the patient how to perform the Valsalva maneuver.	a. The Valsalva maneuver performed during catheter insertion and removal decreases risk of air emboli.
3. Position the patient in supine position.	3. Anatomic access and clinical status of the patient are considered in site selection.
a. Arm vein—extend arm and secure on arm board.	a. Provides for maximum visibility of veins.
b. Jugular veins—place the patient in Trendelenburg position. Place a small rolled towel under the shoulders (subclavian approach).	b. Trendelenburg position reduces the risk of air emboli.
4. Flush IV infusion set and manometer (measuring device) or prepare heparin flush for use with transducer. Secure all connections.	4. Prevents air emboli and bleeding.
a. Attach manometer to IV pole. The zero point of the manometer should be on a level with the patient's right atrium. Mark midaxillary line with indelible ink.	a. The level of the right atrium is at the fourth intercostal space midaxillary line. Marking right atrium ensures consistency of the zero level for subsequent readings.
b. Calibrate/zero transducer and level port with patient's right atrium.	
5. Institute electrocardiogram monitoring.	5. Dysrhythmias may be noted during insertion as catheter is advanced.
Insertion phase (by health care provider)	
1. Health care provider puts on gown, cap, and mask. (Ensure that that there is a "time-out" before starting the procedure.)	1. CVP insertion is a sterile procedure. "Time-out" is a Joint Commission requirement to ensure correct site, correct patient, and correct procedure.
2. The CVP site is surgically cleaned. The health care provider introduces the CVP catheter percutaneously or by direct venous cutdown.	2. The patient may be asked to perform the Valsalva maneuver to protect against risk of air embolus.
3. Assist the patient in remaining motionless during insertion.	3. Prevents trauma or rupture of vessel.
4. Monitor for dysrhythmias, tachypnea, and tachycardia as catheter is threaded to great vein or right atrium.	4. These are signs of pneumothorax or arterial puncture.
5. Connect primed IV tubing/heparin flush system to catheter and allow IV solution to flow at a minimum rate to keep vein open (25 mL maximum).	5. Fluid is administered to prevent clotting of the catheter. Catheter placement must be verified before hypertonic or blood products can be administered.
6. Obtain a chest x-ray.	6. Verifies correct catheter position and absence of pneumothorax.
7. Assist with suturing the catheter in place after placement confirmation.	7. Prevents inadvertent catheter advancement or dislodgement.
8. Place a sterile occlusive dressing over the site.	8. Prevents infection.

Nursing Action	Rationale
To measure CVP (by nurse)	
1. Place the patient in a comfortable position.	1. This baseline position is used for subsequent readings.
2. Position the zero point of the manometer at the level of the right atrium (see accompanying figure).	2. Eliminates the effect of hydrostatic pressure on the transducer.



3. Turn the stopcock so the IV solution flows into the manometer, filling to about the 0–25-cm level. Then turn the stopcock so the solution in the manometer flows into the patient.	3. Eliminates the effects of atmospheric pressure.
4. Observe the fall in the height of the column of fluid in manometer. Record the level at which the solution stabilizes or stops moving downward. This is CVP. Record CVP and the position of the patient.	4. The column of fluid will fall until it meets an equal pressure. The CVP reading is reflected by the height of a column of fluid in the manometer when there is open communication between the catheter and the manometer. The fluid in the manometer will fluctuate slightly with the patient's respirations. This confirms that the CVP line is not obstructed by clotted blood.
5. CVP catheter may be connected to a transducer and an electrical monitor with either digital or calibrated CVP wave readout. Make sure the transducer has been zeroed to atmospheric pressure. To zero the transducer, place the stopcock so it is open between the transducer and air and press zero button on the monitor.	5. Makes sure the transducer reads zero when no pressure is against it. This procedure is like zeroing a scale before weighing something to ensure accuracy.
6. CVP may range from 5 to 12 cm H_2O (absolute numeric values have not been agreed on) or 2 to 6 mm Hg. All values should be determined at the end of expiration.	6. The change in CVP is a more useful indication of adequacy of venous blood volume and alterations of cardiovascular function. The management of the patient is based not on one reading but on repeated serial readings in correlation with patient's clinical status.

Nursing Action	Rationale
7. Assess the patient's clinical condition. Frequent changes in measurements (interpreted within the context of the clinical situation) will serve as a guide to detect whether the heart can handle its fluid load and whether hypovolemia or hypervolemia is present.	7. CVP is interpreted by considering the patient's entire clinical picture: hourly urine output, heart rate, blood pressure, and cardiac output measurements.
	a. CVP near zero indicates that the patient is hypovolemic (verified if rapid IV infusion causes patient to improve)
	b. CVP above 15–20 cm H_2O may be due to either hypervolemia or poor cardiac contractility.
8. Turn the stopcock again to allow IV solution to flow from the solution bottle into the patient's veins. Use an IV pump and monitor the infusion at least hourly.	8. When readings are not being made, IV flow bypasses the manometer but keeps line open; flow should be controlled to prevent fluid overload.
Follow-up phase	
1. Prevent and observe for complications. Report severe shortness of breath, hypotension, hypoxemia, rumbling cardiac murmur.	1. Patient's complaints of new or different pain or shortness of breath must be assessed closely; may indicate development of complications. Air embolism may result in cardiac arrest.
a. *From catheter insertion:* Pneumothorax, hemothorax, air embolism, hematoma, and cardiac tamponade.	
b. *From indwelling catheter:* Infection, air embolism, central venous thrombosis.	
2. Make sure the cap is secure on the end of the CVP monitor and all clamps are closed when not in use.	2. Prevents air from entering system, thereby reducing risk of air embolus.
3. If air embolism is suspected, immediately place the patient in left lateral Trendelenburg position and administer oxygen.	3. Air bubbles will be prevented from moving into the lungs and will be absorbed in 10–15 minutes in the right ventricular outflow tract.
4. Carry out ongoing nursing surveillance of the insertion site and maintain aseptic technique.	
a. Inspect the entry site twice daily for signs of local inflammation and phlebitis. Remove the catheter immediately if there are signs of infection.	a. Local infection could spread rapidly through systemic circulation.
b. Make sure sutures are intact.	b. If the catheter dislodges into the right atrium, dysrhythmias may result.
c. Change dressings, as prescribed.	
d. Label to show date and time of change.	
e. Send the catheter tip for bacteriologic culture when it is removed.	e. Detects bacterial colonization.
5. When discontinued, remove central line.	
a. Position the patient flat with head down.	a. Prevents air from entering blood vessel.
b. Remove dressing and sutures.	
c. Have the patient take a deep breath and hold it while the catheter is gently pulled out.	c. Prevents air emboli by creating positive chest pressure.
d. Apply pressure at the catheter site and apply dressing.	d. Prevents bleeding.
e. Monitor site and vital signs for signs of bleeding or hematoma formation.	

PROCEDURE GUIDELINES 12-2

Measuring Pulmonary Artery Pressure (PAP) by Flow-Directed Balloon-Tipped Catheter (Swan-Ganz Catheter)

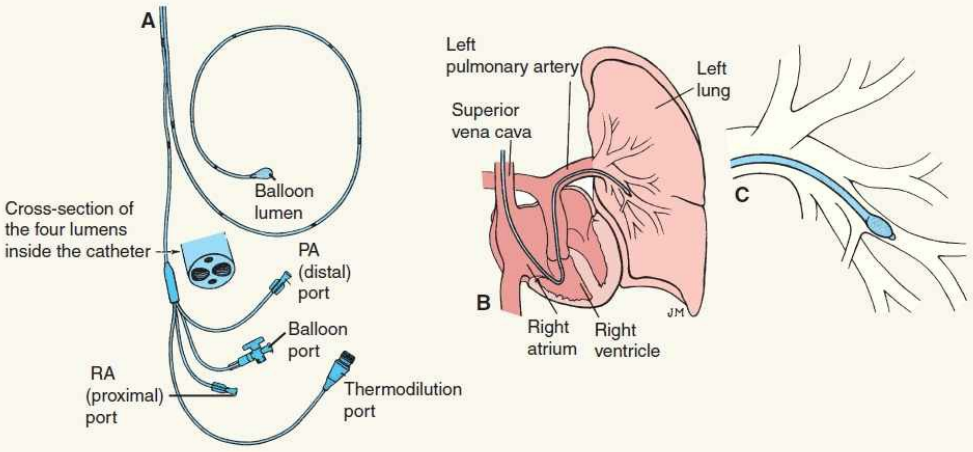
EQUIPMENT

- Swan-Ganz catheter set
- ECG, monitor, and display unit with paper recorder
- For mixed venous oxygen saturations (SvO2) monitoring, fiber-optic pulmonary artery catheter, optical module, and microprocessor unit
- Defibrillator

- Pressure transducer (disposable/reusable) and transducer cable
- Cutdown tray or percutaneous catheter insertion tray with introducer
- Sterile saline solution
- Pressurized bag
- Heparin infusion in plastic bag
- Continuous flush device—for general flushing and rapid flushing after blood draw
- Semirigid pressure tubing—attaches the catheter to transducer setup
- Local anesthetic
- Skin antiseptic
- Transparent/gauze dressing
- Tape

PROCEDURE

Nursing Action	Rationale
Preparatory phase (by nurse)	
1. Explain the procedure to the patient and family/significant other. Make sure that informed consent has been obtained. Explain that the patient may feel the catheter moving through the veins and that this is normal.	1. Allays fear and ensures understanding.
2. Check vital signs and apply electrocardiogram (ECG) electrodes. Have emergency equipment available.	2. Detects dysrhythmias or other complications.
3. Place the patient in a comfortable position; this is the baseline position.	3. Note the angle of elevation if the patient cannot lie flat because subsequent pressure readings are taken from this baseline position to ensure consistency. The patient may need to be in Trendelenburg position briefly if the jugular or subclavian vein is used.



(A) Swan-Ganz catheter. **(B)** Location of the Swan-Ganz catheter within the heart. The catheter enters the right atrium via the superior vena cava. The balloon is then inflated, allowing the catheter to follow the blood flow through the tricuspid valve, through the right ventricle, through the pulmonic valve, and into the main pulmonary artery. Waveform and pressure readings are noted during insertion to identify location of the catheter within the heart. The balloon is deflated after the catheter is in the pulmonary artery and properly secured. **(C)** Pulmonary capillary wedge pressure (PCWP). The catheter floats into a distal branch of the pulmonary artery when the balloon is inflated and becomes "wedged." The wedged catheter occludes blood flow from behind, and the tip of the lumen records pressures in front of the catheter. The balloon is then deflated, allowing the catheter to float back into the main pulmonary artery.

Nursing Action	Rationale
4. Set up equipment according to manufacturer's directions: a. The pulmonary artery catheter requires a transducer and recording, amplifying, and flush systems	a. Monitoring systems may vary greatly. The complexity of equipment requires an understanding of the equipment in use. A constant microdrip of heparin flush solution is maintained to ensure catheter patency
b. Flush the system according to manufacturer's directions.	b. Flushing of the catheter system ensures patency and eliminates air bubbles.
5. Adjust the transducer to the level of the patient's right atrium (phlebostatic axis fourth intercostal space, midaxillary line).	5. Differences between the level of the right atrium and the transducer will result in incorrect pressure readings; the phlebostatic axis is at the level of the right atrium.
6. Calibrate pressure equipment (especially important when reusable transducers are employed).	6. A known quantity of pressure is applied to the transducer (usually by mercury manometer) to ensure accurate monitoring of pressure readings.
7. Clip excess hair. Prepare skin over insertion site.	7. The catheter is inserted percutaneously under sterile conditions.
Performance phase (by health care provider)	
1. The health care provider puts on sterile gown and gloves and places sterile drapes over the patient.	1. Sterile field is established to reduce risk of infection.
2. State a "time-out." (Can be done before donning gown and gloves.)	2. A National Safety Patient Goal by the Joint Commission to eliminate wrong site or procedure to wrong patient.
3. The balloon is inflated with air under sterile water or saline to test for leakage (bubbles). The catheter may be flushed with saline at this time.	3. Ensures that the balloon is intact and removes air from catheter.
4. The Swan-Ganz catheter is inserted through the internal jugular, subclavian, or any easily accessible vein by either percutaneous puncture or venotomy.	4. The internal jugular vein establishes a short route into the central venous system.
5. The catheter is advanced to the superior vena cava. Oscillations of the pressure waveforms will indicate when the tip of the catheter is within the thoracic cavity. The patient may be asked to cough.	5. Catheter placement may be determined by characteristic waveforms and changes. Coughing will produce deflections in the pressure tracing when the catheter tip is in the thorax.
6. The catheter is then advanced gently into the right atrium, and the balloon is inflated with air.	6. The amount of air to be used is indicated on the catheter.
7. The inflated balloon at the tip of the catheter will be guided by the flowing stream of blood through the right atrium and tricuspid valve into the right ventricle. From this position, it finds its way into the main pulmonary artery. The catheter tip pressures are recorded continuously by specific pressure waveforms as the catheter advances through the various chambers of the heart.	7. Ventricular irritability may occur as the catheter passes into the right ventricle. Watch ECG monitor for signs of dysrhythmias and report.
8. The flowing blood will continue to direct the catheter more distally into the pulmonary tree. When the catheter reaches a pulmonary vessel that is approximately the same size or slightly smaller in diameter than the inflated balloon, it cannot be advanced further. This is the wedge position, called the pulmonary artery occlusion pressure (PAOP).	8. With the catheter in the wedge position, the balloon blocks the flow of blood from the right side of the heart toward the lungs. The sensor at the tip of the balloon detects pressures distally, which results in the sensing of retrograde left atrial pressures. PAOP is thus equal to left atrial pressures. a. Normal PAOP is 8–12 mm Hg. Optimal left ventricular function appears to be at a wedge between 14 and 18 mm Hg b. Wedge pressure is a valuable parameter of cardiac function. Filling pressures 20 mm Hg are associated with left-sided heart failure, pulmonary congestion, and hypervolemia.

Nursing Action	Rationale
9. The balloon is deflated, causing the catheter to retract spontaneously into a larger pulmonary artery. This gives continuous pulmonary artery systolic, diastolic, and mean pressure.	9. Normal systolic pulmonary pressure ranges are 20–30 mm Hg, and the diastolic pulmonary pressure ranges are 8–12 mm Hg. The normal mean PAP (average pressure in pulmonary artery throughout the entire cardiac cycle) is 15–20 mm Hg.
10. The catheter is then attached to a continuous heparin flush and transducer.	10. A low-flow continuous irrigation ensures that the catheter remains patent. The transducer converts the pressure wave into an electronic wave that is displayed on the oscilloscope.
11. The catheter is sutured in place and covered with a sterile dressing.	11. Maintains position and prevents infection.
12. A chest x-ray is obtained after Swan-Ganz insertion if fluoroscopy was not used to guide insertion.	12. Confirms catheter position and provides a baseline for future reference.
To obtain wedge pressure reading (by nurse)	
1. Note the amount of air to be injected into the balloon, usually no more than 1.5 mL. Do not introduce more air into the balloon than specified. Use the precalibrated 1.5 mL syringe it comes with because this has a locking guard. Maximum inflation volume only enough to see a change in waveform about 4–15 seconds.	1. Avoids rupturing the balloon.
2. Inflate the balloon slowly until the contour of PAP changes to that of PAOP. As soon as a wedge pattern is observed, no more air is introduced.	2. The transducer converts the pressure wave into an electronic wave that is displayed on a screen.
a. Note the digital pressure recordings on the monitor (an average of pressure waves is displayed, but these waves are not taken at end expiration).	a. PAOP should be determined at end expiration because respiratory variation of the waveform occurs because of changes in intrathoracic pressure.
b. Obtain a strip of the pressure tracing.	b. A calibrated oscilloscope or graph paper is needed to read pressures at end expiration.
c. Determine PAOP from strip at end expiration.	
3. Deflate the balloon as soon as the pressure reading is obtained. Do not draw back with force on the syringe because too forceful a deflation may damage the balloon. Always allow for passive deflation of the balloon.	3. Segmental lung infarction may occur if the catheter balloon is left inflated for long periods. PAOP is only measured intermittently. Never wedge for more than 15 seconds, nor inflate the balloon with more than 1.5 mL of air. Do not allow the catheter to remain in wedge position when the patient is unattended or when not directly taking the measurement.
4. Record PAOP reading and amount of air needed to obtain wedge reading. Document recorded waveform by placing a strip of the waveform in the patient's chart showing wedge tracing reverting to pulmonary artery waveform.	4. Overinflation of the balloon may cause a "superwedge" waveform, and data obtained will be inaccurate. Overinflation of the balloon may cause the balloon to lose elastic properties and rupture. The strip provides documentation that the catheter was not left in wedge position.
To obtain $S\bar{v}O_2$ reading	
1. Before insertion, perform a preinsertion calibration of the catheter.	1. This calibrates the catheter to light intensity in the environment.
2. After insertion, perform a calibration for light intensity and an in vivo calibration every 8 hours.	2. The in vivo calibration ensures that there is minimal difference, or "drift," between the actual value and the value displayed on the monitor. The light calibration adjusts for changes in light in the environment.

NURSING ALERT Also perform in vivo calibration if the optical module is disconnected at the catheter junction, if calibration data are lost, or if the $S\bar{v}O_2$ is within 4% of the $S\bar{v}O_2$ value calculated from mixed venous values obtained from the pulmonary artery catheter.

Nursing Action	Rationale
3. Monitor $S\bar{v}O_2$ at frequent intervals. Values of 60%–80% are normal.	3. Causes of an $S\bar{v}O_2$ 80% include increase in oxygenation or decrease in O_2 consumption.
4. If the $S\bar{v}O_2$ changes are within 10% of the prior value, confirm that the change reflects a change in patient condition.	4. The value displayed may not be accurate if fibrin or a clot is obstructing the catheter tip (low-intensity signal), if the catheter is touching the vessel wall or in a wedged position (high-intensity signal), or if the catheter is no longer calibrated accurately.
5. If the catheter is not functioning properly, initiate steps to resolve the problem.	5. These steps may include aspiration to determine if a clot is obstructing the catheter or notifying the health care provider of the need to reposition the catheter.
6. If no catheter malfunction is identified, report changes to the physician and initiate therapy based on standard of care.	6. Prompt intervention can restore normal tissue oxygen delivery before untoward effects occur.
Follow-up phase	
1. Inspect the insertion site daily. Look for signs of infection, swelling, and bleeding.	1. A foreign body (catheter) in the vascular system increases the risk of sepsis.
2. Record the date and time of dressing change and IV tubing change. Note the centimeter mark on the catheter as it leaves the cordis.	2. The centimeter mark is a reference point in case there is catheter movement.
3. Assess contour of waveform frequently and compare with previously documented waveforms.	3. The catheter may move forward and become lodged in wedge position or drift back into right ventricle. Turn the patient to the left side and ask him or her to cough (may dislodge catheter from wedge position). If not dislodged, notify the health care provider.
4. Assess for complications: pulmonary embolism, dysrhythmias, heart block, damage to tricuspid valve, intracardiac knotting of catheter, thrombophlebitis, infection, balloon rupture, rupture of pulmonary artery.	4. Blood coming back into the syringe indicates balloon rupture. Notify the health care provider immediately. Other signs of complications are dysrhythmias and change in clinical condition of the patient.
5. When indicated, assist with catheter removal without excessive force of traction; apply pressure dressing over the site. Check site periodically for bleeding.	5. Prevents trauma to tissue and excessive bleeding.

PROCEDURE GUIDELINES 12-3

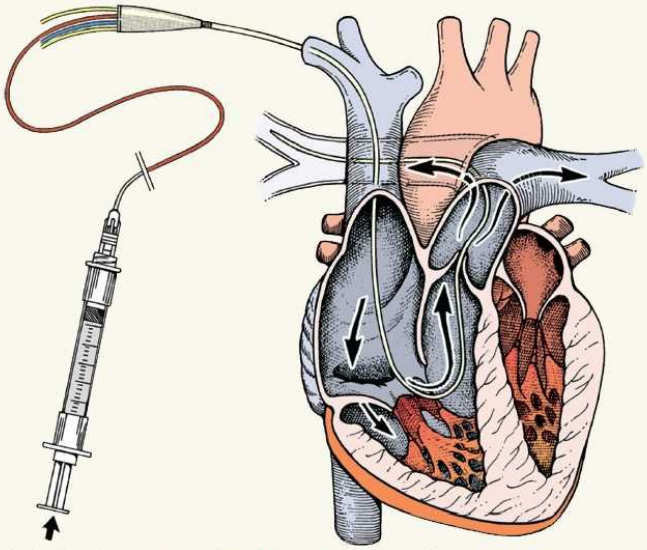
Measurement of Cardiac Output by Thermodilution Method

EQUIPMENT

- Flow-directed thermodilution catheter in place
- Cardiac output (CO) set, which includes IV tubing
- 10-mL syringe and three-way stopcock
- Normal saline or D5W solution bag
- Cardiac monitor with CO computation capability or stand-alone CO computer
- Temperature sensor cable

PROCEDURE

Nursing Action	Rationale



Typical equipment for a closed thermodilution cardiac output setup.

1. Explain the procedure to the patient.	1. Allays anxiety.
2. Connect IV solution bag and CO set maintaining aseptic technique.	2. Solution will be injected directly into the heart and must be sterile.
3. If you do not have a prepackaged CO set, attach IV solution bag to IV tubing, connect a three-way stopcock to the end of the tubing; connect a 10-mL syringe to the middle part of the three-way stopcock.	
4. Attach the three-way stopcock to the proximal injectate port of the thermodilution catheter. This port should be reserved solely for determination of CO.	4. The proximal injectate port should have its distal end in the right atrium. If medications are infusing in this port, they will be flushed through in bolus form when CO measurements are taken.
5. Another three-way stopcock may be used to allow for IV solution to run at a keep-open rate.	5. Once the CO set is connected, the system should remain closed.
6. Connect temperature sensor cable to the thermistor port of the thermodilution catheter.	6. When solution is injected through the catheter, it mixes with the blood in the right side of the heart and flows to the pulmonary artery where blood temperature is detected by the thermistor.

Nursing Action	Rationale
7. Set cardiac monitor to CO computation format. If using a stand-alone CO computer, enter the temperature of the injectable solution and the code number for the size of thermodilution catheter in use (code will be located on the thermodilution catheter packaging).	7. The injectate solution should be 15–20 degrees cooler than the patient's body temperature. Room temperature injectate is usually adequate. Cardiac output is calculated based on change in temperature.
8. Fill 10-mL syringe with injectate solution by turning stopcock off to the patient and open to syringe and solution.	
9. Turn off IV keep-open solution, if present.	9. Need closed system from syringe to catheter.
10. Turn stopcock off to injectate solution and open to the patient and syringe.	
11. Press "inject" button on the CO computer or monitor and inject 10 mL rapidly (within 4 seconds) and smoothly into the proximal port.	11. Delay will interfere with results.
12. Wait for computation to be complete. Repeat the procedure two or three times to obtain an average.	12. Some monitors display a waveform for the injectate dispersal to evaluate the adequacy of dispersal and temperature sensing.
13. Turn stopcock off to the syringe and injectate and allow keep-open IV fluid to infuse through the proximal port.	13. Maintains patency of port.

PROCEDURE GUIDELINES 12-4

Transcutaneous Cardiac Pacing

EQUIPMENT

- Disposable multifunction defibrillator/pacing/ECG electrode pads
- External pacing module
- Resuscitative equipment

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain the procedure to the patient.	1. Allays anxiety.
2. Explain sensation of discomfort with external pacing.	2. Discomfort is felt with each firing but can be relieved with analgesics.
3. Perform Hand hygiene.	3. To evaluate rhythm.
4. Obtain 12-lead EKG if patient condition permits.	4. If IV emergency medications are needed.
5. Establish IV access.	5. To achieve better contact.
6. Remove excessive hair where pads will be placed.	a. Shaving causes microabrasions and increases likelihood of skin irritation.
7. If time allows, remove hair by clipping not shaving. If time does not allow, place the pad on firmly to the skin and then remove. Place a new pad.	b. Decreases the amount of hair.
Performance phase	
1. Place multifunction electrode pads as follows:	1. Electrodes must be placed so the current passes through as much of the myocardium as possible with the least distance between the pads.
a. Anterior/posterior: The negative multifunction electrode pad is placed on the anterior chest at the V_3–V_6 position; the positive multifunction electrode pad is placed directly behind the anterior pad on the patient's back	a. Manufacturer includes diagram on the electrode package and the electrodes themselves.
b. Anterior/lateral: The positive multifunction electrode pad is placed on the upper right chest under the clavicle; the negative multifunction electrode pad is placed at the V_3–V_6 position.	
2. Attach 3-lead electrode monitoring, as required. Some newer multifunctional electrode pads have built-in 3-lead electrodes monitoring	2. Some devices will not pace if 3-lead monitoring is not attached. If multifunctional electrode pads have built in 3-lead electrode monitoring and are not functioning properly convert to independent 3-lead electrode monitoring
3. Make sure that pacing module is off or on standby and that milliamperes (mA) output is set at the minimal level before connecting electrodes to external module.	3. Prevents accidental shock on connection.
4. Connect multifunction pacing electrode pads to defibrillator with transcutaneous pacemaker capability.	
5. Determine rate setting according to instructions and patient condition. If patient's heart rate is consistently too low to maintain adequate cardiac output, set rate at 70–80. If the patient's rate falls only intermittently and the pacemaker will be used in the demand mode, set rate at 60.	5. Can be set at a fixed rate or on demand to pace only if heart rate falls below the set rate.
6. Gradually increase mA output until a pacing spike and a corresponding QRS complex is seen (perhaps as high as 70 mA or more).	6. If using the demand mode, set the rate higher than the patient's rate to establish the correct output and capture, then return the rate to 60.
7. Palpate the pulse on the right side to ensure adequate response to electrical event.	7. Choose either right radial or brachial pulse because muscular contractions that may be transferred down the left arm can cause misinterpretation.
8. Check pad placement frequently.	8. Patient perspiration may cause pads to loosen or slip.

Nursing Action	Rationale
Follow-up phase	
1. Check vital signs at least every 15 minutes while continuous pacing is employed. Check blood pressure in the right arm.	1. Determines if cardiac output is adequate. Muscle contraction from pacing may interfere with blood pressure reading on left.
2. Monitor ECG continuously for pacer functioning.	2. Detects malfunction (may occur because of electrode loosening).
3. Assure the patient that treatment is temporary and prepare the patient for transvenous or permanent pacemaker insertion as indicated.	3. Should only be used continuously for 2 hours because sensation may be uncomfortable.
4. Change the multifunction electrode pads every 24 hours or per manufacturer guidelines.	4. Decreased efficacy of gel pad.

PROCEDURE GUIDELINES 12-5

Direct Current Defibrillation for Ventricular Fibrillation*

EQUIPMENT

- Direct current defibrillator with paddles or multifunctional defibrillator pads
- Highly conductive multipurpose electrolyte gel

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
Monitored patient	
1. If ventricular fibrillation is witnessed, precordial thump may be considered.	1. Minimizes cerebral ischemia and potentially restarts cardiac rhythm.
2. Immediately implement CPR until defibrillator is available.	2. CPR is essential before and after defibrillation to ensure blood supply to the cerebral and coronary arteries.
Unmonitored patient	
1. Expose anterior chest and move jewelry and transdermal patches away from area.	1. Jewelry/transdermal patches may interfere with electrical current and cause serious burns.
2. Immediately implement CPR until defibrillator is available. If response time is greater or equal to 5 minutes, perform 2 minutes of CPR prior to defibrillation.	2. Provides oxygenated blood supply to the cerebral and coronary arteries.
3. Apply multifunctional defibrillator pads or paddles with conductive gel to the patient's bare chest.	3. Multipurpose electrolyte gel provides better conduction than do paddles alone. Do not allow gel to be spread across the chest because this may cause severe burns to the patient's chest and may divert the current from traveling to the heart. Pads are more effective than paddles because they decrease transthoracic impedance.
4. Apply paddles or multifunctional pads.	4. The paddles/pads are placed so that the electrical current flows through as much of the myocardium as possible.
a. Anterolateral position: Apply one paddle/pad to just the right of the sternum below the clavicle and the other paddle/pad to just the left of the cardiac apex (see accompanying figure, page 358).	
b. Anteroposterior position (pads only): Apply anterior pad over left apex and posterior pad under the infrascapular region.	b. In this method, the current directly traverses the heart.
NURSING ALERT Paddles/pads should be placed at least 5 inches (12.7 cm) away from a pacemaker to prevent damage to pacemaker circuitry.	
5. Remove oxygen from immediate area.	5. Prevents danger of fire or explosion.
6. Turn on defibrillator to the prescribed setting. The American Heart Association recommends that initial defibrillation should be 200 joules for biphasic or 360 joules for monophasic.	6. Biphasic is preferred over monophasic. This means that the machine delivers current that flows in one direction for a specified duration and then reverses the current to flow in the other direction. Significantly lower energy levels are required with biphasic defibrillators.
7. For paddles:	
a. Grasp the paddles only by the insulated handles.	a. Prevents getting shocked.
b. Charge the paddles. Once paddles are charged, give the command "ALL CLEAR." Look around quickly to make sure everyone is clear from the patient and bed.	b. Prevents shock to a person who touches the bed.
c. Push the discharge buttons located on both of the handles of the paddles while simultaneously exerting 25 lb of pressure to each of the paddles.	c. If good skin contact is not maintained, the electrical current may take the path of least resistance and arc from one paddle to the other.

Nursing Action	Rationale
 Paddle placement in ventricular defibrillation From Smeltzer, S., & Bare, B. (2000). *Brunner and Suddarth's textbook of medical-surgical nursing* (9th ed.). Philadelphia, PA: Lippincott Williams & Wilkins.	
8. For multifunctional pads: a. Press the charge button on the defibrillator machine. Once the charge is reached, give the command "ALL CLEAR." Look around quickly to make sure everyone is clear from the patient and bed. b. Push the shock button on the defibrillator machine.	8. Multifunctional pads provide hands-free defibrillation.
9. Resume CPR immediately after defibrillation.	9. Oxygenates the patient and restores circulation.
Follow-up phase	
1. After the patient is defibrillated and rhythm is restored, antiarrhythmics are usually given to prevent recurrent episodes.	1. Any resultant arrhythmia may require appropriate drug intervention.
2. Continue with intensive monitoring and care.	2. The patient may remain in an unstable condition.

**Or pulseless ventricular tachycardia.*

PROCEDURE GUIDELINES 12-6

Synchronized Cardioversion

EQUIPMENT

- Direct current defibrillator with paddles or multifunctional pads
- Highly conductive multipurpose electrolyte gel

PROCEDURE

Nursing Action	Rationale
1. If the procedure is elective, it is advisable to have the patient ingest nothing by mouth 12 hours before the cardioversion. Make sure to have working suction equipment available.	1. During sedation or the procedure, the patient may vomit and aspirate if the stomach is full.
2. Prepare the patient for the procedure.	
a. Reassure the patient and make sure that informed consent has been obtained.	a. Allays anxiety and ensures understanding of the procedure.
b. Make sure the patient has not been taking digoxin and that serum potassium level is normal.	b. Low potassium level may precipitate postshock dysrhythmias.
3. Make sure IV line is secure.	3. An IV line is necessary for administration of emergency medications and sedation.
4. Obtain a 12-lead electrocardiogram (ECG) before and after cardioversion with the ECG machine.	4. An ECG is taken to ensure that the patient has not had a recent myocardial infarction or converted back to sinus rhythm prior to the cardioversion.
5. Make sure oxygen is readily available.	5. May be needed if arrhythmias occur after cardioversion.
6. Apple multifunctional defibrillator pads or paddles with conductive gel to patient's bare chest:	6. Placed so that the electrical currents flows through as much of the myocardium as possible.
a. Anterolateral position: Apply one paddle/pad just to the right of the sternum below the clavicle and the other paddle/pad just to the left of the cardiac apex	
b. Anterior position (pads only): Apply anterior pad over left apex and posterior pad under the infrascapular region.	
7. If the patient's condition is appropriate, a short-acting sedative and possibly an analgesic may be given.	7. Helps produce amnesia concerning the cardioversion.
8. Turn the machine to the synchronized mode. Look for marking above the R wave on the machine. Set to the appropriate joules.	8. If the electrical discharge hits the T wave, ventricular fibrillation may occur.
a. Charge the machine. Then give the command "ALL CLEAR." Look around quickly to make sure everyone is clear from the patient and bed.	a. Avoids touching patient and receiving shock.
b. Push the shock button. The discharge may be delayed because it is resynchronizing with the R wave before discharging the electrical energy.	
9. If repeat cardioversion is needed, check if the machine is still in the synchronized mode.	9. Some machines reset to defibrillation mode.
NURSING ALERT If ventricular fibrillation develops, turn synchronized mode off, adjust joules to the appropriate setting for defibrillation, and proceed with defibrillation.	
10. A short-acting sedative and, possibly, an analgesic may be given.	10. Helps produce amnesia concerning the cardioversion.
11. Monitor the ECG after conversion occurs. Blood pressure should be recorded every 15 minutes for 1 hour or according to facility policy.	11. The patient may revert to previous dysrhythmias after conversion.

PROCEDURE GUIDELINES 12-7

Automated External Defibrillator

EQUIPMENT

- Automatic external defibrillator (AED)
- Defibrillator pads

PROCEDURE

Nursing Action	Rationale
1. Assess unresponsiveness and pulselessness.	1. Establishes need for the procedure.
2. Position the patient in the supine position.	2. For access to the chest.
3. Start cardiopulmonary resuscitation (CPR) while automated external defibrillator (AED) is being applied.	3. Early restoration of oxygenation and perfusion is imperative in enhancing the resuscitative effort.

Example of an AED.

4. Place pads in the anterolateral position. Apply one paddle/pad just to the right of the sternum below the clavicle and the other paddle/pad just to the left of the cardiac apex.	4. Anterior placement is preferred because attempting anteroposterior pad placement may delay treatment.
5. Turn on AED.	
6. Follow audio and/or visual instructions from the AED.	6. The AED will analyze the rhythm in 5–15 seconds and determine the need for defibrillation based on that analysis. It will then let the operator know how to proceed.
7. Suspend CPR or any movement of the patient during the analysis.	7. External movement will impair the AED's accuracy in analyzing the rhythm.
8. If, after analyzing the rhythm, a shock is advised, the AED will instruct the operator to prepare for a shock. It will charge the unit, give the warning to "STAND CLEAR," and then deliver the shock or prompt the operator to push the shock button.	8. Prevents person from receiving shock if touching the patient.
9. After the first shock, resume CPR for 2 minutes before reanalyzing the rhythm per American Heart Association guidelines. Most AEDs have an internal clock that will let you know when 2 minutes have past and gives a warning to "STAND CLEAR."	9. Provides oxygenation to the patient.
10. If no shock is indicated, continue CPR for 2 minutes, and then allow the AED to analyze the rhythm. Proceed as above if a shock is now indicated. If a shock is still not indicated, continue CPR and reanalyze the rhythm every 2 minutes.	10. A shock will only be delivered if ventricular fibrillation or tachycardia is present.
11. If the patient regains a pulse, continue to support ventilations. Keep AED pads attached and the unit on in case the patient again loses consciousness.	11. Close monitoring is necessary in case dysrhythmia recurs.

PROCEDURE GUIDELINES 12-8

Assisting the Patient Undergoing Pericardiocentesis

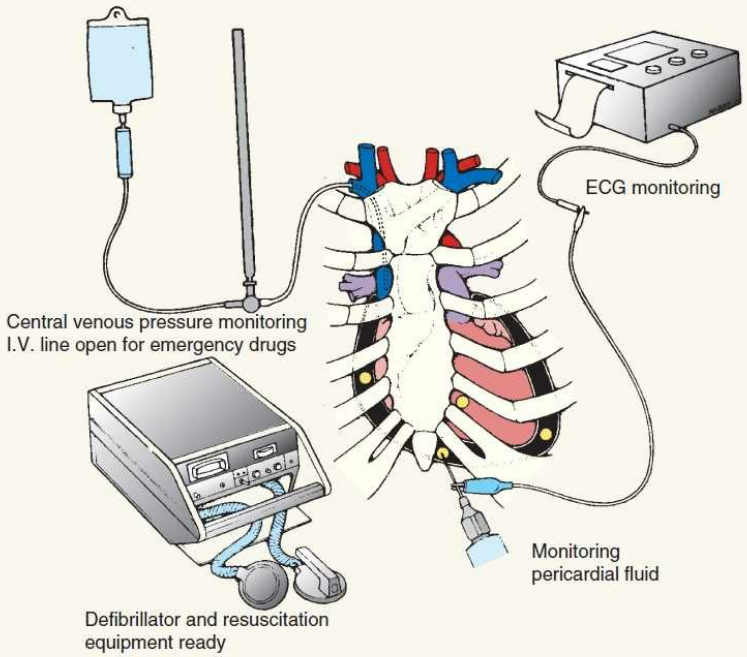
EQUIPMENT

- Pericardiocentesis tray
- Intracath set and 2 three-way stopcock
- Skin antiseptic

- 1% to 2% lidocaine
- Sterile gloves, gown, drape, and mask
- Sterile syringes: 50 mL, 10 mL, 5 mL, 3 mL
- Two packs 4 Ã— 4 gauze and tape
- Electrocardiograph (ECG) for monitoring purposes
- Sterile ground wire to be connected between pericardial needle and V lead of ECG (use alligator clip–type connectors)
- Equipment for cardiopulmonary resuscitation

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Administer sedation as prescribed.	1. Reduces anxiety of the patient. Depending on sedatives used may provide amnesic effect.
2. Establish venous access.	2. Preserves a route for IV therapy in an emergency.
3. Place the patient in a comfortable position with the head of the bed or treatment table raised to a 30- to 45-degree angle.	3. Makes it easier to insert needle into pericardial sac and aids for adequate aspiration of fluid.
4. Apply the limb leads of the ECG to the patient.	4. The patient is monitored during the procedure by ECG for arrhythmias, increased heart rate, and decreased heart rate.
5. Assist all other staff in applying personal protection and draping the patient ensuring exposure of surgical site.	5. Maintains aseptic and sterile technique and protects the provider/s.
6. Have defibrillator available for immediate use.	6. In the event that the patient needs to be shocked from an arrhythmia.
7. Have pacemaker available for immediate use.	7. In the event the patient becomes bradycardic.
8. Open the tray using aseptic technique.	8. Pericardiocentesis is a sterile procedure.



Nursing support of the patient undergoing pericardiocentesis. (*Yellow circles* indicate sites for pericardial aspiration.)

Nursing Action	Rationale
Performance phase (by physician, advance practice nurse, or health care provider)	
1. The site is prepared with skin antiseptic; the area is draped with sterile towels and injected with anesthetic.	1. Cleanses and disinfects the area for pericardial needle insertion.
2. The pericardial aspiration needle is attached to a 50-mL syringe by a three-way stopcock. Lead V (precordial leadwire) of the ECG is attached to the hub of the aspirating needle by a sterile wire and alligator clips or clamp.	2. Left ventricular lead can be monitored directly. There is danger of laceration of myocardium/coronary artery and of cardiac dysrhythmias.
3. The needle is advanced slowly until fluid is obtained.	3. Fluid is generally aspirated at a depth of 1–1½ inches (2.5–4 cm).
4. When the pericardial sac has been entered, a hemostat is clamped to the needle at the chest wall just where it penetrates the skin. Pericardial fluid is aspirated slowly.	4. Prevents movement of the needle and further penetration while fluid is being removed. Aspirated fluid may be cloudy, clear, or bloody.
5. Monitor the patient's ECG, blood pressure, and venous pressure constantly.	a. The ST segment rises if the point of the needle contacts the ventricle; there may be ventricular ectopic beats. b. The PR segment is elevated when the needle touches the atrium. c. Large, erratic QRS complexes indicate penetration of the myocardium.
6. If a large amount of fluid is present, a polyethylene catheter may be inserted through a needle (an Intracath) and left in the pericardial sac. The catheter may be connected to a drainage bag or capped.	6. An indwelling catheter left in the pericardial space permits further slow drainage of fluid and prevents recurrence of cardiac tamponade.
7. Watch for presence of bloody fluid. If blood accumulates rapidly, an immediate thoracotomy and cardiorrhaphy (suturing of heart muscle) may be indicated.	7. Bloody pericardial fluid may be due to trauma. Bloody pericardial effusion fluid does not readily clot, whereas blood obtained from inadvertent puncture of one of the heart chambers does clot.
Follow-up phase	
1. Monitor the patient closely. a. Watch for rising venous pressure and falling arterial pressure. b. Auscultate the area over the heart for pericardial friction rub and decreased intensity of heart sounds.	1. After pericardiocentesis, careful monitoring of blood pressure, venous pressure, and heart sounds will be necessary to indicate possible recurrence of tamponade; repeated aspiration is necessary.
2. Prepare for surgical drainage of pericardium if: a. Pericardial fluid repeatedly accumulates. b. Aspiration is unsuccessful. c. Complications develop (dysrhythmias, puncture of heart chamber, puncture of surrounding organ, laceration of coronary artery or myocardium, damage to left internal mammary artery).	2. In the presence of these signs, the patient is probably experiencing cardiac tamponade. c. Requires immediate intervention.

Hemodynamic Monitoring

Hemodynamic monitoring is the assessment of the patient's circulatory status; it includes measurements of heart rate (HR), precise measurements of intra-arterial pressure, CO, central venous pressure (CVP), PAP, pulmonary artery wedge pressure, mixed venous oxygenation data, and blood volume. It describes the intravascular pressure and flow of blood that occurs when the heart muscle contracts and pumps blood throughout the body.

The primary purpose is the early detection, identification, and treatment of life-threatening conditions, such as AMI, heart failure, cardiac tamponade, and all types of shock (septic, cardiogenic, neurogenic, anaphylactic). It is also useful in determining fluid and vasoactive therapy during the acute phase of patient's care, especially patients with multiorgan dysfunctions. It is also indicated for pre-, peri-, and postoperative surgery as well as for research studies.

Central Venous Pressure Monitoring

1. Refers to the measurement of right atrial pressure or the pressure of the great veins within the thorax (normal range: 5 to 10 cm H_2O or 2 to 8 mm Hg).
   a. Right-sided cardiac function is assessed through the evaluation of CVP.
   b. Left-sided heart function is less accurately reflected by the evaluation of CVP, but may be useful in assessing chronic right- and left-sided heart failure and differentiating right and left ventricular infarctions.
2. Requires the threading of a catheter into a large central vein (subclavian, internal, or external jugular, median basilic, or femoral). The catheter tip is then positioned in the right atrium, upper portion of the superior vena cava, or the inferior vena cava (femoral approach only). See Figure 12-4.
   a. To obtain venous access when peripheral vein sites are inadequate.
   b. To obtain central venous blood samples.
   c. To administer blood products, total parenteral nutrition, and some drug therapies contraindicated for peripheral infusion.
   d. To insert a temporary pacemaker.

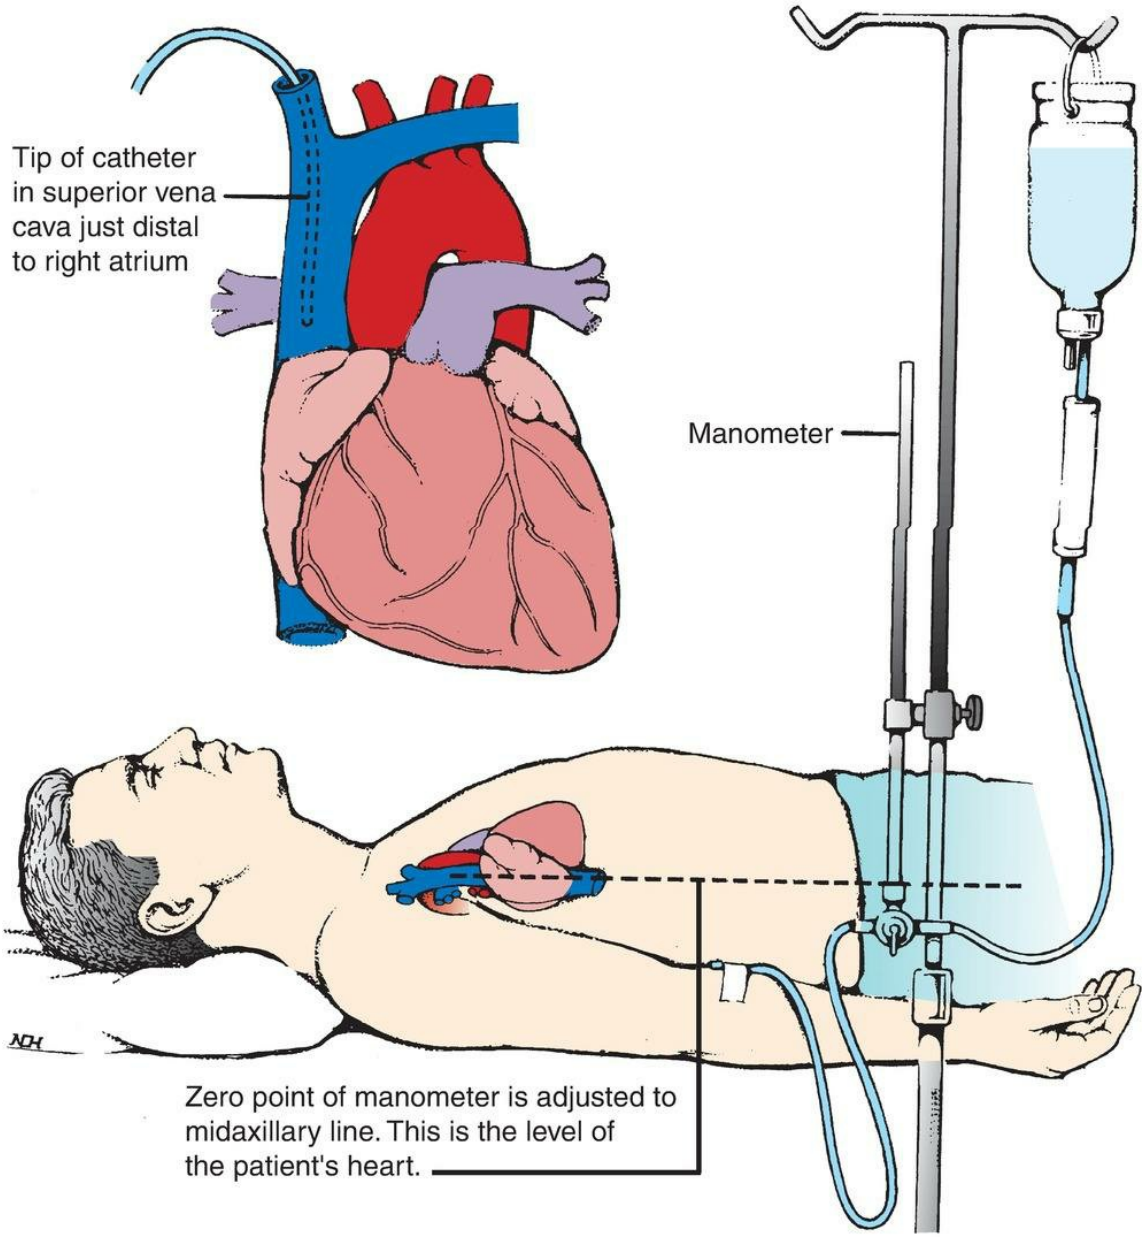


Figure 12-4. CVP monitoring.

Cardiac Output

Cardiac output (CO) is the amount (volume) of blood ejected by the left ventricle into the aorta in 1 minute. Normal CO is 4 to 8 L/minute.

Underlying Considerations

1. CO is determined by stroke volume (SV) and HR. Thus, CO = SV × HR. CO must be maintained to adequately oxygenate the body.
   a. HR = number of cardiac contractions per minute. The integrity of the conduction system and nervous system innervation of the heart influence functioning of this determinant.
   b. SV = amount of blood ejected from ventricle per beat (normal SV is 50 to 100 mL/beat). The amount of blood returning to the heart (preload), venous tone, resistance imposed on the ventricle

before ejection (afterload), and the integrity of the cardiac muscle (contractility) influence the functioning of this determinant.

2. The body alters CO through increases or decreases in one or both of these parameters. CO is maintained if the HR falls by an increase in SV. Likewise, a decrease in SV produces a compensatory rise in HR to keep the CO normal.
3. CO will decrease if either of the determinants cannot inversely compensate for the other.
4. CO measurements are adjusted to patient size by calculating the cardiac index (CI). CI equals CO divided by body surface area (BSA); BSA is determined through standard charts based on individual height and weight. Normal CI is 2.5 to 4 L/minute/m^2.

Assessment of Cardiac Output

Signs of low CO include:

1. Changes in mental status.
2. An increase in HR.
3. Shortness of breath.
4. Cyanosis or duskiness of buccal mucosa, nail beds, and earlobes.
5. Falling blood pressure.
6. Low urine output.
7. Cool, moist skin.
8. Decreased or no appetite.

Methods

1. CO is measured by various techniques. In the clinical setting, it is usually measured by the thermodilution technique in conjunction with a flow-directed balloon-tipped pulmonary artery catheter (commonly known as Swan-Ganz catheter after the inventors).
2. The Swan-Ganz catheter is positioned in its final position in a branch of the pulmonary artery; it has a thermistor (external sensing device) situated 1½ inches (4 cm) from the tip of the catheter, which measures the temperature of the blood that flows by it.

Pulmonary Artery Pressure Monitoring

Purposes

1. To monitor pressures in the right atrium (CVP), right ventricle, pulmonary artery, and distal branches of the pulmonary artery (known as *pulmonary artery occlusion pressure* or *pulmonary artery wedge pressure*). The latter reflects the level of the pressure in the left atrium (or filling pressure in the left ventricle); thus, pressures on the left side of the heart are inferred from pressure measurement obtained on the right side of the circulation. Provides estimation of diastolic filling of the left side of the heart.
2. To measure CO through thermodilution.
3. To obtain blood for central venous oxygen saturation.

4. To continuously monitor mixed venous oxygen saturation (SvO_2); available on special catheters.
5. To provide for temporary atrial/ventricular pacing and intra-atrial ECG (available only on special catheters).
6. To evaluate the hemodynamic response to fluid therapy, medications, and other treatments.

Underlying Considerations

1. Left atrial pressure is closely related to left ventricular end diastolic pressure (LVEDP—filling pressure of the left ventricle) and is therefore an indicator of left ventricular function. Because there are no valves in the pulmonary arterial system when the Swan-Ganz catheter is wedged, it reflects an uninterrupted flow of blood to the left atrium.
2. The pulmonary artery diastolic pressure (PADP) reflects the LVEDP in patients with normal lungs and mitral valve. The PADP can be continuously monitored as an approximation of LVEDP (limits excessive balloon inflation to obtain a PAOP and subsequent risk of balloon rupture or damage to the pulmonary artery).
3. SaO_2 is affected by four factors: CO, hemoglobin, arterial oxygen saturation (SaO_2), and tissue oxygen consumption.
4. Changes in SaO_2 alert the clinician to changes in these factors. More rapid detection of change facilitates interventions to correct problems before significant deterioration in patient's condition occurs.
5. If the amount of oxygen supplied to the tissues is inadequate to meet demands, more oxygen will be extracted from venous blood and SaO_2 will decrease. If oxygen supply exceeds demand, SaO_2 will increase.
6. Pulmonary artery (PA) catheters are associated with significant risk and disadvantages, including increased cost and mortality. Placement of a PA catheter is invasive and does not directly impact patient outcomes.

Methods

1. The Swan-Ganz catheter is a flow-directed (1.5 mL), balloon-tipped, 4- to 5-lumen catheter that is percutaneously inserted at the bedside and allows for continuous PAP monitoring as well as periodic measurement of PAOP and other parameters.
2. The catheter is 110 cm long, marked at increments of 10 cm, and is available in varying diameters. See Figure 12-5.
3. Most catheters in use incorporate thermodilution for determination of CO.
4. If monitoring of SvO_2 is desired, a PA catheter incorporating fiberoptics is used.
5. If temporary cardiac pacing capability is desired, a catheter with a lumen for a pacing wire may be used.
6. Catheter may be inserted under fluoroscopy or at the bedside using the hemodynamic waveform as a guide to correct position.

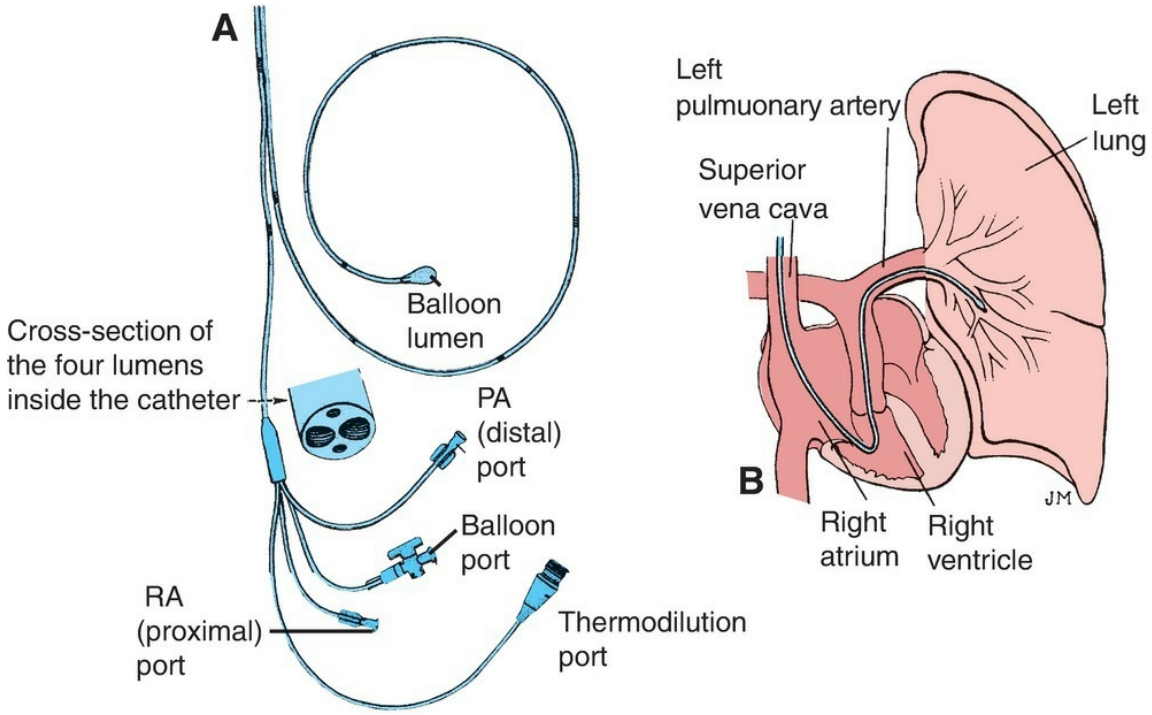

Figure 12-5. Swan-Ganz catheter showing **(A)** multiple lumens and **(B)** location within the heart.

Newer Technology for Hemodynamic Monitoring

Complications associated with insertion of invasive pulmonary artery catheters have led to the development of newer noninvasive or minimally invasive methods of hemodynamic monitoring.

1. Indirect Fick method—modification of the original Fick principle first developed in 1870.
2. Thoracic electrical bioimpedance (TEB)—noninvasive measurement of the electrical resistance of the thorax to a high-frequency, very-low-magnitude current. As thoracic fluid in the chest increases, TEB decreases; changes in CO correspond to changes in aortic blood flow.
3. Pulse contour devices—measure CO by assessing the contours of arterial pressure waveforms in relationship to the patient's stroke volume.
4. Continuous SvO_2 monitoring—measures mixed venous oxygen by means of a modified PA catheter to assess oxygen-carrying hemoglobin (oxyhemoglobin) and non–oxygen-carrying hemoglobin (deoxyhemoglobin).
5. Continuous CO monitoring—utilizes a modified PA catheter.
6. Right ventricular ejection fraction measurement—assesses the amount of blood forced from the ventricle during systole; it is an indication of the strength or contractility of the heart as determined by a special type of arterial catheter.
7. Esophageal Doppler CO monitoring—utilizes sound waves to measure aortic blood flow and thereby determine SV.
8. Exhaled CO_2 monitoring—completely noninvasive technique based on the Fick equation that measures CO.
9. Lithium dilution CO is another thermodilution method that assesses CO through injection of lithium

chloride into a central or peripheral venous catheter and measurement of the concentration of lithium chloride over time using lithium-sensitive electrodes.

10. Cardiac MRI measures cardiac output by looking at blood flow generated by the picture from the magnetic current. It calculates the stroke volume, which is multiplied by heart rate.
11. Bioimpedance CO determination measures changes in the body's resistance to small electrical current. Blood volume in the chest changes during every ejection, which can be detected using eight electrical patches positioned on the neck and thorax. Based on these changes in impedance, a computer can calculate the cardiac output.
12. Ultrasound indicator dilution (mostly used in pediatrics) works off *in situ* catheters and uses an unobjectionable indicator to allow for routine measurements of cardiac output and blood volumes.

Cardiac Pacing

EVIDENCE BASE Wiegand, D. L. (Ed.). (2017). *AACN procedure manual for critical care* (7th ed.). St. Louis, MO: Saunders.

A *cardiac pacemaker* is an electronic device that delivers direct electrical stimulation to stimulate the myocardium to depolarize, initiating a mechanical contraction. The pacemaker initiates and maintains the heart rate when the heart's natural pacemaker is unable to do so. Pacemakers can be used to correct bradycardias, tachycardias, sick sinus syndrome, and second- and third-degree heart blocks and for prophylaxis. Pacing may be accomplished through a permanent implantable system, a temporary system with an external pulse generator and percutaneously threaded leads, or a transcutaneous external system with electrode pads placed over the chest. A recent development is the leadless pacemaker.

Clinical Indications

1. Symptomatic bradydysrhythmias.
2. Symptomatic sinus bradycardia that results from required drug therapy.
3. Symptomatic heart block.
   a. Mobitz II second-degree heart block.
   b. Complete heart block.
   c. Bifascicular and trifascicular bundle-branch blocks.
4. Hypersensitive carotid sinus syndrome and neurocardiogenic syncope.
5. Prophylaxis.
   a. After acute MI: dysrhythmia and conduction defects.
   b. Before or after cardiac surgery.
   c. During cardiac resynchronization therapy in patients with severe systolic heart failure.
   d. During diagnostic and therapeutic procedures such as cardiac catheterization, EPS, percutaneous transluminal coronary angioplasty (PTCA), stress testing, before permanent pacing, and during transcatheter aortic valve replacement (TAVR).
6. Tachydysrhythmias (supraventricular tachycardia, ventricular tachycardia); to override rapid rhythm disturbances.

Types of Pacing

Permanent Pacemakers

There are two types of permanent pacers; the standard pacer that paces one side of the heart causing uncoordinated contraction of the left and right ventricle or biventricular that coordinates the contraction of the left and right ventricle

Standard Pacemakers

1. Used to treat chronic heart conditions; surgically placed utilizing a local anesthetic, the leads are placed transvenously in the appropriate chamber of the heart and then anchored to the endocardium.
2. The pulse generator is placed in a surgically made pocket in subcutaneous tissue under the clavicle or in the abdomen. Choices for types of generators include single- or dual-chamber devices, biventricular devices, unipolar or bipolar pacing/sensing configuration, and various types of sensors for rate response.
3. Once placed, it can be programmed externally as needed.
4. Implantable cardioverter–defibrillators can also have standard pacing functionality.

Biventricular Pacemakers

1. Biventricular pacemakers are also referred to as cardiac resynchronization therapy.
2. Biventricular pacing is used to treat moderate to severe heart failure as a result of left ventricular dyssynchrony.
3. Intraventricular conduction defects result in an uncoordinated contraction of the left and right ventricle, which causes a wide QRS complex and is associated with worsening heart failure and increased mortality.
4. Biventricular pacemakers utilize three leads (one in the right atrium, one in the right ventricle, and one in the left ventricle via the coronary sinus) to coordinate ventricular contraction and improve CO.
5. Biventricular pacemakers can incorporate implantable cardioverter–defibrillators or be used alone.

Leadless Pacemakers

1. Self contained, single chamber, implanted directly through femoral vein into right ventricle.
2. Fixated into the myocardium by a screw helix or nitinol tines.
3. Developed to eliminate complications of pocket or lead related problems.
4. 10 year estimated battery life; retrievable if necessary.

Temporary Pacemakers

1. Temporary pacemakers are usually placed during an emergency, such as when a patient demonstrates signs of decreased CO.
2. Indicated for patients with high-grade AV blocks, bradycardia, or low CO. They serve as a bridge until the patient becomes stable enough for placement of a permanent pacemaker.
3. Can be placed transvenously, epicardially, transcutaneously, and transthoracically.
    a. Transvenous pacemakers are inserted transvenously (into a vein, usually the subclavian, internal jugular, antecubital, or femoral) into the right ventricle (or right atrium and right ventricle for dual-chamber pacing) and then attached to an external pulse generator. This procedure may be done at the bedside or under fluoroscopy.
    b. Epicardial pacemaker wires are attached to the endocardium, brought out through a surgical incision in the thorax. These wires are then connected to an external pulse generator. This is commonly seen after cardiac surgery.

With transcutaneous pacing, noninvasive multifunction electrode pads are placed either anterior-

c. posteriorly (anterior chest wall under the left nipple, slightly midaxillary, and on the patient's back directly behind anterior pad) or anterior-laterally (anterior chest wall under the left nipple, slightly midaxillary, and on patient's upper right chest wall below the clavicle). The multifunction electrode pads are connected to an external energy source (defibrillator with pacing capability). The electrical impulses flow through the multifunction electrode pads and subcutaneous skin to the heart, thereby pacing the heart. Note: transcutaneous pacing should not be utilized continuously for more than 2 hours. Transvenous pacing should then be initiated.

d. The transthoracic pacemaker is a type of temporary pacemaker that is placed only in an emergency via a long needle, using a subxiphoid approach. The pacer wire is then placed directly into the right ventricle.

4. Monitor for evidence of lead migration and perforation of the heart.
   a. Observe for muscle twitching and/or cough (may indicate chest wall or diaphragmatic pacing).
   b. Evaluate patient's complaints of chest pain (may indicate perforation of pericardial sac).
   c. Auscultate for pericardial friction rub.
   d. Observe for signs and symptoms of cardiac tamponade: distant heart sounds, distended jugular veins, pulsus paradoxus, and hypotension.
5. Provide an electrically safe environment for patient. Stray electrical current can enter the heart through temporary pacemaker lead system and induce dysrhythmias.
   a. Protect exposed parts of the electrode lead terminal in temporary pacing systems per manufacturer's recommendations.
   b. Wear rubber gloves when touching temporary pacing leads. Static electricity from your hands can enter the patient's body through the lead system.
   c. Make sure all equipment is grounded with three-prong plugs inserted into a proper outlet when using an external pacing system.
   d. Epicardial pacing wires should have the terminal needle protected by a plastic tube; place tube in rubber glove to protect it from fluids or electrical current when disconnected from generator.

NURSING ALERT Transport patient to other parts of facility with portable ECG monitoring and nurse. Patients with temporary pacemakers should never be placed in unmonitored areas.

---

6. Use sedation, if BP is stable, when transcutaneous pacing a patient. The mA used to overcome the impedance to reach the heart through the skin is high and can be quite painful to the patient.
7. Monitor for infection by checking temperature every 4 hours; report elevations and assess central IV site (where temporary pacing wire is inserted) for signs and symptoms of infection, such as redness and drainage.

8. Prevent accidental pacemaker malfunctions.
    a. Use clear plastic covering over external temporary generators at all times (eliminates potential manipulation of programmed settings).
    b. Secure temporary pacemaker generator to patient's chest or waist; never hang it on an IV pole.
    c. Transfer of patient from bed to stretcher should only be attempted with an adequate number of personnel so that patient can remain passive; caution personnel to avoid underarm lifts.
    d. Evaluate transcutaneous pacing electrode pads every 2 hours for secure contact to chest wall; change electrode pads every 24 hours or if pads do not have complete contact with the skin.

Pacemaker Design

Pulse Generator

Contains the circuitry and batteries to generate the electrical signal.

1. The pulse generator in a permanent pacemaker is encapsulated in a metal box that is embedded under the skin. The box protects the generator from electromagnetic interferences and trauma.
2. In the leadless pacemaker the pulse generator is self contained in the device implanted in the right ventricle.
3. A temporary pacing generator is an external system that either utilized the defibrillator with pacing capability or contained in a small box with dials for programming. It is an external system.
    a. Transcutaneous pacing systems utilize an external energy source such as a defibrillator with pacing ability. Dials for programming the unit are on the device.
    b. Electromechanical interference is more likely to occur with temporary systems.
    c. Temporary pacing systems use batteries, which need replacement based on use of device. The transcutaneous system has rechargeable battery circuitry but should be plugged into an electrical outlet most of the time to ensure adequate battery life for transport.
4. Permanent pacing systems use reliable power sources such as lithium batteries. Lithium batteries have a projected life span of 8 to 12 years.

Pacemaker Lead

Transmits the electrical signal from the pulse generator to the heart. One, two, or three leads may be placed in the heart.

1. "Single-chamber" pacemaker.
    a. "Single-chamber" pacemakers have one lead in either the atrial or ventricular chamber.
    b. The sensing and pacing capabilities of the pacemaker are confined to the chamber where the lead is placed.
2. "Dual-chamber" pacemaker.
    a. A "dual-chamber" pacemaker has two leads.
    b. One lead is in the right atrium and the other lead is located in the right ventricle.

Pacing and sensing can occur in both heart chambers, closely "mimicking" normal heart function

c. (physiologic pacing).

3. Biventricular pacemaker.
   a. One lead is in the right atrium, one is in the right ventricle, and one is in the left ventricle via the coronary sinus.
   b. In single right ventricle (traditional) pacing, there is slight delay of the left ventricle contracting as the electrical impulse begins in the right ventricle and moves to the left ventricle, giving the characteristic left bundle-branch block appearance. By pacing both right and left ventricle at the same time, the pacemaker can resynchronize a heart whose opposing walls do not contract in synchrony.
4. Pacemaker leads may be threaded through a vein into the right atrium and/or right ventricle (endocardial/transvenous approach) or introduced by direct penetration of the chest wall and attached to the left ventricle or right atrium (see Figure 12-6).
5. Fixation devices located at the end of the pacemaker lead allow for secure attachment of the lead to the heart, reducing the possibility of lead dislodgement.
6. Temporary leads protrude from the incision and are connected to the external pulse generator. Permanent leads are connected to the pulse generator implanted underneath the skin.

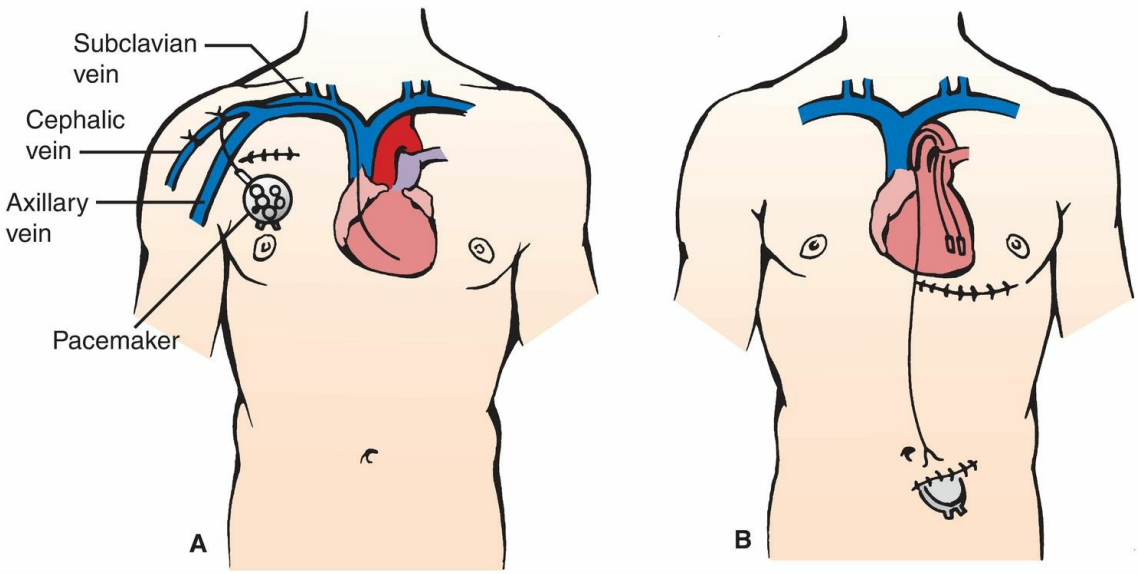

Figure 12-6. Permanent pacemaker insertion with **(A)** unipolar lead (threaded through central vein into the right ventricle) and **(B)** bipolar leads (passed through the chest wall and sutured to external surface of the left ventricle).

Pacemaker Function

Cardiac pacing refers to the ability of the pacemaker to stimulate the atrium, the ventricle, or both heart chambers in sequence and initiate electrical depolarization and cardiac contraction. Cardiac pacing is evidenced on the ECG by the presence of a "spike" or "pacing artifact."

Pacing Functions

1. Atrial pacing—direct stimulation of the right atrium producing a "spike" on the ECG preceding a P wave.
2. Ventricular pacing—direct stimulation of the right or left ventricle producing a "spike" on the ECG preceding a QRS complex causing a widen QRS complex (bundle-branch block appearance).
3. AV pacing—direct stimulation of the right atrium and either ventricle in sequence; mimics normal cardiac conduction, allowing the atria to contract before the ventricles. ("Atrial kick" received by the ventricles allows for an increase in CO.)

Sensing Functions

Cardiac pacemakers have the ability to "see" intrinsic cardiac activity when it occurs (sensing).

1. Demand—ability to "sense" intrinsic cardiac activity and deliver a pacing stimulus only if the heart rate falls below a preset rate limit.
2. Fixed—no ability to "sense" intrinsic cardiac activity; the pacemaker can't "synchronize" with the heart's natural activity and consistently delivers a pacing stimulus at a preset rate.
3. Triggered—ability to deliver pacing stimuli in response to "sensing" a cardiac event.
   a. "Sees" atrial activity (P waves) and delivers a pacing spike to the ventricle after an appropriate delay (usually 0.16 second, similar to PR interval).
   b. Maintains AV synchrony and increases heart rate based on increases in the body demands that occur with exercise or during stress.
   c. "Physiologic" sensors are being developed as alternatives to "trigger" a ventricular response because many patients have atrial dysfunction.
   d. "Sensor-driven" rate-responsive pacemakers do not sense atrial activity; a triggered ventricular beat occurs when the pacemaker senses either increases in muscle activity, temperature, and oxygen utilization or changes in blood pH.

Capture Functions

1. The pacemaker's ability to generate a response from the heart (contraction) after electrical stimulation is referred to as capture. Capture is determined by the strength of the electrical stimulus, measured in milliamperes (mA), the amount of time the stimulus is applied to the heart (pulse width), and by contact of the distal tip of the pacing lead to healthy myocardial tissue.
   a. "Electrical" capture is indicated by a pacer spike followed by a corresponding P wave or QRS complex.
   b. "Mechanical" capture of the ventricles is determined by a palpable pulse corresponding to the electrical event.

Pacemaker Codes

The Intersociety Commission for Heart Disease (ICHD) has established a five-letter code to describe the normal functioning of today's sophisticated pacemakers. Each letter indicates the particular characteristic of

the pacer (see Table 12-2).

Table 12-2 Five-Letter Code for Pacemakers

LETTER OR POSITION	CHARACTERISTIC	CODE KEY
I	Chamber paced (Where is the pacing taking place?)	V = Ventricle A = Atrium D = Dual (Both atrium and ventricle) O = None
II	Chamber sensed (Which chamber is being sensed?)	V = Ventricle A = Atrium D = Dual (Both atrium and ventricle) O = None
III	Mode of response (Response to the sensed events)	T = Triggers pacing I = Inhibits firing in response to a sensed intrinsic event D = Dual (triggers and inhibits at the same time) O = None; asynchronous pacemaker
IV	Programmability (Program functions)	P = Single programmability M = Multiple programmability C = Communication function (telemetry) O = Absence of rate modulation or programmability
V	Antitachyarrhythmia function	P = Overdrive pacing S = Shock intervention for cardioversion or defibrillation D = Dual (Pacing and shocking capabilities) O = Absence of pacing and shocking capabilities

Nursing Process for Permanent Pacemaker Implantation

Nursing Assessment and Preprocedure Care

1. Assess patient's knowledge level of procedure.
2. Instruct patient that he or she may have nothing by mouth before the procedure.
3. Facilitate IV line insertion.
4. Explain to patient that pacemaker insertion will be performed in an operating or special procedures room with fluoroscopically and continuous ECG monitoring.
5. Describe local anesthetic that will be used to minimize discomfort; sedation.
6. Explain to patient that the usual placement for a permanent pacemaker is in the left upper chest.
7. If the patient had a recent infection, ensure that blood cultures are taken and are negative according to hospital policy, before any implantable device procedure so that implant or leads do not become infected.
8. Advise the patient that the incision will be closed with Steri-Strips (suture or staples may also be used).

Nursing Diagnoses

- Decreased Cardiac Output related to potential pacemaker malfunction and dysrhythmias.
- Risk for Injury related to pneumothorax, hemothorax, bleeding, microshock, and accidental malfunction.
- Risk for Infection related to surgical implantation of pacemaker generator and/or leads.
- Anxiety related to pacemaker insertion, fear of death, lack of knowledge, and role change.
- Impaired Physical Mobility related to imposed restrictions of arm movement.
- Acute Pain related to surgical incision and transcutaneous external pacing stimuli.
- Disturbed Body Image related to pacemaker implantation.

Nursing Interventions

Maintaining Adequate Cardiac Output

1. Record the following information after insertion of the pacemaker:
    a. Pacemaker manufacturer, model, and lead type.
    b. Operating mode (based on ICHD code).
    c. Programmed settings: lower rate limit, upper rate limit, AV delay, and pacing thresholds.
    d. Patient's underlying rhythm.
    e. Patient's response to procedure.
2. Attach ECG electrodes for continuous monitoring of heart rate and rhythm.
    a. Set alarm limits 5 beats below lower rate limit and 5 to 10 beats above upper rate limits (ensures immediate detection of pacemaker malfunction or failure).
    b. Keep alarms on at all times.
3. Analyze rhythm strips per facility protocol and as necessary.

a. Identify presence or absence of pacing artifact.
b. Differentiate paced P waves and paced QRS complexes from spontaneous beats.
c. Measure AV delay (if pacemaker has dual chamber functions).
d. Determine the paced rate.
e. Analyze the paced rhythm for presence and consistency of capture (every pacing spike is followed by atrial and/or ventricular depolarization).
f. Analyze the rhythm for presence and consistency of proper sensing. (After a spontaneous beat, the pacemaker should not fire unless the interval between the spontaneous beat and the paced beat equals the lower pacing rate and/or the paced beat follows the programmed AV delay.)

4. Monitor vital signs as per facility protocol and as necessary.
5. Monitor urine output and level of consciousness—ensures adequate cardiac output achieved with paced rhythm.
6. Observe for dysrhythmias (ventricular ectopic activity can occur because of irritation of ventricular wall by lead wire).
   a. Monitor for competitive rhythms, such as runs of atrial fibrillation or flutter, accelerated junctional, or idioventricular or ventricular tachycardia.
   b. Report dysrhythmias.
   c. Administer antidysrhythmic therapy, as directed.
7. Obtain 12-lead ECG, as ordered.

Avoiding Injury

1. Note that a postpacemaker insertion chest x-ray has been taken to ensure correct lead wire position and that no fluid is in lungs.
2. Monitor for signs and symptoms of hemothorax—inadvertent punctures of the subclavian vein or artery, which can cause fatal hemorrhage; observe for diaphoresis, hypotension, shortness of breath, chest deviation, and restlessness; immediate surgical intervention may be necessary.
3. Monitor for signs and symptoms of pneumothorax—inadvertent puncture of the lung; observe for acute onset of dyspnea, cyanosis, chest pain, absent breath sounds over involved lung, acute anxiety, and hypotension. Prepare for chest tube insertion.
4. Evaluate continually for evidence of bleeding/hematoma.
   a. Check incision site frequently for bleeding/hematoma.
   b. Apply manual pressure carefully without pushing against pacemaker generator box.
   c. Palpate for pulses distal to insertion site. (Swelling of tissues from bleeding may impede arterial flow.)
5. Be aware of hazards in the facility that can interfere with pacemaker function or cause pacemaker failure and permanent pacemaker damage.
   a. Avoid use of electric razors.

Avoid direct placement of defibrillator paddles over pacemaker generator; anterior placement of
   b. paddles should be 4 to 5 inches (10 to 12.5 cm) away from pacemaker; always evaluate pacemaker function after defibrillation.
   c. Electrocautery devices and transcutaneous electrical nerve stimulator (TENS) units pose a risk.
   d. Recent studies have shown that patients may safely have an MRI with a permanent pacemaker. Check with the cardiologist.
   e. Caution must be used if patient will receive radiation therapy; the pacemaker should be repositioned if the unit lies directly in the radiation field.
6. Monitor for electrolyte imbalances, hypoxia, and myocardial ischemia. (The amount of energy the pacemaker needs to stimulate depolarization may need adjustment if any of these are present.)

Preventing Infection

1. Take temperature every 4 hours; report elevations. (Suspect permanent pacemaker as infection source if temperature elevation occurs.)
2. Observe incision site for signs and symptoms of local infection: redness, purulent drainage, warmth, and soreness.
3. Be alert to manifestations of bacteremia. (Patients with endocardial leads are at risk for endocarditis; see page 287.)
4. Clean incision site, as directed, using sterile technique.
5. Instruct patient to keep incision site dry, which means no showers for 24 hours.
6. Evaluate patient's complaints of increasing tenderness and discomfort at incision site.
7. Administer antibiotic therapy, as prescribed, after permanent pacemaker insertion.

Relieving Anxiety

1. Offer careful explanations regarding anticipated procedures and treatments, and answer the patient's questions with concise explanations.
2. Encourage patient and family to use coping mechanisms to overcome anxieties—talking, crying, and walking.
3. Encourage patient to accept responsibility for care.
   a. Review care plan with patient and family.
   b. Encourage patient to make decisions regarding a daily schedule of self-care activities.
   c. Engage patient in goal setting. Establish with patient priorities of care and time frames to accomplish goals up until discharge.
4. Monitor for unwarranted fears expressed by patient and family (commonly, pacemaker failure) and provide explanations to alleviate fear. Explain to patient life expectancy of batteries and the measures taken to check for failure (see "Patient Education").

Minimizing the Effects of Immobility

1. Encourage patient to take deep breaths frequently each hour (promotes pulmonary function); however,

caution against vigorous coughing because this could cause lead dislodgement.

2. Instruct patient in dorsiflexion exercises of ankles and tightening of calf muscles. This promotes venous return and prevents venous stasis. Exercises should be done hourly.
3. Restrict movement of affected extremity (no restriction for leadless pacemaker).
   a. Place arm nearest to permanent pacemaker implant in sling as directed. Sling use can range from 6 to 24 hours, according to prescribed order.
   b. Instruct patient to gradually resume range of motion (ROM) of extremity as directed (usually 24 hours for permanent implants); avoid over-the-head motions for approximately 5 days and limit the weight of carried items to less than 3 pounds.
   c. Evaluate patient's arm movements to ensure normal ROM progression; assist patient with passive ROM of extremity as necessary (prevents development of shoulder stiffness caused by prolonged joint immobility); consult physical therapy as directed if stiffness and pain occur.
4. Assist patient with activities of daily living (ADLs) as appropriate.

Relieving Pain

1. Prepare patient for the discomfort he or she may experience after pacemaker implant.
   a. Explain to patient that incisional pain will occur after procedure; pain will subside after the first week, but he or she may have some soreness for up to 4 weeks.
2. Administer analgesics as directed; attempt to coincide peak analgesic effect with performance of ROM exercises and ADLs.
3. Offer back rubs to promote relaxation.
4. Provide patient with diversional activities.
5. Evaluate effectiveness of pain-relieving modalities.
6. Explain to the patient about the potential for discomfort during transcutaneous pacing; however, assure patient that the lowest energy possible will be used and analgesics/anxiolytics will be given.

Maintaining a Positive Body Image

1. Encourage patient and family to express concerns regarding self-image and pacemaker implant.
2. Reassure patient and significant other that sexual activity and modes of dressing will not be altered by pacemaker implantation.
3. Offer pacemaker support group information to the patient.
4. Encourage spouse or significant other to discuss concerns of self-image with patient.

Patient Education and Health Maintenance

Anatomy and Physiology of the Heart

Use diagrams to identify heart structure, conduction system, area where pacemaker is inserted, and why the pacemaker is needed.

Pacemaker Function

1. Give patient the manufacturer's instructions (for particular pacemaker) and help familiarize patient with pacemaker.
2. If available, give patient a pacemaker to hold and identify unique features of patient's pacemaker, or show patient picture of pacemaker.
3. Explain to patient the purpose and function of the component parts of the pacemaker: generator and lead system.

Activity

1. Reassure patient that normal activities will be able to be resumed.
2. Explain to patient that it takes about 2 months to develop full ROM of arm (fibrosis occurs around the lead and stabilizes it in the heart).
3. Specific instructions include the following:
   a. Instruct patient not to lift items over 3 pounds (1.4 kg) or perform difficult arm maneuvers.
   b. Tell patient to avoid activities that involve rough contact around pacemaker site.
   c. Caution patient not to fire a rifle with it resting over pacemaker implant.
   d. Sexual activity may be resumed when desired.
   e. Instruct patient not to rub or massage around pacemaker site.
4. Instruct patient to gauge activities according to sensations of moderate pain in the arm or site of implant and stretching sensation in and around implant site.

Pacemaker Failure

1. Teach patient to check own pulse rate daily for 1 full minute and to keep a chart for physician visit. This pulse check should be done at rest. (Patients may check pulse daily to ensure all is well and promote a sense of control.)
2. Teach patient to:
   a. Immediately report slowing of pulse lower than set rate, or greater than 100.
   b. Report signs and symptoms of dizziness, fainting, palpitation, prolonged hiccups, and chest pain to health care provider immediately. These signs are indicative of pacemaker failure.
   c. Take pulse while these feelings are being experienced.
3. Encourage patient to wear identification bracelet and carry pacemaker identification card that lists pacemaker type, rate, health care provider's name, and facility where the pacemaker was inserted; encourage significant other to also keep a card with patient's pacemaker information.

Electromagnetic Interference

1. Advise patient that improvements in pacemaker design have reduced problems of electromechanical interference (EMI).
2. Caution patient that EMI could interfere with pacemaker function.
   a. Inappropriate inhibition or triggering of pacemaker stimuli causing light-headedness, syncope, or

death.

   b. Atrial oversensing may cause inappropriate pacemaker acceleration and can cause palpitations, hypotension, or angina in patients.
   c. Rapid pacing can also result in ventricular fibrillation.
   d. Reversion to a synchronous pacing mode. A common response to transient reversion is asynchrony pacing, which can cause irregular heartbeats and/or a decrease in CO, and that may stimulate ventricular tachyarrhythmias.
   e. Reprogramming of the pacemaker or permanent damage to the pacemaker's circuitry or the electrode–tissue interface is less frequent in occurrence.
   f. Teach patient to move 4 to 6 feet away from source and to check pulse if dizziness or palpitations occur. Pulse should return to normal after moving away from interference.
3. Explain that high-energy radiation, linear power amplifiers, antennas, industrial arc welders, electrocautery equipment, TENS, unshielded motors (cars, boats), MRI equipment found in facilities, and junkyards may affect pacemaker function.
4. Tell patient that metal detectors or handheld wands may affect pacemaker function and that pacemakers will set off the alarm at metal detector gates. Therefore, patient should show pacemaker identification card and request a hand search.
5. Antitheft devices may interfere with pacemaker function if the patient remains stationary for an extended period of time near the device. Walking by the device should not interfere with pacemaker function.
6. Tell patient that household and kitchen appliances will not affect pacemaker function. Microwave ovens are no longer a threat to pacemaker operation (however, old warning signs may still be near microwave ovens). Cell phones are safe as long as they are 6 inches away from pacemaker site. Encourage patient to use the ear on the opposite side of the pacemaker site.

Care of Pacemaker Site

1. Advise patient to wear loose-fitting clothing around the area of pacemaker implantation until it has healed.
2. Watch for signs and symptoms of infection around generator and leads—fever, heat, pain, and skin breakdown at implant site.
3. Advise patient to keep incision clean and dry. Encourage tub baths rather than showers for the first 10 days after pacemaker implantation.
   a. Instruct patient not to scrub incision site or clean site with bath water.
   b. Teach patient to clean incision site with antiseptic, as directed.
4. Explain to patient that healing will take approximately 3 months.
   a. Instruct patient to maintain a well-balanced diet to promote healing.
5. Inform patient that there is no increased risk of endocarditis with dental cleaning or procedures, so antibiotic prophylaxis is not necessary.

GERONTOLOGIC ALERT Older patients may experience delayed wound healing because of poor nutritional status. Evaluate nutritional intake carefully and offer a balanced diet including vitamin C to ensure proper healing.

Follow-Up

1. Make sure that the patient has a copy of ECG tracing (according to facility policy) for future comparisons. Encourage patient to have regular pacemaker checkups for monitoring function and integrity of pacemaker.
2. Inform patient that transtelephonic evaluation of implanted cardiac pacemakers for battery and electrode failure is available.
3. Review medications with patient before discharge.
4. Inform patient that the pulse generator will have to be surgically removed to replace battery and that it is a relatively simple procedure performed under local anesthesia.

Evaluation: Expected Outcomes

- Vital signs stable; pacing spikes rated on ECG tracing.
- Breath sounds noted throughout; respirations unlabored.
- Incision without drainage.
- Asks questions and participates in care.
- Affected arm and pacer site show decreased edema.
- Reports pain relief.
- Verbalizes acceptance of pacemaker.

Defibrillation and Cardioversion

Defibrillation is the use of electrical energy, delivered over a brief period, to temporarily depolarize the heart, so that when it repolarizes, it has a better chance of resuming normal electrical activity. It is used to treat ventricular fibrillation and ventricular tachycardia without a pulse, with the goal of converting to normal sinus rhythm.

Synchronized cardioversion is the use of electrical energy that is synchronized to the QRS complex so as not to hit the T wave during the cardiac cycle, which may cause ventricular fibrillation. It is used to treat atrial fibrillation, atrial flutter, supraventricular tachycardia, and ventricular tachycardia with a pulse.

Concepts

1. Types of defibrillators:
    a. Direct current defibrillators contain a transformer, an alternating-current–direct current converter, a capacitor to store direct current, a charge switch, and a discharge switch to the electrodes to complete the circuit.
    b. Portable defibrillators have a battery as a power source and must be plugged in at all times when not in use.
    c. Automatic external defibrillator (AED) may be used inside the facility or in the community to deliver electric shock to the heart before trained personnel arrive with a manual defibrillator. AEDs are accurate to be used by less trained individuals because the device has a detection system that analyzes the person's rhythm, detects the presence of ventricular fibrillation or tachycardia, and instructs the operator to discharge a shock.
2. Steps in defibrillation:
    a. Immediately implement CPR until the defibrillator is available.
    b. Expose the patient's bare chest and apply defibrillator paddles or pads according to manufacturer's instructions. See Figure 12-7.
    c. Turn the defibrillator to recommended setting, usually 200 joules, and charge paddles.
    d. Once the defibrillator is charged, give the "all-clear" warning, and ensure that no one is touching the patient. Shock the patient by doing the following:
        i. Paddles: Push the discharge buttons (shock) on the paddles while exerting 25 pounds of pressure on the patient's chest.
        ii. Pads: Push the discharge buttons (shock) on the defibrillator device.
    e. Continue CPR for 2 minutes and repeat defibrillation process unless return of spontaneous circulation (ROSC) has occurred.
    f. Once ROSC is restored, continue supportive care of the patient.
3. Steps in cardioversion:
    a. Ensure that laboratory results are available, serum potassium level is normal, digoxin has not been given, and oxygen is available. The procedure is usually elective; therefore, fasting may be ordered.

b. Have emergency equipment available in the room, such as oxygen and suction.
c. Apply paddles or multifunctional pads according to manufacturer's instructions; for cardioversion, pads are preferred.
d. Turn defibrillator to synchronize setting and charge to the ordered level. Ensure that the synchronized marking is visible.
e. Once the machine is charged, give the "all-clear" warning and ensure that no one is touching the patient. Shock the patient by doing the following:
    i. Paddles: Push the discharge buttons (shock) on the paddles while exerting 25 pounds of pressure on the patient's chest.
    ii. Pads: Push the discharge buttons (shock) on the defibrillator device.
f. Be aware that when the shock button is pressed, there may be a delay while synchronizing with the R wave until the shock is delivered.

Figure 12-7. Paddle placement for ventricular fibrillation.

NURSING ALERT Synchronized cardioversion is generally contraindicated when a patient has been taking a significant amount of digoxin because more lethal dysrhythmias may occur after electric discharge.

Implantable Cardioverter–Defibrillator

The *implantable cardioverter–defibrillator (ICD)* is a device that delivers electric shocks directly to the heart muscle (defibrillation) to terminate lethal dysrhythmias: ventricular fibrillation and ventricular tachycardia. The ICD is surgically placed by one of four approaches: lateral thoracotomy, median sternotomy (in conjunction with cardiac surgery), subxiphoid, or subintercostal. All ICDs have a pacing function, if needed. See Figure 12-8.

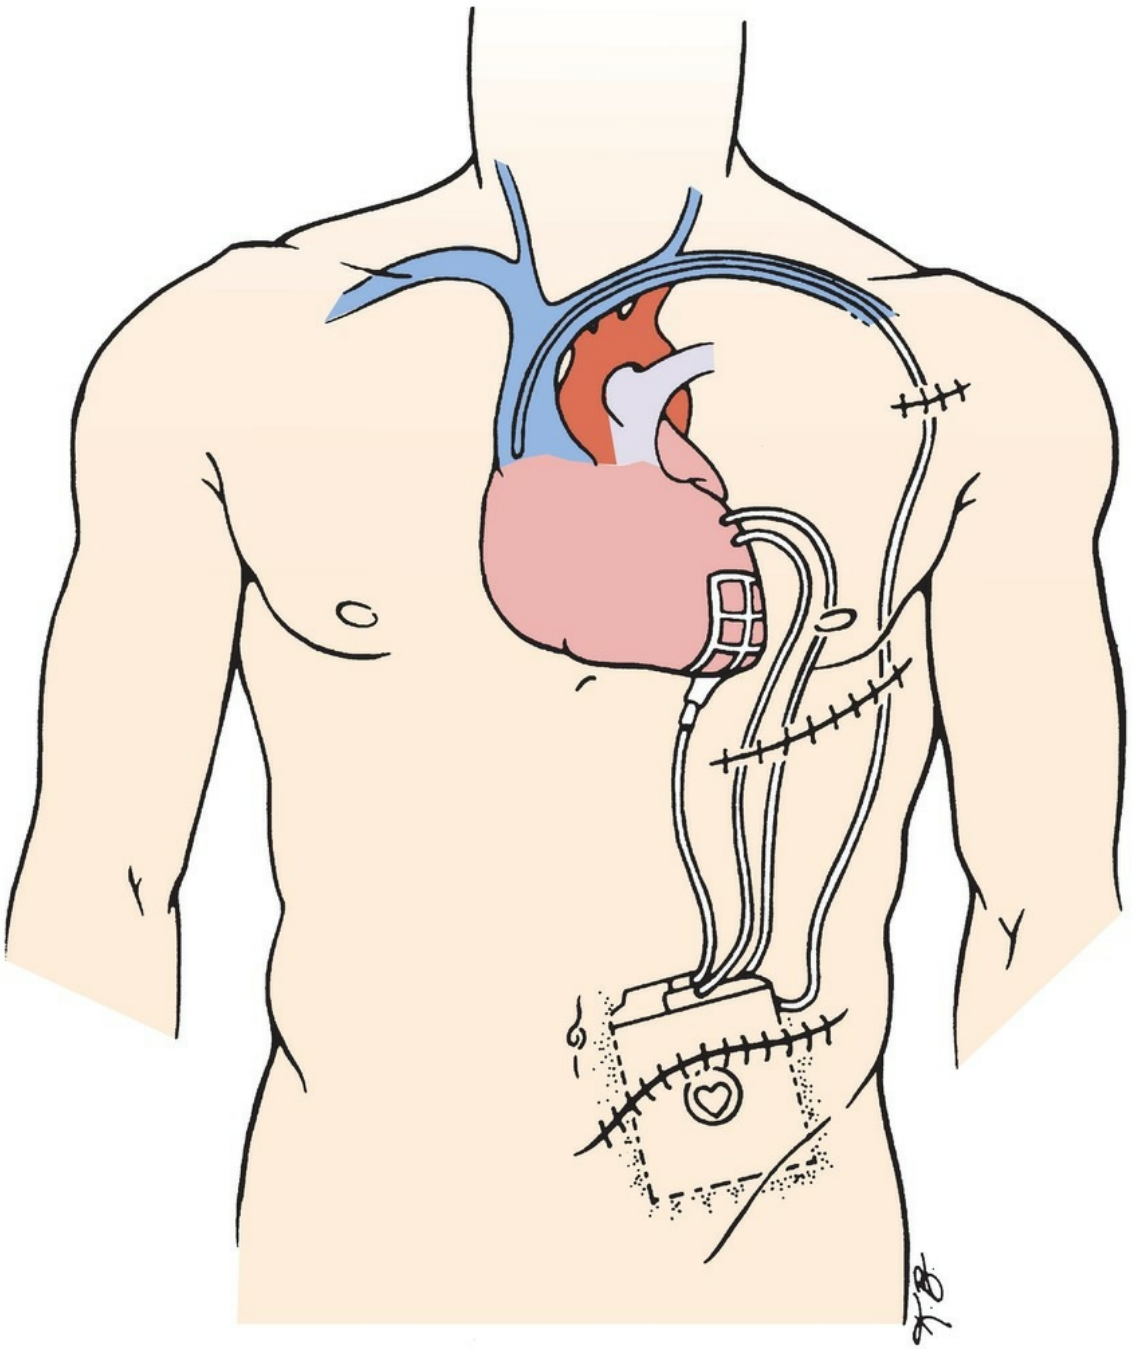

Figure 12-8. Implantable cardioverter–defibrillator.

Concepts

1. Sudden cardiac death as a result of ventricular tachycardia or fibrillation remains the leading cause of death in the United States.
2. ICDs terminate ventricular fibrillation and tachycardia automatically, thereby preventing sudden death.
3. Currently, ICDs can deliver high-energy or low-energy shocks, can be programmed for demand and rate-response pacing, can be programmed for antitachycardic pacing, provide noninvasive electrical stimulation to conduct EPS, can be programmed for tiered therapy, and have the ability to record and store ECGs of tachycardic episodes.

Indications

1. Cardiac arrest because of ventricular fibrillation or tachycardia not because of transient or reversible causes.
2. Spontaneous sustained ventricular tachycardia with structural heart disease.
3. Syncope of undetermined origin with clinically relevant, hemodynamically significant ventricular tachycardia or ventricular fibrillation induced by EPS when drug therapy is not effective or tolerated.
4. Nonsustained ventricular tachycardia in patients with CAD, prior MI, left ventricular dysfunction, and inducible ventricular fibrillation or sustained ventricular tachycardia at EPS that is not suppressed by class I antiarrhythmic drugs.
5. Spontaneous sustained ventricular tachycardia in patients without structural disease not amenable to other treatment.
6. Nonischemic dilated cardiomyopathy with LVEF less than or equal to 35% and who are in the NYHA functional class II or III.

Design

The ICD is slightly larger than a pacemaker and consists of two parts:

1. Pulse generator—contains the circuitry and battery to detect dysrhythmias and generate the electric shock. The generator is usually placed in the left pectoral region and is commonly referred to as the active can or hot-can.
    a. Battery life depends on amount of shocks and pacing and is usually 5 to 6 years.
    b. The direct-current electric shock delivered is 25 to 35 joules. Depending on the device, it can be programmed up to 41 joules.
2. Lead system—consists of two components.
    a. Pace–sense component: monitors the heart rhythm and can deliver pacing output.
    b. Shocking coils: deliver the electrical shocks needed for defibrillation.
3. Most ICDs (but not all) can be noninvasively deactivated by a doughnut-shaped magnet. This will disable the ICD therapies of ATP and electrical cardioversion–defibrillation but will not turn off the pacemaker function. However, the magnet may initiate asynchronous pacing.

Function

Electric shocks are delivered in a programmed sequence:

1. The device detects a lethal dysrhythmia, charges and reconfirms that the lethal dysrhythmia is still present, and then "defibrillates" the heart. The lethal dysrhythmia must meet two programmed criteria (rate and amount of time spent from the isoelectric line) to trigger the device to emit an initial electric shock. The number of joules necessary to convert each patient is determined during insertion and testing of the device; it is usually 15 to 25 joules.
2. Nontermination of the lethal dysrhythmia by the initial shock triggers the device to continue the sequence (detect, charge, and defibrillate) until a total of four or five shocks have been delivered (the number of shocks depends on device model implanted).
    a. Subsequent shocks are slightly higher, at 30 to 32 joules.
    b. The total sequence lasts approximately 2 minutes.
3. Termination of the lethal dysrhythmia after the shock sequence signals the device to revert to the "detection" mode of operation and not to reinitiate the shocking sequence. The device will reinitiate the shocking sequence only if a rhythm other than the lethal dysrhythmia is detected and maintained for at least 35 seconds. If this criterion is met and another lethal dysrhythmia is detected, the device will cycle through the shocking sequence again.
4. Termination of a lethal dysrhythmia at any time during the shocking sequence signals the device to interrupt the sequence, return to a detection mode, and reinitiate the shocking sequence if another lethal dysrhythmia is detected.

Complications

1. Many complications that occurred previously with ICDs have been decreased by the use of the transvenous technique for implantation that is similar to that of permanent pacemaker insertion.
2. Complications associated with implantation of the ICD include:
    a. Acceleration of arrhythmias.
    b. Air emboli.
    c. Bleeding.
    d. Perforation of the myocardium.
    e. Pneumothorax.
    f. Puncture of the subclavian vein.
    g. Thromboemboli.
    h. Venous occlusion.
3. Complications that can occur after placement of an ICD:
    a. Chronic nerve damage.
    b. Diaphragmatic stimulation.
    c. Erosion of pulse generator.

d. Formation of pocket hematoma.
e. Fluid accumulation/seroma.
f. Infection of pocket/system.
g. Keloid formation.
h. Lead dislodgement.
i. Lead fracture and insulation breaks.
j. Venous thrombosis.

Nursing Diagnoses

- Anxiety related to invasive procedure and fear of death.
- Risk for Infection related to invasive procedure and implanted device.
- Decreased Cardiac Output related to surgical procedure, hypotension, cardiac tamponade, and/or dysrhythmias.
- Ineffective Breathing Pattern related to surgical procedure and discomfort.

Nursing Interventions

Reducing Anxiety

1. Explain to patient and family reason for implant, surgical procedure, and preprocedure and postprocedure management:
   a. Performed in the operating room or in an electrophysiology laboratory.
   b. Incision location.
   c. May need endotracheal (ET) intubation if unable to sedate.
   d. IV line; continuous ECG monitoring.
   e. Early mobilization after procedure.
   f. Coughing and deep breathing exercises.
   g. Management of incisional pain.
   h. Device turned on once implanted.
2. Provide emotional support to patient and family.
   a. Assess patient's and family's knowledge level, support systems, and usual coping mechanisms.
   b. Psychiatric counseling may be beneficial because patient is facing life-threatening issues.
   c. Encourage patient and family to verbalize fears and/or expectations of hospitalization, lifestyle adjustments, self-concept, body image, and device malfunction (misfiring or failure to fire).
   d. Reinforce to patient that daily activities will not increase the risk of the device misfiring.
   e. Explain the sensation that might be felt if the device fires and the patient is conscious. (Many patients will become unconscious before the device fires and therefore feel no sensations.) Sensations experienced in conscious patients vary, but are commonly described as a severe chest blow.
3. Allow patient to participate in care as much as possible.

a. Encourage patient to dress in street clothes during hospitalization. (Loose-fitting clothes are recommended to prevent chafing and irritation at implant site.)
b. Allow patient to look at incision site.
c. Give patient instructional booklets about the device.

Preventing Infection

1. Check temperature every 4 hours; report elevations. (Early postoperative fever may be due to atelectasis; defibrillator system as infection source commonly occurs within 5 to 10 days of implantation.)
2. Evaluate incision site every 4 hours for signs of infection.
3. Culture drainage from incision.
4. Evaluate incision for tissue erosion.
5. Monitor WBC count and differential.
6. Clean incision and change dressing as directed, using aseptic technique.
7. Administer antibiotics, as ordered, before and after the procedure.

GERONTOLOGIC ALERT Older patients may not demonstrate abnormal temperature elevations with infections and experience prolonged wound healing.

Maintaining Adequate Cardiac Output

1. Monitor vital signs frequently until stable.
2. Evaluate incision site for evidence of bleeding or hematoma.
3. Evaluate urine output.
4. Be alert to risk for dysrhythmias postoperatively. (Manipulation of the heart and swelling may induce dysrhythmias 24 to 48 hours after implant.)
5. Monitor for changes in blood pressure as a sudden drop may indicate cardiac tamponade.
6. Evaluate carefully all complaints of chest pain (noncardiac pain may be due to lead fracture or dislodgement; pain may be noted along wire pathways).
7. Auscultate heart sounds every 4 hours for presence of friction rub or muffled heart sounds.

NURSING ALERT Cardiopulmonary resuscitation (CPR) should be started immediately on any patient with an implantable defibrillator who becomes unconscious and has no pulse. A slight "buzz" sensation will be felt if the implanted device delivers a shock, but it is not harmful. Gloves may be worn to minimize the sensation.

Promoting Effective Breathing Pattern

1. Ask patient to take several deep breaths every hour to expand lung fields.
2. Encourage coughing and deep breathing exercises frequently; medicate with analgesics before exercises and provide a pillow for splinting.
3. Monitor use of incentive spirometer.
4. Elevate head of bed to promote adequate ventilation.
5. Auscultate lung fields every 4 hours.
6. Assist with position changes every 2 hours while on bed rest.
7. Encourage early ambulation.
8. Administer analgesics, as ordered.

Patient Education and Health Maintenance

Introduction to Implantable Defibrillator

1. Review anatomy of the heart with emphasis on the conduction system, using a diagram of the heart.
2. Give accurate explanations, using correct medical terminology (allows patient to interact with the health care team more effectively), regarding reason for device implantation, components of system, and function of device.
    a. Use manufacturer's instructional booklet and video presentation about the device.
    b. Encourage family members to participate in education process.

Living with the Implantable Defibrillator

1. Instruct patient and family on actions to be taken if the device fires.
    a. Explain signs and symptoms that may be experienced if a lethal dysrhythmia occurs: palpitations, dizziness, shortness of breath, and chest pain.
    b. If signs and symptoms occur, lie down and try to call 911 for help if alone.
    c. Family members should check for a pulse if patient becomes unconscious. CPR should be started immediately if no pulse is present and 911 has been called.
    d. Reinforce that shocks emitted from device are not harmful, and CPR should never be delayed to wait for device to complete the shocking sequence.
    e. If patient remains conscious or is unconscious with a pulse, family members should monitor patient during episode, continually assessing for a pulse during shocking sequence. After the episode, follow health care provider's instructions as directed.
    f. Notify health care provider immediately.
2. Explore with patient and family fears about failure of device, sensation associated with a shock, and injury to others if a shock occurs.
    a. Sensations experienced vary but are most commonly described as a severe blow to the chest.
    b. No injury will occur to others if in contact with patient during a shock; a slight shock may be felt by

your partner if the device fires during sexual intercourse.

c. Battery life depends on frequency of use. The device is evaluated in 4 to 6 weeks after implantation and then every 3 months. Newer devices may allow for checks from home.

3. Review sources of EMI that should be avoided (see page 251).
4. Advise patient that there is no increased risk of endocarditis, so antibiotic prophylaxis before dental work is not necessary.
5. Review with health care provider resumption of activities, such as lifting, driving, sports, and sexual activity.

Other Instructions

1. Review care of incision site (see page 251).
2. Loose-fitting clothing should be worn until healing takes place.
3. Provide MedicAlert card; encourage carrying card at all times and obtaining a corresponding MedicAlert bracelet.
4. Explain how to keep diary of episodes and record dates of 4- to 6-month follow-up appointments.
5. Provide information to family members regarding CPR training courses.
6. Encourage use of support groups.
7. Always carry a list of current medications and name and number of physician and emergency contacts.

Evaluation: Expected Outcomes

- Verbalizes understanding of device and surgical procedure.
- Afebrile; incision without drainage.
- Vital signs stable; no dysrhythmias.
- Respirations unlabored; lungs clear.

Pericardiocentesis

Pericardiocentesis is an invasive procedure, which involves the puncture of the pericardial sac to aspirate fluid. The pericardium typically contains 10 to 50 mL of sterile fluid. Excessive fluid within the pericardial sac can cause compression of the heart chambers, resulting in an acute decrease in CO (cardiac tamponade). Fluid accumulation (pericardial effusion) can occur rapidly (acute) or slowly (subacute). The amount of excess fluid the pericardium is able to accommodate is individually based on the ability of the pericardium to stretch. Once the stretch has been maximized, intrapericardial pressure rises, possibly causing circulatory compromise.

Acute—a rapid increase of fluid into pericardial space (as little as 200 mL) causes a marked rise in intrapericardial pressure. Emergency intervention is required to prevent severe circulatory compromise.

Subacute—slow accumulation of fluid into pericardial sac over weeks or months, causing the pericardium to stretch and accommodate up to 2 L of fluid without severe increases in intrapericardial pressure.

Both of these situations require intervention to remove the pericardial fluid. Pericardiocentesis is frequently performed in the cardiac catheterization laboratory under fluoroscopy or assisted by echocardiographic imaging. In the case of severely decompensated cardiac tamponade, pericardiocentesis can be safely performed at the bedside with echocardiography.

Purposes

1. To remove fluid from the pericardial sac caused by:
    a. Infection.
    b. Malignant neoplasm or lymphoma.
    c. Trauma (blunt or penetrating wounds or from cardiac surgery or procedure).
    d. Drugs and toxins.
    e. Radiation.
    f. MI.
    g. Collagen vascular disease.
    h. Aortic dissection extending to the pericardium.
    i. Metabolic disorders, especially uremia, dialysis, and hypothyroidism.
    j. Cardiac diagnostic or interventional procedures.
    k. An idiopathic condition.
2. To obtain fluid for diagnosis.
3. To instill certain therapeutic drugs.

Sites for Pericardiocentesis

1. Subxiphoid—needle inserted in the angle between left costal margin and xiphoid.
2. Near cardiac apex, three-fourth inch (2 cm) inside left border of cardiac dullness.
3. To the left of the fifth or sixth interspace at the sternal margin.

4. Right side of fourth intercostal space just inside border of dullness.

Nursing Considerations

1. Administer sedation as prescribed to reduce anxiety.
2. If performed at bedside, ensure that patient is monitored and that emergency resuscitation equipment, defibrillator, and pacemaker are immediately available.
3. During and following the procedure, monitor for complications including dysrhythmias and bloody drainage (hemopericardium).
4. Following the procedure, report the presence of pericardial friction rub and distant heart sounds, indicating reaccumulation of fluid causing cardiac tamponade.

Percutaneous Coronary Intervention

EVIDENCE BASE Mitchell, J., & Brown, D. (2016). Update on percutaneous coronary intervention in stable coronary artery disease. *JAMA Internal Medicine, 176*(12), 1855–1856.

Percutaneous coronary intervention (PCI) is a broad term used to describe all invasive coronary interventions. Initially, PCI was limited to balloon angioplasty; however, it now includes intracoronary stenting and a wide spectrum of percutaneous procedures utilized to treat coronary disease. PCI has also replaced coronary artery bypass grafting (CABG) as the preferred treatment for CAD. Commonly performed PCIs include percutaneous transluminal coronary angioplasty (PTCA) with intracoronary stenting, laser-assisted PTCA, and direct coronary atherectomy (DCA). Radial vascular access is recommended over femoral access for PCI, because of lower vascular complication rate and comparable efficacy and safety in relation to the primary outcome of death.

Types of Procedures

Percutaneous Transluminal Coronary Angioplasty

Percutaneous transluminal coronary angioplasty (PTCA) accesses the femoral, brachial, or radial artery, with the right femoral artery being the most common access site. The site is anesthetized and an arterial sheath is placed into the vessel. Under fluoroscopy, a catheter is advanced through the arterial sheath and directed to the coronary lesion. To visualize the coronary anatomy, specific radiographic projections are used with the fluoroscopy tube through the use of an injection of contrast dye. Once a coronary lesion or narrowing is identified, a balloon-tipped catheter is advanced through wire to the lesion. The balloon is then inflated to displace coronary plaque against the vessel wall (see Figure 12-9). Balloon inflation and deflation may be repeated until optimal flow is achieved in the affected vessel.

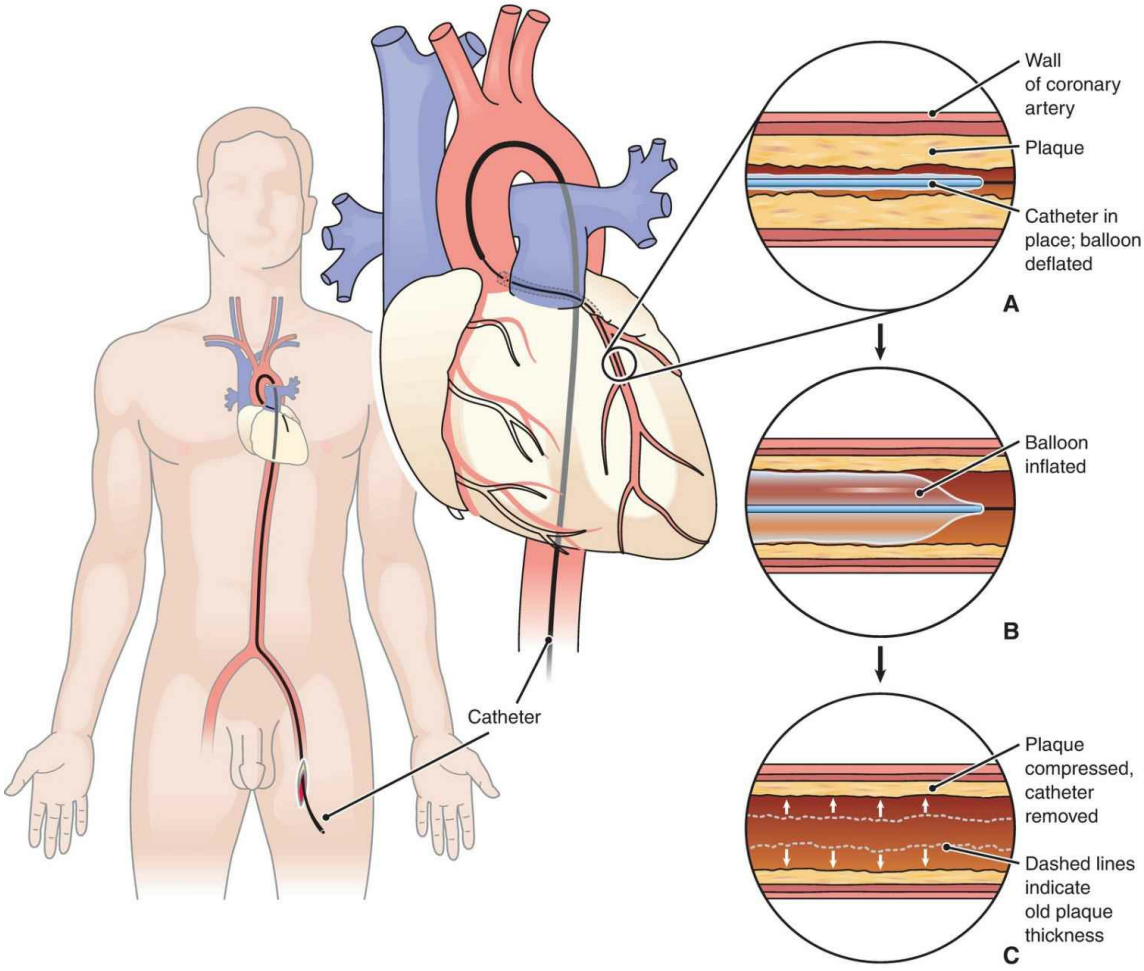

Figure 12-9. Percutaneous transluminal coronary angioplasty. **(A)** The balloon-tipped catheter is passed into the affected coronary artery. **(B)** The balloon is then rapidly inflated and deflated with controlled pressure. **(C)** The balloon disrupts the intima and causes changes in the atheroma, resulting in an increase in the diameter of the lumen of the vessel and improvement of blood flow. (Redrawn from Purcell, J.A., and Giffin, P.A. (1981). Percutaneous transluminal coronary angioplasty. *American Journal of Nursing* 9:1620–1626.)

Intracoronary Stenting

Intracoronary stents are small meshed metal tubes that are mounted onto a balloon angioplasty catheter. Once initial angioplasty is performed, the angioplasty catheter is removed and replaced with a stent catheter. When the balloon is inflated, the stent is deployed and pressed into the intima of the artery where the occlusion existed. The balloon is deflated and the catheter is removed; however, the stent remains. The intracoronary stent acts as a scaffold helping to hold the artery open, thereby improving blood flow and relieving symptoms once caused by the blockage. Stents may be uncoated, called bare metal stents, or coated, called drug-eluting stents (DESs). DESs are intended and are preferred over bare metal stents to limit the overgrowth of normal tissue following implantation.

Laser-Assisted Balloon Angioplasty

A laser light is directed by a percutaneously inserted flexible fiberoptic catheter and can "vaporize"

atheromatous lesions in the coronary vessels. Balloon angioplasty of the vessel may then be performed. This technique may minimize damage to the intimal lining, open diseased vessels more effectively, prevent early and long-term restenosis, and expand the use of angioplasty to calcified, unusual lesions and total occlusions. The most important complication of laser-assisted balloon angioplasty involves minor to major coronary dissection of the treated lesion.

Direct Coronary Atherectomy

Direct coronary atherectomy (DCA) permits more controlled vascular injury and decreases the degree of arterial mural stretch that can occur with PTCA and balloon angioplasty. To remove plaque, DCA works by changing plaque into microscopic debris, thereby opening the diseased vessel more effectively, especially in patients who have coronary lesions not amenable to standard angioplasty. Complications associated with DCA include vascular spasm at the site of plaque removal or distal to the treated site; possible myocardial necrosis, evidenced by elevations of CK-MB; vessel perforation (infrequent but devastating); and groin complications and groin bleeding (more common with atherectomy procedures because of the size of the catheters involved).

Indications

Indications for PCI include the following (only after a comprehensive risk–benefit analysis has been reviewed): recurrent ischemia despite anti-ischemia therapy, elevated troponin levels, new ST-segment depression, symptoms of heart failure or new or worsening mitral insufficiency, depressed left ventricular systolic function, hemodynamic instability, sustained ventricular tachycardia, PCI within 6 months, prior CABG, and high-risk findings from noninvasive testing, including unprotected left main artery disease.

Contraindications

1. PCI is not indicated for patients who have no evidence of high-risk findings associated with single-vessel or multivessel CAD.
2. Procedure-related morbidity or mortality may be linked to the following relative contraindications, many of which may be avoided or reversed prior to PCI:
    a. Allergy (severe) to radiographic contrast dye.
    b. Anticoagulated state.
    c. Decompensated heart failure (eg, acute pulmonary edema).
    d. Digoxin toxicity.
    e. Febrile state.
    f. Severe renal insufficiency.
    g. Uncorrected hypertension.
    h. Uncorrected hypokalemia.
    i. Ventricular irritability, uncontrolled.

Complications

1. Major complications or adverse outcomes include death, postprocedure MI, or need for emergent cardiac bypass surgery.
2. Other complications include:
    a. Anaphylaxis.
    b. Arrhythmias.
    c. Arterial dissection/coronary artery dissection.
    d. Bleeding.
    e. Cardiac perforation.
    f. Coronary occlusion, total.
    g. Hematoma at access site.
    h. Renal failure.
    i. Restenosis—occurs in 30% to 50% of PTCA and 10% to 30% of intracoronary stenting procedures.
    j. Stroke.
    k. Tamponade.

NURSING ALERT Although the occurrence of complications from PCI has declined, immediate CABG surgery must be available with a cardiac surgical team on standby.

DRUG ALERT Missed doses of anticoagulants following intracoronary stenting procedures are clearly linked to restenosis. The patient's ability to adhere to strict anticoagulation protocol will impact on the success of the procedure.

Nursing Diagnoses

- Anxiety related to impending invasive procedure.
- Decreased Cardiac Output related to dysrhythmias, vessel restenosis, or spasm.
- Risk for Injury (bleeding) related to femoral catheter and effect of anticoagulant and/or thrombolytic therapy.
- Acute Pain related to invasive procedure or myocardial ischemia.

Nursing Interventions

Reducing Anxiety

1. Reinforce the reasons for the procedure.
    a. Describe the location of the coronary vessels using a diagram of the heart.

b. Describe/draw the location of the patient's lesion using heart diagram.

2. Explain the events that will occur before, during, and after the procedure. Preparation minimizes anxiety and increases compliance with care regimen.
   a. Performed in the cardiac catheterization laboratory; similar to the cardiac catheterization procedure (see page 243).
   b. Mild sedation given; patient remains awake throughout the procedure to report any chest pain (indicates myocardial ischemia).
   c. Assure patient that chest pain will be taken care of during the procedure.
3. Prepare patient for complications of procedure. Provide preoperative teaching to patient and family regarding procedure, potential complications, and risks associated with heart surgery (see page 260).
4. Explain the necessity of the IV, ECG monitoring, frequent vital sign and groin checks, and remaining NPO before the procedure.

Maintaining Adequate Cardiac Output

1. Check vital signs according to facility policy, typically every 15 minutes for 1 hour, then every 30 minutes for 2 hours, and subsequently every 1 to 2 hours.
2. Continually evaluate for signs and symptoms of restenosis.
   a. Emphasize importance of reporting any chest discomfort or jaw, back, or arm pain and/or nausea and abdominal distress.
   b. Perform ECG for all complaints suspicious of possible myocardial ischemia.
   c. Administer oxygen and vasodilator therapy for pain, as directed.
   d. Obtain CK and isoenzymes as directed.
   e. Keep patient NPO if prolonged chest pain occurs (patient may return to catheterization laboratory).
3. Administer medications to maintain vessel patency.
   a. Antiplatelet or antithrombin agents may be given during and after procedure to prevent reocclusion (eg, cangrelor, tirofiban, bivalirudin, eptifibatide, abciximab). Clopidogrel, or prasugrel, or ticagrelor may be given prior to PCI after STEMI.
   b. Low-dose heparin or low molecular weight heparin (enoxaparin) may also be used.
   c. Many patients are then maintained on medications such as clopidogrel, ticagrelor, or prasugrel. Aspirin and statins are also used. Reinforce compliance with drug therapy.
4. Evaluate fluid and electrolyte balance.
   a. Record intake and output.
   b. Encourage fluid intake or maintain IV fluids pre- and postprocedure to ensure adequate hydration to prevent contrast medium–induced nephropathy.
   c. Observe for dysrhythmias possibly related to potassium imbalance. Excessive diuresis causes potassium depletion.
   d. Administer potassium supplement, as prescribed.

5. Be alert to the risk of vasovagal reaction during removal of groin catheter if closure device is not employed.
    a. Observe for bradycardia, hypotension, diaphoresis, or nausea.
    b. Administer IV atropine, as directed.
    c. Place patient in Trendelenburg position to promote blood return to the heart and improve hypotension.
    d. Give fluid challenge as directed.

Preventing Bleeding

1. Refer to facility policy for activity progression regimen, usually gradual head elevation with ambulation within 4 to 6 hours after sheath removal. Maintain bed rest with affected extremity immobilized and head of bed elevated no more than 30 degrees (in the event the catheter remains) to prevent catheter dislodgement and bleeding.
2. Mark peripheral pulses before procedure with indelible ink.
3. Check peripheral pulse of affected extremity and insertion site with each vital sign check.
4. Observe color, temperature, and sensation of affected extremity with each vital sign check.
5. Report if extremities become cool and pale and pulses become significantly diminished or absent.
6. Look for presence of hematoma and mark hematoma to note change in size. Report if hematoma continues to enlarge.
7. Note petechiae, hematuria, and complaints of flank pain (vessel patency is maintained by not reversing intraprocedure heparinization; chance of bleeding is increased).
8. Apply direct pressure over insertion site if bleeding is observed and report immediately.
9. Check bed linen under patient frequently for blood.
10. Ask patient to report sensation of warmth at groin area.

Relieving Pain

1. Administer analgesics and anxiolytic medication, as directed.
2. Ensure a restful environment.
    a. Provide back rubs for muscle relaxation.
    b. Minimize noise and interruptions.
    c. Offer sleep medication, as indicated.
3. Progress patient's diet as tolerated (clear liquids/full liquid diet until catheters removed); assist patient with meals.

Patient Education and Health Maintenance

Instruct patient as follows:

1. Modification of cardiac risk factors as means of controlling progression of CAD.
2. Name of medications, action, dosage, and adverse effects.

a. Common medications to prevent clot formation.
b. Medications to increase blood flow to the heart.
c. Medications to slow heart rate and reduce chest pain.
d. Medications to increase blood flow and prevent coronary artery spasm.

3. Dates and importance of any follow-up tests.
4. Symptoms for which patient should seek medical attention, such as adverse effects of medication and chest pain—especially chest pain unrelieved by nitroglycerin.
5. Restenosis (with or without stent) can occur; the patient typically presents with the previous same symptoms; however, the symptoms may vary if a different lesion is involved.

Evaluation: Expected Outcomes

- Verbalizes understanding of procedure.
- Vital signs stable; urine output adequate.
- No bleeding or hematoma at insertion site.
- Verbalizes relief of pain.

Intra-Aortic Balloon Pump Counterpulsation

Counterpulsation is a method of assisting the failing heart and circulation by mechanical support when the myocardium is unable to generate adequate CO. The mechanism of counterpulsation therapy is opposite to the normal pumping action of the heart; counterpulsation devices pump while the heart muscle relaxes (diastole) and relax when the heart muscle contracts (systole).

Indications

1. Postcardiotomy support; low cardiac output after cardiopulmonary bypass.
2. Severe unstable angina that is refractory to pharmacologic therapy.
3. Cardiogenic shock/left-sided heart failure after MI, myocarditis, cardiomyopathy, myocardial contusion, and refractory heart failure.
4. Postinfarction ventricular septal defects or mitral insufficiency resulting in shock.
5. Emergency support following PTCA or high-risk percutaneous coronary interventions.
6. Hemodynamic deterioration in patients awaiting heart transplant.
7. Refractory ventricular arrhythmias.
8. Patients with severe left main coronary arterial stenosis whom surgery is pending.
9. Adjunctive therapy after fibrinolysis in patients at high-risk restenosis.

Function

1. A balloon catheter is introduced into the femoral artery percutaneously or surgically, threaded to the proximal descending thoracic aorta, and positioned 1 to 2 cm distal to the origin of the left subclavian artery (see Figure 12-10).
2. In patients with severe peripheral arterial disease, axillary artery approach should be considered, especially if longer support is needed (see Figure 12-10). This allows for early mobilization and reduces the risk of infection.
3. The balloon catheter is attached to an external console, allowing for inflation and deflation of the balloon with gas such as He (helium). Helium has low viscosity that allows quick travel through the long connecting tubes, and it has low potential for gas embolization should the balloon rupture.
4. The external console integrates the inflation and deflation sequence with the mechanical events of the cardiac cycle (systole–diastole) by "triggering" gas delivery in synchronization with the patient's ECG, the patient's arterial waveform, atrial/ventricular paced rhythm, or intrinsic pump rate.
    a. The most common method of "triggering" or signaling the intra-aortic balloon pump (IABP) is from the R wave of the patient's ECG signal.
    b. The balloon is automatically set to inflate in the middle of the T wave or at the dicrotic notch of the arterial waveform. This occurs immediately after aortic valve closure.
5. Eases the workload of a damaged heart by increasing coronary blood flow (diastolic augmentation) and decreasing the resistance in the arterial tree against which the heart must pump (afterload reduction).

6. This results in an increase in CO and a reduction in myocardial oxygen requirements.
7. The balloon is inflated at the onset of diastole; this results in an increase in diastolic aortic pressure (diastolic augmentation), which increases blood flow through the coronary arteries.
8. The balloon is deflated just before the onset of systole (just before aortic valve opening), facilitating the emptying of blood from the left ventricle and decreasing pressure within the aorta. This action results in less work for the left ventricle.

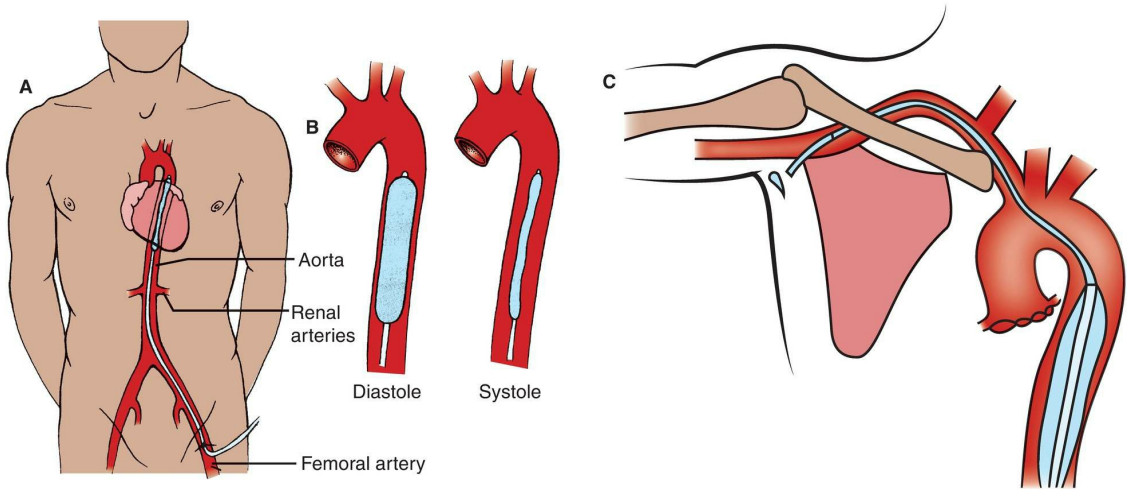

Figure 12-10. Counterpulsation. **(A)** Introduction of the intra-aortic balloon catheter via the femoral artery. **(B)** The intra-aortic balloon pump augments diastole, resulting in increased perfusion of the coronary arteries and myocardium and a decrease in the left ventricular workload. **(C)** Axillary approach.

Contraindications

1. Aortic insufficiency—IABP will increase aortic insufficiency.
2. Aortic aneurysm or aortic dissection—IABP catheter may perforate a weakened vessel wall leading to thrombus formation, and inflation and deflation of the catheter may cause a thrombus to break off to become an embolus.
3. Peripheral vascular disease—femoral or iliac artery insertion may be impossible in a patient with severe vascular disease.
4. Terminal illness—outcome will not be affected, unless the patient meets the criteria for heart transplantation.
5. Prosthetic graft in thoracic aorta—may disrupt graft.
6. Coagulopathy—increases the risk of bleeding.
7. Uncontrolled sepsis.

Complications

1. Vascular injuries that may occur from IABP are:

a. Plaque dislodging.
b. Dissection of the aorta.
c. Laceration of the aorta.
d. Ischemia of the limb distal to the insertion site.
e. Arterial perforation.

2. Peripheral nerve damage can occur from IABP if a cut down was used to insert the catheter.
3. Impairment of cerebral circulation because of balloon migration occluding the subclavian artery or by embolus and impairment of renal circulation because of balloon malposition or embolus. (Impaired circulation occurs more frequently in patients with peripheral vascular occlusive disease, in women with small vessels, and in patients with insulin-dependent diabetes.)
4. Infection at the insertion site and septicemia occur in 0.2% of patients with IABP.
5. Thrombocytopenia.
6. Hemorrhage because of anticoagulation.
7. Aortic dissection.

Nursing Diagnoses

- Anxiety related to invasive procedure, critical illness, and environment.
- Decreased Cardiac Output related to myocardial ischemia and/or mechanical intervention.
- Impaired Tissue Perfusion related to foreign body in the aorta.
- Impaired Skin Integrity related to decreased mobility.

Nursing Interventions

Relieving Anxiety

1. Explain IABP therapy to patient and family geared to their level of understanding.
   a. Review purpose of therapy and how the IABP functions.
   b. Reinforce mobility restrictions: supine position with head of bed elevated 15 to 30 degrees and no movement or flexing of leg with IABP catheter.
   c. Explain the need for frequent monitoring of vital signs, rhythm, insertion site of affected extremity, and pulses.
   d. Discuss the sounds associated with functioning external console: balloon inflation and deflation and alarms.
2. Encourage family members to participate in patient's care.
   a. Allow family to visit patient frequently.
   b. Solicit family members' assistance in reinforcing mobility restrictions to patient and notifying nursing staff of patient comfort needs.
   c. Encourage family members to ask questions.
3. Allow patient to verbalize fears regarding therapy and illness.

4. Make sure that informed consent is obtained.
5. Administer anxiolytic medications as prescribed and indicated.
6. Keep the family informed of changes in the patient's condition.
7. Encourage realistic hope based on the patient's condition and discuss the patient's progress with the family.
8. Determine the family's previous coping mechanism to stressful situations.

Maintaining Adequate Cardiac Output

1. Assist during insertion of IABP catheter.
   a. Offer patient reassurance and comfort measures (patient is only mildly sedated).
   b. Ensure strict aseptic environment during insertion.
   c. Establish ECG monitoring, choosing the lead with the largest R wave (external console senses R wave of ECG to trigger gas delivery) and without artifact (integration of the patient's cardiac cycle with the inflation and deflation balloon sequence depends on a continuous clear ECG tracing).
   d. Record date, time, and the patient's tolerance to procedure.
   e. Obtain chest x-ray to ensure placement of IABP catheter.
2. Start IABP counterpulsation immediately after insertion, as directed; review manufacturer's manual for IABP equipment in use. Updated manufacturer software allows the IABP to start up with one press of a button and automatically adjust balloon inflation and/or timing. Deflation can be manually adjusted. New software automatically chooses the best trigger and mode that best suits the patient's condition.
   a. Adjust the duration of balloon deflation by the arterial waveform because inflation is timed automatically; inflation is "timed" to begin at the dicrotic notch of the arterial waveform, and deflation occurs before the next systole. Current IABPs can choose the best trigger for the patient (mostly ECG trigger and if in "auto" mode) independently from a user.
   b. Compare the patient's arterial pressure waveform with and without balloon augmentation to evaluate effectiveness of therapy. Note difference in patient's end-diastolic pressure and balloon-assisted end-diastolic pressure (the balloon-assisted end-diastolic pressure should be lower, indicating a reduction in afterload).
   c. Monitor hemodynamic parameters with Swan-Ganz catheter (see page 245). Record mean arterial pressure (MAP), CVP, PAP, pulmonary capillary wedge pressure (PCWP), and CO to evaluate overall effectiveness of therapy. Perform hemodynamic calculations to evaluate systemic vascular resistance and left ventricular stroke work. Use IABP MAP when titrating vasoactive medications.
   d. Assess capillary refill, pedal, and left radial pulses every 15 minutes for the first hour and then hourly. The balloon catheter or a thrombus can obstruct flow to the distal extremities. If the catheter migrates too high, it can obstruct flow of the left subclavian artery.
3. Monitor vital signs every 15 to 30 minutes for 4 to 6 hours and then hourly, if stable.
4. Monitor the IABP catheter site with vital signs and check for distal pulses to prevent limb ischemia.
5. Monitor neurologic status at least every 2 to 4 hours.

6. Monitor urine output from indwelling catheter every hour.
7. Maintain accurate intake and output and weigh patient daily (preferably at the same time every day).
8. Report chest pain immediately.
9. Treat dysrhythmias as directed.
10. Check for blood oozing around IABP catheter every hour for 8 hours and then every 4 hours (anticoagulation therapy is used to prevent thrombus formation); apply direct pressure and report bleeding.

Maintaining Adequate Tissue Perfusion

1. Evaluate for ischemia of extremity with IABP catheter.
   a. Mark pulses with indelible ink to facilitate checks.
   b. Monitor peripheral pulses (dorsalis pedis, posterior tibial, popliteal, and left radial) for rhythm, character, and pulse quality every 15 minutes for 1 hour, then every 30 minutes for 1 hour, and then hourly.
   c. Use Doppler device for pulses difficult to palpate and to auscultate for bruits and hums.
   d. Observe skin temperature, color, sensation, and movement of affected extremity. (Dusky, cool, mottled, painful, numb/tingling extremity indicates ischemia.)
2. Observe for possible indications of thromboemboli.
   a. Note decreases in urine output after initiation of therapy—may indicate renal artery emboli.
   b. Perform neurologic checks every hour to evaluate for cerebral emboli.
   c. Auscultate bowel sounds to detect evidence of ischemia.
3. Recognize early signs and symptoms of compartment syndrome. Increased pressure in tissue reduces blood flow.
   a. Note complaints of pain, pressure, and numbness of affected extremity induced by passive stretching.
   b. Palpate affected extremity for swelling and tension.
   c. Monitor CK values. Highly elevated CK may indicate compartment syndrome.
4. Ideally, keep head of bed elevated 30 degrees versus supine to avoid aspiration, but prevent upward migration of catheter.

Maintaining Skin Integrity

1. Assess skin frequently for signs of redness or breakdown.
2. Place patient on specialty mattress or bed designed to prevent pressure ulcers (preferably before balloon insertion).
3. Pad bony prominences.
4. Implement passive ROM exercises with exception of extremity with IABP catheter.
5. Turn patient from side to side as a unit every 2 hours. Patients are usually debilitated and prone to pressure ulcers.

Evaluation: Expected Outcomes

1. States activity restrictions and rationale.
2. Blood pressure and CO readings improved.
3. Peripheral pulses strong; extremities warm and nail beds pink.
4. No skin redness or breakdown.

Heart Surgery

Open-heart surgery is most commonly performed for CAD, valvular dysfunction, and congenital heart defects. The procedure may require temporary cardiopulmonary bypass (blood is diverted from the heart and the lungs and mechanically oxygenated and circulated) to provide a bloodless field that leads to increased visibility of cardiac structures during the operation.

Newer and less invasive procedures include *minimally invasive direct coronary artery bypass (MIDCAB)* and *robotic-assisted coronary bypass and valve surgeries*. An estimated 405,000 coronary bypass graft surgeries occur yearly in the United States. Heart transplant will not be discussed. For information on percutaneous ventricular assist devices, see Box 12-3.

BOX 12-3 Percutaneous Ventricular Assist Device Therapy

The use of the percutaneous left ventricular assist device (LVAD) constitutes important advances in management of patients with severe cardiogenic shock and may serve as a bridge to recovery or heart transplantation for some patients. The immediate therapeutic benefit of the percutaneous LVAD in patients with cardiogenic shock is the restoration of normal hemodynamics and vital organ perfusion. Although the intra-aortic balloon pump (IABP) decreases preload and afterload, the percutaneous LVAD augments cardiac output and may even completely replace left ventricular function. In severe cases of cardiogenic shock, the IABP and percutaneous LVAD may be used at the same time. For the high-risk percutaneous coronary intervention patient, short-term hemodynamic stability can be provided, and the device can be implanted rapidly and percutaneously in a prophylactic or emergency setting.

There are three principal indications for percutaneous LVAD support:

- Reversible, severe left-sided heart failure (providing temporary circulatory support until recovery has ensued or revascularization has been performed).
- Large ischemic area at risk (temporary circulatory support during high-risk percutaneous or surgical revascularization procedures).
- Bridging therapy (temporary circulatory support as bridge to a permanent surgical assist device or heart transplantation).

The percutaneous LVAD works by creating a left ventricular bypass in one of two ways. One approach is to enter the left atrium transseptally by placing a catheter that pulls oxygenated blood into a centrifugal pump and then flows it back into the femoral artery, thus creating a left atrial-to-femoral bypass. The second technique is retrograde placement of a "caged" blood flow inlet in the left ventricle, which pulls oxygenated blood via catheter to a microaxial pump into the ascending aorta, thereby creating a left ventricular-to-aortic bypass. There are advantages to both systems, and selection should be patient specific.

Historically, surgically implanted right ventricular assist devices (RVADs) have been used mostly for support of cardiac surgical patients. In several reported cases, percutaneous RVADs have successfully supported patients with right ventricular infarct complicated by shock. However, further investigation of this newer therapy is warranted to determine patient outcomes and potential benefits for patients requiring RV

support.

Types of Procedures

Coronary Artery Bypass Graft

EVIDENCE BASE Fudulu, D., Benedetto, U., Pecchinenda, G. G., et al. (2016). Current outcomes of off-pump versus on-pump coronary artery bypass grafting: evidence from randomized controlled trials. *Journal of Thoracic Disease, 8*(S10), S758–S771.Parasca, C. A., Head, S. J., Milojevic, M., et al. (2016). Incidence, characteristics, predictors, and outcomes of repeat revascularization after percutaneous coronary intervention and coronary artery bypass grafting. *JACC Cardiovascular Intervention, 9*(24), 2493–2507.Benedetto, U., Gaudino, M., Ng, C., et al. (2016). Coronary surgery is superior to drug eluting stents in multivessel disease. Systematic review and meta-analysis of contemporary randomized controlled trials. *International Journal of Cardiology, 210*, 19–24.

---

1. Coronary artery bypass graft (CABG) surgery involves anastomosis of a graft (vein or artery) with distal portion bypassing the blocked coronary vessel restoring adequate blood supply to the heart muscle. The proximal end, in some cases, is anastomosed to the aorta (when the internal mammary artery is chosen as conduit, the proximal end remains attached in its normal circulation pattern). The choice of conduit is often multifactorial. Arterial conduit has been shown to have a longer patency rate. For this reason, the internal mammary artery is often chosen if time allows for its dissection from the chest wall and the length is adequate to bypass the blocked vessel. The saphenous vein remains the most commonly used because it is easily accessed and does not require extra prepping to prevent spasm (as is the case with a radial graft). Several studies suggest poor graft vein patency and increased revascularization rate for patients undergoing off-pump CABG compared to on-pump CABG
    a. Multiple grafts can be placed to bypass multiple lesions.
    b. Traditional procedure is done through sternotomy, whereas newer procedures are less invasive.
2. The heart is stopped (in some cases) and the patient is placed on a cardiopulmonary bypass machine (on-pump CABG). In other situations, CABG is performed while the heart is beating using a stabilizer to decrease movement (off-pump CABG). Compared to CABG, PCI with drug-eluding stents has been shown to increase relative risk of death, risk of myocardial infarction, and revascularization rates at 3.4 years after initial treatment. Primarily done to alleviate anginal symptoms and improve survival and quality of life.
3. Indications for CABG include:
    a. Left main coronary artery stenosis of 70% or greater.
    b. Proximal vessel disease greater than 50% to 70% stenosis of three main coronary arteries.
    c. Multivessel disease and decreased left ventricular function.

d. Unstable angina (UA).
e. Chronic stable angina that is lifestyle-limiting and unresponsive to medical therapies or PTCA and stenting cannot be achieved.

4. Relative contraindications for CABG include:
   a. Small coronary arteries distal to the stenosis.
   b. Severe aortic stenosis.
   c. Severe left ventricular failure with coexisting pulmonary, renal, carotid, and peripheral vascular disease.

Valvular Surgery

1. Prosthetic or biologic valves are placed in the heart as definitive therapy for incompetent heart valves. Mechanical valves are of man-made material and require a lifetime of anticoagulation therapy. Biologic valves are general either porcine or bovine derivatives. The decision for mechanic or biologic valve is a shared decision between the patient and provider.
2. Valve repair or replacement can be done in conjunction with CABG surgery.
3. Usually done as an open-heart procedure through sternotomy incision or minithoracotomy. A selected group of patients may need a transcutaneous valvular replacement (ie, TAVR).
4. Postoperative care of a patient with either a mitral valve or an aortic valve is similar to that of a patient who has undergone post-CABG surgery. Patients who have mechanical valve need lifetime anticoagulation therapy regardless of the position of the valve replaced. Generally, MVR need higher INR goals (ie, INR = 3 or greater) than AVR (ie, INR = 2.5 or lower in cases of increased risk of bleeding), which is partially influenced by the pressure gradient. In the immediate postoperative period, heparin infusion can be used as a bridge anticoagulation until warfarin can be institute to the therapeutic INR goal. It is important to educate patients to not stop the anticoagulation and to always seek medical advice prior to doing so.

Congenital Heart Surgery

1. Defects of the heart can be surgically repaired and reconstructed.
2. Temporary cardiopulmonary bypass is not always required.

Minimally Invasive Direct Coronary Artery Bypass (MIDCAB)

1. Done through a left anterior small thoracotomy, a short parasternal incision, or a small incision using a port access and video-assisted technology.
2. Cardiopulmonary bypass machine is not needed because the heart remains beating.
3. The procedure is limited to proximal disease of the left anterior descending or right coronary artery.
4. With this procedure, there is less blood transfusion, less pain and discomfort, less infection, and less time under anesthesia; therefore, intensive care unit (ICU) length of stay is significantly shorter.

Off-Pump CABG (Beating-Heart Bypass Surgery)

1. CABG surgery is done using a median sternotomy without the use of cardiopulmonary bypass machine; preferred method in high-risk patients (eg, patients with poor ventricular function or with severe aortic atherosclerosis).
2. Postaccess procedures are performed through a small anterior thoracotomy incision and a few 1-cm lateral port incisions that allow direct access to the heart and good visualization through a thoracoscope.
   a. Multiple vessel bypass can be performed as well as mitral valve surgery and repair of atrial septal defect.
   b. In emergency, if the heart stops, cardiopulmonary bypass can be used during surgery.
   c. Reduces postoperative length of stay to 1 to 3 days.
   d. Contraindicated in patients with occlusion in posterior and lateral arteries, severe atherosclerosis, and aortic aneurysms.
3. Transmyocardial laser revascularization (TMLR) provides relief to patients having refractory angina that is not amendable to conventional revascularization. Indications for TMLR include severe coronary heart disease, viable myocardium with reversible ischemia, LVEF of more than 20%, and target vessels that are too small for catheter revascularization.

Preoperative Management

1. Review of patient's condition to determine status of vascular, pulmonary, renal, hepatic, hematologic, and metabolic systems.
   a. Cardiac history; circulatory studies.
   b. Pulmonary health—patients with COPD may require prolonged postoperative respiratory support. Chest computed tomography scans, baseline arterial blood gas, or pulmonary function tests should be ordered and used as reliable predictors of long-term pulmonary outcomes. (Vital capacity greater than 2.5 L and forced expiratory volume in 1 second greater than 1.5 L are ideal for favorable outcomes.)
   c. Depression—can produce a serious postoperative depressive state and can affect postoperative morbidity and mortality.
   d. Present alcohol intake; smoking history.
2. Preoperative laboratory studies.
   a. Complete blood count, serum electrolytes, lipid profile, and hemoglobin A1C, if diabetic.
   b. Ensure active blood type and cross with the correct number of packed red blood cells (PRBCs) and other blood products on hold at the blood bank.
   c. Antibody screen, urine, and other cultures.
   d. Preoperative coagulation survey (platelet count, prothrombin time, partial thromboplastin time)—extracorporeal circulation will affect certain coagulation factors.
   e. Renal and hepatic function tests.
3. Evaluation of medication regimen. These patients are usually taking multiple drugs.
   a. Digoxin—may be receiving large doses to improve myocardial contractility; may be stopped several days before surgery to avoid digitoxic dysrhythmias from cardiopulmonary bypass.

b. Diuretics—assess for potassium depletion and volume depletion; give potassium supplement to replenish body stores.
c. Beta-adrenergic blockers such as metoprolol and propranolol—usually continued.
d. Psychotropic drugs such as benzodiazepines (diazepam, alprazolam)—postoperative withdrawal may cause extreme agitation.
e. Alcohol—sudden withdrawal may produce delirium.
f. Anticoagulant/antiplatelet aggregate drugs, such as warfarin and clopidogrel—discontinued several days before operation to allow coagulation mechanism to return to normal.
g. Corticosteroids—if taken within the year before surgery, may lead to adrenal crisis. It is essential that these patients be dosed adequately to prevent hypotension or death.
h. Prophylactic antibiotics—may be given preoperatively.
i. Drug sensitivities or allergies are noted.
j. If patients are taking herbal supplements, they should be discontinued as far in advance as possible to prevent interactions with certain types of anesthesia.

4. If patient is taking any antihyperglycemic agents (ie, insulin, metformin), discuss with provider the need to reduce basal insulin doses and holding metformin before surgery. Ensure that basal insulin is not completely withheld, because this may result in diabetic ketoacidosis or hyperosmolar hyperglycemia state.
5. Improvement of underlying pulmonary disease and respiratory function to reduce risk of complications.
   a. Encourage patient to stop smoking.
   b. Treat infection and pulmonary vascular congestion.
6. Preparation for events in the postoperative period.
   a. Take the patient and family on tour of ICU. This lessens anxiety about being in ICU.
      i. Introduce the patient to staff personnel who will be caring for him or her.
      ii. Give family a schedule of visiting hours and times for phone contact.
   b. Teach chest physical therapy procedures to optimize pulmonary function.
      i. Have the patient practice with incentive spirometer.
      ii. Show and practice diaphragmatic breathing techniques.
      iii. Have the patient practice effective coughing and leg exercises.
   c. Prepare patient for presence of monitors, chest tubes, IV lines, blood transfusion, ET tube, nasogastric (NG) tube, pacing wires, arterial line, and indwelling catheter.
      i. Explain to the patient that chest tubes will be inserted below incision into the chest cavity for drainage and maintenance of negative pressure.
      ii. Explain to the patient that ET tube will prevent speaking, but communication will be possible through writing until tube is removed (usually within 6 hours when the patient is awake and able to maintain own airway).
      iii. Explain to the patient that diet will consist of liquids until 24 hours after surgery.

iv. Explain that monitoring equipment and IV lines will restrict movement and nursing staff will position the patient comfortably every 2 hours and as necessary.

d. Discuss with the patient the need to monitor vital signs frequently and the likelihood of frequent disturbances of the patient's rest.

e. Discuss pain management with the patient; assure the patient that analgesics will be administered as necessary to control pain. Discuss the use of the patient control analgesia (PCA) machine.

f. Tell the patient that both hands may be loosely restrained for a few hours after surgery to eliminate possibility of pulling out tubes and IV lines inadvertently.

g. Discuss with the patient the importance of physical and occupational therapy to increase mobility and decrease hospital stay. Patient will be assisted from the bed to chair by the morning of postoperative day 1.

7. Evaluation of emotional state to reduce anxieties.
   a. Patients undergoing heart surgery are more anxious and fearful than other surgical patients. (Moderate anxiety assists patient to cope with stresses of surgery. Low anxiety level may indicate that the patient is in denial. High anxiety may impair the patient's ability to learn and listen.)
   b. Offer support and help patient and family mobilize positive coping mechanisms.
   c. Answer questions and alleviates fears and misconceptions.
8. Surgical preparation.
   a. Shave anterior and lateral surfaces of the trunk and neck; shave entire body down to ankles (for coronary bypass).
   b. Shower or bathe per facility policy. Assist patient with antiseptic scrubs used on their chest prior to surgery.
   c. Give sedative and/or antibiotics before going to the operating room, as ordered.
   d. Ensure removable dental work, jewelry, and nail polish removed.

GERONTOLOGIC ALERT Older patients with underlying respiratory problems (ie, smoking, COPD, asthma) and debilitated patients are at greater risk for postoperative respiratory complications.

Complications

Complications following cardiac surgery can be divided into early complications (cardiovascular, pulmonary, renal, GI, and neuropsychologic) and late postoperative complications.

Early Complications

EVIDENCE BASE Sheth, K. N., & Nourollahzadeh, E. (2017). Neurologic complications of

cardiac and vascular surgery. *Handbook of Clinical Neurology, 141*, 573–592.Ha, A. C. T., Mazer, C. D., Verma, S., et al. (2016). Management of postoperative atrial fibrillation after cardiac surgery. *Current Opinion in Cardiology, 31*(2), 183–190.

---

1. Cardiovascular dysfunction or low output syndrome can occur as a result of decreased preload (from bleeding or volume loss), increased afterload, arrhythmias, cardiac tamponade, or myocardial depression with or without myocardial necrosis.
2. Postoperative bleeding can occur secondary to coagulopathy, uncontrolled hypertension, or inadequate hemostasis.
3. Cardiac tamponade results from bleeding into the pericardial sac or accumulation of fluids in the sac, which compresses the heart and prevents adequate filling of the ventricles. Cardiac tamponade should be suspected when there is low CO, hypotension, tachycardia, increased CVP, narrow pulse pressure, or sharp drop in chest tube output postoperatively.
4. Myocardial depression (impaired myocardial contractility), which can be reversible, occurs secondary as a result of myocardial necrosis in 15% of all CABG surgeries.
5. Perioperative MI continues to be a serious problem that can occur in 5% of patients with stable angina and up to 10% of patients with unstable angina postoperatively as a result of the surgical procedure.
6. Cardiac dysrhythmias commonly occur after heart surgery. Ischemia, hypoxia, electrolyte imbalances, alterations in autonomic nervous system, hypertension, and increased catecholamine levels, among others, may attribute to dysrhythmia development.
    a. Atrial arrhythmias may occur after CABG or after valvular surgery; can occur anytime during the first 2 to 3 weeks postoperatively, but peak incidence is 3 to 5 days. Studies suggest perioperative beta-blockade is an effective therapy for prevention.
    b. PVCs occur in 8.9% to 24% of patients, most frequently after aortic valve replacement and CABG.
7. Hypotension may be caused by inadequate cardiac contractility and reduction in blood volume or by mechanical ventilation (when the patient "fights" the ventilator or positive end-expiratory pressure is used), all of which can produce a reduction in CO.
8. Pulmonary complications occur as a result of intubation and coronary pulmonary bypass.
    a. Continuous pulse oximetry, arterial blood gas (ABG) studies, and chest x-ray are done frequently to monitor pulmonary function of a patient after heart surgery.
    b. Noncardiac pulmonary edema can occur immediately after surgery and can occur the first several days after surgery as a result of increased pulmonary capillary permeability.
    c. Pneumothorax can occur anytime postoperatively, especially when chest tubes are removed.
    d. Phrenic nerve damage can occur, resulting in diaphragmatic paralysis.
    e. Pulmonary emboli, although uncommon, can result from atrial fibrillation, heart failure, obesity, hypercoagulability, and immobilization.
    f. Older patients are at increased risk of developing pneumonia, atelectasis, and pulmonary effusions.

g. Be vigilant and report copious amounts of secretion or any changes in patient's secretion.

9. Renal insufficiency or failure can occur as a result of deficient perfusion (can be due to heart–lung machine), hemolysis, low CO before and after open-heart surgery, hypotension, and by use of vasopressor agents to increase blood pressure.
10. GI postoperative complications can include abdominal distention, ileus, gastroduodenal bleeding, cholecystitis, hepatic dysfunction, "shock liver syndrome," pancreatitis, mesenteric ischemia, diarrhea, or constipation.
11. Neuropsychologic complications postoperatively include ischemic stroke, neuropsychologic dysfunction, postcardiotomy delirium, and peripheral neurologic deficits.

GERONTOLOGIC ALERT Older patients postoperatively are more sensitive to hypovolemia, excessive bleeding, and cardiac tamponade, which affect preload and result in a decrease in CO.

GERONTOLOGIC ALERT Atrial fibrillation occurs in 35% of elderly patients postoperatively and may need to be treated with antiarrhythmics, cardioversion, and anticoagulants.

GERONTOLOGIC ALERT Neurologic complications increase disproportionate to cardiac risk in elderly patients.

Late Complications

1. Late complications of cardiac surgery usually occur after the 4th day of surgery and include postpericardiotomy syndrome, cardiac tamponade, and incisional wound infections.
2. Postpericardiotomy syndrome is a group of symptoms occurring in 10% to 40% of patients several days after cardiac surgery.
   a. The cause of postpericardiotomy syndrome is not certain, but it may result from anticardiac antibodies, viral etiology (such as cytomegalovirus), or other causes.
   b. Postpericardiotomy syndrome occurs as the result of tissue trauma, which triggers an autoimmune response and inflammation of the pericardial cavity, resulting in pericardial and severe pleural pain.
   c. Manifestations—fever, malaise, arthralgias, dyspnea, pericardial effusion, pleural effusion and friction rub, and pleural/pericardial pain.
   d. Treatment regimen may include corticosteroids, aspirin, or colchicine. Pericardiocentesis or thoracentesis may be needed for persistent effusion.

3. Cardiac tamponade can occur in 1% to 2% of patients and is commonly associated with administration of anticoagulants or antiplatelet therapy, usually occurring after 72 hours following surgery.
4. Wound infections, including sternal wound infections and mediastinitis, occur in 0.4% to 5% of all patients having cardiac surgery. Mortality rate associated with sternal wound infection and mediastinitis can vary between 8% and 45%.
    a. Wound infections usually appear 4 to 14 days postoperatively with symptoms of fever, leukocytosis, inflammation, and purulent drainage.
    b. *Staphylococcus epidermidis* and *Staphylococcus aureus* organisms are the most common causative organism, but the infection can be caused by a number of pathogens ranging from gram positives, gram negatives, or even fungi.
5. MIs (postoperative) can occur at a rate of 1.34% because of bypass time greater than 100 minutes and presence of unstable angina.
6. Constrictive pericarditis has an incidence of 0.2% to 2.0%. Risk factors reveal normal left ventricular function, warfarin administration, and inadequate drainage of early postoperative pericardial effusion as the significant causes.
7. Respiratory complications—chest wall pain and prolonged ventilation—more than 14 days of ventilatory support (morbidity rate of 9.9%).
8. Renal dysfunction—up to 40% developed transient oliguria, with 2% progressing to renal failure requiring dialysis. Postoperative renal dysfunction results from postoperative hypovolemia, anemia, hypotension, low output syndrome, sepsis, and pericardial tamponade.

Other Complications

1. Postperfusion syndrome—diffuse syndrome characterized by systemic inflammatory response syndrome.
2. Febrile complications—probably from body's reaction to tissue trauma or accumulation of blood and serum in pleural and pericardial spaces.
3. In older patients, decreased kidney function can increase the risk of developing drug toxicities, adverse reactions, oliguria, and renal failure.
4. Failure to wean from the ventilator because of underlying pulmonary disease or postoperative pulmonary complications.

Postoperative Management

1. Adequate oxygenation is ensured; respiratory insufficiency is common after open-heart surgery.
    a. Patients require intubation during cardiac surgery, and the majority of them continued to require mechanical ventilation after being transported to the cardiac surgery ICU.
    b. Chest x-ray taken immediately after surgery and daily thereafter to evaluate state of lung expansion and to detect atelectasis or pneumothorax and to demonstrate heart size and contour and confirm placement of central line, ET tube, and chest drains.
2. Hemodynamic monitoring during the immediate postoperative period for cardiovascular and respiratory

status and fluid and electrolyte balance to prevent or recognize complications.

3. Drainage of mediastinal and pleural chest tubes is monitored.
4. Fluid and electrolyte balance is monitored closely with daily weight.
5. Hypokalemia may be caused by inadequate intake, diuretics, vomiting, excessive NG drainage, and stress from surgery.
    a. Hyperkalemia may be caused by increased intake, red cell breakdown (from the pump, bleeding, or transfusion), acidosis, renal insufficiency, tissue necrosis, and adrenal cortical insufficiency.
    b. Hyponatremia may be due to reduction of total body sodium or to an increased water intake, causing a dilution of body sodium.
    c. Hypocalcemia may be due to alkalosis (which reduces the amount of calcium in the extracellular fluid) because hydrogen ions dissociate from serum albumin and more calcium binds to albumin, reducing ionized calcium level in the blood) and multiple blood transfusions.
    d. Hypercalcemia may cause dysrhythmias imitating those caused by digoxin toxicity.
6. Postoperative medications include:
    a. Aspirin daily as MI prophylaxis.
    b. Analgesics.
    c. Antihypertensives or antiarrhythmics, if needed.
    d. Beta-blockers.
    e. ACE inhibitors for patients with ejection fraction less than 30%.
    f. Antibiotics, if indicated.
7. Monitoring for complications.
8. Cardiac pacing, if indicated, by way of temporary pacing wires from the incision.

Nursing Diagnoses

- Anxiety related to fear of unknown, fear of death, and fear of pain.
- Impaired Gas Exchange related to alveolar capillary membrane changes, immobility, and altered blood flow.
- Decreased Cardiac Output related to mechanical factors: decreased preload and impaired contractility.
- Risk for Deficient Fluid Volume related to physiologic effects of heart–lung machine.
- Acute Pain related to sternotomy and leg incisions.
- Sleep Deprivation related to intensive care environment.
- Risk for Injury related to postoperative complications.

Nursing Interventions

Minimizing Anxiety

1. Orient to surroundings as soon as patient awakens from surgical procedure. Tell patient that the surgery is over and orient to location, time of day, and your name.

2. Allow family members to visit patient as soon as condition stabilizes. Encourage family members to talk to and touch patient. (Family members may be overwhelmed by intensive care environment.)
3. As patient becomes more alert, explain purpose of all equipment in environment. Continually orient patient to time and place. Make sure patient has glasses and hearing aids, if needed.
4. Administer anxiolytics, as directed.
5. Remove lines and tubing once medically appropriate.

Promoting Adequate Gas Exchange

1. Frequently check function of mechanical ventilator, patient's respiratory effort, and ABG levels.
2. Check ET tube placement (note location and measurement).
3. Auscultate chest for breath sounds. Crackles indicate pulmonary congestion; decreased or absent breath sounds indicate pneumothorax; rales may indicate pulmonary edema.
4. Sedate patient adequately to help tolerate ET tube and cope with ventilatory sensations. Implement ventilator care bundle (ie, routine mouth care with chlorhexidine, keep HOB at 30 degrees) to prevent ventilator-associated pneumonia.
5. Use chest physiotherapy for patients with lung congestion to prevent retention of secretions and atelectasis.
6. Promote coughing, deep breathing, and turning to keep airway patent, prevent atelectasis, and facilitate lung expansion. Have patient sit at least 30 degrees unless medically contraindicated.
7. Suction tracheobronchial secretions carefully. Prolonged suctioning leads to hypoxia and possible cardiac arrest.
8. Administer diuretics, as prescribed.
9. Institute ventilatory weaning protocol when patient is awake and can initiate own breaths and assist with extubation (see page 183), when indicated.

Maintaining Adequate Cardiac Output

1. Monitor cardiovascular status to determine effectiveness of CO. Continuous monitoring of blood pressure by way of intra-arterial line, heart rate, CVP, left atrial or PAP, and PCWP from monitor modules is observed, correlated with the patient's condition, and recorded.
2. Monitor and record urine output every hour (normal urinary output 0.5 to 1 mL/kg/hr).
3. Observe buccal mucosa, nail beds, lips, earlobes, and extremities for duskiness, cyanosis—late signs of low CO.
4. Feel the skin; cool, moist skin or weak pulses reveal lowered CO. Note temperature and color of extremities.
5. Monitor neurologic status.
    a. Observe for symptoms of hypoxia—restlessness, headache, confusion, dyspnea, hypotension, and cyanosis. Obtain ABG values and core temperature.
    b. Note the patient's neurologic status hourly in terms of level of responsiveness, response to verbal

commands and painful stimuli, pupillary size and reaction to light, and movement of extremities, handgrasp ability.

c. Monitor for and treat postoperative seizures.

Maintaining Adequate Fluid Volume

1. Administer IV fluids as ordered, but limit if signs of fluid overloading occur.
2. Keep intake and output flow sheets as a method of determining positive or negative fluid balance and the patient's fluid requirements.
   a. IV fluids (including flush solutions through arterial and venous lines) are considered intake.
   b. Measure postoperative chest drainage—should not exceed 200 mL/hr for first 4 to 6 hours.
3. Be alert to changes in serum electrolyte levels.
   a. Hypokalemia may cause dysrhythmias, digoxin toxicity, metabolic alkalosis, weakened myocardium, and cardiac arrest.
      i. Watch for specific ECG changes.
      ii. Replace electrolytes, as needed.
   b. Hyperkalemia may cause mental confusion, restlessness, nausea, weakness, and paresthesia of extremities. Treatment may include administering an ion-exchange resin and sodium polystyrene sulfonate, which binds the potassium or hemodialysis. Temporary treatment includes sodium bicarbonate, insulin (with dextrose), albuterol, and calcium.
   c. Hyponatremia may cause weakness, fatigue, confusion, seizures, and coma.
   d. Hypocalcemia may cause numbness and tingling in the fingertips, toes, ears, and nose, carpopedal spasm, muscle cramps, and tetany. Give replacement therapy, as needed.
   e. Hypercalcemia may cause digoxin toxicity.
      i. Treatment may include fluids, diuretics, calcitonin, or hemodialysis.
      ii. This condition may lead to asystole and death.
4. Monitor hematocrit and hemoglobin (frequency depends on hemodynamics and evidence of bleeding) and report any significant change in findings.
   a. Ensure that patient has current blood type and screen. Transfuse blood products, as ordered.
   b. Check coagulation tests, including prothrombin time, international normalized ratio, and partial thromboplastin time, if patient is coagulopathic, bleeding, or anticoagulated for mechanical device.

Relieving Pain

1. Examine surgical incision sites.
2. Record nature, type, location, duration of pain, and contributing factors.
3. Differentiate between incisional pain and anginal pain. Obtain ECG and have provider confirm if there are any changes.
4. Report restlessness and apprehension not corrected by analgesics—may be from hypoxia or a low output state.

5. Administer medications as prescribed, or monitor constant infusion to reduce amount of pain and to aid the patient in performing deep breathing and coughing exercises more effectively.
6. Assist patient to position of comfort.
7. Encourage early mobilization.

Promoting Sleep and Recovery

1. Watch for symptoms of postcardiotomy delirium (may appear after brief lucid period).
    a. Signs and symptoms include delirium (impairment of orientation, memory, intellectual function, judgment), transient perceptual distortions, visual and auditory hallucinations, disorientation, and paranoid delusions.
    b. Symptoms may be related to sleep deprivation, increased sensory output, disorientation to night and day, prolonged inability to speak because of ET intubation, age, and preoperative cardiac status.
2. Keep the patient oriented to time and place; notify the patient of procedures and expectations of cooperation.
3. Encourage family to visit at regular times—helps patient regain sense of reality.
4. Plan care to allow rest periods, day–night pattern, and uninterrupted sleep.
5. Encourage mobility as soon as possible.
    a. Keep environment as free as possible of excessive auditory and sensory input.
    b. Prevent bodily injury.
    c. Have physical therapy work with patient and provide analgesics prior to therapy.
6. Reassure patient and family that psychiatric disorders after cardiac surgery are usually transient.
7. Remove patient from the ICU as soon as possible. Allow patient to talk about psychotic episode—helps deal with and assimilate experience.

Avoiding Complications

1. Monitor ECG continuously for arrhythmias.
    a. Evaluate possible cause of dysrhythmias—inadequate oxygenation, electrolyte imbalance, MI, mechanical irritation (eg, pacing wires, invasive lines, chest tubes), and any vasopressor or inotropic medications.
    b. Treat dysrhythmias immediately because they may lead to decreased CO. Atrial or AV pacing is used to treat sinus bradycardia or junctional rhythm with heart rates less than 70 beats/minute.
2. Assess for signs of cardiac tamponade—arterial hypotension; rising CVP; rising left atrial pressure; muffled heart sounds; weak, thready pulse; jugular vein distention; and falling urine output.
    a. Check for diminished amount of drainage in the chest collection bottle; may indicate that fluid is accumulating elsewhere, reposition as needed to facilitate fluid drainage.
    b. Prepare for pericardiocentesis.
    c. Assist with echocardiogram to evaluate tamponade.
3. Check cardiac enzyme levels daily. Elevations may indicate MI. (Symptoms may be masked by the usual

postoperative discomfort.)

   a. Watch for decreased CO in the presence of normal circulating volume and filling pressure.
   b. Obtain serial ECGs and isoenzymes to determine extent of myocardial injury.
   c. Assess pain to differentiate myocardial pain from incisional pain.

4. Monitor for hypertension or hypotension.
   a. Mild systolic hypertension occurs in 48% to 55% of all CABG patients within the first 6 hours postoperatively.
   b. Hypotension may be caused by bleeding, hypovolemia, decreased systemic vascular resistance (eg, systemic inflammatory response syndrome), cardiogenic shock, tamponade, medications, or arrhythmias.
   c. Blood pressure goal following cardiac surgery is dependent on the patient's conditions (eg, carotid disease, renal disease, bleeding).
5. Initiate measures to prevent embolization such as antiembolic stockings, not putting pressure on popliteal space (leg crossing, raising knee gatch), and starting passive and active exercises.
   a. Assess for signs of DVT and pulmonary embolism.
   b. Maintain integrity of all invasive lines.
6. Monitor for bleeding.
   a. Watch for steady and continuous drainage of blood.
   b. Assess for arterial hypotension, low CVP, increasing pulse rate, and low left atrial pressure and PCWP.
   c. Prepare to administer blood products, IV solutions, or protamine sulfate, antifibrinolytics, DDAVP, or vitamin K.
   d. Prepare for potential return to surgery if bleeding persists (over 300 mL/hr) for 2 hours.
   e. Monitor hemoglobin levels; if the patient's hemoglobin drops below 8 g/dL, transfusions of red blood cells or platelets may be necessary.
   f. During the first 4 to 12 hours, blood recovered from mediastinal tubes can be autotransfused to the patient.
7. Be alert for fever and signs of infection. Check blood glucose levels as ordered.
   a. Administer prophylactic antibiotics, if ordered, for the first 48 hours.
   b. Control higher degrees of fever through use of hypothermia mattress.
   c. Evaluate for atelectasis, pleural effusion, or pneumonia if fever persists. (The most common cause of early postoperative fever [within 24 hours] is atelectasis.)
   d. Evaluate for urinary tract infection and wound infection.
   e. Draw blood cultures to rule out infectious cause if fever persists.
8. Measure urine volume; less than 0.5 to 1 mL/kg/hr can indicate decreased renal function.
   a. Monitor BUN and serum creatinine levels as well as urine and serum electrolyte levels.
   b. Give rapid-acting diuretics and/or inotropic drugs (dopamine, dobutamine) to increase CO and renal

blood flow.

c. Prepare the patient for peritoneal dialysis or hemodialysis if indicated. (Renal insufficiency may produce serious cardiac dysrhythmias.)

Community and Home Care Considerations

Preparing the patient with cardiovascular disease or after cardiac surgery for the return home and optimizing the patient's health status in the home are important nursing functions. The key areas on which to focus include assessment, education, and evaluating responses.

1. Perform a thorough assessment of the patient's clinical condition, functional status, and home safety and support systems. Based on assessment, determine the patient's need for supportive services.
2. Coordinate services such as home health aides.
3. Refer patients to area meal delivery service as appropriate. These services provide special diets in most cases (eg, low sodium or low cholesterol).
4. Coordinate outpatient cardiac rehabilitation services as appropriate.
5. Establish outpatient or home-based physical and occupational therapy as appropriate for graduated exercise and energy conservation techniques.
6. If therapist recommends inpatient rehabilitation, coordinate with facility social worker/discharge planner to find a rehabilitation facility suited for patient as well as his or her family.
7. Educate patient, family, and caregivers about potential complications and medication regimen.

TRANSITIONAL CARE ALERT Medication management is a key issue when a cardiac surgery patient is leaving the hospital. Ensure that patient is discharged with an accurate medication list, and clear instructions on what has changed compared to previous home medications. Ensure that prescriptions are given to the patient or transmitted to chosen pharmacy and that insurance coverage of medications and cost of all medications have been determined.

Patient Education and Health Maintenance

Note: Specific guidelines will vary slightly among facilities and health care providers. Check facility policy and orders.

1. Instruct about activities.
   a. Increase activities gradually within limits. (Avoid strenuous activities until after exercise stress testing.)
   b. Take short rest periods.
   c. Avoid lifting more than 20 pound (9.1 kg).
   d. Participate in activities that do not cause pain or discomfort.
   e. Increase walking time and distance each day.

f. Stairs (one to two times daily) the first week; increase as tolerated.

g. Avoid large crowds at first.

h. Avoid driving until after first postoperative checkup.

i. Resumption of sexual relations parallels ability to participate in other activities.

   i. Usually may resume sexual activity 2 weeks after surgery.

   ii. Avoid sexual activity if tired or after heavy meal.

   iii. Consult health care provider if chest discomfort, difficult breathing, or palpitations occur and last longer than 15 minutes after intercourse.

j. Return to work after first postoperative checkup, as advised by health care provider.

2. Expect some chest discomfort.

3. Advise about diet.

   a. Some patients are placed on minimum salt restriction (eg, no salt added at table); cholesterol may be limited. Have a dietitian talk to the patient and family regarding diet.

   b. Weigh daily and report weight gain of more than 5 pound (2.3 kg) per week.

   c. If the patient is taking warfarin, advise patient not to change normal dietary habits, but to maintain similar intake pattern each day to prevent changes in INR.

4. Tight blood glucose control is recommended (keeping blood sugars 80 to 110 mg/dL) to prevent sternal wound infection.

5. Teach patient and family about wound care and how to avoid infections.

6. Teach about medications.

   a. Label all medications; give purposes and adverse effects.

   b. Patients with mechanical valves may continue warfarin regimen indefinitely. Explain bleeding precautions and need for periodic laboratory studies.

7. Advise patients with prosthetic valves:

   a. Pregnancy is usually discouraged because of anticoagulation therapy.

   b. Need for antibiotic coverage before dental and surgical procedures.

   c. Patients taking anticoagulants should watch for bleeding and should avoid use of aspirin (and many other drugs)—interferes with action of warfarin.

8. Advise the patient to carry an identification card stating cardiac condition and medications being taken.

9. Encourage compliance with rehabilitation and exercise program after exercise stress testing.

10. Inform the patient whom to contact (and how) in case of an emergency.

11. See also section on patient education after MI, page 280, and patient education about infective endocarditis, page 289.

12. Explore community support groups such as AHA (*www.americanheart.org*).

13. Be diligent in providing older patients with education and discharge instructions that they will be able to follow because of sensory impairments, immobility, and transportation barriers.

GERONTOLOGIC ALERT Older patients are extremely vulnerable to complications because of decreased functional ability and the normal process of aging.

Evaluation: Expected Outcomes

- Verbalizes understanding of surgical procedure, reduction of fear.
- Extubated 24 hours postoperative; spontaneous unlabored respirations 14 to 18 per minute.
- Blood pressure and heart rate stable; adequate urine output.
- Serum electrolytes within normal range.
- Verbalizes reduced pain.
- Sleeps for 2- to 3-hour intervals during night; oriented to time and place; no hallucinations.
- No bleeding noted; afebrile; ECG shows normal sinus rhythm.

Nursing Care Plan 13-1

Caring for a Patient with Acute Myocardial Infarction

Mr. M. is a 60-year-old male admitted to your unit with a diagnosis of an acute inferior wall myocardial infarction (MI). From your assessment and knowledge of acute MI, you develop your care plan.

Subjective data: Mr. M. is complaining of severe, crushing chest pain unrelieved by rest, which has lasted for 2 hours. The pain is substernal and does not radiate. He tells you that he smokes two packs of cigarettes per day, is a manager at an electronics firm, and that his father died at age 59 from a heart attack.

Objective data: Vital signs: pulse, 110 and irregular; blood pressure (BP), 90/68 mm Hg; respirations, 28 breaths/minute. His cardiac monitor shows sinus tachycardia with frequent premature ventricular contractions (PVCs), and his 12-lead electrocardiogram (ECG) shows ST elevation in leads II, III, and AVF. He has no significant Q waves at this time. His heart sounds are normal except for the irregularity, and his lungs are clear. He is pale, diaphoretic, and clutching his chest.

NURSING DIAGNOSIS

Acute Pain related to an imbalance in oxygen supply and demand.

GOAL/EXPECTED OUTCOME

Pain will be reduced.

Nursing Interventions	Rationale	Actual Outcomes (Evaluation)
1. Position Mr. M. in bed in semi-Fowler's position. Handle carefully while providing initial care.	1. Allows for rest and adequate chest excursion, to increase available oxygen, and to decrease cardiac work.	1. Resting in semi-Fowler's position.
2. Administer oxygen by nasal cannula at 2 L/min. Maintain O_2 saturation at 95% or above. Encourage slower, deep breaths as necessary.	2. Increases oxygen supply. May decrease pain and PVCs.	2. Color improved and verbalizes decreased pain.
3. Administer nitroglycerin and morphine based on vital signs and pain relief. Hold nitrate if SBP < 90, HR < 50 or > 100, suspected RV infarction, or ingestion of phosphodiesterase inhibitor such as sildenafil within 48 hours.	3. Both medications help to alleviate pain by decreasing venous return to the heart, thereby decreasing cardiac work. Morphine also helps to decrease the patient's sensation of pain. Nitrates may exacerbate hypotension.	3. Verbalizes decreased pain, from level 7 to level 3 (on scale of 0 to 10).
4. Monitor BP before administration and 10 minutes after each dose. Place patient in supine position to minimize hypotension.	4. Both medications may decrease BP because both decrease venous return. Continuous intra-arterial BP monitoring may be used if condition warrants.	4. BP remains stable with a mean arterial pressure of 60 mm Hg or above.
5. Attach electrodes for continuous bedside cardiac monitor. Monitor heart rate and rhythm frequently.	5. Increased rate may indicate heart block; dysrhythmias are common initially, increased frequency suggests ischemia.	5. Heart rate <90 beats/minute; normal sinus rhythm.
6. Offer support and reassurance to patient that pain relief is a priority. Encourage patient to report increasing pain. Perform pain assessment regularly.	6. Pain perception can be reduced by reducing anxiety. Increasing pain may indicate increasing ischemia.	6. Pain reduced from 10/10 to 5/10 after 30 minutes.

NURSING DIAGNOSIS

Decreased Cardiac Output related to decreased cardiac contractility and dysrhythmias.

GOAL (EXPECTED OUTCOME)

Cardiac output will improve.

Nursing Interventions	Rationale	Actual Outcomes (Evaluation)
1. Administer IV fluids as ordered.	1. IV fluid may be necessary to compensate for the decreased venous return caused by nitrates and morphine.	1. Improved BP.
2. Monitor closely for dyspnea, crackles, and S_3, which may indicate developing left-sided heart failure.	2. Left-sided heart failure may develop as a result of the decreased myocardial contractility and/or the administration of excess IV fluids.	2. Lungs clear; adequate respiratory rate; heart sounds normal.
3. Monitor urine output hourly.	3. A decrease in urine output may indicate a decrease in renal blood flow.	3. Urine output >30 mL/hr.
4. Monitor mental status for drowsiness, confusion, restlessness, or disorientation.	4. A change in mental status may indicate a decrease in cardiac output.	4. Remains alert and oriented.
5. Evaluate skin and nail bed color and temperature and quality of major arterial pulses.	5. Pallor and cool, clammy skin are associated with vasoconstriction secondary to reduced CO. Weak pulse or presence of pulsus alternans indicate decreased CO.	5. Skin warm and dry with good capillary refill. Radial, femoral, and pedal pulses palpable.
6. Employ hemodynamic monitoring: central venous pressure (CVP) and pulmonary artery pressure (PAP) by way of a pulmonary artery catheter; calculate CO and CI and systemic vascular resistance.	6. These parameters will help to guide fluid volume administration, vasoactive drug administration, and assess cardiac performance.	6. CVP, PAP, pulmonary capillary wedge pressure, CO, CI, and systemic vascular resistance remain within normal limits.
7. Interpret rhythm strip at least every 4 hours, more frequently as condition warrants. Administer antiarrhythmics, if indicated. Anticipate reperfusion dysrhythmias after fibrinolytic therapy. Report electrolyte values that may increase risk of dysrhythmias. Keep emergency equipment at bedside.	7. Dysrhythmias such as PVCs result in a decreased stroke volume and less coronary artery filling time. Frequent monitoring, especially during the first few hours of an acute MI and during fibrinolytic therapy administration, is necessary to prevent and treat lethal dysrhythmias.	7. PVCs decreasing in frequency.
8. Administer vasopressors as directed; titrate to goal BP and/or MAP.	8. Administration of vasopressors with acute MI is controversial in that they may cause an increase in systemic vascular resistance, which increases cardiac work.	8. BP improved without worsening chest pain or ECG changes.

Coronary Artery Disease

EVIDENCE BASE Smith, J., Negrelli, J., Manek, M., et al. (2015). Diagnosis and management of acute coronary syndrome: An evidence-based update. *Journal of the American Board of Family Medicine, 28*(2), 283–293.

Fihn, S. D., Blankenship, J. C., Alexander, K. P., et al. (2014). 2014 ACC/AHA/AATS/PCNA/SCAI/STS focused update of the guideline for the diagnosis and management of patients with stable ischemic heart disease: A report of the American College of Cardiology/American Heart Association Task Force on Practice Cardiovascular Guidelines, and the American Association for Thoracic Surgery, Preventive Cardiovascular Nurses Association, Society for Cardiovascular Angiography and Interventions, and Society of Thoracic Surgeons. *Circulation, 130*, 1749–1767.

Coronary artery disease (CAD) is the leading cause of death worldwide. CAD is characterized by the accumulation of plaque within the layers of the coronary arteries. The plaques progressively enlarge, thicken, and calcify, causing a critical narrowing (greater than 70% occlusion) of the coronary artery lumen, resulting in a decrease in coronary blood flow and an inadequate supply of oxygen to the heart muscle.

Acute coronary syndrome (ACS) is an umbrella term that is used to describe many of the complications associated with CAD. These include unstable angina, non–ST-elevation myocardial infarction (NSTEMI), and ST-elevation myocardial infarction (STEMI).

Pathophysiology and Etiology

1. The most widely accepted cause of CAD is atherosclerosis (see Figure 13-1), which is the gradual accumulation of plaque within an artery forming an atheroma. Plaque consists of lipid-filled macrophages (foam cells), fibrin, cellular waste products, and plasma proteins, covered by a fibrous outer layer (smooth muscle cells and dense connective tissue).
    a. When the endothelium is injured by being exposed to low-density lipoproteins, by-products of cigarette smoke, hypertension, hyperglycemia, infection, and increased homocysteine, hyperfibrinogenemia, and lipoprotein(a), an inflammatory response occurs, making the endothelium sticky and thereby attracting adhesion molecules.
    b. Over time, the plaque thickens, extends, and calcifies, causing narrowing of the lumen.
    c. Eventual hemorrhage and ulceration of the plaque may cause significant coronary obstruction.
2. Angina pectoris, caused by inadequate blood flow to the myocardium, is the most common manifestation of CAD.
    a. Angina is usually precipitated by physical exertion or emotional stress, which puts an increased demand on the heart to circulate more blood and oxygen.
    b. The ability of the coronary artery to deliver blood to the myocardium is impaired because of

obstruction by a significant coronary lesion (greater than 70% narrowing of the vessel).

c. Angina can also occur in other cardiac problems, such as arterial spasm, aortic stenosis, cardiomyopathy, or uncontrolled hypertension.

d. Noncardiac causes include anemia, fever, thyrotoxicosis, and anxiety/panic attacks.

3. ACS is caused by a decrease in the oxygen available to the myocardium because of:

a. Unstable or ruptured atherosclerotic plaque.

b. Coronary vasospasm.

c. Atherosclerotic obstruction without clot or vasospasm.

d. Inflammation or infection.

e. Unstable angina because of a noncardiac cause.

f. Thrombus formation with subsequent coronary artery occlusion (the most common cause) (see "Myocardial Infarction," page 274).

4. Risk factors for the development of CAD include:

a. Nonmodifiable: age (risk increases with age), male sex (women typically suffer from heart disease 10 years later than men because of the postmenopausal decrease in cardiac-protective estrogen), race (nonwhite populations have increased risk), and family history.

b. Modifiable: elevated lipid levels, hypertension, obesity, tobacco use, metabolic syndrome (obesity, hypertension, and diabetes mellitus), sedentary lifestyle, and stress.

c. Recent studies have shown that there are new risk factors associated with the development of CAD. These include increased levels of homocysteine, fibrin, and lipoprotein(a) and infection or inflammation (measured by C-reactive protein [CRP]).

d. The American Heart Association (AHA) also lists left ventricular hypertrophy (LVH) as a risk factor.

5. An atherosclerotic cardiovascular disease (ASCVD) risk assessment every 4 to 6 years is promoted for short-term and long-term prediction of the development of cardiovascular disease based on age, sex, race, lipid panel, systolic blood pressure, blood pressure medication use, smoking status, and diabetes status. Additional risk markers are diastolic blood pressure, chronic kidney disease, body mass index (BMI), and family history.

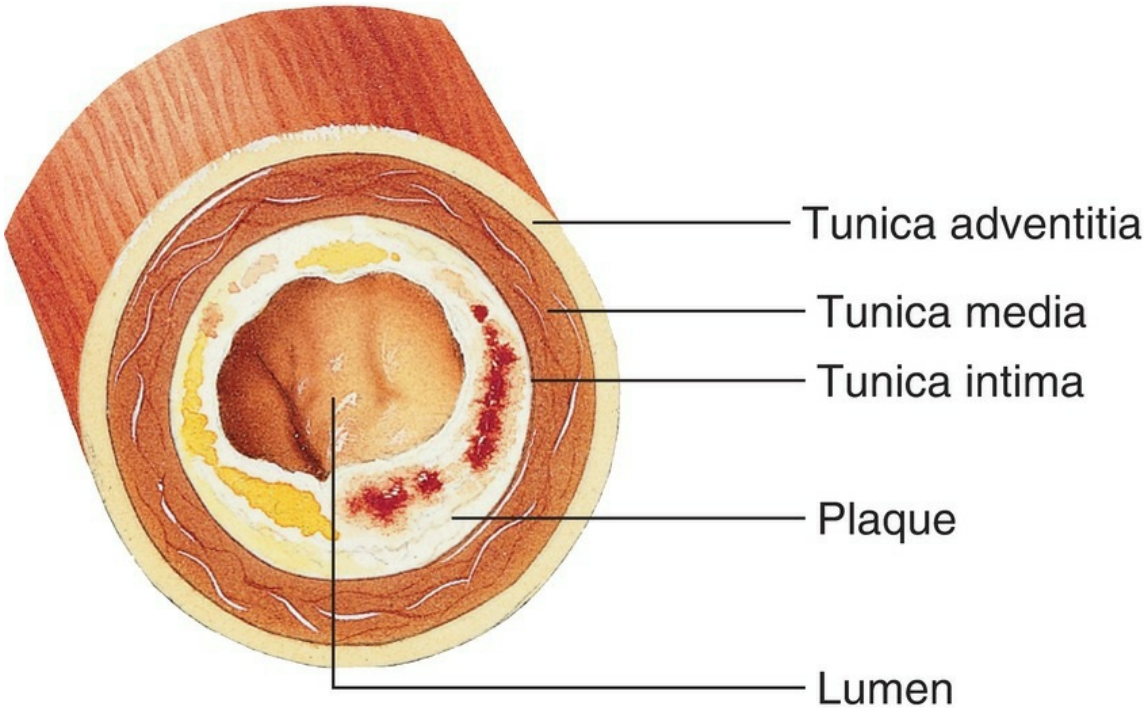

Figure 13-1. The pathogenesis of atherosclerosis.

EVIDENCE BASE Goff, D., Lloyd-Jones, D., D'Agostino, R. Sr., et al. (2014). Assessing cardiovascular risk: Systematic evidence review from the Risk Assessment Work Group. *Journal of the American College of Cardiology, 63*(25), 2935–2959.

Clinical Manifestations

See Standards of Care Guidelines 13-1

STANDARDS OF CARE GUIDELINES 13-1

Chest Pain

- Thoroughly evaluate any complaint of chest pain.
- Be alert to those at highest risk for myocardial infarction (MI)—smokers, those with hypertension, diabetes, or hyperlipidemia—but do not discount that MI may occur in those without risk factors.
- Be alert to common alternative presentation of coronary artery disease and MI in women, diabetics, and older patients (nausea, indigestion, fatigue).
- Notify health care provider and obtain electrocardiogram for complaint of chest pain.
- For chest pain not relieved by rest or nitroglycerin, assist and advise patient to obtain emergency care immediately. Call 911 for emergency response team if pain is consistent with MI.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative

measures and approaches.

Chronic Stable Angina Pectoris

Chest pain or discomfort that is provoked by exertion or emotional stress and relieved by rest and nitroglycerin.

1. Character—substernal chest pain, pressure, heaviness, or discomfort. Other sensations include a squeezing, aching, burning, choking, strangling, and/or cramping pain.
   a. Pain may be mild or severe and typically presents with a gradual buildup of discomfort and subsequent gradual fading.
   b. May produce numbness or weakness in the arms, wrists, or hands.
   c. Associated symptoms include diaphoresis, nausea, indigestion, dyspnea, tachycardia, and increase in blood pressure.
   d. Women may experience atypical symptoms of chest pain, such as jaw pain, shortness of breath, or indigestion. Patients with diabetes or history of heart transplant may not experience chest pain.
2. Location—behind middle or upper third of the sternum; the patient will generally make a fist over the site of the pain (positive Levine sign, indicating diffuse deep visceral pain) rather than point to it with his or her finger.
3. Radiation—usually radiates to the neck, jaw, shoulders, arms, hands, and posterior intrascapular area. Pain occurs more commonly on the left side than the right.
4. Duration—usually lasts 2 to 15 minutes after stopping activity; nitroglycerin relieves pain within 1 minute.
5. Other precipitating factors—exposure to weather extremes, eating a heavy meal, and sexual intercourse all increase the workload of the heart, thus increasing oxygen demand.

Unstable (Preinfarction) Angina Pectoris

Chest pain occurring at rest; no increase in oxygen demand is placed on the heart, but an acute lack of blood flow to the heart occurs because of coronary artery spasm or the presence of an enlarged plaque or hemorrhage/ulceration of a complicated lesion. Critical narrowing of the vessel lumen occurs abruptly in either instance.

1. A change in frequency, duration, and intensity of stable angina symptoms is indicative of progression to unstable angina.
2. Unstable angina pain lasts longer than 10 minutes, is unrelieved by rest or sublingual nitroglycerin, and mimics signs and symptoms of impending MI.

NURSING ALERT Unstable angina can cause sudden death or result in MI. Early recognition and treatment are imperative to prevent complications.

Silent Ischemia

The absence of chest pain with documented evidence of an imbalance between myocardial oxygen supply and demand (ST depression of 1 mm or more) as determined by electrocardiography (ECG), exercise stress test, or ambulatory (Holter) ECG monitoring.

1. Silent ischemia most commonly occurs during the first few hours after awakening (circadian event) because of an increase in sympathetic nervous system activity, causing an increase in heart rate, blood pressure, coronary vessel tone, and blood viscosity.

Diagnostic Evaluation

1. Characteristic chest pain and clinical history.
2. Nitroglycerin test—relief of pain with nitroglycerin.
3. Blood tests.
   a. Cardiac markers, creatine kinase (CK) and its isoenzyme CK-MB, and troponin-I to determine the presence and severity if acute cardiac insult is suspected.
   b. HbA_{1C} and fasting lipid panel to rule out modifiable risk factors for CAD.
   c. Coagulation studies, CRP, homocysteine, and lipoprotein(a) (increased levels are associated with a twofold risk in developing CAD).
   d. Hemoglobin to rule out anemia, which may reduce myocardial oxygen supply.
4. Twelve-lead ECG—may show LVH, ST- and T-wave changes (2 mm or greater ST elevation in contiguous leads for male and 1.5 mm or greater in female diagnostics for myocardial infarction), arrhythmias, and Q waves.
5. ECG stress testing—progressive increases of speed and elevation while walking on a treadmill increase the workload of the heart. ST- and T-wave changes occur if myocardial ischemia is induced.
6. Radionuclide imaging—a radioisotope, thallium-201, injected during exercise is imaged by camera. Low uptake of the isotope by heart muscle indicates regions of ischemia induced by exercise. Images taken during rest show a reversal of ischemia in those regions affected.
7. Radionuclide ventriculography (gated blood pool scanning)—red blood cells tagged with a radioisotope are imaged by camera during exercise and at rest. Wall motion abnormalities of the heart can be detected and ejection fraction estimated.
8. Cardiac catheterization—coronary angiography performed during the procedure determines the presence, location, and extent of coronary lesions.
9. Positron emission tomography (PET)—cardiac perfusion imaging with high resolution to detect very small perfusion differences caused by stenotic arteries. Not available in all settings.
10. Coronary computed tomography angiography (CTA)—scans the coronary arteries that supply blood to the heart and determines whether they are narrowed by plaques. Three-dimensional images can be created. Recommended for low- to intermediate-risk patients with chest pain.

Management

Drug Therapy

Antianginal medications (nitrates, beta-adrenergic blockers, calcium channel blockers, and angiotensin-converting enzyme [ACE] inhibitors) are used to maintain a balance between oxygen supply and demand. Coronary vessel relaxation promotes blood flow to the heart, thereby increasing oxygen supply. Reduction of the workload of the heart decreases oxygen demand and consumption. The goal of drug therapy is to maintain a balance between oxygen supply and demand.

1. Nitrates—caused by generalized vasodilation throughout the body. Nitrates can be administered via oral, sublingual, transdermal, intravenous (IV), or intracoronary (IC) route and may provide short- or long-acting effects.
   a. Short-acting nitrates (sublingual) provide immediate relief of acute anginal attacks or prophylaxis if taken before activity.
   b. Long-acting nitrates prevent anginal episodes and/or reduce severity and frequency of attacks.
2. Beta-adrenergic blockers—inhibit sympathetic stimulation of receptors that are located in the conduction system of the heart and in heart muscle.
   a. Some beta-adrenergic blockers inhibit sympathetic stimulation of receptors in the lungs as well as the heart ("nonselective" beta-adrenergic blockers); vasoconstriction of the large airways in the lung occurs; generally contraindicated for patients with chronic obstructive lung disease or asthma.
   b. "Cardioselective" beta-adrenergic blockers (in recommended dose ranges) affect only the heart and can be used safely in patients with lung disease.
3. Calcium channel blockers—inhibit movement of calcium within the heart muscle and coronary vessels; promote vasodilation and prevent/control coronary artery spasm.
4. ACE inhibitors—have therapeutic effects by remodeling the vascular endothelium and have been shown to reduce the risk of worsening angina.
5. Antilipid agents—reduce total cholesterol and triglyceride levels and have been shown to assist in the stabilization of plaque.
6. Antiplatelet agents—decrease platelet aggregation to inhibit thrombus formation.
7. Folic acid and B complex vitamins—treat increased homocysteine levels.

Percutaneous Coronary Interventions

1. Percutaneous transluminal angioplasty.
   a. A balloon-tipped catheter is placed in a coronary vessel narrowed by plaque.
   b. The balloon is inflated and deflated to stretch the vessel wall and flatten the plaque (see page 255).
   c. Blood flows freely through the unclogged vessel to the heart.
2. IC atherectomy.
   a. A blade-tipped catheter is guided into a coronary vessel to the site of the plaque.
   b. Depending on the type of blade, the plaque is cut, shaved, or pulverized and then removed.
   c. Requires a larger catheter introduction sheath, so its use is limited to larger vessels.

3. IC stent.
    a. A diamond mesh tubular device is placed in the coronary vessel.
    b. Prevents restenosis by providing a "skeletal" support.
    c. Drug-eluting stents contain an anti-inflammatory drug, which decreases the inflammatory response within the artery.

Other Interventional Strategies

1. Coronary artery bypass graft (CABG) surgery.
    a. A graft is surgically attached to the aorta, and the other end of the graft is attached to a distal portion of a coronary vessel.
    b. Bypasses obstructive lesions in the vessel and returns adequate blood flow to the heart muscle supplied by the artery (see page 260).
    c. Recommended for patients with diabetes mellitus, multivessel CAD, and acceptable surgical risk instead of PCI.
2. Transmyocardial revascularization—by means of a laser beam, small channels are formed in the myocardium to encourage new blood flow.

Secondary Prevention

EVIDENCE BASE Eckel, R., Jakicic, J., Ard, J., et al. (2014). 2013 AHA/ACC guideline on lifestyle management to reduce cardiovascular risk: A report of the American College of Cardiology American/Heart Association Task Force on Practice Guidelines. *Circulation, 129*(25 Suppl 2), S76–S99.

---

1. Cessation of smoking.
2. Control of high blood pressure (below 130/85 mm Hg in those with renal insufficiency or heart failure; below 130/80 mm Hg in those with diabetes; below 140/90 mm Hg in all others).
3. Diet low in saturated fat (less than 7% of calories), cholesterol (less than 200 mg/day), trans fatty acids, sodium (less than 2 g/day), alcohol (2 or fewer drinks/day in men, 1 or fewer in women).
4. Low-dose aspirin daily for those at high risk.
5. Physical exercise (at least 30 to 60 minutes of moderate-intensity exercise most days).
6. Weight control (ideal body mass index 18.5 to 24.9 kg/m^2); waist circumference less than 40 inches for men and less than 35 inches for women.
7. Control of diabetes mellitus (fasting glucose less than 110 mg/dL and HbA_{1C} less than 7%).
8. Control of blood lipids with low-density lipoprotein (LDL) goal less than 100 mg/dL (less than 70 mg/dL in high-risk patients).

Complications

1. Sudden death because of lethal dysrhythmias.
2. Heart failure.
3. MI.

Nursing Assessment

1. Ask patient to describe anginal attacks.
    a. When do attacks tend to occur? After a meal? After engaging in certain activities? After physical activities in general? After visits of family/others?
    b. Where is the pain located? Does it radiate?
    c. Was the onset of pain sudden? Gradual?
    d. How long did it last—Seconds? Minutes? Hours?
    e. Was the pain steady and unwavering in quality?
    f. Is the discomfort accompanied by other symptoms? Sweating? Light-headedness? Nausea? Palpitations? Shortness of breath?
    g. Is there anything that makes it worse (such as moving, deep breathing, food)?
    h. How is the pain relieved? How long does it take for pain relief?
2. Obtain a baseline 12-lead ECG.
3. Assess patient's and family's knowledge of disease.
4. Identify patient's and family's level of anxiety and use of appropriate coping mechanisms.
5. Gather information about the patient's cardiac risk factors. Use the patient's age, total cholesterol level, LDL and HDL levels, systolic BP, and smoking status to determine the patient's 10-year risk for development of CHD according to the Framingham Risk Scoring Method.
6. Evaluate patient's medical history for such conditions as diabetes, heart failure, previous MI, or obstructive lung disease that may influence choice of drug therapy.
7. Identify factors that may contribute to noncompliance with prescribed drug therapy.
8. Review renal and hepatic studies and complete blood count (CBC).
9. Discuss with patient current activity levels. (Effectiveness of antianginal drug therapy is evaluated by patient's ability to attain higher activity levels.)
10. Discuss patient's beliefs about modification of risk factors and willingness to change.

Nursing Diagnoses

- Acute Pain related to an imbalance in oxygen supply and demand.
- Decreased Cardiac Output related to reduced preload, afterload, contractility, and heart rate secondary to hemodynamic effects of drug therapy.
- Anxiety related to chest pain, uncertain prognosis, and threatening environment.

Nursing Interventions

Relieving Pain

1. Determine intensity of patient's angina.
    a. Ask patient to compare the pain with other pain experienced in the past and, on a scale of 0 (no pain) to 10 (worst pain), rate current pain.
    b. Observe for associated signs and symptoms, including diaphoresis, shortness of breath, protective body posture, dusky facial color, and/or changes in level of consciousness (LOC).
2. Position patient for comfort; Fowler position promotes ventilation.
3. Administer oxygen, if appropriate.
4. Obtain BP, apical heart rate, and respiratory rate.
5. Obtain a 12-lead ECG.
6. Administer antianginal drug(s), as prescribed.
7. Report findings to health care providers.
8. Monitor for relief of pain and note duration of anginal episode.
9. Take vital signs every 5 to 10 minutes until angina pain subsides.
10. Monitor for progression of stable angina to unstable angina: increase in frequency and intensity of pain, pain occurring at rest or at low levels of exertion, pain lasting longer than 5 minutes.
11. Determine level of activity that precipitated anginal episode.
12. Identify specific activities patient may engage in that are below the level at which anginal pain occurs.
13. Reinforce the importance of notifying nursing staff when angina pain is experienced.

Maintaining Cardiac Output

1. Carefully monitor the patient's response to drug therapy.
    a. Take BP and heart rate in a sitting and a lying position on initiation of long-term therapy (provides baseline data to evaluate for orthostatic hypotension that may occur with drug therapy).
    b. Recheck vital signs as indicated by onset of action of drug and at the time of drug's peak effect.
    c. Note changes in BP of more than 10 mm Hg and changes in heart rate of more than 10 beats/minute.
    d. Note patient complaints of headache (especially with use of nitrates) and dizziness (more common with ACE inhibitors).
        i. Administer or teach self-administration of analgesics, as directed, for headache.
        ii. Encourage supine position to relieve dizziness (usually associated with a decrease in BP; preload is enhanced by lying supine, thereby providing a temporary increase in BP).
    e. Institute continuous ECG monitoring or obtain 12-lead ECG as directed. Interpret rhythm strip every 4 hours and as needed for patients on continuous monitoring (beta-adrenergic blockers and calcium channel blockers can cause significant bradycardia and varying degrees of heart block).
    f. Evaluate for development of heart failure (beta-adrenergic blockers and some calcium channel blockers have negative inotropic properties).

i. Obtain daily weight and intake and output.
ii. Auscultate lung fields for crackles and assess for shortness of breath and decrease in oxygen saturation.
iii. Monitor for the presence of edema.
iv. Monitor central venous pressure (CVP), if applicable.
v. Assess jugular vein distention.
vi. Assess liver engorgement and check liver function studies.

g. Monitor laboratory tests as indicated (cardiac markers).

2. Monitor for poor perfusion.
   a. Decreasing blood pressure.
   b. Weak pulses.
   c. Dizziness.
   d. Shortness of breath.
   e. Cool extremities.
   f. Pale.
   g. Diaphoretic.
3. Be sure to remove previous nitrate patch or paste before applying new paste or patch (prevents hypotension) and to reapply on different body site. To decrease nitrate tolerance, transdermal nitroglycerin may be worn only in the daytime hours and taken off at night when physical exertion is decreased.
4. Be alert to adverse reaction related to abrupt discontinuation of beta-adrenergic blocker and calcium channel blocker therapy. These drugs must be tapered to prevent a "rebound phenomenon": tachycardia, increase in chest pain, hypertension.
5. Discuss use of chromotherapeutic therapy with health care provider (tailoring of antianginal drug therapy to the timing of circadian events).
6. Report adverse drug effects to health care provider.

Decreasing Anxiety

1. Rule out physiologic etiologies for increasing or new-onset anxiety before administering as-needed sedatives. Physiologic causes must be identified and treated in a timely fashion to prevent irreversible adverse or even fatal outcomes; sedatives may mask symptoms delaying timely identification and diagnosis and treatment.
2. Assess patient for signs of hypoperfusion, auscultate heart and lung sounds, obtain a rhythm strip, and administer oxygen, as prescribed. Notify the health care provider immediately.
3. Document all assessment findings, health care provider notification and response, and interventions and response.
4. Explain to patient and family reasons for hospitalization, diagnostic tests, and therapies administered.

5. Encourage patient to verbalize fears and concerns about illness through frequent conversations—conveys to patient a willingness to listen.
6. Answer patient's questions with concise explanations.
7. Administer medications to relieve patient's anxiety as directed. Sedatives and tranquilizers may be used to prevent attacks precipitated by aggravation, excitement, or tension.
8. Explain to patient the importance of anxiety reduction to assist in control of angina. (Anxiety and fear put increased stress on the heart, requiring the heart to use more oxygen.) Teach relaxation techniques.
9. Discuss measures to be taken when an anginal episode occurs. (Preparing patient decreases anxiety and allows patient to describe angina accurately.)
    a. Review the questions that will be asked during anginal episodes.
    b. Review the interventions that will be employed to relieve anginal attacks.

Patient Education and Health Maintenance

Instruct Patient and Family about CAD

1. Assess readiness to learn (pain free, shows interest, and comfortable), learning style, cognition, and education level.
2. Review the chambers of the heart and the coronary artery system, using a diagram of the heart.
3. Show patient a diagram of a clogged artery; explain how the blockage occurs; point out on the diagram the location of patient's lesions.
4. Explain what angina is (a warning sign from the heart that there is not enough blood and oxygen because of the blocked artery or spasm).
5. Review specific risk factors that affect CAD development and progression; highlight those risk factors that can be modified and controlled to reduce risk.
6. Discuss the signs and symptoms of angina, precipitating factors, and treatment for attacks. Stress to patient the importance of treating angina symptoms at once.
7. Distinguish for patient the different signs and symptoms associated with stable angina versus preinfarction angina.
8. Give patient and family handouts to review and encourage questions for a later teaching session.

Identify Suitable Activity Level to Prevent Angina

Advise the patient about the following:

1. Participate in a normal daily program of activities that do not produce chest discomfort, shortness of breath, and undue fatigue. Spread daily activities out over the course of the day; avoid doing everything at one time. Begin regular exercise regimen, as directed by health care provider.
2. Avoid activities known to cause anginal pain—sudden exertion, walking against the wind, extremes of temperature, high altitude, and emotionally stressful situations, which my accelerate heart rate, raise BP, and increase cardiac workload.
3. Refrain from engaging in physical activity for 2 hours after meals. Rest after each meal, if possible.

4. Do not perform activities requiring heavy effort (eg, carrying heavy objects).
5. Try to avoid cold weather, if possible; dress warmly and walk more slowly. Wear scarf over the nose and mouth when in cold air.
6. Lose weight, if necessary, to reduce cardiac load.
7. Instruct patient that sexual activity is not prohibited and should be discussed with health care provider.

Instruct about Appropriate Use of Medications and Adverse Effects

1. Carry nitroglycerin at all times.
   a. Nitroglycerin is volatile and is inactivated by heat, moisture, air, light, and time.
   b. Keep nitroglycerin in original dark glass container, tightly closed to prevent absorption of drug by other pills or pillbox.
   c. Nitroglycerin should cause a slight burning or stinging sensation under the tongue when it is potent.
2. Place nitroglycerin under the tongue at first sign of chest discomfort.
   a. Stop all effort or activity, sit, and take nitroglycerin tablet—relief should be obtained in a few minutes.
   b. Repeat dosage in 5 minutes for total of three tablets if relief is not obtained.
   c. Keep a record of the number of tablets taken to evaluate change in anginal pattern.
   d. Take nitroglycerin prophylactically to avoid pain known to occur with certain activities.
3. Demonstrate for patient how to administer nitroglycerin paste correctly.
   a. Place paste on calibrated strip.
   b. Remove previous paste on the skin by wiping gently with tissue. Be careful to avoid touching paste to fingertips as this will lead to increased dosing from absorption.
   c. Rotate site of administration to avoid skin irritation.
   d. Apply paste to the skin; use plastic wrap to protect clothing if not provided on strip.
   e. Have patient return demonstration.
4. Instruct patient on administration of transdermal nitroglycerin patches.
   a. Remove previous patch; fold in half so that medication does not touch fingertips and will not be accessible in trash. Wipe area with tissue to remove any residual medication.
   b. Apply patch to a clean, dry, nonhairy area of the body.
   c. Rotate administration sites.
   d. Instruct patient not to remove patch for swimming or bathing.
   e. If patch loosens and part of it becomes nonadherent, it should be folded in half and discarded. A new patch should be applied.
5. Teach patient about potential adverse effects of other medications. Instruct patient not to stop taking any of these without discussing with health care provider.
   a. Constipation—verapamil.
   b. Ankle edema—nifedipine.

c. Heart failure (shortness of breath, weight gain, edema)—beta-adrenergic blockers or calcium channel blockers.

d. Dizziness—vasodilators, antihypertensives.

e. Impotence–decreased libido and sexual functioning—beta-adrenergic blockers.

6. Ensure that patient has enough medication until next follow-up appointment or trip to the pharmacy. Warn against abrupt withdrawal of beta-adrenergic blockers or calcium channel blockers to prevent rebound effect.

NURSING ALERT Instruct patient to call 911 if chest pain persists or has worsened after the first sublingual nitroglycerin tablet was administered (5 minutes). Furthermore, instruct patient to continue to take other sublingual nitroglycerin tablets every 5 minutes until emergency medical services have arrived (instruct patient not drive self to the hospital).

Counsel on Risk Factors and Lifestyle Changes

1. Inform patient of methods of stress reduction, such as biofeedback and relaxation techniques.
2. Review low-fat and low-cholesterol diet. Explain AHA guidelines (see *www.heart.org*), which recommend eating fish at least twice per week, especially fish high in omega-3 oils.
   a. Omega-3 oils have been shown to improve arterial health and decrease BP, triglycerides, and the growth of atherosclerotic plaque.
   b. Omega-3 oils can be found in fatty fish, such as mackerel, salmon, sardines, herring, and albacore tuna.
   c. Suggest available cookbooks (AHA) that may assist in planning and preparing foods.
   d. Have patient meet with dietitian to design a menu plan.
3. Inform patient of available cardiac rehabilitation programs that offer structured classes on exercise, smoking cessation, and weight control.
4. Instruct patient to avoid excessive caffeine intake (coffee, cola drinks), which can increase the heart rate and produce angina.
5. Tell patient not to use "diet pills," nasal decongestants, or any over-the-counter (OTC) medications that can increase heart rate or stimulate high BP.
6. Encourage patient to avoid alcohol or drink only in moderation (alcohol can increase hypotensive adverse effects of drugs).
7. Encourage follow-up visits for control of diabetes, hypertension, and hyperlipidemia.
8. Have patient discuss supplement therapy (ie, vitamins B_6, B_{12}, C, E, folic acid, and L-arginine) with health care provider.
9. For additional information, refer patient to the AHA (*www.americanheart.org*).
10. Refer patient to health care provider to discuss the use of phosphodiesterase inhibitors (PDE5) for

erectile dysfunction.

DRUG ALERT Patient should not take PDE5, such as sildenafil, concurrently with nitrates or alpha-adrenergic blockers because severe hypotension and cardiac event may occur.

Evaluation: Expected Outcomes

- Verbalizes relief of pain.
- BP and heart rate stable.
- Verbalizes lessening anxiety, ability to cope.

Myocardial Infarction

EVIDENCE BASE Gara, P. T., Kushner, F. G., Ascheim, D. D., et al. (2013). ACCF/AHA guideline for the management of ST elevation myocardial infarction. *Circulation, 127*, 529–555.

Myocardial infarction (MI) is one of the manifestations of acute coronary syndrome (ACS) and refers to a dynamic process by which one or more regions of the heart experience a prolonged decrease or cessation in oxygen supply because of insufficient coronary blood flow; subsequently, necrosis or "death" to the affected myocardial tissue occurs. The onset of the MI process may be sudden or gradual, and the progression of the event to cell death takes approximately 3 to 6 hours.

Pathophysiology and Etiology

1. Acute coronary thrombosis (partial or total)—associated with 90% of MIs.
   a. Severe atherosclerosis (greater than 70% narrowing of the artery) precipitates thrombus.
   b. Thrombus formation begins with plaque rupture and platelets' adhesion to the damaged area.
   c. Activation of the exposed platelets causes expression of glycoprotein IIb/IIIa receptors that bind fibrinogen.
   d. Further platelet aggregation and adhesion occurs, enlarging the thrombus and occluding blood supply.
2. Other etiologic factors include coronary artery spasm, coronary artery embolism, infectious diseases causing arterial inflammation, hypoxia, anemia, and severe exertion or stress on the heart in the presence of significant CAD (ie, surgical procedures, shoveling snow).
3. Different degrees of damage occur to the heart muscle (see Figure 13-2):
   a. Zone of necrosis—death to the heart muscle caused by extensive and complete oxygen deprivation; irreversible damage.
   b. Zone of injury—region of the heart muscle surrounding the area of necrosis; inflamed and injured, but still viable if adequate oxygenation can be restored.
   c. Zone of ischemia—region of the heart muscle surrounding the area of injury, which is ischemic and viable; not endangered unless extension of the infarction occurs.
4. Classification of MI:
   a. STEMI—whereby ST-segment elevations are seen on ECG. The area of necrosis may or may not occur through the entire wall of heart muscle.
   b. NSTEMI—no ST-segment elevations can be seen on ECG. ST depressions may be noted as well as positive cardiac markers, T-wave inversions, and clinical equivalents (chest pain). Area of necrosis may or may not occur through the entire myocardium.
5. The region(s) of the heart muscle that becomes affected depends on which coronary artery(ies) is/are

obstructed (see Figure 13-3).

a. The left ventricle is a common and dangerous location for an MI because it is the main pumping chamber of the heart. The left anterior descending artery supplies oxygen to this part of the heart.

b. Right ventricular infarctions commonly occur with damage to the inferior and/or posterior wall of the left ventricle. Occlusion in the right coronary or circumflex arteries can lead to this type of infarct.

6. The severity and location of the MI determine prognosis.

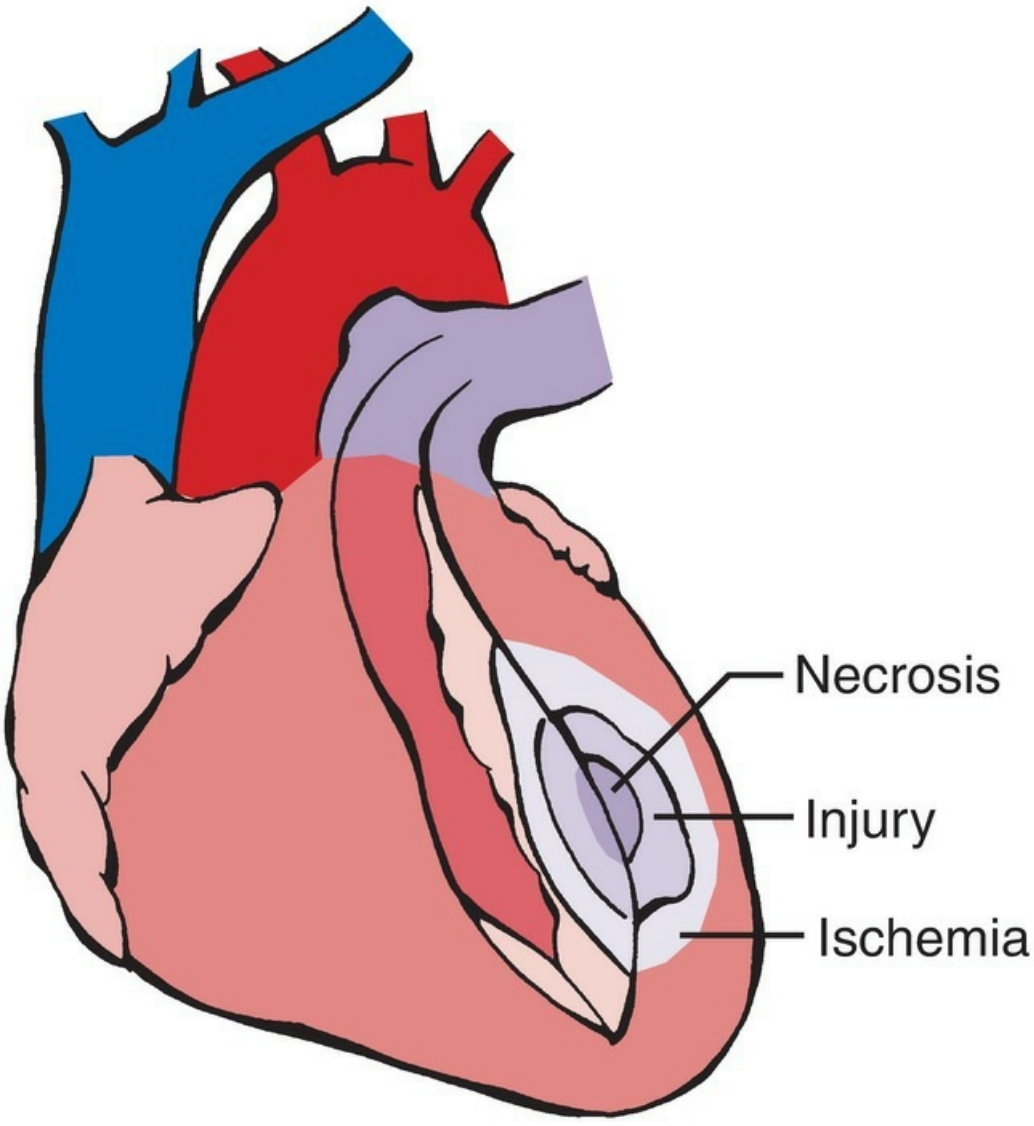

Figure 13-2. Different degrees of damage occur to the heart muscle after a myocardial infarction. This diagram shows the zones of necrosis, injury, and ischemia.

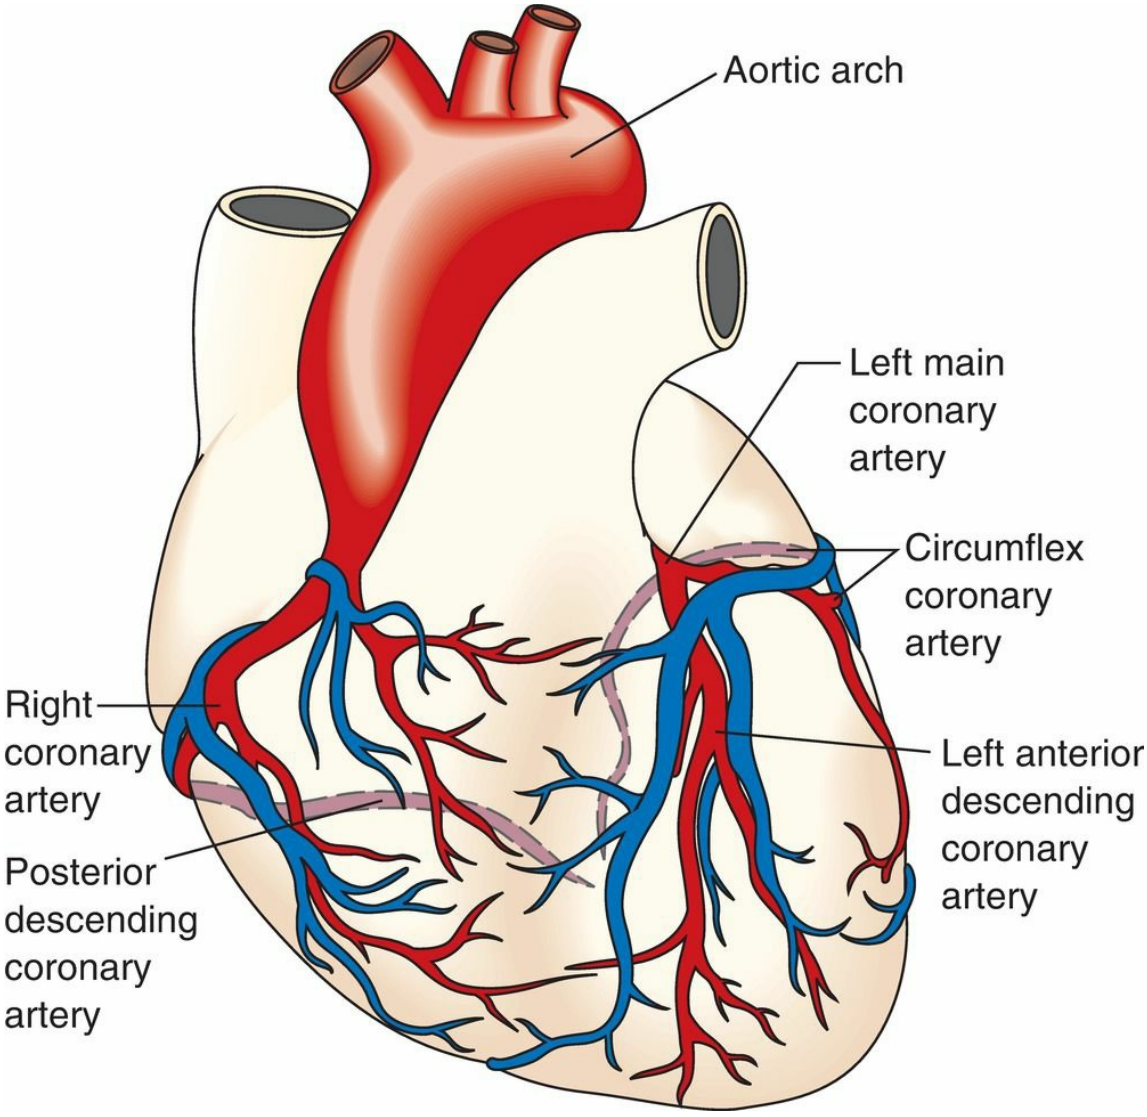

Figure 13-3. Diagram of the coronary arteries arising from the aorta and encircling the heart. Some of the coronary veins are also shown. (Smeltzer, S., and Bare, B. [2000]. Brunner and Suddarth's textbook of medical-surgical nursing [9th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

NURSING ALERT Early reperfusion and revascularization (ie, within 24 hours) are recommended for NSTEMI. Although revascularization can be delayed in low-risk patients, studies show this can increase length of stay and cost. Reperfusion can occur via femoral or radial approach. Radial approach is associated with reduced complications and mortality.

Clinical Manifestations

1. Chest pain.
    a. Severe, diffuse, steady substernal pain; may be described as crushing, squeezing, or dull.

b. Not relieved by rest or sublingual vasodilator therapy such as nitroglycerine, but requires opioids (ie, morphine).
c. May radiate to the arms (usually the left), shoulders, neck, back, and/or jaw.
d. Continues for more than 15 minutes.
e. May produce anxiety and fear, resulting in increased heart rate, blood pressure, and respiratory rate.
f. Some patients, women or diabetics, may exhibit no complaints of pain (silent MI).

2. Diaphoresis; cool, clammy skin; facial pallor.
3. Hypertension or hypotension.
4. Bradycardia or tachycardia.
5. Premature ventricular and/or atrial beats.
6. Palpitations, severe anxiety, dyspnea.
7. Disorientation, confusion, restlessness.
8. Fainting, marked weakness.
9. Nausea, vomiting, hiccups.
10. Atypical symptoms: epigastric or abdominal distress, dull aching or tingling sensations, shortness of breath, extreme fatigue.

NURSING ALERT Many patients do not have symptoms; these are "silent MIs." Nevertheless, there is still resultant damage to the heart. Women and diabetics usually present with atypical and/or vague complaints (eg, indigestion, fatigue). These patients are at higher risk of death during hospitalization. This is influenced by delay in seeking medical attention, and they are less likely to receive therapies that have been shown to be effective in MI treatment (ie, fibrinolytics or primary PCI, aspirin, beta-blockers, or heparin).

GERONTOLOGIC ALERT Older patients are more likely to experience silent MIs or have atypical signs and symptoms, such as hypotension, low body temperature, shortness of breath, vague complaints of discomfort, mild perspiration, strokelike symptoms, dizziness, or change in sensorium.

Diagnostic Evaluation

ECG Changes

1. Generally occurs within 2 to 12 hours, but may take 72 to 96 hours.
2. Necrotic, injured, and ischemic tissues alter ventricular depolarization and repolarization.
   a. ST-segment depression and T-wave inversion indicate a pattern of ischemia.
   b. ST elevation indicates an injury pattern.

c. Q waves (see Figure 13-4) indicate tissue necrosis and are permanent. A pathologic Q wave is one that is greater than 3 mm in depth or greater than one third the height of the R wave.

3. Location of the infarction (anterior, anteroseptal, inferior, posterior, lateral) is determined by the leads in which the ST changes (elevation vs. depression) are seen. Of note, the changes must be in two contiguous or related leads to be diagnostic.

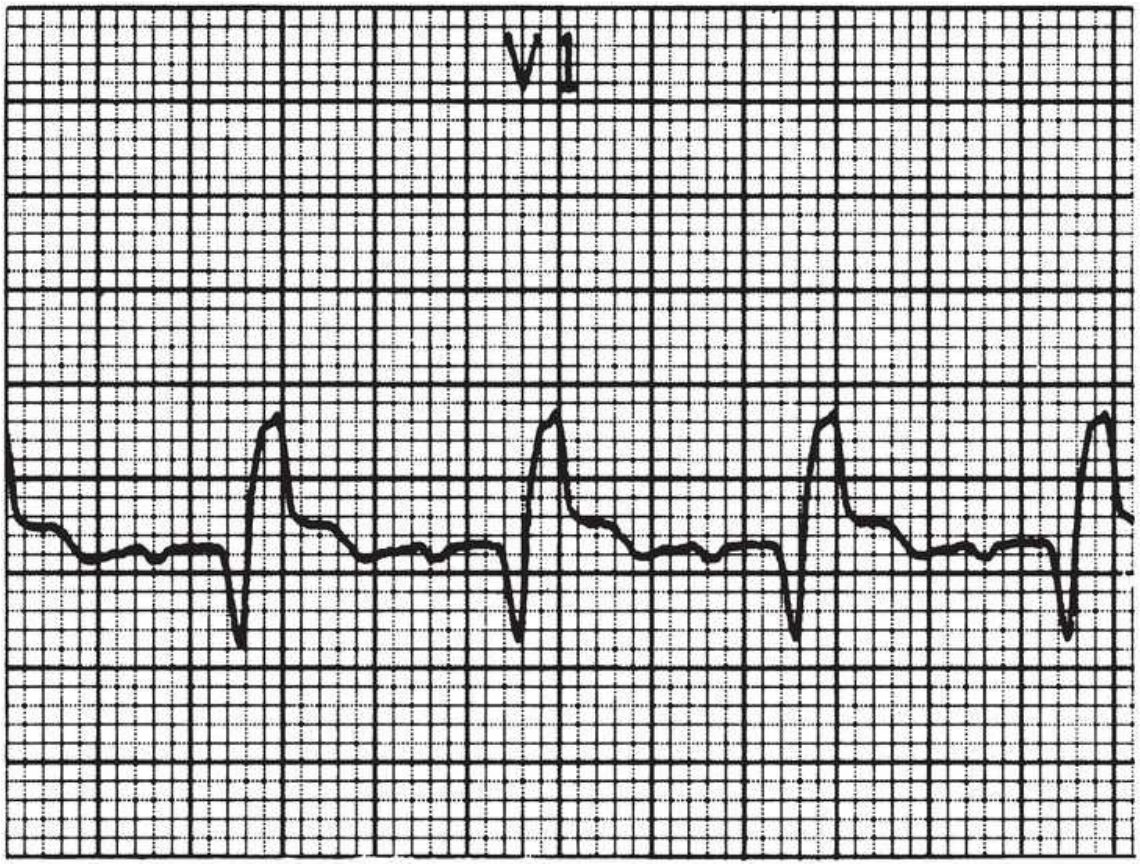

Figure 13-4. Abnormal Q wave.

NURSING ALERT A normal ECG does not rule out the possibility of infarction because ECG changes can be subtle and obscured by underlying conditions (bundle-branch blocks, electrolyte disturbances).

Cardiac Markers

1. Cardiac enzymes (biochemical markers) are not diagnostic of an acute MI with a single elevation; serial markers are drawn (see page 236).
   a. Marker elevation is then correlated to the extent of heart muscle damage.
   b. Characteristic elevation over several hours confirms an MI (see Figure 13-5).

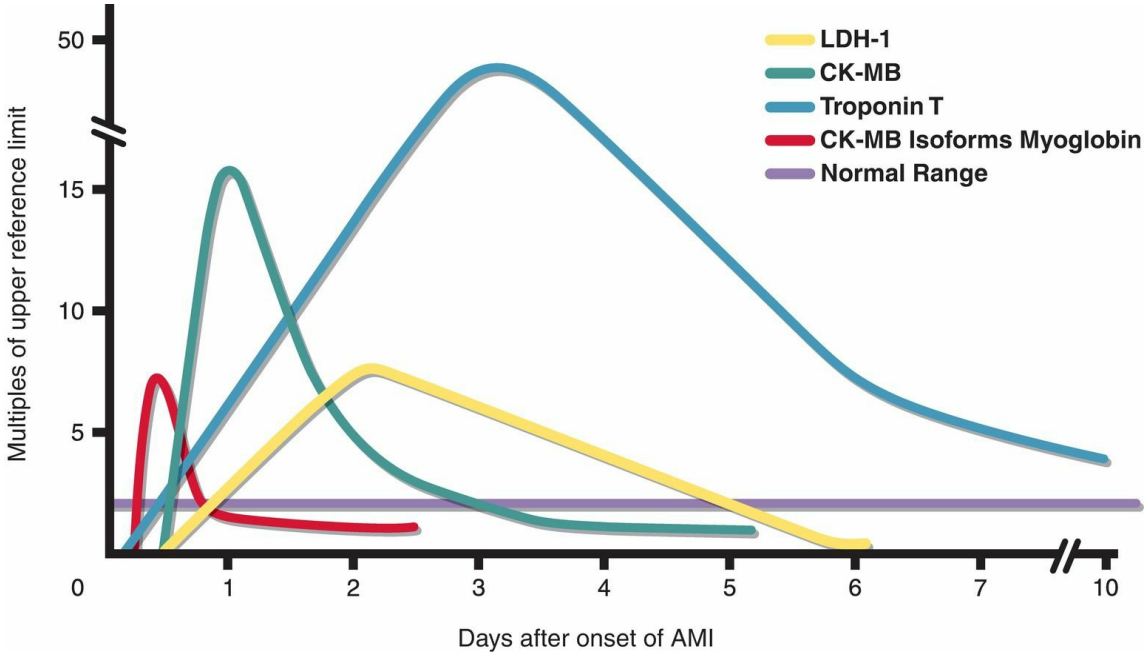

Figure 13-5. Release of cardiac markers after acute myocardial infarction (AMI). Following AMI, myoglobin and CK-MB levels rise, but the increases last only a few days. Levels of troponin T can be sustained for 4 to 10 days following AMI, allowing for more accurate diagnosis. All results are normalized to the upper reference limit. (Wu, A. H. B. [1995]. Cardiac troponins T and I in coronary artery diseases. *Endocrinology and Metabolism In-Service Training and Continuing Education*. 13, 81. © American Association for Clinical Chemistry, Inc.)

Other Findings

1. Elevated CRP and lipoprotein(s) because of inflammation in the coronary arteries.
2. Abnormal coagulation studies (prothrombin time [PT], partial thromboplastin time [PTT]).
3. Elevated white blood cell (WBC) count and sedimentation rate because of the inflammatory process involved in heart muscle cell damage.
4. Radionuclide imaging allows recognition of areas of decreased perfusion.
5. PET scan determines the presence of reversible heart muscle injury and irreversible or necrotic tissue; extent to which the injured heart muscle has responded to treatment can also be determined.
6. Cardiac muscle dysfunction can be noted on echocardiography or cardiac magnetic resonance imaging (MRI).

Management

The goals for UA/NSTEMI therapy are immediate relief of ischemia and prevention of severe outcomes such as death or myocardial infarction or reinfarction. To achieve this requires administration of anti-ischemic therapy (ie, rest, supplemental oxygen, nitroglycerin, beta-blockers, ACE inhibitors) and antithrombotic therapy (ie, aspirin, clopidogrel, ticlopidine) and ongoing risk stratification and use of invasive procedure (ie, cardiac catheterization) to provide early restoration of coronary blood flow. Growing evidence suggest the use of supplemental oxygen in the absence of hypoxia may lead to increase infarct size. Caution should be

exercised when administering oxygen to patients experiencing STEMI.

EVIDENCE BASE Nehme, Z., Stub, D., Bernard, S., et al. (2016). Effect of supplemental oxygen exposure on myocardial injury in ST elevation myocardial infarction. *Heart, 2016*, 444–451.

Pharmacologic Therapy

The pharmacologic therapy for MI is standard (see Table 13-1, page 278). Use the MONA acronym to outline immediate pharmacologic interventions.

Table 13-1 ACS Medications at a Glance

DRUG AND ACTION	CLINICAL CONSIDERATIONS
Aspirin Antiplatelet drug that blocks prostaglandin synthesis and thromboxane A_2 formation	• Administer as soon as acute coronary syndrome (ACS) is suspected. • Give patient 160 to 325 mg; if not already taking aspirin, patient should chew this dose. • If patient is allergic to aspirin, give clopidogrel or ticlopidine instead.
Clopidogrel, ticagrelor Antiplatelet drugs that inhibit platelet aggregation	• Alternatives for patients who cannot use aspirin. • Recent research indicates that using clopidogrel and aspirin concurrently reduces risk of myocardial infarction (MI), stroke, and death.
Note: Restenosis is possible after PCI in those patients with the CYP2C19 gene, which causes significantly lower levels of the active metabolite of clopidogrel	
Unfractionated heparin, low molecular weight heparin (dalteparin, enoxaparin) Potentiate antithrombin III activity, inactivate thrombin, prevent conversion of fibrinogen to fibrin	***Unfractionated heparin*** • Weight-adjusted dosage is given to achieve therapeutic partial thromboplastin time (PTT) and activated clotting time. • Reversible with protamine sulfate. ***Low molecular weight heparin*** • PTT is not monitored. • Give by subcutaneous injection. • Effects are not reversible.
Glycoprotein (GP) IIb/IIIa inhibitors (abciximab, tirofiban, eptifibatide) Block GP sites on platelets, preventing platelet aggregation	• Indicated for intermediate- or high-risk ACS or with percutaneous coronary intervention. • Each drug has specific indications and dosage ranges. Consult package insert for specifics.
Fibrinolytics (alteplase, tenecteplase, streptokinase, reteplase) Break up the fibrin meshwork in clots	• Indicated in ST-segment elevation ACS only. • Certain agents require weight-adjusted dose. See package inserts for details.
Beta-adrenergic blockers (metoprolol, atenolol) Reduce cardiac output and heart rate, reduce ventricular remodeling, and decrease endothelial dysfunction	• Start all ACS patients on a beta-adrenergic blocker as tolerated. • As ordered, titrate dosage to meet therapeutic goals: heart rate, 60 beats/minute; blood pressure (BP), >90 mm Hg systolic.
Angiotensin-converting enzyme inhibitors (captopril, enalapril) Decrease endothelial dysfunction and prevent conversion of angiotensin I to angiotensin II	• Indicated for patients with heart failure, those with a heart rate above 100 beats/minute, and those with an anterior MI, hypertension, or diabetes. • Start with a drug with a short half-life, such as captopril, within 24 hours to treat acute MI; on discharge, switch to a longer-acting drug, such as lisinopril or enalapril.
Nitroglycerin Dilates peripheral vessels, relaxes vascular smooth muscle, and decreases preload	• Can be given sublingually, orally, or via IV line spray in an acute care setting • Do not allow BP to drop below 90 mm Hg systolic. • Switch the patient to a topical patch or an oral form for long-term use.
Morphine Acts as an analgesic and sedative	• Indicated in acute care setting only; not for prolonged use. • Give until patient is free from chest pain or to relieve pulmonary congestion. • Monitor BP, level of consciousness, and respiratory rate.

Granger, B., & Miller, C. (2001). Acute coronary syndromes: Putting the new guidelines to work. Nursing 2001, 31(11), 42.

1. M (morphine)—IV rather than intramuscular (IM) is used to treat chest pain. Endogenous catecholamine release during pain imposes an increase in the workload on the heart, thus causing an increase in oxygen demand. Morphine's analgesic effects decrease the pain, relieve anxiety, and improve

cardiac output by reducing preload and afterload.

2. O (oxygen)—given via nasal cannula or face mask. Increases oxygenation to ischemic heart muscle.
3. N (nitrates)—given sublingually via spray or through IV administration. Vasodilator therapy reduces preload by decreasing blood return to the heart and decreasing oxygen demand.
4. A (aspirin)—immediate dosing by mouth (chewed) is recommended to halt platelet aggregation.

Other Medications

1. Fibrinolytic agents such as tissue plasma activator, streptokinase, and reteplase are given IV to reestablish blood flow in coronary vessels by dissolving thrombus.
   a. Contraindicated in the management of unstable angina or NSTEMI or posterior wall MI. Studies have shown no clinical benefits in the absence of ST elevation MI or bundle-branch block.
   b. No effect on the underlying stenosis that precipitated the thrombus to form.
2. Antiarrhythmics, such as amiodarone to decrease the ventricular irritability that occurs after MI.
   a. Bolus of amiodarone is given via IV line over 10 minutes; then, an infusion is given in varying doses over 24 hours (1 mg/minute for 6 hours then 0.5 mg/minute for 18 hours).
   b. Correction of electrolyte imbalances such as hyperkalemia that also causes ventricular irritability.

Percutaneous Coronary Interventions

EVIDENCE BASE Tricoci, P., Lokhnygina, Y., Berdan, L. G., et al. (2016). ACC/AHA/SCAI focused update on primary percutaneous coronary intervention for patients with ST elevation myocardial infarction : An update of the 2011 ACCF/AHA/SCAI guideline for percutaneous coronary intervention and the 2013 ACCF/AHA guideline for the management of ST-elevation myocardial infarction: A report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines and the Society for Cardiovascular Angiography and Interventions. *Journal of the American College of Cardiology, 67*(10).

---

1. Mechanical opening of the coronary vessel can be performed during an evolving infarction.
2. Percutaneous coronary interventions (PCIs), including percutaneous transluminal coronary angioplasty, coronary stenting, and atherectomy, can be used instead of, or as an adjunct to, fibrinolytic therapy (see page 255).
3. Fibrinolytic therapy is considered in STEMI patients if PCI is not able to be performed within 90 minutes. The guidelines suggest patients presenting to non–PCI capacity facilities should be transferred to PCI-capable facility within 120 minutes of presentation for immediate PCI. However, if delays are anticipated (ie, transfer delay by greater than 120 minutes), then fibrinolytic therapy should be considered within 30 minutes of presentation to facility.

GERONTOLOGIC ALERT Older patients are extremely susceptible to respiratory depression in response to opioids. Titrate dose carefully and monitor respiratory status.

Surgical Revascularization

1. Cardiac surgery (ie, CABG) following STEMI is associated with high mortality in the first 3 to 7 days; thus, the benefit of revascularization must be weighed against the risk of cardiac surgery. However, newer surgical approaches such as off-pump CABG have mitigated this risk for some patients.
2. Benefits of this therapy include definitive treatment of the stenosis and less scar formation on the heart.

Complications

1. Dysrhythmias.
2. Sudden cardiac death because of ventricular arrhythmias.
3. Infarct expansion (thinning and dilation of the necrotic zone).
4. Infarct extension (additional heart muscle necrosis occurring after 24 hours of acute infarction).
5. Heart failure (with 20% to 35% left ventricle damage).
6. Cardiogenic shock.
7. Reinfarction.
8. Ischemic cardiomyopathy.
9. Cardiac rupture.
10. Papillary muscle rupture.
11. Ventricular mural thrombus.
12. Ischemic stroke.
13. Thromboemboli (deep vein thrombosis and pulmonary embolism).
14. Ventricular aneurysm.
15. Cardiac tamponade.
16. Pericarditis (2 to 3 days after MI).
17. Dissection of coronary arteries during angioplasty.
18. Psychiatric problems—depression, personality changes.

Nursing Assessment

1. Gather information regarding the patient's chest pain:
    a. Nature and intensity—describe the pain in patient's own words and compare it with pain previously experienced.
    b. Onset and duration—exact time pain occurred as well as the time pain relieved or diminished (if applicable).

c. Location and radiation—point to the area where the pain is located and to other areas where the pain seems to travel.
d. Precipitating and aggravating factors—describe the activity performed just before the onset of pain and if any maneuvers and/or medications alleviated the pain.

2. Question patient about other symptoms experienced associated with the pain. Observe patient for diaphoresis, facial pallor, dyspnea, guarding behaviors, rigid body posture, extreme weakness, and confusion.
3. Evaluate cognitive, behavioral, and emotional status.
4. Question patient about prior health status with emphasis on current medications, allergies (opiate analgesics, iodine, shellfish), recent trauma or surgery, nonsteroidal anti-inflammatory drug (NSAID) ingestion, peptic ulcers, fainting spells, drug and alcohol use.
5. Analyze information for contraindications for fibrinolytic therapy and PCI.
6. Gather information about presence or absence of cardiac risk factors.
7. Identify patient's social support system and potential caregivers.
8. Identify significant others' reaction to the crisis situation.

Nursing Diagnoses

- Anxiety related to chest pain, fear of death, threatening environment.
- Activity Intolerance related to insufficient oxygenation to perform activities of daily living, deconditioning effects of bed rest.
- Risk for Bleeding related to dissolution of protective clots.
- Risk for Decreased Cardiac Tissue Perfusion related to coronary restenosis, extension of infarction.
- Ineffective Coping related to threats to self-esteem, disruption of sleep–rest pattern, lack of significant support system, loss of control, and change in lifestyle.

Nursing Interventions

Alleviating Anxiety

1. Rule out physiologic etiologies for increasing or new-onset anxiety before administering as-needed sedatives. Physiologic causes must be identified and treated in a timely fashion to prevent irreversible adverse or even fatal outcomes; sedatives may mask symptoms, delaying timely identification, diagnosis, and treatment.
   a. Autonomic signs of anxiety are increases in heart rate, BP, respiratory rate, and tremulousness, but they may also be signs of physiologic complications.
   b. Anxiety with dyspnea, tachypnea, and tachycardia may indicate pulmonary embolism; frothy pink sputum and orthopnea indicate pulmonary edema.
   c. Appearance of heart murmurs or friction rub indicates valvular dysfunction, possible intraventricular septal rupture, and pericarditis.
2. Whenever anxiety increases, assess patient for signs of hypoperfusion, auscultate heart and lung sounds,

obtain a rhythm strip, and administer oxygen, as prescribed. Notify the health care provider immediately.

3. Assess and document emotional status frequently. Document all assessment findings, health care provider notification and response, and interventions and response.
4. Explain to patient and family reasons for hospitalization, diagnostic tests, and therapies administered.
5. Explain equipment, procedures, and need for frequent assessment to patient and significant others.
6. Discuss with patient and family the anticipated nursing and medical regimen.
   a. Explain visiting hours and need to limit number of visitors per facility policy.
   b. Offer family preferred times to phone unit to check on patient's status.
7. Administer antianxiety agents, as prescribed.
   a. Explain to patient the reason for sedation: undue anxiety can make the heart more irritable and require more oxygen.
   b. Assure patient that the goal of sedation is to promote comfort and, therefore, should be requested if anxious, excitable, or "jittery" feelings occur.
   c. Observe for adverse effects of sedation, such as lethargy, confusion, and/or increased agitation.
8. Maintain consistency of care with one or two nurses regularly assisting patient, especially if severe anxiety is present.
9. Offer massage, imagery, and progressive muscle relaxation to promote relaxation, reduce muscle tension, and reduce workload on the heart.

Increasing Activity Tolerance

1. Promote activity tolerance with early gradual increase in mobilization—prevents deconditioning, which occurs with bed rest.
   a. Minimize environmental noise.
   b. Provide a comfortable environmental temperature.
   c. Avoid unnecessary interruptions and procedures.
   d. Structure routine care measures to include rest periods after activity.
   e. Discuss with patient and family the purpose of limited activity and visitors—to help the heart heal by lowering heart rate and BP, maintaining cardiac workload at lowest level, and decreasing oxygen consumption.
   f. Promote restful diversional activities for patient (reading, listening to music, drawing, crossword puzzles, crafts).
   g. Encourage frequent position changes while in bed.
2. Assist patient with prescribed activities.
   a. Assist patient to rise slowly from a supine position to minimize orthostatic hypotension related to medications.
   b. Encourage passive and active range-of-motion (ROM) exercise as directed while on bed rest.
   c. Measure the length and width of the unit so patients can gradually increase their activity levels with

specific guidelines (walk one width [150 feet] of the unit).

d. Elevate patient's feet when out of bed in chair to promote venous return.
e. Implement a step-by-step program for progressive activity, as directed. Typically can progress to the next step if they are free from chest pain and ECG changes during the activity.

Preventing Bleeding

1. Take vital signs every 15 minutes during infusion of fibrinolytic agent and then hourly.
2. Observe for hematomas or skin breakdown, especially in potential pressure areas such as the sacrum, back, elbows, ankles.
3. Be alert to verbal complaints of back pain indicative of possible retroperitoneal bleeding.
4. Observe all puncture sites every 15 minutes during infusion of fibrinolytic therapy and then hourly for bleeding.
5. Apply manual pressure to venous or arterial sites if bleeding occurs. Use pressure dressings for coverage of all access sites.
6. Observe for blood in stool, emesis, urine, and sputum.
7. Minimize venipunctures and arterial punctures; use heparin lock for blood sampling and medication administration.
8. Avoid IM injections.
9. Caution patient about vigorous tooth brushing or shaving.
10. Avoid trauma to patient by minimizing frequent handling of patient.
11. Monitor laboratory values: PT, international normalized ratio, PTT, hematocrit (HCT), and hemoglobin.
12. Check for current blood type and crossmatch.
13. Administer antacids or GI prophylaxis, as directed, to prevent stress ulcers.
14. Implement emergency interventions, as directed, in the event of bleeding: fluid, volume expanders, blood products.
15. Monitor for changes in mental status and headache.
16. Avoid vigorous oral suctioning.
17. Avoid use of automatic BP device above puncture sites or hematoma. Use care in taking BP; use arm not being used for fibrinolytic therapy.

Maintaining Cardiac Tissue Perfusion

1. Observe for persistent and/or recurrence of signs and symptoms of ischemia, including chest pain, diaphoresis, hypotension—may indicate extension of MI and/or reocclusion of coronary vessel.
2. Report immediately.
3. Administer oxygen, as directed.
4. Record a 12-lead ECG.
5. Prepare patient for possible emergency procedures: cardiac catheterization, bypass surgery, PCI,

fibrinolytic therapy, intra-aortic balloon pump.

Strengthening Coping Abilities

1. Listen carefully to patient and family to ascertain their cognitive appraisals of stressors and threats.
2. Assist patient to establish a positive attitude toward illness and progress adaptively through the grieving process.
3. Manipulate environment to promote restful sleep by maintaining patient's usual sleep patterns.
4. Be alert to signs and symptoms of sleep deprivation—irritability, disorientation, hallucinations, diminished pain tolerance, aggressiveness.
5. Minimize possible adverse emotional response to transfer from the intensive care unit to the intermediate care unit:
    a. Introduce the admitting nurse from the intermediate care unit to the patient before transfer.
    b. Plan for the intermediate care nurse to answer questions the patient may have and to inform patient what to expect relative to physical layout of unit, nursing routines, and visiting hours.

Patient Education and Health Maintenance

Goals are to restore patient to optimal physiologic, psychological, social, and work level; to aid in restoring confidence and self-esteem; to develop patient's self-monitoring skills; to assist in managing cardiac problems; and to modify risk factors.

1. Inform the patient and family about what has happened to patient's heart.
    a. Explain basic cardiac anatomy and physiology.
    b. Identify the difference between angina and MI.
    c. Describe how the heart heals and that healing will not be complete for 6 to 8 weeks after infarction.
    d. Discuss what the patient can do to assist in the recovery process and reduce the chance of future heart attacks.
2. Instruct patient on how to judge the body's response to activity.
    a. Introduce the concept that different activities require varying expenditures of oxygen.
    b. Emphasize the importance of rest and relaxation alternating with activity.
    c. Instruct patient how to take pulse before and after activity as well as guidelines for the acceptable increases in heart rate that should occur.
    d. Review signs and symptoms indicative of a poor response to increased activity levels: chest pain, extreme fatigue, shortness of breath.
3. Design an individualized activity progression program for patient as directed.
    a. Determine activity levels appropriate for patient, as prescribed, and by predischarge low-level exercise stress test.
    b. Encourage patient to list activities he or she enjoys and would like to resume.
    c. Establish the energy expenditure of each activity (ie, which are most demanding on the heart) and rank activities from lowest to highest.

d. Instruct patient to move from one activity to another after the heart has been able to manage the previous workload as determined by signs and symptoms and pulse rate.

4. Give patient specific activity guidelines and explain that activity guidelines will be reevaluated after the heart heals.
   a. Walk daily, gradually increasing distance and time, as prescribed.
   b. Avoid activities that tense muscles, such as weight lifting, lifting heavy objects, isometric exercises, pushing and/or pulling heavy loads, all of which can cause vagal stimulation.
   c. Avoid working with arms overhead.
   d. Gradually return to work.
   e. Avoid extremes in temperature.
   f. Do not rush; avoid tension.
   g. Advise getting at least 7 hours of sleep each night and taking 20- to 30-minute rest periods twice per day.
   h. Advise limiting visitors to three to four daily for 15 to 30 minutes and shorten phone conversations.
5. Tell patient that sexual relations may be resumed on advice of health care provider, usually after exercise tolerance is assessed.
   a. If patient can walk briskly or climb two flights of stairs, he or she can usually resume sexual activity; resumption of sexual activity parallels resumption of usual activities.
   b. Sexual activity should be avoided after eating a heavy meal, after drinking alcohol, or when tired.
   c. Discuss impotence as an adverse effect of drug therapy and phosphodiesterase contraindications.
6. Advise eating three to four small meals per day rather than large, heavy meals. Rest for 1 hour after meals.
7. Advise limiting caffeine and alcohol intake.
8. Driving a car must be cleared with health care provider at a follow-up visit.
9. Teach patient about medication regimen and adverse effects.
10. Instruct the patient to call 911 when chest pressure or pain not relieved in 5 minutes by nitroglycerin or rest.
11. Instruct the patient to notify health care provider when the following symptoms appear:
    a. Shortness of breath.
    b. Unusual fatigue.
    c. Swelling of feet and ankles.
    d. Fainting, dizziness.
    e. Very slow or rapid heartbeat.
12. Assist patient to reduce risk of another MI by risk factor modification.
    a. Explain to patient the major risk factors that can increase chances for having another MI.
    b. Instruct patient in strategies to modify risk factors.

13. For additional information and support, refer patient to AHA (*www.americanheart.org*) and the ACC (*www.acc.org*).

Evaluation: Expected Outcomes

- No signs of anxiety or agitation.
- Activity slowly progressing and tolerated well.
- No signs of bleeding.
- No recurrent chest pain.
- Sleeps well; emotionally stable.

Hyperlipidemia

Hyperlipidemia is a group of metabolic abnormalities resulting in combinations of elevated serum cholesterol. Total cholesterol (TC) and triglycerides (TG) are two of the major lipids in the body. The liver serves as the key organ for cholesterol metabolism and regulation. Lipids are transported through the bloodstream by lipoproteins. Lipoproteins are made up of a phospholipid and specific proteins called *apoproteins* or *apolipoproteins*. There are five main classes of lipoproteins:

- Chylomicrons.
- Very-low-density lipoproteins (VLDLs).
- Intermediate-density lipoproteins (IDLs).
- Low-density lipoproteins (LDLs).
- High-density lipoproteins (HDLs).

Pathophysiology and Etiology

Primary Hyperlipidemias

1. Genetic metabolic abnormalities resulting in the overproduction or underproduction of specific lipoproteins or enzymes. They tend to be familial, autosomal codominant genetic disorders characterized by raised serum LDL-C levels resulting from defects in hepatic uptake.
2. Primary hyperlipidemias include hypercholesterolemia, defective apolipoproteinemia, hypertriglyceridemia, combined hyperlipidemia, dysbetalipoproteinemia, polygenic hypercholesterolemia, lipoprotein lipase deficiency, apoprotein C-II deficiency, lethicin cholesterol acetyltransferase deficiency.

Secondary Hyperlipidemias

1. Very common and are multifactorial.
2. Etiologic factors include chronic diseases, such as diabetes, hypothyroidism, nephrotic syndrome, and liver disease.
3. Other etiologic factors are obesity, dietary intake, pregnancy, alcoholism.
4. Medications include beta-adrenergic blockers, alpha-adrenergic blockers, diuretics, glucocorticoid and anabolic steroids, and estrogen preparations.

Consequences

1. Atherosclerotic plaque formation in blood vessels.
2. Causes narrowing and possible ischemia and may lead to thromboembolus formation.
3. Result in cardiovascular, cerebrovascular, and peripheral vascular disease.
4. Familial genetic hyperlipidemia increases the risk of early onset of cardiovascular disease.

Clinical Manifestations

1. Usually asymptomatic until significant target organ damage is done.

2. May be metabolic signs, such as corneal arcus, xanthoma, xanthelasma, pancreatitis.
3. Chest pain, MI.
4. Carotid bruit, transient ischemic attacks, stroke.
5. Intermittent claudication, arterial occlusion of lower extremities, loss of pulses.

Diagnostic Evaluation and Management

Diagnosis and management of hyperlipidemia begin with serum lipoprotein evaluation and review of history to determine which of four statin benefit groups the individual falls within and then focuses on tailoring statin therapy in those most likely to benefit in terms of primary and secondary risk reduction. Heart-healthy lifestyle habits should be encouraged for all individuals (Table 13-2 and Box 13-1).

Table 13-2 Classification of Serum Lipids

TOTAL CHOLESTEROL (TC) mg/dL (mmol/L)	CATEGORY
<200 (<5.2)	Normal
200–239 (5.2–6.1)	Borderline high
≥240 (≥6.2)	High
LDL-Cholesterol mg/dL (mmol/L)	
<100 (<2.6)	Normal
100–129 (2.6–3.3)	Above, near optimal
130–159 (3.4–4.0)	Borderline high
160–189 (4.1–4.8)	High
≥190 (≥4.9)	Very high
HDL-Cholesterol mg/dL (mmol/L)	
<40 (<1.0)	Low
≥60 (≥1.6)	High
Triglycerides (TG) mg/dL (mmol/L)	
<150 (<1.7)	Normal
150–199 (1.7–2.2)	Borderline high
200–499 (2.3–5.6)	High
≥500 (≥5.6)	Very high

Management of Dyslipidemia Working Group. (2006). VA/DoD clinical practice guideline for the management of dyslipidemia. Washington, DC: Department of Veterans Affairs, Department of Defense, p. 140.

BOX 13-1 LDL Goal-Directed Hyperlipidemia Treatment

LDL goal <70 mg/dL: Considered an optional goal for high-risk patients with coronary heart disease or a risk equivalent (peripheral artery disease, carotid artery disease, diabetes, aortic aneurysm). Treatment recommendation: therapeutic lifestyle changes; optional drug therapy if LDL < 100 mg/dL.

LDL goal <100 mg/dL: Goal for high-risk patients who have coronary heart disease or a risk equivalent and 10-year risk >20%. Treatment recommendations: therapeutic lifestyle changes and drug therapy if LDL ≥ 100 mg/dL; optional drug therapy if LDL < 100 mg/dL.

LDL goal <130 mg/dL: Goal for moderately high-risk patients with two or more risk factors and 10-year risk 10% to 20%. Treatment recommendations: therapeutic lifestyle changes initiated if LDL ≥ 130 mg/dL;

drug therapy if LDL ≥ 130 mg/dL; optional drug therapy if LDL is 100 to 129 mg/dL.

LDL goal <130 mg/dL: Goal for moderate-risk patients with two or more risk factors and 10-year risk <10%. Treatment recommendation: therapeutic lifestyle changes initiated if LDL ≥ 130 mg/dL; drug therapy initiated if LDL ≥ 160 mg/dL.

LDL goal <160 mg/dL: Goal for lower-risk patients with 0 to 1 risk factors. Treatment recommendations: therapeutic lifestyle changes initiated if LDL ≥ 160 mg/dL; drug therapy initiated if LDL ≥ 190 mg/dL; optional drug therapy if LDL is 160 to 189 mg/dL.

EVIDENCE BASE Stone, N. J., Robinson, J. G., Lichtenstein, A. H., et al. (2014). 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. *Journal of American College of Cardiology, 63*(25), 2889–2934.

---

1. The appropriate intensity of statin therapy should be initiated or continued:
    a. Clinical ASCVD (history of MI, unstable or stable angina, coronary artery procedures, or evidence or clinically significant MI or other revascularization, stroke, TIA and peripheral arterial disease presumed to be of atherosclerotic origin)
        i. Age ≤ 75 years and no safety concerns: high-intensity statin.
        ii. Age greater than 75 years or safety concerns: moderate-intensity statin.
    b. Primary prevention—primary LDL-C ≥190 mg/dL.
        i. Rule out secondary causes of hyperlipidemia.
        ii. Age ≥ 21 years: high-intensity statin.
        iii. Achieve at least a 50% reduction in LDL-C.
        iv. LDL-C–lowering nonstatin therapy may be considered to further reduce LDL-C.
    c. Primary prevention—Diabetes 40 to 75 years of age and LDL-C 70 to 189 mg/dL.
        i. Moderate-intensity statin.
        ii. Consider high-intensity statin when ≥7.5% 10-year ASCVD risk using the Pooled Cohort Equations (defined as nonfatal MI, CHD death, or nonfatal and fatal stroke).
    d. Primary prevention—no diabetes 40 to 75 years of age and LDL-C 70 to 189 mg/dL.
        i. Estimate 10-year ASCVD risk using the Risk Calculator based on the Pooled Cohort Equations in those NOT receiving a statin; estimate risk every 4 to 6 years.
        ii. To determine whether to initiate a statin, engage in a clinician–patient discussion of the potential ASCVD risk reduction, adverse effects, drug–drug interaction, and patient preferences.
        iii. Re-emphasize heart-healthy lifestyle habits and address other risk factors.
        iv. ≥7.5% 10-year ASCVD risk: consider moderate- or high-intensity statin.

v. 5 to less than 7.5% 10-year ASCVD risk: consider moderate-intensity statin.

vi. Other factors may be considered: LDL-C ≥160 mg/dL, family history of premature ASCVD, hs-CRP ≥2.0 mg/L, CAC score ≥300 Agatston units, ABI less than 0.9, or lifetime ASCVD risk.

e. Primary prevention when LDL-C less than 190 mg/dL and age less than 40 or greater than 75 years or less than 5% 10-year ASCVD risk.

i. Statin therapy may be considered in selected individuals.

f. Statin therapy is not routinely recommended for individuals with NYHA class II to IV heart failure or who are receiving maintenance hemodialysis.

2. Regularly monitor adherence to lifestyle and drug therapy with lipid and safety assessments, and assess adherence, response to therapy, and adverse effects with 4 to 12 weeks following statin initiation or change in therapy.

a. Measure a fasting lipid panel.

b. Do not routinely monitor ALT or CK unless symptomatic.

c. Screen and treat type 2 diabetes according to current practice guidelines. Heart-healthy lifestyle habits should be encouraged to prevent progression to diabetes.

d. Anticipate therapeutic response: approximately ≥50% reduction in LDL-C from baseline for high-intensity statin and 30% to less than 50% for moderate-intensity statin.

i. Insufficient evidence for LDL-C or non–HDL-C treatment targets from RCTs.

ii. For those with unknown baseline LDL-C, and LDL-C, 100 mg/dL was observed in RCTs of high-intensity statin therapy.

e. Less than anticipated therapeutic response:

i. Reinforce improved adherence to lifestyle and drug therapy.

ii. Evaluate for secondary causes of hyperlipidemia if indicated.

iii. Increase statin intensity or if on maximally tolerated statin, consider addition of nonstatin therapy in selected high-risk individuals.

f. Regularly monitor adherence to lifestyle and drug therapy every 3 to 12 month once adherence has been established. Continue assessment of adherence for optimal ASCVD risk reduction and safety.

3. In individuals intolerant of the recommended intensity of statin therapy, use the maximally tolerated intensity of statin. If there are muscle or other symptoms, establish that they are related to the statin.

Drug Classifications

See Table 13-3.

Table 13-3 Drugs Affecting Lipoprotein Metabolism

DRUG CLASS	AGENTS AND DAILY DOSES	LIPID/LIPOPROTEIN EFFECTS		ADVERSE EFFECTS	CONTRAINDICATIONS
HMG-CoA reductase inhibitors (statins)	• Lovastatin (20–80 mg) • Pravastatin (20–40 mg) • Simvastatin (20–80 mg) • Fluvastatin (20–80 mg) • Atorvastatin (10–80 mg) • Rosuvastatin (5–40 mg) • Pitavastatin (1–4 mg)	LDL HDL TG	↓ 18%–55% ↑ 5%–15% ↓ 7%–30%	• Myopathy • Increased liver enzymes	*Absolute*: • Active or chronic liver disease *Relative*: • Concomitant use of certain drugs*
Bile acid sequestrants	• Cholestyramine (4–16 g) • Colestipol (5–20 g) • Colesevelam (2.6–3.8 g)	LDL HDL TG	↓ 15%–30% ↑ 3%–5% No change or increase	• GI distress • Constipation	*Absolute*: • Bowel obstruction • Biliary obstruction
Nicotinic acid	• Immediate-release (crystalline) nicotinic acid (1.5–3 g) • Extended-release nicotinic acid (Niaspan®) (1–2 g); sustained-release nicotinic acid (1–2 g)	LDL HDL TG	↓ 5%–25% ↑ 15%–35% ↓ 20%–50%	• Flushing (may be reduced by taking with aspirin and food) • Hyperglycemia • Hyperuricemia, gout • Upper GI distress • Hepatotoxicity • New onset of atrial fibrillation • Weight loss	*Absolute*: • Hepatic dysfunction • Active peptic ulcer disease *Relative*: • Diabetes • Hyperphosphatemia • Gout • Unstable angina, MI
Fibric acids	• Gemfibrozil (600 mg BID) • Fenofibrate (200 mg) • Clofibrate (1,000 mg BID)	LDL (*may be increased in patients with high TG*) HDL TG	↓ 5%–20% ↑ 10%–20% ↓ 20%–50%	• Dyspepsia • Gallstones • Myopathy • Pancreatitis • Rhabdomyolysis in conjunction with statin use • Muscle symptoms	*Absolute*: • Severe renal disease • Severe hepatic disease
Cholesterol absorption inhibitors	• Ezetimibe (10 mg)	LDL Apoprotein B	↓ (additional 25% over a statin when used in combination; also a TG reduction) ↓	• Back pain • Arthralgia • Diarrhea • Abdominal pain • Sinusitis	• Contraindicated in active liver disease if combined with a statin
PCSK9 inhibitors	• Alirocumab (75–150 mg SQ every 2 weeks) • Evolocumab (140 mg SQ every 2 weeks or 420 mg SQ monthly in the abdomen, thigh, or upper arm)	LDL-C	↓29.9%–67%	• Nasopharyngitis • Injection site reaction • Influenza-like symptoms • Bruising	

**Cyclosporine, macrolide antibiotics, various antifungal agents, and cytochrome P-450 inhibitors (fibrates and niacin) should be used with appropriate caution.*

Adapted from ATP III guidelines at a glance quick desk reference. National Cholesterol Education Program [Electronic]. Available: https://www.nhlbi.nih.gov/files/docs/guidelines/atglance.pdf.

1. HMG-CoA reductase inhibitors (statins) are the most effective way to lower elevated LDL and TC, as a result of lower intrahepatic cholesterol and an uptake of hepatic cell surface LDL receptors. They also raise levels of HDL, lower levels of CRP, and may lower TGs. They can be used alone or in combination with other lipid-lowering drugs.
   a. Require periodic liver function monitoring.
   b. Should not be taken with large volume of grapefruit juice; can increase risk of myopathy.
   c. Should not be taken by women who are pregnant, lactating, or plan to get pregnant.
   d. Musculoskeletal side effects include myalgia, rhabdomyolysis, elevated creatine kinase.
2. Cholesterol absorption inhibitors—the newest class of lipid-lowering drugs; inhibit intestinal absorption of phytosterols and cholesterol and reduce LDL. Do not require liver function testing if given as monotherapy.

3. Bile acid sequestrants bind to cholesterol in the gut, decreasing absorption. Contraindicated in those with history of bile obstruction and phenylketonuria (aspartame-containing agent only).
4. Nicotinic acid (vitamin B_3)—works by inhibiting VLDL secretion, thus decreasing production of LDL. The main adverse effect is severe flushing; however, taking 81 to 325 mg of aspirin beforehand may help. Newer sustained-release forms have fewer adverse effects. Niacin should be avoided in patients with severe peptic disease.
5. Fibric acid derivatives—inhibit synthesis of VLDL, decrease TG, increase HDL. Contraindicated in liver, biliary, or kidney disease.
6. PCSK9 inhibitors are monoclonal antibodies. They target and inactivate a specific protein in the liver called proprotein convertase subtilisin/kexin 9. This protein binds to the LDL receptor and acts as an enzyme to break down the receptor so it can no longer remove LDL from the bloodstream. By inhibiting this protein, a dramatic reduction of LDL is seen in the bloodstream.

Other Treatment Considerations

1. TLC should be considered immediately for all patients with hyperlipidemia and is an important adjunct therapy for patients who receive medications.
2. Children and adolescents should be considered for screening and treatment of hyperlipidemia if they have positive family history and a family history of obesity. Other indications for screening (in these populations) include being overweight and exhibiting features of metabolic syndrome (hypertension, type 2 diabetes, central adiposity).
3. Drug therapy is recommended for boys at or older than age 10 and after the onset of menses in girls following a 6- to 12-month dietary trial. HMG-CoA reductase inhibitors are the drug class of choice.
4. Some dietary products may serve as adjunct therapy, such as omega-3 fatty acids, soy protein, plant stanols, and fiber.

Complications

1. Disability from MI, stroke, and lower extremity ischemia.

Nursing Interventions and Patient Education

1. Teach diet basics and obtain nutritional consult.
2. Teach patient to engage in exercise.
3. Engage patient in smoking cessation program.
4. Tell patients that for every 1% increase in HDL, there is a 2% to 3% decrease in risk for CHD.
5. Explain the goal of recommended cholesterol levels. Encourage patients to keep a log of lipid results.
6. Encourage follow-up laboratory work—repeat lipoprotein analysis and liver function test monitoring every 3 months for those on HMG-CoA reductase inhibitors.
7. Teach patient taking bile acid sequestrants not to take other medications for 1 hour before or 2 hours after because it prevents absorption of many medications.

8. For more information on hyperlipidemia and TLC, refer patient to AHA (*www.heart.org*) or the National Heart, Lung, and Blood Institute diseases and conditions index (*www.nhlbi.nih.gov/health/dci*).

Cardiogenic Shock

Cardiogenic shock is the failure of the heart to pump blood adequately to meet the oxygenation needs of the body. It occurs when the heart muscle loses its contractile power. It most commonly occurs as a result of acute myocardial infarction (AMI), and left ventricular pump failure is the primary insult. It is the most common cause of death in the post-AMI patient (about 5% to 10% of AMI patients develop cardiogenic shock), with a resulting mortality of 50% to 60%.

Pathophysiology and Etiology

1. Persistent hypotension with a marked systolic of less than 80 to 90 mm Hg or mean arterial pressure 30 mm Hg lower than baseline because of left ventricular failure.
2. Impaired contractility causes a marked reduction in CO and ejection fraction.
3. Decreased CO results in a lack of blood and oxygen to the heart as well as other vital organs (brain and kidneys).
4. Lack of blood and oxygen to the heart muscle results in continued damage to the muscle, a further decline in contractile power, and a continued inability of the heart to provide blood and oxygen to vital organs.
5. MI causing extensive damage (40% or greater) to the left ventricular myocardium is the most common cause.
6. Mechanical complications such as ventricular septal rupture, contained free wall rupture, and papillary muscle rupture are strongly suspected in patients with shock, particularly a first MI.
7. In addition to MI with or without complications, common causes of cardiogenic shock include:
    a. Aortic dissection—complicated by acute severe aortic insufficiency or MI.
    b. Acute decompensation of heart failure.
    c. Acute myocarditis.
    d. Takotsubo stress-induced cardiomyopathy.
    e. Postcardiotomy.
    f. Cardiac tamponade.
    g. Peripartum cardiomyopathy.
    h. Hypertrophic cardiomyopathy with severe outflow obstruction.
    i. Massive pulmonary embolism.

Clinical Manifestations

1. Confusion, restlessness, mental lethargy (because of poor perfusion of the brain or metabolic encephalopathy).
2. Low systolic blood pressure (90 mm Hg or 30 mm Hg less than previous levels) or MAP <65 mm Hg.
3. Oliguria—urine output less than 30 mL/hour for at least 2 hours (because of decreased perfusion of kidneys).

4. Cold, clammy skin (blood is shunted from the peripheral circulation to perfuse vital organs); profoundly diaphoretic with mottled extremities.
5. Weak, thready peripheral pulses, fatigue, hypotension (because of inadequate CO).
6. Dyspnea, tachypnea, cyanosis (increased left ventricular pressures result in elevation of left atrial and pulmonary pressures, causing pulmonary congestion).
7. Dysrhythmias (because of lack of oxygen to heart muscle) and sinus tachycardia (as a compensatory mechanism for a decreased CO).
8. Chest pain (because of lack of oxygen and blood to heart muscle).
9. Decreased bowel sounds, nausea, or abdominal pain (because of paralytic ileus from decreased perfusion to GI tract).
10. Metabolic acidosis because of increased lactate production and reduced clearance (caused by anaerobic metabolism and liver dysfunction).
11. Hypoperfusion causes release of catecholamines, which increase contractility and peripheral blood flow but also may increase myocardial oxygen demand and have proarrhythmic effects.

Diagnostic Evaluation

1. Altered hemodynamic parameters (pulmonary artery wedge pressure 15 mm Hg or greater, cardiac index (CI) less than 2.0, elevated systemic vascular resistance [SVR], high right ventricular end-diastolic pressure (RVEDP) greater than 20 mm Hg and decreased mixed venous oxygen saturation).
2. Chest x-ray—pulmonary vascular congestion.
3. Abnormal laboratory values—elevated blood urea nitrogen (BUN) and creatinine, elevated liver enzymes, increased PTT and PT, elevated serum lactate, elevated brain natriuretic peptide (BNP). BNP may be useful as an indicator of heart failure and as an independent prognostic indicator of survival. Abnormally elevated cardiac enzymes.
4. ECG—acute injury pattern consistent with an AMI.
5. Doppler echocardiogram—reveals any ventricular wall motion or surgically correctable cause, such as valvular dysfunction and tamponade.
6. Pulmonary artery catheterization for severely hypotensive patient.

Management

Recent studies have suggested that treatment for cardiogenic shock resulting from an AMI should focus on revascularization and thrombolytics. Reduction in mortality related to early revascularization in patients with STEMI is supported by research. Augmenting CO with devices (intra-aortic balloon pump [IABP] is a method of choice) is crucial until revascularization is established. Mechanical ventilation is supportive and left ventricular assist device and extracorporeal membrane oxygenation may be used.

The standard treatment of beta-adrenergic blockers, ACE inhibitors, analgesics, and nitrates after acute MI does little to treat cardiogenic shock and may exacerbate systolic hypotension.

Pharmacologic Therapy

Pharmacologic therapy may need to be discontinued or its use decreased when a patient has gone into cardiogenic shock. Standard therapy for a failing heart includes:

1. Positive inotropic drugs (epinephrine, dopamine, dobutamine, amrinone, milrinone) stimulate cardiac contractility. Dobutamine, amrinone, and milrinone may lower BP because of vasodilatory effect.
2. Vasodilator therapy.
   a. Decreases the workload of the heart by reducing venous return and lessening the resistance against which the heart pumps (preload and afterload reduction).
   b. CO improves, left ventricular pressures and pulmonary congestion decrease, and myocardial oxygen consumption is reduced.
3. Vasopressor therapy may be needed to maintain adequate perfusion pressure (MAP 70 mm Hg or greater). These medications are norepinephrine, epinephrine, vasopressin, and phenylephrine. These should be used in the lowest possible dose. Higher vasopressor doses are associated with poor survival.
4. Diuretic therapy is used to reduce plasma volume and peripheral edema. The reduction in extracellular fluid and plasma volume associated with diuresis may initially decrease cardiac output and, consequently, blood pressure, with a compensatory increase in peripheral vascular resistance. Continuous renal replacement therapy has been considered for patients in cardiogenic shock if unable to diurese because of low renal perfusion.

DRUG ALERT Use vasoactive drugs with extreme caution in the presence of cardiogenic shock. They require constant vigilance and astute observation to maintain an adequate perfusion pressure while achieving afterload reduction.

Reperfusion Therapy

Revascularization in cardiogenic shock patient may increase the patient's survival rate.

See pages 255–260.

1. Percutaneous cardiac interventions (PCI)—prompt restoration of blood flow can lead to improved left ventricular function, thus salvaged ischemic myocardium. Timing of revascularization less than 90 minutes of door-to-door angioplasty after onset of symptoms provides better survival rates of CS patients. Antithrombotic therapy such as antiplatelets and anticoagulation is a mainspring during PCI. They showed to reduce mortality of cardiogenic shock patients following an acute MI.
2. Thrombolytics—use of fibrinolytic drugs lead to improved left ventricular systolic function and survival in patients with myocardial infarction associated with either ST-segment elevation or left bundle-branch block. Limitation to its use due to contraindication generally because of allergy and bleeding concerns such as recent hemorrhagic stroke.

Counterpulsation Therapy

See page 258.

1. Improves blood flow to the heart muscle and reduces myocardial oxygen needs.
2. Results in improved CO (1.5 L/minute increase) and preservation of viable heart tissue.
3. Should be instituted as quickly as possible to increase survival because of its overall benefits.

Total Circulatory and Mechanical Support

1. Left ventricular assist device (LVAD) or right ventricular assist device may be used as bridge to recovery in some patients.
2. Extracorporeal life support (ECMO)- circulates blood using a membrane oxygenator which relieves both left and right heart and the lungs of part of their workload.

Emergency Cardiac Surgery

1. Bypass graft (see page 260).
2. Heart transplantation.

Complications

1. Neurologic impairment/stroke.
2. Acute respiratory distress syndrome.
3. Renal failure.
4. Cardiopulmonary arrest.
5. Dysrhythmia.
6. Ventricular aneurysm.
7. Multiorgan dysfunction syndrome.
8. Bowel ischemia.
9. Limb ischemia.
10. Death.

Nursing Assessment

Clinical assessment begins with attention to the airway/breathing/circulation and vital signs.

1. Identify patients at risk for development of cardiogenic shock.
2. Assess for early signs and symptoms indicative of shock:
    a. Restlessness, confusion, or change in mental status.
    b. Increasing heart rate and decreasing blood pressure.
    c. Decreasing pulse pressure (indicates impaired CO).
    d. Presence of pulsus alternans (indicates left-sided heart failure).
    e. Decreasing urine output, weakness, fatigue.
3. Observe for presence of central and peripheral cyanosis.
4. Observe for development of edema and cool extremities.
5. Identify signs and symptoms indicative of extension of MI—recurrence of chest pain, diaphoresis.

6. Identify patient's and significant other's reaction to crisis situation.

NURSING ALERT Cardiogenic shock carries an extremely high mortality (above 50% to 60% in hospital). Astute assessments and immediate actions are essential to prevent death.

Nursing Diagnoses

- Decreased Cardiac Output related to impaired contractility because of extensive heart muscle damage.
- Impaired Gas Exchange related to pulmonary congestion because of elevated left ventricular pressures.
- Ineffective Tissue Perfusion (renal, cerebral, cardiopulmonary, GI, and peripheral) related to decreased blood flow.
- Anxiety related to intensive care environment and threat of death.

Nursing Interventions

1. Administer oxygen by face mask or artificial airway to ensure adequate oxygenation of tissues and adjust oxygen flow rate as blood gas measurement indicates.
2. Administer diuretic with caution if ordered to increase renal blood flow and urine output.
3. Monitor and record blood pressure, pulse, respiratory rate, and peripheral pulse every 1 to 5 minutes until the patient stabilizes. Record hemodynamic pressure readings according to hospital protocol.
4. Monitor ABG values, complete blood count, and electrolyte levels.
5. To ease emotional stress, allow frequent rest periods as possible.
6. Allow family members to visit and comfort the patient as much as possible.
7. During therapy, assess skin color and temperature and note any changes. Cold and clammy skin may be a sign of continuing peripheral vascular constriction, indicating progressive shock.

Improving Cardiac Output

1. Establish continuous ECG monitoring to detect dysrhythmias, which increase myocardial oxygen consumption.
2. Monitor hemodynamic parameters continually with pulmonary artery catheter (see page 245) to evaluate effectiveness of implemented therapy.
   a. Obtain pulmonary artery pressure (PAP), pulmonary artery wedge pressure, and CO readings, as indicated.
   b. Calculate the CI (CO relative to body size) and SVR (estimation of afterload).
   c. Cautiously titrate vasoactive drug therapy according to hemodynamic parameters.
3. Be alert to adverse responses to drug therapy.
   a. Dopamine may cause an increase in heart rate, which may result in ischemia.
   b. Vasodilators, such as nitroglycerin and nitroprusside, may worsen hypotension.

c. Dobutamine may result in dysrhythmias.
d. Diuretics may cause hyponatremia, hypokalemia, and hypovolemia.

4. Administer vasoactive drug therapy through central venous access (peripheral tissue necrosis can occur if peripheral IV access infiltrates and peripheral drug distribution may be lessened from vasoconstriction).
5. Monitor blood pressure and MAP with intra-arterial line continuously during active titration of vasoactive drug therapy.
6. Maintain MAP greater than 65 mm Hg (blood flow through coronary vessels is inadequate with MAP less than 65 mm Hg).
7. Measure and record urine output every hour from indwelling catheter and fluid intake.
8. Obtain daily weight.
9. Evaluate serum electrolytes for hyponatremia, hypomagnesemia, and hypokalemia.
10. Be alert to incidence of chest pain (indicates myocardial ischemia and may further extend heart damage).
    a. Report immediately.
    b. Obtain a 12-lead ECG; check cardiac enzymes—CK, CK-MB, myoglobin, and troponin.
    c. Anticipate use of counterpulsation therapy.
11. Anticipate pump failure; evaluate need for surgical intervention (ie, ventricular assist device, extracorporeal membrane oxygenation).

Improving Oxygenation

1. Monitor rate and rhythm of respirations every hour.
2. Auscultate lung fields for abnormal sounds (coarse crackles indicate severe pulmonary congestion) every hour; notify health care provider.
3. Evaluate arterial blood gas (ABG) levels and correlate with oxygen saturation.
4. Administer oxygen therapy to increase oxygen tension and improve hypoxia.
5. Elevate head of bed 20 to 30 degrees, as tolerated (may worsen hypotension), to facilitate lung expansion.
6. Reposition patient frequently to promote ventilation and maintain skin integrity.
7. Observe for frothy pink sputum and cough (may indicate pulmonary edema); report immediately.

Maintaining Tissue Perfusion

1. Perform a neurologic check every hour using the Glasgow Coma Scale.
2. Report changes immediately.
3. Obtain BUN and creatinine blood levels and monitor urine output to evaluate renal function.
4. Auscultate for bowel sounds every 2 hours.
5. Evaluate character, rate, rhythm, and quality of arterial pulses every 2 hours.
6. Monitor temperature every 2 to 4 hours.
7. Use sheepskin foot and elbow protectors to prevent skin breakdown.
8. Obtain serum lactate to evaluate tissue perfusion and acidosis.

Relieving Anxiety

1. As with the above, always evaluate signs of increasing anxiety and/or new-onset anxiety for a physiologic cause before treating with anxiolytics.
2. Explain equipment and rationale for therapy to patient and family. Increasing knowledge assists in alleviating fear and anxiety.
3. Encourage patient to verbalize fears about diagnosis and prognosis.
4. Explain sensations patient will experience before procedures and routine care measures.
5. Offer reassurance and encouragement.
6. Utilize social worker or pastoral care for support.
7. Provide for periods of uninterrupted rest and sleep.
8. Assist patient to maintain as much control as possible over environment and care.
    a. Develop a schedule for routine care measures and rest periods with patient.
    b. Make sure that a calendar and clock are in view of patient.

Patient Education and Health Maintenance

1. Assess patient's readiness to learn.
2. Teach patients taking digoxin the importance of taking their medication as prescribed, taking pulse before daily dose, and reporting for periodic blood levels.
3. Teach signs of impending heart failure—increasing edema, shortness of breath, decreasing urine output, decreasing BP, increasing pulse—and tell patient to notify health care provider immediately.
4. See specific measures for MI (see page 280), cardiomyopathy (see page 296), and valvular disease (see page 307).
5. Teach patient importance of keeping follow-up appointments with his or her primary care physician and cardiologist.
6. Have dietitian teach patient and family about a low-sodium, low-fat diet, and reiterate the importance of adhering to this diet.
7. Explain to the patient the need to work with a physical and occupational therapist—especially if the patient has low ejection fraction—for energy conservation.

Evaluation: Expected Outcomes

- CO greater than 4 L/minute; CI greater than 2.2; PCWP less than 18 mm Hg.
- Respirations unlabored and regular; normal breath sounds throughout lung fields.
- Normal sensorium; urine output adequate; skin warm and dry.
- Verbalizes lessened anxiety and fear.

Infective Endocarditis

Infective endocarditis (IE; bacterial endocarditis) is an infection of the inner lining of the heart caused by direct invasion of bacteria or other organisms that could potentially result in myocardial abscess or heart failure and other complications.

Pathophysiology and Etiology

1. When the inner lining of the heart (endocardium) becomes inflamed, a fibrin clot (vegetation) forms.
2. The fibrin clot may become colonized by pathogens during transient episodes of bacteremia resulting from invasive procedures (venous and arterial cannulation, dental work causing gingival bleeding, GI tract surgery, liver biopsy, sigmoidoscopy), indwelling catheters, urinary tract infections, and wound and skin infections.
3. Platelets and fibrin surround the invading microorganisms, forming a protective covering and causing the infected vegetation to enlarge.
    a. The enlarged vegetation (the basic lesion of endocarditis) can deform, thicken, stiffen, and scar the free margins of valve leaflets as well as the fibrous ring (annulus) supporting the valve.
    b. The vegetations may also travel to various organs and tissues (spleen, kidney, coronary artery, brain, and lungs) and obstruct blood flow.
    c. The "protective covering" surrounding the vegetation makes it difficult for WBCs and antimicrobial agents to infiltrate and destroy the infected lesion.
4. Some of the bacterial causes include:
    a. *Streptococcus viridans*—bacteremia occurs after dental work or upper respiratory infection.
    b. *Staphylococcus aureus*—most common cause of IE; bacteremia occurs after cardiac surgery or parenteral drug abuse.
    c. *Staphylococcus epidermidis*—bacteremia occurs due to prosthetic heart valves and IV access procedures.
    d. Enterococci (penicillin-resistant group *D. streptococci*)—bacteremia usually occurs in older patients (over age 60) with genitourinary tract infection.
    e. Gram-negative bacteria such as *Pseudomonas aeruginosa*, *Actinobacter*, and HACEK group bacteria. The HACEK group consists of *Haemophilus* species, *Aggregatibacter* species, *Cardiobacterium hominis*, *Eikenella corrodens*, and *Kingella* species.
    f. Facultative intracellular parasites such as *Bartonella* and other opportunistic pathogens such as *Salmonella* and *Brucella* can cause infective endocarditis.
5. Fungi (*Candida albicans*, *Aspergillus*) and rickettsiae are additional causes.
6. IE may develop on a heart valve already injured by rheumatic fever, congenital defects, on abnormally vascularized valves, normal heart valves, and mechanical and biological heart valves.
7. IE may be acute or subacute, depending on the microorganisms involved. Acute IE manifests rapidly with danger of intractable heart failure and occurs more commonly on normal heart valves.
8. Subacute IE manifests as a prolonged chronic course with a lesser risk of complications and occurs more

commonly on damaged or defective valves.

9. IE may follow cardiac surgery, especially when prosthetic heart valves are used. Foreign bodies, such as pacemakers, patches, grafts, and dialysis shunts, predispose to infection.
10. High incidence among drug abusers, in whom the disease mainly affects normal valves, usually the tricuspid.
11. Hospitalized patients with indwelling catheters, those on prolonged IV therapy or prolonged antibiotic therapy, those with burns, and those on immunosuppressive drugs or steroids may develop fungal endocarditis.
12. Relapse because of metastatic infection is possible, usually within the first 2 months after completion of antibiotic regimen.
13. Genitourinary disorders, infection, and manipulations, which includes pregnancy, delivery, and abortion, may predispose to infection as well.

NURSING ALERT The incidence of nosocomial bacteremias is commonly associated with intravascular lines, and wound care may result in infective endocarditis.

Clinical Manifestations

Severity of manifestations depends on invading microorganism.

General Manifestations

1. Fever, chills, sweats (fever may be absent in older patients or those with uremia).
2. Anorexia, weight loss, weakness.
3. Cough and back and joint pain (especially in patients over age 60).
4. Splenomegaly.

Skin and Nail Manifestations

1. Janeway lesions—light pink macules on palms or soles, nontender, may change to light tan within several days or fade in 1 to 2 weeks; usually an early sign of endocardial infection.
2. Petechiae—conjunctiva and mucous membranes.
3. Splinter hemorrhages in nail beds.
4. Osler nodes—painful red nodes on pads of fingers and toes; usually late sign of infection and found with a subacute infection.
5. Clubbing of fingers and toes—primarily occurs in patients who have an extended course of untreated infective endocarditis.

Heart Manifestations

1. New pathologic or changing murmur—no murmur with other signs and symptoms may indicate right-

sided heart infection.

2. Tachycardia—related to decreased CO.
3. Symptoms consistent of heart failure, pericardial friction rub.
4. New heart block or arrhythmia.

Central Nervous System Manifestations

1. Localized headaches, stiff neck.
2. Transient cerebral ischemia or other neurological symptoms.
3. Altered mental status, aphasia.
4. Hemiplegia.
5. Cortical sensory loss.
6. Roth spots on fundi (retinal hemorrhages).

Pulmonary Manifestations

1. Pneumonitis, pleuritis, pulmonary edema, infiltrates, effusions (causing friction rub)—occur with right heart involvement.

Embolic Phenomena

1. Lung—hemoptysis, chest pain, shortness of breath.
2. Kidney—hematuria, abnormal urine color.
3. Spleen—pain in the left upper quadrant of the abdomen radiating to left shoulder.
4. Heart—MI, aortic insufficiency, heart failure.
5. Brain—sudden blindness, paralysis, brain abscess, meningitis, CVA.
6. Blood vessels—mycotic aneurysms.
7. Abdomen—melena, acute pain.

Diagnostic Evaluation

Varied clinical manifestations and similarities to other diseases make early diagnosis of IE difficult. Accurate diagnosis is essential to guide therapy. A definitive clinical diagnosis can be made based on the finding of 2 major criteria, 5 minor criteria, or 1 major and 3 minor criteria.

Major Criteria (Based on Modified Duke Criteria)

1. Blood cultures—at least two positive serial blood cultures (90% of IE patients have positive blood cultures).
2. Endocardial involvement (diagnosed with transesophageal echocardiogram)—identification of vegetations and assessment of location and size of lesions.
3. New valvular insufficiency/regurgitation.
4. Development of abscess or new partial dehiscence of prosthetic valve or new valvular regurgitation.

Minor Criteria

1. Predisposing cardiac condition or IV drug use.
2. Fever higher than 100.4°F (38°C).
3. Vascular factors—pulmonary complication, arterial emboli, Janeway lesions, mycotic aneurysm, intracranial hemorrhage.
4. Immunologic factors—Osler nodes, Roth spots, rheumatoid factor, glomerulonephritis.
5. Microbiology—positive cultures, but not meeting major criteria.

Management

1. IV antimicrobial therapy, based on sensitivity of causative agent. Six weeks of therapy is recommended for most patients except uncomplicated right-sided IE in whom 2 weeks of therapy is recommended.
2. Combination antibiotic therapy is highly effective and can be given for 2 weeks, depending on what group of pathogens identified. Bactericidal serum levels of selected antibiotics are monitored by serial titers; if serum lacks adequate bactericidal activity, higher dosage or a different antibiotic is needed.
3. Supplemental nutrition.
4. Surgical intervention for specific complications but surgery should be delayed for at least a month in patients who suffered a hemorrhagic CVA. Surgery should not be delayed in patients following silent embolic event or transient ischemic attack, associated heart failure, abscess, or high embolic risk patients.
    a. Acute destructive valvular lesion—excision of infected valves or removal of prosthetic valve.
    b. Hemodynamic impairment, severe heart failure.
    c. Recurrent emboli.
    d. Resistant infection.
    e. Drainage of abscess or empyema.
    f. Repair of peripheral or cerebral mycotic aneurysm.

Complications

1. Severe heart failure because of valvular insufficiency.
2. Uncontrolled/refractory infection.
3. Embolic episodes (brain ischemia or necrosis of extremities and organs).
4. Conduction disturbances.
5. Organ dysfunction resulting from immunological process (kidneys, eyes, skin).
6. Tissue destruction by microorganism, valvular damage, mycotic aneurysms, hemorrhage, and abscess formation.

Nursing Assessment

1. Identify factors that may predispose to endocarditis, such as rheumatic heart disease, congenital heart defects, idiopathic hypertrophic subaortic stenosis, IV drug abuse, prosthetic heart valves, aortic or mitral

stenosis, previous history of endocarditis, recent genitourinary surgery, as well as homelessness or squalid living conditions.

2. Determine onset of signs and symptoms of endocarditis (early treatment of infection improves prognosis).
3. Identify potential incidents that may have precipitated a transient bacteremia capable of causing endocarditis.
4. Obtain blood cultures, CBC, sedimentation rate, C-reactive protein, renal and hepatic studies, and a baseline 12-lead ECG.
5. Assess patient for allergies, with special emphasis on adverse reactions to antibiotic therapy.
6. Note if patient is currently on antibiotic therapy (may affect blood culture results).
7. Identify patient's and family's level of anxiety and use of appropriate coping mechanisms.

Nursing Diagnoses

- Decreased Cardiac Output related to structural factors (incompetent valves).
- Ineffective Tissue Perfusion (renal, cerebral, cardiopulmonary, GI, and peripheral) related to interruption of blood flow.
- Hyperthermia related to illness, potential dehydration, and aggressive antibiotic therapy.
- Imbalanced Nutrition: Less Than Body Requirements related to anorexia.
- Anxiety related to acute illness and hospitalization.

Nursing Interventions

Maintaining Adequate Cardiac Output

1. Auscultate heart to detect new murmur or change in existing murmur; presence of gallop.
2. Monitor BP and pulse.
    a. Note presence of pulsus alternans (indicative of left-sided heart failure).
    b. Evaluate pulse pressure (30 to 40 mm Hg indicates adequate CO).
3. Evaluate jugular vein distention.
4. Record intake and output.
5. Record daily weight.
6. Auscultate lung fields for evidence of crackles (rales).
7. Monitor liver function studies (elevated with liver engorgement related to right heart failure).
8. Assess skin color and temperature.

Maintaining Tissue Perfusion

1. Observe patient for altered mentation, hemoptysis, hematuria, aphasia, loss of muscle strength, and complaints of pain.
2. Monitor vital signs.

3. Monitor urine output.
4. Observe for splinter hemorrhages of nail beds, Osler nodes, and Janeway lesions.
5. Notify health care provider of observed changes in the patient's status.
6. Assess skin color and temperature.
7. Reposition patient frequently to prevent skin breakdown and pulmonary complications associated with bed rest.

Maintaining Normothermia

1. Observe basic principles of asepsis, good handwashing techniques, and continuity of patient care by primary nurse.
2. Employ meticulous IV care for long-term antibiotic therapy.
   a. Note the date of needle or cannula insertion on nursing care plan.
   b. If a peripheral site is used, rotate the site every 72 hours or if site becomes tender, reddened, infiltrated, or has purulent drainage.
   c. Change gauze or transparent dressing every 24 hours to prevent infection.
   d. If a continuous venous access device is used, follow facility policy for site care and dressing changes and flushing procedures.
3. For IM antibiotic therapy, develop chart for rotation of sites.
4. Note that missed doses of antibiotic may have irreversible deleterious consequences, so scheduling is essential to prevent the patient being off the unit when antibiotic is due.
5. Observe for allergic reaction to antibiotic therapy (severe respiratory distress, rash, itching, fever), stop the antibiotic, and notify health care provider promptly so a substitute can be ordered.
6. Obtain audiogram before potentially ototoxic antibiotic is started, and observe for adverse effects such as ototoxicity and renal failure.
7. Assess effectiveness of therapy by obtaining urine culture after 48 hours of drug therapy, and blood cultures after 24 to 48 hours of therapy.
8. Monitor temperature every 4 hours.
   a. Document results on a graph.
   b. Note increases in heart rate and/or respirations with elevated temperatures.
   c. Provide blankets and temperature-controlled comfortable environment if patient has shaking chills; change bed linens, as necessary.
   d. Administer antipyretic or analgesic medications, as directed.
9. Observe patient for a general "sense of well-being" within 5 to 7 days after initiation of therapy.
10. Promote adequate hydration because diaphoresis and increased metabolic rate may cause dehydration.
11. Encourage oral fluid intake.
12. Administer IV fluids as directed.
13. Observe skin turgor and mucous membranes.

DRUG ALERT Rapid infusion of vancomycin (less than 1 hour) may cause red neck syndrome (intense red rash over the upper half of the body) because of histamine release. Slow the rate of infusion and the rash will clear.

Improving Nutritional Status

1. Assess patient's daily caloric intake and monitor weight.
2. Discuss food preferences with patient.
3. Consult with a dietitian about nutritional needs of patient and food preferences.
4. Encourage small meals and snacks throughout the day.
5. Educate family about the patient's caloric needs.
6. Encourage family to assist the patient with meals and bring in patient's favorite foods.

Reducing Anxiety

1. Rule out physiologic etiologies for increasing or new-onset anxiety before administering as-needed sedatives. Physiologic causes must be identified and treated in a timely fashion to prevent irreversible adverse or even fatal outcomes; sedatives may mask symptoms, delaying timely identification, diagnosis, and treatment.
2. Assess patient for signs of hypoperfusion, auscultate heart and lung sounds, obtain a rhythm strip, and administer oxygen, as prescribed. Notify the health care provider immediately.
3. Document assessment findings, health care provider notification and response, and interventions and response.
4. Explain to patient and family reasons for hospitalization, diagnostic tests, and therapies administered.
5. Encourage patient to verbalize fears about illness and hospitalization.
6. Explain procedures to patient before initiation.
7. Encourage diversional activities for patient, such as television, reading, and interaction with other patients.

Patient Education and Health Maintenance

For Patients at Risk for Infective Endocarditis

1. Discuss anatomy of the heart and changes that occur during endocarditis, using diagrams of the heart.
2. Give patient written literature on early signs and symptoms of disease; review these with patient.
3. Discuss with patient the mode of entry of infection.
4. Indicate that antibiotic prophylaxis is recommended prior to dental procedures that manipulate the gingival and some respiratory procedures (see Table 13-4), for patients with the following conditions:
   a. Congenital heart disease (particularly unrepaired cyanotic defects) repaired with prosthetic material (for 6 months following repair) or repaired with residual defect.

b. Prosthetic cardiac valve.

c. Previous IE.

d. Heart transplantation recipient with cardiac valvular disease.

5. Identify individual steps necessary to prevent infection.

a. Practice good oral hygiene, regular tooth brushing, and flossing. See dentist regularly.

b. Notify health care personnel of any history of congenital heart disease or valvular disease.

c. Discuss importance of carrying emergency identification with information of medical history at all times.

d. Take temperature if infection is suspected, and notify health care provider of elevation.

e. Educate patients at risk to look for and treat signs and symptoms of illness indicating bacteremia—injuries, sore throats, furuncles, and so forth.

6. Encourage at-risk individuals to receive pneumococcal and influenza vaccines.

Table 13-4 Preventing Endocarditis: Regimens for a Dental Procedure

		REGIMEN: SINGLE DOSE 30–60 MINUTES BEFORE PROCEDURE	
SITUATION	**AGENT**	**ADULTS**	**CHILDREN**
Oral	Amoxicillin	2 g	50 mg/kg
Unable to take oral medication	Ampicillin OR	2 g IM or IV	50 mg/kg IM or IV
	Cefazolin or ceftriaxone	1 g IM or IV	50 mg/kg IM or IV
Allergic to penicillins or ampicillin—oral	Cephalexin*,†	2 g	50 mg/kg
	OR		
	Clindamycin	600 mg	20 mg/kg
	OR		
	Azithromycin or clarithromycin	500 mg	15 mg/kg IM or IV
Allergic to penicillins or ampicillin and unable to take oral medication	Cefazolin or ceftriaxone†	1 g IM or IV	50 mg/kg IM or IV
	OR		
	Clindamycin	600 mg IM or IV	20 mg/kg IM or IV

**Or other first- or second-generation oral cephalosporin in equivalent adult or pediatric dosage.*

†Cephalosporins should not be used in individuals with a history of anaphylaxis, angioedema, or urticaria with penicillins or ampicillin.

IM, intramuscular; IV, intravenous.

For Individuals Who Have Had Endocarditis Regarding Possible Relapse

1. Discuss importance of keeping follow-up appointments after discharge (infection can recur in 1 to 2 months).
2. Review the tests that will be performed after discharge—blood cultures, physical examination, echocardiography.
3. Teach patient to inspect soles for Janeway lesions (indicative of possible relapse).
4. Contact social worker or case manager to assist patient with financial planning and home discharge arrangements, if applicable.

Evaluation: Expected Outcomes

- BP stable; no change in murmur; no gallop noted.
- No change in LOC, strength, or neurologic function.

- Normal temperature; negative blood cultures; no hearing impairment.
- Tolerates increased daily caloric intake well.
- Verbalizes decrease in anxiety.

Rheumatic Endocarditis (Rheumatic Heart Disease)

Rheumatic endocarditis is an acute, recurrent inflammatory disease that causes damage to the heart as a sequela to group A beta-hemolytic streptococcal infection, particularly the valves, resulting in valve leakage (insufficiency) and/or obstruction (narrowing or stenosis). There are associated compensatory changes in the size of the heart's chambers and the thickness of chamber walls. It is a major burden in developing countries where it causes most of the cardiovascular morbidity and mortality in young people, leading to about 250,000 deaths per year worldwide.

See discussion of rheumatic fever in children in Chapter 45, page 1220.

Pathophysiology and Etiology

1. Rheumatic fever is a sequela to group A beta-hemolytic streptococcal infection that occurs in about 3% of untreated infections. It is a preventable disease through detection and adequate treatment of streptococcal pharyngitis.
2. Connective tissue of the heart, blood vessels, joints, and subcutaneous tissues can be affected.
3. Lesions in connective tissue are known as Aschoff bodies, which are localized areas of tissue necrosis surrounded by immune cells.
4. Heart valves, mainly the mitral valve, are affected, resulting in valve leakage and narrowing.
5. Compensatory changes in the chamber sizes and thickness of chamber walls occur.
6. Heart involvement (pancarditis) also includes pericarditis, myocarditis, epicarditis, and endocarditis.

Clinical Manifestations

1. Symptoms of streptococcal pharyngitis may precede rheumatic symptoms.
   a. Sudden onset of sore throat; throat reddened with exudates.
   b. Swollen, tender lymph nodes at angle of the jaw.
   c. Headache and fever 101°F to 104°F (38.3°C to 40°C).
   d. Abdominal pain (children).
   e. Some cases of streptococcal throat infection relatively asymptomatic.
2. Warm and swollen joints (polyarthritis), beginning in the lower extremities (knees and ankles) and may include the large joints in the upper extremities (elbows, wrists). Pain in joints.
3. Sydenham chorea (irregular, jerky, involuntary, unpredictable muscular movements).
4. Erythema marginatum (transient mesh-like macular rash on the trunk and extremities, never on the face, in about 5% to 13% of patients).
5. Subcutaneous nodules (hard, painless nodules over extensor surfaces of extremities; rare).
6. Fever.
7. Prolonged PR interval as shown on ECG.
8. Heart murmurs; pleural and pericardial rubs.
9. History of previous rheumatic fever or rheumatic heart disease.

Diagnostic Evaluation

1. Throat culture—streptococcal organisms.
2. Sedimentation rate, WBC count and differential, and CRP—increased during acute phase of infection.
3. Elevated antistreptolysin-O (ASO)/streptococcal antibody titer.
4. ECG—prolonged PR interval or heart block.
5. Echocardiography and Doppler study.
6. Cardiac catheterization to evaluate valvular damage and left ventricular function in those with severe cardiac dysfunction.

Management

1. Antimicrobial therapy—penicillin, erythromycin, or cephalosporin. Early treatment is key to survival.
2. Rest—to maintain optimal cardiac function.
3. Salicylates or NSAIDs—fever and pain; should be used with caution, especially in the elderly, due to risk of renal failure and gastrointestinal bleeding.
4. Steroids—during acute inflammatory phase.
5. Prevention of recurrent episodes through long-term penicillin therapy for 5 years or until 21 years old, whichever is longer, if patient does not have carditis, or 10 years if with carditis; periodic prophylaxis throughout life.
6. Beta-blockers, ACE inhibitors, digoxin, other afterload reduction medications, diuretics, supplemental oxygen, rest, sodium and fluid restrictions—to manage heart failure.
7. Though chorea is self-limiting, phenobarbital and diazepam may relieve the symptom.
8. Percutaneous mitral balloon valvuloplasty (PMBV) is recommended for patients with rheumatic mitral stenosis.

Complications

1. Valvular heart disease.
2. Cardiomyopathy.
3. Heart failure.
4. Atrial arrhythmias.
5. Pulmonary and systemic embolism.

Nursing Assessment

1. Ask patient about symptoms of fever or throat or joint pain.
2. Ask patient about chest pain, dyspnea, fatigue.
3. Observe for skin lesions or rash on the trunk and extremities.
4. Palpate for firm, nontender movable nodules near tendons or joints.
5. Auscultate heart sounds for murmurs and/or rubs.

Nursing Diagnoses

- Hyperthermia related to disease process.
- Decreased Cardiac Output related to decreased cardiac contractility.
- Activity Intolerance related to joint pain and easy fatigability.

Nursing Interventions

Reducing Fever

1. Administer penicillin therapy, as prescribed, to eradicate hemolytic streptococcus; an alternative drug may be prescribed if patient is allergic to penicillin or sensitivity testing and desensitization may be done.
    a. Coordinate schedule to prevent missed or delayed dose of antibiotic because of patient being off unit to prevent deleterious effects.
2. Give salicylates or NSAIDs, as prescribed, to suppress rheumatic activity by controlling toxic manifestations, to reduce fever, and to relieve joint pain.
3. Assess for effectiveness of drug therapy.
    a. Take and record temperature every 3 hours.
    b. Evaluate patient's comfort level every 3 hours.

Maintaining Adequate Cardiac Output

1. Assess for signs and symptoms of acute rheumatic carditis.
    a. Be alert to patient's complaints of chest pain, palpitations, and/or precordial "tightness."
    b. Monitor for tachycardia (usually persistent when patient sleeps) or bradycardia.
    c. Be alert to development of second-degree heart block or Wenckebach disease (acute rheumatic carditis causes PR-interval prolongation).
2. Auscultate heart sounds every 4 hours.
    a. Document presence of murmur or pericardial friction rub.
    b. Document extra heart sounds (S_3 gallop, S_4 gallop).
3. Monitor for development of chronic rheumatic endocarditis, which may include valvular disease and heart failure.

Maintaining Activity

1. Maintain bed rest for duration of fever or if signs of active carditis are present.
2. Provide ROM exercise program.
3. Provide diversional activities that prevent exertion.
4. Discuss the need for tutorial services with parents to help child keep up with schoolwork.

Patient Education and Health Maintenance

1. Counsel patient to maintain good nutrition.

2. Counsel patient on hygienic practices.
    a. Discuss proper handwashing, disposal of tissues, laundering of handkerchiefs (decrease risk of exposure to microbes).
    b. Discuss importance of using patient's own toothbrush, soap, and washcloths when living in group situations.
3. Counsel patient on importance of receiving adequate rest.
4. Instruct patient to seek treatment immediately should sore throat or fever occur.
5. Support patients in long-term antibiotic therapy to prevent relapse (5 years for most adults).
6. Instruct patient with valvular disease to use prophylactic antibiotic therapy an hour before certain procedures and surgery (see page 289).
7. Discuss patient's ability to pay for medical treatment. If appropriate, contact social services for patient. (Financial difficulties may inhibit patient from seeking early treatment of symptoms.)

Evaluation: Expected Outcomes

- Afebrile.
- Denies chest pain; normal sinus rhythm.
- Maintains bed rest while febrile.

Myocarditis

Myocarditis is an inflammatory process involving the myocardium, thus damaging the heart muscle. Although the exact cause of myocarditis is still unknown, it is thought to attack otherwise healthy individuals. It is thought the cause of sudden death among young adults and cause acute or chronic dilated cardiomyopathy.

Pathophysiology and Etiology

1. Focal or diffuse inflammation of the myocardium; may be acute or chronic.
2. May follow infectious process—viral or "idiopathic" (particularly coxsackie group B and may develop after influenza A or B, herpes simplex, parvovirus, cytomegalovirus, adenovirus, enterovirus, Epstein-Barr, rubella, and human immunodeficiency virus [HIV]), bacterial, parasitic, protozoal, rickettsial, spirochetal, and fungal (*Candida*, *Aspergillus*, and *Histoplasma*).
3. Hepatitis C virus has been associated with myocarditis by identification of HCV antibodies.
4. May be associated with chemotherapy (especially doxorubicin), immunosuppressive therapy, or vaccinia virus inoculation for protection against smallpox infection.
5. Systemic disorders such as sarcoidosis and celiac disease, autoimmune conditions such as systemic lupus, and other collagen diseases may cause myocarditis.
6. May be associated with exposures to certain chemicals (arsenic and hydrocarbons); allergic or toxic reactions to penicillin or sulfonamides; insect/snake bites; cocaine use.
7. Radiation exposure—most cases are the result of therapy for Hodgkin lymphoma or breast or lung cancer. Less common is exposure to a nuclear reactor or after detonation of a nuclear device.

Clinical Manifestations

1. Symptoms depend on type of infection, degree of myocardial damage, capacity of the myocardium to recover, and host resistance. Can be acute or chronic and can occur at any age. Symptoms may be minor and go unnoticed.
    a. Fatigue and dyspnea.
    b. Palpitations.
    c. Occasional precordial discomfort/vague chest pain.
2. Cardiac enlargement.
3. Abnormal heart sounds: murmur, S_3 or S_4, or friction rubs.
4. Signs of heart failure (eg, pulsus alternans, dyspnea, crackles, lower extremity edema, low urine output).
5. Fever with tachycardia or other signs of viral infection, such as headache, joint pain, and sore throat.
6. Joint pain or swelling; leg swelling

Diagnostic Evaluation

1. Transient ECG changes—ST segment flattened, T-wave inversion, conduction defects, extrasystoles, supraventricular and ventricular ectopic beats, brady- or tachyarrhythmias.

2. Elevated WBC count, C-reactive protein, and sedimentation rate.
3. Measurement of serum cardiac biomarkers such as CPK and troponin—may be elevated.
4. Chest x-ray—may show heart enlargement and lung congestion.
5. Elevated antibody titers (ASO titer as in rheumatic fever).
6. Stool and throat cultures isolating bacteria or a virus.
7. Endomyocardial biopsy for definitive diagnosis. This is the gold standard for establishing the diagnosis.
8. Echocardiogram—defines size, structure, and function of the heart.
9. Cardiovascular MRI—may be helpful to determine structural alterations; can provide accurate tissue characterization
10. Nuclear imaging using *gallium* (detects the extent of myocardial inflammation) or *indium* (antimyosin antibodies—shows the extent of myocyte necrosis)

Management

Treatment objectives are targeted toward management of complications. Supportive care is the first line of treatment.

1. Elevated ventricular filling pressures should be treated with intravenous diuretics and vasodilators (when feasible) such as nitroprusside.
2. Antidysrhythmic therapy (usually amiodarone).
3. Strict bed rest to promote healing of damaged myocardium.
4. Antimicrobial therapy if causative bacteria are isolated.
5. Anticoagulation therapy.
6. ACE inhibitor or beta-adrenergic blocker (should be used with caution; may cause hypotension)—to strengthen the heart's pumping ability and to reduce its workload, thus improving left ventricular systolic dysfunction.
7. In severe cases, aggressive therapy may be necessary: inotropes, such as dobutamine and dopamine; IABP counterpulsation therapy.
8. A ventricular assist device or extracorporeal membrane oxygenation may rarely be required to sustain patients with refractory cardiogenic shock as well as consideration of urgent heart transplantation.
9. IV immunoglobulin has antiviral effects; interferon-α and interferon-β; immunosuppressive regimen of steroids and cyclosporine or azathioprine improves systolic function.

Complications

1. Heart failure, pericarditis.
2. Cardiomyopathy.
3. Arrhythmias.
4. Sudden cardiac death.

Nursing Assessment

1. Assess for fatigue, palpitations, fever, dyspnea, and chest pain.
2. Auscultate heart sounds.
3. Assess limbs for swelling, discoloration of the skin, and temperature of the skin.
4. Evaluate history for precipitating factors.
5. Pay special attention to variation in blood pressure, increased heart rate with ectopies, and tachypnea.

Nursing Diagnoses

- Hyperthermia related to inflammatory/infectious process.
- Decreased Cardiac Output related to decreased cardiac contractility and dysrhythmias.
- Activity Intolerance related to impaired cardiac performance and febrile illness.
- Acute Pain related to disease process

Nursing Interventions

Reducing Fever

1. Administer antipyretics as directed.
2. Check temperature every 4 hours.
3. Administer antibiotics as directed.

Maintaining Cardiac Output

1. Evaluate for clinical evidence that disease is subsiding—monitor pulse, auscultate for abnormal heart sounds (murmur or change in existing murmur), check temperature, auscultate lung fields, monitor respirations.
2. Record daily intake and output.
3. Record daily weight.
4. Check for peripheral edema.
5. Elevate head of bed, if necessary, to enhance respiration. Encourage use of incentive spirometry.
6. Treat the symptoms of heart failure as prescribed (see page 298).
7. Evaluate patient's pulse and apical rate for signs of tachycardia and gallop rhythm—indications that heart failure is recurring.
8. Evaluate for evidence of dysrhythmias—patients with myocarditis are prone to develop dysrhythmias.
   a. Institute continuous cardiac monitoring if evidence of a dysrhythmia develops.
   b. Have equipment for resuscitation, defibrillation, and cardiac pacing available in case of life-threatening dysrhythmia.

DRUG ALERT Digoxin should not be considered for patients with myocarditis. High doses of digoxin may increase production of proinflammatory cytokines and may worsen myocardial injury. If digoxin

was given, assess for toxic signs and symptoms, such as anorexia, nausea, fatigue, weakness, yellow-green halos around visual images, or prolonged PR interval.

Reducing Fatigue

1. Ensure bed rest to reduce heart rate, stroke volume, BP, and heart contractility; also helps to decrease residual damage and complications of myocarditis and promotes healing.
    a. Prolonged bed rest may be required until there is reduction in heart size and improvement of function.
2. Provide diversional activities for patient.
3. Allow patient to use bedside commode rather than bed pan (reduces cardiovascular workload).
4. Discuss with patient activities that can be continued after discharge.
    a. Discuss the need to modify activities in the immediate future.
    b. Explore patient's feelings and concerns about role fulfillment.

Reducing Chest Pain

1. Assess for chest pain; provide pain medication if not contraindicated.
2. Provide a quiet environment and comfort measures such as change in position, back rub, emotional support.
3. Provide supplemental oxygen as indicated.

Patient Education and Health Maintenance

Instruct patient as follows:

1. There is usually some residual heart enlargement; physical activity may be slowly increased; begin with chair rest for increasing periods; follow with walking in the room and then outdoors.
2. Report any symptom involving rapid heartbeat.
3. Avoid competitive sports, cigarettes, illicit drugs, and alcohol. Myocardial toxic medications such as doxorubicin cannot be used.
4. Pregnancy is not advisable for women with cardiomyopathies associated with myocarditis.
5. Prevent infectious diseases with appropriate immunizations (pneumococcal and influenza vaccines).
6. Refer patient to cardiac phase II rehabilitation—a safe, monitored environment to increase patient's exercise work capacity.

Evaluation: Expected Outcomes

- Afebrile.
- BP and heart rate stable; no dysrhythmias noted.
- Maintains bed rest.
- Pain reported at 2 on a scale of 0 to 10.

Pericarditis

Pericarditis is an inflammation of the pericardium, the membranous sac enveloping the heart. It is usually a manifestation of a more generalized disease. In healthy individuals, the pericardial cavity contains about 15 to 50 mL of an ultrafiltrate of plasma. Diseases of the pericardium present clinically in four ways:

Acute and recurrent pericarditis. Pericardial effusion is an abnormal accumulation of fluid in the pericardial cavity.

Cardiac tamponade is an acute type of pericardial effusion in which the heart is compressed, either by blood or by a penetrating injury, so that its normal function is impeded.

Constrictive pericarditis is a condition in which a chronic inflammatory thickening of the pericardium compresses the heart so it is unable to fill normally during diastole.

Pathophysiology and Etiology

1. Acute idiopathic pericarditis is the most common and typical form; etiology unknown.
2. Infection.
    a. Viral—Coxsackievirus; Herpes viruses; adenovirus; parvovirus B19, HIV.
    b. Bacterial—*Staphylococcus*, meningococcus, *Streptococcus*, pneumococcus, gonococcus, *Mycobacterium tuberculosis*.
    c. Fungal (rare)—Histoplasma, Aspergillus, Blastomyces and Candida species.
    d. Parasitic (rare)—Echinococcus and Toxoplasma.
3. Connective tissue disorders (lupus erythematosus, periarteritis nodosa) and gastrointestinal diseases (ulcerative colitis, Crohn and Whipple disease).
4. MI; early, 24 to 72 hours; or late, 1 week to 2 years after MI (Dressler syndrome).
5. Malignant disease; thoracic irradiation (primary or metastatic pericardial tumors).
6. Chest trauma, heart surgery, pacemaker insertion, coronary percutaneous interventions and radiofrequency ablation.
7. Drug-induced—procainamide, phenytoin, hydralazine, methyldopa, and isoniazid.
8. Asbestosis (may induce pericardial as well as lung lesions).
9. Metabolic disorders such as uremia; hypothyroidism may cause pericardial effusion, not necessarily pericarditis.

Clinical Manifestations

1. Pain in anterior chest, aggravated by thoracic motion—may vary from mild to sharp and severe; located in precordial area (may be felt beneath the clavicle, neck, scapular region); may be relieved by leaning forward.
2. Pericardial friction rub—scratchy, grating, or creaking sound occurring in the presence of pericardial inflammation.
3. Edema, ascites, and dyspnea—from pericardial effusion and cardiac tamponade.

4. Fever, sweating, chills—because of inflammation of the pericardium.
5. Dysrhythmias.

Diagnostic Evaluation

1. Echocardiogram—most sensitive method for detecting pericardial effusion.
2. Chest x-ray—may show enlarged cardiac silhouette with clear lung fields.
3. ECG—to evaluate for MI (acute stage of pericarditis, ST elevation is found in several or all leads).
4. WBC count and differential indicating infection.
5. Antinuclear antibody serologic tests elevated in lupus erythematosus.
6. Purified protein derivative test positive in tuberculosis.
7. ASO titers—elevated if rheumatic fever is present.
8. BUN—to evaluate for uremia.
9. Elevated erythrocyte sedimentation rate and serum C-reactive protein levels.
10. Elevated cardiac biomarkers—troponin and MB fraction of creatinine kinase.
11. Pericardiocentesis—for examination of pericardial fluid for etiologic diagnosis and relief from cardiac tamponade.
12. Cardiac MRI or CT.

Management

The objectives of treatment are targeted toward determining the etiology of the problem; administering pharmacologic therapy for specified etiology, when known; and being alert to the possible complication of cardiac tamponade.

1. Bacterial pericarditis—penicillin or other antimicrobials.
2. Rheumatic fever—penicillin G and other antimicrobials (see page 291).
3. Tuberculosis—antituberculosis chemotherapy (see page 206).
4. Fungal pericarditis—amphotericin B and fluconazole.
5. Systemic lupus erythematosus—corticosteroids.
6. Renal pericarditis—dialysis biochemical control of end-stage renal disease.
7. Neoplastic pericarditis—intrapericardial instillation of chemotherapy; radiotherapy.
8. Post-MI syndrome—bed rest, aspirin, prednisone.
9. Postpericardiotomy syndrome (after open heart surgery)—treat symptomatically.
10. Emergency pericardiocentesis if cardiac tamponade develops.
11. Partial pericardiectomy (pericardial “window”) or total pericardiectomy for recurrent constrictive pericarditis.
12. NSAIDs are recommended for symptom relief of acute pericarditis; colchicine and steroid regimen are used as adjunct to NSAID therapy.

Complications

1. Cardiac tamponade.
2. Heart failure.
3. Hemopericardium (especially patients receiving anticoagulants after MI).

Nursing Assessment

1. Assess chest pain.
    a. Ask the patient if pain is aggravated by breathing, turning in bed, twisting body, coughing, yawning, or swallowing.
    b. Assess for relief with sitting up and/or leaning forward.
    c. Be alert to the patient's medical diagnoses when assessing pain. Post-MI patients may experience a dull, crushing pain radiating to the neck, arm, and shoulders, mimicking an extension of infarction. Report change in character of chest pain or worsening pain.
2. Auscultate heart sounds.
    a. Listen for pericardial friction rub by asking patient to hold breath briefly.
    b. Listen to the heart with patient in different positions.
    c. Assess for pulsus paradoxus.
3. Evaluate history for precipitating factors.

Nursing Diagnoses

- Acute Pain related to pericardial inflammation.
- Decreased Cardiac Output related to impaired ventricular expansion.

Nursing Interventions

Reducing Discomfort

1. Give prescribed drug regimen for pain and symptomatic relief.
2. Relieve anxiety of patient and family by explaining the difference between pain of pericarditis and pain of recurrent MI. (Patients may fear extension of myocardial tissue damage.)
3. Explain to patient and family that pericarditis does not indicate further heart damage.
4. Encourage patient to remain on bed rest when chest pain, fever, and friction rub occur.
5. Assist patient to position of comfort.

Maintaining Cardiac Output

NURSING ALERT Normal pericardial sac contains less than 30 mL of fluid; pericardial fluid may accumulate slowly without noticeable symptoms. However, a rapidly developing effusion can produce serious

hemodynamic alterations.

---

1. Assess heart rate, rhythm, BP, respirations at least hourly in the acute phase; continuously if hemodynamically unstable.
2. Assess for signs of cardiac tamponade—increased heart rate, decreased BP, presence of paradoxical pulse, distended jugular veins, restlessness, muffled heart sounds.
3. Prepare for emergency pericardiocentesis or surgery. Keep pericardiocentesis tray at bedside (see page 253).
4. Assess for signs of heart failure (see page 298).
5. Monitor closely for the development of dysrhythmias.

Patient Education and Health Maintenance

1. Advise restriction of activity until biomarkers are normal.
2. Instruct patient about signs and symptoms of pericarditis and the need for long-term medication therapy to help relieve symptoms.
3. Review all medications with the patient—purpose, adverse effects, dosage, and special precautions.

Evaluation: Expected Outcomes

- Verbalizes relief of pain.
- Pulse and heart rate stable, no dysrhythmias, no friction rub.

Cardiomyopathy

Cardiomyopathy refers to disease of the heart muscle or electrical dysfunction. Causes of cardiomyopathy are classified as primary or secondary. Primary cardiomyopathies have genetic, mixed, or acquired etiologies, whereas secondary cardiomyopathies have infiltrative, toxic, or inflammatory causes. The four main types are dilated, hypertrophic, restrictive (less common), and arrhythmogenic right ventricular cardiomyopathy.

Pathophysiology and Etiology

Dilated Cardiomyopathy

Dilated cardiomyopathy is the most common form of cardiomyopathy. It can be divided into ischemic and nonischemic cardiomyopathy.

1. Ischemic cardiomyopathy.
    a. It is caused by inadequate oxygen supply because of obstruction in coronary arteries.
    b. The lack of oxygen interrupts both mechanical and electrical functions of the cells, decreases contractility, and causes dysrhythmia.
    c. The scar formed from MI leads to systolic dysfunction.
2. Nonischemic cardiomyopathy.
    a. Cause is idiopathic (unknown).
    b. 10% to 50% of cases are identified by genetic mutation.
3. Both the right and left ventricles dilate (enlarge) significantly, causing a decrease in the ability of the heart to pump blood efficiently to the body.
4. Blood remaining in the ventricles after contraction causes increases in ventricular, atrial, and pulmonary pressures.
5. Increased pressures continue to diminish the ability of the heart to pump blood to the body, and heart failure symptoms occur after all compensatory mechanisms are exhausted.
6. Alcohol abuse, chemotherapy, chemical agents, myocarditis, pregnancy (third trimester, postpartum), valve disease, endocrine disorders such as thyroid disease, and infections, such as HIV, can cause dilated cardiomyopathy.

Hypertrophic Cardiomyopathy

1. Hypertrophic cardiomyopathy is primarily due to the abnormal thickening of the ventricular septum of the heart.
2. The thickening of the heart muscle commonly occurs asymmetrically (septum is proportionately thicker than the other ventricular walls), but may also occur symmetrically (septum and the ventricular free wall both become equally thickened).
3. The ultrastructure of the heart is also disrupted by patches of myocardial fibrosis, disorganization of myocardial fibers, and abnormalities of the coronary microvasculature.
4. The thickened heart muscle and ultrastructure disruption change the shape, size, and distensibility of the

ventricular cavity and alter the normal thickness and functioning of the mitral valve; as a result, the heart's ability to relax and contract normally is impaired.

   a. Muscle stiffness impairs the filling of the ventricle with blood during relaxation.
   b. Forceful contractions eject blood from the heart too rapidly, causing abnormal pressure gradients; mechanical narrowing of the passage by which the blood leaves the heart also may occur, acutely obstructing blood flow to the body.

5. Some forms of hypertrophic cardiomyopathy have familial presentation suggestive of genetic mutations.

Restrictive Cardiomyopathy

1. The heart muscle becomes infiltrated by various substances, resulting in severe fibrosis.
2. The heart muscle becomes stiff and nondistensible, impairing the ability of the ventricle to fill with blood adequately.
3. Amyloidosis and hemochromatosis (excess iron deposition) may cause restrictive cardiomyopathy.

Arrhythmogenic Right Ventricular Cardiomyopathy

1. Autosomal genetic disorder; affects 1 in 2,000 to 5,000; more common among men.
   a. Characterized by placement of the right ventricular myocytes by fibrofatty tissue, right ventricular dysfunction, and ventricular dysrhythmias.

Clinical Manifestations

1. Exertional dyspnea.
2. Chest pain.
3. Signs of heart failure (see page 298).
4. Pulmonary edema (see page 304).
5. Dysrhythmias (frequent atrial/ventricular ectopic beats; sinus, atrial, and ventricular tachycardia).
6. Pericardial effusions (with restrictive cardiomyopathy).
7. Cardiac murmur.
8. Syncope.
9. Sudden cardiac death may be the first sign with arrhythmogenic right ventricular cardiomyopathy.

Diagnostic Evaluation

1. Chest x-ray (cardiomegaly).
2. ECG—may show dysrhythmia, LV hypertrophy.
3. Echocardiogram to detect abnormalities of heart wall movements.
4. Twenty-four–hour Holter monitoring to detect dysrhythmias.
5. Radionuclide imaging to assess ventricular function.
6. Cardiac catheterization to help determine cause (ischemic or nonischemic).
7. Pulmonary artery catheter for hemodynamic monitoring.

Management

The goal of therapy is to maximize ventricular function and prevent complications.

Dilated Cardiomyopathy

1. Effective management of heart failure by conventional therapy (see page 298).
2. Oral anticoagulants may be instituted to prevent thrombus and pulmonary embolus.
3. Heart transplantation may be considered in eligible patients.
4. Mechanical circulatory support device (ie, LVAD or BiVAD) may also be considered.

DRUG ALERT Patients with dilated cardiomyopathy and other forms of heart failure (HF) are susceptible to digoxin toxicity, especially with the concomitant use of amiodarone, furosemide, or verapamil and in patients with renal impairment. Monitor patient carefully for evidence of nausea, vomiting, yellow vision, and dysrhythmias.

Hypertrophic Cardiomyopathy

1. Guidelines for the management of cardiomyopathy and heart failure in general center around the measurement of ejection fraction (EF). Patients with EF greater than 50 are considered to have heart failure with preserved ejection fraction (HF*p*EF). Those with EF less than or equal to 40 are considered to have heart failure with reduced ejection fraction (HF*r*EF). Beta-adrenergic blockers—reduce the force of the heart muscle's contraction, diminish obstructive pressure gradients, and decrease oxygen requirements. Three beta-blockers have been shown to be effective in reducing mortality in patients with chronic HF*r*EF; these include metoprolol sustained release, bisoprolol, and carvedilol.
2. Antidysrhythmic therapy—digoxin is most commonly used to slow ventricular response and increase myocardial contractility in patients with HF, although beta-blockers have been shown to be more effective than digoxin during exercise. Combination of beta-blockers and digoxin is more effective than either drug alone. If contraindicated, amiodarone may be an alternative.
3. Myotomy and myectomy—surgical resection of a portion of the septum to reduce muscle thickness and provide symptom relief.
4. Device implantation—pacemakers and automatic internal defibrillators may be implanted to prevent sudden death.

DRUG ALERT Verapamil and diltiazem should be avoided in heart failure treatment because they depress myocardial function with increasing heart failure.

DRUG ALERT Chest pain experienced by patients with hypertrophic cardiomyopathy is managed by rest and elevation of the feet (improves venous return to the heart). Vasodilator therapy (nitroglycerin) may worsen chest pain by decreasing venous return to the heart and further increasing obstruction of blood flow from the heart; agents that increase contractility of the heart muscle (dopamine, dobutamine) should also be avoided or used with extreme caution.

Restrictive Cardiomyopathy

1. Therapy is palliative unless specific underlying process is established.
2. Heart failure can be controlled with fluid restriction and diuretic therapy.
3. Digoxin is beneficial for controlling atrial fibrillation.
4. Oral anticoagulants are instituted to prevent emboli.

Arrhythmogenic Right Ventricular Cardiomyopathy

Antidysrhythmic agents such as carvedilol, sotalol, amiodarone.

1. Implantable cardioverter–defibrillator.
2. Myocardial ablation or transplantation.

Complications

1. Mural thrombus (because of blood stasis in ventricles with dilated cardiomyopathy).
2. Severe heart failure.
3. Sudden cardiac death.
4. Pulmonary embolism.

Nursing Assessment

1. Evaluate patient's chief complaint, which may include fever, syncope, general aches, fatigue, palpitations, dyspnea.
2. Evaluate etiologic factors, such as alcohol abuse, pregnancy, recent infection, or history of endocrine disorders.
3. Assess for positive family history.
4. Auscultate lung sounds for crackles (pulmonary edema) or decreased sounds (pleural effusion).
5. Assess heart size through palpation of the chest for point of maximal impulse (PMI) and auscultate for abnormal sounds.
6. Evaluate cardiac rhythm and ECG for evidence of atrial or ventricular enlargement and infarction.

Nursing Diagnoses

- Decreased Cardiac Output related to decreased ventricular function and/or dysrhythmias.

- Anxiety related to fear of death and hospitalization.
- Fatigue related to disease process.

Nursing Interventions

Improving Cardiac Output

1. Monitor heart rate, rhythm, temperature, and respiratory rate at least every 4 hours.
2. Evaluate CVP, pulmonary artery wedge pressure, and PCWP by pulmonary artery catheter to assess progress and effect of drug therapy.
3. Calculate CO, CI, and SVR.
4. Observe for changes in CO, such as decreased BP, change in mental status, decreased urine output.
5. Administer pharmacologic support, as directed, and observe for changes in hemodynamic and clinical status.
6. Administer medications to control or eradicate dysrhythmias, as directed.
7. Administer anticoagulants as directed, especially for patients in atrial fibrillation.
   a. Monitor coagulation studies.
   b. Observe for evidence of bleeding.

Relieving Anxiety

1. Always evaluate increasing and/or new-onset anxiety for a physiologic cause and report to the health care provider before administration of anxiolytics.
2. Explain all procedures and treatments.
3. Inform patient and visitors of visiting hours and policy and whom to contact for information.
4. Orient patient to unit, purpose of equipment, and care plan.
5. Encourage questions and voicing of fears and concerns.

Reducing Fatigue

1. Make sure that patient and visitors understand the importance of rest.
2. Assist patient in identifying stressors and reducing their effect (important for patients with hypertrophic cardiomyopathy because stress worsens the outflow obstruction).
3. Provide uninterrupted periods and assist with ambulation, as ordered.
4. Teach the use of diversional activities and relaxation techniques to relieve tension.

Patient Education and Health Maintenance

1. Medication education such as digoxin.
   a. Take daily only after taking pulse; notify health care provider if pulse is below 60 beats/minute (or other specified rate).
   b. Report signs of digoxin toxicity—anorexia, nausea, vomiting, yellow vision.
   c. Follow-up for periodic blood levels.

2. Advise low-sodium diet (less than 1,500 g daily). Teach how to read labels.
3. Advise reporting signs of heart failure—weight gain, edema, shortness of breath, increased fatigue.
4. Make sure that family members know cardiopulmonary resuscitation (CPR) because sudden cardiac arrest is possible.

Evaluation: Expected Outcomes

- Blood pressure and hemodynamic parameters stable; urine output adequate; baseline mental status.
- Asks questions and cooperates with care.
- Rests at intervals.

Heart Failure

EVIDENCE BASE Yancy, C. W., Jessup, M., Bozkurt, B., et al. (2016). 2016 ACC/AHA/HFSA focused update on new pharmacological therapy for heart failure: An update of the 2013 ACCF/AHA guideline for the management of heart failure: A report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines and the Society for Cardiovascular Angiography and Interventions. *American Journal of Cardiology, 68*(13).

Heart failure is a clinical syndrome that results from the progressive process of remodeling, in which mechanical and biochemical forces alter the size, shape, and function of the ventricle's ability to fill with or pump enough oxygenated blood to meet the metabolic demands of the body.

Pathophysiology and Etiology

1. Cardiac compensatory mechanisms (increased heart rate, vasoconstriction, heart enlargement) initially occur to assist the struggling heart.
   a. These mechanisms are able to "compensate" for the heart's inability to pump effectively and maintain sufficient blood flow to organs and tissue at rest.
   b. Physiologic stressors that increase the workload of the heart (exercise, infection) may cause these mechanisms to fail and precipitate the "clinical syndrome" associated with a failing heart (elevated ventricular/atrial pressures, sodium and water retention, decreased CO, circulatory and pulmonary congestion).
   c. The compensatory mechanisms may hasten the onset of failure because they increase afterload and cardiac work.
2. Caused by disorders of heart muscle resulting in decreased contractile properties of the heart, such as coronary artery disease, hypertension, dilated cardiomyopathy, and valvular heart disease.
3. Risk factors include:
   a. Hypertension.
   b. Hyperlipidemia.
   c. Diabetes.
   d. CAD.
   e. Family history.
   f. Smoking.
   g. Alcohol consumption.
   h. Use of cardiotoxic drugs.
   i. Ventricular dysrhythmias.
   j. Atrial dysrhythmias.

Systolic versus Diastolic Failure

Heart failure (HF) is classified as either HFpEF or HFrEF. Systolic and/or diastolic dysfunction may exist in either HF types (see Figure 13-6).

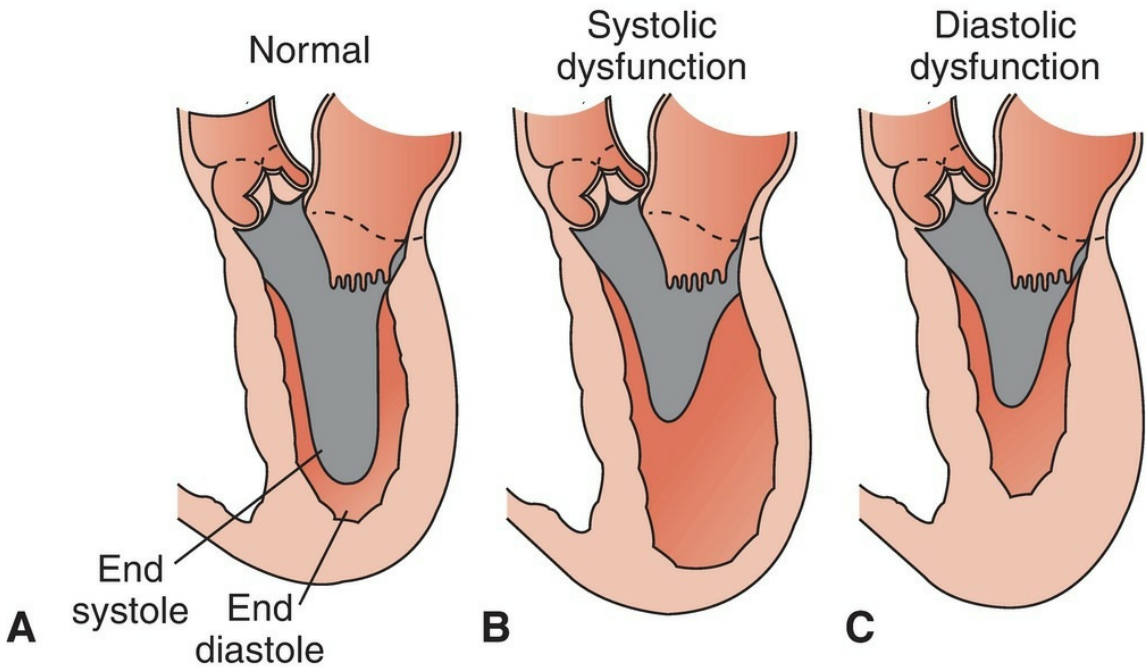

Figure 13-6. Heart failure because of systolic and diastolic dysfunction. The ejection fraction represents the difference between end-diastolic function and end-systolic volume. **(A)** Normal systolic and diastolic function with normal ejection fraction; **(B)** systolic dysfunction with decreased ejection fraction because of impaired systolic function; **(C)**diastolic dysfunction with decreased ejection fraction because of decreased diastolic filling. (Porth, C. M. [2005]. *Pathophysiology: Concepts of altered health states* [7th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

1. Systolic failure—poor contractility of the myocardium results in decreased CO and an elevated SVR.
2. Diastolic failure—stiff myocardium, which impairs the ability of the left ventricle to fill up with blood. This causes an increase in pressure in the left atrium and pulmonary vasculature, causing the pulmonary signs of heart failure.

Acute versus Chronic Heart Failure

1. Acute failure—sudden onset of symptoms such as acute pulmonary edema and decreased CO; requires intervention and medical attention.
2. Chronic failure—long-term process with accompanying compensatory mechanism; can progress to acute phase in the setting of dysrhythmias, ischemia, or sudden illness.
3. Acute on chronic HF—patients with established history of HF who presents with exacerbation.

Neurohormonal Compensatory Mechanisms in Heart Failure

1. Sympathetic Nervous System
    a. Increased catecholamines to compensate for low CO.
    b. Shunting of blood from nonvital to vital organs.
    c. Increased oxygen demand, decreased coronary artery perfusion, and decreased diastolic filling.
2. Renin–Angiotensin–Aldosterone System
    a. Increased fluid retention in response to decreased CO.
    b. Increased vasoconstriction (action of angiotensin II).
    c. Increased SVR.
    d. Increased workload of the heart.
    e. Further decreased CO over time.
3. Ventricular Hypertrophy
    a. Compensatory mechanism to overcome the increased afterload.
4. Ventricular Remodeling
    a. Change of round bowl shape of the heart as a result of compensation.

Clinical Manifestations

Initially, there may be isolated left-sided heart failure, but eventually, the right ventricle fails because of the additional workload. Combined left- and right-sided heart failure is common. Heart failure may be classified according to physical activity (New York Heart Association Functional Classification) or disease progression (ACC/AHA Guidelines); see page 299.

Signs of Left-Sided Heart Failure (Forward Failure)

Altering the filling and pumping function of left ventricle, congestion occurs mainly in the lungs from blood backing up into pulmonary veins and capillaries.

1. Shortness of breath, dyspnea on exertion, tachypnea, paroxysmal nocturnal dyspnea (because of reabsorption of dependent edema that has developed during the day), orthopnea, cyanosis, pulmonary edema, and hemoptysis.
2. Cough—may be dry, unproductive; usually occurs at night.
3. Fatigability—from low CO, nocturia, insomnia, dyspnea, catabolic effect of chronic failure.
4. Insomnia, restlessness.
5. Tachycardia—ventricular gallop (S_3 and S_4).

Signs of Right-Sided Heart Failure (Backward Failure)

Altering the pumping function of right ventricle, there are signs and symptoms of elevated pressures and congestion in systemic veins and capillaries.

1. Edema of ankles; unexplained weight gain (pitting edema is obvious only after retention of at least 10 pound [4.5 kg] of fluid).
2. Liver congestion—may produce upper abdominal pain.

3. Distended jugular veins, increased CVP, pulmonary hypertension (increased PCWP).
4. Abnormal fluid in body cavities (pleural space, abdominal cavity), splenomegaly
5. Anorexia and nausea—from hepatic and visceral engorgement.
6. Nocturia—diuresis occurs at night with supine position and improved CO.
7. Weakness.

Cardiovascular Findings in Both Types

1. Cardiomegaly (enlargement of the heart)—detected by physical examination and chest x-ray.
2. Ventricular gallop—evident on auscultation.
3. Rapid heart rate.
4. Development of pulsus alternans (alternation in strength of beat).

Diagnostic Evaluation

1. Echocardiography—two-dimensional with Doppler flow studies—may show ventricular hypertrophy, dilation of chambers, and abnormal wall motion.
2. ECG (resting and exercise)—may show ventricular hypertrophy and ischemia.
3. Chest x-ray may show cardiomegaly, pleural effusion, and vascular congestion.
4. Cardiac catheterization—(left heart catheterization to rule out CAD).
    a. Right-sided heart catheterization—to measure pulmonary pressure and left ventricular function.
5. ABG studies may show hypoxemia because of pulmonary vascular congestion.
6. Bloodwork: CBC, electrolytes, Ca, Mg, renal function, glycohemoglobin, lipid profile, thyroid function, and liver function studies to fully assess patient condition that may impact heart failure.
7. Human B-type natriuretic peptide (BNP, triage BNP, N-terminal prohormone brain NP, or proBNP).
    a. As volume and pressure in the cardiac chambers rise, cardiac cells produce and release more BNP. This test aids in the differentiation of heart failure from other pulmonary diseases (ie, chronic obstructive pulmonary disease) and establish acute exacerbation of HF.
    b. A level greater than 100/mL is diagnostic for heart failure. In addition, the higher the BNP, the more severe the heart failure. BNP has inverse relationship with BMI so severity or degree of volume retention cannot be determined by the BNP values in obese patients.
    c. BNP is used in emergency departments to quickly diagnose and start treatment.
8. Radionuclide ventriculogram.
9. Thallium scan to rule out underlying causes.

Management

Overview Based on ACC/AHA Stage

See Table 13-5.

Table 13-5 Heart Failure Guidelines and Recommendations

NEW YORK HEART ASSOCIATION CLASSIFICATION	AMERICAN COLLEGE OF CARDIOLOGY/AMERICAN HEART ASSOCIATION GUIDELINES	RECOMMENDATIONS
—	**Stage A.** People at high risk of developing heart failure but without structural heart disease or symptoms of heart failure.	• Treat hypertension, lipid disorders, diabetes • Encourage patient to stop smoking and to exercise regularly • Discourage use of alcohol , illicit drugs • Angiotensin-converting enzyme (ACE) inhibitor, if indicated
Class I. Patients with cardiac disease without limitations of physical activity. Ordinary physical activity does not cause undue fatigue, palpitations, dyspnea, or anginal pain.	**Stage B.** People who have structural heart disease but no symptoms of heart failure.	• All stage A therapies • ACE inhibitor unless contraindicated • Beta-adrenergic blocker unless contraindicated
Class II. Patients with cardiac disease who have slight limitations of physical activity. They are comfortable at rest. Ordinary physical activity results in fatigue, palpitations, dyspnea, or anginal pain. **Class III.** Patients with cardiac disease who have marked limitation of physical activity. They are comfortable at rest. Less than ordinary physical activity causes fatigue, palpitations, dyspnea, or anginal pain.	**Stage C.** People who have structural heart disease with current or prior symptoms of heart failure.	• All stage A and B therapies • Sodium-restricted diet • Diuretics • Digoxin • Avoid or withdraw antiarrhythmic agents, most calcium channel blockers, and nonsteroidal anti-inflammatories • Consider aldosterone antagonists, angiotensin receptor blockers, hydralazine, and nitrates
Class IV. Patients with cardiac disease who cannot carry out any physical activity without discomfort. Symptoms of cardiac insufficiency or of anginal syndrome may be present even at rest. Any physical activity increases discomfort.	**Stage D.** People with refractory heart failure who require specialized interventions.	• All therapies for stages A, B, and C • Mechanical assist device, such as biventricular pacemaker or left ventricular assist device • Continuous inotropic therapy • Hospice care

Caboral, M., & Mitchell, J. (2003). New guidelines for heart failure: Focus on prevention. Nurse Practitioner, 28(1), 13–16, 22–23.

1. Stage A—focuses on eliminating risk factors by initiating therapeutic lifestyle changes, such as smoking cessation, increasing physical activity, and decreasing alcohol consumption. This stage also focuses on controlling chronic diseases, such as hypertension, high cholesterol, and diabetes. Beta-adrenergic blockers, ACE inhibitors, and diuretics are useful in treating this stage.
2. Stage B—treatment similar to stage A, with emphasis on use of ACE inhibitors and beta-adrenergic blockers.
3. Stage C—same as A and B, but with closer surveillance and follow-up.
    a. Digoxin is typically added to the treatment plan in this stage.
    b. Use of diuretic, hydralazine, nitrate, aldosterone antagonist, as indicated.
    c. Drug classes to be avoided due to worsening of heart failure symptoms include antiarrhythmic agents, calcium channel blockers, and NSAIDs.
    d. Patients post-MI (ie, 40 days post MI) with EF 35 or less who have New York State Heart Association class II or III symptoms and on guideline-supported medical therapies are recommended for implantable cardioverter–defibrillator placement.
4. Stage D—may need mechanical circulatory support, continuous inotropic therapy, cardiac transplantation, or palliative care.
    a. Treatment aimed at decreasing excess body fluid.
    b. May not tolerate other classes of drugs used in previous stages.
5. Unlike NYHA functional class, once a patient progresses to stage C, for example, they cannot go back to stage B.

Drug Classes

1. Diuretics (preload reduction).
    a. Eliminate excess body water and decrease ventricular pressures.
    b. A low-sodium diet and fluid restriction complement this therapy.
    c. Some diuretics may have slight venodilator properties.
2. Positive inotropic agents—increase the heart's ability to pump more effectively by improving the contractile force of the muscle.
    a. Digoxin may be initiated at any time to reduce symptoms of HF, prevent hospitalizations, control rhythm, and improve exercise tolerance.
    b. Dopamine improves blood flow and urine output.
    c. Dobutamine.
    d. Milrinone and amrinone are potent vasodilators and increase contractility.
3. Vasodilator therapy—decreases the workload of the heart by dilating peripheral vessels. By relaxing capacitance vessels (veins and venules), vasodilators reduce ventricular filling pressures (preload) and volumes. By relaxing resistance vessels (arterioles), vasodilators can reduce impedance to left ventricular ejection and improve stroke volume.
    a. Nitrates (preload reducers), such as nitroglycerin, isosorbide, nitroglycerin ointment—predominantly dilate systemic veins.
    b. Hydralazine—predominantly affects arterioles; reduces arteriolar tone.
    c. Prazosin—balanced effects on both arterial and venous circulation.
    d. Sodium nitroprusside—afterload reducer; predominantly affects arterioles.
    e. Morphine—analgesic of choice because it enhances peripheral dilation, decreases venous return, and decreases anxiety, thus decreasing workload of the heart.
4. ACE inhibitors (decrease left ventricle dilation and remodeling)—inhibit the formation of angiotensin II. In doing so, produce vasodilation. Also prevent ventricular remodeling with chronic use.
    a. Studies have shown ACE inhibitors can alleviate HF symptoms and improve clinical status as well as overall sense of well-being among HF patients.
    b. The following ACE inhibitors have been shown to reduce morbidity and mortality: captopril, enalapril, lisinopril, perindopril, ramipril, and trandolapril.
5. Beta-adrenergic blockers—negative inotropes that decrease myocardial workload and protect against fatal dysrhythmias by blocking norepinephrine effects of the sympathetic nervous system.
    a. Metoprolol or metoprolol sustained release is commonly used.
    b. Carvedilol is a nonselective beta- and alpha-adrenergic blocker. Patients may actually experience increase in general malaise for a 2- to 3-week period while they adjust to the medication. To reduce the risk of orthostatic hypotension, instruct patient to take medicine with food.
6. Angiotensin II-receptor blockers—similar effects as ACE inhibitors, although mechanism of action is different. Used in patients who cannot tolerate ACE inhibitors because of cough or angioedema.

7. Aldosterone antagonists—decrease sodium retention, sympathetic nervous system activation, and cardiac remodeling.
   a. Spironolactone is most commonly used.
   b. May cause hyperkalemia, especially in those with impaired renal function, in those taking high doses of ACE inhibitors, or in those who use potassium supplements.
8. Nesiritide (decreases pulmonary artery pressure)—used in patients with decompensated heart failure. It produces smooth muscle cell relaxation and diuresis and a reduction in afterload and dyspnea.
9. Amiodarone—to treat arrhythmias.

DRUG ALERT Assess patient's risk for hyperkalemia when administering aldosterone antagonists, such as their use of ACE inhibitors, prescription or OTC potassium supplements, and NSAIDs; monitor serum creatinine and potassium levels closely.

Diet Therapy

1. Restricted sodium.
2. Restricted fluids.

Mechanical Circulatory Support

May be used in stage D heart failure and acute exacerbation of heart failure.

1. IABP; see page 256, helps decrease afterload.
2. Cardiac resynchronization therapy or biventricular pacing—helps to restore synchronous ventricular contractions, improves ventricular left ventricle filling, and improves CO.
3. Total artificial heart or left, right, or biventricular assist device.
4. Partial left ventriculectomy (reduction ventriculoplasty or Batista procedure)—a triangular section of the weakened heart muscle is removed to reduce ventricular wall tension. This procedure is not commonly used.
5. Endoventricular circular patch plasty or the Dor procedure—removal of diseased portion of septum or left ventricle with a synthetic or autologous tissue patch, thus providing a more normal shape and size of the heart, which improves hemodynamics.
6. Acorn cardiac support device—a polyester mesh, custom-fitted jacket is surgically placed on the epicardial surface, providing diastolic support. Over time, it decreases or halts remodeling.
7. Intubation—for pulmonary edema or respiratory distress.
8. ICD—for patients with previous cardiac arrest, sustained ventricular arrhythmias, and in those post-MI with ejection fraction less than 30%.
9. Heart transplant.

Complications

1. Intractable or refractory heart failure—becomes progressively refractory to therapy (does not yield to treatment).
2. Cardiac arrhythmias.
3. Myocardial failure and cardiac arrest.
4. Digoxin toxicity—from decreased renal function and potassium depletion.
5. Pulmonary infarction, pneumonia, and emboli.

Nursing Assessment

1. Obtain history of symptoms, onset and duration of the symptoms, limits of activity, response to rest, and history of response to drug therapy. Determine neurologic status during the history.
2. Assess heart sounds, rhythm, PMI, and blood pressure. Assess peripheral vascular system, particularly for edema (see Figure 13-7). Assess respiratory effort, auscultate chest for breath sounds and presence of wheezes and crackles, and percuss for possible pleural effusion.
3. Inspect for jugular vein distention and obtain hemodynamic measurements, as indicated, and note change from baseline.
4. Assess abdomen for ascites and determine weight and change from baseline weight.
5. Note results of serum electrolyte levels and other laboratory tests.
6. Identify sleep problems and signs of depression that is often present in patients with heart failure.

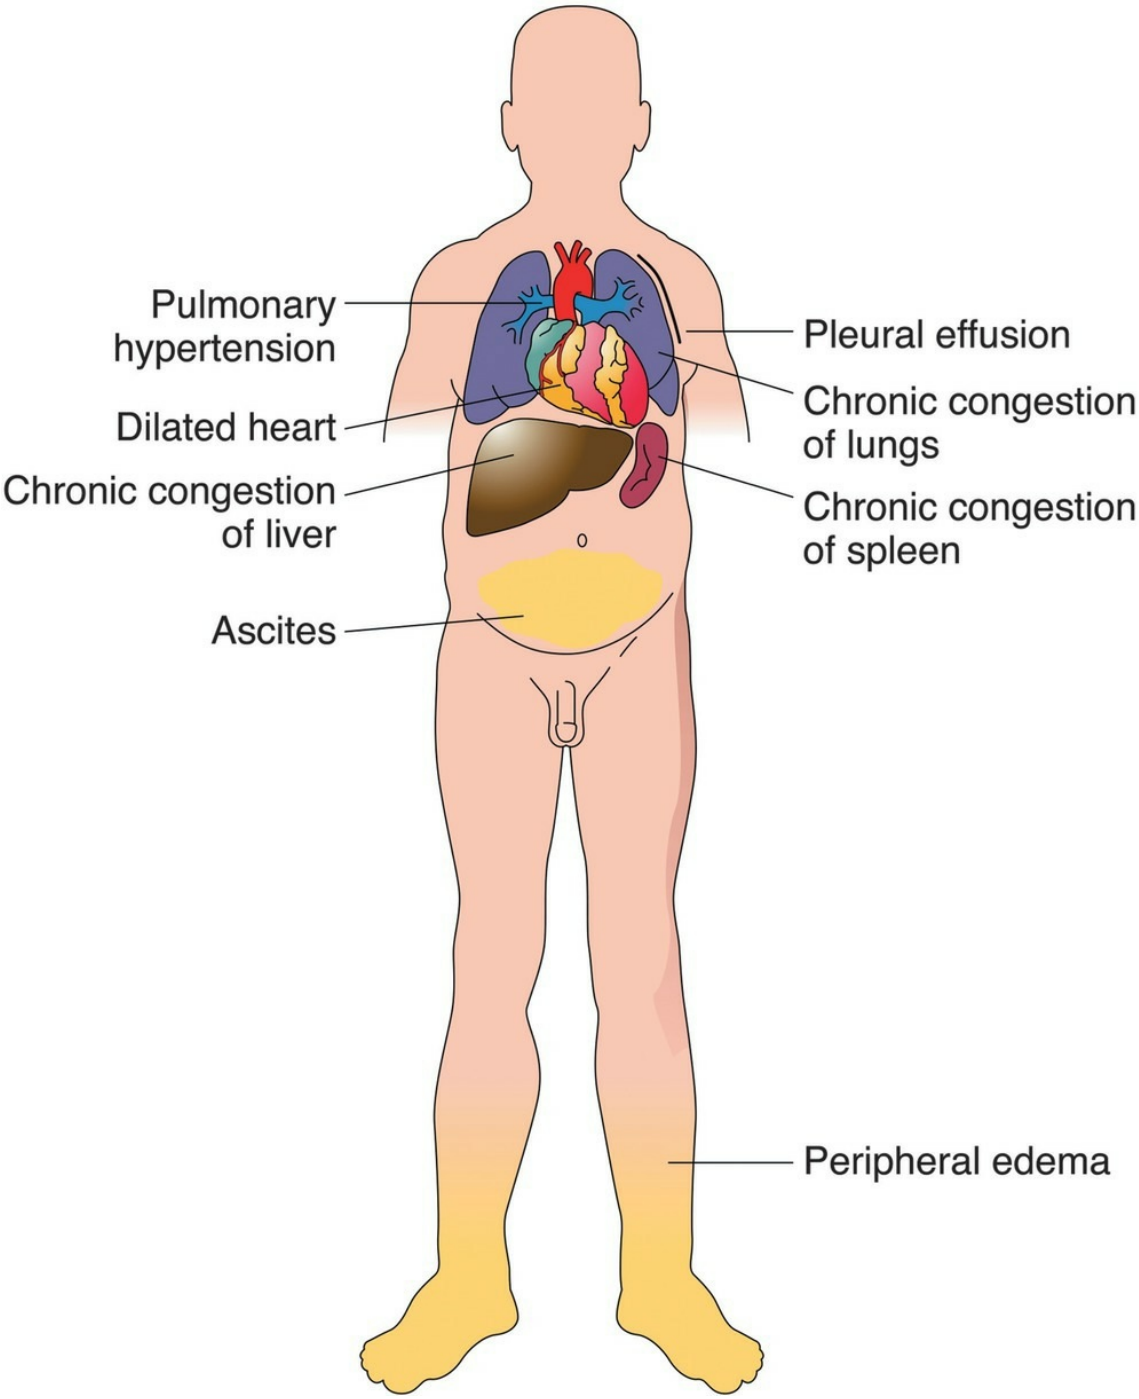

Figure 13-7. Consequences of heart failure.

Nursing Diagnoses

- Decreased Cardiac Output related to impaired contractility and increased preload and afterload.
- Impaired Gas Exchange related to alveolar edema because of elevated ventricular pressures.
- Excess Fluid Volume related to sodium and water retention.
- Activity Intolerance related to oxygen supply and demand imbalance.
- Deficient Knowledge related to lack of previous exposure to information.

Nursing Interventions

Maintaining Adequate Cardiac Output

1. Place patient at physical and emotional rest to reduce work of the heart.
    a. Provide rest in semirecumbent position or in armchair in air-conditioned environment—reduces work of the heart, increases heart reserve, reduces BP, decreases work of respiratory muscles and oxygen utilization, and improves efficiency of heart contraction; recumbency promotes diuresis by improving renal perfusion.
    b. Provide bedside commode—to reduce work of getting to bathroom and for defecation.
    c. Provide for psychological rest—emotional stress produces vasoconstriction, elevates arterial pressure, and speeds the heart.
        i. Promote physical comfort.
        ii. Avoid situations that tend to promote anxiety and agitation.
        iii. Offer careful explanations and answers to the patient's questions.
2. Evaluate frequently for progression of left-sided heart failure. Take frequent blood pressure readings.
    a. Watch for decreasing mean arterial pressure.
    b. Note narrowing of pulse pressure.
    c. Note alternating strong and weak pulsations (pulsus alternans).
3. Auscultate heart sounds frequently and monitor cardiac rhythm.
    a. Note presence of S_3 or S_4 gallop (S_3 gallop is a significant indicator of heart failure).
    b. Monitor for premature ventricular beats.
    c. Assess chest pain.
    d. Measure CVP or JVP.
4. Observe for signs and symptoms of reduced peripheral tissue perfusion: cool temperature of the skin, facial pallor, poor capillary refill of nail beds.
5. Administer pharmacotherapy as directed.
    a. Monitor for adverse effects and effect of drug therapy.
6. Monitor clinical response of patient with respect to relief of symptoms (lessening dyspnea and orthopnea, decrease in crackles, relief of peripheral edema).

NURSING ALERT Watch for sudden unexpected hypotension, which can cause myocardial ischemia and decrease perfusion to vital organs.

Improving Oxygenation

1. Raise head of bed 8 to 10 inches (20 to 25 cm)—reduces venous return to heart and lungs; alleviates

pulmonary congestion.

   a. Support lower arms with pillows—eliminates pull of patient's weight on shoulder muscles.
   b. Sit orthopneic patient on side of bed with feet supported by a chair, head and arms resting on an over-the-bed table, and lumbosacral area supported with pillows.

2. Auscultate lung fields at least every 4 hours for crackles and wheezes in dependent lung fields (fluid accumulates in areas affected by gravity).
   a. Mark with indelible ink the level on the patient's back where adventitious breath sounds are heard.
   b. Use markings for comparative assessment over time and among different care providers.
3. Observe for increased rate of respirations (could be indicative of falling arterial pH).
4. Observe for Cheyne-Stokes respirations (may occur in older patients because of a decrease in cerebral perfusion stimulating a neurogenic response).
5. Reposition the patient every 2 hours (or encourage the patient to change position frequently)—to help prevent atelectasis and pneumonia.
6. Encourage deep breathing exercises every 1 to 2 hours—to avoid atelectasis. The use of incentive spirometry can be beneficial.
7. Offer small, frequent feedings—to avoid excessive gastric filling and abdominal distention with subsequent elevation of diaphragm that causes decrease in lung capacity.
8. Administer oxygen, as directed.

Restoring Fluid Balance

1. Administer prescribed diuretic, as ordered.
2. Give diuretic early in the morning—nighttime diuresis disturbs sleep.
3. Keep input and output record—patient may lose large volume of fluid after a single dose of diuretic. Watch fluid intake. Monitor urinary output; it should be 0.5 to 1 mL/kg/hour.
4. Weigh patient daily—to determine if edema is being controlled; weight loss should not exceed 1 to 2 pound (0.5 to 1 kg/day).
5. Assess for signs of hypovolemia caused by diuretic therapy—thirst; decreased urine output; orthostatic hypotension; weak, thready pulse; increased serum osmolality; and increased urine specific gravity.
6. Be alert for signs of hypokalemia, which may cause weakening of cardiac contractions and may precipitate digoxin toxicity in the form of dysrhythmias, anorexia, nausea, vomiting, abdominal distention, paralytic ileus, paresthesias, muscle weakness and cramps, confusion. Check electrolytes frequently.
7. Give potassium supplements, as prescribed.
8. Be aware of disorders that may be worsened by diuretic therapy, including hyperuricemia, gout, volume depletion, hyponatremia, magnesium depletion, hyperglycemia, and diabetes mellitus. There is no evidence to support that patients who are allergic to sulfa drugs are also allergic to thiazide diuretics.
9. Watch for signs of bladder distention in older male patients with prostatic hyperplasia.
10. Administer IV fluids carefully through an intermittent access device to prevent fluid overload.

11. Monitor for pitting edema of lower extremities and sacral area. Use convoluted foam mattress and sheepskin to prevent pressure ulcers (poor blood flow and edema increase susceptibility).
12. Observe for the complications of bed rest—pressure ulcers (especially in edematous patients), phlebothrombosis, pulmonary embolism.
13. Be alert to complaints of right upper quadrant abdominal pain, poor appetite, nausea, and abdominal distention (may indicate hepatic and visceral engorgement).
14. Monitor patient's diet. Diet may be limited in sodium—to prevent, control, or eliminate edema; may also be limited in calories.
15. Caution patients to avoid adding salt to food and foods with high-sodium content.

Improving Activity Tolerance

1. Increase patient's activities gradually. Alter or modify patient's activities to keep within the limits of his or her cardiac reserve.
    a. Assist patient with self-care activities early in the day (fatigue sets in as day progresses).
    b. Be alert to complaints of chest pain or skeletal pain during or after activities.
2. Observe the pulse, symptoms, and behavioral response to increased activity.
    a. Monitor patient's heart rate during self-care activities.
    b. Allow heart rate to decrease to preactivity level before initiating a new activity.
        i. Note time lapse between cessation of activity and decrease in heart rate (decreased stroke volume causes immediate rise in heart rate).
        ii. Document time lapse and revise patient care plan as appropriate (progressive increase in time lapse may be indicative of increased left-sided heart failure).
3. Relieve nighttime anxiety and provide for rest and sleep—patients with heart failure have a tendency to be restless at night because of cerebral hypoxia with superimposed nitrogen retention. Give appropriate sedation to relieve insomnia and restlessness.

Improving Knowledge

1. Explain the disease process; note that the term "failure" may be terrifying.
    a. Explain the pumping action of the heart: to move blood through the body to provide nutrients and aid in the removal of waste.
    b. Explain the difference between heart failure and heart attack.
2. Provide teaching about the signs and symptoms of recurrence.
    a. Watch for weight gain and report a gain or loss of more than 2 to 3 pound (1 to 1.4 kg) in a few days.
    b. Weigh patient at same time daily to detect any tendency toward fluid retention: swelling of ankles, feet, abdomen; persistent cough; tiredness; loss of appetite; frequent urination at night.
3. Review medication regimen.
    a. Medications recommended for patients with ejection fraction less than 40% include preload reductors, such as diuretics, and afterload reductors, such as ACE inhibitors.

b. Medications to control heart rate include digoxin or beta-adrenergic blockers.

c. Anticoagulation, if indicated.

TRANSITIONAL CARE ALERT To reduce readmission for heart failure, ensure that the patient and caregiver understand how each medication works to optimize heart function and that they will be able to obtain all prescriptions; that they understand who to notify for increase in daily weight; that salt and fluid restriction are clear; and that follow-up for up for lab work and office visit is arranged.

Patient Education and Health Maintenance

1. Advise patient of symptoms that need to be reported to health care provider.
   a. Sudden weight gain.
   b. Increased shortness of breath, inability to lie down, wheezing, increased cough.
   c. Increased swelling of feet, legs, abdomen.
2. Help patient understand all medications.
   a. Give written instructions.
   b. Make sure the patient has a pill organizer or check-off system to show that medications have been taken.
   c. Inform the patient of adverse drug effects.
   d. If the patient is taking oral potassium solution, it may be diluted with juice and taken after a meal.
   e. Tell the patient to weigh self daily at same time and log weight if on diuretic therapy.
   f. Ask whether patient is taking coenzyme Q10 or other supplements; should discuss with health care provider.
3. Review activity program instructions:
   a. Increase walking and other activities gradually, provided they do not cause fatigue and dyspnea.
   b. In general, continue at whatever activity level can be maintained without the appearance of symptoms.
   c. Avoid excesses in eating and drinking.
   d. Undertake a weight reduction program until optimal weight is reached.
   e. Avoid extremes in heat and cold, which increase the work of the heart; air conditioning may be essential in a hot, humid environment.
   f. Keep *regular* appointment with health care provider or clinic.
4. Restrict sodium as directed.
   a. Teach restricted sodium diet (less than 1,500 mg/day) and the DASH diet; see page 342.
   b. Give patient a written diet plan with lists of permitted and restricted foods.
   c. Advise patient to look at all labels to ascertain sodium content. Take into account serving size.

d. Teach the patient to rinse the mouth well after using tooth cleansers and mouthwashes—some of these contain large amounts of sodium. Water softeners should be checked for salt content.
e. Teach the patient that sodium is often hidden in foods, such as bread, and in medications such as antacids, cough remedies, pain relievers, estrogens, and other drugs.
f. Encourage use of flavorings, spices, herbs, and lemon juice.
g. Avoid salt substitutes with renal disease.

5. Instruct patient to buy frozen foods over canned foods.
6. Make sure patient sets up follow-up appointments.
7. Advise patient on smoking cessation; provide information, if indicated.

Evaluation: Expected Outcomes

- Normal BP and heart rate.
- Respiratory rate, 16 to 20 breaths/minute; ABG levels within normal limits; no signs of crackles or wheezes in lung fields.
- Weight decrease of 2.2 pound (1 kg) every 2 days; no pitting edema of lower extremities and sacral area.
- Heart rate within normal limits; rests between activities.
- States recurrent symptoms to watch for and knows medications and doses.

Acute Pulmonary Edema

Acute pulmonary edema refers to excess fluid in the lung, either in the interstitial spaces or in the alveoli.

Pathophysiology and Etiology

1. The presence of fluid in the alveoli impedes gas exchange, especially oxygen movement into pulmonary capillaries (see Figure 13-8).
2. May be caused by:
    a. Heart disease—acute left-sided heart failure, MI, aortic stenosis, severe mitral valve disease, hypertension, heart failure.
    b. Circulatory overload—transfusions and infusions.
    c. Drug hypersensitivity, allergy, poisoning.
    d. Lung injuries—smoke inhalation, shock lung, pulmonary embolism, or infarct.
    e. Central nervous system injuries—stroke, head trauma.
    f. Infection and fever—infectious pneumonia (viral, bacterial, parasitic).
    g. Postcardioversion, postanesthesia, postcardiopulmonary bypass.
    h. Adverse drug reaction—many drugs including heroin, cocaine, aspirin, nicardipine as tocolytic for pregnant women and chemotherapy agents.
    i. Renal disease.
    j. High altitude
    k. Near drowning.

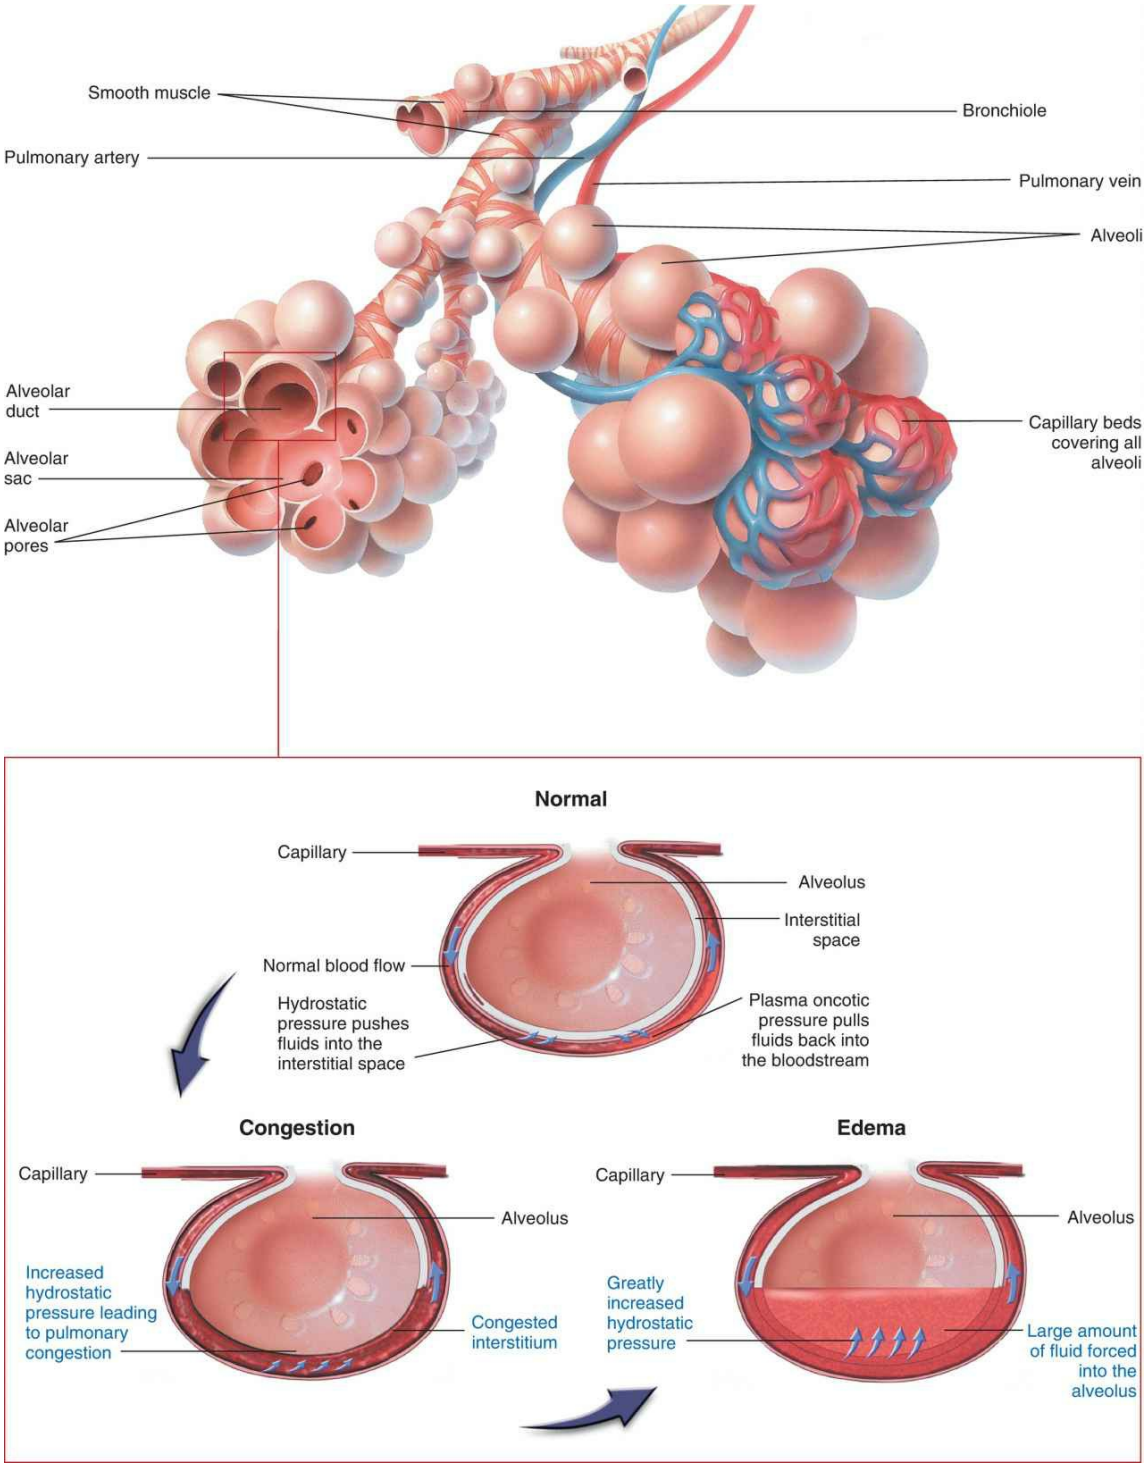

Figure 13-8. Normal alveoli and how pulmonary edema develops.

Clinical Manifestations

1. Coughing and restlessness during sleep (premonitory symptoms).
2. Extreme dyspnea and orthopnea—patient usually uses accessory muscles of respiration with retraction of intercostal spaces and supraclavicular areas.
3. Cough with varying amounts of white- or pink-tinged frothy sputum.

4. Extreme anxiety and panic.
5. Noisy breathing—inspiratory and expiratory wheezing and bubbling sounds.
6. Cyanosis with profuse cold, clammy perspiration.
7. Distended jugular veins.
8. Tachycardia.
9. Precordial pain (if pulmonary edema secondary to MI).
10. Decreased urine output.

Diagnostic Evaluation

1. Chest x-ray—shows interstitial edema.
2. Echocardiogram—evaluates valves and ejection fraction.
3. Measurement of pulmonary artery wedge pressure by Swan-Ganz catheter (differentiates etiology of pulmonary edema—cardiogenic or altered alveolar–capillary membrane).
4. Blood cultures in suspected infection—may be positive.
5. Cardiac markers in suspected MI—may be elevated.
6. BUN, creatinine, serum electrolytes, and blood counts.
7. proBNP elevated in heart failure.
8. ABG analysis—may show impending respiratory failure.
9. Thoracentesis-fluid sample for diagnosis and treatment.
10. Lung ultrasound—valuable in early detection; B-lines indicate interstitial edema.

Management

1. The immediate objective of treatment is to improve oxygenation and reduce pulmonary congestion.
2. Identification and correction of precipitating factors and underlying conditions are then necessary to prevent recurrence.
3. Increasing oxygen tension (oxygen therapy), reducing fluid volume (diuretics, vasodilators), improving the heart's ability to pump effectively (glycosides, beta agonists), and decreasing anxiety guide therapeutic interventions.
4. Oxygen therapy—high concentrations of oxygen are used to combat hypoxemia. Intubation and/or ventilatory support may be necessary to improve hypoxemia and prevent hypercarbia. Noninvasive ventilation (NIV) is the first line of intervention.
5. Morphine—reduces anxiety, promotes venous pooling of blood in the periphery, and reduces resistance against which the heart must pump.
6. Vasodilator therapy (nitroglycerin and nitroprusside)—reduces the amount of blood returning to the heart and resistance against which the heart must pump.
7. Reduction of intravascular volume (diuresis or immediate dialysis)—decreases blood volume and pulmonary congestion.

8. Contractility enhancement therapy (digoxin, dobutamine, nesiritide, milrinone) improves the ability of the heart muscle to pump more effectively, allowing for complete emptying of blood from the ventricle and a subsequent decrease in fluid backing up into the lungs.
9. Aminophylline may prevent bronchospasm associated with pulmonary congestion. Use with caution because it may also increase heart rate and induce tachydysrhythmias.
10. Intra-aortic balloon pump—to decrease afterload and improve coronary blood flow.

DRUG ALERT Use extreme caution in administering nitroglycerin to patients with aortic stenosis who are preload dependent.

Complications

1. Dysrhythmias.
2. Respiratory failure.
3. Right ventricular failure—lower extremity edema, ascites, pleural effusion, hepatomegaly.

Nursing Assessment

1. Be alert to development of a new nonproductive cough.
2. Assess for signs and symptoms of hypoxia—restlessness, confusion, headache.
3. Auscultate lung fields frequently.
    a. Note inspiratory and expiratory wheezes, rhonchi, moist fine crackles appearing initially in lung bases and extending upward.
4. Auscultate for extra heart sounds.
    a. Note presence of third heart sound (may be difficult to hear because of respiratory sounds).
5. Identify precipitating factors that place patient at risk for development of pulmonary edema.

NURSING ALERT Acute pulmonary edema is a true medical emergency; it is a life-threatening condition. Act promptly to assess patient and notify health care provider of findings.

Nursing Diagnoses

- Impaired Gas Exchange related to excess fluid in the lungs.
- Anxiety related to sensation of suffocation and fear.

Nursing Interventions

Improving Oxygenation

1. Give oxygen in high concentration to relieve hypoxia and dyspnea and to keep oxygen saturation greater than 94% or patient's baseline.
2. Position the patient to reduce venous return to the heart—upright position, head and shoulders up, and feet and legs hanging down to favor pooling of blood in dependent portions of body by gravitational forces and to decrease venous return.
3. Give morphine in small, titrated intermittent doses (IV) as directed.
   a. Morphine usually is not given if pulmonary edema is caused by stroke or occurs with chronic pulmonary disease or cardiogenic shock.
   b. Watch for excessive respiratory depression.
   c. Monitor BP because morphine may intensify hypotension.
   d. Have morphine antagonist available—naloxone.
4. Give diuretics IV or monitor during dialysis.
   a. Insert an indwelling catheter—large urinary volume will accumulate rapidly.
   b. Watch for falling BP, increasing heart rate, and decreasing urinary output—indications that the total circulation is not tolerating diuresis and that hypovolemia may develop.
   c. Check electrolyte levels because potassium loss may be significant.
   d. Watch for signs of urinary obstruction in men with prostatic hyperplasia.
5. Administer vasodilator if patient fails to respond to therapy.
   a. Monitor by measuring BP, PAP, and CO.
6. Assist with insertion of IABP, if needed, and monitor patient according to facility's protocol.
7. Administer aminophylline, if ordered.
   a. Monitor blood levels of drug.
   b. Evaluate for adverse effects of drug—ventricular dysrhythmias, hypotension, headache.
8. Administer cardiac glycosides as ordered.
9. Assist with cardioversion, if indicated (pulmonary edema may precipitate tachycardias).
10. Give appropriate drugs for severe, sustained hypertension.
11. Continually evaluate the patient's response to therapy. Reevaluate lung fields and cardiac assessment and monitor urine output and laboratory values.

Decreasing Anxiety

1. Stay with patient and display a confident attitude—the presence of another person is therapeutic because the acute anxiety of the patient may tend to intensify the severity of patient's condition. (Arterial vasoconstriction diminishes as anxiety is relieved.)
2. Explain to patient in a calm manner all therapies administered and the reason for their use. Explain to patient the importance of wearing oxygen mask. Assure patient that mask will not increase sensation of suffocation.
3. Inform patient and family of progress toward resolution of pulmonary edema.

4. Allow time for patient and family to voice concerns and fears.

Patient Education and Health Maintenance

During convalescence, instruct patient as follows to prevent recurrence of pulmonary edema:

1. Remind patient of early symptoms before onset of acute pulmonary edema; these should be reported promptly.
2. If coughing develops (a wet cough), sit with legs dangling over side of bed.
3. See "Patient Education, Heart Failure," page 302.

Evaluation: Expected Outcomes

- Unlabored respirations at 12 to 20 breaths/minute, lungs clear on auscultation, pulse oximetry greater than 94%.
- Appears calm and rests comfortably.

Acquired Valvular Disease of the Heart

EVIDENCE BASE Nishimura, R., Otto, C., Bonow, R., et al. (2014). 2014 AHA/ACC guideline for the management of patients with valvular heart disease: Executive summary: A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. *Circulation, 129*, 2440–2492.

The function of normal heart valves is to maintain the forward flow of blood from the atria to the ventricles and from the ventricles to the great vessels.

Valvular damage may interfere with valvular function by stenosis (obstruction) or by impaired closure that allows backward leakage of blood (valvular insufficiency, regurgitation, or incompetence).

Pathophysiology and Etiology

Mitral Stenosis

1. Mitral stenosis is the progressive thickening and contracture of valve cusps with narrowing of the orifice and progressive obstruction to blood flow. Rheumatic fever is the most common cause of mitral stenosis in adults. Calcium deposit around the valves is rare with mitral stenosis. In children, the cause may be congenital.
2. Acute rheumatic valvulitis has "glued" the mitral valve flaps (commissures) together, thus shortening the chordae tendineae, so that the flap edges are pulled down, greatly narrowing the mitral orifice.
3. The left atrium has difficulty emptying itself through the narrow orifice into the left ventricle; therefore, it dilates and hypertrophies. Pulmonary circulation becomes congested.
4. As a result of the abnormally high PAP that must be maintained, the right ventricle is subjected to a pressure overload and may eventually fail.

Mitral Insufficiency

1. Mitral insufficiency (regurgitation or incompetence) is incomplete closure of the mitral valve during systole, allowing blood to flow back into the left atrium.
2. Left atrial pressures increase, reflected by increases in PAP and PCWP.
3. LVH may develop due to inefficient emptying.
4. May be due to myxomatous (connective tissue) degeneration, which causes stretching of leaflets and chordae tendineae; chronic rheumatic heart disease, ischemic heart disease, CAD, and infective endocarditis may also result due to medications and penetrating and nonpenetrating trauma.

Aortic Stenosis

1. Aortic stenosis is a narrowing of the orifice between the left ventricle and the aorta.

2. The obstruction to the aortic outflow places a pressure load on the left ventricle that results in hypertrophy and failure.
3. Left atrial pressure increases.
4. Pulmonary vascular pressure increases, which may eventually lead to right-sided heart failure.
5. May be caused by congenital anomalies (bicuspid aortic valve), calcification, or acute rheumatic fever.

Aortic Insufficiency

1. Because of abnormalities of aortic valve or aortic root.
2. Valve flaps fail to completely seal the aortic orifice during diastole and thus permit backflow of blood from the aorta into the left ventricle.
3. The left ventricle increases the force of contraction to maintain an adequate CO, usually resulting in hypertrophy.
4. The low aortic diastolic pressures result in decreased coronary artery perfusion.
5. May be caused by rheumatic or infective endocarditis, congenital malformation, aortic root dilation, Marfan syndrome, Ehlers-Danlos syndrome, Reiter syndrome, hypertension, systemic lupus erythematosus, or diseases that cause dilation or tearing of the ascending aorta (syphilitic disease, rheumatoid spondylitis, dissecting aneurysm).

Tricuspid Stenosis

1. Tricuspid stenosis is restriction or narrowing of the tricuspid valve orifice because of commissural fusion and fibrosis.
2. Usually follows rheumatic fever and is commonly associated with diseases of the mitral valve. Could be congenital in origin.

Tricuspid Insufficiency

1. Tricuspid insufficiency (regurgitation) allows the regurgitation of blood from the right ventricle into the right atrium during ventricular systole.
2. Common causes include dilation of right ventricle, rheumatic fever, and congenital anomalies.

Clinical Manifestations

1. Fatigue, weakness.
2. Dyspnea, cough, orthopnea, nocturnal dyspnea.
3. Characteristic murmur (see “Nursing Assessment”).
4. Dysrhythmias, palpitations.
5. Hemoptysis (from pulmonary hypertension) and hoarseness (from compression of left recurrent laryngeal nerve by dilated left atrium) in mitral stenosis.
6. Low BP, dizziness, syncope, angina, and symptoms of heart failure in aortic stenosis.
7. Arterial pulsations visible and palpable over the precordium and visible in the neck, widened pulse pressure, and water-hammer (Corrigan) pulse (pulse strikes palpating finger with a quick, sharp stroke

and then suddenly collapses) in aortic insufficiency.

8. Symptoms of right-sided heart failure—edema, ascites, hepatomegaly—in tricuspid stenosis and insufficiency.

Diagnostic Evaluation

1. ECG may show dysrhythmias.
2. Echocardiography (including 3D) may show abnormalities of valve structure and function and chamber size and thickness.
3. Chest x-ray may show cardiomegaly and pulmonary vascular congestion.
4. Cardiac catheterization and angiocardiography confirm diagnosis and determine severity.
5. Cardiac MRI provides more information and confirms diagnosis.
6. Exercise testing for patients with severe valvular disease to determine prognosis.

Management

Medical Therapy

1. Antibiotic prophylaxis for endocarditis before invasive procedures—indicated in most cases; see page 289.
2. Treatment of heart failure—diuretics, sodium restriction, vasodilators, cardiac glycosides, as indicated.

Surgical Intervention

See page 260 for care of the patient undergoing heart surgery.

1. For mitral stenosis:
   a. Closed mitral valvotomy—introduction of a dilator through the mitral valve to split its commissures.
   b. Open mitral valvotomy—direct incision of the commissures.
   c. Mitral valve replacement.
   d. Balloon valvuloplasty—a balloon-tipped catheter is percutaneously inserted, threaded to the affected valve, and positioned across the narrowed orifice. The balloon is inflated and deflated, causing a "cracking" of the calcified commissures and enlargement of the valve orifice.
2. For mitral insufficiency—mitral valve replacement or annuloplasty (retailoring of the valve ring).
3. For aortic stenosis or insufficiency:
   a. Replacement of aortic valve with prosthetic or tissue valves.
   b. Balloon valvuloplasty (aortic stenosis).
4. For tricuspid stenosis or insufficiency—valvuloplasty or replacement may be done at the time of surgical intervention for associated rheumatic mitral or aortic disease.
5. Transcatheter aortic valve implantation or replacement (TAVR)—a less invasive procedure where a bioprosthetic valve is used. Mostly for patients with severe symptomatic AS aged 75 years or older with surgical risk but expected to survive.

6. Percutaneous pulmonary valve implantation (PPVI)—for patients with pulmonary valve and right ventricular outflow tract defects.

Complications

1. Left-sided heart failure.
2. Possible, right-sided heart failure.
3. Dysrhythmias.
4. Pulmonary edema.

Nursing Assessment

Mitral Stenosis

1. Auscultate for accentuated first heart sound, usually accompanied by an "opening snap" (because of sudden tensing of valve leaflets) at the apex with diaphragm of stethoscope.
2. Place the patient in left lateral recumbent position. With bell of stethoscope at the apex, auscultate for a low-pitched diastolic murmur (rumbling murmur). Note duration of murmur (long duration is indicative of significant stenosis).

Mitral Insufficiency

1. Auscultate for diminished first heart sound.
2. Auscultate for systolic murmur (prominent finding), commencing immediately after first heart sound at apex, and note radiation of sound to the axilla and left intrascapular area.
3. Mild insufficiency may produce a pansystolic murmur (little connection between severity of mitral insufficiency and intensity of murmur auscultated).

Aortic Stenosis

1. Auscultate for prominent fourth heart sound and possible paradoxical splitting of second heart sound (suggestive of associated left ventricular dysfunction). First heart sound is normal.
2. Auscultate for a midsystolic murmur at the base of the heart (right upper sternal border) and at the apex of the heart. Note harsh and rasping quality at the base of the heart and a higher pitch at the apex of the heart.
3. There may be a palpable thrill.

Aortic Insufficiency

1. Auscultate for soft first heart sound.
2. Place the patient in sitting position, leaning forward.
3. Place diaphragm of stethoscope along left sternal border at the third and fourth intercostal space and then along the right sternal border. Auscultate for a high-pitched decrescendo diastolic murmur. To increase audibility of murmur, ask the patient to hold breath at end of deep expiration. Reauscultate for murmur.

Tricuspid Stenosis

1. Auscultate for a rumbling or blowing middiastolic murmur at the left sternal border (increases with inspiration).

Tricuspid Insufficiency

1. Auscultate for a third heart sound (may be accentuated by inspiration).
2. Auscultate for a pansystolic murmur in the parasternal region at the fourth intercostal space. Murmur is usually high-pitched.

Nursing Diagnoses

- Decreased Cardiac Output related to altered preload, afterload, or contractility.
- Activity Intolerance related to reduced oxygen supply.
- Ineffective Coping related to acute or chronic illness.

Nursing Interventions

Maintaining Adequate Cardiac Output

1. Assess frequently for change in existing murmur or new murmur.
2. Assess for signs of left- or right-sided heart failure; see page 298.
3. Assess for pulmonary edema.
4. Monitor and treat dysrhythmias, as ordered.
5. Prepare the patient for surgical intervention (see page 260).

Improving Tolerance

1. Maintain bed rest while symptoms of heart failure are present.
2. Allow patient to rest between interventions.
3. Begin activities gradually (eg, chair sitting for brief periods).
4. Assist with or perform hygiene needs for patient to reserve strength for ambulation.

Strengthening Coping Abilities

1. Instruct the patient about specific valvular dysfunction, possible etiology, and therapies implemented to relieve symptoms.
   a. Include family members in discussions with the patient.
   b. Stress the importance of adapting lifestyle to cope with illness.
2. Discuss with patient surgical intervention as the treatment modality, if applicable.
3. Assess the patient's use of appropriate coping mechanisms.
4. Refer the patient to appropriate counseling services, if indicated (vocational, social work, cardiac rehabilitation, substance abuse).

Patient Education and Health Maintenance

1. Review activity restriction and schedule with patient and family.
2. Instruct patient to report signs of impending or worsening heart failure—dyspnea, cough, increased fatigue, ankle swelling.
3. Review sodium and fluid restrictions.
4. Review medications—purpose, action, schedule, and adverse effects.
5. See "Patient Education, Heart Failure," page 302; "Infective Endocarditis," page 289; and "Rheumatic Endocarditis," page 291.

Evaluation: Expected Outcomes

- Blood pressure and heart rate within normal limits.
- Tolerates chair sitting for 15 minutes every 2 hours.
- Discusses ways to cope with lifestyle and activity changes.

Cardiac Dysrhythmias

Cardiac dysrhythmias are disturbances in regular heart rate and/or rhythm because of change in electrical conduction or automaticity. Dysrhythmias may arise from the sinoatrial (SA) node (sinus bradycardia or tachycardia) or anywhere within the atria or ventricles (known as ectopy or ectopic beats). Some may be benign and asymptomatic, whereas other dysrhythmias are life-threatening.

Dysrhythmias may be detected by change in pulse, abnormality on auscultation of heart rate, or ECG abnormality. Continuous cardiac monitoring is indicated for potentially life-threatening dysrhythmias.

Sinus Tachycardia

See Figure 13-9.

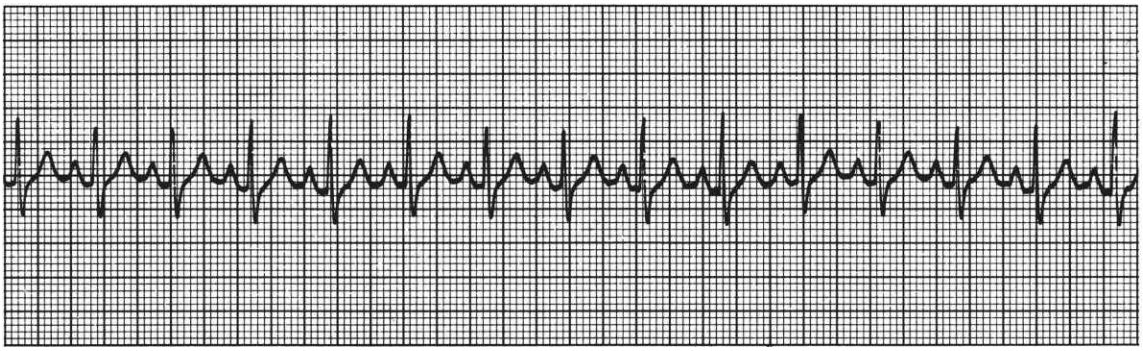

Figure 13-9. Sinus tachycardia.

Etiology

1. Sympathetic nerve fibers, which act to speed up excitation of the SA node, are stimulated by underlying causes, such as anxiety, exercise, fever, shock, drugs, altered metabolic states (such as hyperthyroidism), or electrolyte disturbances.
2. The wave of impulse is transmitted through the normal conduction pathways; the rate of sinus stimulation is simply greater than normal (rate exceeds 100 beats/minute).

Analysis

Rate: 100 to 150 beats/minute.

Rhythm: R–R intervals are regular.

P wave: present for each QRS complex, normal configuration, and each P wave is identical or may be buried in previous T wave.

PR interval: falls between 0.12 and 0.20, or 0.16 second. P wave may be hidden in preceding T wave in rapid rates.

QRS complex: normal in appearance; one follows each P wave.

QRS interval: less than 0.11 seconds.

T wave: follows each QRS complex and is positively conducted.

QT interval: less than 0.48 seconds. This is usually corrected for heart rate and gender.

Management

1. Treatment is directed toward elimination of the cause rather than the dysrhythmia. Sometime, this is a compensatory mechanism for decreased cardiac output; thus, correction is not needed.
2. Urgency is dependent on the effect of rapid heart rate on coronary artery filling time to prevent cardiac ischemia.
3. Administration of oxygen and normal saline solution should be considered as initial treatment.

Sinus Bradycardia

See Figure 13-10.

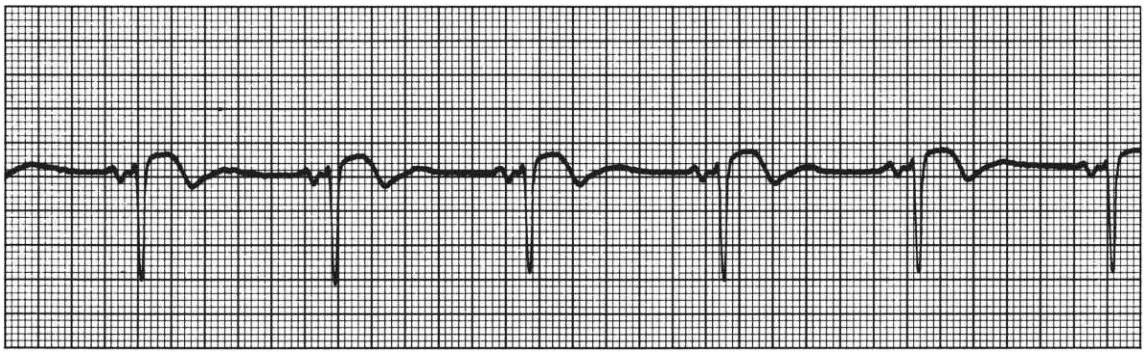

Figure 13-10. Sinus bradycardia.

Etiology

1. The parasympathetic fibers (vagal tone) are stimulated and cause the sinus node to slow.
2. Underlying causes:
   a. Drugs.
   b. Altered metabolic states such as hypothyroidism.
   c. The process of aging, which causes increasing fibrotic tissue and scarring of the SA node.
   d. Certain cardiac diseases such as acute MI (especially inferior wall MI).
3. The wave of impulse is transmitted through the normal conduction pathways; the rate of sinus stimulation is simply less than normal (less than 60 beats/minute).

Analysis

Rate: less than 60 beats/minute.

Rhythm: R–R interval is regular.

P wave: present for each QRS complex, normal configuration, and each P wave is identical.

PR interval: falls between 0.12 and 0.18 second.

QRS complex: normal in appearance; one follows each P wave.

QRS interval: 0.04 to 0.11 second.

T wave: follows each QRS and is positively conducted.

Management

1. The urgency of treatment depends on the effect of the slow rate on maintenance of CO.
2. Atropine 0.5 mg IV push blocks vagal stimulation to the SA node and therefore accelerates heart rate. Dopamine and epinephrine are alternatives if atropine is ineffective.
3. If bradycardia persists, a pacemaker may be required.
4. Sinus bradycardia is common in athletic individuals and does not require treatment.

Premature Atrial Contraction

See Figure 13-11.

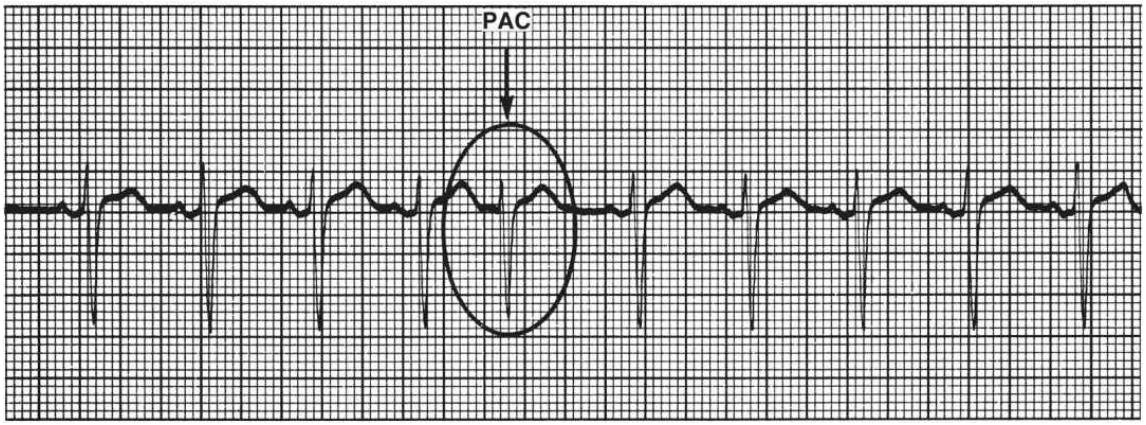

Figure 13-11. Normal sinus rhythm with premature atrial contraction.

Etiology

1. May occur in the healthy heart where they are idiopathic and benign.
2. In the diseased heart, premature atrial contractions (PACs) may represent ischemia and a resultant irritability in the atria. They may increase in frequency and be the precursor of more serious dysrhythmias.
3. May be caused by electrolyte abnormalities, hypoxia, MI, heart failure, and acid–base disturbances.
4. The wave of impulse of the PAC originates within the atria and outside the sinus node. Because the impulse originates within the atria, the P wave will be present, but it will be different in appearance as compared with those beats originating within the sinus node. The impulse traverses the remainder of the conduction system in a normal pattern; thus, the QRS complex is identical in configuration to the normal sinus beats.

Analysis

Rate: may be slow or fast.

Rhythm: will be irregular; caused by the early occurrence of the PAC.

P wave: will be present for each normal QRS complex; the P wave of the premature contraction will be distorted in shape.

PR interval: may be normal but can also be shortened, depending on where in the atria the impulse originated. (The closer the site of atrial impulse formation to the atrioventricular [AV] node, the shorter the PR interval will be.)

QRS complex: within normal limits because all conduction below the atria is normal.

T wave: normally conducted.

Management

1. Generally requires no treatment if laboratory values are normal.
2. PACs should be monitored for increasing frequency.

Paroxysmal Atrial Tachycardia

See Figure 13-12.

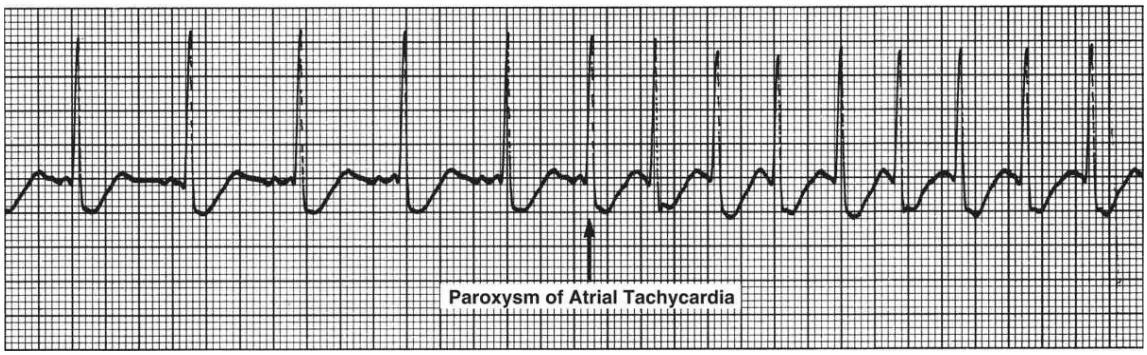

Figure 13-12. Paroxysmal atrial tachycardia.

Etiology

1. Causes include:
   a. Syndromes of accelerated pathways (eg, Wolff-Parkinson-White syndrome).
   b. Syndrome of mitral valve prolapse.
   c. Ischemic CAD.
   d. Excessive use of alcohol, cigarettes, caffeine.
   e. Drugs—digoxin is a frequent cause.
2. An ectopic atrial focus captures the rhythm of the heart and is stimulated at a very rapid rate; the impulse is conducted normally through the conduction system so the QRS complex usually appears within normal limits.
3. The rate is often so rapid that P waves are not obvious but may be "buried" in the preceding T wave.

Analysis

Rate: between 150 and 250 beats/minute.

Rhythm: regular.

P wave: present before each QRS complex; however, the faster the rate, the more difficult it becomes to

visualize P waves. (The P waves can frequently be measured with calipers by observing the varying configuration of the preceding T waves.)

PR interval: usually not measurable.

QRS complex: will appear normal in configuration and within 0.06 to 0.10 second.

T wave: will be distorted in appearance as a result of P waves being buried in them.

Management

1. Treatment is directed first to slowing the rate and, second, to reverting the dysrhythmia to a normal sinus rhythm.
2. Reducing the rate may be accomplished by having the patient perform a Valsalva maneuver. This stimulates the vagus nerve to slow the heart.
   a. A Valsalva maneuver may be done by having the patient gag or "bear down" as though attempting to have a bowel movement.
   b. The health care provider may choose to perform carotid massage.
3. Adenosine is the drug of choice for paroxysmal atrial tachycardia associated with hypotension, chest pain, or shortness of breath.
   a. The initial dose is 6 mg rapid IV push followed by a fast normal saline flush. If there is no response in 1 to 2 minutes, a second and third bolus of 12 mg may be given, each followed by fast normal saline flushes.
   b. Has a very short half-life and is therefore eliminated quickly.
4. IV beta-adrenergic blockers, such as esmolol, may be used.
5. Calcium channel blockers (eg, verapamil) are effective in reverting this dysrhythmia. Beware of hypotension, however, especially in the volume-depleted patient.
6. If drug therapy is ineffective, elective cardioversion can be used.

Atrial Flutter

See Figure 13-13.

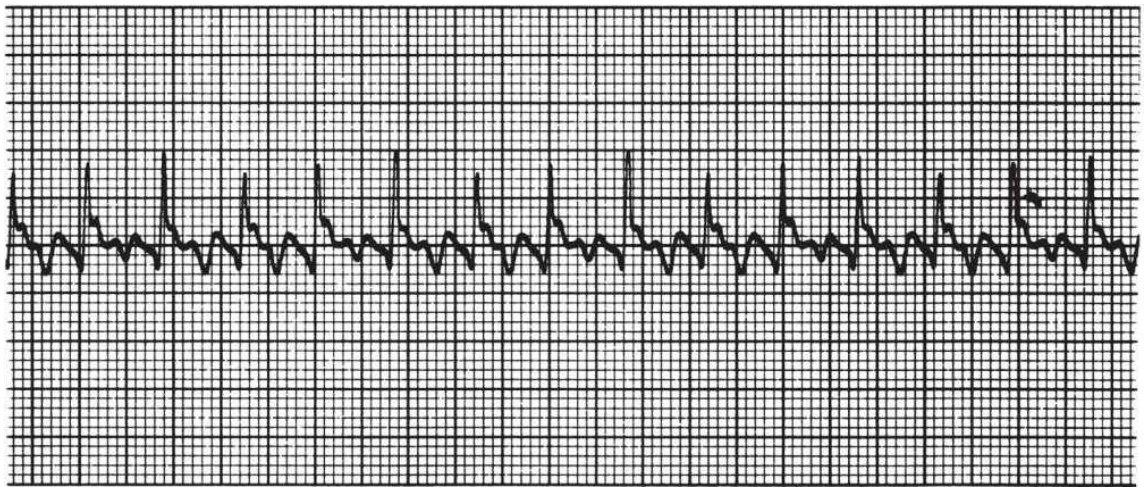

Figure 13-13. Atrial flutter.

Etiology

1. Occurs with atrial stretching or enlargement (as in AV valvular disease), MI, and heart failure.
2. An ectopic atrial focus captures the rhythm in atrial flutter and fires at an extremely rapid rate (200 to 400 beats/minute) with regularity.
3. Conduction of the impulse through the conduction system is normal; thus, the QRS complex is unaffected.
4. An important feature of this dysrhythmia is that the AV node sets up a therapeutic block, which disallows some impulse transmission.
    a. This can produce a varying block or a fixed block (ie, sometimes the AV node will transmit every second flutter wave, producing a 2:1 block, or the rhythm can be 3:1 or 4:1).
    b. If the AV node conducted 1:1, then the outcome would be a ventricular rate of about 300 beats/minute. The patient would rapidly deteriorate.

Analysis

Rate: atrial rate between 250 and 400 beats/minute; ventricular rate will depend on degree of block.

Rhythm: regular or irregular, depending on kind of block (eg, 2:1, 3:1, or a combination).

P wave: not present; instead, it is replaced by a saw-toothed pattern that is produced by the rapid. firing of the atrial focus. These waves are also referred to as "F" waves.

PR interval: not measurable.

QRS complex: normal configuration and normal conduction time.

T wave: present but may be obscured by flutter waves.

Management

1. The urgency of treatment depends on the ventricular response rate and resultant symptoms. Too rapid or slow a rate will decrease CO.
2. A calcium channel blocker, such as diltiazem, may be used to slow AV nodal conduction. Use with caution in the patient with heart failure, hypotension, or concomitant beta-adrenergic blocker therapy.
3. Digoxin may be used.
4. An IV beta-adrenergic blocker, such as esmolol, may also be used.
5. If drug therapy is unsuccessful, atrial flutter will typically respond to cardioversion. Small doses of biphasic electrical current (50 to 100 joules) are usually successful.
6. Electrophysiologic studies and subsequent ablation therapy are highly effective because the ectopic focus is usually readily identified.

Atrial Fibrillation

See Figure 13-14.

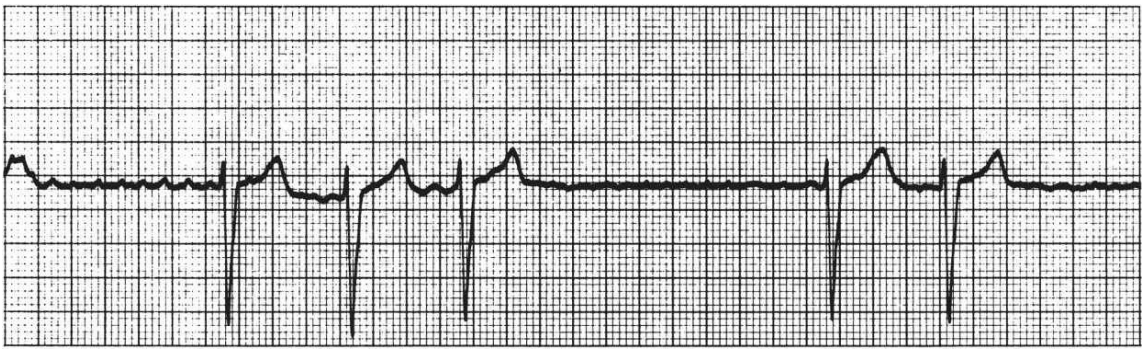

Figure 13-14. Atrial fibrillation with slow ventricular response (controlled).

Etiology

1. Fibrotic changes associated with the aging process, acute MI, valvular diseases, and digoxin preparations may cause atrial fibrillation.
2. Fluid shifts in the body (ie, after hemodialysis or surgery).
3. Multiple atrial foci fire impulses at rapid and disorganized rates.
4. The atria are not depolarized effectively; thus, there are no well-formed P waves.
5. Instead, the baseline between QRS complexes is filled with a "wiggly" line that is described as fine or coarse.
6. If the atrial rate is rapid enough, the line will appear almost flat. The atria are said to be firing at rates of between 300 and 500 times per minute.
7. The conduction of a QRS complex is so random that the rhythm is extremely irregular.
8. Atrial fibrillation may be described as controlled if the ventricular response is 100 beats/minute or less; the dysrhythmia is uncontrolled if the rate is above 100 beats/minute.

Analysis

Rate: atrial fibrillation is usually immeasurable because fibrillatory waves replace P waves; ventricular rate may vary from bradycardia to tachycardia.

Rhythm: classically described as an "irregular irregularity."

P wave: replaced by fibrillatory waves, sometimes called "little f" waves.

PR interval: not measurable.

QRS complex: a normally conducted complex.

T wave: normally conducted.

Management

1. Controlled atrial fibrillation of long-standing duration requires no treatment as long as the patient is experiencing no untoward effects. Most cardiologists agree that reversion of long-standing atrial fibrillation is hazardous because of the potential for a thrombus to be dislodged from the atria at the time of reversion.
2. Uncontrolled atrial fibrillation (ventricular responses of 100 beats/minute or greater) is treated with beta-

adrenergic blocker or calcium channel blockers to control rate at rest and activity. If the atrial fibrillation is of recent onset, the cardiologist may choose to revert the rhythm to a sinus rhythm.

3. Digoxin is a second-line drug for rate control because it only controls rate at rest.
4. Cardioversion (electrical or pharmacologic) for recent-onset atrial fibrillation may be required starting with low amounts of biphasic electrical current (100 to 200 joules).
5. Chronic anticoagulation therapy may be warranted to prevent microemboli.

Premature Ventricular Contraction

See Figure 13-15.

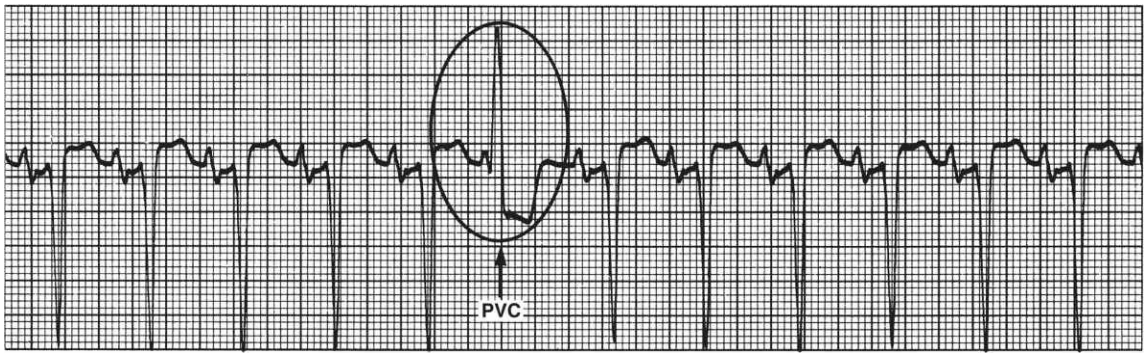

Figure 13-15. Normal sinus rhythm with premature ventricular contraction.

Etiology

1. May be caused by acute MI, other forms of heart disease, pulmonary diseases, electrolyte disturbances, metabolic instability, and drug abuse.
2. The wave of impulse originates from an ectopic focus (foci) within the ventricles at a rate faster than the next normally occurring beat.
3. Because the normal conduction pathway is bypassed, the configuration of the premature ventricular contraction (PVC) is wider than normal and is distorted in appearance. PVCs may occur in regular sequence with normal rhythm—every other beat (bigeminy), every third beat (trigeminy), and so forth (see Figure 13-16).

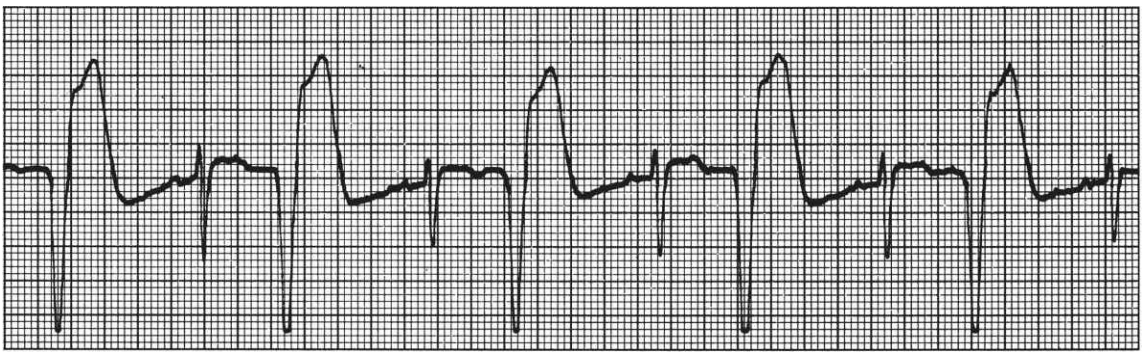

Figure 13-16. Ventricular bigeminy.

Analysis

Rate: may be slow or fast.

Rhythm: will be irregular because of the premature firing of the ventricular ectopic focus.

P wave: will be absent because the impulse originates in the ventricle, bypassing the atria and AV node.

PR interval: not measurable.

QRS complex: will be widened greater than 0.12 second, bizarre in appearance when compared with normal QRS complex. (The QRS of a PVC is commonly referred to as having a "sore thumb" appearance.)

T wave: the T wave of the PVC is usually deflected opposite to the QRS.

Management

1. PVCs are usually the precursors of more serious ventricular dysrhythmias. The following conditions involving PVCs require prompt and vigorous treatment, especially if the patient is symptomatic or unstable:
   a. PVCs occurring at a rate exceeding six per minute.
   b. Occur as two or more consecutively.
   c. PVCs fall on the peak or down slope of the T wave (period of vulnerability).
   d. Are of varying configurations, indicating a multiplicity of foci.
2. Historically, the standard treatment for PVCs has been lidocaine. Today, however, amiodarone IV is the preferred method because of lidocaine's risk for toxicity.
   a. Can be given by bolus of 150 mg IV over 10 minutes.
   b. IV infusion consists of a loading dose of 1 mg/minute for 6 hours, followed by a maintenance rate of 0.5 mg/minute for 18 hours.
   c. After IV load, patient may require oral dosing.
3. Lidocaine toxicities include confusion and slurred speech. It should be used with caution in older adults and in those with liver disease.
4. Amiodarone toxicities include pulmonary fibrotic changes, hypothyroidism, and liver dysfunction.
5. If ventricular premature beats occur in conjunction with a bradydysrhythmia, atropine may be chosen to accelerate the heart rate and eliminate ectopic beats.
6. Atropine should be used with caution with acute MI. The injured myocardium may not be able to tolerate the accelerated rate.
7. Electrolyte infusions may also be needed to treat PVCs. Magnesium sulfate may be used, especially in patients with acute MI. It may be given as 1 g IV over 1 hour or according to facility policy. Potassium infusions can be given at 10 mmol/hour and should be diluted accordingly to route of IV administration.

DRUG ALERT Be alert to the development of confusion, slurring of speech, and diminished mentation because lidocaine toxicity affects the central nervous system. Should these symptoms appear,

slowing the lidocaine may cause them to abate.

Ventricular Tachycardia

See Figure 13-17.

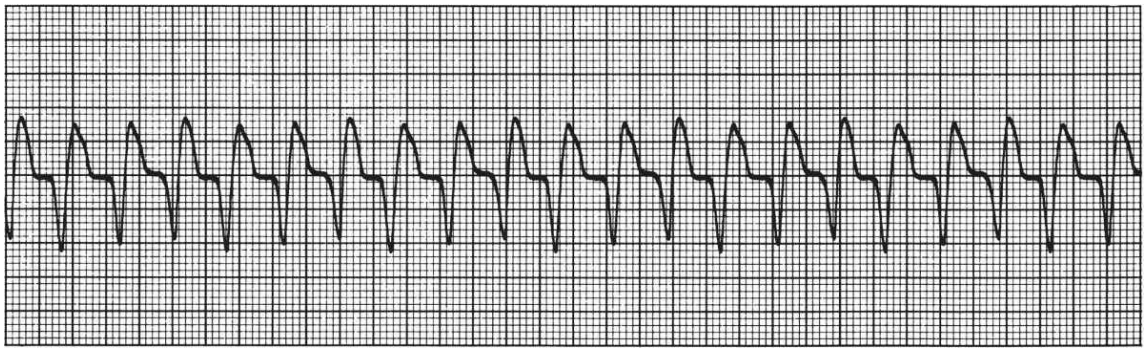

Figure 13-17. Ventricular tachycardia.

Etiology

1. Occurs with:
   a. Acute MI, cardiomyopathy.
   b. Syndromes of accelerated rhythm that deteriorate (eg, Wolff-Parkinson-White syndrome).
   c. Metabolic acidosis, especially lactic acidosis.
   d. Electrolyte disturbance.
   e. Toxicity to certain drugs, such as digoxin or isoproterenol.
2. A life-threatening dysrhythmia that originates from an irritable focus within the ventricle at a rapid rate. Because the ventricles are capable of an inherent rate of 40 beats/minute or less, a ventricular rhythm at a rate of 100 beats/minute may be considered tachycardia.

Analysis

Rate: usually between 100 and 220 beats/minute.

Rhythm: usually regular but may be irregular.

P wave: not present.

PR interval: not measurable.

QRS complex: broad, bizarre in configuration, widened greater than 0.12 second.

T wave: usually deflected opposite to the QRS complex.

Management

1. Ventricular tachycardia (VT) less than 30 seconds is called nonsustained VT. VT more than 30 seconds is sustained VT and requires immediate treatment.
2. If the patient has a pulse and is hemodynamically stable, medications are the initial treatments. Amiodarone IV bolus can be given to halt the dysrhythmia. Other potential medications that may be

used (if amiodarone fails) include lidocaine and procainamide. If patient becomes hemodynamically unstable, prepare for synchronized cardioversion with 200 joules of biphasic electrical current.

3. If the patient is pulseless, defibrillation is recommended with 200 joules of biphasic electrical current.
4. The purpose of cardioversion–defibrillation is to abolish all abnormal electrical activity and allow the intrinsic cardiac rhythm the opportunity to restart.
5. In some cases, VT may be refractory to drug therapy. Nonpharmacologic treatments, such as endocardial resection, aneurysmectomy, antitachycardia pacemakers, cryoablation, automatic internal defibrillators, and catheter ablation, are alternative treatment modalities.
6. An atypical form of VT, referred to as polymorphous VT or *torsades de pointes* (twisting of the points), can result as a consequence of drug therapy (eg, quinidine therapy) or electrolyte imbalance such as hypomagnesemia. It is important to diagnose polymorphous VT as the treatment differs from monomorphic VT.
    a. *Torsades de pointes* is characterized by a QT interval prolonged to greater than 0.60 second, varying R–R intervals, and polymorphous QRS complexes.
    b. The treatment of choice is administration of magnesium sulfate 1 g IV over 5 to 60 minutes.
    c. If the patient loses consciousness and pulse, defibrillate with 120 to 200 joules of biphasic electrical current.
    d. Ventricular pacing to override the ventricular rate and, thus, capture the rhythm is also an acceptable treatment.
    e. Procainamide should be avoided because its effect is to prolong the QT interval.

NURSING ALERT VT is life-threatening and its presentation calls for immediate intervention by the nurse.

Ventricular Fibrillation

See Figure 13-18.

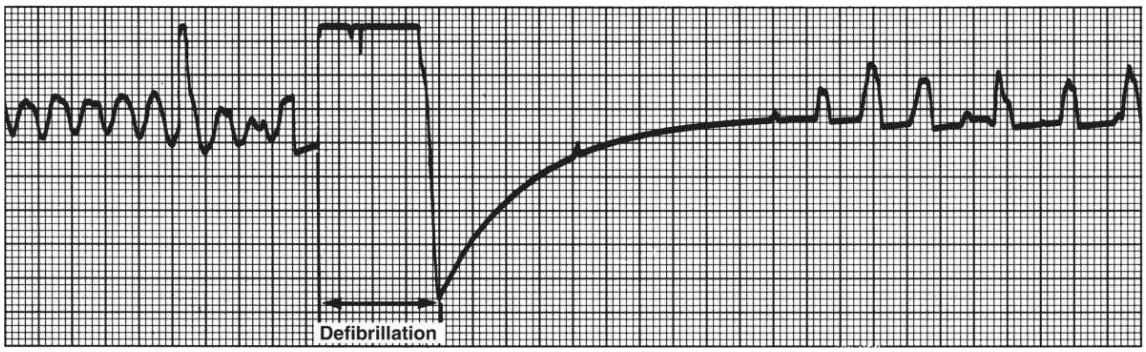

Figure 13-18. Ventricular fibrillation with defibrillation.

Etiology

1. Occurs in acute MI, acidosis, electrolyte disturbances, and other deteriorating ventricular rhythms.
2. The ventricles are firing chaotically at rates that exceed 300 beats/minute, resulting in ineffective impulse conduction. CO ceases, and the patient loses pulse, BP, and consciousness.
3. Must be reversed immediately or the patient will die.

Analysis

Rate: not measurable because of absence of well-formed QRS complexes.

Rhythm: chaotic.

P wave: not present.

QRS complex: bizarre, chaotic, no definite contour.

T wave: not apparent.

Management

1. The only treatment for ventricular fibrillation is immediate defibrillation. Defibrillate at 120 to 200 joules with a biphasic defibrillator. Current advanced cardiac life support guidelines no longer recommend three stacked shocks before initiating CPR and medication administration. Epinephrine and vasopressin are first-line drugs after defibrillation because these drugs may make the fibrillation more vulnerable to defibrillation.
2. Unsuccessful defibrillation may be a result of lactic acidosis (treatable with sodium bicarbonate).
3. Check adequacy of the high-quality CPR being performed: 100 compressions/minute at a 2 to 2½-inch depth.

Atrioventricular Block

Etiology

1. May be caused by ischemia or inferior wall MI, digoxin toxicity, hypothyroidism, or Stokes-Adams syndrome.
2. Impaired tissue at the level of the AV node prevents the timely passage of the wave of impulse through the conduction system.
3. In first-degree AV block, the impulse is transmitted normally, but it is delayed at the level of the AV node. The PR interval exceeds 0.20 second.
4. In second-degree AV block, two or more atrial impulses occur before the ventricles are stimulated.
    a. Second-degree type 1 (Mobitz 1 Wenckebach)—block occurs above the AV node. There is an increase in delay of electrical impulse (increasing PR interval) with every beat until one P wave fails to conduct and is not followed by a QRS complex (beat is dropped). Mobitz type 1 is usually a temporary and benign dysrhythmia and seldom requires intervention (pacing) unless ventricular rate is slow and the patient is unstable.
    b. Second-degree type 2 (Mobitz 2)—block occurs below the AV node in the bundle of His or bundle-

branch system. The atria and ventricles are discharging impulses, but the activity bears no relationship to each other. There is a sudden failure to conduct an atrial impulse to the ventricles without a delay of the PR interval.

5. In third-degree AV block, or complete heart block, the electrical impulse is completely blocked from the SA node to the AV node. An independent pacemaker in the ventricles takes over at a much slower rate than the atria and are firing independently of each other.

Analysis

1. First-degree AV block (see Figure 13-19).

   Rate: usually normal but may be slow.

   Rhythm: regular.

   P wave: present for each QRS complex, identical in configuration.

   PR interval: prolonged to greater than 0.20 second.

   QRS complex: normal in appearance and between 0.06 and 0.10 second.

   T wave: normally conducted.

2. Second-degree AV block (see Figure 13-20).

   Rate: usually normal.

   Rhythm: may be regular or irregular.

   P wave: present but some may not be followed by a QRS complex. A ratio of two, three, or four P waves to one QRS complex may exist.

   PR interval: varies in Mobitz I (Wenckebach), usually lengthens until one is not conducted; constant in Mobitz II, but not all P waves conducted.

   T wave: normally conducted.

3. Third-degree AV block (complete heart block) (see Figure 13-21).

   Rate: atrial rate is measured independently of the ventricular rate; the ventricular rate is usually very slow.

   Rhythm: each independent rhythm will be regular, but they will bear no relationship to each other.

   P wave: present but no consistent relationship with the QRS.

   PR interval: not really measurable.

   QRS complex: depends on the escape mechanism (ie, AV node will have normal QRS, ventricular will be wide, and the rate will be slower).

   T wave: normally conducted.

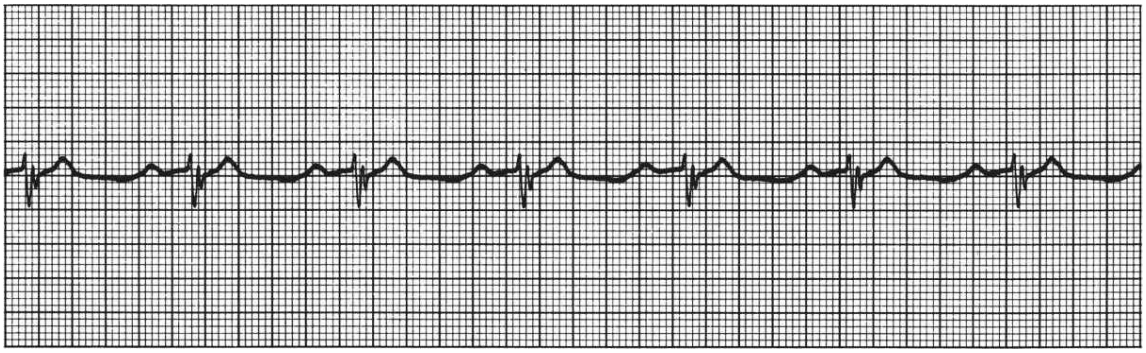

Figure 13-19. First-degree AV block.

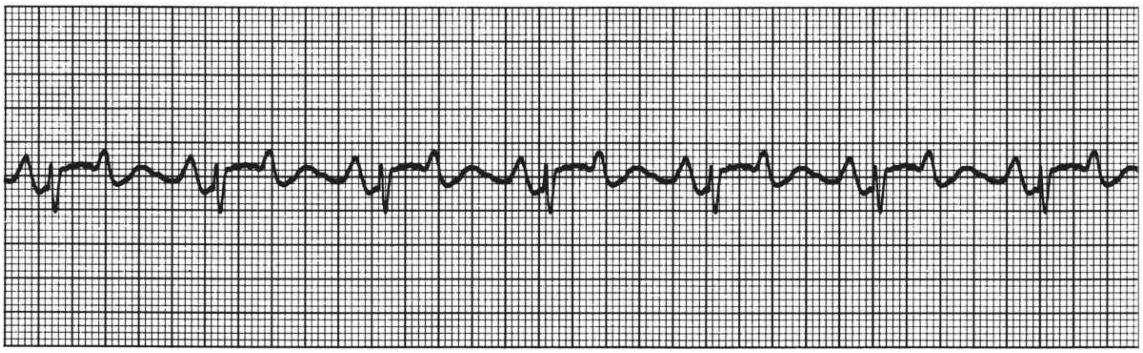

Figure 13-20. Second-degree AV block (Mobitz I).

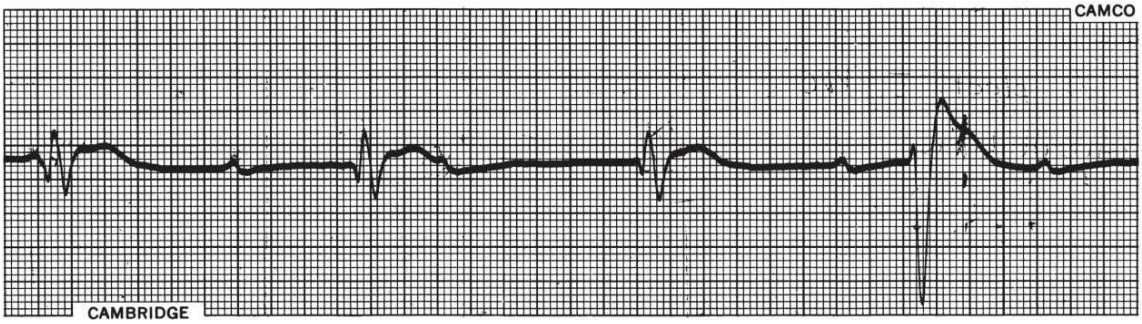

Figure 13-21. Third-degree AV block.

Management

Like that of other dysrhythmias, the treatment of heart blocks depends on the effect the rate is having on CO.

1. First-degree AV block usually requires no treatment.
2. Second-degree AV block, type 1 and type 2, may require treatment if the ventricular rate falls too low to maintain effective CO. Mobitz type 2 is more serious than Mobitz type 1.
3. Third-degree AV block usually requires intervention. However, some patients may be able to tolerate third-degree block for a length of time.
4. Transcutaneous pacing should be employed in the emergent situation while transvenous pacing is being set up.
5. Atropine may be given while awaiting the pacemaker, but it must be remembered that the effect of

atropine is to block vagal tone, and the vagus acts on the sinus node. Because the AV node is the culprit in heart block, atropine may not be helpful.

PROCEDURE GUIDELINES 14-1

Anticoagulant Injection of Anticoagulant

PURPOSE

When prolonged therapy is indicated, unfractionated heparin, low molecular weight heparin (LMWH), or a factor Xa inhibitor may be given SC into fatty tissues. These anticoagulants are often given postoperatively to prevent deep vein thrombosis.

EQUIPMENT

- A 1- or 2-mL disposable syringe, such as disposable tuberculin syringe, prefilled LMWH, or fondaparinux syringe
- Fine sharp needle, #27, 5/8-inch long
- Skin antiseptic

Nursing Action	Rationale
Preparatory phase	
1. Gather equipment and perform hand hygiene.	1. Complies with universal precautions.
2. Choose an injection site.	2.
a. Most convenient sites are along lower abdominal fat pad.	a. Avoids inadvertent intramuscular injection, injection near an incision, and hematoma formation.
b. A common site is the fatty area anterior to either iliac crest.	
c. Avoid injection sites within 2 inches (5 cm) of the umbilicus.	c. Because of possibility of entering a larger blood vessel.
3. Areas where subcutaneous layer is thin should also be avoided.	3. Ensures absorption and avoids tissue damage.

GERONTOLOGIC ALERT The aging individual begins to lose subcutaneous fat padding. Examine patient for best site for subcutaneous administration of heparin.

PROCEDURE

Nursing Action	Rationale
Performance phase	
1. Sponge the area gently with alcohol. *Do not rub.*	1. Rubbing or pinching skin might initiate damage to the tissue; anticoagulant would aggravate any bleeding.
2. Attempt to stretch skin out, using palm of nondominant hand. Some prefer to (gently) pick up a well-defined fold of skin.	2. Try to empty blood vessels in local area to lessen likelihood of their being pierced by needle—with subsequent hematoma formation.
3. Holding the shaft of the syringe in dart fashion, insert needle directly through the skin at a right angle just into the subcutaneous fatty layer.	3. Right angle achieves adequate depth into subcutaneous tissue.
4. Move dominant hand into position to direct plunger.	4. Aspiration in a forcible manner can damage small blood vessels and frequently lead to bleeding and hematoma formation, especially in the presence of high local concentration of heparin.
a. Do not move needle tip when it is inserted.	
b. Do not pull back plunger for testing.	
5. Firmly push plunger down as far as it will go.	5. Ensures administration of total dose of medication.
6. When injection has been made, withdraw needle gently at the same angle at which it entered, releasing skin on withdrawal of needle.	6. Minimizes tissue damage.
7. Press an alcohol sponge to the site for a few seconds.	7. Minimizes oozing or bleeding.

Nursing Action	Rationale
Follow-up care	
1. Do not rub the area. Instruct patient not to rub area.	1. Rubbing would increase the likelihood of bleeding.
2. Site of injection.	2. Avoids tissue damage from repeated injection, which may alter absorption.
a. Change site of injection each time medication is administered.	
b. A chart can be marked with time, date, and measured dosage.	b. Ensures adequate rotation of sites.
3. Teach patient and family the procedure if being discharged with self-injections.	3. For continuity of therapy.

Anticoagulant Therapy

EVIDENCE BASE Guyatt, G., Akl, E., Crowther, M., et al. (2012). Executive summary: Antithrombotic therapy and prevention of thrombosis, 9th ed: American College of Chest Physicians Evidence-Based Clinical Practice Guidelines. *Chest*, *141*(2 Suppl), 7S–47S.

Anticoagulant therapy is the administration of medications to achieve the following:

- Disrupt the blood's natural clotting mechanism when there is a risk of pathologic clotting.
- Prevent formation of a thrombus in immobile and/or postoperative patients.
- Intercept the extension of a thrombus once it has formed.
- Agents are used in the acute treatment of thromboembolic disorders, for long-term prevention of recurrent thromboembolism, or for short-term prevention following surgery for some orthopedic conditions.

Types of anticoagulants include Coumadin derivatives, such as warfarin given orally; unfractionated heparin (UFH) given subcutaneously (SC) or intravenously (IV); Coumadin or low molecular weight heparin (LMWH) given SC, particularly dalteparin and enoxaparin; factor Xa inhibitors, particularly fondaparinux given SC and rivaroxaban, apixaban, edoxaban given orally; direct thrombin inhibitors, such as dabigatran given orally, and argatroban, bivalirudin, or hirudin given through IV administration.

NURSING ALERT Anticoagulants may be contraindicated or used with extreme caution in conditions that may lead to bleeding, in patients who may have poor follow-up, and in patients with hepatic and renal insufficiency.

Anticoagulant Indications

1. LMWH (dalteparin, enoxaparin) may be given prophylactically pre- and postoperatively in specific patient populations with high-risk procedures, such as active malignancy with an abdominal surgery; following some orthopedic surgical procedures such as total hip replacement, knee replacement, or arthroscopic procedures; and for long surgical procedures or periods of immobility in high-risk patients. They are also used for the acute treatment of deep vein thrombosis (DVT) (often while warfarin is being started). Dalteparin is indicated for prevention of unstable angina or non-Q-wave infarction. The benefits over heparin include:
   a. Steady bioavailability.
   b. Longer half-life.

c. Less platelet inhibition (than UFH).
d. More mobility for the patient (it may be given at home).
e. Does not cause paradoxical thrombotic events.

2. Factor Xa inhibitor fondaparinux is given prophylactically before and after some orthopedic procedures or abdominal surgery in high-risk patients and for the acute treatment of DVT (with warfarin). Edoxaban, rivaroxaban, and apixaban are indicated for treatment of acute DVT and pulmonary embolus, for prevention of DVT after hip and knee surgery, and for reducing risk of stroke in patients with nonvalvular atrial fibrillation.
3. Warfarin is used following DVT and pulmonary emboli and for long-term prophylaxis, such as prevention of thromboembolic complications of atrial fibrillation, cardiac valve replacement, or recurrent myocardial infarctions (MIs) and lower-extremity arterial bypass surgeries.
4. Direct thrombin inhibitors are the newest class of anticoagulant.
   a. Dabigatran is indicated for prevention of thromboembolic complications/stroke in patients with nonvalvular atrial fibrillation.
   b. Argatroban, bivalirudin, and hirudin are administered via IV line, so they are used on a shorter-term basis. They are indicated for patients who have a history of heparin-induced thrombocytopenia (HIT).
5. Perioperative considerations include discontinuing oral anticoagulants.
   a. IV UFH may be prescribed preoperatively because its half-life is short; thus, the anticoagulant effects are reversed within 30 minutes to 1 hour after discontinuation.
   b. LMWH may be given preoperatively several hours before surgery and 4 to 8 hours after surgery.
   c. It is recommended that the initial dose of fondaparinux be given 6 to 8 hours following surgery.
   d. Rivaroxaban and apixaban may be given as soon as postoperative hemostasis occurs.

DRUG ALERT Oral anticoagulants should be discontinued preoperatively according to manufacturer guidelines to reduce the risk of hemorrhage in the intraoperative phase.

Nursing and Patient Care Considerations

Administering Unfractionated Heparin

1. Obtain baseline coagulation and hematologic studies before initiating anticoagulation therapy to ensure that the patient does not have an underlying bleeding or clotting disorder.
2. Weigh patient before initiating therapy because UFH, as well as some forms of LMWH, are calculated based on weight.
3. Administer subcutaneously into lower abdomen.
4. For IV administration, begin continuous infusion.

a. Use continuous infusion pump.
b. Assess frequently to make sure the pump is functioning properly, that there are no kinks or leaks in IV tubing, and that the IV site is without signs or symptoms of infiltration.

5. Double-check concentration and dose of heparin, especially when giving high dosages.
6. Be aware that heparin may be continued for 4 to 5 days after oral anticoagulant is initiated due to the delayed onset of therapeutic effectiveness with some oral anticoagulants.

NURSING ALERT Active life-threatening bleeding is a contraindication to antithrombotic therapy. The decision for treatment in each patient should be weighed against the individual risk of bleeding.

Administering Other Anticoagulants

1. Administer low molecular weight heparin SC; dosage varies with drug and its intended purpose.
   a. Usually begun 1 to 24 hours before surgery or once or twice daily after surgery, limited to 7 to 14 days.
   b. If warfarin is started, continue LMWH until warfarin becomes therapeutic.
2. Administer fondaparinux once daily; dosage depends on whether it is prophylactic or treatment for thrombosis.
   a. Must be continued for at least 5 days or until warfarin level is therapeutic. May be given for longer following orthopedic procedures.
   b. Provided in preloaded syringes. (*Note:* Do not expel the air bubble from the syringe. Must not be given intramuscularly.)
3. Give rivaroxaban orally at the same time every day, such as with the evening meal.
   a. Obtain a baseline creatinine level, as dosage may be decreased in patients with renal insufficiency.
   b. Usually given for 35 days post hip replacement; 12 days post knee replacement.
   c. Give twice daily first 21 days then once daily in treatment of acute PE or DVT.
4. Give warfarin orally at the same time every day, usually in the afternoon or at dinnertime.
   a. Therapeutic range is monitored by international normalized ratio (INR), usually drawn at least 16 hours after last dose.
   b. Monitor frequently until stable, with any medication changes, and then every 12 weeks when consistently stable INR.
5. Give dabigatran orally twice daily. Instruct patient to swallow capsules whole; do not open, crush, or chew.
6. Give apixaban orally twice daily.
   a. Decrease dose in patients with at least two of the following: 80 years or older, weight less than 60 kg, or Cr greater than 1.5.

b. For DVT prophylaxis in hip replacement 2.5 mg orally twice daily for 35 days.
c. For DVT prophylaxis in knee replacement 2.5 mg orally twice daily for 12 days.
d. For DVT/PE treatment start 10 mg orally twice daily for 7 days and then reduce to 5 mg dose.

DRUG ALERT Be aware that dabigatran has a 60-day shelf life.

Monitoring Clotting Profiles

1. Partial thromboplastin time (PTT) is the coagulation test used to monitor the anticoagulation effects of UFH.
   a. The patient's PTT should be 2 to 2½ times the control.
   b. Obtain PTT levels daily or as ordered. Heparin dose will be adjusted to achieve the desired level of anticoagulation.
2. Prothrombin time (PT) and INR are the coagulation tests used to monitor the anticoagulation effects of warfarin.
   a. The patient's INR should be 2 to 3½ times the control. *Note:* The desired levels of INR are determined by protocol for condition and risk factors being followed or by the health care provider.
   b. Obtain PT/INR levels daily or as ordered. Warfarin dose will be adjusted to achieve the desired level of anticoagulation.
3. Other laboratory studies to monitor as ordered or if bleeding is suspected:
   a. Platelet count—HIT may occur, particularly with UFH; 50% decrease in platelet count causing local bleeding or systemic reaction with IV.
   b. Hemoglobin and hematocrit—baseline and periodically.
   c. Fibrinogen—if abnormal bleeding while on UFH.
4. Be aware of drug–drug (including over-the-counter [OTC] and herbal supplements) and food–drug interactions that may alter the effects of warfarin. This occurs because of alterations in the clearance of the drug or the rate of intestinal absorption. The patient is encouraged to eat a consistent diet and to notify health care provider of any new drugs, so that INR can be tested more frequently, if indicated. Consult a pharmacist, drug reference book, or online list for information on specific foods and drugs.
5. No monitoring of PTT or other coagulation tests is required for LMWH, factor Xa inhibitors, or direct thrombin inhibitors; however, PTT may be monitored for LMWH therapy in patients with renal disease and patients weighing less than 110.2 pound (50 kg) or more than 176.4 pound (80 kg).

DRUG ALERT Drug and food interactions can alter the effect of some anticoagulants. A change in intake should prompt more frequent monitoring and, possibly, a change in dose.

Preventing Bleeding

1. Follow precautions to prevent bleeding.
   a. Handle patient carefully while turning and positioning.
   b. Maintain pressure on IV and venipuncture sites for at least 5 minutes. Apply ice if patient is prone to bleeding.
   c. Assist with ambulation and keep walkways/hallways free from clutter to prevent falls.
2. Observe carefully for any possible signs of bleeding and report immediately so that anticoagulant dosage may be reviewed and altered, if necessary:
   a. Hematuria—frank blood in urine or microhematuria as detected on the test strip.
   b. Melena—assess for dark/tarry stools; use test cards for occult blood.
   c. Hemoptysis—assess for frank blood in emesis; use test cards for occult blood.
   d. Bleeding gums—note any pink saliva or frank bleeding with dental hygiene.
   e. Epistaxis—frequent/persistent nosebleeds.
   f. Bruising/hematomas—inspect skin carefully.
3. Have on hand the antidotes to reverse anticoagulants being used (see Table 14-1, page 320).
   a. Heparin—protamine sulfate, by IV injection.
   b. Warfarin—phytonadione (vitamin K_1, AquaMEPHYTON); oral or IV and dose is dependent on the INR level and the degree or risk of patient bleeding
   c. Dabigatran—idarucizumab by IV injection

Table 14-1 Guide to Anticoagulants

DRUG	CONTRAINDICATIONS	MONITORING	ANTIDOTE	OTHER CONSIDERATIONS
Unfractionated heparin (UFH)	• Allergy • Acute major bleeding • Thrombolytic therapy given within past 24 hr in stroke victim • HIT most frequently develops 1–2 wk after starting therapy	• Get baseline complete blood count, platelet count, prothrombin time/INR, and creatinine before starting therapy; liver function tests and albumin with suspected liver disease • Daily partial thromboplastin time or heparin assay • Monitor platelet count every other day (for HIT).	• Protamine sulfate IV over 10 min • Risk for anaphylaxis is 1%	• Generally safe in pregnancy unless patient has mechanical heart valve. • Safe in the breastfeeding patient. • Monitor for HIT: reaction at injection site, systemic reaction after bolus injection, 50% decrease in platelets
Low molecular weight heparins (LMWH)	• Allergy • Acute major bleeding • Thrombolytic therapy given within past 24 hr in stroke victim • HIT • Renal failure	• Same baseline as UFH • Monitor platelet count every 2–3 d if also receiving UFH	• No agent for complete reversal • Protamine sulfate provides for 60%–75% reversal.	• Generally safe in pregnancy unless patient has mechanical heart valve. • Generally safe in the breastfeeding patient • Monitor for HIT
Factor Xa inhibitors	• Allergy • Acute major bleeding • Thrombolytic therapy given within past 24 hr in stroke victim • Renal failure	• Same baseline as UFH • No routine monitoring of PTT or INR • Fondaparinux: monitor heparin assay regularly in those with renal insufficiency, body weight <50 kg, or those who are obese.	• No antidote for apixaban, edoxaban • Idarucizumab is the reversal agent for dabigatran; 5 g dose (2–50 mL vials of 2.5 g) given IV • Fondaparinux: possible partial reversal with recombinant factor VIIa. • Rivaroxaban: activated charcoal to reduce absorption in overdose	• Safety unknown in the pregnant or breastfeeding patient. • Use cautiously in bacterial endocarditis, uncontrolled hypertension, and other conditions. • Increased risk of bleeding in renal or hepatic impairment. • Risk of spinal or epidural hematoma with spinal procedures
Warfarin sodium	• Allergy • Hemorrhage • Pregnancy	• Same baseline as UFH • Monitor INR daily to every few days until stable and then monthly (best time is at least 16 hr after last dose). • If starting medication that can affect warfarin, check INR in 3–4 d.	• Vitamin K orally or IV over 60 min. • May lead to warfarin resistance and thromboembolism • Transfusion of fresh frozen plasma may be given.	• Only small amount secreted in breast milk • Hold for 4 d prior to surgery. • Increased risk of thromboembolism if INR < 1.7; increased risk of bleeding if INR > 4.0. • Purple toe syndrome may occur 3–10 wk after starting therapy. • Numerous drug and food interactions
Direct thrombin inhibitors	• Allergy • Active bleeding	• Assess baseline renal function, and annually if creatinine clearance <50 mL/min or age >75 yr	• No known antidote • About 60% of drug may be cleared with dialysis over 3–4 hr • Transfusion of fresh frozen plasma or packed red cells may be given.	• Safety not known in pregnancy or breastfeeding • Risk of bleeding increases with age • Consult medication reference for drug interactions.

DRUG ALERT When epidural anesthesia or spinal puncture is employed, anticoagulants increase the risk of epidural or spinal hematoma, which may result in paralysis. Monitor these patients closely for sensory and motor dysfunction.

DRUG ALERT Vitamin K ingestion can lead to warfarin resistance and subsequently increased risk of thromboembolism.

NURSING ALERT There is a risk of bleeding in any patient receiving anticoagulants. Risk of bleeding is patient and treatment dependent. Recent updates for labeling on warfarin include genetic variations that may produce resistance to drug therapeutic levels. Advanced age and hypertension add an increased risk for intracerebral hemorrhage.

Patient Education and Health Maintenance

1. Instruct patient about taking anticoagulants.
    a. Follow instructions carefully and take medications exactly as prescribed; if a dose is missed, do NOT double up dose; rather, notify the health care provider.
    b. Notify all health care providers, including dentist, that you are taking anticoagulants.
    c. Avoid foods that may alter the effects of anticoagulants or, if used, should be used in the same quantity every day: green, leafy vegetables, fish, liver, green tea, and tomatoes.
    d. Take medications at the same time each day and do not stop taking them unless directed by health care provider, even if symptoms of thrombus/embolus are not present.
    e. Wear a medical identification bracelet or carry a card indicating that you are taking anticoagulants; include name, address, and telephone number of health care provider.
2. Advise the patient to notify the health care provider of the following:
    a. All medications both prescribed and OTC (including vitamins and herbal supplements) that patient is currently taking.
    b. Accidents, infections, excessive diarrhea, and other significant illnesses that may affect blood clotting.
    c. Scheduled invasive procedures by other health care providers, including routine dental examinations and other dental procedures or cardiac catheterizations. If surgical care by another health care provider or dentist is needed, inform other provider that anticoagulants are being taken.
3. Advise the patient to avoid:
    a. Taking any other medications without first checking with health care provider, particularly:
        i. Vitamins, especially if they contain vitamin K.
        ii. Herbal supplements.
        iii. Aspirin or nonsteroidal anti-inflammatory drugs (NSAIDs).
        iv. Mineral oil.
        v. Cold medicines, antibiotics.

vi. Oral contraceptives and hormones.

vii. Antireflux medicines.

viii. Oral antifungals.

b. Excessive use of alcohol; may affect clotting ability; check on acceptable limits for social drinking.

c. Participation in activities in which there is high risk of injury.

d. Foods that may cause diarrhea or upset stomach; rapid changes in diet.

e. Shaving with a sharp razor.

4. Instruct the patient to be alert for these warning signs:

a. Excessive bleeding that does not stop quickly (such as following shaving, a small cut, tooth brushing with gum injury, nosebleed).

b. Excessive menstrual bleeding.

c. Skin discoloration or bruises that appear suddenly—particularly on the fingers and toes or deep purple spots anywhere on the body ("blue toe syndrome").

d. Black or bloody stools; for questionable stool discoloration, test for occult blood.

e. Blood in urine.

f. Faintness, dizziness, or unusual weakness.

5. Stress the importance of close follow-up and compliance with periodic laboratory work for blood clotting profiles, need to notify health care provider if unable to keep scheduled appointments, and contact provider with questions about dosage.

Thrombolytic Therapy

Thrombolytic therapy is the administration of thrombolytic agents to dissolve any formed thrombus and to inhibit the body's hemostatic function. Thrombolytic agents are available for parenteral use only. Commonly used thrombolytics include streptokinase, tissue plasminogen activator, and urokinase.

Thrombolytic therapy is contraindicated in conditions that may lead to bleeding and should be given only in a controlled setting, such as a cardiac catheterization laboratory, endovascular OR, or an intensive care unit (ICU). Thrombolytic therapy for deep vein or peripheral arterial thrombosis, however, may be given on stepdown units or medical–surgical floors in some facilities with appropriate staff education.

Clinical Indications

1. Acute MI from coronary thrombosis
2. Pulmonary embolus
3. Acute occlusion of peripheral arteries/prosthetic grafts
4. Iliofemoral DVT

Nursing and Patient Care Considerations

1. Monitor clotting profiles every 2 to 4 hours; these are essential before the initiation of treatment to disclose any bleeding tendencies and to serve as a baseline for assessment of drug efficacy. UFH will generally be given parenterally at the same time.
2. Observe for signs of bleeding and report immediately.
    a. Have typed and crossmatched blood on hold in case bleeding is severe.
    b. Have aminocaproic acid on hand to treat bleeding.
3. Monitor for allergic reaction. A small number of patients (less than 5%) may experience an allergic reaction.
    a. Observe patient for onset of a new rash, fever, and chills.
    b. Report any suspected allergic reaction immediately.
    c. Administer corticosteroids, if ordered, to treat reaction.
4. Monitor electrocardiogram (ECG) for dysrhythmias after reperfusion if thrombolytic therapy is being used for coronary thrombus.
5. Frequently assess color, warmth, and sensation of extremity if therapy is being used for peripheral arterial occlusion.
6. Move patient as little as possible.
7. Minimize phlebotomy.
8. Observe for changes in level of consciousness or other signs of intracranial bleeding.

Care of the Patient Undergoing Vascular Surgery

Vascular surgery may involve operations of the arteries, veins, or lymphatic system. Surgery may be performed on an urgent basis, as in *embolectomy* for acute arterial embolism, or electively for *vein ligation and stripping* for varicose veins after conservative management fails. Other vascular procedures include *thrombectomy* and *vena cava filter insertion* for venous problems and *arterial bypass grafting* (aortoiliac, aortofemoral, femoral–femoral, femoropopliteal, and femoral–distal), *endarterectomy, endovascular grafting*, and *percutaneous transluminal angioplasty (PTA)* for arterial problems with or without placement of an intraluminal stent.

Preoperative Management

1. Additional health conditions, such as heart disease, hypertension, diabetes mellitus, and chronic lung disease, are fully evaluated, and management is adjusted to decrease operative risks.
2. Chronic skin and tissue changes are assessed preoperatively, and impairment is minimized through protection of the affected parts, treatment with antibiotics, and proper positioning to enhance circulation (elevated for venous and lymphatic problems, level or slightly dependent for arterial problems).
3. Nutritional status is assessed and improved preoperatively to aid in wound healing postoperatively.
4. Risk factors for vascular disease, such as smoking, obesity, and sedentary lifestyle, are reviewed, and patient teaching is initiated to prevent recurrence or progression of vascular disorder.
5. The patient is prepared emotionally and physically for surgery, with teaching focusing on positioning in bed; expected exercises and activity to be followed postoperatively; frequent checking of circulation and wound; and prevention of complications, such as bleeding, infection, and neurovascular compromise.

Postoperative Management

1. Bed rest may be maintained for 24 hours in some cases to reduce swelling and the risk of bleeding.
2. If surgery involved revascularization, peripheral pulses are assessed distal from operative site to ensure adequate tissue perfusion. (Use portable Doppler, if necessary.)
3. If surgery involved use of bypass graft, the graft site is protected and assessed for patency as well.
4. Extremity is positioned with the popliteal space supported to prevent trauma and promote circulation.
5. Anticoagulation may be continued, but it increases chance of bleeding following surgery.
6. Hydration, nutrition, and oxygenation are promoted to ensure wound healing.
7. Surgical incisions are assessed for redness, drainage, and approximation and may be covered with dry dressings, and possible incisional wound vacuum devices.
8. Endovascular and PTA procedures are less invasive, but incision site of catheter is carefully monitored for bleeding and peripheral circulation is assessed.
9. Breathing exercises using an incentive spirometer are performed every 2 hours while patient is awake to prevent postoperative pulmonary complications if the patient is immobilized.

Nursing Diagnoses

- Ineffective Peripheral Tissue Perfusion related to underlying vascular disorder, postoperative swelling.
- Risk for Infection related to surgical incision and impaired circulation.
- Acute Pain related to surgical incision and swelling.
- Impaired Physical Mobility related to pain and imposed restrictions.

Nursing Interventions

Promoting Tissue Perfusion

1. Maintain dressing or compression bandages, as directed.
2. Monitor for bleeding through dressing—reinforce and notify surgeon, as indicated.
3. Monitor for hematoma formation beneath skin—increased pain and swelling. Apply pressure and notify surgeon.
4. Measure vital signs frequently for tachycardia and hypotension, which may indicate hemorrhage.
5. Perform frequent neurovascular checks to involved extremity. Check warmth, color, capillary refill, sensation, movement, and pulses; compare with other side.
6. Position as directed—usually legs elevated and fully supported.

Preventing Infection

1. Maintain IV infusion or heparin lock for antibiotic administration, as ordered, and assess daily for signs of infiltration and infection.
2. Check incision site for drainage, warmth, and erythema, which indicate infection.
3. Change incision dressing, as ordered and as needed, for drainage or soiling.
4. Monitor temperature for elevation.
5. Monitor hematologic profiles for elevation in white blood cell (WBC) count.

Relieving Pain

1. Assess pain level and administer analgesic as ordered.
2. If patient-controlled anesthesia is being used, instruct patient on use and make sure the pump is functioning properly.
3. Position for comfort, using pillows for support.
4. Watch for adverse effects of opioids, such as hypotension, respiratory depression, nausea and vomiting, and constipation.
5. Administer pain medication before activity.
6. Instruct patient in alternative coping methods such as visualization.

Minimizing Immobility

1. Encourage isometric and range-of-motion (ROM) exercises while on bed rest.
    a. Exercise affected extremity by pushing foot into footboard, making a fist, or simply contracting muscles without movement if approved by surgeon.

b. Perform full ROM of other extremities.

2. Encourage ambulation as soon as allowed.
   a. Avoid dangling legs because of possible compression against the back of bed or chair.
   b. Avoid long periods of sitting or standing.
   c. Encourage short periods of walking every 2 hours.

Patient Education and Health Maintenance

1. Instruct patient and significant other in care of incision and wound at home. Make sure that patient has proper resources available.
2. Instruct patient about wearing elastic stockings or applying ace wrap, if ordered. Have patient perform return demonstration.
3. Instruct patient and significant other in signs of infection, graft failure, or worsening circulatory problem that should be reported.
4. Refer patient to vascular rehabilitation (if available), physical therapy, and occupational therapy as indicated.
5. Refer for additional support for risk factor modification, such as supervised weight loss programs, nutritional counseling, and smoking cessation.
6. Instruct patient to avoid restrictive clothing (including socks, hose, shoes), especially over areas of revascularization.
7. Instruct patient to inspect feet (using a mirror, if necessary), including plantar aspect and between toes, daily and to inspect shoes for foreign objects, such as small stones, before putting them on.
8. Instruct patient to wear thick socks and well-fitting shoes with wide toe box to avoid development of breakdown/ulceration on pressure points. Instruct patient not to wear sandals.
9. Instruct patient never to walk barefoot.
10. Review any medications, especially anticoagulants.
11. Make sure that the patient knows when and where to follow up.

Evaluation: Expected Outcomes

- Affected extremity with good color, capillary refill, and pulses; warm and sensitive to touch; moving adequately.
- Incision site is well approximated and without signs and symptoms of infection.
- Reports adequate pain control on current regimen.
- Ambulates for 10 minutes every 2 hours without difficulty or shows signs of progressing independence with the assistance of physical or occupational therapy.

CONDITIONS OF VEINS

See additional online content: Procedure Guidelines 14-2, 14-3

PROCEDURE GUIDELINES 14-2

Obtaining Leg Measurements to Detect Early Swelling

PURPOSE

To obtain leg measurements for detection and monitoring of thrombophlebitis.

EQUIPMENT

- Flexible tape measure in inches/centimeters
- Black felt-tip pen

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Instruct patient to lie in dorsal recumbent position.	
Performance	
1. On initial assessment of the patient, measure the circumference of the ankle, calf, and thigh.	1. Provides baseline data.
2. Obtain measurements at the narrowest part of the ankle, and widest part of calf and thigh.	2. Provides a consistent anatomic place of measurement, some facilities have a predetermined starting point, such as 6 to 8 inches (15 or 20 cm) from the kneecap.
3. Mark the leg with a black felt-tip pen where measurements taken. Thereafter, when measuring, place the measuring tape on the marked line.	3. Promotes consistency of measurements.
4. Repeat measurements taken on admission the next morning before any patient activity.	4. Otherwise, later measurements may give a false reading because of gravitational edema.
5. Thereafter, obtain measurements at the same time of day weekly unless there is evidence of swelling, in which case it is done daily.	5. Weekly—to detect swelling. Daily—to monitor swelling and its response to treatment.
6. Record measurements: **LEG MEASUREMENTS** Date: _____ Time: _____ **Right** Ankle _____ inches/cm Calf _____ inches/cm Thigh _____ inches/cm **Left** Ankle _____ inches/cm Calf _____ inches/cm Thigh _____ inches/cm	6. Evaluates trends.
7. Compare measurements: a. Check one leg with the other. b. Check each leg with baseline data.	*Significant findings* Males: 1.5 cm difference between legs or compared with baseline. Females: 1 cm difference between legs or compared with baseline.

PROCEDURE GUIDELINES 14-3

Applying Compression Stockings

PURPOSE

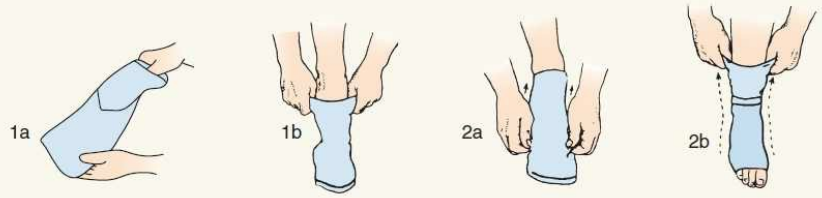
To prevent postphlebitic syndrome following deep vein thrombosis (DVT) or to prevent acute DVT or pulmonary embolism postoperatively or during periods of immobility.

EQUIPMENT

Stockings that have been properly fitted to patient (see manufacturer's information on measuring and fitting)

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Make sure that stockings are clean and dry and without excessive wear.	1. Damp stockings are difficult to apply and excessive wear reduces elasticity and effectiveness.
2. Make sure that patient's skin is dry. Do not apply moisturizing lotion before application; can apply a thin layer of cornstarch to reduce friction.	2. Moisture will cause difficulty with application.
3. Remove any jewelry that may get caught on stockings.	3. Could damage stockings.
Performance phase	
1. Insert hand into stocking as far as heel pocket.	
2. Grasp center of heel pocket and pull back, turning stocking inside out as far as heel.	2. Creates shorter length to maneuver.
3. Using two hands, position stocking over foot and heel, centering heel.	3. Centering over the foot will be more difficult once application is complete.
4. Pull stocking up around ankle, then calf, then into final position (1 to 2 inches below knee for knee-high stockings).	4. Working it upward slowly will prevent excessive pulling, which puts stress on the elastic.
5. Run hands over stocking to smooth it into position. Do not allow top band to roll down.	5. Creases could place excessive pressure on the skin. The top band could bunch up over popliteal area, impeding venous return.
Follow-up care	
1. Ensure that stockings are cleaned according to manufacturer's instructions. The stockings may be hand washed with mild soap and hung to dry or placed in washer and dryer on low settings.	1. Excessive heat and bleach will decrease life of elastic. Manufacturer may recommend replacement after 3 to 6 months of use.
2. Teach patient how to don and care for stockings at home. Refer the patient to the manufacturer's website or phone number for additional information.*	2. Manufacturers, such as Jobst and TED, offer products to help with donning and additional care information.



Hand positions for stocking application.

*Manufacturer's websites such as www.jobst-usa.com; www.rescuelegs.com; www.compressionstockings.com

Table 14-2 Comparison of Arterial and Venous Obstruction

FACTOR	ARTERIAL OBSTRUCTION	VENOUS OBSTRUCTION
Onset	May be sudden	Gradual
Color	Pale later—mottled, cyanotic	Slightly cyanotic rubescent
Skin temperature	Cold	Warm
Leg size	May be reduced	Enlarged
Leg hair and nails	Decreased hair; thick, brittle nails	No change
Edema	None to mild	Typically calf to foot
Sensation	Sensory changes	Normal sensation
Arterial pulses	Pulse deficit	Normal
Effect of elevating leg	Condition worsens	Slight improvement

Venous Thrombus

EVIDENCE BASE Dupras, D., Bluhm, J., Felty, C., et al. (2013). Institute for Clinical Systems Improvement. *Venous thromboembolism diagnosis and treatment*. Available: *www.icsi.org/guidelines__more/catalog_guidelines_and_more/catalog_guidelines/catalog_cardiovascular_guidelines/*

See Table 14-2. There are several types of venous thrombosis:

Phlebitis is an inflammation in the wall of a vein. The term is used clinically to indicate a superficial and localized condition that can be treated with application of heat.

Superficial thrombophlebitis is a condition in which a clot forms in a vein secondary to phlebitis or because of partial obstruction of the vein. It is more commonly seen in the greater or lesser saphenous veins of the lower extremities but may also be seen in the upper extremities, most commonly at IV sites.

Phlebothrombosis is the formation of a thrombus or thrombi in a vein; in general, the clotting is related to (1) stasis, (2) abnormality of the walls of the vein, and (3) abnormality of the clotting mechanism. Superficial or deep veins may be affected; however, deep veins of the lower extremities are most commonly involved.

DVT is thrombosis of deep rather than superficial veins. Two serious complications are pulmonary embolism and postphlebitic syndrome.

Note: Although phlebothrombosis and DVT do not necessarily represent identical pathologies, for clinical purposes, they are used interchangeably when discussing the same process.

Pathophysiology and Etiology

General Points

1. Three antecedent factors are believed to play a significant role in the development of venous thromboses: (1) stasis of blood, (2) injury to the vessel wall, and (3) altered blood coagulation (Virchow triad). Thrombosis does not occur with stasis alone.
2. Usually two of the three factors occur before thrombosis develops.

Thrombosis-Related Situations

1. Venous stasis—following operations, childbirth, or bed rest for any prolonged illness.
2. Prolonged sitting or as a complication of varicose veins.
3. Injury (bruise) to a vein; may result from direct trauma or internal trauma such as from IV catheters, infusion of medications, and/or infiltration of medications.
4. Extension of an infection of tissues surrounding the vessel.
5. Continuous pressure of a tumor, aneurysm, or excessive weight gain in pregnancy.
6. Unusual activity in a person who has been sedentary (particularly heavy lifting or prolonged holding of

heavy objects)increases risk of upper-extremity thromboses.

7. Hypercoagulability associated with malignant disease and blood dyscrasias.

High-Risk Factors

1. Malignancy.
2. Previous venous insufficiency.
3. Conditions causing prolonged bed rest—MI, heart failure, sepsis, traction, end-stage cancer, and human immunodeficiency virus/acquired immunodeficiency syndrome.
4. Leg trauma—fractures, cast, joint replacements.
5. General surgery—over age 40.
6. Obesity, smoking.
7. Inherited coagulopathy (eg, antithrombin III deficiency, protein C&S deficiency, factor V Leiden thrombophilia, and others).

Clinical Manifestations

Clinical features vary with site and length of affected vein.

1. DVT may occur asymptomatically or may produce severe pain, fevers, chills, malaise, and swelling and cyanosis of affected arm or leg. The chief symptom is unilateral limb edema in which the onset is sudden.
2. Superficial thrombophlebitis produces visible and palpable signs, such as heat, pain, swelling, erythema, tenderness, and induration, along the length of the affected vein.
3. Extensive vein involvement may cause lymphadenitis or arterial compromise if the swelling is extensive enough.

Diagnostic Evaluation

1. Venous duplex/color duplex ultrasound—this commonly done, noninvasive test allows for visualization of the thrombus, including any free-floating or unstable thrombi that may cause emboli. It is to detect thrombi of the upper and lower extremities.
2. Impedance plethysmography—a noninvasive measurement of changes in calf volume corresponding to changes in blood volume brought about by temporary venous occlusion with a high-pneumatic cuff. Electrodes measure electrical impedance as cuff is deflated. Slow decrease in impedance indicates diminished blood flow associated with thrombus.
3. Venography—IV injection of a radiocontrast agent. The vascular tree is visualized and obstruction is identified.
4. Intravascular ultrasound (IVUS)—a catheter-based intervention for VTE, 360-degree ultrasound imaging of a vein.
5. Coagulation profiles—PTT, PT/INR, circulating fibrin, monomer complexes, fibrinopeptide A, serum fibrin, D-dimer, proteins C and S, antithrombin III levels, factor V Leiden, and prothrombin gene mutation. Detect intravascular coagulation or coagulopathies.

Management

Goals of management are to prevent propagation of the thrombus, prevent recurrent thrombus formation, prevent pulmonary emboli, and limit venous valvular damage.

Anticoagulation

For documented cases of DVT to prevent embolization.

1. UFH may be given IV administration initially, followed by 3 to 6 months of oral anticoagulant therapy.
2. Oral anticoagulants, rivaroxaban and apixaban, may also be initiated for acute treatment; no IV medication dosing is needed. Dabigatran requires parental anticoagulation for 5 to 10 days prior to oral dosing.
3. LMWH is safely given in isolated DVT and/or pulmonary embolism; when the patient is taught the proper technique, it may be safely used at home. It is followed by 3 to 6 months of oral anticoagulation.
4. Dabigatran, rivaroxaban, and apixaban may be given as surgical prophylaxis in elective hip or knee surgery.
5. UFH and LMWH may also be given SC as prophylaxis for the prevention of DVT, especially in postoperative and immobile patients.
6. Fondaparinux may be used for treatment and is given SC. It is beneficial for patients with sensitivity to heparins or HIT.

Thrombolytic Therapy

1. May be used in life- or limb-threatening situations.
2. Most effective in dissolving existing clots within the first 24 hours of thromboembolic event and may be considered up to 14 days.
3. Ultrasound-assisted delivery of thrombolytic works faster and with less risk of bleeding than regular infusion.

Nonpharmacologic Therapies

For superficial thrombophlebitis and as an adjunct to anticoagulation with DVT.

1. Ambulation is encouraged unless there is mobile thrombus in a proximal deep vein
2. Elevation of effected extremity: at least 10 to 20 degrees above the level of the heart to enhance venous return and decrease swelling (see Figure 14-1).
    a. The popliteal space should be supported but not constricted.
    b. If the upper extremity is affected, a sling or stockinette attached to an IV pole may be used.
3. Compression: promotes venous return and reduces swelling
    a. Electrically or pneumatically controlled stockings, boots, or sleeve.
    b. Gradient compression stockings or garments after the acute phase to prevent postphlebitic syndrome or to prevent DVT during periods of immobility for high-risk patients. Level of compression ordered according to condition and severity.

i. 8 to 15 mm Hg (light)—tired, achy legs; mild fatigue; prevention.

ii. 15 to 20 mm Hg (therapeutic)—spider veins, minor swelling, aching, pregnancy.

iii. 20 to 30 mm Hg (medical grade)—fatigue, low-grade varicosities, postsclerotherapy.

iv. 30 to 40 mm Hg (medical grade)—heaviness, fatigue, postsurgery/sclerotherapy, thrombosis, complications of varicose veins, postphlebitic syndrome, treatment of edema, venous ulcers, varices with pregnancy, stasis dermatitis, and lymphedema.

v. 40 to 50 mm Hg (medical grade)—severe edema for above causes, severe chronic venous insufficiency.

4. Dry heat
   a. Warm water bottles, heating pad.
   b. Ultrasound (acoustic vibration with frequencies beyond human ear perception).
5. Moist heat
   a. Hydrotherapy.
   b. Whirlpool bath.
   c. Warm compresses.

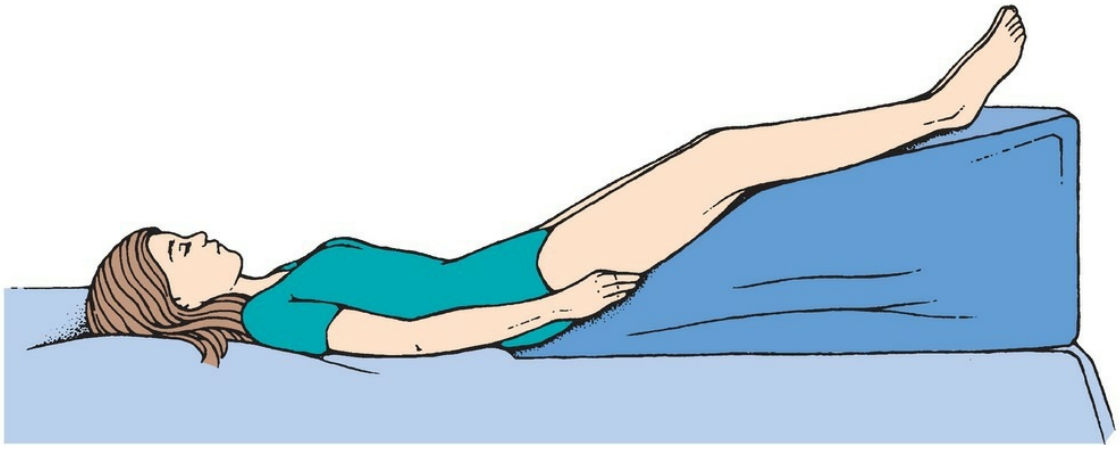


Figure 14-1. Elevation of entire legs above the level of the heart using a foam wedge.

Surgery

1. Placement of a filter into the inferior vena cava to prevent fatal pulmonary embolism in a patient who cannot tolerate prolonged anticoagulant therapy or who has recurrent emboli in the presence of adequate anticoagulation.
2. Thrombectomy may be necessary for severely compromised venous drainage of the extremity.
3. Endovascular thrombolysis with direct catheter infused lytic therapy to the affected limb
4. See page 321 for surgical care.

Complications

1. Pulmonary embolism.

2. Postphlebitic syndrome.

Nursing Assessment

1. Obtain history of risk factors for thrombophlebitis.
2. Note symmetry or asymmetry of legs. Measure and record leg circumferences daily. Acute, unilateral edema may be first sign of a DVT.
3. Observe for evidence of venous distention or edema, puffiness, stretched skin, and hardness to touch.
4. Examine for signs of obstruction because of occluding thrombus—swelling, particularly in loose connective tissue or popliteal space, ankle, or suprapubic area.
5. Monitor for signs of pulmonary embolus, including shortness of breath, chest pain, and tachycardia.
6. Hand-test extremities for temperature variations—use dorsum (back) of same hand; first compare ankles, then move to the calf and up to the knee.
7. Assess for calf pain, which may be aggravated when foot is dorsiflexed with the knee flexed. Unfortunately, this sign is nonspecific and has a low sensitivity for detecting thrombophlebitis.
8. Assess all IV catheter insertion sites for signs and symptoms of infection and infiltration. Rotate peripheral IV sites every 72 hours or as needed.

Nursing Diagnoses

- Acute Pain related to decreased venous blood flow.
- Risk for Bleeding related to anticoagulant therapy.
- Impaired Physical Mobility related to pain and imposed treatment.

Nursing Interventions

1. Elevate legs as directed to promote venous drainage and reduce swelling.
2. Apply warm compresses or heating pad as directed to promote circulation and reduce pain.
   a. Make sure that water temperature is not too hot.
   b. Cover plastic water bottle or heating pad with towel before applying to skin.
3. Administer acetaminophen, codeine, or other analgesic, as prescribed and as needed. Avoid the use of aspirin (or aspirin-containing drugs) and NSAIDs during anticoagulant therapy to prevent further risk of bleeding.

NURSING ALERT Avoid massaging or rubbing calf because of the danger of breaking up the clot, which can then circulate as an embolus.

Preventing Bleeding

See page 319 for nursing interventions for patients on anticoagulant therapy.

Preventing Other Hazards of Immobility

1. Prevent venous stasis by proper positioning in bed.
   a. Support full length of legs when they are to be elevated.
   b. Prevent pressure ulcers that may occur over bony prominences, such as sacrum, hips, knees, and heels. Be aware of bony prominence of one leg pressing on soft tissue of other leg (in side-lying position, place a soft pillow between legs).
   c. Avoid hyperflexion at knee as in jackknife position (head up, knees up, pelvis, and legs down); this promotes stasis in pelvis and extremities.
2. Initiate active exercises unless contraindicated, in which case, use passive exercises.
   a. If the patient is on bed rest:
      i. Simulate walking if lying on back—5 minutes every 2 hours.
      ii. Simulate bicycle pedaling if lying on side—5 minutes every 2 hours.
   b. If contraindicated, resort to passive exercises—5 minutes every 2 hours.
3. Encourage adequate fluid intake, frequent changes of position, and effective coughing and deep-breathing exercises.
4. Be alert for signs of pulmonary embolism—chest pain, dyspnea, anxiety, and apprehension—and report immediately.
5. After the acute phase (48 hours), apply compression stockings as directed. Check color, warmth, and capillary refill through opening at toe if using open-toe stocking and remove at least once per day to look for skin changes, pressure points, and calf tenderness. Educate patient about continued use of compression stockings at home as directed.
6. Encourage walking when allowed.
   a. If permissible, have the patient sit up and move to side of bed in sitting position. Provide a foot support (stool or chair)—dangling of feet is not desirable because pressure may be exerted against popliteal vessels and may obstruct blood flow.
   b. If the patient is permitted out of bed, encourage walking 10 minutes each hour.
   c. Discourage crossing of legs and long periods of sitting because compression of vessels can restrict blood flow.

EVIDENCE BASE National Collaborating Center for Acute Care. (2015). *Venous thromboembolism: Reducing the risk*. NICE Clinical Guideline 92. Update 2015. Available: *www.nice.org.uk/guidance/CG092*.

Community and Home Care Considerations

Practice preventive measures for bedridden patients who are prone to develop thrombosis:

1. Have the patient lie in bed in the slightly reversed Trendelenburg position because it is better for the veins to be full of blood than empty.
2. Place a padded footboard across the foot of the bed.
   a. Instruct the patient to press the balls of the feet against the footboard, as if rising up on toes.
   b. Have the patient relax the foot.
   c. Request that the patient do this 5 to 10 times per hour.
3. Make sure the patient wears prescription compression stockings at all times when legs are dependent or as ordered by the provider. If having difficulty applying stockings, the patient can use a plastic sandwich bag over forefoot while sliding on foot of stocking and then pull it out the open toe. There are also devices available from various manufacturers to assist with applying stockings

Patient Education and Health Maintenance

1. Teach patient signs of recurrent thrombophlebitis and pulmonary embolism to report immediately.
2. Provide thorough instructions about anticoagulant therapy (see page 319).
3. Teach patient to promote circulation and prevent stasis by applying compression stockings at home.
4. Advise against straining or any maneuver that increases venous pressure in the leg. Eliminate the necessity to strain at bowel movement by increasing fiber and fluids in the diet.
5. Warn patient of hazards of smoking and obesity: nicotine constricts veins, decreasing venous blood flow. Extra pounds increase pressure on leg veins. Make appropriate referrals to nutritionist, smoking-cessation classes, etc., as needed.
6. Advise patient to avoid prolonged periods of sitting or standing. If necessary, perform exercises to encourage venous return.

NURSING ALERT Prescription compression stockings have no role in the management of the acute phase of DVT, the first 48 hours, but are of value after ambulation has begun. Their use will minimize or delay the development of postphlebitic syndrome.

Evaluation: Expected Outcomes

- Patient verbalizes reduced pain.
- No bleeding is observed.
- Normal respiratory status is maintained.

Chronic Venous Insufficiency

Chronic venous insufficiency may be a residual effect of phlebitis, or thrombosis, also called *postphlebitic syndrome*. It may also occur as a result of heredity. It results from chronic occlusion of the veins, destruction of the valves, congenitally weak or absent valves, or weakness in the calf muscle pump of the lower extremity.

Pathophysiology and Etiology

1. In the case of venous thrombosis, smaller vessels dilate because the main channel for returning blood from the leg to the heart is blocked by a thrombus.
2. Valves of diseased connecting veins (perforators) that serve to keep blood flowing from the superficial system into the deep system can no longer prevent backflow. The result is chronic venous stasis, resulting in swelling and edema, as well as superficial varicose veins.
3. The lower leg becomes discolored because of venous stasis, which leads to edema and pigmentation changes because of hemosiderin buildup in the skin resulting in a brownish discoloration. Uncontrolled edema may lead to dermatitis and ulceration.
4. Most commonly involved deep veins are the iliac and femoral veins. The saphenous vein is the most common superficial vein affected.

Clinical Manifestations

1. Chronic edema; worse while legs are dependent.
2. Intractable induration, discoloration, pain, and ulceration; area surrounding medial malleolus is the most common site.

Diagnostic Evaluation and Management

1. Doppler, plethysmography—noninvasive screening that shows obstruction and valve incompetency.
2. Best treatment is prevention of phlebitis and constant use of compression if phlebitis has occurred.
3. After this syndrome has developed, only palliative and symptomatic treatment is possible because the damage is irreparable.

Complications

1. Stasis ulcers.
2. Cellulitis.
3. Recurrent thrombosis.

Nursing Interventions and Patient Education

Instruct the patient as follows:

1. Wear prescription compression stockings to prevent edema.
2. Avoid sitting or standing for long periods or sitting with legs crossed.
3. Elevate legs on a chair for 5 minutes every 2 hours.

4. Elevate legs above level of head by lying down two or three times daily.
5. Raise foot of bed 6 to 8 inches (15 to 20 cm) at night to allow venous drainage by gravity.
6. Apply bland, oily lotions to prevent scaling and dryness of the skin.
7. Avoid constricting bandages.
8. Prevent injury, bruising, scratching, or other trauma to the skin of the leg and foot.
9. Be alert for signs of ulceration, drainage, warmth, erythema, and pain, indicating infection.
10. Ambulate several times a day, as tolerated, to improve blood flow by contraction of the calf muscle pump of the lower leg.

Stasis Ulcers

Stasis ulcer is an excavation of the skin surface produced by sloughing of inflammatory necrotic tissue, usually caused by venous insufficiency in the lower extremity.

Pathophysiology and Etiology

1. Stasis ulcer results from inadequate oxygen and other nutrients to the tissues because of edema and decreased circulation.
2. Secondary bacterial infection occurs because of decreased microcirculation that limits the body's response to infection.
3. Postphlebitic syndrome and stasis with uncontrolled edema are responsible for most leg ulcers.

Clinical Manifestations

Severity of symptoms depends on the extent and duration of venous insufficiency.

1. Open sore that is inflamed (see Figure 14-2) (beefy red base) and has irregular edges. The ulcers are most often found in the ankle area.
2. Drainage may be present or the area may be covered by a dark crust.
3. Patient may complain of swelling, heaviness, aching, and fatigue.
4. Edema and pigmentation around ulcer.
5. Crusting of the skin around ulcer.

Figure 14-2. Venous ulcer.

GERONTOLOGIC ALERT Most venous ulcers occur in people older than age 65.

Diagnostic Evaluation

1. Noninvasive tests, such as plethysmography and venous Doppler, may show impeded blood flow and incompetent valves.
2. Wound cultures will identify microorganisms, if infected.

Management

Removing Devitalized Tissue

1. Necrotic material is flushed out with cleaning agents to dissolve slough. These agents are chemically or naturally derived enzymes that are proteolytic or fibrinolytic.
2. Surgical excision of slough—if necrotic tissue is loose, this procedure can be done without anesthesia; if

the tissue is adherent, anesthesia will be required. Some debridements may be done at the bedside or in the clinic with topical anesthetic.

Stimulating Formation of Granulation Tissue

1. Dressing of choice:
   a. Nonadherent so that removal is painless and does not damage newly forming tissue.
   b. Highly absorbent.
   c. Safe, nontoxic.
   d. Sterile, accessible, and inexpensive.
2. Application of compression over dressings, generally through the use of bandages or elastic stockings. In some circumstances, inflatable pneumatic leggings may be appropriate.
3. Unna's boot or other layered compression bandage, an effective treatment of choice, is an example of a combined dressing and compression bandage.
4. The use of human growth factor ointment to the ulcer may be appropriate to stimulate tissue growth.
5. Bed rest with leg elevation.
6. Diuretic therapy for edema reduction may improve capillary circulation.
7. Application of skin grafts.
   a. Skin grafts are used for ulcers that will not heal.
   b. They are not recommended for first-line treatment.
   c. Skin-equivalent grafts may be used particularly if skin grafts fail.

Preventing Recurrence

1. Ligation of the saphenofemoral or saphenopopliteal vessels with stripping.
2. Laser or radiofrequency ablation of the saphenofemoral or greater saphenous vein and saphenofemoral junction.
3. Ligation of the lower leg communicating veins (usually endoscopic).
4. Deep vein bypass or reconstruction.
5. Injection compression sclerotherapy.
6. See page 321 for surgical care.

Complications

1. Infection.
2. Sepsis.

Nursing Assessment

1. Observe appearance and temperature of the skin.
2. Note location and appearance of ulcer.
3. Determine presence and quality of all peripheral pulses. Use Doppler, if needed.

4. Observe for drainage and signs of infection.

Nursing Diagnoses

- Impaired Tissue Integrity related to stasis ulcer.
- Acute Pain related to stasis ulcer.

Nursing Interventions

Restoring Tissue Integrity

1. Elevate affected extremity to decrease edema.
2. Place lamb's wool between toes to prevent pressure on a toe.
3. Provide overbed cradle to protect leg from pressure of bed linens.
4. Consider air-fluidized bed to provide pressure relief.
5. Administer prescribed antibiotics.
6. Apply wet-to-moist dressings, chemical beads or ointments, and topical antibiotics, as ordered. Wounds should not be allowed to completely dry out. Slight moisture aids the healing process.
7. Apply Unna's boot or other compression system to lower extremity, as ordered.
8. Ensure adequate nutritional intake to enhance wound healing.

Reducing Pain

1. Administer prescribed analgesics, such as NSAIDs, to reduce pain and inflammation.
2. Medicate 30 to 45 minutes before a dressing change.
3. Encourage short periods of ambulation after pain medication is given.

Community and Home Care Considerations

1. Make sure that all supplies are obtained for home care. Utilize social services and other resources to help with financial arrangements, as needed.
2. Assess the patient's ability to perform dressing changes at home. Include significant others in teaching to assist patient.
3. Make home visits several times per week to assess healing of ulcer, assess for infection, and assist family in carrying out dressing changes and other measures.

Patient Education and Health Maintenance

1. Stress the importance of following explicitly the recommendations of the health care provider.
2. Explain the hazards of trying other remedies without professional advice.
3. Indicate that the treatment may be long but that patience is an important aspect.
4. Encourage maintenance of healthy tissue when the ulcer has healed by continuing with the safeguards practiced before because breakdown of healed tissue frequently occurs.
5. Encourage participation in physical therapy and a regular exercise program.

6. Encourage weight control and proper dietary intake to ensure adequate amounts of protein, vitamins (A, C, E), zinc, and a reduced sodium intake.
7. Teach patient the correct method of dressing changes.
8. Instruct patient on injury prevention, including keeping hallways and walkways clear of obstacles and using a nightlight to avoid injury if awakened at night.
9. Encourage use of compression stockings when ordered.

Evaluation: Expected Outcomes

- Skin is of normal color and temperature, nontender and nonswollen, and demonstrates new epithelium.
- Verbalizes only minimal discomfort with dressing changes.

Varicose Veins

Primary varicose veins are unilateral or bilateral dilation and elongation of saphenous veins; deeper veins are normal. As the condition progresses, because of hydrostatic pressure and vein weakness, the vein walls become distended, with asymmetric dilation, and some of the valves become incompetent. The process is irreversible. *Secondary varicose veins* result from obstruction of deep veins.

Telangiectasias (spider veins) are dilated superficial capillaries, arterioles, and venules. They may be cosmetically unattractive but do not pose a threat to circulation.

Pathophysiology and Etiology

1. Dilation of the vein prevents the valve cusps from meeting; this results in increased backup pressure, which is passed into the next lower segment of the vein. The combination of vein dilation and valve incompetence produces the varicosity (see Figure 14-3).
2. Varicosities may occur elsewhere in the body (esophageal and hemorrhoidal veins) when flow or pressure is abnormally high.
3. Predisposing factors:
    a. Hereditary weakness of vein wall or valves.
    b. Long-standing distention of veins brought about by pregnancy, obesity, or prolonged standing.
    c. Advanced age—loss of tissue elasticity.

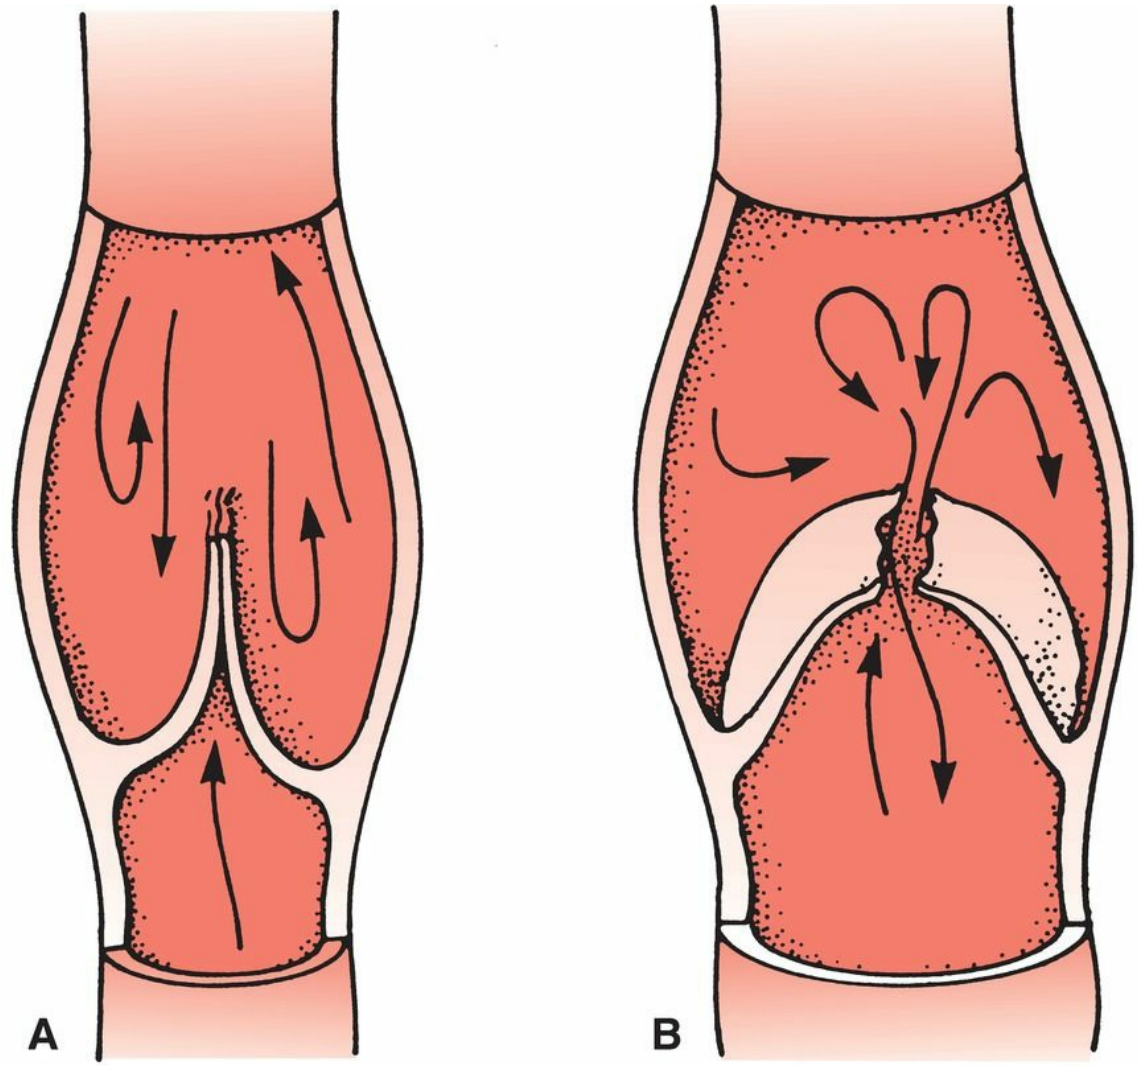

Figure 14-3. Valve incompetence develops as dilation of a vessel prevents effective approximation of valve cusps. **(A)** Closed venous valve. **(B)** Incompetent venous valve.

Clinical Manifestations

1. Disfigurement because of large, discolored, tortuous leg veins.
2. Easy leg fatigue, cramps in leg, heavy feeling, increased pain during menstruation, and nocturnal muscle cramps.

Diagnostic Evaluation

1. Photoplethysmography—a noninvasive technique to observe venous flow hemodynamics by noting changes in the blood content of the skin; used to detect incompetence in valves located inside the vein.
2. Doppler ultrasound and duplex imaging—can detect accurately and rapidly the presence or absence of venous reflux in deep or superficial vessels.
3. Venous outflow and reflux plethysmography—able to detect deep venous occlusion.
4. Ascending and descending venography—an invasive technique that can also demonstrate venous occlusion and patterns of collateral flow. This test is expensive and may not be required if a careful

history, physical examination, and laboratory testing are done.

Management

1. Conservative therapies, such as encouraging weight loss if appropriate and avoiding activities that cause venous stasis by obstructing venous flow.
2. Surgery may be considered for ulceration, bleeding, and cosmetic purposes in selected patients if patency of deep veins is ensured.
3. Surgical procedures—a single method or combination of methods is tailored to meet the needs of the individual:
    a. Sclerosing injection—may be combined with ligation or limited to treatment of isolated varicosities. The affected vessel may be sclerosed by injecting sodium tetradecyl sulfate or similar sclerosing agent. Compression bandage is then applied without interruption for 2 to 6 weeks; inflamed endothelial surfaces adhere by direct contact.
    b. Multiple vein ligation—either by multiple incisions or ambulatory phlebectomy (veins are removed using tiny incisions and hooks to grasp the veins).
    c. Ligation and stripping of the greater and lesser saphenous systems.
    d. Laser or radiotherapy treatment—small catheter is inserted via the groin and the veins ablated.
    e. Laser therapy—eliminates small veins under the skin.

Complications

1. Hemorrhage because of weakening of and pressure on the vein wall.
2. Skin infection and breakdown, producing ulcers (rare in primary varices).
3. Skin discoloration over the veins injected.

Nursing Assessment

1. Inspect for dilated, tortuous vessel.
2. Perforating veins that are incompetent may be felt as bulging circles at intervals beneath the skin. New varices are palpated along the surface of the muscle or bone. Chronic varices create deep pockets and may feel "boggy" with deep palpation.
3. Assess for any ulceration, chronic venous insufficiency, or signs of infection.

Nursing Diagnoses

- Impaired Tissue Integrity related to chronic changes and postoperative inflammation.
- Acute Pain related to surgical incisions, inflammation.

Nursing Interventions

Promoting Tissue Integrity Postoperatively

1. Maintain compression bandages from toes to groin. Monitor neurovascular status of feet (color, warmth,

capillary refill, sensation, and pulses) to prevent compromise from swelling.

2. Elevate legs about 30 degrees, providing support for the entire leg. Make sure that knee gatch of the bed is positioned for straight incline. Encourage early ambulation.
3. Monitor for signs of bleeding, especially during the first 24 hours.
   a. Blood soaked through bandages.
   b. Increased pain, hematoma formation.
   c. Hypotension and tachycardia.
4. If incisional bleeding occurs, elevate the leg above the level of the heart, apply pressure over the site, and notify the surgeon.
5. Be alert for complaints of pain over bony prominences of the foot and ankle; if the elastic bandage is too tight, loosen it.
6. Maintain IV for fluids and antibiotics, as ordered.
7. After removal of compression bandages (about 7 days postoperatively), observe or teach patient to observe for signs of cellulitis or incisional infection.
8. Encourage use of prescription compression stockings for several weeks to months following surgery.

Relieving Pain

1. Administer analgesics, as prescribed.
2. Encourage early and frequent ambulation with legs elevated when not walking.
3. When ambulatory, advise patient to avoid prolonged standing, sitting, or crossing or dangling legs to prevent obstruction.

Patient Education and Health Maintenance

Postoperative Instructions

Instruct the patient to:

1. Wear pressure bandages or compression stockings as prescribed—usually for 3 to 4 weeks after surgery.
2. Elevate legs about 30 degrees and provide adequate support for entire leg.
3. Take analgesics for pain, as ordered.
4. Report such signs as sensory loss, calf pain, or fever to the health care provider.
5. Avoid dangling of legs.
6. Walk frequently.
7. Be aware that patchy numbness can be expected but should disappear in less than 1 year.
8. Follow conservative management instructions (below) to prevent recurrence.

Conservative Management

Instruct the patient to:

1. Avoid activities that cause venous stasis by obstructing venous flow:

   a. Wearing tight garters, tight girdle, compression around popliteal area.
   b. Sitting or standing for prolonged periods of time.
   c. Crossing the legs at knees for prolonged periods while sitting (reduces circulation by 15%).
2. Control excessive weight gain.
3. Wear firm elastic support, as prescribed, from toe to knee when in upright position.
   a. Put compression stockings on in bed before getting up.
   b. Thigh-high compression may be ordered presenting a compliance challenge.
4. Elevate foot of bed 6 to 8 inches (15 to 20 cm) or use a wedge for night sleeping.
5. Avoid injuring legs.

Evaluation: Expected Outcomes

- Skin is of normal color and temperature, nontender and nonswollen, and intact.
- Actively moves extremity; verbalizes reduced pain.

CONDITIONS OF THE ARTERIES

Arteriosclerosis and Atherosclerosis

Arteriosclerosis is an arterial disease manifested by a loss of elasticity and a hardening of the vessel wall. More commonly known as "hardening of the arteries," it is a normal part of the aging process and generally occurs uniformly throughout the arterial system.

Atherosclerosis is the most common type of arteriosclerosis, manifested by the formation of atheromas (patchy lipoidal degeneration of the intima). Lesions, or plaques, form throughout the arterial wall, reducing the size of the vessel and limiting the flow of blood. Over time, atherosclerotic lesions can completely occlude the lumen by buildup of the plaque material and may contribute to thrombus formation.

Pathophysiology and Etiology

1. Etiology thought to be a reaction to injury:
   a. Endothelial cell injury causes increased platelet and monocyte aggregation to site of injury.
   b. Smooth muscle cells migrate and proliferate.
   c. Matrix of collagen and elastic fibers forms.
2. There are two types of atherosclerotic lesions: fatty streaks and fibrous plaques (see Figure 14-4).
3. Risk factors include heredity, increasing age, male gender, cigarette smoking, hypertension, dyslipidemia, diabetes mellitus, renal disease, obesity, physical inactivity, and stress.

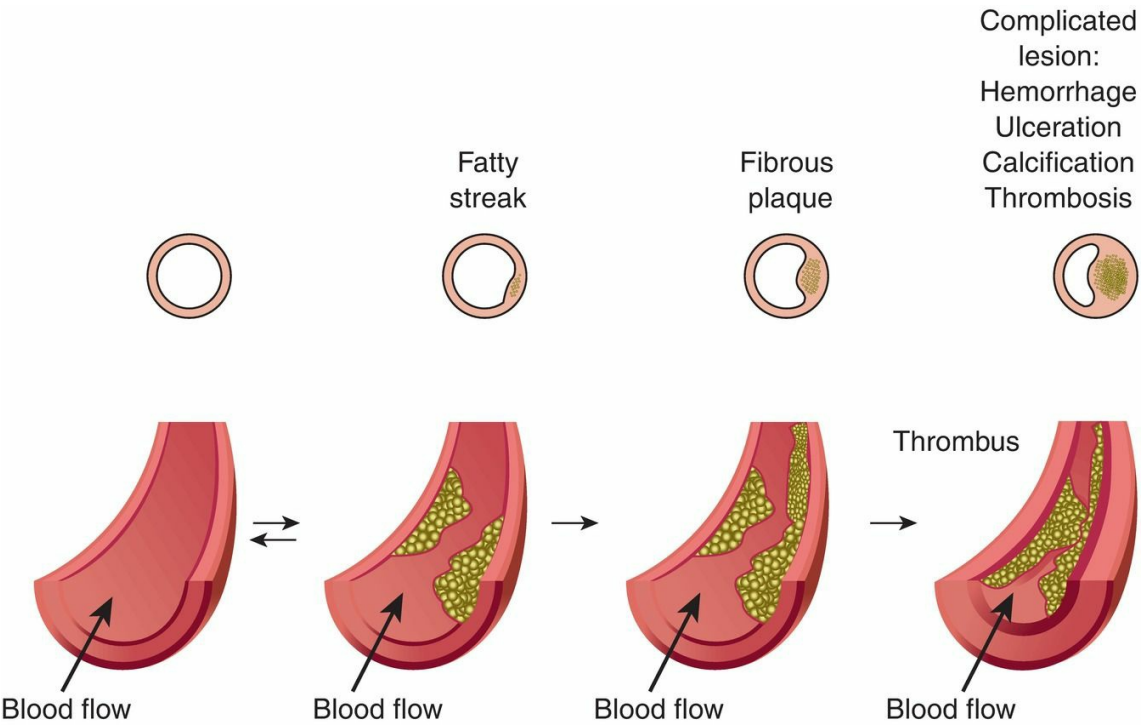

Figure 14-4. Atherosclerosis is a progressive process that occurs over decades. The earliest lesion is a fatty streak, which may regress or progress to a fibrous plaque. Irreversible fibrous plaques may eventually develop into atheroma, which may be complicated by hemorrhage, ulceration, calcification, and thrombus. Target organ disease includes myocardial infarction, stoke, and

peripheral arterial occlusion.

NURSING ALERT Smoking is the number one risk factor for atherosclerosis.

Clinical Manifestations

1. May affect entire vascular system or one segment of the vascular tree.
2. Symptoms and signs are based on area affected:
   a. Brain (cerebroarteriosclerosis)—transient ischemic attacks (TIA); stroke; vision disturbances, such as amaurosis fugax (one type of TIA), which is described by patients as a shade over a portion of eye (see Chapter 15).
   b. Heart (coronary artery disease [CAD])—angina, MI, and heart failure (see Chapter 13).
   c. GI tract (aortic occlusive disease, aortic aneurysm, and mesenteric ischemia)—abdominal pain, unintentional weight loss, and lower back pain.
   d. Kidneys (renal artery stenosis)—renal insufficiency and poorly controlled hypertension.
   e. Extremities (peripheral arterial disease [PAD])—intermittent claudication (pain in a muscle associated with exercise caused by lack of oxygen to the muscle), pain at rest, tissue loss (with or without presence of infection or gangrene), and embolic events.
      i. PAD is often undiagnosed because pain is attributed to arthritis or accepted as a normal change because of aging.
      ii. It affects approximately 8 to 12 million Americans and approximately 800,000 Canadians.
3. Decreased or absent pulses; bruits of major vessels.

GERONTOLOGIC ALERT Atherosclerotic cardiovascular disease afflicts 80% of the population older than age 65 and is the most common condition of the arterial system in older adults.

Diagnostic Evaluation

Specific to body system affected:

1. Arteriography of involved area may show stenosis and increased collateral circulation.
2. Computed tomography (CT) scan.
3. Magnetic resonance imaging (MRI)/magnetic resonance angiography (MRA).
4. Noninvasive testing of the vascular system: duplex studies, sequential Doppler studies, pulse volume resistance, and ankle–brachial index (ABI).
   a. For ABI, systolic pressure of the posterior tibial and dorsalis pedis arteries are determined by Doppler

for each side as measures of ankle pressure.

b. The greater ankle systolic pressure for each side is divided by the brachial systolic pressure of the same side. Normally, the systolic pressures are equal. In presence of atherosclerotic disease, the pressure below an occluded area is less than the arm pressure.

c. Normal ABI is 1.00 to 1.40.

d. Result below 0.90 indicates obstruction of the lower-extremity arteries.

e. Result greater than 1.40 indicates noncompressible vessels because of calcification, so ABI cannot be interpreted.

5. ECG, Holter monitoring, exercise stress testing, myocardial imaging, and cardiac catheterization may be done to evaluate CAD.

Management

Medical Management

1. Modification of risk factors—stress, weight loss, exercise, dietary changes, and monitoring for type 2 diabetes.
2. Prescriptive management—anticoagulants, antiplatelet therapy (see Table 14-3), lipid-lowering agents, and antihypertensives.
3. Specific treatment for end-organ dysfunction—see cerebrovascular insufficiency (page 365), CAD (page 269), peripheral arterial occlusive disease (page 331).
4. Vascular rehabilitation/exercise (if available).

Table 14-3 Antiplatelet Therapy

Antiplatelet therapy is used to prevent platelet aggregation and thrombus formation. It is used in the treatment of cerebrovascular disease, coronary artery disease, and intermittent claudication. This table lists some common antiplatelet medications, their indications, and potential contraindications/precautions.

MEDICATION	USE	CONTRAINDICATIONS/PRECAUTIONS
Aspirin	Prevention of myocardial infarction, transient ischemic attack, stroke	• Allergy to ASA • Active gastric ulcers
Ticlopidine	Prevention of stroke	• Sensitivity to drug • Neutropenia, thrombocytopenia, history of TTP, active bleeding disorders* • Liver and renal impairment • See drug–drug interactions
Ticagrelor	Decreased platelet aggregation Prevention of MI/coronary artery stent thrombosis	• Sensitivity to drug • GI and Intracranial bleeding • Liver impairment
Pentoxifylline	Treatment of intermittent claudication	• Sensitivity to drug • Recent cerebral or retinal hemorrhage • Caffeine or theophylline intolerance
Clopidogrel	Reduction of atherosclerotic events	• Sensitivity to drug • Active pathologic bleeding (eg, peptic ulcer, intracranial hemorrhage) • Severe hepatic or renal disease • See drug–drug interactions
Cilostazol	Treatment of intermittent claudication—has antiplatelet, vasodilatory, and antithrombotic effects	• Sensitivity to drug • Heart failure, liver impairment • Liver impairment • See drug–drug interactions
Dipyridamole, 200 mg; aspirin, 25 mg	Prevention of stroke	• Allergy to ASA • Active ulcer disease • Renal and hepatic impairment • Bleeding disorders • See drug–drug interactions

**Monitor complete blood count and platelet count every 2 weeks.*

ASA, acetylsalicylic acid; TTP, thrombotic thrombocytopenia.

Surgical Management

1. Endovascular procedures:
    a. PTA with or without placement of intraluminal stent—to relieve arterial stenosis when lesions are accessible, as in superficial femoral and iliac arteries, through the use of special inflatable balloon catheters and metal stents.
    b. Endovascular grafting—placement of prosthetic graft via a transluminal approach. Graft material covers a metallic stent, which may or may not be impregnated with medication to decrease failure. The stent is placed via femoral artery or radial artery and is deployed. This is commonly used for abdominal aortic aneurysms, renal arteries, and mesenteric and iliac arteries.
    c. Rotational atherectomy—high-speed rotary cutter that removes lesions by abrading plaque. Benefits of this therapy are minimal damage to the normal endothelium and low incidence of complications.
    d. Laser angioplasty—amplified light waves are transmitted by fiberoptic catheters. Laser beam heats the tip of a percutaneous catheter and vaporizes the atherosclerotic plaque.
2. Surgical revascularization of the affected vessels, including:
    a. Embolectomy—removal of blood clot from the artery.
    b. Thrombectomy—removal of thrombus from the artery.
    c. Endarterectomy—removal of atherosclerotic plaque from the artery.
    d. Bypass—use of a graft, either vein graft or prosthetic material, to route blood flow around blocked

area.

Complications

Long-term complications of atherosclerosis are related to the specific body system affected:

1. Brain—long- and short-term disabilities associated with stroke.
2. Heart—stable or unstable angina, MI, and heart failure.
3. Aorta—ischemic bowel, aneurysms, impotence, renal failure, and nephrectomy.
4. Lower extremities—intermittent claudication, nonhealing ulcers, infections or gangrene, and amputation.

Nursing Interventions and Patient Education

See "Care of the Patient Undergoing Vascular Surgery," page 321. In addition, attention is directed at reducing risk factors by smoking cessation (page 24), stress reduction (page 25), weight reduction (page 23), adequate control of diabetes (Chapter 25) and/or hypertension (page 338), adjusting diet to reduce cholesterol intake (page 274), and taking lipid-lowering medications. Encourage active lifestyle to promote cardiovascular health and empower patients to manage their care.

Peripheral Arterial Occlusive Disease (Aorta and Distal Arteries)

Peripheral arterial occlusive disease (PAOD) (also known as peripheral artery disease or PAD) is a form of arteriosclerosis in which the peripheral arteries become blocked. Chronic occlusive arterial disease occurs much more frequently than does acute (which is the sudden and complete blocking of a vessel by a thrombus or embolus). Patients at increased risk for PAD include patients aged 65 or older and those with other risk factors for atherosclerosis, such as diabetes, smoking history, hyperlipidemia, hypertension, family history of PAD or other forms of atherosclerotic disease such as renal or mesenteric atherosclerosis, or abdominal aortic aneurysms, CAD, or carotid atherosclerosis.

EVIDENCE BASE Gerhard-Herman, M., Gornik, H., Barrett, C., et al. (2017). AHA/ACC guideline on the management of patients with lower extremity peripheral artery disease. A report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines. *Journal of the American College of Cardiology*, *69*(11), e71–e126.

Pathophysiology and Etiology

Arteriosclerosis Obliterans

1. Most commonly caused by atherosclerosis with contributing factors as discussed in previous section.
2. May involve the following vessels in isolation or combination:
   a. Aortoiliac system.
   b. Femoral arteries—superficial femoral, profunda femoris.
   c. Popliteal artery.
   d. Trifurcating vessels—anterior tibial (AT), posterior tibial (PT), and peroneal arteries.
   e. Dorsalis pedis (DP) artery.
   f. Pedal arch.
3. Lesions tend to form at areas of bifurcation of the vessels.
4. Pattern of disease differs in nondiabetics and diabetics:
   a. Nondiabetics—disease usually involves macrocirculation (larger vessels [eg, aorta, iliac, femoral arteries]) and is more common in isolated segments.
   b. Diabetics—disease usually involves microcirculation (smaller vessels [eg, popliteal, tibial, peroneal, and small vessels in the foot/digits]) and occurs in more diffuse segments.

Thromboangiitis Obliterans (Buerger Disease)

Inflammatory process of arterial wall, which is followed by thrombosis. Also affects adjacent veins and nerves. Associated with heavy cigarette smoking.

Clinical Manifestations

Symptoms appear gradually and are specific to the area affected.

Aortoiliac

1. Mesenteric ischemia, pain after eating that increases as disease progresses.
2. Unintentional weight loss.
3. Renal insufficiency.
4. Poorly controlled hypertension.
5. Impotence.
6. Intermittent claudication (including gluteal claudication).

Femoral, Popliteal, and Distal Arteries

1. Intermittent claudication (calf, thigh, and foot).
2. Pain at rest—associated with severe arterial ischemia. Severe pain in feet aggravated by elevation of lower extremity. Pain is relieved by placing foot in dependent position.
3. Dependent rubor—dusky purple color of extremity when in dependent position; changes to pallor when elevated.
4. Numbness or tingling of feet or toes.
5. Trophic changes associated with tissue malnutrition:
   a. Hair loss.
   b. Thick toenails.
   c. Thin, shiny skin.
   d. Cool temperature of extremity.
6. Tissue loss or nonhealing ulcers, which may develop wet or dry gangrene (see Figure 14-5). Arterial ulcers are usually painful, pale, and have well-demarcated (punched-out) edges.

Figure 14-5. Arterial ulcer.

Diagnostic Evaluation

Noninvasive

1. Vascular physical examination.

2. ABI—see page 330; may be done before and after exercise.
    a. A toe brachial index (TBI) should be measured in patients that have suspected PAD when the resting ABI is greater than 1.40.
    b. This is particularly useful in diabetic patients as the associated increased calcification of the distal arteries may artificially elevate the ABI result.
3. Doppler ultrasound—decreased velocity of flow through a stenotic vessel or no flow with total occlusion.
4. Segmental plethysmography—decreased pressure distal to region of occlusion.

Invasive

1. Angiography—to confirm occlusion.
2. MRA—to confirm occlusion.
3. Spiral CT—to obtain a three-dimensional view of artery and occlusion.

Management

1. Goals:
    a. Reestablish blood flow to areas of critical ischemia.
    b. Preserve the extremity.
    c. Relieve pain associated with intermittent claudication or pain at rest.
    d. Provide sufficient blood flow for wound healing.
2. Aggressive risk factor management to prevent progression, including walking, weight reduction, smoking cessation, and control of other conditions such as hypertension, dyslipidemia, and diabetes mellitus.
3. Pharmacologic treatment with antiplatelet agents or anticoagulants to improve blood flow by increasing erythrocyte flexibility and lowering blood viscosity.
4. When conservative measures clearly are not enough, revascularization surgery (endarterectomy, arterial bypass grafting, or a combination) may be required.
5. Endovascular procedures, such as PTA with stenting, may be used alone or with revascularization surgery for dilatation of localized noncalcified segments of narrowed arteries with or without intraluminal stenting.
6. Hyperbaric oxygen therapy may be used for nonhealing wounds and gas gangrene. This is limited to centers that have a hyperbaric oxygen chamber (most commonly used for diving accidents).
    a. Increased atmospheric pressure inside the chamber combined with 100% oxygen delivery allows for greater concentration of oxygen to be delivered to all parts of the body.
    b. Typical treatment programs last 2 hours, five or six times per week for 4 weeks or more.
    c. Adverse effects include pressure or popping in ears, slight light-headedness at the end of treatment sessions, and possible temporary change in vision.
7. Amputation of affected extremity in cases of severe infection and gangrene, failed attempts at revascularization, or when revascularization is not considered a viable option.
8. See page 321 for surgical care.

Complications

1. Ulceration with slow healing.
2. Gangrene, sepsis.
3. Severe occlusion may necessitate limb or partial limb amputation.

Nursing Assessment

1. Auscultate abdomen and listen for presence of bruits.
2. Observe lower extremities for color, sensation, and temperature. Compare bilaterally for differences.
3. Palpate pulses (see Figure 14-6) and record. If pulses are nonpalpable, attempt to locate pulse with a handheld Doppler. About 10% of people have absent DP artery from birth.
4. Inspect nails for thickening and opacity; inspect skin for shiny, atrophic, hairless, and dry appearance—reflect chronic changes.
5. Assess for pain:
   a. Severe abdominal pain after eating.
   b. Pain in legs with exercise.
   c. Pain in feet at rest.
6. Assess for ulcers of toes and feet.

HARDY

Figure 14-6. Salient points in evaluating peripheral arterial insufficiency. Reduced or absent femoral pulses indicate aortoiliac disease. Absent popliteal pulses indicate superficial femoral occlusion. Pulse deficits in one extremity, with normal pulses in the contralateral extremity, may suggest acute arterial embolus. Absent pedal pulses indicate tibioperoneal artery involvement.

Nursing Diagnoses

- Ineffective Peripheral Tissue Perfusion related to decreased arterial blood flow.
- Risk for Peripheral Neurovascular Dysfunction of lower extremities.
- Risk for Infection related to decreased arterial flow.

Nursing Interventions

Promoting Tissue Perfusion

1. Perform frequent neurovascular checks of affected extremity.
2. Inspect lower extremity and feet for new areas of ulceration or extension of existing ulceration.
3. Provide and encourage well-balanced diet to enhance wound healing.
4. Encourage walking or performance of ROM exercises to increase blood flow, which will increase collateral circulation.
5. Administer or teach self-administration of pain medication to achieve comfort level conducive to ambulation.

Protecting Lower Extremities

1. Encourage patient to wear protective footwear, such as rubber-soled slippers or shoes with closed, wide toe box when out of bed.
2. Instruct patient and family to keep hallways and walkways free of clutter to avoid injury.
3. Avoid tight-fitting socks and shoes.
4. Instruct patient to avoid sitting with legs crossed.
5. Avoid using adhesive tape and harsh soaps on the affected skin.
6. Instruct patient to check temperature of bath water with forearm before entering tub.
7. Perform and teach foot care, including washing and carefully drying and inspecting feet daily.

Preventing Infection

1. Apply moisturizing lotion to intact skin of lower extremities to prevent drying and cracking of the skin.
2. Encourage patient to wear clean hose or socks daily: woolen socks for winter and cotton for summer.
3. Teach patient to:
   a. Trim toenails straight across after soaking the feet in warm water.
   b. Place wisps of cotton under corner of great toenail if there is a tendency toward ingrown toenails.
   c. Have a podiatrist cut corns and calluses; do not use corn pads or strong medications.

4. Teach patient signs to report:
    a. Redness, swelling, irritation, blistering, and foul odor.
    b. Itching, burning, and rashes.
    c. Bruises, cuts, and unusual appearance of the skin.
    d. New areas of ulceration.
5. Instruct patient to check with physician before using any OTC or topical lotions or creams on wound.
6. Administer antibiotics postoperatively to prevent infection around prosthetic graft material.

Patient Education and Health Maintenance

1. Instruct patient on the importance of walking to improve circulation; set up a plan for incremental increase in distance.
2. Instruct patient not to sit or stand in one position for long periods.
3. Instruct patient, when sitting, to keep knees below the level of the hips to avoid hip flexion.
4. Instruct patient to avoid tight-fitting clothing (eg, elastic-topped socks or clothing made out of Lycra/Spandex), especially over area of graft placement.
5. Instruct patient not to cross legs when sitting or lying down.
6. Instruct patient on methods to promote vasodilation by keeping extremity warm and stopping use of other vasoconstricting substances such as caffeine.
7. Instruct patient on the importance of daily foot care.
8. Encourage patient to stop smoking.
9. Encourage follow-up for control of chronic conditions and ongoing risk factor management.

Evaluation: Expected Outcomes

- No new ulcer formation.
- Verbalizes importance of wearing protective shoes and washing and inspecting feet daily.
- No signs of infection of lower extremities.

Aneurysm

An *aneurysm* is a distention of an artery brought about by a weakening/destruction of the arterial wall. They are lined with intraluminal debris, such as plaque and thrombi. Because of the high pressure in the arterial system, aneurysms can enlarge, producing complications by compressing surrounding structures; left untreated, and they may rupture, causing a fatal hemorrhage. A dissection occurs when the layers of the artery become separated. Blood flows between the layers, causing further disruption of the arterial wall. Additionally, the intraluminal thrombus may totally occlude the artery, leading to acute ischemia to all arteries distal to the area of thrombosis, or they may embolize clot and/or plaque to the arteries distal to the aneurysm.

The *aorta* is the most common site for aneurysms; however, they may form in any vessel. Peripheral vessel aneurysms may involve the renal artery, subclavian artery, popliteal artery (knee), or any major artery. These produce a pulsating mass and may cause pain or pressure on surrounding structures.

Pathophysiology and Etiology

1. Aneurysms may form as the result of:
    a. Atherosclerosis.
    b. Heredity.
    c. Infection.
    d. Trauma.
    e. Immunologic conditions.
2. False aneurysms (pseudoaneurysm) are associated with trauma to the arterial wall, as in blunt trauma or trauma associated with arterial punctures for angiography and/or cardiac catheterization.
3. The ascending aorta and the aortic arch are the sites of greatest hemodynamic stress and also are the most common sites of arterial dissection.
4. Contributing factors include:
    a. Hypertension.
    b. Arteriosclerosis.
    c. Local infection, pyogenic or fungal (mycotic aneurysm).
    d. Congenital weakness of vessels.
    e. Syphilis.
    f. Trauma.
5. Morphologically, aneurysms may be classified as follows:
    a. Saccular—distention of a vessel projecting from one side.
    b. Fusiform—distention of the whole artery (ie, entire circumference is involved).
    c. Dissecting—hemorrhagic or intramural hematoma, separating the medial layers of the aortic wall.
6. Abdominal aortic aneurysms are described as infrarenal, when the "neck" of the aneurysm is located below the level of the renal arteries, juxtarenal, when the aneurysm involves the renal arteries, or

suprarenal, when the aneurysm is located above the level of the renal arteries or involves the renal arteries.

Clinical Manifestations

Aneurysm of the Thoracoabdominal Aorta

From the aortic arch to the level of the diaphragm. At first, no symptoms; later, symptoms may come from heart failure or a pulsating tumor mass in the chest.

1. Pulse and BP difference in upper extremities if aneurysm interferes with circulation in the left subclavian artery.
2. Pain and pressure symptoms.
3. Constant, boring pain because of pressure.
4. Intermittent and neuralgic pain because of impingement on nerves.
5. Dyspnea, causing pressure against trachea.
6. Cough, often paroxysmal and brassy in sound.
7. Hoarseness, voice weakness, or complete aphonia, resulting from pressure against recurrent laryngeal nerve.
8. Dysphagia because of impingement on esophagus.
9. Edema of chest wall—infrequent.
10. Dilated superficial veins on chest.
11. Cyanosis because of vein compression of chest vessels.
12. Ipsilateral dilation of pupils because of pressure against cervical sympathetic chain.
13. Abnormal pulsation apparent on chest wall, because of erosion of aneurysm through rib cage—in syphilis.

Abdominal Aneurysm

1. Many of these patients asymptomatic.
2. Abdominal pain most common, either persistent or intermittent—often localized in middle or lower abdomen to the left of midline.
3. Lower back pain caused by pressure on the spine from enlarging aneurysm.
4. Feeling of an abdominal pulsating mass, palpated as a thrill, auscultated as a bruit.
5. Hypertension.
6. Distal variability of BP; pressure in arm greater than thigh.
7. Upon rupture, will present with hypotension and/or hypovolemic shock.

GERONTOLOGIC ALERT Most abdominal aneurysms occur between ages 60 and 90. Rupture of the aneurysm is likely if there is coexistent hypertension or if the aneurysm is larger than 2.4 inches (5.5 to

6 cm).

Diagnostic Evaluation

1. Abdominal or chest x-ray may show calcification that outlines aneurysm.
2. CT scanning and ultrasonography are used to detect and monitor size of aneurysm.
3. MRI/MRA.
4. Spiral CT gives three-dimensional view of the aneurysm and any attendant atherosclerosis.
5. Arteriography allows visualization of aneurysm and vessel.

Management

1. May follow small aneurysms (1.6 inches [4 cm] or less) with CT scanning or ultrasound every 6 months and aggressively control BP.
2. The prognosis is poor for untreated patients as aneurysm enlarges. It is especially true if it enlarges 5 mm in 3 months or in patients with chronic obstructive pulmonary disease.
3. Surgery:
   a. Resection of the aneurysm via abdominal incision and placement of a prosthetic graft to restore vascular continuity.
   b. Endovascular grafting involves repair of aneurysm using a stent graft, which is deployed via the femoral artery. It attaches above and below the aneurysm and provides a new channel for the blood.
   c. Thoracic aneurysms are the most difficult to treat, endovascular grafting is possible, and some require the use of atrial–femoral circulatory bypass intraoperatively.

Complications

1. Fatal hemorrhage.
2. Myocardial ischemia.
3. Stroke.
4. Paraplegia because of interruption of anterior spinal artery.
5. Abdominal ischemia.
6. Ileus.
7. Graft occlusion.
8. Graft infections.
9. Acute renal failure.
10. Impotence.
11. Lower-extremity ischemia.
12. “Trash toes”—results from distal embolization of plaque and blood clots.

Nursing Assessment

1. In patient with thoracoabdominal aortic aneurysm, be alert for sudden onset of sharp, ripping, or tearing pain located in the anterior chest, epigastric area, shoulders, or back, indicating acute dissection or rupture.
2. In patients with abdominal aortic aneurysm, assess for abdominal (particularly left lower quadrant) pain and intense lower back pain caused by rapid expansion. Be alert for syncope, tachycardia, and hypotension, which may be followed by fatal hemorrhage because of rupture.

Nursing Diagnoses

- Risk for Ineffective Gastrointestinal, Renal, Cardiac, Cerebral Tissue Perfusion (vital organs) related to aneurysm or aneurysm rupture or dissection.
- Risk for Infection related to surgery.
- Acute Pain related to pressure of aneurysm on nerves and postoperatively.

Nursing Interventions

Maintaining Perfusion of Vital Organs

Preoperatively:

1. Assess for chest pain and abdominal pain.
2. Prepare patient for diagnostic studies or surgery, as indicated.
3. Monitor for signs and symptoms of hypovolemic shock.
4. Perform mental status and neurologic assessment regularly.

Postoperatively:

1. Monitor vital signs frequently.
2. Assess for signs and symptoms of bleeding:
    a. Hypotension.
    b. Tachycardia.
    c. Tachypnea.
    d. Diaphoresis.
3. Monitor laboratory values, as ordered.
4. Monitor urine output hourly.
5. Assess abdomen for bowel sounds and distention. Observe for diarrhea, which occurs sooner than one would expect bowel function.
6. Perform neurovascular checks to distal extremities.
7. Assess feet for signs and symptoms of embolization:
    a. Cold feet.
    b. Cyanotic toes or patchy blue areas on plantar surface of feet.
    c. Pain in feet.

8. Maintain IV infusion to administer medications to control BP and provide fluids postoperatively.
9. Position patient to avoid hip flexion, keeping knees below the level of the hips when sitting in chair.
10. If thoracoabdominal aneurysm repair has been performed, monitor for signs and symptoms of spinal cord ischemia:
    a. Pain.
    b. Numbness.
    c. Paresthesia.
    d. Weakness.

Preventing Infection

1. Monitor temperature.
2. Monitor changes in WBC count.
3. Monitor incision for signs of infection.
4. Administer antibiotics, if ordered, to prevent bacterial seeding of the graft.

Relieving Pain

1. Administer pain medication, as ordered, or monitor patient-controlled analgesia.
2. Keep head of bed elevated no more than 45 degrees for the first 3 days postoperatively to prevent pressure on incision site.
3. Rarely—administer nasogastric decompression for ileus following surgery, until bowel sounds return.
4. Assess abdomen for bowel sounds and distention.

Patient Education and Health Maintenance

1. Instruct patient about medications to control BP and the importance of taking them.
2. Discuss disease process and signs and symptoms of expanding aneurysm or impending rupture, or rupture, to be reported.
3. For postsurgical patients, discuss warning signs of postoperative complications (fever, inflammation of operative site, bleeding, and swelling).
4. Encourage adequate balanced intake for wound healing.
5. Encourage patient to maintain an exercise schedule postoperatively.
6. Instruct patient that due to use of a prosthetic graft to repair the aneurysm, prophylactic antibiotics will be used for invasive procedures, including routine dental examinations and dental cleaning for 6 to 12 months after aneurysm repair.
7. Make all patients aware that a one-time screening for abdominal aortic aneurysm by ultrasound has been recommended for men ages 65 to 75 who ever smoked. If the patient has an aortic aneurysm, members of the family over age 55 should be screened with ultrasound to rule out abdominal aortic aneurysm, both male and female.

EVIDENCE BASE U.S. Preventive Taskforce. (2014). *Guide to clinical preventive services: Screening for abdominal aortic aneurysm*. Available: *www.ahrq.gov/professionals/clinicians-providers/guidelines-recommendations/guide/section2.html*.

Evaluation: Expected Outcomes

- No change in mental status, bowel sounds, vital signs, or urine output.
- Afebrile and no signs of infection.
- Reports control of pain with medication.

Acute Arterial Occlusion

Acute arterial occlusion is the sudden interruption of blood flow, which may cause complete or partial obstruction of the artery. There is no time for development of collateral circulation. Critical ischemia of the extremity develops and may result in loss of affected extremity and/or death.

Pathophysiology and Etiology

1. Embolization is the most common cause of acute arterial occlusion.
2. Emboli may consist of thrombus, atheromatous debris, or tumor.
3. Emboli most commonly originate in the heart as a result of atrial fibrillation, MI, or heart failure (about 85%) but can also occur after invasive procedures, such as cardiac catheterization, angiography, and surgery.
4. Arteriosclerosis may cause roughening or ulceration of atheromatous plaques, which can lead to emboli.
5. May also be associated with immobility, anemia, and dehydration.
6. Emboli tend to lodge at bifurcations and atherosclerotic narrowings.
7. Other causes of acute occlusion include:
    a. Trauma.
    b. Thrombus.
    c. Venous outflow obstruction, which includes compartment syndrome.

Clinical Manifestations

1. The patient may experience acute pain and loss of sensory and motor function because of emboli blocking the artery and associated vasomotor reflex.
    a. Paralysis of part.
    b. Anesthesia of part.
    c. Pallor and coldness.
    d. Edema.
    e. Rigidity of extremity.
    f. Pulselessness.

Diagnostic Evaluation

1. Neurovascular assessment of affected area.
2. Doppler ultrasonography, segmental limb pressure, and pulse volume recordings—may indicate decreased flow.
3. Arteriography—confirms diagnosis.
4. MRA or spiral CT—to confirm diagnosis and give a three-dimensional view of the area.
5. Digital subtraction angiography, MRA, and MRI may be done for cerebral embolization.

Management

1. Drug therapy—anticoagulants (see page 317) and thrombolytics (see page 319).
2. Surgery:
   a. Embolectomy (see Figure 14-7) must be performed within 6 to 10 hours to prevent muscle necrosis and loss of extremity.
   b. Fasciotomy—incisions made over leg compartments to aid expansion of edematous tissue and relief of pressure on the arterial system.
   c. Amputation of the affected limb if revascularization is inappropriate due to metabolic complications.
3. Treatment of shock.
4. Bed rest.

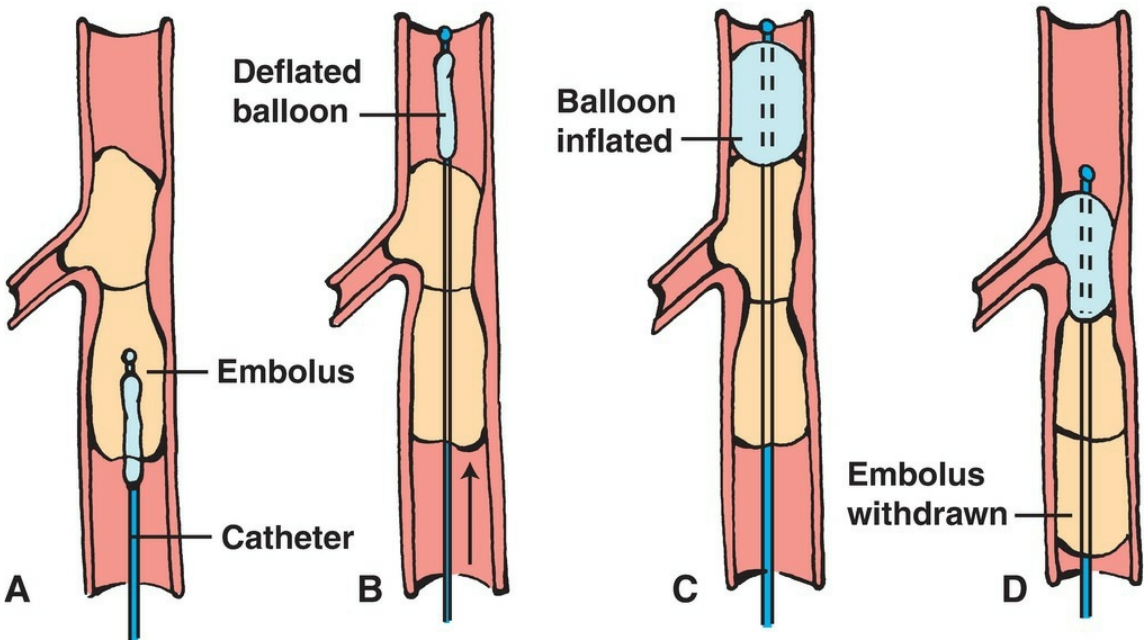

Figure 14-7. Extracting an embolus from a vessel can be done with the use of a Fogarty embolectomy catheter. The catheter, with a soft, deflated balloon near the tip, is threaded through the artery via an arteriotomy. **(A,B)** It is passed through the embolus and its thrombus; **(C)** it is then inflated. **(D)** A steady pull downward withdraws the embolus along with the catheter.

NURSING ALERT Arterial embolization of a large artery, such as the iliac, is life-threatening and requires emergency operative intervention.

Complications

1. Irreversible ischemia and loss of extremity.
2. Metabolic complications:

a. Acidosis.
b. Hyperkalemia.
c. Renal failure.

3. Shock.

Nursing Assessment

1. Assess for acute, severe pain.
2. Assess for gradual or acute loss of sensory and motor function.
3. Check for aggravation of pain by movement of and pressure on the extremity.
4. Palpate for loss of distal pulses.
5. Inspect for pale, mottled, and numb extremity.
6. Inspect for collapse of superficial veins because of decreased blood flow to the extremity.
7. Inspect for sharp line of color and temperature demarcation. This may occur distal to the site of occlusion as a result of ischemia.
8. Assess for edema.

Nursing Diagnoses

- Impaired Comfort related to impaired blood supply.
- Ineffective Peripheral Tissue Perfusion related to lack of blood flow by clot.
- Risk for Infection related to surgery.

Nursing Interventions

Protecting the Extremity

1. Protect extremity by keeping it at or below the body's horizontal plane.
2. Protect leg from hard surfaces, tight or heavy surfaces, and tight or heavy overlying bed linens.
3. Handle extremity gently and prevent pressure or friction while repositioning.
4. Administer pain medications, as ordered.

Promoting Tissue Perfusion

1. Administer UFH IV line to reduce tendency of emboli to form or expand (useful in smaller arteries).
2. Monitor thrombolytic therapy IV line to dissolve clot, as ordered.
3. Monitor patient for signs of bleeding (gums, urine, and stool).
4. Monitor coagulation, hematology, and electrolyte studies.
5. Prepare the patient for surgery (see page 321).
6. Postoperatively, promote movement of extremity to stimulate circulation and prevent stasis.

Preventing Infection

1. Postoperatively, check surgical wound for bleeding, swelling, erythema, and discharge.
2. Maintain IV infusion or venous access device to administer IV antibiotics, if indicated.
3. Continue to monitor the patient for tachycardia, fever, pain, erythema, warmth, swelling, and drainage at incision site.

Patient Education and Health Maintenance

1. Teach prevention techniques, such as daily aerobic activity, observation for skin breakdown, and prevention of injury.
2. Teach patient the medical regimen and importance of taking prescribed medications, such as oral anticoagulants, to prevent reembolization.
3. Encourage patient to report symptoms of arterial occlusion: paralysis, numbness, tingling, pallor, and coldness of extremity.

Evaluation: Expected Outcomes

- Patient reports no pain; no injury noted.
- Limb has normal color, sensation, movement, and temperature.
- No signs of infection.

Vasospastic Disorder (Raynaud Phenomenon)

Raynaud phenomenon is a vasospastic disorder that is brought on by an unusual sensitivity to cold, emotional stress, or autoimmune disorders. It is termed primary Raynaud disease when it is idiopathic, unaccompanied by other systemic manifestations. It is termed secondary Raynaud syndrome when it is associated with autoimmune disorders.

Pathophysiology and Etiology

1. The condition is a form of intermittent arteriolar vasoconstriction that results in coldness, pain, and pallor of fingertips, toes, or tip of the nose and a rebound circulation with redness and pain.
2. The cause is unknown, although it may be secondary to connective tissue and other immunologic disorders such as scleroderma, systemic lupus, polymyositis, and Sjögren syndrome.
3. Episodes may be triggered by emotional factors or by unusual sensitivity to cold.
4. Most common in women between ages 16 and 40 and seen much more commonly in cold climates and during the winter months.

Clinical Manifestations

1. Intermittent arteriolar vasoconstriction resulting in coldness, pain, and pallor.
2. Involvement of the fingers appears to be asymmetric; thumbs are less often involved.
3. Characteristic color changes: white–blue–red.
    a. White—blanching, dead-white appearance if spasm is severe.
    b. Blue—cyanotic, relatively stagnant blood flow.
    c. Red—a reactive hyperemia on rewarming.
4. Occasionally, there is ulceration of the fingertips (most common in autoimmune disorders).

Diagnostic Evaluation

1. Clinical symptoms must last at least 2 years to confirm the diagnosis.
2. Tests may be done to rule out secondary disease processes, such as chronic arterial occlusive or connective tissue disease.
3. Noninvasive blood flow tests for finger pressures and arterial waveforms.

Management

1. Avoidance of trigger and aggravating factors.
2. Protection of the fingers and toes with warm mittens (not gloves) and warm boots in cold weather.
3. Longer-acting calcium channel blockers are frequently used to prevent or reduce vasospasm.
4. Nitroglycerin or sympatholytics, such as reserpine, guanethidine, or prazosin, may be helpful for some. Adverse effects, such as headache, dizziness, and orthostatic hypotension, may be prohibitive.
5. Antiplatelet agents, such as aspirin or dipyridamole, may be given to prevent total occlusion.

6. Sympathectomy—removal of the sympathetic ganglia or division of their branches; may offer some improvement (extremely rare).

Complications

1. Chronic disease may cause atrophy of the skin and muscles.
2. Ulceration and gangrene (rare).

Nursing Assessment

1. Perform thorough history and review of systems for clues to underlying disorder.
2. Assess for blanching of digits when exposed to cold. Color turns cyanotic and then red with normal temperature.
3. Note whether warmth brings about symptom relief.

Nursing Diagnoses

- Risk for Peripheral Neurovascular Dysfunction related to vasospastic process.
- Acute Pain related to hyperemic stage.

Nursing Interventions

Minimizing Sensory Alteration

1. Assist patient in avoiding exposure to cold; for example, use mittens to handle cold items (water pitcher, refrigerated items). Always wear mittens outside in the cold. Teach patient rewarming techniques—warm water, putting fingers in axillary or groin area.
2. Encourage patient to stop smoking.
3. Help patient to understand the need to avoid stressful situations.
4. Offer patient options for stress management.
5. Administer and teach patient about drug therapy.
6. Instruct patient about the need to take drugs every day to prevent or minimize symptoms.
7. Monitor for orthostatic hypotension precaution if taking sympatholytics.
8. Advise patient that episode may be terminated by placing hands (or feet) in warm water.

Relieving Pain

1. Explain to patient that pain may be experienced when spasm is relieved—hyperemic phase.
2. Administer or teach self-administration of analgesics.
3. Reassure patient that pain is temporary; persistent pain, ulceration, or signs of infection should be reported.

Patient Education and Health Maintenance

1. Avoid whatever provokes vasoconstriction of vessels of hands.

2. Prevent injury to hands, which can aggravate vasoconstriction and lead to ulceration.
3. Minimize exposure to cold because this precipitates a reaction. Avoid wet and windy environments.
4. Wear warm clothing—boots, mittens, and hooded jackets—when going out in cold weather and waterproof clothing when raining or snowing.
5. Avoid placing hands in cold water, the freezer, or the refrigerator unless protective mittens are worn.
6. Use extra precautions to avoid injuries to fingers and hands from needlesticks and knife cuts.

Evaluation: Expected Outcomes

- Follows medication regimen, avoiding triggers.
- Reports decreased length of painful phase with episodes.

HYPERTENSIVE DISORDERS

Hypertension

EVIDENCE BASE James, P., Oparil, S., Carter, B., et al. (2014). Evidence based guidelines for the management of high blood pressure in adults (JNC 8). *JAMA*, *311*(5), 507–520.

The American Heart Association defines *blood pressure* (BP) as the force of blood pushing against the arterial wall as it relates to blood viscosity (thickness) and resistance of blood vessel. Systolic blood pressure (SBP) is the highest arterial pressure when the heart contracts and empties. Diastolic blood pressure (DBP) is the lowest arterial pressure when the heart relaxes to fill with blood. *Hypertension* (high BP) is a disease of vascular regulation in which the mechanisms that control arterial pressure within the normal range are altered. The predominant mechanisms of blood pressure control are the central nervous system (CNS), the renin–angiotensin–aldosterone system, and extracellular fluid volume. Why these mechanisms fail is not known.

Pathophysiology and Etiology

Elevated diastolic pressure leads to strain on the arterial wall, which over time causes thickening and calcification of the arterial media (a condition called sclerosis) and eventually narrowing of the blood vessel lumen. Elevated blood pressure is seen when there is increased cardiac output and increased peripheral resistance.

Primary or Essential Hypertension

(Approximately 95% of patients with hypertension.)

1. When the diastolic pressure is 90 mm Hg and/or the systolic pressure is 140 mm Hg or higher and other causes of hypertension are absent, the condition is said to be primary hypertension. More specifically, an individual is considered hypertensive when the average of two or more properly measured, seated BP readings taken at rest on each of two or more office visits exceeds the upper limits of normal (see Box 14-1).
2. Cause of essential hypertension is unknown; however, there are several areas of investigation:
    a. Hyperactivity of sympathetic vasoconstricting nerves.
    b. Presence of vasoactive substance released from the arterial endothelial cells, which acts on smooth muscle, sensitizing it to vasoconstriction.
    c. Increased cardiac output, followed by arteriole constriction.
    d. Excessive dietary sodium intake, sodium retention, insulin resistance, and hyperinsulinemia play roles that are not clear. There is a growing body of evidence implicating excess sodium intake in the pathogenesis of elevated BP.
    e. Familial (genetic) tendency.
3. Systolic BP elevation in the absence of elevated diastolic BP is termed isolated systolic hypertension and is treated in the same manner.

BOX 14-1 Hypertension Classification for Adults

- <120 systolic and <80 diastolic—normal
- 120–139 systolic or 80–89 diastolic—prehypertension
- 140–159 systolic or 90–99 diastolic—stage 1 hypertension
- ≥160 systolic or ≥100 diastolic—stage 2 hypertension

Secondary Hypertension

1. Occurs in approximately 5% of patients with hypertension secondary to other pathology.
2. Renal pathology:
   a. Chronic kidney disease, congenital anomalies, pyelonephritis, renal artery stenosis, acute and chronic glomerulonephritis, and obstructive uropathy (hydronephrosis).
   b. Reduced blood flow to kidney causes release of renin. Renin reacts with a serum protein to form angiotensin I, which is converted to angiotensin II through the action of angiotensin-converting enzyme in the lungs, leading to vasoconstriction and increased salt and water retention.
3. Coarctation of the aorta (stenosis of the aorta)—blood flow to upper extremities is greater than flow to the kidneys. The kidneys release renin when they sense hypotension.
4. Endocrine disturbances:
   a. Pheochromocytoma—a tumor of the adrenal gland that causes release of epinephrine and norepinephrine and a rise in BP (extremely rare).
   b. Adrenal cortex tumors lead to an increase in aldosterone secretion (hyperaldosteronism) and an elevated BP (rare).
   c. Cushing syndrome leads to an increase in adrenocortical steroids (causing sodium and fluid retention) and hypertension.
   d. Hyperthyroidism causes increased cardiac output.
5. Obstructive sleep apnea causes nocturnal hypertension, which leads to sustained daytime hypertension.
6. Prescription medications such as estrogens and steroids (cause fluid retention), sympathomimetics (cause vasoconstriction and tachycardia), antidepressants (prevent the breakdown of epinephrine), appetite suppressants (cause tachycardia and vasoconstriction), and NSAIDs (cause fluid retention and can lead to renal insufficiency).
7. Nonprescription drugs and substances such as cocaine (cause vasoconstriction and tachycardia); NSAIDs; herbal agents such as St. John's wort, ginseng, ephedra (unclear etiology of hypertension); antihistamines (cause vasoconstriction and tachycardia); and nicotine (causes vasoconstriction).
8. Food substrates such as sodium chloride, ethanol, licorice, and glucose, all of which can cause increased fluid retention.

Consequences of Hypertension

1. Hypertension can cause intimal wall injury in the arteries, which can lead to arteriosclerosis in which

smooth muscle cell proliferation, lipid infiltration, and calcium accumulation occur in the vascular endothelium.

2. Prolonged hypertension damages small blood vessels in the brain, eyes, heart, and kidneys.
3. The major objective in patients with high BP is to prevent target organ damage of the heart (left ventricular hypertrophy, angina, myocardial infarction, heart failure), brain (stroke, transient ischemic attack, dementia), kidneys (chronic kidney disease), eyes (retinopathy, blindness), or vasculature (aneurysm, PAD).
4. The Heart Disease and Stroke Statistics 2016 Update reported that compared to individuals with normal BP (120/80 mm Hg), those patients with prehypertension have a 1.5- to 2-fold risk for major cardiovascular events between the ages 60 to 80 years.

Prevalence and Risk Factors

EVIDENCE BASE Mozaffarian, D., Benjamin, E., Go, A., et al. (2015). Heart disease and stroke statistics-2015 update: A report from the American Heart Association. *Circulation*, *131*(4), e29–e322.

1. Hypertension affects approximately 1 billion people worldwide and is the most common modifiable risk factor for arteriosclerosis.
2. There are an estimated 80 million Americans with hypertension (about 32.6% of the adult population), and this number is expected to increase due to the aging of the population. Only a fraction of these people are aware of their hypertension and are treated for it, and even fewer have gained adequate control of their BP.
3. The National Health and Nutrition Examination Surveys (NHANES), designed to monitor the health and nutritional status of the civilian US population, showed that among US adults with high blood pressure, the percentage of individuals with hypertension who were aware of their condition increased from 69.6% in 1999–2000 to 80.6% in 2007–2008. The number of individuals who take antihypertensive medications and attained control of their blood pressure also increased during this period.
4. Risk factors include age between 30 and 70, African American race, overweight or obese, sleep apnea, family history, tobacco use, sedentary lifestyle, diabetes mellitus, metabolic syndrome, lower education/socioeconomic status, psychological stressors, and dietary factors (increased consumption of fats, sodium, and alcohol, with lower intake of potassium-rich foods).

NURSING ALERT There is a higher incidence of hypertension in the African American population, along with higher mortality rate and risk for complications such as stroke, left ventricular hypertrophy, heart failure, and kidney disease.

Clinical Manifestations

1. Usually asymptomatic; known as the silent killer.
2. May cause headache, dizziness, blurred vision, chest pain, and shortness of breath when greatly elevated.
3. Elevated BP readings taken in a seated position on at least two occasions.

Diagnostic Evaluation

1. ECG—to determine effects of hypertension on the heart (left ventricular hypertrophy, ischemia) or presence of underlying heart disease.
2. Chest x-ray—may show cardiomegaly or aortic dilation by the presence of a widened mediastinum.
3. Proteinuria, elevated serum blood urea nitrogen (BUN), and elevated creatinine levels—indicate kidney disease as a cause or effect of hypertension; first voided urine microalbumin or spot urine for albumin–creatinine ratio are early indicators.
4. Serum potassium—decreased in primary hyperaldosteronism; elevated in Cushing syndrome; both are causes of secondary hypertension.
5. Urine (24-hour) for catecholamines—increased in pheochromocytoma.
6. Renal ultrasound to detect renal vascular diseases.
7. Renal artery duplex imaging to identify renal artery stenosis.
8. Outpatient ambulatory BP measurements.
9. Tests for causes of secondary hypertension are done if hypertension is resistant to treatment or specific signs and symptoms of secondary hypertension are present.

Management

Blood Pressure Target Goals

1. Blood pressure (BP) goals are based on research and published guidelines and/or consensus statements. Clinicians must be aware of their patients' target BP goals.
2. Guidelines from the 8th Report of the Joint National Commission (JNC-8):
   a. BP goals for all patients are less than 150/90 mm Hg.
   b. BP goals for patients with diabetes and chronic kidney disease are less than 140/90 mm Hg.
3. Guidelines from the American Heart Association:
   a. Individuals with ischemic heart disease, CAD equivalents, and high risk for CAD have a target BP goal of less than 130/80 mm Hg.
   b. If the patient has LV dysfunction, the target BP is less than 120/80 mm Hg.
4. Guidelines from the American Diabetes Association indicate that individuals with diabetes should have a target BP of less than 140/90 mm Hg.

Lifestyle Modifications

Lifestyle modifications reduce BP, prevent or delay the incidence of hypertension, enhance antihypertensive

drug therapy, and decrease cardiovascular risk (see Box 14-2).

BOX 14-2 Lifestyle Therapy for Blood PressureControl

- Weight control—may reduce BP 5–20 mm Hg per 10 kg (22 pound) weight loss; goal is to maintain normal BMI of 18.5–24.9 kg/m^2.
- DASH eating plan—may reduce systolic BP 8–14 mm Hg; diet is rich in fruits, vegetables, and low-fat dairy products; reduced intake of saturated and total fat.
- Reduced sodium intake—may reduce systolic BP 2–8 mm Hg; salt intake is limited to no more than 2,400 mg sodium per day.
- Physical activity—may reduce systolic BP 4–9 mm Hg; regular aerobic physical activity (such as brisk walking) should occur at least 30 minutes most days per week.
- Moderate alcohol intake—may reduce systolic BP 2–4 mm Hg; alcohol intake is limited to no more than two drinks per day for most men and no more than one drink per day for women and lighter-weight persons. One drink is equivalent to 12 ounce beer, 5 ounce wine, or 1 ounce 80-proof whiskey.

If, despite lifestyle changes, BP remains at or above 140/90 mm Hg (or is not at optimal level in the presence of other cardiovascular risk factors) over 3 to 6 months, drug therapy should be initiated. If BP is extremely elevated or in presence of cardiovascular risk factors, single-drug therapy may be initiated.

Drug Therapy

See Table 14-4.

Table 14-4 Evidence-Based Dosing for Antihypertensive Drugs

ANTIHYPERTENSIVE MEDICATION	INITIAL DAILY DOSE/NO. OF DOSES PER DAY	TARGET DOSE IN RCTs REVIEWED (mg)
ACE inhibitor		
Captopril	50 (2)	150–200
Enalapril	5 (1–2)	20
Lisinopril	10 (1)	40
Angiotensin receptor blockers		
Eprosartan	400 (1–2)	600–800
Candesartan	4 (1)	12–32
Losartan	50 (1–2)	100
Valsartan	40–80 (1)	160–320
Irbesartan	75 (1)	300
Beta-blockers		
Atenolol	25–50 (1)	100
Metoprolol	50 (1–2)	100–200
Calcium channel blockers		
Amlodipine	2.5 (1)	10
Diltiazem extended release	120–180 (1)	360
Nitrendipine	10 (1–2)	20
Thiazide-type diuretics		
Bendroflumethiazide	5 (1)	10
Chlorthalidone	12.5 (1)	12.5–25
Hydrochlorothiazide	12.5–25 (1–2)	25–100
Indapamide	1.25 (1)	1.25–2.5

These dosages may vary from those listed in the Physicians' Desk Reference. Please review current medication reference materials for most current dosing. Many antihypertensive agents are combination medications. RCT, randomized controlled trial.

1. Considerations in selecting therapy include:
    a. Race—African Americans respond well to calcium channel blockers and thiazide diuretics, if compelling conditions are not noted. A renin–angiotensin system (RAS) blocker is first line for African Americans with kidney disease, diabetes, or heart failure. Caucasians respond well to angiotensin converting enzyme (ACE) inhibitors.
    b. Age—some adverse effects such as fatigue and light-headedness may not be tolerated well by older adults. Diuretics are typically the first drug prescribed.
    c. Concomitant diseases and therapies—some agents also treat migraines, benign prostatic hyperplasia, heart failure; have beneficial effects on conditions such as renal insufficiency; or have adverse effects on such conditions as diabetes or asthma.
    d. Quality-of-life impact—tolerance of adverse effects.
    e. Cost considerations—newer and brand name agents usually more expensive.
    f. Dosing—multiple doses may reduce adherence.
2. Medications available:
    a. Diuretics—lower BP by promoting urinary excretion of water and sodium to lower blood volume.
    b. Beta-adrenergic blockers—lower BP by slowing the heart and reducing cardiac output by blocking beta-adrenergic receptors that produce epinephrine.
    c. Alpha-receptor blockers—lower BP by dilating peripheral blood vessels and lowering peripheral vascular resistance. Research has indicated these medications provide little protection against heart failure but are effective in improving benign prosthetic hypertrophy.
    d. Central alpha agonists—lower BP by diminishing sympathetic outflow from the CNS, thereby lowering peripheral resistance.
    e. Peripheral adrenergic agents—inhibit peripheral adrenergic release of vasoconstricting catecholamines such as norepinephrine.
    f. Combined alpha and beta-adrenergic blockers—work through alpha- and beta-receptors.
    g. ACE inhibitors—lower BP by blocking the enzyme that converts angiotensin I to the potent vasoconstrictor angiotensin II and reducing sympathetic nervous system activity; also raise the level of bradykinin, a potent vasodilator, and lower aldosterone levels.
    h. Angiotensin receptor blockers—similar in action to ACE inhibitors.
    i. Calcium antagonists (calcium channel blockers, or CCB)—stop the movement of calcium into the cells; relax smooth muscle, which causes vasodilation; and inhibit reabsorption of sodium in the renal tubules. Nondihydropyridine CCB (verapamil and diltiazem) have a negative inotropic effect and may worsen heart failure.
    j. Direct vasodilators—smooth muscle relaxants that primarily dilate arteries and arterioles.
    k. Aldosterone inhibitors—antagonize aldosterone receptors and inhibit sodium reabsorption in the collecting duct of the nephron in the kidneys.
    l. Direct renin inhibitors—inhibits renin within the renin–angiotensin system (RAS).

3. If hypertension is not controlled with the first drug within 1 to 3 months, three options can be considered:
    a. If the patient has faithfully taken the drug and not developed adverse effects, the dose of the drug may be increased.
    b. If the patient has had adverse effects, another class of drugs can be substituted.
    c. A second drug from another class could be added. If adding the second agent lowers the pressure, the first agent can be slowly withdrawn or, if necessary, combination therapy can be continued.
    d. Some patients require two medications at the time of diagnosis. This should be considered for patients who are 20 mm Hg above their systolic goal or 10 mm Hg above their diastolic goal.
4. The best management of hypertension is to use the fewest drugs at the lowest doses while encouraging the patient to maintain lifestyle changes. After BP has been under control for at least 1 year, a slow, progressive decline in drug therapy can be attempted. However, most patients need to resume medication within 1 year.
5. If the desired BP is still not achieved with the addition of a second drug, a third agent or a diuretic or both (if not already prescribed) could be added. 75% of individuals with hypertension require two or more antihypertensive agents to reach their BP goal.
6. Resistant hypertension is defined as an individual that requires three or more antihypertensive agents to control blood pressure.

DRUG ALERT ACE inhibitors are a drug of choice for diabetics as they delay progression to end-stage renal disease. However, they may worsen renal function in the presence of renal artery stenosis.

Complications

See Figure 14-8.

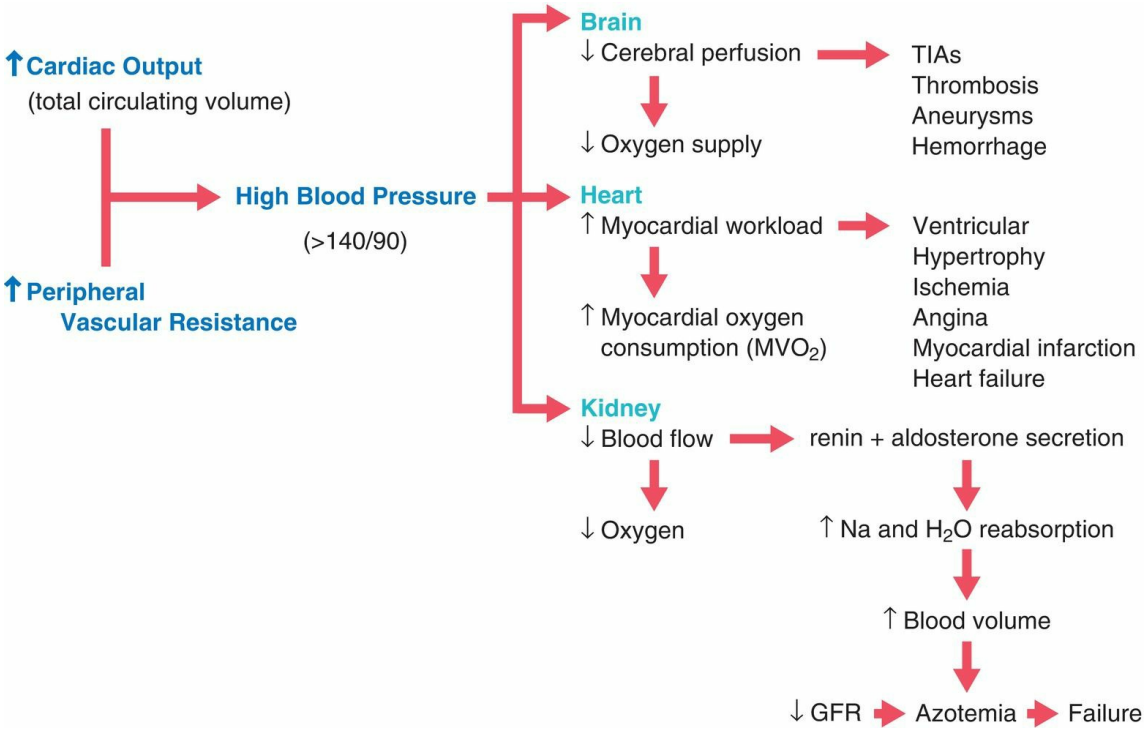

Figure 14-8. Determinants and clinical effects of high blood pressure. GFR, glomerular filtration rate; TIA, transient ischemic attack.

1. Angina pectoris or MI because of decreased coronary perfusion.
2. Left ventricular hypertrophy and heart failure because of consistently elevated aortic pressure.
3. Renal failure because of diminished perfusion to the glomerulus.
4. TIAs, stroke, or cerebral hemorrhage because of cerebral ischemia and arteriosclerosis.
5. Retinopathy.
6. Accelerated hypertension (see page 343).

Nursing Assessment

Nursing History

Query the patient about the following:

1. Family history of high BP.
2. Previous episodes of high BP.
3. Dietary habits and salt intake.
4. Target organ disease or other disease processes that may place the patient in a high-risk group—diabetes, CAD, kidney disease.
5. Tobacco use.
6. Episodes of headache, weakness, muscle cramps, tingling, palpitations, sweating, and vision disturbances.
7. Medication that could elevate BP (refer to "Secondary Hypertension," above):
   a. Hormonal contraceptives, corticosteroids.

b. NSAIDs.

c. Nasal decongestants, appetite suppressants, and tricyclic antidepressants.

8. Other disease processes, such as gout, migraines, asthma, heart failure, and benign prostatic hyperplasia, which may be helped or worsened by particular antihypertensive drugs.

Physical Examination

1. Auscultate heart rate and heart sounds for the presence of an S4, indicating stiffening of the walls of the left ventricle, which may occur in hypertension.
2. If skilled in doing so, perform funduscopic examination of the eyes for the purpose of noting vascular changes. Look for edema, spasm, and hemorrhage of the eye vessels. Refer to ophthalmologist for definitive diagnosis.
3. Palpate the chest wall for a shift of the point of maximal impulse to the left, which occurs in heart enlargement. Palpate peripheral pulses for possible PAD.
4. Auscultate for bruit over the aorta, renal arteries, and peripheral arteries to determine the presence of atherosclerosis.
5. Determine mental status by asking patient about memory, ability to concentrate, and ability to perform simple mathematical calculations.

Blood Pressure Determination

1. Measure BP in both arms to determine whether there is a difference. If the SBP is greater than 15 mm Hg in one arm than the other, this may indicate the presence of subclavian stenosis in the arm with the lower SBP. If this BP differential is found, BP should be monitored in the arm with the highest SBP.
2. Avoid taking BP readings immediately after stressful or taxing situations. Wait 30 minutes after patient has smoked.
3. Have the patient assume position of comfort and remain silent. Make sure feet are on the floor or otherwise supported. The patient should be seated and relaxed for at least 5 minutes, and the blood pressure should be taken around the same time each day it is taken to observe for trends in BP.
4. Support the bared arm; avoid constriction of arm by a rolled sleeve.
5. Use a BP cuff of the correct size.
   a. The bladder within the cuff should encircle at least 80% of the patient's arm.
   b. Many adults will require a large cuff.
   c. Two or more readings separated by 2 minutes should be averaged.
6. Be aware that falsely elevated BPs may be obtained with a cuff that is too narrow; falsely low readings may be obtained with a cuff that is too wide.
7. Auscultate and record precisely the systolic and diastolic pressures.
   a. Systolic—the pressure within the cuff indicated by the level of the mercury column at the moment when the first clear, rhythmic pulsatile sound is heard (phase 1).
   b. Diastolic—the pressure within the cuff just as the sound disappears (ie, the onset of silence).

NURSING ALERT The finding of an isolated elevated BP does not necessarily indicate hypertension. However, the patient should be regarded as at risk for high BP until further assessment—through history taking, repeat BP measurements, and diagnostic testing—either confirms or refutes the diagnosis.

GERONTOLOGIC ALERT Elderly patients are more likely to have hypertension and isolated systolic hypertension because of age-related changes of decreased arterial compliance and arterial stenosis. Another age-related change, autonomic dysregulation, may cause orthostatic hypotension—a risk factor for syncope and falls.

Nursing Diagnoses

- Noncompliance with medication regimen and lifestyle changes.
- Readiness for Enhanced Self-health Management related to control of hypertension and prevention of target organ disease.

Nursing Interventions/Patient Education

Enlisting Cooperation and Compliance

1. Enlist the patient's cooperation in redirecting lifestyle in keeping with the guidelines of therapy, acknowledge the difficulty, and provide support and encouragement.
2. Develop a plan of instruction for medication self-management.
   a. Plan the patient's medication schedule so that they are given at proper and convenient times (once daily, if possible); set up a daily checklist on which the patient can record the medication taken or provide pill sorter.
   b. Be sure the patient knows the generic and brand names for all medications and throws away old medications and dosages so they will not be mixed up with current medications.
   c. Explore the cost of medications and ability for the patient to pay for prescriptions each month. Encourage the patient to discuss generic equivalents, mail-order drugs, or prescription assistance programs with the health care provider. Refer patient to Partnership for Prescription Assistance (*www.pparx.org*).
3. Stress the fact that there may be no correlation between high BP and symptoms; the patient cannot tell by the way he or she feels whether BP is normal or elevated. Because hypertension is chronic, regular follow-up is important to prevent complications and reduce more serious health care interventions in the future.
4. Assess for and try to eliminate side effects of medication regimen.

a. Explain that antihypertensive drugs affect people differently, and side effects such as anorexia, fatigue, nausea, or lightheadedness often occur during the first few days or weeks of therapy until the body develops tolerance to them.
b. Warn the patient of the possibility that orthostatic hypotension may occur initially with some drug therapy, but it can be minimized by being cautious in hot, humid environments; getting up slowly; or sitting or lying down briefly if feeling faint.
c. If constipation occurs, encourage high-fiber diet.
d. If ankle swelling occurs, elevate legs periodically.
e. If dry cough develops, dosage or drug may need to be changed.
f. Advise the patient to notify the health care provider if side effects are significant, dosage may be lowered or a substitute medication may be ordered. However, the patient should not discontinue medication without notifying the health care provider.

5. Educate the patient to be aware of serious adverse effects (fainting, palpitations, shortness of breath) and report them immediately so that adjustments can be made in individual pharmacotherapy.

GERONTOLOGIC ALERT Polypharmacy, cognitive changes, and sensory deficits in older adults may make dosage adjustment and control of BP difficult. Work with the patient, family, and home care nurse to devise a simple method for the patient to take the proper medications. Older patients are also more sensitive to therapeutic levels of drugs and may demonstrate adverse effects while on an otherwise average dosage. Monitor closely for safety and efficacy of therapy. They may be more sensitive to postural hypotension and should be cautioned to change positions with great care.

Encouraging Self-Management

1. Explain the meaning of high BP, risk factors, and their influences on the cardiovascular, cerebral, and renal systems.
2. Stress that there can never be total cure, only control, of essential hypertension; emphasize the consequences of uncontrolled hypertension.
3. Instruct the patient regarding proper method of taking BP at home and at work if health care provider so desires. Inform patient of desired range and the readings that are to be reported.
4. Determine recommended dietary plans and provide dietary education, as appropriate.
   a. Print out copy of the DASH Eating Plan and review with patient. Help patient suggest food preferences that include whole grains, fruits, vegetables, low-fat dairy, and nuts in quantities outlined in plan. Available at *www.nhlbi.nih.gov/health/health-topics/topics/dash*.
   b. Teach patient and family members how to read food labels to monitor sodium intake.
   c. Refer to dietitian for thorough dietary education and planning, as needed.
5. Educate patient about factors that may affect BP, such as dehydration, diarrhea, and other illnesses, so

BP should be monitored closely and treatment adjusted.

6. Encourage the patient to keep follow-up appointments as directed by health care provider, have blood work drawn to monitor serum creatinine and electrolytes, and schedule eye exam by an ophthalmologist yearly.

Evaluation: Expected Outcomes

- Takes medications regularly; keeps follow-up appointments.
- Monitors BP correctly at home; able to identify sodium content on food labels.

Malignant Hypertension

Malignant hypertension, also called *accelerated hypertension*, occurs when the BP elevates extremely rapidly, threatening one or more of the target organs: brain, kidneys, or heart. Malignant hypertension is defined as blood pressure ≥180/120 mm Hg or isolated diastolic BP greater than 130 mm Hg and is a medical emergency.

Pathophysiology and Etiology

1. When rapid hypertension occurs, the normal autoregulation of the artery eventually fails.
2. The rise in pressure in the arterioles and capillaries leads to damage to the vascular wall, which disrupts the endothelium and allows fibrinous material to enter the vascular wall, thereby narrowing or obliterating the vascular lumen.
3. For example, within the brain, the breakthrough vasodilation from failure of autoregulation leads to the development of cerebral edema and symptoms of hypertensive encephalopathy.
4. Etiology includes collagen vascular disorders, renal failure, renal artery stenosis, and toxemia of pregnancy.

Clinical Manifestations

1. Brain effects:
    a. Encephalopathy.
    b. Stroke.
    c. Progressive headache, stupor, and seizures.
2. Kidney effects:
    a. Decreased blood flow and vasoconstriction.
    b. Elevated BUN.
    c. Increased plasma renin activity.
    d. Lowered urine-specific gravity.
    e. Proteinuria.
    f. Renal failure.
3. Cardiac effects:
    a. Left-sided heart failure.
    b. Acute MI.
    c. Right-sided heart failure.

Management

Goal is to lower BP to reduce the probability of permanent damage to target organs.

1. If diastolic BP exceeds 115 to 130 mm Hg, clinical condition is assessed very carefully.
2. Immediate hospitalization and treatment if the following are present:

a. Seizures.
b. Abnormal neurologic signs.
c. Severe occipital headache.
d. Pulmonary edema.

3. The patient is hemodynamically monitored in the ICU.
4. Antihypertensive agents are administered parenterally. Agents include:
   a. Nitroprusside—a rapidly acting arteriolar and venous dilator, given as an IV infusion. Initial dose: 0.25 to 0.5 mcg/kg/minute; maximum dose: 8 to 10 mcg/kg/minute. Avoid in neurologic emergencies. Preferred in perioperative HTN.
   b. Nitroglycerin—a rapidly acting venous and, to a lesser degree, arteriolar dilator, given as an IV infusion. Initial dose: 5 mcg/minute; maximum dose: 200 mcg/minute. Preferred perioperative.
   c. Labetalol—an alpha- and β-adrenergic blocker, given as an IV bolus or infusion. Bolus: 20 mg initially, followed by 20 to 80 mg every 10 minutes to a total dose of 300 mg. Infusion: 0.5 to 2 mg/minute. Preferred in acute ischemic stroke.
   d. Esmolol—antagonizes beta-1 adrenergic receptors, given as bolus 1,000 mcg/kg IV, then 150 mcg/kg/minute IV prn, max 300 mcg/kg/minute, may continue 50 mcg/kg/minute IV q4min prn, taper to d/c.
   e. Nicardipine—a calcium channel blocker, given as an IV infusion. Initial dose: 5 mg/hour; maximum dose: 15 mg/hour. Preferred in acute ischemic stroke.
   f. Clevidipine—a calcium channel blocker. Initial dose: 1 to 2 mg/hour; 32 mg/hour maximum dose: 16 mg/hour.
   g. Fenoldopam—a peripheral dopamine-1 receptor agonist, given as an IV infusion. Initial dose: 0.01 mcg/kg/minute; the dose is titrated at 15-minute intervals, depending on the blood pressure response normal dosing: 0.01 to 1.6 mcg/kg/minute.
   h. Hydralazine—an arteriolar dilator, given as an IV bolus. Initial dose: 10 mg given every 20 to 30 minutes; maximum dose: 20 mg. Avoid in neurologic emergencies.
   i. Propranolol—a β-adrenergic blocker, given as an IV infusion and then followed by oral therapy. Dose: 1 to 10 mg load, followed by 3 mg/hour.
   j. Phentolamine—an alpha-adrenergic blocker, given as an IV bolus. Dose: 5 to 10 mg every 5 to 15 minutes.
   k. Enalaprilat—an ACE inhibitor, given as an IV bolus. Dose: 1.25 to 5 mg every 6 hours.
5. Diuretics may be administered to maintain a sodium diuresis when the arterial pressure falls.
6. Vasopressor agents should be available if the BP responds too vigorously to antihypertensive agents.

Nursing Interventions

1. Record BP frequently or monitor BP via an intra-arterial line or electronically controlled cuff. Some drugs necessitate the taking of BP readings every 5 minutes or more frequently while titrating drug therapies.

2. Monitor for adverse effects of medications—headache, tachycardia, and orthostatic hypotension.
3. Measure urine output accurately.
4. Observe for hypokalemia, especially if patient is placed on diuretic therapy. Monitor for ventricular dysrhythmias.
5. Observe for CNS complications.
    a. Note signs of confusion, irritability, lethargy, and disorientation.
    b. Listen for complaints of headache, difficulty with vision.
    c. Check for evidence of nausea or vomiting.
    d. Be alert for signs of seizure activity. Provide a safe environment—padded side rails. Keep bed in lowest position.
6. Reduce activity and provide quiet environment.
7. Monitor ECG continuously.
8. Maintain constant vigilance until BP is decreased and stable and then begin a hypertension teaching program.

NURSING ALERT BP should be reduced gradually and wide pressure variations avoided because lowered BP may not be adequate to perfuse vital organs.

LYMPHATIC DISORDERS

The lymphatic system is a network of vessels and nodes that are interrelated with the circulatory system. It removes tissue fluid from intercellular spaces and protects the body from bacterial invasion. Lymph nodes are located along the course of the lymphatic vessels and filter lymph before it is returned to the bloodstream.

Lymphedema and Lymphangitis

Lymphedema is a swelling of the tissues (particularly in the dependent position) produced by an obstruction to the lymph flow in an extremity. This results in excessive accumulation of fluid in the interstitial space, which is composed of high molecular weight proteins.

Lymphangitis is an acute inflammation of lymphatic channels, which most commonly arises from a focus of infection in an extremity.

Pathophysiology and Etiology

Lymphedema

1. Classified as primary (congenital malformations) or secondary (acquired obstruction).
2. Swelling in the extremities occurs due to an increased quantity of lymph fluid that results from an obstruction of lymphatics.
3. Obstruction may be in both the lymph nodes and the lymphatic vessels. Eventually, subcutaneous tissue becomes fibrotic, impairing vascular flow and oxygen transfer to tissues.
4. It may be caused or aggravated by radiation therapy, trauma, cancer, morbid obesity, or surgery involving the lymph tissue (particularly radical mastectomy). It may be associated with varicose veins and chronic phlebitis.

Lymphangitis

1. Most commonly caused by infection in an extremity. The pooled protein-rich lymph fluid creates a good medium for growth of bacteria and fungi.
2. The characteristic red streak extending up an arm or leg from the infected wound outlines the course of the lymphatics as they drain.
3. Recurrent lymphangitis is typically associated with lymphedema.

Clinical Manifestations

1. Lymphedema: edema may be massive and is usually firm.
2. Lymphangitis:
    a. Displays characteristic red streaks that extend up an arm or leg from an infection that is not localized and that can lead to septicemia.
    b. Produces general symptoms—high fever and chills.
    c. Produces local symptoms—local pain, tenderness, and swelling along involved lymphatics.
    d. Produces local lymph node symptoms—enlarged, red, and tender (acute lymphadenitis).
    e. Produces an abscess—necrotic and pus-producing (suppurative lymphadenitis)

Diagnostic Evaluation

1. Duplex ultrasound-easy noninvasive study

2. Lymphoscintigraphy—reliable alternative to lymphangiography using radioactive colloid material; detects obstruction or inflammation.
3. CT or MRI.
4. Lymphangiography—outlines lymphatic system.
5. Check feet for tinea pedis (athlete's foot), which is a common cause of bacterial entry into the skin and lymphatics.

Management

Lymphedema

1. Self-monitoring-monitor lymphedema, including serial measurement of limb circumference.
2. Leg elevation to reduce swelling.
3. Diet and exercise and maintenance of ideal body weight. Exercise and weight training.
4. Lymphedema therapy.
   a. Compression garments to help squeeze the fluid out of tissues. This may be in the form of medical-grade stockings or pneumatic compression, which provides intermittent pumping to squeeze fluid from the extremity. These may be used in upper or lower extremities.
   b. Manual lymphatic drainage, massage to help move fluid and myofascial release to break up fibrotic tissue.
   c. Complete decongestive therapy; see Table 14-5.
5. Diuretics are usually not effective and can worsen edema and promote volume depletion.
6. Experimental therapies: low lever laser therapy and gene therapy.
7. Surgery:
   a. Lymphatic bypass procedures.
   b. Excision of affected subcutaneous tissue and fascia with skin grafting.
   c. Transfer of superficial lymphatics to deep lymphatic system by buried dermal flap.
   d. Liposuction of lower-extremity lymphedema—limited; more common for upper extremity.

Table 14-5 Complete Decongestive Therapy

PHASE/TIME FRAME	COMPONENTS
Phase 1: Treatment 2–4 wk	Meticulous skin and nail care to prevent infection Therapeutic exercise Manual lymphatic drainage and compression using multilayer dressings
Phase 2: Maintenance ongoing (to conserve and optimize benefit of phase 1)	Compression garments during active awake hours Self-compression bandaging at night Skin care and continue exercise as needed Self-manual lymphatic drainage

Lymphangitis

1. Administer empiric antibiotics.
2. Treat affected extremity by rest, elevation, and the application of hot, moist dressings.
3. Incise and drain if necrosis and abscess formation occur.
4. Treat tinea pedis, if present.

Complications

1. Abscess formation (rare with lymphangitis).
2. Firm, nonpitting lymphedema unresponsive to treatment (congenital lymphedema, called lymphedema praecox).
3. Elephantiasis secondary to parasite (*Filaria*)—chronic fibrosis of subcutaneous tissue and chronic swelling of the extremity (rare in the United States).
4. Septicemia.
5. Complications of surgery include flap necrosis, hematoma, abscess under flap, and cellulitis.

Nursing Assessment

1. Assess extremity for edema and inflammation.
   a. Palpate edema to evaluate its quality (soft and pitting or firm and nonpitting).
   b. Note any areas of abscess formation (suppurative lymphadenitis).
2. Watch for signs of fever and chills.

Nursing Diagnoses

- Risk for Impaired Skin Integrity related to edema and/or inflammation.
- Acute Pain related to incision and/or surgery.

Nursing Interventions

Maintaining Skin Integrity

1. Apply elastic bandages or prescription compression stockings (after acute attack with lymphangitis).
2. Advise the patient to rest frequently with affected part elevated—each joint higher than the preceding one.
3. Make sure the patient washes and dries thoroughly the crevices of the skin if edema has caused skin folds.
4. Administer diuretics as prescribed to control excess fluid.
5. Give antibiotics or antifungals, as prescribed.
6. Recommend isometric exercises with extremity elevated.
7. Suggest moderate sodium restriction in diet.
8. Observe postoperatively for signs of infection.

Relieving Pain Postoperatively

1. Encourage comfortable positioning and immobilization of affected area.
2. Administer or teach patient to administer analgesics, as prescribed; monitor for adverse effects.
3. The use bed cradle to relieve pressure from bed covers.

Patient Education and Health Maintenance

1. Instruct patient on proper application of compression garments.
2. Encourage compliance with therapy, which often involves frequent rewrapping of compression bandages, exercise, and massage for several months.
3. Advise patient to avoid trauma to extremity.
4. Instruct patient to use lotions that are free of perfumes, which may irritate skin.
5. Advise patient to practice good hygiene to avoid superimposed infections.
6. Instruct patient about the signs and symptoms of infection to report to health care providers.
7. Instruct patient to inspect feet and legs daily for evidence of skin breakdown, particularly between toes, and to look for tinea pedis.

Evaluation: Expected Outcomes

- Skin is normal color and temperature, nontender, nonswollen, and intact.
- Verbalizes no pain on actively moving extremity.

PROCEDURE GUIDELINES 15-1

Assisting the Patient Undergoing Lumbar Puncture

EQUIPMENT

- Sterile lumbar puncture set
- Skin antiseptic (avoid use of chlorhexidine)
- Sterile gloves
- Adhesive bandage
- Xylocaine 1% to 2%

PROCEDURE

Nursing Action	Rationale
1. Before procedure, the patient should empty bladder and/or bowel.	1. Enhances comfort.
2. Give a step-by-step summary of the procedure. For lying position, see accompanying figure.	2. Reassures the patient and gains cooperation.
	3. If patient has signs of increased intracranial pressure, a computed tomography scan should be done to rule out mass effect.	3. Removal of cerebrospinal fluid (CSF) in the presence of mass effect may precipitate brain herniation.
4. Position the patient on side with a small pillow under head and a pillow between legs. Patient should be lying on a firm surface.	4. The spine is maintained in a horizontal position. The pillow between the legs prevents the upper leg from rolling forward.
5. Instruct the patient to arch the lumbar segment of back and draw knees up to abdomen, chin to chest, clasping knees with hands.	5. Offers maximal widening of the interspinous spaces and affords easier entry into the subarachnoid space.
6. Assist the patient in maintaining this position throughout the procedure by supporting behind the knees and upper back and neck.	6. Supporting the patient helps prevent sudden movements, which can produce a traumatic (bloody) tap and thus impede correct diagnosis.
7. Alternately, for sitting position, have the patient straddle a straight-back chair (facing the back) and rest head against arms, which are folded on the back of the chair.	7. In obese patients and those who have difficulty in assuming an arched side-lying position, this posture may allow more accurate identification of the spinous processes and interspaces.

Nursing Action	Rationale
Performance phase (by the health care provider)	
1. The skin is prepared with antiseptic solution (avoiding use of chlorhexidine), and the skin and subcutaneous spaces are infiltrated with local anesthetic agent.	1. Reduces risk of contamination; decreases pain. Chlorhexidine is neurotoxic and should not come in contact with CSF.
2. A spinal needle is introduced at the L3–L4 interspace. The needle is advanced until the "give" of the ligamentum flavum is felt and the needle enters the subarachnoid space. The manometer is attached to the spinal needle.	2. L3–L4 interspace is *below* the level of the spinal cord.
3. After the needle enters the subarachnoid space, help the patient to straighten up slowly.	3. Prevents a false increase in intraspinal pressure. Muscle tension and compression of the abdomen give falsely high pressures.
4. Instruct the patient to breathe quietly (not to hold breath or strain) and not to talk.	4. Hyperventilation may lower a truly elevated pressure. Talking can elevate CSF pressure.
5. The initial pressure reading (opening pressure) is obtained by measuring the level of the fluid column after it comes to rest.	5. With respiration, there is normally some fluctuation of spinal fluid in the manometer. Normal range of spinal fluid pressure with the patient in the lateral recumbent position is 70 to 200 mm H_2O. Opening pressure exceeds normal range when hydrocephalus or increased ICP is present.
6. About 2 to 3 mL of spinal fluid is placed in each of three test tubes for observation, comparison, and laboratory analysis. Spinal fluid should be clear and colorless.	6. Bloody spinal fluid may indicate subarachnoid hemorrhage or a traumatic tap. If traumatic tap, blood should gradually clear with subsequent specimens.
7. Closing pressure is documented; the pressure on the manometer after the CSF specimen is collected and/or excess CSF removed.	7. Closing pressure should be within normal CSF pressure range.
Follow-up phase	
1. After the procedure, the patient is instructed to remain flat for about 2 hr.	1. Reduces pressure on tissue surfaces along the needle track to prevent CSF leakage.
2. Ensure adequate hydration with oral or parenteral fluids.	2. Monitor for spinal headache and observe for CSF leak.
3. Facilitates replacement of CSF and prevents spinal headache.	3. CSF leaks from lumbar puncture are characterized by intractable spinal headache.

EVIDENCE BASE American Association of Neuroscience Nurses. (2011). *Care of the patient undergoing intracranial pressure monitoring/external ventricular drainage or lumbar drainage.* Glenview, IL: Author.

A baseline neurologic assessment is needed to detect changes in neurologic function and includes a patient history, general physical examination, and thorough neurologic examination. An important goal of the neurologic assessment is to identify the minimum amount of stimulation required to elicit maximum response. Common manifestations of neurologic dysfunction include motor, sensory, autonomic, and cognitive deficits. By exploring these symptoms, obtaining a pertinent history, and performing a thorough neurologic examination, the reader will gain an understanding of the underlying disorder and become skilled in planning care for patients with neurologic disorders (see Standards of Care Guidelines 15-1, page 347). See Chapter 5 , page 65, for neurologic examination techniques. Documentation using appropriate terminology and comparison of right to left for asymmetrical findings is important. See Box 15-1, page 347, for definitions of findings.

STANDARDS OF CARE GUIDELINES 15-1

Neurologic Disorders

When caring for patients with neurologic disorders, consider the following assessments and interventions:

- Use age-appropriate assessment and examination techniques.
- Be aware of the status of the patient when assuming care, so comparison can be made with subsequent assessments.

- Perform a thorough systematic assessment, including mental status, vital signs, and cardiovascular status.
- Document the patient's condition to provide a record for continuity of care.
- Provide translation services for patients who have difficulty understanding or speaking English because this may impact the interpretation of the neurologic examination.
- Evaluate for signs of worsening neurologic condition through a systematic examination. Follow the institutional guidelines and clinician's orders regarding the frequency of assessments. If the patient shows signs of neurologic deterioration, more frequent assessment and/or interventions may be necessary.
- Be cautious in the administration of sedatives, opiates, or other medications that affect neurologic functioning because these may mask signs of neurologic deterioration.
- Notify appropriate health care provider of new or worsening neurologic symptoms, such as a change in behavior or level of consciousness; a change in functioning of the cranial nerves; motor, sensory, or neurovascular deficits; or alterations in the pattern of breathing or vital signs. Implement appropriate interventions for acute changes in neurologic status.
- Institute safety precautions for patients with neurologic deficits because they may be especially prone to falls. Follow institutional guidelines for patients with seizure disorder.
- Assess the patient's level of functioning in his or her activities of daily living. For those with cranial nerve or motor deficits, assess for difficulty swallowing prior to eating. For patients with difficulty swallowing, implement appropriate institutional protocols to prevent aspiration. This may include contacting the primary clinician to obtain an evaluation from a speech therapist or changing the diet.
- Use a multidisciplinary approach to care when indicated, including medical and surgical specialists, pharmacists, dietitian/nutritional therapist, physical/occupational/speech therapists, and rehabilitation specialists.
- Be aware that families or caretakers of patients with cognitive impairment or who are nonverbal may be able to provide assistance in the interpretation of behavioral cues.
- Assess family support and coping throughout the trajectory of the disease. Social issues (such as financial, community support systems, etc.) may require the expertise of a social worker or other clinical resource support personnel.

Radiology and Imaging

Structural and functional imaging techniques have evolved to facilitate the rapid diagnosis and treatment of neurologic disorders. Brain mapping describes the process of translating the brain into a functionally useful group of dynamic maps or patterns. The diagnosis and evaluation of neurologic disorders is increasingly guided by functional brain mapping techniques that detect changes in brain patterns associated with neuropathology. Structural or anatomic imaging reveals information about the structure of the nervous system, including the brain and spinal cord. Functional or physiologic imaging focuses on the function of the brain and biochemical and metabolic processes in brain cells.

Computed Tomography

Description

1. Computed tomography (CT) is a structural imaging study that uses a computer-based x-ray to provide a cross-sectional image of the brain. A computer calculates differences in tissue absorption of the x-ray beams. The CT scan produces a three-dimensional view of structures in the brain and distinguishes between soft tissues and water. Intravenous (IV) contrast dye may be used to examine the integrity of the blood–brain barrier. New multidetector scanners allow for rapid imaging.
2. CT of the brain is primarily used to detect cerebral hemorrhage, whereas CT of the brain with contrast is used to detect tumors and inflammatory disorders.
3. Spinal CT may be used to evaluate lower back pain due to bony lesions or degenerative changes. CT myelography is typically reserved for those who have had previous spinal surgery or a questionable diagnosis.
4. May be used when magnetic resonance imaging (MRI) is contraindicated (metallic or electronic implants) or not tolerated (claustrophobia).
5. *Advantages of CT*: Widespread availability, short imaging time, excellent images of bone, and 100% sensitivity for detection of cerebral hemorrhage.
6. *Disadvantages of CT*: Does not provide information about function of tissues; exposes the patient to ionizing radiation at higher doses than traditional x-rays; imposes a weight restriction of 300 pounds; if contrast is used, there is the risk of contrast-induced nephropathy.

Nursing and Patient Care Considerations

1. Instruct the patient to remove metal items, such as earrings, eyeglasses, and hair clips.
2. Ask whether the patient has an allergy to iodine or history of previous allergy to IV dye to determine if the patient needs to be premedicated.
3. Evaluate for adequate renal function if contrast will be used.
4. Tell the patient to expect a sensation of feeling flushed if contrast dye is injected through the IV catheter.
5. Inform the patient that the procedure usually takes less than 5 minutes.
6. Request that the patient remain as immobile as possible during the examination.

7. Tell the patient to resume usual activities after the procedure.
8. Encourage increased fluid intake for the rest of the day to assist in expelling the contrast dye.

BOX 15-1 Definitions of Neurologic Findings

Acalculia—inability to do mathematical calculations.

Agnosia—inability to recognize sensory input.

Amaurosis fugax—sudden, temporary, or fleeting blindness, not caused by disease of the eye.

Anisocoria—inequality in size of the pupils.

Apraxia—inability to perform coordinated movements.

Confabulation—fluent, nonsensical speech.

Decerebrate rigidity (extensor posturing)—dysfunction of vestibulospinal tract and the RAS of the upper brain stem; jaw clenched, neck extended, elbows extended, forearms pronated, wrists flexed, knees extended, and feet plantar flexed.

Decorticate rigidity (flexor posturing)—dysfunction of corticospinal tract above the brain stem; arms adducted, elbows and wrists flexed, legs extended and internally rotated, and feet plantar flexed.

Dyslexia—visual aphasia.

Dysarthria—difficulty speaking.

Dyspraxia—partial loss of ability to perform coordinated movements.

Fluent aphasia (Wernicke's, sensory)—comprehension is poor but speech is fluent and nonsensical.

Homonymous hemianopsia—corresponding visual field deficits in half of the visual field bilaterally.

Micrographia—change in handwriting with the script becoming smaller and more cramped.

Nonfluent aphasia (Broca's, motor)—comprehension intact but has poor expression through speech.

Nystagmus—involuntary oscillation of the eyeball, vertical, horizontal, or rotary.

Paratonia—progressively increasing and irregular resistance to passive movements.

Magnetic Resonance Imaging

Description

1. Conventional MRI is a noninvasive structural imaging procedure that uses powerful magnetic field and radiofrequency waves to create an image. When tissue is placed in a strong magnetic field, hydrogen atoms in the tissue line up within the field. In MRI, pulsating radiofrequency waves are applied to the magnetic field to alter the tissue magnetization, creating a clear image of the tissue.
2. MRI is the imaging procedure of choice for most neurologic diseases (eg, detection of demyelinating diseases, nonacute hemorrhage, and cerebral tumors; evaluation of spinal cord injury (SCI), acute herniated disks, and cerebral infarction) and has largely replaced myelography, a more invasive procedure. See Table 15-1 for comparison to CT.
3. Specific protocols have been developed for trauma, stroke, and epilepsy.
4. MRI may be ordered with or without contrast. The contrast (gadolinium) alters the magnetic properties

of tissue to differentiate tissue types. Contrast may be administered via IV line, by mouth, or through insertion into the rectum.

5. Closed MRI uses scanning equipment that resembles a tunnel-like chamber. Open MRI uses more sophisticated equipment that does not involve a closed chamber. During open MRI, the patient can comfortably see the surroundings from all views while the scan is in progress. This is ideal for patients who are claustrophobic or anxious, children, older adults, and the very obese.
6. Imaging orientation:
   a. Axial—slice dividing the head into upper and lower halves.
   b. Coronal—slice dividing the head into front and back halves.
   c. Sagittal—slice dividing the head into left and right halves.
7. Imaging sequences:
   a. T1—excellent tissue discrimination that provides anatomic images.
   b. T2—sensitive to the presence of increased water and visualization of edema for differentiation of normal tissue and pathologic changes.
   c. MRI with gadolinium—improves specificity of normal/abnormal tissue. With blood–brain barrier disruption, there is leakage of contrast medium. The pattern of contrast uptake into brain tissue helps differentiate such conditions as central nervous system (CNS) infections, neoplasms, meningeal diseases, and noninfectious inflammatory processes.
   d. Fluid-attenuated inversion recovery—evaluates edema within white matter; also used to identify subarachnoid disease.
   e. Diffusion-weighted imaging (DWI)—helps to evaluate the extent of a stroke and demyelinating disease and differentiates tumors from abscesses; shows increased enhancement with cytotoxic edema.
   f. Apparent diffusion coefficient (ADC)—shows decreased attenuation associated with acute stroke.
   g. DWI/ADC mismatch—increased enhancement on DWI in conjunction with decreased enhancement on ADC indicates acute stroke.
   h. Perfusion-weighted imaging (PWI)—evaluates cerebral blood flow, transit time, and blood volume. Useful in the evaluation of the extent of the ischemia stroke and determining whether there is salvageable tissue or a penumbra.
   i. DWI/PWI mismatch—increased enhancement on DWI with flow deficit on PWI indicates acute stroke.
   j. MRI single-photon emission computed tomography (SPECT)—provides assessment of neurochemicals (choline, lactate, *N*-acetylaspartate, glutamine/glutamate) for differentiation of brain tumors, abscess, demyelinating disease, and postradiation necrosis
   k. Swan—useful in the evaluation microscopic bleeds and small blood vessels
   l. GRE—useful in the evaluation of small lesions.
8. *Advantages of MRI*: No ionizing radiation, sensitivity to blood flow, imaging in several planes, and superior visualization of soft tissues. An important advantage is its ability to distinguish water, iron, fat,

and blood. Sensitive to detection of white matter changes and valuable in detecting changes associated with Alzheimer disease and multiple sclerosis.

9. *Disadvantages of MRI*: Contraindicated for patients with pacemakers, nontitanium aneurysm clips, or other implanted objects that could be dislodged by the magnetic field. Dental amalgam, gold, and stainless steel are generally considered safe but may distort the image. If contrast is used, there is the risk of contrast-induced nephropathy. MRI scanner has the appearance of a tunnel-like chamber, and its constricted opening prevents its use for extremely obese people. Because of its narrow dimensions, MRI may induce claustrophobic and anxiety reactions, so antianxiety medication may be necessary before the procedure or an open MRI may be used.

Table 15-1 Comparison of CT and MRI

CONSIDERATIONS	CT	MRI
Radiation exposure	• Minimal	• None
Imaging planes	• Axial, coronal, and sagittal	• Axial, coronal, and sagittal
Cost	• Several hundred dollars	• Several thousand dollars, but dependent on protocol being used
Advantages	• Rapid evaluation for intracranial hemorrhage and subarachnoid hemorrhage	• Detection of stroke, multiple sclerosis, epilepsy, tumors
Disadvantages	• Poor visualization of anatomic structures; radiation exposure	• May result in claustrophobia • May need prior x-rays if metallic fragments are suspected—if identified, cannot complete study

Nursing and Patient Care Considerations

1. Encourage the patient to use the bathroom before the procedure because it may take from 20 to 60 minutes, though the scan time is dependent on the protocol requested and number of scans performed.
2. Instruct the patient to remove metal items, including eyeglasses, jewelry, hair clips, hearing aids, dentures, and clothing with zippers, buckles, or metal buttons.
3. Evaluate for adequate renal function if contrast will be used (see Box 15-2, above).
4. Encourage the patient to remain as still as possible during the procedure.
5. Describe the tunnel-like narrow chamber of the closed MRI scanner and inform the patient that it sometimes causes feelings of anxiety or claustrophobia. Evaluate the need for sedation.

6. Inform the patient the scanner will make a dull, thumping noise throughout the procedure.
7. Tell the patient to resume usual activities after the procedure.

BOX 15-2 Contrast-Induced Nephropathy

When IV contrast medium is to be used in any radiologic study, renal function must be adequate to clear the substance. Check for risk factors for contrast-induced nephropathy:

- Renal insufficiency (creatinine level greater than 1.5 or a glomerular filtration rate of less than 60 mL/minute).
- Diabetic nephropathy and other conditions that cause reduced renal perfusion.
- High total dose of contrast (less than 5 mL/kg or greater than 100 mL).

If risk factors are present, hydration with normal saline starting 1 hour prior to the procedure and for 6 hours following the procedure is recommended.

Metformin should be held for 24 hours before any procedure and for 48 hours after the procedure if IV contrast is utilized.

Functional MRI

Description

1. Functional MRI (fMRI) is an imaging study that aids in identifying regions of the brain activated by particular stimuli and tasks. Imaging is performed during presentation of a stimulus or performance of a specific task and during rest periods. A statistical comparison is performed with images obtained during the stimulus/task periods compared with those performed during the rest periods by evaluating the conversion of oxyhemoglobin to deoxyhemoglobin and utilization of glucose, which occurs during normal brain activity. Involves IV administration of contrast material that lowers signal intensity on MRI in relation to blood flow as the material passes through the brain.
2. *Advantages of fMRI*: Does not use ionizing radiation and can be applied repeatedly in the same patient without risk. Offers potential in early detection of patients with prodromal dementia. It is also useful in preoperative evaluation of patients with lesions (tumors, seizure foci) adjacent to eloquent areas of the brain (speech center, premotor and motor cortex, and memory centers).
3. *Disadvantages of fMRI*: Same as MRI.

Nursing and Patient Care Considerations

1. Instruct the patient as for MRI. Full cooperation of the patient is vital for head motion and task performance reasons. Global cognitive impairment, aphasia, neglect, substantial sensory disturbances, and severe depression are usually exclusion criteria. The performance of motor tasks during imaging should be monitored.
2. Medications that may interfere with performance of tasks during the procedure should be avoided, if possible, including benzodiazepines, sedatives, and opioids.

Positron Emission Tomography

Description

1. Positron emission tomography (PET) is a computer-based imaging technique that permits study of the brain's function by evaluating the metabolism, blood flow, and chemical processes within the brain. PET measures emissions of particles of injected radioisotopes—called positrons—and converts them to an image of the brain.
2. PET scanners are not frequently used or widely available because of their high cost, and PET requires sophisticated equipment to produce its radioisotopes, or positron emitter.
3. A glucose-like solution and mildly radioactive tracers are combined for injection or inhalation. After injection into the arterial bloodstream or inhalation of this radioactive compound, pairs of gamma rays are emitted into adjacent tissue during radioactive decay. The PET scanner measures the gamma rays to determine how quickly the tissues absorb the radioactive isotopes. A computer processes the data into an image that shows where the radioactive material is located, corresponding to cellular metabolism.
4. *Advantages of PET*: Provides information on patterns of glucose and oxygen metabolism. Areas of decreased metabolism indicate dysfunction. PET is useful for early detection of Alzheimer disease and other dementias, Parkinson disease, amyotrophic lateral sclerosis (ALS), Huntington disease, multiple sclerosis, and psychiatric disorders, such as depression or schizophrenia. PET can also help locate/identify abnormal brain activity, such as seizure foci, and assess brain function after stroke.
5. *Disadvantages of PET*: Ionizing radiation, high initial cost.

Nursing and Patient Care Considerations

1. Inform the patient that this procedure requires injection or inhalation of a radioactive substance that emits positively charged particles. Explain that the image is created when the negative particles found in the body combine with the positive particles of the imaging substance.
2. Explain that, after injection of the radioisotope, the patient will be asked to rest quietly on a stretcher for about 45 minutes to allow the substance to circulate.
3. Reassure the patient that radiation exposure is minimal.
4. Encourage the patient to void before the test because the scan and associated procedures may take several hours.
5. Advise the patient to increase fluid intake after the procedure to flush out the radioisotope and to resume meals.
6. Tell the patient that it may take a few days to get results of the PET scan because it requires processing before it is available for interpretation.

Single Photon Emission Computed Tomography

Description

1. SPECT is a widely available noninvasive functional imaging technique that evaluates cerebral vascular supply. A radioactive tracer is administered by inhalation or injection into the bloodstream; the tracer

then decays to emit only a single photon. It uses a rotating camera to track the single photons emitted from radioactive decay and collects information from multiple views. Evaluation of the radioactive tracers creates images that show cerebral blood flow in various regions of the brain.

2. The radioactive tracer compounds used are commercially prepared and do not require the specialized equipment used in PET scanning.
3. SPECT is typically used to evaluate cerebral blood flow in patients with ischemic stroke, subarachnoid hemorrhage (SAH), migraine, dementia (including Alzheimer disease), epilepsy, and other degenerative diseases.
4. *Advantages of SPECT*: Can perform hemodynamic, chemical, and functional imaging; widely available.
5. *Disadvantages of SPECT*: Ionizing radiation, provides only relative measurements.

Nursing and Patient Care Considerations

1. Inform the patient that this is a noninvasive procedure that should cause minimal discomfort.
2. Tell the patient that results of the scan are typically available for interpretation by a specialist immediately after the procedure.

Transcranial Doppler Studies

Description

1. Transcranial Doppler (TCD) ultrasonography involves noninvasive testing to measure flow changes in the form of velocities of the cerebral arteries. It helps evaluate vasospasm post-SAH, occlusion, or flow abnormalities as with stroke.
2. Bone windows (temporal, transorbital, or foramen magnum) are accessed using a fiberoptic probe after application of ultrasound gel. The fiberoptic probe is directed at a specific artery, and the velocities are then recorded.
3. Specific criteria are utilized for identification of each cerebral vessel prior to assessment of the vessel (specific bone window, depth, flow direction, and waveform).
4. *Advantages of TCD studies*: Low cost; can be performed at bedside and repeated as needed (useful in monitoring trends).
5. *Disadvantages of TCD studies*: Results are operator dependent; inability to obtain signal; limited data on sensitivity and specificity.

Nursing and Patient Care Considerations

1. Explain that the study will be done with patient in a reclining position.
2. Inform the patient that the test normally takes less than 1 hour, depending on the number of arteries that are to be studied.

CT Perfusion

Description

1. CT perfusion involves rapid injection (5 to 10 mL/second) of 40 mL of iodine contrast during continuous scanning. Computer analysis of "wash-in" and "wash-out" of the contrast generates a single-slice acquisition blood flow map.
2. The test requires a 20 gauge catheter or larger for injection of the contrast. Contrast is cleared through the kidneys; therefore, renal function should be evaluated prior to study to reduce the risk of contrast-induced nephropathy (see page 349).
3. CT scan is programmed to analyze specific area of concern. Three 1-cm thick computer-generated images are produced that reflect relative cerebral blood flow, relative blood volume, and mean transit time.
4. *Advantages of CT perfusion*: 90% sensitivity and 100% specificity for cerebral ischemia; can be performed in conjunction with CT angiogram. Can be used in evaluating cerebral vasospasm in aneurysmal SAH, though the sensitivity and specificity is unknown.
5. *Disadvantages of CT perfusion*: Limited anatomic assessment; radiation exposure; if contrast is used, there is the risk of contrast-induced nephropathy; requires large-bore catheter.

Nursing and Patient Care Considerations

1. Instruct the patient about the rationale for placement of large-bore catheter.
2. Assess the patient for contrast allergy and premedicate, if indicated.
3. Inform the patient that radiation exposure, although present, is minimal.

Cerebral Angiography

Description

1. Following local anesthesia, a radiopaque dye is injected through a catheter in the femoral artery (or brachial artery if femoral is inaccessible) and passed through one of the major cervical blood vessels to assess cerebral circulation. Serial x-rays are taken after contrast dye illuminates the cerebral arterial and venous systems. The structure and patency of cerebral arteries are examined. Contrast is cleared through the kidneys. The test is frequently performed on an outpatient basis, unless the patient is already hospitalized.
2. Three-dimensional imaging is available for more thorough evaluation of vascular abnormalities.
3. *Advantages of cerebral angiography*: Useful in detection of stenosis or occlusion, aneurysms, and vessel displacement due to pathologic processes (eg, tumor, abscess, hematoma).
4. *Disadvantages of cerebral angiography*: Involves considerable exposure to radiation. Contraindicated in patients with a stroke in evolution. Potential complications: temporary or permanent neurologic deficit, including stroke, anaphylaxis, bleeding or hematoma at the IV site, and impaired circulation in the extremity distal to the injection site, usually the femoral artery. There is risk of contrast-induced nephropathy.

Nursing and Patient Care Considerations

1. Omit the meal before the test, although clear liquids may be taken.

2. Evaluate for adequate renal function; should have recent normal serum creatinine.
3. Ask the patient about allergies and specifically rule out presence of iodine allergy, which requires pretest preparation. Commonly, patients with allergy to iodine also have allergies to radiopaque contrast media that may cause severe reaction.
4. Options for pretest allergy prevention include the following:
   a. Elective procedure: Give prednisone 50 mg orally 13, 7, and 1 hour prior to contrast and diphenhydramine 50 mg orally 1 hour prior to contrast.
   b. Urgent procedure: Give methylprednisolone IV and diphenhydramine 50 mg orally, IM, or IV 1 hour prior to contrast.
5. Mark pedal peripheral pulses.
6. Explain that a local anesthetic will be used to insert a catheter into the femoral artery (brachial artery may be used) and threaded into the required cerebral vessel.
7. Tell the patient to expect some discomfort when the catheter is inserted into the artery. Additionally, the sensation of a warm, flushed feeling and metallic taste should be expected when the dye is injected.
8. Caution the patient that he or she will need to lie still during the procedure and that he or she will be asked to hold breath intermittently during scanning.
9. After angiography:
   a. Maintain bed rest and do not flex lower extremities, as ordered, and monitor vital signs. Instruct the patient to maintain bed rest for up to 6 hours. If a closing device is utilized, the time can be reduced to 2 to 3 hours.
   b. Check the patient frequently for neurologic symptoms, such as motor or sensory alterations, reduced level of consciousness (LOC), speech disturbances, dysrhythmias, or blood pressure (BP) fluctuations.
   c. Monitor puncture site for bleeding, hematoma, and pulses, as ordered. Apply pressure if bleeding or hematoma is noted and inform physician.
   d. Evaluate renal function and monitor for adverse reaction to contrast medium (eg, restlessness, respiratory distress, tachycardia, facial flushing, nausea, and vomiting).
   e. Assess skin color, temperature, and peripheral pulses of the extremity distal to the IV site—change may indicate impaired circulation due to occlusion. Inform physician, if noted.

Computed Tomographic Angiography

Description

1. CT angiography is a minimally invasive three-dimensional (3-D) imaging technique that uses multisectional spiral CT imaging in conjunction with rapid power injection of contrast (50 mL) into a large antecubital vein. Multiple, thin slices are reconstructed to provide 3-D imaging of cerebral vasculature.
2. Proper timing of contrast injection with initialization of CT scans is essential to optimize intravascular enhancement.

3. *Advantages of CT angiography*: Speed of scanning allows for unstable patients to be evaluated; increasing in availability.
4. *Disadvantages of CT angiography*: Exposure to radiation; need for large-bore (18 to 20 gauge) catheter; potential for anaphylaxis; contraindicated for patients with acute/chronic renal failure.

Nursing and Patient Care Considerations

1. Restrict food for 4 to 6 hours before procedure.
2. Assess for contrast allergy and premedicate, if indicated.
3. Evaluate renal function as contrast is cleared through kidneys. Elevated creatinine may preclude the individual from obtaining the study.

Magnetic Resonance Angiography/Venography of the Brain

1. Magnetic resonance angiography/venography (MRA/MRV) is a 3-D phase contrast technique. The test focuses on high signal or blood flow while suppressing background nonactive tissue.
2. Two flow-opposing acquisitions are obtained, and the computer subtracts the background signal to construct the cerebral vasculature.
3. *Advantages of MRA/MRV*: No exposure to radiation.
4. *Disadvantages of MRA/MRV*: Less sensitivity than CT angiography (sensitivity increases in aneurysms larger than 5 mm).

Nursing and Patient Care Considerations

1. Same as those for MRI, page 349.

Dynamic Volume Computed Tomography

Description

1. This scanning technique can include entire organs, such as the heart or brain, in a single rotation and enables dynamic processes, such as blood volume and time to peak, to be observed.
2. The scanning process takes less time and requires a smaller dose of iodinated contrast and less radiation than does conventional CT, making it an ideal diagnostic test in emergency situations (heart attack or stroke) or for those who cannot tolerate large doses of iodine contrast (renal disease).

Nursing and Patient Care Considerations

1. The general considerations for conventional CT are the same.
2. Inform the patient about lying flat on the table while the tube revolves around the area to be scanned.
3. If contrast will be used, the patient will most likely have an IV catheter placed for the injection of dye. A sensation of warmth or metallic taste in the mouth may be experienced after the dye injection.

Other Diagnostic Tests

Other diagnostic tests include lumbar puncture, which provides information about the CNS through direct contact with the cerebrospinal fluid (CSF); a variety of tests that measure electrical impulses in portions of the nervous system; and neuropsychological evaluation.

Lumbar Puncture

Description

1. A needle is inserted into the lumbar subarachnoid space, usually between the third and fourth lumbar vertebrae, and CSF is withdrawn for diagnostic and therapeutic purposes.
2. Purposes include the following:
   a. Obtaining CSF for examination (microbiologic, serologic, cytologic, or chemical analysis).
   b. Measuring cerebrospinal pressure and assisting in detection of obstruction of CSF circulation.
   c. Determining the presence or absence of blood in the spinal fluid.
   d. Aiding in the diagnosis of viral or bacterial meningitis, subarachnoid or intracranial hemorrhage, tumors, and brain abscesses.
   e. Administering antibiotics and cancer chemotherapy intrathecally in certain cases.
   f. Determining levels of tau protein and beta-amyloid in the CSF—a new test that may be used to assist in the diagnosis of Alzheimer disease. Elevated levels of tau protein and decreased levels of beta-amyloid are associated with Alzheimer disease.

Nursing and Patient Care Considerations

1. Assist the patient to side-lying position with small pillow under head and a pillow between legs with back arched and knees drawn up toward abdomen. Alternately a sitting position, leaning forward, may be used, particularly for obese persons.
2. Assist in sending CSF sample tubes for evaluation.
3. After the procedure, support the patient in lying flat for 2 hours, ensuring hydration, and monitor for a spinal headache and CSF leak.

Electroencephalography

Description

1. EEG measures electrical activity of the brain cells. Electrodes are attached to multiple sites on the scalp to provide a recording of electrical activity that is generated in the cerebral cortex. Electrical impulses are transmitted to an electroencephalograph, which magnifies and records these impulses as brain waves on a strip of paper. New devices allow for continuous EEG monitoring of selective areas of the brain; thus limited data are collected. It is useful in the intensive care unit (ICU) setting for continuous monitoring to evaluate for seizure activation.
2. Provides physiologic assessment of cerebral activity for diagnosis of epilepsy, alterations in brain activity

in coma, and organic brain syndrome and sleep disorders. Particularly helpful in the investigation of patients with seizures.

3. Usually performed in a room designed to eliminate electrical interference; however, in the case of a comatose patient, it may be performed at bedside using a portable unit.
4. Restlessness and fatigue can alter brain wave patterns.
5. For a baseline recording, the patient is instructed to lie still and relax with eyes closed. After a baseline recording in a resting phase, the patient may be tested in various stress situations (eg, asked to hyperventilate for 3 minutes, look at a flashing strobe light) to elicit abnormal electrical patterns.
6. In patients with epilepsy, continuous monitoring is performed with video monitoring. This is useful for interpretation and correlation of physiologic seizure activity and clinical seizures.
   a. Grids or strips are placed intraoperatively for more accurate assessment of seizure foci.
   b. Mapping of seizure activity is performed to determine precise location of seizure foci.
   c. Once foci are located, the site is evaluated for possible surgical resection.

Nursing and Patient Care Considerations

1. For routine EEG, tranquilizers, anticonvulsants, sedatives, and stimulants should be held for 24 to 48 hours before the study.
2. Thoroughly wash and dry patient's hair to remove hair sprays, creams, or oils.
3. Explain that the electrodes will be attached to the patient's skull with a special paste.
4. Assure the patient that the electrodes will not cause shock, and encourage the patient to relax during the procedure because anxiety can affect brain wave patterns.
5. Meals should be taken as usual to avoid sudden changes in blood glucose levels.

Evoked Potential Studies

Description

1. These tests measure the brain's electrical responses to visual, somatosensory, or auditory stimuli.
   a. Visual evoked potentials—produced by asking the patient to look at rapidly reversing checkerboard patterns. These assist in evaluating multiple sclerosis and traumatic injury. EEG electrodes are placed over the occiput and record the transmission time from the retina to the occiput.
   b. Somatosensory evoked potentials—generated by stimulating a peripheral sensory nerve and useful in diagnosing peripheral nerve disease and injury. These measure transmission time up the spinal cord to the sensory cortex.
   c. Auditory evoked potentials—produced by applying sound, such as clicks, to help locate auditory lesions and evaluate integrity of the brain stem. The transmission time up the brain stem into the cortex is measured.
2. Can be performed intraoperatively or during interventional procedures in which the patient is under general anesthesia. Acute changes may indicate potential for deficits.

Nursing and Patient Care Considerations

1. Explain that the electrodes will be attached to the patient's scalp to measure the electrical activity of the nervous system. Placement of the electrodes will depend on the type of evoked potentials being measured.
2. Ask the patient to remove all jewelry.
3. Assure the patient that the procedure is not painful and does not cause any electric shock.
4. Inform the patient that the test usually takes 45 to 60 minutes.

Needle Electromyography

Description

1. In combination with nerve conduction studies, needle electromyography (EMG) is the gold standard for assessing the neurophysiologic characteristics of neuromuscular diseases. Because it is invasive and painful, its use is limited when activity from several muscles needs to be monitored simultaneously. It is the recording of a muscle's electrical impulses at rest and during contraction. A needle is attached to an electrode and inserted into a muscle. A mild electrical charge is delivered to stimulate the muscle at rest and during voluntary contraction. The response of the muscle is measured on an oscilloscope screen.
2. Useful in distinguishing lower motor neuron (LMN) disorders from muscle disorders (eg, ALS from muscular dystrophy).
3. Nerve conduction time, another diagnostic test, is often measured simultaneously.

Nursing and Patient Care Considerations

1. Explain that this test measures the electrical activity of muscles.
2. Advise the patient to avoid caffeine and tobacco products for 3 hours before the test, as these substances can affect test results.
3. Inform the patient that the procedure normally takes at least 1 hour.
4. Tell the patient a needle will be inserted through the skin into select muscles and to expect some degree of discomfort when the needle is inserted.
5. Inform the patient that, after the test, a mild analgesic or warm compresses may be needed to relieve muscle soreness.
6. Inform the patient to observe the needle insertion sites for bleeding, hematoma, redness, or other signs of infection and to notify the health care provider if any of these are observed.

Nerve Conduction Studies (Electroneurography)

Description

1. A peripheral nerve is stimulated electrically through the skin and underlying tissues. A recording electrode detects the response from the stimulated nerve. The time between the stimulation of the nerve and the response is measured on an oscilloscope, and speed of conduction along the nerve is calculated.
2. Used to determine LMN dysfunction, differentiating disease or injury in peripheral nerves, spinal nerve

roots, or the anterior horn of the spinal cord by measuring nerve conduction velocity.

Nursing and Patient Care Considerations

1. Explain that surface-stimulating electrodes with special paste are applied and taped to the nerve site (leg, arm, or face).
2. Advise the patient that an electric current is passed through the electrode and that a mild sensation or slight discomfort may be experienced while the current is applied.

Neuropsychological Testing

Description

1. A series of tests that evaluate effects of neurologic disorders on cognitive functioning and behavior.
2. A neuropsychologist selects appropriate tests to determine the extent and type of functional deficits.
3. Paper-and-pencil tests, puzzles, and word and recall games are commonly used. Testing may assess the following:
   a. Intelligence, attention span, memory, judgment.
   b. Motor, speech, and sensory function.
   c. Affect, coping, and adaptation.
   d. Language quality, abstraction, distractibility.
   e. Ability to sequence learned behaviors.
   f. Used in diagnosis of organic brain dysfunction and dementia.
   g. Valuable in determining vocational rehabilitation training needs.
4. Utilized in some facilities to determine competency of a patient with regard to instituting durable power of attorney or need for guardianship.

Nursing and Patient Care Considerations

1. Assure the patient that these tests are not intended to evaluate mental illness.
2. Explain that testing evaluates the ability to remember, calculate numbers, and perform abstract reasoning.
3. The patient should be well rested because testing is mentally tiring and lengthy. A complete examination is a 4- to 6-hour process, depending on the patient's ability to concentrate.
4. Anticipate fatigue and frustration after the examination.

Polysomnography

Description

1. Polysomnography is a noninvasive, all-night sleep study that measures character of sleep, simultaneously monitoring EEG, cardiac and respiratory function, and movements during sleep. It is used to confirm fragmented sleep patterns in narcolepsy and sleep-related epilepsy.
2. Testing is time-consuming and labor-intensive. Procedures typically include multiple physiologic

measures, such as EEG, EMG, electrocardiogram [ECG]), heart rate, respiratory effort, air flow, and oxygen saturation.

Nursing and Patient Care Considerations

1. Explain that the electrodes placed on the scalp, chest, extremities, and face will be uncomfortable but do not deliver electrical current.
2. Reassure the patient that a technician will be in the next room.
3. Advise the patient to wear comfortable nightwear.

Multisleep Latency Test

Description

1. Multisleep latency test (MSLT) is a sleep study performed during the day. It is the most widely objective assessment of daytime sleepiness and is commonly used to confirm a diagnosis of narcolepsy.
2. Testing consists of four "napping" periods of 20 to 35 minutes, during which time the patient lies down on a bed in a darkened room and is allowed to fall asleep. The multiple short sleep periods during the MSLT increase the observation of rapid-eye-movement (REM) periods.

Nursing and Patient Care Considerations

1. Explain the time and duration of the naps.
2. Reassure the patient of freedom to move about between naps.
3. Tell the patient to wear comfortable clothing and to bring reading or other materials for use between naps.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 15-2

PROCEDURE GUIDELINES 15-2

Intracranial Monitoring/Licox Monitoring System/Microdialysis System

EQUIPMENT

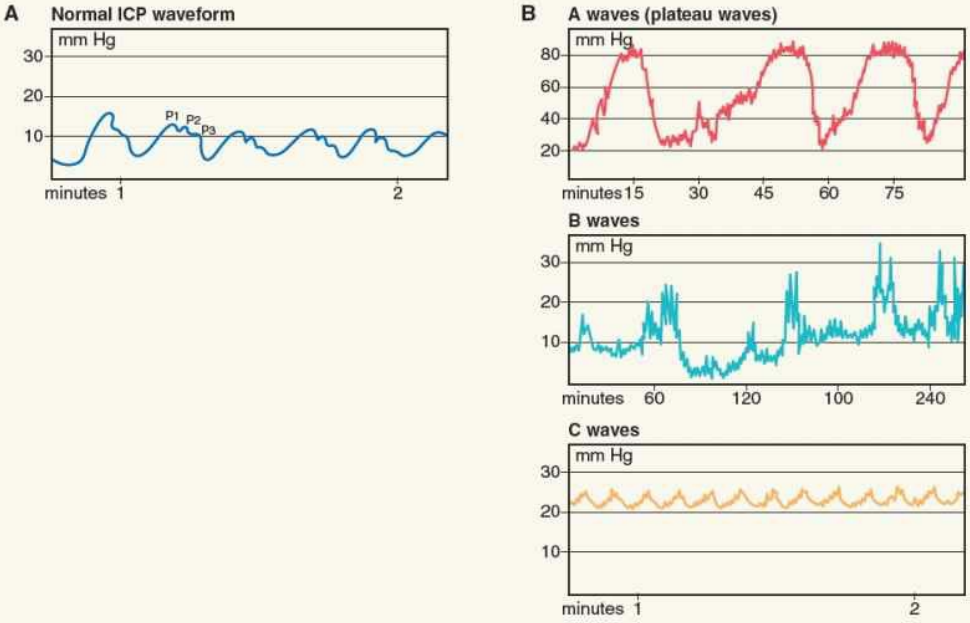
- Sterile gloves, mask, and surgical cap
- Monitoring system (intraventricular, subarachnoid, epidural)
- IV pole or stand on which to mount the system
- IV solutions, as ordered
- IV high-pressure tubing
- Burr hole tray for insertion or as needed
- Topical anesthetic
- Vital sign records

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain the need for extensive, continuous assessment and appropriate nursing intervention to the family and patient, if possible.	1. Explanations will decrease anxiety, allow patient and family a sense of control, and encourage compliance with procedure.
2. Gather and assemble equipment. Flush lines with ordered solution according to manufacturer's directions.	2. Availability of equipment will enhance success of procedure.
3. Calibrate equipment according to directions.	3. Accurate interpretation of intracranial pressure (ICP) values, wave patterns, cerebral temperature, and brain tissue partial pressure of oxygen will depend on appropriate baseline function.
4. Perform neurologic assessment.	4. Patient baseline must be established to determine changes and guide therapy.
5. Administer light sedation or analgesia if patient is agitated.	5. Procedure is invasive and injury may result with excessive patient movement.
Performance phase	
1. Establish head of bed at 30 degrees.	1. Head elevation is a conventional nursing intervention used to control elevated ICP and avoid complications in patients with neurotrauma. a. Head elevation facilitates venous drainage, decreasing intracranial volume, and prevents collapse of the ventricles if ventricular placement. b. However, elevating the head of the bed may decrease cerebral perfusion pressure, creating ischemia in those with low systolic BP.
2. Don mask and surgical cap.	2. Reduces risk of transmission of airborne bacteria.
3. Shave and cleanse the operative site.	3. Removes bacteria from the site, reducing the risk of infection.
4. Establish the sterile field.	4. Reduces the risk of infection.
5. Assist with burr hole and placement of intracranial monitoring system.	5. Direct monitoring of ICP allows for early detection of decompensation and management of complications.
6. Connect monitoring catheter to transducer/monitoring equipment according to directions.	6. Allows for conduction of intracranial and cerebral perfusion pressures (CPP) to the interpretive component of the system.
7. Observe numeric readings and wave patterns. Adjust characteristics to obtain optimal visual reading.	7. Changes in baseline readings indicate alterations in ICP or problems with the mechanics of the monitoring system.
8. Cover the catheter insertion site with a sterile dressing. Observe for possible cerebrospinal fluid (CSF) drainage depending on the placement of the catheter.	8. The skull and meninges have been penetrated, leaving the patient at risk for infection.
9. Adjust alarm system according to ordered parameters.	9. Alarms should be on at all times to alert the nurse of ongoing adverse changes.

Nursing Action	Rationale

KEY DECISION POINT Check ICP waveforms before nursing interventions such as turning or bathing the patient. The presence of an elevated P-2 wave indicates reduced cerebral compliance, meaning that the normal compensatory responses may not be effective in decreasing ICP. Thus, extra precautions and preventive actions should be taken prior to exposing the patient to additional stimuli. Nursing interventions may need to be postponed until cerebral compliance increases. Alert the health care provider if ICP >20 mm Hg and prepare for therapeutic intervention.



(A) Normal waveform; (B) A waves (plateau waves), B waves, and C waves.

Follow-up phase

1. Frequently assess the patient and the system to ascertain neurologic status, assessing ICP and CPP and patency of the system.	1. Manipulation of the system may inadvertently close the system, leaving the patient without benefit of monitoring.
2. Irrigate the system using sterile technique according to policy or as needed to maintain patency.	2. Irrigation helps maintain the patency of the system.
3. Report dampened waveforms, and have 1 mL of normal saline (without preservatives) available for irrigation, if indicated.	3. The tip of the catheter may have migrated against the ventricular wall or cerebral tissue depending on location, or ventricular collapse may be imminent. Irrigation is done by the health care provider in this case.
4. Assess head dressing for CSF drainage. Change dressing according to facility policy.	4. Because of its high glucose content, CSF is an excellent medium for bacterial growth.
5. Adjust the height of the transducer of the system to the level of the patient's ventricles (inner canthus of eye and tip of ear) with every position change for accurate readings and per orders.	5. Position of the transducer in relation to the ventricles will influence the accuracy of the readings because of fluid gradient pressures.

Nursing Management of the Patient with an Altered State of Consciousness

Unconsciousness is a condition in which there is a depression of cerebral function ranging from stupor to coma. Coma results from impairment in both the arousal and the awareness of consciousness. The arousal of consciousness is mediated by the reticular activating system (RAS) in the brain stem, whereas the awareness component is mediated by cortical activity within the cerebral hemispheres.

Both arousal and awareness are assessed when using the Glasgow Coma Scale (GCS) as a measure of LOC (see Table 15-2).

Table 15-2 Glasgow Coma Scale

PARAMETER	FINDING	SCORE
Eye opening	Spontaneously	4
	To speech	3
	To pain	2
	Do not open	1
Best verbal response	Oriented	5
	Confused	4
	Inappropriate speech	3
	Incomprehensible sounds	2
	No verbalization	1
Best motor response	Obeys command	6
	Localizes pain	5
	Withdraws from pain	4
	Abnormal flexion	3
	Abnormal extension	2
	No motor response	1

Interpretation: Best score = 15; worst score = 3; 7 or less generally indicates coma; changes from baseline are most important.

When using the GCS, *coma* may be defined as no eye opening on stimulation, absence of comprehensible speech, and failure to obey commands. The GCS is designed to provide a rapid assessment of LOC and does not provide a means to monitor or localize neurologic dysfunction. Facility-generated neurologic assessment tools may be used in combination with the GCS to assess, monitor, and trend neurologic function.

An altered state of consciousness may be caused by many factors, including hypoxemia; trauma; neoplasms; vascular, degenerative, and infectious disorders; as well as a variety of metabolic disorders and structural neurologic lesions. Diagnostic evaluation and management depend on the underlying cause, overall intracranial dynamics, age, comorbidities, and general state of health.

Nursing Assessment

1. Assess eye opening (level of responsiveness).

   Eye opening = arousal

   Tracking = awareness

2. Assess neurologic function using the GCS. The GCS addresses eye opening, verbal responses, and motor

responses. If the patient's eyes do not open spontaneously or to your voice, then assess responses using painful stimuli by applying pressure against the nail bed, trapezius/axillary pinch, or sternum. Use the least amount of pain for the best response.

3. Assess cognitive function.
    a. Orientation.
        i. Person, place, and time.
        ii. Where are you, why are you here.
        iii. General information—national and local current events.
    b. Speech—aphasia and other problems (see Table 15-3).
        i. Expressive aphasia (motor/Broca's)—inability to express self.
        ii. Receptive aphasia (sensory/Wernicke's)—inability to understand the spoken language.
        iii. Global aphasia—inability to speak or understand spoken language.
        iv. Other aphasia syndromes—amnesia, conduction.
    c. Other alterations include the following:
        i. Confabulation—fluent, nonsensical speech.
        ii. Perseveration—continuation of thought process with inability to change train of thought without direction or repetition.
4. Assess motor function—voluntary versus reflexive:
    a. Voluntary movement.
        i. Normal complex movement—strength and symmetry in the upper extremities (UE), pronator drift proximally and grip strength distally; in the lower extremities (LE), leg lifts proximally and dorsi/plantar flexion distally.
        ii. Localization—ability to determine location of stimuli; patient localizes area of painful stimuli.
        iii. Withdrawal—abduction of the upper extremity; moving away from the stimuli.
    b. Reflexive movement.
        i. Abnormal flexor posturing (decorticate)—dysfunction of corticospinal tracts above the brain stem. Abnormal flexion of the UE with adduction of the UE, internal rotation of the upper extremity, wrist and extension, and internal rotation and plantar flexion of the LE.
        ii. Abnormal extension posturing (decerebrate)—dysfunction of vestibulospinal tract and the RAS of the upper brain stem. Abnormal extension, hyperpronation, and adduction of the UE and wrist flexion; abnormal extension and internal rotation of the LE with plantar flexion of the feet and toes.
        iii. Mixed posturing—varied extensor and flexor tone in UE.
        iv. Flaccid—medullary compression with complete loss of motor tone.
5. Test cranial nerve (CN) reflexes to assess for brain stem dysfunction.
    a. Assess pupil size, symmetry, and reaction to light.
    b. Assess extraocular movements (CNs III, IV, VI) and reflex eye movements elicited by head turning

(oculocephalic response). This should not be performed on patients with suspected cervical spine injury, patients in a cervical collar, or patients known to have cervical spine injuries.

c. The oculovestibular (caloric) response (CNs III, IV, VI, VIII) is tested by medical staff when the patient is comatose, as part of the brain death examination.

d. Assess CNs V and VII together to evaluate facial pain, blink, eye closure, and grimace.

e. Assess CNs IX, X, XII to evaluate gag, swallowing reflex, tongue protrusion, and patient's ability to handle own secretions.

6. Assess respiratory rate and pattern (normal, Kussmaul, Cheyne-Stokes, apneic).
7. Assess deep tendon reflexes; evaluate tone for spasticity, rigidity, and paratonia (abnormal resistance increasing throughout flexion and extension, indicating frontal lobe dysfunction).
8. Examine head for signs of trauma, and mouth, nose, and ears for evidence of edema, blood, and CSF (may indicate basilar skull fracture).
9. Monitor any change in neurologic status over time and report changes to health care provider, as indicated.

Table 15-3 Differentiating Aphasia

APHASIA	FLUENCY	RATE	COMPREHENSION	GRAMMAR	REPETITION
Fluent (Wernicke/receptive aphasia)	Intact, although speech is nonsensical	Normal	Absent to poor	Intact	Intact
Nonfluent (Broca/expressive aphasia)	Poor	Slow, halting	Intact	Absent	Poor
Global	Poor	Slow	Absent	Absent	Poor
Conduction	Intact, although there is functional transposition of sounds with phonetic paraphrases	Normal	Intact	Intact	Poor
Anomic or amnesiac aphasia	Difficulty naming and finding words	Halting	Intact	Intact	Intact

KEY DECISION POINT A critical indicator of neurologic function is the LOC. A change in GCS of two or more points may be significant. If patient demonstrates deterioration, as evidenced by a change in neurologic examination, notify the health care provider without delay and reevaluate the neurologic status more often than required by orders based on nursing judgment.

Nursing Diagnoses

- Decreased Intracranial Adaptive Capacity.
- Ineffective Airway Clearance related to upper airway obstruction by tongue and soft tissues, inability to clear respiratory secretions.
- Risk for Imbalanced Fluid Volume related to inability to ingest fluids, dehydration from osmotic therapy (when used to reduce intracranial pressure [ICP]).
- Impaired Oral Mucous Membranes related to mouth breathing, absence of pharyngeal reflex, inability to ingest fluid.

- Risk for Impaired Skin Integrity related to immobility or restlessness.
- Impaired Tissue Integrity of cornea related to diminished/absent corneal reflex.
- Hyperthermia related to infectious process; damage to hypothalamic center.
- Impaired Urinary Elimination related to unconscious state.
- Bowel Incontinence related to unconscious state.

Nursing Interventions

Minimizing Secondary Brain Injury

1. Monitor for change in neurologic status, decreased LOC, onset of CN deficits.
2. Identify trends in neurologic function and communicate findings to medical staff.
3. Monitor response to pharmacologic therapy, including drug levels, as indicated.
4. Monitor laboratory data, CSF cultures, and Gram stain, if applicable, and communicate findings to medical staff.
5. Assess neurologic drains and dressings for patency and characteristics of drainage.
6. Institute measures to minimize risk for increased ICP, cerebral edema, seizures, or neurovascular compromise.
7. Adjust care to reduce risk of increasing ICP: body positioning in a neutral position (head aligned with shoulders) without flexing head, reduce hip flexion, distribute care throughout 24-hour period sufficiently for ICP to return to baseline.
8. Monitor temperature status; maintain normothermia. Institute cooling procedure as ordered.

Maintaining an Effective Airway

1. Position the patient to prevent the tongue from obstructing the airway, encourage drainage of respiratory secretions, and promote adequate exchange of oxygen and carbon dioxide.
2. Keep the airway free from secretions with suctioning. In the absence of cough and swallowing reflexes, secretions rapidly accumulate in the posterior pharynx and upper trachea and can lead to respiratory complications (eg, aspiration).
    a. Insert oral airway if tongue is paralyzed or is obstructing the airway. An obstructed airway increases ICP. This is considered a short-term measure.
    b. Prepare for insertion of cuffed endotracheal tube to protect the airway from aspiration and to allow efficient removal of tracheobronchial secretions.
    c. See page 176 for technique of tracheal suctioning.
    d. Use oxygen therapy as prescribed to deliver oxygenated blood to the CNS.
    e. Before suctioning, pretreat with sedative, opioid, or endotracheal lidocaine, if indicated.

Attaining and Maintaining Fluid and Electrolyte Balance

1. Monitor prescribed IV fluids carefully, maintaining euvolemia and minimizing large volumes of "free water," which may aggravate cerebral edema.

2. Maintain hydration and enhance nutritional status with use of enteral or parenteral fluids.
3. Measure urine output.
4. Evaluate pulses (radial, carotid, apical, and pedal) and measure BP; these parameters are a measure of circulatory adequacy/inadequacy.
5. Maintain circulation; support the BP and treat life-threatening cardiac dysrhythmias.

Maintaining Healthy Oral Mucous Membranes

1. Remove dentures. Inspect the patient's mouth for dryness, inflammation, and the presence of crusting.
2. Provide mouth care by brushing teeth and cleansing the mouth with appropriate solution every 2 to 4 hours to prevent parotitis (inflammation of parotid gland).
3. Apply lip emollient to maintain hydration and prevent dryness.

Skin Integrity

1. Keep the skin clean, dry, well lubricated, and free from pressure because comatose patients are susceptible to the formation of pressure ulcers.
