5. When used as basal insulin, NPH is typically administered twice daily—in the morning to address

afternoon hyperglycemia and again at bedtime to provide overnight coverage. Typically, $_2/^3$ to $_3/^4$ of the daily dosage is given before breakfast and $_1/^3$ to $_1/^4$ is given at bedtime.

Basal Plus Prandial Insulin (Figure 25-1B, 2 Mixed Injections/Day)

1. Short-acting regular insulin or rapid-acting lispro, glulisine, or aspart insulin is added to NPH to promote postprandial glucose control.
2. Short- or rapid-acting insulin added to morning NPH controls glucose elevations after breakfast.
3. Increased blood glucose levels after supper can be controlled by the addition of short- or rapid-acting insulin before supper.
4. NPH and regular, lispro, glulisine, or aspart insulin given before breakfast and before supper is termed a "split-mix" regimen, providing 24-hour insulin coverage. However, there is an increased risk of nocturnal hypoglycemia (2:00 to 3:00 A.M.) when NPH is given before supper. Therefore, an alternative is to administer the prandial insulin alone before the evening meal and the NPH at bedtime (see Figure 25-1C).

Intensive Insulin Therapy (Figure 25-1D)

1. Designed to mimic the body's normal insulin responses to glucose.
2. Characterized by at least 1 basal injection daily with additional mealtime injections for every meal and snack consumed. Typically consists of four to five injections of insulin daily.
3. Long-acting (detemir or glargine insulin) or ultra–long-acting (glargine u-300 or degludec insulin) analog is used for basal insulin control. These are often administered once daily at bedtime; however, any time of the day can be used for the once-daily administration and this allows for greater patient adherence.
4. Regular insulin acts as a premeal bolus given 30 minutes before each meal. However, analog rapid-acting insulin (lispro, glulisine, or aspart) are used more frequently instead of regular. The rapid-acting insulin is taken within 1 to 15 minutes before eating. As with NPH, regular human insulin is available without a prescription and is often a more affordable choice for some patients.
5. Twenty-four–hour insulin coverage designed in this way can be flexible to accommodate mealtimes and physical activity.

Sliding Scale versus Algorithm Therapy

1. Sliding scale therapy uses short- or rapid-acting insulin to retrospectively correct hyperglycemia. Sliding scale dosing is not recommended because it fails to prevent and adequately address hyperglycemia and places patients at significant risk for hypoglycemia hours later.
2. Algorithm therapy prospectively determines short- or rapid-acting insulin dosages, considering meal content, premeal blood glucose level, and physical activity.
3. Individualization of insulin dosages is the most important aspect of sliding scale and algorithm therapy.
   a. The patient is encouraged to test blood glucoses to analyze insulin dose response.
   b. A pattern of increased blood glucose associated with certain foods (eg, pasta, pizza) can help

determine the appropriate regimen of insulin dosage.

c. Physical activity, which enhances insulin activity and decreases serum glucose, may indicate the need to reduce the dosage of premeal insulin.

Continuous Subcutaneous Insulin Infusion (Insulin Pump Therapy)

Pump therapy is more commonly considered for treatment of T1DM, but it is becoming more common in the treatment of T2DM when multiple daily injections/intensive insulin management is required.

1. Continuous subcutaneous insulin infusion (CSII) or insulin pump therapy provides continuous infusion of regular, lispro, glulisine, or aspart insulin via subcutaneous catheter.
2. There are several different pumps available. The type of insulin pump used by the patient is determined by the patient with the guidance of an expert clinician.
3. The catheter should be replaced every 72 hours or sooner if the site becomes painful or inflamed.
   a. Usually, the insulin pump is removed for bathing and tubing and catheter are changed at that time. Several pumps are waterproof and do not need to be disconnected with bathing, showering, or even swimming.
   b. To reduce tubing and catheter blockage, diluted insulin may be used. However, this is less of a problem with the newer insulin analogs (lispro, glulisine, and aspart).
   c. A tube-free pump is available. The patient wears a "pod" filled with enough insulin to last 2 to 3 days. The pod is discarded and a new pod placed every 2 to 3 days. The delivery of insulin is remotely controlled via a handheld device.
4. Intensive insulin management by pump therapy requires patient motivation.
   a. Blood glucose monitoring must be done at least four to six times per day. Most insulin pumps are now available as integrated systems, which utilize CGM. (See Glucose Monitoring.)
   b. Frequent contact with health care team is necessary to adjust insulin dosage.
   c. Careful recordings of diet, insulin, and activity are required to evaluate adjustments.
   d. Increased cost of insulin pump and infusion set compared to usual syringe method.
   e. Heightened risk of hypoglycemia with tighter glucose control.
   f. Danger of hyperglycemia exists should insulin catheter become kinked or dislodged, and patient then fails to receive appropriate insulin dosage.
   g. Increased visibility of diabetes by use of an external device, although newer pumps are smaller and more discreet.
5. Advantages of CSII in improving blood glucose control:
   a. Insulin pump can deliver basal insulin at individualized programmed rates throughout a 24-hour period.
   b. Bolus injections of short-acting insulin given 30 minutes before eating or rapid-acting insulin no more than 15 minutes before a meal allow for flexibility in meal content and timing.
   c. Correction supplements of short- or rapid-acting insulin are easily given to rapidly correct elevated glucose levels.

Combination Noninsulin Agents and Insulin Therapy

1. Except for using pramlintide in addition to insulin, all other combinations of insulin with noninsulin agents are only FDA-approved to be used for patients with T2DM.
2. Always refer to the full prescribing information for each noninsulin agent to determine if and how they are FDA-approved for use with insulin therapy.
3. Because of the increased risk for hypoglycemia, concomitant use of insulin and sulfonylureas is not recommended.

DIABETES MELLITUS AND RELATED DISORDERS

See additional online content: Procedure Guidelines 25-3

PROCEDURE GUIDELINES 25-3

Foot Care Guidelines

Perform foot care and teach the patient the following guidelines.

EQUIPMENT

- Mirror (optional)
- Moisturizing lotion or cream
- Toenail clipper and nail file
- Magnifying glass (optional)
- Lamb's wool (if needed)

PROCEDURE

Teaching Action	Rationale/Comment
1. Inspect the feet carefully and daily for calluses, corns, blisters, abrasions, redness, and nail abnormalities.	1. a. Use a small mirror to check bottom of each foot. b. Use a magnifying glass under good light if eyesight is poor, or have someone else check feet.
2. Bathe the feet in warm (never hot) water.	2. a. Do not soak the feet for prolonged periods (soaking is drying). b. Dry feet carefully, especially between the toes.
3. Massage the feet with an absorbable agent.	3. a. Use lanolin or a cream moisturizer, but avoid between the toes to prevent maceration.
4. Prevent moisture between the toes to prevent maceration of the skin.	4. a. Insert lamb's wool between overlapping toes. b. Use foot powder, especially if feet perspire.
5. Wear well-fitting, noncompressive shoes and socks—long enough, wide enough, soft, supple, and low-heeled.	5. a. Buy shoes with a wide toe box for room to wiggle toes without friction. b. Buy shoes in the afternoon—feet are larger in the afternoon than in the morning. c. Have each foot measured before buying shoes—feet enlarge with age. d. Have the measurement taken while standing because foot is larger in the standing position. e. Do not "break in" shoes all at one time. f. Avoid rubber- or plastic-soled shoes or vinyl shoes, which cause the feet to perspire and aggravate fungal infections. g. Avoid walking in soft-soled bedroom slippers or other nonsupportive footwear.
6. Go to a podiatrist on a regular basis if corns, calluses, and ingrown toenails are present.	6. a. Trim toenails straight across to prevent ingrown toenails. b. File any rough corners with an emery board.
7. Avoid heat, chemicals, and injuries to the feet.	7. a. Do not go barefoot or expose feet to hot-water bottles, heating pads, caustic solutions. b. Check bath temperature with thermometer or elbow before bathing if neuropathy is present. c. Switch off electric blanket before going to bed; wear socks at night to keep feet warm, if necessary. d. Avoid sitting too close to a fire.
8. Inspect inside of shoes for foreign objects or areas of roughness.	8. a. Inspect seams and lining of shoes for possible areas of pressure or abrasion. b. Avoid the use of constricting sandals, high heels, or boots, which are more likely to cause injury.
9. Take action if an injury occurs to the foot.	9. a. Wash the area with mild soap and water. b. Cover with a dry sterile dressing without adhesive. c. Wear white cotton socks; dye in colored socks and wool may serve as irritants when skin is already irritated. d. Call health care provider.

Diabetes Mellitus

Diabetes mellitus is a metabolic disorder characterized by hyperglycemia and results from defective insulin production, secretion, or utilization. T1DM in children is covered in Chapter 50.

Pathophysiology and Etiology

1. There is an absolute or relative lack of insulin produced by beta cells, resulting in hyperglycemia.
2. Defects at the cell level, impaired secretory response of insulin to rises in glucose, and increased nocturnal hepatic glucose production (gluconeogenesis) are seen in type 2 diabetes.
3. Etiology of type 1 diabetes is not well understood; viral, autoimmune, and environmental theories are under review.
4. Etiology of type 2 diabetes involves heredity, genetics, and obesity.
5. Risk factors for type 2 diabetes in adults and children include family history and ethnicity and a variety of other factors (see page 728).

Clinical Manifestations

1. Onset is usually abrupt with T1DM and insidious with T2DM.
2. Classic symptoms of hyperglycemia include polyuria, polydipsia, polyphagia, weight loss, fatigue, and blurred vision.
3. Chronic hyperglycemia often presents as disorders of altered tissue response, evidenced by poor wound healing and recurrent infections of the skin and genitourinary tract.

Diagnostic Evaluation

See page 729.

Management

EVIDENCE BASE AACE/ACE. (2018). Consensus statement by the AACE and ACE on the comprehensive type 2 diabetes management algorithm—2018 Executive Summary. *Endocrine Practice, 24*(1), 91–120.

ADA. (2018). Standards of medical care in diabetes—2018. *Diabetes Care, 41*(Suppl. 1).

A multidisciplinary approach, which combines diet, exercise, behavioral/psychosocial therapy, and pharmacological agents, is required to optimally manage glucose control and the comorbid conditions of hypertension, dyslipidemia, and obesity.

Diet

1. The goal of meal planning is to meet nutritional requirements essential for healthy growth/development,

achieve/maintain healthy weight, and control blood glucose and lipid levels (see Table 25-2).

2. Weight reduction is a primary treatment for T2DM. A target of greater than 5% weight loss is desired.
3. Medical nutrition therapy should be conducted by a registered dietitian, preferably one who is also a certified diabetes educator.

Table 25-2 Meal Planning Guidelines

PRINCIPLE	ACTION
Each meal should consist of a balance of carbohydrates, proteins, and fats.	• Carbohydrates should be varied to include fruits, starches, and vegetables. • Protein selections that are lean will help reduce fat and cholesterol intake. • Fats should be used sparingly with <10% of total calories derived from saturated fats. High in calories, fats contribute to weight gain in type 2 diabetes mellitus (DM).
Consistency in timing of meals and amounts of food eaten on a day-to-day basis help regulate blood glucose levels.	• Avoid skipping or delaying meals. • Measure portion sizes using a scale or measuring cups. • Know the equivalent amounts of commonly used foods within a food group (eg, 1 slice of bread = ½ cup cooked pasta).
Increase the intake of soluble and insoluble fiber.	• Substitute foods high in fiber for processed foods when possible (eg, whole-grain bread in place of white bread). • Eat fresh fruits and vegetables in place of juices.
Avoid salt whenever possible.	• Do not season foods with salt or salt-containing spices. • Limit use of foods with "hidden" sodium content (eg, crackers, pickled foods, cheese, processed meats). • Use salt-containing condiments sparingly (ketchup, soy sauce, gravies, bouillon).
Prepare foods to retain vitamins and minerals and reduce fats.	• Do not fry foods. • Bake, broil, or boil foods and discard fat. • Eat raw fruits and vegetables or steam vegetables to retain fiber. • Avoid adding calories with butter or cream sauces, fatback, and bacon. • Trim all visible fat from meat; skim off fat from stews or other prepared dishes.
Distribute snacks in the meal plan depending on insulin/medication regimens, physical activity, and lifestyle.	• Smaller, more frequent meals may enhance glucose control in type 2 DM. • Unplanned activity may call for an additional snack to avoid hypoglycemia.
Use alcohol only in moderation.	• Always consume alcohol with food to avoid hypoglycemia. • Do not omit food from meal plan in exchange for alcohol. • Limit intake to 1 to 2 drinks/wk (4 oz. dry wine, 12 oz. beer, or 1.5 oz. distilled liquor = 1 alcohol serving).
Use alternative nonnutritive, noncaloric sweeteners in moderation.	• Limit "diet" soda intake to 2 L/day. • Avoid frequent use of foods and beverages with concentrated sucrose.

Exercise

Regularly scheduled, moderate exercise performed 30 to 60 minutes at least every other day promotes the utilization of carbohydrates, assists with weight control, enhances the action of insulin, and improves cardiovascular fitness.

Psychosocial Care

1. Psychosocial care should be an integrated component of comprehensive diabetes management for all patients with diabetes.
2. Assess for symptoms of diabetes distress, depression, anxiety, disordered eating, and cognitive capacity.
3. Assess for life circumstances that impact patient ability to perform self-care management. Include input from family members/caregivers.
4. Promptly refer to behavioral health specialist when problems are identified.

EVIDENCE BASE Young-Hyman, D., de Groot, M., Hill-Briggs, F., Gonzalez, J. S., et al.

(2016). Psychosocial care for people with diabetes: A position statement of the ADA. *Diabetes Care, 39*(12), 2126–2140.

Medication

Both the ADA and AACE/ACE treatment algorithms place emphasis on individualizing pharmacological treatment based on effectiveness, risk of hypoglycemia, risk of weight gain, cost, and patient preferences. Lifestyle management (diet and exercise) will always remain the cornerstone of management even when medications are required. Insulin is always an appropriate therapy for glucose management and should be discussed with the patient early in the disease process to alleviate fears and other stigma associated with its use.

Only insulin and amylin analogs are approved for use in patients with T1DM.

1. Oral and injectable antidiabetic agents for patients with T2DM who do not achieve glucose control with diet and exercise only (see Table 25-3, pages 736 to 737).
2. Insulin therapy is essential for patients with T1DM who require replacement (see pages 731 to 735). Insulin therapy may also be used for T2DM when glucose management is unresponsive to diet, exercise, and noninsulin therapy as well as when β-cell failure progresses or they are unable to tolerate/safely use other diabetes medications.

DRUG ALERT Hypoglycemia may result from insulin therapy as well as rebound hyperglycemia (Somogyi effect). Insulin therapy commonly results in increased appetite and weight gain.

---

3. Sulfonylurea compounds promote the increased secretion of insulin by the pancreas and partially normalize both receptor and postreceptor defects.
   a. Many drug interactions exist, so patient should alert all health care providers of use.
   b. Potential adverse reactions include hypoglycemia, photosensitivity, GI upset, allergic reaction, reaction to alcohol, cholestatic jaundice, and blood dyscrasias.
4. Metformin, a biguanide compound, appears to diminish insulin resistance. It decreases hepatic glucose production and intestinal reabsorption of glucose and increases insulin reception and glucose transport in cells.
   a. Many drug interactions exist, so patient should alert all health care providers of its use.
   b. Metformin must be used cautiously in renal insufficiency, conditions that may cause dehydration, and hepatic impairment.
   c. Potential adverse reactions include GI disturbances, metallic taste, and lactic acidosis (rare). Riomet is the only formulation available as an oral solution.

DRUG ALERT Lactic acidosis is a rare complication of metformin that prompts caution when dehydration, vomiting, diarrhea, fasting states, hemodynamic instability, heavy alcholol use, and use of iodinated contrast media occur.

5. Alpha glucosidase inhibitors (AGI) (acarbose and miglitol) delay the digestion and absorption of complex carbohydrates (including sucrose or table sugar) into simple sugars, such as glucose and fructose, thereby lowering postprandial and fasting glucose levels.
   a. Contraindicated in inflammatory bowel disease and other conditions of the intestinal tract. They are used cautiously in renal insufficiency and with several other drugs.
   b. Flatulence, abdominal pain, and diarrhea are common.
   c. If these medications are taken in conjunction with insulin secretagogues (ie, sulfonylureas) and hypoglycemia occurs, patient must use a monosaccharide (glucose tablets) or milk to treat hypoglycemia because sucrose will not be broken down to an absorbable sugar. Juice will not be effective.
6. Thiazolidinedione (TZD) derivatives (rosiglitazone and pioglitazone) primarily decrease resistance to insulin in skeletal muscle and adipose tissue without increasing insulin secretion. Secondarily, they reduce hepatic glucose production.
   a. They should be used cautiously in liver disease and heart failure. Liver function tests should be monitored periodically.
   b. Ovulation may occur in anovulatory premenopausal women.
   c. Adverse reactions include edema, weight gain, anemia, elevation in serum transaminases, and increased incidence of bone fracture.
   d. Pioglitazone is associated with increased risk of bladder cancer; therefore, it should not be used in patients with a history of bladder cancer.
   e. Thiazolidinediones themselves do not cause hypoglycemia; however, when administered with insulin or oral medications that increase the secretion of insulin, the risk for hypoglycemia is increased. Be aware that insulin requirements will reduce with TZD therapy, so glucose monitoring and insulin adjustments should be done regularly.

DRUG ALERT Both pioglitazone and rosiglitazone can cause or worsen heart failure and are contraindicated for use in patients with New York Heart Association class III or class IV heart failure.

7. Meglitinide analogues (repaglinide) and amino acid derivatives (nateglinide) stimulate pancreatic release of insulin in response to a meal. They have a more rapid onset and shorter duration than sulfonylureas.

a. Should not be taken when a meal is skipped or missed.
b. Should be used cautiously in patients with renal and hepatic dysfunction and may cause hypoglycemia.

8. Dipeptidyl peptidase 4 inhibitors (DPP-4i) (sitagliptin, linagliptin, saxagliptin, alogliptin) inhibit the breakdown of glucagon-like peptide-1 (GLP-1). GLP-1 stimulates insulin release from the pancreas and decreases glucagon secretion, which inhibits glycogenolysis and gluconeogenesis. These agents are most effective at controlling postprandial blood glucose and, when used alone or in combination with metformin or TZD, do not cause hypoglycemia.
   a. Dose is based on renal function.
   b. Generally well tolerated and weight-neutral. Adverse reactions include upper respiratory infections, nasopharyngitis, and headaches.
   c. Can be combined with all other diabetes medication except for those in the GLP-1 RA class.

NURSING ALERT Patients with a history of pancreatitis should not be prescribed either DPP4-i or GLP-1 RA.

---

9. Sodium glucose cotransporter 2 inhibitors (SGLT2i) (canagliflozin, empagliflozin, dapagliflozin, ertugliflozin) block glucose absorption in the proximal renal tubule by inhibiting SGLT2 receptors. Glucose is excreted in the urine, which leads to modest weight loss and some improvement in systolic blood pressure.
   a. Dose is based on renal function.
   b. These have been known to cause ketoacidosis in the absence of significant glucose elevations (euglycemic diabetic ketoacidosis), especially in patients who are ill, suffer trauma, or require surgery. These should be stopped and resumed only when patient is stable. Patients should be advised to stop these medications and seek medical assistance immediately if they experience any symptoms consistent with DKA (nausea/vomiting, abdominal pain).
   c. Adverse reactions include urinary tract infections (cystitis and mycotic infection of the genital tract) in both men and women.
10. Bile acid sequestrant (colesevelam) is traditionally a cholesterol-lowering agent that has now been indicated for the treatment of T2DM. The exact mechanism of action is unclear but may have effect on sensitizing the liver to insulin, reducing hepatic glucose production. May also work by reducing intestinal absorption of glucose.
    a. Side effects include nausea, bloating, and constipation.

DRUG ALERT Bile acid sequestrant cause triglyceride levels to rise and therefore should not be

used in patients with baseline elevation of triglyceride levels.

---

11. Dopamine agonist (bromocriptine) is another agent in which the mechanism of action is unclear and its role in diabetes management ill defined. It is believed it acts to reduce glucose levels by reducing the effects of insulin resistance on the central nervous system.
    a. Side effects include hypotension and syncope, especially with dose titrations. Proceed slowly and cautiously, especially in older patients.
12. GLP-1 receptor agonists (GLP-1 RA) (exenatide, liraglutide, exenatide long-acting, albiglutide, dulaglutide, lixisenatide, semaglutide) work to lower blood glucose by enhancing first-phase insulin secretion by the pancreas, slowing gastric emptying, suppressing glucagon secretion, and reducing appetite, which can facilitate weight loss.
    a. Exenatide is injected twice daily within 1 to 60 minutes before breakfast and dinner.
    b. Liraglutide is injected once daily without regard to meals.
    c. Lixisenatide is also injected once daily but recommended before breakfast.
    d. Exanatide long-acting, albiglutide, dulaglutide and semaglutide are all injected once-weekly. They differ in the preparation involved prior to administration. These tend to be better tolerated than the agents requiring more frequent administration.
    e. These are used as add-on therapy to all other diabetes medication with the exception of DPP-4; all but long-acting exenatide are approved for use with insulin. Please refer to full prescribing information available with each product. They are not to be used as a substitute for insulin.
    f. Most common adverse effects are nausea and vomiting. Other adverse reactions include GI upset, headache, and pancreatitis.
    g. All are available in a disposable pen device.
    h. Lixisenatide and liraglutide are each available as daily fixed ratio combination therapies with long-acting insulin (lixisenatide plus insulin glargine; liraglutide plus insulin degludec).

DRUG ALERT GLP-1 RA can cause hypoglycemia when used with sulfonylureas or insulin. They should not be used in patients with severe GI disorders, such as gastroparesis, and used cautiously when renal impairment is present. They have also been associated with medullary thyroid cancer in rodents.

---

13. Amylin analog (pramlintide). Amylin is cosecreted by the B cells of the pancreas to assist with postprandial glucose control. Its actions are like GLP-1 incretin mimetics (reduced gastric emptying, suppression of glucagon, increased satiety, and weight loss). It is indicated for patients with either type 1 or type 2 diabetes who require a mealtime insulin bolus.
    a. It is not a substitute for insulin but must be administered immediately prior to meals that must consist of at least 250 kcal or at least 30 g of carbohydrates.

b. If used with insulin, mealtime dose of insulin must be reduced by 50%. Pramlintide cannot be mixed with insulin and must be injected at least 1 inch (2.5 cm) away from insulin injection site.

c. It is contraindicated in patients with confirmed gastroparesis and should be used with caution in patients who require the use of drugs to stimulate gastric motility.

d. The most common adverse effects are GI related (nausea/vomiting). It is available in a disposable pen device.

Table 25-3 Antidiabetic Medications (Noninsulin)

AGENT	HOW GIVEN
Insulin-Secreting Agents	
Second-Generation Sulfonylureas	
• Glyburide	1.25–20 mg PO in single or divided doses with meals
• Glyburide, micronized	0.75–12 mg PO in single or divided dose
• Glipizide	2.5–40 mg PO in single or divided doses with meals
• Glipizide, long-acting	2.5–20 mg PO in single dose, usually before breakfast
• Glimepiride	1–8 mg PO in single dose with first main meal
Meglitinide Analog	
• Repaglinide	0.5–16 mg PO in 2–4 divided doses, 1–30 min before meals Do not take if meal is skipped.
Amino Acid Derivative	
• Nateglinide	120–360 mg PO in 3 divided doses, 1–30 min before meals Do not take if meal is skipped.
Insulin-Sensitizing Agents	
Biguanides	
• Metformin	500–2,550 mg PO in 2–3 divided doses
• Metformin, long-acting	500–2,000 mg PO in single or two divided doses
Thiazolidinediones	
• Pioglitazone	15–45 mg PO once daily
• Rosiglitazone	4–8 mg PO in single or two divided doses
Glucose Absorption–Delaying Agents	
Alpha Glucosidase Inhibitors	
• Acarbose	50–300 mg PO in 3 divided doses before meals
• Miglitol	50–300 mg PO in 3 divided doses before meals

Incretin Agents	
DPP-4 Inhibitors	
• Sitagliptin	25–100 mg PO once daily
• Linagliptin	5 mg PO once daily
• Saxagliptin	2.5–5 mg PO once daily
• Alogliptin	6.25–25 mg PO once daily
GLP-1 Receptor Agonists	
• Exenatide	5–10 mcg subcutaneously twice daily 1–60 min before meals
• Liraglutide	1.2–1.8 mg subcutaneously once daily
• Lixisenatide	10–20 mcg subcutaneously once daily
• Exenatide, extended release	2 mg subcutaneously every 7 days
• Albiglutide	20–50 mg subcutaneously every 7 days
• Dulaglutide	0.75–1.5 mg subcutaneously every 7 days
• Semaglutide	0.5–1 mg subcutaneously every 7 days
Glucose-Excreting Agents	
SGLT2 Inhibitors	
• Canagliflozin	100–300 mg PO once daily
• Empagliflozin	10–25 mg PO once daily
• Dapagliflozin	5–10 mg PO once daily
• Ertugliflozin	5–15 mg PO once daily
Amylin Analog	
• Pramlintide	Type 1: 15–60 mcg subcutaneously with each main meal Type 2: 60–120 mcg subcutaneously with each main meal
Other Agents	
Bile Acid Sequestrant	
• Colesevelam	625 mg tablets: 3 tabs PO twice daily or 6 tabs PO once daily
Dopamine Agonist	
• Bromocriptine	0.8–4.8 mg PO once daily in the morning
Combination Agents with Brand Names	
• Actoplus Met, Actoplus Met XR (pioglitazone + metformin)	• Kazano (alogliptin + metformin)
• Amaryl M (glimepiride + metformin)	• Kombiglyze XR (saxagliptin + metformin)
• Avandamet (rosiglitazone + metformin)	• Metaglip (glipizide + metformin)
• Avandaryl (rosiglitazone + glimepiride)	• Oseni (alogliptin + pioglitazone)
• Duetact (pioglitazone + glimepiride)	• PrandiMet (repaglinide + metformin)
• Glucovance (glyburide + metformin)	• Qtern (dapagliflozin + saxagliptin)
• Glyxambi (linagliptin + empagliflozin)	• Soliqua 100/33 (lixisenatide + insulin glargine)
• Invokamet, Invokamet XR (canagliflozin + metformin)	• Steglatro (ertugliflozin + metformin)
• Janumet, Janumet XR (sitagliptin + metformin)	• Steglujan (ertugliflozin + sitagliptin)
• Jentadueto (linagliptin + metformin)	• Synjardy (empagliflozin + metformin)
	• Xigduo, Xigduo XR (dapagliflozin + metformin)
	• Xultophy 100/3.6 (liraglutide + insulin degludec)

DPP-4, dipeptidyl peptidase 4; GLP-1 RA, glucagon-like peptide-1 receptor agonist; PO, by mouth; XR, extended release.

DRUG ALERT Pramlintide may cause severe insulin-induced hypoglycemia and is contraindicated in patients with hypoglycemia unawareness.

General Health

In addition to the glycemic and A1C goals discussed previously, prevention and management guidelines have been established for blood pressure (BP), lipid values, and kidney function to prevent complications. Patients with diabetes are at a much higher risk for cardiovascular disease than the general population; therefore, cardiovascular risk factors must be monitored and aggressively treated. Several authoritative groups recommend the following goals of treatment for nonpregnant adults, adolescents, and children with diabetes mellitus.

EVIDENCE BASE AACE/ACE. (2018). Consensus statement by the AACE and ACE on the comprehensive type 2 diabetes management algorithm—2018 Executive Summary, *Endocrine Practice, 24*(1), 91–120.

Adults:

1. BP < 140/90 mm Hg (all ages) (ADA); <130/80 mm Hg (AACE/ACE; Whelton, et al.); pregnant women: 120 to 160/80 to105 mm Hg
   a. Measure at every visit; goal may be individualized.
2. Lipid control (all ages)
   a. Low-density lipoprotein less than 100 mg/dL.
   b. High-density lipoprotein greater than 40 mg/dL; greater than 50 mg/dL women.
   c. Triglycerides less than 150 mg/dL.
   d. Diabetes is considered an independent risk factor for cardiovascular disease; therefore, according to the ACA/AHA guidelines, all patients with diabetes between the ages of 45 and 75 years should be prescribed a moderate-intensity statin (without regard to the above parameters). More aggressive treatment is recommended if additional cardiovascular risk factors are present. Use careful consideration of benefit/risk ratio when prescribing statin therapy in adults younger than 45 and older than 75 years of age.
   e. Statins are contraindicated during pregnancy; use with extreme caution in all women of child-bearing age.
3. Microalbumin (spot urine) less than 30 mg/g creatinine (monitor at least annually).
4. Aspirin (75 to 162 mg/day) for most men and women ≥50 years with at least one additional major cardiovascular risk factor.

Children and adolescents:

1. BP below the 90th percentile for sex, age, and height.
2. Lipid control:
   a. Low-density lipoprotein less than 100 mg/dL. Statin may be required if LDL greater than 160 despite lifestyle modifications

Complications

Acute

1. Hypoglycemia (blood glucose ≤70 mg/dL) occurs because of an imbalance in food, activity, and insulin/oral antidiabetic agent. Blood glucose less than 54 mg/dL is considered serious, clinically important hypoglycemia.
2. Diabetic ketoacidosis (DKA) occurs primarily in type 1 diabetes during times of severe insulin deficiency

or illness, producing severe hyperglycemia, ketonuria, dehydration, and acidosis (see page 748).

3. Hyperosmolar hyperglycemic state (HHS) primarily affects patients with type 2 diabetes, causing severe dehydration, hyperglycemia, hyperosmolarity, and stupor (see page 749).

Chronic

See Table 25-4.

Table 25-4 Chronic Complications of Diabetes Mellitus

CONDITION	ASSESSMENT
Macrovascular Complications	
Cerebrovascular Disease	
• *Incidence:* Two to four times more likely in diabetes. • Hypertension, increased lipids, smoking, uncontrolled blood glucose, increase risk of stroke and transient ischemic attack	• Increased BP • Change in mental status • Hemiparesis • Aphasia • Clinical presentation mimics that of nondiabetic patient.
Coronary Artery Disease	
• *Incidence:* Increased vessel disease with more vessels affected in diabetes. Higher incidence of "silent" myocardial infarctions (MIs). • Hyperglycemia contributes to atherosclerosis and vessel deterioration.	• Severe CAD is commonly asymptomatic, seen only in ECG changes. ECG changes may indicate silent MI. • Symptoms can also present as pain in the jaw, neck, or epigastric area.
Peripheral Vascular Disease	
• *Incidence:* 60% of nontraumatic amputations are related to diabetes. • Intermittent claudication, absent pedal pulses, and ischemic gangrene are increased in diabetes.	• Physical examination of the lower extremities may reveal changes in skin integrity associated with diminished circulation. • Decreased lower leg hair, absent or decreased anterior tibial or dorsal pedis pulses, poor capillary refill of toenails may occur. The extremity may appear pale/cool. Further examination for neurologic changes is indicated.
Microvascular Complications	
Retinopathy	
• *Incidence:* Type 1—Will develop after 3–5 yr of diagnosis and by 15–20 yr of diabetes duration. Almost all patients will have some degree of retinopathy. Type 2—Approximately 7% present with retinopathy at diagnosis, which increases to 50%–80% after 20 yr. DM is the leading cause of preventable blindness in the United States. • Appearance of hard exudates, blot hemorrhages, and microaneurysms on the retina in background retinopathy. Progresses to neovascularization in proliferative diabetic retinopathy.	• Usually asymptomatic in the early stages. Symptoms occurring with acute visual problems—"floaters," flashing lights, blurred vision—may indicate hemorrhage or retinal detachment. Funduscopic examination should be done by an ophthalmologist for full retinal visualization.
Nephropathy	
• *Incidence:* Type 1—20% to 30% will have renal impairment after 15-yr duration of diabetes; 4%–17% will progress to end-stage renal disease (ESRD) after 20 yr. Type 2—25% will have at least mild renal impairment and another 5% will have ESRD after 10 yr of diabetes duration. The incidence is higher in Native Americans, Hispanics, and blacks. DM is the leading cause of kidney failure in the United States. • Thickening of the glomerular basement membrane, mesangial expansion, and renal vessel sclerosis are caused by diabetes. • Subsequently, diffuse and nodular intercapillary glomerulosclerosis diminishes renal function.	• Evidence of increased glomerular filtration rate. • Microalbuminuria is the first clinical sign of renal disease. • Elevation in blood urea nitrogen and creatinine levels indicates advanced renal disease. • Gross proteinuria is a further indication of renal deterioration.
Peripheral Neuropathy	
• In general, neuropathy affects 60%–70% of persons with diabetes, with nearly 50% asymptomatic. • It can affect almost every organ system with varying specific symptoms. • Distal symmetrical polyneuropathy involving the lower extremities is most commonly seen. • In conjunction with peripheral vascular disease, neuropathy to the feet increases susceptibility to trauma and infection. The more severe forms of peripheral neuropathy are a major contributing cause of lower extremity amputations. • Three clinical syndromes of distal symmetrical polyneuropathy are seen: acute painful, small-fiber, and large-fiber neuropathy.	• Decreased light touch, vibratory, temperature sensation. Loss of foot proprioception, followed by ataxia, gait disturbances. • Diminished ankle jerk response. • Formation of "hammertoes," Charcot joint disease, which predispose patient to new pressure point areas. • Hypersensitivity or other dysesthetic symptoms are experienced, followed by hypnoanesthesia or anesthesia, which is not reversible.
Autonomic Neuropathy	
Cardiac Autonomic Neuropathy	
• Affects 30% of patients with T1DM after 20 yr and 60% of patients with T2DM after 15 yr. • Asymptomatic in early stages. Loss of heart rate variability detected on ECG. • Late stages: resting tachycardia, orthostatic hypotension, exercise intolerance. • >3-fold mortality; 38% "silent" MI	• Patients may report episodes of syncope, weakness, or visual impairment, particularly with positional changes. Evaluate BP and pulse in lying and standing position at each visit. BP changes that indicate neuropathic involvement: fall in systolic pressure of >30 mm Hg or fall in diastolic pressure of >10 mm Hg with change from lying to standing position.
Gastroparesis	
• *Incidence:* Occurs in 50% of people with long-standing diabetes. • *Characteristics:* Delayed gastric emptying, prolonged pyloric spasms, and loss of the powerful contractions of the distal stomach to grind and mix foods.	• Typical symptoms may include nausea/vomiting, early satiety, abdominal bloating, epigastric pain, change in appetite. Wide fluctuations in blood glucoses and postmeal hypoglycemia caused by poor glucose absorption. Visualization of the gut by upper GI barium series may show retained food after an 8- to 12-hr fast.
Diarrhea	
• *Incidence:* Approximately 20% of patients with diabetes. • *Characteristics:* Frequent, watery movements. • Mild steatorrhea. • Can be intermittent, persistent, or alternate with constipation.	• Diarrhea occurs without warning, frequently at night or after meals. Fecal incontinence may be caused by loss of internal sphincter control and anorectal sensation. Other causes, such as celiac sprue, pancreatic insufficiency, and lactose intolerance, must be investigated. Bacterial overgrowth in the bowel is also suspected.
Sexual Dysfunction	
• Affects 35%–75% men and 46% women with diabetes. • Sexual dysfunction in both men and women can involve changes in libido, ability to achieve orgasm, and sexual satisfaction.	• *Men:* History of poor erectile function despite stimulation. Absence of early-morning erection in response to increased hormonal levels. • *Women:* May experience decreased vaginal lubrication and dyspareunia. • Screening for use of ethanol or other medications associated with impotence (eg, antidepressants, antihypertensives).
Bladder Dysfunction	
• *Incidence:* Affects 37%–50% of people with diabetes, W > M. • Inability to sense a full bladder, incomplete void/overflow incontinence. Increased frequency of UTI and pyelonephritis leading to or exacerbating renal failure.	• Overflow incontinence is common problem for women. Inquire about use of pads in undergarments, which may be clue. • Distended bladder • Burning/pain with voiding; straining to empty bladder. Nocturia.
Hypoglycemia Unawareness	
• *Incidence:* Severe hypoglycemia occurs most frequently in patients with T1DM (30%–40% annual prevalence); however, it will also occur in patients with T2DM who are treated with insulin, sulfonylureas, and/or glinides. • Occurs in ~17% of type 1 diabetic patients and at a rate of two to three times more frequently than those with T2DM. • Condition in which the usual warning signs of hypoglycemia are no longer experienced. The symptoms may be different (and therefore not recognized), less pronounced, or even absent. • Can eventually lead to hypoglycemia-associated autonomic failure, which includes both hypoglycemia unawareness and defective glucose counterregulatory hormones.	• Patients may exhibit irrational thought; unprovoked anger or irritability; insisting that they "feel fine" in the midst of very unusual behavior; inappropriate laughing/silliness/giddiness/crying.
Hypoglycemia Unawareness (Continued)	
• *Causes:* Long-standing diabetes, reduced glucagon excretion, frequent low blood sugars, alcohol consumption within the previous 12 hr, previous low blood sugar within the last 24–48 hr, certain medications (ie, beta-adrenergic blockers) • Women more susceptible because of reduced counterregulatory response and reduced symptoms. • More likely to occur in patients with other types of autonomic neuropathy.	• Grand mal seizures can occur if hypoglycemia is not recognized and treated.

BP, blood pressure; CAD, coronary artery disease; ECG, electrocardiography.

1. In type 1 diabetes, chronic complications usually appear about 5 years after the initial diagnosis.
2. The prevalence of microvascular complications (retinopathy, nephropathy, and neuropathy) is higher in type 1 diabetes.
3. Because of its insidious onset, chronic complications can appear at any point in type 2 diabetes. Approximately 50% will have at least one complication at time of diagnosis.
4. Macrovascular complications (ie, cardiovascular disease)—occurring in type 1 and type 2 diabetes—are the leading cause of morbidity and mortality among persons with diabetes.

Nursing Assessment

1. Obtain a history of current problems, family history, and general health history.
   a. Has the patient experienced polyuria, polydipsia, polyphagia, and any other symptoms?
   b. Number of years since initial diagnosis of diabetes.
   c. Family members diagnosed with diabetes, their subsequent treatment, and complications.
2. Perform a review of systems and physical examination to assess for signs and symptoms of diabetes, general health of patient, and presence of complications.
   a. General: recent weight loss or gain, increased fatigue, tiredness, anxiety.
   b. Skin: skin lesions, infections, dehydration, evidence of poor wound healing.
   c. Eyes: changes in vision—floaters, halos, blurred vision, dry or burning eyes, cataracts, glaucoma.
   d. Mouth: gingivitis, periodontal disease.
   e. Cardiovascular: orthostatic hypotension, cold extremities, weak pedal pulses, leg claudication.
   f. GI: diarrhea, constipation, early satiety, bloating, increased flatulence, hunger, or thirst.
   g. GU: increased urination, nocturia, impotence, vaginal discharge.
   h. Neurologic: numbness and tingling of the extremities, decreased pain and temperature perception, changes in gait and balance.

Nursing Diagnoses

- Imbalanced Nutrition: More than Body Requirements related to intake in excess of activity expenditures.
- Fear related to medication injection.
- Risk for Unstable Blood Glucose Level related to effects of insulin, inability to eat.
- Activity Intolerance related to poor glucose control.
- Deficient Knowledge related to use of oral hypoglycemic agents and injectable agents.
- Risk for Impaired Skin Integrity related to decreased sensation and circulation to lower extremities.
- Readiness for Enhanced Self-Health Management related to shared goal of avoiding readmission.

Nursing Interventions

STANDARDS OF CARE GUIDELINES 25-1

Caring for Patients with Diabetes Mellitus

When caring for patients with diabetes mellitus:

- Assess level of knowledge of disease and ability to care for self.
- Assess adherence to diet therapy, monitoring procedures, medication treatment, and exercise regimen.
- Assess resources/support system available to patient; involve behavioral health, social work services, and case management as needed.
- Assess for signs of hyperglycemia: polyuria, polydipsia, polyphagia, weight loss, fatigue, blurred vision.
- Assess for signs of hypoglycemia: sweating, tremor, nervousness, tachycardia, light-headedness, confusion.
- Perform thorough skin and extremity assessment for peripheral neuropathy or peripheral vascular disease and any injury to the feet or lower extremities.
- Assess for trends in blood glucose and other laboratory results.
- Reinforce appropriate insulin dosage is given at the right time and in relation to meals and exercise.
- Assess adequate knowledge of diet, exercise, and medication treatment and cognitive skills to safely adhere to prescribed regimen.
- Immediately report to health care provider any signs of skin or soft tissue infection (redness, swelling, warmth, tenderness, drainage).
- Get help immediately for signs of hypoglycemia that do not respond to usual glucose replacement.
- Get help immediately for patient presenting with signs of either ketoacidosis (nausea and vomiting, Kussmaul respirations, fruity breath odor, hypotension, and altered level of consciousness) or hyperosmolar hyperglycemic nonketotic syndrome (nausea and vomiting, hypothermia, muscle weakness, seizures, stupor, coma).

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

See Standards of Care Guidelines 25-1.

Improving Nutrition

1. Assess current timing and content of meals.
2. Advise patient on the importance of an individualized meal plan in meeting weight-loss goals. Reducing intake of carbohydrates may benefit some patients; however, fad diets or diet plans that stress one food group and eliminate another are generally not recommended.
3. Discuss the goals of dietary therapy for the patient. Setting a goal of greater than 5% weight loss over several months is usually achievable and effective in reducing blood sugar and other metabolic parameters.

4. Assist patient to identify problems that may have an impact on dietary adherence and possible solutions to these problems. Emphasize that lifestyle changes should be maintainable for life.
5. Explain the importance of exercise in maintaining/reducing body weight.
   a. Caloric expenditure for energy in exercise.
   b. Carryover of enhanced metabolic rate and efficient food utilization.
6. Assist patient to establish goals for weekly weight loss and incentives to assist in achieving them.
7. Strategize with patient to address the potential social pitfalls of weight reduction.

Teaching About Insulin

1. Assist patient to reduce fear of injection by encouraging verbalization of fears regarding insulin injection, conveying a sense of empathy, and identifying supportive coping techniques.
2. Demonstrate and explain thoroughly the procedure for insulin self-injection.
3. Help patient to master technique by taking a step-by-step approach.
   a. Allow patient time to handle insulin and syringe/pen to become familiar with the equipment.
   b. Teach self-injection first to alleviate fear of pain from injection.
   c. Instruct patient in filling syringe when he or she expresses confidence in self-injection procedure.
4. Review dosage and time of injections in relation to meals, activity, and bedtime based on patient's individualized insulin regimen.

GERONTOLOGIC ALERT Assess older patients for sensory deficits, such as impaired vision, hearing, fine touch, and tremors that may have an impact on learning and ability to self-administer insulin. Suggest use of an insulin pen or magnifying glass to assist with drawing up insulin. Pen must be inverted 10 times to ensure mixing.

Preventing Injury Secondary to Hypoglycemia

1. Closely monitor blood glucose levels to detect hypoglycemia (blood glucose ≤70 mg/dL).
2. Instruct patient in the importance of accuracy in insulin preparation, administration, and meal timing to avoid hypoglycemia.
3. Assess patient for the signs and symptoms of hypoglycemia.
   a. Adrenergic (early symptoms)—sweating, tremor, pallor, tachycardia, palpitations, nervousness from the release of adrenalin when blood glucose falls rapidly.
   b. Neurologic (later symptoms)—light-headedness, headache, confusion, irritability, slurred speech, lack of coordination, staggering gait from depression of central nervous system as glucose level progressively falls.
4. Treat hypoglycemia promptly using the 15-g/15-minute rule according to the ADA with 15-g of rapidly absorbed carbohydrates.

a. One-half cup (4 oz.) juice, 1 cup skim milk, 4 glucose tablets, 1 tablespoon of sugar/honey, or five to six pieces of hard candy may be taken orally.
b. Wait 15 minutes.
c. Repeat blood glucose; if less than 70 mg/dL, repeat the treatment.
d. If greater than 70 mg/dL and more than 3 hours since last dose of rapid-acting insulin, no further treatment required.
e. If greater than 70 mg/dL but less than 3 hours since last dose of rapid-acting insulin, follow with a snack of 75 to 100 calories.
f. If using a "split-mix" or REG/NPH insulins and more than 30 minutes before next planned meal/snack, have meal/snack now.
g. Nutrition bar specially designed for diabetics—supplies glucose from sucrose, starch, and protein sources with some fat to delay gastric emptying and prolong effect; may prevent relapse. Used after hypoglycemia treated with fast-acting carbohydrate.
h. Glucagon 1 mg (SubQ or IM) is given if the patient cannot safely ingest a treatment. Family member or staff must administer injection.
i. IV bolus of 50 mL of 50% dextrose solution can be given if the patient fails to respond to glucagon within 15 minutes.

5. Encourage patient to carry a portable treatment for hypoglycemia at all times.
6. Assess patient for cognitive or physical impairments that may interfere with ability to accurately administer insulin.
7. Between-meal snacks as well as extra food taken before exercise should be encouraged to prevent hypoglycemia.
8. Encourage patients to wear an identification bracelet or card that may assist in prompt treatment in a hypoglycemic emergency.
   a. Identification bracelet can be obtained from MedicAlert Foundation International (*www.medicalert.org*).
   b. Identification card may be requested from the ADA (*www.diabetes.org*).
9. If hypoglycemia occurs frequently, please discuss with health care provider. Dose adjustments of insulin and/or oral medications may be necessary.
10. Address safety issues if patient has hypoglycemic attacks—driving, operating machinery, and exertional activity. Cognitive recovery takes 45 to 75 minutes following blood glucose levels of less than 50 mg/dL.

DRUG ALERT If the patient is taking an alpha glucosidase inhibitor, he or she must use a monosaccharide (glucose tablets) to treat hypoglycemia because sucrose will not be broken down to an absorbable sugar.

Improving Activity Tolerance

1. Advise patient to assess blood glucose level before and after strenuous exercise.
2. Instruct patient to plan exercises on a regular basis each day.
3. Encourage patient to eat a carbohydrate snack before exercising to avoid hypoglycemia.
4. Advise patient that prolonged strenuous exercise may require increased food at bedtime to avoid nocturnal hypoglycemia.
5. Instruct patient to avoid exercise whenever blood glucose levels exceed 250 mg/day and urine ketones are present. Patient should contact health care provider if levels remain elevated.
6. Counsel patient to inject insulin into the abdominal site on days when arms or legs are exercised.

Providing Information About Noninsulin Agents

1. Identify barriers to learning, such as visual or hearing impairments, low literacy, and distractive environment.
2. Encourage active participation of the patient and family in the educational process.
3. Teach the action, use, and adverse effects of noninsulin agents (see pages 735 to 739).
4. Identify financial barriers to accessing medications and follow-up care. Offer resources such as Partnership for Prescription Assistance (*www.PPARx.org*).

Maintaining Skin Integrity

1. Assess feet and legs for skin temperature, sensation, soft tissue injuries, corns, calluses, dryness, hammertoe or bunion deformation, hair distribution, pulses, deep tendon reflexes.
   a. Use a monofilament to test sensation of the feet and detect early signs of peripheral neuropathy (see Figure 25-2).
   b. Test vibratory sense over interphalangeal joints of the feet using a low-frequency (128 Hz) tuning fork. Vibratory sense is typically lost before tactile sensation. The test is considered abnormal if the vibratory sensation is felt for less than 10 seconds.
2. Protect skin from dryness and breakdown.
   a. Use heel protectors, special mattresses, and foot cradles for patients on bed rest.
   b. Avoid applying drying agents to skin (eg, alcohol).
   c. Apply skin moisturizers (preferably creams) to maintain suppleness and prevent cracking and fissures.
3. Instruct patient in foot care.
4. Advise the patient who smokes to stop smoking, or reduce if possible to reduce vasoconstriction and enhance peripheral blood flow. Help patient to establish behavior modification techniques to eliminate smoking in the hospital and to continue them at home for smoking cessation program.

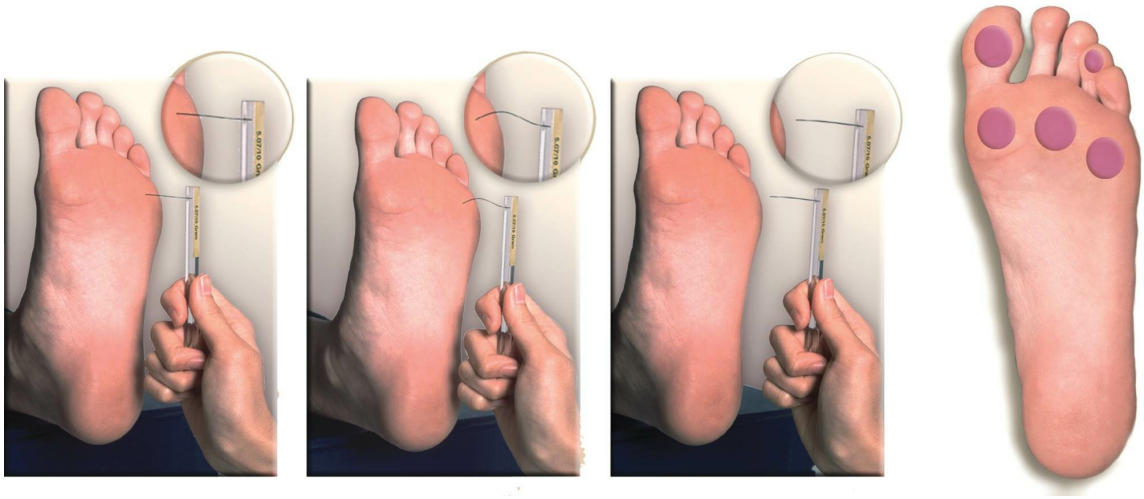

Figure 25-2. The Semmes-Weinstein 5.07 (10-g) monofilament test. (From Cameron, B. L. [2002]. Making diabetes management routine. *American Journal of Nursing*, 102[2], 27.)

Focusing on Transitional Care

Some strategies that nursing staff can employ to facilitate safer transition out of the hospital and reduce the chance for readmission are:

1. Promote diabetes education at the bedside. This should start as early as possible during the inpatient stay, as soon as the patient is able to participate.
   a. Use routine blood glucose monitoring, insulin administration, and meal selection as teaching moments—allow the patient to actively participate in these activities.
   b. Provide clear instructions and printed materials.
   c. Assess patient technique for insulin administration and glucose testing.
2. Ensure patients are being discharged with all medications with correct dose and adequate supplies.
   a. Insulin pens must have pen needles ordered.
   b. Make certain that the glucose test strips are compatible with the patient's glucose meter.
   c. Assess patient understanding of all medications prescribed, including timing with meals.
   d. Ensure that all chronic medications were not inadvertently stopped; all changes in medications must be made very clear to patient to prevent medication errors.
3. Ensure a 7-day follow-up appointment with the patient's primary care or specialist provider is scheduled prior to discharge and that the patient has a secured means of transportation.
4. Provide patient with written discharge summary and instructions with symptoms to report and phone number to call.
5. Establish a transitional care team who can provide 3-day postdischarge follow-up phone call and coordination with home health care professionals.

TRANSITIONAL CARE ALERT People with diabetes are involved in almost 22% of all inpatient hospitalizations, and 13% will have diabetes as the primary reason for admission. Unfortunately, the 30-day readmission rates can be as high as 21% for patients with diabetes mellitus. The risk increases based on comorbidities, if admitted via emergency department, low socioeconomic status, and/or lack of health insurance. Discharge planning must begin upon admission and updated as the patient's needs change or are more clearly understood. A1c levels should be obtained on all patients known to have diabetes—even if diabetes was not the primary reason for hospitalization. Patients with an A1c greater than 9% upon admission are very high risk for poor outcomes and readmission.

Community and Home Care Considerations

1. A home care or visiting nurse referral can be initiated to follow up on patient education initiated in the hospital or clinic and ensure that the patient has the resources to care for self at home.
2. Patient should be checking fingerstick glucose at home, and glucometer should be checked by home care or clinic nurse periodically to make sure it is properly calibrated and correlates with meter used at clinic or hospital.
3. As long as the home is clean and the patient uses reasonable hygiene, procedures for glucose self-monitoring and insulin injection do not need to be sterile. No alcohol preparation of the skin or insulin vial is needed.
4. Assist patients with choosing the diabetes self-care products and devices that best meet their needs/circumstances. An annual update is available at *www.forecast.diabetes.org/consumerguide*.
5. Insulin syringes may be reused, so long as the needle is kept clean and no pain or signs of skin irritation develop after multiple uses.
6. Insulin pens should be used when possible.
7. Although urine glucose testing is no longer used to monitor diabetes control, the patient may benefit from urine ketone testing, especially when ill. Teach the patient how to test urine with ketone test strip and to notify health care provider if ketosis persists.
8. Make sure that all patients have a handy source of glucose for hypoglycemic episodes. A small tube of glossy decorating gel for cakes or 3 sugar packets, easily carried in a pocket or purse, contains about 15 g glucose and can be used to treat hypoglycemia.
9. Draw blood for analysis or ensure that patients attend laboratory appointments.
    a. For patients taking a thiazolidinedione, baseline serum transaminases (aspartate aminotransferase and alanine aminotransferase) should be obtained prior to initiation and repeated anytime the patient is suspected of liver injury (fatigue, anorexia, RUQ pain, dark urine).
    b. Renal function tests (serum creatinine and estimated glomerular filtration rate) and urine for microalbuminuria or microalbumin/creatinine ratio will be monitored at least yearly.
    c. Glycated hemoglobin is followed every 3 to 6 months and does not require fasting.

d. Fasting lipid panel (12 to 14 hours fasting) is done at least annually.

Patient Education and Health Maintenance

1. Ongoing education of patient to include advanced skills and rationales for treatment, prevention, and management of complications.
2. Educational focus—lifestyle management issues, to include sick day management.
3. For additional information and support, refer to drug manufacturers' Web sites for special programs for people with diabetes and to agencies, such as ADA (*www.diabetes.org*) and American Dietetic Association (*www.eatright.org*). Travel recommendations can be found at *www.joslin.org/info/diabetes_and_travel_10_tips_for_a_safe_trip.html.*

PATIENT EDUCATION GUIDELINES 25-1

Diabetes Sick-Day Guidelines

- Never omit insulin dosage. Check with health care provider about noninsulin medication. For instance, metformin, GLP-1 RA, and SGLT2i should be withheld if vomiting or in danger of becoming dehydrated.
    - Take at least the usual dosage of insulin.
    - Keep regular insulin on hand for supplemental doses, as prescribed by health care provider.
- Monitor blood glucose and urine ketones every 2 to 4 hours.
    - Whenever blood glucose is greater than 240 mg/dL, test urine ketones.
    - Record all test results.
- Drink plenty of fluids.
    - Six to eight ounce of fluid every hour is recommended; every 3rd hour, the fluid should include sodium (i.e., broth).
    - If unable to eat, drink fluids that contain carbohydrates (e.g., fruit juices, regular soda); patient must consume 150 to 200 g of carbohydrates/day.
- Contact health care provider or report to nearest ER if illness becomes severe or unmanageable.
    - Fever, nausea, vomiting (greater than 1 episode), and diarrhea (greater than 5 episodes or for longer than 6 hours) increase risk of dehydration.
    - Signs and symptoms of infection—redness, swelling, drainage—need immediate attention.
- Large amount of urine ketones or other signs and symptoms of diabetic ketoacidosis: call health care provider immediately.

Evaluation: Expected Outcomes

- Maintains appropriate weight with minimal to no gain.
- Demonstrates correct technique for self-injection of insulin.
- Signs and symptoms of hypoglycemia identified and treated appropriately.
- Exercises daily.

- Verbalizes appropriate use and action of noninsulin agents.
- No skin breakdown.
- Patient verbalizes understanding of discharge instructions and has medications and injection supplies before leaving hospital.

Diabetic Ketoacidosis

EVIDENCE BASE Gosmanov, A. R., Gosmonova, E. O., & Kitabchi, A. E. (2015). Hyperglycemic crises: Diabetic ketoacidosis (DKA) and hyperglycemic hyperosmolar state (HHS). In K. Dungan (Ed.), *Endotext*. Available: *www.endotext.org/chapter/diabetic-complications/hyperglycemic-crises-diabetic-ketoacidosis-dka-and-hyperglycemic.*

Wolfsdorf, J. I., Allgrove, J., Craig, M. E., Edge, J., et al. (2014). Diabetic ketoacidosis and hyperglycemic hyperosmolar state. *Pediatric Diabetes, 15*(Suppl. 20), 154–179.

Diabetic ketoacidosis (DKA) is an acute complication of diabetes mellitus (usually type 1 diabetes) characterized by hyperglycemia, ketonuria, acidosis, and dehydration. Underlying infection is the most common cause of this acute complication.

Pathophysiology and Etiology

1. Insulin deficiency prevents glucose from being used for energy, forcing the body to metabolize fat for fuel.
2. Free fatty acids, released from the metabolism of fat, are converted to ketone bodies in the liver.
3. Ketone bodies are organic acids that cause metabolic acidosis.
4. Increase in the secretion of glucagon, catecholamines, growth hormone, and cortisol, in response to the hyperglycemia caused by insulin deficiency, accelerates the development of DKA.
5. Osmotic diuresis caused by hyperglycemia creates a shift in electrolytes, with losses in potassium, sodium, phosphate, and water.
6. Caused by inadequate amounts of endogenous or exogenous insulin.
    a. Commonly occurs due to failure to increase the dose of insulin during periods of stress (eg, infection, surgery, pregnancy).
    b. May occur in previously undiagnosed or untreated diabetics.

Clinical Manifestations

Early

1. Polydipsia, polyuria.
2. Fatigue, malaise, drowsiness.
3. Anorexia, nausea, vomiting.
4. Abdominal pain, muscle cramps.

Later

1. Kussmaul respirations (deep respirations).

2. Fruity, sweet breath.
3. Hypotension, weak pulse.
4. Stupor and coma.

Diagnostic Evaluation

1. Serum glucose level is elevated over 250 mg/dL.
2. Serum and urine ketone bodies are present.
3. Serum bicarbonate and pH are decreased because of metabolic acidosis, and partial pressure of carbon dioxide is decreased as a respiratory compensation mechanism.
4. Serum sodium and potassium levels may be low, normal, or high because of fluid shifts and dehydration, despite total body depletion.
5. BUN, creatinine, hemoglobin, and hematocrit are elevated because of dehydration.
6. Urine glucose is present in high concentration and specific gravity is increased, reflecting osmotic diuresis and dehydration.

NURSING ALERT Severity of DKA is not determined by serum glucose levels; the degree of acidosis determines severity of DKA.

Management

1. IV fluids to replace losses from osmotic diuresis, vomiting.
2. IV insulin drip to increase glucose utilization and decrease lipolysis. Only use insulin preparations approved for IV administration. Should not be started until serum potassium is greater than 3.3 mEq/L.
3. Electrolyte replacement—sodium chloride and phosphate as required and potassium chloride and bicarbonate based on laboratory results.

Complications

1. Premature discontinuation of IV insulin or the failure to initiate subcutaneous insulin injections prior to discontinuing IV insulin will result in rebound of DKA.
2. Too-rapid infusion of IV fluids in cases of severe dehydration can cause cerebral edema and death.

Nursing Assessment

1. Assess skin for dehydration—poor turgor, flushing, dry mucous membranes.
2. Observe for cardiac changes reflecting dehydration, metabolic acidosis, and electrolyte imbalance—hypotension; tachycardia; weak pulse; electrocardiographic changes, including elevated P wave, flattened T wave, or inverted, prolonged QT interval.
3. Assess respiratory status—Kussmaul respirations, acetone breath characteristic of metabolic acidosis.

4. Perform GI assessment—nausea, vomiting, extreme thirst, abdominal bloating and cramping, diarrhea.
5. Determine GU symptoms—nocturia, polyuria.
6. Observe for neurologic signs—crying, restlessness, twitching, tremors, drowsiness, lethargy, headache, decreased reflexes.
7. Interview family or significant other regarding precipitating events to episode of DKA.
   a. Patient self-care management before hospitalization.
   b. Unusual events that may have precipitated episode (eg, chest pain, trauma, illness).

Nursing Diagnoses

- Deficient Fluid Volume related to hyperglycemia.
- Ineffective Therapeutic Regimen Management related to failure to increase insulin during illness.

Nursing Interventions

Restoring Fluid and Electrolyte Balance

1. Assess BP and heart rate frequently, depending on patient's condition; assess skin turgor and temperature.
2. Monitor intake and output every hour.
3. Replace fluids, as ordered, through peripheral IV line.
4. Monitor urine specific gravity to assess fluid changes.
5. Monitor blood glucose frequently.
6. Assess for symptoms of hypokalemia—fatigue, anorexia, nausea, vomiting, muscle weakness, decreased bowel sounds, paresthesia, arrhythmias, flat T waves, ST-segment depression.
7. Administer replacement electrolytes and insulin, as ordered. Flush the entire IV infusion set with solution containing insulin and discard the first 50 mL because plastic bags and tubing may absorb some insulin and the initial solution may contain decreased concentration of insulin.
8. Monitor serum glucose, bicarbonate, and pH levels periodically.
9. Provide reassurance about improvement of condition and that correction of fluid imbalance will help reduce discomfort.

NURSING ALERT Electrolyte levels may not reflect the total body deficit of potassium (primarily) and sodium (to a lesser extent) because of compartment shifts and fluid volume loss. Replacement is necessary despite normal to high values.

DRUG ALERT Premature interruption of IV insulin administration may result in reaccumulation

of ketone bodies and worsening acidosis. Glucose will normalize before acidosis resolves, so IV insulin is continued until bicarbonate levels normalize, subcutaneous insulin takes effect, and the patient tolerates oral caloric intake.

Preventing Further Episodes of DKA

1. Review with patients precipitating events and causes of DKA.
2. Assist patient in identifying warning signs and symptoms of DKA.
3. Instruct patient on sick-day guidelines (see page 748).

Patient Education and Health Maintenance

1. Make sure that patient and caretakers can demonstrate drawing up and administering insulin in the proper dose, blood glucose monitoring, and urine ketone testing.
2. Make sure that patient and caretakers know whom to notify in the event of hyperglycemia, stressful situation, or symptoms of DKA.

Evaluation: Expected Outcomes

- BP and heart rate stable; glucose and bicarbonate levels improving.
- Verbalizes sick-day guidelines correctly.

Hyperosmolar Hyperglycemic State

EVIDENCE BASE Gosmanov, A. R., Gosmonova, E. O., & Kitabchi, A. E. (2015). Hyperglycemic crises: Diabetic ketoacidosis (DKA) and hyperglycemic hyperosmolar state (HHS). In K. Dungan (Ed.), *Endotext*. Available: *www.endotext.org/chapter/diabetic-complications/hyperglycemic-crises-diabetic-ketoacidosis-dka-and-hyperglycemic.*

Wolfsdorf, J. I., Allgrove, J., Craig, M. E., Edge, J., et al. (2014). Diabetic ketoacidosis and hyperglycemic hyperosmolar state. *Pediatric Diabetes, 15*(Suppl. 20), 154–179.

Hyperosmolar hyperglycemic state (HHS) is an acute complication of diabetes mellitus (particularly type 2 diabetes) characterized by hyperglycemia, dehydration, and hyperosmolarity, with little or no ketosis. Underlying infection is the most common cause of this acute complication.

Pathophysiology and Etiology

1. Prolonged hyperglycemia with glucosuria produces osmotic diuresis.
2. Loss of water, sodium, and potassium results in severe dehydration, causing hypovolemia and hemoconcentration.
3. Hyperosmolarity is a result of excessive blood sugar and increasing sodium concentration in dehydration.
4. Insulin continues to be produced at a level that prevents ketosis.
5. Increased blood viscosity decreases blood flow to the organs, creating tissue hypoxia.
6. Intracellular fluid and electrolyte shifts produce neurologic signs and symptoms.
7. Caused by inadequate amounts of endogenous/exogenous insulin to control hyperglycemia.
    a. Precipitating event may occur, such as cardiac failure, burn, or chronic illness that increases need for insulin.
    b. Use of therapeutic agents that increase blood glucose levels (eg, glucocorticoids, immunosuppressive agents).
    c. Use of therapeutic procedures that cause stress or increase blood glucose levels (eg, hyperosmolar hyperalimentation, peritoneal dialysis).

Clinical Manifestations

Early

1. Polyuria, dehydration.
2. Fatigue, malaise.
3. Nausea, vomiting.

Later

1. Hypothermia.
2. Muscle weakness.
3. Seizures, stupor, coma.

Diagnostic Evaluation

1. Serum glucose and osmolality are greatly elevated, with glucose values usually greater than 600 mg/dL.
2. Serum and urine ketone bodies are minimal to absent.
3. Serum sodium and potassium levels may be elevated, depending on degree of dehydration, despite total body losses.
4. BUN and creatinine may be elevated because of dehydration.
5. Urine specific gravity is elevated because of dehydration.

Management

1. Correct fluid and electrolyte imbalances with IV fluids.
2. Provide insulin via IV drip to lower plasma glucose.
3. Evaluate complications, such as stupor, seizures, or shock, and treat appropriately.
4. Identify and treat underlying illnesses or events that precipitated HHS.

Complications

1. Too rapid infusion of IV fluids can cause cerebral edema and death.
2. HHS is a medical emergency that, if not treated properly, can cause death (10% to 50% mortality).
3. Patients who become comatose will need nasogastric (NG) tubes to prevent aspiration.

Nursing Assessment

1. Assess level of consciousness (LOC).
2. Assess for dehydration—poor turgor, flushing, dry mucous membranes.
3. Assess cardiovascular status for shock—rapid, thready pulse, cool extremities, hypotension, electrocardiogram changes.
4. Interview family or significant other regarding precipitating events to episode of HHS.
    a. Evaluate patient's self-care regimen before hospitalization.
    b. Determine events, treatments, or drugs that may have caused the event.

Nursing Diagnoses

- Deficient Fluid Volume related to severe dehydration.
- Risk for Aspiration related to reduced LOC and vomiting.

Nursing Interventions

Restoring Fluid Balance

1. Assess patient for increasing signs and symptoms of dehydration, hyperglycemia, or electrolyte imbalance.
2. Institute fluid replacement therapy, as ordered (usually normal or half-strength saline initially), maintaining patent IV line.
3. Assess patient for signs and symptoms of fluid overload and cerebral edema as IV therapy progresses.
4. Administer regular insulin IV, as ordered, and add dextrose to IV infusion as blood glucose falls below 300 mg/dL, to prevent hypoglycemia.
5. Monitor hydration status by monitoring hourly intake and output and urine specific gravity.

Preventing Aspiration

1. Assess patient's LOC and ability to handle oral secretions.
   a. Cough and gag reflex.
   b. Ability to swallow.
2. Properly position patient to reduce possibility of aspiration.
   a. Elevate head of bed unless contraindicated.
   b. If nausea is present, use sidelying position.
3. Suction as frequently as needed to maintain patent airway.
4. Withhold oral intake until patient is no longer in danger of aspiration.
5. Insert NG tube as indicated for gastric decompression.
6. Monitor respiratory rate and breath sounds for signs of aspiration pneumonia.
7. Provide mouth care to maintain adequate mucosal hydration.

Patient Education and Health Maintenance

1. Advise patient and family that it may take 3 to 5 days for symptoms to resolve.
2. Instruct patient and family in signs and symptoms of hyperglycemia and use of sick-day guidelines (see page 748).
3. Explain possible causes of HHS.
4. Review changes in medication, activity, meal plan, or glucose monitoring for home care. It may not be necessary to continue insulin therapy following HHS; many patients can be treated with diet and oral agents.

Evaluation: Expected Outcomes

- BP stable, dehydration resolved.
- No evidence of aspiration.

Metabolic Syndrome

Metabolic syndrome (also known as syndrome X, insulin resistance syndrome, and dysmetabolic syndrome) is a term that has been used to characterize a constellation of related risk factors that increase the risk of developing several significant health problems to include T2DM and cardiovascular disease. There has been much discussion and debate in the literature as to whether or not metabolic syndrome is an actual diagnosis and if so, which diagnostic criteria should be included when screening. To improve consistency, a "harmonized definition" was set forth in 2009 by the International Diabetes Federation Task Force on Epidemiology and Prevention; National Heart, Lung, and Blood Institute; American Heart Association; World Heart Federation; International Atherosclerosis Society; and International Association for the Study of Obesity.

Three of the following five criteria must be met:

- Increased waist circumference (population-specific and country-specific criteria) (in the United States, greater than 35 inches for women and greater than 40 inches for men).
- Hypertriglyceridemia: ≥150 mg/dL*.
- Low HDL cholesterol: less than 40 mg/dL in men and less than 50 mg/dL in women*.
- Elevated BP: systolic BP ≥ 130 mm Hg or diastolic BP ≥ 85 mm Hg*.
- Elevated fasting glucose: ≥100 mg/dL*.

*= or taking medications to address.

EVIDENCE BASE Alberti, K. G., Eckel, R. H., Grundy, S. M., Zimmet, P. Z., et al. (2009). Harmonizing the metabolic syndrome: A joint interim statement of the International Diabetes Federation Task Force on Epidemiology and Prevention; National Heart, Lung, and Blood Institute; American Heart Association; World Heart Federation; International Atherosclerosis Society; and International Association for the Study of Obesity. *Circulation, 120*(16), 1640–1645.

Pathophysiology and Etiology

1. The central feature of this metabolic disorder is the diminished responsiveness of peripheral tissues to circulating insulin (insulin resistance).
2. The typical physiological response of the body to this condition is the increased production and secretion of insulin, leading to a state of compensatory hyperinsulinemia to maintain glucose homeostasis.
3. Although this response is beneficial from the standpoint of glucose metabolism, it is now understood that the state of hyperinsulinemia necessary to prevent glucose intolerance gives rise to other abnormalities that have significant health consequences.
4. In addition to increased risk of type 2 diabetes associated with insulin resistance, hyperinsulinemia has also been associated with the development of hypertension, dyslipidemia, atherosclerotic cardiovascular

disease, cerebrovascular disease, polycystic ovarian syndrome (PCOS), nonalcoholic fatty liver disease (NAFLD), and obstructive sleep apnea (OSA).

5. Because these clinical features are associated with insulin resistance, the term "syndrome" has been applied to signify that these conditions are linked to a common problem.
6. Although the pathogenesis of insulin resistance is not fully understood, genetic factors, lifestyle (diet, physical activity), and obesity play an important role in the development and natural course of this condition.

Risk Factors

1. Prediabetes, cardiovascular disease, PCOS, hypertension, hyperlipidemia, or acanthosis nigricans.
2. History of glucose intolerance or gestational diabetes.
3. Family history of type 2 diabetes, cardiovascular disease, or hypertension.
4. Sedentary lifestyle.
5. Obesity.

Management

1. Treatment of metabolic syndrome involves measures that are directed at treating any diagnosed disease resulting from insulin resistance (diabetes, hypertension, hypercholesterolemia) as well as the underlying insulin resistance. This is accomplished by interventions that improve insulin sensitivity.
2. Nonpharmacological interventions effective in reducing insulin resistance include lifestyle changes that can have a direct impact on insulin sensitivity and include regular physical activity and nutritional management designed to reduce body weight. Smoking cessation and reduced alcohol intake are also important lifestyle changes.
3. No pharmacologic agents have been FDA-approved for use in the treatment of metabolic syndrome or prediabetes. However, metformin is being used more frequently, especially if the risk for developing T2DM is very high. Other agents currently available with known insulin-sensitizing effects (ie, thiazolidinedione compounds) have shown effectiveness in treating individuals with PCOS and prediabetes. The potential role of these agents in the management of metabolic syndrome is under investigation.
4. Antiobesity medications are available to treat patients struggling with obesity (BMI greater than 30 kg/m^2). Surgical interventions (ie, bariatric surgery) are recommended for morbidly obese patients (BMI greater than 40 kg/m^2 or greater than 35 kg/m^2 with comorbid conditions).

OVERVIEW AND ASSESSMENT

See additional online content: Procedure Guidelines 26-1

PROCEDURE GUIDELINES 26-1

Obtaining Blood by Venipuncture

EQUIPMENT

- Chlorhexidine–alcohol (if blood cultures will be obtained) or 70% alcohol
- Dry sterile gauze pads
- Vacutainer or syringe
- 20G needles or equivalent "(needleless)" supplies
- Blood tubes
- Disposable gloves

PROCEDURE

Nursing Action	Rationale
Performance phase	
1. Reassure the patient. Explain that relatively little blood will be taken.	1. Allays anxiety and enlists cooperation.
2. Wash hands and put on gloves.	2. Universal precautions.
3. Instruct the patient to extend the arm; the arm should be held straight at the elbow.	3. Exposes the antecubital area.
4. Apply the tourniquet directly above the elbow (or targeted vein) with just sufficient pressure to prevent venous return.	4. Increases venous pressure and makes the vein more prominent and easier to enter.
5. Inspect the area to visualize the vein, including the antecubital area, wrist, dorsum (back) of hand, and top of foot (if necessary). Palpate the vein.	5. Select a vein that is visible, palpable, and well fixed to surrounding tissue so that it does not roll away. (Some veins may be deep and can only be palpated.)
6. Clean the skin with chlorhexidine–alcohol or alcohol. Allow to dry.	6. Sterile procedures.
7. Fix the chosen vein with the thumb and draw the skin taut immediately below the site before inserting needle to stabilize the vein.	7. The vein may roll beneath the skin when the needle approaches its outer surface (especially in older and extremely thin patients).
8. Hold the syringe or Vacutainer between the thumb and last three fingers with the bevel of the needle up and directly in line with the course of the vein. Insert the needle quickly and smoothly under the skin and into the vein.	8. A pop may be felt as the needle enters the vein.
KEY DECISION POINT If a pop is not heard, gently reposition the needle. If a pop is still not heard, a hematoma becomes visible, or blood does not flow into the tube when inserted into the Vacutainer, release the tourniquet and remove the needle. Try an alternate site.	
9. Insert the tube into the Vacutainer and allow to fill. For syringe, gently pull back on the plunger until desired amount of blood is obtained.	9. Use minimal suction on syringe to prevent hemolysis of blood and collapse of the vein.
10. Release the tourniquet as soon as specimen is obtained, and then remove the tube from the Vacutainer.	
11. Withdraw the needle slowly.	11. Slow withdrawal of the needle is less painful.
12. Apply a dry sterile gauze pad to puncture site and request the patient to apply gentle but firm pressure to the site for 2 to 4 minutes.	12. Firm pressure over the puncture site prevents leakage of blood into surrounding tissues with subsequent hematoma development.
13. Make a blood smear from the needle, if ordered.	13. Physical characteristics of blood cells can be observed under the microscope.
14. If blood was obtained in a syringe, use needleless supplies per facility procedure and gently eject the blood sample into tubes.	14. Slow transfer of blood into the test tube without forming bubbles prevents hemolysis, which may alter results.
15. Invert the tube gently several times to mix blood with anticoagulant, if present.	15. For some tests, the blood is allowed to coagulate in the test tube.
16. Label samples correctly and send to laboratory immediately.	16. Samples should be sent to the laboratory with a minimum of delay for optimum reliability.
17. Dispose needle and syringe in appropriate containers to avoid possible spread of blood-borne viral diseases. Clean spills with 10% bleach solution. Remove gloves and wash hands.	17. Bleach will kill any pathogens, such as HIV.

Blood, the body fluid circulating through the heart, arteries, capillaries, and veins, consists of plasma and cellular components. The average male adult has about 5.5 L of blood and the average female 4.5 L. Plasma, the fluid portion, accounts for 55% of the blood volume and is composed of 92% water, 7% protein, and 1% inorganic salts; nonprotein organic substances such as urea; dissolved gases; hormones; and enzymes. Plasma proteins include albumin, fibrinogen, and globulins. Cellular components include erythrocytes (red blood cells [RBCs]), leukocytes and lymphocytes (white blood cells [WBCs]), and platelets. These cells are derived from pluripotent stem cells in the bone marrow, a process known as hematopoiesis (see Figure 26-1). Under normal conditions, only mature cells are found in circulating blood. The cellular components of blood account for 45% of the blood volume.

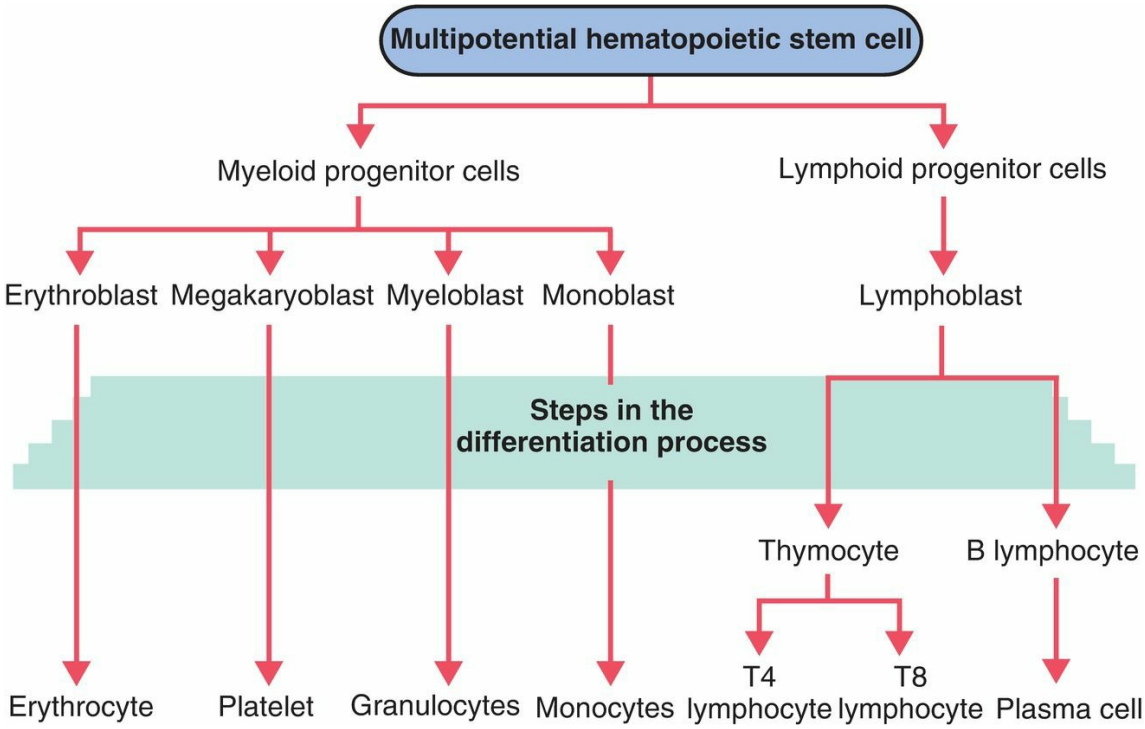

Figure 26-1. Steps in differentiation of blood cells.

Characteristics of Cellular Components

Blood has multiple functions that are carried out by plasma or the cellular components (see Table 26-1, page 754).

Table 26-1 Functions of Blood

METHOD	INVOLVED	CELLS AND SUBSTANCES FUNCTION
Oxygen and carbon dioxide transport	Binding to hemoglobin; dissolved in plasma	• Erythrocyte • Hemoglobin • Plasma
Nutrient and metabolite transport	Bound to plasma proteins; dissolved in plasma	• Plasma proteins • Plasma
Hormone transport	In plasma	• Plasma
Transport of waste products to kidneys and liver	In plasma	• Plasma
Transport of cells and substances involved in immune reactions	In plasma to site of infection or foreign body	• Granulocytes • Monocytes • Lymphocytes • Immunoglobulins • Other substances
Clotting at breaks in blood vessels	Hemostasis	• Platelets • Clotting factors
Maintenance of fluid balance	Blood volume regulation	• Water • Electrolytes
Body temperature regulation	Peripheral vasoconstriction or dilation	—
Maintenance of acid–base balance	Acid–base regulation	• Electrolytes

Erythrocytes (RBCs)

1. Enucleated, biconcave disc.
2. Approximately 5 million erythrocytes per cubic millimeter of blood.
3. Cell contents consist primarily of hemoglobin, essential for oxygen transport. Whole blood contains 14 to 15 g of hemoglobin per 100 mL of blood.
4. Circulate about 115 to 130 days before elimination by reticuloendothelial system, primarily in the spleen and liver.

Leukocytes (WBCs)

See Table 26-2, page 754.

Table 26-2 Characteristics of White Blood Cells

CELL	MAJOR FUNCTION	PHYSICAL CHARACTERISTICS
Neutrophil	Ingest and destroy microorganisms (phagocytosis)	Small cell, multilobed nucleus, most plentiful leukocyte
Eosinophil	Host resistance to helminthic infections; also allergic response	Bilobed nucleus; red-staining granules
Basophil	Allergic response	Bilobed nucleus; granules containing heparin and histamine
Monocyte	Phagocytosis	Large cell, kidney-shaped nucleus
B lymphocyte	Produce antibodies (immunoglobulins); humoral immunity	Small, agranular
T lymphocyte	Regulation of immune response; cellular immunity	Small, agranular; include cytotoxic, helper (T4) and suppressor (T8) T cells; identified by surface markers

1. Approximately 5,000 to 10,000 leukocytes (WBCs) per cubic millimeter of blood.
2. Classified as granulocytes or mononuclear leukocytes.
    a. Granulocytes account for about 70% of all WBCs; have abundant granules in cytoplasm; include neutrophils, basophils, and eosinophils.
    b. Mononuclear leukocytes have single-lobed nucleus and granule-free cytoplasm; include monocytes and lymphocytes.

Platelets (Thrombocytes)

1. Approximately 150,000 to 450,000 platelets per cubic millimeter of blood.
2. Small particles without nuclei arise as a result of budding from giant cells (megakaryocytes) in bone marrow.
3. Primary function is to control bleeding through hemostasis.

Subjective and Objective Data

The patient who presents with a hematologic disorder may have a disruption of the hematologic, immune, or coagulation system, producing a diverse array of symptoms and physical examination findings. Patients commonly present with vague complaints of fatigue, frequent infections, swollen glands, and bleeding tendencies. Characterize these complaints and obtain a review of systems, concentrating on the neurologic, respiratory, cardiovascular, GI, genitourinary (GU), and integumentary systems to look for more clues of hematologic dysfunction. Perform a systematic physical examination, paying careful attention to the cardiovascular, respiratory, and integumentary systems.

Review of Systems

1. Skin and mucous membranes: Any bruises, infections, drainage, or bleeding from wound sites?
2. Neurologic: Any dizziness, tingling or numbness (paresthesia), headache, forgetfulness or confusion, difficulty walking (disturbance in gait), tiredness (fatigue), or weakness?
3. Respiratory: Experiencing shortness of breath, especially on exertion?
4. Cardiovascular: Chest pain or feelings of funny heartbeats (palpitations)?
5. GI: Any bleeding from gums, abdominal pain, black stools, or blood-streaked vomit (emesis)? Any mouth sores, rectal pain, or diarrhea?
6. GU: Excessive menstrual flow? Any blood in urine or discomfort on urination?

Key History Questions

1. What are your present medications? Do you take over-the-counter (OTC) medications, vitamins, herbals, or nutritional supplements? What else have you taken in the past several months?
2. What medical problems have you had in the past? Any surgeries? Ask specifically about partial or total gastrectomy, splenic injury or splenectomy, tendency to bleed (eg, with dental procedures), infectious diseases, human immunodeficiency virus (HIV) infection, and cancer.
3. What is your occupation? Ask about exposure to substances such as benzene, pesticides, and ionizing radiation.
4. Do you have a family history of hematologic or malignant disorder?
5. Determine the social history and lifestyle. Do you use illicit drugs or alcohol? What is your pattern of sexual activity?

Key Examination Findings

1. Dyspnea; shiny smooth tongue; ataxia; and pallor of conjunctivae, nail beds, lips, and oral mucosa—suggest anemia.
2. Decreased blood pressure (BP), tachycardia, and possibly altered level of consciousness (LOC)—suggest anemia or altered blood clotting.
3. Hematuria, tarry stools, petechiae, and bleeding sites—suggest altered clotting.
4. Fever; tachycardia; abnormal breath sounds; delirium; oral lesions; and erythema, swelling, tenderness,

and drainage of the skin—suggest infection.

Laboratory Studies

Laboratory studies routinely done for patients with hematologic disorders include complete blood count (CBC), blood smear, and iron profile.

Complete Blood Count

Description

1. Generally includes absolute numbers or percentages of erythrocytes, leukocytes, platelets, hemoglobin, and hematocrit in blood sample.
    a. Erythrocyte (RBC) indices—can be done to provide information on the size, hemoglobin concentration, and hemoglobin weight of an average RBC; aids in diagnosis and classification of anemias.
    b. Leukocyte (WBC) differential—can be done to determine the percentage of each type of granulocyte (neutrophils, eosinophils, and basophils) and nongranulocytes (lymphocytes and monocytes).
2. Absolute value of each is determined by multiplying the percentage by the total number of WBCs.
3. Used to evaluate infection or potential for infection and identify various types of leukemia.

Nursing and Patient Care Considerations

Blood sample can be drawn at any time without fasting or patient preparation.

Blood Smear

Description

Blood sample prepared for microscopic viewing using appropriate stains, allowing visual analysis of numbers and characteristics of cells; can identify abnormal cells of certain anemias, leukemias, and other disorders that affect the bloodstream.

Nursing and Patient Care Considerations

Can be done from blood sample drawn for CBC; no additional sample or patient preparation is necessary.

Iron Profile

Description

Test completed on blood sample that generally includes levels of serum ferritin, iron, total iron-binding capacity, folate, and vitamin B_{12}; used to determine type and severity of anemia.

Nursing and Patient Care Considerations

Recent administration of chloramphenicol, hormonal contraceptives, iron supplements, and corticotropin may affect results of serum iron and iron-binding capacity. No patient preparation needed.

Other Diagnostic Procedures

Bone Marrow Aspiration and Biopsy

Description

1. Aspiration and biopsy of bone marrow from the iliac crest or (rarely) sternum to obtain specimen to examine microscopically. Special needles are inserted into the bone to collect the specimens directly from the bone marrow.
2. Purposes include diagnosis of hematologic disorders; monitoring of course of illness and response to treatment; diagnosis of other disorders, such as primary and metastatic tumors, infectious diseases, and certain granulomas; and isolation of bacteria and other pathogens by culture.

Nursing and Patient Care Considerations

1. Give medication for pain and anxiety before or after the procedure, as ordered. A bone marrow aspiration with biopsy is more painful and may require use of mild to moderate sedation with appropriate monitoring.
2. Watch for bleeding and hematoma formation after procedure.

Lymph Node Biopsy

Description

1. Surgical excision or needle aspiration usually of a superficial lymph node in the cervical, supraclavicular, axillary, or inguinal region.
2. Performed to determine the cause of lymph node enlargement, to distinguish between benign and malignant lymph node tumors, and to stage metastatic carcinoma.

Nursing and Patient Care Considerations

1. Local anesthetic is usually given.
2. Specimen is placed in normal saline or 10% formaldehyde solution for transportation to the laboratory for cytologic and histologic evaluation.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 26-2

PROCEDURE GUIDELINES 26-2

Bone Marrow Aspiration and Biopsy

EQUIPMENT

- Bone marrow aspiration tray
- Marrow aspiration needles with stylets
- Towels
- 25G and 22G needles
- Two 25-mL syringes
- Three 5-mL syringes
- Local anesthetic (1% procaine or lidocaine)
- Sterile gauze squares
- Sterile gloves, drape
- Skin antiseptic
- Masks and protective eyewear for physician and nurse (check your facility's policy)
- Laboratory equipment
- Coverslips
- Microscopic slides
- Test tubes (plain and heparinized)
- Scalpel blade and handle

PROCEDURE

Nursing Action	Rationale
1. Explain the procedure to the patient. Tell the patient when the skin will be marked, antiseptic applied, and the needle puncture performed.	1. Allays anxiety and enlists cooperation. Tactile sensations (pressure, cold) can be misinterpreted as pain unless the patient is forewarned.
2. Give analgesic or tranquilizer, as requested, 30 minutes before procedure. May not be necessary for aspiration.	2. May minimize pain, discomfort, and anxiety during procedure.
3. Place the patient in prone or supine position for the desired site:	3. Exposes the desired site.
a. Posterior superior iliac crest—prone	
b. Anterior iliac crest (if patient is very obese)—supine	
Iliac Crest Aspiration/biopsy	
Performance phase (nurse assists)	
1. If the patient cannot tolerate prone position, assist the patient to side-lying position with top knee flexed.	1.
a. The posterior iliac crest is located and marked.	a. The iliac crest provides a large marrow cavity at the posterior superior iliac spine away from nearby abdominal organs.
b. The skin area is prepared and draped. The marked area is infiltrated with local anesthetic through the skin and subcutaneous tissue to the periosteum of the bone.	b. Tell the patient to expect a needle prick followed by a burning sensation. The periosteum is the region of greatest sensitivity.
c. A small incision may be made.	c. The biopsy needle is large and a small incision facilitates insertion.
d. The bone marrow needle, with stylet in place, is introduced through the incision.	d. The needle is pointed toward the anterior superior iliac spine and brought into contact with the posterior iliac spine.
e. The needle is advanced and rotated by using firm and steady pressure. When the needle is felt to enter the outer cortex of the bone marrow cavity, the stylet is removed and the syringe attached. Negative pressure is applied and a small volume of blood and marrow is aspirated.	e. There is usually decreased resistance when the bone marrow cavity is entered. The actual aspiration may cause brief pain and the patient should be forewarned.
f. A biopsy is taken by using a special needle equipped with a sharp cutting edge and a hollow core.	f. Bone marrow appears rusty-red and normally has a thick, fluidlike consistency.
g. After removal of needle, apply pressure to site and dressing.	g. Prevents bleeding from the puncture site. Dressing keeps the site clean and dry until healed.

Splenectomy

The *spleen* is a fist-size organ located in the upper left quadrant of the abdomen. It includes a central "white pulp" where storage and some proliferation of lymphocytes and other leukocytes occurs and a peripheral "red pulp" involved in fetal erythropoiesis, and later in erythrocyte destruction and the conversion of hemoglobin to bilirubin. It may be surgically removed because of trauma or to treat certain hemolytic or malignant disorders with accompanying splenomegaly. A laparoscopic technique, usually with a lateral approach, is preferred to remove a normal to slightly enlarged spleen in benign conditions, such as idiopathic thrombocytopenic purpura, hemolytic anemia, or sickle cell disease. Compared with open surgery, laparoscopic splenectomies have a shortened hospital stay, decreased postoperative pain, and decreased risk of wound complications such as adhesions and infections.

Preoperative Management

1. For general aspects of preoperative nursing management, see Chapter 7.
2. Stabilization of preexisting condition:
    a. For trauma: volume replacement with intravenous (IV) fluids, evacuation of stomach contents via nasogastric tube to prevent aspiration, urinary catheterization to monitor urine output, assessment for pneumothorax or hemothorax, and possible chest tube placement.
    b. For hemolytic or malignant disorder with accompanying thrombocytopenia: coagulation studies, administration of coagulation factors (eg, vitamin K, fresh-frozen plasma, cryoprecipitate), and platelet and red cell transfusions.
3. Preoperative pulmonary evaluation and teaching.
4. For patients undergoing elective splenectomy, vaccination against pneumococcus, *Haemophilus influenzae* type b, and meningococcus are given at least 2 weeks before surgery.

Postoperative Management

1. For general aspects of postoperative nursing management, see Chapter 7.
2. Prevention of respiratory complications: hypoventilation and limited diaphragmatic movement, atelectasis of left lower lobe, pneumonia, and left pleural effusion.
3. Monitoring for hemorrhage.
4. Pharmacologic deep vein thrombosis (DVT) prophylaxis, begun in the operating room or if the patient is at increased bleeding risk, as soon as bleeding risk subsides.
5. Administration of opioids for pain and observance for adverse effects.
6. Monitoring for fever.
    a. Postsplenectomy fever—mild, transient fever is expected.
    b. Persistent fever may indicate subphrenic abscess or hematoma.
7. Monitoring daily platelet count: thrombocytosis (elevation of platelet count) may appear a few days after splenectomy and may persist during first 2 weeks.

Potential Complications

1. Pancreatitis and fistula formation: tail of pancreas is anatomically close to splenic hilum.
2. Hemorrhage.
3. Atelectasis and pneumonia.
4. Overwhelming postsplenectomy infection (OPSI)—increased risk of developing a life-threatening bacterial infection with encapsulated organisms, such as *Streptococcus pneumoniae*, *Neisseria meningitidis*, or *H. influenzae* type b. The incidence of OPSI is 0.23% to 0.42% per year with a lifetime risk of 5%. An OPSI is a medical emergency and requires immediate IV antibiotics in an intensive care setting. IV immunoglobulins are also used.

NURSING ALERT The risk of OPSI is highest soon after splenectomy and in patients whose splenectomy occurred during childhood or for a malignant disease. Early symptoms include fever and malaise; the infection may progress within hours to sepsis and death, with mortality as high as 50% to 70%. Patient education before and after splenectomy is imperative. The nurse should include the risks of OPSI; recognition of early symptoms and prompt medical attention; use of medical alert identification; immunization against *S. pneumoniae*, *H. influenzae* type b, and *N. meningitidis*; and, in some cases, prophylactic and standby antibiotics.

Nursing Diagnoses

- Ineffective Breathing Pattern related to pain and guarding of surgical incision.
- Risk for Deficient Fluid Volume related to hemorrhage caused by surgery of highly vascular organ.
- Risk for Injury (thromboembolism) related to thrombocytosis.
- Risk for Infection related to surgical incision and removal of the spleen.
- Acute Pain related to surgical incision.

Nursing Interventions

Maintaining Effective Breathing

1. Assess breath sounds and report absent, diminished, or adventitious sounds.
2. Assist with aggressive chest physiotherapy and incentive spirometry.
3. Encourage early and progressive mobilization.

Monitoring for Hemorrhage

1. Monitor vital signs frequently and as condition warrants.
2. Measure abdominal girth and report abdominal distention.
3. Assess for pain and report increasing pain.
4. Prepare the patient for surgical re-exploration if bleeding is suspected.

Avoiding Thromboembolic Complications

1. Monitor platelet count daily; report abnormal result promptly.
2. Administer DVT prophylaxis, as ordered.
3. Assess for possible thromboembolism.
    a. Assess skin color, temperature, tenderness, and swelling.
    b. Advise the patient to report chest pain, shortness of breath, pain, or weakness.
4. Report signs of thromboembolism immediately.

Preventing Infection

1. Assess surgical incision daily or if increased pain, fever, or foul smell.
2. Maintain meticulous hand washing and change dressings using sterile technique.
3. Teach the patient to report signs of infection (fever, malaise) immediately.
4. Educate the patient and family regarding OPSI, including plan for postsplenectomy immunizations, recognition of symptoms, and use of prophylactic and standby antibiotics.

Relieving Pain

1. Administer opioids or teach self-administration, as prescribed and as necessary, to maintain level of comfort.
2. Warn the patient of adverse effects, such as nausea and drowsiness; watch for hypotension and decreased respirations.
3. Teach the use of nonpharmacologic methods, such as music, relaxation breathing, progressive muscle relaxation, distraction, and imagery to help manage pain.
4. Document dosage of medications and response to medication.
5. Make sure the patient has analgesics for use postdischarge.

Patient Education and Health Maintenance

1. Teach care of incision.
2. Encourage to gradually increase activity according to guidelines given by the surgeon.
3. Advise proper rest, nutrition, and stress avoidance while recovering from surgery.
4. Encourage follow-up as directed by the surgeon and primary care provider to maintain immunizations.
5. Encourage the patient to seek prompt medical attention for any infections and to contact health care provider immediately for high fever.

Evaluation: Expected Outcomes

- Respirations unlabored, breath sounds clear.
- Vital signs stable, abdominal girth unchanged.
- No warmth, redness, swelling, or tenderness of extremity.
- Afebrile, no purulent drainage from incision.

- Verbalizes decreased pain.

ANEMIAS

Anemia is the lack of sufficient circulating hemoglobin to deliver oxygen to tissues. Anemia has multiple causes and is commonly associated with other diseases and disorders (eg, renal disease, cancer, Crohn disease, alcoholism). Anemia may be caused by inadequate production of RBCs, abnormal hemolysis and sequestration of RBCs, or blood loss. Iron deficiency anemia, pernicious anemia, folic acid deficiency anemia, and aplastic anemia are the anemias most commonly seen in adults. Hereditary hemolytic disorders include spherocytosis, hemoglobinopathies (eg, sickle cell), and enzymatic deficiencies such as glucose 6-phosphate dehydrogenase (G6PD). Treatments for anemia include nutritional counseling, supplements, RBC transfusions, and, for some patients, administration of exogenous erythropoietin (epoetin alfa or darbepoetin alfa), a growth factor stimulating production and maturation of erythrocytes. New erythropoiesis-stimulating agents are under development. Erythropoietin is used to stimulate RBC production in anemias associated with chronic renal failure, chemotherapy treatment, and HIV.

DRUG ALERT Erythropoietic-stimulating agents, such as epoetin alfa and darbepoetin alfa, have been associated with increased risk of death and serious cardiovascular events. Use the lowest possible dose and monitor for such potential problems as hypertension—particularly in patients with chronic kidney disease—and deep venous thrombosis.

Iron Deficiency Anemia (Microcytic, Hypochromic)

Iron deficiency anemia is a condition in which the total body iron content is decreased below a normal level, affecting hemoglobin synthesis. RBCs appear pale and are small.

Pathophysiology and Etiology

1. The most common cause is chronic blood loss (GI bleeding including occult colorectal cancers, excessive menstrual bleeding, and hookworm infestation), but anemia may also be caused by insufficient intake of iron (weight loss, inadequate diet), iron malabsorption (end-stage renal disease, small-bowel disease, gastroenterostomy), or increased requirements (pregnancy, periods of rapid growth).
2. Decreased hemoglobin may result in insufficient oxygen delivery to body tissues.
3. The incidence of iron deficiency anemia, the most common type of anemia, varies widely by age, sex, and race. In the United States, it is more than twice as common in women as compared to men, affecting 10% of non-Hispanic white women and 20% of black and Hispanic women. It is a major health problem in developing countries.
4. Symptoms generally develop when hemoglobin has fallen to less than 11 g/100 mL.

Clinical Manifestations

1. Headache, dizziness, fatigue, and tinnitus.
2. Palpitations, dyspnea on exertion, and pallor of skin and mucous membranes.
3. In developing world: smooth, sore tongue; cheilosis (lesions at corners of mouth), koilonychia (spoon-shaped fingernails), and pica (craving to eat unusual substances).

Diagnostic Evaluation

1. CBC and iron profile—decreased hemoglobin, hematocrit, serum iron, and ferritin; elevated red cell distribution width and normal or elevated total iron-binding capacity (transferrin).
2. Determination of source of chronic blood loss may include sigmoidoscopy, colonoscopy, upper and lower GI studies, and stools and urine for occult blood examination.

Management

1. Diagnosis and correction of chronic blood loss.
2. Oral or parenteral iron therapy.
    a. Oral ferrous sulfate preferred and least expensive; treatment continues until hemoglobin level is normalized and iron stores replaced (up to 6 months).
    b. Parenteral therapy may be used when the patient cannot tolerate or is noncompliant with oral therapy. May use sodium ferric gluconate, iron sucrose, or iron dextran.

Complications

1. Severe compromise of the oxygen-carrying capacity of the blood may predispose to ischemic organ

damage, such as myocardial infarction or stroke.

2. Anaphylaxis to parenteral iron therapy, especially with iron dextran.

Nursing Assessment

1. Obtain history of symptoms, dietary intake, past history of anemia, and possible sources of blood loss.
2. Examine for tachycardia, pallor, dyspnea, and signs of GI or other bleeding.

Nursing Diagnoses

- Imbalanced Nutrition: Less Than Body Requirements related to inadequate intake of iron.
- Activity Intolerance related to decreased oxygen-carrying capacity of the blood.
- Ineffective Tissue Perfusion related to decreased oxygen-carrying capacity of the blood.

Nursing Interventions

Promoting Iron Intake

1. Assess diet for inclusion of foods rich in iron. Arrange nutritionist referral, as appropriate.
2. Administer iron replacement, as ordered. Monitor iron levels of patients on chronic therapy.

DRUG ALERT Anaphylactic reactions may occur after parenteral iron administration. Monitor the patient closely for hypotension, angioedema, and stridor after injection. Do not administer with oral iron.

Increasing Activity Tolerance

1. Assess level of fatigue and normal sleep pattern; determine activities that cause fatigue.
2. Assist in developing a schedule of activity, rest periods, and sleep.
3. Encourage conditioning exercises to increase strength and endurance.

Maximizing Tissue Perfusion

1. Assess the patient for palpitations, chest pain, dizziness, and shortness of breath; minimize activities that cause these symptoms.
2. Elevate head of bed and provide supplemental oxygen, as ordered.
3. Monitor vital signs and fluid balance.

Patient Education and Health Maintenance

1. Educate the patient on proper nutrition and good sources of iron: select a well-balanced diet that includes animal proteins, iron-fortified cereals and bread, beans, dried fruits, legumes, and tofu (see Table 26-3). The daily requirement of iron for adult females age 19 to 50 is 18 mg, for men 8 mg; however, more is needed to build iron stores in those who have been anemic and for those who are at risk for anemia.

2. Teach the patient about iron supplementation.
   a. Take iron on empty stomach, with full glass of water or fruit juice.
   b. Liquid forms may stain teeth; mix well with water or fruit juice and use a straw.
   c. Anticipate some epigastric discomfort, change in color of stools to green or black, and, in some cases, nausea, constipation, or diarrhea. Prevent and treat constipation with increased fiber, fluids, and exercise. Report GI intolerance to health care provider.
   d. Keep iron medications away from children as overdose may be fatal.
3. Encourage follow-up laboratory studies and visits to health care provider.

Table 26-3 Dietary Sources of Iron

FOOD	SERVING SIZE	MG PER SERVING
Cereal (fortified)	1 oz	1.8–21
Chicken liver	3.5 oz	12.8
Oatmeal (fortified)	1 cup	10
Soybeans	1 cup	8.8
Beef liver	3 oz	7.5
Lentils	1 cup	6.6
Beans (kidney, lima, navy, pinto)	1 cup	3.6–5.2
Oysters	6 pieces	4.5
Pumpkin seeds, roasted	1 oz	4.2
Beef (various cuts)	3–3.5 oz	2–3.9
Molasses	1 tbsp	3.5
Tofu	1/2 cup	3.4
Spinach, cooked	1/2 cup	3.2
Clams	3/4 cup	3.0
Sardines	3 oz	2.5
Turkey	3.5 oz	1.6–2.3
Macaroni (enriched, cooked)	1 cup	1.9
Bread (enriched)	2 slices	1.8
Rice (cooked)	1 cup	1.8
Apricots (dried)	10 pieces	1.7
Raisins	1/2 cup	1.5
Prune juice	1/2 cup	1.5
Pork	3–3.5 oz	1.2–1.5
Peas	1/2 cup	1.3
Chicken	3–3.5 oz	1.1–1.3

Evaluation: Expected Outcomes

- Incorporates several foods high in iron into diet; takes prescribed iron supplementation, as ordered.
- Tolerates increased activity; obtains sufficient rest.

- Vital signs stable without complaints of chest pain, palpitations, or shortness of breath.

Megaloblastic Anemia: Pernicious (Macrocytic, Normochromic)

A *megaloblast* is a large, nucleated erythrocyte with delayed and abnormal nuclear maturation. *Pernicious anemia* is a type of megaloblastic anemia associated with vitamin B_{12} deficiency.

Pathophysiology and Etiology

1. Vitamin B_{12} is necessary for normal deoxyribonucleic acid synthesis in maturing RBCs.
2. Pernicious anemia demonstrates familial incidence related to autoimmune gastric mucosal atrophy.
3. Normal gastric mucosa secretes a substance called intrinsic factor, necessary for absorption of vitamin B_{12} in ileum. If a defect exists in gastric mucosa, or after gastrectomy or small-bowel disease, intrinsic factor may not be secreted and orally ingested B_{12} may not be absorbed.
4. Some drugs interfere with B_{12} absorption, notably ascorbic acid, cholestyramine, colchicine, neomycin, cimetidine, and hormonal contraceptives.
5. Lower serum vitamin B_{12} concentrations are associated with aging, but the evidence linking subnormal vitamin B_{12} to anemia in older people remains limited and inconclusive.

Clinical Manifestations

1. Of anemia—pallor, fatigue, dyspnea on exertion, and palpitations. May be angina pectoris and heart failure in older adults or those predisposed to heart disease.
2. Of underlying GI dysfunction—sore mouth, glossitis, anorexia, nausea, vomiting, loss of weight, indigestion, epigastric discomfort, recurring diarrhea, or constipation.
3. Of neuropathy (occurs in high percentage of untreated patients)—paresthesia that involves hands and feet, gait disturbance, bladder and bowel dysfunction, and psychiatric symptoms caused by cerebral dysfunction.

Diagnostic Evaluation

1. CBC and blood smear—decreased hemoglobin and hematocrit; marked variation in size and shape of RBCs with a variable number of unusually large cells.
2. Folic acid (normal) and B_{12} levels (decreased).
3. Gastric analysis—volume and acidity of gastric juice diminished.
4. Schilling test for absorption of vitamin B_{12} uses small amount of radioactive B_{12} orally and 24-hour urine collection to measure uptake—decreased.

Management

Parenteral replacement with hydroxocobalamin or cyanocobalamin (B_{12}) is necessary by intramuscular (IM) injection from health care provider, generally every month.

Complications

Neurologic: paresthesia, gait disturbances, bowel and bladder dysfunction, and cerebral dysfunction may be

persistent.

Nursing Assessment

1. Assess for pallor, tachycardia, dyspnea on exertion, and exercise intolerance to determine the patient's response to anemia.
2. Assess for paresthesia, gait disturbances, changes in bladder or bowel function, and altered thought processes indicating neurologic involvement.
3. Obtain history of gastric surgery or GI disease.

Nursing Diagnoses

- Chronic Confusion related to neurologic dysfunction in absence of vitamin B_{12}.
- Impaired Comfort related to neurologic dysfunction in absence of vitamin B_{12}.

Nursing Interventions

Improving Thought Processes

1. Administer parenteral vitamin B_{12}, as prescribed.
2. Provide the patient with quiet, supportive environment; reorient to time, place, and person, if needed; give instructions and information in short, simple sentences and reinforce frequently.

Minimizing the Effects of Paresthesia

1. Assess extent and severity of paresthesia, imbalance, or other sensory alterations.
2. Refer the patient for physical therapy and occupational therapy, as appropriate.
3. Provide safe, uncluttered environment; make sure personal belongings are within reach; provide assistance with activities, as needed.

Patient Education and Health Maintenance

1. Advise the patient that monthly vitamin B_{12} administration should be continued for life.
2. Instruct the patient to see health care provider approximately every 6 months for hematologic studies and GI evaluation; may develop hematologic or neurologic relapse if therapy inadequate.

GERONTOLOGIC ALERT Patients with pernicious anemia have higher incidence of gastric cancer and thyroid dysfunction; therefore, periodic stool examinations for occult blood, gastric cytology, and thyroid function tests should be done. It is important to ensure that patient has access to a primary care provider and that patient records with follow up recommendations are communicated. Patients should also be educated on the signs and symptoms to report.

Evaluation: Expected Outcomes

- Oriented, cooperative, and follows instructions.
- Carries out activities without injury.

Megaloblastic Anemia: Folic Acid Deficiency

Chronic *megaloblastic anemia* is caused by folic acid (folate) deficiency.

Pathophysiology and Etiology

1. Dietary deficiency, malnutrition, marginal diets, excessive cooking of foods; commonly associated with alcoholism.
2. Impaired absorption in jejunum (eg, with small-bowel disease).
3. Increased requirements (eg, with chronic hemolytic anemia, exfoliative dermatitis, pregnancy).
4. Impaired utilization from folic acid antagonists (methotrexate) and other drugs (phenytoin, broad-spectrum antibiotics, sulfamethoxazole, alcohol, hormonal contraceptives).

Clinical Manifestations

1. Of anemia: fatigue, weakness, pallor, dizziness, headache, tachycardia.
2. Of folic acid deficiency: sore tongue, cracked lips.

Diagnostic Evaluation

1. Vitamin B_{12} and folic acid level—folic acid will be decreased.
2. CBC will show decreased RBC, hemoglobin, and hematocrit with increased mean corpuscular volume and mean corpuscular hemoglobin concentration.

Management

Oral folic acid (folate) replacement on daily basis.

Complications

Folic acid deficiency has been implicated in the etiology of congenitally acquired neural tube defects.

Nursing Assessment

1. Obtain nutritional history.
2. Monitor level of dyspnea, tachycardia, and development of chest pain or shortness of breath for worsening of condition.

Nursing Diagnosis

- Imbalanced Nutrition: Less Than Body Requirements related to inadequate intake of folic acid.

Nursing Interventions

Improving Folic Acid Intake

1. Assess diet for inclusion of foods rich in folic acid: beef liver, peanut butter, red beans, oatmeal, broccoli, and asparagus.

2. Arrange nutritionist referral, as appropriate.
3. Administer folic acid (folate) supplement.
4. Assist alcoholic patient to obtain counseling and additional medical care, as needed.

Community and Home Care Considerations

1. Encourage pregnant patient to maintain prenatal care and to take folic acid supplement.
2. Provide alcoholic patient with information about treatment programs and Alcoholics Anonymous meetings in the community.

Patient Education and Health Maintenance

1. Teach the patient to select balanced diet that includes green vegetables (asparagus, broccoli, spinach), yeast, liver and other organ meats, and some fresh fruits; avoid overcooking vegetables.
2. Encourage the patient to follow up periodically to monitor CBC.

Evaluation: Expected Outcomes

- Eats appropriate and nutritious diet; takes folic acid supplements, as prescribed.

Aplastic Anemia

Aplastic anemia is a rare disorder characterized by bone marrow hypoplasia or aplasia resulting in pancytopenia (insufficient numbers of RBCs, WBCs, and platelets).

Pathophysiology and Etiology

Destruction of hematopoietic stem cells is thought to be through an immune-mediated mechanism.

1. Most often (70% to 80% of patients) characterized as idiopathic because no cause is found.
2. May be caused by exposure to chemical toxins (eg, benzene); ionizing radiation; viral infections, particularly hepatitis; certain drugs (eg, chloramphenicol).
3. May be congenital (eg, Fanconi anemia, Diamond-Blackfan anemia, and Shwachman-Diamond syndrome).
4. Clinical course is variable and dependent on degree of bone marrow failure; severe aplastic anemia is almost always fatal if untreated.

Clinical Manifestations

1. From anemia: pallor, weakness, fatigue, exertional dyspnea, palpitations.
2. From infections associated with neutropenia: fever, headache, and malaise; adventitious breath sounds; abdominal pain, diarrhea; erythema, pain, exudate at wounds, or sites of invasive procedures.
3. From thrombocytopenia: bleeding from gums, nose, GI or GU tracts; purpura, petechiae, ecchymoses.

Diagnostic Evaluation

1. CBC and peripheral blood smear show decreased RBC, WBC, and platelets (pancytopenia).
2. Bone marrow aspiration and biopsy: bone marrow is hypocellular or empty with greatly reduced or absent hematopoiesis.

Management

1. Removal of causative agent or toxin.
2. Allogeneic bone marrow transplantation (BMT)—treatment of choice for patients with severe aplastic anemia (see page 784). This treatment option provides long-term survival for 75% to 90% of patients, depending on the age of the patient, history of prior blood transfusions, and source of marrow.
3. Immunosuppressive treatment with cyclosporine and antithymocyte globulin or cyclophosphamide. This treatment option provides long-term survival for 60% to 70% of patients.
4. Androgens (oxymetholone or testosterone enanthate) may stimulate bone marrow regeneration; significant toxicity encountered. They may be used when other treatments have failed.
5. Supportive treatment includes platelet and RBC transfusions, antibiotics, and antifungals. Blood components should be irradiated for patients eligible for BMT, and this approach is also recommended for patients receiving immunosuppressive therapy.

Complications

1. Untreated severe aplastic anemia is almost always fatal, generally because of overwhelming infection. Even with treatment, morbidity and mortality caused by infections and bleeding are high.
2. Late complications, even after successful treatment, include clonal hematologic diseases such as paroxysmal nocturnal hemoglobinuria, myelodysplasia, and acute myelogenous leukemia (AML).

Nursing Assessment

1. Obtain a thorough history that includes medications, past medical history, occupation, and hobbies.
2. Monitor for signs of bleeding and infection.

Nursing Diagnoses

- Risk for Infection related to granulocytopenia secondary to bone marrow aplasia.
- Risk for Bleeding related to disease process.

Nursing Interventions

Minimizing Risk of Infection

1. Care for patient in protective environment while hospitalized (eg, private room with strict hand washing and avoidance of any contaminants).
2. Encourage good personal hygiene, including daily shower or bath with mild soap, mouth care, and perirectal care after using the toilet.
3. Monitor vital signs, including temperature, frequently; notify health care provider of oral temperature of 101˚F (38.3˚C) or higher.
4. Minimize invasive procedures or possible trauma to skin or mucous membranes.
5. Obtain cultures of suspected infected sites or body fluids.

Minimizing Risk of Bleeding

1. Use only soft toothbrush or toothette for mouth care and electric razor for shaving; keep nails short by filing.
2. Avoid IM injections and other invasive procedures.
3. Prevent constipation with stool softeners, as prescribed.
4. Restrict activity based on platelet count and active bleeding.
5. Monitor pad count for menstruating patient; avoid use of vaginal tampons.
6. Control bleeding by applying pressure to site, using ice packs and prescribed topical hemostatic agents.
7. Administer blood product replacement, as ordered; monitor for allergic reaction, anaphylaxis, and volume overload.

Patient Education and Health Maintenance

1. Teach the patient how to minimize risk of infection.
    a. Wash hands after contact with possible source of infection.
    b. Immediately clean any abrasion or wound of mucous membranes or skin.
    c. Monitor temperature and report fever or other sign of infection immediately.
    d. Avoid crowds and people with illnesses.
    e. Avoid raw or undercooked foods.
    f. Use condoms and other safe-sex practices.
2. Teach the patient how to minimize risk of bleeding.
    a. Avoid falls or other injury.
    b. Use electric razor rather than plain razor.
    c. Use nail clippers or file rather than scissors.
    d. Avoid blowing nose.
    e. Use soft toothbrush or toothette for mouth care.
    f. Use water-soluble lubricants, as needed, during sexual activity.
3. Advise the patient to avoid exposure to potential bone marrow toxins: solvents, sprays, paints, and pesticides.
4. Teach the patient to take only prescribed medications; avoid aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs), which may interfere with platelet function. As some vitamins and herbs may also affect platelet function, instruct the patient to check with physician before using any supplements.
5. Resources for the patient and family include the Aplastic Anemia & MDS International Foundation (*www.aamds.org*).

Evaluation: Expected Outcomes

- Remains afebrile with no signs or symptoms of infection.
- Episodes of bleeding rapidly controlled.

MYELOPROLIFERATIVE DISORDERS

See additional online content: Patient Education Guidelines 26-1, 26-2 and Nursing Care Plan 26-1

PATIENT EDUCATION GUIDELINES 26-1

Preventing, Recognizing, and Treating Infection

Question 1. What kinds of infections am I at risk for?

a. Because some of your white blood cells (called neutrophils) are not present in their normal numbers, you are at risk for infections. Neutrophils attack bacteria and other organisms that cause infections. You are at risk for infections from bacteria (eg, wound infections, urinary tract infections, pneumonia) and some viral infections (eg, cold sores) and fungal infections (eg, thrush, fungal pneumonia).

Question 2. How do I know when I have an infection?

a. With low numbers of neutrophils, some of the normal signs of infection, such as pus, may not be present. If you have a fever greater than 100°F (37.8°C), you should contact your health care provider immediately. Other signs of infection include chills and sweating, redness near a wound or a catheter, white patches in your mouth, or shortness of breath.

Question 3. How can I protect myself from infection?

a. The most important thing you can do is to wash your hands thoroughly after using the bathroom or after any other "(dirty)" activity (such as taking out the trash). You should keep your mouth clean by brushing your teeth with a soft toothbrush after every meal or snack and by rinsing with a mild mouth rinse. You should shower daily using a mild soap.

Question 4. Can I have visitors? Can I go out?

a. It is important to ask friends and family not to visit if they are not feeling well. You can certainly go out (unless your physician or nurse gives you different instructions), but you

should avoid crowded, poorly ventilated places. You may be taught how to wear a special mask when you are outside.

Question 5. Do I need to get rid of my pet?

a. If you have pets and gardens, you can still enjoy them. If possible, find someone else who will clean your cat's litter box or scoop your dog's waste. Wear gloves when gardening and be careful not to get cuts and abrasions.

Question 6. Should I stop having sexual intercourse?

a. With your low neutrophil count, you are also at higher risk for sexually transmitted diseases. However, this does not mean you have to stop having sexual intercourse. It is important to use a condom and make sure your sexual practice is safe. Depending on your general health, your physician or nurse may recommend that you avoid sexual intercourse.

Question 7. If I get an infection, how will it be treated?

a. A new infection typically requires hospital admission to diagnose it and to begin treatment. You may be given many tests to find out exactly what infection you have. Blood will be drawn and examined for infection, x-rays and computed tomography scans may be done, and you may need a lumbar puncture to look for an infection in your spinal fluid. Before the results of all the tests are available, your physician will begin treatment with IV antibiotics. If your infection does not get better (eg, if you still have a fever in a couple of days), your antibiotics may be changed or other medications may be added. When your infection begins to improve, it is usually possible to go home and continue taking IV or oral antibiotics at home.

PATIENT EDUCATION GUIDELINES 26-2

Preventing, Recognizing, and Treating Bleeding

Question 1. Why am I at risk for bleeding?

a. You could be at risk for bleeding because you do not have enough platelets (cells that help make clots), because your platelets are not working properly, or because you do not have enough clotting factors in your blood (substances that help make clots). Some people need treatment with drugs, such as heparin and Coumadin, to prevent dangerous clots in the legs and lungs. These drugs increase the risk of bleeding.

Question 2. How will I know if I have bleeding?

a. You might have visible bleeding, such as a nosebleed or bleeding from your gums. You might have very heavy bleeding with your menses (period), which might go on longer than usual. You might notice blood in your stools or black stools (black stools can also occur if you take iron). You might see blood streaks or black flecks in your emesis (vomit). The color of your urine might be pink or red, or you might see red streaks in it. You might have small bruises appear on your skin or redness in the white part of your eyes. If you have bleeding internally you might have symptoms, such as pain, swelling, shortness of breath (bleeding in the lungs), or confusion or stroke symptoms (bleeding in the brain).

Question 3. What should I do to stop something from bleeding?

a. If your nose is bleeding, you can apply pressure by squeezing the bridge of the nose. If you have a wound that is bleeding, apply pressure to the site with a clean or sterile pad. Ice packs can also help; apply ice for 20 minutes at a time, then remove and reapply every hour or 2, if needed. If you have bleeding in the mouth, biting on a tea bag may also help. If bleeding does not stop quickly or seems to be

a lot, you should contact your health care provider or go to an emergency department. You should also seek help right away if you are coughing up blood or vomiting blood, if you feel weak or confused, or if you are worried that it is serious.

Question 4. What can I do to prevent bleeding?

a. There are lots of things you can do to decrease the risk of bleeding. Avoid activities where you have a high risk of injury (eg, contact sports). Use a soft toothbrush (you can floss gently if it does not cause bleeding). Avoid blowing your nose. Use an electric razor instead of a regular razor. Keep your fingernails and toenails short and smooth using a nail clipper and file rather than scissors. Make sure you do not get constipated—straining may cause bleeding. Do not take aspirin, ibuprofen, or naproxen. Acetaminophen is a safe alternative to these types of medications. Other medications and several vitamins and herbs can increase your

risk of bleeding. Do not take over-the-counter medications or herbal and nutritional supplements and vitamins until you have checked with your health care provider. Take medicine to suppress your menses (period) as ordered. Use water-soluble lubricants during sexual activity to decrease the risk of abrasions.

Question 5. What else should I do?

a. Talk with your health care provider and nurse about your activities. If you are at high risk for bleeding, you may need to restrict or change your exercise and activities. You may need to change sexual practices. Keep your appointments with your health care providers and take medications, as prescribed. If you visit another physician or dentist or need surgery, be sure to tell health care providers about your risk of bleeding. Wear a MedicAlert bracelet if you will be at risk for bleeding for some time.

Nursing Care Plan 26-1

Care of the Patient with Acute Leukemia

You are assigned Charles Wintry, a 48-year-old with acute myelogenous leukemia (AML) who has been admitted with neutropenia and thrombocytopenia following chemotherapy. From your assessment and your knowledge of AML, you develop your care plan.

Subjective data: Charles tells you he has felt very tired during the past week and has stopped working at his part-time store manager job. Since yesterday evening, he has had a low-grade fever and pain in his chest with inspiration. He has also noticed

new bruises on his lower legs and abdomen. This morning
he had a nosebleed.

Objective data: Vital signs are temperature 101˚F (38.3˚C), pulse 104, blood pressure 145/90, respirations On examination, you notice extensive petechiae; dried blood around the nares and gingival bleeding; warm, dry skin; and crackles heard in the bases of both lungs. Complete blood count reveals 30,000 platelets, 1,200 white blood cells with 450 neutrophils, and hematocrit of 32%.

NURSING DIAGNOSIS

Risk for Infection related to granulocytopenia secondary to leukemia or its treatment with chemotherapy or radiation.

GOAL/EXPECTED OUTCOME

Risk of infection will be minimized.

Nursing Intervention	Rationale	Evaluation: Actual Outcome
Place the patient in a private room with hand-washing precautions strictly enforced.	Meticulous hand washing is the single most important method of preventing transmission of endogenous and exogenous nosocomial infections.	Staff and visitors comply with hand-washing precautions.
Avoid exposure to all sources of stagnant water (eg, flower vases, denture cups, water pitchers, humidifiers) and plants.	Stagnant water and soil are good media for anaerobic bacterial growth.	No visible sources of bacterial growth found in the room.
Encourage or assist with personal hygiene—mouth care, perirectal care, daily shower or bath with mild soap. Inspect skin and mucous membranes daily for possible signs of infection.	Skin care and good oral hygiene may help prevent skin, oral, respiratory, and GI infections. Signs of infection may be minimal in a neutropenic patient.	Skin remains clean and lubricated. Oropharynx has no lesions, plaques, or erythema.
Monitor vital signs every 4 hours. Obtain baseline pulse oximeter reading (SaO_2).	Infections may progress rapidly in immunocompromised patient.	Vital signs stable with no changes to report to health care provider.
Assess respiratory function every 4 hours while symptoms present, otherwise every 8 hours. Encourage ambulation, deep breathing, and coughing.	Neutropenic patient may have significant bacterial or fungal pneumonia with minimal changes on chest x-ray or physical examination.	Ambulates and uses incentive spirometer every 4 hours.
Assess for changes in mental status at least every 8 hours, including restlessness, irritability, confusion, headache, or changes in level of consciousness.	Mental status changes are commonly first subtle signs of sepsis.	Mental status remains stable; appears alert and oriented.
Avoid invasive procedures if possible (eg, urinary catheterization). Use strict sterile technique if procedure unavoidable.	Risk of infection from invasive procedure is high.	No invasive procedures initiated. Injections given via IV line.
Prevent rectal trauma by avoiding rectal temperatures, enemas, or suppositories. Use sitz bath and barrier cream for patients with diarrhea and hemorrhoids. Use stool softeners, as needed, to prevent constipation.	Perianal area is a high-risk site for infection, including rectal abscesses.	Perianal area remains clean and intact.
Obtain cultures of suspected infected sites or body fluids.	Pus may not be present with neutropenia. Cultures may reveal bacterial, fungal, or viral pathogens.	Sputum sent for culture.

NURSING DIAGNOSIS

Risk for Injury related to bleeding secondary to thrombocytopenia, disseminated intravascular coagulation, or leukostasis associated with leukemia.

GOAL/EXPECTED OUTCOME

Risk of bleeding will be minimized.

Nursing Intervention	Rationale	Evaluation: Actual Outcome
Assess for signs of bleeding at least every 8 hours.	Overt and covert spontaneous bleeding is possible at platelet counts <50,000/mm^3.	No further bleeding noted.
Provide soft toothbrush or toothettes and mild mouthwash for mouth care.	Minimize damage to mucous membranes.	Uses soft toothbrush after meals for gentle cleansing.
Use only an electric razor for shaving. Keep fingernails and toenails short and smooth. Lubricate skin with mild lotion.	Minimize skin excoriation.	Family member or spouse brings electric razor from home.
Avoid IM injections, invasive procedures, rectal procedures. Use stool softeners to prevent constipation.	Minimize risk of bleeding.	Invasive procedures minimized. Injections given via IV line.
Restrict activity based on assessment of platelet count and presence of active bleeding.	Injury to muscles or spontaneous bleeding may be minimized by restricting activity at lower platelet counts.	Ambulates within room with assistance until bleeding controlled and platelet count stabilized.

Nursing Intervention	Rationale	Evaluation: Actual Outcome
Menstrual suppression may be necessary for females. Monitor pad count/amount. Avoid use of vaginal tampons.	Menorrhagia may be severe in thrombocytopenic patient.	Menstrual bleeding not exceeding 4 to 5 pads per day.
Control bleeding by applying pressure to site, ice packs, and prescribed topical hemostatic agents, such as microfibrillar collagen hemostat or thrombin.	Topical interventions generally adequate to control most bleeding episodes.	No further bleeding episodes.
Administer blood product replacement, as ordered. Monitor for signs and symptoms of allergic reactions, anaphylaxis, and volume overload.	Platelet transfusions may be necessary when platelet count <20,000/mm^3 or with active bleeding. Other blood products (red blood cells, fresh frozen plasma, cryoprecipitate) may also be required.	Platelet products given every 2 to 3 days until thrombocytopenia resolved.
Teach the patient to avoid activities likely to cause injury (eg, contact sports) and other methods to prevent bleeding.	Risk of bleeding remains after discharge.	States preventive measures.

NURSING DIAGNOSIS

Acute pain related to tumor growth, infection, or adverse effects of chemotherapy.

GOAL/EXPECTED OUTCOME

Pain will be controlled.

Nursing Intervention	Rationale	Evaluation: Actual Outcome
Assess at least every 4 hours for presence, location, intensity, and characteristics of pain.	Pain is potentially distressing symptom. Pain may be a symptom of infection.	Rates pain between 1 and 3 on scale of 0 to 10 after first day.
Administer analgesics, as ordered, to control pain. Administer on regular schedule rather than as needed. Avoid aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs) in thrombocytopenic patients. If oral analgesics in optimal doses are not effective or not tolerated, consider IV route.	Analgesics on regular schedule at appropriate doses should be used to control pain. Aspirin and NSAIDs interfere with platelet function. IM and SubQ injections should be avoided in thrombocytopenia.	Oral analgesia (codeine 30 mg every 4 hours) well tolerated.
Teach and use nonpharmacologic measures, such as the use of music, relaxation breathing, progressive muscle relaxation, distraction, and imagery to help manage pain.	Nonpharmacologic measures may be useful adjunctive treatments for patients with pain.	Heat packs to right chest area provide additional relief.

NURSING DIAGNOSIS

Powerlessness related to diagnosis and perceived lack of support/resources.

GOAL/EXPECTED OUTCOME

The patient and family will be empowered to seek appropriate help.

Nursing Intervention	Rationale	Evaluation: Actual Outcome
Encourage verbalization of feelings regarding diagnosis, treatment plan, and anticipated course of illness.	Nurse–patient relationship allows appropriate discussion of concerns.	Verbalizes feelings through discussion, crying.
Refer, as needed, to social worker, psychiatric liaison nurse, psychologist.	Further assistance and support may be needed.	Referred to social worker for assistance with financial concerns.
Share information regarding national and local resources.	National and local organizations may be significant sources of support for patients and families.	Attends American Cancer Society support group after discharge.

Myeloproliferative disorders are disorders of the bone marrow that result from abnormal proliferation of cells from the myeloid line of the hematopoietic system. They include polycythemia vera, acute lymphocytic and AML, and chronic myelogenous leukemia (CML).

Polycythemia Vera

Polycythemia vera is a chronic myeloproliferative disorder that involves all bone marrow elements, resulting in an increase in RBC mass and hemoglobin.

Pathophysiology and Etiology

1. Hyperplasia of all bone marrow elements results in the following:
    a. Overproduction of all three blood cell lines, most prominently RBCs.
    b. Increased red cell mass.
    c. Increased blood volume and viscosity.
    d. Decreased marrow iron reserve.
    e. Splenomegaly.
2. Increased mass of blood cells increases viscosity and leads to engorgement of blood vessels and possible thrombosis.
3. Underlying cause is unknown.
4. Usually occurs in middle and later years.

Clinical Manifestations

Result from increased blood volume and viscosity.

1. Reddish purple skin and mucosa, pruritus (especially after bathing).
2. Splenomegaly, hepatomegaly.
3. Epigastric discomfort, abdominal discomfort.
4. Painful fingers and toes from arterial and venous insufficiency, paresthesia.
5. Headache, fullness in head, dizziness, visual abnormalities, altered mentation from disturbed cerebral circulation.
6. Weakness, fatigue, night sweats, bleeding tendency.
7. Hyperuricemia from increased formation and destruction of erythrocytes and leukocytes and increased metabolism of nucleic acids.
8. Itching related to histamine release from basophils.

Diagnostic Evaluation

1. CBC—elevated RBC and hemoglobin and hematocrit (greater than 60%); elevated platelets.
2. Bone marrow aspirate and biopsy—hyperplasia.
3. Elevated uric acid.

Management

1. Of hyperviscosity: phlebotomy (withdrawal of blood) at intervals determined by CBC results to reduce RBC mass; generally, 250 to 500 mL removed at a time to maintain hematocrit less than 45%. The

British Committee for Standards in Hematology recommendations also include aspirin at 75 mg/day unless contraindicated.

2. Of marrow hyperplasia: chronic myelosuppressive therapy, generally using hydroxycarbamide (formerly known as hydroxyurea) or IV radioactive phosphorus; biologic response modifier (ie, alpha interferon). Aggressive chemotherapy is not recommended because of increased risk of secondary leukemia.
3. Of hyperuricemia: allopurinol.
4. Of pruritus: antihistamines (cimetidine or cyproheptadine); low-dose aspirin; certain antidepressants (doxepin, paroxetine); phototherapy; cholestyramine; alpha interferon.

EVIDENCE BASE Tefferi, A., & Barbui, T. (2017). Polycythemia vera and essential thrombocythemia: 2017 update on diagnosis, risk-stratification, and management. *American Journal of Hematology, 92*(1), 94–108.

Complications

1. Thromboembolic events caused by hyperviscosity, including deep vein thrombophlebitis, myocardial and cerebral infarction, transient ischemic attacks, pulmonary embolism, retinal vein thrombosis, and thrombotic occlusion of the splenic, hepatic, portal, and mesenteric veins.
2. Spontaneous hemorrhage caused by venous and capillary distention and abnormal platelet function.
3. Gout caused by hyperuricemia.
4. Heart failure caused by increased blood volume and hypertension.
5. Myelofibrosis or acute myeloid leukemia may be terminal complications.

Nursing Assessment

1. Obtain history of symptoms, including changes in skin, epigastric discomfort, bleeding tendencies, circulatory problems, or painful, swollen joints.
2. Monitor for signs of bleeding or thromboembolism.
3. Monitor for hypertension and signs and symptoms of heart failure, including shortness of breath, distended neck veins.

Nursing Diagnosis

- Ineffective Tissue Perfusion (multiple organs) related to hyperviscosity of blood.

Nursing Interventions

Preventing Thromboembolic Complications

1. Encourage or assist with ambulation. Employ thromboembolism precautions during periods of immobility.

2. Assess for early signs of thromboembolic complications—swelling of limb, increased warmth, pain, shortness of breath, and chest pain. Report immediately.
3. Monitor CBC and assist with phlebotomy, as ordered.

Patient Education and Health Maintenance

1. Educate the patient about risk of thrombosis; encourage the patient to maintain normal activity patterns and avoid long periods of bed rest.
2. Advise the patient to avoid taking hot showers or baths because rapid skin cooling worsens pruritus; use skin emollients; take antihistamines, as prescribed; may find starch baths helpful.
3. Instruct the patient to take only prescribed medications.
4. Encourage the patient to report at prescribed intervals for follow-up blood (hematocrit) studies and phlebotomies.
5. Instruct the patient in technique of subcutaneous injection for alpha interferon.

Evaluation: Expected Outcomes

- Hematocrit less than 45%; no signs or symptoms of thromboembolism, heart failure, or bleeding.

Acute Lymphocytic and Acute Myelogenous Leukemia

Leukemias are malignant disorders of the blood and bone marrow that result in an accumulation of dysfunctional, immature cells that are caused by loss of regulation of cell division. They are classified as acute or chronic based on the development rate of symptoms and further classified by the predominant cell type. Acute leukemias affect immature cells and are characterized by rapid progression of symptoms. When lymphocytes (B or T cell) are the predominant malignant cell, the disorder is *acute lymphocytic leukemia (ALL)*; when monocytes or granulocytes are predominant, it is *acute myelogenous leukemia (AML)*.

Pathophysiology and Etiology

1. The development of leukemia has been associated with the following:
    a. Exposure to ionizing radiation.
    b. Exposure to certain chemicals and toxins (eg, benzene, alkylating agents).
    c. Human T-cell leukemia—lymphoma virus (HTLV-1 and HTLV-2) in certain areas of the world, including the Caribbean and southern Japan.
    d. Familial susceptibility.
    e. Genetic disorders (eg, Down syndrome, Fanconi anemia).
    f. Childhood leukemia is often not associated with a specific cause.
2. Approximately one half of new leukemias are acute. Approximately 85% of acute leukemias in adults are AML. ALL is most common in children, with peak incidence between ages 2 and 9.
3. Childhood ALL is usually cured with chemotherapy alone (greater than 75%), whereas only 30% to 40% of adults with ALL are cured.
4. AML is a disease of older people, with a median age at diagnosis of 67. However, it does also occur in children, though much less common than ALL. Even in the younger adults (patients who are younger than age 60), AML is difficult to treat, with a median survival of 5 to 6 months, despite intensive therapy.

Clinical Manifestations

1. Common symptoms include pallor, fatigue, weakness, fever, weight loss, abnormal bleeding and bruising, lymphadenopathy (in ALL), and recurrent infections.
2. Other presenting symptoms may include bone and joint pain, headache, splenomegaly, hepatomegaly, and neurologic dysfunction.

Diagnostic Evaluation

1. CBC and blood smear—peripheral WBC count varies widely from 1,000 to 100,000/mm^3 and may include significant numbers of abnormal immature (blast) cells; anemia may be profound; platelet count may be abnormal and coagulopathies may exist.
2. Bone marrow aspiration and biopsy—cells also studied for chromosomal abnormalities (cytogenetics) and immunologic markers to classify type of leukemia further.

3. Lumbar puncture and examination of cerebrospinal fluid for leukemic cells (especially in ALL).

Management

1. National Comprehensive Cancer Network (NCCN; *www.nccn.org*) guidelines provide recommendations for workup, management, and supportive care of patients with various subtypes of AML. Evidence-based treatment guidelines for management of ALL are published by the National Cancer Institute (*www.cancer.gov/cancertopics/pdq/treatment/adultALL/HealthProfessional*).
2. Management of AML and ALL is designed to eradicate leukemic cells and allow restoration of normal hematopoiesis.
   a. High-dose chemotherapy given as an induction course to obtain remission (disappearance of abnormal cells in bone marrow and blood) and then in cycles as consolidation or maintenance therapy to prevent recurrence of disease (see Table 26-4).
   b. Leukapheresis (or exchange transfusion in infants) may be used when abnormally high numbers of white cells are present to reduce the risk of leukostasis and tumor burden before chemotherapy.
   c. Radiation, particularly of central nervous system (CNS) in ALL.
   d. Targeted therapies are being developed to stop cancer cell growth by targeting specific genes or proteins; may be used in conjunction with other chemotherapy.
   e. Autologous or allogeneic bone marrow or stem cell transplantation.

Table 26-4 Common Chemotherapeutic Drugs Used in Acute Leukemias

DRUG	MAJOR ADVERSE EFFECTS	CLASSIFICATION	PRIMARY USE
All-trans retinoic acid	Dry skin and mucous membranes, headaches, eyesight changes, bone pain, flulike symptoms, bone marrow suppression, and retinoic acid syndrome (includes weight gain, peripheral edema, dyspnea, and fever)	Retinoid	Therapy for AML subtype M3 (APL)
Cyclophosphamide	Bone marrow suppression, alopecia, nausea and vomiting, diarrhea, hemorrhagic cystitis, and cardiomyopathy	Alkylating agent	Induction and consolidation therapy for ALL
Cytarabine	Bone marrow suppression, nausea and vomiting, pulmonary toxicity, mucositis, lethargy, cerebellar toxicity, dermatitis, and keratoconjunctivitis	Antimetabolite	Induction and consolidation therapy for AML
Daunorubicin	Bone marrow suppression, nausea and vomiting, alopecia, cardiotoxicity, and vesicant	Antibiotic	Induction and consolidation therapy for AML
Doxorubicin	Leukopenia, nausea and vomiting, alopecia, cardiotoxicity, photosensitivity, and vesicant	Antibiotic	Induction and consolidation therapy for AML
Imatinib mesylate	Edema, nausea and vomiting, musculoskeletal pain, and rash	Tyrosine kinase inhibitor	Induction and consolidation therapy for Philadelphia chromosome–positive adult ALL
L-Asparaginase	Liver dysfunction, nausea and vomiting, hypersensitivity reaction, depression, and lethargy	Miscellaneous: enzyme	Induction therapy for ALL
6-Mercaptopurine	Mild bone marrow suppression, GI disturbances, and hepatotoxicity	Antimetabolite	Maintenance therapy for ALL
Methotrexate	Bone marrow suppression, stomatitis, nausea, diarrhea, hepatotoxicity, and neurotoxicity with intrathecal doses	Antimetabolite	Intrathecal central nervous system treatment and prophylaxis for ALL; maintenance therapy for ALL
Prednisone	Appetite stimulation, mood alteration, Cushing syndrome, hypertension, diabetes, and peptic ulcer	Corticosteroid	Induction therapy for ALL
Vincristine	Neurotoxicity, alopecia, and vesicant	Plant alkaloid	Induction therapy for ALL

ALL, acute lymphocytic leukemia; AML, acute myelogenous leukemia; APL, acute promyelocytic leukemia.

Complications

1. Leukostasis: in setting of high numbers (greater than 50,000/mm^3) of circulating leukemic cells (blasts), blood vessel walls are infiltrated and weakened, with high risk of rupture and bleeding, including intracranial hemorrhage.
2. Disseminated intravascular coagulation (DIC).
3. Tumor lysis syndrome: rapid destruction of large numbers of malignant cells leads to alterations in electrolytes (hyperuricemia, hyperkalemia, hyperphosphatemia, and hypocalcemia), renal failure, and other complications.
4. Infection, bleeding, organ damage.

DRUG ALERT Allopurinol and/or rasburicase are commonly used as part of a regimen to prevent tumor lysis syndrome. In rare cases, they may cause severe, even lethal, skin reactions (toxic epidermolysis syndrome). Allopurinol should be discontinued for any patient who develops a new skin rash.

Nursing Assessment

1. Take nursing history, focusing on weight loss, fever, frequency of infections, progressively increasing fatigability, shortness of breath, palpitations, and visual changes (retinal bleeding).
2. Ask about difficulty in swallowing, coughing, and rectal pain.
3. Examine the patient for enlarged lymph nodes, hepatosplenomegaly, evidence of bleeding, abnormal breath sounds, and skin lesions.
4. Look for evidence of infection: mouth, tongue, and throat for reddened areas or white patches. Examine skin for breakdown, which is a potential source of infection.

Nursing Diagnoses

- Risk for Infection related to granulocytopenia of disease and treatment.
- Risk for Bleeding secondary to bone marrow failure and thrombocytopenia.

Nursing Interventions

Preventing Infection

1. Especially monitor for pneumonia, pharyngitis, esophagitis, perianal cellulitis, urinary tract infection, and cellulitis, which are common in leukemia and which carry significant morbidity and mortality.
2. Monitor for fever, flushed appearance, chills, and tachycardia; appearance of white patches in mouth; redness, swelling, heat, or pain of eyes, ears, throat, skin, joints, abdomen, and rectal and perineal areas; cough, changes in sputum; skin rash.
3. Check results of granulocyte counts. Concentrations less than 500/mm^3 put the patient at serious risk for infection. Administer granulocyte-stimulating and erythropoiesis-stimulating agents, as ordered (eg, epoetin alfa or darbepoetin alfa).

4. Avoid invasive procedures and trauma to skin or mucous membrane to prevent entry of microorganisms.
5. Use the following rectal precautions to prevent infection:
   a. Avoid diarrhea and constipation, which can irritate the rectal mucosa.
   b. Avoid use of rectal thermometers.
   c. Keep the perianal area clean.
6. Care for the patient in private room with strict hand washing practice. Patients with prolonged neutropenia may benefit from high-efficiency particulate air filtration.
7. Encourage and assist the patient with personal hygiene, bathing, and oral care.
8. Obtain cultures and administer antimicrobials promptly, as directed. Prophylactic antimicrobials, antifungals, and antivirals serve to protect the patient from life-threatening infections.

Preventing and Managing Bleeding

1. Watch for signs of minor bleeding, such as petechiae, ecchymosis, conjunctival hemorrhage, epistaxis, bleeding gums, bleeding at puncture sites, vaginal spotting, and heavy menses.
2. Be alert for signs of serious bleeding, such as headache with change in responsiveness, blurred vision, hemoptysis, hematemesis, melena, hypotension, tachycardia, and dizziness.
3. Monitor urine, stools, and emesis for gross and occult blood.
4. Monitor platelet counts daily.
5. Administer blood components, as directed.
6. Keep the patient on bed rest during bleeding episodes.

Patient Education and Health Maintenance

1. Teach infection precautions (see page 761).
2. Teach signs and symptoms of infection and advise whom to notify.
3. Encourage adequate nutrition to prevent emaciation from chemotherapy.
4. Teach avoidance of constipation with increased fluid and fiber and good perianal care.
5. Teach bleeding precautions (see page 761).
6. Encourage regular dental visits to detect and treat dental infections and disease.
7. Provide the patient and family with information about resources in the community, see Box 26-1.

Resources, support, and educational materials for patients and families

Evaluation: Expected Outcomes

- Afebrile, without signs of infection.
- No signs of bleeding.

Chronic Myelogenous Leukemia

Chronic myelogenous leukemia (CML) (ie, involving more mature cells than acute leukemia) is characterized by proliferation of myeloid cell lines, including granulocytes, monocytes, platelets, and, occasionally, RBCs.

Pathophysiology and Etiology

1. Specific etiology unknown, associated with exposure to ionizing radiation and family history of leukemia. Results from malignant transformation of pluripotent hematopoietic stem cell.
2. First cancer associated with chromosomal abnormality (the Philadelphia [Ph] chromosome), present in more than 90% of patients.
3. Accounts for 25% of adult leukemias and less than 5% of childhood leukemias. Generally presents between ages 25 and 60 with peak incidence in the mid-40s.
4. May progress to an accelerated phase or blast crisis, resembling an acute leukemia.

Clinical Manifestations

1. Insidious onset; may be discovered during routine physical examination.
2. About 70% of patients have symptoms at diagnosis such as fatigue, pallor, activity intolerance, fever, weight loss, night sweats, and abdominal fullness (splenomegaly).

Diagnostic Evaluation

1. CBC and blood smear: large numbers of granulocytes (usually more than 100,000/mm^3), platelets may be decreased.
2. Bone marrow aspiration and biopsy: hypercellular, usually demonstrates Philadelphia (Ph^1) chromosome.

Management

Treatment guidelines for the management of CML are provided by NCCN (*www.nccn.org*).

Chronic Phase

1. Tyrosine kinase inhibitors are oral agents used as primary treatment for most patients with CML. They include imatinib mesylate, dasatinib, and nilotinib.
   a. These agents work by inhibiting proliferation of abnormal cells and inducing cell death (apoptosis) in abnormal cells.
   b. Adverse effects vary based on the agent used but include edema, diarrhea, headache, muscle cramps, muscle and bone pain, rash, and, rarely, hepatotoxicity, pleural or pericardial effusion, and myelosuppression.
2. For patients who do not respond to tyrosine kinase inhibitors, allogeneic (related or unrelated) BMT may be an option.

Accelerated Phase or Blast Crisis

1. High-dose tyrosine kinase inhibitors or chemotherapy (ALL or AML regimens) may be used to attempt

to regain chronic phase.

2. Supportive care and palliative care may be appropriate because this phase is usually terminal.

Complications

1. Leukostasis.
2. Infection, bleeding, and organ damage.
3. If untreated, CML is a terminal disease with unpredictable survival, on average 3 years.

Nursing Assessment

1. Obtain health history, focusing on fatigue, weight loss, night sweats, and activity intolerance.
2. Assess for signs of bleeding and infection.
3. Evaluate for splenomegaly and hepatomegaly.
4. Assess for weight gain and edema in patients taking tyrosine kinase inhibitors.

Nursing Diagnosis

- Fear related to disease progression and death.

Nursing Interventions

Also see nursing interventions for acute leukemia, page 762.

Allaying Fear

1. Encourage appropriate verbalization of feelings and concerns.
2. Provide comprehensive patient teaching about disease, using methods and content appropriate to the patient's needs.
3. Assist the patient in identifying resources and support (eg, family and friends, spiritual support, community or national organizations, support groups).
4. Facilitate use of effective coping mechanisms.

Patient Education and Health Maintenance

1. Teach the patient to take medications, as prescribed, and monitor for adverse effects.
2. Teach the patient method of subcutaneous injection for self-administration of alpha interferon and teach strategies for managing such adverse effects as fatigue and fever.
3. Provide the patient and family with information about resources in the community (see Box 26-1).

Evaluation: Expected Outcomes

- Demonstrates effective coping skills.

TRANSITIONAL CARE ALERT Profound neutropenia is a serious threat to all people with a hematologic malignancy. Patients and family must be provided with appropriate education before and after discharge about reporting early signs such as fever, nausea and vomiting, and increasing pain, so there is no delay in getting evaluation and treatment. Hospital observation or admission is likely, but outcome can be fatal if prompt action is not taken.

LYMPHOPROLIFERATIVE DISORDERS

Lymphoproliferative disorders result from proliferation of cells from the lymphoid line of the hematopoietic system. They include chronic lymphocytic leukemia, Hodgkin lymphoma, non-Hodgkin lymphoma, and multiple myeloma.

Chronic Lymphocytic Leukemia

Chronic lymphocytic leukemia (CLL) (ie, involving more mature cells than acute leukemia) is characterized by proliferation of morphologically normal but functionally inert B lymphocytes. In CLL, the abnormal lymphocytes are found in the bone marrow and blood, whereas in *small lymphocytic lymphoma (SLL)*, the same abnormal lymphocytes are found predominantly in lymph nodes. The differential diagnosis includes *hairy cell leukemia* and *Waldenström macroglobulinemia*.

Pathophysiology and Etiology

1. Specific etiology unknown. Tends to cluster in families, much more common in Western hemisphere. Male hormones may play role.
2. Most common adult leukemia in the United States and Europe. Disease of later years (90% over age 50); 1.5 times more common in men than in women.
3. Lymphocytes are immunoincompetent and respond poorly to antigenic stimulation.
4. In late stages, organ damage may occur from direct lymphocytic infiltration of tissue.
5. Variable course: may be indolent for years, with gradual transformation to more malignant or aggressive disease with 1- to 2-year course.

Clinical Manifestations

1. Insidious onset; may be discovered during routine physical examination.
2. Early symptoms may include painless lymph node swelling, commonly in cervical area, history of frequent skin or respiratory infections, mild splenomegaly and hepatomegaly, and fatigue.
3. Symptoms of more advanced disease include fever, night sweats, weight loss, pallor, activity intolerance, easy bruising, skin lesions, bone tenderness, and abdominal discomfort.

Diagnostic Evaluation

1. CBC and blood smear: large numbers of lymphocytes (10,000 to 150,000/mm^3); may also be anemia, thrombocytopenia, and hypogammaglobulinemia.
2. Bone marrow aspirate and biopsy: lymphocytic infiltration of bone marrow.
3. Lymph node biopsy to detect spread.

Management

Symptom Control and Treatments

1. The patient with newly diagnosed and indolent CLL is generally observed and followed closely until symptoms develop. Treatment is individualized; NCCN guidelines suggest clinical trial or various chemotherapy and monoclonal antibody combinations (*www.nccn.org*).
2. Lymphocyte proliferation can be suppressed with chlorambucil, cyclophosphamide, and prednisone.
3. The purine analogue fludarabine has significant activity in CLL alone or in combination with rituximab

and/or cyclophosphamide.

4. Monoclonal antibodies, such as alemtuzumab and rituximab, may be used.
5. Hairy cell leukemia, a distinctive type of B-cell leukemia with hairlike projections of cytoplasm from lymphocytes, may be successfully treated with cladribine, pentostatin, or alpha interferon.
6. Splenic irradiation or splenectomy for painful splenomegaly or platelet sequestration, hemolytic anemia.
7. Irradiation of painful enlarged lymph nodes.
8. Allogeneic bone marrow transplant is also used to treat CLL.

Supportive Care

1. Transfusion therapy to replace platelets and RBCs.
2. Antibiotics, antivirals, and antifungals, as needed, to control infections.
3. IV immunoglobulins or gamma globulin to treat hypogammaglobulinemia.

Complications

1. Thrombophlebitis from venous or lymphatic obstruction caused by enlarged lymph nodes.
2. Infection, bleeding.
3. Median survival depends on severity of disease; varies from 2 to 7 years.

Nursing Assessment

1. Obtain health history, focusing on history of infections, fatigue, bruising and bleeding, and swollen lymph nodes.
2. Assess for signs of anemia, bleeding, or infection.
3. Evaluate for splenomegaly, hepatomegaly, and lymphadenopathy.

Nursing Diagnoses

- Acute Pain related to tumor growth, infection, or adverse effects of chemotherapy.
- Activity Intolerance related to anemia and adverse effects of chemotherapy.

Nursing Interventions

Reducing Pain

1. Assess the patient frequently for pain and administer or teach the patient to administer analgesics on regular schedule, as prescribed; monitor for adverse effects.
2. Teach the patient the use of nonpharmacologic methods, such as music, relaxation breathing, progressive muscle relaxation, distraction, and imagery to help manage pain.

Improving Activity Tolerance

1. Encourage frequent rest periods alternating with ambulation and light activity, as tolerated.
2. Assist the patient with hygiene and physical care, as necessary.

3. Encourage balanced diet or nutritional supplements, as tolerated.
4. Teach the patient to use energy conservation techniques while performing activities of daily living, such as sitting while bathing, minimizing trips up and down stairs, using shoulder bag or push cart to carry articles.

Patient Education and Health Maintenance

1. Teach the patient to minimize risk of infection (see page 761).
2. Teach the patient use of medications, as ordered, and possible adverse effects and their management; also teach the patient to avoid aspirin and NSAIDs, which may interfere with platelet function.
3. Provide the patient and family with information about resources in the community (see page 765).

Evaluation: Expected Outcomes

- States pain relief.
- Performs activities without complaints of fatigue.

Hodgkin Lymphoma

Lymphomas are malignant disorders of the reticuloendothelial system that result in an accumulation of dysfunctional, immature lymphoid-derived cells. They are classified according to the predominant cell type and by the degree of malignant cell maturity (eg, well differentiated, poorly differentiated, or undifferentiated). Hodgkin lymphoma originates in the lymphoid system and involves predominantly lymph nodes. It accounts for about 12% of all lymphomas.

Pathophysiology and Etiology

1. Etiology is unknown.
2. Characterized by appearance of "Reed-Sternberg" multinucleated giant cell in tumor.
3. Generally spreads via lymphatic channels, involving lymph nodes, spleen, and ultimately extralymphatic sites. May also spread via bloodstream to such sites as GI tract, bone marrow, skin, upper air passages, and other organs.
4. Incidence demonstrates two peaks, between ages 20 and 30 and after age 55. Risk is increased in males, for patients with HIV, in individuals with previous Epstein-Barr viral infection, and in individuals with first-degree relative with Hodgkin lymphoma.

Clinical Manifestations

1. Common symptoms include painless enlargement of lymph nodes (generally unilateral cervical or supraclavicular), splenomegaly, fever, chills, night sweats, weight loss, and pruritus.
2. Various symptoms may occur with pulmonary involvement, superior vena cava obstruction, and hepatic or bone involvement.

Diagnostic Evaluation

Tests are used to determine extent of disease involvement before treatment and followed at regular intervals to assess response to treatment.

1. CBC—determines abnormal cells.
2. Lymph node biopsy—determines type of lymphoma.
3. Bilateral bone marrow aspirate and biopsy—determine whether bone marrow is involved.
4. Radiographic tests (eg, x-rays, positron emission tomography [PET] scan, computed tomography [CT] scan, magnetic resonance imaging [MRI])—detect deep nodal involvement.
5. Gallium-67 scan—detects areas of active disease and may be used to determine aggressiveness of disease.
6. Liver function tests—determine hepatic involvement; liver biopsy may be indicated if results abnormal.
7. Lymphangiogram—detects size and location of deep nodes involved, including abdominal nodes, which may not be readily seen via CT scan.
8. Surgical staging (laparotomy with splenectomy, liver biopsy, and multiple lymph node biopsies)—in selected patients.

Management

Choice of treatment depends on extent of disease, histopathologic findings, and prognostic indicators. Hodgkin lymphoma is more readily cured than other lymphomas, with a 5-year survival rate of 80%. The NCCN guidelines for Hodgkin lymphoma (*www.nccn.org*) provide recommendations for diagnosis and treatment with chemotherapy, chemotherapy and radiation, and/or hematopoietic stem cell transplant for select patients. Hodgkin lymphoma arising in presence of HIV requires specialized treatment.

1. Radiation therapy.
    a. Treatment of choice for localized disease.
    b. Areas of body where lymph node chains are located can generally tolerate high radiation doses.
    c. Vital organs are protected with lead shielding during radiation treatments.
2. Chemotherapy.
    a. Initial treatment commonly consists of ABVD regimen of doxorubicin (Adriamycin), bleomycin, vinblastine (Velban), and dacarbazine; or MOPP regimen of nitrogen mustard (Mustargen), vincristine (Oncovin), procarbazine, and prednisone.
    b. Three or four drugs may be given in intermittent or cyclical courses with periods off treatment to allow recovery from toxicities.
    c. Brentuximab vedotin is an antibody drug conjugate that targets CD30 positive cells and has shown to be effective in treating Hodgkin lymphoma, both as part of upfront therapy and therapy for relapsed disease.
3. Autologous or allogeneic bone marrow or stem cell transplantation.

Complications

1. Adverse effects of radiation or chemotherapy (see page 763).
2. Dependent on location and extent of malignancy, but may include splenomegaly, hepatomegaly, thromboembolic complications, and spinal cord compression.

Nursing Assessment

1. Obtain health history, focusing on fatigue, fever, chills, night sweats, and swollen lymph nodes.
2. Evaluate splenomegaly, hepatomegaly, and lymphadenopathy.

Nursing Diagnoses

- Impaired Tissue Integrity related to high-dose radiation therapy.
- Impaired Oral Mucous Membrane related to high-dose radiation therapy.

Nursing Interventions

Maintaining Tissue Integrity

1. Avoid rubbing, powders, deodorants, lotions, or ointments (unless prescribed) or application of heat and

cold to treated area.

2. Encourage the patient to keep the treated area clean and dry, bathing area gently with tepid water and mild soap.
3. Encourage wearing loose-fitting clothes.
4. Advise the patient to protect skin from exposure to sun, chlorine, and temperature extremes.

Preserving Oral and GI Tract Mucous Membranes

1. Encourage frequent small meals, using bland and soft diet at mild temperatures.
2. Teach the patient to avoid irritants, such as alcohol, tobacco, spices, and extreme food temperatures.
3. Administer or teach self-administration of pain medication or antiemetic before eating or drinking, if needed.
4. Encourage mouth care at least twice per day and after meals using gentle flossing, soft toothbrush or toothette, and mild mouth rinse.
5. Assess for ulcers, plaques, or discharge that may be indicative of superimposed infection.
6. For diarrhea, switch to low-residue diet and administer antidiarrheals, as ordered.

Patient Education and Health Maintenance

1. Teach the patient about risk of infection (see page 761).
2. Teach the patient how to take medications, as ordered, and instruct about possible adverse effects and management.
3. Explain to the patient that radiation therapy may cause sterility; men should be given opportunity for sperm banking before treatment; women may develop ovarian failure and require hormone replacement therapy.
4. Reassure the patient that fatigue will decrease after treatment is completed; encourage frequent naps and rest periods.
5. Provide the patient and family with information about resources in the community (see page 765).

Evaluation: Expected Outcomes

- Skin intact without erythema or swelling.
- Oral mucosa intact, patient eating.

Non-Hodgkin Lymphomas

Non-Hodgkin lymphomas are a group of malignancies of lymphoid tissue arising from T or B lymphocytes or their precursors; it includes both indolent and aggressive forms. In the United States, B-cell lymphomas represent about 80% of all cases. Types of non-Hodgkin lymphomas include chronic lymphocytic leukemia or small lymphocytic lymphoma (CLL/SLL; see page 766), follicular lymphoma, diffuse large B-cell lymphoma, and primary cutaneous B-cell lymphoma.

Pathophysiology and Etiology

1. Association with defective or altered immune system; higher incidence in patients receiving immunosuppression for organ transplant, in HIV-positive people, and in people with some viruses (eg, HTLV-1 and Epstein-Barr). Other risk factors include family history, male gender, white ethnicity, autoimmune diseases such as rheumatoid arthritis, history of *Helicobacter* gastritis (for gastric B-cell lymphoma), history of Hodgkin lymphoma, history of radiation therapy, diet high in meats and fat, and exposure to certain pesticides.
2. Arise from malignant transformation of lymphocyte at some stage during development; level of differentiation and type of lymphocyte influences course of illness and prognosis.
3. Incidence rises steadily from age 40.

Clinical Manifestations

1. Common symptoms include painless enlargement of lymph nodes (generally unilateral); fever; chills; night sweats; weight loss; unexplained pain in chest, abdomen, or bones. Unlike Hodgkin lymphoma, is more likely to be advanced disease at presentation.
2. Various symptoms may occur with pulmonary involvement, superior vena cava obstruction, and hepatic or bone involvement.

Diagnostic Evaluation

1. Incisional or excisional lymph node biopsy to detect type.
2. CBC, bone marrow aspirate, and biopsy to detect bone marrow involvement.
3. CT scan of the chest, abdomen, and pelvis with oral and intravenous contrast or PET with CT scan to detect deep nodal involvement.
4. Liver function tests, liver scan to detect liver involvement. Hepatitis B testing is recommended because of risk of reactivation.
5. Lumbar puncture to detect CNS involvement (for some lymphoma types).
6. Surgical staging (laparotomy with splenectomy, liver biopsy, multiple lymph node biopsies).

Management

1. The NCCN guidelines for non-Hodgkin lymphomas (*www.nccn.org*) describe a variety of regimens, using radiation therapy, chemotherapy, monoclonal antibodies, radioimmune therapy, and hematopoietic

stem cell transplant. Precise diagnosis and staging is needed to ensure appropriate treatment.

2. Radiation therapy is generally palliative, not curative.
3. Chemotherapy: various regimens available, including CHOP regimen of cyclophosphamide, doxorubicin (Adriamycin), vincristine (Oncovin), and prednisone; or BACOP regimen of bleomycin, doxorubicin (Adriamycin), cyclophosphamide, vincristine (Oncovin), and prednisone.
4. Monoclonal antibody therapy: rituximab may be given alone or with chemotherapy to patients with CD20 positive lymphomas. Hepatitis B-positive patients receiving rituximab are at high risk for reactivation and need antiviral prophylaxis and close monitoring.
5. Radioimmune therapies, such as yttrium-90–labeled ibritumomab tiuxetan and ^{131}I tositumomab, have been effective for patients with certain lymphomas who do not respond to rituximab.
6. There are also many new therapies currently being studied as a more targeted approach to the treatment of specific gene mutations found in non-Hodgkin lymphoma.
7. Autologous or allogeneic bone marrow or stem cell transplantation.

Complications

1. Of radiation therapy and chemotherapy (see page 763).
2. Of disease: depends on location and extent of malignancy, but may include splenomegaly, hepatomegaly, thromboembolic complications, and spinal cord compression.

Nursing Assessment

1. Obtain health history, focusing on fatigue, fever, chills, night sweats, swollen lymph nodes, and history of illness or therapy causing immunosuppression.
2. Evaluate splenomegaly, hepatomegaly, and lymphadenopathy.

Nursing Diagnosis

- Risk for Infection related to altered immune response because of lymphoma and leukopenia caused by chemotherapy or radiation therapy.

Nursing Interventions

Minimizing Risk of Infection

1. Care for patient in protected environment with strict hand washing observed.
2. Avoid invasive procedures, such as urinary catheterization, if possible.
3. Assess temperature and vital signs, breath sounds, LOC, and skin and mucous membranes frequently for signs of infection.
4. Notify the health care provider of fever greater than 101°F (38.3°C) or change in condition.
5. Obtain cultures of suspected infected sites or body fluids.

Patient Education and Health Maintenance

1. Teach the patient infection precautions (see page 761).
2. Encourage frequent follow-up visits for monitoring of CBC and condition.
3. Provide the patient and family with information about resources in the community (see page 765).

Evaluation: Expected Outcomes

- Remains afebrile with no signs or symptoms of infection.

Multiple Myeloma

Multiple myeloma is a malignant disorder of plasma cells accounting for approximately 13% of all hematologic malignancies.

EVIDENCE BASE Terpos, E., International Myeloma Society. (2017). Multiple myeloma: Clinical updates from the American Society of Hematology Annual Meeting 2016. *Clinical Lymphoma, Myeloma and Leukemia, 17*(6), 329–339.

Pathophysiology and Etiology

1. Etiology unknown; genetic and environmental factors, such as chronic exposure to low levels of ionizing radiation and agricultural exposures to herbicides, may play a part.
2. Characterized by proliferation of neoplastic plasma cells derived from one B lymphocyte (clone) and producing a homogeneous immunoglobulin (M protein or Bence Jones protein) without any apparent antigenic stimulation.
3. Plasma cells produce osteoclast-activating factor leading to extensive bone loss, severe pain, and pathologic fractures.
4. Abnormal immunoglobulin affects renal function, platelet function, resistance to infection, and may cause hyperviscosity of blood.
5. Generally affects older people (median age at diagnosis is 68) and is twice as common among African Americans as among Caucasians.

Clinical Manifestations

1. Constant, usually severe bone pain caused by bone lesions and pathologic fractures; sites commonly affected include thoracic and lumbar vertebrae, ribs, skull, pelvis, and proximal long bones.
2. Fatigue and weakness related to anemia caused by crowding of marrow by plasma cells.
3. Proteinuria and renal insufficiency.
4. Electrolyte disturbances, including hypercalcemia (bone destruction) and hyperuricemia (cell death, renal insufficiency).

Diagnostic Evaluation

1. Bone marrow aspiration and biopsy—demonstrate increased number and abnormal form of plasma cells.
2. CBC and blood smear—changes reflect anemia.
3. Urine and serum analysis for presence and quantity of abnormal immunoglobulin.
4. Skeletal x-rays—osteolytic bone lesions.

Management

1. Patients with "smoldering" multiple myeloma do not require treatment.
2. The NCCN guidelines for symptomatic multiple myeloma (*www.nccn.org*) and other clinical guidelines currently recommend two treatment approaches: either melphalan plus thalidomide or melphalan plus bortezomib as initial treatment.
   a. Melphalan is a chemotherapy agent.
   b. Thalidomide is an antiangiogenesis agent and bortezomib is a proteasome inhibitor.
   c. Another option is low-dose dexamethasone plus lenalidomide, a structural analogue of thalidomide.
3. Autologous bone marrow or peripheral blood stem cell transplant in selected cases (usually younger than age 65 with no renal failure, few bone lesions, and good organ function).
4. Supportive care options:
   a. Plasmapheresis to treat hyperviscosity or bleeding.
   b. Radiation therapy for bone lesions.
   c. Bisphosphonates (eg, pamidronate), potent inhibitors of bone resorption, to treat hypercalcemia and alleviate bone pain.
   d. Allopurinol and fluids to treat hyperuricemia.
   e. Hemodialysis to manage renal failure.
   f. Surgical stabilization and fixation of fractures.

DRUG ALERT Pamidronate and other bisphosphonates may cause transient temperature elevations, hypophosphatemia, hypomagnesemia, hypocalcemia, and local reactions at the site of IV administration, such as thrombophlebitis, pain, and erythema. Bisphosphonates are administered as IV infusions, generally during 4 or more hours; rapid IV administration may cause renal failure. Long-term bisphosphonate use has been associated with jaw osteonecrosis—patients should be monitored closely and advised to maintain good oral health and avoid invasive dental procedures.

Complications

1. Pathologic fractures, spinal cord compression.
2. Recurrent infections, particularly bacterial.
3. Electrolyte abnormalities (hypercalcemia, hypophosphatemia).
4. Renal failure, pyelonephritis.
5. Bleeding.
6. Thromboembolic complications caused by hyperviscosity.
7. Patients with multiple myeloma treated by chemotherapy have a median survival of 2 to 3 years; the impact of newer treatment options on survival is still unknown.

Nursing Assessment

1. Obtain health history, focusing on pain, fatigue.
2. Evaluate for evidence of bone deformities and bone tenderness or pain.
3. Assess the patient's support system and personal coping skills.

Nursing Diagnoses

- Acute Pain related to destruction of bone and possible pathologic fractures.
- Impaired Physical Mobility related to pain and possible fracture.
- Fear related to poor prognosis.
- Risk for Injury related to complications of disease process.

Nursing Interventions

Controlling Pain

1. Assess for presence, location, intensity, and characteristics of pain.
2. Administer pharmacologic agents, as ordered, to control pain. Use adequate doses of regularly scheduled, around-the-clock analgesics.
3. Teach the use of nonpharmacologic methods, such as music, relaxation breathing, progressive muscle relaxation, distraction, and imagery, to help manage pain.
4. Assess effectiveness of analgesics and adjust dosage or drug used, as necessary, to control pain.

Promoting Mobility

1. Encourage the patient to wear a back brace for lumbar lesion.
2. Recommend physical and occupational therapy consultation.
3. Discourage bed rest to prevent hypercalcemia but ensure safety of environment to prevent fractures.
4. Assist the patient with measures to prevent injury and decrease risk of fractures. Advise avoidance of lifting and straining; use walker and other assistive devices, as appropriate.

Relieving Fear

1. Develop trusting, supportive relationship with the patient and his or her significant others.
2. Encourage the patient to discuss medical condition and prognosis with the health care provider when the patient is ready.
3. Assure the patient that you are available for support, to provide comfort measures, and to answer questions.
4. Encourage use of the patient's own support network, religious and community services, and national agencies.

Monitoring for Complications

1. Report sudden, severe pain, especially of back, which could indicate pathologic fracture.

2. Provide assistance, safety precautions, and supervision to prevent injury.
3. Watch for nausea, drowsiness, confusion, polyuria, which could indicate hypercalcemia caused by bony destruction or immobilization. Monitor serum calcium levels.
4. Check results of blood urea nitrogen (BUN) and creatinine and urine protein tests to detect renal insufficiency, caused by nephrotoxicity of abnormal proteins in multiple myeloma.
5. Increase fluid intake, monitor intake and output, and weigh the patient daily.

Community and Home Care Considerations

1. Make sure that the patient has appropriate housing and equipment to support decreased mobility and risk of pathologic fractures (eg, stair handrails, cane or walker, commode chair).
2. Inspect home environment for throw rugs, cluttered furnishings, dark hallways, or difficult stairs that may cause a fall and possible fracture.

Patient Education and Health Maintenance

1. Teach the patient about risk of infection caused by impaired antibody production and chemotherapy (see page 761).
2. Teach the patient to take medications, as prescribed, and monitor for possible adverse effects; avoid aspirin and NSAIDs unless prescribed by health care provider because these drugs may interfere with platelet function.
3. Teach the patient to minimize risk of fractures. Use proper body mechanics and assistive devices, as appropriate; avoid bed rest, remain ambulatory.
4. Advise the patient to report new onset of pain, new location, or sudden increase in pain intensity immediately. Report new onset or worsening of neurologic symptoms (eg, changes in sensation) immediately.
5. Encourage the patient to maintain high fluid intake (2 to 3 L/day) to avoid dehydration and prevent renal insufficiency; also not to fast before diagnostic tests.
6. Provide the patient and family with information about resources in the community (see page 765).

Evaluation: Expected Outcomes

- States decreased pain.
- Ambulates without injury.
- Asks questions about disease; contacts support group.
- No development of complications.

BLEEDING DISORDERS

Bleeding disorders may be congenital or acquired and may be caused by dysfunction in any phase of hemostasis (clot formation and dissolution). Bleeding disorders seen in adults include thrombocytopenia, idiopathic thrombocytopenic purpura (ITP), DIC, and von Willebrand disease.

Thrombocytopenia

Thrombocytopenia is characterized by a decreased platelet count (less than 150,000/mm^3), the most common cause of bleeding disorders.

Pathophysiology and Etiology

Classification by Etiology

1. Decreased platelet production—infiltrative diseases of bone marrow, leukemia, aplastic anemia, myelofibrosis, myelosuppressive therapy, and radiation therapy; may include inherited disorders, such as Fanconi anemia and Wiskott-Aldrich syndrome.
2. Increased platelet destruction—infection (eg, HIV or hepatitis C), drug-induced (eg, heparin or quinidine), ITP, and DIC.
3. Abnormal distribution or sequestration in spleen.
4. Dilutional thrombocytopenia—after hemorrhage, RBC transfusions.

Clinical Manifestations

1. Usually asymptomatic.
2. When platelet count drops below 20,000/mm^3:
   a. Petechiae occur spontaneously.
   b. Ecchymoses occur at sites of minor trauma (venipuncture, pressure).
   c. Bleeding may occur from mucosal surfaces, nose, GI and GU tracts, respiratory system, and within CNS.
   d. Menorrhagia is common.
3. Excessive bleeding may occur after procedures (dental extractions, minor surgery, biopsies).
4. Thrombotic complications (arterial and venous) and areas of skin necrosis are associated with heparin-induced thrombocytopenia.

Diagnostic Evaluation

1. CBC with platelet count—decreased hemoglobin, hematocrit, platelets.
2. Bleeding time, prothrombin time (PT), partial thromboplastin time (PTT)—prolonged.
3. Platelet aggregation test for heparin-dependent platelet antibodies—positive.

Management

1. Treat underlying cause.
2. Platelet transfusions.
3. Steroids or IV immunoglobulins may be helpful in selected patients.
4. Heparin-induced thrombocytopenia: discontinue heparin, use alternate anticoagulant therapy because of high risk of venous and arterial thromboses in these patients (direct thrombin inhibitors, such as

lepirudin or argatroban hirudin), and avoid platelet transfusions. Although incidence varies dependent upon patient population and heparin preparation, any exposure to heparin can precipitate this serious autoimmune syndrome.

Complications

Severe blood loss or bleeding into vital organs may be life threatening.

Nursing Assessment

1. Obtain health history, focusing on prior illnesses and episodes of bleeding, past surgical experiences, exposure to toxins or ionizing radiation, and family history of bleeding.
2. Obtain list of current and recent medications (including OTC preparations, herbal and dietary supplements).
3. Perform complete physical examination for signs of bleeding.

Nursing Diagnosis

- Risk for Bleeding related to thrombocytopenia.

Nursing Interventions

Minimizing Bleeding

1. Institute bleeding precautions.
   a. Avoid use of plain razor, hard toothbrush or floss, IM injections, tourniquets, rectal procedures, and suppositories.
   b. Administer stool softeners, as necessary, to prevent constipation.
   c. Restrict activity and exercise when platelet count is less than 20,000/mm^3 or when active bleeding occurs.
2. Monitor pad count and amount of saturation during menses; administer or teach self-administration of hormones to suppress menstruation, as prescribed.
3. Administer blood products, as ordered. Monitor for signs and symptoms of allergic reactions, anaphylaxis, and volume overload.
4. Evaluate urine, stools, and emesis for gross and occult blood.

Patient Education and Health Maintenance

1. Teach the patient bleeding precautions (see page 761).
2. Demonstrate the use of direct, steady pressure at bleeding site if bleeding develops.
3. Encourage routine follow-up for platelet counts.

Evaluation: Expected Outcomes

- Episodes of bleeding rapidly controlled; platelet count maintained at goal (usually 20,000/mm^3).

Idiopathic Thrombocytopenic Purpura

Idiopathic thrombocytopenic purpura (ITP), is an acute or chronic bleeding disorder that results from immune destruction of platelets by antiplatelet antibodies.

Pathophysiology and Etiology

1. Proteins on the platelet cell membrane stimulate production of autoantibodies that bind to circulating platelets, leading to destruction of platelets in spleen and liver.
2. Acute disorder more common in childhood, typically following viral illness; has good prognosis, with 80% to 90% recovering uneventfully within 6 months.
3. Chronic disorder (more than 6-month course) most common between ages 20 and 50, three times more common in women, may last for years or even indefinitely. May be associated with pregnancy or with development of systemic lupus erythematosus, thyroid disease, and infections (eg, *Helicobater pylori*, cytomegalovirus, varicella zoster, hepatitis C, and HIV) or malignancy (eg, CLL).

Clinical Manifestations

May have no signs and symptoms with mild disease (platelet counts 30,000 to 100,000/mm^3). Platelet counts less than 30,000/mm^3: bruising, petechiae, bleeding from nares and gums, and menorrhagia.

Diagnostic Evaluation

1. CBC demonstrates platelet count less than 100,000/mm^3; may also be lymphocytosis and eosinophilia.
2. Testing for hepatitis C, HIV, *Helicobacter pylori*, and Epstein-Barr virus, which have been found to be associated with ITP.
3. Bone marrow aspirate (not necessary for most patients with typical features of ITP) shows increased numbers of young megakaryocytes, sometimes increased numbers of eosinophils.
4. Assay for platelet autoantibodies sometimes helpful.
5. Bleeding times are typically normal.

Management

1. Supportive care: judicious use of platelet transfusions, control of bleeding.
2. High-dose corticosteroids, IV immunoglobulins, and parenteral anti-D (for Rhesus-positive patients with spleens). Thrombopoietin receptor agonists may be used to treat patients at risk for bleeding with chronic or relapsed ITP.
3. Splenectomy (see page 756) removes potential site for sequestration and destruction of platelets and is used to treat chronic refractory ITP in adults.

Complications

Severe blood loss or bleeding into vital organs may be life threatening.

Nursing Assessment

1. Obtain history of bleeding episodes, including bruising and petechiae, bleeding of gums, and heavy menses.
2. Perform physical examination for signs of bleeding.

Nursing Diagnosis

- Risk for Bleeding related to thrombocytopenia.

Nursing Interventions

Minimizing Bleeding

1. Institute bleeding precautions.
2. Monitor pad count and amount of saturation during menses; administer or teach self-administration of hormones to suppress menstruation, as prescribed.
3. Administer blood products, as ordered. Monitor for signs and symptoms of allergic reactions, anaphylaxis, and volume overload.
4. Evaluate all urine and stools for gross and occult blood.

Patient Education and Health Maintenance

1. Teach the patient bleeding precautions (see page 761).
2. Demonstrate the use of direct, steady pressure at bleeding site if bleeding does develop.
3. Encourage routine follow-up for platelet counts.

Evaluation: Expected Outcomes

- Episodes of bleeding rapidly controlled.

Disseminated Intravascular Coagulation

Disseminated intravascular coagulation (DIC) is an acquired thrombotic and hemorrhagic syndrome characterized by abnormal activation of the clotting cascade and accelerated fibrinolysis. This results in widespread clotting in small vessels with consumption of clotting factors and platelets, so that bleeding and thrombosis occur simultaneously.

Pathophysiology and Etiology

1. A syndrome arising secondary to an underlying disorder or event.
    a. Overwhelming infections, particularly bacterial sepsis.
    b. Obstetric complications: abruptio placentae, eclampsia, amniotic fluid embolism, retention of dead fetus.
    c. Massive tissue injury: burns, trauma, fractures, major surgery, fat embolism, organ destruction (eg, severe pancreatitis, hepatic failure).
    d. Malignancy: particularly lung, colon, stomach, and pancreas.
    e. Vascular and circulatory collapse, shock.
    f. Severe toxic or immunologic reactions: hemolytic transfusion reaction, snake bites, recreational drugs.

Clinical Manifestations

1. Signs of abnormal clotting:
    a. Coolness and mottling of extremities.
    b. Acrocyanosis (cold, mottled extremities with clear demarcation from normal tissue).
    c. Dyspnea, adventitious breath sounds.
    d. Altered mental status.
    e. Acute renal failure.
    f. Pain (eg, related to bowel infarction).
2. Signs of abnormal bleeding:
    a. Oozing, bleeding from sites of procedures, IV catheter insertion sites, suture lines, mucous membranes, and orifices.
    b. Internal bleeding leading to changes in vital organ function, altered vital signs.

Diagnostic Evaluation

1. Platelet count—diminished.
2. PT, PTT, and thrombin time—prolonged.
3. Fibrinogen—decreased level.
4. Fibrin split (degradation) products—increased level.
5. D-dimer fibrin degradation product—increased level.
6. Antithrombin III—decreased level.

7. Protein C—decreased level.

Management

1. Treat underlying disorder.
2. Replacement therapy for serious hemorrhagic manifestations:
   a. Fresh frozen plasma replaces clotting factors.
   b. Platelet transfusions.
   c. Cryoprecipitate replaces clotting factors and fibrinogen.
3. Supportive measures including fluid replacement, oxygenation, maintenance of BP, and renal perfusion.
4. Heparin or other anticoagulant therapy (controversial) inhibits clotting component of DIC.

Complications

1. Thromboembolic: pulmonary embolism; cerebral, myocardial, splenic, or bowel infarction; acute renal failure; tissue necrosis or gangrene.
2. Hemorrhagic: cerebral hemorrhage is the most common cause of death in DIC.

Nursing Assessment

1. Be aware that seriously ill patients are at risk; monitor condition closely.
2. Assess for signs of bleeding and thrombosis, including chest pain, shortness of breath, hematuria, abdominal pain, headache, and numbness and coolness of an extremity.

Nursing Diagnoses

- Risk for Bleeding related to thrombocytopenia.
- Ineffective Tissue Perfusion (all tissues) related to ischemia due to microthrombi formation.

Nursing Interventions

Minimizing Bleeding

1. Institute bleeding precautions.
2. Monitor pad count and amount of saturation during menses; administer or teach self-administration of hormones to suppress menstruation, as prescribed.
3. Administer blood products, as ordered. Monitor for signs and symptoms of allergic reactions, anaphylaxis, and volume overload.
4. Avoid dislodging clots. Apply pressure to sites of bleeding for at least 20 minutes, use topical hemostatic agents. Use tape cautiously.
5. Maintain bed rest during bleeding episode.
6. If internal bleeding is suspected, assess bowel sounds and abdominal girth.
7. Evaluate fluid status and bleeding by frequent measurement of vital signs, central venous pressure, intake, and output.

Promoting Tissue Perfusion

1. Keep the patient warm.
2. Avoid vasoconstrictive agents (systemic or topical).
3. Change the patient's position frequently and perform range-of-motion exercises.
4. Monitor electrocardiogram and laboratory tests for dysfunction of vital organs caused by ischemia—arrhythmias, abnormal arterial blood gas levels, and increased BUN and creatinine levels.
5. Monitor for signs of vascular occlusion and report immediately.
    a. Brain—decreased LOC, sensory and motor deficits, seizures, and coma.
    b. Eyes—visual deficits.
    c. Bone—bone pain.
    d. Pulmonary vasculature—chest pain, shortness of breath, tachycardia.
    e. Extremities—cold, mottling, numbness.
    f. Coronary arteries—chest pain, arrhythmias.
    g. Bowel—pain, tenderness, decreased bowel sounds.

Patient Education and Health Maintenance

Explain the syndrome and its management to the patient and family members as part of reassurance and support during this critical illness.

Evaluation: Expected Outcomes

- Episodes of bleeding rapidly controlled.
- Alert, vital signs stable, urine output adequate, and no complaints of chest pain or shortness of breath.

von Willebrand Disease

von Willebrand disease is an inherited (autosomal dominant) or acquired bleeding disorder characterized by decreased level of von Willebrand factor and prolonged bleeding time.

Pathophysiology and Etiology

1. von Willebrand factor synthesized in vascular endothelium, megakaryocytes, and platelets; enhances platelet adhesion as first step in clot formation, also acts as carrier of factor VIII in blood.
2. von Willebrand is most common inherited bleeding disorder, with estimated incidence as high as 1 in 90 people; includes multiple subtypes with varying severity; affects males and females.
3. Acquired form is rare, generally appears late in life, typically in association with lymphoma, leukemia, multiple myeloma, or autoimmune disorder.

Clinical Manifestations

1. Mucosal and cutaneous bleeding (eg, bruising, gingival bleeding, epistaxis, menorrhagia).
2. Prolonged bleeding from cuts or after dental and surgical procedures.

Diagnostic Evaluation

1. Bleeding time—prolonged.
2. Ristocetin cofactor—abnormal.
3. von Willebrand factor—decreased.
4. von Willebrand factor multimers—demonstrate defective von Willebrand factor in some types.
5. Factor VIII—generally decreased.

Management

1. Replacement of von Willebrand factor and factor VIII using clotting factor concentrates.
2. Antifibrinolytic medications (aminocaproic acid, tranexamic acid) to stabilize clot formation before dental procedures and before minor surgery.
3. Desmopressin acetate, a synthetic analogue of vasopressin, may be used to manage mild to moderate bleeding.
4. Estrogen and progesterone stimulate production of von Willebrand factor and factor VIII and may be particularly helpful in control of menorrhagia.

Complications

Severe blood loss or bleeding into vital organs may be life threatening.

Nursing Assessment

1. Obtain history of bleeding episodes such as menstrual flow. Ask quantitative questions (eg, how many nosebleeds do you have each year?) as the patient may not realize his or her experience is abnormal.

2. Perform physical examination for signs of bleeding.

Nursing Diagnosis

- Risk for Bleeding related to decreased level of von Willebrand factor and factor VIII.

Nursing Interventions

Minimizing Bleeding

1. Institute bleeding precautions:
   a. Avoid use of plain razor, hard toothbrush, or floss.
   b. Avoid IM injections, tourniquets, rectal procedures, or suppositories.
   c. Administer stool softeners, as necessary, to prevent constipation.
   d. Restrict activity and exercise when platelet count less than 20,000/mm^3 or when active bleeding occurs.
2. Monitor pad count and amount of saturation during menses; administer or teach self-administration of hormones to suppress menstruation, as prescribed.
3. Administer blood products, as ordered. Monitor for signs and symptoms of allergic reactions, anaphylaxis, and volume overload.
4. Use topical hemostatic agents, such as absorbable gelatin, oxidized cellulose, topical adrenaline, or phenylephrine, if pressure and use of ice does not stop bleeding.

Patient Education and Health Maintenance

1. Teach the patient bleeding precautions (see page 761).
2. Demonstrate the use of direct, steady pressure at bleeding site if bleeding develops.

Evaluation: Expected Outcomes

- Episodes of bleeding rapidly controlled.

PROCEDURE GUIDELINES 27-1

Administering Blood and Blood Components

EQUIPMENT

- Tourniquet
- Iodine-containing skin antiseptic
- Needle or venous catheter
- Y-type blood infusion set
- 170-μm filter
- Normal saline
- Blood product as described

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Verify that the patient has given informed consent for the procedure.	1. Transfusions have known risks and complications. The patient has the right to know these risks and alternatives to transfusions. The patient has the right to consent or refuse.
2. Inform the patient of the procedure, blood product to be given, approximate length of time, and desired outcome.	2. Allays fear and anxiety.
DRUG ALERT Crystalloid solutions other than 0.9% saline and all medications are incompatible with blood products. They may cause agglutination or hemolysis.	
3. Obtain and record baseline vital signs.	3. If the patient's clinical status permits, delay transfusion if baseline temperature is greater than 101.7°F (38.7°C).
4. Prepare infusion site. Select a large vein that allows the patient some degree of mobility. Start the prescribed IV infusion.	4. Antecubital veins are not recommended for lengthy infusions. Prolonged restriction of arm movement is uncomfortable and inconvenient for the patient. In the event of an acute reaction, the IV catheter should be maintained with normal saline.
5. Obtain the blood product from the blood bank. Inspect for abnormal color, cloudiness, clots, and excess air. Read instructions on the product label regarding storage and infusion. Check expiration date. If the transfusion cannot begin immediately, return product to blood bank.	5. Platelets are normally cloudy. Blood out of proper storage (above 50°F [10°C]) for more than 30 minutes cannot be reissued. Never store blood in unauthorized refrigerators, such as those on the nursing unit, because proper storage conditions cannot be verified.
6. Verify patient identification.	6. The majority of acute fatal transfusion reactions are caused by clerical errors. Patient and product verification is the single most important function of the nurse. It is strongly recommended that two qualified individuals perform this task.
a. Ask the patient to state full name and date of birth or other identifier and compare with information on the wristband. If the patient is unable to provide two identifiers, verify identity with an individual familiar with the patient.	
b. Compare the name, date of birth, and ID number on the wristband with the bag tag, transfusion form, and medical order.	
c. Confirm ABO and Rh compatibility by comparing the bag label, bag tag, medical record, and transfusion form.	
d. Check bag labels for expiration date and satisfactory serologic testing.	
KEY DECISION POINT Do not proceed with the transfusion if there is a discrepancy in labeling, patient identification, or expiration date. Contact the blood bank immediately.	

Nursing Action	Rationale
Performance phase	
1. Start infusion slowly (ie, 2 mL/min). Remain at bedside 15 to 30 minutes. If there are no signs of adverse effect, increase flow to the prescribed rate.	1. Institutional policy may vary regarding flow rates and patient monitoring. Signs of a severe transfusion reaction (ie, acute hemolytic, anaphylactic) are usually manifested during infusion of the initial 50 to 100 mL.
2. Observe the patient closely and check vital signs at least hourly until 1 hour after transfusion.	2. Acute reactions may occur at any time during the transfusion.
KEY DECISION POINT Observe for fever, chills, flushing, urticaria, difficulty breathing, anxiety, or change in vital signs. Stop transfusion and report signs of adverse effect to health care provider immediately if acute reaction is suspected.	
3. Record the following information on the patient's chart:	3. Facts relating to the transfusion should be charted exactly.
a. Time and names of individuals starting and ending the transfusion.	
b. Names of individuals verifying patient ID.	
c. Unique product identification number.	c. It must be possible to trace each transfusion product to the original blood donor.
d. Product and volume infused.	
e. Immediate response—eg, "no apparent reaction."	

Principles of Transfusion Therapy

Because of the potentially life-threatening consequences of blood type ABO incompatibility and disease transmission through blood products, transfusion therapy is limited to occasions when it is absolutely necessary, and stringent screening techniques are required before transfusion begins. Alternatives to transfusion therapy should also be considered, as appropriate, such as erythropoietin-stimulating agents, iron supplementation, blood loss prevention during surgery, and volume replacement with other solutions. Blood product procurement, storage, preparation, and testing are regulated by the Food and Drug Administration (FDA), the American Association of Blood Banks, and the Joint Commission.

Blood Compatibility

Antigens

1. The surface membrane of the red blood cell (RBC) is characterized by glycoproteins known as antigens.
2. More than 400 different antigens have been identified on the RBC membrane.
3. There are fewer than a dozen clinically significant antigens, and of these, only two antigenic systems (ABO and Rh) require routine prospective matching before the transfusion.
4. The ABO blood group system is clinically the most significant because A and B antigens elicit the strongest immune response.
5. The presence or absence of A and B antigens on the RBC membrane determines the person's ABO group (see Table 27-1). The ability to make A or B antigens is inherited.
6. Antibody formation without specific exposure to the antigen is unique to the ABO system. Antibody directed against the missing antigens is produced in neonates by 3 months of age.

Table 27-1 Blood Group Antigens and Antibodies of ABO System

BLOOD GROUP	ANTIGEN ON RBC	ANTIBODY IN PLASMA	APPROXIMATE FREQUENCY OF OCCURRENCE IN POPULATION
A	A	Anti-B	45%
B	B	Anti-A	8%
AB	A and B	None	3%
O	None	Anti-A and anti-B	44%

Antibodies

1. Antibodies (or immunoglobulins) are proteins produced by B lymphocytes; they consist of two light and two heavy chains that form a Y shape.
2. Antibodies generally have a high degree of specificity and interact only with the antigen that stimulated their production.
3. The five classes of immunoglobulins are determined by differences in their heavy chains: immunoglobulins (Ig) G, IgA, IgM, IgD, and IgE.

4. The interaction of antibodies and antigens triggers the humoral immune response.
5. Antibodies against the A and B antigens are large IgM molecules. When they interact with and coat the A and B antigens on the RBC surface, the antibody/RBC complexes clump together (agglutinate).
6. Antibody/RBC complexes also activate the complement cascade, resulting in the release of numerous active substances and RBC lysis. The large antibody/RBC complexes also become trapped in capillaries, where they may cause thrombotic complications to vital organs, and in the reticuloendothelial system, where they are removed from circulation by the spleen.
7. The extent of the humoral response elicited by anti-A and anti-B interaction with A and B antigens depends on the quantity of antibody and antigen.

Other Red Blood Cell Antigens

1. Non-ABO RBC antigen–antibody reactions usually do not produce powerful immediate hemolytic reactions but several have clinical significance.
2. After A and B, D is the most immunogenic antigen. It is part of the rhesus system, which includes C, D, and E antigens.
   a. D (Rh)–negative people do not develop anti-D without specific exposure, but have a high incidence of antibody development (alloimmunization) after exposure to D.
   b. Two common methods of sensitization to these RBC antigens are by transfusion or fetomaternal hemorrhage during pregnancy and delivery.
   c. Anti-D can complicate future transfusions and pregnancies. For the D (Rh)–negative person, exposure to D should be avoided by the use of Rh-negative blood products. In the case of Rh-negative mother and Rh-positive fetus, prophylaxis for exposure to D uses Rh immunoglobulin (RhoGAM), which will prevent anti-D formation.
   d. Exposure to RBC antigens from other antigenic systems (such as Lewis, Kidd, or Duffy) may also cause alloimmunization, which becomes clinically significant in people who receive multiple blood products for extended periods of time.

Blood Transfusion Options

Autologous Transfusion

1. Before elective procedures, the patient may donate blood to be set aside for later transfusion. Patients may donate up to 3 days prior to surgery provided hemoglobin is greater than 11 g/dL.
2. Autologous RBCs can also be salvaged during some surgical procedures or after trauma-induced hemorrhage by use of automated cell-saver devices or by manual suction equipment.
3. Autologous blood products must be clearly labeled and identified.
4. Autologous transfusion eliminates the risks of alloimmunization, immune-mediated transfusion reactions, and transmission of disease, making it the safest transfusion choice.

NURSING ALERT Patients who do not meet standard criteria for blood donation may still be eligible to donate autologous blood before elective surgeries. The nurse should encourage suitable candidates to consider this underused option.

Homologous Transfusion

1. With this most common option, volunteer donors' blood products are assigned to patients randomly.
2. Before donation, volunteer donors receive information about the process, potential adverse effects, tests that will be performed on donated blood, postdonation instructions, and education regarding risk of human immunodeficiency virus (HIV) infection and signs and symptoms.
3. Donors are screened against eligibility criteria designed to protect donor and recipient (see Table 27-2).

Table 27-2 General Blood Donor Eligibility Criteria

Age	≥17 years *or* 16 years with parental consent if state law allows
Weight	Minimum 110 lb (49.9 kg) (additional rules apply for donors ≤18 years)
Vital signs	Afebrile, normotensive, pulse 50–100, blood pressure < 180/100 mm Hg
Hemoglobin	≥12.5 g/dL
History	Travel, exposures, and past illnesses or events may defer or disallow blood donation. *Examples*: travel to malarial areas, living in areas exposed to bovine spongiform encephalopathy, blood transfusion or tattoo within 12 months, recent surgery or pregnancy, corneal transplant, history of hepatitis or unexplained jaundice, history of blood cancer or recent cancer, history of behaviors at high risk for human immunodeficiency virus.
Immunizations	Recent attenuated and live vaccines generally result in deferral.
Illnesses	A variety of current illnesses may defer or disallow blood donation. *Examples*: clotting disorders, sickle cell disease, systemic lupus erythematosus, multiple sclerosis, Lyme disease, tuberculosis, chronic fatigue syndrome.
Medications	Blood thinners, such as heparin and warfarin, disallow donation. Some other medications may result in deferral.

EVIDENCE BASE American Red Cross. (2017). *Donate blood: Eligibility requirements*. Available: *www.redcrossblood.org/donating-blood/eligibility-requirements*.

Directed Transfusion

1. In directed transfusion, blood products are donated by a person for transfusion to a specified recipient.
2. This option may be used in certain circumstances (eg, a parent who provides sole transfusion support for a child), but in general, no evidence exists that directed donation reduces transfusion risks.

Blood Product Screening

Serologic Testing

1. Routine laboratory testing is performed to assess the compatibility of a particular blood product with the recipient before release of the blood product from the blood bank (see Table 27-3).
   a. ABO group and Rh type: determines the presence of A, B, and D antigens on the surface of the patient's RBCs.
   b. Direct Coombs test: determines the antibody attached to the patient's RBCs.
   c. Crossmatch (compatibility test): detects agglutination of donor RBCs caused by antibodies in the patient's serum.
   d. Indirect Coombs test: identifies lower molecular weight antibodies (IgG) directed against blood group antigens.

Table 27-3 ABO and Rh Compatibility Chart

This chart identifies ABO and Rh compatibility when transfusing whole blood, red blood cells, and plasma. Components suspended in plasma, such as platelets and cryoprecipitate, usually follow plasma compatibility rules if the total volume exceeds 120 mL for an adult patient.

WHOLE BLOOD

	Donor					
Recipient	A	B	O	AB	Rh positive	Rh negative
A	✓					
B		✓				
O			✓			
AB				✓		
Rh positive					✓	✓
Rh negative						✓

RED BLOOD CELLS

	Donor					
Recipient	A	B	O	AB	Rh positive	Rh negative
A	✓		✓			
B		✓	✓			
O			✓	✓		
AB	✓	✓	✓			
Rh positive					✓	✓
Rh negative						✓

PLASMA

	Donor					
Recipient	A	B	O	AB	Rh positive	Rh negative
A	✓			✓		
B		✓		✓		
O	✓	✓	✓	✓		
AB				✓		
Rh positive					✓	✓
Rh negative					✓	✓

Screening for Infectious Diseases

1. Routine laboratory testing is performed to identify antigens or antibodies in donor blood that may indicate prior exposure to specific blood-borne diseases.
2. Such testing supplements other principles of donation designed to decrease the risk of disease transmission via blood products, including the use of volunteer donors, the exclusion of high-risk populations, and the screening of donors via health and social history.
3. Through the use of donor screening and blood testing, the risk of infections transmitted with donated blood is less than 1% and continues to decline.

4. Specific conditions screened for include:
    a. Hepatitis: Per FDA recommendations, each unit of blood is tested for the presence of hepatitis B core antibody, surface antigen, and more recently hepatitis B viral DNA through nucleic acid testing (NAT). Hepatitis C antibody and viral DNA tests (NAT) are also completed.
    b. HIV-1 and HIV-2: tests for prior exposure to the virus.
        i. All blood products in the United States have been screened since the test first became available in 1985. Current tests include testing for antibodies with enzyme-linked immunosorbent assay or enzyme immunoassay or antigen with the P24 test. NAT is becoming more widely used and provides a mechanism to look for the presence of HIV-1 and HIV-2 before antibody formation.
        ii. Because antibody to the virus is not produced until at least 6 weeks after exposure, diligent donor screening and exclusion of high-risk groups (eg, homosexual men, intravenous [IV] drug abusers, prostitutes, and sexual partners of high-risk people) remain important parts of preventing transmission of HIV via blood products.
        iii. A low risk of HIV transmission (estimated to be less than 1/2,000,000 units of blood) remains.
    c. Cytomegalovirus (CMV): tests for the antibody against CMV.
        i. Approximately 50% to 75% of blood donors have been exposed to CMV, and 10% to 20% carry CMV virus in their white blood cells (WBCs).
        ii. Patients with impaired immune function (eg, bone marrow and organ transplant recipients, premature babies) are at risk for CMV infection from transfused blood. It is recommended that these patients receive CMV-seronegative blood or leukoreduced products.
    d. Syphilis: tests for the presence of antibody against the spirochete.
    e. Bacteria: contamination of blood products with bacteria may occur during and after collection of blood. This risk is managed by adherence to sterile technique during phlebotomy and blood-processing procedures, correct storage techniques, visual inspection of blood products, and limitations on shelf life.
    f. Other infections that may be transmitted via blood transfusions include West Nile virus, human T-cell lymphoma virus (HTLV) 1 and 2, human herpesvirus 8 (implicated as the causative agent of Kaposi sarcoma), malaria, babesiosis, Chagas disease, and *Yersinia*. Variant Creutzfeldt-Jakob disease has also been transmitted via blood transfusions, which has led to restrictions on donation by individuals who have lived in areas with bovine spongiform encephalopathy or “mad cow” disease.

Administration of Whole Blood and Blood Components

Whole blood and blood components are administered to increase the amount of oxygen being delivered to the tissues and organs, to prevent or stop bleeding because of platelet defects or because of deficiencies or coagulation abnormalities, and to combat infection caused by decreased or defective WBCs or antibodies. See Standard of Care Guidelines 27-1, page 778.

STANDARDS OF CARE GUIDELINES 27-1

Blood Transfusion

When administering whole blood or blood components, ensure the following:

- Follow up on results of complete blood count (CBC) and report to health care provider so appropriate blood product can be ordered based on patient's condition.
- Verify informed consent.
- Contact the blood bank with health care provider's order and ensure timely delivery of blood product.
- Establish a patent IV line with compatible IV fluid.
- Use appropriate administration setup, filter, warmer, etc.
- Obtain baseline vital signs.
- Ensure proper blood product is given to the right patient by verifying at least two identifiers (eg, full name and date of birth) with patient, blood product, and original order.
- Transfuse at prescribed rate during prescribed time, as tolerated by patient.
- Observe for acute reactions—allergic, febrile, septic, hemolytic, air embolism, and circulatory overload—by assessing vital signs, breath sounds, edema, flushing, urticaria, vomiting, headache, and back pain.
- Stop transfusion and notify patient's health care provider or available house officer if signs of reaction or other abnormalities occur.
- Be aware of delayed reactions and educate patient on risk and what to look for: hemolytic, iron overload, graft versus host disease, hepatitis, and other infectious diseases.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

General Considerations

1. A unit of whole blood is usually separated into its various components shortly after collection.
2. The use of blood components conserves the limited supply of blood, provides optimal therapeutic benefit, and reduces the risk of circulatory overload. Less than 3% of the blood collected nationwide is transfused as whole blood.
3. Because of the risks, blood components should be administered only with informed consent, meticulous identification procedures, careful protocol, and close monitoring.

DRUG ALERT Crystalloid solutions other than 0.9% saline and all medications are incompatible with blood products. They may cause agglutination or hemolysis.

KEY DECISION POINT

Observe the patient closely and check vital signs at least hourly until 1 hour after transfusion. Observe for fever, chills, flushing, urticaria, difficulty breathing, anxiety, and change in vital signs. Stop transfusion and report signs of adverse effect to health care provider immediately if acute reaction is suspected.

Whole Blood

Description

1. Consists of RBCs, plasma, plasma proteins, and approximately 60-mL anticoagulant/preservative solution in a total volume of approximately 500 mL.
2. Indications include acute, massive blood loss of greater than 1,000 mL, requiring the oxygen-carrying properties of RBCs and the volume expansion provided by plasma. In general, even acute loss of as much as one third of a patient's total blood volume (1,000 to 1,200 mL) can be safely and rapidly replaced with crystalline or colloidal solutions.

Nursing and Patient Care Considerations

1. For rapid infusions of large volumes of whole blood, additional steps may be taken to deliver product rapidly and safely.
   a. A small-pore (20 to 40 mm) filter may be used to remove microaggregates (platelets, WBCs) that have been identified in the lungs of massively transfused patients.
   b. An approved blood warmer may be indicated to prevent hypothermia and cardiac arrhythmias associated with the rapid infusion of refrigerated solutions.
   c. Electromechanical infusion devices to deliver blood at high flow rates can hemolyze RBCs and should be used with caution.
2. Observe closely for the most common acute complication associated with whole blood transfusion—circulatory overload (rise in venous pressure, distended neck veins, dyspnea, cough, crackles at bases of lungs).

Packed RBCs

Description

1. Consist primarily of RBCs, a small amount of plasma, and approximately 100-mL anticoagulant/preservative solution in a total volume of approximately 250 to 300 mL/unit.

2. Packed RBCs may be contaminated with WBCs that may increase the risk of minor transfusion reactions and alloimmunization. For patients who receive multiple blood products during a specific period (eg, patients with leukemia or aplastic anemia), packed RBCs may be further manipulated to remove WBCs (leukoreduced) by washing or freezing the product in the blood bank or by the use of small-pore (20 to 40 mm) leukoreduction filters during administration.
3. Indications include restoration or maintenance of adequate organ oxygenation with minimal expansion of blood volume.
4. Dosage: average adult dose administered is 2 units; pediatric doses are generally calculated as 5 to 15 mL/kg.

Nursing and Patient Care Considerations

1. Infuse at the prescribed rate. Generally, a unit can be given to an adult in 90 to 120 minutes. Pediatric patients are usually transfused at a rate of 2 to 5 mL/kg/hour.
2. To reduce the risk of bacterial contamination and sepsis, RBCs must be transfused within 4 hours of leaving the blood bank.
3. Observe closely (particularly during first 15 to 30 minutes) for the most common acute complications associated with packed RBCs, allergic and febrile transfusion reactions. Signs and symptoms of the more serious, but rare, hemolytic transfusion reactions are usually manifested during infusion of the first 50 mL.

Platelet Concentrates

Description

1. Consist of platelets suspended in plasma. Products vary according to the number of units (each unit is a minimum of 5.5×10^{10} platelets) and the volume of plasma (50 to 400 mL).
2. Platelets may be obtained by centrifuging multiple units of whole blood and expressing off the platelet-rich plasma (multiple-donor platelets) or from a single volunteer platelet donor using automated cell separation techniques (apheresis). The use of single-donor products decreases the number of donor exposures, thus decreasing the risk of alloimmunization and transfusion-transmitted disease.
3. Patients may become alloimmunized to human leukocyte antigens (HLAs) through exposure to multiple platelet products. When this occurs, apheresis products from HLA-matched platelet donors may be necessary. However, HLA-matched transfusions are commonly difficult to obtain because of the vast number of possible HLA combinations among the human population.
4. Indications include prevention or resolution of hemorrhage in patients with thrombocytopenia or platelet dysfunction.
5. Platelet transfusions are generally contraindicated in heparin-induced thrombocytopenia, where they may precipitate arterial thrombosis, and in immune (idiopathic) thrombocytopenia, where they may worsen this autoimmune destruction of platelets.
6. Dosage: average dose is generally 1 unit of platelets for each 10 kg of body weight; however, patients who

are actively bleeding or undergoing surgical procedures may require more.

Nursing and Patient Care Considerations

1. Infuse at the rate prescribed. Generally, the infusion can be completed within 20 to 60 minutes, depending on total volume.
2. Observe closely for the most common acute complications associated with platelet transfusions, allergic and febrile transfusion reactions.
3. Platelets are stored at 68°F to 75°F (20°C to 24°C), a warmer environment than other blood products and more conducive to bacterial growth. This increases the risk of bacterial contamination of a platelet product, which occurs in 4 to 10 per 10,000 units, limiting their shelf life.

Plasma (Fresh or Fresh Frozen)

Description

1. Consists of water (91%), plasma proteins including essential clotting factors (7%), and carbohydrates (2%). Each unit is the volume removed from a unit of whole blood (200 to 250 mL).
2. May be stored in a liquid state or frozen within 6 hours of collection.
3. Indications include treatment of blood loss or blood-clotting disorders related to liver disease and failure, disseminated intravascular coagulation (DIC), overanticoagulation with warfarin, all congenital or acquired clotting factor deficiencies, and dilutional coagulopathy resulting from massive blood replacement. Storage in liquid state results in the loss of labile clotting factors V and VIII, so that only plasma that has been fresh-frozen can be used to treat factor V and VIII deficiencies.
4. Dosage: depends on the clinical situation and assessment of prothrombin time, partial thromboplastin time, or specific factor assays.

Nursing and Patient Care Considerations

1. Infuse at the rate prescribed. Generally, the infusion can be completed within 15 to 30 minutes, depending on total volume.
2. Observe closely for the most common acute complication associated with plasma infusion, volume overload.

Cryoprecipitate

Description

1. Consists of certain clotting factors suspended in 10 to 20 mL plasma. Each unit contains approximately 80 to 120 units of factor VIII (antihemophilic and von Willebrand factors), 250 mg fibrinogen, and 20% to 30% of the factor XIII present in a unit of whole blood.
2. Indications include correction of deficiencies of factor VIII (ie, hemophilia A and von Willebrand disease), factor XIII, and fibrinogen (ie, DIC).
3. Dosage: adult dosage is generally 10 units, which may be repeated every 8 to 12 hours until the deficiency

is corrected or until hemostasis is achieved.

Nursing and Patient Care Considerations

Infuse at the rate prescribed. Generally, the infusion can be completed within 3 to 15 minutes.

Fractionated Plasma Products

Description

1. Various highly concentrated plasma protein products are commercially prepared by pooling thousands of single plasma units and by extracting the desired protein. Most techniques involve heat or chemical treatments, which eliminate the risk of transmitting blood-borne viruses, such as hepatitis B and HIV.
2. Colloid solutions provide volume expansion in situations where crystalloid solutions are not adequate, such as therapeutic plasma exchange, shock, and massive hemorrhage. They may also be used in the treatment of acute liver failure, burns, and hemolytic disease of the neonate.
    a. Albumin is available as a 5% solution, which is oncotically equivalent to plasma, and as a concentrated 25% solution.
    b. Plasma protein fraction (PPF) is available as a 5% solution. Rapid infusion of PPF has been associated with hypotension.
    c. Albumin and PPF are pasteurized and carry no risk of viral disease. They do not contain preservatives and should be used immediately after opening.
3. Immune serum globulins (ISGs) are concentrated aqueous solutions of gamma globulin that contain high titers of antibody.
    a. Must be administered by deep intramuscular (IM) injection.
    b. Nonspecific ISG is prepared from random donor plasma and is used to increase gamma globulin levels and to enhance general immune response in mild inherited or acquired immune disorders such as hypogammaglobulinemia.
    c. Specific ISG is prepared from donors who have high antibody titers to known antigens and is used to treat specific disorders or conditions. Hepatitis B immunoglobulin, varicella-zoster immunoglobulin, and Rh immunoglobulin are examples of specific ISGs.
    d. ISGs carry no risk of hepatitis B, HIV, or other blood-borne infections.
    e. Problems associated with use include pain at the injection site, limitations on volume administered, loss of IgG into extravascular tissue, or by degradation at the injection site.
4. IV immunoglobulins (IVIGs) are aqueous solutions of immunoglobulins at a higher concentration and are given in larger volumes than ISGs.
    a. Like ISGs, they may be nonspecific or specific.
    b. Indications include chronic replacement therapy in patients with congenital or acquired immunodeficiency syndromes, acute autoimmune disorders such as immune (idiopathic) thrombocytopenia, and the treatment of chronic lymphocytic leukemia. Also, there are numerous investigational uses, such as Guillain-Barré syndrome, myasthenia gravis, rheumatoid arthritis,

multiple sclerosis, lupus, and viral infections such as CMV, adenovirus, and influenza. IVIGs may also be used to treat platelet alloimmunization.

c. IVIGs do not appear to transmit HIV, but have been reported to transmit hepatitis C.

d. Administration of IVIG should be closely monitored because of the possibility of anaphylactic reactions. Dosage and rate of infusion depend on the manufacturer's formulation.

5. Factor VIII concentrate is a lyophilized concentrate used to treat moderate to severe hemophilia A and severe von Willebrand disease.
6. Factor IX concentrate is a lyophilized concentrate used to treat factor IX deficiency (Christmas disease).

Nursing and Patient Care Considerations

1. These products are often distributed by a pharmacy rather than by a blood bank.
2. Check order and product insert to ensure proper dosage and administration route.

Granulocyte Concentrates

Description

1. Consist of a minimum of 1×10^{10} granulocytes, variable amounts of lymphocytes (usually less than 10% of the total number of WBCs), 6 to 10 units of platelets, 30 to 50 mL RBCs, and 200 to 400 mL plasma.
2. Obtained via apheresis, generally of multiple donors.
3. Indications include treatment of life-threatening bacterial or fungal infection unresponsive to other therapy in a patient with severe neutropenia.
4. Dosage: generally 1 unit daily for approximately 5 to 10 days, discontinuing if no therapeutic response.

Nursing and Patient Care Considerations

1. Product must be ABO compatible and, if possible, Rh compatible because of the high erythrocyte content. Granulocytes are irradiated prior to transfusion to prevent the risk of graft-versus-host disease.
2. Transfuse granulocytes as soon as they are available. WBCs have a short survival time and therapeutic benefit is directly related to dose and viability.
3. Premedicate per order to prevent adverse effects, generally with antihistamine and acetaminophen. Steroids may also be required.
4. Begin the transfusion slowly and increase to the rate prescribed and as tolerated. The recommended length of infusion is 1 to 2 hours.
5. Observe the patient closely throughout the transfusion for signs and symptoms of febrile, allergic, and anaphylactic reactions, which may be severe. Have emergency medications and equipment readily available.
6. Agitate the bag approximately every 15 minutes to prevent granulocytes from clumping at the bottom of the bag.
7. Do not administer amphotericin products immediately before or after granulocyte transfusion because

pulmonary insufficiency has been reported with concurrent administration of amphotericin and granulocytes. Many institutions recommend a 4-hour gap to avoid this risk.

Modified Blood Products

Purpose

1. To reduce the risk of specific transfusion-related complications, blood products may receive further processing or treatment.
    a. Leukocytes are removed from blood products through filtration, washing, and freezing to reduce the risk of febrile, nonhemolytic transfusion reactions and alloimmunization to HLA.
    b. Function and proliferation of donor lymphocytes are inhibited by irradiation, to decrease the risk of posttransfusion graft-versus-host disease (GVHD) in immunocompromised patients including oncology patients, lung or heart transplant patients, and pediatric patients under age 6.

Methods

1. Filtration.
    a. Standard filters (170 μm) effectively remove gross fibrin clots.
    b. Microaggregate filters (approximately 40 μm) remove microscopic aggregates of fibrin, platelets, and leukocytes that accumulate in RBC products during storage. Their use is recommended during rapid, massive transfusion of whole blood or packed RBCs to prevent pulmonary complications. They reduce the risk of CMV transmission and may also decrease the incidence of febrile transfusion reactions by removing many of the leukocytes present.
    c. Special leukocyte-depletion filters have been developed for use with platelet products that remove 80% to 95% of leukocytes and that retain 80% of the platelets. These filters also reduce the risk of CMV transmission.
    d. A product may be filtered before release from the blood bank, but more commonly is released with the appropriate filter that must be attached to the standard infusion set at the bedside per manufacturer's or blood bank's instructions.
2. Washing.
    a. Washing RBCs or platelets with a normal saline solution removes 80% to 95% of the WBCs and virtually all of the plasma to reduce the incidence of febrile, nonhemolytic transfusion reactions.
    b. Washing requires an additional hour of processing time, and the shelf life of the product is reduced to 24 hours after this additional manipulation.
3. Freezing.
    a. RBCs can be frozen within 7 days of blood collection and then remain viable for 7 to 10 years.
    b. Removal of the hypertonic freezing preservative (glycerol) before transfusion eliminates all of the plasma and 99% of WBCs.
    c. Thawing and deglycerolization of RBCs require an additional 90 minutes of preparation time and reduce shelf life to 24 hours after this additional manipulation.

d. Freezing is also an effective method of storing rare blood types and autologous RBCs.

4. Irradiation.

a. Exposure of blood products to a measured amount of gamma irradiation inhibits lymphocyte function and proliferation without damaging RBCs, platelets, or granulocytes. This eliminates the ability of transfused lymphocytes to engraft in the immunocompromised transfusion recipient and the accompanying risk of posttransfusion GVHD.

b. Patients at risk for posttransfusion GVHD include bone marrow and peripheral stem cell transplant recipients, lung or heart transplant patients, premature neonates, and patients with congenital immunodeficiency disorders, Hodgkin and non-Hodgkin lymphomas, and HIV.

Transfusion Reactions

Every transfusion of blood components can result in an adverse effect. Reactions can be placed into two general categories: acute and delayed.

Acute Reactions

1. Acute reactions may occur during the infusion or within minutes to hours after the blood product has been infused.
2. Acute reactions include allergic, febrile, septic, and hemolytic reactions, air embolism, and circulatory overload. Patients who also receive multiple blood products within a short time frame may also be at risk for hyperkalemia, hypocalcemia, and hypothermia.
3. Because reactions may exhibit similar clinical manifestations, every symptom should be considered potentially serious and the transfusion should be discontinued until the cause is determined.
4. When a reaction is suspected, the health care provider should be notified immediately, and blood bags with tubing from all products recently transfused should be returned to the blood bank for evaluation.
5. The following samples should also be obtained if an acute reaction is suspected.
   a. A clotted blood specimen to examine serum for hemoglobin and confirm RBC group and type.
   b. An anticoagulated blood sample for a direct Coombs test to determine the presence of antibody on the RBCs.
   c. The first-voided urine specimen to test for hemoglobinuria (this does not need to be a clean-catch specimen).
6. Precautions must be taken to avoid the hemolysis of RBCs during venipuncture and sample collection because this could lead to invalid test results. Whenever possible, blood samples should be drawn from a fresh venipuncture and not from existing needles or catheters.
7. If the only symptoms are those resulting from a mild allergic reaction (eg, urticaria), extensive evaluation may not be necessary. In the event of a severe reaction (eg, hypotension, tachypnea), more tests may be required to determine the cause of the reaction.
8. Causes, clinical manifestations, management, and prevention of acute reactions are summarized in Table 27-4.

Table 27-4 Acute Reactions to Blood Transfusion

ACUTE REACTION	CAUSE	CLINICAL MANIFESTATIONS	MANAGEMENT	PREVENTION
Allergic	Sensitivity to plasma protein or donor antibody, which reacts with recipient antigen	• Flushing • Itching, rash • Urticaria, hives • Asthmatic wheezing • Laryngeal edema • Anaphylaxis	• Stop transfusion immediately. Keep vein open (KVO) with normal saline. Notify health care provider and blood bank. • Give antihistamine, as directed (diphenhydramine). • Observe for anaphylaxis—prepare epinephrine if respiratory distress is severe. • If hives are the only clinical manifestation, the transfusion can sometimes continue at a slower rate. • Send blood samples and blood bags to blood bank. Collect urine specimens for testing.	• Before transfusion, ask patient about past reactions. If patient has history of anaphylaxis, alert health care provider, have emergency drugs available, and remain at bedside for the first 30 minutes.

Febrile, nonhemolytic	Hypersensitivity to donor white blood cells, platelets, or plasma proteins	• Sudden chills and fever • Headache • Flushing • Anxiety	• Stop transfusion immediately and KVO with normal saline. Notify health care provider and blood bank. • Send blood samples and blood bags to blood bank. Collect urine specimens for testing. • Check temperature 30 minutes after chill and as indicated thereafter. • Give antipyretics, as prescribed—treat symptomatically.	• Give antipyretic (acetaminophen or aspirin) before transfusion as directed. • Leukocyte-poor blood products may be recommended for future transfusions.
Septic reactions	Transfusion of blood or components contaminated with bacteria	• Rapid onset of chills • High fever • Vomiting, diarrhea • Marked hypotension	• Stop transfusion immediately and KVO with normal saline. Notify health care provider and blood bank. • Obtain cultures of patient's blood and return blood bags with administration set to blood bank for culture. • Treat septicemia, as directed—antibiotics, IV fluids, vasopressors, and steroids.	• Do not permit blood to stand at room temperature longer than necessary. Warm temperatures promote bacterial growth. • Inspect blood for gas bubbles, clotting, or abnormal color before transfusion. • Complete infusions within 4 hours. Change administration set after 4 hours of use.
Circulatory overload	Fluid administered at a rate or volume greater than the circulatory system can accommodate. Increased blood in pulmonary vessels and decreased lung compliance	• Rise in venous pressure • Distended neck veins • Dyspnea • Cough • Crackles at base of lungs	• Stop transfusion and KVO with normal saline. Notify health care provider. • Place patient upright with feet in dependent position. • Administer prescribed diuretics, oxygen, morphine, and aminophylline.	• Concentrated blood products should be given whenever positive. • Transfuse at a rate within the circulatory reserve of the patient. • Monitor central venous pressure of patient with heart disease.
Hemolytic reaction	Infusion of incompatible blood products: • Antibodies in recipient's plasma attach to transfused red blood cells (RBCs), hemolyzing the cells either in circulation or in the reticuloendothelial system. • Antibodies in donor plasma attach to recipient RBCs, causing hemolysis (may result from infusion of incompatible plasma—less severe than incompatible RBCs).	• Chills; fever • Lower back pain • Feeling of head fullness; flushing • Oppressive feeling • Tachycardia, tachypnea • Hypotension, vascular collapse • Hemoglobinuria, hemoglobinemia • Bleeding • Acute renal failure	• Stop transfusion immediately—KVO with 0.9% saline. Notify health care provider and blood bank. • Treat shock, if present. • Draw testing samples; collect urine specimen. • Maintain blood pressure with IV colloid solutions. • Give diuretics, as prescribed, to maintain urine flow, glomerular filtration, and renal blood flow. • Insert indwelling catheter to monitor hourly urine output. Patient may require dialysis if renal failure occurs.	• Meticulously verify patient identification—from sample collection to product infusion. • Begin infusion slowly and observe closely for 30 minutes—consequences are in proportion to the amount of incompatible blood transfused.

Delayed Reactions

1. Delayed reactions occur days to years after the transfusion.
2. Delayed reactions include delayed hemolytic reactions, iron overload (hemosiderosis), GVHD, and infectious diseases (eg, hepatitis B, hepatitis C, CMV, Epstein-Barr virus, malaria, HIV, HTLV).
3. Symptoms of a delayed reaction can vary from mild to severe. Diagnosis may be complicated by the long incubation period between transfusion and reaction and the complexity of diagnostic tests.
4. Causes, clinical manifestations, management, and prevention of delayed reactions are summarized in Table 27-5, pages 783 and 784.

Table 27-5 Delayed Reactions to Transfusion Therapy

DELAYED REACTION	CAUSE	CLINICAL MANIFESTATIONS	MANAGEMENT	PREVENTION
Delayed hemolytic reaction	The destruction of transfused red blood cells by antibody not detectable during crossmatch, but formed rapidly after transfusion. Rapid production may occur because of antigen exposure during previous transfusions or pregnancy.	• Fever • Mild jaundice • Decreased hematocrit	• Generally, no acute treatment is required, but hemolysis may be severe enough to cause shock and renal failure. If this occurs, manage as outlined under acute hemolytic reactions.	• The crossmatch blood sample should be drawn within 3 days of blood transfusion. Antibody formation may occur within 90 days of transfusion or pregnancy.
Iron overload (hemosiderosis)	Deposition of iron in the heart, endocrine organs, liver, spleen, skin, and other major organs as a result of multiple, long-term transfusions (aplastic anemia, thalassemia).	• Diabetes • Decreased thyroid function • Arrhythmias • Heart failure and other symptoms related to major organ failure	• Treat symptomatically. • Deferoxamine, which chelates and removes accumulated iron through the kidneys; administered via IV line, IM, or SubQ	—
Graft-versus-host disease	Engraftment of lymphocytes in the bone marrow of immunosuppressed patients, setting up an immune response of the graft against the host	• Erythematous skin rash • Liver function test abnormalities • Profuse, watery diarrhea	• Immunosuppression with corticosteroids, cyclosporine A • Symptomatic management of pruritus, pain • Fluid and electrolyte replacement for diarrhea	• Transfuse with irradiated blood products.
Hepatitis B	Hepatitis B virus transmitted from blood donor to recipient via infected blood products	• Elevated liver enzymes (ALT/AST) • Anorexia, malaise • Nausea and vomiting • Fever • Dark urine • Jaundice	• Usually resolves spontaneously within 4–6 wk. Can result in permanent liver damage. Treat symptomatically.	• Screen blood donors, temporarily rejecting those who may have had contact with the virus. Those with a history of hepatitis after age 11 are permanently deferred; pretest all blood products (EIA).
Hepatitis C (formerly non-A, non-B hepatitis)	Hepatitis C virus transmitted from blood donor to recipient via infected blood products	• Similar to serum B hepatitis, but symptoms are usually less severe. • Chronic liver disease and cirrhosis may develop.	• Symptoms usually mild. Interferon and ribavirin may be used to treat chronic liver disease.	• Pretest all blood donors (ALT, anti-HBc antibody, anti-hepatitis C antibody).
Epstein-Barr virus, cytomegalovirus, malaria	Transmitted through infected blood products	• Fever • Fatigue • Hepatomegaly • Splenomegaly	• Rest and supportive management	• Question prospective blood donors regarding colds, flu, and foreign travel.
Acquired immunodeficiency syndrome (AIDS)	Human immunodeficiency virus (HIV) transmitted from blood donor to recipient via infected blood products	• Night sweats • Unexplained weight loss • Lymphadenopathy • Pneumocystis pneumonia • Kaposi sarcoma • Diarrhea	• Combination antiretroviral therapy	• Test each donor for HIV antibody. • Reject prospective high-risk donors: males who have had sex with another male since 1977; users of self-injected IV drugs; male or female partners of prostitutes; hemophiliacs or their sexual partners; partners of those with AIDS or high risk for AIDS; immigrants from Haiti or sub-Saharan Africa.

Human T-lymphotropic virus type 1 (HTLV-1) associated myelopathy and tropical spastic paraparesis (HAM/TSP) Adult T-cell leukemia	HTLV-1 transmitted from blood donor to recipient via blood products	• Signs of neuromuscular disease • Signs of T-cell leukemia	• HTLV-1–infected individuals have a low risk of developing disease (3%–5%). Incubation period 10–20 yr. • Should disease occur, treat symptomatically.	• Screen all prospective blood donors for anti–HTLV-1 antibody.
Syphilis	Spirochetemia caused by *Treponema pallidum*. Incubation 4–18 wk.	• Presence of chancre • Regional lymphadenopathy • Generalized rash	• Penicillin therapy	• Test blood before transfusion (rapid plasma reagin). Organism will not remain viable in blood stored 24–48 hr at 39.2°F (4°C).

TRANSITIONAL CARE ALERT Nurses must educate patients about the potential for a delayed blood transfusion reaction at the time of discharge, including signs and symptoms to be on the lookout for and notify their health care provider for timely diagnosis and outpatient treatment.

BLOOD AND MARROW STEM CELL TRANSPLANTATION

Blood and marrow stem cell transplantation is a potentially lifesaving treatment with application in many malignant and nonmalignant disorders. Decades of research have advanced this technology from an experimental treatment of last resort to the preferred method of intervention for selected diseases. Although the basic procedures are now well established, this field continues to grow rapidly through ongoing research in areas such as nonmyeloablative ("mini") allogeneic transplants, the application of biologic response modifiers to modulate the immune response, and the use of donor lymphocyte infusions to prevent or treat posttransplant relapse.

Principles of Blood and Marrow Stem Cell Transplantation

Types of Stem Cell Transplant

The type of transplant selected is contingent on a variety of factors, such as the underlying disorder, the availability of a histocompatible (HLA-matched) donor, and the clinical condition of the patient. Stem cells may come from the patient (autologous), an identical twin (syngeneic), or another donor (allogeneic). Stem cells are found in bone marrow, in peripheral blood (especially if the donor is treated to increase the numbers of circulating stem cells), and in umbilical cord blood.

Autologous Bone Marrow Transplantation

1. Bone marrow is removed from the patient during an operative harvesting procedure, frozen, and reinfused after the patient has undergone high-dose chemotherapy and possibly radiotherapy.
2. Advantages: readily available and usually lower morbidity and mortality than allogeneic bone marrow transplantation (BMT).
3. Disadvantages: operative procedure; marrow must be disease-free; sufficient quantity of cellular marrow must be aspirable; in most cases has higher rate of relapse than allogeneic BMT.

Syngeneic Bone Marrow Transplantation

1. Bone marrow is removed from an identical twin during an operative harvesting procedure and infused into the recipient, who has undergone high-dose chemotherapy and possibly radiotherapy.
2. Advantages: recipient's marrow does not need to be harvestable (as in hypocellular or tumor-contaminated bone marrow), generally lower morbidity and mortality than allogeneic BMT.
3. Disadvantages: higher disease relapse rate than in allogeneic BMT.

Allogeneic Bone Marrow Transplantation

1. Bone marrow is removed from a donor who is most commonly a sibling or other close relative (related) but may be a volunteer donor (unrelated).
    a. Identical or mismatched HLA phenotypes may be used, though identical phenotypes are often preferred. HLA mismatches require additional immunosuppression and GVHD prophylaxis and can be associated with higher morbidity and mortality.
    b. Bone marrow is removed from the donor during an operative harvesting procedure and infused into the recipient, who has undergone high-dose chemotherapy and possibly radiotherapy.
    c. Allogeneic bone marrow may be treated in various ways before infusion, including removing RBCs if ABO incompatible and removing T lymphocytes to reduce the risk of GVHD.
2. Advantages: recipient's marrow does not need to be harvestable (as in hypocellular or tumor-contaminated bone marrow) and lowest rate of relapse.
3. Disadvantages: risk for GVHD and generally higher morbidity and mortality than other types of BMT. Unrelated and HLA-mismatched transplants have higher risk of GVHD and infectious complications and some risk of graft rejection or failure.

Autologous, Syngeneic, or Allogeneic Peripheral Blood Stem Cell Transplantation

1. Although hematopoietic stem cells are primarily found in the bone marrow, they can also be found in the peripheral circulation in smaller numbers.
2. Peripheral blood stem cells are collected using one or more apheresis procedures after the patient or donor has been treated to increase the number of circulating stem cells. This is done by methods such as timed administration of chemotherapy (patient only) and stem cell growth factors. After the collection, the cells are frozen and stored for reinfusion into the patient after high-dose chemotherapy and possibly radiotherapy.
3. Advantages: patient's marrow does not need to be harvestable (as in hypocellular or tumor-contaminated bone marrow); there is no operative risk to the patient or donor.
4. Disadvantages: for allogeneic donors, the long-term risks of boosting healthy bone marrow production with growth factors, and in some cases chemotherapy, are not yet known. Research has shown that allogeneic peripheral blood stem cell transplant may be associated with a higher incidence of chronic GVHD than allogeneic bone marrow transplant.

Umbilical Cord Blood Stem Cell Transplantation

1. Umbilical cord blood is rich in stem cells and may be stored at birth for later autologous use, related allogeneic use, or unrelated allogeneic use. Cord blood transplantation requires less stringent HLA matching because mismatched cord blood stem cells are less likely to cause GVHD than mature stem cells from other sources.
2. Advantages: may provide lifesaving allogeneic stem cells from new sibling to older child at no risk to the donor. Cord blood banks provide options for unrelated donor transplantation when there is an urgent need.
3. Disadvantages: may have higher risk of graft failure than other types of transplants; number of stem cells may be insufficient for older patients.

Nonmyeloablative or "Mini" Transplants

1. Conventional conditioning for blood and marrow stem cell transplants requires high doses of chemotherapy and radiotherapy (myeloablative) to destroy existing bone marrow cells. This results in significant morbidity and mortality, particularly in certain patient populations (eg, older patients, those with poor organ function).
2. Research has demonstrated that under certain conditions, individuals can exist with bone marrow stem cells from two sources (self and allogeneic donor), a state known as *mixed chimerism*. These changes in the immune system appear to enhance the antitumor immune response, creating a desired graft-versus-tumor effect.
3. The goals of nonmyeloablative conditioning regimens are to prevent graft rejection and promote mixed chimerism. The nonmyeloablative preparative regimen uses combinations of agents such as cyclophosphamide, fludarabine, antithymocyte globulin, and low-dose total body irradiation. Alemtuzumab is often considered as well. After the completion of the reduced intensity regimen, the

allogeneic bone marrow or peripheral blood stem cells are then infused.

4. Donor lymphocytes may also be given at specific intervals following transplant to enhance the immune antitumor effect further.
5. Advantages: patients otherwise ineligible for allogeneic transplant because of age, comorbid conditions, or organ function are more likely to tolerate the less-toxic preparative regimen. Patients do not usually experience significant neutropenia, thrombocytopenia, anemia, and other complications that typically accompany myeloablative therapy. Patients generally have shorter episodes of neutropenia and a reduced need for RBC and platelet transfusions, allowing an opportunity for outpatient transplants to be performed.
6. Disadvantages: Increased risk of graft failure.

The Human Leukocyte Antigen System and Transplantation

1. The human leukocyte antigen (HLA) system is part of the major histocompatibility complex.
2. The immune-mediated recognition of the differences in each individual's HLA system is the first step in the rejection of a transplanted organ or graft or in GVHD.
3. The HLA antigens are complex proteins expressed on the surface of all nucleated cells (A, B, C antigens—class I) or cells of the immune system (D antigens—class II).
   a. More than 100 different antigens have been identified.
   b. Antigens are classified according to their location on chromosome 6, which encodes them.
   c. A person's genetically inherited mixture of antigens expressed on cell surfaces is their individual phenotype or tissue type.
4. Determination of an individual's HLA type is completed by complex DNA phenotyping or gene sequencing.
   a. The gold standard for HLA typing in bone marrow transplantation is to complete the above testing at high resolution (allelic level), identifying both the class I (A, B, C) and class II (D) groups.
   b. A phenotypically identical donor is considered to be one who matches at all 10 antigens at their associated allelic level—A, B, C, DR, and DQ.
5. Siblings have a 1-in-4 chance of having identical sets of HLA antigens. With a decreasing national birthrate, however, only 35% of people in the United States can anticipate having an HLA-identical sibling.
6. Because of the complexity of the HLA system, unrelated people have less than a 1-in-5,000 chance of being HLA identical.
7. The National Bone Marrow Donor Program (BeTheMatch Registry), established in 1987, maintains a computerized list of potential HLA-matched peripheral blood stem cell and bone marrow donors, providing assistance to patients who seek an unrelated donor. Information on becoming a volunteer bone marrow donor or on initiating a computerized search for a donor can be obtained by calling the National Marrow Donor Program ((800) 507-5427 or *www.marrow.org*), for additional resources for patients undergoing blood and marrow stem cell transplantation.

Indications

1. If an HLA-matched related donor is available, allogeneic bone marrow or stem cell transplantation is generally considered the treatment of choice in certain disorders, including:
   a. Severe aplastic anemia.
   b. Inherited immunodeficiency disorders, such as severe combined immunodeficiency disease and Wiskott-Aldrich syndrome.
   c. Allogeneic bone marrow and peripheral blood stem cell transplantation has also been used with varying success in the treatment of other genetic disorders (eg, thalassemia, sickle cell disease).
2. Allogeneic, syngeneic, and autologous bone marrow and peripheral blood stem cell transplantation is also widely applied in the treatment of malignancies, where success rates depend largely on factors such as the age of the patient, disease status at time of transplant, the extent of prior treatment, and existing comorbidities.
3. Autologous peripheral blood stem cell transplantation is used in the treatment of certain lymphomas, multiple myeloma, and solid tumors such as Ewing sarcoma and neuroblastoma. Allogeneic bone marrow and peripheral blood stem cell transplantation is generally used in the treatment of leukemias as well as certain lymphomas.
4. Diseases and disorders treated with this technology are summarized in Box 27-1.

BOX 27-1 Indications for Blood and Marrow Stem Cell Transplantation

ALLOGENEIC

Nonmalignant

- Aplastic anemia.
- Myelofibrosis.
- Wiskott-Aldrich syndrome.
- Thalassemia.
- Severe combined immunodeficiency diseases.
- Mucopolysaccharidoses.
- Sickle cell disease.

Malignant

- Acute myeloid leukemia.
- Acute lymphocytic leukemia.
- Hodgkin lymphoma.
- Non-Hodgkin lymphoma.
- Myelofibrosis.
- Multiple myeloma.
- Selected solid tumors.

AUTOLOGOUS

- Hodgkin lymphoma.
- Non-Hodgkin lymphoma.
- Multiple myeloma.
- Selected solid tumors.

Harvesting of Bone Marrow and Peripheral Blood Stem Cells

Evaluation of Recipient

1. Eligibility criteria include age (generally younger than age 65 for allogeneic myeloablative transplants and autologous and syngeneic transplants and younger than age 75 for allogeneic nonmyeloablative transplants) and availability of suitable donor and stem cell source.
2. Before undergoing transplantation, an extensive workup is completed to ensure that the patient's disease is treatable with the selected type of transplant and that the patient has no limitations that will increase the risk of mortality.
3. Specific criteria may vary among transplant centers and treatment protocols, but generally include:
   a. Disease-specific evaluation of severity and extent of current disease manifestations.
   b. Adequate cardiac function: generally left ventricular ejection fraction greater than 45%.
   c. Adequate pulmonary function: generally, forced expiratory capacity and forced vital capacity greater than 50%.
   d. Adequate renal function: generally, creatinine less than 2 mg/dL.
   e. Adequate hepatic function: generally, bilirubin less than 2 mg/dL.
   f. No active infections (including HIV).
   g. No coexisting severe or uncontrolled medical conditions.

Evaluation of Blood and Marrow Donors

1. Because bone marrow donation for allogeneic or syngeneic BMT is an elective procedure with no benefit to the donor, great care is taken to ensure that the potential donor is fit for surgery and understands the potential risks. Autologous bone marrow donors must generally meet the same criteria. Evaluation includes:
   a. Thorough medical history and physical examination.
   b. Chest x-ray.
   c. Electrocardiogram.
   d. Laboratory evaluation (CBC; chemistry profile; testing for CMV, hepatitis B and C, HIV, HTLV, and syphilis; ABO and Rh determination; coagulation studies).
2. Informed consent including potential donor complications must be obtained.
3. Relatively common complications include:
   a. Bruising.
   b. Pain at aspiration sites.
   c. Mild bleeding.
4. Rare complications include:
   a. Adverse effects of anesthesia (general, spinal, or epidural).
   b. Infection of aspiration sites.

c. Persistent pain.
d. Transient neuropathies.

5. Because of the significant loss of blood volume and RBCs during the harvest procedure, donors are advised to give one or two units of autologous blood 1 to 3 weeks before surgery, which may be reinfused during marrow collection, if needed.
6. Evaluation of donors for peripheral blood stem cell transplantation is similar, but less stringent as there is generally no anesthesia required. The apheresis procedure is similar to donating platelets.

Stem Cell Collection Procedure

Bone Marrow Harvest (Autologous, Syngeneic, or Allogeneic)

1. Performed under epidural, spinal, or general anesthesia under sterile conditions in operating room.
2. An aspiration needle is used to puncture the skin and puncture the iliac crest multiple times without exiting the skin, removing marrow in 2- to 5-mL aliquots (samples).
3. Marrow is drawn up into heparinized syringes and filtered to remove fibrin clots and other debris.
4. Marrow may be infused immediately, treated and infused, or frozen in a preservative solution containing dimethyl sulfoxide (DMSO) until needed.
5. Bone marrow donation is a relatively safe operative procedure with few serious complications.

Postharvest Care of the Bone Marrow Donor

1. Procedure is generally done as same-day care, with discharge after recovery from anesthesia.
2. Observe for potential complications (bleeding, hypotension caused by fluid loss).
3. Instruct patient to resume normal activities gradually during the week after donation.
4. Instruct patient to keep aspiration sites clean and dry and observe for signs of infection (redness, swelling, warmth or discharge at sites, fever, malaise).
5. Provide adequate analgesia and instruct patient about pain management.

Harvesting of Peripheral Blood Stem Cells

1. Involves donor preparation by "priming" hematopoietic system with timed chemotherapy (autologous stem cell collection only) and sequential growth factor administration to increase the number of circulating stem cells.
2. A large-bore central catheter suitable for apheresis procedures is inserted.
3. One to ten apheresis procedures may be needed to collect sufficient numbers of suitable cells.
4. Cells are frozen in a preservative solution that contains DMSO until needed.
5. Acute complications of apheresis include citrate toxicity, which may be managed by increasing dietary calcium intake 2 to 3 days before procedure and by using calcium-based antacids during the procedure. Blood calcium levels are carefully monitored throughout the procedure and IV calcium is given, as needed.

TRANSITIONAL CARE ALERT After donation of bone marrow and peripheral blood stem cells, attention to follow-up should be given to the donor to ensure there are no signs of complications from the donation procedure. It is also important that adequate pain management medications be prescribed and that the donor and caregiver are instructed on concerns that warrant medical attention such as fever, numbness or tingling, or severe pain not relieved by medications.

Preparation and Performance of the Transplant

Preparation of Recipient

1. A long-term central catheter is inserted for multiple IV treatments, including blood products, total parenteral nutrition, and blood drawing.
2. High-dose chemotherapy or radiotherapy is administered to:
   a. Destroy residual tumor cells.
   b. Suppress immune response against new stem cells.
   c. Create space within recipient's marrow for the new stem cells.
3. Symptoms immediately associated with high-dose chemotherapy or radiotherapy regimens used in blood and marrow stem cell transplantation may include:
   a. Severe nausea and vomiting (with most regimens).
   b. Cardiomyopathy and hemorrhagic cystitis (with cyclophosphamide).
   c. Seizures (with busulfan).
   d. Fever, generalized erythema, and parotitis (with total body irradiation).

Infusion of Bone Marrow or Peripheral Blood Stem Cells

See Table 27-6.

Table 27-6 Infusion Guidelines for Bone Marrow or Peripheral Blood Stem Cells

TYPE OF STEM CELLS	PROCESSING PRIOR TO INFUSION	VOLUME	POTENTIAL ADVERSE EFFECTS	NURSING CONSIDERATIONS
ABO-compatible untreated allogeneic bone marrow	Filtered to remove large particles	500–2,000 mL	Volume overload, allergic reactions, pulmonary compromise (fat emboli, cell aggregates)	Emergency medications available, close monitoring
ABO-incompatible bone marrow	Removal of red blood cells and plasma	200–600 mL	Allergic reactions, intravascular hemolysis (rare)	Prehydrate to ensure adequate renal perfusion and alkaline urine, emergency medications available, close monitoring
Autologous bone marrow	Filtered and frozen with DMSO as preservative, thawed in warm water bath immediately prior to infusion	100–500 mL	Related to DMSO: histamine release reaction (flushing, chest tightness, abdominal cramping, nausea), cardiac arrhythmias, anaphylaxis	Emergency medications available, close monitoring, cardiac monitoring recommended
Peripheral blood stem cells	Frozen with DMSO as preservative, thawed in warm water bath immediately prior to infusion	100–1,000 mL	Related to DMSO: histamine release reaction (flushing, chest tightness, abdominal cramping, nausea), cardiac arrhythmias, anaphylaxis	Administer as tolerated (may be high volume and DMSO content), premedicate with antihistamine and antiemetic, emergency medications available, close monitoring, cardiac monitoring recommended

DMSO, dimethyl sulfoxide.

NURSING ALERT Unlike all other blood products administered to transplant recipients, stem cells should never be irradiated. In addition, infusion pumps and filters should be avoided because they may remove or damage stem cells.

Posttransplant Care

General Considerations

1. Significant complications that require specialized medical and nursing care may occur during the first few weeks and months after blood and marrow stem cell transplantation.
   a. Risk is highest in mismatched unrelated allogeneic BMT.
   b. Followed by matched unrelated and mismatched related allogeneic BMT.
   c. Followed by matched related allogeneic BMT.
   d. Followed by syngeneic BMT.
   e. Followed by autologous BMT.
   f. Followed by autologous peripheral blood stem cell transplantation (lowest risk).
2. Nursing care is aimed at early identification and treatment of problems and includes:
   a. Comprehensive physical and psychosocial assessment.
   b. Immediate notification of health care provider of any abnormal assessment parameters found.
   c. Early recognition and intervention for life-threatening complications, such as sepsis, respiratory failure, gastrointestinal (GI) bleeding, renal and hepatic failure, and veno-occlusive disease (VOD).
   d. Prevention of infection.
   e. Prevention of bleeding.
   f. Expert symptom management of problems that may occur after blood and marrow stem cell transplantation, such as nausea, vomiting, diarrhea, pain, fatigue, anxiety, and delirium.

Hematopoietic Complications

1. Blood and marrow stem cell transplant patients, particularly allogeneic recipients, are at risk for life-threatening bacterial, viral, and fungal infections because of their profound neutropenia and prolonged immunosuppression.
   a. Transplant recipients are usually cared for in a protective environment, most commonly single HEPA-filtered rooms.
   b. In an ambulatory or home setting, the patient and family must pay strict attention to methods of preventing infection, including wearing high-filtration masks, handwashing, safe food handling, and avoidance of crowded areas and exposure to illnesses.
   c. Blood and marrow stem cell recipients are at high risk for nosocomial bloodstream infections related to long-term central venous catheters, neutropenia, and immunosuppression. Strict adherence to an evidence-based procedure for insertion and management of central venous catheters is essential in this population.
   d. Colony-stimulating factors such as GCSF and GM-CSF have been shown to reduce the duration of neutropenia, though the optimal timing for administration has not been determined.
   e. Additional preventive interventions vary widely and include elaborate disinfection procedures, modified or sterile diets, prophylactic antibiotics, antivirals, and antifungals, and surveillance cultures.

2. The megakaryocyte is generally the last cell produced by new stem cells, and platelet counts may take months to return to normal.
    a. Blood and marrow stem cell transplant patients require frequent assessment for signs and symptoms of overt or covert bleeding, protection from injury, and support with platelet products.
3. Anemia is a common complication caused by loss of RBCs through aging, destruction, bleeding, and routine phlebotomy. Blood and marrow stem cell transplant patients require frequent RBC transfusions. Erythropoietin alfa and darbepoetin alfa may also be used to stimulate RBC production. Delayed erythropoiesis and immune hemolytic anemia are complications of ABO-incompatible allogeneic stem cell transplants.

Gastrointestinal Complications

1. Mucositis may develop because of high-dose chemotherapy and radiation therapy that destroy rapidly dividing cells, including cells lining the mouth, esophagus, and GI tract. Management includes meticulous oral hygiene, local and systemic analgesia, and antimicrobial therapy.
2. Nausea and vomiting may arise from multiple causes, including high-dose chemotherapy, infection, GI bleeding, acute GVHD, and medications. Management includes pharmacologic and nonpharmacologic interventions, adequate replacement of fluids and electrolytes, and support of nutritional requirements.
3. Diarrhea may have multiple causes, including high-dose chemotherapy, infection, GI bleeding, GVHD, and medications. Management includes cautious use of antidiarrheals, adequate replacement of fluids and electrolytes, support of nutritional requirements, and protection of perirectal skin from excoriation.

Renal and Genitourinary Complications

1. Renal failure may arise from multiple factors, including drug toxicity, infection, and ischemia. Management includes maintenance of fluid and electrolyte balance, monitoring of drug levels, and hemodialysis or continuous venovenous hemodialysis.
2. Hemorrhagic cystitis may occur as a result of high-dose cyclophosphamide or with certain viral infections, such as adenovirus and BK virus (a polyoma virus, named for the first patient). Management includes hydration, blood product support, continuous bladder irrigation, and rare invasive procedures, such as instillation of alum or formalin, or surgery.

Hepatic Complications

Sinusoidal obstruction syndrome or VOD may occur as a result of damage to the liver from high-dose chemotherapy and radiation therapy; incidence is approximately 30%.

1. Signs and symptoms include hepatomegaly (generally painful), hyperbilirubinemia, and weight gain.
2. May progress to hepatic encephalopathy, coagulopathies, coma, and death in up to 50% of patients with VOD.
3. Management is generally aimed at preventing further damage and at treating symptoms. The antithrombotic and thrombolytic agent defibrotide may be administered for severe VOD; however, the risk of bleeding is high with the administration of this agent; other agents being studied include heparin,

recombinant tissue plasminogen activator, and ursodeoxycholic acid.

Pulmonary Complications

1. Life-threatening pulmonary infections in stem cell recipients include bacterial pneumonias, fungal infections including aspergillosis, viral infections such as CMV (especially in allogeneic recipients), respiratory syncytial virus, parainfluenza, and, less commonly, *Pneumocystis carinii* pneumonia (PCP), Legionnaires' disease, toxoplasmosis, and tuberculosis.
   a. Preventive measures include hand hygiene, encouragement of exercise, deep breathing, and coughing; routine CMV polymerase chain reaction monitoring if recipient or donor is CMV IgG positive at the time of transplant; administration of CMV-screened and/or leukoreduced blood products, high-dose acyclovir or ganciclovir, and IVIG for allogeneic BMT patients at high risk for CMV; and prophylactic co-trimoxazole for patients at risk for PCP.
   b. Staff, patient, and family education regarding risk factors and transmission of these infectious agents may help prevent primary and nosocomial infections.
   c. Supportive care if symptomatic includes pulmonary hygiene, oxygen therapy, and mechanical ventilation.
2. Noninfectious pulmonary disease includes idiopathic pneumonitis, diffuse alveolar hemorrhage, pulmonary fibrosis, and bronchiolitis obliterans.

Graft-Versus-Host Disease

1. Acute GVHD occurs in 40% to 60% of allogeneic recipients even with HLA matching, generally within first 3 months after transplant as a manifestation of the immune system's response to activated donor T lymphocytes against the recipient's cells and organs.
   a. Primarily affects the skin, liver, and GI tract; may also affect conjunctivae and lungs.
   b. Severity ranges from mild and self-limited erythematous rash to widespread blistering of the skin, profuse watery diarrhea, and liver failure.
   c. Prophylaxis generally includes immunosuppression with such medications as cyclosporine, tacrolimus, and methotrexate; may also include T-cell depletion of bone marrow.
   d. Recently, research has demonstrated that administration of high-dose cyclophosphamide a few days after the stem cell transplant decreases the rate of acute GVHD.
   e. Treatment generally includes increased doses of routine immunosuppressive drugs and additional drugs, such as corticosteroids, antithymocyte globulin, and monoclonal antibodies.
2. Chronic GVHD occurs in approximately 20% of long-term survivors; usually appears within first year after allogeneic blood and marrow stem cell transplant.
   a. It has many similarities to autoimmune disorders such as scleroderma.
   b. It affects the skin, mouth, salivary glands, eyes, musculoskeletal system, liver, esophagus, GI tract, and vagina.
   c. Treatment generally consists of corticosteroids and other immunosuppressive drugs, such as mycophenolate and thalidomide.

d. Immune system frequently suppressed beyond the effects of medications; patient is at risk for infections, particularly from encapsulated bacteria, and should receive prophylaxis with suitable antibiotic such as penicillin.

Long-Term Sequelae and Survivorship Issues

1. Long-term, disease-free survival varies from 5% to 20% for patients with resistant, aggressive leukemias or lymphomas to 75% to 80% for aplastic anemia.
2. Long-term complications of blood and marrow stem cell transplantation include:
   a. Relapse of original disease.
   b. Secondary malignancy, including skin, oral mucosa, brain, thyroid, bone, and acute leukemia.
   c. Sterility.
   d. Endocrine dysfunction, including reduced levels of human growth hormone, estrogens, and testosterone.
   e. Cataracts (risk increased with radiation therapy, corticosteroids).
   f. Chronic GVHD (allogeneic).
   g. Aseptic necrosis and osteoporosis (risk increased with corticosteroids).
   h. Encephalopathy (risk increased with cranial irradiation and intrathecal chemotherapy).
3. Survivorship issues after this intensive and potentially life-threatening treatment include:
   a. Feelings of isolation, guilt, and loss.
   b. Altered family dynamics.
   c. Delayed puberty, decreased libido, early menopause, and other physical problems that have an impact on sexual relationships.
   d. Readjustment to school or work setting.
   e. Financial burden of blood and marrow stem cell transplantation.
   f. Chronic health problems and fatigue.
   g. Difficulty obtaining adequate health insurance.
4. Despite the complex issues blood and marrow stem cell transplant survivors face, several quality-of-life studies have demonstrated that the majority rate their quality of life highly and would choose to undergo transplant again.

PROCEDURE GUIDELINES 28-1

Epicutaneous Skin Testing

EQUIPMENT

- Antigens for testing
- Controls
- Positive—histamine 1 mg/mL
- Negative—glycerol saline
- Disposable pricking devices (sterile needles or lancets)
- Alcohol swabs
- Paper tissues
- Skin-marking pencil
- Millimeter ruler
- Tourniquet
- Epinephrine 1:1,000 aqueous
  solution for injection for emergency use

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain the procedure to the patient. Ask if the patient has taken antihistamines in the past 72 hours.	1. Oral antihistamines taken within 72 hours of skin testing are likely to prevent a reaction from occurring. Desloratadine can affect skin testing up to 7 days.
2. Prepare the site (volar surface of forearm or back) by cleansing with alcohol.	2. The forearm is usually preferable because in the event of a significant local or systemic reaction, a tourniquet may be placed proximal to the skin test to slow the diffusion of the antigen into the circulation.
3. Mark the test sites with a skin-marking pencil approximately 3 to 4 cm apart.	3. Sites need to be spaced appropriately so that reactions will remain distinct from one another, thus allowing an accurate reading.
Implementation phase	
1. Apply positive (histamine) and negative (saline) controls next to the appropriate markings. Apply pricking device to skin per manufacturer's instructions. Discard pricking device after each puncture.	1. Because of interpatient variability in cutaneous reactivity, it is necessary to include positive and negative controls whenever skin testing is performed. A response to the positive control confirms an immunologic ability to react. A response to the negative control indicates reactivity to the diluting solution or mechanical trauma. Care must be taken to prevent cross-contamination between antigens.
2. Apply small drops of antigens next to the skin markings and prick the drops as described above.	2. Large drops may run and cross-contaminate, affecting interpretation.
3. Instruct the patient not to scratch the test area during the 15-minute waiting interval before the reactions are graded.	3. It is normal for sensitive individuals to have a pruritic sensation at the testing site because of the histamine released by the mast cells.
4. Observe the patient closely for signs of impending anaphylaxis (such as itching, flushing, abnormal sensation in throat).	4. General systemic or anaphylactic reactions are rare, but do occur. If suspected, apply tourniquet above test site and administer epinephrine 1:1,000 subcutaneously in a dose of 0.01 mL/kg (maximum 0.3 mL).
Follow-up phase	
1. Fifteen minutes after pricking the antigens, measure the diameter of induration (wheal) and erythema (flare) in two perpendicular axes through the center of the reaction; record in millimeters.	1. Amount of induration indicates the extent of reaction, but erythema is noted as well.
2. Document the procedure, test results, patient tolerance, and any other pertinent observations.	2. Continuity of care.

PROCEDURE GUIDELINES 28-2

Intradermal Skin Testing

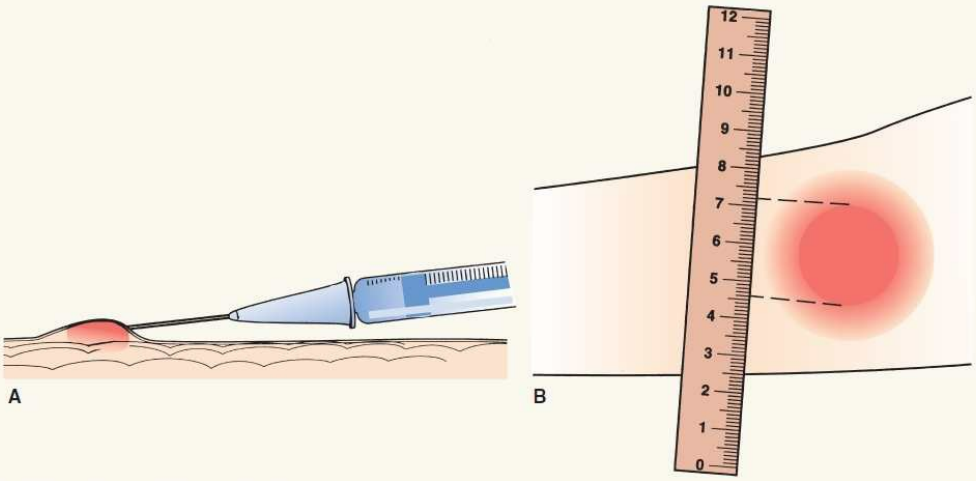
EQUIPMENT

- Antigens for testing
- Controls
- Positive—histamine 0.1 mg/mL
- Negative—human serum albumin/saline
- 1-mL syringes with 26G or 27G intradermal needle
- Alcohol swabs
- Paper tissues
- Skin-marking pencil
- Millimeter ruler
- Tourniquet
- Gloves

- Epinephrine for emergency use

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Explain the procedure to the patient. Ask if the patient has taken antihistamines in the past 72 hours.	1. Oral antihistamines taken 72 hours before skin testing are likely to prevent a reaction from occurring. Desloratadine should be held for 7 days.
2. Prepare the site (volar surface of forearm or upper arm) by cleansing with alcohol. Allow to dry.	2. Allowing alcohol to dry ensures antisepsis.
3. Mark the test sites with a skin-marking pencil approximately 3 to 4 cm apart.	3. Sites need to be spaced appropriately so that reactions will remain distinct from one another, thus allowing an accurate reading.
Implementation phase	
1. Using sterile technique, draw up 0.05 mL of each testing material. All bubbles must be carefully expelled to avoid "splash reactions," which reduce precision. While wearing gloves, place the syringe at a 10- to 15-degree angle to the skin with the bevel up. Stretch the skin taut and insert 0.02 mL of the positive and negative controls. The bevel should penetrate the skin entirely and end between the layers of skin. A bleb approximately 2 mm in diameter should be produced.	1. Gloves should be worn when there is any possibility of exposure to blood or body fluids. Only a small amount needs to be deposited into skin—enough to raise a bleb.
2. Inject approximately 0.02 mL of test antigens intradermally next to the skin markings. A different syringe and needle must be used for each antigen.	2. Avoids antigen and microbial contamination.



(A) Intradermal injection producing a wheal.
(B) Measuring area of induration.

Nursing Action	Rationale
3. Instruct the patient not to scratch the test area during the 15-minute waiting interval before the reaction is graded.	3. It is normal for sensitive individuals to have a pruritic sensation at the testing site because of the histamine released by the mast cells.
4. Observe the patient closely for signs of impending anaphylaxis (itching, flushing, lump in throat).	4. There is an increased possibility of anaphylactic reactions with intradermal skin testing. If suspected, apply tourniquet above test site and administer epinephrine 1:1,000 I.M. in a dose of 0.3 mL (0.01 mL/kg in children <30 kg)
5. Fifteen minutes after applying antigens, measure the diameter of induration (wheal) and erythema (flare) in two perpendicular axes through the center of the reaction and record in millimeters.	
Follow-up phase	
1. Document the procedure, test results, patient tolerance, and any other pertinent observations.	1. For continuity of care.
2. Monitor for the following complications during and following testing:	2. Any significant reaction may be anxiety provoking for the patient, but anaphylaxis occurs suddenly and may be life threatening.
Local reactions—unusually large reactions (>25 mm in duration) a. Apply prescribed steroid cream to affected area. b. If no relief, administer prescribed oral antihistamine.	
Vasovagal reactions—fainting episode a. Monitor vital signs. b. Reassure the patient. c. Finish skin testing, if possible.	
Systemic Anaphylaxis	

KEY DECISION POINT If signs of anaphylaxis develop, stop testing and apply tourniquet above skin testing site. Administer epinephrine I.M. (using vastus lateralis muscle) and administer oxygen. Alert provider or emergency responders.

EVIDENCE BASE Lieberman, P., Nicklas, R. A., Randolph, C., et al. (2015). Anaphylaxis—a practice parameter update 2015. *Annals of Allergy, Asthma and Immunology, 115*, 341–384.

The Allergic Reaction

An allergic reaction results from antigen–antibody reaction on sensitized mast cells or basophils, causing the release of chemical mediators. The reaction may be characterized by inflammation, increased secretions, and bronchoconstriction.

Definitions

1. Antigen (Ag)—a protein that is found on the surface of a pathogen and stimulates an immune reaction, causing the production of antibodies.
2. Antibody (Ab)—immunoglobulin (Ig)(protein) secreted by B cells as a defense mechanism against foreign material such as antigen.
3. Atopy—ability to produce immunoglobulin E antibodies to common allergens. The genetic tendency to develop classic allergic disease or hypersensitivity reaction.
4. Immunity:
    a. Humoral—process by which B lymphocytes produce and secrete circulating antibodies to act against antigens.
    b. Cell-mediated—part of the immune system comprised of T lymphocytes responsible for antigen-specific cell-mediated immunity (CMI) by activating cytotoxic T cells that identify infectious pathogens such as virus, bacteria, fungi, and protozoan cells. Cell-mediated response also fights cancers.
5. Mast cell—type of WBC tissue cell similar to peripheral blood basophil, which contains granules with chemical mediators. Known for its role in allergic and anaphylactic reactions
6. Basophil—leukocyte with large granules that contain the vasodilator histamine and the anticoagulant heparin.
7. Hypersensitivity—reaction to an antigen after reexposure; there are four types.
    a. Type I (immediate, IgE)—allergic reactions such as atopy, anaphylaxis, asthma
    b. Type IV (delayed)—occurs 48 to 72 hours after exposure, as in contact dermatitis, tuberculin reaction, and transplant rejection (also considered allergic reaction).
    c. Type 2 (IgM, IgG antibody dependent)—autoimmune hemolytic anemia.
    d. Type 3 (IgG)—immune complex disease as in rheumatoid arthritis.

Immunoglobulins

Antibodies that are formed by lymphocytes and plasma cells in response to an immunogenic stimulus comprise a group of serum proteins called *immunoglobulins*.

1. The abbreviation for immunoglobulin is Ig.
2. Antibodies combine with antigens in lock-and-key style.
3. There are five major classes of immunoglobulins.
    a. IgM—produced by B cells constitutes 10% of immunoglobulin pool; found mostly in intravascular

fluid and primarily engaged in initial defense; levels elevated with recent infection or exposure to antigen.

b. IgG—major immunoglobulin that accounts for 70% to 75% of secondary immune responses and combats tissue infection.

c. IgA—15% to 20% of immunoglobulins; predominantly found in seromucous secretions (such as saliva, tears, sweat, and secretions from the gastrointestinal tract, genitourinary tract, prostate, and respiratory epithelium). It provides a primary defense mechanism.

d. IgD—less than 1% of immunoglobulin pool; found on circulating B lymphocytes, and signals B cells to become activated.

e. IgE—only a trace found in serum; attaches to surface membrane of basophils and mast cells; responsible for immediate types of allergic reactions (Type 1 hypersensitivity).

Immunologic Reactions

Immediate Hypersensitivity (Type I)

1. Characterized by:
   a. IgE-mediated allergic reaction Mast cells and/or basophils (see Figure 28-1).
   b. Occurs immediately after contact with the antigen.
   c. Causes release and neo-synthesis of preformed chemical mediators.
   d. Can occur 2nd to medications.
2. Examples—anaphylaxis, allergic rhinitis, urticaria.

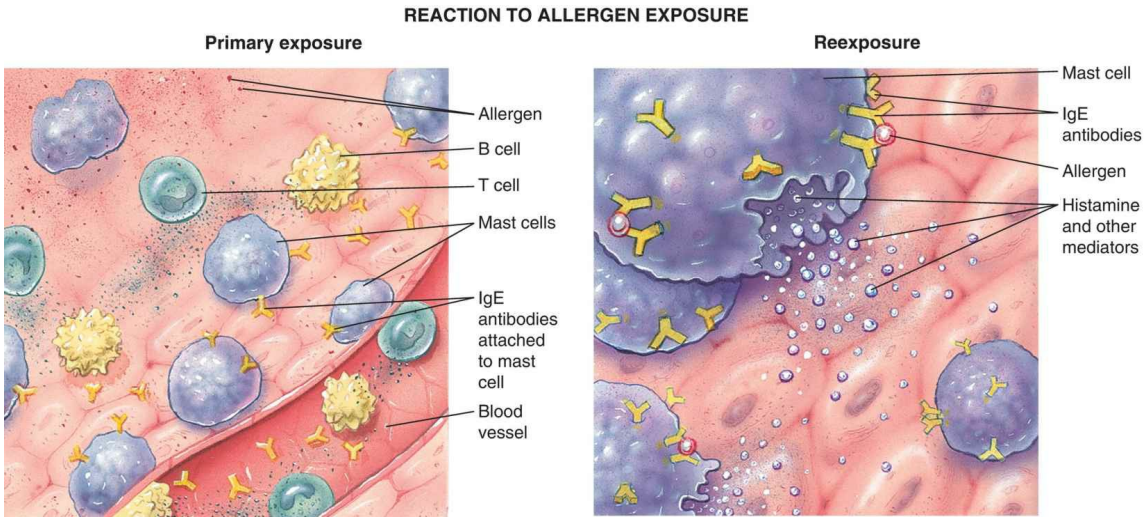


Figure 28-1. Type I immediate hypersensitivity. During the initial exposure, T cells recognize foreign allergens and release chemicals to instruct B cells to produce immunoglobulin (Ig) E. These antibodies attach themselves to mast cells. Upon reexposure, the allergen comes in contact with the IgE antibodies attached to mast cells, causing degranulation and release of chemical mediators. (Stewart, J.G. [2017]. Anatomical Chart Company Atlas of Pathophysiology [4th ed.]. Philadelphia: Lippincott Williams & Wilkins.)

Products of Immediate Hypersensitivity (Chemical Mediators)

1. Histamine—bioactive amine stored in granules of mast cells and basophils.
2. Leukotrienes—newly synthesized potent bronchoconstrictors; cause increased venous permeability.
3. Prostaglandins—potent vasodilators and potent bronchoconstrictors.
4. Platelet-activating factor—has many properties; causes the aggregation of platelets.
5. Cytokines—control and regulate immunologic functions (eg, interleukins, tumor necrosis factor).
6. Proteases—enzymes, such as tryptase and chymase, increase vascular permeability.
7. Eosinophil chemotactic factor of anaphylaxis—causes an influx of eosinophils into the area of allergic inflammation (fevers, stomatitis, sepsis).
8. Examples—drug-induced hemolytic anemia, drug-induced thrombocytopenia, drug-induced neutropenia.

Effects of Chemical Mediators and Their Manifestations

1. Generalized vasodilation (histamine, nitric oxide, prostaglandin) hypotension, flushing.
2. Increased permeability (histamine, bradykinin, leukotrienes, among others)
    a. Capillaries of the skin—edema.
    b. Mucous membranes—edema.
3. Smooth muscle contraction.
    a. Bronchioles—bronchospasm.
    b. Intestines—abdominal cramps, diarrhea.
4. Increased secretions.
    a. Nasal mucous glands—rhinorrhea.
    b. Bronchioles—increased mucus in airways.
    c. GI—increased gastric secretions.
    d. Lacrimal—tearing.
    e. Salivary—salivation.
5. Pruritus (itching).
    a. Skin.
    b. Mucous membrane.

Delayed Hypersensitivity (Type IV)

1. Characterized by a cell-mediated reaction between antigens and antigen-responsive T lymphocytes (IgG, IgM).
2. Maximal intensity occurs between 24 and 48 hours.
3. Usually consists of erythema and induration.
4. Examples—tuberculin skin test, contact dermatitis such as poison ivy, Hashimoto thyroiditis

Allergy Assessment

Subjective and Objective Data

1. Evaluate for symptoms related to hay fever, asthma, skin reactions, insect allergy, and food allergy.
2. Determine exacerbating factors such as contact with pets, outdoor exposure, a certain season, contact with mold, exposure to dust.
3. Obtain complete medical history for past illnesses, medication allergies, family history, medications that have been tried, exercise, smoking, and work environment.
4. Perform physical examination based on patient presentation and specific allergy condition, usually skin, head, chest, eye, ear, nose, and throat examination.

Skin Testing

The purpose of skin testing is to identify antigens responsible for immediate hypersensitivity. The types of skin tests used in clinical allergy are epicutaneous (prick, puncture, or scratch) and intradermal methods. The skin test remains unequaled as a sensitive, specific, and effective test for the diagnosis of allergies.

Epicutaneous (Prick) Method

1. Advantages:
    a. Efficient—results within 15 minutes.
    b. Little discomfort to the patient/relatively safe.
    c. Only rare instances of anaphylaxis because of minimal systemic absorption.
2. Disadvantages:
    a. Old or thick, leathery skin decreases reactivity.
    b. Lack of standardization and quantification.
    c. Drops have a tendency to run together, which would affect the accuracy of the test.

Intradermal Method

1. Advantages:
    a. Useful to confirm equivocal epicutaneous results with some antigens.
    b. Moderate sensitivity and reproducibility.
2. Disadvantages:
    a. Less specific than prick testing/subjective interpretation.
    b. Increased possibility for anaphylactic reactions.
    c. Requires more time and skill to perform.
    d. Increased discomfort to the patient/variation in wheal size and erythema.

In Vitro Testing

Description

1. *In vitro*—using blood samples—tests for IgE antibodies to specific allergens. Instead of looking for a reaction *in vivo* (with the patient's body—as in skin testing), *in vitro* testing measures the IgE response to specific antigens added to blood samples.
2. Advantages over skin testing include the following:
   a. Can be done without special knowledge of skin testing or availability of allergen extract.
   b. Patient does not need to stop antihistamine before testing.
   c. Can be done even with severe eczema or other skin-related diseases.
   d. There is no risk of systemic anaphylactic reaction.
3. An immunofluorescent process is preferred for specific IgE testing because of high degree of sensitivity and specificity.
4. Some labs may offer a radioallergosorbent test (RAST); measures the allergen-specific IgE antibodies in serum samples after panel of allergens have been added to samples.

Nursing and Patient Care Considerations

1. Tell the patient that it is allergy testing without the risk of causing severe allergic reaction.
2. Obtain adequate venous blood for each allergen panel to be tested.
3. A positive result depends on the standards for that particular laboratory. The test does not indicate clinical significance of symptoms and must be interpreted with patient's history.
4. Arrange for a follow-up visit for the patient with the health care provider to discuss test results.

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 28-3.

PROCEDURE GUIDELINES 28-3

Giving an Allergy Injection

EQUIPMENT

- individualized allergy vaccine
- 1-mL syringe
- 25G to 27G - ½- to -⅝ -inch needle
- Gauze or cotton ball
- Alcohol sponges

NURSING ALERT Because of the risk of anaphylaxis, have epinephrine 1:1,000 readily available for injection, as well as oxygen, parenteral diphenhydramine, and IV supplies.

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Check record and ask the patient about reaction to last injection. Note how many weeks since last shot.	1. Local erythema and induration may have occurred during observation period or later.
2. Check order for prescribed dosage and any special instructions based on reaction history.	2. Significant reaction (>2–3 cm and lasting 24 h) may require injection at same or lower dose. Missed weeks may require dosage adjustment.
3. Draw up dose, checking strength of allergy vaccine and amount (usually 0.05–0.5 mL)	3. Vaccine will be replaced periodically with a stronger preparation.
4. Verify the correct dose for the patient.	4. Incorrect vaccine or dose may cause anaphylaxis.
Performance phase	
1. Select the appropriate site for subcutaneous injection, usually the midlateral upper arms. If two injections are necessary, give in opposite arms.	1. Because injections are usually only given once per week, no need to use abdomen or thighs. Using different arms for two injections allows for determining which vaccine may have caused reaction if one occurs.
2. Wear gloves if pressure is applied to the patient's arm.	2. Prevents contact with the patient's blood.
3. Cleanse the site with alcohol and allow to dry.	3. Disinfects skin.
4. Grasp the upper arm with nondominant hand so that tissue is elevated slightly.	4. Secures arm and subcutaneous tissue beneath outer skin.
5. Insert needle at a 45- to 90-degree angle, depending on thickness of subcutaneous tissue at the site.	5. Thickness of subcutaneous tissue varies among individuals.
6. Aspirate for blood return and if none occurs, inject serum.	6. If blood enters the syringe, dispose of it and begin again rather than injecting into a blood vessel.
7. Withdraw the syringe, cover site the with alcohol sponge, and dispose of the needle and syringe. Check the site for bleeding or bruising.	7. Follow facility policy; do not resheath the needle.
Follow-up phase	
1. Have the patient wait 30 minutes before leaving the facility. Check for local reaction periodically and tell the patient to report any sudden swelling, itching, or respiratory difficulty.	1. Significant local or systemic reaction may occur; most likely with increased dose or new vaccine vial.
KEY DECISION POINT If angioedema, respiratory distress, or hypotension develop, institute emergency actions, including administration of oxygen, application of tourniquet above the injection site, and injection of epinephrine 1:1000 0.3–0.5 mL in the opposite arm.	
2. Record the amount and concentration of vaccine, site given, and appearance of site after 30 minutes.	2. Flow sheet serves as official documentation of medication given and may be reviewed by allergist when evaluating therapy.
3. Dismiss the patient with instructions on whom to call if reaction occurs and when to return for the next injection.	3. May call allergist or primary care provider, or go to emergency department if systemic reaction occurs.

Immunotherapy

Immunotherapy is the modulation of the immune system to develop tolerance to a known allergen that causes IgE, type I (immediate) hypersensitivity. Given in appropriate doses, it can significantly decrease patient symptoms in most patients. It is indicated for significant symptoms of allergic rhinitis, allergic conjunctivitis, allergic asthma, and stinging insect allergy that cannot be controlled by avoidance of the allergen. Considerable compliance and time commitment are essential for successful therapy.

Features of Immunotherapy

1. Specific allergens are identified by skin or blood testing.
2. Serial injections are begun that contain extracts from identified allergens (allergy vaccine).
3. Initially, a small amount of dilute allergy vaccine is given, usually at weekly intervals.
4. Amount and concentration are slowly increased to maximum tolerable dose.
5. The maintenance dose is injected every 2 to 4 weeks for a period of several years to achieve maximal benefit.
6. Several allergens are now standardized (dust mite, cat, grass and ragweed pollens, Hymenoptera venoms [yellow jacket, yellow and white-faced hornet, honey bee, wasp]).

Precautions and Considerations

1. Anaphylaxis rarely occurs after injection but risk remains.
   a. Usually given in health care facility with epinephrine, trained personnel, and emergency equipment available. See Standards of Care Guidelines 28-1, page 793.

STANDARDS OF CARE GUIDELINES 28-1

Immunotherapy

To perform immunotherapy or allergy testing, have Epinephrine 1:1,000 available with a 1-mL syringe and a 1-inch (2.5 cm) needle.

- Make sure that the patient remains under observation for at least 30 minutes after injection and assess for local reaction and respiratory distress before the patient leaves.
- If a significant reaction occurred after the last injection or if the patient is late for his or her dosage, follow written protocol for those cases or call the patient's health care provider for instructions.
- Be prepared to inject 0.3 to 0.5 mL (or 0.01 mL/kg for children less than 30 kg) of epinephrine IM as directed by health care provider present or facility protocol if signs of anaphylaxis develop. Call for immediate help and transfer to an acute care facility.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches. IM, intramuscular.

b. Patient should remain in office for 30 minutes after injection, after which the risk of anaphylaxis is greatly reduced.
c. If large, local reaction (erythema, induration) occurs after an injection, the next dose should not be increased without checking with prescribing health care provider because a systemic reaction may occur.

2. If several weeks are missed, dosage may need to be decreased to prevent a reaction.
3. Medication, such as antihistamines and decongestants, should be continued until significant symptom relief occurs (may take 12 to 24 months).
4. Environmental controls should be maintained to enhance effectiveness of therapy.

NURSING ALERT With immunotherapy (allergy shots), the risk of systemic reaction is always present, occurring in 0.02% of injections. Skin testing can also result in systemic reactions. Have epinephrine 1:1,000 available during these procedures (with syringe and tourniquet) and have patient remain in office or clinic for at least 30 minutes after administration.

ALLERGIC DISORDERS

Anaphylaxis

Anaphylaxis is an immediate, life-threatening systemic reaction that can occur on exposure to a particular substance. It can occur within an hour or longer. It is a result of a type I hypersensitivity reaction in which chemical mediators released from mast cells and basophils affect many types of tissue and organ systems. It can be an IgE-mediated allergen such as immunotherapy or a non– IgE-mediated allergen as in contrast media.

EVIDENCE BASE Lieberman, P., Nicklas, R. A., Randolph, C., et al. (2015). Anaphylaxis—a practice parameter update 2015. *Annals of Allergy, Asthma and Immunology, 115*, 341–384.

Pathophysiology and Etiology

1. May be caused by:
   a. Immunotherapy.
   b. Stinging insects such as honeybee, Australian native ants, wasps
   c. Skin testing.
   d. Medications, most commonly antibiotics and nonsteroidal anti-inflammatory drugs (NSAIDs).
   e. Contrast media infusion.
   f. Foods such as peanuts, seeds, cow's milk, sea food, dairy products, eggs.
   g. Exercise and exposure to cold.
   h. Latex.
2. Mast cell activation causes release of chemical mediators (histamine, leukotrienes, tumor necrosis factor, cytokines), which results in massive vasodilation, increased capillary permeability, smooth muscle contraction, and increased mucosal secretions, which results in bronchoconstriction and decreased peristalsis.

Clinical Manifestations

1. Respiratory—laryngeal edema, bronchospasm, cough, wheezing, dyspnea, feeling of lump in throat.
2. Cardiovascular—hypotension, tachycardia (as a compensatory response to the hypotension), palpitations, syncope, bradycardia with cardiovascular collapse can occur before cutaneous changes occur.
3. Cutaneous—urticaria (hives), angioedema, pruritus, erythema (flushing).
4. GI—nausea, vomiting, diarrhea, abdominal pain, bloating.

DRUG ALERT Before administering any drug, ask if the patient has ever had a reaction to it. Do not rely on the medical record alone.

Management

Prompt identification of signs and symptoms and immediate intervention are essential; a reaction that occurs quickly tends to be more severe.

Immediate Treatment

www.aaaai.org/conditions-and-treatments/allergies/anaphylaxis

1. Place patient supine and check vital signs.
2. Immediately administer epinephrine 1:1,000—adolescents and adults, 0.3 to 0.5 mL; children, 0.01 mL/kg via intramuscular (IM) route into vastus lateralis muscle. This may be repeated every 5 to 10 minutes if necessary—causes vasoconstriction, decreases capillary permeability, relaxes airway smooth muscle, and inhibits mast cell mediator release.
3. Monitor vital signs continuously.
4. Administer oxygen, if needed.
5. A tourniquet is applied above site of antigen injection (allergy injection, insect sting, etc.) or skin test site to slow the absorption of antigen into the system.

Subsequent Adjunct Treatment

1. An adequate airway is established, and bronchodialtor (albuterol or salbutamol) is administered by nebulization (using face mask or handheld mouthpiece), as needed.
2. Hypotension and shock are treated with IV fluids (normal saline) and vasopressors.
3. Additional bronchodilators are given to relax bronchial smooth muscle.
4. Histamine-1 (H_1) antihistamines, such as diphenhydramine, and, possibly, H_2 antihistamines, such as ranitidine, are given to block the effects of histamine by relieving itching and urticaria.
5. Corticosteroids such as methylprednisolone are given to decrease vascular permeability and diminish the migration of inflammatory cells; may be helpful in preventing late-phase responses.

Complications

1. Cardiovascular collapse.
2. Respiratory failure.

Nursing Assessment

1. Promptly assess airway, breathing, and circulation (ABCs) with severe presentation and intervene with cardiopulmonary resuscitation, as appropriate.
2. When ABCs are stable, assess vital signs, degree of respiratory distress, and angioedema.
3. Obtain a history of onset of symptoms and of exposure to allergen.

Nursing Diagnoses

- Ineffective Breathing Pattern related to bronchospasm and laryngeal edema.
- Decreased Cardiac Output related to vasodilation.
- Anxiety related to respiratory distress and life-threatening situation.

Nursing Interventions

Restoring Effective Breathing

1. Establish and maintain an adequate airway.
    a. If epinephrine has not stabilized bronchospasm, assist with endotracheal intubation, emergency tracheostomy, or cricothyroidotomy, as indicated.
    b. Continually monitor respiratory rate, depth, and breath sounds for decreased work of breathing and effective ventilation.
2. Administer nebulized albuterol or other bronchodilators, as ordered. Monitor heart rate (increased with bronchodilators).
3. Provide oxygen via nasal cannula at 2 to 5 L/minute or by alternative means, as ordered.
4. Administer intravenous (IV) corticosteroids, as ordered.

Increasing Cardiac Output

1. Monitor blood pressure (BP) by continuous automatic cuff, if available.
2. Administer rapid infusion of IV fluids to fill vasodilated circulatory system and raise BP.
3. Monitor central venous pressure (CVP) to ensure adequate fluid volume and to prevent fluid overload.
4. Insert indwelling catheter and monitor urine output hourly to ensure kidney perfusion.
5. Initiate and titrate vasopressor, as ordered, based on BP response.

Reducing Anxiety

1. Provide care in a prompt, calm, and confident manner.
2. Remain responsive to the patient, who may remain alert but not completely coherent because of hypotension, hypoxemia, and effects of medication.
3. Keep family or significant others informed of patient's condition and the treatment being given.
4. When patient is stable and alert, give a simple, honest explanation of anaphylaxis and the treatment that was given.

Community and Home Care Considerations

1. Make sure that patient who has experienced anaphylaxis or severe local reactions obtains a prescription for self-injectable epinephrine to have available at all times.
2. Even if treatment is given successfully at home, encourage the patient to follow-up with the health care provider immediately.
3. Make sure that the patient with history of anaphylaxis has access to emergency medical system and does not spend time alone if risk of reaction is present.

Patient Education and Health Maintenance

1. Teach the patient at risk for anaphylaxis about the potential seriousness of these reactions, avoiding allergens, and identifying early signs and symptoms of anaphylaxis.
2. Instruct the patient and family members on the injection technique upon exposure to known antigen or at the first signs of a systemic reaction.
   a. Provide patient with information on epinephrine, including dose, drug action, possible adverse effects, and the importance of prompt administration at the first sign of a systemic reaction.
   b. Encourage the patient to check expiration date regularly and obtain replacement of outdated epinephrine.
   c. Ensure day care providers, coworkers, and school personnel are aware of patient's potential for anaphylaxis and have access to and are able to administer epinephrine.
3. People allergic to venom stings should avoid wearing brightly colored or black clothes, perfumes, and hair spray. Shoes should be worn at all times.
4. For exercise-induced anaphylaxis, patient should exercise in moderation, preferably with another person, and in a controlled setting, where assistance is readily available.
5. Instruct patient to wear a medical alert tag at all times.
6. For potential drug allergies, teach the patient to:
   a. Read labels and be familiar with the generic name of the drug thought to cause a reaction.
   b. Discard all unused drugs. Make sure any drug kept in the medicine cabinet is clearly labeled.
   c. Become familiar with drugs that may cross-react with a drug to which patient is allergic.
   d. Always know the name of every drug taken.
   e. Clear all herbals and nutraceuticals with health care provider.
7. Advise patient with a known sensitivity to a food product to be extremely careful about everything he or she eats—allergen compounds may be hidden in a preparation (such as caseinate, lactalbumin).
8. Advise that if food is associated with exercise-induced anaphylaxis, wait at least 2 hours after eating to exercise.

Evaluation: Expected Outcomes

- Respirations unlabored with clear lung fields, minimal wheezing.
- BP and CVP within normal range; urine output adequate.
- Responsive and cooperative.

Allergic Rhinitis

Allergic rhinitis is an inflammation of the nasal mucosa caused by an allergen that affects 10% to 30% of the population and up to 40% of children.

Pathophysiology and Etiology

1. Type I hypersensitivity causes local vasodilation and increased capillary permeability.
2. Caused by airborne allergens.
3. IgE-mediated inflammatory process is now believed to be the same disease process for asthma and allergic rhinitis. IgE antibodies bind to IgE receptors on mast cells in respiratory mucosa. When patient is exposed to the same allergen, then mast cells activates chemical mediators resulting in allergic rhinitis.
4. Allergic rhinitis was formerly classified as seasonal or perennial; current classifications are intermittent or persistent.
    a. Intermittent—symptoms present less than 4 days per week and less than 4 weeks per year.
    b. Persistent—symptoms present more than 4 days per week and more than 4 weeks per year.
5. Severity is classified as mild (no interference with daily activities or troublesome symptoms) or moderate-severe (presence of at least one: impaired sleep, daily activity, work, or school; troublesome symptoms).

Clinical Manifestations

1. Nasal—mucous membrane congestion, edema, itching, rhinorrhea with clear secretions, sneezing, nasal obstruction, or nasal drip.
2. Eyes—edema, itching, burning, tearing, redness, dark circles under eyes (allergic shiners).
3. Ears—itching, fullness.
4. Other—postnasal drainage, palatal itching, throat itching, nonproductive cough.

Diagnostic Evaluation

1. Skin testing—confirms a hypersensitivity to certain allergens. Quick and cost-effective.
2. Nasal smear—increased number of eosinophils suggests allergic disease.
3. ImmunoCAP or other *in vitro* IgE-specific antigen testing—positive test result for offending allergens.
4. Rhinoscopy—allows better visualization of the nasopharynx; helps rule out physical obstruction (septal deviation, nasal polyps).
5. Evaluation for asthma.

Management

Avoidance

1. Patient should minimize contact with offending allergens, regardless of other treatment.
2. Patient may be instructed to reduce dust mite exposure by encasing bed pillows and mattress in allergen-proof covering; however, studies have not shown that this alone improves symptoms. Use of allergen-

proof bedding should be carried out in conjunction with broad environmental controls (see Patient Education Guidelines 28-1).

PATIENT EDUCATION GUIDELINES 28-1

Environmental Control for Allergic Rhinitis

The following environmental modifications may help reduce symptoms of allergic rhinitis (hay fever):

- Encase pillows and mattress in allergen-proof covers.
- Wash all bed linens (mattress pad, sheets, blanket, comforter, and bedspread) in hot water weekly.
- Keep clothing in a closet with door shut or in dresser drawers that are kept closed.
- Use easily cleaned shades, blinds, and curtains.
- Avoid stuffed animals and other items that collect dust.
- Vacuum and damp-dust weekly; wear a mask while doing it.
- If you have severe symptoms of dust allergy, leave the house during cleaning. Allergic reaction is possible for about 30 minutes after vacuuming because dust mite feces and other allergens become airborne. Fine-filtering face masks may provide some protection.
- Eliminate upholstered furniture, carpets, and draperies.
- Use air conditioning and keep windows closed during high pollen and mold seasons to reduce antigen load indoors.
- Change furnace and air conditioner filters frequently.
- Using a high-efficiency air filtering system may help.
- Avoid smoking and smoke-filled areas.
- Avoid rapid changes in temperature.
- If you are allergic to animal dander, you should not have household pets. If pets are present in your household, keep them out of the bedroom and run a high-efficiency particulate air filter (place on table).
- Avoid mold growth by dehumidification (less than 45% ambient humidity) and use of a fungicide in bathrooms, damp basements, food storage areas, and garbage containers.
- Avoid outdoor activities when pollen or other pollutants are in the air.

Medications: Antihistamines

H_1 antihistamines—block the effects of histamine on smooth muscle and blood vessels by blocking histamine receptor sites, thereby preventing the symptoms of allergic rhinitis.

1. Loratadine, fexofenadine, and cetirizine are long-acting antihistamines sold over-the-counter (OTC) and are considered nonsedating (cetirizine is considered less sedating).
2. Long-acting, nonsedating antihistamines available by prescription include desloratadine and levocetirizine.
3. Topical antihistamine nasal spray available by prescription (azelastine or olopatadine).
4. Older, sedating antihistamines (diphenhydramine, chlorpheniramine) are inexpensive, available OTC,

short-acting, and effective if tolerated by the patient. Older antihistamines are sedating. They also have an anticholinergic effect—inhibit mucous secretions, act as drying agents.

Medications: Controllers

1. Intranasal corticosteroids: beclomethasone, flunisolide, budesonide, mometasone
   a. Reduce inflammation of nasal mucosa.
   b. Prevent mediator release.
   c. Can be used safely every day.
   d. May be given systemically for a short course during a disabling attack.
2. Mast cell stabilizers—such as intranasal cromolyn sodium or ophthalmic cromolyn and lodoxamide hinder the release of chemical mediators. These medications are used before and during allergen season.
3. Leukotriene receptor antagonists, including montelukast and zafirlukast, are systemic agents used for asthma; montelukast also has an indication in allergic rhinitis and reduces the inflammation, edema, and mucous secretion of allergic rhinitis.

Medications: Symptom Relief

1. Oral corticosteroids may be given systematically for a short course during a disabling attack.
2. Decongestants—shrink nasal mucous membrane by vasoconstriction; oral and topical, many available OTC and in combination with antihistamines, pain relievers, and anticholinergics.
3. Topical eye preparations—sold OTC and by prescription; reduce inflammation and relieve itching and burning.

Immunotherapy

1. Regimen consists of administering subcutaneous injections of increasing amounts of an allergen to which the patient is sensitive to decrease sensitivity and reduce the severity of symptoms (see page 792).
2. Immunotherapy produces the following immunologic changes:
   a. Production of IgG-blocking antibody that combines with antigen before it reacts with IgE antibodies.
   b. Decreases IgE antibodies against specific antigens.
   c. Modulation from T helper (Th) 2 to Th1 T lymphocytes (Th2 associated with allergy).
3. Possible adverse effects of immunotherapy.
   a. Systemic reactions—anaphylaxis is rare, but potentially fatal.
   b. Local reactions—consist of erythema and induration at the site of injection.

NURSING ALERT Immunotherapy should be administered with caution to patients taking beta-adrenergic blockers and should not be given to patients whose asthma is not controlled.

Complications

1. Allergic asthma.
2. Chronic otitis media, hearing loss.
3. Chronic nasal obstruction, nasal polyps, sinusitis.
4. Orthodontic malocclusion in children.

Nursing Assessment

1. Obtain history of severity and seasonality of symptoms.
2. Inspect for characteristic tearing, conjunctival erythema, pale nasal mucous membranes with clear discharge, allergic shiners, and mouth breathing.
3. Auscultate lungs for wheezing or prolonged expiration characteristic of asthma.

Nursing Diagnosis

- Ineffective Breathing Pattern related to nasal obstruction.

Nursing Interventions

Facilitating Normal Breathing Pattern

1. Reassure patient that suffocation will not occur because of nasal obstruction; mouth breathing will occur.
2. Use intranasal saline to soothe irritated mucous membranes and increase oral fluid intake to prevent drying of mucous membranes and increased insensible loss through mouth breathing.
3. Administer and teach self-administration of antihistamines, decongestants, intranasal corticosteroids and antihistamine, and other medications, as directed.
    a. Instruct patients on proper use of nasal sprays—clear mucus from nose first, exhale, flex neck to point nose downward, direct spray away from the nasal septum (toward the eye), activate the spray, and gently sniff while releasing medication. Report any nasal irritation or nose bleeds to provider.
    b. Warn patient to avoid driving or other situations that require alertness if sedating antihistamines, such as diphenhydramine or chlorpheniramine, are being used.
    c. Do not use OTC nasal decongestants for more than 4 to 5 days because their effect is short term and a rebound effect, which causes nasal mucosal edema, commonly occurs.

DRUG ALERT Long-term use of nasal corticosteroids may cause nasal septum rupture. Teach patients to direct spray or aerosol away from septum.

Patient Education and Health Maintenance

1. Provide information on purpose, administration method, time frame of expected results, and possible

risks involved (local reactions, anaphylaxis) with immunotherapy.

2. Inform the patient that close observation for 30 minutes is essential after each injection.
3. Alert patient to the possibility of a delayed reaction during immunotherapy that should be reported to the nurse or health care provider.
4. Teach lifestyle and environmental changes to reduce exposure to allergens.
5. For additional information and support, refer to American Academy of Allergy, Asthma, and Immunology (*www.aaaai.org*), American College of Allergy, Asthma & Immunology (*www.acaai.org*), and National Institute of Allergy and Infectious Diseases Office of Communications (*www.niaid.nih.gov*).

Evaluation: Expected Outcomes

- Decreased nasal congestion, no mouth breathing, and no complaints of dry mouth.

Urticaria and Angioedema

Urticaria, or hives, may affect 25% of the population at any given time. Lesion is intensely pruritic erythematous. *Angioedema* is a similar lesion but involves deep dermis and subcutaneous tissues. Urticaria and angioedema can occur individually or in combination.

Pathophysiology and Etiology

1. Acute urticaria:
    a. Hives that last less than 6 weeks.
    b. A detectable cause is often determined.
2. Chronic urticaria:
    a. Hives that last 6 weeks or longer.
    b. Up to 50% of cases may be autoimmune chronic urticaria with autoantibodies against high-affinity IgE receptor or IgE.
    c. At least 50% are idiopathic.
3. Cause may be undetermined or may include:
    a. Ingested substances—food, food additives, latex, drugs (such as penicillins, cephalosporins).
    b. Infections—viral, bacterial, parasitic.
    c. Physical factors—heat, sunlight, cold, pressure, vibration.
    d. Emotional stress.
    e. Insect stings (bees, wasps, hornets, fire ants).

Clinical Manifestations

1. Raised, red, edematous wheals.
2. Intense pruritus.
3. May affect any body region.
4. Diffuse swelling with angioedema, especially of the lips, eyelids, cheeks, hands, and feet.
5. Symptoms may develop within seconds or over 1 to 2 hours and may last up to 24 to 36 hours.

Diagnostic Evaluation

1. Laboratory—serum tryptase is elevated in the acute phase, complement study results can be abnormal, total serum IgE elevated.
2. Challenge testing to determine physical cause.
    a. Dermographism (most common).
    b. Exercise challenge.
    c. Ice cube challenge.
    d. Heat challenge.

e. Pressure challenge.

Management

Acute Urticaria

1. Identification and elimination of causative factors.
2. Medications.
   a. H_1 antihistamines, such as diphenhydramine and cetirizine.
   b. Corticosteroids—limited to severe cases; unresponsive to antihistamines.
   c. Epinephrine 1:1,000 (0.3 to 0.5 mL IM) for severe angioedema or urticaria.

Chronic Urticaria

1. Avoid causative factors.
2. Medications.
   a. H_1 antihistamines.
   b. H_2 antihistamines, such as ranitidine, may be of some value.
   c. Tricyclic antidepressants, such as doxepin, given for antihistaminic effect.
   d. Topical agents to relieve itching (moisturizer or oatmeal baths).
3. Severe, unremitting urticarial treatment may include low-dose cyclosporine, tacrolimus, or omalizumab therapy.

Complications

1. Neurovascular impairment because of swelling.
2. Rarely, edema of the larynx or bronchi.

Nursing Assessment

1. Assess for time frame during which lesions appear and disappear.
2. Assess for triggering factors.
3. Assess for family history of angioedema; may indicate hereditary angioedema rather than allergic reaction.

Nursing Diagnosis

- Impaired comfort related to pruritus.

Nursing Interventions

Relieving Pruritus

1. Administer or teach self-administration of antihistamines, corticosteroids, and additional medications, as prescribed.

2. Encourage the proper use of topical and OTC agents, as directed.
3. Advise patient to avoid exposure to heat, exercise, sunburn, and alcohol and to promptly control fever and anxiety—factors that may aggravate reactions caused by vasodilation.
4. Warn patient to avoid identified triggers.
5. Teach relaxation techniques and methods of distraction to enhance coping.
6. Assess effectiveness of therapy.

Patient Education and Health Maintenance

1. Warn the patient to monitor for symptoms of laryngeal edema and to seek medical intervention immediately if respiratory distress occurs.
2. Instruct patients with laryngeal edema how to self-administer epinephrine.

Evaluation: Expected Outcomes

- Reports relief of pruritus with antihistamines and distraction methods.

Food Allergies

Food allergies result when the body's immune system overreacts to certain, otherwise harmless, substances. Food allergies occur in 8% of children and in 2% of adults, although the perceived prevalence is much higher because other existing adverse food reactions cause similar symptoms.

Pathophysiology and Etiology

1. Food hypersensitivity—a true food allergy is an IgE-mediated response to a food allergen (protein).
2. Food intolerance—an abnormal physical response to a food or additive; may be immunologic but not IgE-mediated.
   a. Toxicity (poisoning)—caused by toxins contained in foods, microorganisms, or parasites.
   b. Pharmacologic (chemical)—such as caffeine.
   c. Idiosyncratic—etiology unknown.
3. Common food allergens include cow's milk, eggs, shellfish, peanuts, tree nuts, soybean, and wheat.

Clinical Manifestations

1. Respiratory—rhinoconjunctivitis, sneezing, laryngeal edema, wheezing.
2. Cutaneous—urticaria, angioedema, atopic dermatitis.
3. Gastroenteritis—lip swelling, palatal itching, nausea, abdominal cramping, diarrhea, vomiting.
4. Neurologic—migraine headache in some patients.

Diagnostic Evaluation

1. Skin testing.
   a. Limited to those foods suspected of provoking symptoms based on history.
   b. Only epicutaneous testing is recommended.
   c. Intradermal testing has not been demonstrated to have a high degree of clinical correlation.
2. ImmunoCAP, RAST, or other IgE-specific antigen *in vitro* testing—positive result.
3. Oral challenge—the suspected food is given to the patient to identify the allergen by reproducing the symptoms caused by the initial reaction.
   a. Open—may be used if the suspected food skin test result is negative; suspected food is openly administered and the patient is monitored for a reaction.
   b. Single-blind—suspected food is disguised in capsules, liquids, or other foods and administered to the patient in increasing doses at intervals determined by history and may be interspersed with placebo. Some bias exists, however.
   c. Double-blind placebo-controlled—the "gold standard" and most definitive technique to confirm or refute food allergy. The suspected food is administered in capsules or via some other vehicle that masks its identity; it is interspersed with placebo so neither the health care provider nor the patient knows whether the suspected food or placebo is being ingested.

4. Elimination diet.
    a. To determine if the patient's symptoms will stop when certain foods are avoided.
    b. Restrict one or two foods at a time if certain foods are suspected.
    c. If no particular food is suspected, a highly restricted diet for 14 days is preferable.

Management

1. Avoidance of specific foods is the only way of effectively preventing food allergy reactions.
2. Medications:
    a. Antihistamines—may modify IgE-mediated symptoms but will not eliminate them.
    b. Corticosteroids—only used in the treatment of food allergy if associated with eosinophilic gastroenteritis or gastroenteropathy.
    c. Epinephrine—if history of anaphylaxis, patient should carry subcutaneous self-injection at all times.
3. Oral desensitization may be considered under careful observation.

Complications

Anaphylaxis.

Nursing Assessment

1. Assist with assessment for offending foods; encourage the patient to keep a food and symptom diary.
2. Auscultate lungs and document any wheezing.
3. Assess adherence with prescribed diet and relief of symptoms.

Nursing Diagnosis

- Imbalanced Nutrition: Less Than Body Requirements related to restrictive diet.

Nursing Interventions

Promoting Adequate Nutrition

1. Consult with dietitian to ensure a balanced diet that excludes identified allergens and incorporates patient's food preferences.
2. Administer dietary supplements, as needed.
3. Discuss alternative food preparation techniques and methods of substitution (such as using extra baking powder in place of eggs).
4. Administer and teach self-administration of medications, if necessary, to reduce abdominal cramping and diarrhea, which may deter food intake.
5. Monitor weight.

Patient Education and Health Maintenance

1. Instruct the patient with history of anaphylactic reaction about self-injection technique for the

administration of epinephrine.

2. Caution highly allergic patient about restaurant food; when eating out, avoid buffets and patient should request ingredient information; brochures listing ingredients of various dishes are now available in many restaurants, including fast food establishments.
3. Explain hidden sources of foods to decrease the risk of unexpected exposure to an offending allergen. Some foods may contain allergens not as primary ingredients but as fillers or additives. Likewise, a food that has been prepared or stored in the same container or cooled on the same surface as an allergen-containing food may become contaminated with a sufficient quantity of the allergen to cause a reaction. Encourage label reading.
4. Advise patient that most young children and about one third of older children and adults lose their food sensitivity after several years of avoidance. Compliance with elimination is the key. Sensitivity to shellfish and nuts is rarely lost, however.
5. Provide resource for patient to obtain more information: The Food Allergy & Anaphylaxis Network (*www.foodallergy.org*).

Evaluation: Expected Outcomes

- Decreased frequency and severity of food allergy reactions by log; verbalizes acceptance of diet; weight stable.

Latex Sensitivity

Latex sensitivity is becoming a major health concern for health care workers, patients, and others at risk by occupation. Allergic reaction may be immediate or delayed. Latex is present in approximately 40,000 medical and other products, including household products and toys. The prevalence of latex sensitivity is estimated to be 1% in the general population, 20% in nurses, and more than 60% in children with spina bifida.

Pathophysiology and Etiology

1. Natural rubber latex, manufactured from the sap of rubber trees, is highly irritating and allergenic in some people.
2. Increased use of latex, in the form of sterile and unsterile gloves, has made latex sensitivity a problem for many health care workers since the inception of Universal Precautions in the 1980s.
3. Three types of reactions to latex may occur:
   a. Irritant dermatitis—not an allergic reaction.
   b. Type IV (cell-mediated, delayed) hypersensitivity—a localized contact allergic reaction.
   c. Type I (IgE-mediated, immediate)—a systemic allergic reaction.
4. No predictable pattern exists for the progression of reactions; anaphylaxis may occur at any time. More severe reaction occurs with latex contact with mucous membrane than with intact skin.
5. Those at risk include children with spina bifida, health care workers, people with atopic allergies, people with a history of multiple surgeries, and workers in factories that produce latex products.

Clinical Manifestations

1. Irritant dermatitis—may be caused by powder or chemical residue on gloves; erythema and pruritus localized to area of contact; occurs immediately.
2. Type IV (delayed) hypersensitivity—contact allergic reaction; erythema, pruritus, urticaria; possible flushing, localized edema, rhinitis, coughing, and conjunctivitis. Symptoms occur 1 to 48 hours after contact with product.
3. Type I (immediate) hypersensitivity—urticaria, angioedema, conjunctivitis, dyspnea, pharyngeal edema, arrhythmias, and anaphylaxis. Symptoms are immediate and may be moderate to life-threatening in intensity.

Diagnostic Evaluation

1. History of symptoms gives presumptive diagnosis, but confirmation is difficult because standardized tests are not yet widely available.
2. A crude skin prick test uses a fragment of latex glove soaked in saline for 15 minutes as the solution. This is not standardized, but a positive test result is considered proof of latex sensitivity.
3. A challenge test can be done by having the patient wear a latex glove or fingertip of a glove for 15 minutes; look for a reaction. LatEX-free gloves can be used as a control. Severe reactions may occur with this test.

4. Standardized skin testing will become more available pending Food and Drug Administration approval of standardized latex solution, but the threat of anaphylaxis will still exist.
5. RAST or other IgE *in vitro* blood testing is safe but expensive and is limited due to both false-positive and false-negative results.

Management

1. Avoidance is the key. See Box 28-1 for safety and prevention techniques in the health care workplace.
2. For irritant reactions, changing brands of gloves or changing to a powder-free glove may be sufficient.
3. Decreasing length of exposure time or wearing cotton liners in gloves may help, but may not solve the problem.
4. Use of latEX-free gloves and products is usually necessary. Although more hospitals and medical offices are making latEX-free products available, a job change may be necessary for some people.
5. A latEX-free environment is necessary for treatment.
6. Topical corticosteroid creams may be used for local reactions.
7. Oral antihistamines may be used for mild to moderate reactions.
8. Epinephrine, oral or parenteral corticosteroids, and IM antihistamines are given for severe reactions.
9. IV fluids, oxygen, and intubation may be needed for cardiovascular and pulmonary support with severe reactions.

BOX 28-1 Latex Safety for Patients and Health Care Workers

- Use latEX-free gloves of synthetic rubber, vinyl, nitrile, neoprene, or other material.
- Be aware that removing latex gloves with power may cause latex particles to become aerosolized for up to 5 hours and be carried to other areas on clothing and equipment.
- Do not enter OR with latex gloves or without having scrubbed after removing latex gloves in another area and remove possibly latEX-laden clothing.
- Schedule latEX-sensitive patients early in the day or as first surgical case.
- Post signs indicating Latex Allergy or Latex Alert.
- Encourage latEX-sensitive individuals to wear identification bracelets.
- Evaluate all equipment for latex prior to use.
- A latEX-free cart should accompany a latEX-sensitive patient throughout the facility.
- Each facility should form a latex allergy task force with representatives from all departments.

Complications

Unpredictable anaphylaxis and death.

Nursing Assessment

1. Assess patient for history of risk factors and pattern of suspected reactions.
2. Assess skin for erythema, swelling, vesicles, and other lesions.

3. Assess mucous membranes for conjunctivitis, rhinitis, and other lesions.
4. For suspected systemic reactions, assess vital signs for hypotension, tachycardia, arrhythmia, and respiratory distress.
5. Assess respiratory status for stridor caused by laryngeal edema and breath sounds for wheezing.
6. Assess for signs of internal edema with systemic reaction, such as nausea, vomiting, and diarrhea.

Nursing Diagnosis

- Deficient Knowledge related to sources of latex and how to avoid latex.

Nursing Interventions and Patient Education

Increasing Knowledge about Latex Avoidance

1. Educate patients about the widespread use of latex; latEX-free alternatives are usually available (see Table 28-1).
2. Ensure that patients with history of type I reaction have self-injectable epinephrine and antihistamines on hand at all times to use at first sign of a reaction.
3. Encourage patients who have had immediate hypersensitivity reactions to wear a medical alert tag.
4. Encourage patients to notify all their health care providers, labs, and clinics before they make a visit, to facilitate the use of latEX-free products. These patients should be given the first appointment of the day and all supplies that contain latex should be removed from the room or covered with a cotton cloth. Only latEX-free products should be used, and staff members should be careful to avoid wearing or removing latex gloves in the hall while the patient is in the office.
5. Support the patient who has had a severe reaction in the workplace. Remind the patient that the Americans with Disabilities Act guarantees workers reasonable modifications to the workplace to accommodate a disability. However, the area of latex sensitivity as a disability is controversial.
6. For further information, contact the American Latex Allergy Association (*www.latexallergyresources.org*) and the National Institute for Occupational Safety and Health (*www.cdc.gov/NIOSH/homepage.html*).

Table 28-1 Sources of Latex in Health Care Facilities and at Home

HEALTH CARE FACILITY	HOME AND COMMUNITY
Syringes	Mattresses and foam in furniture
Medication vial stoppers	Undergarments and clothing
Intravenous catheters, tubing	Bathmats and rugs
Stopcocks	Pacifiers and diapers
Tourniquet	Toys such as balls and dolls
Tape, dressings, drains	Pet toys
Elastic wraps	Bicycle helmets
Waterproof pads	Cosmetics
Blood pressure cuff	Food storage bags
Stethoscope	Drain stoppers
Reflex hammer	Spatulas
Electrocardiograph electrodes	Earphones
Oximetry sensor	Garden hose
Manual resuscitation bag	Rubber-handled tools
Oxygen canula, mask, tubing	Weather stripping
Airways, endotracheal tube	Plants—rubber, poinsettia, ficus
Urinary catheters	Scratch-off tickets and advertisements
Suction catheters	Raincoats and waterproof boots
Casting materials	Glue, envelopes, stamps

Evaluation: Expected Outcomes

- Verbalizes signs of reaction and appropriate treatment.

Bronchial Asthma

EVIDENCE BASE National Heart, Lung and Blood Institute, National Asthma Education and Prevention Program Expert Panel Report 3. (2007). Guidelines for the diagnosis and management of asthma. *Summary Report 2007, NIH Publication No. 08–5846*. Bethesda, MD: National Institutes of Health. Available: *www.nhlbi.nih.gov/guidelines/asthma/asthsumm.pdf.*Global Initiative for Asthma. (2016). Global strategy for asthma management and prevention. Available: *www.ginasthma.org*

Asthma is a chronic inflammatory disease of the airways, characterized by airflow obstruction, which is at least partially reversible; bronchial hyperreactivity; and mucus production. The course of asthma is highly variable. In 2007, the National Asthma Education and Prevention Program Expert Panel Report 3 and in 2010, the Global Initiative for Asthma guidelines were updated. These updates are evidence-based and continue to recommend treatment that is stepwise and based on severity; however, the updates emphasize assessment of control, impairment of daily function, and risk for exacerbation at subsequent patient visits. Although severity is best established prior to the use of asthma medications, it may be determined based on the medications necessary to gain control and directs initial therapy.

Asthma therapy is characterized by periodic follow-up visits and continual reassessment. One such factor that is always assessed includes control, which can be measured at home by the patient and family and evaluated and discussed at subsequent visits. The level of control guides adjustment of medications. Nurses can use control assessment to identify patients and families who need more asthma education to gain better control of asthma.

Pharmacotherapy for asthma is now based on three age groups: ages 0 to 4 years, ages 5 to 11 (see Chapter 44), and ages 12 and older. It is comprised of six steps and has expanded to include more medications for asthma; however, inhaled corticosteroids continue as the preferred long-term control therapy for all ages.

Pathophysiology and Etiology

The basic defect appears to be an abnormality in the host, which intermittently leads to an increased constriction of smooth muscle, hypersecretion of mucus in the bronchial tree, and mucosal edema.

Neuromechanisms (Autonomic Nervous System)

1. Stimulation of the vagus nerve (which is responsible for bronchomotor tone) by viral respiratory infections, air pollutants, and other stimuli causes bronchoconstriction, increased secretion of mucus, and dilation of the pulmonary vessels.
2. Beta-adrenergic receptor cells that line the airways are also responsible for bronchomotor tone. Abnormal functioning of these cells predisposes patients to bronchoconstriction.

Antigen–Antibody Reaction

1. Susceptible individuals form abnormally large amounts of IgE when exposed to certain allergens. Most children and more than half of adults with asthma are sensitized to at least one common inhaled allergen.
2. Antigen-specific IgE fixes itself to the mast cells of the bronchial mucosa.
3. When the person is exposed to certain allergens, the resulting antigen combines with the cell-bound IgE molecules, causing the mast cell and basophil to degranulate and release chemical mediators.
4. These chemical mediators act on bronchial smooth muscle to cause bronchoconstriction, on dilated epithelium to reduce mucociliary clearance, on bronchial glands to cause mucus secretion, on blood vessels to cause vasodilation and increased permeability, and on leukocytes to cause cellular infiltration and inflammation.
5. Late-phase reactions (these occur 4 to 8 hours after the initial response) include the influx of eosinophils, neutrophils, lymphocytes, and monocytes.

Bronchial Inflammation

1. Occurs in both the immediate- and late-phase reactions caused by antigen–antibody response.
2. Factors other than allergens (such as noxious environmental stimuli) cause bronchial inflammation and hyperreactivity by mast cell activation.

Classification

Extrinsic Asthma

1. Hypersensitivity reaction to inhalant allergens (dust mites, animal allergens, cockroaches, pollen, and mold are the major ones).
2. Mediated by immunoglobulin E (IgE mediated).

Intrinsic Asthma

1. No inciting allergen.
2. Infection, typically viral.
3. Environmental stimuli (such as air pollution).

Mixed Asthma

Immediate type I reactivity appears to be combined with intrinsic factors.

Aspirin-Induced Asthma

1. Induced by ingestion of aspirin and related compounds.
2. “Samter Triad” has been described as a combination of aspirin-induced asthma, nasal polyps, and sinusitis.

Exercise-Induced Bronchoconstriction

Symptoms vary from slight chest tightness and cough to severe wheezing and cough and shortness of breath that usually occurs after 5 to 20 minutes of sustained exercise.

Occupational Asthma

Caused by inhalation of industrial fumes, dust, allergens, and gases.

Classification by Severity

1. Asthma severity for purposes of treatment is classified as intermittent, mild persistent, moderate persistent, and severe persistent based on level of impairment and risk for exacerbation.
2. Level of impairment parameters include degree of symptoms, nighttime awakenings, need to use short-acting beta$_2$-agonist for symptom control, interference with normal activity, and lung function by spirometry.
3. Risk level is based on the number of exacerbations that required oral corticosteroids within the past year and how severe they were.
4. See details of classifying asthma severity at *www.nhlbi.nih.gov/guidelines/asthma/asthgdln.pdf*.

Clinical Manifestations

1. Episodes of coughing.
2. Wheezing.
3. Dyspnea.
4. Feeling of chest tightness.

NURSING ALERT Do not be fooled by lack of wheezing on auscultation when the patient reports severe shortness of breath. Airflow may be so restricted that wheezing ceases.

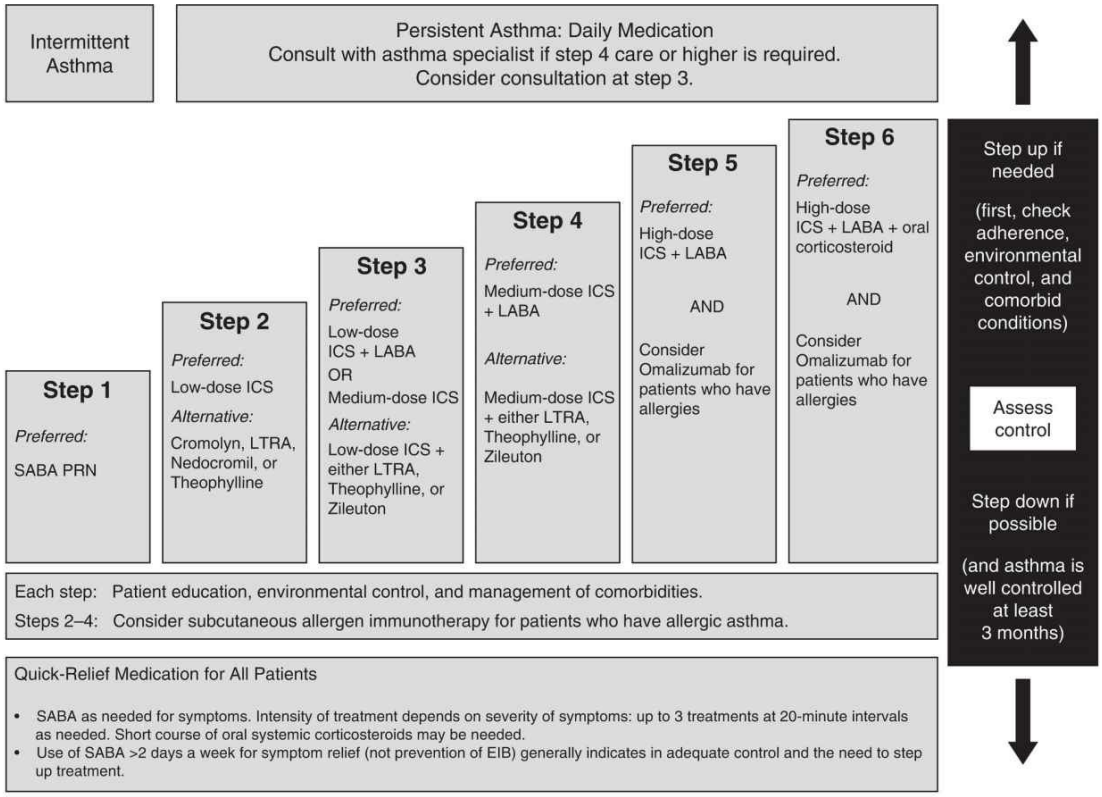
Diagnostic Evaluation

1. Pulmonary function testing (spirometry)—more than 12% increase over baseline in forced expiratory volume in first second of exhalation (FEV_1) following inhalation of bronchodilator. Peak flow more than 20% variability between A.M. and P.M. measurements.
2. Bronchial challenge with airborne agent resulting in airway hyperreactivity; a positive challenge is determined by decrease in FEV_1 from baseline.
   a. Methacholine bronchial challenge (nebulized)—20% decrease in FEV_1.
   b. Mannitol (dry powder inhalation)—15% decrease in FEV_1.
3. Skin testing to identify causative allergens.
4. Chest x-ray to exclude other lung diseases in new-onset asthma in adult.

Management

The goal is to allow the person with asthma to live a normal life. The treatment plan should be as simple as possible and individualized to the patient's lifestyle. See Figure 28-2 for stepwise therapy for those ages 12 and

older; see pages 1183 and 1184 for stepwise therapy for children younger than age 12. See Table 28-2, pages 802 and 803, and Table 28-3, page 803, for medication information. For additional information on treatment and specific dosages, see "Expert Panel Report 3: Guidelines for the Diagnosis and Management of Asthma" (National Heart, Lung and Blood Institute, 2007), pages 346–352 (*www.nhlbi.nih.gov/guidelines/asthma/asthgdln.pdf*).



Key: **Alphabetical order is used when more than one treatment option is listed within either preferred or alternative therapy.** EIB, exercise-induced bronchospasm; ICS, inhaled corticosteroid; LABA, long-acting inhaled beta-agonist; LTRA, leukotriene receptor antagonist; SABA, inhaled short-acting beta$_2$-agonist

Figure 28-2. Stepwise approach for managing asthma in youths age 12 or older and adults.

Table 28-2 Long-Term Control Medications

DRUG/INDICATION	MECHANISM	POTENTIAL ADVERSE EFFECTS
Inhaled Corticosteroids		
Beclomethasone, budesonide, flunisolide, ciclesonide, fluticasone, mometasone *Indications:* Long-term suppression of symptoms of asthma; suppression, control, and reversal of airway inflammation; reduced need for oral corticosteroids.	*Anti-inflammatory:* Block late reaction to allergen and reduce airway hyperresponsiveness; inhibit cytokine production, adhesion protein activation, and inflammatory cell migration and activation. Reverse beta$_2$-receptor down-regulation. Inhibit microvascular leakage.	Cough, dysphonia, oral candidiasis. In high doses, systemic effects may occur (adrenal suppression, osteoporosis, skin thinning, easy bruising), although studies are not conclusive, and clinical significance has not been established. In low to medium doses, suppression of growth velocity has been observed in children, but this effect may be transient and the clinical significance has not been established.
Systemic Corticosteroids		
Methylprednisolone, prednisolone, prednisone *Indications:* Short-term burst therapy to gain control of inadequately controlled asthma; long-term prevention of symptoms in severe persistent asthma.	*Anti-inflammatory:* Block late reaction to allergen and reduce airway hyperresponsiveness; inhibit cytokine production, adhesion protein activation, and inflammatory cell migration and activation. Reverse beta$_2$-receptor down-regulation. Inhibit microvascular leakage.	Short-term use: reversible abnormalities in glucose metabolism, increased appetite, fluid retention, weight gain, mood alteration, hypertension, peptic ulcer, and, rarely, aseptic necrosis. Long-term use: adrenal axis suppression, growth suppression, dermal thinning, hypertension, diabetes, Cushing syndrome, cataracts, muscle weakness, and, rarely, impaired immune function. Consideration should be given to coexisting conditions that could be worsened by systemic corticosteroids, such as herpes virus infections, varicella, tuberculosis, hypertension, peptic ulcer, diabetes mellitus, osteoporosis, and *Strongyloides*.
Mast Cell Stabilizers		
Cromolyn sodium (nebulizer solution only) *Indications:* Long-term prevention of symptoms in mild persistent asthma; may modify inflammation; preventive treatment prior to exposure to exercise or known allergen.	*Anti-inflammatory:* Block early and late reaction to allergen; interfere with chloride channel function. Stabilize mast cell membranes and inhibit activation and release of mediators from eosinophils and epithelial cells. Inhibit acute response to exercise, cold dry air, and SO_2.	Cough and irritation.
Immunomodulators		
Omalizumab *Indications:* Long-term control and prevention of symptoms in patients (≥age 12) who have moderate or severe persistent allergic asthma inadequately controlled with ICS.	Binds to circulating IgE, preventing it from binding to high-affinity receptors on basophils and mast cells. Decreases mast cell mediator release from allergen exposure and the number of high-affinity receptors in basophils and submucosal cells.	Pain and bruising at injection sites has been reported in 45% of patients. Anaphylaxis has been reported in 0.2% of treated patients. Malignant neoplasms have been reported in 0.5% of patients compared to 0.2% of patients receiving placebo; however, relationship to drug is unlikely.
Leukotriene Modifiers		
Montelukast, zafirlukast, zileuton *Indications:* Long-term control and prevention of symptoms in mild persistent asthma; may be used in combination with ICS in moderate persistent asthma. Montelukast is indicated in patients >age 1; zafirlukast, >age 7; zileuton, >age 12.	*Leukotriene receptor antagonist* (montelukast and zafirlukast): Selective competitive inhibitors of CysLT1 receptor. *5-Lipoxygenase inhibitor* (zileuton): Inhibits the production of leukotrienes—LTB_4 and cysteinyl leukotrienes—from arachidonic acid.	With zafirlukast, rare cases of Churg-Strauss have occurred, but the association is unclear; postmarketing surveillance has reported cases of reversible hepatitis and, rarely, irreversible hepatic failure resulting in liver transplantation and death. Elevation of liver enzymes has been reported with zileuton. There have been limited case reports of reversible hepatitis and hyperbilirubinemia.
Long-Acting Beta$_2$-Agonists		
Formoterol, salmeterol, oral sustained-release albuterol *Indications:* Long-term prevention of symptoms, added to ICS; prevention of exercise-induced bronchospasm. *Note:* Not to be used to treat acute exacerbations; only used in combination with inhaled corticosteroid.	*Bronchodilation:* Smooth muscle relaxation following adenylate cyclase activation and increase in cyclic AMP, producing functional antagonism of bronchoconstriction. Compared to SABA, salmeterol (but not formoterol) has slower onset of action (15 to 30 min). Both salmeterol and formoterol have longer duration (>12 hr) compared to SABA.	Tachycardia, skeletal muscle tremor, hypokalemia, prolongation of QTc interval in overdose. A diminished bronchoprotective effect may occur within 1 wk of chronic therapy (clinical significance has not been established). Potential risk of severe, life-threatening, or fatal exacerbation.
Methylxanthines		
Theophylline sustained release *Indications:* Long-term control and prevention of symptoms in mild persistent asthma or as an adjunct to ICS in moderate or persistent asthma.	*Bronchodilation:* Smooth muscle relaxation from phosphodiesterase inhibition and possibly adenosine antagonism. May affect eosinophilic infiltration into bronchial mucosa as well as decreases T-lymphocyte numbers in epithelium. Increases diaphragm contractility and mucociliary clearance.	Dose-related acute toxicities include tachycardia, nausea and vomiting, tachyarrhythmias (supraventricular tachycardia), central nervous system stimulation, headache, seizures, hematemesis, hyperglycemia, and hypokalemia. Adverse effects at usual therapeutic doses include insomnia, gastric upset, aggravation of ulcer or reflux, increase in hyperactivity in some children, difficult urination in older males who have prostatism.

ICS, inhaled corticosteroid; SABA, short-acting beta-agonist.

Modified from Heart, Lung and Blood Institute, National Asthma Education and Prevention Program. (2007). Expert Panel Report 3: Guidelines for the diagnosis and management of asthma. Full Report 2007 (pp. 245–246). Available: www.nhlbi.nih.gov/guidelines/asthma/asthgdln.pdf.

Table 28-3 Quick Relief Medications

DRUG/INDICATION	MECHANISM	POTENTIAL ADVERSE EFFECTS
Short-Acting Beta$_2$-Agonists		
Albuterol, levalbuterol, pirbuterol *Indications:* Relief of acute symptoms; preventive treatment for exercise-induced bronchospasm prior to exercise.	*Bronchodilation:* Bind to the beta$_2$-adrenergic receptor, producing smooth muscle relaxation following adenylate cyclase activation and increase in cyclic AMP, producing functional antagonism of bronchoconstriction.	Tachycardia, skeletal muscle tremor, hypokalemia, increased lactic acid, headache, hyperglycemia. Inhaled route, in general, causes few systemic adverse effects. Patients with preexisting cardiovascular disease, especially older adults, may have adverse cardiovascular reactions with inhaled therapy.
Anticholinergic		
Ipratropium *Indications:* Acute bronchospasm; reverses only cholinergically mediated bronchospasm; does not modify reaction to antigen; does not block exercise-induced bronchospasm. Multiple doses of ipratropium in the emergency department provide additive effects to SABA. May be alternative for patients who do not tolerate SABA. Treatment of choice for bronchospasm because of beta-blocker medication.	*Bronchodilation:* Competitive inhibition of muscarinic cholinergic receptors. Reduces intrinsic vagal tone of the airways. May block reflex bronchoconstriction secondary to irritants or to reflux esophagitis. May decrease mucous gland secretion.	Drying of mouth and respiratory secretions, increased wheezing in some individuals, blurred vision if sprayed in eyes. If used in the emergency department, produces less cardiac stimulation than SABAs.
Systemic Corticosteroids		
Methylprednisolone, prednisolone, prednisone *Indications:* For moderate or severe exacerbations to prevent progression of exacerbation, reverse inflammation, speed recovery, and reduce rate of relapse.	*Anti-inflammatory:* Block late reaction to allergen and reduce airway hyperresponsiveness; inhibit cytokine production, adhesion protein activation, and inflammatory cell migration and activation. Reverse beta$_2$-receptor down-regulation. Inhibit microvascular leakage.	Short-term use: reversible abnormalities in glucose metabolism, increased appetite, fluid retention, weight gain, facial flushing, mood alteration, hypertension, peptic ulcer, and, rarely, aseptic necrosis. Consideration should be given to coexisting conditions that could be worsened by systemic corticosteroids, such as herpes virus infections, varicella, tuberculosis, hypertension, peptic ulcer, diabetes mellitus, osteoporosis, and *Strongyloides*.

SABA, short-acting beta agonist.

Modified from Heart, Lung and Blood Institute, National Asthma Education and Prevention Program. (2007). Expert Panel Report 3: Guidelines for the diagnosis and management of asthma. Full Report 2007 (pp. 247–248). Available: www.nhlbi.nih.gov/guidelines/asthma/asthgdln.pdf.

Long-Term Controllers

1. Inhaled corticosteroids (ICSs), such as beclomethasone, budesonide, ciclesonide, flunisolide, fluticasone, mometasone.
2. Long-acting inhaled beta-agonists (LABA) include salmeterol, formoterol. *Note:* arformoterol is a LABA that is indicated for long-term control of chronic obstructive pulmonary disease, not asthma.
3. Combination inhalers, such as fluticasone and salmeterol, budesonide and formoterol, mometasone and formoterol.
4. Leukotriene modifiers, such as montelukast and zafirlukast.
5. Inhaled mast cell stabilizer: cromolyn sodium.
6. Long-acting oral beta-agonists, such as albuterol extended-release tablets.
7. Oral corticosteroids (maintenance dose).
8. Methylxanthines such as theophylline.
9. Muscarinic agents, namely tiotropium, as adjunct therapy.

10. An IgE blocker (omalizumab) can be added to standard maintenance therapy to reduce exacerbations in moderate to severe allergic asthma.
    a. It is given by subcutaneous injection every 2 to 4 weeks.
    b. The most common adverse reactions are injection site reactions and viral infection.

NURSING ALERT The most convenient and inexpensive method of aerosol delivery to patients is the metered-dose or dry powder inhaler; however, nebulization offers alternative delivery for those with unreliable inhaler technique.

DRUG ALERT Beta-adrenergic blockers, such as propranolol, have the potential to cause bronchoconstriction and should not be given to patients with asthma. Cardiac selective beta-blockers can be used such as carvedilol.

Quick-Relief Medications

1. Short-acting bronchodilators by inhalation.
    a. Short-acting beta-agonists (SABAs), such as albuterol, pirbuterol, and levalbuterol.
    b. Anticholinergic agent, such as ipratropium bromide.
2. Systemic corticosteroids (short course)—prednisone, prednisolone, and methylprednisolone.

DRUG ALERT Patients should be encouraged to use SABAs appropriately when needed and not to wait for severe symptoms.

Other Measures

1. Environmental control (see page 795).
2. Immunotherapy (see page 792).
3. Avoidance of foods that contain tartrazine (yellow dye number 5) in aspirin-sensitive patients.
4. Regular aerobic exercise should be encouraged.
5. Use of an inhaled beta-adrenergic agonist or cromolyn taken 5 to 10 minutes before exercise will decrease exercise-induced bronchoconstriction.
6. Antibiotics are prescribed only during acute exacerbations if signs and symptoms of bacterial infection are present.
7. Alternative and complementary therapies that include acupuncture, herbal preparations, yoga, and

chiropractic treatment have been suggested for acute and chronic asthma control; however, none is a substitute for usual medical treatment. In fact, glucosamine and chondroitin have been suspected of causing asthma exacerbation in some patients.

Nursing Assessment

1. Review patient's record: ask about coughing, dyspnea, chest tightness, wheezing, exertional changes, nighttime awakenings with asthma, use of SABA, and recent unscheduled or ER visits. Use an assessment tool such as the Asthma Control Test, Asthma Control Questionnaire, and Asthma Therapy Assessment Questionnaire. These tools quantify symptoms, quick-relief medication usage, effect of asthma on quality of life, and patient/family perception of control. They can be found at *www.nhlbi.nih.gov/guidelines/asthma/asthgdln.pdf.*
2. Observe the patient and assess the rate, depth, and character of respirations, especially on expiration; observe for hyperinflation. Assess peak flow.
3. Auscultate the chest for breath sounds or wheezing.
4. Assess for triggers of asthma that include the following:
   a. Allergens.
   b. Respiratory infections.
   c. Inhalation of irritating substances (dust, fumes, and gases).
   d. Environmental factors (weather, air pollution, and humidity).
   e. Exercise, particularly in cold weather.
   f. Aspirin and its derivatives.
   g. Sulfite-containing agents used as food preservatives.
   h. Emotional factors.
5. After acute episode subsides, attempt to determine patient's degree of adherence with medications and management regimen.
6. Observe and correct inhalation technique and discuss care of inhaler (eg, cleaning, priming).

Nursing Diagnoses

- Ineffective Breathing Pattern related to bronchospasm.
- Anxiety related to fear of suffocating, difficulty in breathing, death.
- Readiness for Enhanced Knowledge related to drug treatment and potential adverse effects.

Nursing Interventions

Attaining Relief of Dyspneic Breathing

1. Monitor vital signs, skin color, retraction, oxygen saturation, and degree of restlessness, which may indicate hypoxia.
2. Provide medication and oxygen therapy, as prescribed.

3. Monitor airway functioning through peak flow meter or spirometry (FEV_1, FEV_1/FVC) to assess effectiveness of treatment.
4. Encourage intake of fluids to liquefy secretions.
5. Instruct patient on positioning to facilitate breathing—sitting upright (leaning forward on a table).
6. Encourage patient to use adaptive breathing techniques (eg, pursued-lip breathing) to decrease the work of breathing.

Relieving Anxiety

1. Explain rationale for interventions to gain patient's cooperation. Provide care in prompt, confident manner.
2. Help patient clarify sources of anxiety; suggest measures to reduce anxiety and to control breathing.
3. Encourage active participation and support efforts to adhere to management plan.

Preventing Adverse Effects of Drugs

1. Teach patient to rinse mouth and spit out after using ICS to prevent growth of fungi and be alert for sore throat or mouth caused by oropharyngeal candidiasis.
2. Suggest a spacer if patient is prone to candidiasis and ensure proper dosing and inhalation technique. Blood glucose testing may also be indicated to rule out hyperglycemia.
3. Monitor liver function enzymes, as directed, for patients taking zileuton and zafirlukast, and advise patient to report signs of liver dysfunction: abdominal pain, nausea, itching, and jaundice.
4. Make sure patient is aware that LABAs are not used for acute symptoms or as anti-inflammatory therapy or monotherapy for asthma. Duration of protection against exercised-induced bronchospasm may decrease with regular use.
5. Monitor serum theophylline concentration periodically and maintain steady-state serum concentrations between 5 and 15 mcg/mL. Routine serum concentration monitoring is essential because of significant toxicities, narrow therapeutic range, and individual differences in metabolism. Absorption variation can produce significant changes in steady-state serum theophylline concentrations.
6. Warn patients that regular use (greater than 2 days/week) of SABA for symptom control (not prevention of exercise-induced bronchospasm), increasing use, or lack of expected effect indicates inadequate asthma control. For patients frequently using SABA, anti-inflammatory medication should be initiated or intensified.

Community and Home Care Considerations

1. Initiate peak flow monitoring, if indicated. This may be done twice daily by the patient with persistent asthma. Provide written and verbal instruction and have the patient demonstrate the procedure.
2. The patient can buy a peak flow meter from a pharmacy or from a medical supply company.
3. Once optimal asthma control is obtained, daily peak flow measurements in the early morning and early afternoon should be used during a 2- to 3-week period to determine the patient's personal best. The personal best peak flow measurement will be used to monitor control and to guide self-therapy in an

individualized action plan.

4. Teach the patient how to obtain peak flow measurement.
   a. Place the indicator at the base of the numbered scale.
   b. Stand (preferably) or sit upright.
   c. Take a deep breath.
   d. Place the meter in mouth and close lips around mouthpiece, with tongue under the mouthpiece.
   e. Blow out as hard and as fast as possible. Coughing or spitting will result in a falsely elevated level.
   f. Note the measurement that the indicator is pointing to on the number scale.
   g. Repeat previous steps twice more and record the highest number.
5. Provide written and verbal instruction on an action plan for self-management of asthma exacerbation as outlined by the health care provider. National Asthma Education and Prevention Program Guidelines suggest the following:
   a. For symptomatic worsening of asthma or asymptomatic decrease in peak flow measurement, use initial inhalation of a short-acting beta-adrenergic agonist by metered-dose inhaler (MDI), two to four puffs for up to three treatments at 20-minute intervals, or a single nebulization treatment.
   b. After initial treatment, recheck peak flow; if it is more than 80% of personal best and no wheezing or shortness of breath, continue beta-adrenergic agonist every 3 to 4 hours for 24 to 48 hours. The patient should contact the health care provider for further instructions.
   c. If peak flow is 40% to 80% of personal best, or if the patient has persistent wheezing and shortness of breath, an oral corticosteroid should be initiated and beta-adrenergic agonist should be continued. The patient should contact the health care provider the same day for further instructions.
   d. If peak flow is less than 40% of personal best or if the patient has significant wheezing and shortness of breath, an oral corticosteroid should be started, beta-adrenergic agonist should be repeated immediately, and the patient should proceed to the emergency department.

Patient Education and Health Maintenance

1. Provide information on the nature of asthma and methods of treatment.
2. Provide information regarding medications, including the difference between long-term controllers and quick-relief medications and the proper use of inhalers and spacer devices; stress avoiding overuse of inhalers and nebulizers. Ensure that patient understands that long-acting bronchodilating inhalers, such as salmeterol, are not effective for asthma exacerbations.
3. Demonstrate the use of MDIs (see Patient Education Guidelines 28-2) and nebulization equipment.
   a. Inhalers vary widely with hydrofluoroalkane (HFA) propellant and breath-actuated devices currently on the market; familiarize yourself with the manufacturer's instructions to help the patient.
   b. Teach patients how to clean inhalers according to manufacturer's instructions.
   c. Advise patients to count number of inhalations if the inhaler does not have an automatic counter.
4. Help the patient to identify what triggers asthma, warning signs of an impending attack, and strategies for preventing and treating an attack.

5. Teach adaptive breathing techniques and breathing exercises such as pursed lip breathing.
6. Discuss environmental control.
    a. Avoid people with respiratory infections. Get an annual flu shot.
    b. Avoid substances and situations known to precipitate bronchospasm, such as allergens, irritants, strong odors, gases, fumes, and smoke.
    c. Wear a mask if cold weather precipitates bronchospasm.
    d. Stay inside when air pollution is high.
    e. Also see Patient Education Guidelines 28-1, page 795.
7. Promote optimal health practices, including nutrition, rest, and exercise.
    a. Encourage regular exercise to improve cardiorespiratory and musculoskeletal conditioning.
    b. Drink liberal amounts of fluids to keep secretions thin.
    c. Try to avoid upsetting situations.
    d. Use relaxation techniques, biofeedback management.
    e. Use community resources for smoking-cessation classes, stress management, exercises for relaxation, asthma support groups, etc.
8. Make sure that patient knows with whom to follow-up and the frequency of follow-up. Discuss with patient how to overcome any barriers to follow-up, such as transportation, limited office or clinic hours, childcare, and work requirements.
9. For additional information and support, refer to American Academy of Allergy, Asthma and Immunology (*www.aaaai.org*).

PATIENT EDUCATION GUIDELINES 28-2

How to Use an Inhaler and Spacer

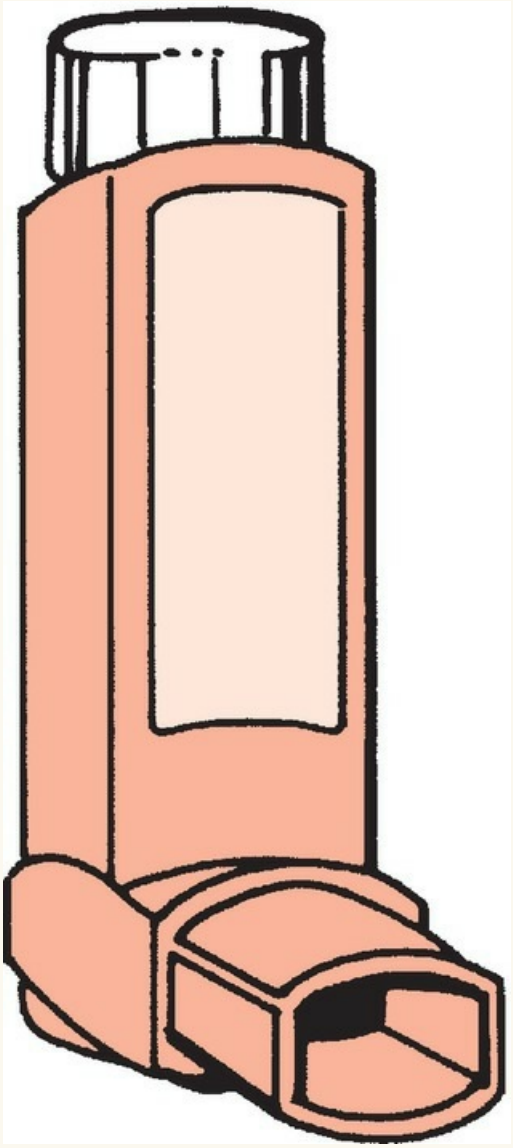
Using an Inhaler

1. Make sure that the medication canister is attached to the plastic inhaler and shake well or, if using a dry powder inhaler system (DPI), load the medication according to the manufacturer's instructions.
2. If recommended, attach a spacer to your metered-dose inhaler (MDI) (see Using a spacer, below).
3. If using the closed-mouth method (recommended for DPI and HFA systems):
    a. Exhale fully and place the mouthpiece of the inhaler in your mouth and close lips tightly around it.
    b. While starting to inhale, use your index finger to press down firmly on the top of the canister.
    c. Continue to inhale for 3 to 5 seconds to obtain a full breath, then hold your breath for 5 to 10 seconds.
    d. Remove the inhaler from your mouth before you exhale and breathe normally.
4. If more than one inhalation of a beta$_2$-agonist is prescribed, wait 30 seconds before taking another inhalation, then repeat steps 1 to 5.
5. Replace the mouthpiece cap after each use.

6. Clean the inhaler according to the manufacturer's instructions.
7. Discard the canister after you have used the labeled number of inhalations. You should not use it beyond this indicated number because the correct dose amount can no longer be guaranteed.
8. For dry powdered inhalers, use a forceful, rapid inhalation with closed-mouth technique. See the instructions provided by the manufacturer of the device you use.

Using a Spacer

Unless you use your inhaler correctly, much of the medicine can end up on your tongue, on the back of your throat, or in the air. If you experience this problem, your health care provider may recommend using a spacer. Also called a valved holding chamber, a spacer is a device that attaches to a MDI. It holds the medicine in its chamber long enough for you to inhale it in one or two slow, deep breaths, thereby enabling you to get your full dose of medicine. It also prevents you from coughing and may prevent a yeast infection in your mouth if you use a steroid inhaler. Several types of spacers are available; these devices may be purchased through your pharmacist.



1. Attach the inhaler to the spacer or holding chamber as shown in the product instructions.

2. Shake well.
3. Press the canister on the inhaler, which will put one puff of medicine into the holding chamber.
4. Place the mouthpiece of the spacer into your mouth and inhale slowly.
5. Hold your breath a few seconds, then exhale.

EVIDENCE BASE Center for Disease Control and Prevention. (2018). Know how to use your asthma inhaler. [multimedia] Available: https://www.cdc.gov/asthma/inhaler_video/default.htm

---

DRUG ALERT Never submerge an inhalation canister in water to determine if any medication remains. Moisture in the tip will ruin the canister.

Evaluation: Expected Outcomes

- Symptoms (wheezing, coughing, dyspnea, chest tightness) reduced; peak flow improved.
- Verbalizes relief of anxiety.
- No adverse reactions to drug therapy reported.

Status Asthmaticus

Status asthmaticus is a severe form of asthma in which the airway obstruction is unresponsive to usual drug therapy.

Contributing Factors

1. Infection.
2. Inhalation of air pollutants and allergens to which sensitized.
3. Noncompliance in taking medications, including overuse of bronchodilators.
4. Ingestion of aspirin or related drugs in aspirin-sensitive patient.
5. Aspiration of gastric acid.

Clinical Manifestations

1. Tachypnea, labored respirations, with increased effort on exhalation.
2. Suprasternal retractions, use of accessory muscles of respiration.
3. Diminished breath sounds, decreased ability to speak in phrases or sentences.
4. Anxiety, irritability, fatigue, headache, impaired mental functioning.
5. Muscle twitching, somnolence, diaphoresis—from continued carbon dioxide retention.
6. Tachycardia, elevated BP.
7. Heart failure and death from suffocation.

Management and Nursing Interventions

1. Monitor respiratory rate and oxygen saturation continuously; frequently monitor arterial blood gas levels, BP, electrocardiogram.
2. Administer repeated aerosol treatments with $beta_2$-agonist bronchodilators, such as albuterol or levalbuterol; add anticholinergic ipratropium, as prescribed—administer with caution until the metabolic and respiratory acidosis and hypoxemia have been corrected.
3. Monitor IV therapy.
    a. Corticosteroids are given to treat inflammation of airways; because these act slowly, their beneficial effects may not be apparent for several hours.
    b. Fluids are given to treat dehydration and loosen secretions.
4. Provide continuous humidified oxygen via nasal cannula, as prescribed. (Patients with associated chronic obstructive pulmonary disease or emphysema are at risk for depressed hypoxemic ventilatory drive, thus compounding respiratory insufficiency, so use oxygen cautiously.)
5. Initiate mechanical ventilation, if necessary.
6. Assist with mobilization of obstructing bronchial mucus.
    a. Perform chest physiotherapy (chest wall percussion and vibration).
    b. Administer expectorant and mucolytic drugs, as prescribed.

c. Remove secretions by suctioning or prepare for bronchoscopy, if needed.

7. Provide adequate hydration.
8. Obtain portable chest x-ray and administer antibiotic, as prescribed, to treat any underlying respiratory infection.
9. Alleviate the patient's anxiety and fear by acting calmly and by reassuring the patient during an attack. Stay with the patient until the attack subsides.

NURSING ALERT In status asthmaticus, the return to normal or increasing partial pressure of carbon dioxide does not necessarily mean that the patient with asthma is improving—it may indicate a fatigue state that develops just before the patient slips into respiratory failure.

Health Maintenance

Nursing Management of HIV Infection and AIDS

OVERVIEW

Human immunodeficiency virus (HIV) is an RNA retroviral infection that is transmitted from person to person most often through sexual and blood-to-blood contact. Over time, HIV interferes with the immune system's ability to coordinate an effective response against infection. This loss of immune function takes years to occur, eventually leading to the stage of disease called *acquired immune deficiency syndrome (AIDS*), which is marked by vulnerability to opportunistic infections. Without antiretroviral treatment, HIV infection is almost universally fatal.

Since the immune deficiency syndrome associated with HIV was first described in 1981, great strides have been made in care and treatment of persons living with HIV. Medication regimens have been simplified into fixed dose combination tablets with once daily dosing. The cost of medication has decreased globally, clearing the way for more widespread access to treatment. There is international will to test and treat more people and prevent new infection among those who are at risk for acquiring HIV. Life expectancy on antiretroviral therapy (ART) has increased significantly across all income settings of the world. The Joint United Nations Programme on HIV/AIDS (UNAIDS) is rolling out effective treatment across the globe with the aim of an AIDS-free generation by 2030. This program sets ambitious 90-90-90 goals: 90% of people with HIV diagnosed, 90% of them on ART, and 90% being virally suppressed by 2020. In support of this momentum toward an AIDS-free generation, the US President's Emergency Plan for AIDS Relief (PEPFAR) has committed to interventions that target persons at high risk in areas of the world with the highest HIV incidence. Scientists are actively modeling a cure strategy.

Nevertheless, HIV has claimed more than 35 million lives in the past 35 years, and approximately 37 million persons were living with HIV in 2016 globally. As of 2015, the Centers for Disease Control (CDC) estimates that more than 1.1 million persons are living with HIV in the United States. The Patient Protection and Affordable Care Act (ACA) has provided expanded opportunity to millions who had been uninsured or underinsured; however, only 40% of HIV-infected persons in the United States are in care, 35% are receiving treatment, and 30% have a very low or undetectable viral load (see Figure 29-1). A goal of the National HIV/AIDS Strategy is to achieve 80% viral suppression by 2020. There is work to do. Nurses are present at each point in the HIV care continuum: testing, treatment, retention to care, and preventing new infections. Endless possibility exists for nursing's contribution toward achieving national and international goals.

Transmission and Natural History

Epidemiology and Pathophysiology

1. Today, most new HIV infections are found among men who have sex with men (MSM) (67% of new infections in 2015). Among MSM, adult racial minorities and adolescent/young adult Black and Hispanic men aged 13 to 24 are disproportionately affected. Heterosexual transmission accounted for 24% of new HIV infections in 2015. The trend in new infections from injection drug use has declined to approximately 6%. Geographic distribution of new infections is uneven across the United States. The South represented the highest burden of incident infections (16.8), the Northeast (11.6), the West (9.8), and the Midwest (7.6). The availability of HIV prevention and treatment programs across all regions will be important to decreasing the rate of new infections.
2. HIV enters the body through condomless sexual contact or blood-to-blood transmission and then targets T helper immune cells that carry $CD4^+$ receptors. Once inside the host cell, HIV uses the cell's components as a factory to reproduce. Replicating HIV within the host cell ruptures the cell membrane, releasing more HIV virions into the plasma that bind to and disable other $CD4^+$ cells.
3. Antiretroviral drugs interfere with viral replication at specific points in the viral life cycle.
4. HIV infection can be viewed as a chronic condition in patients who strictly adhere to antiretroviral treatment and care. Some patients have difficulty managing highly structured medication and appointment regimens. They need encouragement or special interventions to support their treatment plan. Nursing is important for working with patients to tailor a plan that optimizes their opportunity for successful and enduring treatment.

NURSING ALERT Globally, approximately 1.8 million persons became infected in 2016. Despite prevention efforts, there have been a persistent 40,000 new infections in the United States each year, pointing to the inadequacy of efforts to reach everyone who is at risk.

Natural History of HIV Infection

1. Approximately 50% to 90% of patients who become infected experience some symptom of primary HIV infection at around 2 to 4 weeks after exposure to HIV. Typical symptoms of acute HIV seroconversion include fever, lymphadenopathy, sore throat, rash, myalgia/arthralgia, diarrhea, weight loss, and headache. Many new HIV infections evade diagnosis because symptoms of acute HIV infection mimic other common infections. Seroconversion is marked by a sudden decrease in T4 helper cells and a sharp increase in HIV viral load for a brief period before establishing a steady viral set point.
2. The time to detection of s depends upon the test being used. A fourth-generation antigen/antibody combination HIV-1/2 immunoassay can capture early infection, because the assay detects HIV p24 antigen prior to antibody formation. If positive, a confirmatory antigen/antibody combination HIV-1/2

immunoassay is performed. If a patient is suspect of being in the window period before antibody formation, a plasma HIV RNA level can be drawn.

3. The CDC provides a case definition for staging HIV infection and defining progression to AIDS (see Table 29-1). A normal $CD4^+$ count is approximately 1,000/mm^3. HIV replication destroys $CD4^+$ T cells, causing the number of CD4 cells to diminish slowly over time.
4. Waning immunity in persons who have untreated infection or are on a failing antiretroviral regimen leads to frequent infections, severe opportunistic infections, and malignancies. See Figure 29-2.

Table 29-1 AIDS Surveillance Case Definition for Adolescents and Adults

	CLINICAL CATEGORIES*		
	A	B	C
$CD4^+$ CELL CATEGORIES	ASYMPTOMATIC OR PGL OR ACUTE HIV INFECTION	SYMPTOMATIC† (NOT A OR C)	AIDS INDICATOR CONDITION (1987)
1 ≥500/mm^3 (≥29%)	A1	B1	C1
2 200–499 mm^3 (14%–8%)	A2	B2	C2
3 200/mm^3 (<14%)	A3	B3	C3

** All patients in categories A3, B3, and C1–3 are reported as acquired immunodeficiency syndrome (AIDS), based on the AIDS indicator conditions and a CD4 cell count less than 200/mm^3. AIDS indicator conditions include three new entries: recurrent bacterial pneumonia, invasive cervical cancer, and pulmonary tuberculosis.*

† Symptomatic conditions not included in category C that are (a) attributed to human immunodeficiency virus (HIV) infection or indicative of a defect in cell-mediated immunity or (b) considered to have a clinical course or management that is complicated by HIV infection. Examples of B conditions include, but are not limited to, bacillary angiomatosis; thrush; vulvovaginal candidiasis that is persistent, frequent, or poorly responsive to therapy; cervical dysplasia (moderate or severe); cervical carcinoma in situ; constitutional symptoms, such as fever (101.3°F [38.5°C]) or diarrhea for 1 month; oral hairy leukoplakia; herpes zoster involving two episodes or more than one dermatome; idiopathic thrombocytopenic purpura; listeriosis; pelvic inflammatory infection (especially if complicated by a tubo-ovarian abscess); and peripheral neuropathy.

PGL, persistent generalized lymphadenopathy.

Centers for Infection Control and Prevention. (1993). AIDS surveillance case definition for adolescents and adults. Morbidity and Mortality Weekly Report, 41(RR-17), 2.

NURSING ALERT The period around acute seroconversion is a time when the patient is highly infectious to others. High HIV viral load is linked to a high rate of transmission. Counsel patients to use effective measures to prevent transmission through sexual contact and/or needle sharing. Encourage and refer newly diagnosed persons into care and treatment. Ask patients to talk with their partner(s) about preexposure prophylaxis (PrEP) or refer them to a PrEP center for advice.

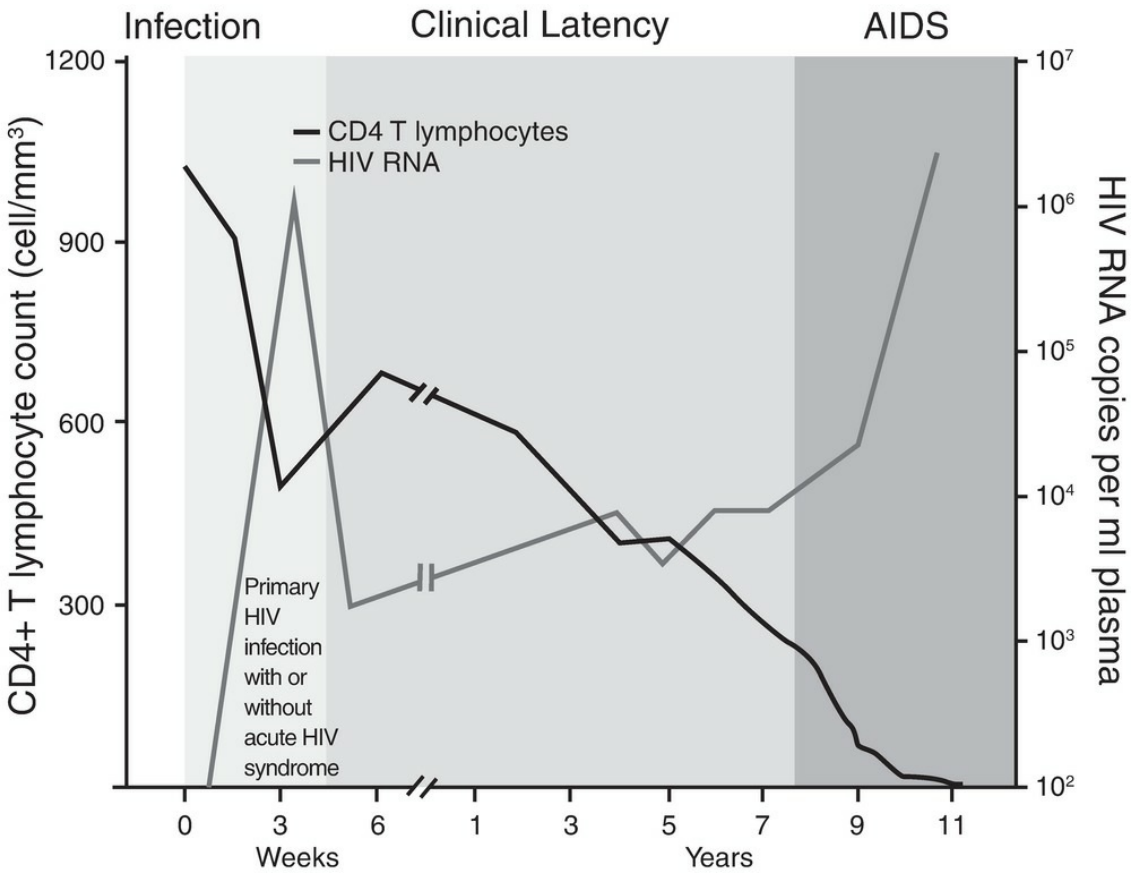

Figure 29-2. Natural history of untreated HIV Infection.

Diagnostic Evaluation

EVIDENCE BASE Dumitru, G., Irwin, K., & Tailor, A. (2017). Updated federal recommendations for HIV prevention with adults and adolescents with HIV in the United States: The pivotal role of nurses. *Journal of the Association of Nurses in AIDS Care*, *28*(1), 8–18.Simeone, C. A., Seal, S. M., & Savage, C. (2017). Implementing HIV testing in substance use treatment programs: A systematic review. *Journal of the Association of Nurses in AIDS Care*, *28*(2), 199–215.

HIV Testing

Description

1. Enzyme-linked immunoassay (ELISA) is a method of serologic testing.
   a. First- and second-generation tests detect HIV IgG antibody. Their approximate time to positivity is 25 to 45 days after exposure.
   b. Third-generation tests detect HIV IgM and IgG antibody within approximately 20 to 30 days from exposure.
   c. Fourth-generation tests detect HIV IgM and IgG antibody and p24 antigen within approximately 15 to 20 days from exposure.
2. Western blot is considered a confirmatory test and detects HIV IgM and IgG antibody within approximately 45 to 60 days from exposure. Indeterminate results may occur prior to this interval.
3. HIV viral load assays detect HIV RNA.
   a. Assays that are sensitive to less than 50 copies/mL can measure viral load within 10 to 15 days of exposure.
   b. Ultrasensitive assays that are sensitive to less than 5 copies/mL can measure viral load within 5 days of exposure.

Nursing and Patient Care Considerations

1. Occasionally, a positive ELISA screen may yield an indeterminate result by Western blot.
   a. The cause of an indeterminate result may be early HIV seroconversion, HIV vaccine, infection with O strain or HIV-2, or a false-positive in a low-risk individual.
   b. The test should be repeated at 1, 2, and 6 months until Western blot becomes positive or there is no longer suspicion of HIV infection. If a conclusive test is needed quickly, HIV RNA viral load testing can be done.
2. The CDC recommends opt-out HIV testing for patients age 13 to 64 informing them that screening is routine, but allowing that they may decline. Written consent and pretest and posttest counseling are no longer recommended, but consult state law to be in local compliance.

Other Laboratory Tests

1. Lymphocyte panel may show decreased $CD4^+$ count. In early infection or in long-term nonprogressors and elite controllers, $CD4^+$ count may be nearly normal.
2. A complete blood count (CBC) may show anemia, leukopenia, and/or thrombocytopenia.
3. HIV viral load testing is a measure of the amount of HIV in the blood. The lower the better, with an undetectable level being the goal. High viral loads (greater than 750,000) tend to be found in acute seroconversion and late untreated infection.
4. Resistance testing is done to determine if the patient is infected with or has acquired a drug-resistant virus. The test uses genotypic assays that amplify HIV virus for mutations in the viral genotype, which block or impair the efficacy of specific antiretrivirals (ARVs).

NURSING ALERT An undetectable HIV viral load result does not indicate that the patient is free of HIV. Latent reservoirs exist in lymphoid tissue and resting memory $CD4^+$ T cells indefinitely. These reservoirs are not reached by antiretroviral agents. Therefore, counsel patients that they must still maintain strict adherence to ART.

MANAGEMENT

Pharmacologic Treatment

EVIDENCE BASE U.S. Department of Health and Human Services, Panel on Antiretroviral Guidelines for Adults and Adolescents. (2018). Guidelines for the use of antiretroviral agents in adults an adolescents living with HIV. Rockville, MD: Author. Available: *https://aidsinfo.nih.gov/contentfiles/lvguidelines/AdultandAdolescentGL.pdf.*

Turner, L., Roepke, A., Wardell, E., & Teitelman, A. (2017). Do you PrEP? A review of primary care provider knowledge of PrEP and attitudes on prescribing PrEP. *Journal of the Association of Nurses in AIDS Care*, 29(1), 83–92.

Treatment Overview

1. ART serves a four-part purpose: (1) to decrease HIV viral burden and increase immune function, (2) to reduce morbidity and mortality, (3) to increase quality of life and life expectancy, and (4) to prevent HIV transmission. Successful treatment requires strict adherence to medication, which means taking about 95% of doses.
   a. Before initiating antiretrovirals, patients should be assessed for readiness to start, as treatment is lifelong. However, some trepidation is expected and is not a complete barrier to initiating treatment.
   b. An emerging treatment strategy encourages real-time testing and treatment if positive, or, testing and prevention using PrEP, if negative and at high risk for acquiring HIV infection. See Table 29-2.
2. New guidelines recommend universal treatment for all HIV-positive patients regardless of CD4 count. The purpose of earlier treatment is to prevent patients from experiencing a decline in CD4 count that places them at risk for consequences of ongoing inflammatory response and for acquiring opportunistic infections.
3. When a patient's CD4 counts falls below 200 cells/mm^3, some opportunistic infections can be prevented by prophylactic medication. This is known as primary prophylaxis. See Table 29-3.
   a. All persons with CD4 less than 200 cells/mm^3 must receive prophylaxis against PCP.
   b. Those who have CD4 less than 100 cells/mm^3 and are *Toxoplasma gondii* serum IgG+ must receive prophylaxis against toxoplasmosis.
   c. Those who have CD4 less than 50 cells/mm^3 must receive prophylaxis against *Mycobacterium avium* complex, after initial culture for *M. avium intracellulare* is negative.
4. Care and treatment of HIV infection and AIDS can require consultation with the expertise of many specialties including infectious diseases, nephrology, pulmonology, gastroenterology, neurology, obstetrics and gynecology, dentistry, dermatology, cardiology, oncology, surgery, psychiatry, rheumatology, nursing, nutrition, and social work.
5. Many patients are coinfected with hepatitis C, which is now curable with 8 to 12 weeks of treatment.

Referral to specialty hepatitis C care can significantly reduce morbidity and mortality that is associated with chronic liver disease.

Table 29-2 Summary of Guidance for Preexposure Prophylaxis for the Prevention of HIV

	MEN WHO HAVE SEX WITH MEN	HETEROSEXUAL WOMEN AND MEN	INJECTION DRUG USERS
Detecting substantial risk of acquiring HIV infection	HIV-positive sexual partner Recent bacterial STI High number of sex partners History of inconsistent or no condom use Commercial sex work	HIV-positive sexual partner Recent bacterial STI High number of sex partners History of inconsistent or no condom use Commercial sex work In high-prevalence area or network	HIV-positive injecting partner Sharing injection equipment Recent drug treatment (but currently injecting)
Clinically eligible	Documented negative HIV test result before prescribing PrEP No signs/symptoms of acute HIV infection Normal renal function; no contraindicated medications Documented hepatitis B virus infection and vaccination status		
PRESCRIPTION	**DAILY, CONTINUING, ORAL DOSES OF TDF/FTC (TRUVADA), ≤90-DAY SUPPLY**		
Other services	Follow-up visits at least every 3 months to provide the following: HIV test, medication adherence counseling, behavioral risk reduction support, side effect assessment, STI symptom assessment At 3 months and every 6 months thereafter, assess renal function Every 6 months, test for bacterial STIs		
	Do oral rectal STI testing	Assess pregnancy intent Pregnancy test every 3 mo	Access to clean needles/syringes and drug treatment services

STI, sexually transmitted infection.

From Centers for Disease Control and Prevention. (2017). US Public Health Service preexposure prophylaxis for the prevention of HIV infection in the United States—2017 Update: A clinical practice guideline. Atlanta, GA: Author. Available: https://www.cdc.gov/hiv/pdf/risk/prep/cdc-hiv-prep-guidelines-2017.pdf.

Table 29-3 Opportunistic Infections and Drug Therapies

NAME	CLINICAL MANIFESTATIONS	DIAGNOSTIC TESTS	MEDICATIONS
Pneumocystis jirovecii pneumonia (PCP)	• Low-grade fever • Shortness of breath • Cough: dry or scant white sputum production	• Chest x-ray • Induced sputum specimen • Bronchoscopy • Microscopy • PCR	• Co-trimoxazole (+/− steroids) • Clindamycin with primaquine +/− steroids • Atovaquone
Oral *Candida* and *Candida* esophagitis	• White coating in mouth • White coating down throat • Sensation of food getting caught in throat while swallowing	• Gross observation • Microscopy for hyphae • Endoscopy	• Nystatin • Clotrimazole • Itraconazole • Fluconazole • Liposomal amphotericin B
Mycobacterium avium complex (MAC)	• Fever • Weakness • Weight loss • Diarrhea • Bone marrow suppression	• Blood culture for acid-fast bacilli • Bone marrow biopsy	• Rifabutin • Ethambutol • Azithromycin • Clarithromycin
Kaposi sarcoma	• Pink, purple, or brown spots or nodules • +/− Pain, edema of affected area	• Gross observation • Biopsy	• ART (improved immune function) • Chemotherapy
Toxoplasmosis	• Fever • Headache • Change in mental status • Confusion • Lethargy • Psychosis	• CT • MRI • Serum *Toxoplasma* IgG antibodies	• Pyrimethamine • Sulfadiazine • Folinic acid
Tuberculosis	• Fever • Cough: none, dry or scant frothy white or pink sputum, hemoptysis • Shortness of breath • Weight loss • Lymphadenopathy	• Chest x-ray • Sputum for acid-fast bacilli (AFB) smear, microscopy, Gene Xpert, and culture • Positive purified protein derivative (PPD) (≥5 mm induration) • Interferon-gamma release assays (IGRAs) • * Note that PPD and IGRAs detect evidence of past exposure and are not conclusive for TB disease)	• Rifampin • Isoniazid • Pyrazinamide • Ethambutol • Pyridoxine
Cryptosporidium	• Severe watery diarrhea • Severe abdominal cramping	• Stool microscopy for Cryptosporidium	• ART (improved immune function) • Nitazoxanide +aggressive ART
Cryptococcal meningitis	• Headache • Confusion, memory loss • Nausea • Seizures • Change in mental status • Fever • Photophobia	• Serum and CSF cryptococcal antigen • CSF fungal culture	• Liposomal amphotericin B • Flucytosine • Fluconazole
Cytomegalovirus (CMV)	• Visual changes; floaters, flashes or blind spots, and blindness • Difficulty swallowing • Nausea, vomiting • Abdominal cramping • Altered mental status • Adrenal insufficiency	• Ophthalmologic examination • Blood, urine, tissue culture for CMV • PCR • Immunohistochemistry • Histopathology (visualization of characteristic owl's eyes inclusion bodies)	• Valganciclovir • Ganciclovir • Foscarnet • Cidofovir • Intraocular ganciclovir release device
Herpes simplex virus 1 and 2	• Blisters or ulcerations: mouth, lips, genitalia, perianal area	• PCR • Viral culture • Clinical observation	• Acyclovir • Famciclovir • Valacyclovir
Herpes zoster	• Painful vesicular rash on one or more dermatome(s)	• PCR • Viral culture • Clinical observation	• Famciclovir • Valacyclovir • Acyclovir

ART, antiretroviral therapy; CMV, cytomegalovirus; CSF, cerebrospinal fluid; CT, computed tomography; IV, intravenous; MRI, magnetic resonance imaging.

Initiating Antiretroviral Therapy in Treatment-Naive Patients

1. Universal treatment is recommended for all HIV-infected persons, regardless of CD4 count. ART medications belong to six drug classifications that interfere with HIV replication at six different points in

the viral life cycle. To simplify medication taking and reduce pill burden, there is a growing arsenal of multiclass combination products.

2. The standard of care for ART is to use a minimum of three different drugs from at least two different drug classifications. Treatment guidelines make specific drug choice recommendations and are updated frequently.
3. Classes of antiretroviral drugs:
   a. Nucleoside/nucleotide reverse transcriptase inhibitors (NRTI).
   b. Nonnucleoside reverse transcriptase inhibitors (NNRTIs).
   c. Protease inhibitors (PIs).
   d. Entry/fusion inhibitor.
   e. Entry inhibitor/CCR5 antagonist.
   f. Integrase inhibitor (INSTI).
   g. Multiclass combination products.

Adverse Effects of Antiretroviral Medications

EVIDENCE BASE Panel on Antiretroviral Guidelines for Adults and Adolescents. Guidelines for the Use of Antiretroviral Agents in Adults and Adolescents Living with HIV. (2018) Department of Health and Human Services. Available at *http://aidsinfo.nih.gov/contentfiles/lvguidelines/ AdultandAdolescentGL.pdf.*

1. New medications have simplified medication dosing and reduced side effects significantly.
2. Bone density reduction is especially associated with tenofovir disoproxil fumarate (TDF). Effect can be reduced by switching to the newer formulation tenofovir alafenamide (TAF).
3. Cardiac disease and/or cardiac effects are associated with NRTIs, some NNRTIs, and PIs.
4. Diabetes mellitus and insulin resistance are associated with NRTIs and some PIs.
5. Dyslipidemia is associated with NRTIs, NNRTIs, PIs, and INSTI.
6. Gastrointestinal effects such as nausea, vomiting, and diarrhea are associated with NRTIs and some PI-containing regimens.
7. Hepatotoxicities can occur with most NRTIs, some NNRTIs, and all PIs. Check hepatitis B status before discontinuing the NRTIs TAF, TDF, lamivudine, or emtricitabine, as discontinuation can cause severe HBV flares. The PI combination TPV/r is contraindicated in patients with hepatic disease that is characterized as Child-Pugh B or C.
8. Hypersensitivity reaction (HSR) is associated with the NRTI abacavir (ABC), the NNRTI nevirapine (NVP), and the INSTI raltegravir (RAL) and can present with any combination of the following symptoms: fever, rash, malaise, nausea, headache, myalgia, chills, diarrhea, vomiting, abdominal pain, dyspnea, fatigue, blisters, oral lesions, facial swelling, eosinophilia, granulocytopenia, arthralgia,

lymphadenopathy, and respiratory symptoms.

9. Lactic acidosis/steatohepatitis occurs with some NRTI medications; presents with nausea, vomiting, fatigue, and abdominal pain. May progress rapidly to a life-threatening condition.
10. Myopathy and elevated creatinine phosphokinase (CPK) are associated with the NRTI ZDV and the INSTI RAL.
11. Central nervous system and psychiatric effects are associated with the NRTI d4T, the NNRTI efavirenz (EFV), and all INSTI.
12. Rash is associated with nearly all ARVs.
13. Renal effects such as elevated serum creatinine and kidney stones are associated with the NRTI TDF (elevated creatinine) and some PIs (elevated creatinine and stone/crystal formation).
14. Stevens-Johnson syndrome and toxic epidermal necrosis have been reported among NRTIs, NNRTIs, PIs, and INSTI.
15. Treatment fatigue is an emotional reaction to medication dosing and adverse effects. It can be managed effectively by switching to a simplified regimen, if possible, and by offering supportive care. Drug "holidays" are not recommended, since HIV replication recurs almost immediately.

DRUG ALERT If a patient decides to stop taking antiretroviral therapy, then all ARV medications should be stopped at the same time. Taking only some of the ARVs creates resistance to HIV, which could lead to loss of effective treatment options for this patient in the future. Resistance can develop within a few days to a few weeks of inadequate dosing. Special rules exist for stopping a regimen that contains drugs with a different half-life. Consult the literature before a planned treatment interruption or discontinuation and counsel patients to contact their provider for advice before stopping a regimen on their own.

Health Maintenance

EVIDENCE BASE U.S. Department of Health and Human Services, Panel on Opportunistic Infections in HIV-Infected Adults and Adolescents. (2018). Guidelines for the prevention and treatment of opportunistic infections in HIV-infected adults and adolescents: recommendations from the Centers for Disease Control and Prevention, the National Institutes of Health, and the HIV Medicine Association of the Infectious Diseases Society of America. Rockville, MD: Author. Available: *http://aidsinfo.nih.gov/contentfiles/lvguidelines/adult_oi.pdf*.

Patient Education and Health Maintenance

1. Emphasize importance of ART to improve health, to promote longevity, and to prevent transmission to others.
2. Encourage patient to disclose HIV status to sex partner(s) and/or needle-sharing partner(s).
3. Discuss risk of acquiring and/or transmitting other sexually transmitted infections and assist patient in developing a prevention strategy.
4. Discuss advances in hepatitis C treatment that now make cure possible in 8 to 12 weeks.
5. Discuss family planning with all patients, if relevant. Some ARVs should not be taken by women who could become pregnant.
6. Encourage routine health maintenance such as dental care, immunizations, eye exams, annual cervical Pap smear for women and consider anal Pap smear for MSM, lipid screening, glucose and A1C monitoring, and routine screening for the ageing patient.
7. Teach patient to recognize and report a new symptom or complaint.
8. Discuss smoking cessation.
9. Ask patient if he or she uses complementary or alternative therapies, such as vitamins, herbs, and teas.
10. Refer patient to resources such as:
    a. Patient-oriented site with many resources including a list of hotlines for persons at risk for acquiring HIV and HIV-infected consumers, *www.thebody.com*.
    b. Consumer-oriented magazine, which is available online and by mail, *www.poz.com*.
    c. *100 Question and Answers about HIV and AIDS*, by Joel Gallant, Third Edition (2016) (paperback available online and at bookstores). Excellent resource for patients in easy to understand language.
    d. 100 Questions and Answers about HIV/AIDS, (updated 2014) by the New York State Health Department, *www.health.ny.gov/publications/0213.pdf*.
    e. Information about hepatitis C testing, treatment and support at The American Liver Foundation *http://hepc.liverfoundation.org/*.
    f. Information about clinical trials that are open to enrollment at ClinicalTrials.gov,

https://clinicaltrials.gov/.

g. Preexposure prophylaxis. *www.cdc.gov/hiv/risk/prep/index.html*.

11. Resources for health care professionals:

a. U.S. Department of Health and Human Services, *https://aidsinfo.nih.gov*. Comprehensive website with links to a variety of information sources, including a list of resources for consumers.

b. Centers for Disease Control and Prevention, *https://cdc.gov/hiv*. General HIV/AIDS information, publications, resources, and statistics.

c. Johns Hopkins University AIDS Service, *www.hopkinsguides.com/hopkins/ub*. Look up testing, treating infections, complications, pathogens, management, and resistance.

d. International resources, *www.unaids.org/en/*. Provides statistics and guidance about the international HIV/AIDS epidemic with links to other international resources.

DRUG ALERT Oral contraceptives interact with many protease inhibitors and NNRTI medications. Encourage patient to discuss this with her women's health provider because she may need alternative contraception.

DRUG ALERT PI levels can be affected by St. John's wort and grapefruit products. Discourage patients who are on PIs from using this over-the-counter herbal remedy and taking grapefruit products.

Preventing Opportunistic Infections

1. *Pneumocystis jirovecii* pneumonia (PCP) prophylaxis is started when the $CD4^+$ count is ≤200/mm^3. The most effective medication is trimethoprim/sulfamethoxazole (TMP/SMZ); others are dapsone, atovaquone, and aerosolized pentamidine. To reduce pill burden and prevent unnecessary antibiotic exposure, primary PCP prophylaxis should be discontinued when the CD4 count has increased to ≥200 cells/mm^3 for greater than 3 months.

2. Toxoplasmosis prophylaxis is appropriate in patients who are *Toxoplasma* IgG ab+ when the $CD4^+$ count is ≤100/mm^3. TMP/SMZ is the preferred agent, which is an added benefit when the patient is on concomitant PCP prophylaxis using TMP/SMZ. Alternative drug combinations are available for patients who cannot tolerate sulfa drugs, and these combinations are also effective prophylaxis against PCP. The recommendation for discontinuation of primary prophylaxis follows the model for primary PCP prophylaxis above.

3. *Mycobacterium avium* complex (MAC) prophylaxis is started when the $CD4^+$ count is ≤50/mm^3 and blood cultures for *M. avium* are negative; medications include azithromycin or clarithromycin. Alternative therapy is available for patients who cannot tolerate a macrolide antibiotic.

4. CMV end-organ prophylaxis, including for CMV retinitis, is no longer recommended, owing to high cost and toxicities. The best prevention is effective ART that maintains the CD4 count above 100/mm^3. Clinician monitoring for symptoms of disseminated disease and patient education about the hallmark symptoms of CMV retinitis (decreased visual acuity/floaters/flashes) are the current recommendations for preventing severe CMV progression.

Immunizations

1. Pneumococcal pneumonia—all patients should receive both types of pneumococcal vaccine (PPV13 and PPV23) and immunization should be repeated when a patient attains a $CD4^+$ count of ≥200/mm^3.
2. Influenza—all patients should receive the inactivated flu vaccine each Fall.
3. Tetanus booster—all patients should receive routine booster every 10 years, or in the case of a wound, after 5 years.
4. Hepatitis A—recommended if at risk and baseline total antibody test is negative.
   a. Risk factors include MSM, IDU, travel to endemic areas, and hemophiliacs.
   b. Persons who are coinfected with viral hepatitis or chronic liver disease should be vaccinated to prevent morbidity and mortality associated with acute hepatitis A infection.
5. Hepatitis B—recommended if baseline antibody test is negative.
6. Human papilloma virus—Gardasil is recommended for women and men aged 9 to 26.
7. Meningococcal—recommended if a risk exists (college freshman living in dormitory, military recruits, asplenia, complement component deficiency, travel to or residence in area with outbreaks, occupational exposure).
8. Measles, Mumps, Rubella (MMR)— recommended for all nonimmune patients with CD4 ≥ 200/mm^3 (live virus is contraindicated in patients with CD4 ≤ 200/mm^3).

Nursing Management of HIV Infection and AIDS

See Standards of Care Guidelines 29-1.

STANDARDS OF CARE GUIDELINES 29-1

HIV/AIDS

When caring for patients with HIV infection

- Practice standard precautions.
- Protect confidentiality.
- Educate the patient about methods that prevent HIV transmission to others.
- Perform a psychosocial assessment and identify mental health needs.
- Develop adherence strategies for patients taking antiretroviral therapy.
- Provide education and interventions for HIV symptom management.
- Assist with tobacco, alcohol, and substance abuse cessation.

Nursing Assessment

1. Obtain history of date of HIV diagnosis, $CD4^+$ count at time of diagnosis, risk factors for infection, constitutional signs and symptoms, recent infections, positive test result for HIV, most recent $CD4^+$ count, and HIV RNA viral load.
2. Review patient's present complaints, if any.
3. Assess patient's knowledge about HIV/AIDS, including causes, signs and symptoms, modes of transmission, methods for preventing transmission to others, disease progression, and importance of $CD4^+$ count and HIV RNA viral load monitoring.
4. Assess the patient's adherence to medications by reviewing all prescribed drugs, dosing, and frequency. Ask the patient how many times over the last day or week he or she missed a dose. Encourage honest reporting by acknowledging that missed doses occur.

TRANSITIONAL CARE ALERT Medication reconciliation should occur periodically, especially after hospitalizations or specialty consultations, to check for possible interactions and ensure that the patient is taking all medications appropriately. Some antiretrovirals may have drug–drug interactions with new medications. Encourage patient to use the same pharmacy for all prescription drugs, so the pharmacist can detect possible interactions.

---

5. Evaluate nutritional and general health status by assessing weight, body mass index, anemia, lipid profile, fasting glucose, hemoglobin A1C, and other pertinent labs and anthropometric measures.

6. Assess respiratory rate and depth and auscultate lungs for breath sounds; assess skin color and temperature, palpate lymph nodes, and ask about fever and night sweats.
7. Inspect mouth for lesions and dentition.
8. Examine skin for temperature, condition, and presence of rash, sores, and other changes.
9. Ask about bowel movement patterns, changes in habits, constipation, abdominal cramping, number and volume of stools, and presence of perianal pain and ulceration.
10. Assess patient's orientation to time, place, and person. Note patient's affect. Ask about any problem with memory and concentration, headaches, seizures, visual changes.
11. Find out as much as possible about patient's lifestyle (assessing for ongoing risk behavior), experience and skills, social support system.

Clinical Manifestations of HIV/AIDS with Advancing Infection

1. Pulmonary manifestations.
   a. Persistent or acute cough, with or without sputum production, shortness of breath, chest pain, fever, hemoptysis.
   b. Possible causes: *Pneumocystis jirovec*i pneumonia (PCP), bacterial pneumonia (community-acquired pneumonia), *Mycobacterium* tuberculosis, disseminated *Mycobacterium avium* complex, *Aspergillus*, *Pseudomonas*, cytomegalovirus (CMV), *Histoplasma*, Kaposi sarcoma, lung cancer, lymphoma, *Cryptococcus*, *Legionella*, or other pathogens and malignancies.
2. GI manifestations.
   a. Diarrhea, weight loss, anorexia, abdominal cramping, feeling of fullness, rectal urgency (tenesmus).
   b. Possible causes: enteric pathogens or malignancies including *Salmonella*, *Shigella*, *Campylobacter*, *Entamoeba histolytica*, *C. difficile*, CMV, *M. avium* complex, herpes simplex, *Strongyloides*, *Giardia*, *Cryptosporidium*, *Isospora belli*, *Chlamydia*, lymphoma, Kaposi's sarcoma, and others.
   c. Difficulty swallowing or substernal pain upon swallowing (feeling of food being stuck), usually caused by *Candida* esophagitis. Also, consider an esophageal ulcer caused by herpes simplex, CMV, or aphthous stomatitis, malignancy.
3. Oral manifestations.
   a. Appearance of oral lesions, white plaques on oral mucosa, particularly in the posterior pharynx, and angular cheilitis from *Candida albicans* of mouth.
   b. Vesicles with ulceration from herpes simplex virus.
   c. White, thickened lesions on lateral margins of tongue from oral hairy leukoplakia.
   d. Oral warts because of human papillomavirus.
   e. Periodontitis progressing to gingival necrosis.
   f. Painful, solitary lesions with raised margins may be aphthous ulcers of unclear etiology.
   g. Appearance of flat or nodular purple lesions on the hard or soft palate, buccal mucosa, posterior pharynx from Kaposi sarcoma.

4. CNS manifestations.
    a. Cognitive, motor, and behavioral symptoms may be caused by HIV encephalopathy, AIDS dementia, acute infection, toxicity from alcohol or drugs, adverse reaction to medication, psychiatric condition, and other infectious and malignant causes.
    b. Acute symptoms of infection with fever, malaise, headache, and/or mental status change, seizure, hemiparesis, abnormal gait or speech may be caused by toxoplasmosis, cryptococcal meningitis, herpes virus infections, CMV encephalitis, progressive multifocal leukoencephalopathy, CNS lymphoma, neurosyphilis, or other pathogens and malignancies.
    c. May also have sensory symptoms that present as numbness, tingling, and neuropathic pain of the feet or hands.
5. Ocular manifestations.
    a. Seeing floaters in the visual field, flashes of light, or sudden loss of a visual field in persons with less than 100 CD4/mm^3 because of CMV retinitis with or without retinal detachment, a sight-threatening infection that requires urgent evaluation by an ophthalmologist.
    b. Blurry vision, dry eyes, double vision, or swelling of the eyelid or conjunctiva, caused by bacterial or viral conjunctival infection, adverse reaction to medication, syphilis, Kaposi's sarcoma, or other pathogens and malignancies.
6. Malignancies—may be AIDS-defining cancer (ADC) or non-ADC.
    a. Kaposi's sarcoma (ADC).
    b. Non-Hodgkin's lymphoma (ADC) and other lymphomas (non-ADC).
    c. Cervical cancer (ADC).
    d. Liver cancer (non-ADC).
    e. Lung cancer (non-ADC).
    f. Anal cancer (non-ADC).
7. Skin manifestations.
    a. Pruritic rash with raised, erythematous papules, located on surfaces that contain hair follicles known as HIV folliculitis. Check for eosinophilia.
    b. Abscess caused by methicillin-sensitive and methicillin-resistant *S. aureus* infections, Streptococcus, or other common skin pathogens.
    c. Pruritic nodular rash located on any skin surface, known as prurigo nodularis.
    d. Purple, flat, or nodular lesions located on any skin surface including soles of feet, palms of hands, oral mucosa including hard palate is likely to be Kaposi's sarcoma and should be biopsied.

Nursing Diagnoses

- Ineffective Therapeutic Regimen Management related to complicated regimen of medications, treatment plans, clinical appointments, lack of social support, impaired cognitive functioning, substance use, or psychiatric illness.

- Fear of infection progression, treatment effects, isolation, and death related to having HIV/AIDS.
- Risk for infection related to immunodeficiency.
- Imbalanced Nutrition: Less Than Body Requirements related to infection or medication side effects, More than Body Requirements related to diet choices and exercise deficit.
- Impaired Oral Mucous Membranes related to infection or adverse effects of medication.
- Diarrhea related to infection or adverse effects of medication.
- Confusion related to infection or adverse effects of medicine.
- Hyperthermia related to opportunistic infection or malignancy.
- Ineffective Breathing Pattern related to infection or malignancy.
- Other nursing diagnoses may include:
    - Fatigue related to underlying HIV infection or depression.
    - Disturbed Body Image related to body changes from disease process or adverse effects of medication.
    - Hopelessness related to chronic illness, sense of loss of control, depression, or vulnerability associated with HIV/AIDS.
    - Acute and Chronic Pain related to infection, peripheral neuropathy, avascular necrosis, or other condition.
    - Anticipatory Grieving related to awareness of implications of HIV/AIDS, changes in lifestyle, possible death.
    - Disabled Family Coping related to crisis created by HIV/AIDS, guilt, fear, overwhelming caretaking responsibilities.

Nursing Interventions

Managing ART

1. *Assess patient*'s adherence to medications and clinical appointments; work together to problem solve a plan to improve adherence.
2. Provide education about prescribed medications before ART is started and periodically thereafter; provide educational materials that the patient can take home.
3. Develop a medication schedule for the patient that incorporates his or her usual day-to-day activities; place pills in a medication box per the schedule.
4. Encourage the involvement of a household member in the education and administration of the patient's medications.
5. Continue to monitor for medication adherence after patient has achieved an undetectable viral load.
6. Routinely ask about adverse effects. Encourage patient to call if these become a problem and teach management of common symptoms.
7. Encourage patient to keep his or her insurance and prescription drug coverage active and up to date, to prevent lapses in refills and periods without insurance.

DRUG ALERT Successful ART requires about 95% adherence to medication dose and frequency. Stress this before starting ART and at every visit. Problem-solve barriers to adherence. Develop strategies that anticipate going off course, such as late or missed doses, change in daily routine, vacation, spending the night away from home, and other life events.

Promoting Dignity and Reducing Fear

1. Maintain nonjudgmental approach.
2. Anticipate that the patient may pass through a series of stages: initial crisis, transitional stage, acceptance state, and possibly preparation for death if treatment options have been exhausted.
3. Allow patient to use some degree of denial as a protective mechanism, which gives some control over when and how patient will confront the diagnosis and his or her prognosis.
   a. Expect some displaced anger; avoid being personally affronted by patient's anger.
   b. Allow patient to acknowledge reality of the situation without giving false assurance.
4. Acknowledge that symptoms of anxiety and depression are common initially but generally improve with time and support. Refer patient to counseling or psychiatric care, if needed.
5. Anticipate that patients who have active substance use may exhibit antisocial behaviors and feelings of alienation and isolation. Refer for counseling and treatment.
6. Provide careful discussion and clarification of treatment options.
7. Help patient set realistic goals and expectations.
8. Obtain social work consult for available insurance-related, prescription drug and other social resources, and community-based case management.
9. Help patient identify and strengthen personal resources, such as positive coping skills, relaxation techniques, support network, and optimistic outlook.
10. Encourage patient to join a support group.
11. Observe for emerging psychiatric problems, especially in patients who are socially isolated, those who have guilt or shame about sexuality and lifestyle, and those with a history of psychiatric illness.
12. Discuss the importance of advance directives and legal guardianship for minor children. Cognitive deterioration may make it impossible for patient to act on his or her own behalf in the future.
13. The population of HIV-infected patients is ageing, with approximately half of patients being over age 50. Consider the needs of an ageing population with regard to health maintenance, socialization, adaptive equipment, and home safety considerations. Consultation with a geriatrician may be helpful.

NURSING ALERT Never assume that the patient's family or friends know the patient's HIV status. Always ask the patient who knows of his or her status. Encourage the patient to share his or her

diagnosis to decrease isolation. Offer to be with the patient when the diagnosis is shared with family or friend(s); role-playing before disclosing status can be helpful.

Preventing Infection

1. Assess for overt and subtle signs of infection at every visit.
2. Follow standard precautions with all patients.
3. Discuss food safety regarding storage and preparation.
4. Promote proper skin care to prevent breaks in the skin.
5. Teach wound care and management; monitor wound for signs of worsening or infection, if applicable.
6. Discuss preventing STIs at every visit, if relevant.
7. Teach patient to take all antibiotics as directed.
8. Teach patient to maintain a clean living environment.
9. Use aseptic techniques when performing invasive procedures.
10. Counsel the patient to have someone else clean a cat box or bird cage. If no one else is available, then use rubber gloves, wear a mask, change clothes, and wash hands afterward.
11. Ensure that the patient is up to date with immunizations.

Improving Nutritional Status

1. Monitor nutritional status by weighing patient, calculating BMI, and reviewing dietary choices
2. Include patient in decision making regarding nutritional care. Consult with dietitian to develop strategies for optimizing patient's nutritional status.
3. Review ART dosing in relation to meal times to optimize ART absorption; some medications should be taken with food and others should be taken on an empty stomach.
4. Administer or teach patient to take prescribed antiemetic 30 minutes before meals or medication, if nausea is a problem. Use antidiarrheal medication if advised after consultation with provider.
5. For patient with oral or esophageal pain from *Candida* esophagitis or another cause:
   a. Administer prescribed antifungal and/or antiviral therapy.
   b. Avoid highly seasoned or acidic foods.
   c. Offer fluids and pureed or soft foods to minimize chewing and ease swallowing. Offer liquid nutritional supplements.
6. Discourage alcohol use because it has immunosuppressive effect and is contraindicated in patients with chronic hepatitis.
7. Make appropriate community referral if patient is unable to grocery shop or prepare meals. Inform patient of local online grocery shopping options and services that deliver prepared meals.

Relieving Oral Discomfort

1. Ask about tooth pain, sore throat, dysphagia, and heartburn.

2. Examine mouth for oral candida and other lesions and teach patient to do the same.
3. Administer antifungal treatment as indicated.
4. Refer to dental care in the community for poor dentition and/or gum disease.

Minimizing the Effects of Diarrhea

1. Diarrhea is common and can have many causes.
2. Review medication list for causative agents.
3. Send new diarrheal stool for ova and parasite studies, microscopy, and culture.
4. Counsel patient to monitor stools, and report frequency, consistency, and presence of blood.
5. Monitor intake and output; assess skin and mucous membranes for poor turgor and dryness, indicating dehydration.
6. Monitor electrolytes. Administer fluids and electrolytes as prescribed.
7. Follow contact precautions and practice strict handwashing.
8. Plan skin care regimen that includes bathing and drying by blotting. Apply ointment or skin barrier cream to the area.
9. Advise patient to eliminate caffeine, alcohol, dairy products, high fat foods, and acidic juices.
10. Drink liquids at room temperature.
11. Advise patient to avoid foods that increase motility and distention such as gas-forming fruits and vegetables.

Managing Altered Mental Status

1. HIV has an affinity for the brain and is a target organ for opportunistic infections in advanced HIV infection.
2. Take measures to keep the patient safe. Refer altered outpatients to an acute care appointment or to the emergency department.
3. In inpatients, promote patient safety: bed alarm on, call signal available, articles within patient's reach. Anticipate a plan for toileting the patient. Make frequent checks.
4. Assess for depressive or suicidal symptoms.
5. Provide daily assessment of mental status; monitor for changes in behavior, memory, concentration ability, and motor dysfunction.
6. Check labs for abnormalities, diagnostic test results, and medication side effect profiles for possible cause.
7. Maintain a low stimulus environment such as dim lighting, low noise, promote sleep/wake cycle, quiet activities such as coloring or doing puzzles, light socialization, light exercise, and listening to quiet music.
8. Reorient patient frequently: use calendar, clock, family and friends' pictures, lists, and structured care plan.
9. Provide reassurance.
10. Anticipate need for advance directives or guardianship, durable power of attorney for health care and financial matters, and managing the process of informed consent if patient has impaired cognition.

Reducing Fever

1. Assess for chills, fever, tachycardia, and tachypnea.
2. Aggressively treat the underlying cause.
3. Encourage high fluid intake to replace insensible water losses incurred by fever or diaphoresis.
4. Administer or teach patient to administer antipyretics as prescribed.

Improving Breathing Pattern

1. Provide supplemental oxygen as ordered. Monitor for increased oxygen demand.
2. Position patient to optimize effective breathing, elevate head of bed, support head and neck to maintain patent airway.
3. Monitor for change in respiratory status.
4. Administer or teach patient to take cough medication.
5. Encourage smoking cessation.
6. Answer questions and provide support if patient has made decision for or against resuscitation and mechanical ventilation.

Community and Home Care Considerations for the Patient with End-Stage AIDS

1. Assist patient, family, or significant other to locate care and support services in the community.
2. If patient is homebound, contact an agency that offers help specifically for HIV-infected patients and provides home visits for services such as light housekeeping and food delivery.
3. Assess the home for safety and function; provide durable medical goods that can enhance safety and comfort, and improve function.
4. Provide latex gloves to the family for handling body fluids of the HIV-positive household member.
5. Reinforce that routine household cleaning of the bathroom, dishes, and laundry is sufficient to prevent household transmission of HIV.

TRANSITIONAL CARE ALERT If the patient is inpatient and transitioning to home for care by the family or friends, invite the caretakers to learn basic care from the hospital nurses. Invite caretakers to spend the night to learn the treatments and care that occur around the clock. This can help caretakers to identify gaps in services in the home and decide their readiness to take responsibility prior to the patient's discharge.For family members/friends who are taking care of a patient at home over a long period, provide information about day care services that the patient can attend or about respite care so that caregivers can receive a break from the caretaking role.

Evaluation: Expected Outcomes

- Takes prescribed ART at least 95% of the time; maintains an undetectable viral load.

- Speaks openly about HIV infection with health care providers and significant others; manages life stressors effectively.
- No signs of opportunistic infections; practices safe sex.
- Eating balanced meals.
- Oral mucosa moist and without lesions.
- Having formed stools and no perianal skin breakdown.
- Oriented to time, person, and place.
- Afebrile.
- Respirations unlabored, no cough or sputum production.

General Procedures and Treatment Modalities

Pharmacologic Agents

Physical and Occupational Therapy

Disorders

Rheumatoid Arthritis

Systemic Lupus Erythematosus

Systemic Sclerosis

Gout

Sjögren Syndrome

Fibromyalgia

Other Rheumatologic Disorders

OVERVIEW AND ASSESSMENT

Connective tissue is a fibrous tissue that supports and connects internal organs, forms bones and the walls of blood vessels, attaches muscles and bones to bones (tendons and ligaments), and replaces tissue following injury (scar tissue). The long fibers of connective tissue contain a protein called *collagen*.

Connective tissue disorders are also known as *rheumatologic disorders*. They affect the integrity of the musculoskeletal system and may also affect blood vessels, the skin, and a variety of organs. They are chronic and may lead to disability; however, they can usually be controlled with medication.

Musculoskeletal and Related Assessment

Assessment for connective tissue disorders not only focuses on the musculoskeletal system but also involves remote body systems. Clues to connective tissue disorders may be found in the skin, eyes, lungs, and neurologic system. Functional assessment is also important; many questionnaires and scales have been developed to assess patient function or disability related to connective tissue disorders, such as the Health Assessment Questionnaire first published in 1980, available: *www.chcr.brown.edu/pcoc/ehaqdescrscoringhaq372.pdf*.

Subjective Data

Obtain history of presenting symptoms, including duration and intensity, course of the illness, and impact of symptoms on the patient's life.

1. Musculoskeletal pain—characteristics.
    a. Joint swelling.
    b. Morning stiffness.
2. Constitutional symptoms.
    a. Fever.
    b. Weight loss and anorexia.
    c. Fatigue.
3. Involvement of other body symptoms.
    a. Skin.
    b. Ocular.
    c. Pulmonary.
    d. Neurologic.
    e. Mucous membranes.
    f. Gastrointestinal (GI).
4. Depression or psychosis.
5. Self-care activities and functional ability.
6. Social activities and roles.
7. Family history of rheumatic or autoimmune disorders.

Objective Data

1. Musculoskeletal examination:
    a. Pain on palpation or range of motion (ROM).
    b. Joint swelling, warmth, or erythema.
    c. Joint motion restriction.
    d. Pain, swelling, or warmth of soft tissues surrounding joints.

e. Deformities.

2. Skin:

a. Skin rash or other abnormalities such as thickening.

b. Alopecia.

3. Oral mucosa:

a. Ulcerations.

b. Dryness.

4. Ocular:

a. Conjunctival inflammation.

b. Dryness.

5. Pulmonary:

a. Adventitious sounds.

b. Friction rub.

6. Neurologic:

a. Foot drop.

b. Muscle weakness.

c. Neurologic deficits.

Laboratory Studies

Anti–Double-Stranded DNA

Anti–double-stranded DNA (anti-dsDNA) is a highly specific marker for diagnosing systemic lupus erythematosus (SLE). This antibody is also useful for monitoring disease progression because anti-dsDNA levels fluctuate with disease activity.

Nursing and Patient Care Considerations

1. High anti-dsDNA levels are associated with the development of lupus nephritis.
2. There is a low false-positive rate (about 5%) in patients with other connective tissue disorders; in patients taking medications such as minocycline, etanercept, infliximab, and penicillamine; in first-degree relatives of patients with lupus; and in some laboratory workers.
3. There is no special preparation for this blood test.

Anticyclic Citrullinated Peptide

Anticyclic citrullinated peptide (anti-CCP) is a marker that helps diagnose rheumatoid arthritis (RA). These autoantibodies are produced in the joint as a result of the synovial immune response of patients with RA.

Nursing and Patient Care Considerations

1. Anti-CCP is about as sensitive, but more specific (95% to 98%), than the rheumatoid factor (RF) test. Found in approximately 50% to 55% of patients with RA.
2. It may be valuable in cases of early arthritis when symptoms are mild and nonspecific and aggressive treatment is being contemplated. Anti-CCP antibody is now used with the RF as the gold standard in making the diagnosis of RA.
3. No specific preparation is needed for this blood test, but the specimen may need to be sent out for processing, as not all labs perform this test.

Antinuclear Antibody

Antinuclear antibody (ANA) is a test for antibodies to nucleoprotein (autoantibodies or a heterogeneous group of gamma globulins); it is highly sensitive for detecting SLE but is nonspecific (high false-positive rate).

Nursing and Patient Care Considerations

1. Be alert for drugs that may cause false-positive results.
2. Results will be reported in a staining pattern (speckled, homogeneous, peripheral, nucleolar) if positive, which correlates to various types of connective tissue disorders and various subsets of SLE (see Table 30-1).
3. Titer will also be reported with positive ANA but does not reflect disease activity or prognosis.

Table 30-1 ANA Staining Patterns and Connective Tissue Disorders

ANA PATTERN	CONNECTIVE TISSUE DISORDER
Peripheral (rim, ring, membranous)	Active SLE, usually with renal disease
Homogenous (diffuse)	SLE, RA
Speckled	SLE, RA, scleroderma, Sjögren syndrome, mixed connective tissue disorder
Nucleolar	Scleroderma

ANA, antinuclear antibody; RA, rheumatoid arthritis; SLE, systemic lupus erythematosus.

Complement

1. *Complement* is a complex cascade system that activates proteins as part of the body's defense against infection.
2. Specific components include CH50 (total complement), C3, and C4; measurement helps determine immune complex formation or agammaglobulinemia.
3. Complement levels are decreased in certain autoimmune diseases, particularly SLE, because of complement consumption and because of activation of proteolytic enzymes and tissue damage. C3 and C4 are often monitored to evaluate activity in SLE.

Nursing and Patient Care Considerations

1. Obtain venous blood sample and refrigerate; send to laboratory promptly because complement deteriorates at room temperature.
2. Serial measurements may be helpful in monitoring the activity of some rheumatic diseases; decreased levels indicate increased disease activity.

C-Reactive Protein

C-reactive protein (CRP) is produced by the liver and is a nonspecific marker for infection and inflammation. It can be used to support the diagnosis for immune-mediated inflammatory diseases such as psoriatic arthritis, RA, and Crohn disease.

Nursing and Patient Care Considerations

1. CRP reacts quicker to inflammatory changes than erythrocyte sedimentation rate (ESR); it rises within a few hours of an infection or inflammatory condition and then decreases quickly when inflammation resolves.
2. CRP can be used to differentiate inflammatory from noninflammatory conditions and to monitor effectiveness of treatment.
3. Normal CRP is usually below 10 mg/L; a level over 100 mg/L usually indicates infection or inflammation; however, some inflammatory conditions can raise CRP a thousandfold.

Erythrocyte Sedimentation Rate

1. *Erythrocyte sedimentation rate (ESR)* determines the rate at which red blood cells (RBCs) fall out of

unclotted blood in 1 hour.

2. The test is based on the premise that inflammatory and other disease processes create changes in blood proteins, thus causing aggregation of RBCs that makes them heavier.

Nursing and Patient Care Considerations

1. ESR is generally elevated in most rheumatic illnesses.
2. The test is sensitive for inflammatory condition, but not specific to connective tissue disorders.
   a. Result may be elevated by pregnancy, menstruation, medications (such as heparin and oral contraceptives), infection, malignancy, anemia, and advanced age.
   b. Result may be reduced by elevated blood glucose or albumin, high phospholipids, or drugs, such as corticosteroids or high-dose aspirin.
3. Most beneficial in monitoring inflammatory disease activity.

Rheumatoid Factor

Rheumatoid factor (RF) is a test for macroglobulin found in the blood of patients with RA and other disorders. RF has properties of an antibody and may be directed against immunoglobulin.

Nursing and Patient Care Considerations

1. It is not a highly sensitive or specific test.
2. May be positive in 50% to 75% of patients with RA, SLE, and Sjögren syndrome. May be false-positive with endocarditis, tuberculosis, syphilis, sarcoidosis, cancer, viral infections, hepatitis C, patients with skin or renal allographs, and in some liver, lung, or kidney diseases.
3. Negative RF does not exclude the diagnosis of RA.
4. Certain disease manifestations, such as severe joint involvement and extra-articular manifestations, may be more frequent in those with high-titer RF.

Other Tests

Synovial Fluid Analysis

1. A sample of synovial (joint) fluid is analyzed for several components.
   a. Color.
   b. Clarity/turbidity.
   c. Viscosity.
   d. White blood cell (WBC) count with differential.
   e. Crystals and their identification.
2. Arthrocentesis, a sterile procedure, requires antiseptic cleaning agent, local anesthetic, a 20-G needle (an 18-G needle if infected fluid is suspected), and a 10- to 20-mL syringe.

Nursing and Patient Care Considerations

1. Patients are generally apprehensive about having a needle inserted into a joint. They require reassurance and explanation of the importance of information derived from test results.
2. Assist the health care provider with the test by collecting supplies, maintaining a sterile field, sending joint fluid samples for testing, and monitoring for bleeding following the procedure.
3. Results help to differentiate infection, inflammation, and crystal deposition in a painful joint (see Table 30-2).

Table 30-2 Synovial Fluid Analysis

	NORMAL COLOR	WHITE BLOOD CELL COUNT	VISCOSITY	CRYSTALS
Normal	Clear, yellow	200/μm³	Normal	None
Osteoarthritis	Clear, slightly turbid	200–600/μm³	Low	None
Gout	Turbid	2,000–75,000/μm³	Low	Monosodium urate
Inflammatory Arthritis (Rheumatoid arthritis, systemic lupus erythematosus, Sjögren syndrome, psoriatic)	Turbid, yellow	2,000–75,000/μm³	Low	None
Septic Arthritis	Pus, very turbid	Generally 80,000/μm³	Low	None

GENERAL PROCEDURES AND TREATMENT MODALITIES

Pharmacologic Agents

EVIDENCE BASE American College of Rheumatology. (2012). *Update of the 2008 American College of Rheumatology recommendations for the use of disease-modifying antirheumatic drugs and biologic agents in the treatment of rheumatoid arthritis*. Atlanta, GA: Author. Available: *www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines.*

Connective tissue disorders may be treated with various drugs to relieve pain and to halt or minimize the disease process. Types of agents include nonsteroidal anti-inflammatory drugs (NSAIDs), corticosteroids, immunosuppressive agents, and a group of unrelated drugs known as disease-modifying antirheumatic drugs (DMARDs). Drug therapy may be long term and may require frequent evaluation for adverse effects (see Table 30-3). Patient education information about pharmacologic agents used to treat various disorders can be obtained from the National Institute of Arthritis and Musculoskeletal and Skin Disease (*www.niams.nih.gov/Health_Info/default.asp*) or from the American College of Rheumatology (ACR; *www.rheumatology.org*).

Table 30-3 Drug Therapy for Connective Tissue Disorders

DRUG	ACTION	ADVERSE EFFECTS
Anti-Inflammatory Agents		
Salicylates		
• Aspirin (may be buffered or enteric coated)	• Anti-inflammatory, antipyretic, and analgesic effects	• Tinnitus, gastric intolerance or GI bleeding, and purpuric tendencies
Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)		
• Ibuprofen • Fenoprofen • Naproxen • Tolmetin • Sulindac • Meclofenamate • Ketoprofen • Salsalate • Diclofenac • Nabumetone • Ketorolac • Oxaprozin • Flurbiprofen • Diflunisal • Piroxicam • Etodolac • Indomethacin • Trisalicylate	• Anti-inflammatory and analgesic effects • Mechanism of action may be related to inhibition of prostaglandin synthesis (prostaglandins have a role in inflammatory process, pain, and fever). • Nonsteroidal anti-inflammatory agents for adjunctive treatment of rheumatoid arthritis • Sometimes remarkably effective in the control of articular symptoms	• GI irritation: nausea, vomiting, epigastric distress, precipitation and reactivation of peptic ulcer, hepatitis • Hematologic: bone marrow depression, anemia, leukopenia, thrombocytopenia purpura • Decrease in renal function can precipitate renal failure. • Central nervous system: headache, dizziness, drowsiness, aseptic meningitis • Cardiovascular: edema, dyspnea palpitations
COX-2 Inhibitors		
• Celecoxib • Meloxicam	• Selective prostaglandin inhibition so that the inflammatory process is reduced without reducing protective prostaglandin effects on gastric mucosa	• Same adverse effects as other NSAIDs, with less risk for GI bleeding
Disease-Modifying Agents		
Antimalarial Agents		
• Hydroxychloroquine sulfate • Chloroquine phosphate	• Remission-induction agents for inflammatory arthritis usually in combination with other DMARDs • Used frequently for lupus	• Ocular toxicity (retinopathy that can result in permanent loss of vision; blurred vision, night blindness, scotoma)
Sulfonamides		
• Sulfasalazine	• Salicylate, sulfonamide	• Anorexia, rash, hemolytic anemia
Immunomodulators		
• Etanercept • Adalimumab • Golimumab • Certolizumab pegol	• Tumor necrosis factor blocker (subcutaneous)	• Infection, injection site reaction (SQ), dyspepsia, aplastic anemia, demyelinating disorders, activation of latent TB infection, reactivation of hepatitis B
• Infliximab • Golimumab	• IV tumor necrosis factor blocker	• Infusion reaction (IV), headache, optic neuritis, lupuslike syndrome, risk of severe infection
• Abatacept	• Selective costimulation modulator; available as IV or SC	• Risk of serious infection • Worsening of COPD
• Tocilizumab	• Interleukin 6-receptor blocker available as IV or SC	• Risk of severe infection, hypersensitivity reaction, gastrointestinal perforation, demyelinating disorder, malignancy, injection site reaction (SQ), infusion reaction (IV)
Immunosuppressives		
• Methotrexate	• Exert anti-inflammatory effect by inhibition of cellular replication	• Bone marrow suppression, hepatic and pulmonary toxicity, reduced resistance to infection, teratogenic
• Azathioprine	• Suppresses cell-mediated hypersensitivities and alters antibody production	• Bone marrow depression, GI and hepatic toxicity, carcinogenesis
• Cyclophosphamide	• Alkylating agent that interferes with the growth of rapidly dividing cells	• Possibility of a malignancy occurring many years later after initiating therapy can cause sterility, urinary bladder, fibrosis, cystitis

• Cyclosporine	• Inhibition of immunocompetent lymphocytes also inhibits lymphokine production and release.	• Renal dysfunction, tremor, hypertension, gum hyperplasia
• Leflunomide	• Pyrimidine synthesis inhibitor	• Diarrhea, liver function test abnormalities, alopecia, rash, upper respiratory infection, hypertension
• Mycophenolate mofetil	• Inhibits T lymphocyte activation	• Bone marrow suppression, hepatic, reactivation of hepatitis B or C, reduced resistance to infection, teratogenic
Corticosteroids		
• Prednisone • Prednisolone • Triamcinolone • Betamethasone • Hydrocortisone • Dexamethasone • Methylprednisolone	• Alter immune response by binding to intracellular corticosteroid receptors • Potent anti-inflammatory action • Usually used for short-term management of patients with severe limitations	• Osteoporosis, fractures, avascular necrosis • Gastric ulcers, infection susceptibility • Hirsutism, acne, moon facies, abnormal fat deposition, edema, emotional disorders, menstrual disorders • Hyperglycemia, hypokalemia • Hypertension, cataracts

IV, intravenous; SC, subcutaneous.

Physical and Occupational Therapy

Physical and occupational therapy provides a multimodal program to help reduce pain and to improve joint function. Many other measures can be taught to patients for home practice. Components of the program may include:

- Joint conservation.
- Energy conservation.
- Splinting (in rare instances).
- ROM exercises.
- Application of heat and cold.
- Endurance or aerobic conditioning.
- Modification of home and work environment.

Joint Conservation

Teach or reinforce the following practices:

1. Perform activities using good body mechanics.
2. Avoid overuse of joints. Pace task and include rest in long or repetitive activities.
3. Use large joints to perform activities—spread the load over as many joints as possible.
4. Perform activities in smooth movements to avoid trauma induced by abrupt movements.

Energy Conservation

Teach or reinforce the following practices:

1. Organize materials, utensils, and tools.
2. Perform lengthy activities in a seated position.
3. Work at an even pace—avoid rushing.
4. Delegate work to others when possible.

Splinting

1. May be used for wrists and hands.
2. Ensure proper application.
3. Periodically inspect for skin irritation, neurovascular compromise, or improper fit.
4. Usually worn during acute stage of inflammation to protect joint.

Exercise

Instruct and reinforce correct method of exercise:

1. Avoid exercising inflamed joints—putting these joints through ROM exercises one to two times per day when inflamed is sufficient.
2. Perform exercises daily, as prescribed.

3. Aerobic conditioning exercises may be indicated when disease activity permits.
4. Walking, biking, swimming, and water walking for 30 minutes, three times per week. Regular exercise three times per week for at least 20 minutes for 6 months has been shown to reduce fatigue and disability in patients with RA compared to those who didn't exercise.

Other Measures

1. Reinforce correct use and application of heat and cold.
2. Obtain and teach correct use of assistive devices.
3. Reinforce use of behavior-modification and relaxation techniques as adjuncts to therapy.
4. Suggest discussion with health care provider about complementary and alternative therapies. A wide variety of herbal and nutraceutical products have been used and studied, but data remain inconclusive about efficacy (see Table 30-4).
    a. Many herbal and supplemental products are marketed for pain, inflammation, repair of cartilage, and boosting the immune system; however, scientific evidence for clear-cut treatment benefit is lacking. There is preliminary evidence for fish oil, gamma linolenic acid, and the herb thunder god vine.
    b. Reflexology, tai chi, and acupressure or acupuncture have benefited some patients with arthritis and connective tissue disorders. Assist the patient in finding certified providers in these disciplines, if desired.
    c. Use of magnets to relieve pain has not shown effectiveness in numerous studies since the concept was introduced.
    d. For more information, refer patients to the National Center for Complimentary and Alternative Medicine at *https://nccam.nih.gov/health/RA/getthefacts.htm*.
5. Advise patient to modify home and work environments, as needed, to install safety devices, and to maintain a safe environment.
6. Advise patient to seek counseling regarding sexuality if joint pain and inflammation are barriers to performance.
7. Reinforce the chronic waxing-and-waning nature of the illness to lessen susceptibility to quackery.

Table 30-4 Complementary and Alternative Drug Therapy for Arthritis

DRUG	EFFECT	COMMENTS
Fish oil (omega-3 fatty acid)	May reduce tenderness and stiffness; may reduce the need for NSAIDs	May interact with blood thinners, antihypertensives. Avoid high-dose fish liver oil, which may cause vitamin A and D toxicity.
Gamma-linoleic acid (GLA) (omega-6 fatty acid, evening primrose oil, borage, black currant)	Converted into substances that reduce inflammation to relieve joint pain, stiffness, tenderness, and possibly NSAID use	Appears to be safe but some borage oil preparations contain hepatotoxic chemicals. More research on dose and duration is needed.
Thunder god vine (*Tripterygium wilfordii*)	May fight inflammation and suppress the immune system; may relieve rheumatoid arthritis symptoms	May cause serious side effects—diarrhea, stomach upset, hair loss, headache, skin rash, menstrual changes, male infertility; long-term use may reduce bone mineral density.
Boswellia	Anti-inflammatory and analgesic effects	Generally safe. Lab and animal studies have been done; need clinical studies.
Ginger	Anti-inflammatory and analgesic effects	Large doses may cause GI adverse effects; may cause bleeding if given with anticoagulant. Lab studies have been done; need clinical studies.
Green tea	Substances might be useful in rheumatoid arthritis and osteoarthritis.	More information is needed.
Turmeric (curcumin)	Animal studies show protection of joints from inflammation and damage.	Generally safe, no adverse effects; however, may cause stomach ulcers in high doses with prolonged use. Animal studies have been done; need clinical studies.
Cayenne pepper (capsicum)	Thought to deplete substance P, reducing pain transmission Applied topically to the skin over joints in concentrations of 0.025%–0.25%	Takes several days to obtain pain relief; do not use with heat application.
Glucosamine and chondroitin	Cartilage repair, pain relief Glucosamine: 1,000–2,000 mg daily chondroitin: 800–1,600 mg daily, based on weight	Bleeding risk if ASA taken with chondroitin; may be effective either alone or as combination; must be taken for several months to achieve noticeable effect. Studies showed conflicting results.

GLA, gamma-linoleic acid.

EVIDENCE BASE National Center for Complementary and Alternative Medicine. (2013). *Rheumatoid arthritis and complementary and alternative medicine*. Bethesda, MD: Author. Available: *https://nccam.nih.gov/health/RA/getthefacts.htm.* Cameron, M., Gangier, J. J., & Chrubasik, S. (2011). Herbal therapy for treating rheumatoid arthritis. *The Cochrane Database of Systematic Reviews,* (2), CD002948.

DISORDERS

Rheumatoid Arthritis

Rheumatoid arthritis (RA) is a chronic inflammatory disease that affects joints and other organ systems. RA affects 0.5% to 1% of the population worldwide. The 2010 criteria include synovitis in any joint where no alternative diagnosis can explain the synovitis, and a score of 6/10 in four domains: number and site of involved joints, serologic abnormality, elevated acute phase response (markers of inflammation), and symptom duration. Joint erosions as seen on imaging confirm diagnosis regardless of score.

EVIDENCE BASE American College of Rheumatology. (2015). *2015 American College of Rheumatology guideline for the treatment of rheumatoid arthritis*. Atlanta, GA: Author. Available: *https://www.rheumatology.org/Portals/0/Files/ACR%202015%20RA%20Guideline.pdf.*

Pathophysiology and Etiology

1. Immunologic processes result in inflammation of synovium, producing antigens and inflammatory by-products that lead to destruction of articular cartilage and bone, synovitis, and production of a granular tissue called *pannus* (see Figure 30-1).
2. Granulation tissue forms adhesions that lead to decreased joint mobility.
3. Similar adhesions can occur in supporting structures, such as ligaments and tendons, and cause contractures and ruptures that further affect joint structure and mobility.
4. The etiology is unknown but is probably a combined effect of environmental, epidemiologic, infectious, and genetic factors. Smoking is known to worsen the symptoms of RA.
5. Women are affected more frequently than men.
6. Differential diagnosis includes reactive arthritis, psoriatic arthritis, and other inflammatory arthritides.

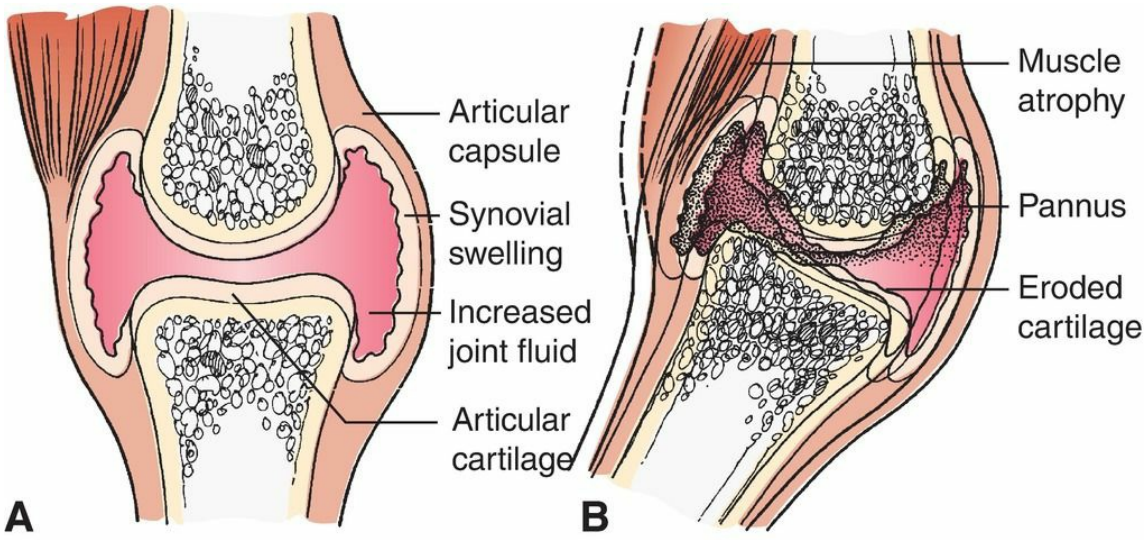

Figure 30-1. Pathophysiology of rheumatoid arthritis. **(A)** Joint structure with synovial swelling

and fluid accumulation in the joint. **(B)** Pannus, eroded articular cartilage with joint space narrowing, muscle atrophy, and ankylosis.

Clinical Manifestations

1. Arthritis—2010 criteria include synovitis in any joint, rather than symmetrical joints in the 1987 ACR criteria (see Figure 30-2, page 825).
2. Skin manifestations.
   a. Rheumatoid nodules—elbows, occiput, and sacrum.
   b. Vasculitic changes—brown, splinter-like lesions in fingers or nail folds.
3. Cardiac manifestations.
   a. Acute pericarditis.
   b. Conduction defects.
   c. Valvular insufficiency.
   d. Coronary arteritis.
   e. Cardiac tamponade—rare.
   f. Myocardial infarction and sudden death—rare.
4. Pulmonary manifestations.
   a. Asymptomatic pulmonary disease.
   b. Pleural effusion and pleurisy.
   c. Interstitial fibrosis.
   d. Laryngeal obstruction caused by involvement of the cricoarytenoid joint—rare.
   e. Pulmonary nodules.
5. Neurologic manifestations.
   a. Mononeuritis multiplex—wrist drop and foot drop.
   b. Carpal tunnel syndrome.
   c. Compression of spinal nerve roots (cervical spine only).
   d. Distal sensory neuropathy.
6. Other manifestations.
   a. Fever.
   b. Fatigue.
   c. Weight loss.
   d. Episcleritis.

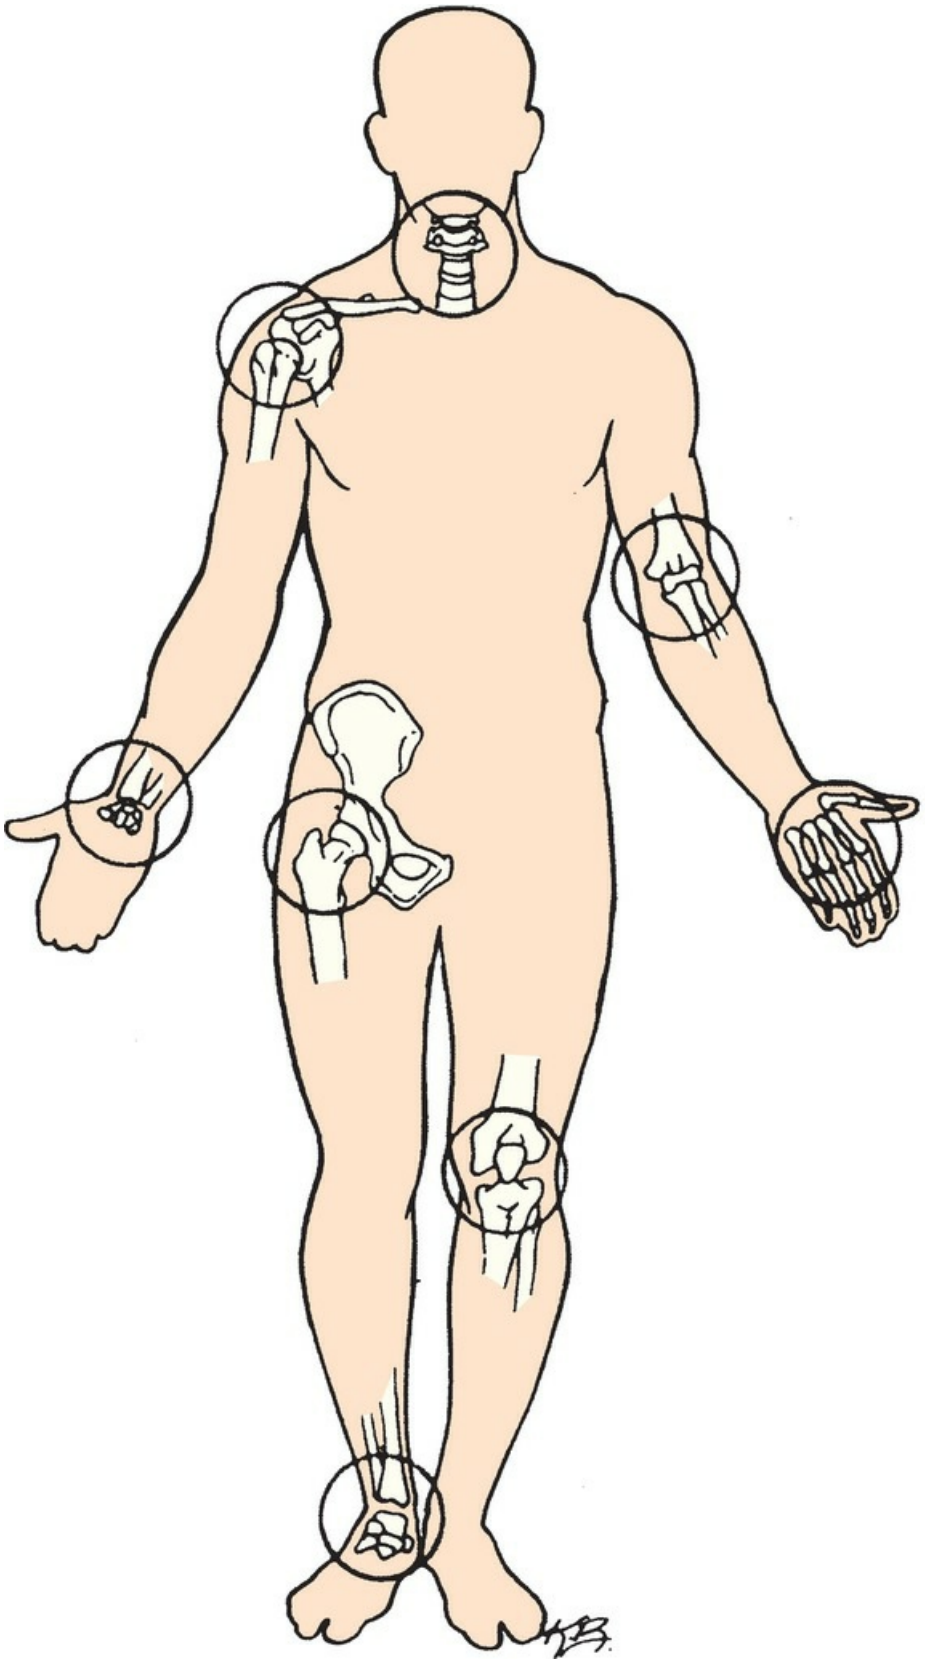

Figure 30-2. Rheumatoid arthritis characteristically involves the joints of the hands, wrist, feet, ankles, knees, and elbows, the glenohumeral and acromioclavicular joints, and the hips. The articulations of the cervical spine are also affected.

Diagnostic Evaluation

1. Complete blood count (CBC)—normochromic, normocytic anemia of chronic disease; may also have iron deficiency anemia (hypochromic, microcytic); platelets may be elevated with inflammation.
2. RF—positive in up to 70% to 80% of patients with RA; CCP is more specific for RA than RF testing.
3. ESR and CRP—often elevated due to active inflammation.
4. Synovial fluid analysis may be done in acute swollen large joint—see page 821.
5. X-rays—changes develop within 2 years.
   a. Hands/wrists—marginal erosions of the proximal interphalangeal (PIP), metacarpophalangeal, and carpal joints; generalized osteopenia.
   b. Cervical spine—erosions that produce atlantoaxial subluxation (generally after many years).
6. Magnetic resonance imaging (MRI)—detects spinal cord compression that results from C1 to C2 subluxation and compression of surrounding vascular structures. Also detects erosions earlier than x-ray.
7. Ultrasound—detects synovitis and erosion (very user dependent).

Management

EVIDENCE BASE Singh, J. A., Furst, D. E., Bharat, A., et al. (2012). 2012 update of the 2008 American College of Rheumatology Recommendations for the use of disease-modifying antirheumatic drugs and biologic agents in the treatment of rheumatoid arthritis. *Arthritis Care Research, 64*, 625–639.

---

1. NSAIDs to relieve pain and inflammation.
2. DMARDs to reduce disease activity.
   a. Monotherapy or combination of older agent, such as methotrexate or hydroxychloroquine, with newer agents immunomodulatory referred to as biologics.
   b. TNF inhibitor and methotrexate have shown greater benefit in improving signs and symptoms, preventing radiologic deterioration of the joint, and improving physical function in comparison with monotherapy.
   c. The goal is to have long-term impact on the joints and to prevent disability.
3. Corticosteroids (by mouth or intra-articular administration) to reduce inflammatory process. Generally used for short periods, because of multiple side effects.
4. Local comfort measures:
   a. Application of heat and cold did not show benefit in a meta-analysis, but treatment can be individualized.
   b. Use of splints to support painful, swollen joints.
   c. Paraffin wax baths with exercise may be of some benefit.

5. Nonpharmacologic modalities:
    a. Behavior modification.
    b. Relaxation techniques.
6. Surgery:
    a. Synovectomy.
    b. Arthrodesis—joint fusion.
    c. Total joint replacement.

DRUG ALERT Do not give biologic DMARDs (immunomodulators) within 2 to 3 weeks of any live vaccine. Oral DMARDs, such as methotrexate, leflunomide, hydroxychloroquine, and sulfasalazine, may be used. Watch for signs of infection, including reactivation of viral infection, while patients are receiving these medications.

Complications

1. Loss of joint function because of bony adhesions, erosions, and damage of supporting structures—7% of patients become disabled within 5 years of onset; 32% cannot work after 10 years.
2. Anemia of chronic disease.
3. Felty syndrome—neutropenia, splenomegaly, frequent infections, and leg ulcers; occurs in 1% of patients.

Nursing Assessment

1. Perform joint examination, if indicated, noting which joints affected; ROM of each joint; presence of heat, redness, synovial swelling; and possible joint effusion.
2. Note presence of deformities (see Figure 30-3):
    a. Swan neck—PIP joints hyperextend.
    b. Boutonniere—PIP joints flex.
    c. Ulnar deviation—fingers point toward the ulna.
3. Assess pain using a pain measurement scale such as the visual analog scale (10-cm straight line scored 0 to 100; patient makes a mark indicating intensity of pain).
4. Assess functional status using the ACR revised criteria for classification for global functional status.
    a. Class I—Completely able to perform usual activities of daily living (ADLs).
    b. Class II—able to perform usual self-care and vocational activities, but limited in avocational activities.
    c. Class III—able to perform usual self-care activities, but limited in vocational and avocational activities.
    d. Class IV—limited ability to perform usual self-care, vocational, and avocational activities.

5. Assess for adherence to treatment plan, any complementary methods used, and any adverse reactions to medications.

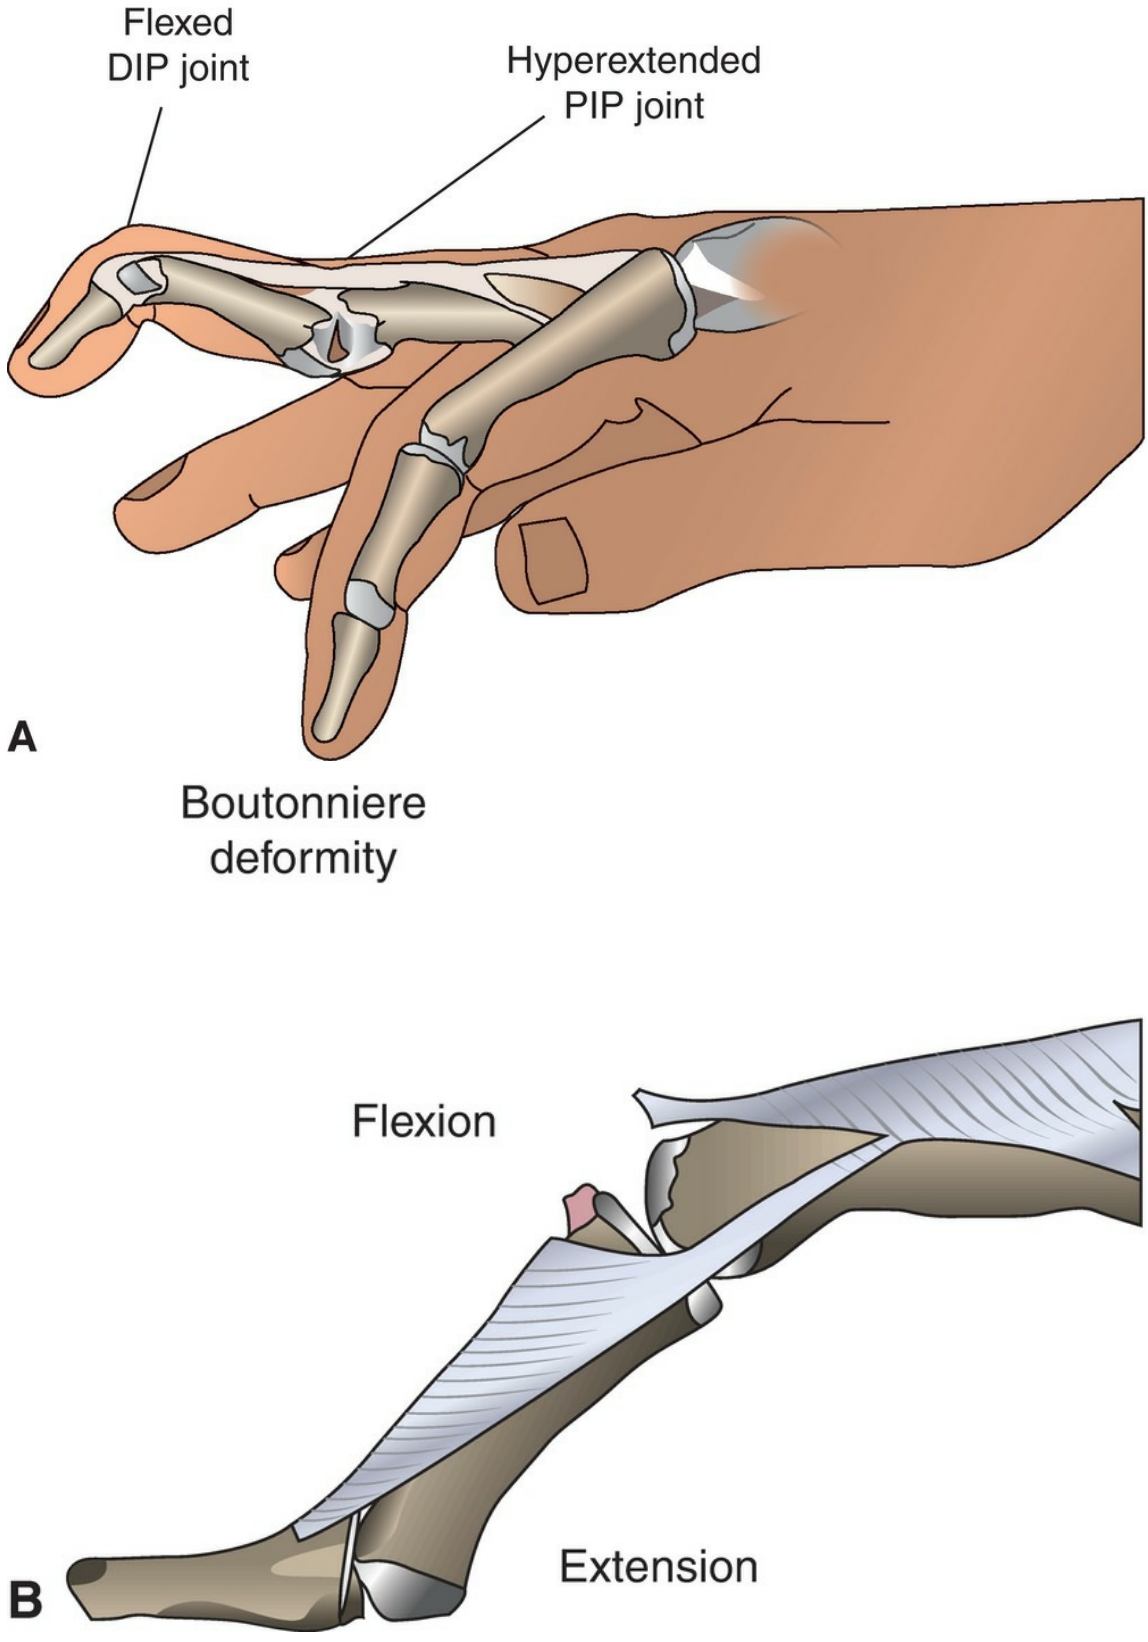

Figure 30-3. Swan neck **(A)** and boutonniere **(B)** deformities.

Nursing Diagnoses

- Chronic Pain related to disease process.
- Impaired Physical Mobility related to pain and limited joint motion.
- Risk for Infection related to side effects/toxicities of DMARD therapy.
- Dressing or Grooming Self-Care Deficit related to limitations secondary to disease process.
- Ineffective Coping related to pain, physical limitations, and chronicity of RA.

Nursing Interventions

Controlling Pain

1. Apply local heat or cold to affected joints for 15 to 20 minutes, three to four times per day. Avoid temperatures likely to cause skin or tissue damage by checking temperature of warm soaks or by covering cold packs with a towel.
2. Administer or teach self-administration of pharmacologic agents.
   a. Advise patient when to expect pain relief, based on mechanism of action of the drug.
3. Encourage use of adjunctive pain control measures.
   a. Progressive muscle relaxation.
   b. Biofeedback.
   c. Meditation.
   d. Acupuncture or similar therapies.
4. Note frequency, location, and degree of pain. Tracking and trending "flares" of disease important in setting plan of care and change in medication regime.

Optimizing Mobility

1. Encourage warm bath or shower in the morning to decrease morning stiffness.
2. Encourage measures to protect affected joints.
   a. Perform gentle ROM exercises.
   b. Use splints, if necessary.
   c. Assist with ADLs, if necessary.
3. Encourage exercise consistent with degree of disease activity.
4. Refer to physical therapy and occupational therapy.

Preventing Infection and Adverse Reactions to Drug Therapy

1. Review drug information before administration to ensure that baseline blood work, such as CBC and liver function tests, has been done; there are no drug interactions; and you understand reconstitution and administration information.
2. Ensure that a tuberculin test has been done prior to starting biologics. If positive, treatment for latent tuberculosis (TB) and biologic may be started simultaneously.

a. In immunocompromised individuals, including those with autoimmune diseases, greater than 5-mm reaction to tuberculin skin test is considered positive.
b. Interferon-gamma release assays for tuberculosis screening are preferred method of detecting mycobacterial exposure.

3. Make sure that no live vaccines have been administered in the past 2 to 3 weeks before initiating biologic therapy because infection with vaccine agent could result. Oral DMARDs may be used safely.
4. Ensure that the patient has no active or untreated infections. Be aware that suppressed viral infections, such as hepatitis, herpes, and varicella, can result from immune therapy.
5. Administer or teach patient to administer medication subcutaneously by rotating sites of the abdomen, thigh, and upper arm, as directed.
   a. Many biologics, such as etanercept, adalimumab, certolizumab, golimumab, and abatacept, ustekinumab, and secukinumab are available in prefilled syringe or pen form. Etanercept and certolizumab are also available in powder form for reconstitution.
   b. Give IV drugs (abatacept, rituximab, infliximab, golimumab, belimumab, and tocilizumab) by recommended time as identified in the prescribing information, monitoring for fever and chills and cutaneous reaction (as per infusion protocol).

TRANSITIONAL CARE ALERT Teach patients taking biologics the early signs and symptoms of infection and the appropriate action to take (call provider or proceed to emergency department) to reduce the risk of overwhelming infection and readmission. Also, teach patients that biologics are generally held when an antibiotic is prescribed.

Promoting Self-Care

1. Provide pain relief before self-care activities.
2. Provide privacy and an environment conducive to performance of daily activities.
3. Schedule adequate rest periods during flare.
4. Discuss importance of promoting the patient's self-care at an appropriate level with patient and family.
5. Help patient attain appropriate assistive devices, such as raised toilet seats, special eating utensils, and zipper pulls. Contact occupational therapist, social worker, or Arthritis Foundation for information.

Strengthening Coping Skills

1. Be aware of potential job, childcare, home maintenance, and social and family functioning problems that may result from RA.
2. Encourage patient to vocalize problems and feelings.
3. Assist with problem-solving approach to explore options and to gain control of problem areas, such as cost of drugs and medical care and limited resources at home.

a. Patient assistance programs are available for drug therapy through the manufacturer or Partnership for Prescription Assistance (*www.pparx.org*). There are also several foundations that may be able to assist with copays and other costs.
   b. Obtain order for home care nursing or physical or occupational therapy for treatment and monitoring, as needed.
   c. Consult social worker, the Arthritis Foundation, or other community resources for additional services, as needed.
4. Reinforce effective coping mechanisms.
5. Refer to social worker or mental health counselor, as needed.

Patient Education and Health Maintenance

1. Instruct patient and family in the nature of disease.
   a. Chronic nature of RA with characteristic exacerbations and remissions with time.
   b. Disease can have systemic effects that result in constitutional symptoms and involvement of other organ systems.
   c. Severity of RA is variable, but most patients are *not* confined to bed or wheelchair.
   d. RA has no cure; avoid "miracle cures."
2. Educate patient about pharmacologic agents.
   a. Medication must be taken consistently to achieve maximum benefit.
   b. Most medications used in the treatment of RA require periodic laboratory testing, such as CBC and liver functions, to monitor for potential adverse effects.
   c. Advise patient of possible adverse effects of medications and need to report adverse effects to health care provider, including fever, chills, lethargy, rash, difficulty breathing, swelling, worsening of arthritis, and severe diarrhea.
   d. Advise patients to discuss the use of any complementary or alternative therapies with their health care provider.
   e. Reinforce to patient the need for lifelong treatment.
3. During periods of remission, encourage patient to exercise regularly, choosing an activity that is inexpensive, convenient, enjoyable, and not dependent on the weather. Suggest dancing, mall walking, use of stationary bicycle in the home, or contacting the local YMCA about special programs for arthritis.
4. For additional information and support, refer to the Arthritis Foundation (*www.arthritis.org*) or the American College of Rheumatology (*www.rheumatology.org/public/factsheets/index.asp*).

Evaluation: Expected Outcomes

- Reports reduction in pain and fatigue.
- Protects joints from overuse. No signs of infection and no adverse reactions to drug therapy.
- Maintains independent toiletry, bathing, and feeding.
- Verbalizes concerns about cleaning and cooking; meets with occupational therapist.

Systemic Lupus Erythematosus

Systemic lupus erythematosus (SLE) is a chronic, multisystem autoimmune disease. Discoid lupus may also occur with predominant skin lesions.

Diagnostic criteria for SLE include the presence of at least 4/17 findings, as outlined in the Systemic Lupus International Collaborating Clinics classification criteria, updating the SLICC/ACR Damage Index for SLE. Criteria include clinical manifestations and laboratory criteria.

EVIDENCE BASE Petri, M., Orbai, A. M., Alarcon, G. S., et al. (2012). Derivation and validation of the Systemic Lupus International Collaborating Clinics classification criteria for systemic lupus erythematosus. *Arthritis and Rheumatism, 64*(8), 2677–2686.

Pathophysiology and Etiology

1. The T-lymphocyte system is affected for unknown reasons, and the failure of its regulatory system may result in an inability to slow or to halt the production of inappropriate autoantibodies.
2. B-lymphocyte–stimulating factors are produced and this too may lead to production of autoantibodies.
3. Autoantibodies may combine with other elements of the immune system to activate immune complexes. These immune complexes and other immune system constituents combine to form complement, which is deposited in organs, causing inflammation and tissue necrosis.
4. More women, particularly in child-bearing years, are affected than men.

Clinical Manifestations

1. Skin:
   a. Butterfly-shaped rash of the malar region of the face, characterized by erythema and edema.
   b. Discoid lesions are scarring, ring-shaped, involving the shoulders, arms, and upper back.
   c. Discoid lesions may also result in erythematous, scaly plaques on the face, scalp, external ear, and neck, resulting in alopecia.
2. Arthritis:
   a. Generally bilateral and symmetric, involving the hands, wrists, and other joints.
   b. Can resemble RA and may be mistaken for it, especially early in the course of the disease.
   c. Unlike RA, the arthritis is primarily nonerosive; may (occasionally) be erosive, representing some overlap with RA.
   d. Tendon involvement is common and may lead to deformities or tendon rupture.
3. Cardiac:
   a. Pericarditis.
   b. Pleural effusion.

c. Myocarditis.
d. Endocarditis.
e. Coronary artery disease.

4. Pulmonary:
   a. Pleuritis.
   b. Pleural effusion.
   c. Lupus pneumonitis.
   d. Pulmonary hemorrhage.
   e. Pulmonary embolism.
5. GI:
   a. Oral ulcers.
   b. Acute or subacute abdominal pain.
   c. Pancreatitis.
   d. Spontaneous bacterial peritonitis.
   e. Bowel infarction.
6. Renal: occurs in 50% of patients, with as many as 15% of patients developing renal failure. Renal thrombosis is rare. Lupus nephritis is more common.
   a. Mesangial nephritis—mild form, can be reversible, best prognosis.
   b. Focal segmental glomerulonephritis—active necrotic or sclerosing lesions.
   c. Proliferative—may be focal or diffuse; diffuse carries good prognosis.
   d. Membranous nephritis—may persist for years without serious renal function decline; may present as nephrotic syndrome.
   e. Sclerosing nephritis—increase in the amount of matrix material in the glomeruli.
7. Central nervous system:
   a. Neuropsychiatric disorders—depression and psychosis.
   b. Transient ischemic attacks and stroke.
   c. Seizures.
   d. Migraine headache.
   e. Myelopathy.
   f. Guillain-Barré syndrome.
   g. Chorea and other movement disorders.
   h. Poor concentration and "lupus fog."
8. Hematologic:
   a. Hemolytic anemia.
   b. Leukopenia.
   c. Thrombocytopenia.

9. Vascular:
    a. Hypertension.
    b. Raynaud phenomenon (see Figure 30-4).
10. Constitutional:
    a. Fever.
    b. Weight loss.
    c. Fatigue.

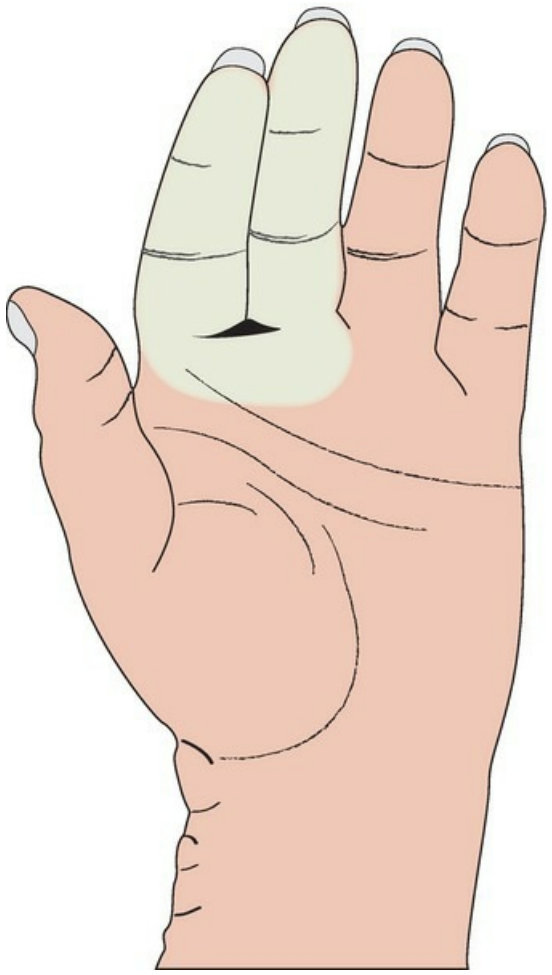

Figure 30-4. Characteristic pallor because of vasospasm in Raynaud phenomenon.

Diagnostic Evaluation

1. CBC—leukopenia, anemia (may be hemolytic), and thrombocytopenia.
2. ANA—positive in more than 90% of patients with SLE; predominant pattern is homogeneous.
3. Anti-dsDNA—97% specific for lupus.
4. ESR—generally elevated.
5. Complement levels—generally decreased when disease is active.
6. Urinalysis—hematuria, proteinuria, and active sediment (RBC casts).

7. Twenty-four–hour urine for protein and creatinine clearance.
8. Chest x-ray may show changes.
9. X-ray of hands and wrists—nondestructive arthritis.
10. Computed tomography (CT) or MRI may be clinically indicated.
    a. Brain—to define any neurologic manifestations.
    b. Abdomen—to rule out other abdominal processes in a patient with abdominal pain.
    c. Cerebral arteriogram—to look for evidence of cerebral vasculitis.
    d. Magnetic resonance angiography.

Management

Pharmacologic

1. NSAIDs to reduce pain and inflammation.
2. Antimalarials to decrease disease activity.
3. Corticosteroids to reduce inflammatory process.
4. Immunosuppressives to suppress immune process and to act as steroid-sparing agents.
    a. Research is ongoing to develop lymphocyte-specific immunosuppressants and biologic modifiers to stop autoantibody production.
    b. Belimumab is a human monoclonal antibody that neutralizes the B-cell survival factor and B-lymphocyte stimulator (BLyS). Belimumab is available in SQ or IV delivery systems.
5. Antihypertensives and diuretics to treat hypertension and fluid overload, if present due to renal disease.
6. Calcium channel blockers, angiotensin receptor blockers, or sildenafil for Raynaud phenomenon.

EVIDENCE BASE Stohl, W., & Hilbert, D. M. (2012). The discovery and development of belimumab: The anti BLyS–lupus connection. *Nature Biotechnology, 30*(1), 69–77.

Nonpharmacologic

1. Avoid direct exposure to sunlight to reduce the chance of exacerbation. Protective clothing and sunblock with an SPF of 50 should also be used.
2. Behavior modification to prevent exacerbations and to reduce symptoms.
3. Joint protection and energy conservation.

Other Management

1. Close follow-up for evaluation of cardiac, neurologic, renal, and other body systems.
2. Referral to specialists for systemic manifestations.

Complications

1. Renal failure.
2. Permanent neurologic impairment.
3. Infection.
4. Death caused by disease process.

Nursing Assessment

1. Obtain clinical history, review systems, and perform physical examination for characteristic findings.
2. Assess for signs and symptoms of infection and other adverse effects to medications.
3. Assess patient's and family's ability to cope with impact of prolonged disease.

Nursing Diagnoses

- Chronic Pain related to inflammation of joints and juxta-articular structures.
- Powerlessness related to unpredictable course of disease.
- Risk for Impaired Skin and Oral Mucous Membrane Integrity related to skin/oral lesions.
- Fatigue related to chronic inflammatory process.
- Impaired Urinary Elimination related to renal involvement.

Nursing Interventions

Reducing Pain

1. Administer and teach self-administration of medications to reduce disease activity and of additional analgesics as ordered.
2. Suggest the use of hot or cold applications, relaxation techniques, and nonstrenuous exercise to enhance pain relief.
3. Monitor for adverse reactions to corticosteroids (see page 823).

Increasing Control over Disease Process

1. Instruct patient to avoid factors that may exacerbate disease.
    a. Avoid exposure to sunlight and ultraviolet light.
        i. Use sunscreen with sun protection factor of 30 or greater. Avoid prolonged sun exposure.
        ii. Wear protective, lightweight clothing with long sleeves and wide-brimmed hats.
        iii. Avoid use of tanning beds.
    b. Avoid exposure to drugs and chemicals.
        i. Avoid exposure to hairspray.
        ii. Avoid exposure to hair-coloring agents.
        iii. Medications—obtain provider advice before taking any medications or supplements.
2. Teach self-administration of pharmacologic agents to reduce disease activity. Reinforce importance of adhering to antimalarial therapy (hydroxychloroquine).

3. Encourage good nutrition, sleep habits, exercise, rest, and relaxation to improve general health and to help prevent infection.
4. Encourage expression of feelings, counseling, or referrals to social work and occupational therapy, as needed.

Maintaining Skin and Mucous Membrane Integrity

1. Apply topical corticosteroids to skin lesions, as ordered.
2. Suggest alternative hairstyles, scarves, and wigs to cover significant areas of alopecia.
3. Encourage good oral hygiene and inspect mouth for oral ulcers.
   a. Avoid hot or spicy foods that may irritate oral ulcers.
   b. Apply topical agents or analgesics to reduce pain and to promote eating.

Reducing Fatigue

1. Advise patient that fatigue level will fluctuate with disease activity.
2. Encourage patient to modify schedule to include several rest periods during the day; pace activity and exercise according to body's tolerance; use energy conservation techniques in daily activities.
3. Teach relaxation techniques, such as deep breathing, progressive muscle relaxation, and imagery, to reduce emotional stress that causes fatigue.

Preserving Urinary Elimination

1. Assist with monitoring of urinary status as indicated by degree of renal involvement.
   a. Monitor intake and output and urine specific gravity.
   b. Measure urine protein and microalbumin, or obtain 24-hour creatinine clearance, as ordered.
   c. Check test results of serum blood urea nitrogen and creatinine.
2. See page 595 for care of patients on dialysis.

Patient Education and Health Maintenance

1. Stress that close follow-up is essential, even in times of remission, to detect early progression of organ involvement and to alter drug therapy.
2. Advise on the use of special cosmetics to cover skin lesions.
3. Advise about reproduction.
   a. Avoid pregnancy during the time of severe disease activity. Should have stable disease for 1 year before planning pregnancy.
   b. Immunomodulators may have teratogenic effects.
   c. Use of some drugs for treatment of SLE can result in sterility.
   d. Hydroxychloroquine is proven safe during pregnancy.
4. Stress that any complementary or alternative therapies should be discussed with the health care provider.
5. For additional information and support, refer to agencies such as the Lupus Foundation (*www.lupus.org*)

or the American Occupational Therapy Association (*www.aota.org*).

Evaluation: Expected Outcomes

- Reports pain reduction.
- Verbalizes appropriate use of medications, avoidance of sun and chemicals, and need for nutrition and sleep to minimize disease process.
- Reports oral ulcers healing without interference with appetite.
- Reports resting three times per day, with adequate energy to carry out activities.
- Urine output adequate; specific gravity stable.

Systemic Sclerosis

Systemic sclerosis is a generalized disorder of connective tissue, characterized by hardening and thickening of the skin (scleroderma), blood vessels, synovium, skeletal muscles, and internal organs. Fibrotic, degenerative, and inflammatory changes result in changes in joints and several organ systems. New diagnostic criteria being evaluated and validated by the ACR and EULAR include 23 items.

EVIDENCE BASE Johnson, S. R., Fransensen, J., Khanna, D., et al. (2012). Validation of potential classification criteria for systemic sclerosis. *Arthritis Care Research, 64*(3), 358–367.

Pathophysiology and Etiology

1. The changes seen in the skin and internal organs in systemic sclerosis are most likely caused by overproduction of collagen by fibroblasts.
2. The etiology of systemic sclerosis is unknown.
3. Systemic sclerosis affects three to four times as many women as men.
4. Major subtypes include:
   a. Diffuse scleroderma—rapidly progressive, generalized skin thickening of the proximal and distal extremities and trunk and tendency toward early internal organ involvement.
   b. Limited scleroderma—skin thickening is limited to the distal extremities and face.
   c. Localized forms of scleroderma—do not include visceral involvement.
   d. Overlap with other connective tissue disorders.

Clinical Manifestations

Skin

1. Bilateral symmetric swelling of the hands and, sometimes, the feet.
2. After the edematous phase, the skin becomes hard and thick.
3. Digits, dorsum of the hand, neck, face, and trunk are involved.
4. Normal landmarks in the skin are absent—no skin folds.
5. Increased or decreased skin pigmentation (salt and pepper skin).
6. Skin changes may regress after several years.
7. Telangiectasia—on/under the tongue, face, fingers, and lips.
8. Areas of calcinosis—late in the course of disease.
9. Raynaud phenomenon.
10. Decreased oral aperture.

GI

1. Esophageal dysmotility—resulting in reflux and dysphagia.
2. Distal esophageal dilation and esophagitis.
3. Barrett metaplasia—may predispose to adenocarcinoma of the esophagus.
4. Duodenal atrophy dilation—may cause postprandial abdominal pain, malabsorption, diarrhea, and abdominal distention.
5. Colonic hypomotility—results in constipation.

Musculoskeletal

1. Joint pain.
2. Polyarthritis—large and small joints affected.
3. Carpal tunnel syndrome.
4. Flexion contractures.
5. Inflammatory muscle atrophy.

Cardiac

1. Left ventricular dysfunction.
2. Myocardial involvement—heart failure and atrial and ventricular arrhythmias.
3. Right ventricular involvement—secondary to pulmonary disease.

Pulmonary

1. Interstitial fibrosis.
2. Restrictive lung disease.
3. Pulmonary hypertension.

Renal

Scleroderma renal crisis—rapid malignant hypertension with encephalopathy.

Localized Scleroderma

1. CREST—*c*alcinosis (calcium deposits of the subcutaneous tissue and periarticular tissue), *R*aynaud phenomenon, *e*sophageal dysmotility, *s*clerodactyly (shiny, tight, atrophic appearance of the skin of the fingers or toes), *and telangiectasia*.
2. Morphea—scattered patches may be several centimeters and may have a purple border.
3. Linear—lesions appear as streaks or bands.
4. Generally, no visceral involvement exists in localized scleroderma.

Diagnostic Evaluation

1. CBC and ESR—generally normal.
2. RF—positive in approximately 30% of patients.
3. ANA—generally positive with speckled or nucleolar patterns.

a. Antisclerodermal antibody (Scl-70)—positive in diffuse cutaneous disease.
b. Anticentromere antibody—highly specific for limited cutaneous disease.

4. Additional antibodies that have been identified include anti-RNA polymerase III antibody and antitopoisomerase I antibody.
5. X-ray of hands and wrists—muscle atrophy, osteopenia, and osteolysis.
6. Barium swallow—esophageal dysmotility.
7. Pulmonary function test—decreased diffusion capacity and vital capacity; CT of the chest to evaluate for pulmonary fibrosis.
8. Multiple-gated acquisition scan—to determine left ventricular function; echocardiogram to evaluate for pulmonary hypertension.
9. Endoscopy—to biopsy for Barrett metaplasia.
10. Esophageal manometry—to determine contractile capacity of esophageal muscles.

Management

Pharmacologic

1. Calcium channel blockers; losartan or other angiotensin receptor blockers or sildenafil for more severe cases of Raynaud phenomenon. Nitroglycerin ointment is sometimes used. Prazosin, an alpha-adrenergic agent, has a modest effect but may cause dizziness, headache, and lack of energy.
2. NSAIDs and/or other analgesics for arthralgias, polyarthritis, and painful calcinosis.
3. Proton pump inhibitors for reflux.
4. Antibiotics for malabsorption because of bacterial overgrowth or secondarily infected skin ulcerations.
5. Antihypertensive agents, particularly a high-dose angiotensin-converting enzyme inhibitor such as enalapril.
6. Bronchodilators for pulmonary involvement; oxygen and cyclophosphamide may also be used in severe cases.
7. For Raynaud phenomenon, topical L-arginine has been used on the hands to stimulate formation of nitric oxide, a vasodilator. Sildenafil may be helpful with symptoms. Severe symptoms may also respond to injections of Botox.

DRUG ALERT L-Arginine should not be used with nitrates and antihypertensives; vasodilating effect may cause excessive drop in blood pressure.

Nonpharmacologic

1. Skin lubricants and care for ulcerations to promote healing.
2. Lifestyle modification for control of Raynaud phenomenon:

a. Increased environmental temperature.
b. Appropriate dress with gloves and heavy socks.
c. Avoidance of handling cold and frozen items without gloves.
d. Avoidance of wind and exposure to cold weather.
e. Use of hand and foot warmers.
f. Smoking cessation.

3. Raynaud attack can possibly be aborted by placing the hand or foot in tepid water.
4. Biofeedback to abort or prevent Raynaud attack.
5. Smoking cessation and immunization against pneumococcal pneumonia and influenza for pulmonary involvement.
6. Dietary modifications for GI involvement:
   a. Avoidance of caffeinated beverages.
   b. Eating smaller meals.
   c. Remaining upright after meals for at least 3 hours.
   d. Avoidance of alcohol.
   e. Elevating the head of the bed.
7. Physical therapy to help prevent contractures.

Complications

1. Skin ulcers.
2. Malabsorption.
3. Esophageal adenocarcinoma.
4. Pulmonary hypertension.
5. Renal failure.
6. Heart failure.
7. Death caused by disease process.

Nursing Assessment

1. Focus physical assessment on:
   a. Skin ulcers, thickening, subcutaneous deposits, and secondary infection.
   b. Joint examination—flexion contractures.
   c. Pulmonary examination—for shortness of breath and wheezing.
   d. Blood pressure and renal status.
2. Determine nutritional intake.
3. Assess mood, support system, and coping ability.

Nursing Diagnoses

- Ineffective Peripheral Tissue Perfusion related to Raynaud phenomenon.
- Risk for Impaired Skin Integrity related to effects of disease process.
- Imbalanced Nutrition: Less Than Body Requirements related to impaired swallowing and GI involvement.
- Disturbed Body Image related to effects of disease.

Nursing Interventions

Maintaining Tissue Perfusion

1. Teach patient to identify Raynaud phenomenon.
    a. Characteristic color change of the fingers—white, blue, and red.
    b. Coldness, pallor, numbness, and pain.
2. Teach patient to reduce factors associated with precipitation or exacerbation of Raynaud phenomenon.
    a. Dress warmly—cover head and extremities; keep trunk warm.
    b. Discontinue tobacco usage.
    c. Avoid prolonged exposure to cold.
        i. Weather.
        ii. Artificially controlled environments (eg, air conditioning).
        iii. Limit contact with cold food items, such as frozen foods and ice cube trays—use gloves or tongs.
3. Protect ulcerated digits and report signs of infection.

Preserving Skin Integrity

1. Use moisturizers on the skin daily.
2. Advise patient to avoid use of drying soaps and detergents.
3. Use protective padding (eg, elbow pads) to protect the skin from friction or trauma.
4. Inspect the skin daily for cracking, ulceration, and signs of infection.
5. Soak ulcerations, apply topical antibiotic, and use occlusive dressings, as directed.

Achieving Optimal Nutritional Status

1. Make sure patient is in proper position for meals to avoid aspiration (ie, in chair if possible).
2. Provide smaller, more frequent feedings of a well-balanced diet.
3. Encourage patient to remain upright after meals for 45 to 60 minutes and raise head of bed during sleep to avoid reflux.
4. Administer or teach self-administration of medications to prevent nausea and reflux, as ordered.
5. Encourage good oral hygiene and frequent dental visits.
6. Advise the use of lubricating agents, if necessary, to treat dry mouth and to teach stretching exercises of the mouth to maintain aperture.
7. Weigh weekly and ask patient to keep food diary.

Strengthening Body Image

1. Encourage patient to take an active role in treatment plan to feel in control of body changes.
2. Explain that changes may be gradual and slow; although not noticeable, internal organ involvement is even more important than external changes.
3. Suggest continuance of activities that patient enjoys and foster strong support network.
4. Refer for counseling, as needed.

Patient Education and Health Maintenance

1. Explain diagnostic tests and their purpose in detecting GI, pulmonary, or renal involvement.
2. Teach about drug treatment and adverse effects.
3. Advise on modifying activity and using bronchodilators and oxygen to prevent dyspnea caused by restrictive lung disease.
4. Encourage regular follow-up visits and prompt attention to worsening symptoms.
5. Refer to agencies such as United Scleroderma Foundation (*www.scleroderma.org*).

Evaluation: Expected Outcomes

- Relates factors that precipitate Raynaud phenomenon.
- Reports no skin cracking or ulceration.
- Reports no weight loss.
- Reports participating in community and church activities and groups.

Gout

Gout is a disorder of purine metabolism, characterized by elevated uric acid levels and deposition of urate (usually in the form of crystals) in joints and other tissues. More common in men, but may affect postmenopausal women, especially those taking diuretics.

Pathophysiology and Etiology

Gout results from an overabundant accumulation and subsequent deposition of monosodium urate crystals in joints and other connective tissue. This can occur in one of two ways.

Overproduction of Uric Acid (10% of Cases)

1. Inherited enzyme defects.
2. Certain conditions:
    a. Myeloproliferative disorders.
    b. Lymphoproliferative disorders.
    c. Cancer chemotherapy.
    d. Hemolytic anemias.
    e. Psoriasis.

Underexcretion of Uric Acid (90% of Cases)

1. Renal disease.
2. Endocrine disorders.
3. Medications and chemicals:
    a. Diuretics, beta-blockers, and angiotensin-converting enzyme inhibitors.
    b. Ethanol (alcohol).
    c. Low-dose aspirin.
    d. Pyrazinamide—antituberculosis agent.
    e. Lead.
4. Volume depletion states—nephrogenic diabetes insipidus.

Clinical Manifestations

Acute Gouty Arthritis

1. Generally affects one joint—commonly the first metatarsophalangeal joint (called podagra); however, in women is often polyarticular.
2. Other joints can be affected, such as the ankle, tarsals, and knee; upper extremities are less commonly involved.
3. Pain, warmth, erythema, and swelling of tissue surrounding the affected joint.
4. Fever may occur.

5. Onset of symptoms is sudden; intensity is severe.
6. Duration of symptoms is self-limiting; lasts approximately 3 to 10 days without treatment.

Chronic Tophaceous Gout

1. Occurs if acute gout is inadequately treated or if it goes untreated.
2. Characterized by development of tophi or deposits of uric acid in and around joints, cartilage, and soft tissues.
3. Arthritis is more prolonged in nature with discrete attacks less common.
4. Arthritis can produce bone erosions and subsequent bony deformities that can resemble RA.

Hyperuricemia

1. Produces no symptoms but is characterized by persistent elevation of uric acid in the blood.
2. Renal calculi composed of uric acid may develop.
3. Deposition of uric acid in kidney tissue causing nephropathy.

Diagnostic Evaluation

1. Synovial fluid analysis.
   a. Identification of monosodium urate crystals under polarized microscopy.
   b. Synovial WBC count can range from 2,000 to 100,000/mm^3.
   c. Culture of synovial fluid to rule out infection.
2. Twenty-four–hour urine for uric acid to determine overproduction of uric acid versus underexcretion.
3. ESR—elevated.
4. X-rays of affected joints may show changes consistent with diagnosis of gout.

Management

Acute Management

1. NSAIDs for acute attacks to relieve pain and swelling; considered first-line therapy.
2. Colchicine for acute treatment and prevention of attacks; considered second-line therapy.
   a. May be given orally at onset of an attack, taken bid to tid as tolerated (may cause nausea, cramping, diarrhea).
   b. Taken once daily on continuous basis to prevent attack, usually while transitioning to urate-lowering medications. May be used every other day for patients with chronic kidney disease.
3. Corticosteroids.
   a. Intra-articular if attack confined to one or two joints.
   b. Oral—in short-tapering course if other treatments are contraindicated or if attack involves many joints.
4. Increase fluids (orally because usually treated as outpatient) and rest joint for 48 hours.

Chronic Management

1. Urate-lowering agents (antihyperurecemic agents) are taken to prevent progressive articular damage in cases of asymptomatic hyperuricemia and chronic tophaceous gout.
   a. Allopurinol—interferes with conversion of hypoxanthine and xanthine to uric acid. May also be given to prevent renal calculi and kidney disease.
   b. Febuxostat—a xanthine oxidase inhibitor, lowers uric acid and is associated with fewer drug interactions than allopurinol.
   c. Uricosuric drugs, such as probenecid—interfere with tubular reabsorption of uric acid.
   d. Lesinurad, a URAT1 inhibitor indicated in combination with a xanthine oxidase inhibitor (XOI) for the treatment of hyperuricemia associated with gout in patients who have not achieved target serum uric acid levels with an XOI alone.
   e. Pegloticase is a pegylated uric acid–specific enzyme indicated for the treatment of chronic gout in adult patients refractory to conventional therapy.
2. Adverse reactions for these drugs include headache, anorexia, nausea and vomiting, allergic reaction, hemolytic anemia and other blood dyscrasias, and worsening of gout. Urinary frequency and uric acid kidney stones may occur with probenecid.
3. Rapid increase or decrease of uric acid may precipitate a gout flare, so medication usually started at a low dose and titrated up.
4. Uric acid levels and renal function are monitored during chronic therapy. A small percentage of patients develop elevated liver functions with urate-lowering treatment.

DRUG ALERT Exfoliative dermatitis (sometimes fatal) and liver and biliary dysfunction may occur with use of allopurinol and febuxostat.

Lifestyle Modification

1. Avoidance of obesity and fluctuations in weight.
2. Avoidance of alcohol—can precipitate gout attacks through overproduction and decreased excretion of urate.
3. Low-purine diet gives only a minor decrease in serum uric acid levels.
4. Moderate coffee consumption has been linked to decreased uric acid levels.

Complications

1. Uric acid renal calculus.
2. Urate nephropathy.
3. Erosive, deforming arthritis/contractures.

Nursing Assessment

1. Obtain history for factors predisposing to gout, such as malignancy, alcoholism, and renal insufficiency.
2. Perform physical examination.
    a. Inspect the involved joint for pain, swelling, redness, warmth, and effusion.
    b. Observe for tophi over the pinna of the ear, olecranon bursa, Achilles tendon, and fingertips.
3. Assess pain and pain relief pattern if attack is acute.

Nursing Diagnoses

- Acute Pain related to acute arthritis.
- Impaired Physical Mobility related to arthritis.

Nursing Interventions

Relieving Pain

1. Administer and teach self-administration of pain-relieving medications, as prescribed.
2. Encourage adequate fluid intake to assist with excretion of uric acid and to decrease likelihood of stone formation.
3. Instruct patient to take prescribed medications consistently because interruptions in therapy can precipitate acute attacks.
4. Encourage patient to follow-up as directed, usually in 48 hours and then 4 to 8 weeks after acute attack to evaluate for chronic therapy.

Facilitating Mobility

1. Elevate and protect affected joint during acute attack.
2. Assist with ADLs.
3. Encourage exercise and maintenance of routine activity in chronic gout, except during acute attacks.
4. Protect draining tophi by covering and applying antibiotic ointment, as needed.

Patient Education and Health Maintenance

1. Instruct patient and family in the nature of disease.
    a. Generally, acute attacks are followed by periods of remission.
    b. Once need for chronic treatment has been determined, it will generally be lifelong.
2. Encourage avoidance of alcohol.
3. Avoid rapid weight loss by fasting or crash diets because rapid weight loss results in production of chemicals that compete with uric acid for excretion from the body, resulting in increased uric acid levels.
4. Avoid medications known to increase uric acid levels, such as aspirin, diuretics, and cyclosporine.
5. Advise prompt treatment of acute attack to reduce joint damage associated with repeated attacks.
6. Instruct about signs and symptoms of allopurinol hypersensitivity syndrome and need to report promptly.

7. Advise patients to avoid foods containing purines (ie, sardines, anchovies, shellfish, organ meats) and, in general, to consume meat, seafood, and high-calorie food in moderation.

Evaluation: Expected Outcomes

- Reports relief from pain.
- Performs ADLs with minimal assistance.

Sjögren Syndrome

Sjögren syndrome is a chronic inflammatory autoimmune process that affects the lacrimal and salivary glands. The disease can be primary or secondary. Secondary Sjögren syndrome is seen most commonly in RA but can be seen in SLE and some other connective tissue diseases. Diagnostic criteria involve at least two of three items (presence of antibodies, ocular staining score, lymphocytic sialadenitis).

EVIDENCE BASE Shiboski, S. C., Shiboski, C. H., Criswell, L., et al. (2012). American College of Rheumatology classification criteria for Sjögren's syndrome: A data-driven, expert consensus approach in the Sjögren's International Collaborative Clinical Alliance cohort. *Arthritis Care and Research, 64*(4), 475–487.

Pathophysiology and Etiology

1. The etiology of the syndrome is unknown, but is thought to include several factors: genetic predisposition, immunologic, infectious, and hormonal.
2. It is thought that antibodies directed at exocrine glands are produced, leading to disturbed function of the involved tissue.
3. Lymphocytes are found infiltrating affected tissues.
4. Sjögren syndrome occurs primarily in middle-aged women.

Clinical Manifestations

1. Ocular—xerophthalmia (dry eyes) because of decreased tear formation that leads to keratoconjunctivitis and photophobia, greater than 3 months. Positive Schirmer or positive vital dying test.
2. Oral—xerostomia (dry mouth) caused by diminished production of saliva, mucosal ulcers, and stomatitis, greater than 3 months. Need for fluids to swallow food.
3. Recurrent or persistent salivary gland enlargement—unilateral or bilateral.
4. Dryness of the skin, vagina, and other tissues may also occur.
5. Extraglandular features include rash, dysphagia, Raynaud phenomenon, arthralgias/arthritis, and myalgias.
6. Less commonly, major organ dysfunction, such as interstitial pneumonitis, glomerulonephritis, vasculitis, thyroid disease, and central and peripheral neuropathy may occur.

Diagnostic Evaluation

1. CBC—mild anemia and leukopenia present in 30% of patients.
2. ESR—elevated in 90% of patients.
3. RF—positive in 75% to 90% of patients.

4. ANA—positive in 70% of patients; speckled and nucleolar patterns are most common; titer more than 1:320.
5. Antibodies to SSA/SSB—detects antibodies to specific nuclear proteins.
    a. SSA (Ro antibody)—positive in patients with Sjögren syndrome and SLE.
    b. SSB (La antibody)—positive in patients with Sjögren syndrome; also in patients with SLE.
6. Organ-specific antibodies—antibodies directed against specific organ tissues have been found (eg, antithyroid antibodies).
7. Salivary scintigraphy—salivary gland function is measured by determining excretion of radioisotope dye.
8. X-rays of affected joints to rule out erosive arthritis.
9. Salivary gland biopsy—to determine lymphocytic infiltration of tissue and confirm diagnosis; usually done on one of the minor salivary glands and in the lower lip.

Management

Systemic Drugs

1. NSAIDs and hydroxychloroquine may be used to try to control symptoms.
2. Corticosteroids and immunosuppressants may be used in severe cases.
3. Antifungal agents—used for oral candidiasis.
4. Pilocarpine or cevimeline, systemic parasympathomimetic agents—used to improve salivation when there is some salivary gland function.

Topical Agents

1. Cyclosporine emulsion eye drops to reduce ocular inflammation and increase tear production.
2. Over-the-counter products that contain salivary stimulants or substitutes.
    a. A meta-analysis of 36 randomized controlled trials showed slight benefit with oxygenated glycerol triester sprays over enzyme sprays as saliva substitutes.
    b. Integrated mouth care systems (toothpaste, gel, mouthwash) and oral reservoir devices show promising results, but more research is needed.
    c. Chewing gum is effective for people with residual salivary capacity.
3. Symptomatic relief of dryness.
    a. Artificial tears and lubricant inserts.
    b. Frequent use of sugar-free liquids, gums, and candies.
    c. Vaginal lubricants.
4. Dental care.
    a. Frequent brushing and flossing.
    b. Topical fluoride treatments.
    c. Avoidance of high-sucrose foods.
5. Avoidance of drying.

a. Avoid windy, low-humidity environments and cigarette smoke.
b. Avoid anticholinergic medications, such as antihistamines.
c. Use of occlusive goggles at bedtime to prevent drying.

Complications

1. Ocular complications, such as corneal ulceration, corneal opacification, vascularization of the cornea, infection, glaucoma, and cataract formation.
2. Dental caries and tooth loss.
3. Lymphoma.

Nursing Assessment

1. Obtain history of signs and symptoms, emphasizing dryness.
2. Perform complete physical examination, focusing on the oral cavity, eyes, skin, lungs, GI, and neurologic systems.
3. Assess nutritional status because decreased saliva may make eating difficult.

Nursing Diagnoses

- Impaired Oral Mucous Membrane related to disease process.
- Risk for Impaired Skin Integrity related to dryness.
- Imbalanced Nutrition: Less Than Body Requirements related to disturbances in saliva production, taste, and difficulty swallowing.
- Sexual Dysfunction related to discomfort of decreased vaginal secretions.

Nursing Interventions

Maintaining Mucous Membranes

EVIDENCE BASE Furness, S., Worthington, H. V., Bryan, G., et al. (2011). Interventions for the management of dry mouth: Topical therapies. *The Cochrane Database of Systematic Reviews,* (12), CD008934.

---

1. Inspect oral mucosa for oral *Candida*, ulcers, saliva pools, and dental hygiene.
2. Instruct and assist patient in proper oral hygiene.
   a. At least twice-daily brushing.
   b. Frequent rinsing with antiseptic mouthwash.
3. Encourage frequent intake of noncaffeinated, nonsugared liquids. Keep pitcher filled with cool water.
4. Promptly report any ulcers or signs of infections.

Protecting Skin Integrity

1. Instruct and assist patient with daily inspection of the skin for areas of trauma or for potential breakdown.
2. Apply lubricants to the skin daily.
3. Avoid shearing forces and encourage or perform frequent position changes.

Promoting Adequate Nutritional Intake

1. Increase liquid intake with meals.
2. Assist and instruct patient to avoid choosing spicy or dry foods from menu choices.
3. Suggest small, more frequent meals.
4. Weigh weekly and review diet history for deficiency in basic nutrients.

Promoting Optimal Sexual Functioning

1. Encourage patient to discuss sexual difficulty and to explain its relation to disease process.
2. Advise on proper use of water-soluble vaginal lubrication.
3. Suggest alternative positioning and practices to prevent discomfort.
4. Teach patient to report symptoms of vaginitis—discharge, irritation, and itching—because infection may result from altered mucosal barrier.

Patient Education and Health Maintenance

1. Advise patient of commercially available artificial saliva preparations, artificial tears, moisturizing nasal sprays, and artificial vaginal moisturizers.
2. Encourage frequent dental visits. Dental cavities are more frequent in Sjögren syndrome.
3. Advise patient to check with health care provider before using any medications because many, such as diuretics, tricyclic antidepressants, and antihistamines, have the adverse effect of mouth dryness.
4. Advise patient to wear protective eyewear while outdoors.
5. Encourage support through Sjögren's Syndrome Foundation (*www.sjogrens.org*) or the American College of Rheumatology (*www.rheumatology.org/public/factsheets/index.asp*).

Evaluation: Expected Outcomes

- Demonstrates proper oral hygiene.
- Reports skin without cracking, scaling, or other lesions.
- Maintains weight.
- Describes correct use of water-soluble lubricants.

Fibromyalgia

Fibromyalgia is a syndrome characterized by fatigue, diffuse muscle pain and stiffness, sleep disturbance, and tender points on physical examination. The American College of Rheumatology has stated that fibromyalgia is not a rheumatic disease.

Pathophysiology and Etiology

1. Etiology is unknown.
2. It affects 3 to 6 million Americans, usually women between ages 29 and 37.
3. Fibromyalgia most likely represents a complex pain syndrome in which there is abnormality in central sensory processing, dysregulation of peripheral pain receptors, and psychoneuroendocrine dysfunction.
4. Clinical features include:
   a. Reduction in pain threshold.
   b. Increased response to painful stimuli.
   c. Mild muscle contraction or tension results in postexertion muscle pain.
   d. Decreased muscle strength and endurance, resulting in deconditioning.

Clinical Manifestations

EVIDENCE BASE Wolfe, F., Clauw, D. J., Fitzcharles, M., et al. (2010). The American College of Rheumatology preliminary diagnostic criteria for fibromyalgia and measurement of symptom severity. *Arthritis Care and Research, 62*(5), 600–610.

---

1. Widespread pain and tenderness on physical exam. Diagnostic criteria proposed in 2010 include a widespread pain index, fatigue, and awakening unrefreshed.
2. Additional symptoms include:
   a. Chronic fatigue and easy fatigability.
   b. Sleep is poor or nonrestorative.
   c. Possible joint pain and stiffness.
   d. Additional somatic complaints such as headache, nausea, and abdominal pain.
3. Exacerbation of symptoms occurs due to cold weather, stress, poor sleep, infection, and exertion.

Diagnostic Evaluation

1. To rule out other disorders—test results generally normal in fibromyalgia.
2. Complete history and physical examination.
3. Sleep study may be done to rule out organic sleep disorder causing fatigue.

Management

EVIDENCE BASE Macfarlane, G., Kronisch, C., Dean, L. (2016). EULAR revised recommendations for the management of fibromyalgia. *Annuls of Rheumatic Disease, 76*(2), 318–328.

Treatment is aimed at symptom management and should be individualized, comprehensive, and goal-oriented.

Pharmacologic

1. Nonopioid analgesics are used to relieve pain.
   a. NSAIDs and acetaminophen are rarely effective alone.
   b. Tramadol may be effective if taken regularly at 50 to 100 mg every 4 to 6 hours.
   c. Naltrexone has been shown to relieve symptoms.
2. Low-dose tricyclic antidepressants improve sleep quality and help control chronic pain and depression. Other antidepressants may also be used for concomitant depression.
3. Sleep medication may be used occasionally or on a regular basis in some cases.
4. Periodic limb movements and restless leg syndrome that interfere with sleep can be treated with such medication as ropinirole or clonazepam.
5. Gabapentin and pregabalin, antiepileptics, may be tried for chronic pain control. Dosage is titrated and effects are seen over time for some patients.
6. Duloxetine and milnacipran, serotonin and norepinephrine reuptake inhibitors, are approved by the FDA for symptom relief in fibromyalgia.

DRUG ALERT There are risks for birth defects for women and men of child-bearing years while taking pregabalin.

Nonpharmacologic

1. Exercise is important and should be initiated at a level below the level expected for the patient and gradually increased.
   a. Overtraining is to be avoided to prevent muscle microtrauma, which increases pain.
   b. Stretching, strength training, and aerobic exercise should be included in every patient's exercise plan.
   c. Walking; water aerobics; daily activities, such as gardening; and use of exercise equipment, such as a bike or treadmill, can be part of the patient's exercise routine.
2. Relaxation training through visualization, electromyogram biofeedback, and other techniques.

3. Cognitive–behavioral therapy for feelings of depression, confusion, and irritability.
    a. Patient may learn to think nonnegatively by visualizing a stop sign when negative thoughts enter the mind.
    b. Patient can be taught to control anxiety by learning to stop, become aware of his body, and take deep breaths.
4. Meditation, prayer, and other spiritual practices.

Complications

1. Deconditioning.
2. Work disability.
3. Inability to fulfill social role.
4. Unnecessary diagnostic and therapeutic maneuvers.

Nursing Assessment

1. Assess pain level because it varies during the day/week.
2. Assess functional ability.
3. Assess mood, support system, and coping mechanisms.
4. Assess lifestyle factors that may be impairing well-being—smoking, lack of exercise, and poor posture.

Nursing Diagnoses

- Chronic Pain related to disease process.
- Disturbed Sleep Pattern related to disease process.
- Ineffective Role Performance related to disabling disease process.

Nursing Interventions

Controlling Pain

1. Encourage regular use of analgesics and antidepressants, as directed.
2. Encourage regular exercise routine, including stretching, aerobic activity, and muscle-strengthening exercises.
3. Suggest referrals to physical therapist or pain specialist for additional pain-control modalities, as needed.
4. Suggest referral to psychiatrist or therapist for anxiety, depression, and cognitive or behavioral impairments. Up to 80% of fibromyalgia patients have these symptoms, but only 10% are referred.

Improving Sleep

1. Suggest regular nighttime ritual to promote sleep. Advise avoidance of reading, watching television, or using a computer while in bed.
2. Discourage staying up late and other erratic sleep habits.
3. Encourage relaxation periods or short naps during the day, as needed, for fatigue.

4. Advise limiting caffeine intake during the day, especially after 4:00 P.M.
5. Discourage alcohol as a sleep aid; instead, advise patient to discuss sleep problems with health care provider.

Strengthening Roles

1. Encourage patient to look at fibromyalgia as a chronic condition that can be controlled.
2. Suggest a fibromyalgia support group.
3. Tell the patient that fibromyalgia is not a progressive debilitating disease and that most people gain control of their symptoms.
4. Help patient plan schedule and pace activities to accomplish routine activities.

Patient Education and Health Maintenance

1. Educate patient and family that fibromyalgia is a real disorder that causes pain and fatigue despite normal test results and lack of ill appearance.
2. Explain proper use of analgesics and potential adverse effects.
3. Encourage regular activity as much as possible and avoid physical and emotional stress.
4. Advise patient to discuss all types of alternative and complementary therapy with health care provider.
5. Encourage regular follow-up visits with primary care provider, rheumatologist, and physical therapist, as indicated.
6. Suggest further help and information from Fibromyalgia Network (*www.fmnetnews.com*) or the Arthritis Foundation (*www.arthritis.org*). Many local support groups are also available through community hospitals.

Evaluation: Expected Outcomes

- States pain at 0 to 2 level.
- Sleeping 8 hours per night with 0 to 1 short awakenings.
- Goes to work; takes care of children.

Other Rheumatologic Disorders

A number of other conditions affect the joints and periarticular tissue. Nursing care for patients with these disorders is similar to that for RA (see page 826).

Seronegative Spondyloarthropathies

Seronegative spondyloarthropathies are inflammatory conditions with negative RF or other autoantibodies, but are associated with HLA-B27 antigen. NSAIDs are generally used for treatment, but DMARDs and biologic agents may also be used. Seronegative spondyloarthropathies include the following:

1. Ankylosing spondylitis (AS)—characterized by lower back stiffness (sacroiliac involvement), uveitis, cardiac, and decreased chest expansion. Untreated AS may result in fusion of affected joints.
2. Reiter disease—characterized by the triad of urethritis, arthritis, and conjunctivitis.
3. Arthritis-associated inflammatory bowel disease—overlap of ulcerative colitis and arthritis of the large and small joints, with synovitis.
4. Psoriatic arthritis—characterized by arthritis with synovitis, enthesitis, and the skin lesions of psoriasis.

Additional Common Rheumatic Diseases

1. Polymyositis (dermatomyositis if rash around the eyes is present)—an inflammatory disease of striated muscles that most commonly affects the proximal limb girdle, neck, pharynx, proximal third of the esophagus, and occasionally the heart. Corticosteroids and methotrexate are used for treatment, but response is slow.
2. Calcium pyrophosphate dihydrate crystal deposition disease, also known as pseudogout—results in crystal deposition in the joint cartilage and menisci, bursae, and periarticular tissue and can present similar to gout. Treatment is similar, although urate-lowering therapies have no place in treatment.
3. Polymyalgia rheumatica—an inflammatory disease with elevated ESR that affects mostly women older than age 50 and presents with profound stiffness, usually in the shoulder girdle and hips. It responds well to low-dose corticosteroids.
4. Sarcoidosis—a chronic, granulomatous multisystem disorder that most notably affects the lungs but can mimic rheumatic disease by causing fever, arthritis, uveitis, myositis, and rash. May also be treated with steroid-sparing DMARDs and biologic agents, such as infliximab or adalimumab.

Infection Prevention

Selected Infectious Diseases

Hot Topics in Communicable Diseases

OVERVIEW AND ASSESSMENT

An infection results when a microorganism or pathogen colonizes a host organism, using its resources to live and replicate. A disease results when there is a change or impairment of normal tissue function because of the pathogen. An infectious disease differs from other types of disease, in that it is transmissible from the host to other individuals.

Public health experts agree and literature supports that infection prevention can positively impact patient outcomes. Being a primary advocate of patient safety, nurses have a significant responsibility to learn about and ensure that infection prevention strategies are part of practice and being upheld at the bedside as well as in the community settings.

The Infectious Disease Process

The chain of infection includes six components that must be in succession for any infectious disease to evolve. If one link is eliminated from the chain, then transmission of the pathogen will not occur. Infection control strategies are based on breaking the chain of infection. The six components of the chain of infection include the pathogenic microorganism, reservoir, portal of exit from reservoir, mode of transmission, portal of entry into host, and susceptible host (Figure 31-1).

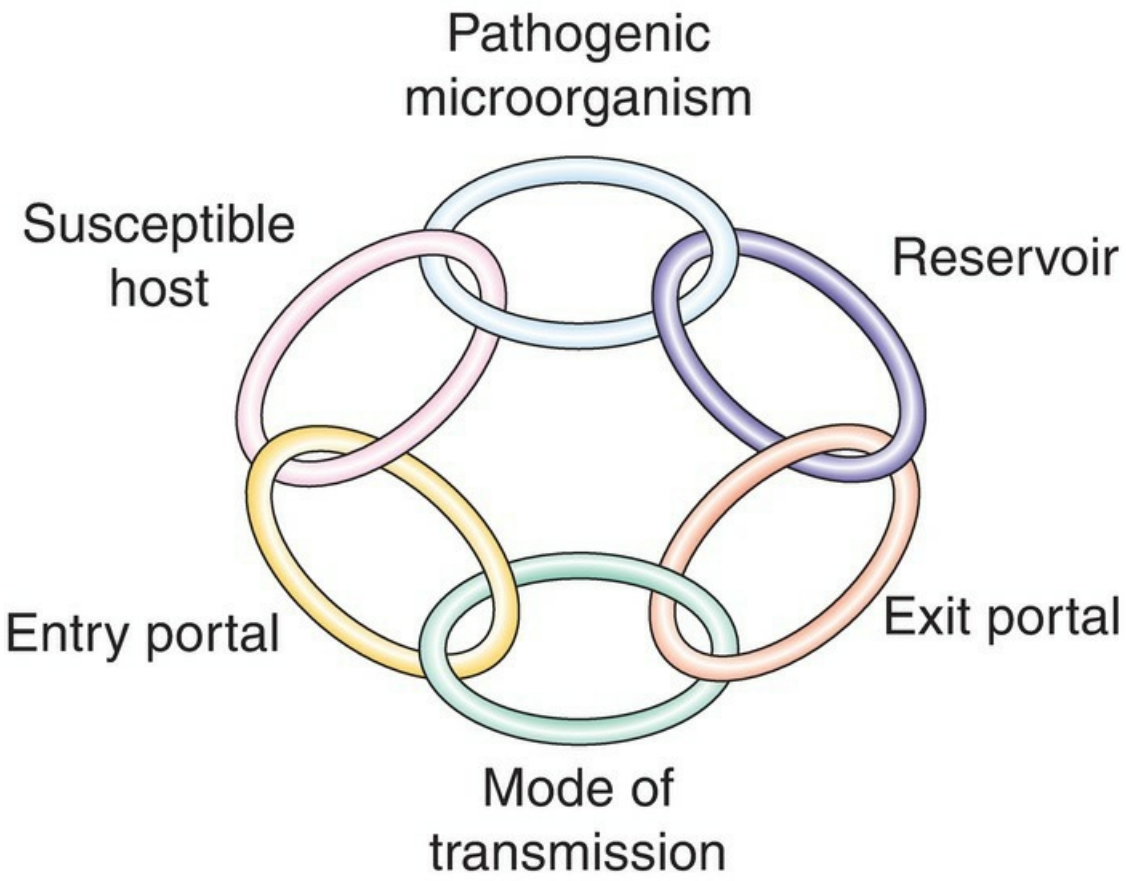

Figure 31-1. Chain of infection.

Pathogenic Microorganism

Must be able to enter the body and invade or colonize host tissue by attaching to specific host cells then cause damage to those cells by production of toxins or destructive enzymes. The pathogen may enter the body through a body orifice or broken skin.

Types

There are six types of infectious agents: bacteria (including mycobacteria), viruses, fungi, protozoa, helminths, and prions.

Characteristics

1. Pathogenicity—ability to produce disease.

2. Virulence—disease severity.
3. Infectious dose—number of organisms needed to initiate infection.
4. Toxigenicity—capacity to produce injurious substances that damage the host.
5. Adaptability—ability to adjust to changing conditions, that is, resistance to antimicrobial agents (see Table 31-1).

Table 31-1 Multidrug-Resistant Organisms (MDROs)

ORGANISM	OVERVIEW AND TRANSMISSION	PREVENTION (ALL)
Methicillin-resistant *Staphylococcus aureus* (MRSA)	Found in various body sites but especially in nares and on skin. Can produce toxins and invade body tissues. Transmitted via direct and indirect contact. Drug of choice: vancomycin.	• Hand hygiene with soap or alcohol-based hand sanitizer. • Use of gloves and gowns for patient contact. • Isolate patient in private room or cohort patients with the same organisms on contact isolation. • Use disposable equipment or disinfect reusable items after removal from room. • Utilize a system for prompt identification and isolation of patients upon readmission and for discharge planning. • Health care worker, patient and family education.
Vancomycin-resistant enterococci (VRE)	Found in GI tract and female GU tract. Not highly pathogenic but can cause serious illness in immunocompromised persons. If infection occurs, treatment options are limited. Transmitted via direct and indirect contact.	
Vancomycin-intermediate *or -resistant Staphylococcus aureus* (VISA/VRSA)	Transmitted via direct and indirect contact. Must be reported to the Centers for Disease Control and Prevention (CDC) and the local health department. Strictly follow contact precautions and dedicate staff for one-to-one care. Treatment options are limited.	
Multidrug-resistant gram-negative rods such as *Escherichia coli*, *Klebsiella pneumoniae*, *Acinetobacter* species, and *Pseudomonas aeruginosa*.	Found in various body sites, especially sputum. Spread via direct and indirect contact.	
Emerging MDROs • Extended-spectrum metallo-beta lactamase (ESBLs) producers • Carbapenem-resistant enterobacteriaceae (CRE) • New Delhi metallo-beta lactamase	Produced by some gram-negative bacteria, making them resistant to multiple antibiotics. Spread via direct and indirect contact. Limited treatment options because of resistance. There is world-wide concern for growing pan-resistance creating "super-bugs".	

Reservoir

The environment in which a pathogenic microorganism lives and survives naturally, can be human, animal, or environmental. Examples of each type include:

1. Human—*Mycobacterium tuberculosis* in human lungs.
2. Animal—Zika virus via *Aedes aegypti* and/or *Aedes albopictus* mosquitoes.
3. Environment—Legionnaires disease (*Legionella pneumophila*) through water.
4. Fomite—Methicillin (oxacillin)-resistant *Staphylococcus aureus* bacteria on a bedside table.

Portal of Exit from Reservoir

The portal of exit are routes in which infectious agents leave their reservoir and include:

1. Droplets from the respiratory tract.
2. Vomitus and feces.
3. Body fluids (except for sweat).

Mode of Transmission

How the pathogenic microorganism is spread to a host by an infectious source. Horizontal transmission is the

spread of a pathogen from one individual to another individual. Vertical transmission is from mother to offspring via transplacental transmission, contact through the birth canal, or through breastfeeding or close contact after birth.

There are two main types of transmission: direct and indirect.

Direct Transmission

1. Direct contact—by touching the reservoir (eg, touching a wound infection with MRSA) or sexual contact (eg, human papillomavirus).
2. Droplet transmission.
    a. Droplets of large particles more than 5 microns in size usually from respiratory secretions.
    b. Transmitted through coughing, sneezing, or talking to an infected person (eg, human metapneumovirus spread through coughing).
    c. Transmitted through aerosolizing procedures (eg, sprays of infectious agents during a nebulization treatment or a sputum induction).
3. Airborne transmission.
    a. Droplet nuclei—less than 5 microns that remains suspended in air (eg, Tuberculosis and Varicella [Primary Chickenpox]).
    b. Dust particles in the air containing the infectious agent (eg, *Aspergillus* fungi through dust).

Indirect Transmission

Touching an inanimate object or fomite that has had direct contact with the reservoir (eg, touching a tissue of a child with Influenza virus or touching a bedside table contaminated with *Clostridium difficile*).

1. Common vehicle route (through contaminated items).
    a. Food (eg, *Salmonella* and *Campylobacter*).
    b. Water (eg, *Vibrio cholera* and *Legionella* species).
    c. Medications (eg, bloodborne pathogens including hepatitis B, hepatitis C, and HIV from contaminated multidose vials).
2. Vector-borne transmission.
    a. A living creature acts as an intermediary acquiring a pathogen from one living host and transmits the disease agent to another living organism, often an arthropod (fly, mosquito, tick).
    b. Can be mechanical or biological vectors. Mechanical transmission occurs when the vector transports the pathogen on its feet or body surfaces to the host. Biological transmission occurs when the vector takes the pathogen into its body where it develops, produces copies, and then is put in the host by bite or sting, such as the plague transmitted by infected fleas from rats to humans.

Portal of Entry

Defined as how an infectious agent enters a new host. Entry sites include:

1. Respiratory tract

2. Gastrointestinal/genitourinary
3. Mucous membranes
4. Nonintact skin
5. Blood

Susceptible Host

Host susceptibility is determined by a complex interrelationship between host and an infectious agent, by factors that influence infection or disease, such as:

1. Pathogenicity—the ability to produce disease in a host. The organism invades a host, enters tissue, colonizes then spreads from host to host while not necessarily causing death to the host.
2. Virulence—the wide range of damage that can occur to the host because of the toxic capabilities of the pathogen. Given that the host–pathogen relationship is fluid, the outcome can be dictated by:
    a. Number of pathogens to which the host is exposed; route and duration of exposure.
    b. Invasiveness of the pathogen and its ability to produce toxins.
    c. Ability to bypass or overcome host defense mechanisms (immunologic response).
3. Host factors—susceptibility of the new host to infection including age, nutritional status, immune status (eg, vaccination), genetic constitution, and general physical, mental, and emotional health and nutritional status of host.

Collection of Specimens for Infectious Disease Identification

EVIDENCE BASE Leber, A. L. et al. (Ed.-in-Chief). (2016). *Clinical microbiology procedures handbook* (4th ed.). Washington, DC: American Society for Microbiology Press.

Proper collection and transport of laboratory specimens is important to maximize the outcome of tests for the diagnosis of infectious diseases. A variety of laboratory tests can be performed to make a presumptive or definitive diagnosis so that therapy can begin.

Principles

1. Review local laboratory guidelines for the specimen collection recommendations for each test. These guidelines should be readily available and include information on the appropriate specimen containers, sample size, and transport requirements (temperature, time, etc.).
2. It is imperative that specimens be collected and handling carefully by following standard precautions (see Standards of Care Guidelines 31-1).

STANDARDS OF CARE GUIDELINES 31-1

Universal Precautions (Referenced OSHA 1910.1030)

These infection control precautions are mandated by the Occupational Safety and Health Administration (OSHA) and recommend that all blood and certain body fluids are treated as potentially infectious for human immunodeficiency virus (HIV), hepatitis B virus (HBV), hepatitis C virus (HCV), and other bloodborne pathogens:

- Employers are required to provide appropriate personal protective equipment (PPE) and other engineering/work practice controls to eliminate or minimize employee exposure to bloodborne pathogens as mandated in OSHA regulation 1910.
- Gloves are to be worn when there is anticipation of contact with blood, other potentially infectious materials, mucous membranes, and nonintact skin.
- Gowns, aprons, or other protective body clothing are to be worn when contamination of clothing with blood or other potentially infectious materials is anticipated.
- Masks in combination with protective eyewear are to be worn when performing procedures likely to generate sprays or splashes of blood or other potentially infectious materials into the eyes, nose, or mouth.
- Hands and other skin surfaces are to be washed immediately if contaminated with blood or other potentially infectious materials.
- Utilize safety devices for needles and other sharps and do not manipulate by hand (eg, recapping, purposely bending or breaking, or removing from syringes, etc.).

- Needles and other sharps are to be placed in puncture-resistant containers for disposal.
- All specimens and items with blood or other potentially infectious materials are to be transported in containers that prevent leakage.
- Blood and body fluid spills are to be cleaned up promptly with an appropriate germicide, such as a bleach solution or phenolic.

3. Specimen collection should occur before the initiation of antibiotic therapy whenever possible.
4. To prevent contamination, specimens should be collected using aseptic technique.
5. Obtain an adequate amount of the specimen necessary for all tests.
6. Label the container properly according to local laboratory protocol with at least two patient identifiers (eg, patient's name, date of birth, medical record number) and include on a requisition the source of the specimen, date and time collected, test to be performed, and any special instructions.
7. Seal specimen containers tightly and place in a biohazard bag to transport the specimen to the laboratory as soon as possible according to laboratory guidelines.
8. Be familiar with hospital policy recommending the transport of specified pathogens by staff personnel to the laboratory instead of via a pneumatic tube system.

Types of Specimen Collection

Blood Culture

1. Normally a sterile body fluid.
2. Specimens obtained by peripheral venipuncture are preferred over sampling from vascular catheters because of contamination of the catheter. Culturing hardware to determine a central line infection is not recommended in the literature.
3. Aseptic technique is essential to avoid contaminating the specimen with organisms colonizing the skin or the collector's hands.
4. Cleanse the venipuncture site with 70% alcohol followed by povidone iodine or chlorhexidine gluconate and allow to fully dry.
5. The diaphragm tops of the culture bottles are not sterile and must be cleaned with alcohol before injection of blood.

Urine Culture

1. Normally a sterile body fluid.
2. A clean-catch, midstream urine collection provides the best method for obtaining a specimen to detect a urinary tract infection.
3. Patients who are catheterized should have the specimen withdrawn using a sterile syringe from the catheter sampling port.
4. Urine specimens must be transported to the laboratory promptly. If not cultured within 30 minutes of

collection, urine must be refrigerated and cultured within 24 hours.

5. Other types of urine specimens may be collected, such as a straight in-and-out catheter specimen or suprapubic bladder drainage.

Stool Culture

1. Obtained to culture organisms that are not part of the normal bowel flora (eg, *Salmonella* species, *Shigella* species).
2. Patient should defecate into a sterilized container or bedpan. Stool specimens should not contain urine or water from the toilet bowl.
3. Stool specimens can also be obtained directly from the rectum using a sterile swab.

Sputum Culture

1. Specimen needs to be from the lower respiratory tract, not oropharyngeal secretions. The laboratory will perform a Gram stain on all sputum specimens to determine if they are representative of pulmonary secretions and appropriately collected. A specimen containing a majority of cells from squamous epithelium may be rejected.
2. The most common method of collection is expectoration from a cooperative patient with a productive cough. Early morning is the optimal time to collect sputum specimens.
3. A sputum specimen can be collected in a sputum trap from patients who have artificial airways and require suctioning.
4. If a patient cannot produce sputum, sputum induction using an aerosol nebulizer may assist with loosening thickened secretions.
5. Bronchoscopy may be required to obtain sputum if induction fails.

Wound Culture

1. Specimens are usually cultured for aerobic and anaerobic organisms.
2. Specimens may be collected by multiple techniques, depending on the depth of the wound, including tissue samples, needle aspiration, and swabbing the surface.
3. Surface cultures are not as valuable as can often be heavily contaminated and hard to distinguish the causative infectious agent.
4. To collect a wound culture using a sterile swab, cleanse the surface with 70% alcohol and collect as much exudate as possible from the advancing margin of the lesion. Avoid swabbing surrounding skin.
5. Place the swab immediately in appropriate transport culture tube and send to the laboratory.
6. Label with the specific anatomic site.

Throat Culture

1. Use a tongue depressor to hold the tongue down.
2. Carefully yet firmly rub swab over areas of exudate or over the tonsils and posterior pharynx, avoiding the cheeks, teeth, and gums.

3. Insert swab into packet and follow directions for handling the transport medium.

Laboratory Tests

Microbiologic Evaluation

Microscopy

1. Microscopic examination distinguishes tissue cells from microorganisms.
2. Various stains are used to highlight the structural characteristics of microorganisms (eg, Gram stain to identify groups of bacteria, acid-fast stains to isolate mycobacteria).
3. Classification is conducted according to physical appearance such as shape, size, or tendency to form chains or clusters and stain reactions such as gram-positive versus gram-negative.
4. Results of microscopy are usually available within minutes, which permits early initiation of treatment based on a presumptive diagnosis.

Culture

1. Culture was the gold standard for positive identification of many microorganisms, although technological advances have transitioned to molecular and other innovative testing for several microbes.
2. Different culture media are used for suspected pathogens and can be selective (allow growth of only certain microorganisms) and/or differential (distinguish between different bacteria based on different characteristics).
    a. A liquid medium is used for blood specimens because lower numbers of microorganisms are detectable.
    b. A solid medium is used to isolate mixtures of organisms and grow pure cultures of each type of organism found.
3. Recovery of pathogens from culture varies depending on the microorganism type, test selected, and stage of illness.
    a. Most common pathogens, such as staphylococci, streptococci, and enterococci, are often identifiable to genus and species within 48 hours.
    b. Fungal organisms may take 10 to 14 days to grow in culture medium.
    c. Viruses may take 2 to 3 weeks to grow in culture medium.
    d. Mycobacteria may take up to 6 weeks to grow in culture medium.

Mass Spectrometry

1. Biomolecules absorb energy from a short laser pulse to become ionized which are then accelerated in an electrical field and collide with a detector. They are then separated based upon their mass to charge ratio and leads to molecular detections into mass spectrum.
2. Based upon databases of mass spectrum profiles, identifies a microorganism, including bacteria and fungus, to the genus and species level within minutes versus several hours to days with traditional cultures.

Antibiotic Susceptibility Testing

1. Used to determine minimal concentration of antibiotics that will inhibit growth of an organism.
    a. Minimum inhibitory concentration (MIC) is the lowest concentration of an antimicrobial drug that will inhibit organism growth and is measured by the size of the zone around the antimicrobial disk in which growth is inhibited.
    b. Based on Clinical and Laboratory Standards Institute (CLSI) guidelines for each organism, the size of the inhibitory zone diffusion tests are interpreted as resistant (R), sensitive (S), and intermediate (I).

Molecular Testing

1. There are several technologies to detect specific genetic portions of pathogenic organisms or to identify the specific host's response to the presence of the pathogen. Examples include DNA probe testing and polymerase chain reaction (PCR).
2. These tests may be more sensitive for lower amounts of organism and often yield a more rapid result than culture.
3. Some tests including multiplex PCRs, detect the presence of multiple organisms at once such as respiratory viruses or gastrointestinal infectious agents.

White Blood Cell Count

1. An increase in white blood cell count or "leukocytosis" may indicate infection, inflammatory response, tissue necrosis, or bone marrow failure.
2. The total number of circulating leukocytes and the differential (given as a percent of the total white blood cell [WBC] count) may change during a bacterial or viral infection.
3. During an acute bacterial infection, the WBC count often increases (greater than 11,000/mm^3), accompanied by increased neutrophils and increased bands (immature neutrophils) in the differential. The shift (to the left) in differential reflects phagocytic activity.

Immunologic Tests

1. Pathogens that are antigenic stimulate antibodies that can be detected in the serum of patients.
2. Detection of antibodies is not necessarily diagnostic of current infection.
3. Antigen–antibody reactions must be evaluated over a period of time.
4. Immunoglobulin M (IgM) antibody production peaks during active infection and decreases during convalescence.
5. IgG antibodies peak during convalescence and persist.
6. A fourfold rise in antibody titer between the acute and convalescence samples indicates recent infection.

GENERAL PROCEDURES AND TREATMENT MODALITIES

Immunity

The human body is equipped with defense mechanisms to protect against disease. These include anatomical barriers, such as the skin, and physiological barriers, such as enzymes in saliva. The normal flora of microorganisms on and in the body also helps to prevent invasion of pathogens. If these nonspecific defense mechanisms fail, the body's specific immune response usually provides protection. Specific immunity to a particular organism implies that an individual has either generated the appropriate antibody in his or her own body or received ready-made antibodies from another source. Immunity may be natural or acquired or passive or active.

Natural active immunity occurs when antibodies are acquired following an infection. Antibodies are also acquired through natural passive immunity, such as from mother to fetus through the placenta or to infant via breast milk.

Passive artificial immunity is achieved through administration of immune globulin or antitoxin. *Active artificial immunity* occurs when antibodies are produced in response to a vaccine or toxoid (see Table 31-2).

Table 31-2 ecommended Immunization Schedule for Adults Aged 19 Years or Older, United States, 2018

Vaccine	19–21 years	22–26 years	27–49 years	50–64 years	≥65 years
Influenza	1 dose annually				
Tdap or Td	1 dose Tdap, then Td booster every 10 yrs				
MMR	1 or 2 doses depending on indication (if born in 1957 or later)				
VAR	2 doses				
RZV (preferred)				2 doses RZV (preferred)	
or				or	
ZVL					1 dose ZVL
HPV–Female	2 or 3 doses depending on age at series initiation				
HPV–Male	2 or 3 doses depending on age at series initiation				
PCV13	1 dose				
PPSV23	1 or 2 doses depending on indication				1 dose
HepA	2 or 3 doses depending on vaccine				
HepB	3 doses				
MenACWY	1 or 2 doses depending on indication, then booster every 5 yrs if risk remains				
MenB	2 or 3 doses depending on vaccine				
Hib	1 or 3 doses depending on indication				

Recommended for adults who meet the age requirement, lack documentation of vaccination, or lack evidence of past infection

Recommended for adults with other indications

No recommendation

There has been debate over the possibility of a link between childhood vaccines and subsequent development of autism. Public fear and refusal to obtain childhood vaccines for preventable diseases has shown an increase of these diseases in the community. There have been multiple studies in the scientific community to refute these fears (see cdc.gov/vaccinesafety/research/index.html).

Vaccines are the best protection against infections that may cause serious complications and possible poor outcomes in children and adults.

For further updated recommendations see *www.cdc.gov/vaccines/schedules/hcp/imz/adult.html* and

www.cdc.gov/vaccines/schedules/hcp/imz/child-adolescent.html.

Infection Prevention

Health care–associated infections (HAIs) occur when a patient comes to a health care facility and acquires a new infection during their care. HAIs affect 722,000 patients a year (2011) and 75,000 of those people die annually as a result. Approximately 1 in 25 hospital patients has a HAI. The majority of these infections, however, are potentially preventable by following infection prevention practices.

Infection prevention efforts include surveillance and reporting, monitoring transmission of multidrug-resistant organisms (MDROs), hospital-wide hand hygiene compliance, antimicrobial stewardship, and cleaning and disinfection. In addition, occupational health measures include vaccine compliance, staff education, and performance improvement initiatives to reduce HAIs. Infection prevention strategies are aimed at breaking the chain of infection.

HAI Surveillance

1. The four most common HAIs for which hospitals perform surveillance are:
    a. Surgical site infection (SSI).
    b. Central line–associated bloodstream infection (CLABSI).
    c. Ventilator-associated events (VAE).
    d. Catheter-associated urinary tract infection (CAUTI).
2. HAI rates are increasingly being used as indicators of quality and patient safety in health care facilities.
3. Hospitals are reporting infection rates to the National Health Safety Network, part of the Centers for Disease Control and Prevention (CDC), and the data is being published and made available to the public via state/local health department Web sites and Centers for Medicare and Medicaid's Hospital Compare site.
4. Each year, the bottom quartile of performers in hospital quality metrics including HAI rates receive a penalty of reduced CMS reimbursement of expenses.

Fundamentals of Standard Precautions

Standard precautions were issued by the CDC as an isolation guideline for hospitals but have become common practice for the care of all patients in any setting, every time. They apply to (1) blood; (2) all body fluids, secretions, and excretions, regardless of whether or not they contain visible blood; (3) nonintact skin; and (4) mucous membranes. If there is a chance of coming into contact with a potentially infectious material, a barrier is recommended to be placed between the patient and the care provider. The barrier may be a gown, glove, mask, or goggles, depending on the reason and area of contact.

Hand Hygiene

1. Hand hygiene is the single most recommended measure to reduce the risks of transmitting microorganisms.
2. Hand hygiene should be performed between patient contacts; after contact with blood, body fluids, secretions, excretions, and contaminated equipment or articles; before donning and after removing gloves

is vital for infection control. It may be necessary to clean hands between tasks on the same patient to prevent cross-contamination of different body sites.

3. To perform hand hygiene, clean hands with soap and water, applying friction for 15 seconds upon all surfaces of the hands, or applying alcohol-based waterless hand sanitizer covering all surfaces of both hands until completely dry.
4. Waterless hand cleaners are recommended unless there is visible soil on the hands, before eating, after using the restroom, and when there is significant buildup of waterless hand cleaners.
5. If caring for a patient with a spore-producing pathogen such as *C. difficile*-associated disease (CDAD), then use hand hygiene with soap and water applying friction for 15 seconds, as the spores this organism forms are resistant to alcohol hand gel.
6. Similarly, for other pathogens known or suspected to be resistant to alcohol waterless hand gels—such as *Norovirus*—hand hygiene with soap and water while applying friction for 15 seconds.

Respiratory Hygiene/Cough Etiquette

1. When coughing or sneezing, cover the mouth and nose with a tissue or the fabric of your sleeve.
2. Use the nearest waste receptacle to dispose of the tissue after use.
3. Perform hand hygiene immediately.
4. Apply a mask when coughing or sneezing to contain secretions.
5. Sit at least 3 feet from others.

Transmission-Based Precautions

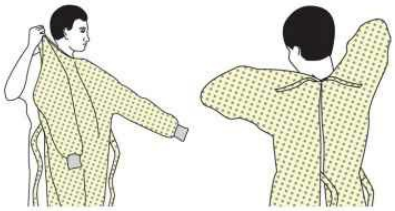
In addition to standard precautions, the CDC recommends instituting transmission-based precautions when there is a suspicion for, or a laboratory confirmed case involving, an epidemiologically significant pathogen. There are three types of transmission-based precautions recommended by the CDC: contact, droplet, and airborne. Each type of isolation takes into account the pathogen and its mode of transmission. Always refer to each health care facility's infection control policies as hospitals may be more restrictive than the CDC recommendations influenced by endemic or newly emerging pathogens in that region. Care should be taken when donning and doffing personal protective equipment (PPE) to avoid contamination. See Figure 31-2.

SEQUENCE FOR PUTTING ON PERSONAL PROTECTIVE EQUIPMENT (PPE)

The type of PPE used will vary based on the level of precautions required, such as standard and contact, droplet or airborne infection isolation precautions. The procedure for putting on and removing PPE should be tailored to the specific type of PPE.

1. GOWN

- Fully cover torso from neck to knees, arms to end of wrists, and wrap around the back
- Fasten in back of neck and

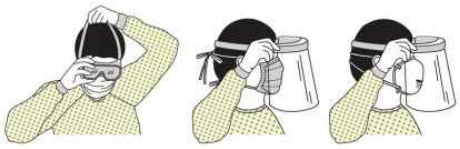


2. MASK OR RESPIRATOR

- Secure ties or elastic bands at middle of head and neck
- Fit flexible band to nose bridge
- Fit snug to face and below chin
- Fit-check respirator

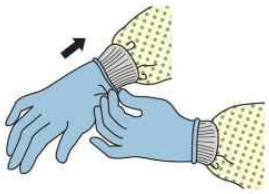
3. GOGGLES OR FACE SHIELD

- Place over face and eyes and adjust to fit



4. GLOVES

- Extend to cover wrist of isolation gown



USE SAFE WORK PRACTICES TO PROTECT YOURSELF AND LIMIT THE SPREAD OF CONTAMINATION

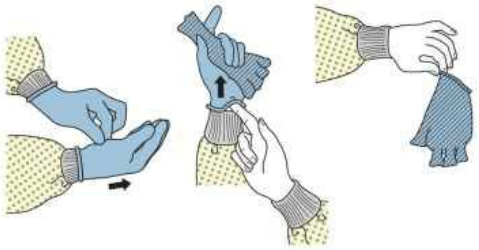
- Keep hands away from face
- Limit surfaces touched
- Change gloves when torn or heavily contaminated
- Perform hand hygiene

HOW TO SAFELY REMOVE PERSONAL PROTECTIVE EQUIPMENT (PPE) EXAMPLE 1

There are a variety of ways to safely remove PPE without contaminating your clothing, skin, or mucous membranes with potentially infectious materials. Here is one example. **Remove all PPE before exiting the patient room** except a respirator, if worn. Remove the respirator **after** leaving the patient room and closing the door. Remove PPE in the following sequence:

1. GLOVES

- Outside of gloves are contaminated!
- If your hands get contaminated during glove removal, immediately wash your hands or use an alcohol-based hand sanitizer
- Using a gloved hand, grasp the palm area of the other gloved hand and peel off first glove
- Hold removed glove in gloved hand
- Slide fingers of ungloved hand under remaining glove at wrist and peel off second glove over first glove
- Discard gloves in a waste container



2. GOGGLES OR FACE SHIELD

- Outside of goggles or face shield is contaminated!
- If your hands get contaminated during goggle or face shield removal, immediately wash your hands or use an alcohol-based hand sanitizer
- Remove goggles or face shield from the back by lifting head band or ear pieces
- If the item is reusable, place in designated receptacle for reprocessing. Otherwise, discard in a waste container

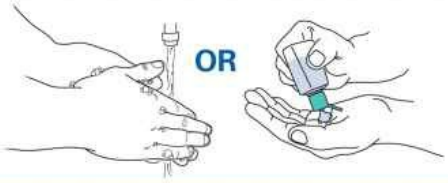
3. GOWN

- Gown front and sleeves are contaminated!
- If your hands get contaminated during gown removal, immediately wash your hands or use an alcohol-based hand sanitizer
- Unfasten gown ties, taking care that sleeves don't contact your body when reaching for ties
- Pull gown away from neck and shoulders, touching inside of gown only
- Turn gown inside out
- Fold or roll into a bundle and discard in a waste container

4. MASK OR RESPIRATOR

- Front of mask/respirator is contaminated — DO NOT TOUCH!
- If your hands get contaminated during mask/respirator removal, immediately wash your hands or use an alcohol-based hand sanitizer
- Grasp bottom ties or elastics of the mask/respirator, then the ones at the top, and remove without touching the front
- Discard in a waste container

5. WASH HANDS OR USE AN ALCOHOL-BASED HAND SANITIZER IMMEDIATELY AFTER REMOVING ALL PPE



PERFORM HAND HYGIENE BETWEEN STEPS IF HANDS BECOME CONTAMINATED AND IMMEDIATELY AFTER REMOVING ALL PPE

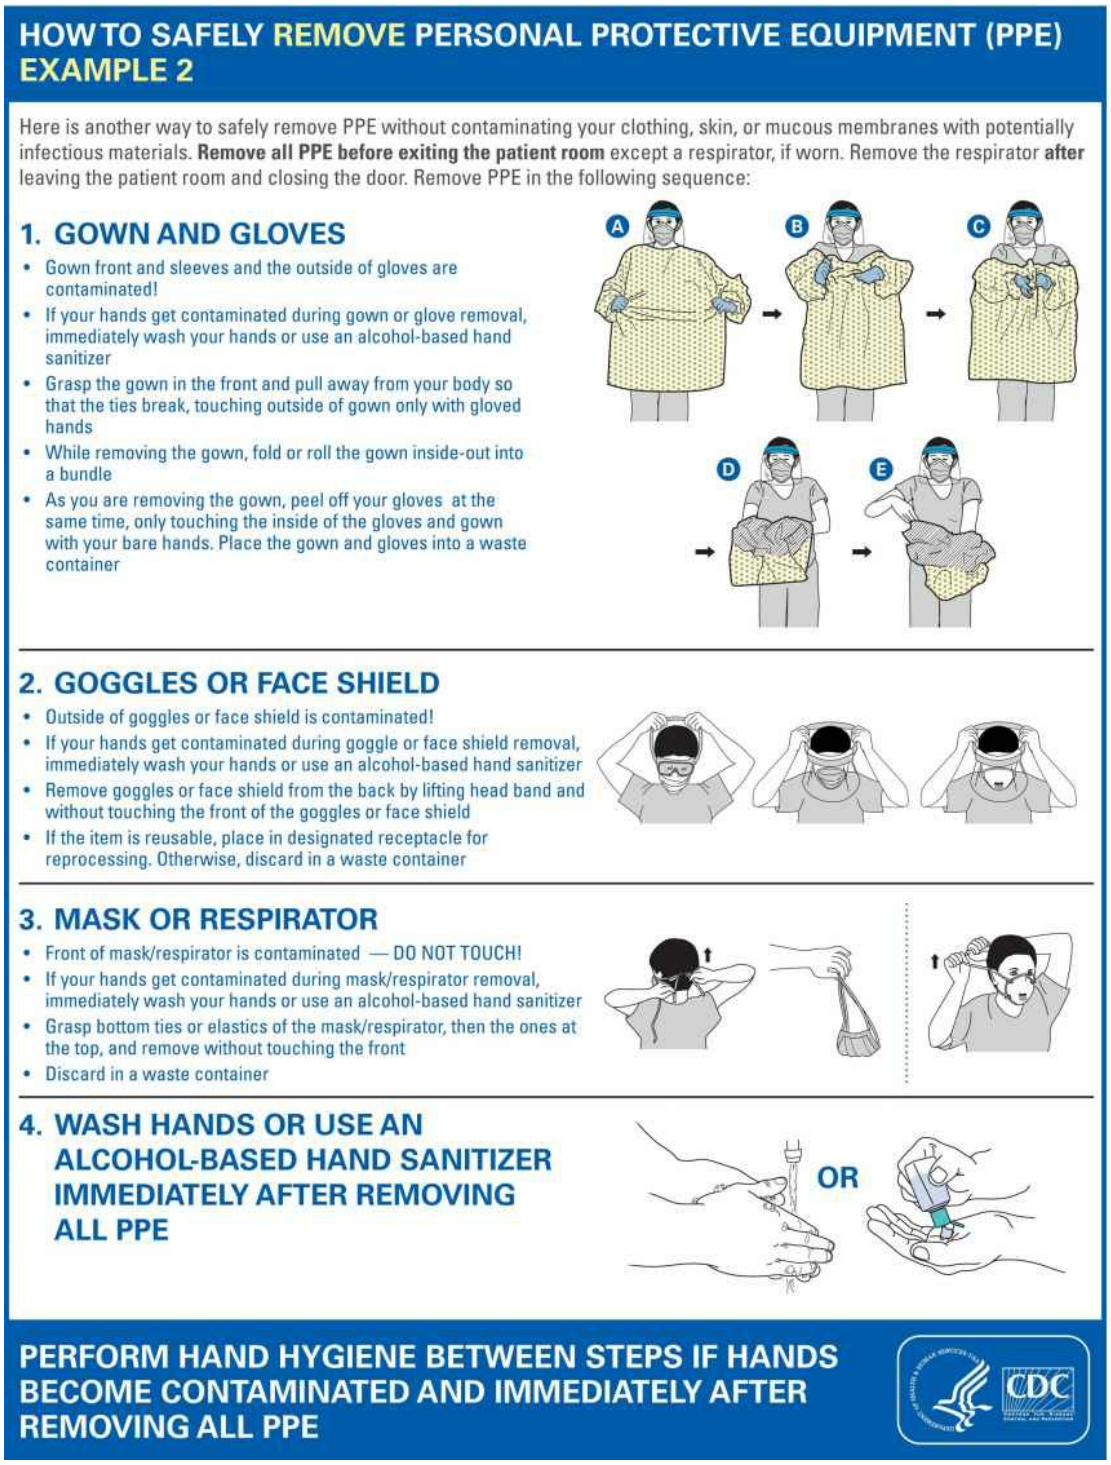


Figure 31-2. CDC guide to donning and doffing PPE (https://www.cdc.gov/hai/pdfs/ppe/ppe-sequence.pdf).

NURSING ALERT Standard precautions are recommended for the care of each patient in all circumstances even if already on another type of isolation. When possible, dedicate the use of noncritical patient care equipment to a single patient. Thoroughly clean and disinfect reusable equipment before use on

another patient.

Contact Precautions

1. Used for patients known or suspected to be infected or colonized with epidemiologically significant microorganisms, which can be transmitted by direct contact with the patient or indirect contact with environmental surfaces (fomites) or patient care items in the patient's environment.
2. Examples of microorganisms requiring contact precautions:
   a. Methicillin (oxacillin)-resistant *Staphylococcus aureus* (MRSA).
   b. Vancomycin-resistant *Enterococcus*.
   c. Vancomycin-intermediate or vancomycin-resistant *S. aureus*.
   d. CDAD.
3. Place the patient in a private room or in a room with a patient who has the same microorganism (cohorting).
4. Wear PPE when entering a room marked as contact isolation, including gloves and a gown (see Box 31-1). Many hospitals encourage visitors to follow the same precautions.
5. All equipment, including intravenous poles, handles on carts, and other devices, should be cleaned, disinfected, and identified as clean prior to transport in halls, elevators, or before provided to a new patient—doing so protects the environment, staff, visitors, and patients from contamination with potentially infectious germs.

BOX 31-1 Personal Protective Equipment

GLOVES

Gloves are worn to provide a protective barrier and prevent gross contamination of the hands of health care workers; if used properly, they reduce the transmission of microorganisms and help prevent cross-contamination within a patient. Wearing gloves does not replace the need for hand hygiene because gloves may have small defects or may be torn during use, and during the removal of gloves, hands may become contaminated.

- Perform hand hygiene before putting on gloves.
- Change gloves after contact with infective material, such as feces and wound drainage.
- Remove gloves before leaving the patient's environment and perform appropriate hand hygiene immediately with soap and water or alcohol-based waterless antiseptic agent.
- Gloves also must be changed between procedures on the same patient, such as central line dressing change and wound care or catheter drainage bag manipulation.
- As a general practice, examination gloves are not to be worn outside a patient's room.

GOWNS

Gowns are to be worn during the care of patients infected with epidemiologically significant pathogens to reduce contamination of the health care worker's clothing. Contaminated clothing can transmit pathogens to patients.

- The gown must be tied at the neck and sides, covering the nurse completely.
- If the gown is too small, two gowns can be used to cover any exposed areas of the nurse.
- Water-impermeable gowns, leg coverings, boots, or shoe covers provide greater protection to the skin when large splashes of blood or body fluid are possible such as in the OR.
- Gowns must be removed and discarded prior to leaving the patient's environment, and appropriate hand hygiene must be performed.

Droplet Precautions

1. Designed for care of patients known or suspected to be infected with microorganisms transmitted by large-particle droplets generated by the patient when coughing, sneezing, talking, or during the performance of certain procedures, such as sputum induction or nebulization.
2. These large-particle droplets fall out of the air 3 to 6 feet from the patient's mouth so use of surgical mask, eye protection, gown, and gloves is mandatory.
3. Examples of illnesses requiring droplet precautions: *Neisseria meningitidis*, pneumonic plague, scarlet fever, pertussis, adenoviruses, parainfluenza viruses, influenza, respiratory syncytial virus, human metapneumovirus, rhinovirus, mumps, parvovirus B12, rubella.
4. Place the patient in a private room.
    a. When a private room is not available, place patients with the same microorganism together (cohorting).
    b. If neither of these is possible, maintain spatial separation of at least 3 feet between the infected patient and other patients and visitors.
5. Special air handling and ventilation are not necessary and the door may remain open.
6. PPE includes surgical masks; gowns and gloves may also be required based on the disease, refer to the disease-specific hospital policy.
    a. Wear a mask when working within 3 feet (0.9 m) of the patient.
    b. To protect the mucous membranes of the eyes, nose, and mouth, masks and goggles or face shields are worn by health care workers during patient care to protect against splashes or sprays of blood, body fluids, or secretions.
7. Limit transport of the patient from the room for essential purposes only. If transport is necessary, minimize dispersal of droplets by masking the patient immediately prior to and during transport. See below for additional measures.

Airborne Precautions

1. Designed to reduce the risk of airborne transmission of infectious agents through dissemination of small-droplet nuclei less than 5 microns in size, which remain suspended in the air for long periods of time.
2. Microorganisms can be dispersed widely by air currents and may become inhaled by or deposited on a susceptible host within the same room or over a longer distance from the source patient. Therefore, special air handling, filtration, and ventilation are required.

3. Examples of illnesses requiring airborne precautions: measles, varicella (including disseminated zoster), and tuberculosis.
4. PPE—respirators are required (N95 respirator, a high-efficiency particulate air [HEPA] filter respirator, or a powered air-purifying respirator [PAPR]); gowns and gloves may also be required based on the disease, refer to the disease-specific hospital policy.
    a. Staff members are required to be trained in the use of protective respirators and/or PAPRs annually in a program of respiratory protection that includes a "fit test." This test ensures that the respirator seals to the face of the staff member, teaches the staff member how to use the respirator, and optimizes the protection for the staff member.
    b. Persons immune to rubeola or varicella need not wear a mask but must wear gown and gloves when having exposure to lesions, to prevent carrying contaminant to a nonimmune patient outside of the room.
5. Place the patient in a private room that has:
    a. Monitored negative air pressure in relation to the surrounding areas.
    b. At least 6 but preferably 12 air changes per hour.
    c. Appropriate discharge of air outdoors or monitored high-efficiency filtration of room air before recirculation.
    d. Door that is closed at all times with the patient in the room.
6. Limit the transport of the patient from the room to essential purposes only. If transport is necessary, minimize patient dispersal of droplet nuclei by placing a surgical or procedural mask on the patient. See below for additional measures.

Other Considerations

Limiting the Movement of Patients

1. Limiting the movement of patients with epidemiologically significant microorganisms reduces transmission. Every effort should be made to limit the movement of patients on airborne precautions.
2. When transport is necessary for a contact, droplet, or airborne patient:
    a. Patient should be in a clean hospital gown with clean linens.
    b. Appropriate barriers (such as masks and impervious dressings) are to be worn by the patient.
    c. Personnel in the area to which the patient is taken need notification with time to collect PPE, prepare a room that will meet specifications for the identified isolation, and communicate with cleaning staff and ensure the patient will not sit in a waiting area with other patients, visitors, and staff.
    d. Unless transporting staff are giving care during the transport, there is no need to wear PPE. If the patient may require care in the hallway, consider having two transporters: one to remain without PPE to open doors, touch elevator buttons and push the patient, whereas the other person with PPE will only touch the patient.
3. When appropriate, patients are taught how they can assist in preventing transmission.

Attention to Equipment, Linens, and Supplies

1. Medical equipment should be cleaned in-between each patient according to the equipment manufacturer's instructions for use (IFUs) according to the Spaulding classification of medical equipment.
    a. Noncritical equipment are devices such as a stethoscope and blood pressure cuff used on intact skin. Routine cleaning and low-level to intermediate-level disinfection are required.
    b. Semicritical equipment are devices such as a vaginal speculum or fiberoptic endoscope, used on mucous membranes or nonintact skin. High-level disinfection is required.
    c. Critical equipment are devices used in sterile areas of the body such as the blood stream and for surgical procedures. Sterilization is required.
2. Soiled linen should be handled, transported, and laundered in a manner that avoids transfer of microorganisms to patients, personnel, and environments in consistent with best practice guidelines. With some organisms, such as smallpox or anthrax, care must be taken to not expel the air from plastic linen bags outside of airborne patient rooms.
3. There is currently no evidence indicating a need for special precautions for dishes, glasses, cups, or eating utensils because the combination of hot water and detergents used in hospital dishwashers is sufficient for decontamination for most infectious diseases. However, appropriate hand hygiene is required when removing food trays from some isolated rooms.
4. Patient-care equipment that is soiled with blood, body fluids, secretions, and excretions must be handled in a manner that prevents skin and mucous membrane exposures, contamination of clothing, and transfer of microorganisms to other patients and environments.
    a. There must be a procedural mechanism in place labeling or otherwise identifying used equipment as not to be used on another patient.
    b. Clean and dirty equipment should be stored in separate physical locations.
    c. Reusable equipment must be transported in a manner to prevent contamination of the staff, the environment, and visitors until it reaches the area where it will be cleaned, disinfected, and reprocessed appropriately before use for another patient.
    d. Single-use items must be discarded properly.
5. Care must be taken to prevent injuries from needles, scalpels, and other sharp objects. Used needles must never be recapped using both hands, removed from syringes, bent, broken, or otherwise manipulated. Used needles and sharps must have the engineered sharps injury protection activated and be disposed of immediately into an OSHA-approved puncture-resistant container. These containers should be mounted per the National Institute of Occupational Safety and Health guidelines and be located as close as is practical to the area of use.
6. Protective mouthpieces, resuscitation bags, or other ventilation devices are used instead of mouth-to-mouth resuscitation methods.

Infection Prevention Bundles

In addition to standard and isolation precautions, hand hygiene, and appropriate equipment/supply handling, there are inclusive, grouped steps called bundles, which are evidence-based practices shown to prevent specific HAIs when all steps are followed. Bundled practices exist for the prevention of CLABSI, CAUTI, VAE, CDAD, and VAE. Bundles prevent infection through aseptic/sterile technique at the time of device insertion as well as properly maintaining devices. An essential component is daily review of necessity for indwelling devices and prompt early removal of devices and to avoid infection.

TRANSITIONAL CARE ALERT Provide education on basic infection prevention practices for all patients who will be discharged with devices and caring for them while at home. For example, for central lines, the patient should be taught to wash hands before and after touching the lines; when and how to change dressings; how to shower or bathe with the dressing (depending on the type of supplies used); ongoing monitoring for early signs and symptoms of infection; and to communicate to the health care provider immediately. Proper care of devices in the home setting will reduce the risk for infections and other complications and potential readmission to the hospital.

SELECTED INFECTIOUS DISEASES

Infectious disorders are covered throughout the book in a variety of body system chapters. See Table 31-3 for selected infectious disorders. Be aware that new data on infectious diseases are emerging daily. For the latest information on infectious diseases, contact your state public health department or the CDC at *www.cdc.gov*.

Table 31-3 Selected Infectious Diseases

DISEASE, INFECTIOUS AGENT, AND TRANSMISSION	PRESENTATION	NURSING CONSIDERATIONS
Rocky Mountain Spotted Fever		
Rickettsia rickettsii • Transmission usually occurs via an infected tick bite with a minimum of 4–6 hr of attachment for infection to occur. May also be transmitted via contamination of breaks in the skin or mucous membranes with crushed tissues or feces of the tick. • Reservoir includes the American dog tick in the east and south, the Rocky Mountain wood tick in the northwest, and the brown dog tick. • Coinfection with other tickborne pathogens should be considered.	• Incubation period is 2–14 d. • Sudden high fever, malaise, headache, chills, and conjunctival injection (red eyes). • Maculopapular rash may begin on day 2–5 on the extremities, which progresses to the soles, palms, and body trunk (in 35%–60%) into petechia and purpura on or after the 6th day. • Mortality ranges depending on the region but occurs in 3%–5% of cases after treatment.	• Not communicable person to person. • Instruct patient to report reoccurrence of symptoms immediately; may be relapse. • Stress prevention through avoidance of tick-infested areas, wearing protective clothing and tick repellent, inspecting body and clothes for ticks every 3–4 hr. • Remove ticks with tweezers or forceps to avoid leaving mouth parts of the skin. Avoid folklore remedies of painting tick with nail polish or petroleum jelly or using heat to make tick detach from the skin. Remove tick from skin as soon as it is found.
Lyme Disease		
Borrelia burgdorferi • Endemic in the Northern Hemisphere temperate regions but found worldwide. • Ixodid ticks reservoir (affecting primarily small mammals and deer). • Coinfection with other tickborne pathogens should always be considered.	• Incubation period is 3–32 d. • Erythema migrans rash occurs in 70%–80% of infected patients after a delay of 3–30 d. Appears at the site of the tick bite and gradually expands over a period of days. May be anywhere on the body. Feels warm but is rarely itchy or painful. May have a bull's-eye appearance. • Flulike symptoms—malaise, fever, headache, stiff neck, myalgia, migratory arthralgias, lymphadenopathy. • Weeks to months—limb weakness, pain and swelling in the large joints, facial palsy, aseptic meningitis. • Months to years—arthritis with severe joint pain and swelling, chronic neurologic symptoms.	• Not communicable person to person. • Preventive measures include: (a) avoiding tick-infested areas; (b) wearing protective clothing; (c) using insect repellent; (d) inspecting the body and clothing daily while working or playing in tick-infested areas. • Ticks should be removed from the skin with tweezers or forceps, using gentle, steady traction to avoid leaving mouth parts in the skin. Protect hands with gloves, cloth, or tissue when removing ticks. • Condition of most patients improves after initial antibiotic treatment. The literature doesn't show a benefit for long-term treatment so is not recommended.
Influenza		
• Acute viral disease of the respiratory tract. • Spread from person to person by large-particle respiratory droplet transmission or by contact with articles recently contaminated with respiratory secretions. • Animal influenza viruses may also be spread via direct contact with infected animals.	• Incubation is 1–4 d. • Usually self-limited febrile illness associated with upper and lower respiratory infection. • Characterized by sudden onset of fever, chills or rigors, headache, malaise, myalgia, and nonproductive cough, typically followed by sore throat, nasal congestion, and rhinorrhea. • Among children—otitis media, abdominal pain, and vomiting are commonly reported. • Cough may last 2 wk or more but other symptoms generally resolve within 5–7 d.	• Highly infectious via aerosolization or droplets from the respiratory tract of infected persons. • Implement droplet precautions for patients for the duration of symptoms. • Best means of prevention—annual influenza vaccination for individuals 6 mo and older, particularly for high-risk groups and HCWs. • Maintain bed rest for at least 48 hr after fever subsides. Encourage fluids. Report symptoms of secondary infection (purulent nasal drainage or sputum, ear pain, increase in fever) to health care provider. • Stay home. • At onset of symptoms contact medical provider for antiviral treatment (including children, pregnant women and those at high risk for severe flu complications). • Bacterial coinfection with Flu can cause severe complications such as with MRSA. • Continue antibiotics prescribed for bacterial complications for defined time period (usually 7–10 d). • Educate on the misuse of antibiotics to treat viral illness.

Mononucleosis Most common cause: Epstein-Barr virus (EBV) Spread via bodily fluids, especially saliva but also through blood, semen, and transplant.	• Incubation period is 4–6 wk. • Fever, sore throat (exudative pharyngotonsillitis), fatigue, splenomegaly, and lymphadenopathy.	• Person-to-person spread via saliva is prolonged—can be months to a year or more after infection. • Convalescence may be as long as several months. • Patients with splenomegaly should avoid activity that may increase the risk of injury to the spleen, such as contact sports and heavy lifting. • Report any excess bruising or bleeding, jaundice, or abnormal CNS functioning.
Cytomegalovirus (CMV) Spread by intimate contact with mucous membranes, secretions, and excretions and by blood transfusion and organ transplant. A fetus may be infected in utero or at delivery.	• Incubation period is 3–8 wk following transplant or transfusion; 3–12 wk delivery. • Ordinarily asymptomatic, especially in children. • Can be a cause of mononucleosis. • More extensive organ involvement in the immunosuppressed host: colitis, pneumonitis, and retinitis may occur. • GI tract disorders. • Congenital infections are serious and lead to irreversible CNS and liver damage.	• Patients with splenomegaly should avoid activity that may increase the risk of injury to the spleen, such as contact sports and heavy lifting. • Report any excess bruising or bleeding, jaundice, or abnormal CNS functioning. • Pregnant personnel should be counseled about potential risks and urged to practice. • Good hygiene (especially hand hygiene) and to follow standard precautions. • Most healthy nonpregnant people do not require treatment.
Rabies Rabies virus Spread by direct contact of virus-laden saliva of a rabid animal into a bite or scratch; may also be transmitted via transplanted corneas and, possibly, other organs removed from patients dying of undiagnosed rabies.	• Incubation is highly variable, usually 3–8 wk; if the bite occurs on the head rather than on an extremity, incubation is shorter. • Initial symptoms apprehension, malaise, fatigue, headache, and fever; possible pain or paresthesia at the site of exposure. • Usually lasts 2–6 d. • Progresses to paresis or paralysis, hydrophobia, eventually to delirium and convulsions. • Respiratory arrest usually occurs, followed by death.	• Avoid contact with respiratory secretions, especially saliva, for duration of illness. • Preexposure prophylaxis should be offered to persons at high risk for exposure to rabies, such as veterinarians, veterinary students, wildlife personnel, park rangers, staff of kennels, and laboratory workers working with rabies. • Bites from animals, particularly dogs and cats, should be thoroughly flushed and cleaned with soap and water immediately. Wounds should not be sutured unless unavoidable. • Domestic dogs and cats should be quarantined for 10 d. • Wild animal carriers include skunks, bats, foxes, coyotes, raccoons, bobcats, wolves, jackals, and other carnivores. • Contact local health department and provider for treatment.
Malaria *Plasmodium vivax, P. falciparum, P. malariae,* and *P. ovale* Malaria is vector-borne through the bite of a female *Anopheles* mosquito; may be congenital or transmitted by transfusions or dirty needles.	• Incubation is 7 d to 10 mo, depending on the strain. • Malarial paroxysm characterized by variations of high fever, chills, sweats, headache, rigor, cough, diarrhea, respiratory distress, nausea, vomiting, and arthralgia. • As infection becomes synchronized, fever and paroxysms are generally cyclic. • Moderate splenomegaly and tender hepatomegaly.	• Maintain standard precautions. • Obtain a travel history. • Fever and recent travel to malaria endemic area should be evaluated using diagnostics. • Symptoms may recur; instruct patient to report recurrence immediately. • Travelers to malaria endemic countries should follow preventive measures: 1. Proper use of mosquito netting at night. 2. Clothing that minimizes contact with mosquitoes. 3. Use of insect repellents. 4. Chemoprophylaxis with suppressive drugs, based on local endemicity and resistance.

Amebiasis		
Entamoeba histolytica Transmitted by ingestion of fecally contaminated food or water, or sexually by oral–anal contact. Amebic dysentery is a severe form.	• Incubation usually 2–4 wk but range is 3 d to as long as months or even years. • Only 10%–20% of infected people become sick. • Intestinal disease: may be asymptomatic or mild symptoms such as abdominal distention, flatulence, constipation, and, occasionally, loose stools. • Nondysenteric colitis: recurring episodes of loose stools; vague abdominal pain; hemorrhoids with occasional rectal bleeding. • Dysenteric colitis: abdominal cramps and diarrhea containing blood and mucus, alternating with periods of constipation or remission.	• Maintain standard precautions. • Instruct patient to wash hands thoroughly after defecating to prevent transmission to others. • Household and sexual contacts should seek medical examination and treatment. • Instruct patient on safer sex practices. • Travelers to areas where the water supply is not chemically treated or protected from sewage should boil all water used for drinking and cooking.
Giardiasis		
Giardia lamblia Transmitted by ingestion of fecally contaminated water or food, or sexually.	• Incubation is 1–3 wk. • Acute: explosive, watery diarrheal stool; abdominal cramping and flatulence; nausea. • Lasts 2–6 wk. • Chronic: intermittent foul-smelling diarrheal stools; increased flatulence and distention; anorexia.	• Maintain standard precautions. • Instruct patient to wash hands thoroughly after defecating to prevent transmission to others. • Household and sexual contacts should seek medical examination and treatment. • Instruct patient on safer sex practices. • Travelers to areas where the water supply is not chemically treated or protected from sewage should boil all water used for drinking and cooking. • Can be tolerant to chlorine disinfection. • Spread mostly in drinking water and recreational water not properly disinfected.
Hookworm		
Ancylostoma duodenale, *Necator americanus* Transmitted by entry into the skin of soil contaminated with feces from humans, or animals.	• Incubation is a few weeks to many months, depending on intensity of infection. • Chronic, debilitating disease leading to iron deficiency and hypochromic, microcytic anemia because of intestinal blood loss to the hookworm.	• Follow-up examination of the stool 2 wk after therapy is necessary. Repeat therapy if heavy worm burden persists. • Nutrition counseling and taking iron supplements are recommended until deficiencies are corrected. • Family members and close contacts should be examined and treated for parasites. • Educate public about dangers of soil contamination and importance of wearing shoes.
Trichinosis, Trichinellosis		
Trichinella spiralis Transmitted by ingestion of raw or insufficiently cooked meat, chiefly pork and pork products infected with the larvae. Other meats are wild carnivores and omnivores—bear, cougar, fox, dog, wolf, horse, seal, walrus, wild boar.	• Incubation is 1–2 d for abdominal symptoms; further symptoms start 2–8 wk after eating contaminated meat. • Clinical disease is highly variable, from inapparent infection to a fulminating fatal disease. • During first week: abdominal discomfort, nausea, vomiting, and, possibly, diarrhea. • Early signs: sudden appearance of muscle soreness and pain accompanied by edema of upper eyelids, pain, and photophobia; ocular signs may progress to subconjunctival, subungual, and retinal hemorrhages. • Remittent fever is usual, sometimes as high as 104°F (40°C).	• Instruct patient to thoroughly wash hands after defecation. • Do not eat raw or uncooked meats; curing, smoking, or microwaving meat doesn't consistently kill infected worms; homemade jerky and sausage cause many cases. • Proper cooking of meats: pork to 160°F (71°C) is necessary. • Family members and close contacts of patients should be examined and treated for parasites.

Histoplasmosis		
Histoplasma capsulatum Transmitted by inhalation of airborne particles from soil or dust that harbor chicken or other bird droppings or bat droppings.	• Incubation is variable, 3–17 d after exposure. • May be asymptomatic with only hypersensitivity to histoplasmin. • Four other clinical forms of disease: 1. Acute benign respiratory—mild respiratory illness to temporary flulike illness. 2. Acute disseminated—debilitating fever, GI symptoms, bone marrow suppression, hepatosplenomegaly, and lymphadenopathy; usually fatal in infants and immunocompromised unless treated. 3. Chronic disseminated—intermittent fever, weight loss, weakness, hepatosplenomegaly, hematologic abnormalities, and focal disease, such as endocarditis, meningitis, and mucosal ulcers; usually fatal unless treated. 4. Chronic pulmonary disease—resembles pulmonary tuberculosis with cavitation; occurs most commonly with underlying emphysema.	• Investigation for the common source of infection should be done in outbreaks. • Educate public to minimize exposure to dust in chicken coops, attics, and caves—use protective masks, gloves, and disposable clothing.
Typhoid Fever		
Salmonella typhi Typhoid Fever Transmitted by ingestion of food and water contaminated by feces, sewage, or by direct contact with excrement.	• Incubation usually 8–14 d; may range 3–30 d. • Systemic—insidious onset of fever, severe headache, malaise, anorexia, bradycardia, and splenomegaly. • Ulceration of the distal ileum; can progress to hemorrhage or perforation.	• Instruct patient to wash hands thoroughly after defecation and before preparing food. • Educate public—control flies, avoid raw shellfish, thoroughly rinse raw fruits and vegetables. • Family and close contacts should be examined and treated.
Botulism		
Clostridium botulinum Transmitted by ingestion of contaminated food or by contact with a contaminated wound.	• Incubation usually 18–36 hr or up to 10 d after eating contaminated food; 4–14 d when transmitted through a wound. • Severe intoxication characterized by visual difficulty, dysphagia, and dry mouth, followed by descending symmetrical flaccid paralysis. • Vomiting and constipation or diarrhea may be present initially.	• All patient contacts known to have eaten the same food should have gastric lavage, high enemas, and cathartics and be kept under close medical supervision. • Instruct patient/patient contacts to wash hands thoroughly after defecation and before handling food. • No questionable canned food should ever be tasted.
Tetanus		
Clostridium tetani Transmitted by direct contact of soil contaminated with animal or human feces into a wound (primarily puncture wounds), burn, or laceration.	• Usually 3–21 d (average is 10 d); may range from 1 d to several months. • Painful muscular contractions, primarily of the masseter and neck muscles. • Abdominal rigidity. • Generalized spasms frequently induced by sensory stimuli—opisthotonos (arching of the trunk) and risus sardonicus (distorted grin).	• Refer persons with skin injuries for tetanus prophylaxis. • Remind adults to receive a tetanus booster every 10 yr. • For major wounds, booster dose of vaccine should be given if none received in past 5 yr.

Staphylococcal Infections		
Staphylococcus aureus, *S. epidermidis*, *S. haemolyticus*, coagulase-negative *staphylococci* Transmitted by direct contact with draining lesions or by autoinfection from colonized nares; hands are the most common vehicle of transmission.	• Incubation usually 4–10 d. • Skin and soft tissue infections—furuncles (boils), impetigo, carbuncles, cellulitis, abscesses, and infected lacerations. • Seeding of the bloodstream may lead to pneumonia, lung abscess, osteomyelitis, septicemia, endocarditis, bacteremia, pyarthrosis, meningitis, and brain abscess.	• Monitor patient's response to prescribed therapy. • Emphasize meticulous hand hygiene among patients and visitors. • Contain purulent drainage with a dressing. • Place soiled dressings in a paper bag before disposal.
Group A Streptococcal Infections		
Streptococcus pyogenes, group A, with ~ 80 serologically distinct types Transmitted by large respiratory droplets or direct contact with secretions, or by ingestion of contaminated food and milk.	• Incubation usually 2–5 d. • Streptococcal pharyngitis (most common). • Wound and skin infections—impetigo, cellulitis, and erysipelas. • Scarlet fever—streptococcal sore throat with a rash that occurs if infectious agent produces erythrogenic toxin to which patient is not immune.	• Repeated attacks of sore throat or other streptococcal disease because of different types of streptococci are relatively frequent. • Make sure the patient understands the importance of completing the course of antimicrobial therapy. • Emphasize the relationship of streptococcal infections to heart disease and glomerulonephritis. • Children should not return to school and HCWs should not return to work until afebrile and at least 24 hr after appropriate antimicrobial therapy has begun.
Syphilis		
Treponema pallidum, a spirochete Transmitted sexually or by direct contact with infectious exudates; transplacental infection of fetus can occur.	• Incubation usually 3 wk or up to 3 mo; signs of secondary syphilis develop 6 wk to 6 mo after primary syphilis. • Congenital: can result in spontaneous abortion or stillbirth, hydrops fetalis, prematurity, and multisystem abnormalities, including deafness. • Primary: indurated, painless, clean ulcer (chancre) with serous exudates. May not see it. Will heal without treatment. • Secondary: generalized macular-papular rash including palms and soles; fever; generalized lymphadenopathy, condylomata, malaise, headache, and splenomegaly. • Tertiary: aortitis, neurosyphilis; ocular syphilis gummatous changes of skin, bone, viscera, and mucosal surfaces.	• Ensure that sexual activity is not resumed until treatment is complete for patient and partner. • Consider testing for HIV and other sexually transmitted diseases. • Encourage follow-up at 3 mo for repeat serologic testing. • All women should be screened serologically for syphilis early in pregnancy. • All individuals, including HCWs, who have had close, unprotected contact with patient with early congenital syphilis before or during the first 24 hr of therapy should be examined for lesions in 3 wk and again in 3 mo.
Prion Disease		
Creutzfeldt-Jakob disease (CJD) and variant CJD (vCJD) Prion proteinaceous infectious particles. Transmission unknown in most cases; transmission of vCJD probably occurs through consumption of beef infected with BSE. Potential infectious organs and body fluids include the brain, spinal cord, eye, and CSF.	• Incubation is 15 mo to more than 30 yr. • Insidious onset with confusion, progressive defects in memory and personality, ataxia, rigidity, and myoclonus. • vCJD is distinguished by onset at early age, absence of EEG changes, and prolonged duration.	• Prion is extremely hardy and resistant to many disinfectants and to normal sterilization practices. • Use disposables as much as possible. • Health care facilities should have protocols in place for identification of cases and for instrument reprocessing at a higher temperature and for longer periods than typical. • Tissue from infected patients must not be used for transplants.

Hot Topics in Communicable Diseases

Ebola Virus

The Ebola virus disease epidemic of 2013 to 2016 in Guinea, Liberia, and Sierra Leone was the largest ever reported. Likely originating in Guinea in 2013 as an epizootic case in a remote village, it spread person to person quickly, moving across borders and to more populated areas. As of June 2016, there were 28,616 cases and 11,310 deaths. The World Health Organization (WHO) in August 2014, declared Ebola in West Africa to be a public health emergency of international concern. Vaccine trials are underway with efforts in several countries. Marburg virus is another filovirus with similar symptoms.

1. Filoviruses cause severe hemorrhagic fevers, commonly accompanied by hepatic and renal damage.
2. Wildlife reservoir host exposure and human-to-human transmission.
3. Central nervous system (CNS) involvement and shock with multiorgan failure can occur.
4. Case mortality rate—Ebola virus, 50% to 90%; Marburg virus, 23% to 90%.

Symptoms

1. Sudden onset of fever, myalgia, and headache; followed by vomiting, diarrhea, and maculopapular rash.
2. Commonly leads to hepatic damage, renal failure, CNS involvement, and terminal shock with multiorgan dysfunction.

Transmission

1. Person to person by direct contact to infected blood and body fluids (included but not limited to feces, saliva, sweat, urine, vomit, breast milk and semen).
2. Direct contact with objects that have been contaminated with infectious blood or body fluids (e.g., equipment and supplies, bathroom surfaces).
3. Risk is highest during later stages when patient is vomiting, experiencing diarrhea, and hemorrhaging.
4. Enters the body through broken skin or mucous membranes.

Implications for Nursing

1. When caring for someone with suspected, probable or confirmed cases of illness, follow strict adherence to use of PPE that fully covers skin and clothing preventing exposure to the eyes, nose, and mouth.
2. HAI have occurred frequently; virtually all Ebola cases in outbreaks that were acquired from contaminated syringes and needles have been fatal.
3. To decrease the likelihood of exposure, there are recommendations for facilities to maintain safety for all workers including clinical and nonclinical staff and visitors who may come in contact with infected patients, equipment or the environment.
    a. Administrative oversight is recommended to ensure strict adherence to infection control policies, such as having a "buddy" not helping with the equipment but to directly observe staff donning and doffing PPE.
    b. The CDC recommends a combination of measures targeted at prevention of virus transmission and

infection in hospitals.

Zika Virus

Since its discovery in Uganda in the mid-1900s, outbreaks of Zika virus have occurred in Africa, Southeast Asia, South America, and the Pacific Islands. Zika has made international headlines after the discovered link between the virus and infant microcephaly and other birth defects in 2016. There is no treatment beyond supportive therapy.

Symptoms

1. Often asymptomatic, or signs and symptoms may last up to a week and death is extremely rare.
2. Fever, rash.
3. Joint and muscle pain, headache.
4. Complications include Guillain-Barré syndrome and birth complications including microcephaly, miscarriage, and stillbirth.

Transmission

1. Mosquito bites.
2. Transplacental from mother to baby.
3. Vaginal, oral, and anal sex.
4. Potentially via blood transfusions (not confirmed in the United States, however).

Implications for Nursing

1. Conduct a thorough travel history assessment of the patient.
2. Educate patients who are traveling to areas with known Zika transmission on safe sex practices and mosquito bite prevention including long-sleeves and insect repellent.
3. Educate patients who are trying to conceive on safe conception after travel to areas with Zika transmission and after Zika infection to reduce risk of complications.
4. Follow standard precautions and routine cleaning/disinfection practices when caring for patients suspected or known to have Zika virus.
5. Zika virus is a reportable condition so participate in reporting to the local/state health department in accordance with state/local laws.

Avian Flu

EVIDENCE BASE Centers for Disease Control and Prevention. (2017). Avian influenza A virus infections of humans. Atlanta, GA: Author. Available: *www.cdc.gov/flu/avian/gen-info/facts.htm*.

Avian flu refers to novel influenza A viruses found in wild and domestic birds, and rare cases of human-to-

human transmission have occurred. Asian lineage H7N9 and H5N1viruses have been of most concern for causing serious illness or death. Because there is a potential for the virus to change becoming more virulent and potentially more easily transmissible from person to person, monitoring human infection is important for public health safety.

Symptoms

1. Conjunctivitis.
2. Fever, cough, sore throat, muscle aches.
3. Pneumonia, acute respiratory distress.
4. Nausea, vomiting.
5. Neurologic changes.

Transmission

1. Reports of human-to-human transmission have been limited; however, because the virus has the potential to change, transmission is being monitored.
2. Direct contact or inhaling particles associated with sick or dead, infected birds or poultry.

Implications for Nursing

1. Conduct a thorough travel history assessment of the patient.
2. Teach patients that for those at risk because of contact with birds or poultry, good hand hygiene and use of PPE are recommended (mask, gloves).
3. Do not rub your eyes, nose, or mouth when around infected poultry or the environment where they live. Infection can occur without touching poultry because of contaminated dust and scratching, flapping, or head-shaking bird behavior.
4. Avoid contact with birds that appear sick and avoid contact with surfaces contaminated with feces from wild or domestic birds.
5. Report the presence of dead birds to the public health agency in your area.
6. For suspected contact with an infected bird, the patient should be monitored for symptoms throughout the week following exposure.
7. The CDC and World Health Organization recommend oseltamivir, peramivir, and zanamivir (as with other types of influenza A) for treatment of infection and as prophylaxis for exposure to infection.

Clostridium difficile-Associated Disease

Clostridium difficile is the most common HAI in US hospitals and is usually associated with previous antibiotic use. This organism is a spore-forming bacteria, shed in feces and spread by touching surfaces contaminated by stool then subsequently ingest or contact mucous membranes without proper hand washing. The bacterium causes inflammation of the colon, known as colitis.

1. The use of antibiotics disrupts the indigenous gut microbiota allowing the *C. difficile* to overgrow causing anything from mild to severe diarrhea. The disease is associated with the use of almost every class of

antibiotics, but the use of fluoroquinolones has become the leading class of antibiotics associated with this disease.

2. This bacterial spore producer is highly resistant to most cleaning supplies and alcohol-based hand sanitizers routinely used in hospital settings.
3. An especially toxic strain, NAP-1, has emerged as the leading cause of outbreaks in hospitals across the world.

Symptoms

1. Although incubation rates have not been clearly established, they can range from less than 7 days to 6 months depending on the clinical picture of the patient.
2. The patient may be an asymptomatic carrier or may present with abdominal cramps, diarrhea, colitis, pseudomembranous colitis, fulminant colitis, and toxic megacolon.
3. The most common presentation is nonbloody, watery diarrhea (at least three bowel movements per day for two or more days), cramps, fever, and loss of appetite.
4. Recurrence of the disease is common.

Transmission

1. Contaminated environment and the contaminated hands of those who touch surfaces in that environment leads to transmission.
2. The use of alcohol hand gels is not recommended following care of a patient with CDAD. Staff and visitors should wash their hand with soap, warm water, and friction for 15 seconds to perform adequate hand hygiene.
3. The use of sodium hypochlorite at 5,000-ppm, bleach diluted 1:10, buffered commercially prepared bleach solutions, or FDA-approved sporicidal disinfectant is recommended for cleaning the patient's environment and equipment.

Implications for Nursing

1. Collect stool samples for testing for *C. difficile* or its toxins only on diarrheal (unformed) stool, unless ileus because of *C. difficile* is suspected.
2. Follow contact precautions strictly and use diligent hand hygiene with soap and water, for all who enter the environment.
3. Dedicate patient equipment and disposable items as much as possible.
4. Closely monitor antimicrobial use and advocacy judiciously for discontinuation of antibiotics when appropriate.
5. Consider using a bleach-based disinfectant (or other FDA-approved sporicidal) and a highly trained environmental staff.
6. Studies show that patients continue to shed following cessation of diarrhea so consider isolation practices for several days beyond resolution of symptoms or for the rest of the hospitalization.
7. Advocate for an antimicrobial stewardship program if not one in your facility, see Box 31-2.

BOX 31-2 Antimicrobial Resistance and Antimicrobial Stewardship

Antimicrobial resistance (AMR) occurs when microorganisms (such as bacteria, fungi, viruses, and parasites) evolve or mutate after exposure to antimicrobial drugs (such as antibiotics, antifungals, antivirals, antimalarials, and antihelmintics). Resistance occurs naturally overtime, however, has accelerated due to overuse and misuse of antibiotics without oversight. Examples for types of misuse is prescribing antibiotics for viruses such as the common cold or Influenza or giving them to animals such as fish or livestock as growth promoters. AMR is an increasing global concern and has been recognized as a major public health threat. Antimicrobial stewardship in institutions is the coordinated effort by infectious disease and pathology leaders to educate providers, develop treatment strategies, and enact treatment standards to drive the appropriate use of antibiotics based on the established evidence. The concern for overuse and misuse of antibiotics and subsequent antibiotic resistance has prompted national discussion and convergence of the Antibacterial Resistance Leadership Group (ARLG). This group's focus is to prioritize and promotion research trials for an ongoing acquisition of knowledge while collaborating with international partners to combat and reduce the threat of resistance.

Transmissible Spongiform Encephalopathy/ Prion Disease

Transmissible spongiform encephalopathies (TSEs) are rare and a family of progressive neurodegenerative disorders that affect both animals and humans. The causative agent is called a "prion." This pathogen is not well understood but thought to be transmissible and induce abnormal folding of normal proteins called prion proteins found mostly in the brain. This group of diseases has long incubation periods, associated with neuronal loss and a failure to induce inflammatory response. Once the symptoms begin, it progresses rapidly and is always fatal. Prion diseases in humans include—Creutzfeldt-Jakob disease (CJD), Variant Creutzfeldt-Jakob disease (vCJD), Gerstmann-Sträussler-Scheinker syndrome, fatal familial insomnia, and Kuru. Transmission has been reported in 250 cases worldwide and linked to human growth hormone, dura mater and corneal grafts, or neurosurgical equipment. Special considerations are taken with treatments, procedures or surgeries involving contact with high infectivity tissues (brain, spinal cord, and eyes) of patients thought to have TSEs. The CDC and WHO have developed infection control guidelines for individuals caring for CJD patients. For more information, see (*www.cdc.gov/prions/index.html*).

OVERVIEW AND ASSESSMENT

Subjective Data

Much can be learned about musculoskeletal disorders from subjective data. History of injury, description of symptoms, and associated personal health and family history can give clues to the underlying problem and appropriate care for that problem.

Common Manifestations of Musculoskeletal Problems

Pain

1. Where is the pain located?
    a. Joints, as in osteoarthritis (OA).
    b. Muscles or soft tissue, as in contusions, sprains, or strains.
    c. Bone, as in fractures or tumors.
2. Is it sharp, as in a fracture or sprain, or dull, as in a bone tumor?
3. Does the pain radiate?
    a. To buttocks or legs, as in lower back pain.
    b. To thigh or knee, as in hip fracture, or arm, as in shoulder injury.
4. What makes the pain increase? What makes it better?
5. When was the onset of pain?

Limited Range of Motion

1. Is stiffness present? How long does it last?
    a. Present in the morning for less than 30 minutes or after sitting for long period when due to OA.
    b. May persist and is associated with acute pain when due to spasm of lower back strain.
2. Is swelling present and limiting mobility?
    a. May be due to fracture.
    b. May be soft tissue injury, such as sprain, strain, or contusion.
3. How does limited mobility affect activities of daily living (ADLs)?

Associated Symptoms

1. Any sensory or motor deficits, such as numbness, paresthesias, or weakness, indicating neurovascular compromise?
2. Any weight loss, fever, or malaise, as in bone tumors?
3. Any bony nodules or deformity, as in rheumatoid arthritis?

History

Mechanism of Injury

1. How did the injury occur? Essential for all trauma, including fractures, contusions, sprains, and strains, to help identify the extent of injury.

2. What was the progression of symptoms?
3. If not an acute injury, was there any repetitive movement or strain that may have contributed to problem, as in tendinitis?

Medical History

1. What medications are you taking (include name, dosage schedule, and last time taken—include prescription medications, vitamins, over-the-counter [OTC] medications, and herbal products)?
2. Any history of corticosteroid use that predisposes to osteoporosis?
3. Is the woman postmenopausal? On estrogen replacement? If estrogen deficient, may predispose to osteoporosis.
4. Any history of prostate, breast, or lung cancer, which may metastasize to the bone?
5. What are other conditions that may affect immobility imposed by casting, traction, or surgery?
6. Any chronic illnesses such as diabetes that may affect healing?

Social History

1. What is the patient's occupation and specific job activities, which may contribute to lower back strain or OA?
2. Does the patient exercise? What type of exercise is performed, how frequently, and what is the duration of exercise? When was the last time this was performed?
3. What activities or sports does the patient participate in, such as running or tennis, which may cause repetitive injury?
4. Are there risk factors for osteoporosis, such as smoking, inactivity, low calcium intake, or lack of exposure to the sun?
5. Is there a family history of osteoporosis or arthritis?
6. What cultural issues/religious beliefs contribute to this history?
7. Does the patient drink alcohol? If yes, what is the daily alcohol consumption?

Objective Data

Data on current condition and functional abilities are secured through inspection, palpation, and measurement. Always compare with contralateral side (one side of the body to the other).

Musculoskeletal System

Skeletal Component

1. Note deviation from normal structure—bony deformities, length discrepancies, alignment, symmetry, amputations.
2. Identify abnormal motion and crepitus (grating sensation), as found with fractures.

Joint Component

1. Identify swelling that may be due to inflammation or effusion.
2. Note deformity associated with contractures or dislocations.
3. Evaluate stability, which may be altered.
4. Estimate active and passive range of motion (ROM).

Muscle Component

1. Inspect for size and contour of muscles.
2. Assess coordination of movement.
3. Palpate for muscle tone.
4. Estimate strength through resistance testing using scaled criteria (ie, 0 = no palpable contraction; 5 = normal ROM against gravity with full resistance).
5. Measure girth to note increases due to swelling or bleeding into muscle or decreases due to atrophy (difference of more than 1 cm is significant).
6. Identify abnormal clonus (rhythmic contraction and relaxation) or fasciculation (contraction of isolated muscle fibers).

Additional Assessment

Neurovascular Component

1. Assess circulatory status of involved extremities by noting skin color and temperature, peripheral pulses, capillary refill response, pain, and edema.
2. Assess neurologic status of involved extremities by the patient's ability to move distal muscles and description of sensation (eg, paresthesia).
3. Test reflexes of extremities.
4. Compare all to uninjured/unaffected extremity.

Skin Component

1. Inspect traumatic injuries (eg, cuts, bruises).
2. Assess chronic conditions (eg, dermatitis, stasis ulcers, scars overlying joints).
3. Note hair distribution and nail condition.
4. Inspect for Heberden or Bouchard nodes.
5. Assess for warmth or coolness of skin.

NURSING ALERT The subjective and objective data will help to differentiate acute from chronic processes. Signs and symptoms of infection, neurovascular compromise, and fracture require immediate diagnostic testing.

Radiologic and Imaging Studies

Many radiologic and imaging studies are helpful in evaluating musculoskeletal problems to rule out fracture or skeletal changes and to differentiate soft tissue injury.

DRUG ALERT Many radiologic studies include injection or oral contrast. Check the patient's allergies and make sure a recent creatinine level has been obtained. To prevent contrast-induced nephropathy, make sure that elevated creatinine or reduced estimated glomerular filtration (eGFR) is reported to the radiology department. Ensure that nephrotoxic drugs and metformin are held according to facility protocol (usually if eGFR is less than 30 mL/minute, for 48 hours before the procedure and for 48 hours following). The patient should be well hydrated before and after the procedure.

X-rays

1. Of bone—to determine bone density, texture, integrity, erosion, changes in bone relationships.
2. Of cortex—to detect any widening, narrowing, irregularity.
3. Of medullary cavity—to detect any alteration in density.
4. Of involved joint—to show fluid, irregularity, spur formation, narrowing, changes in joint contour.
5. Tomogram—special x-ray technique for detailed view of special plane of bone.

Nursing and Patient Care Considerations

1. Tell the patient that proper positioning is important to obtain a good x-ray, so cooperation is essential.
2. Advise the patient to remove all jewelry, clothing with zippers or snaps, change from pockets, or other items that may interfere with x-ray.
3. Medicate the patient for pain prior to x-ray, as needed.

Bone Scan

A *bone scan* consists of parenteral injection of bone-seeking radiopharmaceutical (such as gallium); concentration of isotope uptake revealed in primary skeletal disease (osteosarcoma), metastatic bone disease, inflammatory skeletal disease (osteomyelitis); fracture.

Nursing and Patient Care Considerations

1. There is usually no special preparation prior to the scan.
2. Injectable radionuclide is given several hours before the scan.
3. Reassure the patient that the procedure will not cause pain and that the scan will take 1 to 2 hours.
4. Analgesics or sedatives may be ordered for patients for whom lying immobile for any length of time is difficult.
5. Breast-feeding should be discontinued for at least 4 weeks after test to prevent radionuclide exposure to

infant.

6. Inform the patient that the exposure to radioactive substances is small (dose of radiation is less than a chest x-ray), and substances are excreted quickly by the body.

Bone Densitometry

Bone densitometry is a noninvasive study that yields an actual measurement of bone density and is diagnostic for osteoporosis (see page 152). It is most often performed on the lower spine and hips; however, simple portable screening tests that analyze the wrist or heel are also available.

Nursing and Patient Care Considerations

1. Calcium supplements should be avoided 24 hours prior to exam.
2. DXA scan should be avoided for 10 to 14 days if the patient recently had a barium examination or has been injected with a contrast material for a computed tomography (CT) scan or radioisotope scan.
3. Have the patient remove clothing and all jewelry or other metal objects.
4. Advise the patient to lie still with hips flexed for 10 to 30 minutes; during test; technician will remain in the room.
5. Reassure the patient that radiation exposure is minimal.

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI) uses magnetic fields to demonstrate differences in hydrogen density of various tissues. Demonstrates tumors and soft tissue (muscle, ligament, tendon) abnormalities. Although it is more costly than CT scans, the cost is typically validated through the diagnostic accuracy. MRI not only clearly defines internal organs but also is able to detect nerve damage and changes, such as edema or bruises, of bone. Bone bruises (osseous contusions) with traumatic injuries have some predictive value for future development of posttraumatic arthritis.

Nursing and Patient Care Considerations

1. Prepare the patient for the need to lie still for about 1 hour; repetitive clanging noise of machine will be heard; patients may feel closed in.
2. Practice relaxation techniques, such as relaxation breathing and imagery, ahead of time.
3. Some patients may need sedation; claustrophobic patients may be unable to undergo procedure or may need open MRI.
4. May be contraindicated for patients with some types of metal implants and devices. Notify the technologist or radiologist of any surgical implants, medical devices, or hardware for evaluation prior to MRI.
    a. In general, metal objects used in orthopedic surgery pose no risk during MRI. However, a recently placed artificial joint may require the use of another imaging procedure. If there is any question of their presence, an x-ray may be taken to detect the presence of and identify any metal objects.
    b. Patients who might have metal objects in certain parts of their bodies may also require an x-ray prior

to an MRI. Notify the technologist or radiologist of any shrapnel, bullets, or other pieces of metal that may be present because of accidents.

c. Dyes used in tattoos may contain iron and could heat up during MRI, but this is rarely a problem.

d. Tooth fillings and braces usually are not affected by the magnetic field but they may distort images of the facial area or brain, so the radiologist should be aware of them.

e. Parents who accompany children into the scanning room also need to remove metal objects and notify the technologist of any medical or electronic devices they may have.

NURSING ALERT In most cases, an MRI exam is safe for patients with metal implants, except for a few types. People with the following implants cannot be scanned and should not enter the MRI scanning area unless cleared by a radiologist:

- Internal (implanted) defibrillator or pacemaker
- Cochlear (ear) implant
- Some types of clips used on brain aneurysms
- Some types of metal coils placed within blood vessels

Other Tests

1. CT scan—narrow beam of x-ray that scans the area in successive layers to evaluate disease, bone structure, joint abnormalities, and trauma (fractures).
2. Arthrogram—injection of radiopaque substance or air into joint cavity to outline soft tissue structures (eg, meniscus) and contour of joint.
3. Myelogram—injection of contrast medium into subarachnoid space at lumbar spine to determine level of disk herniation or site of tumor.
4. Diskogram—injection of small amount of contrast medium into lumbar disk abnormalities.
5. Arthrocentesis—insertion of needle into joint and aspiration of synovial fluid for purposes of examination or injection of therapeutic medications.
6. Arthroscopy—endoscopic procedure that allows direct visualization of joint structures (synovium, articular surfaces, menisci, ligaments) through a small needle incision. May be combined with arthrography.
7. Nerve studies—to differentiate nerve root compression, muscle disease (eg, dystrophy, myositis), peripheral neuropathies, central nervous system–anterior horn cell neuropathies, neuromuscular junction problems.
   a. Electromyography (EMG)—measures electrical potential generated by the muscle during relaxation and contraction.
   b. Nerve conduction velocities—measure the rate of potential generation along specific nerves (speed of

impulse conduction).

GENERAL PROCEDURES AND TREATMENT MODALITIES

See additional online content: Procedure Guidelines 32-1–32-3

PROCEDURE GUIDELINES 32-1

Application of a Cast

EQUIPMENT

- Plaster or synthetic bandages in desired widths
- Stockinette (tubular knitted material)*
- Cast padding (roll padding)*
- Splints (for reinforcement)
- Cotton, polyester, or polyurethane foam padding for bony prominences*
- Cast knives, scissors
- Polyethylene sheeting or newspaper—to protect floor
- Disposable gloves—to protect hands of operator
- Large, plastic-lined pail of water at room temperature—70° to 75°F (21° to 24°C)—or as recommended by cast material manufacturer
- Cast finishing hand cream for synthetic cast, as needed

CONSIDERATIONS

1. The application of a cast requires two to three persons: one to apply the plaster (operator), one to dip and hand the plaster bandages to the operator, and a third person to hold the extremity in correct position. (Body spicas may require additional personnel.)

2. The time required for the cast to become rigid varies with the material used—generally 2 to 6 min.

3. There should be no movement of the extremity while the cast is being applied and set.

4. In general, the joints above and below the involved bone are immobilized.

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Spread polyethylene sheeting or newspaper on floor.	1. Contains mess.
2. Explain to the patient that there will be a feeling of warmth as the plaster is applied.	2. Heat is produced by an endothermic reaction causing crystallization as plaster sets. The reaction of water with plaster of Paris liberates heat.
3. Apply stockinette and roll cast padding on the extremity or part to be immobilized. a. Apply roll padding as smoothly and snugly as possible so each turn overlaps the preceding turn by one half the width of the roll. b. Extra pieces of padding may be placed over bony prominences: olecranon process, malleoli, patella, or ulnar protuberance.	3. Padding is used to pad the sharp cast margins for patient comfort and to prevent pressure areas, minimize circulatory problems, and facilitate cast removal. It is applied from the distal to the proximal end of the extremity. When too much padding is used, it may shift and produce pressure areas under the cast.
4. While keeping the thumb under the forward edge of the bandage, submerge the plaster bandage vertically in water (room temperature) for a minute or so, or until bubbles cease to rise.	4. Water that is too warm will accelerate setting time, may cause a burn, and may result in excessive plaster loss by loosening the adhesive agents that bond the plaster to the fabric.
5. Expel excess water by squeezing (not wringing) toward the center of the bandage; hand bandage to operator with free end hanging loose.	5. Cast will dry more quickly (thus will acquire maximum strength sooner) if a well-squeezed plaster bandage is used. Maximum strength is achieved by synthetic casts through chemical reaction in about 30 min.
Performance phase (by operator)	
1. Starting at the distal end, roll the bandage gently and evenly on the extremity overlapping the preceding turn by one half the width of the roll.	1. Roll inward toward the patient's body for ease of control.
2. Keep bandage moving and in constant contact with surface of extremity. Smooth and rub down successive layers or turns of each bandage into layers below with the thumbs and thenar eminences (mound on the palm) in circumferential and longitudinal directions.	2. Keeps the cast uniformly thick. Rubbing the plaster as it is applied will form a smooth, solid, and well-fused cast. Avoid indenting the cast with the fingertips because this may produce pressure sores on underlying skin. Handle fresh casts with palms.
3. Make tucks in the lower border of the bandage by lifting the bandage off the surface (without tension) and overlapping it in a V-shaped fashion.	3. Tucking the bandage helps to contour the cast to the changing circumference of the extremity. Do not twist or reverse the bandage to change its direction because this produces sharp cutting edges.

Nursing Action	Rationale
4. Trim the cast to size with a sharp knife. Fold stockinette over edges of cast and anchor with cast material.	4. Stockinette produces smooth, comfortable edges on cast. Do not pull too vigorously on the stockinette because this may cause pressure on bony prominences.
5. Finish synthetic cast with cast hand cream, as indicated.	5. Smooth out rough exterior surface.
6. Ask the patient if there is any discomfort or pain.	6. If a patient complains of pain, it may be due to manipulation of fracture during setting; pain should subside rapidly. If it persists, the cast and encircling dressings are split to avoid constriction, circulatory problems, and pressure sores.
Follow-up phase	
1. Support the cast with the palm of the hand while moving the patient. Avoid indentations from tips of fingers.	1. Finger indentation on a fresh cast can produce pressure sores.
2. Expose the cast to warm, circulating, dry air or blow air over cast with a circulating fan to increase the evaporation of water.	2. Avoid covering the cast when it is drying because this delays drying time. Usually the plaster cast will reach its maximum temperature 5–15 min after it is applied and will then cool rapidly. The ultimate plaster cast strength is obtained after the cast is dry (up to 48 hr, depending on outside temperature and humidity). The synthetic cast strength is maximum within 30 min of application and not dependent on being dry.
3. Clean equipment and store ready for use.	

**Material needs to be nonabsorbent if nonplaster cast is used.*

PROCEDURE GUIDELINES 32-2

Removal of a Cast

EQUIPMENT

- Cast cutter—an electric saw with circular blade that oscillates and is connected to a vacuum collector
- Cast spreader
- Plaster knife
- Scissors
- Felt-tip pen

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Describe to the patient how and where the cast cutter will be used and the expected sensations.	1. Reassures the patient that the cutter produces vibrations but not pain.
2. Determine whether the cast is padded.	2. An electric plaster cast cutter should not be used on unpadded casts.
3. Determine where the cut will be made. Mark the area to be cut with a felt pen.	3. The line should be in front of the lateral malleolus and behind the medial malleolus on a lower-extremity cast. An upper-extremity cast is usually split along the ulnar or flexor surface.
Performance phase	
1. Inform the patient to shield the eyes.	1. Plaster dust may be irritating to the eyes.
2. Grasp the electric cutter as illustrated.	2. Correct grasp is essential for stabilizing the electric cutter.
3. Rest the thumb on the cast.	3. The thumb serves as a depth gauge and acts as a guard in front of the blade.
4. Turn on the electric cutter. Push the blade firmly and gently through the cast while holding the thumb against the cast to steady the blade while cutting through the cast.	 Operating a cast cutter.
5. As the blade cuts through the plaster, a sudden lack of resistance is felt; plaster will "give" (or "dip") when the cut is completed.	
6. Lift the cutting blade up a degree (but not out of the cutting groove) and advance the blade at a slightly higher or lower level. The cast is cut by a series of alternating pressure and linear movements along the line of the cut (see accompanying figure).	
7. Avoid drawing the cutting blade along the extremity in a single motion.	7. This will cut the skin. If saw blade is in contact with padding too long, the patient will feel burning sensation on skin from rapidly oscillating blade.
8. Cut the cast on both sides. Then rock the anterior portion of the cast over the posterior portion.	8. Allows the operator to determine if the cast is completely cut.
9. Insert the blades of the cast spreader in the cut trough. Separate the two halves with the spreader at several sites along the cast split. Separate the cast with the hands.	
10. Cut through the padding and stockinette with scissors, keeping the scissor blade that is closest to the skin parallel to the skin.	10. Use bandage scissors; place the flat blade closest to the skin.
11. Lift the extremity carefully out of the posterior portion of the cast. Support the extremity so it is maintained in the same position as when in the cast.	11. When the support of the cast has been removed, stresses and strain are placed on parts that have been at rest.

Nursing Action	Rationale
After removal of cast	
1. Clean the skin gently with mild soap and water. Blot dry. Apply a skin cream.	1. Explain to the patient that the skin will be scaly and the extremity will appear "thin" from disuse. Reassure him or her that it will take a few weeks to regain normal appearance and function.
2. Emphasize the importance of continuing the prescribed exercises, reporting for physical therapy, and so forth.	2. Exercises are necessary to redevelop and increase strength and function. Pain and stiffness may be expected after cast removal.

EVIDENCE BASE National Association for Orthopaedic Nursing. (2012). *Orthopedic nursing core competencies across the lifespan*, (3rd ed.). Chicago, IL: Author.

PROCEDURE GUIDELINES 32-3

Application of Buck Extension Traction

PURPOSE

Buck extension skin traction is used as a temporary measure to provide immobility, support, and comfort until definitive treatment is accomplished.

EQUIPMENT

- Foam Buck traction boot or traction tape and 4-inch elastic bandage
- Spreader block or metal spreader
- Pulley, nylon rope, and weights (5 to 7 lb [2.5 to 3 kg] is usual [amount of weight is prescribed, generally not more than 10 lb (4.5 kg)])
- Sheepskin pad
- Shock blocks or adjustable bed for Trendelenburg position

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Bed position is usually flat. This depends on the size of the patient and the weight applied.	1. Keeping the patient flat helps prevent the patient from sliding down toward the foot of the bed.
2. Question the patient to determine previous skin conditions (contact dermatitis). Inspect skin for evidences of atrophy, abrasions, and circulatory disturbances.	2. The skin must be in healthy condition to tolerate skin traction.
3. Make sure the skin of the extremity is clean and dry.	3. Clean, dry skin helps traction tape adherence.
4. Document the neurovascular status of the extremity, any evidence of skin problems or varicosities.	4. As baseline for future reference.
Performance phase	
1. Position the patient in center of bed in good alignment; avoid pillow under leg.	1. For effective line of pull.
If traction tape is used:	
2. Apply continuous traction tape to medial and lateral aspects of lower leg (below knee and loosely around foot to allow for attachment of spreader).	2. Avoid pressure over malleoli and head of fibula. Pressure sores develop rapidly over bony prominences. Pressure over the region of the fibular head and common peroneal nerve may produce peroneal palsy and footdrop.
3. Have a second person elevate and support the extremity under the ankle and knee while the elastic bandage is applied. Beginning at the ankle, wrap the elastic bandage snugly over the tape up to the tibial tubercle.	3. The elastic bandage holds tape to the skin and helps prevent slipping.
4. Attach a spreader block (or metal spreader) to the distal end of the tape. Attach a rope to the spreader block and pass it over a pulley fastened to the end of the bed and gently apply weights.	4. The spreader block prevents pressure along the side of the foot. The spreader should not be too narrow (causes pressure sores on ankle) or too wide (pulls traction tape away from the heel).
5. Place a sheepskin pad under the leg (or use a commercial heel protector).	5. Sheepskin is used to reduce friction of the heel against the bed.
If foam boot is used:	
1. Apply antiembolism stockings, if prescribed.	1. Prophylactic measure in high-risk population.
2. Place leg in foam boot, adjusting it so the heel is in the heel of the boot.	2. Preventing sore heels is a primary concern.
3. Secure Velcro bootstraps, avoiding excessive pressure on malleoli and fibular head.	3. Pressure over bony prominences causes skin breakdown and pressure on peroneal nerve may result in footdrop.
4. Attach rope to built-in spreader plate, pass it over pulley, and apply weights gently.	4. The rope should move unobstructed and the weights should hang free of the bed and not touch the floor.

EVIDENCE BASE National Association for Orthopaedic Nursing. (2012). *Orthopedic nursing core competencies across the lifespan*, (3rd ed.). Chicago, IL: Author.

Crutch Walking

Crutches are artificial supports that assist patients who need aid in walking because of disease, injury, or a birth defect.

Preparation for Crutch Walking

The goals are to develop power in the shoulder girdle and upper extremities that bear the patient's weight in crutch walking and strengthen and condition the patient.

Strengthening the Muscles Needed for Ambulation

Instruct the patient as follows:

1. For quadriceps setting:
    a. Contract the quadriceps muscle while attempting to push the popliteal area against the mattress and raise the heel.
    b. Maintain the muscle contraction for a count of 5.
    c. Relax for the count of 5.
    d. Repeat this exercise 10 to 15 times hourly.
2. For gluteal setting:
    a. Contract or pinch the buttocks together for a count of 5.
    b. Relax for the count of 5.
    c. Repeat 10 to 15 times hourly.

Strengthening the Muscles of the Upper Extremities and Shoulder Girdle

Instruct the patient as follows:

1. Flex and extend arms slowly while holding traction weights; gradually increase poundage of weight and number of repetitions to increase strength and endurance.
2. Do push-ups while lying in a prone position.
3. Squeeze rubber ball—increases grasping strength.
4. Raise the head and shoulders from the bed; stretch the hands forward as far as possible.
5. Sit up on bed or chair.
    a. Raise the body from the chair by pushing hands against chair seat (or mattress).
    b. Raise the body out of the seat. Hold. Relax.

Measuring for Crutches

1. When the patient is lying down (an approximate measurement):
    a. Measure from the anterior fold of the axilla to the sole. Then add 2 inches (5 cm).
    b. Alternatively, subtract 16 inches (40 cm) from the patient's height.
2. When the patient is standing erect:

a. Stand the patient against the wall with feet slightly apart and away from the wall.
b. The crutches should be fitted with large rubber suction tips.
c. The elbow is flexed 30 degrees with the hand resting on the grip.
d. There should be a two-finger-width insertion between the axillary fold and the underarm piece grip. A foam rubber pad on the underarm piece will relieve pressure on the upper arm and thoracic cage.
e. The tip of the crutch is placed 6 to 8 inches (15 to 20 cm) lateral to the forefoot.

Teaching the Crutch Stance

1. Have the patient wear well-fitting shoes with firm soles.
2. Before using the crutches, have the patient stand by a chair on the unaffected leg to achieve balance.
3. Position the patient against a wall with head in a neutral position.
4. Tripod position—basic crutch stance for balance and support.
   a. Crutches rest approximately 8 to 10 inches (20 to 25 cm) in front of and to the side of the patient's toes (see Figure 32-1).
   b. A taller patient requires a wider base, whereas a shorter patient needs a narrower base.
5. Teach the patient to support weight on hands; weight borne on the axillae can damage the brachial plexus nerves and produce "crutch paralysis."

Figure 32-1. The tripod position is the basic crutch stance for balance and support. (From

Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins. Photo by Barbara Proud.)

Teaching the Crutch Gait

1. Crutch walking requires balance, coordination, and a high expenditure of energy; these can be acquired with diligent and regular practice.
2. Practice balancing with crutches while leaning against the wall.
3. Practice shifting body weight in different positions while standing with crutches.
4. The selection of the crutch gait depends on the type and severity of the disability, weight-bearing status, and the patient's physical condition, arm and trunk strength, and body balance.
5. Teach the patient at least two gaits—a faster gait to be used for swiftness and a slower one to be used in crowded places.
6. Instruct the patient to change from one gait to another—relieves fatigue because a different combination of muscles is used.

Crutch Gaits

See Figure 32-2 and Patient Education Guidelines 32-1.

4 POINT GAIT	3 POINT GAIT	2 POINT GAIT
• Partial weight bearing both feet • Maximal support provided • Requires constant shift of weight	• Non-weight bearing • Requires good balance • Requires arm strength • Faster gait • Can use with walker	• Partial weight bearing both feet • Provides less support • Faster than a 4 point gait
 4. Advance right foot	 4. Advance right foot	 4. Advance right foot and left crutch
 3. Advance left crutch	 3. Advance left foot and both crutches	 3. Advance left foot and right crutch
 2. Advance left foot	 2. Advance right foot	 2. Advance right foot and left crutch
 1. Advance right crutch	 1. Advance left foot and both crutches	 1. Advance left foot and right crutch
 Beginning stance	 Beginning stance	 Beginning stance

Figure 32-2. Crutch gaits. Shaded areas are weight bearing. *Arrow* indicates advance of foot or crutch. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

PATIENT EDUCATION GUIDELINES 32-1

Crutch-Maneuvering Techniques

STANDING UP

1. Move forward to the edge of the chair with the strong leg slightly under the seat.
2. Place both crutches in the hand on the side of the affected extremity.
3. Push down on the hand pieces while raising the body to a standing position.

SITTING IN A CHAIR

Grasp the crutches at the hand pieces for control and bend forward slightly while assuming a sitting position.

GOING UP STAIRS

1. Advance the stronger leg first up to the next step.
2. Advance the crutches and the weaker extremity.

GOING DOWN STAIRS

1. Place the feet forward as far as possible on the step.
2. Advance the crutches to the lower step. The weaker leg is advanced first and then the stronger one—the stronger extremity shares the work of raising and lowering the body weight with the patient's arms.

Note: Strong leg goes up stairs first and down stairs last.

Four-Point Gait (Four-Point Alternate Crutch Gait)

1. Four-point gait is a slow but stable gait; the patient's weight is constantly being shifted.
2. Four-point gait can be used only by patients who can move each leg separately and bear a considerable amount of weight on each of them.
3. Crutch-foot sequence:
   a. Right crutch.
   b. Left foot.
   c. Left crutch.
   d. Right foot.

Three-Point Gait

1. Three-point gait is used when one leg is affected.
2. Both crutches and the affected lower leg are moved forward simultaneously.

3. Then the stronger lower extremity is moved forward while most of the body weight is put on the crutches.

Two-Point Gait

1. Two-point gait is a progression from the four-point gait that allows faster ambulation.
2. Weight is borne on both lower extremities and both crutches.
3. Advance left foot and right crutch together.
4. Then advance right foot and left crutch together.

Ambulation with a Walker

A walker provides more support than crutches or a cane for the patient who has poor balance and cannot use crutches.

Technique for Using a Walker

1. Be aware that a walker gives stability but does not permit a natural reciprocal walking pattern.
2. Rolling walkers may assist the patient who has painful joints in the lower extremities, decreased balance, or decreased cardiopulmonary function.
3. Teach the following sequence for a patient using a stationary (nonrolling) walker:
    a. Lift the walker, placing it in front of you while leaning your body slightly forward.
    b. Take a step or two into the walker.
    c. Lift the walker and place it in front of you again.
4. Teach the following sequence for a patient using a rolling walker:
    a. Roll the walker and move it forward about 12 inches.
    b. If the patient has an injured leg, a new joint, or a weaker side, step forward with that foot first. Instruct the patient to use the walker to help keep the balance as the patient takes the step.
    c. Bring the other foot forward to the center of the walker.
    d. Repeat the sequence.

Ambulation with a Cane

A cane is used for balance and support. Canes come in a variety of shapes, but the majority have a curved handle and a rubber tip. Quad canes may offer greater support.

Purposes

1. To assist the patient to walk with greater balance and support and less fatigue.
2. To compensate for deficiencies of function normally performed by the neuromuscular skeletal system.
3. To relieve pressure on weight-bearing joints.
4. To provide forces to push or pull the body forward or to restrain the forward motion of the patient while walking.

Principles of Cane Use

1. An adjustable aluminum cane fitted with a 1½-inch (3.8-cm) rubber suction tip to provide traction while walking gives optimal stability to the patient.
2. With bilateral disease, using two canes gives better balance and weight relief.
3. To fit for a cane:
    a. Have the patient flex elbow at a 30-degree angle and hold the cane 6 inches (15 cm) lateral to the base of fifth toe.
    b. Adjust the cane so that the handle is approximately level with the greater trochanter.
4. Alternatively, while the patient is standing with arms at side, the handle of the cane should line up with the crease in wrist.

Technique for Walking with a Cane

1. Hold the cane in the hand opposite to the affected extremity (ie, the cane should be used on the good side)—allows partial weight-bearing relief because the cane is in contact with the floor at the same time as the affected extremity.
2. Advance the cane at the same time the affected leg is moved forward.
3. Keep the cane fairly close to the body to prevent leaning.
4. If the patient cannot use the cane in the opposite hand, the cane may be carried on the same side and advanced when the affected leg is advanced.
5. To go up and down stairs:
    a. Step up on the unaffected extremity.
    b. Then place the cane and affected extremity on the step.
    c. Reverse this procedure for the descending steps.
    d. The strong leg goes up first and comes down last.
6. When using a quad cane, ensure that all four tips are touching the ground.

Casts

A *cast* is an immobilizing device made up of layers of plaster or fiberglass (water-activated polyurethane resin) bandages molded to the body part that it encases.

Purposes

1. To immobilize and hold bone fragments in reduction.
2. To apply uniform compression of soft tissues.
3. To permit early mobilization.
4. To correct and prevent deformities.
5. To support and stabilize weak joints.

Types of Casts

1. Short arm cast—extends from below the elbow to the proximal palmar crease.
2. Gauntlet cast—extends from below the elbow to the proximal palmar crease, including the thumb (thumb spica).
3. Long arm cast—extends from upper level of axillary fold to proximal palmar crease; elbow usually immobilized at right angle.
4. Short leg cast—extends from below knee to base of toes.
5. Long leg cast—extends from upper thigh to the base of toes; foot is at right angle in a neutral position.
6. Body cast—encircles the trunk stabilizing the spine.
7. Spica cast—incorporates the trunk and extremity.
    a. Shoulder spica cast—a body jacket that encloses trunk, shoulder, and elbow.
    b. Hip spica cast—encloses trunk and a lower extremity.
        i. Single hip spica—extends from nipple line to include pelvis and extends to include pelvis and one thigh.
        ii. Double hip spica—extends from nipple line or upper abdomen to include pelvis and extends to include both thighs and lower legs.
        iii. One-and-a-half hip spica—extends from upper abdomen, includes one entire leg and extends to the knee of the other.
8. Cast brace—external support about a fracture that is constructed with hinges to permit early motion of joints, early mobilization, and independence.
    a. Cast bracing is based on the concept that some weight bearing is physiologic and will promote the formation of bone and contain fluid within a tight compartment that compresses soft tissues, providing a distribution of forces across the fracture site.
    b. Cast brace is applied after initial edema and pain have subsided and there is evidence of fracture stability.
9. Cylinder cast—can be used for upper or lower extremity. Used for fracture or dislocation of knee (lower

extremity) or elbow dislocation (upper extremity).

Complications Associated with Casts

1. Pressure of cast on neurovascular and bony structures causes necrosis, pressure sores, and nerve palsies.
2. Compartment syndrome is a condition resulting from increased progressive pressure within a confined space, thus compromising the circulation and the function of tissues within that space. This is a medical emergency and can be limb threatening. A tight cast, trauma, fracture, prolonged compression of an extremity, bleeding, and edema put patients at risk for compartment syndrome.
3. Immobility and confinement in a cast, particularly a body cast, can result in multisystem problems.
    a. Nausea, vomiting, and abdominal distention associated with cast syndrome (superior mesenteric artery syndrome, resulting in diminished blood flow to the bowel), adynamic ileus, and possible intestinal obstruction.
    b. Acute anxiety reaction symptoms (ie, behavioral changes and autonomic responses—increased respiratory and heart rate, elevated blood pressure [BP], diaphoresis) associated with confinement in a space.
    c. Thrombophlebitis and possible pulmonary emboli associated with immobility and ineffective circulation (eg, venous stasis).
    d. Respiratory atelectasis and pneumonia associated with ineffective respiratory effort.
    e. Urinary tract infection—renal and bladder calculi associated with urinary stasis, low fluid intake, and calcium excretion associated with immobility.
    f. Anorexia and constipation associated with decreased activity.
    g. Psychological reaction (eg, depression) associated with immobility, dependence, and loss of control.

Nursing Assessment

1. Assess neurovascular status of the extremity with a cast for signs of compromise.
    a. Pain (pain out of proportion to injury is an indication for compartment syndrome).
    b. Swelling.
    c. Discoloration—pale or blue.
    d. Cool skin distal to injury.
    e. Tingling or numbness (paresthesia).
    f. Pain on passive extension (muscle stretch).
    g. Slow capillary refill; diminished or absent pulse.
    h. Paralysis.
2. Assess skin integrity of casted extremity. Be alert for the following:
    a. Severe initial pain over bony prominences; this is a warning symptom of an impending pressure ulcer. Pain increases when ulceration occurs.
    b. Odor.

c. Drainage on the cast.

3. Carefully assess for positioning and potential pressure sites of the casted extremity (see Figure 32-3).
   a. Lower extremity—heel, malleoli, dorsum of foot, head of fibula, anterior surface of patella.
   b. Upper extremity—medial epicondyle of humerus, ulnar styloid.
   c. Plaster jackets or body spica casts—sacrum, anterior and superior iliac spines, vertebral borders of scapulae.
4. Assess cardiovascular, respiratory, and GI systems for possible complications of immobility.
5. Assess psychological reaction to illness, cast, and immobility.

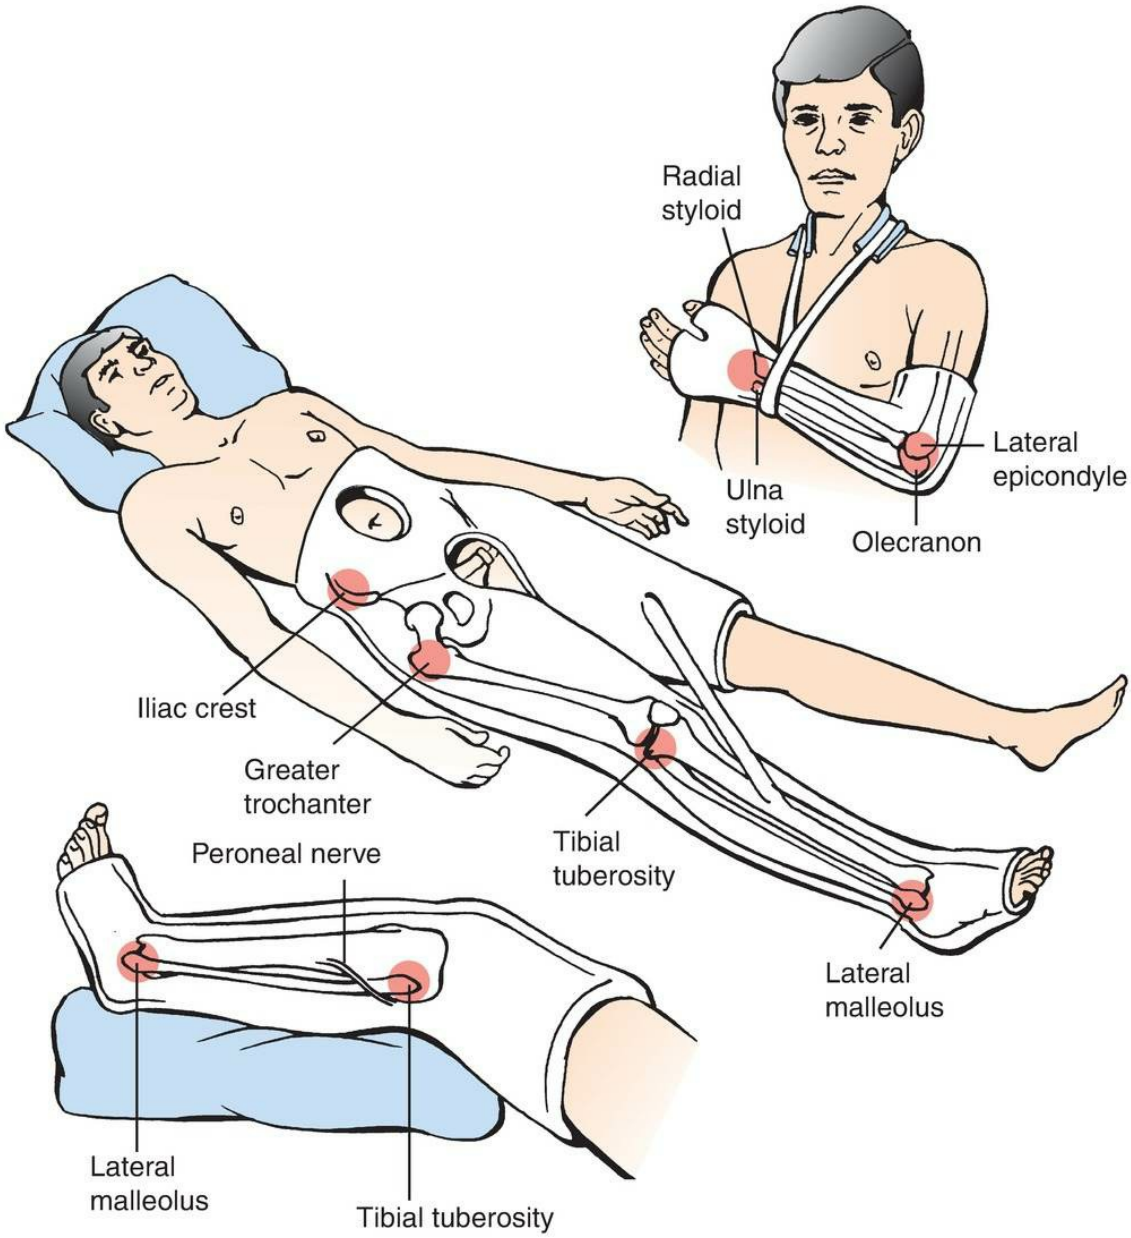

Figure 32-3. Pressure areas in different types of casts.

NURSING ALERT Signs and symptoms of compartment syndrome include pain, paresthesia, pallor, pulselessness, poikilothermia, and paralysis. Pain is the first sign and is usually described as deep, constant, poorly localized, and out of proportion to the injury. The pain is not relieved by analgesia and worsens with stretching of the muscle group. The other signs occur late in the course of compartment syndrome. Unrelenting pain and other signs of compartment syndrome should be reported immediately. The cast may have to be split and removed.

Nursing Diagnoses

- Risk for Neurovascular Injury related to swelling and constrictive bandage or cast.
- Impaired Physical Mobility related to condition and casting.
- Risk for Impaired Gastrointestinal Motility related to cast syndrome.

Nursing Interventions

Maintaining Adequate Tissue Perfusion

1. Elevate the extremity on a cloth-covered pillow above the level of the heart. Keep the heel off the mattress.
2. Avoid resting the cast on hard surfaces or sharp edges that can cause denting or flattening of the cast and consequent pressure sores.
3. Handle moist cast with palms of hands.
4. Turn the patient every 2 hours while cast dries and feel cast for abnormal warm areas when dry.
5. Instruct the patient not to place objects into the cast. Advise the patient of alternative methods of managing itching such as blowing cool air under the cast.
6. Assess neurovascular status hourly during the first 24 hours and then less frequently as condition warrants and swelling resolves.
7. If symptoms of neurovascular compromise occur:
   a. Notify the health care provider immediately.
   b. Bivalve the cast—split cast on each side over its full length into two halves.
   c. Cut the underlying padding—blood-soaked padding may shrink and cause constriction of circulation.
   d. Spread cast sufficiently to relieve constriction.
8. If symptoms of pressure area occur, cast may be "windowed" (hole cut in it) so the skin at the pain point can be examined and treated. The window must be replaced so the tissue does not swell and cause additional pressure problems at window edge.

Minimizing the Effects of Immobility

1. Encourage the patient to move about as normally as possible.

2. Encourage compliance with prescribed exercises to avoid muscle atrophy and loss of strength.
   a. Active ROM for every joint that is not immobilized at regular and frequent intervals.
   b. Isometric exercises for the muscles of the casted extremity. Instruct the patient to alternately contract and relax muscles without moving affected part.
3. Reposition and turn the patient frequently.
4. Avoid pressure behind knees, which reduces venous return and predisposes to thromboembolism.
5. Use antiembolism stockings and sequential compression devices (SCDs), on unaffected limb, as indicated.
6. Administer prophylactic anticoagulants, as prescribed.
7. Encourage deep-breathing exercises and coughing at regular intervals to prevent atelectasis and pneumonia.
8. Encourage the patient to drink liberal quantities of fluid to avoid urinary infection and calculi secondary to immobility.
9. Facilitate patient participation in care planning and activities. Encourage verbalization of feelings and concerns regarding restriction of activities.
10. Provide and encourage diversional activities.
11. Pay special attention to positioning and turning for patients in spica or body cast (see Box 32-1).

BOX 32-1 Specific Care for the Patient in Spica or Body Cast

POSITIONING

1. Place a bed board under the mattress for uniform support of the body.
2. Support the curves of the cast with cloth-covered flexible pillows—prevents cracking and flat spots while cast is drying.
   a. Place three pillows crosswise on bed for body cast.
   b. Place one pillow crosswise at the waist and two pillows lengthwise for affected leg for spica cast. If both legs are involved, use two additional pillows.
3. Encourage the patient to maintain physiologic position by the following:
   a. Using the overhead trapeze.
   b. Placing good foot flat on bed and pushing down while lifting self up on the trapeze.
   c. Avoiding twisting motions.
   d. Avoiding positions that produce pressure on groin, back, chest, and abdomen.

TURNING

1. Move the patient to the side of the bed using a steady, even pulling motion.
2. Place pillows along the other side of the bed—one for the chest and two (lengthwise) for the legs.
3. Instruct the patient to place the arms at the side or above the head.
4. Turn the patient as a unit. Avoid twisting the patient in the cast.

5. Turn the patient toward the leg not encased in plaster or toward the unoperated side if both legs are in plaster.
    a. One nurse stands at other side of bed to receive the patient's shoulders.
    b. Second nurse supports leg in plaster while the third nurse supports the patient's back as he or she is turned.
    c. Turn the patient in body cast to a prone position twice daily—provides postural drainage of bronchial tree; relieves pressure on back.
6. Keep the cast level by elevating the lumbar sacral area with a small pillow when the head of the bed is elevated.

NURSING ALERT Do not grasp crossbar of spica cast to move the patient. The purpose of the bar is to maintain the integrity of the cast.

OTHER CARE

1. Protect cast from soiling.
    a. Cover perineum with a towel. Tuck 4-inch (10-cm) strips of thin polyethylene sheeting under perineal area of cast and tape to cast exterior. Replace when soiling occurs.
    b. Clean outside of soiled cast with a mild powdered cleanser and a *slightly* dampened or dry, clean cloth and pat dry completely, only when necessary.
2. Roll the patient onto fracture bedpan; use small pillow in lumbosacral area for support.
3. Inspect skin for signs of irritation around cast edge, under cast using a flashlight for illumination.
4. Reach up under the cast and massage accessible skin.
5. Protect the toes from the pressure of the bedding.

NURSING ALERT People at high risk for pulmonary emboli include older adults and persons with previous thromboembolism, obesity, heart failure, or multiple trauma. These patients require prophylaxis against thromboembolism.

Preventing Gastrointestinal Impairment

1. Encourage balanced nutritional intake.
    a. Assess the patient's food preferences. Serve small meals.
    b. Provide natural bowel stimulants (eg, fiber) and good fluid intake.
    c. Monitor bowel movements, bowel sounds, and use a bowel program, if necessary.

2. Observe for symptoms of cast syndrome—nausea, vomiting, abdominal distention, abdominal pain, and decreased bowel sounds.
3. If symptoms of cast syndrome develop, report immediately to the health care provider.
    a. Place the patient in a prone position, if tolerated, to relieve pressure symptoms.
    b. Use nasogastric suction as prescribed.
    c. Maintain electrolyte balance by intravenous (IV) replacement of fluids, as prescribed.
    d. Prepare the patient for removal of the cast or surgical relief of duodenal obstruction, if necessary.

NURSING ALERT Cast syndrome (superior mesenteric artery syndrome) is a rare sequela of body cast application, yet it is a potentially fatal complication. It is important to teach patients about this syndrome because this can develop as late as several weeks after cast application.

Patient Education and Health Maintenance

Neurovascular Status

1. Instruct the patient to check neurovascular status and to control swelling.
    a. Watch for signs and symptoms of circulatory disturbance, including blueness or paleness of fingernails or toenails accompanied by pain and tightness, numbness, cold or tingling sensation.
    b. Elevate the affected extremity and wiggle fingers or toes.
    c. Apply ice bags, as prescribed (one third to one half full), to each side of the cast, making sure they do not make indentations in plaster.
    d. Call the health care provider promptly if excessive swelling, paresthesia, persistent pain, pain on passive stretch, or paralysis occurs.
2. Instruct the patient to alternate ambulation with periods of elevation to the cast when seated. Encourage the patient to lie down several times daily with cast elevated.

Skin Irritation

Advise the patient to prevent skin irritation at the cast edge by padding the edges of the cast with moleskin or "petaling" cast edges with strips of tape.

Exercise

1. Instruct the patient to actively exercise every joint that is not immobilized and to perform isometric exercises (contract muscles without moving joint) of those immobilized to maintain muscle strength and to prevent atrophy.
2. Tell the patient to perform hourly when awake:
    a. Leg cast—push down on the popliteal space, hold it, relax, repeat. Move toes back and forth; bend toes down, then pull them back.

b. Arm cast—make a fist, hold it, relax, repeat. Move shoulders.

3. Encourage ambulation with weight-bearing restrictions.

Cast Care

1. Advise to avoid getting cast wet, especially padding under cast—causes skin breakdown as plaster cast becomes soft.
2. Warn against covering a leg cast with plastic or rubber boots because this causes condensation and wetting of the cast.
3. Instruct to avoid weight bearing or stress on plaster cast for 24 hours.
4. Instruct to report to the health care provider if the cast cracks or breaks; instruct the patient not to try to fix it.
5. Teach how to clean the cast:
   a. Remove surface soil with slightly damp cloth.
   b. Rub soiled areas with mild powder cleanser and slightly dampened cloth, and then pat dry completely.
   c. Wipe off residual moisture.

Teaching Safety Measures

To prevent falls, avoid walking on wet floors or sidewalks. To prevent pressure and injury to the skin, do not place objects inside the cast.

After Cast Removal

1. Instruct to clean skin with mild soap and water, blot dry, and apply emollient lotion to dry skin.
2. Warn against scratching the skin.
3. Advise to continue prescribed exercises. Gradually resume activities and elevate extremity to control swelling.

Evaluation: Expected Outcomes

- No pain, discoloration, or sensory or motor impairment of affected extremity; warm, with good capillary refill.
- Ambulates with assistance; performing active ROM and isometric exercises every 1 to 2 hours.
- No signs of cast syndrome.

Traction

Traction is the force applied in a specific direction. To apply the force needed to overcome the natural force or pull of muscle groups, a system of ropes, pulleys, and weights is used.

Purposes of Traction

1. To reduce and immobilize fracture.
2. To regain normal length and alignment of an injured extremity.
3. To lessen or eliminate muscle spasm.
4. To prevent deformity.
5. To give the patient freedom for "in-bed" activities.
6. To reduce pain.

Types of Traction

Running Traction

1. A form of traction in which the pull is exerted in one plane.
2. May use either skin or skeletal traction.
3. Buck extension traction (see Figure 32-4) is an example of running skin traction.

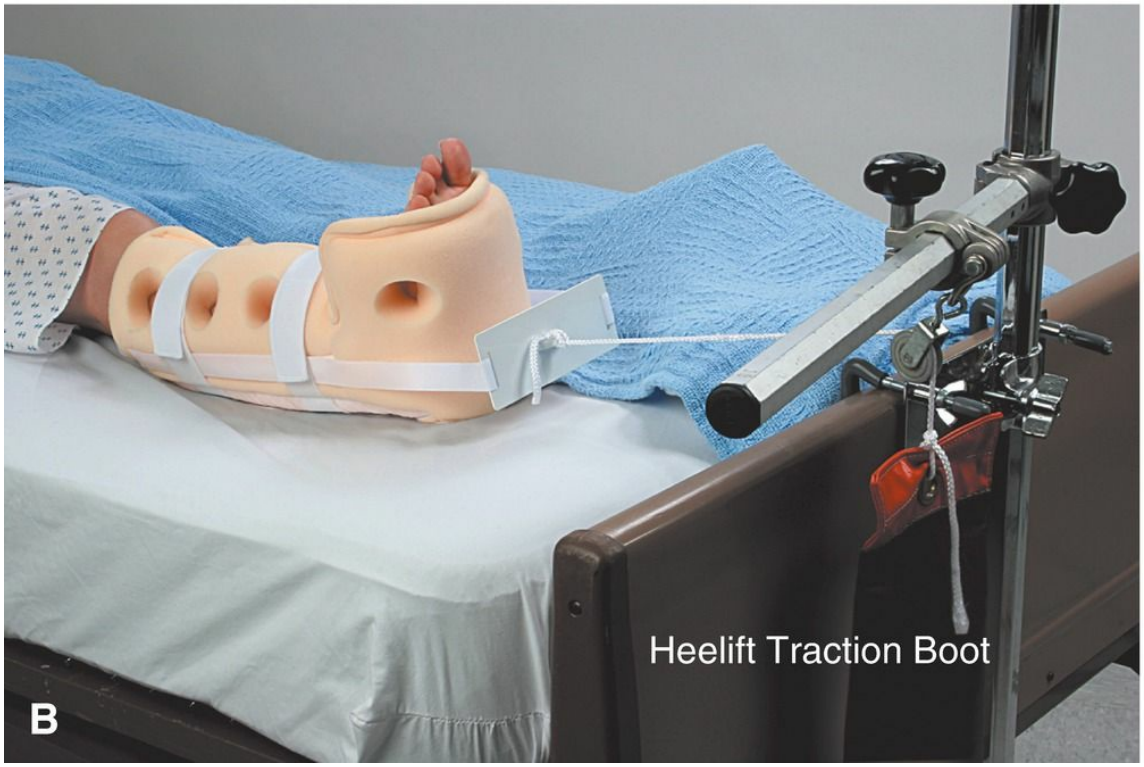

Figure 32-4. Buck extension traction. **(A)** Skin traction is accomplished through a boot device in contact with the skin. **(B)** Weight is applied to exert running traction in one plane, while the body acts as a counterweight. (Courtesy Position Health, *www.positionhealth.com*.)

Balanced Suspension Traction

1. Uses additional weights to counterbalance the traction force and floats the extremity in the traction apparatus.
2. The line of pull on the extremity remains fairly constant despite changes in the patient's position.

Application of Traction

Traction may be applied to the skin or to the skeletal system.

Skin Traction

1. Accomplished by applying a light force that pulls on tape, sponge rubber, or special device (boot, cervical halter, pelvic belt) that is in contact with the skin.
2. The pulling force is transmitted to the musculoskeletal structures.
3. Skin traction is used as a temporary measure in adults to control muscle spasm and pain.
4. It is used before surgery in the treatment of hip fracture (Buck extension) and femoral shaft fractures (Russell traction).
5. It may be used definitively to treat fractures in children.

Skeletal Traction

See Figure 32-5.

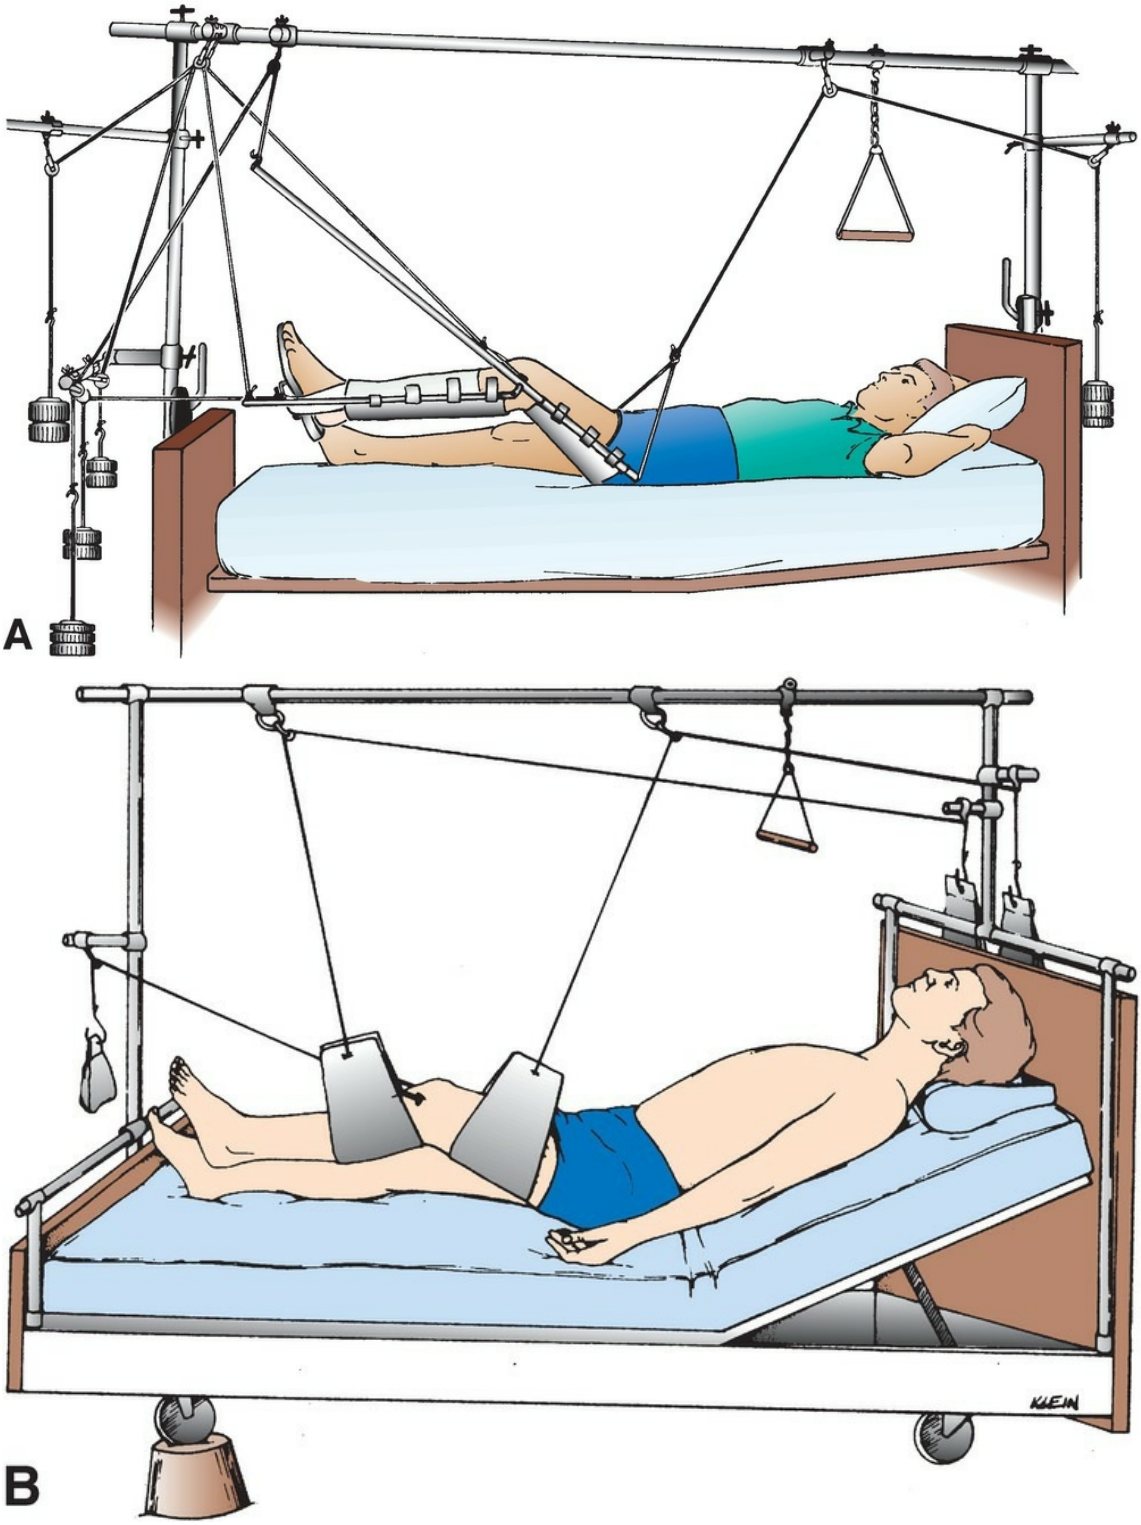

Figure 32-5. Balanced skeletal traction using **(A)** Thomas leg splint and Pearson attachment and **(B)** slings for support and suspension. (**A,** From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins. **B,** Hinkle, J.L., and Cheever, K.H. [2017]. *Brunner and Suddarth's textbook of medical-surgical nursing* [14th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

1. Traction applied by the orthopedic surgeon under aseptic conditions using wires, pins, or tongs placed through bones and provides a strong, steady, continuous pull.
2. Skeletal traction is used most frequently in treating fractures of the femur, humerus (supracondylar fractures), tibia, and cervical spine.

Complications

1. Infection of pin tracts in skeletal traction.
2. Skin breakdown and dermatitis under skin traction.
3. Neurovascular compromise resulting in increased pain, muscle spasms, numbness, tingling, and loss of sensation.
4. Inadequate fracture alignment resulting in posttreatment arthritis.
5. Complications of immobility include the following:
    a. Stasis pneumonia.
    b. Thrombophlebitis.
    c. Pressure ulcers.
    d. Urinary infection and calculi.
    e. Constipation.

Nursing Assessment

1. Assess for pain, deformity, swelling, motor and sensory function, and circulatory status of the affected extremity.
2. Assess skin condition of the affected extremity, under skin traction and around skeletal traction, as well as over bony prominences throughout the body.
3. Assess for alignment of the affected body part.
4. Assess for signs and symptoms of complications.
5. Assess traction equipment for safety and effectiveness.
    a. The patient is placed on a firm mattress.
    b. The ropes and the pulleys should be in alignment.
    c. The pull should be in line with the long axis of the bone.
    d. Any factor that might reduce the pull or alter its direction must be eliminated.
        i. Weights should hang freely.
        ii. Ropes should be unobstructed and not in contact with the bed or equipment.
        iii. The patient's bed should have an overhead trapeze set up to assist the patient to pull self up in bed at frequent intervals.
    e. The amount of weight applied in skin traction must not exceed the tolerance of the skin. The condition of the skin must be inspected frequently.
    f. Cover exposed sharp ends of skeletal pins with cork or other pin covering to protect the patient and

caregivers from injury.

6. Assess emotional reaction to condition and traction.
7. Assess understanding of the treatment plan.

NURSING ALERT Traction is *not* accomplished if the knot in the rope or the footplate is touching the pulley or the foot of the bed or if the weights are resting on the floor. Never remove the weights when repositioning the patient who is in skeletal traction because this will interrupt the line of pull and cause the patient considerable pain.

Nursing Diagnoses

- Impaired Physical Mobility related to traction therapy and underlying pathology.
- Risk for Impaired Skin Integrity related to pressure on soft tissues.
- Risk for Infection related to bacterial invasion at skeletal traction site.
- Risk for Peripheral Neurovascular Dysfunction related to injury or traction therapy.

Nursing Interventions

Minimizing the Effects of Immobility

1. Encourage active exercise of uninvolved muscles and joints to maintain strength and function. Dorsiflex feet hourly to avoid development of footdrop and aid in venous return.
2. Encourage deep breathing hourly to facilitate expansion of lungs and movement of respiratory secretions.
3. Auscultate lung fields at least twice per day.
4. Encourage fluid intake of 2,000 to 2,500 mL daily.
5. Provide balanced high-fiber diet rich in protein; avoid excessive calcium intake.
6. Establish bowel routine through the use of diet and stool softeners, laxatives, and enemas, as prescribed.
7. Prevent pressure on the calf and evaluate twice daily for the development of thrombophlebitis.
8. Check traction apparatus at repeated intervals—the traction must be continuous to be effective, unless prescribed as intermittent, as with pelvic traction.
    a. With *running traction*, the patient may not be turned without disrupting the line of pull.
    b. With *balanced suspension traction*, the patient may be elevated, turned slightly, and moved as desired.
9. Use SCDs and compression stockings, as indicated.
10. Administer prophylactic anticoagulants, as prescribed.

NURSING ALERT Every complaint of the patient in traction should be investigated immediately to prevent injury.

Maintaining Skin Integrity

1. Examine bony prominences frequently for evidence of pressure or friction irritation.
2. Observe for skin irritation around the traction bandage.
3. Observe for pressure at traction–skin contact points.
4. Report complaint of burning sensation under traction.
5. Relieve pressure without disrupting traction effectiveness.
    a. Make sure that linens and clothing are wrinkle free.
    b. Use lambs' wool pads, heel and elbow protectors, and special mattresses, as needed.
6. Special care must be given to the back every 2 hours because the patient maintains a supine position.
    a. Have the patient use trapeze to pull self up and relieve back pressure.
    b. Provide backrubs.

Avoiding Infection at Pin Site

1. Monitor vital signs for fever or tachycardia.
2. Watch for signs of infection, especially around the pin tract.
    a. The pin should be immobile in the bone, and the skin surrounding the wound should be dry. Small amount of serous oozing from pin site may occur.
    b. If infection is suspected, percuss gently over the tibia; this may elicit pain if infection is developing.
    c. Assess for other signs of infection: heat, redness, fever.
3. If directed, clean the pin tract with sterile applicators and prescribed solution or ointment (ie, normal saline, sterile water, chlorhexidine)—to clear drainage at the entrance of tract and around the pin because plugging at this site can predispose to bacterial invasion of the tract and bone.

Preventing Neurovascular Injury

1. Assess motor and sensory function of specific nerves that might be compromised.
    a. Peroneal nerve—have the patient point the great toe toward the nose; check sensation on the dorsum of the foot; presence of footdrop.
    b. Radial nerve—have the patient extend the thumb; check sensation in the web between the thumb and index finger.
    c. Median nerve—thumb–middle finger apposition; check sensation of index finger.
2. Determine adequacy of circulation (eg, color, temperature, motion, capillary refill of peripheral fingers or toes).
    a. With Buck traction, inspect the foot for circulatory difficulties within a few minutes and then periodically after the elastic bandage has been applied.
3. Report promptly if change in neurovascular status is identified.

Patient Education and Health Maintenance

1. Teach the patient the purpose of traction therapy.
2. Delineate limitations of activity necessary to maintain effective traction.
3. Teach the use of patient aids (eg, trapeze).
4. Instruct the patient not to adjust or modify traction apparatus.
5. Instruct the patient in activities designed to minimize effects of immobility on body systems.
6. Teach the patient necessity for reporting changes in sensations, pain, movement.

Evaluation: Expected Outcomes

- Exercises as instructed; deep breaths hourly; fluid intake 2,000 to 2,500 mL/24 hours.
- No signs of skin breakdown under traction bandage or over bony prominences.
- No drainage, redness, or odor at pin site.
- No motor or sensory impairment; good capillary refill, color, and warmth of extremity.

External Fixation

External fixation is a technique of fracture immobilization in which a series of transfixing pins is inserted through bone and attached to a rigid external metal frame (see Figure 32-6). The method is used mainly in the management of open fractures with severe soft tissue damage.

Figure 32-6. External fixation device used for reduction and immobilization of open fracture, allowing treatment of soft tissue wounds. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Advantages

1. Permits rigid support of severely comminuted open fractures, infected nonunions, and infected unstable joints.
2. Facilitates wound care (frequent debridements, irrigations, dressing changes) and soft tissue reconstruction (delayed wound closure, muscle flaps, skin grafts).
3. Allows early function of muscles and joints.
4. Allows early patient comfort.

Circular Fixators

Purpose

May be used for limb lengthening, correction of angulation and rotation defects, and in treatment of nonunion.

Components

1. This fixator apparatus consists of through-the-bone tension wires placed above and below the treatment site.
2. The wires are attached to fixator rings surrounding the limb.
3. The rings are connected to one another by telescoping rods.

Management

1. Adjustments are made daily at about 1 mm/day, stimulating callus and bone formation.
2. Patient compliance is essential.
3. Weight bearing is encouraged.
4. When the desired length or correction is achieved, the fixator is left in place without further adjustment until bone healing occurs.

Application of External Fixator

1. Under general anesthesia, the skin is cleaned and transfixing pins are inserted into the bone through small incisions above and below the fracture.
2. After reduction of the fracture, the appliance is stabilized by adjusting and tightening the bars connecting the sets of pins.
3. The sharp pinheads are covered with plastic, cork, or rubber covers to protect the other extremity and caregivers.

Nursing Assessment

1. Determine the patient's understanding of procedure and fixation device.
2. Evaluate neurovascular status of involved body part.
3. Inspect each pin site for redness, drainage, tenderness, pain, and loosening of the pin.
4. Inspect open wounds for healing, infection, or devitalized tissue.
5. Assess functioning of other body systems affected by injury or immobilization.

Nursing Diagnoses

- Anxiety related to appearance of external fixation device and wound.
- Risk for Peripheral Neurovascular Dysfunction related to swelling, fixator, and underlying condition.
- Risk for Infection related to open injury and skeletal pin insertion.
- Impaired Physical Mobility related to presence of fixator and condition.

Nursing Interventions

Relieving Anxiety

1. If possible, before placement of the device, reassure the patient that, although the fixator appears clumsy and cumbersome, it should not hurt once it is in place.
2. Emphasize the positive aspects of this device in treating complex musculoskeletal problems.
3. Encourage the patient to verbalize reaction to the device.
4. Inform the patient that greater mobility can be achieved with an external fixation device, thereby minimizing the development of other system problems.
5. Involve the patient in care and in the management of external fixator.

Maintaining Intact Neurovascular Status

1. Assess neurovascular status frequently—every 15 minutes to 1 hour while swelling is significant and later, every 2 to 8 hours.
2. Establish baseline of functioning for comparative monitoring. Complex musculoskeletal injuries frequently result in disruption of soft tissue functioning.
3. Elevate extremity to reduce swelling.
4. Report any change in neurovascular status.

NURSING ALERT Assess neurovascular status frequently and record findings. Report abnormal findings or change in status.

Preventing Infection

1. Provide site and fixator care.
    a. Clean pin sites and remove crusts with sterile cotton applicator, using solution as prescribed, or established standard of care.
        i. Crusts formed by serous drainage can prevent fluid from draining and can cause infection.
        ii. A small amount of serous drainage from the pin sites is normal.
    b. Note and report inflammation, swelling, tenderness, and purulent drainage at pin site.
    c. Note skin tension at pin site—tension can cause discomfort.
    d. Report loosened pins.
    e. Clean fixator with clean cloth and water, as needed.
2. Provide wound care.
    a. The open wounds at the fracture site are usually treated by daily dressing changes.
    b. Use sterile technique.
    c. Note wound appearance. Monitor healing. Report signs of infection.
3. Monitor for local and systemic indicators of infection.

Encouraging Mobility

1. Encourage the patient to participate in care activities.
2. Assure the patient that pain associated with injury will diminish as tissue reactions to injury and manipulation resolve and healing progresses.
3. Inform the patient that the external fixator maintains the fracture in a stable position and that the extremity can be moved. Adjustment of the fixator is done by the health care provider. (The patient is taught how to adjust the circular fixator.)
4. To move the extremity, do not grasp the frame, rather support the entire extremity and assist the patient to move. Reassure the patient that the fixator can withstand normal movement.
5. Teach quadriceps exercises and ROM exercises for joints; usually started on first postoperative day.
6. Teach crutch walking when soft tissue swelling has diminished; encourage weight bearing, as prescribed.

Patient Education and Health Maintenance

1. Instruct the patient to inspect around each pin site daily for signs of infection and loosening of pins. Watch for pain, soft tissue swelling, and drainage.
2. Teach the patient how to clean around each pin daily, using aseptic technique. Do not touch the wound with hands.
3. Advise the patient to clean the fixator regularly—to keep it free of dust and contamination.
4. Warn against tampering with clamps or nuts—can alter compression and misalign fracture.
5. Review weight bearing and other restrictions associated with injury and treatment regimen.
6. Encourage the patient to follow rehabilitation regimen.

Evaluation: Expected Outcomes

- Verbalizes understanding of and comfort with fixator device.
- Swelling relieved; neurovascular status intact.
- No drainage or signs of infection at pin sites; pin tracts remain intact, no loosening of pins.
- Ambulating with ambulatory device, as directed.

Orthopedic Surgery

EVIDENCE BASE National Association for Orthopaedic Nursing. (2017). *Orthopaedic Surgery Manual*, (3rd ed.). Chicago, IL: Author.

Types of Surgery

1. Open reduction—reduction and alignment of the fracture through surgical incision.
2. Closed reduction—manipulation of bone fragments or joint dislocation without surgical incision.
3. Internal fixation—stabilization of the reduced fracture with the use of metal screw, plates, nails, or pins.
4. Bone graft—placement of autologous or homologous bone tissue to replace, promote healing of, or stabilize diseased bone.
5. Arthroplasty—repair of a joint through realignment or reconstruction; may be done through arthroscope (arthroscopy) or open joint repair.
6. Joint replacement—type of arthroplasty that involves replacement of joint surfaces with metal or plastic materials.
7. Total joint replacement—replacement of both articular surfaces within a joint.
8. Meniscectomy—excision of damaged meniscus (fibrocartilage) of the knee.
9. Tendon transfer—movement of tendon insertion point to improve function.
10. Fasciotomy—cutting muscle fascia to relieve constriction or contracture.
11. Amputation—removal of a body part.

Note: Joint replacement and amputation will be covered separately.

Preoperative Management

1. Hydration, protein, and caloric intake are assessed. The goal is to maximize healing and reduce risk of complications by providing IV fluids, vitamins, and nutritional supplements, as indicated.
2. Medications, including prescribed, OTC, and herbals, are reviewed, and the patient is instructed on which medications should be held prior to surgery and for how long.
    a. Aspirin, anti-inflammatories, anticoagulants, and antiplatelet agents that may affect clotting may be held for up to a week prior to surgery.
    b. If the patient has had previous corticosteroid therapy, it could contribute to current orthopedic condition (aseptic necrosis of the femoral head, osteoporosis) as well as affect the patient's response to anesthesia and the stress of surgery. History of corticosteroid therapy must be documented.
    c. Metformin is usually held for 48 hours prior to surgery to prevent lactic acidosis due to fasting, a rare complication.
    d. Antidepressants, particularly monoamine oxidase inhibitors, and herbals should be explored for

interaction with anesthetics.

3. Signs of infection (respiratory, dental, skin, urinary), which could contribute to development of osteomyelitis after surgery, are ruled out.
4. Coughing and deep breathing, frequent vital sign and wound checks, repositioning are described to prepare the patient.
5. Prepare the patient for voiding in bedpan or urinal in recumbent position before surgery, if indicated. This helps reduce the need for postoperative catheterization.
6. The patient is acquainted with traction apparatus and the need for splint or cast, as indicated by type of surgery.
7. Type and cross-match is ordered if there is a potential need for the patient to receive blood products. Autologous blood donation may be done several weeks before surgery.
8. Discharge planning is begun prior to surgery with plan for rehabilitation options postoperatively.

GERONTOLOGIC ALERT Many older patients are at risk for poor healing due to poor nutritional status. Suggest obtaining albumin, prealbumin, and transferrin evaluation and nutrition consult in advance of surgery.

Postoperative Management

1. Neurovascular status is monitored, and swelling caused by edema and bleeding into tissues (causing a hematoma) should be assessed and controlled.
2. The affected area is immobilized and activity limited to protect the operative site and stabilize musculoskeletal structures.
3. Hemorrhage is watched for to prevent hypovolemic shock, which may result from significant blood loss.
4. Complications of immobility are prevented through aggressive and vigilant postoperative care. Deconditioning is limited through isometric and isotonic exercises.

Complications

1. Compartment syndrome.
2. Blood loss, shock, anemia.
3. Atelectasis and pneumonia.
4. Osteomyelitis, wound infections.
5. Venous thromboembolic events.
6. Fat embolus.

Nursing Diagnoses

- Risk for Deficient Fluid Volume related to hemorrhage.

- Ineffective Breathing Pattern related to effects of anesthesia, analgesics, and immobility.
- Risk for Peripheral Neurovascular Dysfunction related to swelling.
- Acute Pain related to surgical intervention.
- Risk for Infection related to surgical intervention.
- Impaired Physical Mobility related to immobilization therapy and pain.
- Imbalanced Nutrition: Less Than Body Requirements related to blood loss and the demands of healing and immobility.

Nursing Interventions

Monitoring for Shock and Hemorrhage

1. Evaluate BP and pulse rates frequently—rising pulse rate, widening pulse pressure, or slowly falling BP indicate persistent bleeding or development of a state of shock.
2. Monitor for hemorrhage—orthopedic wounds have a tendency to ooze more than do other surgical wounds.
   a. Measure suction drainage, if used.
   b. Anticipate up to 500 mL of drainage in the first 24 hours, decreasing to less than 30 mL/8 hours within 48 hours, depending on surgical procedure.
   c. Report increased wound drainage or steady increase in pain of the operative area.
3. Administer IV fluids and blood products, as ordered.

Promoting Effective Breathing Pattern

1. Give respiratory depressant drugs cautiously. Monitor respiration depth and rate frequently. Opioid analgesic effects may be cumulative.
2. Change position every 2 hours—mobilizes secretions and helps prevent bronchial obstruction.
3. Encourage the use of incentive spirometer and coughing and deep-breathing exercises every 2 hours.
4. Auscultate the lungs for atelectasis and retention of secretions.

Monitoring Peripheral Neurovascular Status

1. Monitor circulation distal to the part where cast, bandage, or splint has been applied.
2. Prevent constriction leading to interference with blood or nerve supply.
3. Elevate affected extremity and apply covered ice packs, as directed, to reduce swelling and bleeding into tissues.
4. Observe toes and fingers for healthy color and good capillary refill.
5. Check pulses of affected extremity; compare with unaffected extremity.
6. Note skin temperature and sensation.
7. Document observations.

NURSING ALERT If neurovascular problems are identified, loosen cast or dressing at once and notify surgeon.

Relieving Pain

1. Institute comfort measures, as prescribed, as well as nursing measures, as indicated: backrubs; soft light; soft, tranquil music.
2. Be aware that muscle spasms may contribute to discomfort.
3. Use patient-controlled analgesia according to standards of care.
4. Facilitate progression from IV medications to by mouth when tolerated.
5. Prevent constipation due to opioids by obtaining order for bowel regimen and instituting diet regimen.

Preventing Infection

1. Monitor vital signs for fever, tachycardia, or increased respiratory rate, which may indicate infection.
2. Examine incision for redness, increased temperature, swelling, and induration. Document findings.
3. Note and document character of drainage.
4. Evaluate complaints of recurrent or increasing discomfort.
5. Administer antibiotic therapy, as prescribed.
6. Maintain aseptic technique for dressing changes and wound care.

Minimizing the Effects of Immobility

1. Encourage the patient to exercise by self with a planned program of exercise as soon as possible after surgery.
2. Have the patient exercise the unaffected extremity (unless instructed by physical therapist to exercise affected extremity as well): flex knee, extend the knee with hip still flexed, and then lower the extremity to the bed. Passive motion devices may be used to maintain ROM.
3. Encourage the patient to move fingers and toes hourly.
4. Advise the patient to move joints that are not fixed by traction or appliance through their ROM as fully as possible.
5. Suggest muscle-setting exercises (quadriceps setting) if active motion is contraindicated.
6. Apply antiembolism stockings, foot pumps, or SCDs as prescribed by the surgeon.
7. Give prophylactic anticoagulants as directed (eg, heparin, warfarin, aspirin, a low molecular weight heparin).
8. Encourage early resumption of activity.

Providing Adequate Nutrition

1. Provide a balanced diet and increase fluids and fiber to promote healing and reduce incidence of

constipation associated with immobility.

2. Encourage a high-iron diet and administer blood products and iron supplements to counteract significant blood loss, as directed.
3. Monitor hemoglobin and hematocrit levels. Report below-normal results to the health care provider.
4. Watch for signs and symptoms of anemia, especially after fracture of long bones:
   a. Fatigue.
   b. Shortness of breath.
   c. Pallor.
   d. Tachycardia.
5. Maintain good fluid intake and urinary output to prevent infection and calculi. Watch for urinary retention—especially in older men with some degree of prostatism who may have difficulty voiding.

Patient Education and Health Maintenance

1. Teach the patient activities that will minimize the development of complications (eg, turning, ankle pumps, antiembolism stockings, SCDs, coughing, and deep breathing, early mobilization as able).
2. Instruct the patient in dietary considerations to facilitate healing and minimize development of constipation and renal calculi.
3. Inform the patient of techniques that facilitate moving while minimizing associated discomforts (eg, supporting injured area and practicing smooth, gentle position changes).
4. Encourage long-term follow-up and physical therapy (PT) exercises, as prescribed, to regain maximum functional potential.

TRANSITIONAL CARE ALERT When working with musculoskeletal patients, the main focus is the return of function to one's previous physical condition. Upon discharge from the hospital, equipment will be necessary for assistance at home, as well as the help of a caregiver to provide support and safety. Help prepare the patient and caregiver by teaching safe body mechanics and use of mobility aids. Facilitate referrals for durable medical equipment, home health nursing and therapy services, and ongoing caregiver education and support through community resources to help prevent complications and reduce the risk of readmission.

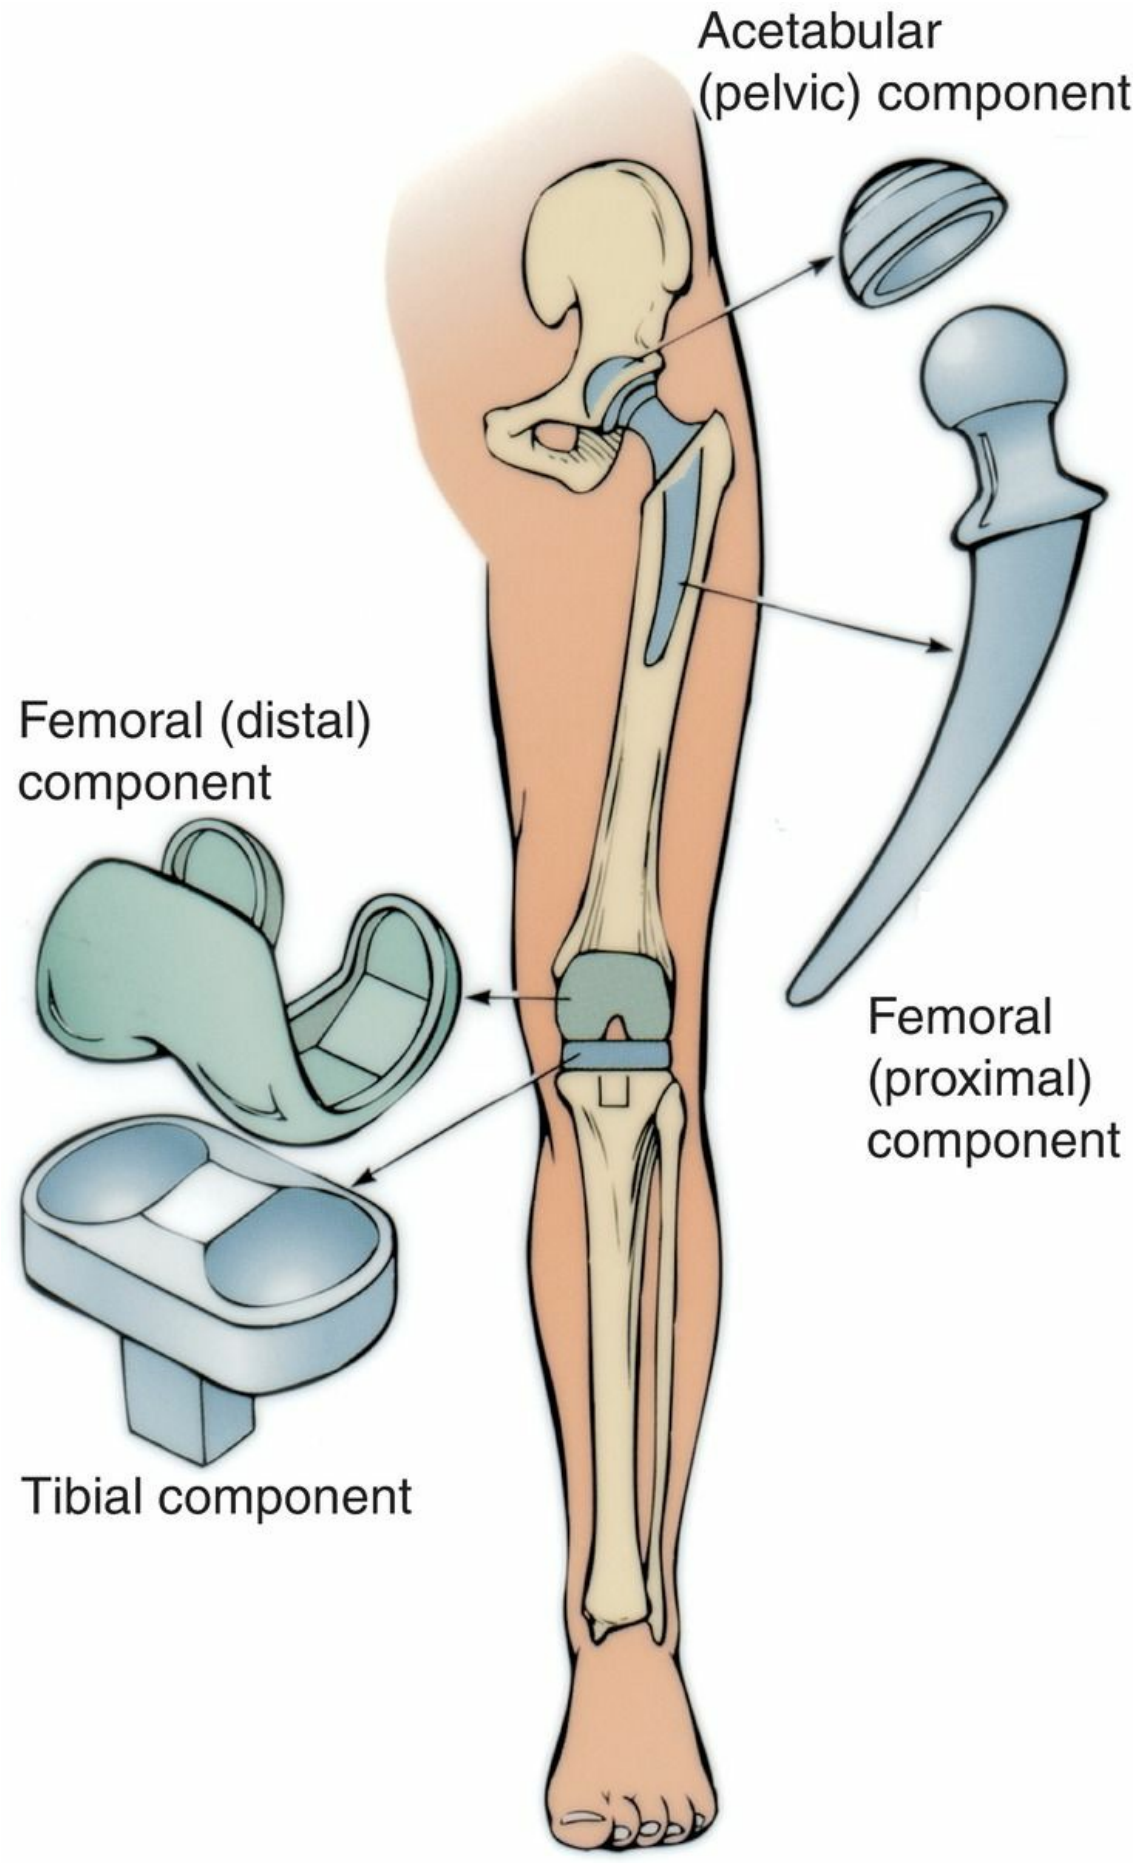
Evaluation: Expected Outcomes

- BP stable; drainage from wound less than 30 mL.
- Respirations, deep; performing effective deep breathing and coughing every 2 hours.
- Extremity beyond operative site neurovascularly intact.
- Verbalizes decreased pain.
- Afebrile; incision without drainage.

- Ambulating as directed.
- Eats a balanced diet high in iron; hemoglobin within normal range.

Arthroplasty and Total Joint Replacement

Arthroplasty is reconstructive surgery to restore joint motion and function and to relieve pain. It generally involves replacement of bony joint structure by a prosthesis. *Total joint arthroplasty* is the replacement of both articular surfaces with metal or plastic components. The most common types of joint replacement (see Figure 32-7) include the following:



Acetabular
(pelvic) component
Femoral (distal)
component
Femoral
(proximal)
component
Tibial component

Figure 32-7. Hip and knee replacement. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Total hip arthroplasty—replacement of a severely damaged hip with an artificial joint. A large number of implants are available, often with a metal femoral component topped by a spherical ball fitted into a plastic acetabular socket. Surgical approach is anterior (muslce sparing) or posterior (involves cutting and reattachment of muscles and longer healing time).

Total knee arthroplasty—implant procedure in which tibial, femoral, and patellar joint surfaces are replaced because of destroyed knee joint.

Total shoulder arthroplasty—replacement of the humeral head and the glenoid surface with prostheses.

Clinical Indications

1. For patients with unremitting pain and irreversibly damaged joints:
   a. Primary OA.
   b. Rheumatoid arthritis (RA).
2. Selected fractures (eg, femoral neck fracture).
3. Failure of previous reconstructive surgery (osteotomy, cup arthroplasty, femoral neck fracture complications—nonunion, avascular necrosis).
4. Congenital hip disease.
5. Pathologic fractures from metastatic cancer.
6. Joint instability.

Considerations

1. The prostheses are of various designs and may be fixed to the remaining bone by cement, press fit, or bone ingrowth.
2. Selection of the prosthesis and fixation technique depends on the patient's bone structure, joint stability, and other individual characteristics, including age, weight, and activity level.
3. Arthroplasty is an exacting and meticulous procedure. To reduce the risk of an infected prosthesis, special precautions are carried out in the operating room (impermeable operating room attire, clean air system) to reduce particulate matter and bacterial count of the air.

Preoperative Management

1. Infections (urinary, dental, skin, respiratory) are ruled out or treated because they are potential foci of infection for seeding prosthesis infection.
2. Preoperative patient teaching is provided.
   a. Postoperative regimen (eg, extended exercise program) that will be carried out after surgery is explained; atrophied muscles must be reeducated and strengthened.

b. Isometric exercises (muscle setting) of quadriceps and gluteal muscles are taught.
c. Bed-to-wheelchair transfer without going beyond the hip flexion limits (usually 60 to 90 degrees) is taught.
d. Non–weight- and partial weight-bearing walking with ambulatory aid (walker, crutches) is taught to facilitate postoperative ambulation.
e. Abduction splint, knee immobilizer, or continuous passive motion is demonstrated if equipment will be used postoperatively.

3. Antiembolism stockings are applied to minimize development of thrombophlebitis.
4. Skin preparation includes antimicrobial solution to reduce skin microorganisms, a potential source of infection.
5. Antibiotics are administered timely, as prescribed, to ensure therapeutic blood level during and immediately after surgery. Antimicrobials usually are given immediately preoperatively, intraoperatively, and postoperatively to reduce incidence of infection.
6. Cardiovascular, respiratory, renal, and hepatic function are assessed, and measures are taken to maximize general health condition.
7. Discharge planning is begun, including rehabilitation options postoperatively.

Postoperative Management

Use of Appropriate Positioning

To prevent dislocation of prosthesis and facilitate healing, numerous modifications are required in positioning these patients postoperatively.

1. After hip arthroplasty (posterior approach):
   a. The patient is usually positioned supine in bed.
   b. The affected extremity is held in slight abduction by either an abduction splint or pillow or Buck extension traction to prevent dislocation of the prosthesis.
   c. Two nurses turn the patient on the unoperated side while supporting the operated hip securely in an abducted position; the entire length of leg is supported by pillows.
      i. Use pillows to keep the leg abducted; place pillow at back for comfort.
      ii. If the bed is equipped, use overhead trapeze to assist with position changes.
   d. The bed is usually not elevated more than 45 to 60 degrees; placing the patient in an upright sitting position puts a strain on the hip joint and may cause dislocation.
   e. A fracture bedpan is used. Instruct the patient to flex the unoperated hip and knee and pull up on the trapeze to lift buttocks onto pan. Instruct the patient *not* to bear down on the operated hip in flexion when getting off the pan.
2. Following anterior hip arthroplasty, the patient can flex the hip and bear weight often within hours. Restrictive positioning is not necessary to prevent dislocation.After knee arthroplasty:
   a. The knee may be immobilized in extension with a firm compression dressing and an adjustable soft

extension splint or long-leg plaster cast.

b. Leg is elevated to control swelling being mindful to assure that there is nothing causing the knee to remain bent if it is not in an immobilizer.

c. Alternatively, continuous passive motion may be started to facilitate joint healing and restoration of joint ROM.

NURSING ALERT The patient must not adduct the hip or flex it beyond recommended degree, as indicated by the surgeon, as this may lead to subluxation or dislocation of the hip. Signs of joint dislocation include shortened extremity, increasing discomfort, inability to move joints.

Deterring Complications

1. Aggressive care and frequent assessment can reduce the complication rate.
2. Prevent thromboembolism by continuous use of elastic hose and SCD while the patient is in bed. Discontinue SCD when the patient is ambulatory.
3. C-reactive protein and erythrocyte sedimentation rate (ESR) can be used to quantify the risk of periprosthetic joint infection. High serum levels indicate a high risk of infection and require further diagnostic testing or biopsy.

Promoting Early Ambulation

1. Ambulation may begin on the day of surgery or the first postoperative day.
2. Transfers to the chair or ambulation with aids, such as walkers, are encouraged as tolerated and based on the patient's condition and type of prosthesis.
3. Caution is taken in moving the patient to upright position, and the patient is monitored for orthostatic hypotension.

Nursing Diagnoses

Also see "Orthopedic Surgery," page 869.

- Impaired Physical Mobility related to prosthetic joint.

Nursing Interventions

Also see page 869.

Promoting Mobility

After posterior hip arthroplasty:

1. Use an abduction splint or pillows while assisting the patient out of bed.
   a. Keep the hip at maximum extension.
   b. Instruct the patient to pivot on unoperated extremity.

c. Assess the patient for orthostatic hypotension.

2. When ready to ambulate, teach the patient to advance the walker and then advance the operated extremity to the walker, permitting weight bearing, as prescribed.
3. With increased stability, assist the patient to use crutches or cane, as prescribed.
4. Encourage practice of PT exercises to strengthen muscles and prevent contractures.
5. Encourage bed mobility by providing an overhead frame/trapeze.

After knee arthroplasty:

1. Assist the patient with transfer out of bed into wheelchair with extension splint in place, if applicable.
2. Encourage weight bearing, as directed by the surgeon.
3. Apply continuous passive motion equipment or carry out passive ROM exercises, as prescribed.

Community and Home Care Considerations

1. Encourage the patient to continue to wear compression stockings after discharge until full activities are resumed.
2. Ensure that the patient avoids excessive hip adduction, flexion, and rotation for 6 weeks after hip arthroplasty (posterior hip precautions).
   a. Avoid sitting in a low chair or toilet seat to avoid flexing the hip more than 90 degrees.
   b. Keep the knees apart; do not cross the legs.
   c. Limit sitting to 30 minutes at a time—to minimize hip flexion and the risk of prosthetic dislocation and to prevent hip stiffness and flexion contracture.
   d. Avoid internal rotation of the hip.
   e. Follow weight-bearing restrictions from the surgeon.
3. Encourage quadriceps setting and ROM exercises, as directed.
   a. Have a daily program of stretching, exercise, and rest throughout lifetime.
   b. Do not participate in any activity placing undue or sudden stress on joint (jogging, jumping, lifting heavy loads, gaining weight, excessive bending and twisting).
   c. Use a cane when taking fairly long walks.
4. Suggest self-help and energy-saving devices.
   a. Handrails by toilet.
   b. Raised toilet seat if there is some residual hip flexion problem.
   c. Bar-type stool for kitchen work.
   d. Occupational therapy (OT) devices for dressing, reaching.
   e. Adequate home lighting to prevent falls.
   f. Removal of scatter rugs.
5. Advise the patient to sleep with two pillows between legs to prevent turning over in sleep. The patient should get out of bed with nonoperative leg.

6. Tell the patient to lie prone when able twice daily for 30 minutes to promote full extension of hip.
7. Monitor for late complications—deep infection, increased pain or decreased function associated with loosening of prosthetic components, implant wear, dislocation, fracture of components, avascular necrosis or dead bone caused by loss of blood supply; heterotrophic ossification (formation of bone in periprosthetic space).
8. Assess home for safety to prevent falls—long phone cords, scatter rugs, pets that run underfoot, slippery floors.

Patient Education and Health Maintenance

1. Teach the patient use of supportive equipment, such as walkers and raised toilet seat, as prescribed.
2. Advise the patient to notify all health care providers about prosthetic joint because prophylactic antibiotic (to prevent implant infection) will be needed prior to other surgical procedures or any procedure known to cause bacteremia (tooth extraction, manipulation of genitourinary tract). Patients with inflammatory arthropathies, immunosuppressive therapies, and immunocompromising conditions are especially at risk.

EVIDENCE BASE American Association of Orthopaedic Surgeons and American Dental Association. (2012). *Prevention of orthopaedic implant infection in patients undergoing dental procedures: Evidence-based guideline and evidence report*. Rosemont, IL: Author.

---

3. Avoid MRI studies because of implanted metal component.
4. Advise the patient that metal component in hip or knee may set off metal detectors (airports, some buildings). The patient should carry a medical identification card.
5. New hip or knee is designed for low-impact exercise, such as walking, golf, dancing. High-impact exercises, such as jogging, may cause the prosthesis to loosen.

Evaluation: Expected Outcomes

Maintains proper positioning without evidence of complications.

Amputation

Amputation is the total or partial surgical removal of digits, foot, lower leg, or forearm. Amputation is considered a surgical reconstructive procedure.

Indications

1. Inadequate tissue perfusion caused by peripheral vascular diseases.
2. Severe trauma.
3. Malignant tumor.
4. Congenital deformity.
5. Osteomyelitis/infection.

Types of Amputation

Open (Guillotine)

1. Used with infection and for patients who are poor surgical risks.
2. Wound heals by granulation over time or secondary closure 1 week later.

Closed (Myoplastic or Flap)

1. Residual limb is covered by a flap of skin.
2. Flap of skin is sutured posteriorly.
3. Most common technique used for vascular disease.

Surgical Considerations

1. The surgeon considers possible limb-salvage techniques.
    a. Revascularization (research is focusing on angiogenesis and stem cell therapy).
    b. Hyperbaric oxygenation.
    c. Tumor resection with bone grafting.
2. Determines level for amputation based on level of maximal viable tissue for wound healing.
3. Develops a functional, nontender, pressure-tolerant residual limb.

Types of Dressings

Soft Dressing

1. Secured with elastic bandage.
2. Permits wound inspection.
3. Used with patients who should avoid early weight bearing (eg, those with peripheral vascular disease).

Closed, Rigid Plaster Dressing

1. Applied immediately after surgery (ie, immediate postoperative prosthesis).

2. Controls edema.
3. Supports circulation, promoting healing.
4. Minimizes pain on movement.
5. Shapes residual limb.
6. Permits attachment of prosthetic extension (pylon) and early ambulation.

Preoperative Management

1. Hemodynamic evaluation is performed through testing, such as angiography, arterial blood flow, and xenon 133 scan, to determine optimal amputation level.
2. Culture and sensitivity tests of draining wounds are done to assist in control of infection preoperatively.
3. Evaluation of contralateral extremity is performed to determine functional potential postoperatively.
4. Evaluation of cardiovascular, respiratory, renal, and other body systems is necessary to determine preoperative condition of the patient and reduce the risks of surgery by optimizing function.
5. Nutritional status is evaluated and optimized with adequate protein to enhance wound healing.
6. Exercises are taught to strengthen muscles for the use of ambulatory aids (lower-limb amputee).
   a. Flex and extend arms while holding traction weights.
   b. Do push-ups from a prone position, if feasible.
   c. Do sit-ups from a seated position, if feasible.
7. Use of ambulatory aids taught to maintain mobility, prepare for postoperative status, and instill confidence in ability.
8. Phantom sensation is explained—the patient will continue to "feel" the amputated body part for some time.
9. Emotional support is given.
   a. Support concept of amputation as a surgical reconstructive procedure.
   b. Explore the patient's perception of procedure and effect on lifestyle.
   c. Avoid unrealistic and misleading reassurance—management of prosthesis can be slow and painful.

GERONTOLOGIC ALERT Amputation of the lower extremity can be a life-threatening procedure, especially in patients older than age 60 with peripheral vascular disease. Significant morbidity accompanies above-knee amputations because of associated poor health and disease as well as the complications of sepsis and malnutrition and the physiologic insult of amputation.

Postoperative Management

1. The extremity should be in full extension and may be elevated, if possible. An extension splint/immobilizer may be indicated.

2. Complications are monitored—hemorrhage, infection, unrelieved phantom pain, nonhealing wound.
3. Rehabilitation is initiated through PT and prosthetic fitting, if indicated.
4. Optimal treatment is provided for diabetes mellitus, heart disease, infection, stroke, chronic obstructive pulmonary disease, peripheral vascular disease, and age-related deterioration, which are factors limiting rehabilitation.
5. If wound breakdown, infection, or delay in healing of residual limb occurs, therapy is provided to prevent delay in rehabilitation.
6. Acceptance of body image change is promoted.

Nursing Diagnoses

- Risk for Deficient Fluid Volume related to hemorrhage from disrupted surgical homeostasis.
- Ineffective Tissue Perfusion related to edema and tissue responses to surgery and prosthesis.
- Ineffective Coping related to change in body image.
- Acute Pain related to surgical procedure.
- Impaired Physical Mobility related to amputation, muscle weakness, alteration in body weight distribution.

Nursing Interventions

NURSING ALERT Prevention of complications associated with a major operation and facilitation of early rehabilitation are essential to prevent prolonged disability. Frequent monitoring of the patient's physiologic responses to anesthesia, surgery, and immobility is required.

Monitoring Fluid Balance

1. Monitor the patient for systemic symptoms of excessive blood loss—hypotension, widening pulse pressure, tachycardia, diaphoresis, decreased level of consciousness.
2. Watch for excessive wound drainage.
   a. Keep tourniquet (in view) attached to end of bed to apply to residual limb (stump) if excessive bleeding occurs.
   b. Reinforce dressing, as required, using aseptic technique.
   c. Measure suction drainage.
   d. Maintain accurate record of bloody drainage on dressing and in drainage system.
3. Monitor intake and output for fluid balance.

Maintaining Adequate Tissue Perfusion

1. Control edema.
   a. Elevate residual limb to promote venous return.

b. Use air splint, if prescribed.

2. Maintain pressure dressing.
   a. Reapply, if necessary, using sterile dressing secured with elastic bandage.
   b. Notify the surgeon if rigid cast dressing comes off.

Supporting Effective Coping

1. Accept patient responses to the loss of body part (ie, depression, withdrawal, denial, frustration).
2. Encourage expression of fears and concerns.
3. Recognize that modification of body image takes time.
4. Encourage participation in rehabilitation planning and self-care.
5. Assist the patient to adapt to changes in self-care activities.
   a. Upper-extremity amputation—encourage independence in one-handed self-care activities using one-handed aids (eg, one-handed knife), as needed.
   b. Lower-extremity amputation—encourage mobility using transfer assistance and ambulatory aids, as needed.

Controlling Pain

1. Surgical pain.
   a. Assess the patient's pain experience.
   b. Administer prescribed medications, as needed, to control postoperative pain.
   c. Use nonpharmaceutical pain-management techniques, such as progressive muscle relaxation and imagery.
   d. Recognize that increasing discomfort may indicate presence of hematoma, infection, or necrosis.
2. Phantom sensations (pain).
   a. Anticipate complaint of pain and sensation located in the missing limb ("phantom pain").
   b. The use of adjunctive pain medications may be prescribed, such as gabapentin.
   c. Use physical modalities (eg, wrapping, temperature changes) and transcutaneous electrical nerve stimulation (TENS), if prescribed, in relieving discomfort.
   d. Encourage patient activity to decrease awareness of phantom limb pain.
   e. Reassure the patient that phantom limb pain will diminish over time.
   f. Patients may benefit from cognitive behavioral therapy to assist in pain management. Virtual reality–based interventions may also be effective.

Promoting Physical Activity

1. Encourage frequent repositioning in bed.
2. Teach the patient to avoid long periods in one position.
   a. Avoids dependent edema.
   b. Avoids flexion deformity.

c. Avoids skin pressure areas.

3. Prevent deformities.
   a. Lower-extremity amputations—hip flexion contracture (avoid placing residual limb on pillow; encourage prone position twice per day) and abduction deformity (use trochanter roll; avoid pillow between legs).
   b. Upper-extremity amputations—postural abnormalities (encourage good posture).
4. Encourage active ROM and muscle-strengthening exercises when prescribed to
   a. Minimize muscle atrophy.
   b. Increase muscle strength.
   c. Prepare residual limb for prosthesis.
5. Promote reestablishment of balance (amputation alters distribution of body weight).
   a. Transfer to chair within 48 hours after surgery.
   b. Instruct and guard lower-limb amputee during balance exercises (ie, arise from chair; stand on toes holding on to chair; bend knee holding on to chair; balance on one leg without support; hop on one foot while holding on to chair).
6. Supervise ambulation, use of wheelchair, and self-care activities.

Patient Education and Health Maintenance

1. Teach the patient and family how to wrap residual limb with elastic bandage to control edema and to form a firm conical shape for prosthesis fitting (see Figures 32-8 and 32-9).
   a. Wrapping generally begins 1 to 3 days after surgery or after hard plaster dressing is removed.
   b. Use diagonal figure-of-8 bandaging technique.
   c. Wrap distal to proximal to maintain pressure gradient and to control edema.
   d. Begin wrapping with minimal tension and increase as wound heals and sutures are removed.
   e. Flatten skin at ends of incision to ensure conical stump shape.
   f. Rewrap residual limb a couple of times per day and as necessary to achieve a smooth, graded tension dressing.
   g. Rewrap if the patient complains of more pain—dressing is probably too tight.
   h. Keep residual limb wrapped at all times except when bathing (when the patient is cleared for bathing by physician).
2. Teach the patient residual limb conditioning.
   a. Push the residual limb against a soft pillow.
   b. Gradually push residual limb against harder surfaces.
   c. Massage healed residual limb to soften scar, decrease tenderness, and improve vascularity.
3. Fitting of prosthesis.
   a. Note residual limb contour.
   b. Assess for residual limb contraction.

c. When maximum shrinkage occurs, the prosthetist measures and fits the prosthesis.

d. Adjustments are made by the prosthetist to minimize skin problems.

4. Continuing care of residual limb and prosthesis.

a. Instruct the patient to wash and dry the limb thoroughly at least twice per day, removing all soap residue, to prevent skin irritation and infection.

b. Avoid soaking residual limb because it results in edema.

c. Inspect residual limb and skin under prosthesis harness daily for pressure, irritation, and actual skin breakdown.

d. Wear residual limb sock or cotton underwear—to absorb perspiration and to avoid direct contact between the prosthetic socket or harness and skin.

e. Avoid wrinkles in residual limb sock—potential pressure areas.

f. Wipe the socket of the prosthesis with a damp cloth when the prosthesis is removed for the evening.

g. Have the prosthesis checked periodically.

5. Teach the patient to protect the remaining extremity from injury and to secure prompt treatment of problems.

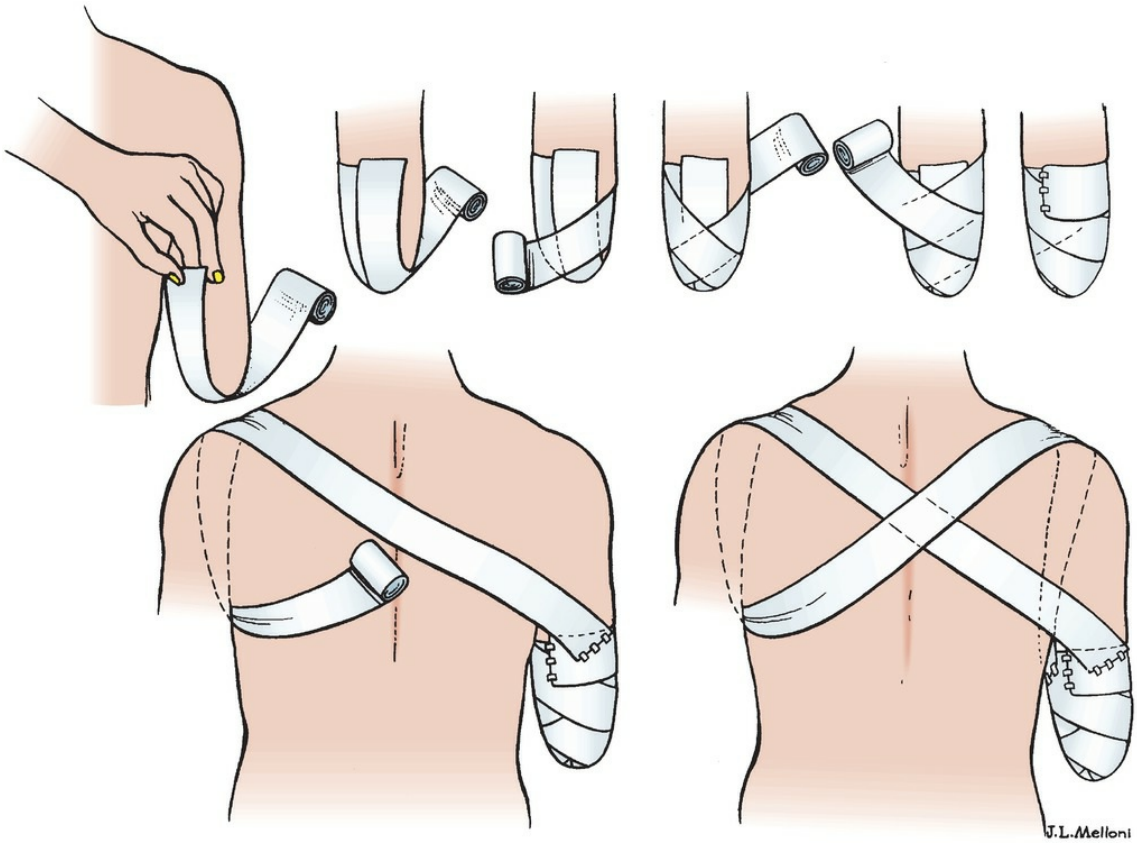


Figure 32-8. Wrapping above-elbow residual limb. Elastic bandaging reduces edema and shapes the residual limb for the prosthesis. Bandage may need to be secured by wrapping across back and shoulders. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

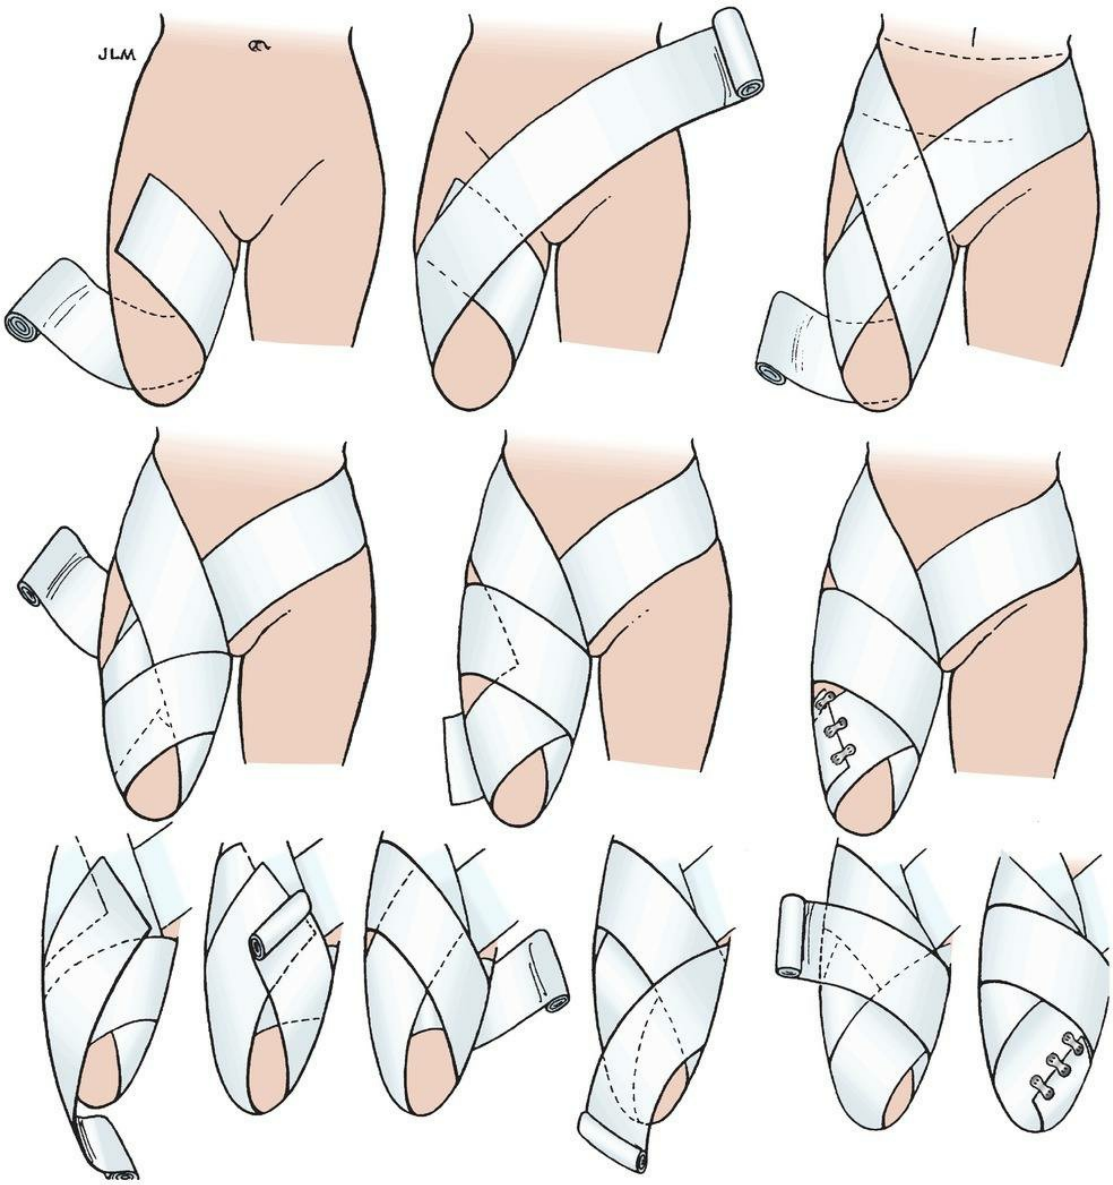

Figure 32-9. Wrapping above-knee residual limb. Elastic bandaging reduces edema and shapes the residual limb in a firm conical form for the prosthesis. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Evaluation: Expected Outcomes

- Vital signs stable; dressing reinforced once in 4 hours.
- Pressure dressing intact; stump elevated without edema.
- Participates in care plan; expresses concerns about independence.
- Verbalizes relief of incisional pain; dull phantom sensation tolerable.
- Performs ROM actively; transfers to wheelchair with assistance; participates in PT and OT activities.

MUSCULOSKELETAL TRAUMA

See Standards of Care Guidelines 32-1.

STANDARDS OF CARE GUIDELINES 32-1

Standards of Care Guidelines 32-1Caring for a Patient with Musculoskeletal Trauma, Surgery, Casting, or Immobilization

When caring for a patient with musculoskeletal trauma, surgery, casting, or immobilization, provide the following care, as indicated:

- Check neurovascular status of involved extremities.
- Palpate for intact and equal pulses bilaterally.
- Palpate for proper warmth of the skin.
- Check for brisk capillary refill.
- Test sensation to light touch and pain.
- Observe for unusual or increased swelling.
- Ensure that the patient can move affected parts.
- Ensure proper positioning for comfort and alignment.
- Determine pressure points and take precautions to prevent pressure sores.
- Medicate to control pain, particularly before movement, procedures, and physical therapy.
- Provide diversional activities and emotional support during long immobilizations.
- Always document assessments and interventions meticulously, realizing that the patient may be involved in workers' compensation claim or litigation due to accident and that records will be essential to the patient's future well-being.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alterative measures and approaches.

Contusions, Strains, and Sprains

A *contusion* is an injury to the soft tissue produced by a blunt force (blow, kick, or fall). A *strain* is a microscopic tearing of the muscle caused by excessive force, stretching, or overuse. A *sprain* is an injury to ligamentous structures surrounding a joint; it is usually caused by a overstretching, sudden twisting, or hyperextension of the joint, resulting in a decrease in joint stability.

Clinical Manifestations

Contusion

1. Hemorrhage into injured part (ecchymosis)—from rupture of small blood vessels; also associated with fractures.
2. Pain, swelling, and ecchymosis.
3. Hyperkalemia may be present with extensive contusions, resulting in destruction of body tissue and loss of blood.

Strain

1. Hemorrhage into the muscle.
2. Swelling.
3. Tenderness.
4. Pain with isometric contraction.
5. May be associated spasm.

Sprain

1. Rapid swelling—due to extravasation of blood within tissues.
2. Pain on passive movement of joint.
3. Increasing pain during first few hours due to continued swelling.

Management

1. X-ray may be done to rule out fracture.
2. Immobilize in splint, elastic wrap, or compression dressing to support painful structures and control swelling.
3. Apply ice while swelling is present.
4. Analgesics usually include nonsteroidal anti-inflammatory drugs (NSAIDs).
5. Severe sprains may require surgical repair or cast immobilization.
6. The acronym PRICE-M is often used to guide treatment at home for minor injuries: Protection—of the affected part from injury; Rest—to promote healing; Ice—to control swelling (do not use heat until acute swelling is relieved); Compression—with an elastic wrap or splint to control swelling and prevent stiffness, can be removed at night; Elevation—above the level of the heart to reduce swelling; Medication

—analgesic and antiinflammatories, often over the counter.

Nursing Interventions and Patient Education

1. Elevate the affected part to reduce swelling. Maintain splint or immobilization, as prescribed.
2. Apply cold compresses for the first several days (15 to 20 minutes at a time every few hours)—to produce vasoconstriction, decrease edema, and reduce discomfort (do not apply ice directly to skin). Ice may be needed for up to a week to control acute swelling.
3. Assess neurovascular status of contused extremity every 1 to 4 hours as the patient's condition indicates.
4. Instruct the patient on the use of pain medication, as prescribed.
5. Ensure the correct use of crutches or other mobility aid with or without weight bearing, as prescribed.
6. Educate on the need to rest injured part for about a month to allow for healing.
7. Teach the patient to resume activities gradually.
8. Teach the patient to avoid excessive exercise of injured part.
9. Teach the patient to avoid reinjury by "warming up" before exercise and stretching tendons and muscles before and after exercise.
10. Complementary methods, such as acupuncture, biofeedback, and imagery, may contribute to healing by reducing anxiety and pain.

Tendinitis

Tendinitis is an inflammation of a tendon caused by a lack of sufficient lubrication of the tendon sheath. May be caused by acute stress on tendon structure or by chronic overuse.

Clinical Manifestations

1. Onset of pain may occur immediately after activity or delayed up to a day later. ROM and resistance testing is painful.
2. Mild swelling occurs and the tendon sheath is tender to the touch.
3. Sudden onset of sharp pain in extremity and hearing or feeling a "snap" are associated with tendon rupture, as in Achilles tendinitis due to running injuries or stop–start activities such as basketball. Also occurs in gastrocnemius and biceps.

Management

1. X-rays are not usually diagnostic.
2. Thompson test helps with diagnosis of Achilles rupture. The patient kneels on a chair or lies prone. Examiner squeezes the calf of the affected leg. Normal response: foot flexes, denoting intact tendon. If the foot does not move, tendon is assumed to be ruptured.
3. Initial treatment includes protection, rest, ice, compression, elevation (PRICE).
4. Splinting or casting for up to 6 weeks in functional position is usually necessary.
5. Surgical intervention may be necessary if rupture is complete.
6. PT to regain strength and function.
7. Corticosteroid injection.
8. NSAIDs for pain and inflammation.

Nursing Interventions and Patient Education

1. Ensure understanding of the need for proper immobilization for full time period even though fracture is not present.
2. Encourage the use of warm compresses after 24 hours to relieve pain and inflammation.
3. Advise the patient not to return to full activity until strength is equal to unaffected extremity.
4. Teach proper warm-up before exercise and sports activities (stretching of all major tendons).

Bursitis

Bursitis is a painful inflammation of the bursae, fluid-filled sacs lined with synovium similar to the lining of the joint spaces. Bursae reduce friction between tendons and bones or tendons and ligaments. They are found over joints with bony prominences, such as the trochanter, patella, and olecranon. Friction between skin and musculoskeletal tissues may result in bursitis.

Clinical Manifestations

1. Pain around a joint—commonly the knee, elbow, shoulder, and hip.
2. Varying degrees of redness, warmth, and swelling may be visible.
3. There is point tenderness and limited ROM on examination.

Management and Nursing Interventions

1. Rest and immobilization of affected joint.
2. Ice for the first 48 hours; moist heat every 4 hours thereafter.
3. Nonopioid analgesics such as NSAIDs.
4. ROM exercises.
5. Corticosteroid injection into the area.
6. Surgery indicated when calcified deposits or adhesions have diminished function.

Plantar Fasciitis

Plantar fasciitis is inflammation of the fascia that runs along the bottom of the foot from heel to toes. As the fascia is stretched, microscopic tears develop at the point where fascia attaches to the calcaneus.

Clinical Manifestations

1. Pain along the sole of the foot, usually unilateral but may be bilateral.
2. Worse upon arising, long period of standing, and walking.
3. Tenderness of heel area.

Management and Nursing Interventions

1. Rest—decrease walking, running, exercise, standing.
2. NSAIDs for pain and inflammation.
3. Good supportive footwear.
4. Orthotic devices may be beneficial.
    a. Heel cup to cushion the heel (OTC).
    b. Arch support orthotics for pes planus (flat foot).
    c. Cushioning of arches for pes cavus (high arch).
5. Stretching exercises several times per day.
6. Massage of the bottom of the foot.
7. Steroid injection into the painful area.
8. Low-intensity extracorporeal shock wave therapy, also known as orthotripsy, may be tried when conservative management has failed.
    a. Using a handheld device, shock waves are focused directly at the painful area, causing microtraumas to the tissue causing the plantar fasciitis.
    b. An inflammatory response occurs, causing increased blood supply to the painful area, as well as breaking down injured tissue and calcifications, allowing a natural healing process.
    c. One or more 15-minute treatments take place in the office setting without anesthesia or any special preparation.
9. Surgery for the release of fascia as last resort.

Traumatic Joint Dislocation

Dislocation of a joint occurs when the surfaces of the bones forming the joint are no longer in anatomic contact. This is a medical emergency because of associated disruption of surrounding blood and nerve supplies. Shoulder, fingers, and elbow are the most commonly dislocated joints. Mechanism of injury can be anterior, posterior (most common), lateral, or medial force.

Clinical Manifestations

1. Pain.
2. Deformity.
3. Change in the length of the extremity.
4. Loss of normal movement.
5. X-ray confirmation of dislocation without associated fracture.

Management

1. Immobilize the part while the patient is transported to emergency department, x-ray department, or clinical unit.
2. Secure reduction of dislocation (bring displaced parts into normal position) as soon as possible to prevent circulatory or nerve impairments; usually performed under anesthesia.
3. Stabilize reduction until joint structures are healed to prevent permanently unstable joint or aseptic necrosis of bone.

Nursing Interventions and Patient Education

1. Assess neurovascular status of extremity before and after reduction of dislocation.
2. Administer or teach self-administration of pain medications such as NSAIDs.
3. Ensure proper use of immobilization device after reduction.
4. Review instructions for activity restrictions and need for PT and follow-up.

Knee Injuries

The knee ligaments provide stability to the knee joint. These ligaments promote rotational stability (*anterior cruciate ligament [ACL]* and *posterior cruciate ligament*) and prevent varus and valgus instability (*medial and lateral collateral ligaments*). Pieces of cartilage that stabilize the knee internally are known as the medial and lateral menisci. *ACL injuries* and *medial meniscus tears* are common because of sports injuries.

Clinical Manifestations

1. Severe stresses are applied to the knee during many sports activities (eg, soccer, skiing, running).
2. Injury to knee structures occurs during rapid position changes involving flexing and twisting of the joint.
3. Torn cartilage (meniscus) causes pain, tenderness, joint effusion, clicking sensations, and decreased ROM.
4. Knee ligaments may be torn, resulting in pain on ambulation, swelling, and joint instability. The patellar tendon may rupture.

Management

1. Special assessment techniques are done to detect ACL injury (see Table 32-1).
2. MRI shows injury to soft tissue involved.
3. Some injuries may be immobilized (splint, brace, or cast) and treated with PT.
4. ACL reconstruction frequently indicated.
    a. Arthroscopic surgery preferred; synthetic ligaments selected where ligaments failed. Graft rejection is a complication.
    b. Postoperative continuous passive motion used.
    c. Postoperative ACL rehabilitation program includes progressive ROM, bracing (not done with synthetic ligaments).
    d. Long-term bracing during sports controversial.
5. Meniscal injury—damaged cartilage removed.
    a. Arthroscopic or open meniscectomy.
    b. Rehabilitation includes progressive ROM and quadriceps strengthening.

Table 32-1 Assessment Techniques for Anterior Cruciate Ligament Injury

TEST	DESCRIPTION	POSITIVE FINDING
Anterior drawer test	Place the patient supine with knee in 90 degrees of flexion with foot flat on table. Proximal tibia is pulled forward by examiner using two hands.	Tibia subluxes (dislocates) forward on femur.
Lachman test	Place the patient supine with knee in 15 to 20 degrees of flexion. Distal femur is grasped by examiner with one hand while the other hand grasps the proximal tibia and applies forward pressure.	Tibia subluxes forward on femur.
Pivot shift test (evaluates anterolateral rotational stability)	Place the patient supine with knee slightly flexed. The examiner grasps the patient's ankle in one hand and places the palm of the other hand over the lateral aspect of the knee distal to the joint. Lower leg is extended and internally rotated, applying a valgus (lateral) stress to knee.	Tibia subluxes and reduces itself ("pivots and shifts").

Nursing Interventions and Patient Education

1. After arthroscopic surgery, ensure proper use of crutches, as indicated, and encourage pain control through medications, as prescribed, and RICE.
2. For open joint surgery, see care of the patient undergoing orthopedic surgery, page 868.
3. Teach the patient strengthening exercises for affected extremity.
4. Teach the patient to prevent fatigue through rest periods, conservation of energy.
5. Advise on prevention of injuries using proper equipment and footwear for sports.

Fractures

A *fracture* is a break in the continuity of bone. A fracture occurs when the stress placed on a bone is greater than the bone can absorb. Muscles, blood vessels, nerves, tendons, joints, and other organs may be injured when fracture occurs.

Types of Fractures

1. Complete—involves the entire cross section of the bone, usually displaced (abnormal position).
2. Incomplete—involves a portion of the cross section of the bone or may be longitudinal.
3. Closed (simple)—skin not broken.
4. Open (compound)—skin broken, leading directly to fracture.
    a. Grade I—minimal soft tissue injury.
    b. Grade II—laceration greater than 1 cm without extensive soft tissue flaps.
    c. Grade III—extensive soft tissue injury, including skin, muscle, neurovascular structure, with crushing.
5. Pathologic—through an area of diseased bone (osteoporosis, bone cyst, bone tumor, bony metastasis).

Patterns of Fracture

See Figure 32-10.

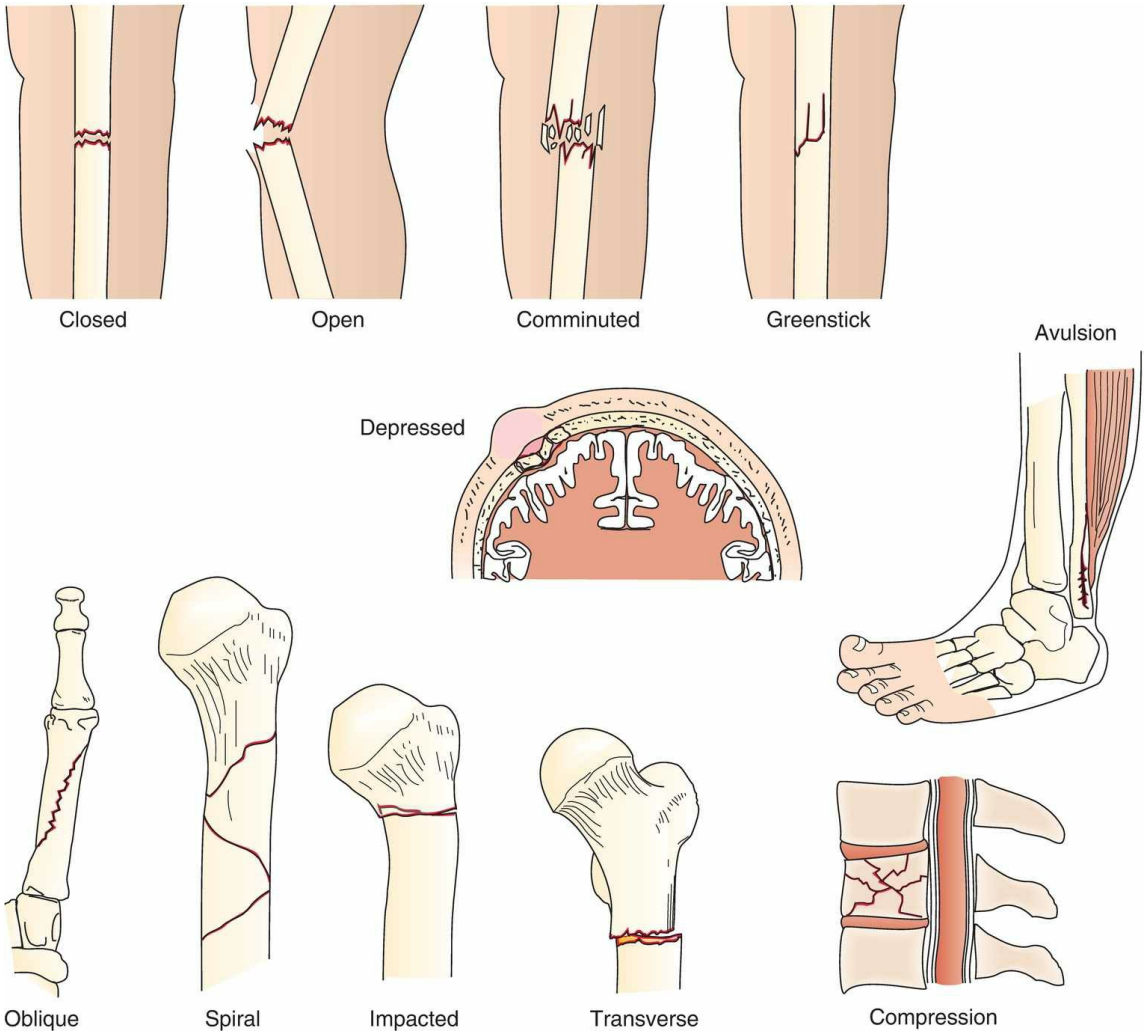

Figure 32-10. Patterns of fractures. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

1. Greenstick—one side of the bone is broken and the other side is bent.
2. Transverse—straight across the bone.
3. Oblique—at an angle across the bone.
4. Spiral—twists around the shaft of the bone.
5. Comminuted—bone splintered into more than three fragments.
6. Depressed—fragments are driven inward (seen in fractures of the skull and facial bones).
7. Compression—bone collapses in on itself (seen in vertebral fractures).
8. Avulsion—fragment of bone pulled off by ligament or tendon attachment.
9. Impacted—fragment of bone wedged into other bone fragment.
10. Fracture dislocation—fracture complicated by the bone being out of the joint.
11. Other—described according to anatomic location: epiphyseal (end of large bones containing growth plate), supracondylar (above the articular prominence of a bone), midshaft, intra-articular.

GERONTOLOGIC ALERT Osteoporosis is a major risk for fractures, particularly hip and vertebral compression fractures.

Clinical Manifestations

Physical Findings

1. Pain at the site of injury.
2. Swelling.
3. Tenderness.
4. False motion and crepitus (grating sensation).
5. Deformity.
6. Loss of function.
7. Ecchymosis.
8. Paresthesia.

Altered Neurovascular Status

1. Injured muscle, blood vessels, nerves.
2. Compression of structures resulting in ischemia.
3. Findings:
    a. Progressive uncontrollable pain.
    b. Pain on passive movement.
    c. Altered sensations (paresthesia).
    d. Loss of active motion.
    e. Diminished capillary refill response, diminished distal pulse.
    f. Pallor.

Shock

1. Bone is very vascular.
2. Overt hemorrhage through open wound.
3. Covert hemorrhage into soft tissues (especially with femoral fracture) or body cavity, as with pelvic fracture.
4. May be fatal if not detected.

Diagnostic Evaluation

1. X-ray and other imaging studies to determine integrity of bone.
2. Blood studies (complete blood count [CBC], electrolytes) with blood loss and extensive muscle damage—may show decreased hemoglobin level and hematocrit.

3. Arthroscopy to detect joint involvement.
4. Angiography if associated with blood vessel injury.
5. Nerve conduction and electromyogram studies to detect nerve injury.

Management

For emergency management, see page 947.

Principles of Management

1. Factors influencing choice of management include the following:
   a. Type, location, and severity of fracture.
   b. Soft tissue damage.
   c. Age and health status of the patient, including type and extent of other injuries.
2. Goals include the following:
   a. To regain and maintain correct position and alignment.
   b. To regain the function of the involved part.
   c. To return the patient to usual activities in the shortest time and at the least expense.
3. The management process is a three-step process:
   a. Reduction—setting the bone; refers to restoration of the fracture fragments into anatomic position and alignment.
   b. Immobilization—maintains reduction until bone healing occurs (see Figures 32-11 and 32-12).
   c. Rehabilitation—regaining normal function of the affected part.

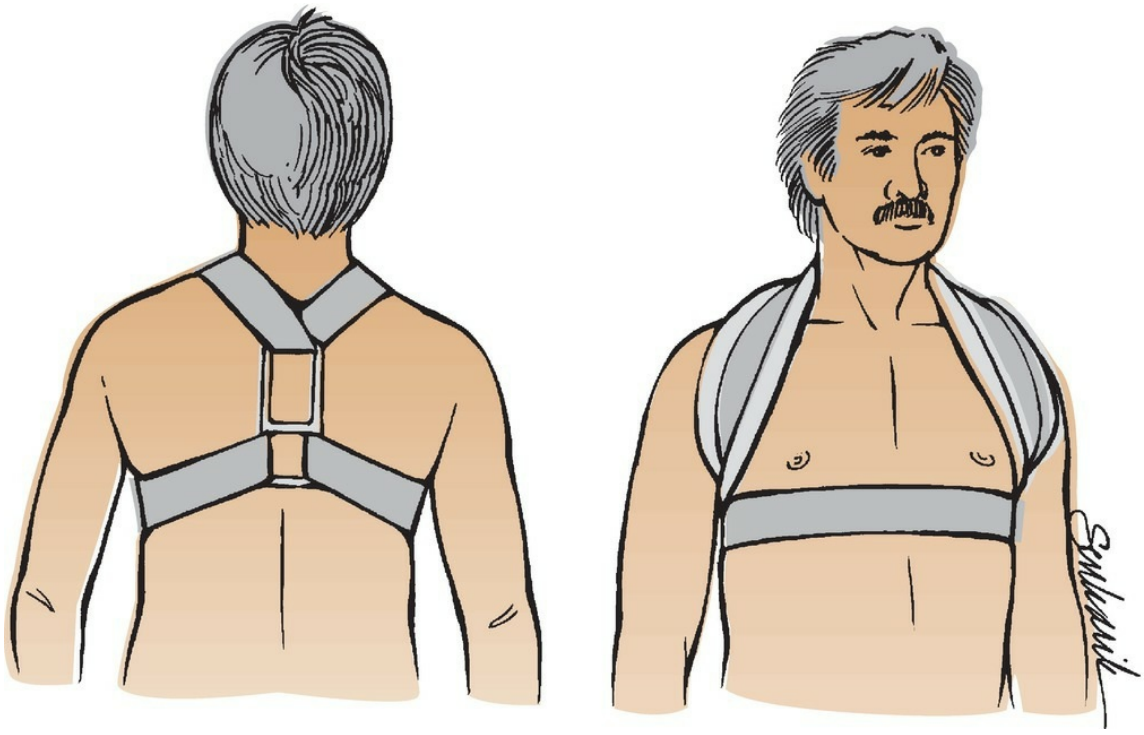

Figure 32-11. Method for immobilizing a clavicular fracture with a clavicular strap. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

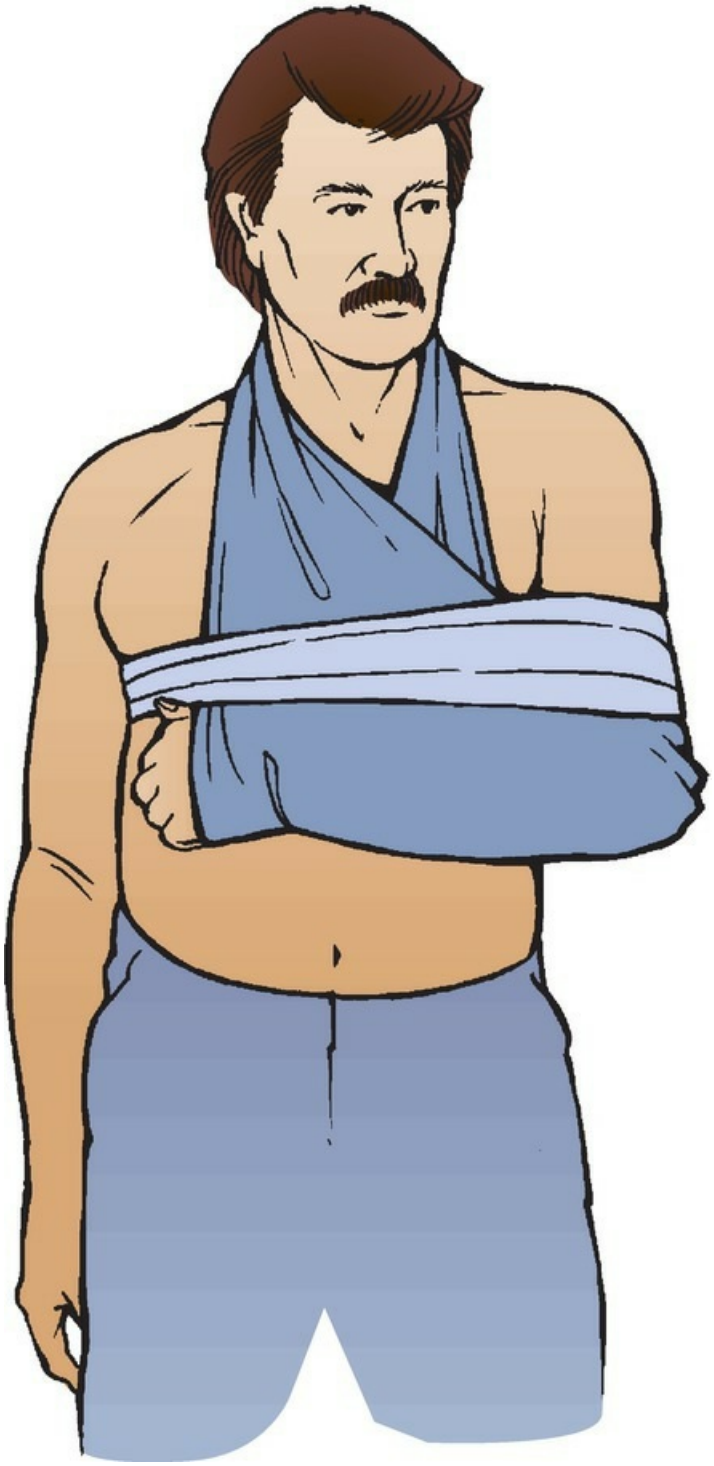

Figure 32-12. Immobilization of fracture of upper humerus can be achieved with conventional sling and swathe. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Approaches to Management

Vary by specific site of fracture (see Table 32-2, pages 880 to 882).

Table 32-2 Fractures of Specific Sites

SITE AND MECHANISM	MANAGEMENT	NURSING CONSIDERATIONS
Clavicle		
Fall on shoulder	• Closed reduction and immobilization with clavicular strap (see Figure 32-11) figure-of-8 bandage or sling. • ORIF for marked displacement, severely comminuted fracture, and extensive soft tissue injury.	• Pad the axilla to prevent nerve damage from pressure of immobilizer. • Assess neurovascular status of arm. • Teach exercises of elbow, wrist, and fingers. • Teach shoulder exercises through full ROM, as prescribed.
Proximal Humerus		
Fall on outstretched arm; osteoporosis is predisposing factor	• Many remain in alignment and are supported by a sling and swathe or Velpeau bandage for comfort (see Figure 32-12). • If displaced, treated with reduction under x-ray control, open reduction, or replacement of humeral head with prosthesis.	• Place a soft pad under the axilla to prevent skin maceration. • Encourage shoulder ROM exercises after specified period of immobilization to prevent frozen shoulder. • Instruct the patient to lean forward and allow affected arm to abduct and rotate.
Shaft of Humerus		

Direct fall, blow to arm, or auto injury; damage to radial nerve may occur	• Immobilize with sling and swathe, splint, or hanging cast.
	• A hanging cast is applied for its weight to correct displaced fractures with shortening of the humeral shaft.
	• ORIF for associated vascular injury or pathologic fracture, followed by support in sling.
		• Hanging cast must remain unsupported to maintain traction.
		  • Teach the patient to avoid supporting elbow in lap or arm on pillow.
		  • The patient should sleep in upright position to maintain 24-hour traction.
		• Encourage exercise of fingers immediately after application of cast.
		• Teach pendulum exercises of arm, as prescribed, to prevent frozen shoulder.

Elbow and Forearm		
Fall on elbow, outstretched hand, or direct blow (sideswipe injury)	• Treatment depends on specific characteristics of fracture—ORIF, arthroplasty, external fixation, casting. • Closed drainage system may be used to decrease hematoma formation and swelling.	• Assess neurovascular status of forearm and hand. • If radial pulse weakens or disappears, report immediately to prevent irreversible ischemia. • Elevate arm to control edema. • Encourage finger and shoulder exercises.
Wrist		

Colles fracture is common (½–1 inch [1.2–2.5 cm] above the wrist with dorsal displacement of lower fragment); caused by fall on outstretched palm; commonly associated with osteoporosis	• Closed reduction with splint or cast support.
	• Percutaneous pins and external fixator or plaster cast.
		• Elevate arm above level of heart for 48 hours after reduction to promote venous and lymphatic return and reduce swelling.
		• Watch for swelling of fingers and check for constricting bandages or cast.
		• Teach finger exercises to reduce swelling and stiffness.
		  • Hold the hand above the level of the heart.
		  • Move fingers from full extension to flexion.
		  • Hold and release.
		  • Repeat at least 10 times every half hour when awake for as long as swelling occurs.
		• Encourage daily-prescribed exercises to restore full extension and supination.

Hand		
Caused by numerous injuries	• Splinting for undisplaced fractures of fingers. • Debridement, irrigation, and Kirchner wire fixation for open fractures. • Reconstructive surgery may be necessary for complex injuries.	• Provide aggressive care and encouragement with rehabilitation plan to regain maximal function of hand.

Hip (Proximal Femur)		

Occur frequently in older adults, women with osteoporosis, and with fall types:
• Intracapsular—femoral neck within joint capsule
• Extracapsular—femoral neck between greater and lesser trochanter (intertrochanteric) or of femoral shaft
• Subtrochanteric—of femur just below level of lesser trochanter
	• Hip fracture identified by shortening and external rotation of affected leg; pain in hip or knee; inability to move leg.
	• Immobilization with Buck extension traction until surgery.
	• Surgery as soon as medically stable; choice depends on location, character, and patient factors.
	  • Internal fixation with nail, nail–plate combination, multiple pins, screw, or sliding nails.
	  • Femoral prosthetic replacement.
	  • Total hip arthroplasty.
		• Provide constant monitoring and nursing care to reduce the risk of complications, such as pneumonia, thrombophlebitis, fat emboli, dislocation of prosthesis, infection, and pressure sores.
		• Administer aspirin, warfarin, subcutaneous heparin, or low molecular weight heparin, as ordered.
		• Use sequential compression devices, as ordered.
		• Provide meticulous skin care to prevent breakdown.
		  • Use trapeze for the patient to assist with position changes.
		  • Use a special bed or mattress, as indicated.
		  • Inspect heels daily and use heel protection measures.
		• Prevent UTI by increasing fluids, limiting use of indwelling catheter, and encouraging frequent voiding.
		• Keep affected leg in abduction and neutral rotation.
		• Teach quadriceps setting exercise to prevent muscle atrophy of affected leg.

Femoral Shaft		
	• Closed reduction and stabilization with skeletal traction—Thomas leg splint with Pearson attachment; followed by use of orthosis (cast brace) to allow weight bearing. • Open reduction with hardware or with bone grafting may be necessary. • External fixator may be used.	• Marked concealed blood loss may occur; watch for signs of shock initially and anemia later. • Examine skin under the ring of the Thomas splint for signs of pressure.
Knee		
Direct blow to knee area; involve distal shaft of femur (supracondylar), articular surfaces, or patella	• Closed reduction and immobilization through casting, traction, braces, splints. • ORIF. • Goal is to preserve knee mobility.	• Elevate extremity by raising foot gatch of bed. • Evaluate for effusion—report and loosen pressure dressing if pain is severe; prepare for joint aspiration. • Teach quadriceps setting exercises and limited weight bearing, as prescribed.
Tibia and Fibula/Ankle		
Distal tibia or fibula, malleoli, or talus fractures generally result from forceful twisting of ankle and commonly associated with ligament disruption; also high incidence of open fractures of tibial shaft because tibia lies superficially beneath the skin	• Closed reduction and toe-to-groin cast for closed fractures, later replaced by short leg cast or orthosis. • ORIF may be necessary for some closed fractures. • External fixator for open fracture.	• Elevate lower leg to control edema. • Avoid dependent position of extremity for prolonged periods. • Prepare the patient for long immobilization period, as union is slow (12–16 weeks, longer for open and comminuted fractures). • Prepare the patient for stiff ankle joint following immobilization.
Foot		
Metatarsal fracture due to crush injuries of the foot	• Immobilization with cast, splint, or strapping.	• Encourage partial weight bearing, as allowed. • Elevate the foot to control edema.
Thoracic and Lumbar Spine		
Trauma from falls, contact sports, or auto accidents, or excessive loading may cause fracture of vertebral body, lamina, spinous and transverse processes; usually stable compression fractures	• Suspected with pain that is worsened by movement and coughing and radiates to extremities, abdomen, or intercostal muscles and presence of sensory and motor deficits. • Bed rest on firm mattress and pain relief followed by progressive ambulation and back strengthening to treat stable fractures; takes about 6 weeks to heal. • ORIF with Harrington rod, body cast, or laminectomy with spinal fusion may be necessary for unstable or displaced fractures.	• Use log roll technique to change positions. • Monitor bowel and bladder dysfunction, as paralytic ileus and bladder distention may occur with nerve root injury. • Assist the patient to ambulate when pain subsides, no neurologic deficit exists, and x-rays reveal no displacement. • Teach proper body mechanics and back preservation techniques. • Encourage weight reduction. • Teach the patient with osteoporosis the importance of safety measures to avoid falls.

Pelvis			

Sacrum, ilium, pubic, ischium, and coccyx fractures may occur from auto accidents, crush injuries, and falls; most are stable fractures that do not involve the pelvic ring and have minimal displacement	• Emergency management to treat multiple trauma, shock from intraperitoneal hemorrhage, and injury to internal organs is necessary (see pages 948 to 952).
	• Bed rest for several days followed by progressive weight bearing for stable fracture.
	• Prolonged bed rest, external fixation, ORIF, skeletal traction, and pelvic sling are options for unstable fracture.
		• Monitor and support vital functions, as indicated.
		• Observe urine output for blood indicating genitourinary injury.
		• Do not attempt to insert urethral catheter until patency of urethra is known; incidence of urethral injury in males is high with anterior fractures.
		• Assist the patient being treated in pelvic sling.
		  • Fold sling back over buttocks to enable the patient to use bedpan.
		  • Reach under the sling to give skin care; line the sling with sheepskin.
		  • Loosen sling only as directed.

ORIF, open reduction with internal function; ROM, range of motion; UTI, urinary tract infection.

1. Closed reduction.
    a. Bony fragments are brought into apposition (ends in contact) by manipulation and manual traction restoring alignment.
    b. May be done under anesthesia for pain relief and muscle relaxation.
    c. Cast or splint applied to immobilize extremity and maintain reduction (see "Casts," page 862).
2. Traction.
    a. Pulling force applied to accomplish and maintain reduction and alignment (see "Traction," page 865).
    b. Used for fractures of long bones.
    c. Techniques.
        i. Skin traction—force applied to the skin using foam rubber, tape.
        ii. Skeletal traction—force applied to the bony skeleton directly, using wires, pins, or tongs placed into or through the bone.
3. Open reduction with internal fixation.
    a. Operative intervention to achieve reduction, alignment, and stabilization.
        i. Bone fragments are directly visualized.
        ii. Internal fixation devices (metal pins, wires, screws, plates, nails, rods) used to hold bone fragments in position until solid bone healing occurs (may be removed when bone is healed).
        iii. After closure of the wound, splints or casts may be used for additional stabilization and support.
4. Endoprosthetic replacement.
    a. Replacement of a fracture fragment with an implanted metal device.
    b. Used when fracture disrupts nutrition of the bone or treatment of choice is bony replacement.
5. External fixation device.
    a. Stabilization of complex and open fracture with the use of a metal frame and pin system.
    b. Permits active treatment of injured soft tissue.
        i. Wound may be left open (delayed primary wound closure).
        ii. Repair of damage to blood vessels, soft tissue, muscles, nerves, and tendons, as indicated.
        iii. Reconstructive surgery may be necessary (see "External Fixation," page 867).

Complications

Complications Associated with Immobility

1. Muscle atrophy, loss of muscle strength, and endurance.
2. Loss of ROM due to joint contracture.
3. Pressure sores at bony prominences from immobilizing device pressing on skin.
4. Diminished respiratory, cardiovascular, GI function, resulting in possible pooling of respiratory secretions, orthostatic hypotension, ileus, anorexia, and constipation.
5. Psychosocial compromise resulting in feelings of isolation and depression.

Other Acute Complications

1. Venous stasis and thromboembolism—particularly with fractures of the hip and lower extremities.
2. Neurovascular compromise.
3. Infection, especially with open fractures.
4. Shock due to significant hemorrhage related to trauma or as a postoperative complication.
5. Pulmonary emboli.

Fat Emboli Syndrome

1. Associated with embolization of marrow or tissue fat or platelets and free fatty acids to the pulmonary capillaries, producing rapid onset of symptoms.
2. Clinical manifestations.
    a. Respiratory distress—tachypnea, hypoxemia, crackles, wheezes, acute pulmonary edema, interstitial pneumonitis.
    b. Mental disturbances—irritability, restlessness, confusion, disorientation, stupor, coma due to systemic embolization, and severe hypoxia.
    c. Fever.
    d. Petechiae in buccal membranes, hard palate, conjunctival sacs, chest, anterior axillary folds, due to occlusion of capillaries.

NURSING ALERT Restlessness, confusion, irritability, and disorientation may be the first signs of fat embolism syndrome. Confirm hypoxia with arterial blood gas (ABG) analysis. Young adults (age 20 to 30) and older adults (age 60 to 70) with multiple fractures or fractures of long bones or pelvis are particularly susceptible to development of fat emboli.

Bone Union Problems

1. Delayed union (takes longer to heal than average for type of fracture).
2. Nonunion (fractured bone fails to unite).
3. Malunion (union occurs but is faulty—misaligned).

Nursing Assessment

1. Ask the patient how the fracture occurred—mechanism of injury important in determining possible associated injuries.
2. Ask the patient to describe location, character, and intensity of pain to help determine possible source of discomfort.
3. Ask the patient to describe sensations in injured extremity to aid in evaluation of neurovascular status.
4. Observe the patient's ability to change position to assess functional mobility.
5. Note the patient's emotional status and behavior—indicators of ability to cope with stress of injury.
6. Assess the patient's support system; identify current and potential sources of support, assistance, and caregiving.
7. Review findings on past and present health status to aid in formulating care plan.
8. Conduct physical examination.
    a. Examine skin for lacerations, abrasions, ecchymosis, edema, and temperature.
    b. Auscultate lungs to establish baseline assessment of respiratory function.
    c. Assess pulses and BP; assess peripheral tissue perfusion, especially in injured extremity, to establish circulatory status baseline.
    d. Determine neurologic status (sensations and movement) of extremity distal to injury.
    e. Note length, alignment, and immobilization of injured extremity.
    f. Evaluate behavior and cognitive functioning of the patient to determine ability to participate in care planning and patient education activities.

NURSING ALERT Change in behavior or cerebral functioning may be an early indicator of cerebral anoxia from shock or pulmonary or fat emboli.

GERONTOLOGIC ALERT Assessment of the patient's health and functional abilities before a fracture along with available support systems facilitates development of realistic rehabilitation and discharge goals.

Nursing Diagnoses

- Risk for Deficient Fluid Volume related to hemorrhage and shock.
- Impaired Gas Exchange related to immobility and potential pulmonary emboli or fat emboli.
- Risk for Peripheral Neurovascular Dysfunction.
- Risk for Vascular Trauma related to thromboembolism.

- Acute Pain related to injury.
- Risk for Infection related to open fracture or surgical intervention.
- Bathing or Hygiene Self-Care Deficit related to immobility.
- Impaired Physical Mobility related to injury/treatment modality.
- Risk for Disuse Syndrome related to injury and immobilization.
- Risk for Posttrauma Syndrome related to cause of injury.

Nursing Interventions

Evaluating for Hemorrhage and Shock

1. Monitor vital signs as frequently as clinical condition indicates, observing for hypotension, elevated pulse, widening pulse pressure, cold clammy skin, restlessness, pallor.
2. Watch for evidence of hemorrhage on dressings or in drainage containers.
3. Review laboratory data; report abnormal values.
4. Administer prescribed fluids/blood to maintain circulating volume.
5. Monitor intake and output. Goal is to maintain at least 30 mL/hour and establish individual's normal voiding pattern.

NURSING ALERT Patients with hip and long bone fractures are at high risk for hemorrhage. Frequent checks for hemodynamics, neurovascular status, and drainage should be performed, particularly in patients with other comorbidities who may not tolerate changes in hematocrit and hemoglobin levels.

Monitoring for Impaired Gas Exchange

1. Evaluate changes in mental status and restlessness that may indicate hypoxia.
2. Review diagnostic evaluation data—especially ABG values and chest x-ray.
3. Position to enhance respiratory effort. Report any sudden or progressive changes in respiratory status.
4. Encourage coughing and deep breathing to promote lung expansion and diminish pooling of pulmonary secretions.
5. Monitor pulse oximetry; administer oxygen, as prescribed.
6. Maintain cervical spine precautions if spinal injury is suspected.

Preventing Neurovascular Compromise

1. Monitor neurovascular status for compression of nerve, diminished circulation, development of compartment syndrome.
    a. Pain—progressive, localized, deep throbbing, persistent, unrelieved by immobilization and medications.
    b. Pain on passive stretch.

c. Weakness progressing to paralysis.
d. Altered sensation, hypoesthesia, paresthesia.
e. Poor capillary refill (greater than 3 seconds).
f. Skin color—pale, cyanotic.
g. Elevated compartment pressure—palpable tightness of muscle compartment, elevated measured tissue pressure.
h. Pulselessness—a late sign.

2. Reduce swelling.
   a. Elevate injured extremity (unless compartment syndrome is suspected—may contribute to vascular compromise).
   b. Apply cold to injury, if prescribed.
3. Relieve pressure caused by immobilizing device, as prescribed (such as bivalving cast, rewrapping elastic bandage, or splinting device).
4. Relieve pressure on skin to prevent development of pressure sore.
   a. Frequent repositioning.
   b. Skin care—do not massage bony prominences.
   c. Special mattresses.

NURSING ALERT Monitoring the neurovascular integrity of the injured extremity is essential. Development of compartment syndrome (increased tissue pressure causing hypoxemia) leads to permanent loss of function in 6 to 8 hours. This situation must be identified and managed promptly.

Preventing Development of Thromboembolism

1. Encourage active and passive ankle exercises.
2. Use elastic stockings, foot pumps, or SCDs, as prescribed.
3. Elevate legs to prevent stasis, avoiding pressure on blood vessels.
4. Encourage mobility; change position frequently; encourage ambulation.
5. Administer anticoagulants, as prescribed.
6. Monitor for development of thrombophlebitis.
   a. Note complaint of pain and tenderness in calf.
   b. Report calf pain.
   c. Report increased size and temperature of calf.
   d. Homans sign has not been proved to be an effective screen for deep vein thrombosis (DVT); therefore, it is no longer an acceptable measure for assessing DVT.

GERONTOLOGIC ALERT Older adults with fractures, trauma, immobility, obesity, or history of thrombophlebitis are at high risk for developing thromboembolism.

Relieving Pain

1. Perform a comprehensive pain assessment.
    a. Have the patient describe the pain, location, characteristics (dull, sharp, continuous, throbbing, bony, radiating, aching).
    b. Ask the patient what causes the pain, makes the pain worse, relieves the pain. Evaluate the patient for proper body alignment, pressure from equipment (casts, traction, splints, appliances).
2. Initiate activities to prevent or modify pain.
    a. Assist the patient with pain-reduction techniques—cutaneous stimulation, distraction, guided imagery, TENS, biofeedback.
    b. Immobilize injured part.
    c. Position the patient in correct alignment.
    d. Support splinted fracture above and below fracture when repositioning or moving the patient.
    e. Reposition the patient with slow and steady motion; use additional personnel, as needed.
    f. Elevate painful extremity to diminish venous congestion.
    g. Apply heat or cold modalities, as prescribed. Heat versus cold is controversial. One randomly controlled trial found significantly less edema with cold packs versus heat 3 to 5 days postinjury.
    h. Modify environment to facilitate rest and relaxation.
3. Administer prescribed medications, as indicated. Encourage the use of less potent drugs as severity of discomfort decreases.
4. Establish a supportive relationship to assist the patient to deal with discomfort.
5. Encourage the patient to become an active participant in rehabilitative plans.

DRUG ALERT Meperidine may cause toxicity as it breaks down into the metabolite normeperidine, which has a 15- to 20-hour half-life, especially in patients with impaired renal function or older patients.

Monitoring for Development of Infection

1. Clean, debride, and irrigate open fracture wound, as prescribed, as soon as possible to minimize risk of infection.
    a. All open fractures are contaminated.
    b. Begin prescribed antibiotic therapy promptly after wound culture obtained.

2. Use sterile technique during dressing changes to minimize infection of wound, soft tissues, and bone.
3. Evaluate the patient for elevation of temperature every 4 hours as indicated by facility or provider order.
4. Note and report elevated white blood cell (WBC) counts.
5. Report areas of inflammation and swelling around incision or open wound.
6. Report purulent odiferous drainage.
7. Obtain specimens for culture and sensitivity to determine causative organism.

Promoting Adequate Hygiene

1. Encourage participation in care.
2. Arrange the patient area and personal items for patient convenience and to promote independence.
3. Modify activities to facilitate maximum independence within prescribed limits.
4. Allow time for the patient to accomplish the task.
5. Teach safe use of mobility and necessary aids.
6. Assist with ADLs, as needed.
7. Teach family how to assist the patient while promoting independence in self-care.

Promoting Physical Mobility

1. Perform active and passive exercises to all nonimmobilized joints.
2. Encourage patient participation in frequent position changes, maintaining support to fracture during position changes.
3. Minimize prolonged periods of physical inactivity, encouraging ambulation when prescribed.
4. Administer prescribed analgesics judiciously to decrease pain associated with movement.

Preventing Disuse Syndrome

1. Teach and encourage isometric exercises to diminish muscle atrophy.
2. Encourage the use of immobilized extremity within prescribed limits.

Minimizing the Psychological Effects of Trauma

1. Monitor the patient for symptoms of posttraumatic stress disorder.
    a. Memory of event; anger, helplessness, vulnerability, mood swings, depression, cognitive impairment, sleep disturbance, increased dependency, and social withdrawal.
2. Assist the patient to move through phases of posttraumatic stress (outcry, denial, intrusiveness, working through, completion).
3. Establish trusting therapeutic relationship with the patient.
4. Encourage the patient to express thoughts and feelings about traumatic event.
5. Encourage the patient to participate in decision-making to reestablish control and overcome feelings of helplessness.
6. Teach relaxation techniques to decrease anxiety.

7. Encourage development of adaptive responses and participation in support groups.
8. Refer the patient to psychiatric liaison nurse or refer for psychotherapy, as needed.

Community and Home Care Considerations

1. Assist the patient to actively exercise joints above and below the immobilized fracture at frequent intervals.
    a. Isometric exercises of muscles covered by cast—start exercise as soon as possible after cast application.
    b. Increase isometric exercises as fracture stabilizes.
2. After removal of immobilizing device (eg, cast, splint), have the patient start isotonic exercises and continue with isometric exercises.
3. Assess the home for any fall hazards when the patient ambulates.
4. Obtain PT/OT consultation for assistance with ADLs, transferring technique, gait strengthening, and conditioning after lengthy immobilization, as needed.
5. Assess orthostatic BP when the patient begins to ambulate to prevent falls.

Patient Education and Health Maintenance

1. Explain the basis for fracture treatment and need for patient participation in therapeutic regimen.
2. Promote adjustment of usual lifestyle and responsibilities to accommodate limitations imposed by fracture.
3. Instruct the patient on exercises to strengthen upper-extremity muscles if crutch walking is planned.
4. Instruct the patient in methods of safe ambulation—walker, crutches, cane.
5. Emphasize instructions concerning amount of weight bearing that will be permitted on fractured extremity.
6. Discuss prevention of recurrent fractures—safety considerations, avoidance of fatigue, proper footwear.
7. Encourage follow-up medical supervision to monitor for union problems.
8. Teach symptoms needing attention, such as numbness, decreased function, increased pain, elevated temperature.
9. Encourage adequate balanced diet to promote bone and soft tissue healing.

Evaluation: Expected Outcomes

- Vital signs within normal parameters; urine output at least 30 mL/hour.
- Respirations unlabored; alert and oriented.
- No signs of neurovascular compromise (ie, circulation, motor, sensory intact).
- No calf pain reported.
- Reports decreased pain with elevation, ice, and analgesic.
- Afebrile; no wound drainage.
- Performing hygiene and dressing practices with minimal assistance.
- Performing active ROM correctly.

- Using affected extremity for light activity, as allowed.
- Denies acute symptoms of stress; reports working through feelings about trauma.

OTHER MUSCULOSKELETAL DISORDERS

Lower Back Pain

EVIDENCE BASE Qaseem, A., Wilt, T. J., McLean, R. M., Forciea, M. A.; for the Clinical Guidelines Committee of the American College of Physicians. (2017). Noninvasive treatments for acute, subacute, and chronic low back pain: A clinical practice guideline from the American College of Physicians. *Annals of Internal Medicine, 166*(7), 514–530.

Lower back pain is characterized by an uncomfortable or acute pain in the lumbosacral area associated with severe spasm of the paraspinal muscles, usually with pain radiating to the lower extremities.

Pathophysiology and Etiology

Acute low back pain lasts up to 4 week, subacute low back pain lasts 4 to 12 weeks, and chronic low back pain lasts longer than 12 weeks. There are multiple causes:

1. Mechanical (joint, muscular, or ligamentous sprain).
2. Degenerative disk disease; acute herniation of disks.
3. Lack of physical activity and exercise; weakness of musculature of back.
4. Arthritic conditions.
5. Diseases of bone (osteoporosis, vertebral fracture, Paget disease, metastatic carcinoma).
6. Congenital disorders.
7. Systemic diseases.
8. Infections of disk spaces or vertebrae.
9. Spinal cord tumors.
10. Referred pain from other areas.

Clinical Manifestations

1. Pain localized or radiating to buttocks or to one or both legs.
2. Paresthesias, numbness, and weakness of lower extremities.
3. Spasm in acute phase.
4. Bowel or bladder dysfunction in cauda equina syndrome.

Diagnostic Evaluation

1. X-rays of lumbar spine are usually negative.
2. CT of spine—to detect arthritic changes, degenerative disk disease, tumor, and other abnormalities.
3. Myelography—to confirm and localize disk herniation.
4. MRI—to detect pathology, disk herniation, soft tissue injury, stenosis, nerve impingement.

5. EMG of lower extremities—to detect nerve changes related to back pathology.
6. Diskogram—to evaluate herniated disk.

Management

For management of herniated disk, see page 428. For management of spinal cord tumors, see page 417. Guidelines call for conservative, nonpharmacologic management as first-line treatment. Most people with acute and subacute low back pain improve over time.

1. Avoid activities that may strain the back until healed, but bed rest is to be avoided as well because it may significantly decrease the rate of recovery, increase pain and disability, and lengthen time spent absent from work.
2. Exercise, PT, and tai chi may be helpful for chronic pain.
3. Heat or ice is used to relax muscle spasm and relieve discomfort. Follow heat with massage.
4. Medications.
   a. Oral analgesic and anti-inflammatory agent—usually NSAID is first-line agent, unless contraindicated because of history or high risk of GI bleeding, renal insufficiency, or allergy. If there is a high risk of GI bleeding, COX-2 inhibitors may be used unless the patient has a sulfa or aspirin allergy or is in the third trimester of pregnancy.
   b. Painful trigger points may be injected with hydrocortisone/xylocaine for pain relief.
   c. Opioids may be sedating.
   d. Muscle relaxant to relieve spasm and tense muscles. Muscle relaxants may be sedating.
   e. Adjunct medications to reduce chronic neuropathic pain include duloxetine.
5. Lumbosacral support may be used—provides abdominal compression and decreases load on lumbar intervertebral disks.
6. Acupuncture is helpful for acute and chronic pain; TENS may be helpful in relieving chronic pain.
7. Behavioral intervention such as mindfulness-based stress reduction techniques is helpful for chronic pain.
   a. Psychotropic medication may be used for treatment of depression and anxiety, which potentiate pain.
   b. Focus on getting back to functional state after long disability.

NURSING ALERT Risk factors of chronic low back pain include high severity of pain, depression, lack of positive coping skills, beliefs that the patient cannot control his or her pain, and high rate of missing work because of low back pain. Cognitive behavioral strategies can be used to help the patient with pain management and strengthen positive coping skills. Screening tools are available to help identify risk factors and guide treatment decisions.

Complications

1. Spinal instability, infection, sensory and motor deficits.

2. Chronic pain.
3. Malingering and other psychosocial reactions.

Nursing Assessment

1. Obtain history to determine when, where, and how the pain occurs, aggravating or relieving factors, relationship of pain to specific activities, presence of numbness or paresthesia.
2. Perform physical examination of neurologic system—spots localized weakness of extremities and reflex and sensory loss.
3. Perform musculoskeletal examination for changes in strength, tone, and ROM.
4. If condition is chronic, assess coping ability of the patient and family or significant others.
5. Assess effect of illness on daily living—work, school.

Nursing Diagnoses

- Acute Pain related to injury.
- Chronic Pain related to injury.
- Impaired Physical Mobility related to pain.

Nursing Interventions

Relieving Pain

1. Advise the patient to stay active and avoid bed rest, in most cases.
2. Keep pillow between flexed knees while in side-lying position—minimizes strain on back muscles.
3. Apply heat or ice, as prescribed.
4. Administer or teach self-administration of pain medications and muscle relaxants, as prescribed.
   a. Give NSAIDs with meals to prevent GI upset and bleeding.
   b. Muscle relaxants and opioids may cause drowsiness.

Coping with Chronic Pain

1. Administer adjunct pain medications, as directed. Explain that medications may not completely relieve pain but will reduce level of discomfort so that the patient can increase daily activities. Encourage adherence to therapy.
2. Teach relaxation techniques such as progressive muscle relaxation and imagery (see page 25).
3. Encourage balanced diet, exercise program, and avoidance of smoking.
4. Suggest consultation with physical/occupational therapist, psychologist, or pain management clinician, as needed.

Promoting Mobility

1. Encourage ROM of all uninvolved muscle groups.
2. Suggest gradual increase of activities and alternating activities with rest in semi-Fowler position.

3. Avoid prolonged periods of sitting, standing, or lying down.
4. Encourage the patient to discuss problems that may be contributing to backache.
5. Encourage the patient to do prescribed back exercises. Exercise keeps postural muscles strong, helps recondition the back and abdominal musculature, and serves as an outlet for emotional tension.

Patient Education and Health Maintenance

Instruct the patient to avoid recurrences as follows:

1. Standing, sitting, lying, and lifting properly are necessary for a healthy back.
2. Alternate periods of activity with periods of rest.
    a. Avoid prolonged sitting (intradiskal pressure in lumbar spine is higher during sitting), standing, and driving.
    b. Change positions and rest at frequent intervals.
    c. Avoid assuming tense, cramped positions.
    d. Sit in a straight-back chair with the knees slightly higher than the hips. Use a footstool, if necessary.
    e. Flatten the hollow of the back by sitting with the buttocks "tucked under." Pelvic tilt (small of back is pressed against a flat surface) decreases lordosis.
    f. Avoid knee and hip extension. When driving a car, have the seat pushed forward as necessary for comfort. Place a cushion in the small of the back for support.
3. When standing for any length of time, rest one foot on a small stool or platform to relieve lumbar lordosis.
4. Avoid fatigue that contributes to spasm of back muscles.
5. Use good body mechanics when lifting or moving about.
6. Daily exercise is important in the prevention of back problems (see Patient Education Guidelines 32-2).
    a. Do prescribed back exercises twice daily—strengthens back, leg, and abdominal muscles.
    b. Walking outdoors (progressively increasing distance and pace) is recommended.
    c. Reduce weight, if necessary—decreases strain on back muscles.

PATIENT EDUCATION GUIDELINES 32-2

Taking Care of Your Lower Back

Almost everyone has lower back pain at some time. Chronic pain will develop in some, and a few will become disabled because of it. Risk factors for chronic lower back pain include being overweight, being deconditioned (out of shape), having poor posture, and having poor abdominal muscle tone. You can relieve pain and avoid disability by adhering to the following instructions.

DO BACK EXERCISES EVERY DAY

- Lie on your back on the floor or a firm mattress. Bend one knee and bring that leg up toward your chest. Hold it against your chest a few seconds. Then repeat with the other leg. Alternate legs several times.

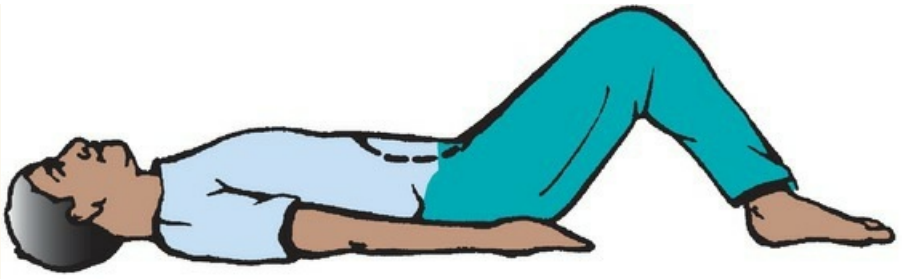
- Lie on your back with your knees bent and feet flat on the floor. Tighten your abdomen and buttocks, and push your lower back to the floor. Hold for a few seconds, and then relax. Repeat several times.
- Lie on your back with knees bent and feet flat on the floor. Do a partial sit-up by crossing your arms on your chest or behind your head and lifting your shoulders off the floor 6 to 12 inches (15 to 30.5 cm). Repeat several times.

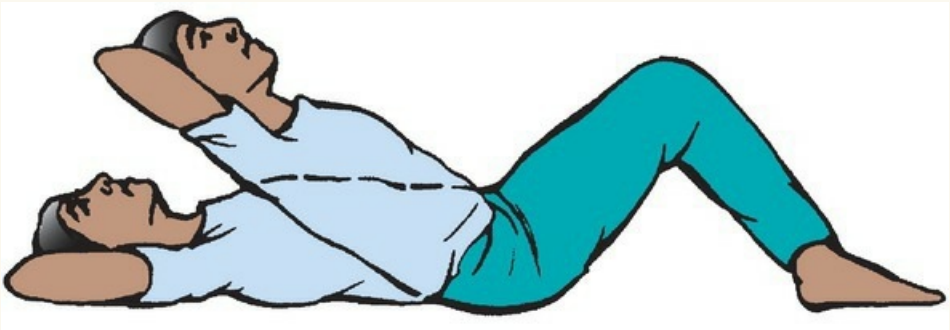
BE CAREFUL HOW YOU LIFT

- Move your body close to an object before picking it up.
- Bend at the knees, not the back, to pick up an object that is low.
- Hold the object close to your abdomen and chest.
- Bend at the knees again to put down an object.
- Avoid reaching, twisting, or turning your back as you lift or carry an object.

PROTECT YOUR BACK WHILE SITTING AND STANDING

- Avoid sitting in soft, cushioned chairs too long.
- If you sit for long periods at work, make sure your knees are level with your hips. Use a step stool, if necessary.
- If you stand for long periods, try to put one foot up on a stool and then the other. Walk around and change position periodically.
- Adjust your car seat so there is a bend in your knees. Do not stretch.
- Put a firm pillow behind your lower back if it does not feel supported while you are sitting.





Back exercises to strengthen abdominal and postural muscles, to stretch contracted back muscles, and to maintain flexibility.

STAY ACTIVE AND IN GOOD HEALTH

- Take a walk every day wearing comfortable, low-heeled shoes.
- Eat a balanced, low-fat diet with plenty of fruits and vegetables to avoid constipation.
- Get plenty of sleep on a firm mattress.
- See your health care provider promptly for worsening pain or new injury.

Evaluation: Expected Outcomes

- Verbalizes relief of pain with rest and medication.
- Able to participate in ADLs with sedation or pain greater than 3/10.
- Performs back exercises correctly.

Osteoarthritis

EVIDENCE BASE National Institute for Health and Clinical Excellence. (2014). *Osteoarthritis: Care and management*. London: Author.

American Association of Orthopaedic Surgeons. (2017). *Management of osteoarthritis of the hip evidence-based clinical practice guideline*. Rosemont, IL: Author.

American Association of Orthopaedic Surgeons. (2013). *Treatment of osteoarthritis of the knee: Evidence-based guideline* (2nd ed.). Rosemont, IL: Author.

Osteoarthritis, or degenerative joint disease, is a chronic, noninflammatory, slowly progressing disorder that causes deterioration of articular cartilage. It affects weight-bearing joints (hips and knees) as well as joints of the distal interphalangeal and proximal interphalangeal joints of the fingers.

Pathophysiology and Etiology

1. Changes in articular cartilage occur first; later, secondary soft tissue changes may occur.
2. Progressive wear and tear on cartilage leads to thinning of joint surface and ulceration into bone.
3. Leads to inflammation of the joint and increased blood flow and hypertrophy of subchondral bone.
4. New cartilage and bone formation at joint margins result in osteophytosis (bone spurs), altering the size and shape of bone.
5. Generally affects adults age 50 to 90; equal in males and females.
6. Cause is unknown, but aging and obesity are contributing factors. Previous trauma may cause secondary OA.

Clinical Manifestations

1. Pain in one or more joints, may be long-standing pain that increases with weight bearing or use of joint; may have been a gradual, insidious onset, or may have been some history of trauma to the joint in the past.
2. Less than 30 minutes of morning stiffness.
3. Bony deformity (osteophyte) or enlargement of the joint.
4. Possible crepitation, effusion.

Diagnostic Evaluation

1. No specific laboratory examination or imaging is necessary to make the diagnosis if person is 45 years or older with activity-related joint pain and less than 30 minutes of morning stiffness.
2. X-rays of affected joints show joint space narrowing, osteophytes, and sclerosis.
3. Radionuclide imaging (bone scan) shows increased uptake in affected bones.

4. Analysis of synovial fluid differentiates OA from RA.

Management

Conservative Management

1. Exercise for muscle strengthening and general fitness, including low-impact aerobic self-management programs; may involve PT and OT to maintain function while preserving the joints. Manipulation and stretching may be added with hip arthritis.
2. Weight loss if overweight or obese to reduce stress on joints.
3. Pain management using nonopioid analgesics, particularly NSAIDs which have proven more effective in many studies than acetaminophen, but side effects must be considered; tramadol may need to be added and opioids should be avoided unless benefits outweigh risks.
4. Hyaluronate and hylan G-F 20, agents known as viscosupplements, have been approved by the Food and Drug Administration. These drugs are administered over time through intra-articular injections into the knee. However, current guidelines no longer recommend their use because of lack of sufficient improvement for a majority of patients.
5. TENS as adjunct to pain management.
6. Proper nutrition, sleep, and stress reduction to improve well-being.
7. OTC supplements glucosamine and chondroitin sulfate are commonly used but have not proven to be more effective than placebo.

NURSING ALERT The patient's body mass index can be used to determine the need for weight loss, a major factor in preventing chronic pain due to osteoarthritis. Long-term management with a primary care provider or weight-loss specialist may assist the patient in successful weight reduction.

Surgical Intervention

Surgical intervention is considered when the pain becomes intolerable to the patient and mobility is severely compromised. Options include osteotomy, debridement, joint fusion, arthroscopy, and arthroplasty.

Complications

1. Limited mobility.
2. Neurologic deficits associated with spinal involvement.

Nursing Assessment

1. Obtain history of pain and its characteristics, including specific joints involved.
2. Evaluate ROM and strength.
3. Assess effect on ADLs and emotional status.

Nursing Diagnoses

- Acute or Chronic Pain related to joint degeneration and muscle spasm.
- Impaired Physical Mobility related to pain and limited joint motion.
- Bathing, Hygiene, Feeding, and Toileting Self-Care Deficits related to pain and limited joint movement.

Nursing Interventions

Relieving Pain

1. Advise the patient to take prescribed NSAIDs or OTC analgesics as directed to relieve inflammation and pain. If tramadol or opioids are prescribed, ensure that the patient is taking them as directed.
2. Provide rest for involved joints—excessive use aggravates the symptoms and accelerates degeneration.
   a. Use splints, braces, cervical collars, traction, and lumbosacral corsets, as ordered by health care provider.
   b. Have prescribed rest periods in recumbent position.
3. Advise the patient to avoid activities that precipitate pain.
4. Apply heat, as prescribed—relieves muscle spasm and stiffness; avoid prolonged application of heat—may cause increased swelling and flare symptoms.
5. Teach correct posture and body mechanics—postural alterations lead to chronic muscle tension and pain.
6. Advise sleeping with a rolled terry cloth towel under the neck—for relief of cervical OA.
7. Provide crutches, braces, walker, or cane when indicated—to reduce weight-bearing stress on hips and knees. Teach proper use of assistive devices, see page 859.
8. Advise wearing corrective shoes and metatarsal supports for foot disorders—also helps in the treatment of arthritis of the knee.
9. Encourage weight loss to decrease stress on weight-bearing joints.
10. Support the patient undergoing orthopedic surgery for unremitting pain and disabling arthritis of joints (see page 868).

GERONTOLOGIC ALERT Older patients are at greater risk for GI bleeding and renal failure associated with NSAID use. Encourage administration with meals and monitor stool for occult blood. Celecoxib and meloxicam are associated with less risk of GI bleeding but may cause an increased risk of cardiovascular embolic events and deleterious effects on the kidneys.

Increasing Physical Mobility

1. Encourage activity as much as possible without causing pain.
2. Teach ROM exercises to maintain joint mobility and muscle tone for joint support, to prevent capsular

and tendon tightening, and to prevent deformities. Avoid flexion and adduction deformities.

3. Teach isometric exercises and graded exercises to improve muscle strength around the involved joint.
4. Advise putting joints through ROM after periods of inactivity (eg, automobile ride).

Promoting Self-Care

1. Suggest performing important activities in morning, after stiffness has been abated and before fatigue and pain become a problem.
2. Advise on modifications, such as wearing looser clothing without buttons, placing bench in tub or shower for bathing, sitting at table or counter in kitchen to prepare meals.
3. Help with obtaining assistive devices, such as padded handles for utensils and grooming aids, to promote independence.
4. Refer to OT for additional assistance.

Patient Education and Health Maintenance

1. Suggest swimming or water aerobics (offered by the YMCA) as a form of nonstressful exercise to preserve mobility.
2. Encourage adequate diet and sleep to enhance general health.
3. Advise the patient to discuss the use of complementary therapies, such as glucosamine and chondroitin sulfate, with health care provider.
4. For additional information and support, refer to the Arthritis Foundation (*www.arthritis.org*).

Evaluation: Expected Outcomes

- Reports reduction in pain while ambulatory.
- Performs ROM exercises.
- Dresses, bathes self, and grooms with assistive devices.

Neoplasms of the Musculoskeletal System

Musculoskeletal neoplasms include primary *sarcomas*, *metastatic bone disease*, and benign tumors (*osteoma*, *chondroma*, *osteoclastoma*) of the bone. More than 60% of bone neoplasms are metastatic from other sites of cancer.

Pathophysiology and Etiology

Benign Bone Tumors

Osteoid osteoma, chondroma, and osteoclastoma (benign giant cell tumor) are examples of benign bone tumors. Malignant transformation occurs with some.

Malignant Bone Tumors

1. Chondrosarcoma and osteosarcoma are examples of primary malignant bone tumors.
    a. Tumors develop in areas of rapid growth.
    b. Risk factors include Paget disease, previous radiation therapy to the bone, and other bone diseases.
    c. Hematogenous spread to the lung occurs.
2. Multiple myeloma is a malignant neoplasm arising from the bone marrow.

Metastatic Bone Tumors

1. Metastatic bone tumors are most frequently associated with cancers of the breast, prostate, and lung (primary malignancy site).
2. Bone metastasis most frequently occurs in the vertebrae and results in pathologic fracture.

Clinical Manifestations

1. Pain in the involved bone—from effects of tumor (destruction, erosion, and expansion of tumor).
    a. Generally mild to constant pain, which may be worse at night or with activity.
    b. Pain will be acute with fracture.
    c. Neurologic symptoms may present with nerve root compression.
2. Swelling and limitation of motion and joint effusion.
3. Physical findings.
    a. Palpable, tender, fixed bony mass.
    b. Increase in skin temperature over mass.
    c. Superficial veins dilated and prominent.

Diagnostic Evaluation

1. X-ray will usually reveal bone tumor; may show increased or decreased bone density. Tomograms may be helpful for some benign osseous lesions.
2. CT and MRI demonstrate soft tissue involvement and location of tumors.

3. Bone scan—helpful in detecting initial extent of malignancy, planning therapy, defining level of amputation, and following course of radiation or chemotherapy.
4. Ultrasound may help with identification of the lesion.
5. Serum alkaline phosphatase—usually increased.
6. Bence Jones protein in urine with multiple myeloma.
7. Biopsy of bone—to confirm suspected diagnosis.
8. Chest x-ray and lung scan—to determine if metastasis is present.
9. Arteriography—to assess soft tissue involvement.

Management

A multidisciplinary approach in a cancer center is usually preferred. The basic objective is to halt the progression of the tumor by destroying or removing the lesion. Treatment depends on the type of tumor. Combinations of chemotherapy, surgery, and radiation may be indicated as most appropriate for specific type of tumor.

Surgery

1. Tumor curettage or resection with bone grafting may be used.
2. Limb-salvaging procedures involve resection of affected bone and surrounding normal muscle tissue and reconstruction using metallic prostheses or allografts for bone or joint replacement and skin grafting, as needed.
3. Amputation is necessary in some cases.

Chemotherapy

May be used as preoperative, adjunctive, and palliative treatment.

1. Chemotherapy may be administered before (to shrink the tumor) and after (to destroy metastasis) surgery.
2. Chemotherapy used in combination to achieve a greater patient response at a lower toxicity rate and to minimize potential problems of drug resistance and may be given in varying courses separated by rest periods.

Radiotherapy

1. Tumor irradiation may be used.
2. Prophylactic lung irradiation may be performed—to suppress metastasis.

Other Therapies

1. Immunotherapy—interferon.
2. Hormone therapy may be used with metastatic tumors of the breast and prostate.
3. If pathologic fracture occurs, the fracture is managed with open reduction and internal fixation or other fracture treatment method.

Complications

1. Lack of tumor control and metastases.
2. Pathologic fracture.
3. Hypercalcemia from bone destruction.

Nursing Assessment

1. Obtain history of progression of disease; presence of pain, fever, weight loss, malaise.
2. Examine for painless mass.
3. Review records for evidence of pathologic fracture.
4. Assess knowledge of cancer, experiences with family or others, and present coping.

Nursing Diagnoses

- Acute Pain related to effects of tumor.
- Risk for Injury related to altered bone structure.
- Ineffective Coping related to diagnosis and treatment options.

Nursing Interventions

See also "Orthopedic Surgery," page 868, and "Amputation," page 873.

Relieving Pain

1. Use multiple approaches to reduce discomfort (see page 1508).
2. Administer pain medications 30 minutes before ambulation or other uncomfortable movement.
3. Support painful extremities on pillows.

Preventing Pathologic Fractures

1. Assist the patient in movement with gentleness and patience.
2. Avoid jarring the patient or bed.
3. Support joints when repositioning the patient.
4. Guard the patient to avoid falls.
5. Create a hazard-free environment.
6. Provide patient education on safety.

Strengthening Coping Ability

1. Create a supportive environment.
2. Use psychological support services, as needed.
3. Answer questions and clear up misconceptions about treatment options.

Patient Education and Health Maintenance

1. Teach about particular treatment selected. See page 112 for information on chemotherapy and page 122 for radiation therapy information.
2. Encourage appropriate follow-up and diagnostic testing for recurrence.
3. Refer for additional information and support to the American Cancer Society (*www.cancer.org*).

Evaluation: Expected Outcomes

- Reports decreased pain with ambulation.
- No signs or symptoms of fractures.
- Verbalizes understanding of treatment options and strength to make decisions.

Osteomyelitis

Osteomyelitis is a severe pyogenic infection of the bone and surrounding tissues, which requires immediate treatment.

Pathophysiology and Etiology

1. Generally, bacteria gain entry to the bone via three routes:
   a. Bloodstream (hematogenous spread).
   b. Adjacent soft tissue infection (contiguous focus).
   c. Direct introduction of microorganisms into the bone.
2. Bacteria lodge and multiply in bone.
3. Pressure increases as pus collects in confined rigid bone, contributing to ischemia and vascular occlusion and leading to bone necrosis.
4. *Staphylococcus aureus* is the most common infecting microorganism, although others are prevalent: *Escherichia coli*, *Pseudomonas*, *Klebsiella*, *Salmonella*, and *Proteus*.

Clinical Manifestations

1. Infection of long bones with acute pain and signs of sepsis.
2. Localized pain and drainage.
3. Symptoms vary in adults and children according to the site of involvement.

Diagnostic Evaluation

1. Acute osteomyelitis diagnosis made on initial clinical signs (history, physical examination, CBC, ESR).
2. Aerobic and anaerobic cultures of bone and deep tissue to identify the organism. Wound cultures are not reliable.
3. ESR elevated, WBC and hemoglobin decreased.
4. Radiographic evidence of osteomyelitis lags behind symptoms by up to 14 days.
5. Radionuclide bone scans used to diagnose early acute osteomyelitis.
6. MRI used increasingly—distinguishes between soft tissue and bone marrow.

Management

1. Acute: full recovery possible with minimal loss of function.
2. Chronic: develops with inadequate or ineffective course of antibiotics or delayed treatment.

Surgical Intervention

1. Needle aspiration or needle biopsy done initially.
2. Surgical intervention may be needed to obtain culture and sensitivity of specimen.
3. Surgical decompression considered when the patient does not improve after 36 to 48 hours of

antimicrobial therapy.

4. Debridement may be done, or antibiotic-impregnated beads used in wound (removed after 2 to 4 weeks and replaced with bone graft).
5. Hyperbaric oxygen therapy may be used as an adjunctive therapy.

Pharmacologic Intervention

1. Employ quickly after presentation of symptoms to avoid chronicity.
2. Parental antimicrobial therapy based on blood/wound cultures.
3. Medications depend on organism but include the following:
   a. Penicillins (penicillin G, penicillin V).
   b. Semisynthetic penicillins (nafcillin, oxacillin, methicillin).
   c. Extended-spectrum penicillins (ampicillin, carbenicillin, amoxicillin).
   d. Beta-lactam agents (imipenem).
   e. Tetracyclines.
   f. Cephalosporins.
   g. Aminoglycosides.
4. Requires 6 to 8 weeks of IV antibiotic therapy, requiring a peripherally inserted central catheter line or other long-term access device and coordination of home care services.

Complications

1. Nonhealing wound.
2. Sepsis.
3. Immobility.
4. Amputation.

Nursing Assessment

1. Obtain detailed history of injury.
2. Assess pain and functional deficits.
3. Be aware that systemic symptoms are acute in children but vary in intensity with adults.
4. Perform general systemic assessment because adults with long bone involvement generally have more systemic septic symptoms.

Nursing Diagnoses

- Acute Pain related to inflammatory process.
- Deficient Knowledge related to disease and medications.
- Impaired Physical Mobility related to rest of affected part.

Nursing Interventions

Relieving Pain

1. Administer opioids for acute pain; nonopioids for chronic pain.
2. Administer medications around the clock versus as necessary to establish a consistent blood level.
3. Report any increase in pain that may indicate worsening infection.

Increasing Knowledge

1. Describe the infectious process and rationale for prolonged treatment with osteomyelitis.
2. Explain IV antibiotic therapy, potential adverse effects, and reactions.
3. Explain strict adherence to infection control practices (sterile technique, hand washing, selection of roommate) to prevent spread of infection in some cases.
4. Initiate home care nursing and infusion service referrals before discharge.

Promoting Rest without Complications

1. Support the affected extremity (splint, traction) to minimize pain.
2. If the patient is on bed rest, prevent hazards of immobility (passive ROM, position changes, coughing, and deep breathing).
3. Encourage distraction activities.

Patient Education and Health Maintenance

1. Advise the patient to adhere to infection control principles—proper hand washing, disposal of wound drainage, dressings to prevent reinfection or transmission of infection at home.
2. Stress adherence to medication regimen, which may be prolonged, with frequent follow-up visits.
3. Teach care of indwelling device for medication delivery.
4. Educate the patient on signs and symptoms of infection to monitor for and when to notify physician.

Evaluation: Expected Outcomes

- Pain managed with nonopioid analgesics.
- Infectious process minimized.
- Functional status of affected joint intact.

Paget Disease (Osteitis Deformans)

Paget disease of the bone is a skeletal disorder resulting from excessive osteoclastic activity, affecting the long bones, pelvis, lumbar vertebrae, and the skull predominantly.

Pathophysiology and Etiology

1. The cause of this disease is unknown, although there is evidence of familial tendency (25% to 40% have at least one affected relative).
2. More common in men than in women.
3. Rare before age 40 and increases as age does—12% after age 80.
4. May be caused by infection from blood-borne viruses. After acute viremia, osteoclasts become chronically infected, stimulating osteoclastic proliferation. See Figure 32-13.

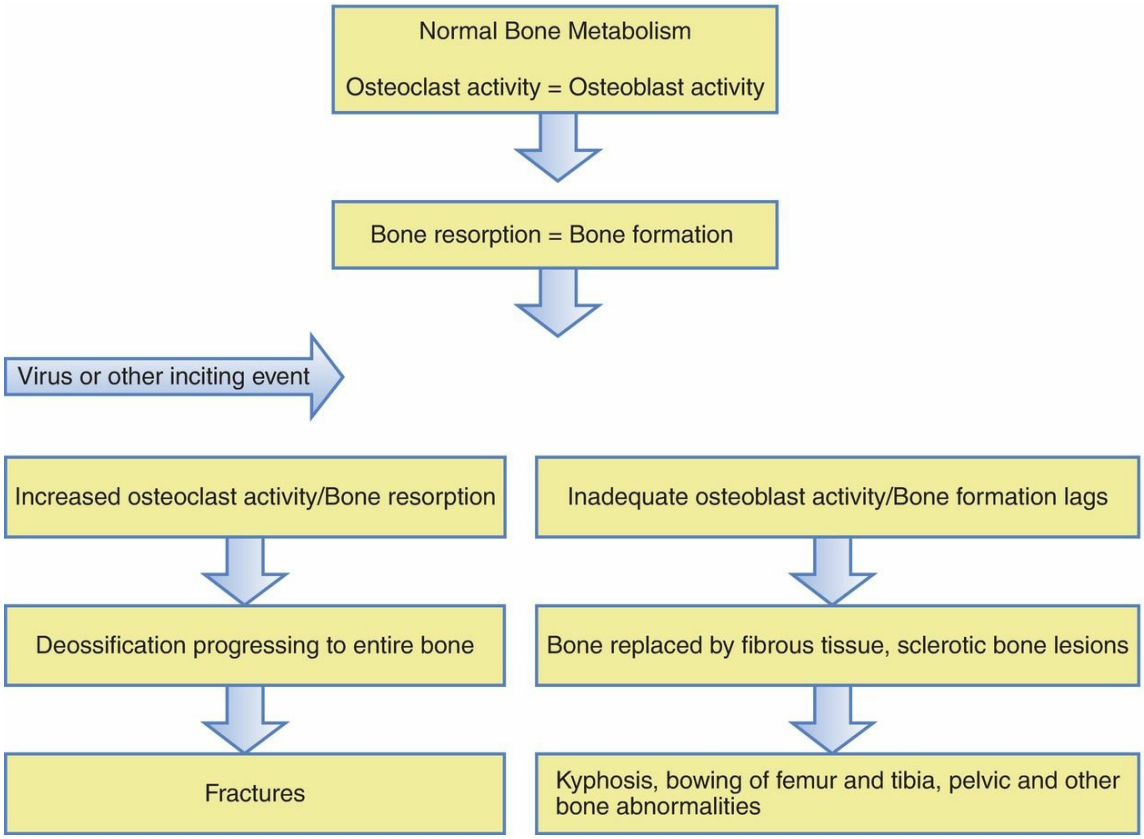


Figure 32-13. Pathophysiology of Paget disease.

Clinical Manifestations

1. Generally asymptomatic.
2. Most common symptoms are pain and predisposition to fracture.
3. Pagetic lesions can lead to OA, joint destruction, spinal deformity.
4. Decrease in hearing, tinnitus, and vertigo as a result of skull abnormality.

5. Waddling gait due to abnormality of pelvis.
6. Radiculopathy and nerve palsies due to effects from the vertebral column.
7. Rarely, heart failure and other cardiovascular effects from increased blood supply over abnormal bone.
8. Malignant bone tumors occur in 5% to 10%.

Diagnostic Evaluation

1. Elevated serum alkaline phosphatase and urine hydroxyproline.
2. Serum calcium, phosphorus, and albumin levels usually normal.
3. Generally confirmed with radiologic examinations showing characteristic abnormalities.
4. Bone scans can evaluate rapid bone turnover.
5. Bone biopsy to differentiate from osteomyelitis or bone tumor.

Management

1. No treatment for asymptomatic Paget.
2. Pain management—NSAIDs, aspirin.
3. Medications—calcitonin is the main medication used to suppress bone turnover, reduce pain, and prevent progression.
4. Other medications used to block bone resorption—the bisphosphonates etidronate disodium, alendronate, pamidronate, risedronate; an antineoplastic agent, plicamycin.
5. Tibial osteotomy done to realign knees and relieve pain.

Nursing Assessment

1. Assess pain and functional ability.
2. Observe for bowing (legs) or complaint that hats feel tight.
3. Assess for cardiovascular complications.
4. Assess for auditory symptoms—tinnitus, vertigo, and hearing loss.

Nursing Diagnoses

- Chronic Pain related to pathophysiologic process.
- Risk for Injury related to falls.

Nursing Interventions

Reducing Pain

1. Administer and teach self-administration of analgesics.
2. Avoid sedation due to opioids, which may increase risk of falls.

Preventing Injury

1. Establish exercise protocols through a PT consult to maintain physical abilities and prevent falls.

2. Teach safe transferring and make sure that the patient can alert nurses if he or she needs help.
3. Assist the patient with activities, as necessary.
4. Provide function and mobility aids such as heel lifts, walking aids, as needed, through an OT consult.

Patient Education and Health Maintenance

1. Teach safety measures in the home—removal of loose rugs and obstacles to prevent falls, good lighting.
2. Provide education about the disease process and medication treatment.
3. Make sure that the patient knows how to use mobility aids.
4. Initiate home care referral, as indicated.
5. Advise the patient that laboratory testing to monitor serum calcium, phosphorous, vitamin D, and kidney function may be ordered.
6. Provide information about The Paget Foundation (*www.paget.org*).
7. Encourage follow-up for periodic hearing tests and blood work.

Evaluation: Expected Outcomes

- The patient reports reduced pain scale score
- No falls

Hallux Valgus

Also called *bunion*, *hallux valgus* is a deformity of the foot involving the first metatarsal and great toe. Occurs in females more frequently than in males and incidence increases with age; may have a genetic predisposition. Commonly occurs with other deformities of the feet, such as hammertoe, mallet toe, and claw toe.

Clinical Manifestations

1. Pain.
2. Possible callus of skin overlying bunion and accompanying toe deformities.
3. Diminished ROM.
4. Generally associated with tight footwear.

Management and Nursing Interventions

Conservative Management

1. Wearing footwear made of soft material with a wider toe box, rounded rather than pointed, and with low heel.
2. Special orthoses can be ordered.
3. Steroid injections to relieve pain.

Surgical Management

Surgical alignment of the great toe by osteotomy of metatarsal or proximal phalanx of the great toe or fusion of the metatarsal–metatarsophalangeal joint.

Postoperative Care

1. Elevation of the foot to reduce pain.
2. Initial non–weight-bearing activity, with very gradual progress in activity.
3. Crutch walking initially, followed by wooden shoe immobilizer for several weeks.
4. NSAIDs and opioid analgesics for pain.
5. Bandages changed by the surgeon initially.

OVERVIEW AND ASSESSMENT

Description of Skin Lesions

The description of dermatologic conditions always includes the morphology of the lesions that appear on the skin (ie, their size, shape, color, pattern, and distribution; see Figure 33-1).

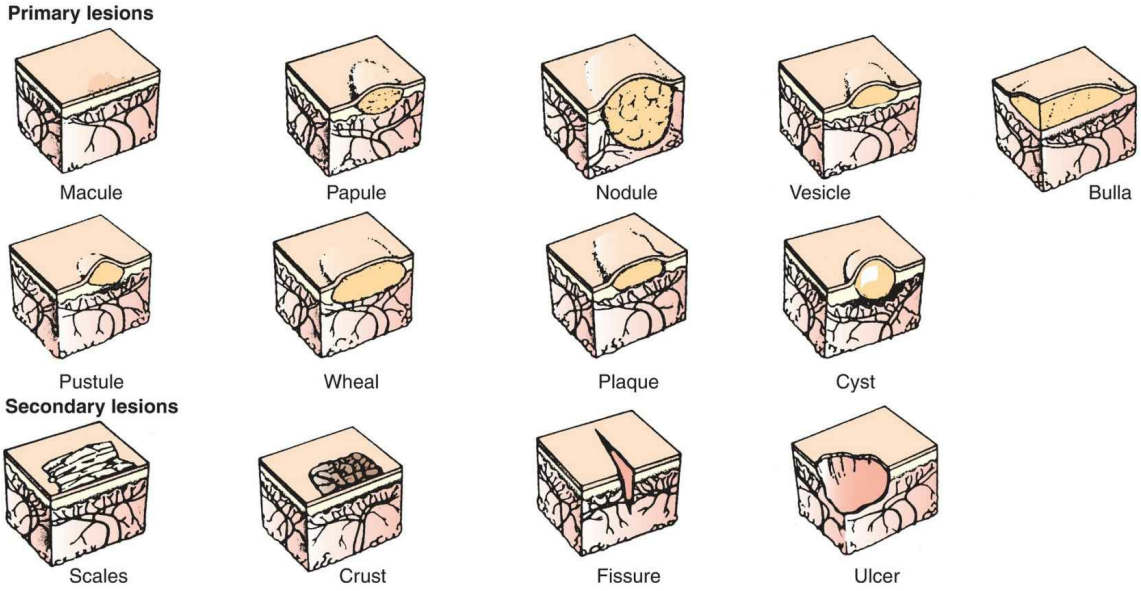

Figure 33-1. Types of skin lesions. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Primary Lesions

1. Macule—flat, circumscribed discoloration of the skin; may have any size or shape.
2. Papule—solid, elevated lesion less than 1 cm wide.
3. Nodule—raised, solid lesion larger than 1 cm wide.
4. Vesicle—circumscribed elevated lesion less than 0.5 cm, containing fluid.
5. Bulla—a vesicle or blister larger than 0.5 cm wide.
6. Pustule—circumscribed raised lesion that contains pus; may form as a result of purulent changes in a vesicle.
7. Wheal—elevation of the skin that lasts less than 24 hours, caused by edema of the dermis; may be surrounded by erythema or blanching.
8. Plaque—solid, elevated lesion on the skin or mucous membrane, larger than 1 cm in diameter; psoriasis is commonly manifested as plaques on the skin; leukoplakia is an example of plaques on mucous membranes.
9. Cyst—soft or firm mass in the skin, filled with semisolid or with liquid material contained in a sac.

Secondary Lesions

Secondary lesions involve changes that take place in primary lesions that modify them.

1. Scale—heaped-up, horny layer of dead epidermis; may develop as a result of inflammatory changes.
2. Crust—covering formed by the drying of serum, blood, or pus on the skin (scab).
3. Excoriation—linear scratch marks or traumatized areas of the skin.
4. Fissure—linear cracks in the skin, usually from marked drying and long-standing inflammation.
5. Ulcer—lesion formed by local destruction of the epidermis and by part or all of the underlying dermis.
6. Lichenification—thickening of the skin accompanied by accentuation of skin markings.
7. Scar/keloid—abnormal new formation of connective tissue that replaces the loss of substance in the dermis as a result of injury or disease. A keloid is a hypertrophic scar that is larger than the original lesion or injury.
8. Atrophy—diminution in size or in loss of skin cells that causes thinning of the skin.

Other Lesions

1. Petechiae—circumscribed deposits of blood or blood pigment 1 to 2 mm wide.
2. Purpura—circumscribed deposits of blood or blood pigment greater than 0.5 cm wide.
3. Comedones—hair follicle obstructed by a sebum and keratin plug; blackheads and whiteheads.
4. Telangiectasia—small, irregular blood vessels visible in the epidermis.
5. Burrow—linear, irregular, elevated tunnel produced by parasites in the skin.

Shape and Configuration

After the type of lesion is identified, the shape, configuration or arrangement (in relation to each other), and pattern of distribution are noted (see Figure 33-2). The following are descriptions commonly used:

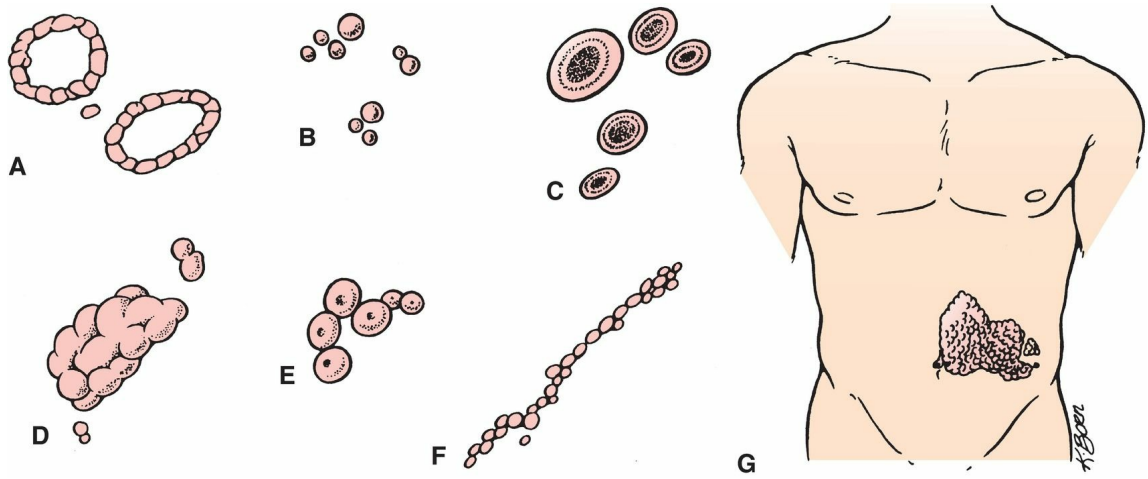

Figure 33-2. Shape and arrangement of skin lesions: **(A)** annular, **(B)** grouped, **(C)** iris, **(D)** confluent, **(E)** herpetiform, **(F)** linear, **(G)** zosteriform or dermatomal.

1. Annular—ring shaped.
2. Circinate—circular.
3. Confluent—lesions run together or join.

4. Discoid—disk shaped.
5. Discrete—lesions remain separate.
6. Generalized—widespread eruption.
7. Grouped—clustering of lesions.
8. Guttate—droplike.
9. Herpetiform—grouped vesicles.
10. Iris—ring or a series of concentric circles (bull's eye).
11. Linear—in lines.
12. Nummular—coin shaped.
13. Polymorphous—occurring in several or many forms.
14. Reticulated—lacelike network.
15. Serpiginous—snakelike or creeping eruption.
16. Telangiectatic—a tiny red thread or line.
17. Zosteriform or dermatomal—bandlike distribution, limited to one or more dermatomes of the skin.

History

Obtaining a thorough history is the key to diagnosing and developing a plan of care for dermatologic conditions, as well as understanding the characteristics of the problem and its effect on the patient.

Characteristics of Rash

1. When did the rash first occur? Was the onset sudden or gradual?
2. What site was first affected? Describe the spread and its severity.
3. What was the initial color and configuration of the rash? Has it changed?
4. Is there associated itching, burning, tingling, pain, or numbness?
5. Has it been constant or intermittent?

Associated Factors

1. What makes the rash worse or better? Is it seasonal? Is it affected by stress?
2. What medications are being taken? What topical products have been used? What effect did they have?
3. What skin products are used? What chemicals have come into contact with the skin: such as laundry detergent, cleaning products, insecticides, or nickel?
4. Has there been pet contact?
5. What is the patient's occupation? Any hobbies, such as gardening or hiking, that may have contributed? Are latex gloves worn routinely? Is frequent handwashing required?
6. What is the sexual history and chance of sexually transmitted disease exposure (if relevant)?
7. Any international travel?

Medical History

1. Is there a history of hay fever, asthma, hives, eczema, or allergies?
2. Has the patient had this particular rash or other skin disorders in the past?
3. What is the family history of skin disorders?
4. Are there any long-standing medical problems? Immunosuppressive therapy?

Physical Examination

1. Focus your examination on the skin, hair, and nails. Some dermatologic conditions affect other body systems (eg, hair loss may be associated with thyroid disease or anemia); perform a general physical exam, as indicated.
2. Ask the patient to show you the area of concern and examine the skin surface under good lighting. Patients should be undressed, in a gown, and the skin of the total body should be examined, not just the area affected.
3. Note the distribution and configuration of skin lesions. Compare right and left sides of the body.
4. Note the shape, border, texture, and surface of the lesions.
5. Palpate the lesions for texture, warmth, and tenderness.
6. Use a metric ruler to determine size of lesions to serve as a baseline for comparison with subsequent measurements.
7. Examine the scalp, nails, and oral mucosa.
8. Perform diascopy—gently press a glass slide or Lucite rule over a skin lesion to detect blanching (caused by dilated blood vessels).
9. Use a Wood light to inspect for fluorescent changes with some fungal infections. Clean the skin prior to examination because some ointments, soaps, or deodorant may fluoresce.
10. For dark-skinned patients, look for black, purple, or gray lesions; palpate carefully to determine if rash is present.

Laboratory Tests

Some dermatologic conditions can be evaluated by laboratory tests such as microscopy and culture.

MicroscopyDescription

1. Sample taken by scraping, swabbing, or aspirating a lesion is transferred to a glass slide for microscopic examination or staining.
    a. Direct visualization of scrapings mixed with mineral oil to detect scabies, mites, or lice nits that cling to the hair.
    b. A Tzanck smear is obtained from vesicular fluid or a moist ulcer and stained to detect characteristics of herpes simplex virus, herpes zoster, and varicella. This is rarely done in the office, but properly obtained specimen could be sent to the lab.
    c. Potassium hydroxide may be added to skin scrapings on a glass slide and heated to dissolve skin cells to detect hyphae and spores in fungal infections.
    d. Gram stain may be performed by the lab or dermatopathologist to tentatively identify bacteria or fungi in certain skin infections.

Nursing and Patient Care Considerations

1. To obtain the specimen for microscopy, use the side of a glass slide or a scalpel held at a 45-degree angle to gently scrape the active border of a dry lesion or of an inflamed area; only mild discomfort and pinpoint bleeding should occur.
2. For moist or semimoist ulcerations or crusted lesions, roll saline-soaked cotton or Dacron-tipped swab over the lesion; for weeping lesions, use a dry swab.
3. For intact vesicles, aspirate fluid from the edge with a 25-G sterile needle; if vesicle is partially broken, gently unroof with forceps and obtain fluid on a swab.

CultureDescription

1. Drainage from lesions may be cultured on specific media to detect causative organism and sensitivity to antimicrobial therapy; also, portions of the skin, hair, and nails may be submitted for fungal culture.
2. Usually takes 24 to 48 hours for results; fungal cultures may take 4 to 5 weeks.

Nursing and Patient Care Considerations

1. Obtain specimen with cotton- or Dacron-tipped swab, and send to laboratory in bacterial culture container clearly labeled with the patient's name, the date, and the site where the specimen was obtained or in a viral culture container also clearly labeled. Refrigerate viral culture if laboratory pickup is delayed.
2. To obtain specimen for fungal culture, scrape or clip the affected skin, hair, or nails; then, place into a dry, sterile container for transport or onto a dermatophyte test medium.

Other Tests

Patch Testing

Description

1. *Patch testing* is an office procedure done to determine if patients are sensitive to contact materials.
2. Materials are applied in patches to the skin and checked for reaction 48 hours after application and possibly again in 1 week.
3. Erythema, itching, swelling, papules, and vesicles indicate an allergic contact dermatitis rather than an irritant contact dermatitis or no reaction.

Nursing and Patient Care Considerations

1. Confirm that patient has been off oral corticosteroids at the time of the test; topical corticosteroids should be discontinued 1 to 2 weeks before testing to prevent a weak reaction or false-negative results. Make sure the patient has followed the health care provider's instructions.
2. When patient returns in 48 hours for the first reading, mark the outline of the patch strip on the patient's back; then, remove the strip. A skin marker or an ultraviolet skin pen marker may be used.
3. Wait 30 minutes; then, do the first reading. Document based on the outcome as follows or take a picture for the patient's record:
   a. 1+ Weak reaction. Nonvesicular, but with erythema, induration, and possible papules.
   b. 2+ Strong reaction. Edematous and vesicular, with erythema, edema, papules, and vesicles.
   c. 3+ Extreme reaction. Spreading, bullous, ulcerative IR (irritant reaction).
   d. Negative reaction.

GENERAL PROCEDURES AND TREATMENT MODALITIES

Baths and Wet Dressings

A therapeutic bath is used to apply medication to the entire skin surface and is useful in treating widespread eruptions and general pruritus. Baths soothe, soften, and reduce inflammation and relieve itching and dryness. See Table 33-1 for types and desired effects. Wet dressings and soaks are damp compresses that contain water, normal saline solution, aluminum acetate (Burow) solution, or magnesium sulfate solution. They may be sterile or clean, or warm or cool, depending on the skin condition and the area to which they are applied.

Table 33-1 Therapeutic Baths

BATH SOLUTION AND MEDICATION	DESIRED EFFECT
Water	• Removes crusts and relieves inflammation
Saline	• Used for widely disseminated lesions
Colloidal Oatmeal	• Antipruritic and demulcent
Sodium Bicarbonate	• Cooling
Starch	• Soothing
Tar Baths (follow package directions)	• Used for psoriasis and chronic eczematous conditions
Bath Oils	• Used for antipruritic and emollient soothing properties • Used for acute and subacute eczematous eruptions
Bleach Baths	• Reduces colonization of harmful bacteria that contribute to acute and chronic eczema

Therapeutic Baths

Indications

1. Vesicular disorders, eczema, atopic dermatitis.
2. Acute inflammatory conditions.
3. Erosions and exudative, crusted surfaces.

Nursing and Patient Care Considerations

1. Prepare the bath or teach patient to prepare a lukewarm bath at 90°F to 100°F (32.2°C to 37.8°C); with the tub half-full, add the prescribed quantity of medication and mix thoroughly to prevent sensitivity reaction. Add oatmeal products or oils to emulsifying baths.
   a. Bleach baths may be used for acute and chronic atopic dermatitis.
   b. Add ½ cup of bleach to full tub or ¼ cup to half tub of warm water, and soak limbs and torso for 5 to 10 minutes (do not submerge head), no more than twice a week.
2. Do not rub the skin. Soaking for at least 5 to 10 minutes will promote removal of loosened scales.
3. Keep the room and water at comfortable temperatures and limit bathing to 20 to 30 minutes; the bath area should be well ventilated if tars are used because they are volatile.

4. Tell patient to use a bath mat inside the tub and to use a rug outside the tub when bathing at home because medication may make the tub and other wet surfaces slippery.
5. Blot skin dry with a towel and apply emollient or topical medication to moist skin. While the skin is wet, apply steroid to inflamed areas, if prescribed.

Open Wet Dressings

Indications

1. Bacterial infections that require drainage.
2. Inflammatory and pruritic conditions.
3. Oozing and crusting conditions.

Nursing and Patient Care Considerations

1. Apply dressing to affected area or teach patient to apply. Moisten to the point of slight dripping; remoisten as necessary.
2. Use warm tap water if warming is desired.
3. Application may be from 5 to 15 minutes three to four times per day, unless otherwise indicated.
4. Keep patient warm and do not treat more than one third of the body at a time because open wet dressings can cause chilling and hypothermia.
5. Teach patients to prevent burns by measuring temperature of solution with a bath thermometer or by testing tap water on the wrist before applying compress. Advise them not to use microwave ovens to warm dressings because uneven heating can occur.

Other Dressings

Occlusive Dressing

An *occlusive dressing* is formed by an airtight plastic or vinyl film applied over medicated areas of the skin (usually with corticosteroids) to enhance absorption of medication and to promote moisture retention.

Indications

Skin conditions with thick scaling, such as psoriasis, eczema, and lichen simplex chronicus.

Nursing and Patient Care Considerations

1. Wash area and pat dry.
2. Apply medication while the skin is still moist.
3. Cover with plastic wrap, vinyl gloves, or plastic bag.
4. Seal with paper tape at edges or cover with other self-adhesive dressing to hold in place.
5. Do not apply to ulcerated or abraded skin; removal is recommended within 12 to 24 hours. High-potency steroids are for short-term use only.

DRUG ALERT Excessive use of occlusive dressings that contain corticosteroids may cause skin atrophy, striae, telangiectasia, folliculitis, nonhealing ulceration, erythema, and systemic absorption of corticosteroids.

Nonocclusive Dressings

Other dressing materials may be used as dry dressings to protect the skin, keep affected areas clean, absorb drainage, or cover medication or hold occlusive dressings in place.

Nursing and Patient Care Considerations

1. Apply dry gauze dressing using clean technique (unless sterile technique is indicated by open wounds).
2. Wrap extremities with elastic or cotton-rolled bandages or apply tape. Avoid constricting circulation.
3. Alternative dressing materials can be used for home care, such as disposable or white cotton gloves for the hands, cotton socks for the feet, sheets or towels for large areas, disposable diapers or towels folded in diaper fashion for the groin, washcloths for the axilla, cotton T-shirt or cotton pajamas for the trunk, turban or plastic shower cap for the scalp, or mask made from gauze for the face, with holes cut for the eyes, mouth, and nose.

Skin Biopsy

Removal of a piece of the skin by shave, punch, or excision technique to detect malignancy or other characteristics of skin disorders.

Types of Biopsy

1. Shave biopsy—scalpel used to remove raised lesions, leaving lower layers of the dermis intact.
2. Punch biopsy—special instrument used to remove round core of lesion, containing all layers of the skin. Biopsy site is usually closed with sutures.
3. Excisional biopsy—scalpel and scissors used to remove the entire lesion, usually with prescribed margins; suturing required.

Nursing and Patient Care Considerations

1. Position patient comfortably with the site exposed; explain that a local anesthetic will be given.
2. Check if patient has any known allergies to local anesthetics.
3. Ask patient what current medication he or she is taking. Aspirin, some herbal supplements, or anticoagulants may cause increased postoperative bleeding.
4. Explain the procedure.
5. Obtain written consent.
6. After the biopsy, apply hemostatic agent and pressure to the site to stop bleeding, along with an appropriate dressing. Pressure dressing may be required for larger wounds or wounds that are bleeding.
7. Place the biopsy specimen in a clearly labeled container with 10% formaldehyde, and transport it to the dermatopathology lab for hematoxylin and eosin staining. It is essential that skin biopsies be sent to a specialized dermatopathology lab for examination by a dermatopathologist to get the best analysis and most complete information on the histology of the skin disease or lesion.

Patient Education

1. Keep the bandage on surgery site for 24 to 48 hours. During this time, keep site clean and dry.
2. After this time, remove the bandage and do the following daily:
    a. Wash the incision with soap and water.
    b. Dry the incision well.
    c. Apply petroleum- or mineral oil–based ointment, such as Vaseline or Aquaphor, one to four times per day, keeping the incision moist at all times.
3. After a few days, the dressing is no longer needed but continue to apply ointment one to four times per day to keep the site moist and help reduce scarring.
4. Do not apply makeup directly to the stitches.
5. Repeat wound care for 2 or 3 days after stitches have been removed, unless otherwise instructed.
6. Use caution when shaving around stitches on the face.

DRUG ALERT Many patients are allergic to neomycin, a component of triple antibiotic ointment. Petrolatum- or mineral oil–based ointments pose less risk of allergic dermatitis.

Wound Coverage: Grafts and Flaps

Wound coverage, using grafts and flaps, is a type of reconstructive (plastic) surgery performed to improve the skin's appearance and function. These are sometimes used following Mohs micrographic surgery to remove skin cancers, especially on the face, head, and neck.

Skin Graft

1. A section of skin tissue is separated from its blood supply and transferred as free tissue to a distant (recipient) site; it must obtain nourishment from capillaries at the recipient site.
2. In dermatology, skin grafting is used to repair defects that result from excision of skin tumors and to cover areas of denuded skin.
3. Definitions.
    a. Autografts—grafts done with tissue transplanted from the patient's own skin.
    b. Allografts—involve the transplant of tissue from one individual of the same species; these grafts are also called allogenic or homografts.
    c. Xenograft or heterograft—involves the transfer of tissue from another species.
4. Classification by thickness.
    a. Split thickness (thin, intermediate, or thick)—graft that is cut at varying thicknesses and is used to cover large wounds because its total potential donor area is virtually unlimited.
    b. Full thickness—graft consists of epidermis and all of the dermis without the underlying fat; used to cover wounds that are too large to close primarily. They are used frequently to cover facial defects because they provide a better contour match and less postoperative contracture.

Skin Flaps

1. A flap is a segment of tissue that has been left attached at one end (called a base or pedicle); the other end has been moved to a recipient area. It is dependent for its survival on functioning arterial and venous blood supplies and on lymphatic drainage in its pedicle or base.
    a. Free flap or free-tissue transfer—one that is completely severed from the body and is transferred to another site; receives early vascular supply from microvascular anastomosis with vessels at recipient site.
2. Flaps may consist of the skin, mucosa, muscle, adipose tissue, and omentum.
3. Used for wound coverage and to provide bulk, especially when bone, tendon, blood vessels, or nerve tissue are exposed.
4. Flaps offer the best aesthetic solution because a flap retains the color, texture, and thickness match of the donor area.
5. Flaps are classified according to the method of movement, composition, location, or function.

Procedure for Skin Grafts

1. Split-thickness skin graft is obtained by razor blade, skin-grafting knife, or electric or air-powered dermatome or drum dermatome. Most commonly obtained from the inner aspect of the upper arm or outer thigh.
2. A full-thickness skin graft is primarily excised, defatted, and tailored to fit accurately over the defect area.
3. Skin is taken from the donor or host site and applied to the wound or defect site, called the recipient site or graft bed.
4. A bolster (pressure) dressing is applied to the graft to enhance the survival of the skin graft by providing stable approximation of the graft to the recipient bed.
5. The bolster dressing is left in place for 1 week. The process of revascularization and reattachment of the skin graft to the recipient bed is referred to as a take.
6. The donor site is maintained clean and dry.
    a. If Scarlet Red (a single-layer dressing impregnated with epithelial growth promoter) is used on the donor site for split-thickness grafts, it is left in place for 2 to 3 weeks to allow the wound to heal.
    b. Occlusive dressings, such as Omniderm or Allevyn, may also be used to decrease pain, alleviate frequent wound care, and speed healing.
    c. Daily wound care and dressing change with an antimicrobial ointment and nonstick dressing may also be used.

NURSING ALERT Patients usually find the donor site more painful than the graft site.

Preoperative Management and Nursing Care

1. Aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs) and vitamin E are discontinued 14 days before the procedure. Coumadin should be held for several days before the procedure, and prothrombin time and international normalized ratio should be measured before the procedure, as ordered. Herbal supplements, such as ginkgo, ginseng, green tea, and vitamin E, can inhibit coagulation.
2. Efforts should be made to enhance wound healing several months to several weeks before the procedure, such as smoking cessation, alcohol avoidance, and proper nutrition.
3. Medical history and examination should be evaluated, particularly for latex sensitivity, cardiovascular problems requiring endocarditis antibiotic prophylaxis, bleeding problems, and high blood pressure (BP).
4. The procedure is usually done under local anesthetic, so no meals are withheld.
5. The operative site should be free from makeup.
6. The patient should have someone available to drive him or her home after surgery unless otherwise notified.

Postoperative Management and Nursing Care

Educate the patient with a skin graft on the following care:

1. Initial pressure dressing will be left in place for 24 to 48 hours.
2. If wound begins to ooze, apply firm pressure for 10 to 15 minutes (without peeking). If bleeding persists, contact surgeon.
3. Do not take aspirin or aspirin-containing medication for pain. May take one to two acetaminophen tablets every 4 to 6 hours, as needed.
4. Most skin grafts are held in place by a bolster dressing (cotton ball or foam). Do not remove the bolster dressing during the next week.
5. May clean site and apply ointment to the surrounding area of the bolster dressing.
6. Do not get the bolster dressing wet.
7. When the bolster dressing is removed, may shower, but *do not* let the water hit the graft directly.
8. Keep the graft edges moist with ointment.
9. Protect the graft from the sun. The sun will cause pigmentation changes in the graft. A sunscreen may be used in 2 to 3 weeks.
10. Skin grafts to the lower leg must be kept elevated because the new capillary connections are fragile and excess venous pressure may cause rupture. Keep leg elevated as much as possible during the next week.
11. Inspect the dressing daily. Report unusual drainage or signs of an inflammatory reaction.
12. After 2 to 3 weeks, any water-based moisturizer may be applied to the skin donor site for split-thickness skin grafts.
13. Expect some loss of sensation in the grafted area for a time.
14. Avoid strenuous exercise (jogging, lifting heavy objects). Anything that causes face flushing will raise BP, cause bleeding, and impair healing.

Aesthetic Procedures

Aesthetic procedures (cosmetic surgery) consist of reconstructive (plastic) surgery or the use of injected substances, which may be performed to reconstruct or to alter congenital or acquired defects or to restore or improve the body's appearance. Noninvasive procedures alter the skin surface through the use of light sources or chemical applications.

Types of Procedures

Rhytidectomy

1. Done through various techniques and incisions to alleviate skin folds and wrinkles to improve the appearance of the aging face (face-lift).
2. The correction can last as long as 10 years, but results vary with each individual. The skin relaxes with time and the muscles may also relax, but seldom does the face revert to its preoperative condition.
3. Surgical procedures include:
    a. Operative: Standard incisions that are either temporal (hidden in hairline) or submental.
    b. Laser: Several laser modalities are now used in facial plastic surgery, including radiofrequency tissue tightening, which causes collagen shrinkage and reduction of deep wrinkles and lines.

Blepharoplasty

1. Removes loose skin, muscle, and excess fat from upper or lower eyelids. It will not remove lines at the lateral corners of the eyes ("crow's feet").
2. The procedure is generally done by either scalpel under local or general anesthetic or by carbon dioxide laser.

Dermabrasion, Chemical Peel, Laser Resurfacing, and Fillers

1. Patients with weathered skin, fine wrinkles (especially at the corners of the eyes and along the vermilion border), or acne pitting and scarring may benefit from these procedures.
2. The use of laser technology allows for a more predictable result and eliminates the porcelain appearance resulting from such chemicals as trichloroacetic acid. There is less risk of hypopigmentation than with dermabrasion.
3. Chemical peels using tretinoin cream and alpha hydroxy acids result in the destruction of portions of the epidermis and dermis, with subsequent regeneration of new tissues.
4. New nonablative laser resurfacing is used for fine wrinkles, smoker lines, sun-damaged skin, and shallow acne scarring with minimal downtime.
5. Contraindications of laser resurfacing include:
    a. History of isotretinoin therapy 6 to 12 months prior to treatment.
    b. Status of postradiation or scleroderma.
    c. History of herpes simplex—requires perioperative treatment.

6. Hyperpigmentation can occur in persons with dark skin.
7. Purified botulinum toxin and fillers (collagen, hyaluronic acid, autologous fat) are used to correct deep wrinkles and facial hollows. Results may last 3 to 12 months.

Liposuction

1. Also called body contouring, liposuction reduces localized deposits of fat not amenable to weight loss with a cannula aided by suction or fitted to a syringe.
2. May be done on the face, neck, breasts, abdomen, flanks, hips, buttocks, and extremities.

Preoperative Management and Nursing Care

1. Local or general anesthetic will be administered. For local anesthetic, patient may eat and drink before surgery. For general anesthetic:
   a. Preoperative assessment may be necessary, depending on health status and patient's age.
   b. No eating or drinking for several hours before surgery.
   c. Patient should have escort and must be reminded not to drive home alone after surgery.
2. Review patient's allergies and medication before surgery.
3. Instruct patient to cleanse the skin with antiseptic agent the night before surgery, if prescribed.
4. Make sure patient thoroughly understands the procedure and has discussed the risks and benefits with the health care provider before surgery.
5. Make sure a consent form is signed before any procedure.
6. Make sure aspirin, warfarin, and NSAIDs have been discontinued for 2 weeks before surgery, unless otherwise indicated. Herbal supplements, such as ginkgo, ginseng, green tea, and vitamin E, can inhibit coagulation.
7. If applicable, instruct the patient to stop smoking for the 2 weeks leading up to rhytidectomy and to continue cessation for 2 weeks postprocedure and permanently, if possible.
8. Be aware of signs of topical lidocaine toxicity (if used)—drowsiness, tingling of lips, and metallic taste—which may lead to seizures.

Postoperative Management and Nursing Care

Rhytidectomy

1. Mild exercise can be resumed in 3 days postoperatively.
2. No strenuous exercise (that will increase the BP) for 1 month.
3. Dressings are usually removed on the first postoperative day. Elastic facial support garment is recommended for 1 to 3 weeks.
4. Eyelid sutures are removed in 3 to 5 days; facial sutures in 7 days.
5. Showering and gentle hair washing may begin on day 2 or 3.
6. The patient is to apply ointment (petroleum or a similar ointment) to all suture lines.

7. Stress to the patient not to remove crusts by "picking" at them along suture lines or scarring may result.
8. Elevate the head at night for 2 weeks after the procedure. Avoid bending and lifting, which may increase edema and provoke bleeding.
9. Expect the face or affected part to be swollen, bruised, and numb for several days to weeks.
10. Be aware that complications include bleeding and hematoma, sloughing of the skin, and possible facial nerve damage. Notify surgeon if the areas become increasingly red or swollen or if they become more tender or painful.

Blepharoplasty

1. Apply iced gauze compresses to eyes for 10 minutes four to six times per day to reduce edema after surgery.
2. Head of bed should be elevated to reduce internal pressure that might cause bleeding.
3. Avoid strenuous exercise for 1 week.
4. Bruising and swelling generally resolve in 2 weeks.
5. Watch for such complications as eyelid hematomas, ocular mobility dysfunction, and postsurgical ectropion (eversion of the edge of the eyelid).

Dermabrasion and Chemical Peel

1. Instruct patients to not pick at crusts because new epithelium will be injured; soak face several times per day and apply emollient, as directed. Crusts form in 2 to 3 days and start to separate by 7 to 10 weeks. Total separation can take up to 3 weeks.
2. Keep treated areas clean and moist.
3. Avoid sun on treated areas. Apply sunscreen with sun protection factor (SPF) of 15 to 30 when outdoors.
4. Manage bruising and swelling from injectables with ice packs.

Laser Resurfacing

1. Dressings, such as hydrogel dressings (see page 152), may be applied to the affected areas immediately and left in place for 24 to 48 hours.
2. Alternately, the open technique involves using petroleum gel and daily face washes with tepid water.

Liposuction

1. After liposuction, increased fluids are required.
2. Aspirin and NSAIDs should be avoided for at least 1 week to prevent bleeding.
3. Wear compression garment, as instructed.
4. Notify the surgeon if increased swelling develops; could indicate development of a seroma.
5. Expect blood-tinged fluids from cannula injection sites for 2 to 3 days.
6. Keep sutured areas moist with ointment, as instructed.
7. Avoid jarring exercise.
8. Complications include development of seromas, lumpiness in treated areas, excessive bruising.

NURSING ALERT Advise all postoperative patients to notify health care provider if sudden pain, swelling, or bruising develops; these suggest hematoma or abscess. Do not take aspirin for postoperative discomfort; follow surgeon's orders.

DERMATOLOGIC DISORDERS

Cellulitis

Cellulitis is a diffuse inflammation of the deep dermal and subcutaneous tissue that results from an infectious process.

Pathophysiology and Etiology

1. Caused by infection with group A beta-hemolytic streptococci, *Staphylococcus aureus*, *Haemophilus influenzae*, or other organisms.
2. Usually results from break in the skin that may be as simple as athlete's foot.
3. Infection can spread rapidly through lymphatic system.

NURSING ALERT Methicillin-resistant *S. aureus* (MRSA) is a significant problem outside of the hospital as well as within. It is resistant to previously effective antistaphylococcal antibiotics and may be fatal.

Clinical Manifestations

1. Tender, warm, erythematous, and swollen area that is poorly demarcated.
2. Tender, warm, erythematous streak that extends proximally from the area, indicating lymph vessel involvement.
3. Possible fluctuant abscesses or purulent drainage.
4. Possible fever, chills, headache, malaise.

Diagnostic Evaluation

1. Gram stain and culture of drainage.
2. Blood cultures.

Management

1. Oral antibiotics (penicillinase-resistant penicillins, cephalosporins, quinolones, or sulfa-based) may be adequate to treat small, localized areas of cellulitis of legs or the trunk.
2. Parenteral antibiotics may be needed for cellulitis of the hands, face, or lymphatic or widespread involvement.
3. Surgical drainage and debridement for suppurative areas recommended for MRSA infections.

Complications

1. Tissue necrosis.
2. Septicemia.

Nursing Assessment

1. Obtain history of trauma to the skin, needlestick, insect bite, or wound.
2. Observe for expanding borders and lymphatic streaking; palpate for fluctuance of abscess formation.
3. Watch for signs of antibiotic sensitivity—shortness of breath, urticaria, angioedema, maculopapular rash, or severe skin reaction, such as erythema multiforme or toxic epidermal necrolysis.
4. Assess for patient and caretaker ability to provide care at home, keep affected area clean, and adhere to medication prescribed.

Nursing Diagnoses

- Impaired Skin Integrity related to infectious process.
- Acute Pain related to inflammation of subcutaneous tissue.

Nursing Interventions

Protecting Skin Integrity

1. Administer or teach patient to administer antibiotics, as prescribed; teach dosage schedule and adverse effects. Assess ability to swallow pills. Recommend crushing or taking with food to avoid stomach irritation, if applicable.
2. Maintain intravenous (IV) infusion or venous access to administer IV antibiotics, if indicated.
3. Elevate affected extremity to promote drainage from area and reduce swelling.
4. Prepare patient for surgical drainage and debridement, if necessary.

Relieving Pain

1. Encourage comfortable position and immobilization of affected area.
2. Administer or teach patient to administer analgesics, as prescribed; monitor for adverse effects.
3. Use bed cradle to relieve pressure from bed covers.

Patient Education and Health Maintenance

1. Make sure that patient understands dosage schedule of antibiotics and the importance of complying with therapy to prevent complications.
2. Advise patient to notify health care provider immediately if condition worsens; hospitalization may be necessary.
3. Outpatient-treated cellulitis should be observed within 24 to 48 hours of starting antibiotics to determine efficacy.
4. Teach patient with impaired circulation or impaired sensation how to perform proper skin care and how to inspect skin for trauma.

Evaluation: Expected Outcomes

- Skin is normal color and temperature, nontender, nonswollen, and intact.
- Actively moves extremity; verbalizes no pain.

Necrotizing Fasciitis

Necrotizing fasciitis is a type of necrotizing infection of the soft tissue that spreads quickly along fascia. It rapidly progresses toward death if not treated quickly.

Pathophysiology and Etiology

1. Usually caused by group A *Streptococcus*, known as flesh-eating bacteria, but may also be a clostridia or polymicrobial infection. It is emerging as a complication of MRSA infection.
2. May result postoperatively or from local injury with superficial or deep infection.
3. More common in patients with diabetes, those that abuse drugs, and other immunocompromised populations.
4. Spreads along fascia, causing extensive necrosis of the skin and subcutaneous tissue.

Clinical Manifestations

1. Increasing pain or pain out of proportion to local infection or injury; increasing redness, edema, and warmth.
2. Fever, rapid pulse.
3. Tissue appears darkened under the skin.
4. Possible bullae or petechiae or appears hemorrhagic.
5. May be foul odor and drainage (delayed).

Diagnostic Evaluation

1. Surgical excision and debridement are diagnostic to determine extent as well as therapeutic.
2. Gram stain and culture from deep tissue to determine exact etiology.
3. Blood cultures to rule out septicemia.

Management

1. Immediate hospitalization with intensive care support.
2. Prompt and repeated surgical debridement.
3. IV antibiotic regimen using multiple agents, including clindamycin, penicillin G, erythromycin, ceftriaxone, and others.

Complications

1. Muscle gangrene—requires amputation.
2. Loss of tissue and function.
3. Death.

Nursing Assessment

1. After trauma, surgery, or with cellulitis, frequently assess for increasing pain, fever, and changes in skin

appearance, which may indicate necrotizing fasciitis.

2. Be aware of underlying conditions that may cause immunocompromise, such as diabetes, alcoholism, malnutrition, IV drug use, cancer and cancer treatment, and HIV/AIDS, which increases the risk and worsens the course of necrotizing fasciitis.
3. Monitor vital signs frequently for any change (rise or fall in BP, temperature, pulse, and respirations) that may indicate worsening condition.
4. Monitor wound dressings after debridement for amount, color, and odor of drainage. Wounds will usually be left open to heal by secondary intention.

NURSING ALERT Inform the health care provider immediately if pain is out of proportion to injury or if progressive skin changes occur. The patient should be assessed for necrotizing fasciitis.

Nursing Diagnoses

- Hyperthermia related to infectious process.
- Acute Pain related to necrosis.

Nursing Interventions

Normalizing Body Temperature

1. Administer antipyretics, as directed.
2. Encourage oral fluids and administer IV fluids, as directed.
3. Monitor intake and output to ensure adequate hydration because of fluid loss through fever and insensible loss.
4. Provide cool compresses, sponge baths, and clothing and linen changes as comfort measures.

Relieving Pain

1. Administer analgesics, as directed and based on pain assessment; however, be alert for sedation that may mask signs of worsening condition.
2. Assist patient to position of comfort that will not place pressure on affected area.
3. Administer analgesic 30 to 60 minutes before wound care and dressing changes.

Education and Health Maintenance

1. Make sure that patient can complete wound care at home and will follow-up as directed.
2. Make home care nursing referral, as necessary.
3. Teach patient signs of infection and to notify health care provider immediately if experiencing increasing pain, fever, redness, swelling, warmth, or increased and odorous drainage.
4. Advise patient to eat a balanced diet rich in protein, vitamin C, iron, and zinc for wound healing.

Evaluation: Expected Outcomes

- Core temperature 97.6˚F to 98.8˚F (36.4˚C to 37.1˚C).
- Patient turning in bed, verbalizing minimal pain.

Toxic Epidermal Necrolysis

Toxic epidermal necrolysis is a severe, potentially fatal skin disease associated with erythema, blistering, and epidermal sloughing. A less severe form is known as *Stevens-Johnson syndrome*.

Pathophysiology and Etiology

1. Exact mechanism is unknown, but can be induced by various drugs, including sulfonamides, anticonvulsants, NSAIDs, allopurinol.
2. Resembles second-degree burns, with sloughing of the skin at epidermal or dermal junction.
3. Mortality ranges from 3.2% to 90%, based on an illness severity score with factors such as age, presence of malignancy, heart rate, and percentage of epidermal detachment.

Clinical Manifestations

1. Malaise, fatigue, vomiting, cough, fever, and diarrhea may be prodromal symptoms.
2. Sudden onset of urticaria and large dark red areas; within 5 to 8 days, large, flaccid bullae appear.
3. Within hours, coma may develop.
4. Bullae become confluent and slough in large sheets, leaving moist, erythematous surface.
5. Positive Nikolsky sign (desquamation of the skin on light pressure).
6. Erosions of mucosal sites, including lips, oral pharynx, or urinary tract.

Diagnostic Evaluation

1. Skin biopsy to determine level of separation.
2. Possible cultures of blood and body fluids to differentiate infection.

Management

1. Treatment in intensive care unit or regional burn center because toxic epidermal necrolysis has similar pathophysiologic characteristics to those of extensive burns (see page 924).
2. Treatment of affected skin.
    a. Wounds are cleaned in operating room under anesthesia; loose skin and blisters are removed, and necrotic areas are debrided to prevent infection.
    b. Temporary biologic dressings (porcine cutaneous xenografts, amnion, collagen-based skin substitute, or plastic semipermeable dressings) applied to prevent secondary skin infection while awaiting reepithelialization.
3. All nonessential drugs are stopped immediately.
4. Fluid replacement therapy, as necessary, and possible enteral nutrition if oral involvement.
5. Topical antimicrobial dressings to enhance reepithelialization.
6. Ophthalmologic examination and removal of corneal adhesions, as necessary.
7. Use of systemic corticosteroids is not recommended and use of human IV immunoglobulin is

controversial.

Complications

1. Sepsis.
2. Pneumonia.
3. Blindness.

Nursing Assessment

1. Obtain medication and immunization history.
2. Monitor vital signs and level of consciousness closely because the condition is rapidly progressive.
3. Monitor fluid and nutritional status through daily weight, vital signs, and laboratory test results (electrolytes, especially glucose, bicarbonate, blood urea nitrogen, creatinine, albumin, and total protein).

Nursing Diagnoses

- Impaired Skin Integrity related to sloughing.
- Risk for Deficient Fluid Volume related to transudation of fluid into bullae.
- Acute Pain related to exposed dermal nerve endings.
- Impaired Oral Mucous Membranes related to oral lesions.

Nursing Interventions

Restoring Skin Integrity

1. Place patient on warmed air-fluidized bed to distribute weight with minimal shearing forces.
2. Use extreme care in handling patient because the skin is very fragile; obtain assistance to move patient.
3. Gently apply warm, wet compresses of prescribed antiseptic solution to reduce bacterial population of wound surface.
4. Inspect xenograft several times daily for dislodgment or purulence; these will require new xenograft.
5. Watch for new areas of toxic epidermal necrolysis; note and record progression of skin slough and chart progress.
6. Patient should be in private room on reverse isolation to prevent infection.
7. Provide nutritional supplements through enteral feeding to ensure healing.

Maintaining Fluid Balance

1. Monitor vital signs for falling BP or for rising pulse that indicates hypovolemia; use an indwelling arterial catheter to provide continuous measurement while avoiding cuff pressure on the skin.
2. Measure hourly urine output.
3. Weigh patient daily.
4. Give IV fluids, as prescribed.
5. Assess bowel sounds and give oral or enteral fluids, as tolerated.

Reducing Pain

1. If patient cannot verbalize, watch for facial expressions, for guarding, or for increased pulse and respirations to indicate pain.
2. Administer analgesics, as prescribed and as required, possibly around the clock; monitor for adverse effects and document effectiveness.
3. Provide distraction through music or other measures to promote relaxation.
4. Provide emotional support and encouragement. Emotional/psychological support to patient and family is crucial.

Protecting Mucous Membranes

1. Use meticulous oral hygiene.
    a. Inspect oral cavity daily; note any changes.
    b. Rinse mouth with normal saline, diluted hydrogen peroxide, or other solution to remove debris and to cleanse ulcerations.
    c. Apply petroleum jelly or other lubricant/protectant to cracked, swollen lips.
2. Assess urethral, vaginal, and anal regions for ulcerations or bleeding.
3. Inspect eyes and remove crusts from eyelid margins using damp compresses or saline-soaked swabs; apply eyedrops as prescribed.

Patient Education and Health Maintenance

1. Encourage follow-up appointments with plastic surgeon and other health care providers as indicated.
2. Encourage compliance with physical therapy, as indicated, to restore function.
3. Advise patient to use sunscreen of at least SPF 15, avoid direct sunlight during the healing phase, and continue to use sunscreen.
4. Advise patient to avoid suspected medication in the future.

Evaluation: Expected Outcomes

- New epithelium noted without scarring.
- Output equals input; weight and vital signs remain stable.
- Patient verbalizes reduced pain.
- Oral mucosa intact.

Herpes Zoster

Herpes zoster (varicella–zoster, shingles) is an inflammatory condition in which reactivation of the chickenpox virus produces a vesicular eruption along the distribution of the nerves from one or more dorsal root ganglia (dermatome). The prevalence increases with age. A varicella–zoster vaccine is available for people older than age 50 to prevent reactivation.

Pathophysiology and Etiology

1. Caused by a varicella–zoster virus, which is a member of a group of deoxyribonucleic acid viruses.
2. Virus is identical to the causative agent of varicella (chickenpox). After the primary infection, the varicella–zoster virus may persist in a dormant state in the dorsal nerve root ganglia. The virus may emerge from this site in later years, either spontaneously or in association with immunosuppression, to cause herpes zoster.

Clinical Manifestations

1. Eruption may be accompanied or preceded by fever, malaise, headache, and pain; pain may be burning, lancinating, stabbing, or aching.
2. Inflammation is usually unilateral, involving the cranial, cervical, thoracic, lumbar, or sacral dermatome in a bandlike configuration.
3. Vesicles appear in 3 to 4 days.
   a. Characteristic patches of grouped vesicles appear on erythematous, edematous skin.
   b. Early vesicles contain serum; they later rupture and form crusts; scarring usually does not occur unless the vesicles are deep and they involve the dermis.
   c. If ophthalmic branch of the facial nerve is involved, patient may have a painful eye. (This can be a medical emergency.) Vesicles on the tip of the nose suggest eye involvement.
   d. In healthy host, lesions resolve in 2 to 3 weeks.
4. A susceptible person can acquire chickenpox if there is contact with the infective vesicular fluid of a zoster patient. A person with a history of chickenpox or who has received the immunization is immune and thus is not at risk from infection after exposure to zoster patients.

NURSING ALERT Varicella–zoster virus may be a life-threatening condition to the patient who is immunosuppressed, who is receiving cytotoxic chemotherapy, or who is a bone marrow transplant recipient.

Diagnostic Evaluation

1. Usually diagnosed by clinical presentation.
2. Culture of varicella–zoster virus from lesions or detection by fluorescent antibody techniques, including viral detection that uses monoclonal antibodies or by electron microscopy, to confirm diagnosis.

Management

1. Antiviral drugs, such as acyclovir, famciclovir, and valacyclovir, interfere with viral replication; may be used in all cases, but especially for treatment of immunosuppressed or debilitated patients. Must be started within 72 hours of onset.
2. Corticosteroids early in illness (controversial)—given for severe herpes zoster if symptomatic measures fail; given for anti-inflammatory effect and for relief of pain.
3. Pain management—aspirin, acetaminophen, NSAIDs, opioids—useful during the acute stage, but not generally effective for postherpetic neuralgia. If treated early (48 to 72 hours), may decrease risk of postherpetic neuralgia.
4. Postherpetic neuralgia may be treated with anticonvulsant agents, such as gabapentin or pregabalin, and 5% lidocaine patch.

Complications

1. Approximately 20% of patients will experience chronic pain syndrome (postherpetic neuralgia), characterized by constant aching and burning pain or by intermittent lancinating pain or hyperesthesia of affected skin after it has healed.
2. Ophthalmic complications with involvement of ophthalmic branch of trigeminal nerve with keratitis, uveitis, corneal ulceration, and possibly blindness.
3. Facial and auditory nerve involvement, resulting in hearing deficits, vertigo, and facial weakness (Ramsay Hunt syndrome).
4. Visceral dissemination—pneumonitis, esophagitis, enterocolitis, myocarditis, pancreatitis.

Nursing Diagnoses

- Acute Pain related to inflammation of cutaneous nerve endings.
- Impaired Skin Integrity related to rupture of vesicles.

Nursing Interventions

Controlling Pain

1. Assess patient's level of discomfort and medicate, as prescribed; monitor for adverse effects of pain medications.
2. Teach patient to apply wet dressings, such as aluminum acetate (Burow) solution, for soothing effect.
3. Encourage distraction techniques such as music therapy.
4. Teach relaxation techniques, such as deep breathing, progressive muscle relaxation, and imagery, to help control pain.

Improving Skin Integrity

1. Apply wet dressings to cool and dry inflamed areas by means of evaporation.
2. Administer antiviral medication in dosage prescribed (usually high dose); warn the patient of adverse

effects such as nausea.

Patient Education and Health Maintenance

1. Teach patient to use proper handwashing technique to avoid spreading herpes zoster virus.
2. Advise patient not to open the blisters to avoid secondary infection and scarring.
3. Reassure patient that shingles is a viral infection of the nerve endings; nervousness does not cause shingles.
4. A caregiver may be required to assist with dressings and meals. In older patients, the pain is more pronounced and incapacitating. Dysesthesia and skin hypersensitivity are distressing.

Evaluation: Expected Outcomes

- Verbalizes decreased pain.
- Reepithelialization of the skin without scarring.

Pemphigus

Pemphigus is a serious autoimmune disease of the skin and of the mucous membranes, characterized by the appearance of flaccid blisters (bullae and vesicles) of various sizes on apparently normal skin and mucous membranes (mouth, esophagus, conjunctiva, or vagina) (see Figure 33-3). Familial benign chronic pemphigus (Hailey-Hailey disease) is a familial type of pemphigus that appears in adults, particularly affecting the axillae and groin.

Figure 33-3. Pemphigus vulgaris blisters on the forearm. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

1. The exact cause is unknown.
2. Certain drugs, other autoimmune diseases, and genetics may play a role in its development.
3. Many variants of pemphigus exist.

Clinical Manifestations

1. Initial lesions may appear in the oral cavity; flaccid blisters (bullae) may arise on normal or erythematous skin.
   a. The bullae enlarge and rupture, forming painful, raw, and denuded areas that eventually become crusted. These areas can become secondarily infected.
   b. The eroded skin heals slowly; eventually, widespread areas of the body may become involved.

c. In the mouth, the blisters are usually multiple, of varying size and irregular shape, painful, and persistent. Oral lesions may appear initially, with lesions of the mucous membranes of the pharynx and esophagus; the conjunctivae, larynx, urethra, cervix, and rectum may become affected as well.

2. An offensive odor may emanate from the bullae because of infection.
3. Positive Nikolsky sign—separation of the epidermis when minimal pressure is applied to the skin; downward pressure on a bulla will cause it to expand laterally.

Diagnostic Evaluation

1. Skin biopsies of blisters and surrounding skin—demonstrate acantholysis (separation of epidermal cells from each other).
2. Immunofluorescence of skin cells shows antibodies that bind to the epidermis in a lacy pattern network (pemphigus antibodies).

Management

1. Corticosteroids in large doses to control the disease and keep skin free from blisters.
2. Immunosuppressive agents, such as cyclophosphamide and azathioprine, are used alone or in combination with steroids, for immunosuppressive and steroid-sparing effect.
3. Plasmapheresis—reinfusion of specially treated plasma cells; temporarily decreases serum level of antibodies.
4. Treatment of denuded skin.

Complications

1. Infections (skin, pneumonia, septicemia).
2. Adverse effects from acute and chronic corticosteroids: GI bleeding, secondary infection, psychosis, hyperglycemia, and others.

Nursing Assessment

1. Assess for odor or drainage from lesions, which may indicate infection.
2. Assess for fever and signs of systemic infection.
3. Assess for adverse effects of corticosteroids, such as abdominal pain, white patches in the mouth that indicate *Candida* infection, and emotional changes.

Nursing Diagnoses

- Impaired Oral Mucous Membrane related to ruptured bullae.
- Impaired Skin Integrity related to ruptured bullae.
- Risk for Deficient Fluid Volume related to transudation of fluid into bullae.
- Disturbed Body Image related to widespread or chronic skin lesions.

Nursing Interventions

Restoring Oral Mucous Membrane Integrity

1. Inspect oral cavity daily; note and report any changes—oral lesions heal slowly.
2. Keep oral mucosa clean and allow regeneration of epithelium.
3. Give topical oral therapy, as directed.
4. Offer prescribed mouthwashes through a straw to rinse the mouth of debris and to soothe ulcerative areas.
5. Teach patient to apply petrolatum to lips frequently.
6. Use cool mist therapy to humidify environmental air.

Restoring Skin Integrity

1. Keep skin clean and eliminate debris and dead skin—the bullae will clear if epithelium at the base is clean and not infected.
2. Obtain swab of bullous fluid for cultures—most common organism is *S. aureus*.
3. Administer cool, wet dressings or baths or teach patient to administer to soothe and cleanse the skin. Large areas of blistering have a characteristic odor that is lessened when secondary infection is under control.
    a. After the bath, dry and cover with talcum powder, as directed; this enables the patient to move more freely in bed. Large amounts are necessary to keep clothes and sheets from sticking.
4. The nursing management of patients with blistering or with bullous skin conditions is similar to that of the patient with a burn (see page 930).

Restoring Fluid Balance

1. Evaluate for fluid and electrolyte imbalance—extensive denudation of the skin leads to fluid and electrolyte imbalance.
    a. Monitor serum albumin and protein levels.
    b. Monitor vital signs for hypotension or tachycardia.
    c. Weigh patient daily.
    d. Monitor intake and output.
2. Administer IV saline solutions, as directed.
3. Encourage the patient to maintain hydration; suggest cool, nonirritating fluids.
    a. Suggest soft, high-protein, high-calorie diet or liquid supplements that will not be irritating to oral mucosa but will replace lost protein.

Promoting Positive Body Image

1. Develop a trusting relationship with the patient.
2. Educate patient and family about the disease and its treatment; this reduces uncertainty and clears up misconceptions.
3. Encourage expression of anxieties, embarrassment, and discouragement.

4. Encourage patient to maintain social contacts and activities among support network.

Patient Education and Health Maintenance

Instruct the patient as follows:

1. The disease may be characterized by relapses that require continuing therapy to maintain control.
2. Long-term administration of immunosuppressive drugs is associated with numerous adverse effects and risks—hyperglycemia, osteoporosis, psychosis, adrenal suppression, and increased risk of cancer. Report for health care follow-up visits regularly.
3. Monitor the skin and mouth for recurrence of pemphigus activity.

Evaluation: Expected Outcomes

- Oral mucous membranes pink with healing lesions and no signs of infection.
- Skin with intact bullae, healing lesions, and no signs of infection.
- Vital signs stable; urine output adequate.
- Patient expresses concerns and plans activities.

Psoriasis

Psoriasis (see Figure 33-4) is a chronic T-cell–mediated inflammatory disorder causing secondary epidermal turnover, which occurs at a rate six to nine times faster than normal.

Figure 33-4. The lesions of psoriasis appear as red, raised patches of the skin covered with silvery scales that in time coalesce, forming irregularly shaped patches.

Pathophysiology and Etiology

1. Affects 2% to 3% of people.
2. Classified as mild if less than 2% of body surface area affected; moderate, if 2% to 10% affected; and severe, if more than 10%.
3. Types of psoriasis include:
   a. Plaque—most common type (about 80% of cases); occurs on the knees, elbows, scalp, and other areas.
   b. Guttate—droplike pattern occurs on the trunk, arms, or legs; often starts in childhood or young adulthood; comes on suddenly, often triggered by streptococcal infection.
   c. Inverse—affects flexural areas, such as the axilla and groin.
   d. Erythrodermic—scalded appearance that affects most of the body; can lead to protein and fluid loss.
   e. Pustular—primarily seen in adults; exacerbated by the sun; blisters contain purulent material on palms and soles or on widespread area.
   f. Psoriatic arthritis—joint involvement, pain, and other abnormalities accompany skin involvement.

4. Formerly considered idiopathic, now thought to be genetically linked and immune system modulated.
    a. May be caused by some antigenic stimuli that activate cytokines and T cells, thus causing an extreme dermal response.
    b. Genes are being identified that may predispose a person to developing psoriasis.
5. Condition tends to last a person's life span, with flares and remissions. May be exacerbated by infection (particularly beta-hemolytic streptococcal infection), stress, injury, hormonal changes, and drugs, such as lithium, beta-adrenergic blockers, angiotensin-converting enzyme inhibitors, antimalarial drugs, and indomethacin.
6. Recent research may indicate that the inflammatory nature of disease may be associated with increased coronary artery calcification. Appropriate medical follow-up should be recommended.

Clinical Manifestations

1. Characteristic rash.
    a. Plaque type—erythematous plaques with silvery scales, symmetric involvement, may be pruritic and painful; often appears at areas of epidermal injury (Koebner reaction).
    b. Guttate—small red individual spots, not as thick as plaque psoriasis.
    c. Inverse—bright red patches that are smooth and shiny, involving skin folds.
    d. Pustular—white blisters and noninfectious pus surrounded by red skin.
    e. Erythrodermic—redness of most of the body, shedding of the skin, severe itching, and signs of systemic illness.
2. Characteristic pitting of nails in 50% of patients.
3. Arthritis in approximately 30% of patients; most frequently occurs between age 30 and 50.

Management

1. Diagnosed by clinical features; rarely, a biopsy may be needed.
2. Coal tar and anthralin preparations inhibit excessive skin turnover.
    a. Applied topically, with no systemic adverse effects.
    b. Application may be messy, odorous, and may stain clothing.
3. Topical corticosteroids are the mainstay topical treatment. Adverse effects may include striae, thinning of the skin, adrenal suppression (rare). Tachyphylaxis may result if used for extended periods.
4. Topical calcipotriene, a vitamin D derivative, used for mild to moderate psoriasis, generally produces no adverse effects.
5. Another topical preparation is tazarotene, a receptor selective retinoid, which is potentially teratogenic (pregnancy category X).
6. Phototherapy—20 to 30 short treatments. Narrowband ultraviolet B (UVB) light is safer than ultraviolet A (UVA), which carries the risk of sunburn and skin cancer.
    a. Photochemotherapy—ingestion of an oral photosensitizer (psoralen) followed by exposure to UVA light therapy (PUVA).

b. Cataracts, nausea, and malaise are possible adverse effects of systemic PUVA.

7. Oral methotrexate, the retinoid acitretin, and cyclosporine also are used.
   a. Hepatotoxicity may occur with methotrexate.
   b. Hypertension and renal failure may occur with cyclosporine.
   c. Acitretin is a potent teratogen and should not be used if any risk of pregnancy up to 3 years posttreatment in women of childbearing age.
8. Biologic agents, such as etanercept, infliximab, ustekinumab, alefacept, and adalimumab, have demonstrated efficacy in the control of moderate to severe symptoms as well as psoriatic arthritis.

DRUG ALERT Cyclosporine is contraindicated in patients with renal disease, uncontrolled hypertension, active infection, internal malignancy, immune deficiency, gout, hepatic disease, and concomitant use of nephrotoxic drugs. Serum creatinine must be followed closely throughout the treatment.

Nursing Interventions and Patient Education

1. Assist patient, as needed, with daily tub bath to soften scales and plaques.
2. Apply topical preparations after bath and gentle debridement of scale removal.
3. Warn patient that coal tar and anthralin preparations may stain clothing; let it dry before dressing.
4. Advise patient to wear goggles for phototherapy to prevent cataracts and to follow-up with periodic eye exams.
5. Encourage patient to follow-up closely with primary care provider or with dermatologist and to report for blood work to check renal function and liver function tests as indicated.
6. Reinforce to women of childbearing age that retinoids and methotrexate are teratogenic; must be using birth control.
7. Encourage patients to try to identify triggers that may cause flare-ups and to practice avoidance techniques, such as relaxation therapy, to avoid stress.
8. Teach patients to avoid direct sun exposure by wearing protective clothing and sunscreen, especially on the day of phototherapy.
9. Advise patients to use good lubricants to prevent drying and cracking of the skin, which can lead to hyperkeratinization.
10. Encourage verbalization of frustration of condition, treatment, and impact on social network.
11. For more information, contact the National Psoriasis Foundation (*www.psoriasis.org*).

Benign Tumors

Benign tumors are common skin growths. Most do not require any treatment but are important to recognize to differentiate from malignant lesions.

Characteristics and Management

Seborrheic Keratoses

1. Lesions are benign and wartlike of varying size and color, ranging from light tan to black that may appear to be stuck on; they are the most common skin tumors in middle-aged and older people.
2. Treatment is usually unnecessary, but lesions can be removed by liquid nitrogen cryotherapy or curettage.

Verrucae (Warts)

1. Common, benign skin tumors caused by human papillomavirus.
2. Often disappear spontaneously without scarring and may not need treatment.
3. Many topical treatment options are available for office and self-treatment, but some may cause scarring.
   a. Cryotherapy with liquid nitrogen—destroys wart and spares rest of the skin.
   b. Area may be treated surgically with curettage or electrodesiccation.
   c. Application of salicylic acid, topical fluorouracil, imiquimod, topical vitamin A acid, cantharidin, or other irritants may be helpful, especially for flat warts, except on the face.
   d. Occlusion with duct tape is controversial. Modest clinical effectiveness has been shown in studies, but not statistically significant.
   e. Apple cider vinegar soak. Apply petroleum ointment on the surrounding skin to protect it. Apply small piece of cotton soaked in vinegar and tape it to the wart overnight and repeat until the wart is gone.
   f. Suggestive therapy (placebo) often works with children through age 10.

NURSING ALERT Several studies have not revealed sufficient evidence in favor of treatment other than salicylic acid and aggressive cryotherapy.

EVIDENCE BASE Habif, T. P. (2016). *Clinical dermatology: A color guide to diagnosis and therapy* (6th ed.). St. Louis, MO: Mosby.

Hemangiomas

1. Hemangiomas are benign tumor of the capillaries, which present shortly after birth.

2. They grow rapidly for 6 to 18 months, followed by stabilization and subsequent regression. Most hemangiomas resolve by age 9.
3. Surgery is reserved for complicated hemangiomas that may be obstructing the airway.
4. Hemangiomas blocking the visual axis or compressing against the eye are treated with high doses of corticosteroids or interferon.
5. For hemangiomas that do not threaten vision or life, no intervention is preferred.
6. Lasers can be used for ulcerated hemangiomas.

Pigmented Nevi (Moles)

1. Common skin tumors of various sizes and shapes, ranging from yellowish to brown to black; may be flat, macular lesions, elevated papules, or nodules that occasionally contain hair.
2. Most pigmented nevi are harmless; however, in rare cases, malignant changes supervene and a melanoma develops at the site of the nevus.
3. Nevi at sites subject to repeated irritation from clothing or jewelry can be removed for comfort.
4. Nevi that show change in size, shape, or color, become symptomatic (itch or bleed), or develop notched borders should be removed to determine if malignant changes have occurred. This is especially true for nevi with irregular borders or variations of red, blue, and blue-black.
5. Use "ABCDE" to recall criteria for evaluation of nevi: A = asymmetry, B = border (irregular), C = color (lack of uniform), D = diameter (greater than 6 mm), and E = evolving or changing.

Keloids

1. Benign overgrowths of connective tissue expanding beyond the site of scar or trauma in predisposed individuals.
2. More prevalent among dark-skinned individuals.
3. Usually asymptomatic—may cause disfigurement and cosmetic concern.
4. Management—intralesional corticosteroid therapy, surgical removal, radiation, or silicone gel sheeting.

Premalignant Lesions: Actinic (Solar) Keratoses

1. Premalignant skin lesions appearing as rough, scaly patches with underlying erythema, which develop as a consequence of prolonged exposure to ultraviolet rays.
2. Develop in areas of the body that experience prolonged sun exposure such as the scalp, face, dorsal hands, and arms; may gradually transform into squamous cell carcinoma.
3. Many topical treatments are available, including the antineoplastic fluorouracil, the immune response modifier imiquimod, liquid nitrogen cryosurgery, and curettage.
4. Photodynamic therapy with application of aminolevulinic acid and exposure to blue light that destroys abnormal cells.

Cancer of the Skin

Skin cancer is the most common malignancy, accounting for about half of all cancers. Nonmelanoma skin cancers are categorized as basal cell carcinoma (BCC) (80%) or squamous cell carcinoma (SCC) (20%). BCCs are more easily curable because of early diagnosis and slow progression. These cancers are locally invasive and tend not to metastasize. SCCs have an increased potential for metastasis. Conversely, malignant melanomas are least common and have a higher risk of metastasis.

EVIDENCE BASE Wernli, K., Henrikson, N., Morrison, C., et al. (2016). Screening for skin cancer in adults: Updated evidence report and systematic review for the US Preventive Services Task Force. *Journal of the American Medical Association, 316*(4), 436–447.

Pathophysiology and Etiology

1. Most BCCs and SCCs are located on sun-exposed areas and are directly related to ultraviolet radiation. Sun damage is cumulative.
2. Risk factors for skin cancer include:
   a. Fair complexion, blue eyes, and blond or red hair; Fitzpatrick skin—type I or II (see page 909).
   b. Working outdoors.
   c. Older people with sun-damaged skin.
   d. History of radiation treatment of skin conditions.
   e. Exposure to certain chemical agents (arsenicals, nitrates, tar and pitch, oils, and paraffins).
   f. Burn scars, damaged skin in areas of chronic osteomyelitis, fistulae openings.
   g. Long-term immunosuppressive therapy, including organ transplants.
   h. Genetic susceptibility.
   i. Multiple dysplastic nevi—moles that are larger, irregular, more numerous, or variable colors — or family history of dysplastic nevi.
   j. Congenital nevi that are large (more than 20 cm in size).
   k. Presence of human papillomavirus.
3. Types of skin cancer:
   a. Basal cell carcinoma—arises from basal layers of the epidermis or hair follicle; most common type but rarely metastasizes; can be locally invasive.
   b. Squamous cell carcinoma—arises from the epidermis; metastasis occurs more commonly than with basal cell carcinoma.
   c. Malignant melanoma—a malignancy of melanocytes; can metastasize.

NURSING ALERT Although only 3% of skin cancers are melanoma, this form of skin cancer causes the majority of skin cancer deaths. Melanoma incidence is increasing at about 3% per year.

Clinical Manifestations

Basal Cell Carcinoma

1. Lesions typically begin as small nodules with a rolled, pearly, translucent border with telangiectasia, crusting, and occasionally ulceration (see Figure 33-5A).
2. Appear most frequently on sun-exposed skin, frequently on the face between the hairline and upper lip or back.
3. If neglected, may cause local destruction, hemorrhage, and infection of adjacent tissues, producing severe functional and cosmetic disabilities.

Figure 33-5. (A) Basal cell carcinoma, **(B)** squamous cell carcinoma. (From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Squamous Cell Carcinoma

1. Appears as reddish, rough, thickened, scaly lesion with bleeding and soreness—may be asymptomatic; border may be wider, more indurated, and more inflammatory than BCC (see Figure 33-5B).
2. May be preceded by leukoplakia (premalignant lesion of mucous membrane) of the mouth or tongue, actinic keratoses, scarred or ulcerated lesions.
3. Seen most commonly on the lower lip, rims of ears, head, neck, and backs of the hands.

Malignant Melanoma

See Figure 33-6.

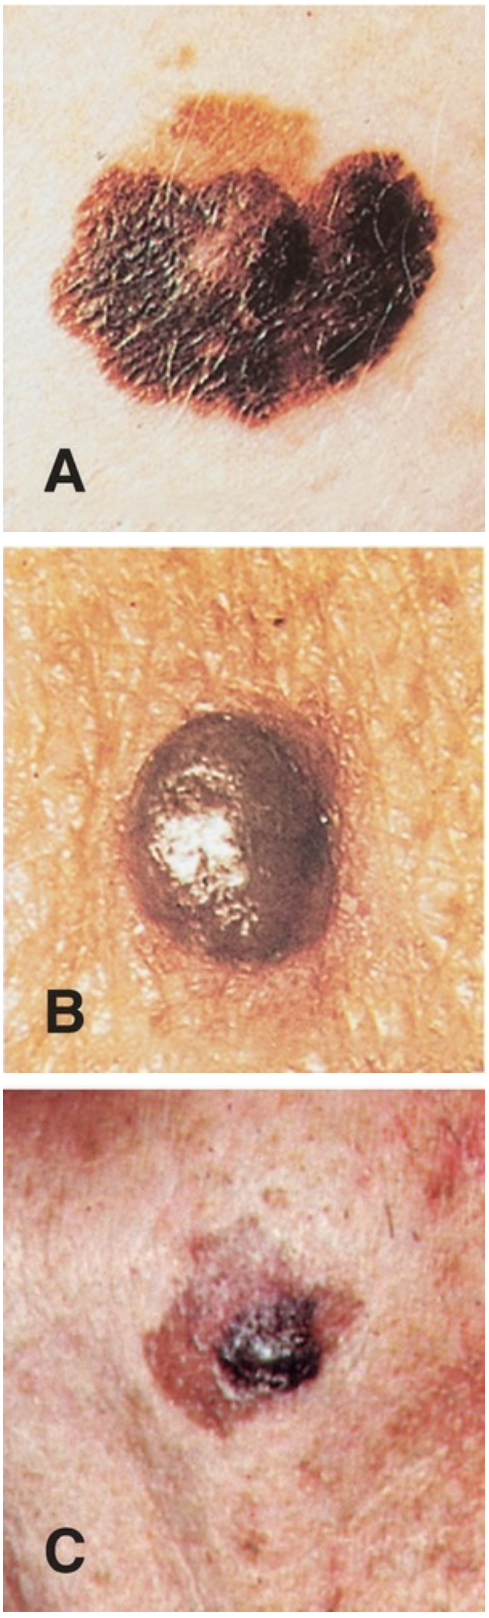

Figure 33-6. (A) Superficial spreading melanoma; note irregular border. **(B)**Nodular melanoma. **(C)**Lentigo maligna melanoma; note irregular pigment pattern. (**A, B:** From Smeltzer, S., & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical-surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins; C: Hall J.C., Hall B.J. [2017]. Sauer's Manual of Skin Diseases [11th ed.] Philadelphia, PA: Lippincott Williams & Wilkins.)

1. Melanoma in situ; earliest phase, difficult to recognize because clinical changes are minimal.
2. Superficial spreading melanoma (most common).
    a. Circular, with irregular outer portions; the margins may be flat or elevated and palpable.
    b. Has combination of colors—hues of tan, brown, and black mixed with gray, bluish black, or white.
    c. May be dull pink-rose color in a small area within the lesion.
    d. Occurs anywhere on the body; usually affects middle-aged people.
3. Nodular melanoma.
    a. Spherical blueberry-like nodule with relatively smooth surface and uniform blue-black, blue-gray, or reddish-blue color.
    b. May be polypoidal and elevated, with smooth surface of rose-gray or black color.
    c. Occurs commonly on the torso and extremities.
    d. Invades directly into the subjacent dermis (vertical growth) and hence has a poorer prognosis.
4. Lentigo malignant melanoma.
    a. First appears as tan, flat macule—malignant degeneration is manifested by changes in color, size, and topography.
    b. Evolves slowly; occurs on sun-exposed skin surfaces of people in their 40s or 50s.
5. Acrolentiginous melanoma (uncommon).
    a. Irregular pigmented macules, which develop nodules; may become invasive early.
    b. Occurs on palms, soles, nail beds, and rarely on mucous membranes.
    c. Most common type of melanoma in Blacks and Asians.

Diagnostic Evaluation

Excisional biopsy (for histopathologic diagnosis) and microstaging determination of thickness and level of invasion; helps determine treatment and prognosis. Shave biopsy is usually performed for suspected BCC or SCC lesions.

Management

Basal Cell Carcinoma and Squamous Cell Carcinoma

Method of treatment depends on tumor location, cell type (location and depth), history of previous treatment, whether it is invasive, or if metastasis has occurred.

1. Curettage followed by electrodesiccation—usually done on small tumors of basal or squamous cell type (less than 1 to 2 cm).
2. Surgical excision by Mohs surgery for larger lesions or for those in areas more likely to recur or located in cosmetically sensitive areas (around the nose, eyes, ears, lips); may be followed by simple closure, flap, or graft.
    a. Microscopically controlled excision, with immediate examination of frozen or chemically fixed sections for evidence of cancer cells.

b. Layers are removed until a reasonable cancer-free margin is achieved.

3. Radiation therapy—should be reserved for older adults, may be used for extensive malignancies where goal is palliation or when other medical conditions contraindicate other forms of therapy.
4. Other therapeutic regimens—topical fluorouracil, the immune response modifier imiquimod, photodynamic therapy.

Malignant Melanoma

1. Complete excision of lesion. If depth is between 1 and 4 mm or there is ulceration present, sentinel lymph node biopsy may be done at the time of reexcision. Margins of 1 to 2 cm are required on reexcision. Close subsequent follow-up is necessary.
2. Systemic chemotherapy—generally used for recurrence of metastasis or palliation; may be combined with autologous bone marrow transplantation or several agents used in combination.
3. Early detection has a 5-year survival rate approaching 95% for thin (less than 1 mm) lesions in primary melanoma. The 10-year survival rate for lesions of 1.01 to 2 mm in thickness is 89% but drops off to 32% for lesions at greater than 4 mm.

Complications

1. BCC arising around the eyes, nasolabial folds, ear canal, or posterior sulcus may invade deeply and cause extensive destruction into muscle, bone, and dura mater. Hemorrhage may result from eroded vessels.
2. SCC may metastasize in 3% to 4% of cases.
3. If left untreated, melanoma will metastasize over months to years.

Nursing Assessment

1. Have a high index of suspicion for people at risk. Fitzpatrick skin type can be used to assess risk for sun damage to the skin.
   a. Type I: very white skin, always burns.
   b. Type II: white, burns easily, tans with difficulty.
   c. Type III: white to olive, tans after initial burn.
   d. Type IV: light brown, tans easily.
   e. Type V: brown, tans easily.
   f. Type VI: black, does not burn.
2. Ask about sunbathing habits and sunburn history. Question patient about pruritus, tenderness, pain, or bleeding, which are not features of a benign nevus (mole).
3. Ask about changes in preexisting moles or about development of a newly pigmented lesion.
4. Use a magnifying lens or dermatoscope in a brightly lit room to look for variegated color and irregular border and surface in the nevus. Use side lighting to assess subtle elevation.
5. Examine entire skin surface, including the scalp, genital area, gluteal folds, and soles of feet.
6. Examine diameter of mole; melanomas are usually larger than 6 mm; look for lesions situated near the

mole.

NURSING ALERT Any skin lesion that changes in size or color, bleeds, ulcerates, or becomes infected may be skin cancer.

Nursing Diagnoses

- Deficient Knowledge related to risk factors for skin cancer.
- Anxiety related to diagnosis of cancer.

Nursing Interventions

Increasing Knowledge and Awareness

1. Encourage follow-up skin examinations and instruct the patient to examine the skin monthly as follows:
   a. Use a full-length mirror and a small hand mirror to aid in examination.
   b. Learn where moles and birthmarks are located.
   c. Inspect all moles and other pigmented lesions; report any change in color, size, elevation, thickness, or development of itching or bleeding.
2. Teach the patient to use a sunscreen with at least SPF 30 routinely and to avoid becoming sunburned. Reapply sunscreen at least every 2 hours.
   a. Sunlight permanently damages DNA in the skin and the cumulative effects of the sun may result in skin cancers.
   b. Avoid tanning, especially if the skin burns easily, never tans, or tans poorly.
   c. Avoid unnecessary exposure to the sun, especially during times when ultraviolet radiation is most intense (10:00 A.M. to 3:00 P.M.).
   d. Wear protective clothing (long sleeves, broad-brimmed hat, high collar, long pants). However, clothing does not provide complete protection of UVA rays.
   e. Do not use sunlamps for indoor tanning; avoid commercial tanning salons.

NURSING ALERT Indoor tanning beds are not safe. All sources of ultraviolet light have been determined to be carcinogenic by the World Health Organization.

Reducing Anxiety

1. Provide dressing changes and wound care while teaching patient to take control, as directed, after surgical intervention.
2. Administer chemotherapy with attention to possible adverse effects, as directed.

3. Allow patient to express feelings about the seriousness of diagnosis.
4. Answer questions, clarify information, and correct misconceptions.
5. Emphasize use of positive coping skills and support system.

Patient Education and Health Maintenance

1. Encourage lifelong follow-up appointments with dermatologist or primary care provider with examinations every 6 months.
2. Encourage all individuals to have moles removed that are accessible to repeated friction and irritation, congenital, or suspicious in any way.
3. Teach all individuals the importance of sun avoidance measures; teach proper use of sunscreen:
   a. Sunscreens with SPF 15 or greater offer good protection. Sunscreen should provide UVA and UVB protection.
   b. Sunscreens should be used from 6 months through old age.
   c. Sunscreens should be applied before going outdoors to all areas that may be exposed, preferably before dressing. They should be applied liberally to achieve the stated SPF.
   d. Newly developed sunscreens are more resistant to removal by water, clothing, sweating; however, periodic reapplication is necessary when spending prolonged periods outdoors, especially when swimming.
   e. Protect lips with a lip balm that contains a sunscreen with the highest SPF.
4. For more information, refer patients to agencies such as the Skin Cancer Foundation (*www.skincancer.org*).

Evaluation: Expected Outcomes

- Uses high-SPF sunscreen, wears protective clothing, and performs monthly skin examinations.
- Verbalizes decreased anxiety.

Other Dermatologic Disorders

See Table 33-2.

Table 33-2 Other Dermatologic Disorders

NAME AND DESCRIPTION	CLINICAL MANIFESTATIONS	MANAGEMENT	NURSING CONSIDERATIONS
Bacterial Infections			
Folliculitis Inflammation of the hair follicle	• Single or multiple papules or pustules. • Commonly seen in the beard area of men and on women's legs from shaving.	• Twice daily cleansing with moisturizing soap and/or BPO. • Topical antibiotic treatment, as prescribed by health care provider. • Systemic antibiotics for recurrent or recalcitrant cases.	• Suggest warm compresses to relieve inflammation and promote drainage.
Furunculosis Perifollicular abscess (boil) caused by *Staphylococcus aureus*; carbuncles are two or more confluent furuncles.	• Tender, circumscribed, erythematous area whose center may become fluctuant and suppurate. • Commonly occur on the back of the neck, axillae, or buttocks. • Common organism is methicillin-resistant *Staphylococcal aureus* (MRSA).	• Warm compresses to reduce inflammation and promote drainage. • When area becomes fluctuant, incision and drainage can be performed, followed by packing. • Furuncles of the ear canal, nares, upper lip, and nose may require systemic antibiotic treatment because these areas drain directly into cranial venous sinuses.	• Suggest warm compresses. • Warn patient not to squeeze or incise the lesion. • Suggest mild analgesics, if needed. • If severe or recurrent, look for underlying immunosuppression by disorders, such as diabetes, AIDS, alcoholism, or malnutrition.
Paronychia Inflammation of skin folds surrounding the fingernail; may be bacterial or fungal or both	• Tender, purulent, erythematous swelling of nail border. • Chronic and recurrent paronychia causes horizontal ridges at the base of the nail.	• Incision and drainage for acutely inflamed paronychia. • Fungicidal or bactericidal ointment for chronic paronychia. • Systemic antibiotic treatment usually is not necessary. • Prevention of trauma and maceration.	• Encourage soaking in warm water for 10 to 15 minutes three to four times per day while acutely inflamed to relieve pain and promote drainage. • Identify persons with work-related chronic paronychia (such as bartenders, dishwashers, and housekeepers) and recommend use of rubber gloves over thin cotton gloves when working around moisture.
Erysipelas Streptococcal infection involving the superficial dermal lymphatics of the head or extremities; may be *S. aureus* of the face	• Prodromal—malaise, fever, chills, headache, vomiting, and joint pain. • Local—redness, warmth, swelling, and characteristic raised indurated border. • Leukocytosis. • Advancing edge of the patch with extension. • May vesiculate.	• Oral, IM, or IV antibiotics, usually penicillinase-resistant penicillin derivatives; cephalosporin or macrolide antibiotic may be used.	• Ice or cold compresses may be soothing. • Prompt treatment required in patient with diabetes to prevent extensive spread and necrotizing fasciitis.
Intertrigo Superficial inflammation and secondary infection where two skin surfaces are in apposition; may be bacterial or fungal or both	• Erythematous and macerated rash under breasts, in abdominal skin fold, or in the groin. • Rash may exhibit erosions, fissures, and drainage. • Burning and itching.	• Topical antibacterial and antifungal agents, as prescribed by health care provider.	• Teach patient to prevent skin maceration by separating opposing skin surfaces with gauze or cotton material. • Skin surfaces should be dried thoroughly after bathing with a hair dryer on low setting. • Absorbent powder can be applied lightly to the area after drying as long as no redness or irritation is present. • Loose, air-permeable clothing should be worn.
Mycotic (Fungal) Infections			
Tinea Pedis Ringworm of the foot*Tinea corporis*—ringworm of the body*Tinea cruris*—ringworm of the groin*Tinea capitis*—ringworm of the scalp	• Caused by the dermatophytes *Trichophyton, Epidermophyton,* or *Microsporum* • Erythematous, inflamed, and vesicular lesions of feet. • Scaling erythematous patches of the body or head with central clearing. • Dull red or brownish rash of upper inner thighs and groin with scaling borders. • Itching and irritation. **DRUG ALERT** Oral antifungal agents are associated with significant drug interactions with such agents as warfarin, simvastatin, lovastatin, triazolam, cisapride, digoxin, cyclosporine, phenytoin, cimetidine, and rifampin. Baseline and periodic liver function test monitoring is recommended. More frequent monitoring of INR or blood levels may be required.	• Examination of rash under Wood light differentiates erythrasma, which will fluoresce; most tinea patches will not. • Skin scraping from leading edge shows characteristic spores and hyphae with KOH preparation under microscope. • Treat with topical antifungals or systemic antifungals for severe cases. • Reduction of moisture in the groin, between toes.	• Advise washing one to two times per day with water and mild soap and then applying talcum powder or cornstarch to well-dried area. • Use hair dryer set on low temperature to dry tender areas. • Encourage wearing cotton socks and underwear and light, air-permeable clothing to promote evaporation. • Warn about contamination from feet to the groin or other areas of the body by hands or clothing. • In tinea pedis, encourage use of open shoes or canvas sneakers and avoidance of tight shoes or plastic or rubber-soled shoes or boots. • Wash contaminated clothing in hot water.
Tinea Versicolor Superficial fungal infection by *Malassezia furfur*	• Patchy macular or mildly scaly rash of the upper trunk and upper arms; yellowish or brownish in light-skinned people, hypopigmented in those with dark skin. • Mild itching and scaling.	• On Wood light examination, may fluoresce and will show hypopigmented patches. • Microscopic examination with KOH preparation of skin scraping shows characteristic "spaghetti and meatball" appearance of hyphae and spores. • Treat with selenium sulfide shampoo (leave on for 40 minutes before showering) daily for 1 week. • Topical or systemic antifungal treatment may be used as prescribed by health care provider.	• Common in high-temperature, high-humidity environments. • Advise patient that discoloration may persist after fungus has been eradicated; lost pigmentation will resolve with sun exposure. • Tell patient that recurrence is common after 2 to 12 weeks if prophylactic treatment is not given periodically.
Onychomycosis (Tinea Unguium) Fungal infection of the nail	• Discoloration (white, yellow, or darkened) of the nail. • Nail becomes brittle, cracked, irregular, and loosened. • May be some inflammation and pain.	• Identification of offending fungus by microscopic examination of shavings with KOH or by culture. • Treatment with appropriate systemic antifungal for prolonged period—usually at least 6 weeks for fingernails and at least 12 weeks for toenails. • Surgical removal of the nail may be necessary.	• Encourage patient to comply with lengthy treatment, as fungal infections of the nail are difficult to treat. • Examine patient for other areas of tinea infection (feet, groin), encourage treatment, and teach patient that infection may be spread from fingernails by scratching. • After nail removal, advise patient to keep hand or foot elevated for several hours and change dressing daily by applying gauze and antibiotic ointment or other prescribed medication until nail bed is free of exudate or blood.
Parasitic and Other Infestations			

Pediculosis
Pediculosis capitis—head lice
Pediculosis corporis—body lice
Pediculosis pubis—crab louse infestation of the genital region
DRUG ALERT Caution pregnant patients who have pediculosis capitis not to use antiparasitic preparations.
	• Itching is primary complaint.
	• Lice and nits may be seen in seams of clothing (body lice) or clinging to hairs (pubic lice).
	• Skin excoriation in affected area.
	• Erythematous macules or wheals may appear at puncture sites.
	• Gray-blue macules may appear on the trunk or inner thighs with pediculosis pubis.
		• Treatment for pediculosis corporis involves washing with soap and water and washing all infested clothing and linens with hot water. Alternatively, clothes may be dry-cleaned or ironed, paying close attention to the seams.
		• Pediculosis capitis and pubis are treated with a topical antiparasitic preparation, such as lindane or permethrin.
		• Manual removal of nits (eggs) may be performed; retreatment with topical antiparasitic in 3 to 7 days is recommended.
		• Petroleum may be applied to eyelashes and then lice and nits removed with swab or tweezers, or pilocarpine drops can be used to paralyze the lice.
		• Items that cannot be washed or dry-cleaned can be stored for 30 days without use.
			• Advise patient that pediculosis pubis is considered a sexually transmitted disease; partners must be examined and treated.
			• Teach patient the proper use of medication:
			  • Apply lotion or cream after bathing to affected hairy and adjacent areas; wash off after 8 to 12 hours.
			  • Alternatively, apply shampoo to affected hairy areas and lather for 4 to 5 minutes, rinse, and let hair dry.
			  • Use fine-tooth comb to remove nits.
			• Urge patient to wash all clothing, towels, linens, combs, and hair items by soaking in hot water for 10 minutes.
			• Advise patient not to use antiparasitic preparations more frequently than recommended.

Scabies
Superficial infestation by itch mite; transmitted by close personal contact
GERONTOLOGIC ALERT Infestation with scabies may be a problem in nursing homes, particularly among debilitated patients who require extensive hands-on care.
	• Itching, more intense at night.
	• Small erythematous papules and short, wavy burrows are seen on skin surface.
	• Frequently seen between fingers or in groin area.
	• Spares head and scalp except in children under age 1.
	• Atypical scabies may be found in immunocompromised people and may be resistant to standard treatment.
		• Parasite identified by microscopic examination of skin scraping.
		• Treated with antiparasitic, such as permethrin or crotamiton, and oral treatment with ivermectin 0.2 mg/kg × 1 dose, if indicated.
		• Machine wash and dry clothing and linens on hot cycle.
		• Topical or systemic steroids may be needed to treat symptoms of allergic reaction to mites.
			• Teach proper use of medication:
			  • Apply thin layer from the neck downward, with particular attention to hands, feet, and intertriginous areas; every inch of the skin must be treated because mites are migratory. Apply to dry skin. (Wet skin allows more penetration and the possibility of toxicity.)
			  • Leave medication on for 8 to 12 hours—but no longer, as doing so will irritate the skin. Wash thoroughly.
			• Advise patient to avoid close contact for 24 hours after treatment to prevent transmission.
			• Encourage treatment of sexual and close contacts simultaneously.
			• Tell patient that itching may persist for days to weeks following treatment because of an allergic reaction to mites; retreatment is not necessary.

Bedbugs Small, nocturnal, blood-sucking insects requiring weekly meals to advance in their life cycle; however can survive up to a year without a meal. Bedbugs hide during the day in seams, crevices, and cracks in mattresses, box springs, walls, and floors.	• Pruritic papules often assume a linear configuration of 3 to 4 lesions ("breakfast, lunch, and dinner"). • Found on exposed areas. • Affected individuals often awake in the early morning because of pruritus as this is the time bedbugs are most active. • May be variance in reaction to bedbugs in household members (not all individuals react to bedbug bites to the same degree).	• Bedbug bite lesions will resolve on their own in 1 to 2 weeks. • Treatment aimed at controlling symptoms; oral antihistamines and topical corticosteroids per health care provider.	• Advise close examination of mattress seams for brown spots (excrement of bedbugs), especially when traveling and staying in hotels (to prevent transporting of bedbugs home on luggage). • Advise professional extermination to eradicate infestation. • Explain to patient that scratching will make itching worse and may lead to secondary skin infection such as impetigo. • Reassure patient that bedbugs do not carry disease and are not associated with uncleanliness.

NAME AND DESCRIPTION	CLINICAL MANIFESTATIONS	MANAGEMENT	NURSING CONSIDERATIONS
Viral Infections			
Herpes Simplex			
Acute vesicular eruption caused by herpes simplex virus type 1 or 2	• Prodromal pain, burning, or tingling, possible fever and malaise. • Tiny vesicles appear on erythematous, swollen base; they rupture, forming painful ulcers and crusting; healing occurs but outbreaks are recurrent. • Can occur anywhere, especially near mucocutaneous junctions. • Viral shedding may occur between symptomatic periods, leading to transmission of the infection.	• Tzanck smear from scraping of ulcer or fluid from vesicle shows characteristic giant cells with intranuclear inclusions; also diagnosed by fluorescent antibody detection or viral culture. • Antiviral treatment with acyclovir, famciclovir, or valacyclovir for acute infection or continuous suppressive therapy to prevent or lessen recurrence. • Analgesics may be needed for widespread and genital eruptions.	• Teach patient that herpes simplex can be transmitted by close and sexual contact; good personal and hand hygiene is required for facial cases; sexual abstinence or condom use is required for genital cases. • Recurrence may be brought on by fever, illness, emotional stress, menses, pregnancy, sunlight, and other factors. • Advise patients with active herpes simplex infection to avoid contact with immunosuppressed individuals, such as those with diabetes, HIV disease, cancer (including those undergoing cancer treatment), alcoholism, and malnutrition, because herpes simplex infection can be severe in these individuals. • Tell patients that lesions usually resolve in 1 to 2 weeks without scarring.
Other Conditions			
Contact Dermatitis			
Inflammatory condition caused by exposure to irritating or allergenic substances, such as plants, cosmetics, cleaning products, soaps and detergents, hair dyes, metals, and rubber	• Itching, burning, erythema, and vesiculation at point of contact. • Progresses to weeping, crusting, drying, fissuring, and peeling. • Lichenification (thickening of the skin) and pigmentation changes may occur with chronicity.	• Topical or oral steroids, depending on severity. Oral steroids usually given in tapered dose—start with high dose and gradually decrease to provide greatest anti-inflammatory effect without adrenal suppression. • Removal or avoidance of causative agent. • Antipruritics—systemic or topical antihistamines or topical calamine preparations. • Desensitization to poison ivy and other substances may be accomplished for those who have severe reactions and cannot avoid contact.	• Take thorough history to determine causative agent or contributing factors; have patient keep log of activities and symptoms if unsure of irritant. • Teach patient to use allergen-free products, wear gloves and protective clothing, wash and rinse skin thoroughly, and wash clothing after contact with potential irritants. • Advise patient that rash—even oozing lesion of poison ivy—is not contagious; however, contaminated clothing may cause spread of poison ivy in those who are sensitive. • Advise patient to perform patch test by applying substance behind the ear or on inside of the wrist before trying new cosmetics, soaps, or hair products.
Exfoliative Dermatitis			
Chronic extensive scaling and inflammation of the skin; may be idiopathic or related to preexisting skin conditions, drug reactions, or underlying malignancy	• Starts as patchy erythema, with possible fever, chills, and malaise. • Rapid spread until whole integument is involved. • Skin color changes to scarlet, desquamates, and may ooze serous fluid. • Pruritus, hair loss, and secondary infection.	• Discontinuation of offending drug or treatment of underlying condition. • Systemic corticosteroids should control most cases. • Supportive treatment—bed rest, warm environment, and fluid and electrolyte replacement. • Soothing baths and topical emollients for symptomatic relief • Possible use of immunosuppressants—azathioprine, methotrexate, and cyclophosphamide.	• Monitor fluid balance and electrolyte values. • Watch for signs of secondary infection and report; antimicrobial therapy may be necessary. • Watch for signs of heart failure caused by chronically increased cutaneous blood flow. • Teach patient how to relieve itching with oatmeal baths and emollient creams. • Tell patient to avoid environments with temperature fluctuations to avoid chilling. • Advise patient to avoid all irritants.
Alopecia			
Hair loss, may be idiopathic (alopecia areata), male-pattern, physiologic, or because of hair pulling (trichotillomania); also because of scarring from other skin or systemic disorders	• Patterned, patchy, or diffuse hair loss. • Inflammation and scarring with some types. • Physiologic alopecia may be associated with hormonal changes, such as childbirth, nutritional factors, or toxin exposure.	• Treatment of underlying causes. • Minoxidil may cause fine hair regrowth in male-pattern baldness and alopecia areata. Finasteride, an oral agent, can be used by men only, with good results. • Other methods of hair replacement—surgical grafting of hair follicles, hair weaving, or hairpieces.	• Explain that alopecia areata and physiologic hair loss are usually temporary and self-limiting. • Encourage female patient to change hairstyle or wear hairpieces or turbans until hair grows back after childbirth. • Counsel male patient on the slow, limited effects of minoxidil treatment and stress that effects reverse when treatment is stopped.
Seborrheic Dermatitis			
Chronic, superficial inflammatory skin disorder	• Crusted pinkish or yellow patches. • Loose scales that may be dry, moist, or greasy. • Mild itching. • Affects the scalp, eyebrows, eyelids, nasolabial creases, lips, ears, chest, axillae, umbilicus, and groin.	• Apply selenium sulfide, tar, zinc, or resorcinol shampoo to the scalp several times per week. • Corticosteroid lotions or creams. • For eyelid margin involvement (blepharitis), daily debridement with cotton-tipped applicator and baby shampoo and application of ophthalmic steroid ointment or lotion. • Zinc soap or selenium lotion for washing once controlled. • For external ear canal involvement, corticosteroid cream.	• Advise patient of chronic nature of seborrhea and that condition may be exacerbated by perspiration, neuroleptic drugs, and emotional stress; also seen more frequently in persons with Parkinson disease, HIV disease, diabetes mellitus, malabsorption syndromes, and epilepsy. • Teach patient to apply topical preparations, as prescribed. • Advise using only baby shampoo and gently rubbing with swab near the eyes to prevent irritation of conjunctiva in seborrheic blepharitis.
NAME AND DESCRIPTION	**CLINICAL MANIFESTATIONS**	**MANAGEMENT**	**NURSING CONSIDERATIONS**
Hidradenitis Suppurativa			
Chronic follicular plugging and secondary infection of the apocrine glands of the groin and axilla	• Development of tender red nodules that enlarge, rupture, and suppurate. • Sinus tracts develop with recurrent lesions, leading to continuous inflammation and drainage.	• Initially, prolonged (2 months or more) administration of an antibiotic, such as tetracycline, clindamycin, or erythromycin, as well as systemic or intralesional corticosteroids; however, progression of the condition is likely. • Surgical treatment necessary when chronic suppuration and fistulas develop. • Incision and drainage or laser stripping. • Cauterization of sinus tracts. • Exteriorization with curettage and electrodesiccation. • Excision with possible skin grafting. • Isotretinoin, antiandrogens, and intralesional or systematic steroid therapy may relieve exacerbations.	• Advise patient to use moisturizing soap and keep axilla and groin dry to reduce bacterial colonization of the skin. • Teach patient the signs of bacterial infection—purulent drainage, odor, pain—that call for notification of health care provider and treatment with antibiotics. • Encourage use of warm compresses to relieve inflammation. • Obesity and cigarette smoking contribute to the disease. Encourage weight loss and smoking cessation, if applicable.
Bullous Pemphigoid			
Chronic bullous disease of autoimmune etiology; occurs in older adults	• Tense vesicles and bullae arise on normal or erythematous skin, rupture, and heal without scarring. • Occurs on flexor aspects of the body, axilla, inguinal areas, abdomen, and, occasionally, on mucous membranes.	• Systemic corticosteroid treatment in widespread involvement. Topical corticosteroids if limited lesions. Immunosuppressant for resistant cases. • Condition may remit within 2 to 4 years even without treatment.	• Keep skin clean and dry to reduce chances of secondary infection. • If patient is immobilized, encourage positioning to prevent undue pressure on lesions to avoid risk of premature rupture and secondary infection. • Make sure to differentiate from early pressure sore development and treat pressure sores appropriately. • Advise patient that lesions usually heal without scarring.
Acne Vulgaris			
Obstruction and inflammation of sebaceous glands and follicles	• Closed comedones (whiteheads). • Open comedones (blackheads). • Papules, pustules, nodules, cysts, or abscesses may develop. • Primary sites are the face, chest, upper back, and shoulder.	• Topical benzoyl peroxide—antibacterial and comedolytic. • Topical retinoic acid, a comedolytic, or adapalene, a more potent synthetic retinoid. • Topical antibiotics—suppress growth of *Propionibacterium* acnes and decrease comedones, papules, and pustules without systemic adverse effects. • Azelaic acid, a topical agent with multiple antiacne effects. • Systemic antibiotics—long-term, low-dose therapy for more inflammatory and extensive causes. • Retinoid therapy—inhibits sebum production and secretion; for severe, disfiguring cystic acne. • Estrogen therapy—antiandrogenic effect decreases sebum production in women taking oral contraceptives. Spironolactone may be added, if needed, to increase antiandrogenic effect. • Intralesional steroid injection—for inflamed lesions. • Dermabrasion—surgical planning or chemical peels to smooth surface configuration of old scars. Should not be done within 6 to 12 months of Accutane use.	• Advise patient to wash face gently with mild soap and water one to two times per day. • Teach proper application of topical preparation—use sparingly and decrease frequency if irritation and redness develop. • Inform patient about adverse effects of systemic antibiotics. • Ensure that women of childbearing potential are using contraceptives and that a negative pregnancy test has been obtained before starting isotretinoin therapy. Female patients must be on two forms of birth control. All patients must be enrolled in the iPLEDGE system. • Encourage follow-up and monitoring of laboratory tests during treatment with isotretinoin for elevated liver enzymes, cholesterol, and triglycerides and for decreased HDL. • Advise patient taking isotretinoin to notify health care provider of persistent headache—could signal pseudotumor cerebri. • Tell patient that initiation of therapy may worsen symptoms for several weeks, but to continue treatment. • Advise patient not to squeeze pimples and avoid friction around the face. • Suggest use of water-based and hypoallergenic cosmetics. • Encourage stress management, balanced diet, and avoidance of foods believed to aggravate acne.
Rosacea			
Erythematous, pustular eruption of the malar cheeks, forehead, nose or around the eyes; most common in adults ages 40 to 60; unknown cause; may affect the eyes in 20% to 50% of cases	• Diffuse redness, papules, and pustules develop over malar cheeks, forehead, nose, or around the eyes. • Later, dilated blood vessels and flushing are seen. • Rhinophyma (hypertrophic, bulbous nose) may develop. More common in men, rare in women.	• Topical metronidazole gel applied bid. • Oral doxycycline. • Treatment necessary for 4 to 6 weeks and repeated if recurrence. May need long-term suppression with oral antibiotics. • Avoid exercise, stress, hot beverages, and spicy foods.	• Teach patient to avoid flushing by reducing stress, replacing strenuous exercise with low-intensity workouts, staying cool, and avoiding the sun. • Suggest contacting the National Rosacea Society (*www.rosacea.org*).

AIDS, acquired immunodeficiency syndrome; HDL, high-density lipoprotein; HIV, human immunodeficiency virus; IM, intramuscular; INR, international normalized ratio; IV, intravenous; KOH, potassium hydroxide.

Nursing Management of the Burn Patient

OVERVIEW AND ASSESSMENT

Burns are a form of traumatic injury caused by thermal, electrical, chemical, or radioactive agents.

Inhalation injury and associated pulmonary complications are a significant factor in mortality and morbidity from burn injury.

Etiology and Pathophysiology

EVIDENCE BASE American Burn Association. (2016). *Resources: Burn incidence and treatment in the United States fact sheet*. Chicago, IL: Author. Available: *www.ameriburn.org/resources_factsheet.php.*

Incidence

1. In the United States, an estimated 436,000 patients seek medical treatment for burn injuries in emergency departments each year, with about 40,000 requiring hospitalization. Seventy-five percent of those patients are admitted to burn centers.
2. With an estimated 3,275 fire-related deaths per year, one civilian fire death occurs every 2 hours and 41 minutes. More than 83% of these deaths are from residential fires and 9% are from vehicle collision fires. Fire deaths decreased by more than 11% from 2005 to 2014.
3. Burns less than 10% total body surface area (TBSA) account for 75% of admissions to burn centers, with a mortality rate of 0.6%. Mortality increases with burn size. Patients with a TBSA of 80% or greater have a mortality rate of 80%. Overall national mortality rate for all admissions to a burn center is 3.3%.
4. Males (68%) are more commonly injured by burns than are females.
5. Flame injury (41%) is the leading cause of burn injuries. Other etiologies include scald (33%), contact with a hot object (9%), electrical injuries (3%), and chemical injuries (3%). Scald burns are more prevalent in children under 5.
6. Most burn injuries occur in the home (73%). Other places of occurrence include industrial environments, streets or highways, and places of recreation and sport.
7. An estimated 7% of patients admitted to burn centers have an inhalation injury, with a mortality rate of 19%. Patients without inhalation injuries have a mortality rate of less than 2%.

Burn Injury

1. A burn injury usually results from energy transfer from a heat source to the body. The type of burn injury may be flame/flash, contact, scald (water, grease), chemical, electrical, inhalation, or any thermal source. Many factors alter the response of body tissues to these sources of heat.
   a. Local tissue conductivity—bone is most resistant to the heat source accumulation. Lesser resistance is seen in nerves, blood vessels, and muscle tissue.
   b. Adequacy of peripheral circulation.
   c. Skin thickness, insulating material of clothing, or dampness of the skin.
2. Physiologic reaction to a burn is dependent on burn size and depth. Smaller burns produce a local response of pain, erythema, and edema at the site of injury. Severe burns, generally described as 20% TBSA or more, may produce a systemic response with widespread hemodynamic and cardiovascular changes.

3. Systemic response to burn injury is a unique combination of distributive and hypovolemic shock. The release of mediators such as tumor necrosis factor-α produce a profound effect on the circulatory system. In burns greater than 20% TBSA, there is an intravascular depletion, low pulmonary artery occlusion pressures, elevated systemic vascular resistance, and depressed cardiac output.
    a. Systemic microcirculation loses its vessel wall integrity, and proteins are lost into the interstitium.
    b. Protein loss causes intravascular colloid osmotic pressure to drop and allows fluid to leak from the vessels.
    c. There is an increase of fluid leaking into the interstitium, caused by decreased interstitial pressure and increased capillary permeability to protein.
    d. Over 24 hours, there is a loss of intravascular fluids, electrolytes, and proteins into the interstitium.
    e. The resultant changes are reflected in massive edema formation, loss of circulating plasma volume, hemoconcentration, decreased urine output, and depressed cardiac function.
4. Burns may be superficial thickness (first-degree), partial-thickness (second-degree), or full-thickness (third-degree) (see Figure 34-1).
    a. Superficial thickness burns are commonly termed first-degree burns. Only the epidermis is involved, remaining intact with no blistering. Local redness and blanching occur similar to a sunburn. Epidermal-only injuries heal within 5 to 7 days.
    b. Partial-thickness burn injuries, commonly known as second-degree burns, involve the epidermis and upper portions of the dermis. Sweat glands, hair follicles, and nerves remain intact. The wound is moist and very painful. Partial-thickness injuries can be categorized as superficial or deep depending on how far into the dermis the damage extends. In superficial partial-thickness burns, some of the dermal appendages remain, from which the wound can spontaneously reepithelialize and heal on its own. A deep partial-thickness burn injury can convert to a full-thickness burn injury if patient is underresuscitated or develops an infection. Healing time is 5 to 35 days.
    c. Full-thickness injuries, commonly known as third-degree burns, involve all layers of the skin, and sometimes, underlying tissues are destroyed. The burn wound is dry, white, brown, or leathery in appearance. Patients typically do not have pain with full-thickness injuries because of the destruction of the nerve endings. At the core is the burn injury. There is then a zone of coagulation surrounded by a zone of stasis, surrounded by hyperemia (erythema) very similar to a bull's-eye pattern, the burn being in the center (see Figure 34-2). Grafting is usually required to close the wound.
5. Burn depth is directly related to the temperature of the burning agent and the duration of contact with body tissue.
    a. Below 112°F (44.4°C), no local damage occurs unless exposure is for a protracted period.
    b. At 120°F (48.9°C), it takes 5 minutes' exposure to create a full-thickness burn.
    c. At 125°F (51.7°C), the time requirement is 2 minutes, and at 140°F (60°C), only 6 seconds is required.
    d. At 159°F (70.6°C), it takes 1 second to create a full-thickness burn in a healthy adult—less time or temperature in children or older adults.

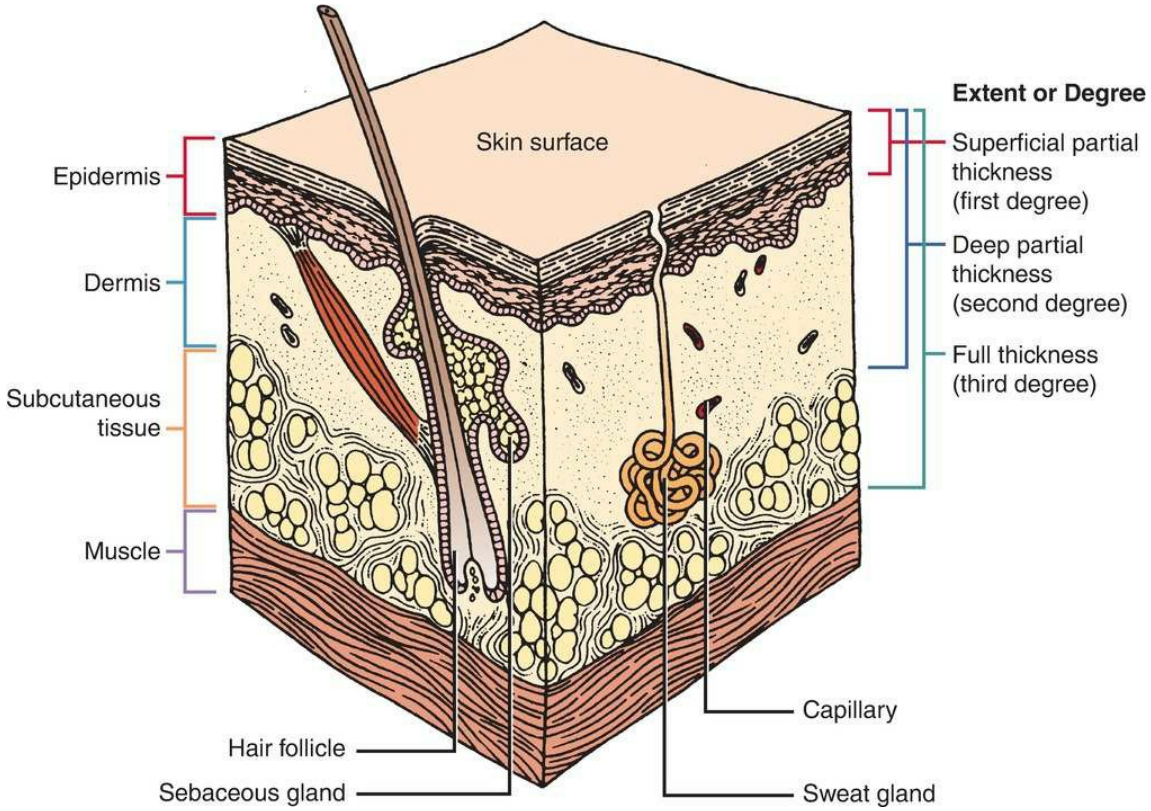

Figure 34-1. Cross-section of the skin depicting blood supply, depth of burn, and relative thickness of skin grafts.

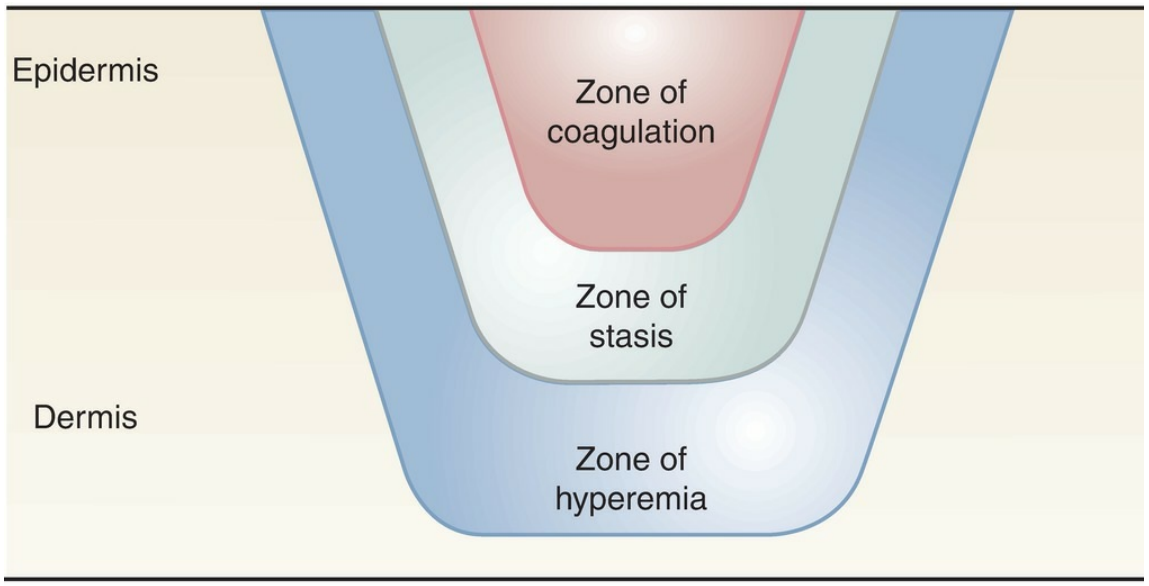

A

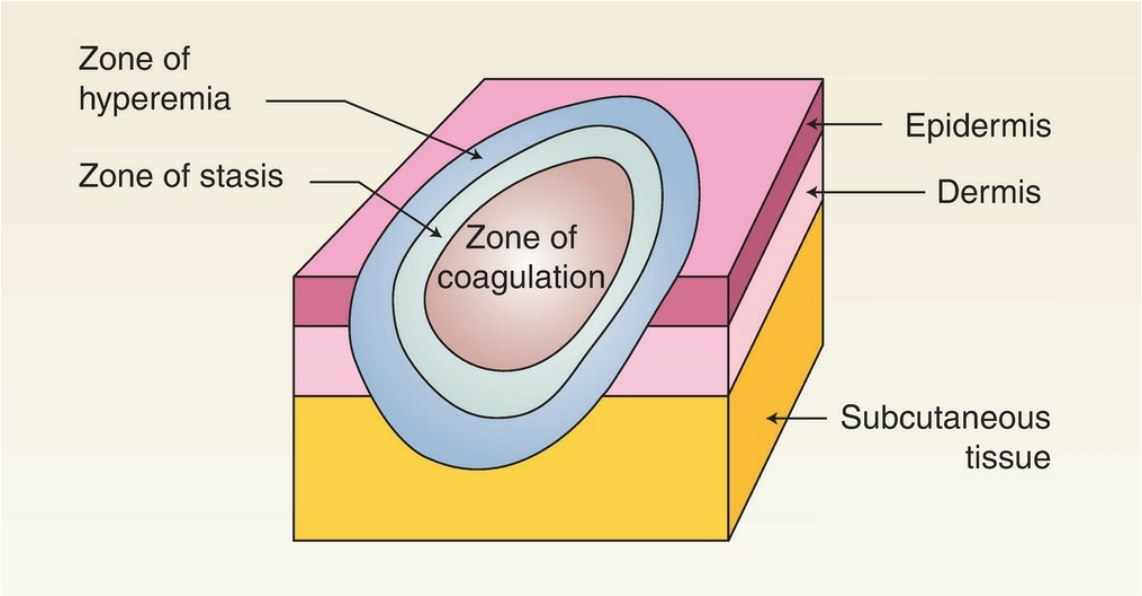

Figure 34-2. (A) Cross-section. **(B)** Surface view and depth.

Inhalation Injury

EVIDENCE BASE Herndon, D. N. (2018). *Total Burn Care*, 5th Edition. New York: Elsevier.

1. Inhalation injury is broadly defined as damage to the airway and pulmonary tissue by heat or chemical irritants. Patients with larger flame burns and those who were trapped in a burning, enclosed space are at the highest risk for inhalation injury. Inhalation injuries combined with extensive cutaneous injury greatly increase risk of mortality.
2. Most inhalation injuries that result in death are a result of hypoxia and inhalation of the toxic by-products of combustion.
3. A patient's smoke exposure will contain a variety of poisonous gases such as cyanide, aldehydes, benzenes, and hydrogen chloride as a result of the synthetic and natural materials that burned near them.
4. Breathing toxic smoke creates a lower airway injury characterized by bronchial casts and constriction, increased pulmonary capillary permeability, and the leakage of protein-filled fluid into the alveolar space.
5. Impaired gas exchange from inhalation injury can be considered a type of acute lung injury (ALI) and may progress to acute respiratory distress syndrome (ARDS).
6. Carbon monoxide toxicity is a complication of inhalation injury and exposure to smoke. Carbon monoxide is a colorless, odorless, tasteless, nonirritating gas produced from incomplete combustion of carbon-containing materials.
7. Carbon monoxide's affinity for hemoglobin is 200 times greater than for oxygen.
8. Toxicity depends on concentration of carbon monoxide in inspired air and the length of time of

exposure.

9. Although oxygen content of the blood is diminished, the amount of dissolved oxygen in the plasma (PaO_2) is unaffected by carbon monoxide poisoning; therefore, the arterial blood gas (ABG) will appear normal.
10. Pulse oximetry only detects saturated hemoglobin and does not measure carbon monoxide; therefore, the pulse oximetry will appear normal.
11. A serum carboxyhemoglobin level must be measured in any patient with possible exposure to carbon monoxide in a fire.
    a. A carboxyhemoglobin level of less than 10% is not a cause for alarm. Normal carboxyhemoglobin in nonsmokers is less than 5%, and smokers can have carboxyhemoglobin levels as high as 10%.
    b. From 10% to 20%, severe headache, flushing, and dilation of skin vessels occur.
    c. Levels of 30% to 50% can produce disorientation, nausea, irritability, dizziness, vomiting, prostration, tachypnea, and tachycardia.
    d. Levels above 50% result in coma, seizures, convulsions, and Cheyne-Stokes respirations, and death is possible.

Systemic Changes in Major Burns

EVIDENCE BASE Rowan, M. P., et al. (2015). Burn wound healing and treatment: Review and advancements. *Critical Care, 19*(1), 243.

NURSING ALERT Smaller burn injuries (TBSA less than 20%) are typically characterized by a local response of pain, erythema, and edema at the site of injury. Major burns involving more than 20% TBSA are at risk for exhibiting systemic cardiovascular and hemodynamic changes resulting in burn shock.

Fluid Shifts

1. The water vapor barrier for the body is the outermost layer of the epidermis. When it is rendered nonfunctioning, severe systemic reactions from fluid losses can occur.
2. Fluid volume deficit is directly proportional to the extent and depth of burn injury.
3. Capillary permeability increases, permitting fluid and protein to move from vascular to interstitial spaces (edema results) for the first 24 to 36 hours, peaking at 12 hours postburn. Protein-rich fluid is lost in blebs of the burned tissues as well as by weeping of second-degree wounds and surface of full-thickness wounds. With reduced vascular volume, the patient will go into shock if untreated.
4. Capillary permeability starts to change in about 48 hours, but protein lost in interstitial spaces may remain there for 5 days to 2 weeks before returning to the vascular system.

a. When fluid mobilizes (moves from interstitial spaces back to vascular compartment), patients with good cardiac and renal function will diurese.
b. Patients with impaired cardiac or renal function are in danger of fluid overload and pulmonary edema at this time.

5. Red blood cell (RBC) mass is also diminished because of thrombosis, sludging, and RBC death from thermal injury; as fluid escapes from capillary walls, however, blood concentrates and the hematocrit rises, causing sluggish flow (see Figure 34-3).
6. Capillary stasis may cause ischemia and even necrosis.
7. The body attempts to compensate for losses of plasma volume.
   a. Constriction of vessels.
   b. Withdrawal of fluid from undamaged extracellular space.
   c. Patient thirst.

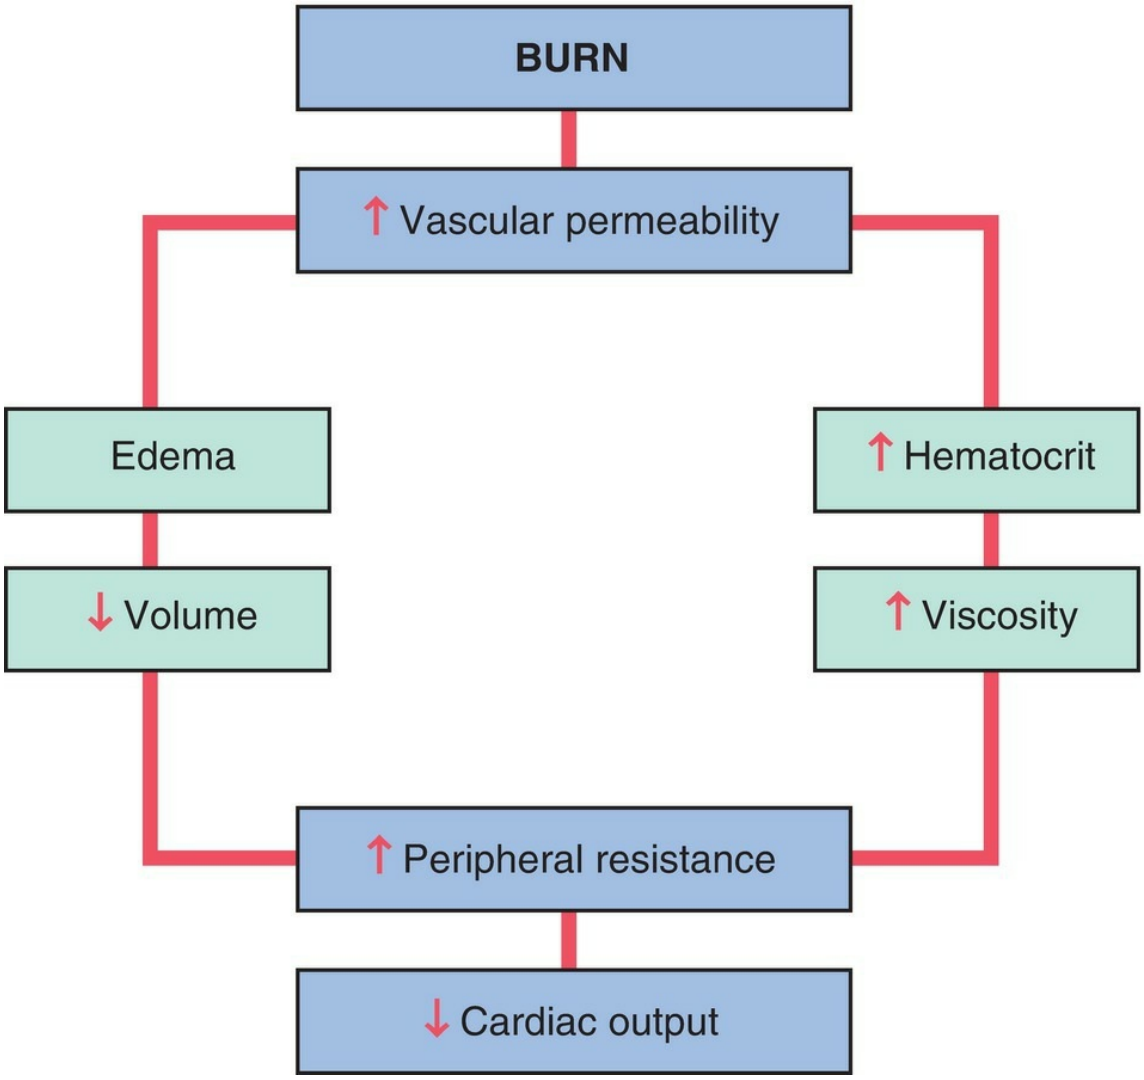

Figure 34-3. Hemodynamic changes in burn injury.

Hemodynamic Changes

1. Decreased circulating blood and plasma volume results in decreased cardiac output initially and increased pulse rate as a result of hypovolemia.
2. Afterload is increased due to a marked increase in systemic vascular resistance resulting from vasoactive mediators such as catecholamines.
3. A decrease in cardiac contractility is a predominant feature of full-thickness injuries covering more than 40% TBSA.
4. This results in inadequate tissue perfusion, which may in turn cause metabolic acidosis, renal failure, and irreversible burn shock.
5. Electrolyte imbalance may also occur.
    a. Hyponatremia usually occurs during the 3rd to 10th day because of fluid shift.
    b. The burn injury also causes hyperkalemia initially because of cell destruction, followed by hypokalemia as fluid shifts occur if potassium is not replaced.

Metabolic Demands

1. The initial metabolic response is thought to be activated by proinflammatory cytokines. The release of catecholamines, cortisol, glucagon, renin–angiotensin, antidiuretic hormone, and aldosterone is also increased. The major fuel source is stored glycogen. Major hypermetabolism and catabolism occur immediately postburn. The degree of the response is directly proportionate to the size of the burn injury.
2. Tachycardia, ranging from 100 to 120 beats/minute, is common and results from persistent elevation of catecholamine levels.
3. "Burn fever" (usually seen during the first week) is common and is dependent on depth of burn and percentage of TBSA involved. An increase of 1°F to 2°F makes it difficult to assess for infection.
4. Total body glucose stores are limited and stored liver and muscle glycogen is exhausted within the first few days postburn, hepatic glucose synthesis (gluconeogenesis) increases, and patients with glucose intolerance (obese patients and older adults) usually develop hyperglycemia.
5. Increased catabolism leads to increased urea production, especially in nutritionally depleted patients.
6. Body levels of protein begin to decrease as high levels of cortisol and inflammatory cytokines continue to circulate. Skeletal and visceral proteins are mobilized to meet increased nutritional demands. Ten to fifteen percent of body protein stores can be lost within 10 days without proper nutritional supplementation. This can lead to muscular weakness, decreased wound healing, and further weakening of the immune system.
7. With adequate fluid resuscitations, the patient's weight will increase during the first few days. Fluid mobilization will result in weight loss, as will the catabolic response. Nutritional support in the form of enteral or total parenteral nutrition (TPN) may be necessary. Weight loss from fluid mobilization usually starts within 3 to 4 days postresuscitation.
8. Despite all nutritional support, it is almost impossible to counteract a negative nitrogen balance; the sooner a burn wound is closed, the more rapidly a positive nitrogen balance is reached.

9. The resting metabolic expenditure increases linearly with the amount of TBSA; a burn of 40% to 50% TBSA has a metabolic rate almost twice normal.
10. The adult burn patient may require 3,000 to 5,000 calories or more per day.
    a. A burn of less than 10% usually requires minimal supplementation.
    b. A high-protein, high-calorie diet is necessary for a 10% to 20% burn.
    c. For burns 20% and greater, beginning enteral nutrition within 24 hours of the injury is recommended.

Renal Needs

1. Glomerular filtration may be decreased in extensive injury.
2. Without resuscitation or with delay, decreased renal blood flow may lead to high output or oliguric renal failure and decreased creatinine clearance.
3. Hemoglobin and myoglobin, present in the urine of patients with deep muscle damage commonly associated with electrical injury, may cause acute tubular necrosis and call for a greater amount of initial fluid therapy and osmotic diuresis.

Pulmonary Changes

1. Hyperventilation and increased oxygen consumption are associated with major burns.
2. The majority of deaths from fire are due to smoke inhalation.
3. Overzealous fluid resuscitation and the effects of burn shock on cell membrane potential may cause pulmonary edema, contributing to decreased alveolar exchange. Therefore, with an inhalation injury, it may be necessary to keep the patient slightly less hydrated.
4. Initial respiratory alkalosis resulting from hyperventilation may change to respiratory acidosis associated with pulmonary insufficiency as a result of major burn trauma.

Hematologic Changes

1. Thrombocytopenia, abnormal platelet function, depressed fibrinogen levels, inhibition of fibrinolysis, and a deficit in several plasma clotting factors occur postburn.
2. Anemia results from the direct effect of destruction of RBCs because of burn injury, reduced life span of surviving RBCs, and blood loss during diagnostic and therapeutic procedures.

Immunologic Activity

1. The loss of the skin barrier and presence of eschar favor bacterial growth. Methicillin-resistant *Staphylococcus aureus* (MRSA) is now being seen in the immunocompromised burn patient.
2. Polymorphonuclear chemotactic activity is suppressed, which results in decreased oxygen consumption and impaired bactericidal activity.
3. Abnormal inflammatory response after burn injury causes a decreased delivery of antibiotics, white blood cells, and oxygen to the injured area.
4. Hypoxia, acidosis, and thrombosis of vessels in the wound area impair host resistance to pathogenic

bacteria.

5. Sera IgA, IgM, and IgG are depressed, reflecting depressed B-cell function.
6. Depressed cellular immunity is reflected by lymphocytopenia, delayed skin sensitivity, decreased allograft rejection potential, depletion of thymus-dependent lymphoid tissue, and increased susceptibility to fungi, viruses, and gram-negative organisms.
7. Burn wound sepsis.
   a. After colonization of the burn wound surface by bacteria, subeschar and intrafollicular colonization develops. Intraeschar and subeschar colonization may progress to invasion of subadjacent, nonburned, previously viable tissue.
   b. A bacterial count of 10^5 per gram of tissue as determined by burn wound biopsy (quantitative culture) indicates burn wound sepsis. Usually, only a swab culture is done of the wound surface.
   c. The wound is fully colonized in 3 to 5 days.
8. Seeding of bacteria from the wound may give rise to systemic septicemia.

GI Impact

1. As a result of sympathetic nervous system response to trauma, peristalsis decreases and gastric distention, nausea, vomiting, and paralytic ileus may occur.
2. Ischemia of the gastric mucosa and other etiologic factors put the burn patient at risk for duodenal and gastric ulcers. Curling ulcers, a gastric ulcer associated with severe burn injuries and well-known for causing life-threatening bleeding, have been noticeably declining in the literature. Although definitive data are lacking, researchers believe Curling ulcers have nearly been eradicated due to the early enteral feeding and gastrointestinal ulcer prophylaxis now routinely given to patients with severe burns.

Immediate Assessment

Immediate assessment of the burned patient is imperative, particularly burn size and depth, as fluid resuscitation is hallmark for initial management of severe burns. As with all trauma patients, it is important to start with the primary and secondary trauma survey. Do not become distracted by the visual appearance of the burn injury. Consider the mechanism of injury and assess for concomitant traumatic injuries.

Severity of Burns

Severity of burns is determined by:

1. Depth—first-, second- (partial-thickness), and third-degree (full-thickness). Patients with deeper burns may experience a greater systemic response. Full-thickness injuries require surgical excision and grafting.
2. Extent—percentage of TBSA. The higher the TBSA, the higher the risk of a systemic response and burn shock.
3. Age—mortality rate increases with age.
4. Area of the body burned—face, hand, feet, perineum, and circumferential burns require special care.
5. Medical history and concomitant injuries and illness. Preexisting conditions such as diabetes, renal failure, and congestive heart failure can complicate the management of even a small burn injury.
6. Inhalation injury.

Assessment for Inhalation Injury

1. If victim was burned in a closed area, there should be a high index of suspicion that smoke inhalation has occurred.
2. Evaluate all patients in closed-space fires for symptoms of carbon monoxide poisoning—headache, visual changes, confusion, irritability, decreased judgment, nausea, ataxia, and collapse (see Table 34-1).
3. Observe for upper body burn erythema or blistering of lips, buccal mucosa, or pharynx; singed nasal hair; soot in the oropharynx; and dark gray or black sputum (see Figure 34-4).
4. Listen for hoarseness and crackles. Increasing hoarseness, stridor, and drooling are indicators of increasing need for intubation.
5. Obtain ABGs, carboxyhemoglobin levels, and spirometry.
6. Direct visualization of the vocal cords may be necessary. Further visualization may be accomplished through bronchoscopy, if necessary.
7. A chest x-ray should be obtained as a baseline.

Table 34-1 Signs and Symptoms of Toxicity from Carbon Monoxide

CO BLOOD LEVEL	MANIFESTATIONS
0%–10%	• None. • Smokers may have 10% carbon monoxide level or greater.
10%–20%	• Headache, vision disturbance, angina in patients with cardiovascular disease, and slowed mental function.
20%–40%	• Tight feeling in the head, rapid fatigue from muscular effort, decreased muscular coordination, confusion, irritability, ataxia, nausea, vomiting, increased pulse rate, decreased blood pressure, and dysrhythmias.
40%–60%	• Pulmonary and cardiac dysfunction, collapse, coma, and convulsions.
>60%	• Commonly fatal.

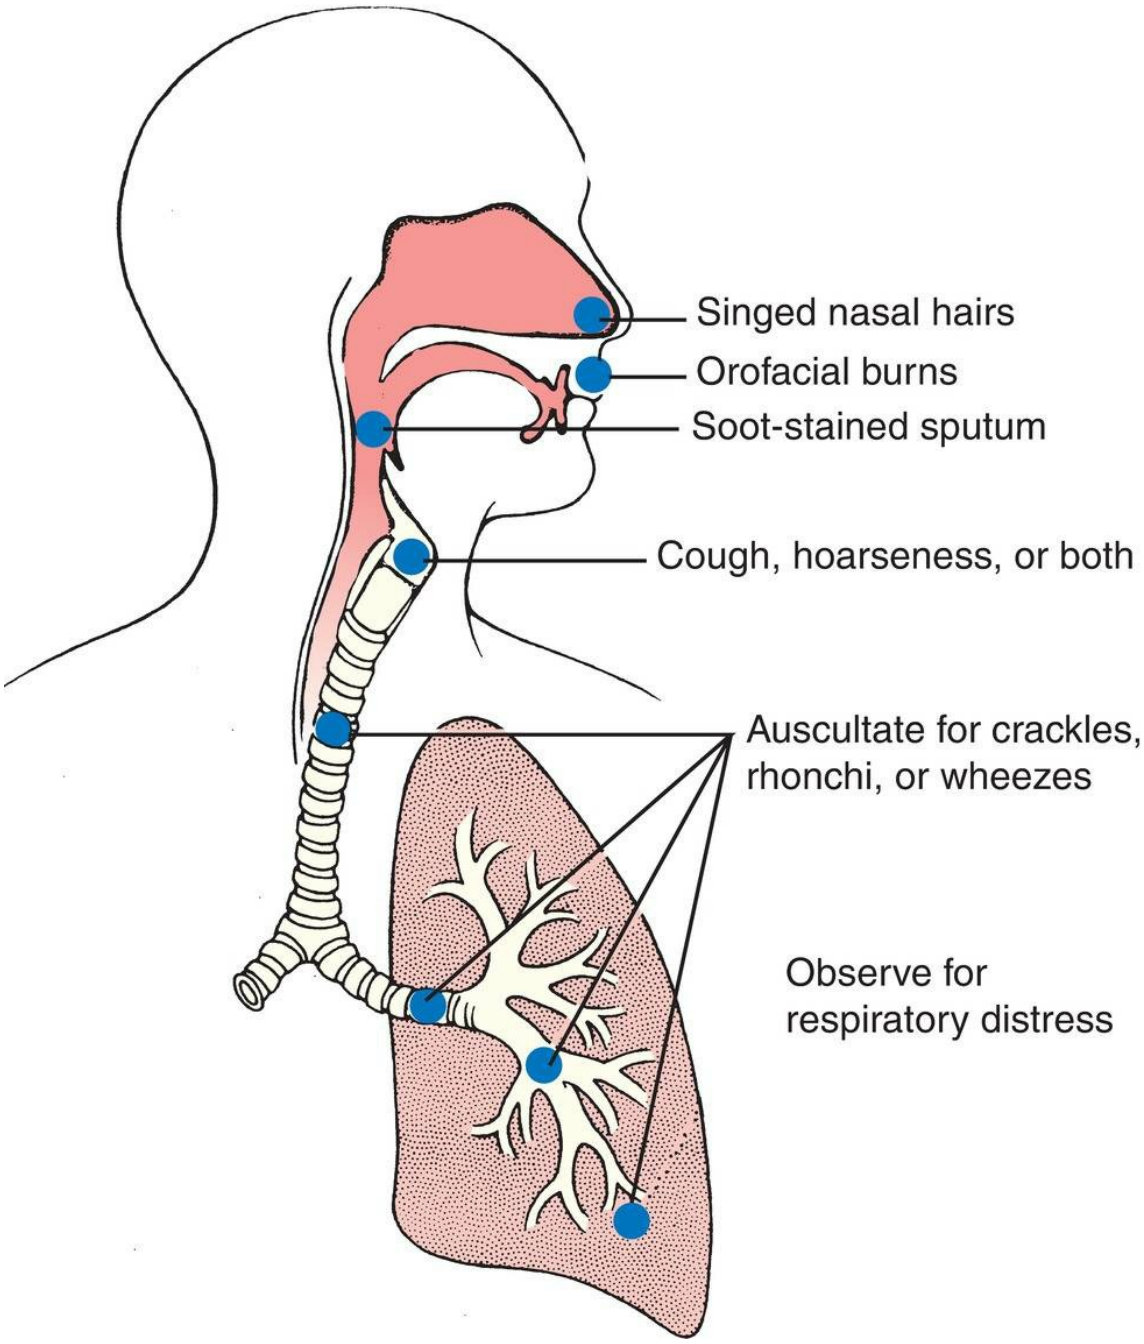

Figure 34-4. Respiratory system signs of inhalation injury.

Extent of Body Surface Burned

1. Anatomic location—burns affecting hands, feet, face, and perineum require specialized care. Circumferential burns also require special attention, possibly escharotomy.
2. Determination is based on the use of tables for this purpose, such as the "rule of nines" (see Figure 34-5), the Lund and Browder chart (see page 1436), or the rule of the palm. The patient's palm (including the fingers) is approximately 1% of the TBSA burned. The Lund and Browder chart is the most accurate. Calculation of the percentage of TBSA burned serves as a guide for fluid therapy. Full fluid resuscitation is necessary for partial- or full-thickness burns of 20% TBSA or greater.

3. Repeat assessment may be performed on the 2nd or 3rd day to verify demarcation of burned areas.

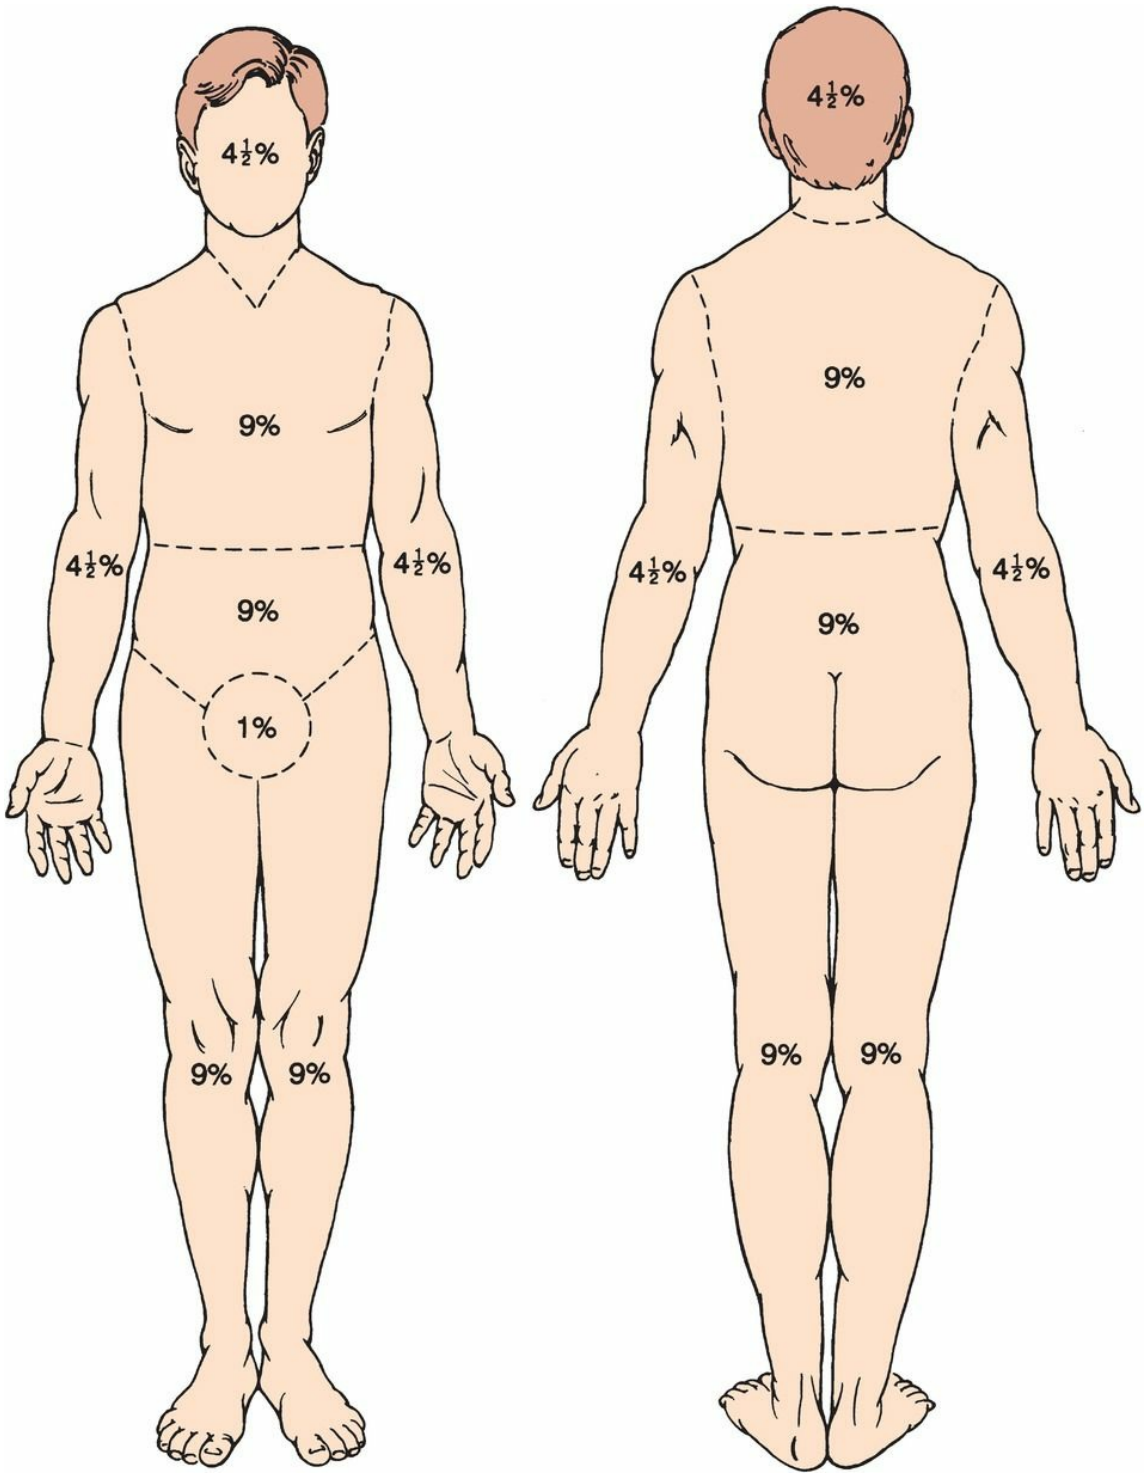

Figure 34-5. Rule of nines for calculating total burn surface area (TBSA).

Depth of Burn and Triage Criteria

1. It may be difficult to differentiate between second- and third-degree wounds initially.
   a. If the areas appear wet and pink and are particularly sensate, then a second-degree (partial-thickness) injury is likely. Blistering is another classic sign of a second-degree (partial-thickness) injury.
   b. If the area is dry, leathery, and firm to the touch, then it is most likely a third-degree (full-thickness)

burn. Third-degree (full-thickness) burns can be a variety of colors such as white, mottled, or charred and may also have decreased sensation to light touch (see Table 34-2).

2. Reassess daily for the first few days because a partial-thickness burn can convert or progress to a full-thickness burn injury.
3. Deep partial-thickness burns of certain extent, full-thickness burns, chemical burns, electrical burns, burns of certain areas of the body, and any airway or inhalation injury should be transferred to a regional burn center (see Box 34-1).

Table 34-2 Assessment of Burn Injury

EXTENT OR DEGREE	ASSESSMENT OF EXTENT	REPARATIVE PROCESS
Superficial (First-degree)	• Pink to red; slight edema, which subsides quickly. • Pain may last up to 48 hours; relieved by cooling. • Sunburn is a typical example.	• In about 5 days, epidermis peels and heals spontaneously. • Itching and pink skin persist for about 1 week. • No scarring. • If burn does not become infected, heals spontaneously within 10–14 days.
Partial-Thickness (Second-degree)	Superficial: • Pink or red; blisters (vesicles) form; weeping, edematous, and elastic. • Superficial layers of the skin are destroyed; wound is moist and painful.	• Heals in 2–3 weeks. • Little to no scarring.
	Deep dermal: • Mottled white and red; edematous reddened areas blanch on pressure. • May be yellowish but soft and elastic—may or may not be sensitive to touch; sensitive to cold air.	• Takes several weeks to heal. • Scarring may occur.
Full-Thickness (Third-degree)	• Destruction of epithelial cells—epidermis and dermis destroyed. • Reddened areas do not blanch with pressure. • Not painful; inelastic; coloration varies from waxy white to brown; leathery devitalized tissue is called eschar. • Destruction of epithelium, fat, muscles, and bone.	• Eschar must be removed. Granulation tissue forms to nearest epithelium from wound margins or support graft. • For areas larger than 1¼–2 inches (3–5 cm), grafting is required. • Expect scarring and loss of skin function. • Area requires debridement, formation of granulation tissue, and grafting.

BOX 34-1 Burn Center Referral Criteria

- Partial-thickness burns of greater than 10% TBSA.
- Involvement of the face, hands, feet, and genitalia.
- Third-degree burns.
- Electrical burns.
- Chemical burns.
- Inhalation injury.
- Preexisting medical conditions that could complicate management.
- Concomitant trauma where burn injury poses greatest risk.
- Burned children where facilities lack qualified staff and equipment.
- Patients who require special social, emotional, or rehabilitative intervention.

MANAGEMENT

Management of the acute burn injury includes hemodynamic stabilization, metabolic support, wound debridement, use of topical antibacterial therapy, biologic dressings, and wound closure. Prevention and treatment of complications, including infection and pulmonary damage, and rehabilitation are also of major importance. The patient will also require physical and occupational therapy and psychiatric and nutritional support.

Hemodynamic Stabilization

IV Fluid Therapy

EVIDENCE BASE American Burn Association. (2016). *Advanced Burn Life Support Provider Manual*. Chicago: Author.

1. The goal of fluid resuscitation is to maintain tissue perfusion and organ function. Careful and continuous fluid management is critical to minimize complications associated with overresuscitation and underresuscitation.
   a. Overzealous fluid resuscitation has been associated with acute coronary syndrome, compartment syndrome of the extremities, ARDS, airway obstruction, and pulmonary edema.
   b. Underresuscitation may lead to inadequate organ and cellular perfusion, stress ulcer development, acute tubular necrosis, and conversion of deep partial-thickness burns to full-thickness burns.
2. The American Burn Association recommends fluid resuscitation for partial-thickness and full-thickness burns exceeding 20% TBSA.
   a. Immediate intravenous (IV) fluid resuscitation is indicated for patients with electrical injury, older patients, or those with cardiac or pulmonary disease.
   b. These patients require meticulous monitoring and may require a modification of fluid requirements.
3. Two large-bore peripheral IV catheters are established for fluid resuscitation and pain management, preferably through nonburned skin. If unable to obtain peripheral IV access, intraosseous or central line catheters may be used.
4. Generally, a crystalloid (Ringer lactate) solution is used for fluid resuscitation. One of several formulas may be used to determine the amount of fluid to be given in the first 48 hours.
   a. Any formula that is utilized is only a guide and a starting point. Some patients will require more or less fluid depending on their response.
   b. The consensus formula (formerly known as the Parkland formula) is most commonly used.
   c. Some burn centers utilized albumin as a rescue therapy for patients requiring excessive amounts of fluids during resuscitation. Albumin may also be used postresuscitation on the 2nd day.
5. The consensus formula:
   a. First 24 hours: 2 to 4 mL of Ringer lactate × weight in kg × % TBSA.
   b. One-half amount of fluid is given in the first 8 hours, calculated from the time of injury. If the starting of fluids is delayed, then the same amount of fluid is given over the remaining time. Remember to deduct any fluids given in the prehospital setting.
   c. The remaining half of the fluid is given over the next 16 hours.
   d. Example:

Patient's weight: 70 kg; % TBSA: 80%.

4 mL × 70 kg × 80% TBSA = 22,400 mL of Ringer lactate.

First 8 hours: 11,200 mL or 1,400 mL/hour.

Second 16 hours: 11,200 mL or 700 mL/hour.

NURSING ALERT Several regional burn centers have developed protocols for fluid resuscitation, such as the Michigan State Burn Coordinating Center, and a number of computer-driven algorithms have been developed, utilizing technology to more precisely guide fluid management.

Wound Care

Diligent wound care is essential to getting the burn wound healed as soon as possible. Treatment of the partial-thickness burn wounds includes daily or twice-daily wound cleansing with debridement or hydrotherapy (tubbing/showering) and dressing changes. Treatment of deep partial-thickness and full-thickness burns requires early surgical excision of eschar, skin grafting, and postoperative wound care.

Cleansing and Debridement

1. Burn wounds must be cleansed initially and usually daily with a mild antibacterial cleansing agent and saline solution or water.
   a. May be done in the hydrotherapy tub, in the bathtub or shower, or at the bedside.
   b. See "Hydrotherapy," below.
2. Nonviable tissue (eschar) may be removed through natural, enzymatic, mechanical, and/or surgical debridement.
3. Burn eschar will begin to separate from the underlying viable tissue by a natural process of bacterial growth, which causes a lysis of protein at the viable–nonviable tissue interface.
4. Loose eschar, dried blood, and exudate can be debrided at the time of wound cleansing.

Hydrotherapy Principles

1. Hydrotherapy ("tubbing," "tanking," or "showering") is bathing of the burn patient in a tub of water or with a water shower to facilitate cleansing and debridement of the burned area. Even ventilator-dependent patients can be safely bathed when a shower table is used.
2. Advantages
   a. Topical medications, adherent dressings, and eschar are more easily removed.
   b. Provides an opportunity for the patient to practice range-of-motion (ROM) exercises.
   c. Total assessment of the burn area is facilitated; total body cleansing can be achieved.
3. Disadvantages
   a. Loss of body heat; loss of sodium.
   b. Uncomfortable and at times painful for the patient.
   c. Maintenance of IV lines and ventilator care may be difficult during bathing and showering.

NURSING ALERT Adequately premedicating the patient with an opioid and anxiolytic allows the patient to participate in and tolerate the bathing and dressing change process.

Hydrotherapy Process

1. Describe the procedure to the patient who is experiencing hydrotherapy for the first time.

2. Select the time for future hydrotherapy sessions in collaboration with the patient; administer a pain control medication, as prescribed, before the treatment so that maximum benefit is realized. Use nursing activities to assist patient with the pain experience.
3. If the patient has an indwelling catheter, drain and plug it or maintain a closed system to avoid contamination.
4. Sterile technique is adhered to as closely as possible in preparing the patient for hydrotherapy, during hydrotherapy, and in redressing the patient's wounds after therapy.
5. During hydrotherapy, after cleansing of the wounds, debride wound, shave adjacent areas at health care provider's direction, shampoo hair, and gently wash normal skin.
6. Limit hydrotherapy to as brief a time as possible to decrease the loss of body temperature and subsequent chilling.
7. Never leave the patient unattended in the tub.
8. Respect the patient's feelings and expressions of stress, pain, cold, and fatigue.
9. After treatment, the patient may be weighed before being carefully dressed and returned to the unit.
10. Document significant data, including status of the wound.

Topical Antimicrobials

1. Topical medications are used to cover burn areas and to reduce the number of organisms. See Table 34-3. Identifying the most effective topical antimicrobial and dressing medium is an essential aspect in promoting wound closure.
2. Factors such as location of burn, burn depth, ease of application and removal, pain, frequency of dressing changes, and cost need to be considered.
3. They are applied directly to the burn area as ointments, creams, or solutions, or they may be incorporated in single-layer dressings that do not stick to the wound but permit drainage.
4. Dressings may take the form of commercial multilayered pads, standard 4 × 4-gauze pads, or several layers of stretch bandage (Kerlix type).
5. If gauze or pads are used, they may be held in place by stretch gauze or net tube dressings.
6. When wet dressings are used, that is, after a surgical procedure, then the same dressings are maintained. They are remoistened every 4 to 6 hours, as ordered. Heat loss may be prevented by limiting evaporative loss with a dry blanket and by warming the bed and room. When wet dressings are used, 20-ply gauze will help retain solution at the proper concentration if rewet every 4 hours. A dry top layer of stockinette or a cotton bath blanket prevents evaporative heat loss.
7. Desired characteristics in a topical antimicrobial:
   a. Demonstrates action against a broad spectrum of bacteria.
   b. Has the ability to diffuse through the wound and penetrate the eschar.
   c. Nontoxic and noninjurious to body tissue.
   d. Is inexpensive, is pleasant to use, is odorless or has pleasant odor; will not stain the skin or clothing.
   e. Will not cause resistant strains of pathogenic organisms to develop.

8. Generally, all of the previously applied topical cream should be removed and the wound gently cleansed before applying new cream with each dressing change. Extremity dressings should be wrapped distally to proximally, taking care to avoid circulatory compromise when edema occurs or dressing is too tight.
9. Some silver-based dressings can be left in place on second-degree (partial-thickness) wounds or donor sites for several days. Most require an outer wrap to secure the dressing in place and this can be changed as needed.
10. Identifying the best evidence on dressings for superficial and partial-thickness burn injuries has produced limited results. A Cochrane Database systematic review of 30 randomized controlled trials showed some evidence that biosynthetic dressings, silver-based dressings, and silicon nylon decrease healing time over silver sulfadiazine. However, methodological shortcomings of the individual studies limit usefulness of the review.

Table 34-3 Topical Antimicrobial Agents for Burns

TOPICAL AGENT	DESCRIPTION AND INDICATIONS	DISADVANTAGES	NURSING CONSIDERATIONS
Silver Sulfadiazine 1%	• White, crystalline, highly insoluble compound in an opaque, odorless, water-miscible cream. • Exerts antimicrobial effect against gram-negative and gram-positive bacteria and yeasts at level of cell membrane and cell wall. • Penetration of silver sulfadiazine into wound is intermediate between silver nitrate and mafenide. • Systemic toxicity is rare. • Most widely used agent and least common incidence of adverse effects.	• May cause transient leukopenia that disappears after 2–3 days of treatment. • May increase possibility of kernicterus; should not be used in pregnant women in the last trimester, premature neonates, or infants younger than age 2 months. • Impairment of hepatic and renal function that results in decreased excretion of drug constituents may preclude therapeutic benefits of continued silver sulfadiazine administration. • Exposure to sunlight produces gray discoloration. • Crystalluria and methemoglobinemia are rare toxic effects. • Protracted use may be associated with emergence of sulfadiazine resistance.	• Use with open treatment or with light or occlusive dressings. • Apply with sterile gloved hand directly to the wound or to gauze dressing 1/16 inch (0.2 cm) thick, once or twice per day after a thorough wound cleansing. • Silver sulfadiazine will be discontinued if white blood cell (WBC) count is <1,500 in an adult or <2,000 in a child; WBC count usually returns to normal in 2–4 days, after which application may be resumed.
Mafenide Acetate 10% cream or 5% solution	• Usually supplied in water-miscible, hydroscopic cream base. • Active against most gram-positive organisms, particularly *Clostridia* spp. • Active against common gram-negative burn wound pathogens but has little antifungal activity. • Not significantly bound by protein and wound exudate. • Good penetrating power and useful for control of established invasive burn wound infection.	• Painful during and for a short period following application. • A potent carbonic anhydrase inhibitor resulting in metabolic acidosis, therefore not used if total body surface area is >20%. • Brisk alkaline diuresis and inappropriate polyuria may result when used on patients with a large burn surface area. • Compensatory hyperventilation and pulmonary failure may ensue if mafenide is not discontinued. • Hemolytic anemia is a rare complication.	• Cream is applied without dressing, if possible and must be reapplied every 12 hours to maintain therapeutic effectiveness. • Therapeutic solution concentration is maintained with bulky wet dressings; rewet every 2–4 hours. • Application is associated with significant pain. • Hypersensitivity evidenced by maculopapular rash; is treated with antihistamines or by discontinuing use. • Requires careful monitoring of pulmonary status and acid–base and fluid balance.
Silver Nitrate (0.5% solution)	• Clear solution with low toxicity and significant antimicrobial effect against common burn wound pathogens. • Absorption is minimal because of the insolubility of its chloride and other salts. • Nonallergenic and not usually painful on application. • Best use is prophylaxis against infection.	• Can cause electrolyte abnormalities by depleting serum sodium, chloride, potassium, and magnesium. • Methemoglobinemia is a rare complication. • Stains everything (including normal skin) brown or black.	• Monitor electrolyte balance carefully; supplementation with sodium and potassium salts is routinely needed for patients with extensive burns. • Use bulky dressings; rewet every 2–4 hours to maintain therapeutic concentration. • Maintain patient warmth and minimize transcutaneous evaporative water loss with dry top layer, such as stockinette or bath blanket.
Silver Sheeting	• Silver impregnated on a neutral backing.	• Cannot be moistened until time of application. • Moisten with sterile water only; saline deactivates the silver. • Need to keep moist with sterile water every 8 hours.	• Dressing change required only every 4–7 days, reducing pain. • Can be used on an outpatient basis.
Mupirocin	• Ointment. • Active against methicillin-resistant *Staphylococcus aureus* (MRSA).	• Allergy is a major contraindication. • Prolonged use may result in superinfection. • Apply bid to tid.	• May be ordered based on culture or prophylactically.

EVIDENCE BASE Wasiak, J., Cleland, H., Campbell, F., et al. (2013). Dressings for superficial and partial thickness burns. *Cochrane Database of Systematic Reviews,* (4), CD0002106.

Surgical Management

Early excision and skin grafting are the goal to early wound closure for deep partial-thickness and full-thickness burn injuries. For types of burn wound coverings, see Table 34-4, page 928.

Table 34-4 Burn Wound Coverings

COVERING AND DESCRIPTION	INDICATIONS	SOURCE OR FORM	NURSING CONSIDERATIONS
Allograft/Homograft • Human cadaver skin, about 0.015 inch thick • Preferred biologic dressing	• To debride untidy wounds. • To protect granulation tissue after escharotomy. • To cover excised wound immediately. • To serve as test graft before autograft.	Fresh, cryopreserved homografts available from tissue banks throughout the United States.	• Remember: Length of time dressing is left in place varies greatly. • Observe for exudate; also, watch for local and systemic signs of infection and rejection.
Xenograft Heterograft • Pigskin similar to human skin, harvested after slaughter, then cryopreserved, or lyophilized for long-term storage	• Same as for homograft. • To cover meshed autografts. • To protect exposed tendons. • To cover partial-thickness burns that are eschar-free and clean or only slightly contaminated.	Available in fresh, frozen, or lyophilized form, in rolls or sheets; also available meshed and impregnated with silver sulfadiazine.	• Change every 2–5 days; wound may be dressed or left open. • Observe for signs of infection.
Biobrane • Nylon fabric bonded to silicon rubber membrane, containing collagenous porcine peptides • Elastic and durable; adheres to wound surface until removed or sloughed by spontaneous re-epithelialization	• To cover donor graft sites. • To protect clean, superficial, partial-thickness burns and excised wounds awaiting autografts. • To cover meshed autografts.	Individually packaged sterile sheets of various sizes; also in glove-shaped form for hand burns.	• Useful for wounds awaiting autograft because it can be left in place 3–14 days and is permeable to antimicrobials, which can be applied over it.
DuoDERM • Hydroactive dressing that interacts with moisture on the skin, creating bond that makes it adhere • Interacts with wound exudate to produce soft, moist gel, facilitating removal	• To cover small partial-thickness burns. • To prevent bacterial contamination.	Individual, peelable, "blister" packages containing sheets of various sizes (from 3 × 3 inches to 8 × 12 inches).	• Use size that allows dressing to extend beyond wound onto healthy skin. • Be careful to distinguish pus from liquefied material that normally remains in the wound. • Used until it falls off, usually 7–10 days.
Integra Artificial Skin • Permanent bilayer membrane composed of a dermal portion consisting of a porous lattice of fibers of cross-linked bovine collagen and glycosaminoglycan composite and an epidermal layer of synthetic polysiloxane polymer	• To create a template for dermal regeneration by formation of a "neodermis." Provides an immediate post-excisional physiologic wound closure. Allows use of a thinner autograft.	Sterile individual sheets.	• Dermal regeneration layer is very soft and fragile. No hydrotherapy immersion should occur while the silicone layer is still in place. • Change outer dressing every 4–5 days. • Removal of the silicon layer is usually done in 14–21 days.
Acticoat • Temporary covering of a nanocrystalline film of pure ionic silver	• To provide a temporary layer with optimal antimicrobial protection. May be used for immediate wound coverage as well as for postgraft site coverage. May also be used as donor site coverage.	Sterile individual sheets.	• Must be moistened immediately before application. It must also be moistened with sterile water every 4–6 hours. Do not apply any topical antimicrobial over or onto the silver sheeting.
Aquacel AG	• To provide wound coverage for superficial to middepth partial-thickness wounds. It dries and remains on the wound until healed, at which time it will loosen and can be peeled from the wound.	Individual sterile rolls.	• Do not try to wet or remove before the wound has healed.

General Considerations

1. Early surgical intervention reduces the potential for wound infection and potentially reduces the length of stay.
2. Operative excision is very stressful metabolically and incurs heavy blood loss; therefore, more conservative measures may be indicated for some patients.
3. As a general consideration, up to 190 mL of blood may be lost per 1% of burn excised in the adult patient.
4. With tangential excision, a special blade is used to remove thin layers of damaged skin until live tissue is evidenced by capillary bleeding. It is commonly used with deep partial-thickness burns and full-thickness burns and followed with immediate coverage with a biosynthetic or biologic dressing or an autograft.
5. With fascial (primary) excision, the skin, lymphatics, and subcutaneous tissue are removed down to fascia, with either immediate autografting or temporary coverage with biologic or biosynthetic dressings. This is repeated until all deep burn areas are removed.

Biologic Dressings

1. Biologic dressings are used to temporarily cover large surfaces of the body. Usually, they are split-thickness grafts harvested either from human cadavers or from other mammalian donors such as pigs.
   a. An allograft is a graft of the skin taken from a person other than the burn patient and applied to a burn wound (most common type of biologic dressing). A cadaver is the most common source. Other sources may be live donors having a panniculectomy or other surgery.
   b. A xenograft or heterograft is a segment of the skin taken from an animal such as a pig.
2. Allograft can provide temporary wound closure for large surface area burns when there is not enough healthy skin available for autografting. They typically adhere for 2 to 3 weeks before sloughing off.
   a. Skin color is unimportant because it is only a temporary graft.
   b. Donor should be an adult, free from infection. All donated skin must be tested and free from contagious diseases before it can be used for donation.

Purpose and Benefits

1. Decreases heat, fluid, and protein losses.
2. Reduces bacterial proliferation.
3. Closes wound temporarily; enhances production and protection of granulation tissue.
4. Protects exposed neurovascular and muscle tissue as well as tendons.
5. Reduces pain and facilitates patient comfort.
6. Acts as a test graft to determine when granulating wounds will accept autograft successfully.
7. Provides an effective donor site dressing.

Clinical Procedures

1. Devitalized tissue is first removed surgically or enzymatically.

2. Allograft is applied directly (shiny side down) to the denuded area. Before applying, it may be dipped in saline solution. It may be trimmed to fit the wound.
3. Grafts are usually secured with adhesive strips or with staples or sutures. The graft is covered with wet nonadherent gauze (antibiotic solution or saline) and covered with stretch gauze; this is again wet down with the appropriate solution.
4. The wound remains unchanged initially for 3 to 5 days, during which time it is wet down every 4 to 6 hours. Sheet grafts do not require the wet-down procedure.
5. After the initial takedown (typically known as the first postoperative dressing removal), dressings are changed daily.
6. If allograft or xenograft is used, the wound bed may be prepared for permanent autografting.

Biosynthetic Dressings

1. Temporary biosynthetic dressings help prevent bacterial contamination.
2. Used when permanent autograft is unavailable or unnecessary (as when partial-thickness wounds will heal spontaneously over time).
3. Biobrane (Woodruff Laboratories) consists of a custom-knit nylon fabric mechanically bonded to an ultrathin silicone rubber membrane, to which collagenous peptides of porcine skin are covalently bonded.
   a. Has a longer shelf life and lower cost than biologic dressings such as pigskin.
   b. Is widely used for coverage of shallow wounds awaiting epithelialization, excised wounds awaiting autografts, widely meshed autografts until closure of interstices, and donor sites awaiting healing.

Artificial Dermis

1. Method being studied in selected burn centers to improve survival of patients with massive burns and little donor skin available.
2. Composed of a porous collagen–chondroitin 6-sulfate fibrillar mat covered with a thin Silastic sheet.
3. Used with an epidermal graft to provide a permanent cover that is at least as satisfactory as other available grafting techniques.
4. Used with donor sites that are thinner and that heal faster; seems to result in less hypertrophic scarring than the usual grafting methods.

Wound Closure

1. Skin grafting is usually required or preferred with full-thickness burns greater than 1¼ to 2 inches (3 to 5 cm) in diameter or in deep partial-thickness wounds or in areas of function.
2. After gradual eschar removal and development of a base of granulating tissue or in the presence of viable tissue after excision, grafts of the patient's own skin (autografts) are applied.
3. Sheet grafts or meshed grafts, providing wider expansion from donor sites, may be used.
4. Blood flow is established by the 3rd or 4th day, and postgrafting, vascular continuity, and wound closure have been established by the 7th to 10th day.

5. Definitive wound closure in patients with extensive full-thickness injuries may require multiple operations over many weeks or even months. To hasten healing, cultured epithelial autografts (cultured skin) may be used for patients with large burns and little available donor skin.
   a. Biopsies of unburned skin are cultured in a specialized laboratory to yield confluent sheets of epithelial cells suitable for grafting in about 3 weeks.
   b. Available donor sites can be used for coverage of the most functional or posterior surfaces, and the more delicate cultured epithelial autografts can be used to cover other large areas.
   c. The sheets of epithelial cells are at higher risk of shearing because they lack a dermis and seem to be less resistant to infection. Some burn centers have improved graft take by using an allograft dermis underneath.
   d. Additional experience is needed to determine the long-term durability of cultured epithelial autografts, which may be lifesaving treatment for the severely burned.
6. Many partial-thickness burn wounds will heal spontaneously within a few weeks, provided they are protected from infection.
7. The donor site requires meticulous care and may be covered with a synthetic dressing, scarlet red, silver sheeting, or an antimicrobial cream such as silver sulfadiazine 1%.

Other Interventions

Pain Management

1. Pain relief should be considered in the primary assessment of all initial burn injuries. A burn injury is one of the most feared painful injuries; all burn injuries are painful.
2. All pain medication should be given via IV line. Pain medication that is given intramuscularly may not be metabolized properly through burned tissue. Acceptable IV pain medications are morphine, hydromorphone, and fentanyl.
3. Careful administration of opioids for pediatrics, older adults, and patients with higher pain tolerances to avoid respiratory suppression or overdose.

Nutrition Support

1. Initially, institute nothing-by-mouth (NPO) status until bowel sounds return (1 to 2 days). However, small amounts (5 to 10 mL/hour) of isotonic enteral tube feedings are typically started within 24 hours to help maintain a functioning GI tract. Small amounts of erythromycin may be used to encourage GI motility.
2. Reduce metabolic stress by allaying pain, fear, and anxiety and maintaining a warm environment.
3. Nutritional management must be aggressive to combat acute nutritional deficiency and weight loss; a positive nitrogen balance should be the goal throughout postburn care.
4. When bowel sounds return, administer oral fluids and advance diet, as tolerated.
5. Offer more solid food after 2 to 3 days postburn as tolerance to food improves.
    a. Build up daily caloric intake to match daily caloric expenditure.
    b. Provide 3-g protein/kg body weight: 20% of needed calories in the form of fats; remainder in carbohydrates.
6. Oral anabolic steroids (oxandrolone) have shown good results in helping to maintain lean muscle mass.
7. When caloric requirements cannot be met by enteral feedings, it may be necessary to initiate TPN (amino acids, carbohydrates, and fat emulsions).
8. Provide potassium and vitamin and mineral supplements (zinc, iron, and vitamin C).

Prevention and Treatment of Complications

Primary causes of morbidity and mortality in burn patients are those related to infection and pulmonary problems.

1. Topical antibacterial agents help to retard the proliferation of pathogenic organisms until wound closure occurs spontaneously or through surgical intervention.
2. Broad-spectrum antibiotics may be necessary to treat systemic gram-positive and gram-negative infections and sometimes fungal infection.
3. Critical diagnostic parameters include observing for signs of burn wound sepsis, obtaining quantitative and qualitative wound biopsy, checking for signs of systemic septicemia, and taking blood for cultures.

4. Meticulous pulmonary care is essential because pneumonia (especially if patient remains intubated) is common.
5. Severe inhalation injury, including ARDS, can contribute significantly to mortality, even though the burn wound size may be small.

Nursing Management of the Burn Patient

See Box 34-2.

BOX 34-2 Innovation in Patient Care

Over a century ago, Parkland Hospital in Dallas, Texas, opened to fulfill a mission created by inherent goodwill. None envisioned the fledgling haven for medical treatment to the poor would become the institution it is today. Parkland is a renowned burn care facility and noted for a number of other firsts including the first high-risk maternity unit and the first pediatric trauma unit in the United States. In 1962, Parkland opened one of the largest civilian burn units in the United States and advanced burn care through the fluid resuscitation formula used in more than 80% of the burn units throughout the country.

The new Parkland hospital, opened in 2015, promotes excellence in clinical care, teaching, and research in a technologically advanced and easily accessible environment. The new hospital was designed and built in a thoughtful, deliberate manner using evidence-based healing concepts and involved nursing at every step. The entire hospital is designed with the patient in mind. The patient-centered approach creates a healing environment with single-patient rooms, windows, and natural light as well as more space for family and visitors. An onstage/offstage model provides comfort for patients as well as efficiency for staff. Vendors and staff utilize separate hallways and elevators from those of patients and visitors. The facility is adaptable to future needs.

Nursing Assessment

1. Obtain a thorough history, including:
    a. Causative agent—hot water, chemical, gasoline, flame, tar, radiation PUVA light, etc.

b. Duration of exposure.
c. Circumstances of injury, including whether in closed or open space, accidental or intentional, or self-inflicted.
d. Initial treatment, including first aid, prefacility emergency care (including fluids, intubation, etc.), or care rendered in another facility (emergency department, etc.).
e. Patient's age and preexisting medical problems, such as heart disease, human immunodeficiency virus, drug abuse, diabetes, ulcers, alcoholism, chronic obstructive pulmonary disease (COPD), epilepsy, psychosis, or hepatitis.
f. Current medications—include both prescription and over the counter.
g. Concomitant injuries (eg, from fall, explosions, assaults).
h. Evidence of inhalation injury.
i. Medication and food allergies and tetanus immunization status.
j. Height and weight.

2. Perform ongoing assessment of hemodynamic and respiratory status, condition of wounds, and signs of infection.
3. Perform pain assessment using simple pain scale and observing for signs of pain.

Nursing Diagnoses

- Impaired Gas Exchange related to inhalation injury.
- Ineffective Breathing Pattern related to circumferential chest burn, upper airway obstruction, or ARDS.
- Decreased Cardiac Output related to fluid shifts and hypovolemic shock.
- Ineffective Tissue Perfusion: Peripheral related to edema and circumferential burns.
- Risk for Imbalanced Fluid Volume related to fluid resuscitation and subsequent mobilization 3 to 5 days postburn.
- Impaired Skin Integrity related to burn injury and surgical interventions (donor sites).
- Impaired Urinary Elimination related to indwelling catheter.
- Ineffective Thermoregulation related to loss of skin microcirculatory regulation and hypothalamic response.
- Risk for Infection related to loss of skin barrier and altered immune response.
- Impaired Physical Mobility related to edema, pain, and skin and joint contractures.
- Imbalanced Nutrition: Less Than Body Requirements related to hypermetabolic response to burn injury.
- Risk for Bleeding related to stress response.
- Acute Pain related to burn injury.
- Ineffective Coping related to fear and anxiety.
- Disturbed Body Image related to cosmetic and functional sequelae of burn wound.
- Disturbed Sleep Pattern related to unfamiliar surroundings and pain.

Nursing Interventions

Achieving Adequate Oxygenation and Respiratory Function

1. Provide humidified 100% oxygen until carbon monoxide level is known. (*Caution:* Adjust oxygen flow rate for patient with COPD, as prescribed.) If the patient is stable, try to get the initial ABG on room air.
2. Assess for signs of hypoxemia (anxiousness, tachypnea, tachycardia) and differentiate this from pain.
3. Suspect respiratory injury if burn occurred in an enclosed space.
4. Observe for and report erythema or blistering of the buccal mucosa; singed nasal hairs; burns of lips, face, or neck; and increasing hoarseness.
5. Monitor respiratory rate, depth, rhythm, and cough.
6. Auscultate chest and note breath sounds.
7. Note character and amount of respiratory secretions; report carbonaceous sputum.
8. Observe for signs of inadequate ventilation and begin serial monitoring of ABG levels and oxygen saturation.
9. Provide mechanical ventilation, continuous positive airway pressure, or positive end-expiratory pressure, if requested.
10. Keep intubation equipment nearby and be alert for signs of respiratory obstruction.
11. In mild inhalation injury:
    a. Provide humidification of inspired air.
    b. Encourage coughing and deep breathing.
    c. Promote clearance of secretions through chest physical therapy (see page 187) or intrapulmonary percussive ventilation.
12. In moderate to severe inhalation injury:
    a. Initiate more frequent bronchial suctioning.
    b. Closely monitor vital signs, urine output, and ABG levels.
    c. Administer bronchodilator treatments, as ordered.
    d. For additional respiratory problems, it may be necessary to have patient intubated and placed on mechanical ventilation.

NURSING ALERT Be prepared to assist with early intubation if inhalation injury is suspected. Progressive airway edema is expected in the first 24 hours following a patient with an inhalation injury.

Maintaining Adequate Tidal Volume and Unrestricted Chest Movement

1. Observe rate and quality of breathing; report if progressively more rapid and shallow.

2. Assess tidal volume; report decreasing volume to health care provider.
3. Encourage deep breathing and incentive spirometry (may use sigh control on ventilator, as needed).
4. Place patient in semi-Fowler position to permit maximal chest excursions if there are no contraindications, such as hypotension or trauma.
5. Make sure that chest dressings are not constricting.
6. Prepare the patient for escharotomy and assist, as indicated.

Supporting Cardiac Output

1. Position the patient to increase venous return.
2. Give fluids, as prescribed.
3. Monitor vital signs, including apical pulse, respirations, central venous pressure, pulmonary artery pressures, and urine output at least hourly.
4. Determine cardiac output, as requested.
5. Monitor sensorium.
6. Document all observations and particularly note trends in vital sign changes.

Promoting Peripheral Circulation

1. Remove all jewelry and clothing.
2. Elevate extremities.
3. Monitor peripheral pulses hourly; use Doppler, as necessary.
4. Prepare the patient for escharotomy if circulation is impaired.
5. Avoid tight, constrictive dressings.

Facilitating Fluid Balance

1. Titrate fluid intake, as tolerated. The initial resuscitation formula is only a base.
2. Maintain accurate intake and output records.
3. Weigh the patient daily.
4. Monitor results of serum potassium and other electrolytes.
5. Be alert to signs of fluid overload and heart failure, especially during initial fluid resuscitation and immediately afterward, when fluid mobilization is occurring.
6. Administer diuretics, as ordered.

GERONTOLOGIC ALERT Older patients and those with impaired renal function, cardiovascular disease, and pulmonary disease are more likely to develop fluid overload. Proceed with caution.

Protecting and Reestablishing Skin Integrity

1. Cleanse wounds and change dressings one to two times per day. Use an antimicrobial solution or mild soap and water. Dry gently. This may be done in the hydrotherapy tank, bathtub, shower, or bedside.
2. Perform debridement of dead tissue at this time. May use gauze, scissors, or forceps as appropriate. Try to limit time to 20 to 30 minutes depending on the patient's tolerance. Additional analgesia may be necessary.
3. Apply topical bacteriostatic agents, as directed. Cream or ointment is applied 1/8 inch (3 mm) thick.
4. Dress wounds, as appropriate, using conventional burn pads, gauze rolls, or any combination. Dressings may be held in place, as necessary, with gauze rolls or netting.
5. For grafted areas, use extreme caution in removing dressings; observe for and report serous or sanguineous blebs or purulent drainage. Redress grafted areas according to facility protocol.
6. Observe all wounds daily and document wound status on the patient's record. Report any odor, drainage, cellulitis, bleeding, or signs of infection.
7. Promote healing of donor sites by:
    a. Preventing contamination of donor sites that are clean wounds.
    b. Opening to air for drying postoperatively if gauze or impregnated gauze dressing is used.
    c. Following health care provider's or manufacturer's instructions for care of sites dressed with synthetic materials.
    d. Allowing dressing to peel off spontaneously.
    e. Cleansing healing donor site with mild soap and water when dressings are removed; lubricating site twice daily and as needed.

Preventing Urinary Infection

1. Maintain closed urinary drainage system and ensure patency. Use a catheter impregnated with an antimicrobial agent whenever possible.
2. Frequently observe color, clarity, and amount of urine.
3. Empty drainage bag per facility protocol.
4. Provide catheter care per facility protocol.
5. Encourage removal of catheter and use of urinal, bed pan, or commode as soon as frequent urine output determinations are not required.

Promoting Stable Body Temperature

1. Be efficient in care; do not expose wounds unnecessarily.
2. Maintain warm ambient temperatures.
3. Use radiant warmers, warming blankets, or adjustment of the bed temperature to keep the patient warm.
4. Obtain urine, sputum, and blood cultures for temperatures above 102°F (38.9°C) rectal or core temperature or if chills are present.
5. Provide a dry top layer for wet dressings to reduce evaporative heat loss.

6. Warm wound cleansing and dressing solutions to body temperature.
7. Use blankets in transporting patient to other areas of the hospital.
8. Administer antipyretics, as prescribed.

Avoiding Wound and Systemic Infection

1. Wash hands with antibacterial cleansing agent before and after all patient contact.
2. Use barrier garments—isolation gown or plastic apron—for all care requiring contact with the patient or the patient's bed.
3. Cover hair and wear mask when wounds are exposed or when performing a sterile procedure.
4. Use sterile examination gloves for all dressing changes and all care involving patient contact.
5. Maintain proper concentration of topical antibacterial agents used in wound care.
6. Be alert for reservoirs of infection and sources of cross-contamination in equipment and assignment of personnel.
7. Check history of tetanus immunization and provide passive or active tetanus prophylaxis as prescribed.
8. Change IV tubing and central line catheters according to Centers for Disease Control and Prevention recommendations.
9. Administer antibiotics, as prescribed, and be alert for toxic effects and incompatibilities.
10. Assess wounds daily for local signs of infection—swelling and redness around wound edges, purulent drainage, discoloration, and loss of grafts.
11. Be alert for early signs of septicemia, including changes in mentation, tachypnea, and decreased peristalsis as well as later signs, such as increased pulse, decreased blood pressure (BP), increased or decreased urine output, facial flushing, increased and later decreased temperatures, increasing hyperglycemia, and malaise. Report to health care provider promptly.
12. Promote optimal personal hygiene for the patient, including daily cleansing of unburned areas, meticulous care of teeth and mouth, shampooing of hair every other day, shaving of hair in or near burned areas, and meticulous care of IV and urinary catheter sites.
13. Inspect the skin carefully for signs of pressure and breakdown.
14. Observe for and report signs of thrombophlebitis or catheter-induced infections.
15. Prevent atelectasis and pneumonia through chest physical therapy, postural drainage, meticulous pulmonary technique, and, if indicated, tracheostomy care.

DRUG ALERT Although pseudomonas has been and continues to be a danger to the burn patient, hospital-acquired MRSA is now another serious threat. Staple antibiotics, such as vancomycin and gentamicin, are not effective. Now, linezolid, clindamycin, sulfamethoxazole–trimethoprim, and even mupirocin ointment are being used to combat MSRA—not only in the hospital setting, but in most burn clinics as well.

Promoting Mobility and Ability to Perform Activities of Daily Living (ADLs)

1. Ensure consultation with physical and occupational therapists, who will exercise the patient at least once or twice daily, as necessary.
2. Encourage the patient to be as active as possible and to perform active ROM exercises throughout the day.
3. Maintain splints in proper position as prescribed by occupational therapist; remove splints on regular schedule and observe for signs of skin irritation before reapplying.
4. Position the patient to decrease edema and avoid flexion of burned joints.
5. Coordinate pain management and other care to allow optimal effort during periods of physical exercise.
6. Initiate passive and active ROM and breathing exercises during early postburn period.
7. Plan with therapists for a conditioning regimen that gradually increases energy expenditure and tolerance for activity.
8. Act as advocate for the patient's need for rest by coordinating the patient's therapeutic and social activities and prioritizing interventions and visits.
9. Help the patient achieve adequate relaxation and sleep through medication and environmental measures.

Ensuring Adequate Nutrition

1. Weigh the patient daily with dressings removed.
2. Obtain consultation from dietitian for calculation of nutritional needs based on age, weight, height, and burn size. Two of the more popular formulas used to estimate nutritional needs are the Harris-Benedict and Curreri formulas.
3. Administer vitamins and mineral supplements, as prescribed. Deficiencies in zinc, copper, and selenium can occur after a burn.
4. Minimize metabolic stress by allaying fears, pain, and anxiety and by maintaining a warm environmental temperature.
5. Generally, for burns less than 10% TBSA, a well-balanced diet with emphasis on protein intake is necessary. For 10% to 20% TBSA, a high-protein, high-calorie diet is ordered. For 20% TBSA and greater, early enteral nutrition believed to decrease the metabolic response and improve outcomes. When the patient is ready for oral fluids, observe tolerance. If there are no problems, advance the diet, as tolerated.
6. Provide nasogastric (NG) tube feedings, as prescribed.
7. Administer IV hyperalimentation and fat emulsions prescribed with usual nursing precautions.
8. Keep record of caloric intake.
9. Encourage the patient to feed self.
10. Supplement meals with between-meal high-protein, high-calorie snacks, such as milkshakes or foods brought from home according to patient's preference.

Preventing Paralytic Ileus and Stress Ulcer

1. Keep on NPO status until bowel sounds resume.
2. Assess bowel sounds every 2 to 4 hours while acutely ill. (Decreased peristalsis may be an early sign of septicemia.)
3. Recent practice now encourages beginning tube feeds within 24 hours of the initial injury to help preserve the function of the gut and prevent paralytic ileus or stress ulcer.
4. Administer histamine-2 blockers and antacids, as prescribed. This will help prevent or diminish the occurrence of stress (Curling's) ulcers.
5. Heed complaints of nausea while intubated by checking for abdominal distention, tube placement, and residual aspirate.
6. Provide mouth care every 2 hours while intubated.

EVIDENCE BASE Mandell, S. P., & Gibran, N. S. (2014). Early enteral nutrition for burn injury. *Advances in Wound Care*, *3*(1), 64–70.

Reducing Pain

1. Assess for pain periodically; do not wait for complaints of pain to intervene. Common opioids used include morphine, fentanyl, hydromorphone, and propofol administered via IV line or by patient-controlled analgesia. Oral agents such as oxycodone, hydrocodone, and long-acting continuous-release agents are appropriate once the patient is tolerating PO food and fluids.
2. Determine previous experience with pain, the patient's response, and coping mechanisms.
3. Offer analgesics before wound care or before particularly painful treatments. Analgesia given orally should be administered 30 to 45 minutes before the procedure. Ketamine IV is now more commonly used than before. It is also becoming more popular to use conscious sedation for dressing changes.
4. Change the patient's position when possible, supporting extremities with pillows.
5. Reduce anxiety by such approaches as sensory-oriented explanations of procedures.
6. Teach relaxation techniques, such as imagery, breathing exercises, and progressive muscle relaxation, to help the patient cope with pain.
7. Allow the patient to make choices regarding care whenever possible, thus allowing some measure of input and control in care.
8. Greater emphasis is now focusing on pain management both from an inpatient and an outpatient perspective. Midrange analgesics are often used rather than just morphine. Medication dosages are being increased if patient is on a ventilator. It is not always possible to make a conscious patient completely pain-free, but increased comfort is the goal.

NURSING ALERT Check with your state board of nursing and facility policy to determine

requirements for administering conscious sedation. Requirements may dictate that an anesthesiologist be in attendance or that the nurse be trained in intubation and airway management.

Enhancing Coping

1. Assess the patient's coping mechanisms from past history and current behavior.
2. Provide opportunities for the patient to express thoughts, feelings, fears, and anxieties regarding injury.
3. Explore with the patient alternative mechanisms for coping with the burn injury and its consequences.
4. Assure the patient of the normality of responses and the effect that time and healing will likely have on current concerns.
5. Interpret patient behavior to concerned family members and significant others.
6. Respect current coping mechanisms and discourage them only when an appropriate alternative can be provided.
7. Support family and friends' communications and visits if this is noted to help the patient.
8. Assess need for mental health consultation.
9. Offer antianxiety medications, as prescribed.

Preserving Positive Body Image

1. Gather data on the patient's preburn self-image and lifestyle.
2. When ready, encourage the patient to express concerns regarding changes in self-image or lifestyle that may result from burn injury.
3. Be honest, but positive, in responding to the patient and family.
4. Positively reinforce appropriate, effective coping mechanisms.
5. Arrange for the patient to see face (if burned) with appropriate supportive personnel before being placed/transferred to a room with access to a mirror.
6. Arrange for the patient to talk with other patients who have had a similar injury and are progressing satisfactorily.
7. Encourage participation in a burn survivor's group such as the Phoenix Society or other local support group.
8. Use and emphasize the concept of being a burn survivor. Survivors continue onward. Avoid the use of the term "burn victim" because it enhances the sick role.
9. Refer to psychological services, as needed. Consider other areas of the patient's traumatic experience that may require intervention as well.

Promoting Sleep

1. Assess patient's pain level at hour of sleep and administer pain medications, as needed.
2. Ensure comfort with room temperature and splints.
3. Administer sleep medications, as needed.
4. Schedule dressing changes accordingly to accommodate patient's sleep–wake cycle.

Community and Home Care Considerations

1. Demonstrate and explain wound care procedures to be continued after discharge:
   a. Wash hands.
   b. Clean small open wounds with mild soap in tub or shower.
   c. Rinse well with tap water.
   d. Pat dry with clean towel.
   e. Apply prescribed topical agent and dressing.
2. Assess for and teach patient to observe for local signs of wound infection:
   a. Increased redness of normal skin around burn area.
   b. Increased or purulent drainage.
   c. Increased pain and foul odor in burn area.
   d. Elevated body temperature.
3. Coordinate physical therapy consultation, and encourage patient to develop a schedule to incorporate exercise regimen as prescribed by physical therapist.
   a. Suggest scheduling exercises immediately after wound cleansing and application of topical agent because the skin may be more pliable and less sensitive to stretching then.
4. Instruct the patient in use and care of splints and pressure garments.
   a. Cleanse with mild soap and rinse well daily.
   b. Keep away from heat; dry garment by laying it flat on towels.
   c. Wear garment, as prescribed. This is usually 23 out of 24 hours/day. The garment is usually worn for 1 to 1½ years.
   d. Small open wounds should be covered with a light dressing under splints or pressure garments.
   e. Observe for signs of skin breakdown. Reassure the patient that small blister formation is normal and generally lessens after the first year.
   f. Wear/bring splints and pressure garments to follow-up visits to be checked for proper fit.

TRANSITIONAL CARE ALERT Ensure the patient or family member is able to demonstrate how they will perform a dressing change from start to finish prior to going home. Confidence with wound care upon discharge may decrease the risk of the patient returning with an infection because of fear of changing the dressings on their own.

Patient Education and Health Maintenance

Health education is closely related to rehabilitation as the burn patient prepares to return to a productive place in society. Functional and cosmetic reconstruction is accomplished and the patient attempts to integrate a new self-concept into social realities. Broadly viewed, health education focuses on biologic, psychological, and

social parameters.

1. Assist the patient in transition from dependence on the health team to independence by assisting the patient to communicate needs and functional abilities to others.
2. Guide the patient in thinking positively about self. Promote ability to redirect others' attention from the scarred body to the self within.
3. Instruct the patient in measures to lubricate and enhance comfort of healing skin:
    a. After cleaning, use moisturizers such as cocoa butter or other nonperfumed hand lotion at least twice per day or more frequently, as needed.
    b. Wear clean white underwear and clothing free from irritating dyes until wounds are well healed.
    c. Take antipruritics, as prescribed.
    d. Stay in a cool environment if itching occurs.
    e. Protect the skin from further trauma; use a sunscreen with a sun protection factor of 24 or higher.
    f. Discuss summer precautions, which should include a hat with a full, wide brim if there were facial or neck burns. Also, limit exposure to sun because the affected areas will sunburn more easily and tan more deeply.
    g. Advise the patient that if wearing a pressure vest with or without sleeves, or tights, the Occupational Safety and Health Administration standards for work in a hot environment should be used. The patient should also be aware of the need for oral fluid replacement.
4. Review with the patient and family common emotional responses during convalescence (depression, withdrawal, grieving, dreaming, anxiety, guilt, excessive sensitivity, emotional lability, insomnia, and fear of future), and discuss usual temporary nature of these as well as effective coping mechanisms.
    a. There may be some psychological sequelae that will require long-term intervention, such as image adjustment disorders or posttraumatic stress issues. If not already in place, psychological referral is appropriate as an outpatient.
    b. Make sure that the patient has a phone number or referral to the counselor to make follow-up appointments, if desired.
5. Make sure that information has been given about follow-up evaluations and home health care services, as needed, in the interim.
6. Offer to connect the patient with a peer support program for burn survivors if available.
7. For additional information and support, contact agencies such as the American Burn Association (*www.ameriburn.org*) or the Phoenix Society for Burn Survivors (*www.phoenix-society.org*). The Phoenix Society is a national foundation with local chapters whose primary function is support of other burn survivors. It has a toll-free number that burn survivors may use: (800) 888-BURN (2876).

Evaluation: Expected Outcomes

- Carboxyhemoglobin level below 10%, ABG levels within normal limits, and respiratory rate 12 to 28 breaths/minute.

- Tidal volume within normal limits.
- Pulse 110 to 120 mm Hg or below and BP stable.
- Peripheral pulses strong.
- Weight stable, no edema, and lungs clear.
- Wounds clean and granulating.
- Catheter patent, urine clear, and quantity sufficient.
- Temperature normal to low-grade fever; no chills.
- No signs of infection.
- Normal ROM achieved and performing ADLs independently.
- Less than 5% weight loss from baseline.
- No gastric distention and aspirate and stool Hemoccult negative.
- Reports minimal pain after analgesic administration.
- Uses appropriate coping mechanisms.
- Verbalizes fears and concerns after viewing self in mirror.
- Sleeping 2- to 4-hour intervals; falls back to sleep easily.

OVERVIEW AND ASSESSMENT

Emergency medicine is the care, diagnosis, and treatment of unforeseen illness or injury. It is provided to patients with conditions ranging from minor to serious or life-threatening. The philosophy of emergency care includes the concept that an emergency is whatever the patient or family considers it to be. Emergency nursing is a dynamic and evolving practice that deals with unstable, undiagnosed patients usually presenting unexpectedly. See Standards of Care Guidelines 35-1, page 937.

STANDARDS OF CARE GUIDELINES 35-1

Emergency Assessment and Intervention

When a patient presents with a potentially life-threatening condition, proceed swiftly with the following:

- Call for help.
- Ensure the area is safe for you to enter, with no live electric current, hazardous materials, dangerous persons, or other threats.
- Remove the patient from potential source of danger, such as live electric current, water, or fire. If hazardous materials are present, consult protocols from the Occupational Safety and Health Association (OSHA) for decontamination procedures.
- Determine whether patient is conscious.
- Assess for adequate airway, breathing, and circulation in systematic manner. If any of these are absent, or inadequate, begin basic life support.
- Assess pupillary reaction and level of responsiveness to voice or touch, as indicated.
- If the patient is unconscious or has sustained a significant head injury, assume there is a spinal cord injury and maintain C-spine stabilization.
- Remove clothing to assess for wounds and skin lesions as indicated. Control any hemorrhage, as needed.
- When help arrives, assist with further assessment and transport, as needed.

This information should serve as a general guideline only. Each patient situation presents a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Emergency Assessment

When first making contact with an emergency patient, it is essential that a systematic approach is used to ensure all factors are identified. The primary and secondary surveys provide the emergency nurse with a methodical approach to help identify and prioritize patient needs.

Primary Survey

The initial, rapid ABCD (**a**irway, **b**reathing, **c**irculation, and neurologic **d**isability) assessment of the patient is meant to identify life-threatening problems. If conditions are identified that present an immediate threat to life, you must stop and take corrective action prior to moving on to the next steps.

ABCD–AVPU

1. **A**—Airway: Does the patient have an open airway? Is the patient able to speak, swallow, or cry? Check for airway obstructions such as loose teeth, foreign objects, bleeding, vomitus, or other secretions. Immediately treat anything that compromises the airway. Never do a blind finger sweep of an airway.
2. **B**—Breathing: Is the patient breathing adequately? Assess for equal rise and fall of the chest (check for bilateral breath sounds), respiratory rate and pattern, skin color, use of accessory muscles, adventitious breath sounds, integrity of the chest wall, and position of the trachea. All major trauma patients require supplemental oxygen via a nonrebreather mask at 12 to 15 L/minute. Dress any penetrating chest injuries with occlusive dressings.
3. **C**—Circulation: Is circulation adequate? Can you palpate central and peripheral pulses? What are the quality of the pulses (strong, weak, slow, rapid)? Is the skin warm and dry? Is the skin color normal? What is the capillary refill? Obtain a blood pressure (BP; in both arms if chest trauma or dissecting aortic aneurysm is suspected). Is there any major bleeding?
4. **D**—Disability: Assess level of consciousness and pupils (a more thorough neurologic survey will be completed in the secondary survey). Assess level of consciousness using the AVPU scale:
    a. **A**—Is the patient alert? Are they looking at you and responding?
    b. **V**—Does the patient respond to voice? Do they open their eyes or respond when you call them?
    c. **P**—Does the patient respond to painful stimulus? Do they respond to sternal rub or nail bed pressure?
    d. **U**—The patient is unresponsive even to painful stimulus.

Secondary Assessment

The secondary assessment is a brief, but thorough, systematic assessment designed to identify all injuries. The steps include *Expose/environmental* control, *Full* set of vital signs, *Five* interventions, *Facilitate* family presence, and *Give* comfort measures. If your emergency department (ED) has enough staff, these interventions may be assigned to multiple staff members and performed simultaneously.

1. Expose/environmental control: It is necessary to remove all of the patient's clothing to identify all injuries. You must then prevent heat loss by using warm blankets, overhead warmers, and warmed

intravenous (IV) fluids unless induced hypothermia is indicated. If your facility has a dedicated trauma or resuscitation room, keep the ambient temperature elevated to prevent heat loss.

2. Full set of vital signs:
   a. Obtain a full set of vital signs including BP, heart rate, respiratory rate, temperature, and oxygen saturation.
   b. As stated previously, obtain BP in both arms if chest trauma or dissecting aortic aneurysm is suspected.
   c. Institute continuous cardiac monitoring.
   d. Assess Glasgow Coma Scale (GCS) (see page 354) and pain scores.
3. Five potential interventions:
   a. Vascular access with two large-bore IV catheters, if possible.
   b. Pulse oximetry to measure the oxygen saturation; consider capnography to measure end-tidal carbon dioxide ($EtCO_2$), noninvasive ultrasonic cardiac output monitor, and 12-lead electrocardiogram (ECG).
   c. Indwelling urinary catheter (do not insert if you note blood at the meatus, blood in the scrotum, or if you suspect a pelvic fracture).
   d. Gastric tube (if there is evidence of facial fractures, insert the tube orally rather than nasally).
   e. Laboratory studies may include type and cross-matching, complete blood count (CBC), urine drug screen, blood alcohol, electrolytes, prothrombin time and partial thromboplastin time, arterial blood gas (ABG), venous blood gases (VBG), lactate, lipase, amylase, and pregnancy test, if applicable.
4. Facilitate family presence: Family presence is important during unexpected, potentially life-threatening events. They often have information that is critical in formulating the correct treatment plan. It is important to assess and respect the family's needs and wishes. Resuscitation rooms are often loud and appear chaotic. Assigning a staff member to any family wishing to be present can do much to alleviate their anxiety and assure them that everything is being done to help their loved one. If a family member does not wish to be present, providing them with a quiet area to wait and assigning a staff member as a contact person or liaison can be helpful.
5. Give comfort measures including pain management and verbal reassurance: Do not forget to give comfort measures to the family as well as the patient during the resuscitation process.

History

1. Obtain prehospital information from emergency personnel, patient, family, or bystanders using the mnemonic MIVT.

   M—Mechanism of injury: It is helpful to understand the mechanism of injury to anticipate probable injuries. It is particularly helpful in motor vehicle accidents to know such information as external and internal damage to the car (or at least if the car was drivable after the accident), if the patient was ejected, if they were wearing a seat belt, if airbags were deployed, and the period of time elapsed before the patient received medical attention.

I—Injuries sustained or suspected: Ask prehospital personnel to list any injuries that they have identified. Most prehospital providers will have completed a rapid trauma survey, including looking for DCAP/BTLS (deformities, contusions, abrasions, punctures/burns, tenderness, lacerations, and swelling).

V—Vital signs: What were the prehospital vital signs?

T—Treatment: What treatment did the patient receive before arriving at the hospital and what was the patient's response to those interventions?

2. If the patient is conscious, it is essential to ask what happened. How did the accident occur? Why did it happen? A fall, for example, may not be a simple fall—perhaps, the patient blacked out and then fell. If the patient is conscious and time permits, explore the chief complaint through the OPQRST mnemonic.

   O—Onset: When did they first notice symptoms? Was today the first time? Has it been ongoing? Is it getting progressively worse?

   P—Provokes, Palliates, and Precipitates: What makes the symptoms better or worse?

   Q—Quality: How would they describe the discomfort? Burning, throbbing, aching, and like an electric shock are all commonly used to describe the quality of pain.

   R—Region and Radiates: Can the patient point to the pain with one finger? Does it move or shoot anywhere?

   S—Severity and Associated Symptoms: How do they rate their symptom? Is it accompanied by anything else such as numbness, tingling, or nausea?

   T—Timing: Have the symptoms been constant or do they come and go? How often?

3. Obtain past medical history from the patient or a family member or friend; it may be helpful to utilize the mnemonic SAMPLE to assist in organizing history information:

   S—Signs and symptoms, including chief complaint and OPQRST.

   A—Allergies to foods and medications.

   M—Medications, including herbal supplements and over-the-counters.

   P—Past medical and surgical history.

   L—Last oral intake.

   E—Events leading up to the incident.

4. Plus any history of alcohol or illicit drug use.

NURSING ALERT To obtain a good descriptive history, use open-ended questioning.

Head-to-Toe Assessment

The head-to-toe assessment begins with assessment of the patient's general appearance, including body position or any guarding or posturing. Work from the head down, systematically assessing the patient one body area at a time.

1. Head and face.
    a. Inspect for any lacerations, abrasions, contusions, avulsions, puncture wounds, impaled objects, ecchymosis, or edema. The hair can hide injuries, so take time to do a complete inspection. Scalp lacerations also tend to bleed profusely, further obscuring the area from quick inspections.
    b. Gently palpate for crepitus, crackling, or bony deformities.
    c. Inspect ears and nares for any bleeding or drainage; if present, check for halo sign.
2. Neck (ensure proper C-spine stabilization is maintained).
    a. Inspect for any punctures, lacerations, contusions, swelling, tracheal deviation, JVD, or subcutaneous emphysema.
    b. Check for stomas or MedicAlert tags.
    c. Gently palpate for midline cervical tenderness.
3. Chest.
    a. Inspect for breathing effectiveness, paradoxical (uneven) chest wall movement, and disruptions in chest wall integrity (lacerations, punctures, subcutaneous emphysema).
    b. Auscultate for bilateral breath sounds and adventitious breath sounds.
    c. Auscultate heart tones (muffled).
    d. Gently palpate for bony crepitus or deformities.
4. Abdomen/flanks.
    a. Inspect for lacerations, abrasions, contusions, avulsions, puncture wounds, impaled objects, ecchymosis, edema, scars, eviscerations, or distention.
    b. Auscultate for the presence of bowel sounds.
    c. Gently palpate for rigidity, guarding, masses, or areas of tenderness.
5. Pelvis/perineum.
    a. Inspect for lacerations, abrasions, contusions, avulsions, puncture wounds, impaled objects, ecchymosis, edema, or scars. Look for blood at the urinary meatus and vagina in females. Look for priapism in males (which could indicate spinal cord injury).
    b. Gently palpate for pelvic instability or tenderness (do not rock the pelvis).
6. Neurologic/spinal (maintaining proper stabilization).
    a. Reassess mental status.
    b. Gently palpate for midline bony spinal tenderness.
    c. Check for paresthesias and determine sensory level.
    d. Check motor function and sphincter tone.
7. Extremities.
    a. Inspect skin color and temperature. Look for signs of injury and bleeding. Does the patient have movement in all four extremities? Touch the patient on a distal extremity and ask them to identify the part you are touching.
    b. Gently palpate peripheral pulses, any bony crepitus, or areas of tenderness.

c. Check capillary refill.

d. Gently palpate extremities for compartment firmness or signs of compartment syndrome.

NURSING ALERT Any penetrating chest wound has the potential to rapidly cause a life-threatening tension pneumothorax and must be treated immediately.

NURSING ALERT Pregnant trauma patients present a unique set of challenges. While performing assessments and interventions, a towel or roll should be placed under the right side of the backboard, tipping the patient slightly to the left and preventing fetal compression of the inferior vena cava and decreased blood return to the heart.

Focused Assessment

Any injuries that were identified during the primary and secondary surveys require a detailed assessment, which will typically include a team approach and radiographic studies.

Emergency Triage

Triage is a French verb meaning "to sort." Emergency triage is a subspecialty of emergency nursing, which requires specific, comprehensive educational preparation. The goal of an efficient triage system is to rapidly connect a patient with the proper level of care and the correct resources in the shortest amount of time. Upon entering an ED, patients are greeted by a triage nurse, who will perform a rapid assessment, to include a general impression, chief complaint, immediate or potential life threats, and pertinent history, and then make a decision about the patient's acuity and the resources needed. These decisions can often be difficult if the patient has an altered mental status, is intoxicated, or is otherwise impaired. Thus, the primary role of the triage nurse is to make acuity and disposition decisions and set priorities while maintaining awareness for potentially violent or communicable disease situations. Secondary triage decisions involve the initiation of triage-extended practices, such as the ordering of standardized labs or radiology studies. With the waiting times in EDs because of overcrowding becoming an increasing problem, the accuracy of the triage nurse in assigning acuity level is of critical importance. With extended wait times, triage is an ongoing process, with the triage nurse frequently reevaluating those who are waiting for changes in condition and updating their status, as needed.

Priorities of Care and Triage Categories

Standardized 5-level triage systems, such as the Australasian Triage Scale, the Canadian Triage and Acuity Scale, and the Emergency Severity Index, have been developed and proven through research to possess utility, validity, reliability, and safety. All three systems utilize similar time frames and are evidence based (the Manchester Triage System is a consensus-based algorithm approach, which utilizes longer time frames).

Triage Level 1: Immediately Life-Threatening or Resuscitation

1. Conditions requiring immediate clinician assessment. Any delay in treatment is potentially life- or limb-threatening. These are the patients that are in active danger of dying if there is no immediate intervention.
2. Includes conditions such as:
    a. Airway or severe respiratory compromise.
    b. Cardiac arrest.
    c. Severe shock.
    d. Symptomatic cervical spine injury.
    e. Multisystem trauma.
    f. Altered level of consciousness (LOC) (GCS less than 10).
    g. Eclampsia.
    h. Acute mental status changes or unresponsiveness.

Triage Level 2: Imminently Life-Threatening or Emergent

1. These are conditions that are not in immediate danger, but have the potential to deteriorate rapidly if not

treated.

2. Conditions include:
    a. Head injuries.
    b. Trauma.
    c. Conscious overdose.
    d. Severe allergic reaction without airway compromise.
    e. Chemical exposure to the eyes.
    f. Chest pain without hemodynamic instability.
    g. Back pain.
    h. GI bleed with unstable vital signs.
    i. Stroke with deficit.
    j. Severe asthma without airway compromise.
    k. Abdominal pain in patients older than age 50.
    l. Vomiting and diarrhea with dehydration.
    m. Fever in infants younger than age 3 months.
    n. Acute psychotic episode.
    o. Severe headache.
    p. Any pain greater than 7 on a scale of 1 to 10.
    q. Any sexual assault.
    r. Any neonate age 7 days or younger.

Triage Level 3: Potentially Life-Threatening/Time Critical or Urgent

1. Conditions requiring urgent care-level activities with stable vital signs, but have the potential to deteriorate and utilize multiple resources.
2. Conditions include:
    a. Alert head injury with vomiting.
    b. Mild to moderate asthma.
    c. Moderate trauma.
    d. Abuse or neglect.
    e. GI bleed with stable vital signs.
    f. History of seizure and alert on arrival.

Triage Level 4: Potentially Life-Serious/Situational Urgency or Semiurgent

1. Stable conditions that use few resources.
2. Conditions include:
    a. Alert head injury without vomiting.
    b. Minor trauma.

c. Vomiting and diarrhea in patient older than age 2 without evidence of dehydration.

d. Earache.

e. Minor allergic reaction.

f. Corneal foreign body.

g. Chronic back pain.

Triage Level 5: Less/Nonurgent

1. Stable conditions that utilize little to no resources.
2. Conditions include:
   a. Minor trauma, such as minor cuts, abrasions, bruises, etc.
   b. Minor symptoms such as rhinorrhea, sneezing, conjunctivitis, etc.

NURSING ALERT When working with pediatric patients in a triage setting, it is important to remember that they can deteriorate rapidly. Pediatric patients should be triaged by those experienced in identifying the subtle clues that often precede this rapid deterioration.

Psychological Considerations

Serious illness or trauma is an insult to physiologic and psychological homeostasis; it requires physiologic and psychological healing. Both patients and families experience high levels of anxiety when being treated in the emergency department. It is important for the emergency nurse to recognize, understand, and alleviate these anxieties whenever possible.

Approach to the Patient

1. Understand and accept the basic anxieties of the acutely ill or traumatized patient. Be aware of the patient's fear of death, disablement, and isolation.
    a. Personalize the situation as much as possible. Speak, react, and respond in a warm manner; give reassurance.
    b. Give explanations on a level that the patient can grasp. An informed patient can cope with psychological/physiologic stress in a more positive manner.
    c. Accept the rights of the patient and family to have and display their own feelings.
    d. Maintain a calm and reassuring manner—helps the emotionally distressed patient or family to mobilize their psychological resources.
    e. Include the patient's family or significant others if the patient wishes.
    f. Encourage the patient or family to reach out to their support system. Often friends, other family members, or clergy can be of great comfort.
2. Understand and support the patient's feelings concerning loss of control (emotional, physical, and intellectual). Whenever possible, give the patient options and choices. This can help alleviate some of their feelings of helplessness.
3. Speak to the unconscious patient. Touch, call by name, and explain every procedure that is done. Avoid making negative comments about the patient's condition.
    a. Orient the patient to person, time, and place as soon as he or she is conscious; reinforce by repeating this information.
    b. Bring the patient back to reality in a calm and reassuring way.
    c. Encourage the family, when possible, to touch the patient and aid in orienting the patient to reality.
4. Be prepared to handle all aspects of acute illness and trauma; know what to expect and what to do. When in doubt, stop, take a deep breath, and refocus. This will help alleviate the nurse's anxiety and increase the patient's confidence.

Approach to the Family

1. Inform the family where the patient is and give as much information as possible about the treatment he or she is receiving.
2. Consider allowing a family member to be present during the resuscitation. Assign a staff person to the family member to explain procedures and offer comfort.

3. Recognize the anxiety of the family and allow them to talk about their feelings. Acknowledge expressions of remorse, anger, guilt, and criticism.
4. Allow the family to relive the events, actions, and feelings preceding admission to the ED.
5. Deal with reality as gently and quickly as possible; avoid encouraging and supporting denial.
6. Assist the family to cope with sudden and unexpected death. Some helpful measures include the following:
    a. Take the family to a private place.
    b. Talk to all of the family together so they can mourn together.
    c. Assure the family that everything possible was done; inform them of the treatment rendered.
    d. Avoid using euphemisms such as "passed on." Show the family that you care by touching, offering coffee.
    e. Allow family to talk about the deceased—permits ventilation of feelings of loss. Encourage family to talk about events preceding admission to the ED.
    f. Encourage family to support each other and to express emotions freely—grief, loss, anger, helplessness, tears, and disbelief.
    g. Avoid volunteering unnecessary information (eg, patient was drinking).
    h. Avoid giving sedation to family members—may mask or delay the grieving process, which is necessary to achieve emotional equilibrium and prevent prolonged depression.
    i. Be cognizant of cultural and religious beliefs and needs.
    j. Encourage family members to view the body if they wish—to do so helps to integrate the loss (cover mutilated areas).
        i. Prepare the family for visual images and explain any legal requirements.
        ii. Go with family to see the body.
        iii. Show acceptance of the body by touching to give family permission to touch and talk to the body.
        iv. Spend a few minutes with the family, listening to them.
        v. Allow the family some private time with the body, if appropriate.
7. Encourage the ED staff to discuss among themselves their reaction to the event to share intense feelings for review and for group support. Organize a formal debriefing session for staff if warranted by circumstances of the event.

Pain Management

Pain is an unpleasant sensory and emotional experience associated with actual or potential tissue damage and is also associated with significant morbidity. Pain inhibits immune function and has detrimental effects on cardiovascular, respiratory, GI, and other body systems. Over 60% of patients report pain on arrival at ED, making pain the most common patient complaint. It is imperative to adequately assess, monitor, and relieve pain in the ED. Despite this, significant evidence–practice gaps continue to be identified with underestimation and undertreatment of pain, as well as gaps in pain documentation, despite available clinical practice guidelines. In general, geriatric and pediatric patients tend to have their pain underestimated and undertreated more frequently than adults do. Pain may be somatic or visceral, acute or chronic, or centrally or peripherally generated.

Primary Assessment

1. ABCD.
2. Evaluate pain using the OPQRST mnemonic.
3. Assess pain score using a pain rating tool, such as the numeric rating scale, visual analogue scale, Wong-Baker FACES pain scale (see page 1151), FLACC (faces, legs, activity, cry, and consolability) behavioral scale, verbal rating scale, or Abbey pain scale.

Primary Interventions

1. Pain is always subjective. Never doubt that a patient has pain based on how they look.
2. Establish a supportive relationship with the patient.
3. Respect the patient's response to pain and its management.
4. Educate the patient regarding methods of pain relief, preventive measures, and expectations.
5. Establish a baseline pain level, as well as a pain level the patient would consider tolerable.
6. Administer pharmaceutical and nonpharmaceutical pain control.
7. Monitor the patient's response to and effectiveness of treatment.
8. If initial interventions do not bring pain down to the tolerable level, explore other options.
9. Always reassure your patient and let them know you take their pain seriously.

NURSING ALERT Pain relief is a moral, humane, and physiologic imperative.

CARDIOPULMONARY RESUSCITATION AND AIRWAY MANAGEMENT

See additional online content: Procedure Guidelines 35-1–35-4

PROCEDURE GUIDELINES 35-1

Cardiopulmonary Resuscitation

EQUIPMENT

- Backboard
- Oral airway
- Bag-valve-mask (BVM) device
- Oxygen
- IV setup
- Defibrillator
- Emergency cardiac drugs
- Cardiac monitor
- Electrocardiograph machine
- Intubation equipment
- Suction

PROCEDURE

Nursing Action	Rationale
Responsiveness	
1. Determine unresponsiveness: tap or gently shake patient while shouting, "Are you okay?"	1. Prevents injury from attempted resuscitation on a person who is not unconscious.
2. Activate emergency medical service (call local emergency telephone number or 911) if outside facility.	2. Obtain help as soon as possible.
3. Place the patient supine on a firm, flat surface. Kneel at the level of the patient's shoulders. If he or she has suspected head or neck trauma, he or she should not be moved unless it is absolutely necessary (eg, at the site of an accident, fire, or other unsafe environment).	3. Enables the rescuer to perform rescue breathing and chest compression without changing position.
Circulation-Airway-Breathing	
Determine if a pulse is present while checking for signs of breathing	
1. Palpate the carotid or femoral pulse for no more than 10 sec, while looking for signs the patient is attempting to breathe. If pulse is not palpable, start chest compressions.	1. Cardiac arrest is recognized by a lack of palpable pulses in the central arteries of a nonresponsive, apneic patient. For patients who are apneic but have a clearly palpable central pulse, begin rescue breathing with a BVM device or pocket mask at a rate of 1 breath every 5 to 6 sec.
External Chest Compressions	
Chest compressions consist of a sequence of rhythmic applications of pressure over the lower half of the sternum, which provides circulation to the vital organs	
1. Kneel as close to the side of the patient's chest as possible, placing the heel of one hand on the lower half of the sternum, taking care to avoid the xiphoid process. Fingers may be interlaced or extended but care must be taken to keep them off the chest.	1. Ensure the main force of the compression is on the sternum by placing the long axis of the hand on the long axis of the sternum.
2. Keep your arms straight and your elbows locked. Ensure your shoulders are directly over your hands and quickly and forcefully depress the patient's sternum straight down to a depth of at least 2 inches.	2. Keeping your arms straight and your elbows locked allows a greater force to be delivered with each compression and aids in preventing fatigue
3. Deliver 30 compressions at a rate of *at least* 100 compressions a minute. Always allow for complete chest recoil after each compression without taking your hands off of the chest between compressions.	3. Allowing complete chest recoil gives the heart time and room to fill with blood. A partially compressed heart will eject less blood than one that is allowed to fill properly.

Nursing Action	Rationale
4. Taking no more than 10 sec, open the airway and deliver 2 breaths	4. Total "hands-off" time between the end of one set of 30 compressions and the start of the next needs to be less than 10 sec to ensure adequate circulation.
a. Head-tilt/chin-lift maneuver: Place one hand on the patient's forehead and apply firm backward pressure with the palm to tilt the head back. Then, place the fingers of the other hand under the bony part of the lower jaw near the chin and lift up to bring the jaw forward and the teeth almost to occlusion.	a. In the absence of sufficient muscle tone, the tongue or epiglottis will obstruct the pharynx and larynx. This supports the jaw and helps tilt the head back.
b. If a cervical spine injury is suspected, use the jaw-thrust maneuver: Grasp the angles of the patient's lower jaw and, lifting with both hands, one on each side, displace the mandible forward while maintaining C-spine immobility.	b. The jaw-thrust technique without head tilt is the safest method for opening the airway in the presence of suspected neck injury.
c. Perform rescue breathing by using a pocket mask or other barrier device	c. Mouth to mouth is only done in extreme circumstances in the hospital setting.
d. While keeping the patient's airway open, place the pocket mask on the patient's face, making sure to maintain a good seal. Take a deep breath and ventilate the patient with two breaths of just enough volume to see chest rise (each over 1 sec), taking a breath after each ventilation. If the initial ventilation attempt is unsuccessful, reposition the patient's head and repeat rescue breathing.	d. Ensuring a good seal with a pocket mask takes practice, but is essential in preventing air leakage. Full breaths are no longer required as gastric inflation can occur. Ventilate just enough to get the chest to rise.
5. When a second rescuer arrives, have them begin compressions while you take over ventilations.	5. The ratio of compressions to ventilations for the adult victim is 30:2 for one- and two- rescuer CPR.
6. While resuscitation proceeds, simultaneous efforts are made to obtain and use special resuscitation equipment to manage breathing and circulation and provide definitive care.	6. Definitive care includes defibrillation, pharmacotherapy for dysrhythmias and acid-base disturbances, and ongoing monitoring and skilled care in an intensive care unit.
7. Utilize the automated external defibrillator (AED) or, if trained, the manual defibrillator as soon as possible. Special circumstances affecting use of AEDs include:	7. The American Heart Association supports the use of AEDs in public places as well as medical centers.
a. For children <1 yr of age, a manual defibrillator is preferred. If there is no manual defibrillator available, or one with pediatric dose attenuators, an adult AED may be used.	a. For children under age 8, an AED with pediatric dose attenuators is preferred. If one is not available, a normal adult AED may be used.
b. The victim should not be lying in water when using an AED. Make sure the patient's chest is dry before attaching the AED.	b. Using an AED when patients are wet or lying in water may result in burns and shocks to the rescuer.
c. Do not place the AED electrode directly over an implanted pacemaker.	c. Placing an AED pad directly over an implanted pacemaker may reduce the effectiveness of the defibrillation.
d. Remove any transdermal medication patches from the patient before using the AED.	d. Placing an AED pad over a transdermal medication patch may make the defibrillation less effective and cause a burn.

Nursing Action	Rationale
8. The four basic steps used in AED operation are:	8. The directions provided for operation of the AED were provided by the device manufacturer. Many machines will walk you through the steps for operation once the power is turned on. Be familiar with the type of device in your facility.
a. Turn the power on. Always do this first to ensure the device has power	
b. Attach the AED pads to the patient's chest, using the diagrams on the pads to show you exactly where to place them.	
c. Analyze the patient's rhythm by pushing the button on the AED labeled ANALYZE. During this time, no one should touch the patient.	c. Some AEDs will analyze automatically once the pads are connected. Touching the patient could create artifact and interfere with analysis.
d. Charge the AED and deliver the shock if indicated by the AED. Make sure that no one is touching the patient. Push the shock button; the AED will provide visual and voice prompts to tell you what to do.	d. Always call "Clear" and visually check for anyone touching the patient prior to delivering a shock. When the machine delivers a shock, anyone touching the patient will feel it.

NURSING ALERT With two rescuers present, do not stop chest compressions to place AED pads. Pads can be correctly placed on the patient while compressions continue. Only stop compressions when instructed to do so for rhythm analysis and shock delivery.

PROCEDURE GUIDELINES 35-2

Induced Hypothermia Post Cardiac Arrest

PURPOSE

Current evidence suggests that mild induced hypothermia may reduce mortality and improve neurologic outcomes in adult post-cardiac arrest patients. Cooling should be started as soon as possible to ensure optimum effectiveness.

EQUIPMENT

- 3 to 6 L bag of refrigerated 39°F (4°C) lactated Ringer's solution
- Small plastic bags
- Ample supply of ice cubes

Note: *Commercially available external cooling device (may be used in addition to or instead of ice packs)

PRE PROCEDURE

Nursing Action	Rationale
1. Consider the inclusion criteria. All patients who are resuscitated from arrest but remain unconscious and are unable to respond to verbal command should be considered for immediate cooling.	1. Research has shown that an improved outcome can be attained if the patient has adequate arterial circulation and oxygenation to the brain. a. Research has shown improved outcomes in arrest patients who remain hemodynamically stable during the post-resuscitation period.
2. Consider exclusion criteria. Patients should not be considered for the following reasons: a. Severe preexisting conditions with DNR orders. b. Active noncompressible bleeding.	2. There are only two absolute contraindications for therapeutic hypothermia. All others must be considered on a case by case basis

PROCEDURE

Nursing Action	Rationale
1. Provide standard advanced life support and ongoing intensive care management. All patients must be intubated and ventilated.	1. Patient's cardiopulmonary status is unstable.
2. Perform and document thorough neurologic examination.	2. The goal of the procedure is improved neurologic outcome.
3. Measure temperature continuously, if possible, or every 15 min. a. Initially, peripherally until continuous core temperature monitoring (central venous, bladder, rectal, oropharyngeal) can be instituted b. As rectal core temperature monitoring may be slow to change, two sites of measurement are preferred.	3. Frequent monitoring of temperature is important to reach goal temperature quickly. a. Central venous temperature monitoring is preferred.
4. Begin cooling as soon as possible. This should begin in the emergency department. a. Apply ice packs to groin, axillae, sides of chest, neck; or apply cooling blanket, wrap, or pads according to manufacturer's instructions. b. Instill 30 mL/kg of refrigerated lactated Ringer's solution over 30 min through a femoral line (if patient is not in acute pulmonary edema).	4. Internal and external cooling are required to bring down core temperature b. One liter of cold saline infused over 15 min can drop the core temperature by 1°C
5. Target temperature is 91.4°F (32°C). Remove ice packs once temperature is less than 91°F (33°C).	5. There is no need to bring down the temperature below 33°C, but temperature should be kept in that range for 12 to 24 hr.

Nursing Action	Rationale
6. Replace ice packs and consider further ice-cold lactated Ringer's solution if temperature remains above 92.3°F (33.5°C).	
7. Use nondepolarizing neuromuscular blockade to prevent shivering. Provide sedation according to standard ICU protocol.	7. Shivering produces heat, which will raise core temperature.
8. Maintain patient at target temperature for a period of 12 to 24 hr once temperature is reached.	
9. After the targeted time has elapsed passive rewarming should occur slowly over 8 to 12 hr.	9. Research has shown that the best risk/benefit ratio is at 12 hr.
10. Monitor for complications:	10. Complications will compromise outcome.
a. Hyperglycemia.	
b. Ileus may occur at <93.2°F (34°C).	
c. Hypovolemia and hypotension, secondary to vasodilation, may occur during rewarming.	
d. Bleeding—this may be of increased significance in patients undergoing urgent angioplasty or thrombolytic therapy who will also receive antiplatelet agents.	
e. Infection, especially pneumonia, during and following the procedure. Fever, one of the cardinal signs of infection, will be absent in people treated with therapeutic hypothermia.	

NURSING ALERT Do not cool below 90°F (32°C) because this increases the risk of complications.

PROCEDURE GUIDELINES 35-3

Management of Foreign-Body Airway Obstruction

PROCEDURE

Nursing Action	Rationale
Airway obstruction with conscious patient sitting or standing	
Abdominal thrusts	
1. Stand behind the patient; wrap your arms around patient's waist, and proceed as follows:	1. If the patient is able to speak or cough forcefully, allow them to attempt to clear their own airway.
a. Make a fist with one hand, placing the thumb side of the fist against the patient's abdomen in the midline, slightly above the navel and well below the xiphoid process. Grasp the fist with your other hand.	
b. Press your fist into the patient's abdomen with a quick upward thrust. Each new thrust should be a separate and distinct maneuver.	b. A subdiaphragmatic abdominal thrust, by elevating the diaphragm, can force air from the lungs to create an artificial cough intended to move and expel an obstructing foreign body in the airway.
c. Continue until the obstruction is cleared, help arrives, or the patient becomes unresponsive.	
d. Should the patient become unresponsive, immediately begin CPR, checking the airway after each set of compressions and prior to attempting ventilations.	d. The obstruction may have become dislodged during chest compressions. Only attempt to remove objects you can see. Never perform a blind finger sweep.
Airway obstruction with conscious patient standing or sitting	
Chest thrust	
1. Stand behind the patient with your arms under the axillae to encircle his or her chest.	1. This technique is to be used only in advanced stages of pregnancy or in a markedly obese patient.
2. Place the thumb side of your fist on the middle of the patient's sternum, taking care to avoid the xiphoid process and rib cage margins.	2. The xiphoid process can be easily injured.
3. Grasp your fist with your other hand and perform backward thrusts until the foreign body is expelled. If the patient becomes unconscious, stop and begin CPR, as noted above.	3. The thrusting motion is intended to relieve the obstruction.

PROCEDURE GUIDELINES 35-4

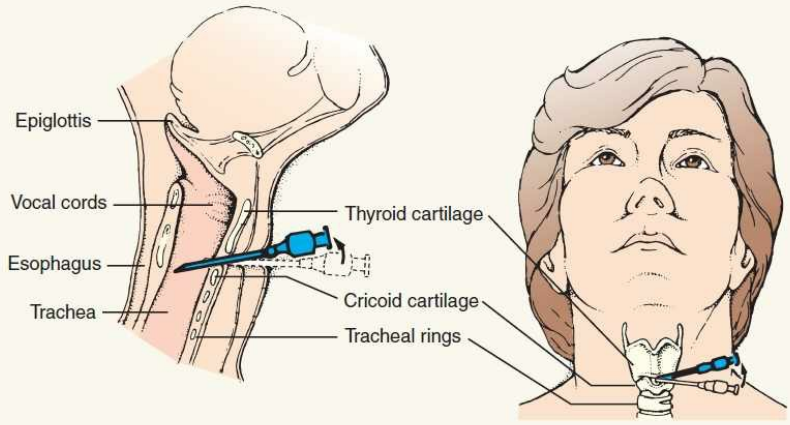
Cricothyroidotomy

EQUIPMENT

- Chlorhexidine or povidone iodine for site cleansing
- Cricothyrotomy catheter (if available)
- IV catheters (if commercial cricothyrotomy catheter is not available):
  - 16G or larger IV catheters (adult)
  - 16G or 18G IV catheters (children)
  - 3.0 endotracheal tube connecter (bag-valve-mask connecter)
  - 10 mL Luer-loc syringe with 5 mL of saline

PROCEDURE

Nursing Action	Rationale
1. Preoxygenate the patient, if possible	1. Boosts oxygen saturation during the procedure.
2. Extend the patient's neck. Place a towel roll beneath the shoulders.	2. Allows the cricothyroid membrane to be palpated readily.
3. Attach a 10-mL syringe containing 5-mL of saline to the insertion catheter	
4. Identify the prominent thyroid cartilage (Adam's apple) and allow your finger to descend in the midline to the depression between the lower border of the thyroid cartilage and the upper border of the cricoid cartilage (see accompanying figure).	4. This depression represents the cricothyroid membrane.



Cricothyroidotomy, or cricothyroid membrane puncture.

5. Scrub insertion site and maintain sterility throughout procedure.	5. Reduces risk of infection.
6. Provide skin tension and hold the trachea in place with the nondominant hand, using the index finger to palpate the cricothyroid membrane.	6. Attains stability and identifies the insertion site.
7. Place the catheter at the inferior margin of the cricothyroid membrane, in the midline of the neck, and direct it caudally at a 30- to 45-degree angle	7. Insertion will be in direction of airway.
8. While maintaining negative pressure on the syringe, advance the catheter through the skin and tissue until air bubbles are seen in the syringe	8. Maintaining negative pressure prevents saline from being injected into the airway.
9. Thread the catheter off of the needle until the hub rests on the skin surface and withdraw the needle.	9. Insertion needle is withdrawn; flexible catheter remains.

Nursing Action	Rationale
10. Listen for air passing back and forth through the needle synchronously with the patient's respirations.	10. Indicates correct positioning and opening of obstructed airway.
11. Secure the needle with adhesive tape or sutures.	11. Maintains stability of airway.
12. Ventilate with bag-valve-mask device, allowing for a prolonged exhalation time.	12. In cases of airway obstruction, prolonged exhalation times are necessary to prevent air trapping, or auto-PEEP.
13. Prepare for tracheostomy.	13. After the patient is stabilized, a more permanent means of ventilatory support is implemented.
14. Potential complications: bleeding, aspiration, subcutaneous emphysema.

Cardiopulmonary Resuscitation

Cardiopulmonary resuscitation (CPR) is a technique of basic life support for the purpose of oxygenating the brain and heart until appropriate, definitive medical treatment can restore normal heart and ventilatory action. Management of foreign body airway obstruction or cricothyroidotomy may be necessary to open the airway while CPR is performed.

Over the years, many changes have been made to the CPR guidelines. The emphasis is now on performing good, high-quality chest compressions, with a minimum of interruptions, in an effort to not only preserve life but prevent anoxic brain injuries as well. The traditional "look–listen and feel" for breathing has been eliminated, as well as the A–B–C order for assessing the unresponsive patient. For the lay public, the focus has changed to a compressions-only resuscitation model, with no interruptions to deliver breaths. For the professional provider, airway, breathing, and circulation are all still important parts of the resuscitation effort; however, A–B–C has become C–A–B, or circulation, airway, and then breathing. All efforts begin with good, high-quality chest compressions.

Indications

1. Cardiac arrest.
    a. Ventricular fibrillation.
    b. Ventricular tachycardia.
    c. Asystole.
    d. Pulseless electrical activity.
2. Respiratory arrest.
    a. Drowning.
    b. Stroke.
    c. Foreign-body airway obstruction.
    d. Smoke inhalation.
    e. Drug overdose.
    f. Electrocution/injury by lightning.
    g. Suffocation.
    h. Accident/injury.
    i. Coma.
    j. Epiglottitis.

Assessment

1. Immediate loss of consciousness.
2. Absence of palpable carotid or femoral pulse; pulselessness in large arteries.
3. Absence of breath sounds or air movement through the nose or mouth.

Interventions

1. Kneel as close to the side of the patient's chest as possible, placing the heel of one hand on the lower half of the sternum, taking care to avoid the xiphoid process. Fingers may be interlaced or extended, but care must be taken to keep them off the chest.
2. Keep your arms straight and your elbows locked. Ensure your shoulders are directly over your hands, and quickly and forcefully depress the patient's sternum straight down to a depth of at least 2 inches.
3. Deliver 30 compressions at a rate of at least 100 compressions a minute. Always allow for complete chest recoil after each compression without taking your hands off of the chest between compressions.
4. Taking no more than 10 seconds, open the airway and deliver 2 breaths.
5. Continue resuscitation at a rate of 30:2 with one or two rescuers.
6. Utilize the automatic external defibrillator according to audio instructions (see page 251).

Complications

1. Postresuscitation distress syndrome (secondary derangements in multiple organs).
2. Neurologic impairment and brain damage.

NURSING ALERT The patient who has been resuscitated is at risk for another episode of cardiac arrest.

Induced Hypothermia Post Cardiac Arrest

In adults with persistent coma (post cardiac arrest), initiating induced hypothermia to a temperature of 89°F to 93°F (32°C to 34°C) for 12 to 24 hours results in neuroprotection, improving neurologic function, and decreasing mortality. It is also associated with beneficial hemodynamic, renal, and acid–base effects. Hypothermia should be initiated within 6 hours of collapse.

Indications

1. Persistent coma in the adult patient following cardiac arrest and return of spontaneous circulation (ROSC).
2. Traumatically induced cerebral anoxia with or without cardiac arrest.
3. Time frame from cardiac arrest to ROSC is less than 60 minutes.
4. SBP greater than 90 mm Hg with a mean arterial pressure (MAP) greater than 60 mm Hg with or without pressors.

NURSING ALERT The patient who responds to verbal stimuli after cardiac arrest should not be treated with induced hypothermia.

Assessment

1. Institute continuous cardiac monitoring. Monitor for bradycardia caused by cooling or other dysrhythmias.
2. Institute continuous temperature monitoring, preferably core temperature.
3. Frequently monitor blood pressure to avoid hypotension, particularly during rewarming.
4. Monitor CBC for signs of infection, because temperature will not be an accurate sign. Monitor electrolyte panel for hypokalemia caused by hypothermia. ABGs should be analyzed at patient's actual body temperature.
5. Assess the skin every 2 hours for pressure and cold injury.
6. Monitor pupils every hour and consider continuous EEG monitoring.

Interventions

1. Apply ice packs to the groin, axillae, sides of the chest, and neck, or apply cooling device according to manufacturer's instructions. A number of commercially available cooling devices are currently available, including cooling blankets, cooling gel pads applied to the skin, and centrally inserted heat exchange catheters.
2. Instill 30 mL/kg of refrigerated lactated Ringer solution over 30 minutes through a femoral line (if patient is not in acute pulmonary edema).
3. Remove ice packs once temperature is less than 91°F (33°C). Target temperature is 91.4°F (32°C).

4. Replace ice packs and consider further ice-cold lactated Ringer solution if temperature remains above 92.3°F (33.5°C).
5. Use nondepolarizing neuromuscular blockade to prevent shivering. Provide sedation according to standard ICU protocol.
6. Maintain patient at target temperature for a period of 12 to 24 hours once temperature is reached.
7. After the targeted time has elapsed, allow passive rewarming slowly over 8 to 12 hours.

Complications

1. Shivering—patient will require sedation and neuromuscular blockade to relieve shivering, which will interfere with hypothermia.
2. Seizures—continuous neuromuscular blockade may mask postcardiac arrest seizure activity.
3. Ileus because of slowing of metabolic processes.
4. Hypotension because of vasodilation.

Foreign-Body Airway Obstruction

Foreign-body obstruction of the airway may be either partial or complete. Abdominal thrusts (the Heimlich maneuver) are recommended for relieving foreign-body airway obstruction in the conscious adult. Back blows and chest thrusts are used in the conscious infant or toddler.

Assessment

1. Weak, ineffective cough.
2. High-pitched noises on inspiration.
3. Respiratory distress.
4. Inability to speak or breathe.
5. Cyanosis.
6. Hands at the throat (universal choking sign).

Interventions

1. If the patient is conscious, stand behind the patient; wrap your arms around patient's waist, and proceed as follows:
   a. Make a fist with one hand, placing the thumb side of the fist against the patient's abdomen in the midline, slightly above the navel and well below the xiphoid process. Grasp the fist with your other hand.
   b. Press your fist into the patient's abdomen with a quick upward thrust. Each new thrust should be a separate and distinct maneuver.
   c. Continue until the obstruction is cleared, help arrives, or the patient becomes unresponsive.
   d. Should the patient become unresponsive, immediately begin CPR, checking the airway after each set of compressions and prior to attempting ventilations.
2. If the patient is obese or pregnant, making abdominal compressions ineffective, follow these steps:
   a. Stand behind the patient with your arms under the axillae to encircle his or her chest.
   b. Place the thumb side of your fist on the middle of the patient's sternum, taking care to avoid the xiphoid process and rib cage margins.
   c. Grasp your fist with your other hand and perform backward thrusts until the foreign body is expelled. If the patient becomes unconscious, stop and begin CPR.

Cricothyroidotomy

Cricothyroidotomy is the puncture or incision of the cricothyroid membrane to establish an emergency airway in certain emergency situations when placement of an endotracheal tube or laryngeal mask airway is not possible or is contraindicated and when adequate oxygenation cannot be maintained utilizing a bag-valve-mask device with 100% oxygen.

Indications

1. Compromised airway and inability to intubate or perform tracheostomy:
    a. Complete foreign-body airway obstruction.
    b. Trauma to the head and neck.
2. Allergic reaction causing laryngeal edema.

Contraindications

1. Laryngeal fracture.
2. Tracheal rupture.
3. Tracheal transection with distal tracheal retraction into the mediastinum.

Interventions

Assist the physician or emergency health care provider as follows:

1. Preoxygenate the patient, if possible.
2. Extend the patient's neck. Place a towel roll beneath the shoulders.
3. Attach a 10-mL syringe containing 5 mL of saline to the insertion catheter.
4. Identify the prominent thyroid cartilage (Adam's apple), and allow your finger to descend in the midline to the depression between the lower border of the thyroid cartilage and the upper border of the cricoid cartilage (see accompanying figure).
5. Scrub insertion site and maintain sterility throughout procedure.
6. Provide skin tension and hold the trachea in place with the nondominant hand, using the index finger to palpate the cricothyroid membrane.
7. Place the catheter at the inferior margin of the cricothyroid membrane, in the midline of the neck, and direct it caudally at a 30- to 45-degree angle.
8. While maintaining negative pressure on the syringe, advance the catheter through the skin and tissue until air bubbles are seen in the syringe.
9. Thread the catheter off of the needle until the hub rests on the skin surface and withdraw the needle.
10. Listen for air passing back and forth through the needle synchronously with the patient's respirations.
11. Secure the needle with adhesive tape or sutures.
12. Ventilate with bag-valve-mask device, allowing for a prolonged exhalation time.

Complications

1. Bleeding.
2. Aspiration.
3. Subcutaneous emphysema.

INJURIES TO THE HEAD, SPINE, AND FACE

Head Injuries

Head injuries can include fractures to the skull and face, direct injuries to the brain (as from a bullet), and indirect injuries to the brain (such as a concussion, contusion, or intracranial hemorrhage). Head injuries commonly occur from motor vehicle accidents, assaults, or falls.

Concussion—a mild diffuse axonal injury resulting in a transient disturbance of neurological function that may or may not include a loss of consciousness.

Contusion—a focal injury resulting in bruising of the brain tissue. Actual small amounts of bleeding into the brain tissue associated with edema formation and possible tissue necrosis and infarction.

Intracranial hemorrhage—significant bleeding into a space or a potential space between the skull and the brain. This is a serious complication of a head injury with a high mortality because of rising intracranial pressure (ICP) and the potential for brain herniation. Intracranial hemorrhages can be classified as *epidural hematomas*, *subdural hematomas*, or *subarachnoid hemorrhages*, depending on the site of bleeding.

NURSING ALERT Always assume a cervical spine fracture for any patient with a significant head injury until proven otherwise.

Primary Assessment

1. Airway: assess for vomitus, bleeding, and foreign objects. Ensure cervical spine immobilization.
2. Breathing: assess for abnormally slow or shallow respirations. An elevated carbon dioxide partial pressure can worsen cerebral edema.
3. Circulation: assess pulse and bleeding.
4. Disability: assess the patient's neurologic status.

Primary Interventions

1. Open the airway using the jaw-thrust technique without head tilt. Oral suction equipment (to handle heavy vomitus) should be at hand. Make sure that you do not stimulate the gag reflex as this can cause increases in ICP.
2. Administer high-flow oxygen.
3. Assist inadequate respirations with a bag-valve-mask, as necessary. Prophylactic hyperventilation is contraindicated.
4. Control bleeding—do not apply pressure to the injury site. Apply a bulky, loose dressing.
5. Initiate two IV lines. The administration of fluid and rate of flow should be determined by the patient's hemodynamic status.

Subsequent Assessment

1. History.
    a. Mechanism of injury.
    b. Presence and duration of loss of consciousness.
    c. Amnesia of the event.
    d. Position found.
2. LOC.
    a. Change in mental status is the most sensitive indicator of a change in the patient's condition.
    b. GCS (see page 354).
3. Vital signs.
    a. Hypertension and bradycardia are late signs of increasing ICP.
    b. Patients with a head injury may have associated cardiac dysrhythmias, noted by an irregular or rapid pulse.
    c. Changing patterns of respiration or apnea may indicate a head injury.
    d. Elevated temperature—high temperatures may be associated with head injury.
4. Unequal or unresponsive pupils.
5. Confusion or personality changes.
6. Impaired vision.
7. One or both eyes appear sunken.
8. Seizure activity.
9. Periauricular ecchymosis—"Battle sign," a bluish discoloration behind the ears (indicates a possible basal skull fracture).
10. Rhinorrhea or otorrhea (indicative of leakage of CSF).
11. Periorbital ecchymosis (indicates anterior basilar fracture).

NURSING ALERT If basilar skull fracture or severe midface fractures are suspected, a nasogastric (NG) tube is contraindicated. An orogastric tube may be considered for insertion.

General Interventions

1. Keep the neck in a neutral position with the cervical spine immobilized.
2. Establish an IV line of normal saline or lactated Ringer solution—fluid volume should be based on the patient's hemodynamic status.
3. Be prepared to manage seizures—if seizures occur, they should be controlled immediately.
4. Maintain normothermia.
5. Pharmacologic interventions may include:
    a. Anticonvulsants—to control seizures.

b. Mannitol or hypertonic saline—to reduce cerebral edema and decrease ICP.

c. Antibiotics.

d. Antipyretics to control hyperthermia.

Cervical Spine Injuries

Injuries to the cervical spine are serious because the crushing, stretching, and rotational shear forces exerted on the cord at the time of trauma can produce severe neurologic deficits. Edema and cord swelling contribute further to the loss of spinal cord function.

Any person with a head, neck, or back injury or fractures to the upper leg bones or to the pelvis should be suspected of having a potential spinal cord injury until proven otherwise.

Primary Assessment

1. Provide immediate immobilization of the spine and maintain immobilization throughout assessment.
2. Airway—determine patency.
3. Breathing.
    a. Intercostal paralysis with diaphragmatic breathing indicates cervical spinal cord injury.
    b. In conscious patient, observe for increased respiratory rate and difficulty in speaking because of shortness of breath.
4. Circulation—heart rate, blood pressure, presence and quality of pulses, and capillary refill.
5. Disability—assess neurologic status.

Primary Interventions

1. Immobilize the cervical spine.
2. Open the airway using the jaw-thrust technique without head tilt.
3. If the patient needs to be intubated, consider nasal intubation.
4. If respirations are shallow, assist with a bag-valve-mask.
5. Administer high-flow oxygen to minimize potential hypoxic spinal cord damage.

Subsequent Assessment

1. Assess the position of the patient when found; this may indicate the type of injury incurred.
2. Hypotension and bradycardia accompanied by warm, dry skin—suggests spinal shock.
3. Neck and back pain/extremity pain or burning sensation to the skin.
4. History of unconsciousness.
5. Total sensory loss and motor paralysis below level of injury.
6. Loss of bowel and bladder control; usually urinary retention and bladder distention.
7. Loss of sweating and vasomotor tone below level of cord lesion.
8. Priapism—persistent erection of the penis.
9. Hypothermia—because of the inability to constrict peripheral blood vessels and conserve body heat.
10. Loss of rectal tone.

General Interventions

NURSING ALERT A spinal cord injury can be made worse during the acute phase of injury, resulting in permanent neurologic damage. Proper positioning and movement of the patient is an immediate priority.

1. Ensure adequacy of airway, breathing, and circulation. Frequently monitor vital signs.
2. Insert an NG/OG tube.
3. Keep the patient warm.
4. Initiate IV access.
5. Insert an indwelling urinary catheter to avoid bladder distention.
6. Continue with repeated neurologic examinations to determine if there is deterioration of the spinal cord injury.
7. Be prepared to manage seizures if head injury is also suspected.
8. Pharmacologic interventions: possible steroids or antiepileptics.

NURSING ALERT Patients with spinal cord injuries can experience autonomic dysreflexia, an exaggerated sympathetic response to noxious stimuli. It has the potential to be life-threatening if signs are not immediately recognized and treated, along with the removal of the offending stimuli.

Maxillofacial Trauma

Injuries to the head frequently result in facial lacerations and fractures to the facial bones (ie, nasal fractures, orbital fractures, maxillary fractures, and mandibular fractures).

Primary Assessment

1. Maintain immobilization of the spine while performing assessment.
2. Airway—obstruction can occur due to tongue swelling, bleeding, or broken or missing teeth.
3. Breathing—have suction ready to prevent aspiration of blood or broken teeth.
4. Circulation—control bleeding; monitor vital signs for signs of instability.
5. Disability—neuro assessment.

Primary Interventions

1. Establish and maintain an airway. Apply high-flow oxygen and assist with intubation. Oral and nasopharyngeal airways should be used with caution. Do not use a nasopharyngeal airway if there is evidence of nasal fractures or CSF leakage from the nose.
2. Control bleeding—do not apply pressure to the injury site. Apply a bulky, loose dressing.

Subsequent Assessment

1. Examine the mouth for broken or missing teeth.
2. Assess for a potential eye injury, vision loss, double vision, or pain in the eye.
3. Examine the eye for disconjugate gaze—uncoordinated eye movements.
4. Paralysis of the upward gaze is indicative of an inferior orbit fracture (blow-out fracture).
5. Crepitus or a crackling feeling on palpation around the nose usually indicates a nasal fracture.
6. Malocclusion of the teeth is indicative of a maxilla or mandible fracture.
7. A palpable flattening of the cheek and a loss of sensation below the orbit may indicate a zygoma (cheek bone) fracture.
8. Spasms of the jaw (trismus) and mobility of the jaw indicate a maxilla fracture.
9. Rhinorrhea or otorrhea (indicative of leakage of CSF).

General Interventions

1. Gently apply ice to areas of swelling or ecchymosis. This may reduce further swelling and pain. However, if you suspect an injury to the eye itself, do not apply ice.
2. If other injuries permit, elevate the head of the bed.
3. Possible pharmacologic interventions:
    a. Pain management.
    b. Sedation.
4. With the potential for a CSF leak, the patient should be instructed not to blow the nose because of the

potential for transmitting infection to the brain or eyes.

INJURIES TO SOFT TISSUE, BONES, AND JOINTS

Soft Tissue Injuries

Soft tissue injuries involve the skin and underlying subcutaneous tissue and muscles. They can be classified as closed or open injuries. A *closed wound* is an injury to the soft tissue but without an associated break in the skin. Closed wounds include:

1. Contusion—bleeding beneath the skin into the subcutaneous tissue. Discoloration, swelling, and pain may be present.
2. Hematoma—well-defined pocket of blood and fluid beneath the skin resulting from a disruption of the deeper veins and arteries. Hematomas present as an appreciable soft mass on palpation.

An *open wound* is an injury to soft tissue with an associated break in the skin. Generally, they are more serious than closed injuries because of the potential for blood loss and infection. Open wounds include:

1. Abrasion—superficial loss of the skin resulting from rubbing or scraping the skin over a rough or uneven surface.
2. Laceration—a tear or cut in the skin. They can be a partial- or full-thickness cut, incisional or jagged.
3. Puncture—occurs when the skin is penetrated by a pointed object. Can be penetrating (entrance wound only) or perforating (entrance and exit wound). Generally, puncture wounds do not cause serious external bleeding, but there may be significant internal bleeding and damage to vital organs, as well as significant risk of infection.
4. Avulsion—involves a tearing off or loss of a full-thickness flap of the skin.
5. Amputation—traumatic cutting or tearing off of an appendage (eg, finger, toe, arm, or leg).
6. Burn—tissue injury that results from thermal, chemical, electrical, or radiation energy.

Primary Assessment

1. Always ensure the adequacy of airway, breathing, and circulation.
2. If the bleeding from the injury has been significant, be aware of the clinical signs and symptoms of shock.
    a. Restlessness, confusion, and anxiety.
    b. Skin pale, mottled, cold, and diaphoretic.
    c. Tachycardia (rapid pulse).
    d. Tachypnea (rapid, shallow breathing).
    e. Hypotension (falling BP is a late sign of shock).
3. Assess for arterial or venous bleeding. Arterial bleeding is bright red and usually spurts from the wound. Venous bleeding is darker red and will flow steadily from a wound.

Primary Interventions

The primary goal and nursing intervention are to control severe bleeding.

NURSING ALERT Wounds that result in severe arterial bleeding should be considered life-threatening, and treatment is second only to CPR.

Direct Pressure

1. Most external bleeding can be controlled with firm direct pressure.
2. Cover the injury with sterile dressings.
3. While maintaining pressure, assess for distal pulses.
4. Pressure should be maintained until the bleeding stops, a pressure dressing is applied, or definitive treatment is undertaken.
5. If the dressing becomes saturated, reinforce the dressing; do not remove the dressing.
6. After bleeding has stopped, apply a pressure dressing.
    a. A pressure bandage is made by securing several gauze pads over the injury with a rolled gauze bandage.
    b. A pressure dressing allows the nurse freedom to continue assessing the patient or attend to other injuries.
    c. After applying a pressure dressing, always ensure that the patient has a pulse distal to the dressing. If no pulse is present, the dressing may be too tight.

Elevation

1. Elevating the injured area while applying direct pressure helps to control bleeding. This measure uses gravity to slow the blood flow.
2. If possible, the injured area should be elevated above the level of the heart.
3. Do not raise a limb if a fracture is suspected or if elevation causes the patient pain or discomfort.

Pressure Points

1. Pressure points are used when direct pressure and elevation cannot control bleeding alone or when direct pressure cannot be applied to a bleeding site because of a protruding bone or an embedded object.
2. Pressure points are located between the site of injury and the heart where a main artery passes over a bone or underlying muscle mass (see Figure 35-1).
3. Locate the pressure point and apply firm, steady pressure with the heel of the hand.
4. If heavy bleeding is still not controlled, the patient may exsanguinate and a tourniquet should be used or a vascular clamp can be applied to the artery.

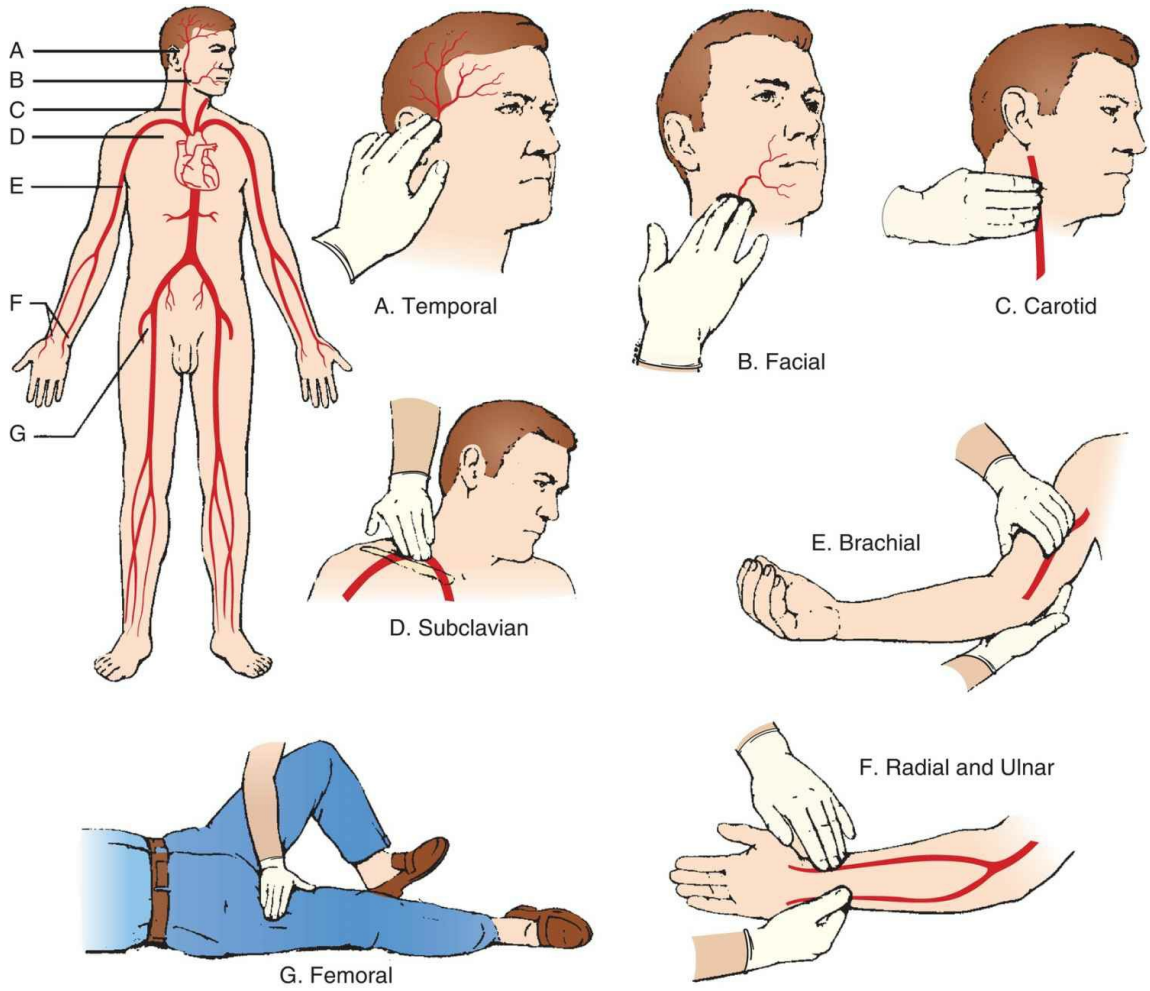

Figure 35-1. Pressure points for control of hemorrhage. (Smeltzer, S. & Bare, B. [2000]. *Brunner and Suddarth's textbook of medical–surgical nursing* [9th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Subsequent Assessment

1. Expose the wound; cut away clothing, if necessary. Secure any impaled objects in place.
2. Assess for the presence of concomitant injuries. The obvious wound is not necessarily the most life-threatening.
3. Assess vascular status distal to the injury and compare it to the uninjured extremity.
   a. Color of the injured extremity—pallor suggests poor arterial perfusion and cyanosis suggests venous congestion.
   b. Test capillary refill time by depressing the nail bed until it blanches and seeing how long until the nail bed returns to pink. A capillary refill time greater than 2 to 3 seconds suggests decreased capillary perfusion.
   c. Test pulses distal to the injury—generally, they should be full and strong.
4. Perform a neurologic assessment of the injured extremity to determine peripheral nerve insult, possibly caused by direct injury, compression, or edema.

a. Sensory function—while the patient's eyes are closed, lightly touch the area distal to the injury and ask them to identify the area being touched. Have them discriminate between sharp and dull touch.
   b. Motor function—have patient move extremity distal to the injury.
5. Determine tetanus immunization status.
6. History of the injury, including when and how the wound occurred. Any wound that is more than 6 hours old is considered at high risk for infection, and primary closure by suturing may not be an option.
7. Allergies to local anesthesia, epinephrine, and antibiotics.

General Interventions

Wound Preparation

1. Shaving is not recommended; instead, clip only the required area. Eyebrows are never clipped.
2. Irrigate gently and copiously with isotonic sterile saline solution to remove dirt and debris. All wounds must be thoroughly explored for retained foreign objects before closure. If the wound is grossly contaminated, it may need to be cleansed with a surgical scrub sponge and then irrigated. If the patient is in pain, anesthetize the wound prior to cleansing and irrigating.
3. Topical anesthetic may be applied to the wound (prior to infiltration with local anesthetic) intradermally through the wound margins or by regional nerve block.
4. Devitalized tissue and foreign matter are removed—devitalized tissue inhibits wound healing and enhances chance of bacterial infection.

Wound Closure

1. Closure by primary intent.
   a. Wound is repaired without delay after the injury; yields the fastest healing.
   b. Primary closure may be with sutures, skin tapes, staples, or tissue adhesives. Location and size of the wound are key factors in determining closure material used.
2. Closure by secondary intent.
   a. Wound is allowed to granulate on its own without surgical closure.
   b. Wound is cleaned and covered with a sterile dressing.
3. Closure by secondary intent with delayed closure.
   a. Wound is cleaned and dressed.
   b. Patient returns in 3 to 4 days for definitive closure.

Wound Dressing

1. Dressing should be applied in three layers.
   a. The first layer is the contact layer. This should consist of a nonabsorbent hydrophilic dressing that will allow exudate to pass through to the second layer without wetting the contact layer. Examples of contact layer dressings are Adaptic, petroleum gauze, and Xeroform gauze.
   b. The second layer is the absorbent layer and is usually constructed of surgical dressing pads or 4 × 4-

gauze dressings.

c. The third layer is the outer wrap that holds the dressing in place. The outer wrap may consist of rolled gauze and tape.

2. There are many different proprietary dressings available for application.

Pharmacologic Interventions

1. Give antimicrobial treatment, as directed, depending on how the injury occurred, age of wound, presence of soil, and infection potential.
2. Give tetanus prophylaxis, as indicated, based on patient's immunization status and wound.
3. Rabies prophylaxis, as indicated. For more information on four-dose postexposure rabies prophylaxis, go to *www.cdc.gov/vaccines/pubs/ACIP-list.htm#rabies*.

Patient Education

1. Inform the patient that pain should subside over the course of the next 24 to 48 hours.
2. Acetaminophen, ibuprofen, or prescribed analgesic to be taken for the first 24 hours after a simple laceration.
3. If pain reappears, a wound infection may be suspected.
4. Recommend that the wound be monitored for signs of infection.
5. Advise that health care provider be contacted if there is sudden or persistent onset of pain, fever/chills, bleeding, rapid swelling, foul odor, purulent fluid, or redness surrounding the wound.

Injuries to Bones and Joints

Injuries to bones and joints are common. *Fractures* may be caused by direct trauma (eg, projectiles, crush injuries) or by indirect trauma (ie, bones being pulled apart or rotational forces). In addition, bones may be fractured due to pathologic reasons. A pathologic fracture is due to a weakness in the bone secondary to a disease process such as metastatic cancer. For the classification of fractures, see page 878.

Other injuries include:

1. Dislocation—complete displacement or separation of a bone from its normal place of articulation. It may be associated with a tearing of the ligaments. The shoulder, elbow, fingers, hips, and ankles are the joints most frequently affected.
2. Subluxation—partial disruption of the articulating surfaces.
3. Sprains—injuries in which ligaments are partially torn or stretched. These types of injuries are usually caused by a twisting of a joint beyond its normal range of motion. The severity can range from mild to severe. The more seriously injured ligaments may resemble a fracture.
4. Strains—stretching or tearing of muscle and tendon fibers. Usually caused by overexertion or overextension.

Primary Assessment

1. Always ensure the adequacy of airway, breathing, and circulation before initiating treatment.
2. Occult blood loss into a closed space from the fracture may be significant enough to produce hypovolemic shock. Death by exsanguination can occur from pelvic and femoral fractures. Estimated blood loss in an adult from closed fractures in liters:
   a. Tibia—1.5 L.
   b. Femur—2 L.
   c. Pelvis—6 L.
   d. Humerus—2 L.
3. A fractured cervical spine, pelvic fracture, or fractured femur may produce life-threatening injuries. Posterior dislocations of the hip are life- and limb-threatening emergencies because of the potential for blood loss and the disruption in blood supply to the head of the femur. Unless this dislocation is promptly reduced, the patient may develop avascular necrosis of the femoral head and subsequently may require a hip replacement.

Primary Interventions

1. Support airway, breathing, and circulation, if compromised.
2. Initiate IV line and treat for shock, if evident.
3. Assess circulation distal to the site of injury. Loss of distal pulses requires immediate intervention.
4. Protect injured part from movement or further trauma. Splinting in the position the patient was found may be helpful if circulation is not compromised.

5. Pain management is essential.

Subsequent Assessment

1. Seek information on the mechanism of injury.
    a. How did the injury occur and when did the injury occur?
    b. In what position was the limb after the injury?
    c. If the mechanism of injury was a fall, how many feet did the person fall? What type of surface did they land on?
    d. If the mechanism was a motor vehicle crash, where was the patient? What was the direction and amount of force? Certain musculoskeletal injuries commonly occur together.
2. Assess for the presence of concomitant injuries.
    a. A fractured calcaneus as the result of a fall from a great height may also include a compression fracture of the spine.
    b. A person with a fractured patella from a motor vehicle accident may also have a fractured or dislocated femur.
    c. A fractured pelvis may occur with lumbosacral spine fractures and bladder injuries.
3. Perform a neurovascular assessment to include the area above and below the injury.
    a. Assess for ischemia to the extremity.
    b. Pallor suggests poor arterial perfusion, whereas cyanosis suggests venous congestion.
        i. A capillary refill time greater than 2 seconds suggests decreased arterial capillary perfusion.
    c. Assess neurologic supply of the injured extremity to determine peripheral nerve insult. Damage to a peripheral nerve can be the result of a direct injury, compression, stretching, or edema.
        i. Test sensory function—with the patient's eyes closed, lightly touch the area distal to the injury. Ask the patient to identify the area being touched.
        ii. Test motor function—have patient move extremity distal to the injury.
        iii. Numbness or paralysis indicates pressure on the nerves and may require immediate medical intervention.
4. Examine the bones and joints adjacent to the injury. If there was enough force to produce one injury, there may be other injuries.
5. Signs and symptoms of fractures:
    a. Pain and tenderness over the fracture site, called "point tenderness."
    b. A grating or crepitus over the fracture site.
    c. Swelling, because of internal bleeding and edema.
    d. Deformity, unnatural position, or movement where there is no joint.
    e. Loss of use or guarding.
    f. Discoloration because of bleeding into the surrounding tissue.
    g. Shortening of an extremity or rotation of the extremity.

6. Signs and symptoms of dislocations:
    a. Loss of joint motion—the joint may appear "frozen."
    b. Obvious deformity—lump, ridge, or excavation.
    c. Pain.
7. Signs and symptoms of sprains:
    a. Pain in the joint area.
    b. Swelling.
    c. Limited use or movement.
    d. Ecchymosis.
8. Signs and symptoms of strains:
    a. Pain located in a muscle or its tendon, not a bone or a joint.
    b. Swelling is usually minimal.
9. Closely monitor vital signs.

General Interventions

Interventions for the Severely Injured Patient

1. Ensure adequacy of airway, breathing, and circulation. Closely monitor vital signs.
2. Initiate two IV lines and start volume replacement with lactated Ringer solution or normal saline.
3. Immobilize the injury—this will prevent further damage and will help to relieve the pain.
4. Prepare the patient for the possibility of needing to go to the OR (operating room)—keep the patient NPO (nothing by mouth).
5. Antibiotics may be started if warranted.

Other Interventions

1. Elevate to prevent or limit swelling.
2. Apply ice packs or cold compresses; ice should not be placed directly on the skin.
3. Cover open fractures with a sterile dressing. If bone is protruding, do not attempt to tuck the ends under the skin. Cover with a sterile dressing.
4. Splint the extremity in as good alignment as possible until definitive care is complete. Immobilize the joint above and below the fracture.
5. Handle the injured part gently and as little as possible.
6. Pain management may include ice packs, simple or opioid analgesics, nonsteroidal anti-inflammatory drugs, or regional nerve blocks.
7. High-flow oxygen should be administered to patients with pelvic or femoral fractures, compartment syndrome, or signs of shock.

Assess for Compartment Syndrome

1. Increased pressure within an extremity resulting from bleeding and swelling into a closed space, causing pressure on vital structures.
2. The six Ps (signs and symptoms) of compartment syndrome are:
    a. Pain—development of a different type of pain, the return of pain after treatment/splinting had caused pain relief, or pain out of proportion to the severity of the injury.
    b. Pallor—deterioration in skin color and an increase in the capillary refill time.
    c. Pulselessness.
    d. Paresthesias.
    e. Paralysis—late sign.
    f. Puffiness—late sign.

NURSING ALERT Compartment syndrome is a limb-threatening event; therefore, if suspected, do not elevate limb above the level of the heart. This may decrease perfusion to the compromised extremity. Emergent fasciotomy is often required.

NURSING ALERT Patients with long bone or pelvic fractures are at risk for developing fat emboli and should be monitored closely.

SHOCK AND INTERNAL INJURIES

Shock

Shock is the common denominator in a wide variety of disease processes that present as an immediate threat to life. Simply defined, *shock* is inadequate tissue perfusion. This inadequate tissue perfusion is the result of failure of one or more of the following: (1) the heart–pump failure, (2) blood volume, (3) arterial resistance vessels, and (4) the capacity of the venous beds. Any condition that significantly affects any of the above may precipitate a shock state. Shock can be classified as compensated (hemodynamically stable) or uncompensated (hemodynamically unstable).

Types of shock are:

1. Hypovolemic shock—occurs when a significant amount of fluid is lost from the intravascular space. May result from hemorrhage, burns, GI losses, or fluid shifts.
2. Cardiogenic shock—occurs when the heart fails as a pump. Primary causes of this failure are myocardial infarction (MI), serious cardiac dysrhythmias, and myocardial depression from diseases such as myocarditis, endocarditis, and pericarditis. Secondary causes include mechanical restriction of cardiac function or venous obstruction, such as occurs with cardiac tamponade, vena cava obstruction, or tension pneumothorax.
3. Distributive—occurs as the result of a loss of vascular tone. It may be anaphylactic, septic, neurogenic, or because of an acute adrenal insufficiency. Septic shock may occur with or without an infection. Sepsis is characterized by a systemic inflammatory response in the presence of suspected or confirmed infection. Systemic inflammatory response syndrome (SIRS) is the body's systemic clinical response to an insult with an acute inflammatory reaction. See Table 35-1 for defining characteristics of SIRS and sepsis.

Table 35-1 Defining Characteristics of Sepsis

SEPTIC CONDITION	CHARACTERISTIC
SIRS, two or more of:	Temperature >100.4°F (38°C) or <96.8°F (36°C)
	HR > 90, RR > 20, arterial CO_2 < 32 mm Hg or need for mechanical ventilation
	WBC > 12,000/mm³ or <4,000/mm³ *or* more than 10% immature band forms
Sepsis	SIRS criteria
	Suspected or confirmed infection
Severe sepsis	Serum lactate level >2 mmol/L
	Hypovolemia responsive to fluid resuscitation
	Signs of tissue hypoperfusion
Septic shock	Profound hypovolemia, hypoxia, and hypoperfusion
	Hypovolemia unresponsive to fluid resuscitation
	Multiple organ failure

bpm, beats per minute; HR, heart rate; RR, respiratory rate; SIRS, systemic inflammatory response syndrome; WBC, white blood cell.

Primary Assessment and Interventions

1. Rapid recognition and prompt intervention are essential to increase the chance of survival because a downward spiral of physiologic responses culminating in multiorgan dysfunction syndrome and eventual death will occur if shock is not treated.
2. The initial priorities in the assessment are the same for all types of shock.
    a. Is the airway open?
    b. Is the patient breathing?
    c. Is there a circulation problem?
3. Initiate immediate interventions, as indicated.
    a. Resuscitate as necessary. Fluid replacement with isotonic fluids and eventually blood products is essential.
    b. Administer oxygen.
    c. Start cardiac monitoring.
    d. Control hemorrhage or other fluid loss, if present.
4. Pain management is essential.

Subsequent Assessment

1. Assess level of consciousness—important indicator of shock because it reflects cerebral perfusion. Changes may include:

a. Confusion.
b. Irritability.
c. Anxiety.
d. Agitation.
e. Inability to concentrate.

2. Watch for increasing lethargy progressing to obtundation and coma, indicating progression of shock.
3. Monitor arterial BP.
   a. If the patient can compensate for the shock state, the BP may initially rise approximately 20%. A significant decrease in BP may not occur until late in the shock state.
   b. Narrowing pulse pressure—early in shock, the diastolic pressure may rise due to an initial vasoconstriction produced by release of catecholamines from the sympathetic nervous system.
   c. Fall in the systolic pressure—there is no absolute value in BP that indicates a shock state. It is the deviation from normal that is important. However, it is generally accepted that a systolic pressure below 80 mm Hg or a mean arterial pressure below 60 mm Hg is indicative of shock.
4. Assess pulse quality and rate change.
   a. The rate is usually increased.
   b. Weak, thready pulse because of decreased cardiac output and increased peripheral vascular resistance.
5. Assess urine output.
   a. A decrease in renal blood flow or pressure will result in decreased urine output.
   b. Ideally in an adult, the urine output should be 50 mL/hour. An output of less than 25 mL/hour may indicate shock in a patient without renal dysfunction.
6. Assess capillary perfusion.
   a. Pale, ashen, mottled, cold, and sweaty skin indicates potent vasoconstriction.
   b. Capillary refill greater than 2 seconds indicates vasoconstriction.
7. Also assess for:
   a. Subjective feeling of impending doom.
   b. Metabolic acidosis because of anaerobic metabolism within the cells.
   c. Excessive thirst.

NURSING ALERT Rapid identification and treatment of SIRS or sepsis are essential in the treatment of septic shock. Although a source of infection may not be identified, signs include fever, tachypnea, tachycardia, and leukocytosis.

General Interventions

1. Administer 100% O_2 by nonrebreather face mask to maintain the partial pressure of arterial oxygen at

90% to 100%.

2. Assist with intubation if the patient is unable to maintain airway.
3. Fluid resuscitation.
    a. Two large-bore IV lines should be established.
    b. Administer IV fluids—lactated Ringer or normal saline. Rate of infusion depends on severity of blood loss and clinical evidence of hypovolemia.
    c. Packed red blood cells or whole blood are infused when there is hypovolemic shock because of blood loss.
    d. Additional platelets and coagulation factors are given when large amounts of blood are needed because replacement blood is deficient in clotting factors.
    e. Warm the blood and fluids using a commercial fluid warmer—massive blood replacement has a cooling effect that can cause cardiac dysrhythmias, paradoxical hypotension, decreased oxyhemoglobin dissociation, or cardiac arrest.
4. Insert an indwelling urinary catheter.
    a. Record urine output every 15 to 30 minutes.
    b. Urinary volume reveals adequacy of kidney and visceral perfusion.
5. Maintain patient in supine position with the legs slightly elevated. (This position is contraindicated in patients with head injuries.)
6. ECG monitoring—dysrhythmias may contribute to shock.
7. Maintain ongoing nursing surveillance of total patient—BP, heart rate, respiratory rate, temperature, color, central venous pressure (CVP), ABG levels, urine output, ECG, hematocrit, hemoglobin, coagulation profiles, and electrolytes—to assess patient response to treatment.
8. Immobilize fractures to minimize blood loss.
9. Maintain normothermia.
    a. Too much heat produces vasodilatation, which counteracts the body's compensatory mechanism of vasoconstriction and also increases fluid loss through perspiration.
    b. A patient who is in septic shock should be kept cool because high fever will increase the cellular metabolic effects of shock.
10. Provide pharmacologic interventions:
    a. Vasopressors may be indicated but should not be used in place of volume replacement except as dictated by cardiogenic or neurogenic shock states.
    b. Antibiotics—broad spectrum for septic shock.

NURSING ALERT Trendelenburg position is no longer recommended because of the potential for respiratory compromise caused by pressure from abdominal organs.

Abdominal Injuries

Abdominal injuries account for a large percentage of trauma-related injuries and deaths. The visceral organs contained within the abdomen can be classified as either hollow or solid. Damage to a hollow organ can result in acute peritonitis, leading to shock within a few hours, and damage to a solid organ can result in lethal hemorrhage. Abdominal injuries may be classified as either penetrating or blunt.

Penetrating abdominal injury—usually the result of gunshot wounds or stab wounds. The mechanism that caused the penetrating abdominal trauma may cross the diaphragm and enter the chest. The opposite can also occur.

Blunt abdominal injury—usually caused by motor vehicle accidents or falls. Trauma to the abdomen is commonly associated with extra-abdominal injuries (ie, chest, head, and extremity injuries) and severe concomitant trauma to multiple intraperitoneal organs. Blunt abdominal injury is often associated with delayed complications, especially if there is injury to the liver, spleen, or blood vessels, which can lead to substantial blood loss into the peritoneal cavity.

Primary Assessment and Interventions

1. Assess airway, breathing, and circulation.
2. Initiate resuscitation, as indicated.
3. Control bleeding and prepare to treat shock.
4. If there is an impaled object in the abdomen, leave it there. Stabilize the object in place with bulky dressings along the sides of the object.

Subsequent Assessment

1. Obtain a history of the mechanism of the injury, type of weapon, and estimated amount of blood loss.
    a. If the patient was stabbed, how long was the blade?
    b. Was the person who stabbed the patient a man or a woman?
        i. Men usually hold a knife underhand and stab/thrust upward.
        ii. Women usually will stab/thrust downward with an overhand motion.
    c. If the patient sustained a gunshot wound, attempt to ascertain the type of gun and range at which shot.
    d. Time of onset of symptoms.
    e. Passenger location (driver frequently sustains spleen/liver rupture). Were seat belts worn? Did the airbag deploy? Were there other injured parties or fatalities involved in the same accident?
2. Inspect the abdomen for obvious signs of injury (penetrating injury, bruises).
3. Evaluate for signs and symptoms of hemorrhage—usually accompanies abdominal injury, especially if the liver and spleen have been traumatized.
4. Note tenderness, rebound tenderness, guarding, rigidity, and spasm.
    a. Firmly press, with the whole hand, the area of maximal tenderness (let the patient point to the area).

b. Remove the fingers quickly to check for rebound tenderness; pain at suspected point indicates peritoneal irritation.

5. Ask about referred pain: Kehr sign—pain radiating to the left shoulder may be a sign of blood beneath the left diaphragm; pain in the right shoulder can result from laceration of the liver. The patient must be lying flat for this type of shoulder pain to occur.
6. Look for increasing abdominal distention. Measure abdominal girth at umbilical level early in your assessment—serves as a baseline from which changes can be determined. Making a mark where you measured can also assist in assuring the same place is measured each time.
7. Auscultate—a silent abdomen accompanies peritoneal irritation or ileus. The presence of bowel sounds in the chest indicates a ruptured diaphragm. Bruits over the aorta or other large arteries may indicate disrupted arterial blood flow.
8. Percuss—tympani over solid organs (liver, spleen)—indicates presence of free air; dullness over regions normally containing gas may indicate presence of blood or other fluids.
9. Look for chest injuries, which frequently accompany intra-abdominal injuries.
10. Cullen sign, a slight bluish discoloration around the navel, is a sign of blood in the abdominal wall. Grey Turner sign, or flank ecchymosis, is indicative of renal injuries or retroperitoneal bleeding.
11. Pain is a poor indicator of the extent of an abdominal injury. Rebound tenderness and boardlike rigidity are indicative of a significant intra-abdominal injury.
12. A rectal examination and examination of the perineum should be done on all patients. The presence of blood may be indicative of trauma.
13. Continually assess vital signs, urine output, CVP readings, hematocrit values, and neurologic status. Tachypnea, tachycardia, and hypotension may be clues to intra-abdominal bleeding.

General Interventions

1. Assess adequacy of airway, breathing, and circulation. Begin frequent monitoring.
2. Goals are to control bleeding, maintain blood volume, and prevent infection.
3. Keep the patient quiet and on the stretcher because movement may fragment or dislodge a clot in a large vessel and produce massive hemorrhage.
4. Cut the clothing away from the wound. Do not cut through bullet holes or stab marks. These will be needed by law enforcement authorities as forensic evidence.
5. Count the number of wounds.
6. Look for entrance and exit wounds.
7. If the patient is comatose, immobilize the cervical spine until after cervical films are taken and cleared.
8. Apply compression to external bleeding.
9. Insert two large-bore IV lines and infuse fluid as dictated by the patient's hemodynamic status.
10. Be prepared to insert an NG tube to decompress the abdomen. This will serve to empty the stomach, relieve gastric distention, and facilitate abdominal assessment. In addition, if blood is found, it may indicate stomach injury or esophageal injury.

11. Cover protruding abdominal viscera; do not attempt to replace the protruding organs into the abdomen. Use sterile saline dressings to protect viscera from drying.
12. Cover open wounds with dry dressings.
13. Withhold oral fluids to prevent increased peristalsis and vomiting.
14. Insert an indwelling urethral catheter to ascertain the presence of hematuria and to monitor urine output. If a fracture of the pelvis is suspected, a catheter should not be placed until the integrity of the urethra is ensured.
15. Pharmacologic interventions.
    a. Analgesics.
    b. Tetanus prophylaxis.
    c. Broad-spectrum antibiotics because bacterial contamination is a frequent complication (depending on history and nature of wound).
16. Prepare for focused ultrasound when there is uncertainty about intraperitoneal bleeding. Focused assessment with sonography in trauma (FAST) is a standard for rapid bedside assessment with ultrasound performed by providers to identify free fluid in the abdomen, pericardium, or peritoneum.
17. Prepare for surgery if the patient shows evidence of unexplained shock, unstable vital signs, peritoneal irritation, bowel protrusion or evisceration, significant penetrating injury, significant GI bleeding, or peritoneal air.
18. Prepare the patient for diagnostic procedures.
    a. Catheterization and urinalysis—as a guide to possible urinary tract injury and to monitor urine output.
    b. Type and crossmatch and serial hemoglobin and hematocrit levels—their trend reflects presence or absence of bleeding.
    c. Complete blood count (CBC)—white blood cell count is generally elevated with trauma.
    d. Serum amylase elevation usually indicates pancreatic injury or perforations of GI tract.
    e. Computed tomography (CT) scans permit detailed evaluation of abdominal and retroperitoneal injuries.
    f. Abdominal and chest x-rays may reveal free air beneath the diaphragm, indicating ruptured hollow viscus.

Multiple Injuries

The patient with multiple injuries requires rapid and definitive interventions during the first hour after the trauma to increase chance of survival; this first hour has been called the "golden hour." During this time, multiple assessments and interventions may be performed simultaneously by the health care team.

Primary Assessment and Interventions

Airway

1. Assume a cervical spine injury and open the airway using the jaw-thrust technique without head tilt.
2. Apply suction to clear the trachea and bronchial tree. Remove debris from the mouth (ie, broken teeth, mucus).
3. Insert an oropharyngeal airway—to prevent occlusion by the tongue. Oropharyngeal airways are used in unconscious patients only to prevent stimulation of the gag reflex.
4. Prepare for endotracheal intubation if adequate airway cannot be maintained.
5. If upper airway trauma or edema exists, a cricothyroidotomy may be indicated.

Breathing

1. Note the character and symmetry of chest wall motion and pattern of breathing. Assess for open wounds, deformity, and flail segments.
2. Auscultate the lungs and assess for tracheal deviation. If a tension pneumothorax is present, the trachea will shift away from the injury. Tracheal deviation is a late sign.
3. Ask the conscious patient if experiencing difficulty in breathing or chest pain with breathing.
4. Administer oxygen by 100% nonrebreather mask or assist the patient's ventilations by bag-valve-mask.
5. Suspect serious intrathoracic injuries if respiratory distress continues after adequate airway has been established.
6. Assess the overall effectiveness of ventilations.

Circulation

1. Assess cardiac function and treat cardiac arrest (hypoxia, metabolic acidosis, and chest trauma may precipitate cardiac arrest).
2. For cardiac arrest, start CPR.
3. Control hemorrhage.
    a. Apply direct pressure over bleeding points, if able.
    b. Expect significant blood loss in patients with fractures to the shaft of the femur, multiple fractures, or pelvic trauma.
    c. Use tourniquet(s) for massive arterial bleeding from extremities that cannot be halted with pressure.
    d. Prepare for immediate surgical intervention if patient is bleeding internally.
4. Palpate the carotid pulse and note its rate and quality. Palpate both central and peripheral pulses and

compare their quality. Patients will lose their peripheral pulses before losing their central pulse. In addition, assess the femoral and radial pulses to determine an approximate systolic pressure.

   a. If the carotid pulse is present, the systolic pressure is at least 60 mm Hg.
   b. If the femoral pulse is present, the systolic pressure is at least 70 mm Hg.
   c. If the radial pulse is present, the systolic pressure is at least 80 mm Hg.

5. Prevent and treat hypovolemic shock.
   a. Insert at least two IV lines.
   b. If indicated, place a central venous catheter to monitor the patient's response to fluid infusion—to prevent fluid overload and as a route for fluid infusion.
   c. Fluid resuscitation—lactated Ringer solution or normal saline is given for volume replacement until blood is available.
   d. Administer blood—massive transfusions have a cooling effect that can cause cardiac irritability and arrest; blood should be warmed.
6. Note presence or absence of pulses in fractured extremities.

Neurologic

1. Assess level of responsiveness, pupil size and reactivity, strength, and reflexes.
2. Determine a Glasgow Coma Score as a baseline (see page 354).
3. If signs of increased ICP exist, ICP monitoring may be instituted.
4. Agitation or other mental status changes are often the first sign of impending problems.

Subsequent Assessment and Interventions

1. The goals are rapid determination of the extent of the injuries and treatment prioritization.
2. Monitor ECG—to detect life-threatening dysrhythmias.
3. Insert indwelling urethral catheter and monitor urine output to aid in diagnosis of shock as well as monitor effectiveness of therapy. Do not force the catheter—the patient may have a ruptured urethra.
4. Perform an ongoing clinical evaluation to observe for improvement or deterioration, such as changes in vital signs, improvement in level of responsiveness, skin warmth, and speed of capillary filling.
5. Prepare for immediate surgical intervention if the patient does not respond to fluids or blood. Inability to restore BP and circulatory volume in the patient usually indicates major internal bleeding.
6. Splint fractures to prevent further trauma to soft tissues and blood vessels and to relieve pain.
7. Examine the patient for abdominal pain, rigidity, tenderness, rebound tenderness, diminished bowel sounds, hypotension, and shock.
8. Prepare for FAST exam or CT scan to assess for intraperitoneal bleeding.
9. Draw blood for laboratory studies (type and cross-matching, hemoglobin, hematocrit, baseline CBC, electrolytes, blood urea nitrogen [BUN], glucose, coagulation studies).
10. Insert an NG tube to prevent vomiting and aspiration.

11. Prepare for laparotomy if the patient shows continuing signs of hemorrhage and deterioration.
12. Continue to monitor urine output every 30 minutes—reflects cardiac output and state of perfusion of vital organs.
13. Assess for hematuria and oliguria.
14. Evaluate the patient for other injuries and institute appropriate treatment, including tetanus immunization.
15. Perform a more thorough physical examination after resuscitation and management of the aforementioned priorities.

ENVIRONMENTAL EMERGENCIES

Heat Exhaustion

Heat exhaustion is the inadequacy or the collapse of peripheral circulation because of volume and electrolyte depletion. Heat exhaustion is one condition in the spectrum of heat-related illnesses, including heat rash, heat edema, heat cramps, and heat syncope. Untreated heat exhaustion may progress to heatstroke.

Primary Assessment and Interventions

1. Expect the patient to be alert without significant cardiorespiratory or neurologic compromise.
2. If vital functions are significantly impaired, suspect secondary condition, such as MI or stroke.

Subsequent Assessment

1. Ask patient about headache, fatigue, dizziness, muscle cramping, and nausea.
2. Inspect the skin—usually pale, ashen, and moist.
3. The temperature may be normal, slightly elevated, or as high as 104˚F (40˚C).
4. Measure vital signs for hypotension, orthostatic changes, tachycardia, and tachypnea.
5. The patient will be awake but may give a history of syncope or confusion.
6. Laboratory analysis will show hemoconcentration and hyponatremia (if sodium depletion is the primary problem) or hypernatremia (if water depletion is the primary problem).
7. The ECG may show dysrhythmias without evidence of infarction.

General Interventions

1. Move the patient to a cool environment and remove all clothing.
2. Position the patient supine with feet slightly elevated.
3. If the patient complains of nausea or vomiting, do not give fluids by mouth.
4. Start an IV line with normal saline until electrolyte results are confirmed.
5. Monitor the patient for changes in the cardiac rhythm and vital signs. Vital signs should be taken at least every 15 minutes until the patient is stable.
6. Provide fans and cool sponge baths as cooling methods.
7. Provide patient education.
    a. Advise the patient to avoid immediate reexposure to high temperatures; the patient may remain hypersensitive to high temperatures for a considerable length of time.
    b. Emphasize the importance of maintaining an adequate fluid intake, wearing loose clothing, and reducing activity in hot weather.
    c. Athletes should monitor fluid losses, replace fluids, and use a gradual approach to physical conditioning, allowing sufficient time for acclimatization.

NURSING ALERT Identify those at increased risk for heat exhaustion and heatstroke so

preventive measures can be taken. Risk factors include such underlying conditions as cardiovascular disease, alcohol abuse, malnutrition, diabetes, skin diseases, and major burn scarring; very young or very old age; drugs such as anticholinergics, phenothiazines, diuretics, antihistamines, antidepressants, and beta-adrenergic blockers; and such behaviors as working outdoors, wearing inappropriate clothing, inadequate fluid intake, and living in poor environmental conditions.

Heatstroke

Heatstroke is a medical emergency that can result in significant morbidity and mortality. It is defined as the combination of hyperpyrexia greater than 104°F (40°C) and neurologic symptoms. It is caused by a shutdown or failure of the heat-regulating mechanisms of the body. It can be classified as exertional or nonexertional.

Primary Assessment and Interventions

1. Assess airway, breathing, and circulation.
2. LOC may be altered.
3. Expect to intervene immediately if cardiovascular collapse occurs.

Subsequent Assessment

1. Obtain a history from accompanying person about environmental conditions, activity, underlying health, and medications that may have contributed to heatstroke.
2. Perform a neurologic assessment.
   a. Initially, the patient may exhibit bizarre behavior or irritability. This may progress to confusion, combativeness, deliriousness, and coma.
   b. Other central nervous system (CNS) disturbances include tremors, seizures, fixed and dilated pupils, and decerebrate or decorticate posturing.
3. Assess vital signs.
   a. Temperature greater than 104°F (40°C).
   b. Hypotension.
   c. Rapid pulse; may be bounding or weak.
   d. Rapid respirations.
4. The skin may appear flushed and hot; in early heatstroke, the skin may be moist, but, as the heatstroke progresses, the skin will become dry as the body loses its ability to sweat.
5. ABGs show metabolic acidosis.

General Interventions

NURSING ALERT When the diagnosis of heatstroke is made or suspected, it is imperative to reduce the patient's temperature.

---

1. Protect the airway in patients with deteriorating mental status or absent gag reflex.
2. Provide cooling measures.
   a. Reduce the core (internal) temperature to 102°F (38.9°C) as rapidly as possible.
   b. Evaporative cooling is the most efficient. Spray tepid water on the skin while electric fans are used to

blow continuously over the patient to augment heat dissipation.

c. Apply ice packs to the neck, groin, axillae, and scalp (areas of maximal heat transfer).

d. Soak sheets/towels in ice water and place on patient, using fans to accelerate evaporation/cooling rate.

e. Immersion in cold or ice water is contraindicated.

f. If the temperature fails to decrease, initiate core cooling: iced saline gastric lavage, cool fluid peritoneal dialysis, cool fluid bladder irrigation, or cool fluid chest irrigation.

g. Cooling blankets may be used after temperature is stabilized.

h. Discontinue active cooling when the temperature reaches 102°F (38.9°C). In most cases, this will reduce the chance of overcooling because the body temperature will continue to fall after cessation of cooling.

3. Oxygenate patient to supply tissue needs that are exaggerated by the hypermetabolic condition: 100% nonrebreather mask or intubate the patient, if necessary, to support a failing cardiorespiratory system.

4. Monitor condition.

a. Monitor and record the core temperature continually during cooling process to avoid hypothermia; also, hyperthermia may recur spontaneously within 3 to 4 hours.

b. Monitor the vital signs continuously, including ECG, CVP, BP, pulse, and respiratory rate.

c. Perform frequent (every 30 minutes) neurologic assessments.

d. Monitor lab values for signs of coagulopathy and liver or renal damage.

5. Replace fluids.

a. Start IV infusion using normal saline solution to replace fluid losses, maintain adequate circulation, and facilitate cooling.

b. If possible, a central line should be established.

c. Fluid replacement is based on the patient's response and laboratory results.

6. Other potential measures:

a. Dialysis for renal failure.

b. Diuretics, such as mannitol, to promote diuresis.

c. Anticonvulsant agents to control seizures.

d. Potassium for hypokalemia and sodium bicarbonate to correct metabolic acidosis, depending on laboratory results.

e. Antipyretics are not useful in treating heatstroke. They may contribute to the complications of coagulopathy and hepatic damage.

f. Intense shivering may be controlled by diazepam. Shivering will generate heat and increase the metabolic rate.

g. Patients with depleted clotting factors may be treated with platelets or fresh frozen plasma.

7. Monitor urine output, likely with an indwelling catheter—acute tubular necrosis is a complication of heatstroke.

8. Perform continuous ECG monitoring and frequent cardiovascular assessments for possible ischemia,

infarction, and dysrhythmias.

9. Perform serial laboratory testing (coagulation studies, electrolytes, glucose, and serum enzymes).
10. The patient should be admitted to an intensive care unit (ICU); complications can occur, including heart failure, cardiovascular collapse, hepatic failure, renal failure, disseminated intravascular coagulation, and rhabdomyolysis.
11. Monitor the patient for the development of seizures and provide for a safe environment in case of seizures.

GERONTOLOGIC ALERT Vigorous fluid replacement in older adults or those with underlying cardiovascular disease may cause pulmonary edema.

Frostbite

Frostbite is trauma because of exposure to freezing temperatures that cause freezing of the tissue fluids in the cell and intracellular spaces, resulting in vascular damage. The areas of the body most likely to develop frostbite are the ear lobes, cheeks, nose, fingers, and toes. Frostbite may be classified as frostnip (initial response to cold, reversible), superficial frostbite, and deep frostbite.

Primary Assessment and Interventions

1. Assess airway, breathing, and circulation.
2. Deficits may indicate coexisting hypothermia or underlying condition.
3. Protect frostbitten tissue while performing other interventions.

Subsequent Assessment

Frostnip

1. History of gradual onset.
2. The skin appears pale.
3. Complaints of numbness or tingling.

Superficial Frostbite

1. Damage is limited to the skin and subcutaneous tissue.
2. The skin will appear white and waxy.
3. On palpation, the skin will feel stiff, but the underlying tissue will be pliable and soft and have its normal "bounce."
4. Sensation is absent.

Deep Frostbite

1. The skin will appear white, yellow–white, or mottled blue–white.
2. On palpation, the surface will feel frozen and the underlying tissue will feel frozen and hard.
3. The affected part is completely insensitive to touch.

General Interventions

1. Frostnip may be treated by placing a warm hand over the chilled area.
2. Leave the frostbitten area alone until definitive rewarming is undertaken. Pad the extremity to prevent damage from trauma.
3. Handle the part gently to avoid further mechanical injury.
4. Remove all constricting clothing that can impair circulation, including watchbands and rings.
5. Rewarming:
    a. Rewarm the extremity by controlled and rapid rewarming. Rewarm with a temperature of 98.6°F to

104°F (37°C to 40°C) in a fairly large, tepid water bath where the part can be fully immersed without touching the side or bottom. If clothing, socks, or gloves are frozen to the extremity, they should be left on and removed after rewarming.

b. More warm water may be added to the container by removing some cooled water and adding warm water.

c. Slow rewarming is less effective and may increase tissue damage.

d. Dry heat is not recommended for rewarming.

e. The rewarming procedure may take 20 to 30 minutes.

f. Rewarming is complete when the area is warm to the touch and pink or flushed.

g. Do not rub or massage a frostbitten extremity. The ice crystals in the tissue will lacerate delicate tissue.

6. Pharmacologic interventions:

a. Opioids or nonsteroidals for pain control.

b. Antibiotics if there is an open wound.

c. Tetanus prophylaxis.

NURSING ALERT When definitive rewarming of a frostbitten extremity has started, it must not be stopped. Refreezing of a partially thawed extremity may increase tissue damage and loss.

Postrewarming Care

1. Protect the thawed part from infection. Large blisters may develop in 1 hour to a few days after rewarming; these blisters should not be broken. If necessary, fluid may be aspirated from the blister with a sterile needle.
2. Place sterile gauze or cotton between affected fingers/toes to absorb moisture.
3. Use strict sterile technique during dressing changes.
4. Elevate the part to help control swelling. Make sure dressings are applied loosely.
5. Use a foot cradle to prevent contact with bedding if the feet are involved—prevent further tissue injury.
6. Perform a physical assessment to look for concomitant injury (soft tissue injury, dehydration, alcohol coma, fat embolism because of fracture, immobility).
7. Restore electrolyte balance; dehydration and hypovolemia are common in frostbite victims.
8. Whirlpool bath for the affected extremity—to aid circulation, debride dead tissue, and help prevent infection.
9. Potential escharotomy (incision through the eschar)—to prevent further tissue damage, allow for normal circulation, and permit joint motion.
10. Potential fasciotomy (incision in fascia to release pressure on the muscles, nerves, blood vessels)—to treat

compartment syndrome.

11. Encourage hourly active motion of the affected digits to promote maximum restoration of function and to prevent contractures.
12. Advise patient not to use tobacco because of the vasoconstrictive effects of nicotine, which further reduce the already deficient blood supply to injured tissues.
13. Perform serial laboratory testing (urinalysis, electrolytes, and serum enzymes) to monitor for the complications of rhabdomyolysis and subsequent renal failure.

Hypothermia

Hypothermia is a condition in which the core (internal) temperature of the body is less than 95°F (35°C) as a result of exposure to cold or a loss of thermoregulation. In response to a decreased core temperature, the body will attempt to produce or conserve more heat by (1) shivering, which produces heat through muscular activity; (2) peripheral vasoconstriction, to decrease heat loss; and (3) raising the basal metabolic rate. Hypothermia may be classified as mild, moderate, or severe.

GERONTOLOGIC ALERT Older patients are at greater risk for hypothermia because of altered compensatory mechanisms.

Primary Assessment and Interventions

NURSING ALERT Extreme caution should be used in moving or transporting hypothermia patients because of the increased risk of cardiac arrhythmias.

---

1. Assess airway and breathing.
    a. Spontaneous respirations may be extremely slow and imperceptible.
    b. Assist breathing and oxygenation with supplemental oxygen at 100% or a bag-valve-mask device.
    c. If intubation is necessary, extreme caution should be used because ventricular fibrillation may be precipitated.
2. Assess circulation.
    a. If the body temperature falls below 86°F (30°C), the heart sounds may not be audible even if the heart is still beating. Tissues conduct sound poorly at low temperatures.
    b. BP readings may be extremely difficult to hear because cold tissue conducts sound waves poorly.
    c. Pupil reflexes may be blocked by a decrease in cerebral blood flow, so the pupils may appear fixed and dilated.
    d. A patient with severe hypothermia may present like a patient in cardiac arrest with fixed dilated pupils, no pulse or perfusing rhythm, and no BP. If there is any doubt about whether a pulse is present, begin CPR.

Subsequent Assessment

1. There is progressive deterioration marked by apathy, poor judgment, ataxia, dysarthria, drowsiness and, eventually, coma.
2. Speech is slow and may be slurred.

3. Shivering may be suppressed below a temperature of 90°F (32.2°C).
4. Cardiac dysrhythmias—cold disrupts the conduction system of the heart and a variety of dysrhythmias may be seen. A hypothermic heart is extremely susceptible to conduction delays. Ventricular fibrillation may occur if the temperature falls below 81°F (25°C). Patients with core temperatures below 86°F (30°C) do not respond to drugs or defibrillation.
5. The heartbeat and the BP may be so weak that the peripheral pulsations become undetectable. Always check a central pulse.
6. Urine output may increase in response to peripheral vasoconstriction—cold diuresis.
7. Initial tachypnea is usually followed by slow and shallow respirations, possibly two or three per minute in severe hypothermia.

General Interventions

The goal is to rewarm without precipitating cardiac dysrhythmias.

Supportive Measures

1. Handle the patient carefully and gently—to avoid triggering arrhythmias.
2. Continuously monitor core temperatures with a low-reading rectal thermometer.
3. Continuously monitor ECG and central pulses. Loss of a central pulse indicates a nonperfusing rhythm and the need for immediate CPR and ACLS interventions.
4. Monitor the patient's condition through vital signs, CVP, urine output, ABG values, and blood chemistry determinations.
5. Maintain an arterial line for recording BP and to facilitate blood sampling—allows rapid detection of acid–base disturbances and assessment of adequacy of ventilation and oxygenation.
6. Start IV therapy with warmed normal saline. Lactated Ringer solution is not recommended because the cold liver may not be able to metabolize the lactate.

Rewarming Techniques

The type of rewarming depends on the degree of hypothermia. Rewarming should continue until the core temperature is 93.2°F (34°C). Death in hypothermia is defined as a failure to revive after rewarming.

1. Passive external rewarming (mild hypothermia).
   a. Remove all the wet or cold clothing and replace with warm clothing.
   b. Provide insulation by wrapping the patient in several blankets.
   c. Provide warmed fluids to drink.
   d. Disadvantage: slow process.
2. Active external rewarming (moderate to severe hypothermia or hemodynamic instability).
   a. Provide external heat for the patient—warm hot water bottles to the armpits, neck, or groin. (Do not apply hot water bottles directly to the skin.)
   b. Warm water immersion.

c. Disadvantages:
    i. Causes peripheral vasodilation, returning cool blood to the core, causing an initial lowering of the core temperature.
    ii. Acidosis because of the "washing out" of lactic acid from the peripheral tissues.
    iii. An increase in the metabolic demands before the heart is warmed to meet these needs.
    iv. A combination of active external rewarming and active core rewarming can be used to minimize rewarming shock.

3. Active core rewarming (severe hypothermia less than 82.4°F [less than 28°C]).
    a. Inhalation of warmed, humidified oxygen by mask or ventilator.
    b. Warmed IV fluids.
    c. Peritoneal dialysis with warmed standard dialysis solution.
    d. Mediastinal irrigation through open thoracotomy has been used successfully but has serious complications.
    e. Cardiopulmonary bypass.
    f. Disadvantage: invasiveness of the procedures.

TOXICOLOGIC EMERGENCIES

Toxicology is the study of the harmful effect of various substances on the body. Toxins are substances that are harmful to the body no matter how much or in what manner they enter the body. Drugs become toxic when they are taken in excess quantities or manners that are not therapeutic. Alcohol is considered a drug. The treatment goals of toxicological emergencies are, first, to support; second, to prevent or minimize absorption; and third, to provide an antidote.

Ingested Poisons

Ingested poisons can produce immediate or delayed effects. Immediate injury is caused when the poison is caustic to the body tissues (ie, a strong acid or a strong alkali). Other ingested poisons must be absorbed into the bloodstream before they become harmful. Ingested poisoning may be accidental or intentional.

Primary Assessment and Interventions

1. Maintain an open airway—some ingested substances may cause soft tissue swelling of the airway.
2. Attain control of the airway, ventilation, and oxygenation; in the absence of cerebral or renal damage, the patient's prognosis depends largely on successful management and support of vital functions.

Subsequent Assessment

1. Identify the poison.
    a. Try to determine the product taken: where, when, why, how much, who witnessed the event, and time since ingestion. Histories obtained from the patient are often inaccurate and should be confirmed if at all possible.
    b. Always contact the local poison control center for assistance in identifying the toxin, if unknown, treatment recommendations, and antidote information. In the United States, local poison control centers can all be reached by calling (800) 222-1222.
2. Continue the focused assessment, observing any significant deviations from normal. Different poisons will affect the body in different ways.
3. Obtain blood and urine tests for toxicology screening. Gastric contents may also be sent for toxicology screening in serious ingestions.
4. Monitor neurologic status, including mentation; monitor the course of vital signs and neurologic status over time.
5. Monitor for fluid and electrolyte imbalance.

General Interventions

Supportive Care

1. Assess and protect the patient's airway, as needed.
2. Administer oxygen and assist ventilations, as needed.
3. Monitor and treat shock.
4. Insert two large-bore IV lines.
5. Give supportive care to maintain vital organ systems.
6. Insert an indwelling urinary catheter to monitor renal function.
7. Support the patient having seizures; many poisons excite the CNS or the patient may convulse from oxygen deprivation.
8. Monitor and treat for complications: hypotension, coma, cardiac dysrhythmias, and seizures.

9. Psychiatric evaluations should be done after the patient is stabilized.

Minimizing Absorption

1. The primary method for preventing or minimizing absorption is to administer activated charcoal. Newer superactivated charcoals can reduce absorption of a toxic substance by as much as 50%. Administering activated charcoal alone is recommended. Insertion of a large-bore orogastric tube and gastric lavage are no longer recommended. The routine use of a cathartic in combination with activated charcoal is also no longer recommended.
   a. Administration of premixed oral-activated charcoal adsorbs the poison on the surface of its particles and allows it to pass with the stool. Multiple doses may be administered.
   b. A routine NG tube may be inserted to facilitate emptying of stomach contents (without lavage) within 30 minutes of ingestion or to instill charcoal if the patient is unable to drink the mixture.

NURSING ALERT Contact your local poison control center for recommendations on giving charcoal. Do not give charcoal if the patient may not be able to maintain airway unless you have an artificial airway established.

---

2. Gastric lavage is contraindicated due to poor outcomes and complications.
3. Procedures to enhance the removal of the ingested substance if the patient is deteriorating.
   a. Forced diuresis with urine pH alteration—to enhance renal clearance.
   b. Hemoperfusion (process of passing blood through an extracorporeal circuit and a cartridge containing an adsorbent, such as charcoal, after which the detoxified blood is returned to patient).
   c. Hemodialysis—used in selected patients to purify blood and accelerate the elimination of circulating toxins.
   d. Repeated doses of charcoal—for binding nonabsorbed drugs/toxins.

NURSING ALERT Do not induce emesis after ingestion of caustic substances, hydrocarbons, iodides, silver nitrates, strychnine, or petroleum distillates, to a patient having seizures, or to pregnant patients.

Providing an Antidote

1. An antidote is a chemical or physiologic antagonist that will neutralize the poison.
2. Administer the specific antidote as early as possible to reverse or diminish effects of the toxin.
3. Repeated antidote doses may be necessary.
4. Follow the recommendations of your poison control center.

Carbon Monoxide Poisoning

Carbon monoxide poisoning is an example of an inhaled poison and is the result of the inhalation of the products of incomplete hydrocarbon combustion. It may occur as an industrial or household accident or as an attempted suicide. Carbon monoxide exerts its toxic effect by binding to circulating hemoglobin to reduce the oxygen-carrying capacity of the blood. The affinity between carbon monoxide and hemoglobin is 200 to 250 times more than between oxygen and hemoglobin. (Carbon monoxide combines with hemoglobin to form carboxyhemoglobin.) As a result, tissue anoxia occurs.

Primary Assessment

1. Assess airway and breathing. Assist with ventilations, as needed.
    a. Respiratory depression may be present.
    b. If the carbon monoxide poisoning is due to smoke inhalation, stridor (indicative of laryngeal edema because of thermal injury) may be present. Check for soot on the back of the hard palate or pharynx if smoke inhalation is suspected.

Primary Interventions

1. Provide 100% oxygen by tight-fitting mask. (The elimination half-life of carboxyhemoglobin, in serum, for a person breathing room air is 5 hours and 20 minutes. If the patient breathes 100% oxygen, the half-life is reduced to 80 minutes; 100% oxygen in a hyperbaric chamber will reduce the half-life to 23 minutes [treatment of choice].)
2. Intubate, if necessary, to protect the airway.

Subsequent Assessment

1. A thorough history is important: determine the type and length of exposure as well as possible other fumes inhaled. An underlying anemia, cardiac disease, or pulmonary disease may place a person at higher risk.
2. Determine LOC—the patient may appear intoxicated from cerebral hypoxia; confusion may progress rapidly to coma.
3. Assess complaints of headache, muscular weakness, palpitation, and dizziness.
4. Inspect the skin: may be pink, cherry red, or cyanotic and pale—skin color is not a reliable sign.
5. Monitor vital signs: increased respiratory and pulse rates are generally present. Be alert for altered breathing patterns and respiratory failure.
6. Listen for rales or wheezes in the lungs (with smoke inhalation, indicates acute respiratory distress syndrome).
7. Obtain arterial or venous blood samples for carboxyhemoglobin levels.
    a. Normal levels for a nonsmoking patient are less than 3%. For a patient who smokes one to two packs per day, 4% to 5%, and two or more packs per day, 8% to 10%.
    b. Toxic concentrations are considered to be greater than 20%.

General Interventions

1. History of exposure to carbon monoxide justifies immediate treatment.
2. Goals are to reverse cerebral and myocardial hypoxia and hasten carbon monoxide elimination.
3. Give 100% oxygen at atmospheric or hyperbaric pressures to reverse hypoxia and accelerate elimination of carbon monoxide. Patients should receive hyperbaric oxygen for CNS or cardiovascular system dysfunction.
4. Use continuous ECG monitoring, treat dysrhythmias, and correct acid–base and electrolyte abnormalities.
5. Observe the patient constantly—psychoses, spastic paralysis, vision disturbances, and deterioration of personality may persist after resuscitation and may be symptoms of permanent CNS damage.

Insect Stings

Insect stings or bites are injected poisons that can produce either local or systemic reactions. Local reactions are characterized by pain, erythema, and edema at the site of injury. Systemic reactions usually begin within minutes and produce mild to severe and life-threatening reactions.

Primary Assessment and Interventions

1. Assess airway, breathing, and circulation.
2. Anaphylactic reactions may produce unconsciousness, laryngeal edema, and cardiovascular collapse.
3. Epinephrine is the drug of choice—the amount and route depend on the severity of the reaction.
4. Administer a bronchodilator to help relieve the bronchospasm.
5. Initiate an IV line with lactated Ringer solution.
6. Prepare for CPR.

Subsequent Assessment

1. Obtain history of insect sting, previous exposure, and allergies.
2. Inspect the skin for local reaction—erythema, edema, and pain at site of injury—as well as generalized pruritus, urticaria, and angioedema.
3. Continue to monitor BP and respiratory status for dyspnea, wheezing, and stridor.

General Interventions

1. Apply ice packs to site to relieve pain.
2. Elevate extremity with large edematous local reaction.
3. Administer oral antihistamine for local reactions.
4. Clean the wound thoroughly with soap and water or an antiseptic solution.
5. Administer tetanus prophylaxis if not up to date.
6. Provide patient education.
    a. Always have epinephrine on hand.
    b. Wear medical emergency bracelets indicating hypersensitivity.
    c. Instructions when sting occurs:
        i. Take epinephrine immediately if stung.
        ii. Remove stinger with one quick scrape of fingernail.
        iii. Do not squeeze venom sac because this may cause additional venom to be injected.
        iv. Report to the nearest health care facility for observation.
    d. Avoid exposure and become desensitized.
        i. Avoid locales with stinging insects (camp and picnic sites).
        ii. Stay away from insect-feeding areas—flower beds, ripe fruit orchards, garbage, and fields of

clover.

iii. Avoid going barefoot outdoors—yellow jackets may nest on ground.

iv. Avoid perfumes, scented soaps, and bright colors, which attract bees.

v. Keep car windows closed.

vi. Spray garbage cans with rapid-acting insecticide and keep areas meticulously clean.

Snakebites

The majority of snakes in the United States are not poisonous. The poisonous varieties are pit vipers (rattlesnakes and copperheads) and coral snakes. Bites by these snakes may result in envenomation, an injected poisoning. Other parts of the world have many snakes capable of lethal bites. Snakebites can cause neurotoxic muscle paralysis, coagulopathy, and hemolysis. Therefore, knowledge of snakes indigenous to your area is important for swift and appropriate treatment.

Primary Assessment and Interventions

1. Assess airway, breathing, and circulation.
2. Severe envenomation may lead to neurotoxicity with respiratory paralysis, shock, coma, and death.
3. Be prepared to resuscitate and provide advanced life support.

Subsequent Assessment

1. Get a description of the snake, the time of the snakebite, and the location of the bite. Bites to the head and trunk may progress more rapidly and be more severe.
   a. Pit vipers have triangular heads, vertical pupils, indentations between the eyes and nostrils, and long fangs.
   b. Coral snakes are small and brightly colored, with short fangs and teeth behind them and a series of bands of yellow, red, yellow, and black (in that order).
   c. Venom detection kits are available in some areas of the world such as Australia where venomous snakes are not uncommon. Specific antivenom may be available.
2. Assess for local reactions—burning, pain, swelling, and numbness at the site. Local reactions to coral snakebites may be delayed by several hours and may be very mild.
3. A few hours after the bite, hemorrhagic blisters may occur at the site and the entire extremity may become edematous.
4. Watch for signs of systemic reactions, including nausea, sweating, weakness, light-headedness, initial euphoria followed by drowsiness, difficulty in swallowing, paralysis of various muscle groups, signs of shock, seizures, and coma.
5. Monitor vital signs closely because tachycardia or bradycardia may develop.

NURSING ALERT Patients will, on occasion, bring the snake that bit them into the emergency department for identification. Even dead, a snake can reflexively bite for several hours. Caution should be used to avoid becoming a second victim.

General Interventions

1. Keep the patient calm and at rest in a recumbent position with the affected extremity immobilized.

Remove jewelry or other constricting items, as the area may become edematous.

2. Administer oxygen.
3. Start an IV line with normal saline or lactated Ringer solution.
4. Administer antivenin and be alert to allergic reaction.
5. Administer vasopressors in the treatment of shock.
6. Monitor for bleeding and administer blood products for coagulopathy.

Drug Intoxication

Substance abuse includes the use of specific substances that are intended to alter mood or behavior.

Drug abuse is the use of drugs for other than legitimate medical purposes. There is a growing tendency among drug users to take a variety of drugs simultaneously (polypharmacy abuse), including alcohol, sedatives, hypnotics, and marijuana, which may have addictive effects. The clinical manifestations may vary with the drug used (see Table 35-2), but the underlying principles of management are essentially the same.

Table 35-2 Specific Drug Overdose Presentations and Interventions

TYPE OF DRUG	PRESENTATION	INTERVENTIONS
CNS Stimulants • Amphetamines • Designer drugs (MDMA, ecstasy, ice, Eve, bath salts) • Cocaine (can be smoked in freebase or crack form, snorted, or injected)	Palpitations, feeling of impending doom, tachycardia, hypertension, dysrhythmia, myocardial ischemia or infarction, euphoria, agitation, combativeness, confusion, hallucinations, paranoia, aggressive or violent behavior, suicide attempts, hyperpyrexia, and seizures. When the drug wears off, depression, exhaustion, irritability, and sleeplessness.	• Secure airway, breathing, and circulation. • Monitor ECG and provide oxygen for ischemia. • Sedate, as necessary. • Administer antiarrhythmics for ventricular dysrhythmia. • Administer diazepam for seizures. • Closely monitor hemodynamic status and provide IV fluids, as indicated.
Hallucinogens • Lysergic acid diethylamide (LSD) • Phencyclidine HCl (PCP) • Mescaline • Psilocybin mushrooms • Jimson weed seeds • Salvia	Marked anxiety bordering on panic, confusion, incoherence, hyperactivity, hallucinations, hazardous behavior, convulsions, coma, circulatory collapse, and death. Flashbacks may occur months to years after initial drug use.	• Reduce sensory stimuli, encourage patient to keep eyes open, and stay with patient. • Monitor for hypertensive crisis and evidence of trauma. • Sedate if hyperactivity cannot be controlled and place patient in a protected environment.
Opioids • Heroin (may be cut with other ingredients in 20:1–200:1 ratios) • Morphine and its derivatives • Codeine and its derivatives	Hypotension, respiratory depression leading to apnea, miosis, and drowsiness progressing to stupor and coma.	• Administer naloxone 0.4–2 mg via IV line or by endotracheal tube (effective in 1–2 min). • Maintain an open airway but defer intubation until naloxone is given, if possible. • Monitor for reappearance of symptoms and readminister naloxone. • Protect the patient from harm (may be combative on awakening).
Sedatives • Barbiturates, such as amobarbital and secobarbital • Benzodiazepines, such as diazepam and flurazepam • Other sedative/hypnotics, such as chloral hydrate and glutethimide	Incoordination, ataxia, impaired thinking and speech, lethargy to coma, early miosis; later, fixed and dilated pupils, hypoventilation, hypotension, hypothermia, and decreased reflexes.	• Administer flumazenil to reverse or diminish effects of benzodiazepines. • Administer activated charcoal. • Protect the airway. • For hypotension, infuse with lactated Ringer solution and give vasopressors.
Alcohol Intoxication generally occurs with blood levels >100 mg/dL. Levels more than 400 mg/dL are due to rapid consumption of alcohol and represent a medical emergency.	Slurred speech, incoordination, ataxia, belligerent behavior progressing to stupor and coma, odor of alcohol on breath and clothing, and respiratory depression.	• Protect the airway. • Closely monitor for CNS and respiratory depression. • Draw blood for ethanol concentration, electrolytes, glucose, and drug screen, using nonalcohol skin cleanser. • Assess for head injury and other trauma, as well as organic disease. • Administer IV fluids, magnesium sulfate (to reduce risk of seizures), thiamine (to prevent Wernicke-Korsakoff syndrome), and glucose (to treat hypoglycemia).

CNS, central nervous system; ECG, electrocardiogram.

Overdose refers to the toxic effects that occur when a drug is taken in a larger-than-normal dose.

Primary Assessment and Interventions

1. Assess airway, breathing, and circulation.

2. Attain control of the airway, ventilation, and oxygenation.
3. Intubate and provide assisted ventilation in patients with severe respiratory depression or in patients lacking gag or cough reflexes. If possible, intubation should be held off until a trial dose of naloxone is given.
4. Begin CPR in the absence of pulse.

Subsequent Assessment

1. Do a thorough physical examination to rule out insulin shock, meningitis, head injury, stroke, or trauma.
2. If the patient is unconscious, consider all possible causes of loss of consciousness.
3. Monitor LOC continuously.
4. Monitor vital signs frequently—some drugs will cause depressed vital signs; others will elevate the vital signs.
5. Monitor the pupils: extreme miosis (pinpoint pupils) may indicate opioid overdose.
6. Look for needle marks and external evidence of trauma.
7. Perform a rapid neurologic survey: level of responsiveness, pupil size and reactivity, reflexes, and focal neurologic findings; these can all give clues for identifying the drug taken.
8. Keep in mind that many drug abusers take multiple drugs simultaneously.
9. Be aware that there is a high incidence of human immunodeficiency virus (HIV), tuberculosis, and infectious hepatitis among drug users.
10. Examine the patient's breath for characteristic odor of alcohol, acetone, and so forth.
11. Try to obtain a history of drug experiences (from the person accompanying the patient or from the patient).

General Interventions

1. Goals:
    a. Support the respiratory and cardiovascular functions.
    b. Give definitive treatment for drug overdose, such as naloxone.
    c. Prevent further absorption, enhance drug elimination, and reduce its toxicity.
2. Measure ABGs for hypoxia because of hypoventilation or for acid–base derangements.
3. Continuously monitor ECG.
4. Draw blood samples for testing glucose, electrolytes, BUN, creatinine, and appropriate toxicology screen.
5. Initiate IV fluids.
6. Administer oxygen.
7. Pharmacologic interventions:
    a. Give specific drug antagonist if drug is known.
    b. Naloxone for CNS depression because of opioids.
    c. Dextrose 50% IV to rule out hypoglycemic coma.

8. If the drug was taken by mouth, the primary method for preventing or minimizing absorption is to administer activated charcoal. Multiple doses may be administered. A routine NG tube may be inserted to facilitate emptying of stomach contents (without lavage) within 30 minutes of ingestion, or charcoal may be instilled if the patient is unable to drink.
9. In unconscious or semiconscious patients who are or may be lacking gag or cough reflexes, use an NG tube only after intubation with cuffed endotracheal tube to prevent aspiration of charcoal stomach contents.
10. Take rectal temperature—extremes of thermoregulation (hyperthermia/hypothermia) must be recognized and treated.
11. Treat seizures with diazepam.
12. Assist with hemodialysis/peritoneal dialysis for potentially lethal poisoning.
13. Catheterize the patient because the drug or its metabolites are excreted in urine.
14. Do not leave the patient alone; there is a potential for the patient to harm self or ED staff.
15. Anticipate complications—sudden death from cerebral hypoxia, dysrhythmias, seizures, respiratory arrest, and MI.
16. Always suspect mixtures of medications and alcohol.

DRUG ALERT Antidotes generally have a shorter half-life than the drugs they are used to treat. Repeated dosing is often necessary.

NURSING ALERT Many drugs will not or cannot be detected in a standard toxicology screen. A negative drug screen does not mean an overdose is not the cause of the emergency.

Alcohol Withdrawal Delirium

Alcohol withdrawal delirium (*delirium tremens* or *alcoholic hallucinosis*) is an acute toxic state that follows a prolonged bout of steady drinking or sudden withdrawal from prolonged intake of alcohol. It may be precipitated by acute injury or infection. Symptoms can begin as early as 4 hours after a reduction of alcohol intake and usually peak at 24 to 48 hours, but may last up to 2 weeks.

NURSING ALERT Alcohol withdrawal delirium is a serious complication of inadequate withdrawal management and is life-threatening.

Primary Assessment and Interventions

1. Patient may present alert, unless experiencing a seizure.
2. Ensure adequacy of airway, breathing, and circulation.

Subsequent Assessment

1. Assess for major symptoms—may occur independently or in combination.
   a. Nausea.
   b. Tremors.
   c. Paroxysmal sweating.
   d. Anxiety.
   e. Agitation.
   f. Headache.
   g. Mental status.
   h. Hallucinations (may be tactile, visual, or auditory).
2. Utilizing a standard Clinical Institute Withdrawal Assessment for Alcohol scale may assist in identifying those at risk for withdrawal problems and guide treatment. See Box 35-1.
   a. Each category is given a score and the total added. The cumulative score provides a basis for treatment. Generally, a score of 8 to 10 or greater is the threshold for treatment to alleviate symptoms and prevent seizures.
   b. Reassess frequently during the first 48 hours and discontinue treatment and assessments when three subsequent determinations have been below the threshold.
3. Obtain drinking history, including the severity of past withdrawal episodes and any recent drug intake. Be aware that people tend to underestimate drinking habits.
4. Perform a thorough examination for signs of autonomic hyperreactivity—tachycardia, diaphoresis, elevated temperature, and dilated but reactive pupils—as well as any coexisting illnesses or injuries (head injury, pneumonia, metabolic disturbances).

5. Observe behavior for talkativeness, restlessness, agitation, or preoccupation.

BOX 35-1 Clinical Institute of Withdrawal from Alcohol Scale Revised (Ciwa-Ar)*

NAUSEA AND VOMITING Ask: "Do you feel sick to your stomach? Have you vomited?" 0 = No nausea, no vomiting 1 = Mild nausea with no retching or vomiting 4 = Intermittent nausea with dry heaves 7 = Constant nausea, frequent dry heaves, and/or vomiting	**TACTILE DISTURBANCES** Ask, "Have you any itching, pins-and-needles sensation, burning or numbness, or do you feel bugs crawling on or under your skin?" 0 = None 1 = Very mild 2 = Mild 3 = Moderate 4 = Moderately severe hallucinations 5 = Severe hallucinations 6 = Extremely severe hallucinations 7 = Continuous hallucinations
TREMOR Arms extended and fingers spread apart. 0 = No tremor 1 = Not visible, but can be felt fingertip to fingertip 4 = Moderate with patients arm extended 7 = Severe, even with arms not extended	**AUDITORY DISTURBANCES** Ask, "Are you more aware of the sounds around you? Are they harsh? Do they frighten you? Are you hearing anything disturbing? Are you hearing things you know are not there?" 0 = Not present hallucinations 1 = Very mild 2 = Mild 3 = Moderate 4 = Moderately severe 5 = severe hallucinations 6 = Extremely severe hallucinations 7 = Continuous hallucinations
SWEATING 0 = No sweat visible 1 = Barely perceptible sweating, palms moist 4 = Beads of sweat obvious on the forehead 7 = Drenching sweat over the face and chest	**VISUAL DISTURBANCES** Ask, "Does the light appear to be too bright? Is its color different? Does it hurt your eyes? Are you seeing anything disturbing to you? Are you seeing things you know are not there?" 0 = Not present 1 = Very mild 2 = Mild 3 = Moderate 4 = Moderately severe 5 = Severe hallucinations 6 = Extremely severe hallucinations 7 = Continuous hallucinations
ANXIETY Ask, "Do you feel nervous?" 0 = No anxiety, at ease 1 = Mildly anxious 4 = Moderately anxious or guarded, so anxiety is inferred 7 = Equivalent to acute panic states, as seen in severe delirium or acute schizophrenic reaction	**HEADACHE, FULLNESS IN HEAD** Ask, "Does your head feel different? Does it feel like there is a band around your head?" Do not rate dizziness or lightheadedness. Otherwise, rate severity. 0 = Not present 1 = Very mild 2 = Mild 3 = Moderate 4 = Moderately severe 5 = Severe 6 = Very severe 7 = Extremely severe
AGITATION 0 = Normal activity 1 = Somewhat more than normal activity (may move legs up and down, shift position occasionally) 4 = Moderately fidgety and restless, shifting position frequently 7 = Paces back and forth or constantly thrashes about	**ORIENTATION AND CLOUDING OF SENSORIUM** Ask, "What day is this? Where are you? Who am I?" 0 = Oriented and can do serial additions 1 = Cannot do serial additions or is uncertain about date 2 = Disoriented for date by no more than 2 calendar days 3 = Disoriented for date by more than 2 calendar days 4 = Disoriented for place and/or person

*Assessment is made in each category and cumulative score is used to determine treatment (institutional protocols vary).

From Sullivan, J. T., Sykora, K., Schneiderman, J., et al. (1989). Assessment of alcohol withdrawal: The

revised Clinical Institute Withdrawal Assessment for Alcohol scale (CIWA-Ar). *British Journal of Addiction*, 84(11), 1373–1357.

General Interventions

1. Protect the patient from injury. Not all patients have hallucinations; however, if they do, the hallucinations may be visual, tactile, or auditory and are frequently frightening. Seizures may also occur.
2. Using a nonalcoholic skin preparation, draw blood for measurement of ethanol concentration, toxicology screen for other drugs of abuse, and other tests, as directed.
3. Pharmacologic interventions:
    a. Diazepam or chlordiazepoxide for sedation. Sedate the patient with sufficient dosage of medication to produce adequate relaxation and to reduce agitation, prevent exhaustion, and promote sleep without compromising airway.
    b. Diazepam or phenytoin for seizure control.
4. Monitor vital signs every 30 minutes.
5. Maintain close observation.
6. Maintain electrolyte balance and hydration through oral or IV route—fluid losses may be extreme because of profuse perspiration, vomiting, and agitation.
7. Assess respiratory, hepatic, and cardiovascular status of patient—pneumonia, liver disease, and cardiac failure are complications.
8. Observe for hypoglycemia and treat appropriately. Hypoglycemia may accompany alcoholic withdrawal because alcohol depletes liver glycogen stores and impairs gluconeogenesis; many patients also suffer from malnutrition.
    a. Administration of thiamine is common.

BEHAVIORAL EMERGENCIES

A *behavioral emergency* is an urgent, serious disturbance of behavior, affect, or thought that makes the patient unable to cope with his or her life situation and interpersonal relationships. A patient presenting with a psychiatric emergency may be overactive or violent, depressed, or suicidal.

Violent Patients

Violent and aggressive behavior is usually episodic and is a means of expressing feelings of anger, fear, or hopelessness about a situation.

Assessment

1. Assess for overactivity, aggression, or anger out of proportion to the circumstances.
2. Determine risk factors for violence, including:
    a. Intoxicated with drugs/alcohol.
    b. Going through drug or alcohol withdrawal.
    c. Acute paranoid schizophrenic states, acute organic brain syndrome, acute psychosis, paranoia, or borderline personality.
3. Obtain psychiatric assessment.

General Interventions

1. Goals are to bring violence under control and protect patient and staff from harm.
2. Establish control.
    a. Keep room door open, and be in clear view of the staff. Always leave a clear exit pathway. Never allow the patient to be between you and safety.
    b. Help the patient bring violence under control.
        i. Give patient space; do not make sudden moves.
        ii. Avoid touching agitated patients or standing close.
        iii. Ask if the patient has a weapon; request that it be placed in a neutral area.
        iv. If the patient will not surrender weapon, leave the room and allow security personnel/police to handle the situation.
    c. Try not to leave the patient alone unless your safety is in jeopardy; this may be interpreted as rejection or the patient may try to harm self.
    d. Adopt a calm nonconfrontational approach and remain in control of the situation. External calm and structure may help the patient gain control.
    e. Give the patient choices and options about treatments or timing of events if at all possible.
3. Provide emotional support.
    a. Talk and listen to the patient.
    b. Crisis intervention is best done with an attitude of interest in the patient's well-being and with an attempt to "tune in" to the patient while remaining firm.
    c. Acknowledge the patient's state of agitation (eg, "I want to work with you to relieve your distress").
    d. Give the patient the opportunity to ventilate anger verbally; avoid challenging the delusional state.
    e. Try to hear what the patient is saying.

f. Convey the expectation of appropriate behavior and make the patient aware that help is available for him or her to gain control.

g. Administer prescribed medications to reduce anxiety and hyperactivity, if verbal management techniques fail to attenuate the patient's tension.

4. Secure assistance.

   a. Allow security personnel/police to intervene if patient does not become calm.

   b. Use of a dedicated safe room is encouraged. The room should be free of cords, cables, or any object capable of being used as a weapon and be easily seen by staff. Shatterproof windows and/or cameras are encouraged. Use restraints when absolutely necessary and per the facility's policy.

   c. Have a specific plan and enough well-trained personnel available when applying restraints; if patient is intoxicated, restrain in a left lateral position and monitor closely for aspiration.

   d. Talk reassuringly while applying restraints; use empathic and supportive verbal interactions.

   e. Monitor patient continuously after restraints are applied; check circulation of restrained extremities.

Depression

Depression may be seen as the presenting condition at the health care facility or may be masked by the presentation of anxiety and somatic complaints.

Assessment

1. Observe for sadness, apathy, feelings of worthlessness, self-blame, suicidal thoughts, desire to escape, worsening of mood in morning, anorexia, weight loss, sleeplessness, lessening interest in sex, reduction of activity, or ceaseless activity.
2. The agitated, depressed person may exhibit motor restlessness and severe anxiety.

General Interventions

1. Listen to the patient in a calm, unhurried manner.
2. The patient will benefit from ventilation of feelings.
3. Give the patient an opportunity to talk about problems.
4. Anticipate that the patient may be suicidal.
5. Attempt to find out if the patient has thought about or attempted suicide and the lethality of the suicide plan.
    a. "Have you ever thought about taking your own life?"
    b. The patient is generally relieved because of the opportunity to discuss feelings.
6. Find out if there is an illness, perceived or real.
7. Assess whether there has been sudden worsening of depression.
8. Notify relatives about a seriously depressed patient. Do not leave the patient alone because suicide is usually an act committed in solitude.
9. Give antidepressant and antianxiety agents, as prescribed.
10. Point out to the patient that depression is treatable.
11. Be aware of crisis and supportive services in the community: telephone counseling and referral, suicide prevention centers, group therapy, marital and family counseling, drug/alcohol counseling, adolescent counseling, or befriending programs.
12. Refer for psychiatric consultation or to psychiatric unit.

Suicide Ideation

According to the Centers for Disease Control and Prevention (CDC), suicide is the 11th leading cause of death in the United States and the third most common cause of death in young people.

Assessment

1. Assess for risk factors:
    a. Associated psychiatric illness (affective disorders and substance abuse in adults; conduct disorders and depression in young people).
    b. Personality traits, such as aggression, impulsivity, depression, hopelessness, borderline personality disorder, or antisocial personality.
    c. Persons who have experienced early loss, decreased social support, chronic illness, or recent divorce.
    d. Genetic and familial factors: family history of suicide, certain psychiatric disorders or alcoholism, alcohol and substance abuse.
2. Determine whether patient has communicated suicidal intent, such as preoccupation with death or talking about someone else's suicide.
3. Determine whether patient has ever attempted suicide—the risk is much greater in these people.
4. Determine whether there is a specific plan for suicide and a means to carry out the plan.

General Interventions

1. Treat the consequences of the suicide attempt, if one has been made.
2. After the patient has been stabilized, or if there was no active attempt made, use crisis intervention (a form of brief psychotherapy) to determine suicide potential, discover areas of depression and conflict, find out about the patient's support system, and determine whether hospitalization, psychiatric referral, and so forth are warranted.
3. Prevent further self-injury—a patient who has made a suicide gesture may do so again.
4. Admit to ICU (if condition warrants), arrange follow-up care, or admit to psychiatric unit, depending on assessment of suicide potential.

SEXUAL ASSAULT

Rape

Rape is defined as any kind of penetration of another person, without her or his consent. This definition includes men and women, as well as the use of objects, rather than just body parts. Lack of consent is the key. *Lack of consent* can imply either force or the incapacity or inability to consent. Children, mentally handicapped individuals, and persons who are intoxicated or drugged are all considered unable to consent to sexual acts.

NURSING ALERT The management of the sexual assault is important, but immediate physical health should be ensured first. A complete primary and focused assessment should take place, being alert for signs of internal hemorrhage, shock, or respiratory distress. If the victim has suffered trauma in the form of physical assault (eg, head or abdominal trauma), the trauma should be managed in the order of established priorities.

Assessment

Initiating a Supportive Relationship

1. The manner in which the patient is received and treated in the ED is important to her or his future psychological well-being. Many areas have sexual assault nurse examiners. These nurses have specialized education and clinical experience to prepare them for forensic examination of sexual assault victims. Some areas of the country have a designated center for treatment of sexual assault victims. If this is true in your area, the patient should have any life-threatening injuries stabilized and then be transferred to the dedicated facility for examination.
    a. Call a rape crisis intervention counselor (if available), who will meet the patient/family in the ED.
    b. Do not leave patient alone. Accept the emotional reactions of the patient (hysteria, stoicism, overwhelmed feeling, etc.).
2. Emotional trauma may be present for weeks, months, or years. Patients may experience complex posttraumatic stress disorder or rape trauma syndrome. Patients may go through phases of psychological reactions:
    a. Acute phase (disorganization)—shock, disbelief, fear, anxiety, guilt, humiliation, and suppression of feelings—may be for a few days to several weeks.
    b. Outward adjustment phase—victim resumes what appears to be a normal life but internally faces continued turmoil, manifested as fear, flashbacks, sleep disturbances, hyperalertness, and psychosomatic reactions.
    c. Resolution phase—the rape is no longer the central focus of the victim's life and she or he is able to move on from the incident.

Interviewing the Patient

1. Consent should be obtained for the examination, the collecting of cultures/evidence, and for release of

information to law enforcement agencies.

2. Record history of event in the patient's own words.
3. Ask if the patient has bathed, douched, gargled or brushed teeth, changed clothes, or urinated or defecated since attack—may alter interpretation of subsequent findings.
4. Record time of admission, time of examination, date and time of sexual assault, and the general appearance of the patient.
    a. Document any evidence of trauma—discoloration, bruises, lacerations, secretions, and torn and bloody clothing.
    b. Record emotional state.

NURSING ALERT Most EDs have commercially prepared rape evidence collection kits as well as written protocols for treatment of injuries, legal documentation, prevention of sexually transmitted infection (STI), HIV testing and postexposure prophylaxis, and pregnancy prevention. Remember that the evidence collection kit is meant to preserve forensic evidence.

Interventions

Preparing for Physical Examination

1. Assist the patient to undress over a sheet/large piece of paper to obtain debris.
2. Place each item of clothing in a separate paper bag (plastic bags promote moisture retention, which may lead to formation of mold and mildew, which can destroy evidence).
3. Label bags appropriately; give to appropriate law enforcement authority.
4. Advise the patient of the nature and necessity of each procedure; give the rationale for each question asked.

Physical Examination

1. Examine the patient (from head to toe) for injuries, especially to the head, neck, breasts, thighs, back, and buttocks.
2. Assess for external evidence of trauma (bruises, contusions, lacerations, stab wounds).
3. Assess for dried semen stains (appearing as crusted, flaking areas) on the patient's body.
4. Inspect fingers for broken nails and tissue and foreign materials under nails. Obtain scrapings or clippings of fingernails.
    a. Conduct an oral examination looking for any contusions and petechiae, and obtain swabs for DNA testing.
5. Document evidence of trauma with body diagrams and photographs if available.

Pelvic and Rectal Examinations

1. Examine the perineum and thighs with an ultraviolet light (Wood lamp) if available. Areas that are found to fluoresce may indicate semen stains. Urine and other stains may also fluoresce.
2. Note color and consistency of any discharge present.
3. Examine external vaginal area and rectum for any bleeding, contusion, ecchymosis, erythema, lacerations, scars, or any other injuries or abnormalities.
4. Use water-moistened vaginal speculum for examination; do not use lubricant (contains chemicals that may interfere with later forensic testing of specimens and acid phosphatase determinations).

Obtaining Laboratory Specimens

1. Obtain separate swabs from the oral, labial, vaginal, and anal areas.
2. Obtain swabs of body orifices for gonorrhea and chlamydia testing, or send a urine sample to test for gonorrhea, chlamydia, and trichomonas if the facility has that testing capability.
3. Comb and trim areas of pubic hair suspected of containing semen; obtain several pubic hairs with follicles; place in separate containers and identify these as patient's pubic hairs.
4. Obtain blood sample for syphilis and hepatitides B and C, and offer the patient HIV testing.
5. Collect foreign material or debris (leaves, grass, dirt, loose hair, string) and place in appropriate container.
6. Conduct a pregnancy test on all females of child-bearing capability.
7. Label all specimens with name of patient, date, time of collection, body area from which specimen was obtained, and names of personnel collecting specimens to preserve chain of evidence; give to designated person (eg, crime laboratory), and document who you gave the collected evidence to in the medical record.
8. Photographs, if taken, should be preserved according to facility policy.

Other Interventions

1. Treat physical trauma as with any patient.
2. Offer the patient treatment for STIs, pregnancy prevention, and HIV postexposure prophylaxis. CDC recommendations for prophylactic treatment following a sexual assault are:
   Ceftriaxone 250 mg IM in a single dose.
   plus
   Metronidazole 2 g by mouth (PO) in a single dose.
   plus
   Azithromycin 1 g PO in a single dose *or* doxycycline 100 mg PO twice per day for 7 days.
3. Protect patient against pregnancy.
   a. It is important to determine whether pregnancy existed before the attack.
   b. Negative pregnancy test should be obtained before administering postcoital therapy.
   c. Hormonal treatment to prevent pregnancy—morning-after pill, as indicated, with patient's consent.
4. Provide the patient with cleansing facilities, including a cleansing douche, shower, and mouthwash after

forensic exam is completed.

Providing for Follow-Up Services

1. Ensure the patient has follow-up for results of her STI cultures, HIV test, and any other lab testing that was done.
2. Ensure the patient has follow-up with counseling services. This is imperative to prevent long-term psychological effects of the assault. Families of the victim may need counseling services as well. Stress to the patient the importance of postassault counseling to return to her previous level of functioning.
3. Provide support to the patient in her decision to involve law enforcement.
4. Ensure a safety plan for the patient prior to discharge. The patient should be accompanied by a family member or friend when leaving the health care facility.

BIOLOGICAL WEAPONS AND PREPAREDNESS

Following the September 11, 2001, terrorist attacks on the United States, bioterrorism has become a real possibility. As frontline responders, emergency nurses must be aware of possible acts of bioterrorism and be familiar with their facilities' policies regarding such emergencies.

Biological Agents

Terrorism may consist of the intentional release of a chemical, biological, radiological, nuclear, or explosive device intended to cause widespread illness or death. Explosive devices tend to announce themselves rather quickly and definitively. Bioterrorism, however, can have a slow, insidious onset, leaving the population with little idea they have been the victim of an attack. The emergency nurse should be on the alert for possible signs of terrorism:

1. Large numbers of people with similar disease.
2. Cases of unexplained illness or death.
3. More severe illness than would normally be expected for a specific pathogen.
4. An illness that is resistant to usual treatment.
5. Unusual routes of exposure for a specific pathogen.
6. Disease that is unusual for an area.
7. A single case of unusual disease (smallpox, hemorrhagic fever).
8. Disease unusual for an age group.

See Table 35-3 for specific agents of bioterrorism, such as smallpox, anthrax, plague, and botulism.

Table 35-3 Potential Biological Weapons

AGENT AND METHOD OF TRANSMISSION	CLINICAL MANIFESTATIONS	MANAGEMENT
Smallpox		
Transmitted by inhalation or direct contact with the variola virus; has a 2-week incubation period.	High fever, fatigue, muscle aches, and rash that progresses to blisters after 3 days. The rash first develops on the face and around the wrists and then spreads to the trunk. Smallpox lesions progress at the same rate, unlike lesions of chickenpox, which may be seen in various stages of progression.	The patient should be isolated (preferably at home) until all of the scabs have fallen off. Management includes IV hydration. Health care providers should use masks, gowns, and gloves when caring for these patients and should receive smallpox vaccination within 2–3 days of exposure. Persons who have had contact with the patient should be isolated for 17 days.
Anthrax		
Transmitted through consumption of contaminated animal products, ingestion of raw meat, or inhalation of airborne spores of *Bacillus anthracis*, a gram-positive, spore-forming bacterium. The incubation period is 1–6 days.	Fever, fatigue, cough, chest discomfort, widened mediastinum on chest x-ray, and respiratory distress	Ensure that standard precautions are observed and that all surfaces are disinfected. Persons who have had contact with the patient should be started on the vaccine schedule and treated with ciprofloxacin or doxycycline.
Pneumonic Plague		
Transmitted by inhalation of *Yersinia pestis*. The incubation period is 2–6 days.	Fever, headache, weakness, and upper respiratory symptoms often including hemoptysis.	Treatment must begin within 24 hours and should include gentamicin or streptomycin drug. Isolate the patient for 48 hours after antibiotics are started. Postexposure prophylaxis consists of tetracycline or doxycycline for 7 days.
Botulism		
Transmitted primarily by ingestion of food contaminated with a preformed toxin produced by *Clostridium botulinum*. An inhalation form has been developed specifically as a biological agent.	Blurred or double vision, slurred speech, nausea, vomiting, diarrhea, and descending muscle weakness.	An antitoxin is effective if used early in the disease. Standard precautions are satisfactory; botulism is not contagious.

For additional information regarding bioterrorism, consult the following web site:

- Center for Disease Control and Prevention, Emergency Preparedness and Response *https://emergency.cdc.gov/bioterrorism/prep.asp*.

Assessment of Fetal Maturity and Well-Being

INTRODUCTION TO MATERNITY NURSING

According to the World Health Organization (WHO), social determinants of health (SDH) directly impact maternal-fetal outcomes. The nurse today faces many evolving challenges to achieve positive birth outcomes. In addition to health concerns during pregnancy, pregnancies with existing health conditions including diabetes and hypertension, lifestyle factors such as substance abuse, late or no prenatal care, and those occurring at extreme ages of reproductive life face unique complications. Furthermore, advances in assisted reproductive technologies (ART) have afforded people opportunities once thought impossible; however, they may experience additional inherent risks. Today's child-bearing families have many options. Childbirth may take place in the traditional hospital setting, a birthing center, or at home. Primary care provider includes physicians, certified registered nurse midwives, or lay midwives. Birth-related choices commonly include the use of labor, delivery, and recovery rooms or labor, delivery, recovery, and postpartum rooms; various birthing positions and analgesic methods; alternative pain-relief strategies such as hydrotherapy; and the decision to allow children and others to be present during labor and delivery. Regionalization of obstetric services has provided child-bearing families with access to the technologic advances and skilled personnel capable of managing pregnancy or neonatal complications. The combination of advancing technology, pregnancy risk factors, and changing economics because of the rising cost of health care challenges the nurse to be proficient in areas of neonatal resuscitation, external fetal monitoring, assessment, and interprofessional communication.

EVIDENCE BASE National Institutes of Health. (2017). What are the factors that put a pregnancy at risk? Bethesda, MD: Author.World Health Organization. (2017). Social determinants of health. Geneva, Switzerland: Author.

Terminology Used in Maternity Nursing

1. Gestation—pregnancy or maternal condition of having a developing fetus in the body.
2. Embryo—human conceptus up to the 10th week of gestation (8th week postconception).
3. Fetus—human conceptus from 10th week of gestation (8th week postconception) until delivery.
4. Periviability—alternately termed the limit of viability; is considered the stage of fetal maturity needed for extrauterine survival between 20 0/7 and 25 6/7 weeks gestation.

EVIDENCE BASE American College of Obstetricians and Gynecologists and Society for Fetal Medicine. (2016). *Periviable birth: Obstetric care consensus*. Washington, DC: ACOG.

---

5. Gravida (G)—woman who is or has been pregnant, regardless of pregnancy outcome.
6. Nulligravida—woman who is not now and never has been pregnant.
7. Primigravida—woman pregnant for the first time.
8. Multigravida—woman who has been pregnant more than once.
9. Para (P)—refers to past pregnancies that have reached viability.
10. Nullipara—woman who has never completed a pregnancy to the period of viability. The woman may or may not have experienced an abortion.
11. Primipara—woman who has completed one pregnancy to the period of viability regardless of the number of infants delivered and regardless of the infant being live or stillborn.
12. Multipara—woman who has completed two or more pregnancies to the stage of viability.
13. Living children—refers to the number of children a woman has delivered who are living.

A woman who is pregnant for the first time is a primigravida and described as gravida 1 para 0 (or G1P0). A woman who delivered one fetus carried to the period of viability and who is pregnant again is described as gravida 2, para 1. A woman with two pregnancies ending in abortions and no viable children is gravida 2, para 0.

Obstetric History

TPAL

In some obstetric services, a woman's obstetric history is summarized by a series of four digits, such as 5-0-2-5. These digits correspond with the abbreviation TPAL.

1. **T**—represents full-term deliveries, 37 completed weeks or more.
2. **P**—represents preterm deliveries, 20 to less than 37 completed weeks.
3. **A**—represents abortions, elective or spontaneous loss (miscarriage) of a pregnancy before the period of viability.
4. **L**—represents the number of children living. If a child has died, further explanation is needed for clarification.
5. If, for example, a particular woman's history is summarized as G7, P5-0-2-5, then she has been pregnant seven times and had five term deliveries, zero preterm deliveries, two abortions, and five living children.

GTPALM

In some institutions, a woman's obstetric history can also be summarized as GTPALM, especially when multiple gestations or births are involved.

1. **G**—represents gravida.
2. **T**—represents full-term deliveries, 37 completed weeks or more.
3. **P**—represents preterm deliveries, 20 to less than 37 completed weeks.
4. **A**—represents abortions, elective or spontaneous loss of a pregnancy before the period of viability.
5. **L**—represents the number of children living. If a child has died, further explanation is needed for clarification.
6. **M**—represents the number of multiple gestations and births (not the number of neonates delivered).

If, for example, a particular woman's history is summarized as G5, P5-0-0-6-1, then she has been pregnant five times and had five term deliveries, zero preterm deliveries, zero abortions, six living children, and one multiple gestation/birth.

THE EXPECTANT MOTHER

EVIDENCE BASE Records, K., & Tanaka, L. (2016). Physiology of pregnancy. In S. Mattson & J. E. Smith (Eds.), *Core curriculum for maternal–newborn nursing* (5th ed., pp. 83–107). St. Louis, MO: Saunders Elsevier.

Blackburn, S. T. (2014). Physiologic changes of pregnancy. In K. R. Simpson & P. A. Creehan (Eds.), *AWHONN's perinatal nursing* (4th ed., pp. 71–88). Philadelphia PA: Wolters, Kluwer|Lippincott.

Manifestations of Pregnancy

Pregnancy may be determined by the cessation of menses, enlargement of the uterus, ultrasound, and/or a positive human chorionic gonadotropin (hCG) test. These and the many other manifestations of pregnancy are classified into three groups: presumptive, probable, and positive.

Presumptive Signs and Symptoms

Physical signs and symptoms that suggest, but do not prove, pregnancy.

1. Abrupt cessation of menses—pregnancy is suspected if more than 10 days have elapsed since the time of the expected onset in a healthy woman who previously had predictable menstrual periods.
2. Breast changes:
    a. Breasts enlarge and become tender. Veins in breasts become increasingly visible.
    b. Nipples become larger and more pigmented. Nipple tingling may also be present.
    c. Colostrum—a thin, milky fluid—may be expressed in the second half of pregnancy.
    d. Montgomery glands—small elevations on the areolae—may appear.
3. Skin pigmentation changes:
    a. Chloasma or melasma gravidarum (the mask of pregnancy)—brownish pigmentation appearing on the face in a butterfly pattern in 50% to 70% of women that is progressive throughout the pregnancy; usually symmetric and distributed on the forehead, cheeks, and nose; more common in dark-haired, brown-eyed women.
    b. Linea nigra—dark vertical line on the abdomen between the sternum and the symphysis pubis.
    c. Striae gravidarum (stretch marks)—reddish or purplish linear markings sometimes appearing on the breasts, abdomen, and buttocks, because of the stretching, rupture, and atrophy of the deep connective tissue of the skin.
4. Nausea (morning sickness)—with or without vomiting occurs mainly in the morning but may occur at any time of the day, lasting a few hours. Begins between 2 and 6 weeks after conception and usually disappears spontaneously near the end of the first trimester (12 weeks).
5. Urinary frequency:
    a. Caused by pressure of the expanding uterus on the bladder.
    b. Decreases when the uterus rises out of the pelvis (around 12 weeks).
    c. Reappears when the fetal head engages in the pelvis at the end of pregnancy.
6. Constipation—because of the decreased absorption of fluid by the gut.
7. Fatigue—characteristic of early pregnancy in response to increased hormonal levels.

Probable Signs and Symptoms

Objective findings detected by 12 to 16 weeks of gestation.

1. Enlargement of abdomen—at about 12 weeks gestation, the uterus can be felt through the abdominal wall, just above the symphysis pubis.

2. Uterine changes:
    a. Uterus enlarges, elongates, and decreases in thickness as pregnancy progresses. The uterus changes from a pear shape to a globe shape.
    b. Hegar sign—lower uterine segment softens 6 to 8 weeks after the onset of the last menstrual period.
3. Cervical changes:
    a. Chadwick sign—bluish or purplish discoloration of cervix and vaginal wall.
    b. Goodell sign—softening of the cervix; may occur as early as 4 weeks.
    c. With inflammation and carcinoma during pregnancy, the cervix may remain firm.
4. Braxton-Hicks contractions—intermittent contractions of the uterus generally painless, palpable contractions occurring at irregular intervals, more frequently felt after 28 weeks. They usually disappear with walking or exercise.
5. Ballottement—sinking and rebounding of the fetus in its surrounding amniotic fluid in response to a sudden tap on the uterus (occurs near midpregnancy).
6. Leukorrhea—increase in vaginal discharge.
7. Quickening—the sensations of fetal movement in the abdomen occurring between the 16th and 20th week after the onset of the last menses.
8. Positive hCG—laboratory (urine or serum) test for pregnancy.

Positive Signs and Symptoms

Diagnostic of Pregnancy

1. Fetal heart tones (FHTs)—usually heard between 16th and 20th week of gestation with a fetoscope or the 10th and 12th week of gestation with a Doppler stethoscope.
2. Fetal movements felt by the examiner (after about 20 weeks gestation).
3. Outlining of the fetal body through the maternal abdomen in the second half of pregnancy with Leopold maneuvers.
4. Sonographic evidence (after 4 weeks gestation) using vaginal ultrasound. Fetal cardiac motion can be detected by 6 weeks gestation.

Maternal Physiology During Pregnancy

Duration of Pregnancy

1. Averages 280 days or 40 weeks (10 lunar months, 9 calendar months) from the first day of the last normal menses.
2. Duration may also be divided into three equal parts, or trimesters, of slightly more than 13 weeks or 3 calendar months each.
3. Estimated date of confinement (EDC), more commonly referred to now as estimated date of delivery (EDD), is calculated by adding 7 days to the date of the first day of the last menses and counting back 3 months (Nägele rule). Additionally, most antenatal clinics have obstetric wheels where the outer wheel has markings for the calendar and an inner, sliding wheel with weeks and days of gestation. These wheels facilitate the estimation of gestational age (GA) and the calculation of the EDD. The accuracy of these wheels may vary.
    a. For example, if a woman's last menstrual period (LMP) began on September 10, 2018, her EDC would be June 17, 2019. The calculation would start with September 10, 2018, plus 7 days (September 17, 2018), minus 3 months (June 17, 2018). If the date of the woman's LMP begins after March 31, an additional year must be added to give a correct EDD.
    b. Another method of calculating the EDD is McDonald rule: after 24 weeks gestation, the fundal height measurement will correspond to the week of gestation plus 2 to 4 weeks.
    c. EDD can also be calculated using ultrasound technology, which is the most accurate assessment—preferably in the first trimester. Gestational age in the first trimester is usually calculated from the fetal crown–rump length (CRL). This is the longest demonstrable length of the embryo or fetus, excluding the limbs and the yolk sac. The correlation between CRL and GA is excellent until about 12 weeks gestation, and the estimate has a 95% confidence interval of plus or minus 6 days.

Reproductive Tract Changes

Uterus

1. Enlargement during pregnancy involves stretching and marked hypertrophy of existing muscle cells secondary to increased estrogen and progesterone levels.
2. In addition to an increase in the size of the uterine muscle cells, there is an increase in fibrous tissue and elastic tissue. The size and number of blood vessels and lymphatics increase.
3. Enlargement and thickening of the uterine wall are most marked in the fundus.
4. By the end of the 3rd month (12 weeks), the uterus is too large to be contained wholly within the pelvic cavity—it can now be palpated suprapubically.
5. As the uterus rises out of the pelvis, it rotates somewhat to the right because of the presence of the rectosigmoid colon on the left side of the pelvis.
6. By 20 weeks gestation, the fundus has reached the level of the umbilicus.
7. By 36 weeks, the fundus has reached the xiphoid process.

8. By the end of the 5th month, the myometrium hypertrophy ends and the walls of the uterus become thinner, allowing palpation of the fetus.
9. During the last 3 weeks, the uterus descends slightly because of fetal descent into the pelvis.
10. Changes in contractility occur from the first trimester with irregular painless contractions beginning later in the second trimester.
11. There is a progressive increase in uteroplacental blood flow during pregnancy.

Cervix

1. Pronounced softening and cyanosis—because of increased vascularity, edema, hypertrophy, and hyperplasia of the cervical glands.
2. Endocervical glands secrete thick mucus that forms a cervical plug and obstructs the cervical canal. This plug prevents bacteria and other substances from entering and ascending into the uterus.
3. Erosions of the cervix, common during pregnancy, represent an extension of proliferating endocervical glands and columnar endocervical epithelium.
4. Evidence of Chadwick sign, the bluish, purplish coloring of the cervix. This sign is due to the increased vascularity and hyperemia caused by increased estrogen levels.

Ovaries

1. Ovulation ceases during pregnancy, and maturation of new follicles is suspended.
2. The corpus luteum functions during early pregnancy (first 10 to 12 weeks), producing progesterone. However, small levels of estrogen and relaxin are also produced by the corpus luteum.
3. After 8 weeks gestation, the corpus luteum remains the source for the hormone relaxin. However, relaxin is not required for a successful pregnancy outcome and normal delivery.

Vagina and Outlet

1. Increased vascularity, hyperemia, and softening of connective tissue occurs in skin and muscles of the perineum and vulva.
2. Vaginal walls prepare for labor as mucosa increases in thickness, connective tissue loosens, and small muscle cells hypertrophy. Secretions are thick, white, and acidic in nature and play a major role in the prevention of infections.
3. Vaginal secretions increase; pH is 3.5 to 6—because of increased production of lactic acid from glycogen in the vaginal epithelium by *Lactobacillus acidophilus*. (Acid pH probably aids in keeping vagina relatively free of pathogenic bacteria.)
4. Hypertrophy of the structures, along with fat deposits, causes the labia majora to close and cover the vaginal introitus (vaginal opening).

Abdominal Changes

1. Striae gravidarum (stretch marks) may develop on the skin of abdomen, breast, and thighs (become glistening silvery lines after pregnancy).

2. Linea nigra may form characterized by a line of dark pigment extending from the umbilicus down the midline to the symphysis. Commonly seen in the first pregnancy, the linea nigra occurs at the height of the uterus. During subsequent pregnancies, the entire line may be present early in gestation.
3. Diastasis recti may occur as muscles (rectus) separate. If severe, a part of the anterior uterine wall may be covered by only a layer of skin, fascia, and peritoneum.

Breast Changes

1. Tenderness and tingling occur in early weeks of pregnancy.
2. Increase in size by 2nd month because of the hypertrophy of mammary alveoli. Veins become more prominent and striae may develop as the breasts enlarge.
3. Nipples become larger, more deeply pigmented, and more erectile early in pregnancy.
4. Colostrum, a yellow secretion rich in antibodies, may be expressed by second trimester.
5. Areolae become broader and more deeply pigmented. The depth of pigmentation varies with the woman's pigmentation.
6. Glands of Montgomery are hypertrophic sebaceous glands scattered through the areola surrounding the nipple.

Metabolic Changes

Numerous and concentrated changes occur in response to rapidly growing fetus and placenta.

Weight Gain Average

Twenty-five to thirty-five pounds (11.5 to 16 kg) (see Table 36-1).

Table 36-1 Components of Weight Gain

AREA	KG	POUND
Fetus	3.2–3.4	7–7.5
Placenta	0.5–0.7	1–1.5
Amniotic fluid	0.9	2
Uterus	1.1	2.5
Breast tissue	0.7–1.4	1.5–3
Blood volume	1.6–2.3	3.5–5
Maternal stores	1.8–4.3	4–9.5

Water Metabolism

1. Total body water increases to 6 to 8 L during the pregnancy because of hormonal influence with approximately 4 to 6 L of fluid moving to the extracellular spaces (ECF) resulting in an increase in blood volume.
2. Many pregnant women experience a normal accumulation of fluid in their legs and ankles at the end of the day. This is most common in the third trimester and is referred to as physiologic edema.
3. Additional sodium is required during pregnancy to meet the need for increased intravascular and

extracellular fluid volumes and to maintain a normal isotonic state. The limitation of sodium is discouraged in pregnancy because it can result in decreased kidney function, resulting in decreased urine output and a potential adverse outcome.

4. Sodium excretion in the pregnant woman is similar to that of the nonpregnant woman.
5. Sodium retention is usually directly proportional to the amount of water accumulated during the pregnancy. However, pregnancy lends itself toward sodium depletion, making sodium regulation more difficult.

Protein Metabolism

1. The fetus, uterus, and maternal blood are rich in protein rather than in fat or carbohydrates.
2. At term, the fetus and placenta contain approximately 500 g of protein or approximately half of the total protein increase of pregnancy.
3. Approximately 500 g more of protein is added to the uterus, breasts, and maternal blood in the form of hemoglobin and plasma proteins.

Carbohydrate Metabolism

1. Carbohydrate metabolism during pregnancy is controlled by glucose levels in the plasma and the metabolism of glucose in the cells.
2. The liver controls the plasma glucose level. Not only does it store glucose as glycogen, but also it converts it into glucose when the woman's blood glucose levels are low.
3. Early in pregnancy, the effects of estrogen and progesterone can induce a state of hyperinsulinemia. As pregnancy advances, there is increased tissue resistance partnered with increased hyperinsulinemia.
4. Approximately 2% to 3% of all women will develop gestational diabetes mellitus during pregnancy regardless if they have a history of carbohydrate intolerance.
5. Pregnant women with preexisting diabetes mellitus (type 1 or 2) may experience a worsening of the disease attributed to hormonal changes occurring with pregnancy.
6. During pregnancy, there is a "sparing" of glucose used by maternal tissues and a shunting of glucose to the placenta for use by the fetus.
7. Human placental lactogen (hPL) promoting lipolysis, increasing plasma-free fatty acids, and thereby providing alternative fuel sources for the mother.
8. Human placental lactogen, estrogen, progesterone, and cortisol oppose the action of insulin during pregnancy and promote maternal lipolysis as well.

Fat Metabolism

1. Lipid metabolism during pregnancy causes an accumulation of fat stores, mostly cholesterol, phospholipids, and triglycerides.
2. This accumulation of fat stores has no negligible effect on the fetus.
3. Fat storage occurs before the 30th week of gestation. After 30 weeks gestation, fat mobilization occurs correlating with increased utilization of glucose and amino acids by the fetus.

Nutrient Requirements

Caloric Requirements

1. Additional calories are usually not required during the first trimester because of the limited metabolic demands.
2. During the second trimester, pregnant women should take in 340 additional calories per day, and in the third trimester, caloric intake should increase to 452 calories daily. However, because of the variety of women and their individualized needs, the exact caloric requirements need to be established on an individual basis.
3. Caloric expenditure varies throughout pregnancy. There is a slight increase in early pregnancy and a sharp increase near the end of the first trimester, continuing throughout pregnancy.

Protein Requirements

1. Protein is required for adequate amino acids to accommodate the normal development of the fetus, blood volume expansion, and growth of maternal breast and uterine tissue. Pregnant women should take in 60 to 80 g of protein daily.
2. The ratio of low-density proteins to high-density proteins is increased during pregnancy.

Carbohydrate and Fat Requirements

1. As in the nonpregnant woman, carbohydrates should supply 55% to 60% of calories in the diet and should be in the form of complex carbohydrates, such as whole-grain cereal products, starchy vegetables, and legumes.
2. Fat intake should not exceed 30% of the diet. Saturated fats should not exceed 10% of the total calories.

Iron Requirements

1. Total circulating red blood cells (RBCs) increase about 20% to 30% (250 to 450 mL) during pregnancy; therefore, iron requirements are increased to 500 mg of iron needed: 270 mg by fetus; 90 mg by the placenta. This equates to 0.8 g/day in early pregnancy and 7.5 mg/day by term. This usually exceeds dietary intake.
2. Supplemental iron is valuable and necessary during pregnancy and for several weeks after pregnancy or lactation.
3. During the last half of pregnancy, iron is transferred to the fetus and stored in the fetal liver. These store lasts 3 to 6 months.

Other Nutritional Requirements

1. If a woman has not increased folic acid intake in preparation for conception, a pregnant woman should increase folic acid intake from 400 to 800 mcg per day.
2. Vitamin D deficiency is the most common nutritional deficit globally. Additionally, vitamin D deficiency has been associated with increased rates of preeclampsia and cesarean births; therefore, pregnant women should take 400 IU (10 mcg) daily. Many manufactured prenatal vitamins increase vitamin D levels.

TRANSITIONAL CARE ALERT Because of the increasing rates of obesity, diabetes, and hypertension in women of reproductive age, it is essential for nurses to focus on maternal and fetal well-being to include nutritional education and appropriate weight gain during pregnancy. The promotion of healthy behaviors may decrease risk for hospitalization and improve maternal and fetal outcomes.

Cardiovascular System Changes

Heart

1. The diaphragm progressively elevates during pregnancy causing displacement of the heart to the left and upward with the apex moved laterally.
2. Heart sounds are exaggerated, splitting of the first heart sound with a loud, easily heard third sound.
3. Heart murmurs—systolic murmurs are common and usually disappear after delivery.

Blood Volume Changes

1. Cardiac output increases by 30% to 50% (1,450 to 1,750 mL), beginning as early as 6 weeks and peaking by 28 to 34 weeks' gestation causing slight hypertrophy of the heart and increased cardiac output. Women with multiple gestation can have higher cardiac outputs, especially after 20 weeks gestation.
2. Cardiac output peaks in the second trimester and plateaus until term, reaching a volume of 6 to 7 L/minute by term.
3. Position greatly influences cardiac output, especially in the third trimester.
    a. In the supine position, the large uterus compresses the venous return from the lower half of the body to the heart. This may cause arterial hypotension, referred to as *supine hypotensive syndrome*.
    b. When the woman turns from her back to lateral position (either left or right side), cardiac output increases by 25% to 30%, with an increase in uterine and renal blood flow.
4. Femoral venous pressure increases due to the slowing of blood flow from lower extremities as a result of pressure of enlarged uterus on pelvic veins and inferior vena cava.
5. Increased cutaneous blood flow dissipates excess heat caused by increased metabolism of pregnancy.
6. Plasma volume increases 40% to 60% (1,200 to 1,600 mL) by term, resulting in hemodilution, more commonly referred to as *physiologic anemia of pregnancy* or *physiologic dilutional anemia*. This "anemic" state is not a true pathologic state and decreases the risk of thrombosis. It is due to the rapid increase in plasma volume and the later increase in RBC volume.

Blood Pressure Changes

1. Blood pressure (BP)—during the first half of pregnancy, there is a slight (5 to 10 mm Hg) decrease in systolic BP (SBP) and diastolic BP (DBP), with the lowest point occurring in the second trimester. By the third trimester, the BP gradually returns to prepregnancy levels.
2. Maternal position influences BP: the highest reading is obtained in the sitting position, the lowest

reading is obtained in the left lateral position, and an intermediate reading is obtained in the supine position. Sitting or standing positions show minimal change in SBP readings; however, they can decrease the DBP by about 10 to 15 mm Hg.

3. Maternal BP will also rise with uterine contractions and returns to the baseline level after the uterine contraction is over.
4. Hypertensive disease affects up to 22% of pregnancies and is associated with maternal and fetal death. According to the National Institutes of Health, women with hypertension in pregnancy should be referred to as having hypertensive disorders of pregnancy. Additionally, the term "gestational hypertension" replaces the term "pregnancy-induced hypertension" to describe cases in which elevated BP without proteinuria occurs in a woman beyond 20 weeks of gestation who previously had a normal BP. Essentially, gestational hypertension is an elevated BP past 20 weeks of gestation without proteinuria.

Hematologic Changes

1. Total volume of circulating RBCs increases 17% to 33%; hemoglobin concentration at term averages 12 to 16 g/dL; hematocrit concentration at term averages 37% to 47%.
2. Average leukocyte (white blood cell [WBC]) count in the third trimester is 5 to 12,000/mm^3. WBC count can be elevated as high as 30,000 or more during labor—cause unknown; probably represents the reappearance in the circulation of leukocytes previously shunted from of active circulation.
3. Pregnancy is a hypercoagulable state because of the increased levels of essential coagulation factors including factor I (fibrinogen by 50%), factor V (proaccelerin or labile factor), factor VII (proconvertin or serum prothrombin conversion accelerator), factor VIII (antihemophilic factor or antihemophilic globulin), factor IX (plasma thromboplastin component or Christmas factor), factor X (Stuart or Prower factor), factor XII (Hageman or glass or contact factor), and vWF (von Willebrand factor antigen). Factor II (prothrombin) increases slightly, whereas factors XI (plasma thromboplastin antecedent) and XIII (fibrin-stabilizing factor) decrease during pregnancy.
4. There is no significant change in the number, appearance, or function of platelets. Average platelet count is 150,000 to 400,000/mm^3, which increases the risk to the pregnant woman for venous thrombosis.

Respiratory Tract Changes

1. Nasal stuffiness and epistaxis (nosebleeds) are also common during pregnancy, secondary to vascular congestion caused from the increased estrogen levels.
2. Approximately 60% to 70% of pregnant women experience shortness of breath.
3. Diaphragm is elevated (about 4 cm) during pregnancy—chiefly by the enlarging uterus that decreases the length of the lungs. Breathing is more diaphragmatic rather than costal.
4. Thoracic cage expands its anteroposterior diameter (by 2 cm). The increased pressure from the uterus also widens the substernal angle by about 50%, causing slight flaring of the ribs—result of increased mobility of rib attachments.
5. Oxygen consumption increases 15% to 20% and as much as 300% in labor. This increase leads to

increased maternal alveolar and arterial oxygen partial pressure levels.

6. Hyperventilation—an increase in respiratory rate, tidal volume (amount of air inspired and expired with normal breath) increases by 30% to 40%, and minute ventilation (amount of air inspired in 1 minute) increases by 40%.
7. Total lung volume (amount of air in lungs at maximum inspiration) decreases by about 5%. Residual volume (amount of air in lungs after maximum expiration), respiratory reserve volume (maximum amount of air expired during rest), and functional residual capacity (amount of air remaining in lungs at rest and allowing for gas exchange) drop by about 18% to 20%.
8. Increased total volume lowers partial pressure of arterial carbon dioxide ($PaCO_2$), causing mild respiratory alkalosis that is compensated for by lowering of the bicarbonate concentration.
9. Partial pressure of arterial oxygen (PaO_2) elevates to 106 to 108 mm Hg in first trimester and 101 to 104 mm Hg at term. $PaCO_2$ is decreased to 27 to 32 mm Hg. Bicarbonate decreases to 18 to 21 mEq/L. Normal pH during pregnancy is 7.40 to 7.45. These changes allow for removal of fetal carbon dioxide via passive diffusion in the placenta.

Renal System Changes

1. Ureters dilate and elongate during pregnancy because of mechanical pressure and perhaps because of the effects of progesterone. When the uterus rises out of the uterine cavity, it rests on the ureters, compressing them at the pelvic brim. Dilation is greater on the right side—the left side is cushioned by the sigmoid colon.
2. Renal plasma flow (RPF) increases by 60% to 80% by the end of the first trimester because of the increases in blood volume and cardiac output as well as a decrease in systemic vascular resistance due to the effects of progesterone. RPF increases early in pregnancy and decreases to nonpregnant levels in the third trimester. These changes may be due to placental lactogen hormone (hPL).
3. Glomerular filtration rate (GFR) increases 40% to 50% by the second trimester and persists almost to term. Glucosuria may be a result from an increase in GFR without an increase in tubular resorptive capacity for filtered glucose.
4. Protein excretion is also increased to a rate not always handled by the kidneys' tubular resorptive capability. Therefore, protein can spill into the urine. However, protein in the urine should not be considered an abnormal finding until 24-hour urine values exceed 300 mg/dL.
5. Toward the end of pregnancy, pressure of the presenting part impedes drainage of blood and lymph from the bladder base, typically leaving the area edematous, easily traumatized, and more susceptible to infection.
6. Because of the increased RPF and GFR, the amount of glucose the kidneys filter increases 10- to 100-fold. The kidneys cannot always keep up with this increase; therefore, whatever glucose that is not filtered is lost in the urine, contributing to glycosuria.
7. Protein excretion is also increased to a rate not always handled by the kidneys' tubular resorptive capability. Therefore, protein can spill into the urine. However, protein in the urine should not be

considered an abnormal finding until 24-hour urine values exceed 300 mg/dL.

Gastrointestinal Tract Changes

1. Gums may become hyperemic and soft; bleeding easily.
2. *Epulis of pregnancy*—a localized vascular swelling of the gums may appear.
3. Stomach and intestines are displaced upward and laterally by the enlarging uterus. Heartburn (pyrosis) is commonly caused by reflux of acid secretions in the lower esophagus.
4. Peptic ulcer formation or exacerbation is uncommon during pregnancy because of decreased hydrochloric acid (caused by increased estrogen levels).
5. Tone and motility of GI tract decrease leading to prolonged gastric emptying because of the large amount of progesterone produced by the placenta. Decreased motility, mechanical obstruction by the fetus, and decreased water absorption from the colon leads to constipation.
6. Hemorrhoids are common because of elevated pressure in veins below the level of the large uterus and constipation.
7. Distention and hypotonia of the gallbladder are common, causing stasis of bile. Additionally, there is a decrease in emptying time and the thickening of bile, resulting in hypercholesterolemia and gallstone formation.
8. Liver function tests are altered. With pregnancy, bilirubin, aspartate aminotransferase, and alanine aminotransferase values are unchanged; prothrombin time may show a slight increase or be unchanged. Liver size and morphology are unchanged.
9. The appendix is pushed superiorly.

Endocrine Changes

1. Anterior pituitary gland enlarges in both weight (30% increase) and volume (twofold increase). Its shape also changes from convex to dome shaped; posterior pituitary gland remains unchanged.
2. Thyroid is moderately enlarged because of hyperplasia of glandular tissue and increased vascularity.
    a. Basal metabolic rate increases progressively during normal pregnancy (as much as 25%) because of metabolic activity of fetus.
    b. Level of protein-bound iodine and thyroxine rises sharply and is maintained until after delivery because of increased circulatory estrogen and hCG.
    c. Hyperthyroidism during pregnancy is rare. Although levels of thyroxine (T_4) and triiodothyronine (T_3) are elevated by as much as 40% to 100% by term, this is a result of estrogen, hCG, and increased urinary iodide secretion, resulting in “euthyroid hyperthyroxinemia.”
3. Parathyroid gland size is known to increase, but there is a decrease in the parathyroid hormone (PTH) during pregnancy. This decrease is balanced by the increased production of PTH by the fetus and placenta.
4. Adrenal secretions considerably increased—amounts of aldosterone increase as early as the 15th week to accommodate for the increased sodium excretion.

5. Pancreas—because of the fetal glucose needs for fetal growth, there are alterations in maternal insulin production and usage.
    a. Estrogen, progesterone, cortisol, and human placental lactogen (hPL) decrease the maternal utilization of glucose.
    b. Cortisol also increases maternal insulin production.
    c. Insulinase, an enzyme produced by the placenta, deactivates maternal insulin.
    d. These changes cause an increased demand for insulin triggering the islets of Langerhans to increase production of insulin.

Integumentary Changes

1. Pigment changes occur because of melanocyte-stimulating hormone as a result of increased estrogen and progesterone and is elevated from the 2nd month of pregnancy until term.
2. Striae gravidarum appear in later months of pregnancy as reddish, slightly depressed streaks in the skin of the abdomen and occasionally over the breasts and thighs and occur in as much at 50% of all pregnant women.
3. Linea nigra—a brownish-black line of pigment is usually formed in the midline of the abdominal skin.
4. Chloasma or melasma (mask of pregnancy)—brownish patches of pigment may form on the face. Chloasma usually disappears after pregnancy but can reappear with excessive exposure to the sun or with oral contraceptive treatment.
5. Angiomas (vascular spider nevus)—minute red elevations commonly on the skin of the face, neck, upper chest, legs, and arms may develop.
6. Palmar erythema—reddening of the palms may also occur.
7. Increased warmth to the skin and variation in hair and nail growth occur.

Musculoskeletal Changes

1. The increasing mobility of sacroiliac, sacrococcygeal, and pelvic joints during pregnancy is a result of hormonal changes, specifically the hormone relaxin.
2. The center of gravity shifts secondary to increased weight gain, fluid retention, lordosis, and mobile ligaments. This mobility and the change in the center of gravity contribute to alteration of maternal posture and to back pain.
3. Late in pregnancy, aching, numbness, and weakness in the upper extremities may occur because of lordosis and paresthesia, which ultimately produces traction on the ulnar and median nerves.
4. Separation of the rectus muscles because of the pressure of the growing uterus creates what is called a diastasis recti. If this is severe, a portion of the anterior uterine wall is covered by only a layer of skin, fascia, and peritoneum.

Neurologic Changes

1. Usually no system changes.

2. Mild frontal headaches are common in the first and second trimester and are usually related to tension or hormonal changes.
3. Dizziness is common and related to vasomotor instability, postural hypotension, or hypoglycemia following long periods of standing or sitting.
4. Tingling sensations in the hands are common and are due to excessive hyperventilation, which decreases maternal $PaCo_2$ levels.

Hormonal Changes

Steroid Hormones

1. Estrogen:
   a. Secreted by the ovaries in early pregnancy, with over half of the estrogen secreted by the placenta by 7 weeks gestation.
   b. The three classic estrogens during pregnancy are estrone, estradiol, and estriol. More than 90% of the estrogen secreted during pregnancy is estriol.
   c. Estrogens also ensure uterine growth and development, maintenance of uterine elasticity and contractility, maintenance of breast growth and its ductal structures, and enlargement of the external genitalia.
2. Progesterone:
   a. Is initially secreted by the corpus luteum and later by the placenta playing a critical role in the maintenance of the pregnancy by suppressing the maternal immunologic response to the fetus and the rejection of the trophoblasts.
   b. Progesterone helps maintain the endometrium, inhibits uterine contractility, helps in the development of breast lobules for lactation, stimulates the maternal respiratory center, and relaxes smooth muscle.

Placental Protein Hormones

1. Human chorionic gonadotropin (hCG):
   a. Secreted by the syncytiotrophoblasts and stimulates the production by the corpus luteum of progesterone and estrogen until the fully developed placenta takes over.
   b. In multiple gestations, hCG can be twice as high as in a single pregnancy.
   c. hCG levels peak around 10 weeks gestation (50,000 to 100,000 mIU/mL), then decrease to 10,000 to 20,000 mIU/mL by 20 weeks gestation.
2. Human chorionic somatomammotropin (hCS) also called human placental lactogen (hPL) is produced by the syncytiotrophoblasts of the placenta; detected in maternal serum as early as 6 weeks gestation.
   a. Serum hCS levels rise concomitantly with placental growth.
   b. hCS is an antagonist of insulin. It increases the amount of free fatty acids available to the fetus for metabolic needs and decreases the maternal metabolism of glucose allowing for protein synthesis. This action allows the fetus to have the needed nutrients when the woman is not eating.

Other Hormones

1. Prostaglandins:
   a. Exact function is still unknown but is essential for the cardiovascular adaptation to pregnancy, cervical ripening, and initiation of labor.
   b. Affect smooth muscle contractility with increased levels leading to vasodilation.
2. Relaxin:
   a. Secreted primarily by the corpus luteum and be secreted in small amounts by the decidua and the placenta.
   b. Inhibits uterine activity and decreases the strength of uterine contractions and cervical ripening.
3. Prolactin:
   a. Released from the anterior pituitary gland and responsible for sustaining milk protein, casein, fatty acids, lactose, and the volume of milk secretion during lactation.

Structure of the Pelvis

Bones of the Pelvis

1. The pelvis is composed of four bones:
   a. Two innominate bones (hip bones) form the sides and front.
   b. Sacrum and coccyx form the back.
2. Pelvic bones are held together by fibrocartilage of the symphysis pubis and several ligaments.

Divisions of the Pelvis

1. False pelvis—lies above an imaginary line called the *linea terminalis* or *pelvic brim* (see Figure 36-1). Function of the false pelvis is to support the enlarged uterus.
2. True pelvis lies below the pelvic brim or linea terminalis; it is the bony canal through which the fetus must pass. It is divided into three planes: the inlet, the midpelvis, and the outlet.
   a. Inlet:
      i. Upper boundary of the true pelvis—Bound by the upper margin of symphysis pubis in front, linea terminalis on the sides, and sacral promontory (first sacral vertebra) in the back.
      ii. Largest diameter of inlet is transverse (see Figure 36-2).
      iii. Smallest diameter of inlet is anteroposterior.
      iv. Anteroposterior diameter is most important diameter of inlet: measured clinically by diagonal conjugate—distance from lower margin of symphysis to the sacral promontory (usually 5½ inches [14 cm]) (see Figure 36-3).
      v. Obstetric (true) conjugate—distance between inner surface of symphysis and sacral promontory measured by subtracting ½ to ¾ inch (1.5 to 2 cm) (thickness of symphysis) from the diagonal conjugate. Adequate diameter is usually 4½ inches (11.5 cm). This is the shortest anteroposterior diameter through which the fetus must pass.

b. Midpelvis:
    i. Bounded by inlet above and outlet below—true bony cavity. Midpelvis contains the narrowest portion of the pelvis.
    ii. Diameters cannot be measured clinically.
    iii. Clinical evaluation of adequacy is made by noting the ischial spines. Prominent spines that protrude into the cavity indicate a contracted midpelvic space. The interspinous diameter is 4 inches (10 cm).
c. Outlet:
    i. Lowest boundary of the true pelvis.
    ii. Bounded by lower margin of symphysis in front, ischial tuberosities on sides, and tip of sacrum posteriorly.
    iii. Most important diameter clinically is distance between the tuberosities (greater than 4 inches).

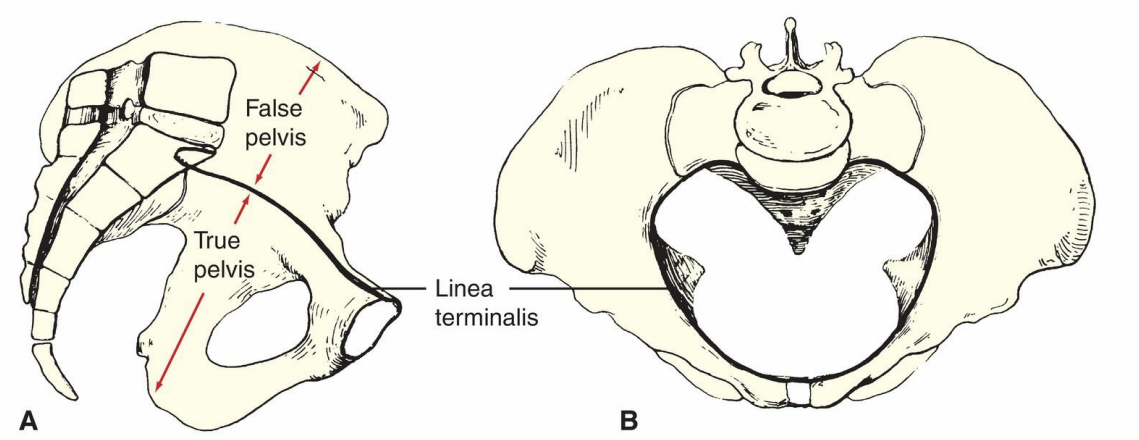

Figure 36-1. (A) Side view of the true and false pelvis. **(B)** Front view showing linea terminalis (pelvic brim).

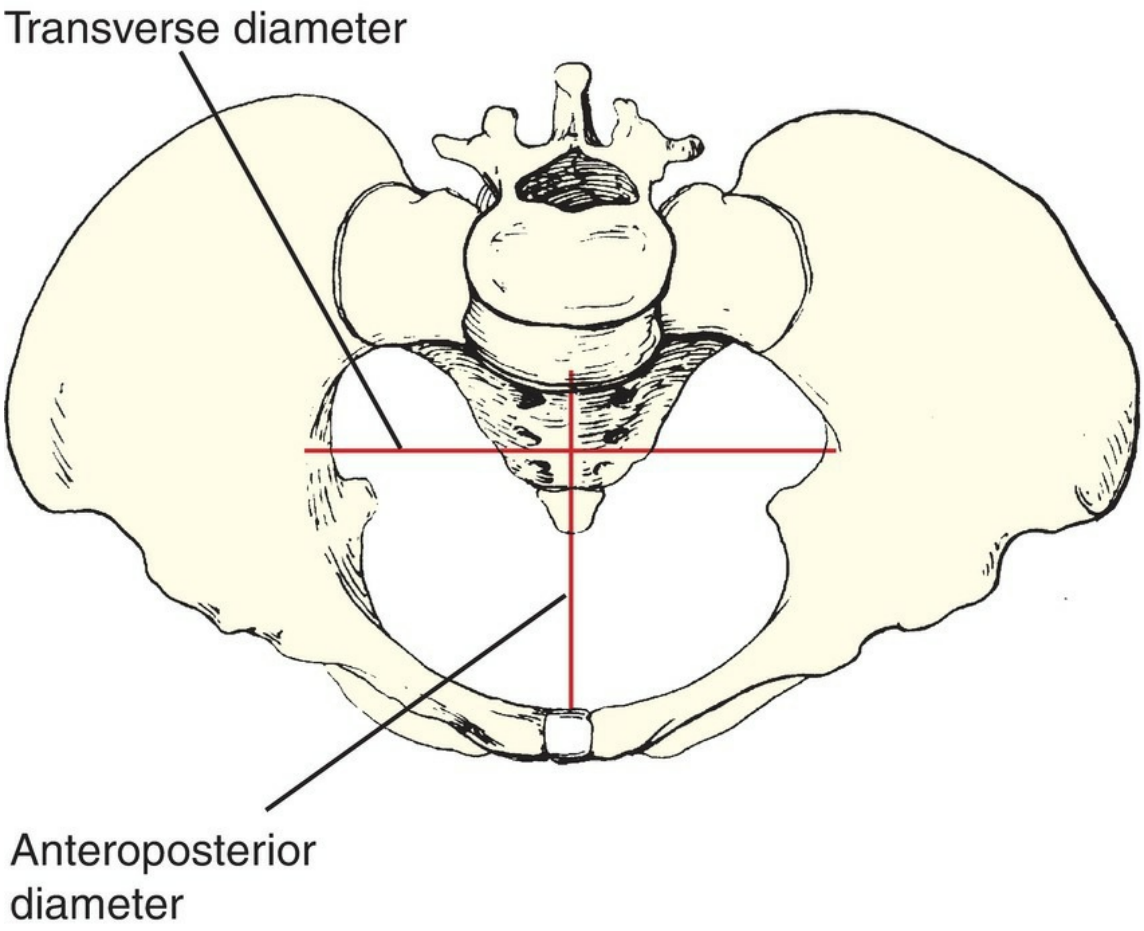

Figure 36-2. Inlet of normal female pelvis showing transverse and anteroposterior diameters.

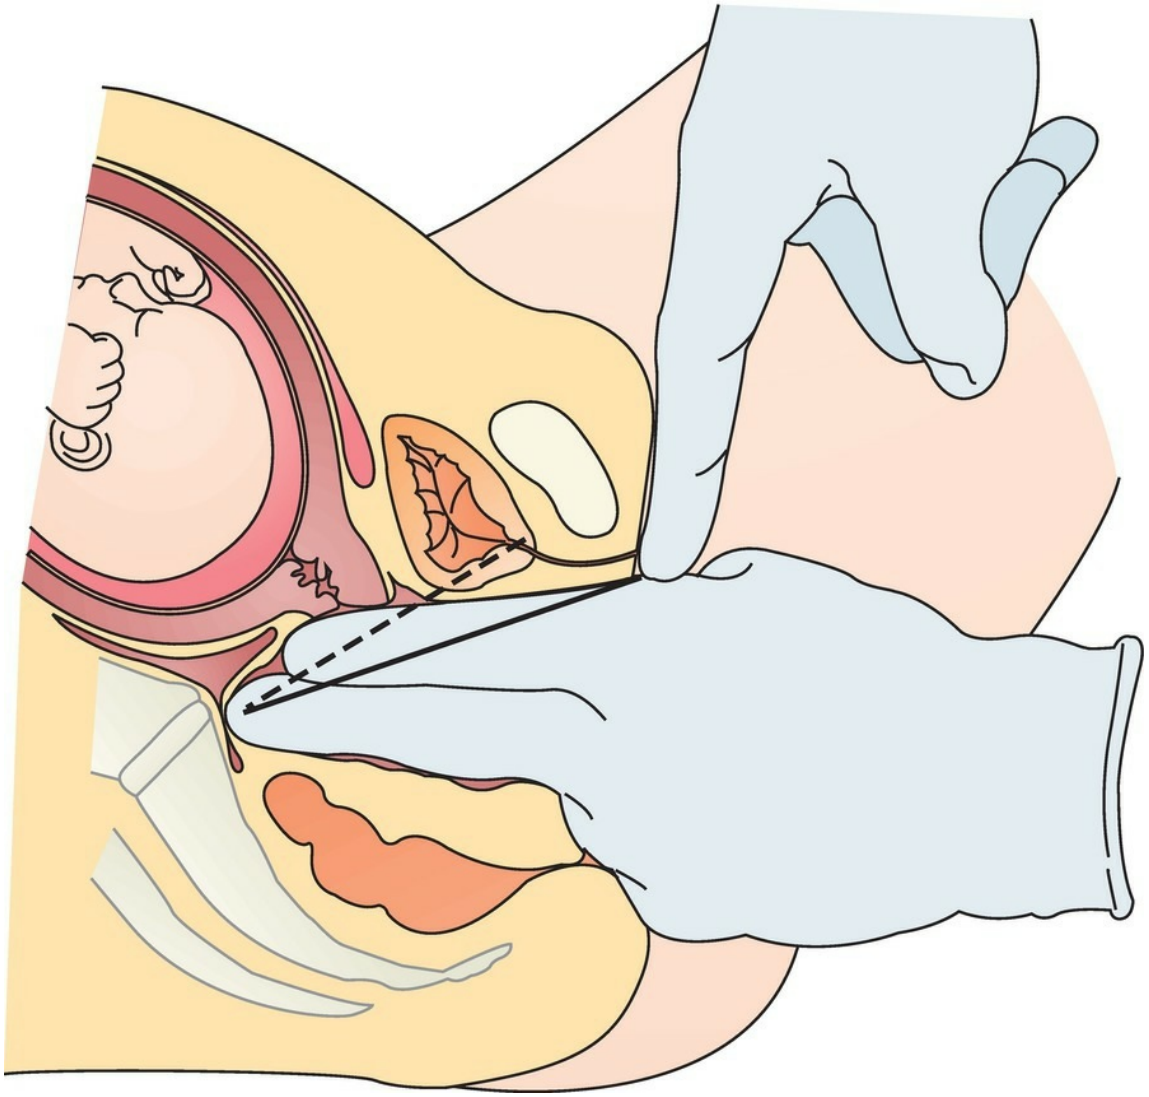

Figure 36-3. Measurement of diagonal conjugate diameter. *Straight line* shows diagonal conjugate; *dotted line* shows true conjugate.

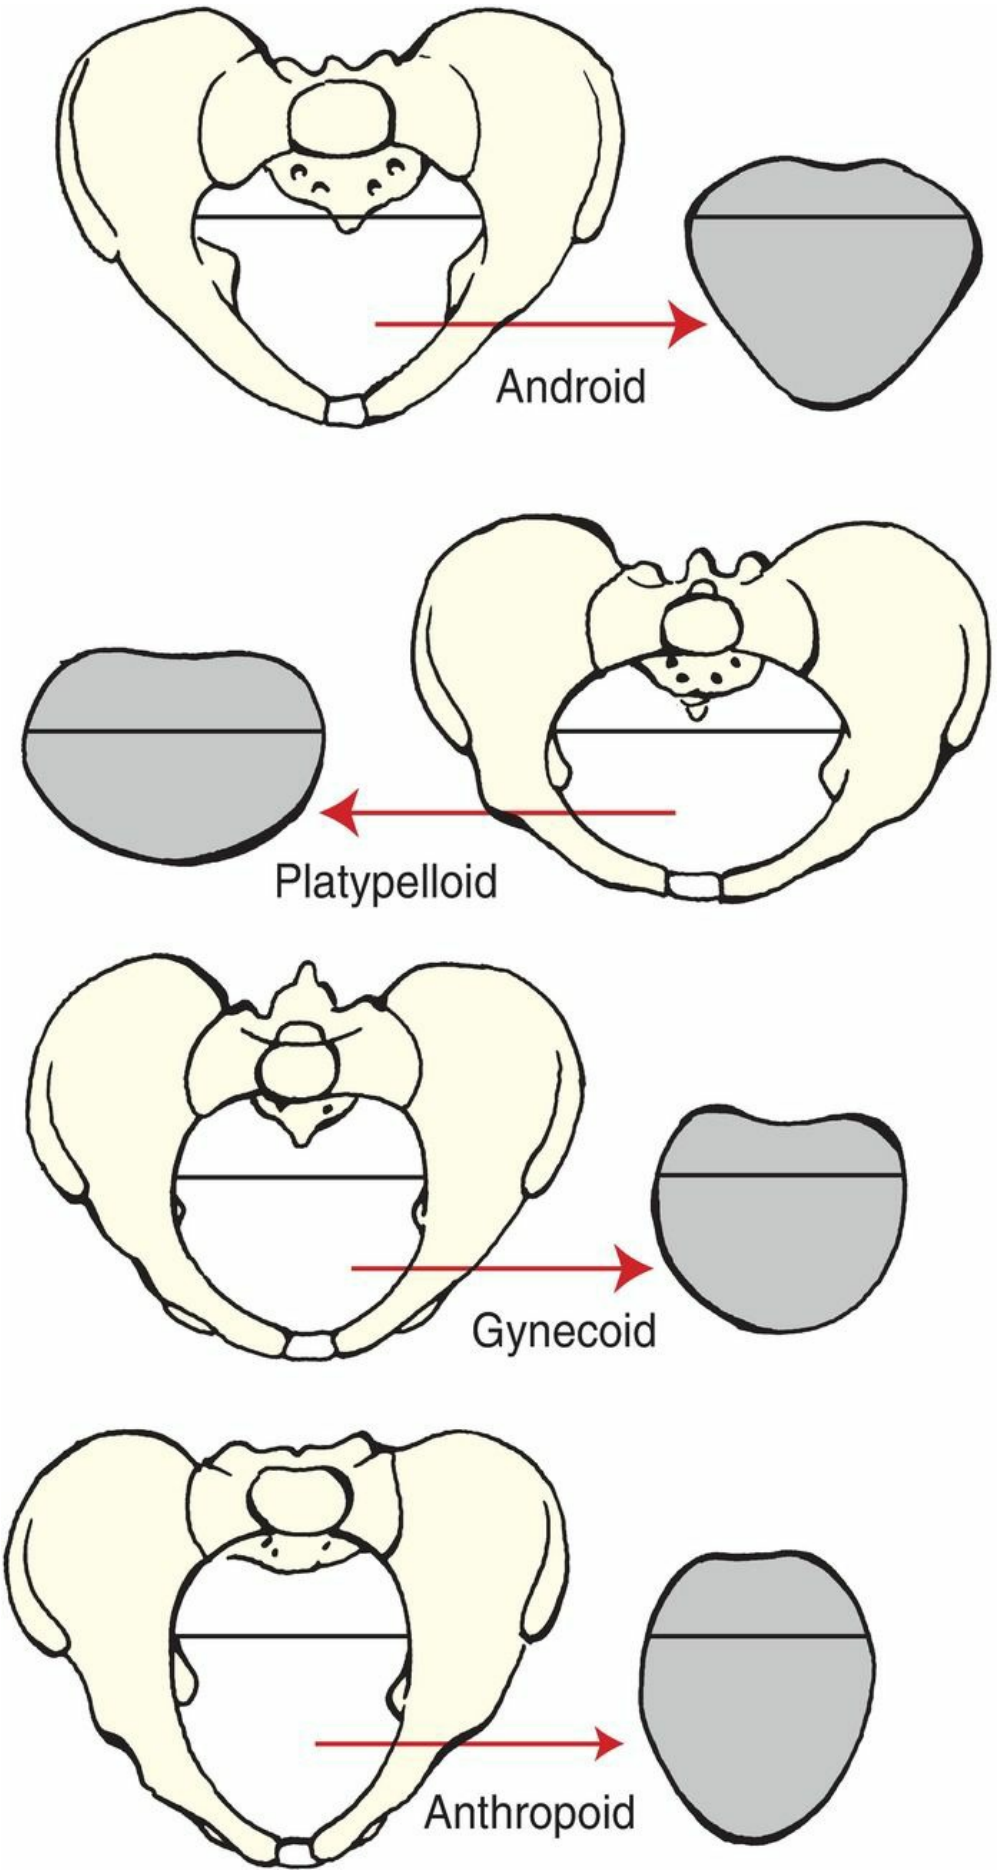
Shapes of the Pelvis

There are four main types of pelvic shapes (see Figure 36-4).



Android
Platypelloid
Gynecoid
Anthropoid

Figure 36-4. The four types of female pelvises. *Android*—male-type pelvis. *Platypelloid*—broad pelvis with shortened anteroposterior diameter and flattened, oval, transverse shape. *Gynecoid*—typical female pelvis in which inlet is round instead of oval. *Anthropoid*—pelvis in which anteroposterior diameter is equal to or greater than the transverse diameter.

1. Gynecoid (normal female pelvis); optimal diameters in all three planes; 50% of all women.
2. Android (normal male pelvis); posterior segments are decreased in all three planes; deep transverse arrest of descent of the fetus and failure of rotation of the fetus are common; 20% of all women.
3. Anthropoid (apelike pelvis with long anteroposterior diameter); may allow for easy delivery of an occiput-posterior presentation of the fetus; 25% of all women.
4. Platypelloid (flat female pelvis with wide transverse diameter); arrest of fetal descent at the pelvic inlet is common; labor progress can be poor in 5% of all women.

Structure of the Uterus

1. Located behind the symphysis pubis between the bladder and the rectum increasing in size after childbirth.
2. Consists of four parts:
    a. Fundus—upper rounded segment that extends above the insertion of the fallopian tubes; fetal growth is measured by fundal height in centimeters correlating with weeks gestation.
    b. Body (corpus)—main portion between cervix and fundus.
    c. Isthmus (neck)—lower uterine segment.
    d. Cervix—divided into two sections:
        i. Supravaginal—portion that extends inside the uterus; contains internal os that opens into the uterine cavity.
        ii. Vaginal—portion that extends outside the uterus into the vagina; contains the external os that is the visible opening of the cervix; portion that is felt during vaginal examination in assessing cervical dilation.
3. Consists of three layers:
    a. Parietal peritoneum—serous coat; covers most of uterus except cervix and anterior portion of body.
    b. Myometrium—three layers:
        i. Outer layer—provides power to expel the fetus.
        ii. Middle layer—provides contractions after childbirth to control blood loss.
        iii. Inner layer—provides sphincter action to help keep cervix closed during pregnancy.
    c. Endometrium—highly vascular mucous membrane; responds to hormonal stimulation with hypertrophy and secretion; sloughs if pregnancy does not occur.

Prenatal Assessment

EVIDENCE BASE Association of Women's Health, Obstetric, Neonatal Nurses. (2015). *Fetal heart monitoring: Principles and practices* (5th ed.). Dubuque, IA: Kendall Hunt Publishing Company.

Health History

Age

Babies born to women at the extremes of reproductive life defined as women younger than 19 years and older than 35 years have an increased risk of prematurity, congenital anomalies, as well as other risks of pregnancy.

1. Adolescent mothers have an increased incidence of anemia, gestational hypertension, preterm labor (PTL), small-for-gestational age (SGA) infants, intrauterine growth–restricted infants, cephalopelvic disproportion, and dystocia.
2. Women of advanced maternal age (AMA) have an increased incidence of hypertension with pregnancies complicated by underlying medical problems such as diabetes, multiple gestation, and infants with genetic abnormalities.

Family History

Includes maternal and paternal history for conditions such as congenital disorders, hereditary diseases, multiple pregnancies, diabetes, heart disease, hypertension, mental retardation, renal disease, and any recent global travel destinations.

Maternal Medical History

1. Childhood diseases and immunization records especially rubella, measles, and chickenpox.
2. Major illnesses, surgery (especially of the reproductive tract, spinal surgery, or appendectomy), blood transfusions.
3. Existing medical conditions, such as epilepsy, cardiac disease, endocrine disorders (eg, diabetes, thyroid disease), asthma, and hypertension.
4. Drug, food, and environmental allergies.
5. Urinary tract infections (UTIs) and sexually transmitted infections (STIs).
6. Menstrual history (onset of menarche, length, amount, regularity, and dysmenorrhea). Also, assess for bleeding between menses.
7. Gynecologic history (reproductive history, contraceptive use, and sexual history).
8. Use of medications (prescription, herbal, and over the counter [OTC]), recreational drugs, alcohol, nicotine, tobacco, and caffeine.
9. History of tuberculosis, hepatitis, group B beta-hemolytic streptococcus (GBS), or human immunodeficiency virus (HIV).

Maternal Nutritional History

1. Adherence to special dietary practices (religious, social, or cultural preferences).
2. History of eating disorders (obesity, bulimia, anorexia nervosa), gastric bypass, absorption problems (eg, phenylketonuria [PKU] and celiac disease), and food allergies.
3. Eating patterns (times and frequency of eating daily), number of servings of food from the five food groups, calories, protein, vitamins, and minerals consumed daily.
4. Additional factors to be considered include where the food was eaten, quantity of food eaten, how food was prepared (ie, fried, baked), and which foods are limited and why.
5. The U.S. Department of Agriculture provides an online interactive diet program, Daily Food Plan for Moms, specifically tailored to pregnant and breastfeeding women. This program gives a personalized plan for nutrition for pregnancy including multiples and lactating women.
6. Weight gain of less than 10 pounds (4.5 kg) or loss of more than 5 pounds (2.3 kg).

EVIDENCE BASE United States Department of Agriculture. (2017). Nutritional needs during pregnancy. Washington, DC: Author. Available: *www.choosemyplate.gov/nutritional-needs-during-pregnancy*.

Woman's Past Obstetric History

1. Infertility issues, dates of previous pregnancies and deliveries, infant weights, length of labors, types of deliveries, anesthesia use, multiple births, abortions, stillbirths, and maternal, fetal, and neonatal complications. Include history of infertility to include treatments, medications, and conceived or lost pregnancies.
2. Last delivery less than 1 year before present conception.
3. Woman's perception of past pregnancy, labor, and delivery experience for herself and effect on her family.

Woman's Current Obstetric Experience

1. Gravidity, parity.
2. Date of last menses.
3. Estimated date of birth—EDC (estimated date of confinement)/EDD (estimated date of delivery).
4. Signs and symptoms of pregnancy—amenorrhea, breast changes, nausea and vomiting, fetal movement, fatigue, urinary frequency, and skin pigment changes.
5. Expectations for her present pregnancy, labor, and delivery.
6. Expectations for her health care providers and her perception of her relationship between herself and her nurse.
7. Rest and sleep patterns—length, quality, and regularity of rest and sleep.
8. Activity and employment—exercise patterns, type and hours of employment, exposure to hazardous

material (occupational hazards), and plans for continued employment.

9. Sexual activity and contraceptive practices.
10. Inadequate prenatal care, intrauterine growth problems, Rh sensitization, or preterm labor.

Psychosocial History

1. Psychiatric and mental status history: history of mood or anxiety disorders; mental illness; medications or treatments for psychiatric or mental problems. Past history of depression, with or without an association with pregnancy.
2. Self-concept or self-esteem issues.
3. Support systems available, including ones she has made contact with.
4. Stressors: personal and occupational stressors that may affect her pregnancy and the fetus; include coping strategies she may use or lack of coping skills.
5. Emotional changes and adjustment to pregnancy.
6. The Psychosocial Screening Tool can be used to determine factors that impact a woman's physical and mental health and may interfere with her following through with prenatal care. Any positive response to the following questions deserves further investigation and intervention.
   a. Do you have any problems (job, transportation, etc.) that prevent you from keeping your health care appointments?
   b. Do you feel unsafe where you live?
   c. In the past 2 months, have you used any form of tobacco?
   d. In the past 2 months, have you used drugs or alcohol (including beer, wine, or mixed drinks)?
   e. On a scale of 1 to 5, how do you rate your current stress level?
   f. How many times have you moved in the past 12 months?
   g. If you could change the timing of this pregnancy, would you want it earlier, later, not at all, no change?

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2016). Screening for perinatal depression (2010/Reaffirmed 2016). (Committee Opinion No. 630). Washington, DC: Author.

---

7. In addition to the Perinatal Screening Tool, the pregnant woman can be asked about intimate partner violence. Examples of questions for this interview are:
   a. Has your current partner ever threatened you or made you feel afraid? Threatened to hurt you or your children if you did or did not do something?
   b. Has current partner ever hit, choked, or physically hurt you? (Includes being slapped, kicked, bitten, pushed, or shoved.)
   c. Has current partner ever forced you to do something sexually that you did not want to do or refused

your request to use condoms?

d. Has current partner ever tampered with your birth control or tried to get you pregnant when you did not want to be pregnant?

e. Has current partner prevented you from using a wheelchair, cane, respirator, or other assistive devices?

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2012). Intimate partner violence (Committee Opinion No. 518). Washington, DC: Author.

Laboratory Data

Urinalysis

1. Urine is tested for glucose, ketones, and protein. Urine is usually collected by a clean-catch, midstream technique.
2. Glucose (glucosuria) may be present in small amounts because the glomerular filtration rate is increased without the same increase in kidney tubular reabsorption. Glucosuria should be investigated to rule out diabetes.
3. Protein in the urine that exceeds 300 mg/dL/24-hour urine collection should be reported because it may be a sign of preeclampsia, renal problems, or UTI.
4. Ketones in the urine should be reported because ketonuria may be a sign of excessive weight loss, dehydration, or electrolyte imbalance. Ketonuria is commonly secondary to nausea and vomiting of pregnancy.
5. If the urine is cloudy and bacteria or leukocytes are present (more than four leukocytes per high-powered field), a urine culture is performed.
6. The presence of bilirubin is indicative of liver or gallbladder disease or breakdown of RBCs.
7. The presence of blood in the urine (hematuria) is suggestive of UTI, kidney disease, or vaginal contamination.

Complete Blood Count

1. Determination of hematocrit and hemoglobin levels and description of the morphology of the RBCs are done to find evidence of anemias, such as sickle cell or thalassemia.
2. Hemoglobin levels average 12 to 16 g/dL.

Blood Type and Screening

1. Blood type, Rh factor, and antibody screen—if the woman is found to be Rh negative or to have a positive antibody screen, her partner is screened and a maternal antibody titer is drawn, as indicated.
   a. Coombs test—retested at 28 weeks in the Rh-negative woman for detection of antibodies.

b. Rh_o (D) immune globulin (RhoGAM) given at 28 weeks, as indicated. Also administered following chorionic villus sampling (CVS), percutaneous umbilical sampling, amniocentesis, trauma, or placental separation (abruptio placentae or placenta previa).

c. Given within 72 hours of birth to a Rh_o (D) mom or Du– and without antibodies if the newborn is Rh positive.

2. Glucose testing—diabetic screening for women who are at average risk conducted at 24 to 28 weeks using a 1-hour 50-g glucose load test. According to the American Diabetes Association, average risk includes age 25 or older, obese women of any age, family history of diabetes mellitus in a first-degree relative, previous delivery resulting in a macrosomic infant, member of an ethnic group with a high prevalence of diabetes (Hispanic, Black, Pacific Islander, Native American, Asian American), history of abnormal glucose tolerance, and history of poor obstetric outcome.
3. Maternal serum alpha-fetoprotein (MS-AFP)—may be done at 15 to 18 weeks. High maternal levels may indicate an open neural tube defect in the fetus; low levels have been associated with Down syndrome. Inaccurate pregnancy dating is the most common cause for an abnormal MS-AFP.

Infection

1. Rapid plasma reagin (RPR), Venereal Disease research lab (VDRL) or fluorescent treponemal antibody absorption test for syphilis is done on the initial visit; repeat testing at 32 weeks, as indicated.
2. Gonorrhea—cervical cultures are usually done at the initial visit and when symptoms are present.
3. HSV—all visible lesions are cultured, and the cervix is cultured weekly beginning 4 to 8 weeks before delivery.
4. Chlamydia—done at the initial visit and when symptoms are present.
5. Rubella titer—immunity is 10 IU/mL or greater.
6. Hepatitis B surface antigen.
7. HIV—screening is recommended for all pregnant women.

Other Tests

1. Toxoplasmosis—done as indicated for women at risk.
2. Tuberculin skin tests—done as indicated.
3. Papanicolaou (Pap) smear—done unless recent results available.
4. Sickle cell screen—done to detect presence of sickle hemoglobin in at-risk women.
5. Group B beta streptococcus (rectovaginal swab)—done to detect carriers or active GBS.
6. Drug screen—done to decrease possible neonatal abstinence syndrome.

Physical Assessment

General Examination

1. The woman is asked to empty her bladder before the examination to enhance her comfort and to facilitate palpation of her uterus and pelvic organs during the vaginal examination.

2. Evaluation of the woman's weight and BP.
3. Examination of the eyes, ears, and nose—nasal congestion during pregnancy may occur as a result of peripheral vasodilation.
4. Examination of the mouth, teeth, throat, and thyroid—the gums may be hyperemic and softened because of increased progesterone.
5. Inspection of breasts and nipples—the breasts may be enlarged and tender; nipple and areolar pigment may be darkened.
6. Auscultation of the heart.
7. Auscultation and percussion of the lungs.

Abdominal Examination

1. Examination for scars or striations, diastasis recti (separation of the rectus muscle), or umbilical hernia.
2. Palpation of the abdomen for fundal height (palpable after 13 weeks of pregnancy); measurement recorded and used as guideline for subsequent calculations.
3. Palpation of the abdomen for fetal outline and position (Leopold maneuvers)—third trimester.
4. Check of FHTs—FHTs are audible with a Doppler after 10 to 12 weeks and at 18 to 20 weeks with a fetoscope.
5. Record fetal position, presentation, and FHTs.

Pelvic Examination

1. The woman is placed in lithotomy position.
2. Inspection of external genitalia.
3. Vaginal examination—done to rule out abnormalities of the birth canal and to obtain cytologic smear (Pap and, if indicated, smears for gonorrhea, vaginal trichomoniasis, candidiasis, herpes, group B beta streptococcus, and chlamydia) (see Figure 36-5).
4. Examination of the cervix for position, size, mobility, and consistency. Cervix is softened and bluish (increased vascularity) during pregnancy.
5. Identification of the ovaries (size, shape, and position).
6. Rectovaginal exploration to identify hemorrhoids, fissures, herniation, or masses.
7. Evaluation of pelvic inlet—anteroposterior diameter by measuring the diagonal conjugate.
8. Evaluation of midpelvis—prominence of the ischial spines.
9. Evaluation of pelvic outlet—distance between ischial tuberosities and mobility of coccyx.

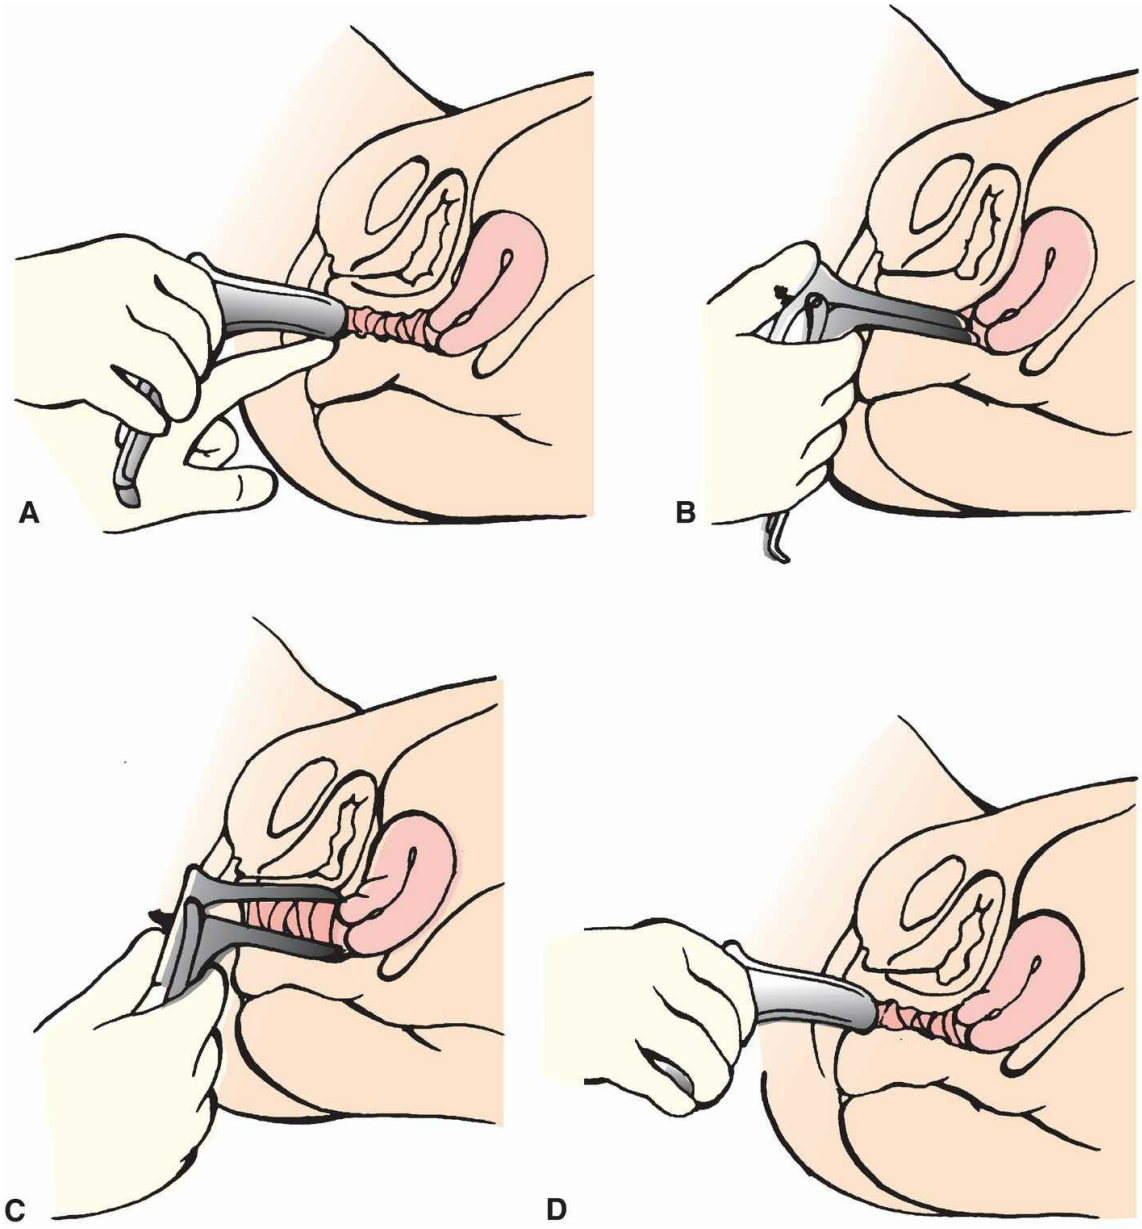


Figure 36-5. Vaginal speculum examination. **(A)** Blades held obliquely on entering the introitus. **(B)** Blades rotated to horizontal position and pushed toward the cervix. **(C)** Blades separated to encircle the cervix. **(D)** Blades removed with gentle pulling.

Subsequent Prenatal Assessments

1. Uterine growth and estimated fetal growth (see Figure 36-6).
    a. Fundus at symphysis pubis indicates 12 weeks gestation.
    b. Fundus at umbilicus indicates 20 weeks gestation.
    c. Fundal height corresponds with gestational age between 22 and 34 weeks.
    d. Fundus at lower border of rib cage indicates 36 weeks gestation.
    e. Uterus becomes globular and drop indicates 40 weeks gestation.
2. A greater fundal height suggests:

a. Multiple pregnancy.
b. Miscalculated due date.
c. Polyhydramnios (excessive amniotic fluid).
d. Gestational throphoblastic disease (degeneration of villi into grapelike clusters; fetus does not usually develop).
e. Uterine fibroids.

3. A lesser fundal height suggests:
   a. Intrauterine fetal growth restriction.
   b. Error in estimating gestation.
   c. Fetal or amniotic fluid abnormalities.
   d. Intrauterine fetal death.
   e. SGA.
4. FHTs—palpate abdomen for fetal position.
   a. Normal—110 to 160 beats/minute (bpm).
5. Weight—major increase in weight occurs during second half of pregnancy; usually between 0.5 pound (0.2 kg)/week and 1 pound (0.5 kg)/week. Greater weight gain may indicate fluid retention and hypertensive disorder.
6. BP—should remain near woman's prepregnant baseline.
7. Complete blood count at 28 and 32 weeks gestation; VDRL—rechecked at 36 to 40 weeks gestation.
8. Antibody serology screen if Rh negative at 36 weeks gestation.
9. Culture smears for gonorrhea, chlamydia, group B beta-hemolytic streptococcus, and herpes, as indicated; usually at 36 and 40 weeks gestation.
10. Urinalysis—for protein, glucose, blood, and nitrates.
11. AFP—done at 15 to 20 weeks.
12. Diabetic screening—done, as indicated, at 24 to 28 weeks.
13. Administer RhoGAM, as indicated, at 28 weeks.
14. Edema—check the lower legs, face, and hands.
15. Evaluate discomforts of pregnancy—fatigue, heartburn, hemorrhoids, constipation, and backache.
16. Evaluate eating and sleeping patterns, general adjustment and coping with the pregnancy.
17. Evaluate concerns of the woman and her family.
18. Evaluate preparation for labor, delivery, and parenting. See Patient Education Guidelines 36-1.

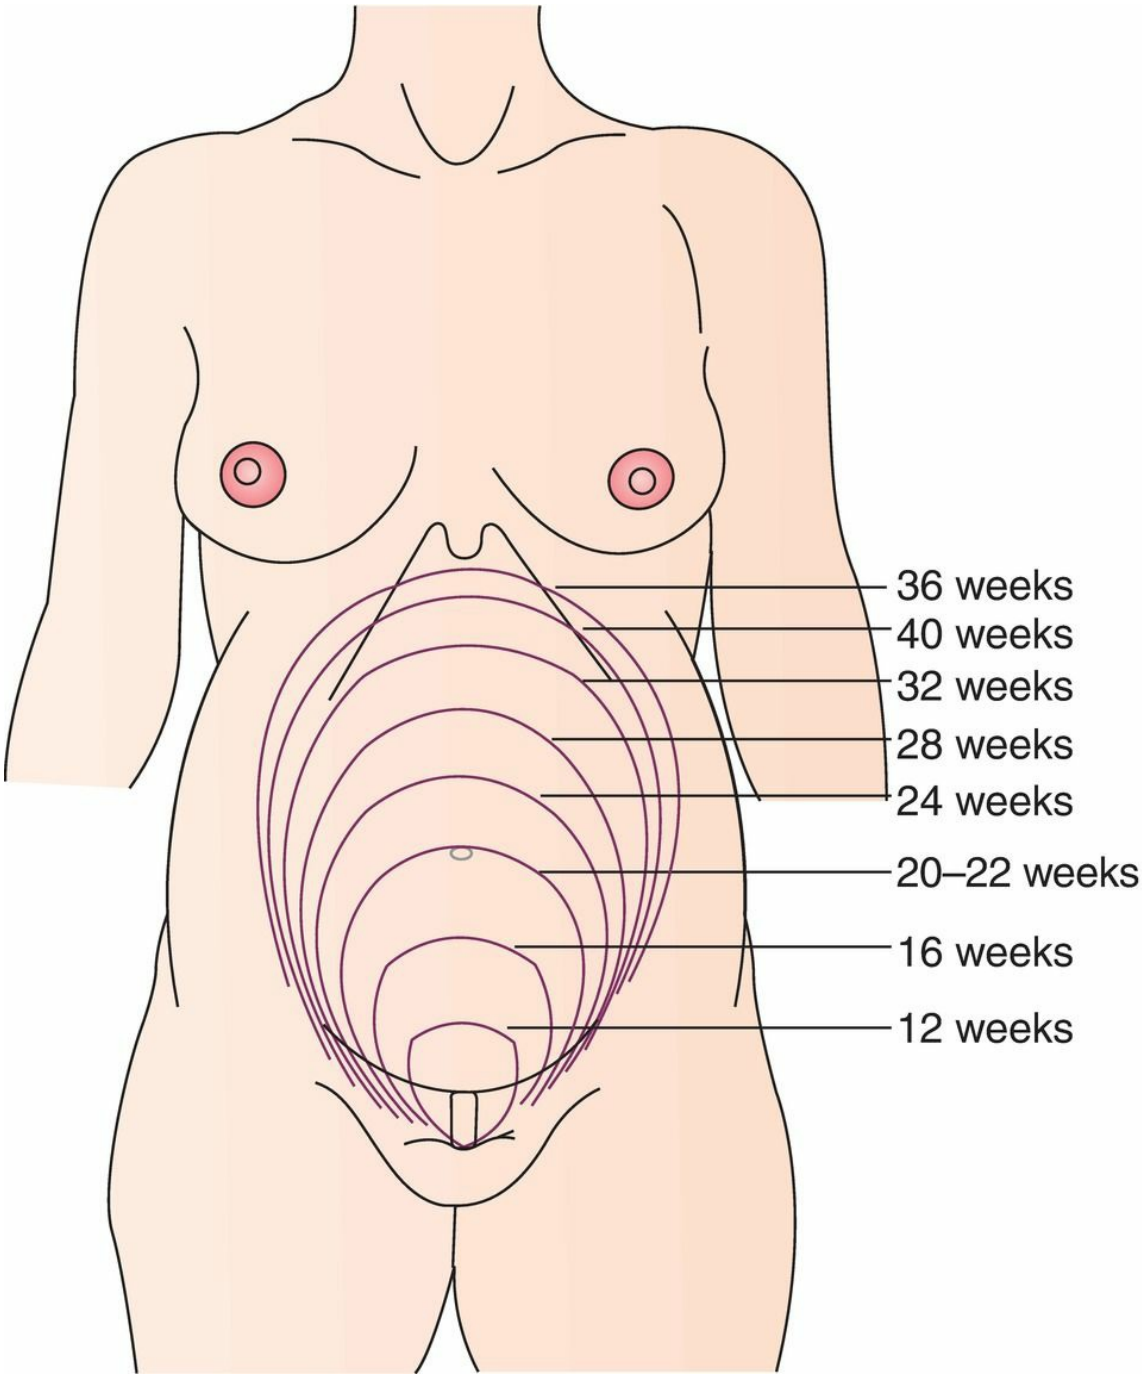

Figure 36-6. Height of fundus. (Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

PATIENT EDUCATION GUIDELINES 36-1

Prenatal Care

- It is important to keep scheduled prenatal care appointments:
  - Weeks 1 to 28: Every month.
  - Weeks 28 to 36: Every 2 weeks.
  - Weeks 36 to delivery: Every week.

- Expect the following discomforts of pregnancy, and speak with your nurse or health care provider about strategies for relief:
    - Back pain, leg cramps, breast tenderness.
    - Morning sickness, heartburn.
    - Frequent urination.
    - Constipation.
    - Swelling of legs, varicose veins.
    - Fatigue.
- Follow a healthy, balanced diet with three meals per day and take prenatal vitamins as directed by your health care provider.
- Get regular exercise and use proper body mechanics to avoid injury.
- Be aware of danger symptoms of pregnancy; these must be reported to your health care provider promptly:
    - Vision disturbances—blurring, spots, or double vision.
    - Vaginal bleeding, new or old blood.
    - Edema of the face, fingers, and sacrum.
    - Headaches—frequent, severe, or continuous.
    - Fluid discharge from vagina; unusual or severe abdominal pain.
    - Chills, fever, or burning on urination.
    - Epigastric pain (severe stomachache).
    - Muscular irritability or convulsions.
    - Inability to tolerate food or liquids, leading to severe nausea and hyperemesis.

Nursing Interventions and Patient Education

Nursing Diagnoses

- Acute Pain (backache, leg cramps, breast tenderness) related to physiologic changes of pregnancy.
- Imbalanced Nutrition: Less Than Body Requirements related to morning sickness, heartburn, lack of knowledge of requirements in pregnancy and growing fetus.
- Impaired Urinary Elimination (frequency) related to increased pressure from the uterus.
- Constipation related to physiologic changes of pregnancy and pressure from the uterus.
- Impaired Tissue Integrity related to pressure from the uterus and increased blood volume.
- Anxiety or Fear related to the birth process and infant care.
- Ineffective Role Performance related to the demands of pregnancy.
- Activity Intolerance related to physiologic changes of pregnancy and enlarging uterus.

Nursing Interventions

Minimizing Pain

1. Teach the woman to use good body mechanics—wear comfortable, low-heeled shoes with good arch support; try the use of a maternity girdle.
2. Instruct the woman in the technique for pelvic-rocking exercises.
3. Encourage the woman to take rest periods with her legs elevated.
4. Inform the woman that adequate calcium intake may decrease leg cramps.
5. Instruct the woman to dorsiflex the foot while applying pressure to the knee to straighten the leg for immediate relief of leg cramps.
6. Instruct the woman to wear a fitted, supportive bra.
7. Instruct the woman to wash her breasts and nipples with water only.
8. Instruct the woman to apply vitamin E or lanolin cream to the breast and nipple area. Lanolin is contraindicated for women with allergies to lamb's wool.

Minimizing Morning Sickness and Heartburn and Maintaining Adequate Nutrition

1. Encourage the woman to eat a few bites of a soda cracker or dry toast before getting out of bed in the morning.
2. Instruct the woman to rise from bed slowly.
3. Encourage the woman to eat low-fat protein foods and dry carbohydrates, such as toast and crackers.
4. Encourage the woman to eat small, frequent meals.
5. Advise the woman to eat slowly.
6. Teach the woman the importance of good nutrition for herself and her fetus. Review the basic food groups with appropriate daily servings for essential vitamins and nutrients.
    a. Seven servings of protein-rich foods, including one serving of a vegetable protein.

b. Three servings of dairy products or other calcium-rich foods.
c. Seven servings of grain products.
d. Two or more servings of vitamin C–rich vegetable or fruit.
e. Three servings of other fruits and vegetables.
f. Three servings of unsaturated fats.
g. Two or more servings of other fruits and vegetables.

7. Encourage the woman to drink soups and liquids between meals to avoid stomach distention and dehydration.
8. Instruct the woman in the use of antacids; caution against the use of sodium bicarbonate because it results in the absorption of excess sodium and fluid retention.
9. Instruct the woman to avoid brushing her teeth soon after eating.
10. Instruct the woman to avoid offensive foods or cooking odors that may trigger nausea.
11. Recommended dietary reference intakes for pregnant women can be obtained from *www.choosemyplate.gov/nutritional-needs-during-pregnancy*. If the woman is a vegetarian, inform her of appropriate intake. Assess type of vegetarian and food intake.
    a. Two broad groups of vegetarians:
        i. Traditional—cultural or religious affiliation prescribes their diet.
        ii. New—adopted vegetarian dietary patterns as a personal or philosophical choice.
    b. Subgroups exist within the above two groups:
        i. Vegan—eat foods from a plant origin; eat no animal foods or anything derived from an animal (ie, eggs, milk, cream, etc.).
        ii. Lacto—eat milk/dairy products, but eat no meat, poultry, fish, seafood, or eggs.
        iii. Lacto-ovo—eat milk/dairy products and eggs, but eat no meat, poultry, fish, or seafood.
        iv. Pesce—eat foods from a plant origin and fish or cheese, but no meat, poultry, or eggs.
    c. Partial vegetarians may exclude a specific type of animal food, usually meat, but may consume fish and poultry.
    d. Recommend iron and folic acid supplements.
12. Inform the woman that average weight gain in pregnancy is 25 to 35 pounds (11 to 16 kg). About 2 to 5 pounds (0.9 to 2.3 kg) are gained in the first trimester and about 1 pound (0.5 kg) per week for the remainder of the gestation.
    a. Average weight gain for obese women is 15 pounds (6.8 kg).
    b. Adolescent weight gain should be about 5 pounds more than for adult women if within 2 years of starting menses.
    c. Women with a multiple pregnancy should gain between 35 and 45 pounds (16 and 20 kg).
    d. Average weight gain for underweight women is 28 to 40 pounds (13 to 18 kg).
    e. Assess for any cultural or religious times of fasting (eg, Lent or Ramadan).
13. Advise the woman to limit the use of caffeine.

14. Inform the woman that alcohol should be eliminated during pregnancy as no safe level of intake has been established.
15. Inform the woman that smoking should be eliminated or severely reduced during pregnancy related to the increased risk of spontaneous abortion, fetal death, low birth weight, and neonatal death.
16. Inform the woman that ingesting any drug during pregnancy may affect fetal growth and should be discussed with her health care provider.

Minimizing Urinary Frequency and Promoting Elimination

1. Instruct the woman to limit fluid intake in the evening and to void before going to bed.
2. Encourage the woman to void after meals, with the urge to void, and after sexual intercourse.
3. Encourage the woman to wear loose-fitting cotton underwear.
4. Cranberry or blueberry juice may be recommended to help prevent UTIs.
5. Caffeine should be avoided.

Avoiding Constipation

1. Instruct the woman to increase fluid intake to at least eight glasses of water per day. One to 2 quarts of fluid per day is desirable.
2. Encourage daily intake of foods high in fiber.
3. Encourage the woman to establish regular patterns of elimination.
4. Encourage daily exercise such as walking.
5. Inform the woman that OTC laxatives should be avoided. Providers may recommend stool softeners or bulk-forming agents as indicated.

Maintaining Tissue Integrity

1. Encourage the woman to take frequent rest periods with her legs elevated.
2. Instruct the woman to wear support stockings and wear loose-fitting clothing for leg varicosities.
3. Instruct the woman to avoid constipation, apply cold compresses, take sitz baths, and use topical anesthetics, such as Tucks, for the relief of anal varicosities (hemorrhoids).

Reducing Anxiety and Fear and Promoting Preparation for Labor, Delivery, and Parenthood

The nurse should facilitate education to the woman and her partner related to the following:

1. Current, knowledge, perceptions, cultural values, and expectations of the labor and delivery process and parenting.
2. Availability of childbirth preparation classes that include infant care, breastfeeding, and parenting and encourage attendance.
3. Availability of sibling and grandparent preparation, as indicated.
4. A tour of the birth facility.
5. Common procedures that may be performed during labor and birth.
6. Creating a personalized birth plan to include coping and relaxation techniques and pain management

options both nonpharmacologic and pharmacologic, for labor and birth.

7. General guidelines for coming to the birth facility.
8. Preparations for the infant, such as a sleeping space, clothing, feeding, changing, and bathing equipment.

NURSING ALERT Women who attended childbirth preparation have reported an increased satisfaction with their birth experience. Additional benefits to childbirth preparation include improved breastfeeding rates and decreased use of pharmacologic pain management.

Enhancing Role Changes

1. Encourage discussion of feelings and concerns regarding the new role of mother and father.
2. Provide emotional support to the woman/partner regarding the altered family roles.
3. Discuss physiologic causes for changes in sexual relationships, such as fatigue, loss of interest, and discomfort from advancing pregnancy. Some women experience heightened sexual activity during the second trimester.
4. Teach the woman/partner that there are no contraindications to intercourse or masturbation to orgasm provided the woman's membranes are intact, there is no vaginal bleeding, and she has no current problems or history of premature labor.
5. Teach the woman or partner that female superior or sidelying positions are usually more comfortable in the latter half of pregnancy.

Minimizing Fatigue

1. Teach the woman reasons for fatigue and have her plan a schedule for adequate rest.
   a. Fatigue in the first trimester is due to increased progesterone and its effects on the sleep center.
   b. Fatigue in the third trimester is due mainly to carrying increased weight of the pregnancy.
   c. About 8 hours of rest are recommended with frequent 15- to 30-minute rest periods to avoid overfatigue.
   d. Whenever possible, the woman should work while sitting with her legs elevated.
   e. The woman should avoid standing for prolonged periods, especially during the third trimester.
   f. To promote placental perfusion, the woman should not lie flat on her back—left lateral position provides the best placental perfusion; however, either side is acceptable. In the third trimester of pregnancy, sleeping with a small pillow under the abdomen may enhance comfort.
2. Help the woman plan for adequate exercise (if not contraindicated).
   a. In general, exercise during pregnancy should be in keeping with the woman's prepregnancy exercise pattern and type.
   b. Activities or sports that have a risk of bodily harm (skiing, snowmobiling, ice skating, inline skating, horseback riding) should be avoided.

c. During pregnancy, endurance during exercise may be decreased.

d. Exercise classes for pregnant women that concentrate on toning and stretching have resulted in enhanced physical condition, increased self-esteem, and greater social support as a result of being in the exercise group.

e. Contraindications to aerobic exercise during pregnancy include hemodynamically significant heart disease, restrictive lung disease, incompetent cervix, cerclage, multiple gestations at risk for PTL, persistent second- or third-trimester bleeding, placenta previa after 26 weeks gestation, ruptured membranes, PTL in current pregnancy, and preeclampsia.

f. Exercise that increases the risk of injury or a woman diagnosed with a pregnancy complication should avoid any strenuous exercise.

NURSING ALERT Exercise in pregnancy benefits both the mother and fetus by enhancing overall health and fitness by promoting adequate weight gain, strengthened muscle tone, and reduced blood sugar. Outcomes demonstrate a decrease in operative delivery, gestational diabetes, and hypertension.

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2016). Exercise during pregnancy FAQs. Washington, DC: Author. *www.acog.org/patients/FAQS/exercise-during-pregnancy*.

Community and Home Care Instructions

1. Community and home care is prevention oriented.
2. Case management coordinates health care management collaboratively.
3. Search out and register for prepared childbirth classes. Preferable to attend those associated with the family's intended delivery facility.
4. Social support available from Women, Infants, and Children's Special Supplemental Feeding Program, breastfeeding groups (La Leche League), and father/partner support groups.
5. Prenatal education should focus on nutrition, sexuality, stress reduction, lifestyle behaviors, and hazards at home or work.
6. Consider cultural practices as they have implications for the provision of nursing care.

Alternative Therapies

General Measures

1. Alternative therapies range from nutrition and lifestyle changes to mind and body programs.
2. Encourage the woman to discuss options with her health care provider and consult a credentialed naturopath, acupuncturist, or other complementary practitioner.

3. Physical activities—maintaining an active lifestyle and healthy diet. Some use macrobiotic diets and isometric exercise.
4. Attitudinal activities—maintaining a positive attitude and self-image; have fun and laugh.
5. Relational activities—maintaining social relationships—friends, pets, and family.
6. Spiritual activities—having faith, hope, prayer, and music and meditating as an active part of daily life.
7. Self-caring activities—taking care of self, balancing life, personal integrity, knowing and trusting self, and own time management.
8. Help-seeking activities—seeking assistance in health care ranging from prescribed treatments to biomedicine (self-healing touch). Help-seeking activities include ethnomedicine (Chinese herbal medicine and acupuncture), structure/energy therapies (therapeutic touch and osteopathy), pharmacologic/biologic treatments (antioxidants), biofeedback, guided imagery, music therapy, meditation, and prayer.

Alternative Therapies Specific to the Prenatal Period

1. It is essential that the woman and her family discuss the use of herbs with her obstetric provider before use, become familiar with manufacturers, and ask questions. Although herbs are natural, they can be harmful if misused. Herbs should be used with the same respect as medications.
2. Many herbs are available to be used during pregnancy including the labor and delivery process. Herbs come in different forms—capsules, tablets, extracts, tinctures, powders, dried and prepared as teas or juices, in combinations, and as external preparations.
3. Herbal therapies that are Food and Drug Administration–approved include:
   a. Aloe, cascara (sacred bark, bitter bark), psyllium (plantago seed), senna as a laxative.
   b. Capsicum or cayenne pepper (chili pepper, red pepper) as a topical analgesic; marketed as a cream and used topically.
   c. Slippery elm (red elm) as an oral demulcent; marketed as throat lozenges.
4. Other herbal preparations including Catnip, fennel, lobelia, papaya, spearmint, and wild yams decrease colic stomach cramps, gas, and heartburn and improve the appetite.
5. Cranberry or blueberry juice for UTI prevention.
6. Nausea is sometimes attributed to vitamin B deficiencies but does not always improve with simple vitamin supplements. Red raspberry, peppermint, spearmint, or chamomile tea and ginger root or ginger ale may be used to alleviate the nausea. To increase the effectiveness of red raspberry tea, alfalfa may be added to the tea.
7. Certain acupressure or acupuncture points may assist with the relief of nausea.
8. Other therapies include therapeutic touch and yoga.

EVIDENCE BASE Louik, C., Gardiner, P., Kelley, K., & Mitchell, A. A. (2010). Use of herbal treatments in pregnancy. *American Journal of Obstetrics and Gynecology, 202*(5), 439.e1–439.e10.

Evaluation: Expected Outcomes

- Verbalizes understanding of proper body mechanics and wears low-heeled shoes.
- Identifies the basic food groups and describes meals to include needed servings for pregnancy.
- Reports limited fluid intake in the evening.
- Describes foods high in fiber.
- Wears support stockings and loose-fitting clothing.
- Discusses expectations for labor, delivery, and parenthood and attends educational classes.
- Verbalizes an understanding of the physiologic causes that may change the sexual relationship.
- Reports engaging in regular exercise.

Psychosocial Adaptation of Pregnancy

EVIDENCE BASE Link, D. G. (2016). Psychology of pregnancy. In S. Mattson & J. E. Smith (Eds.), *Core curriculum for maternal–newborn nursing* (5th ed., pp. 108–122). St. Louis, MO: Saunders Elsevier.

Rubin's Framework for Maternal Role Assumption

1. Attainment of motherhood role occurs with each pregnancy.
2. Involves a series of cognitive operations:
   a. Mimicry—woman begins observing and modeling her behavior after other pregnant women.
   b. Role-play—woman begins acting out behaviors of a mother (eg, rocking a baby to sleep).
   c. Searching for a role "fit"—woman has perceptions of how the motherhood role will be. She observes others' behaviors to determine how well they fit with her expectations of the motherhood role.
   d. Grief work—woman experiences a sense of loss of her "old" self as she prepares to begin her new role as a mother.
3. Maternal tasks—commonly divided by trimesters.
   a. First trimester:
      i. Acceptance of pregnancy—moves from a state of conflict and ambivalence to one of acceptance of the pregnancy, the child, and the motherhood role.
      ii. Realignment of roles—expectant parents begin to realign their roles and responsibilities as they relate to the child.
      iii. Safe passage—although the mother seeks to ensure a safe passage for her fetus and self throughout her pregnancy, the main focus during this trimester is on self-safety.
   b. Second trimester
      i. Safe passage—in this trimester, the mother's main focus is on appropriate nutrition and exercise.
      ii. Acceptance by others—acceptance of the child by each family member.
      iii. Binding-in to the child—maternal perception of the child as a real person.
   c. Third trimester
      i. Safe passage—during this trimester, the main focus is on the safety of the fetus and is inseparable from self-safety.
      ii. Giving of oneself—the most complex task, in which the mother is learning to give to the unborn child and placing the unborn child's need in relation to her own needs.
      iii. Critical to this trimester is the preparation of the nursery because it solidifies the acceptance of the unborn child.

Rubin's Framework for Paternal Role Assumption

1. The fatherhood role can also be attained with the pregnancy.
2. Paternal tasks can also be divided by trimesters.
    a. First trimester
        i. Announcement and realization of the pregnancy—father will exhibit excitement over the announcement of the pregnancy and is more interested in maternal changes. Usually, he will insist on accompanying the mother to each prenatal appointment.
        ii. Some fathers will even begin to experience the same signs and symptoms of pregnancy experienced by the mother. This is more commonly referred to as *couvade syndrome*.
    b. Second trimester
        i. Anticipation—father anticipates and adapts to the role of fatherhood.
        ii. Fantasy and exploration—along with the mother, the father begins to imagine what his child will look like and may also begin to explore the talents and attributes of the unborn child.
        iii. Adjustment of sexual expression to accommodate the pregnancy.
    c. Third trimester
        i. Preparation—now, serious preparation for the forthcoming child includes preparation of the nursery and childbirth education courses to prepare for labor and delivery.
        ii. Reassurance—provided by the father to ease the anxious mother's fears regarding labor and delivery.

THE FETUS

EVIDENCE BASE Callahan, L. (2016). Fetal and placental development and functioning. In S. Mattson & J. E. Smith (Eds.), *Core curriculum for maternal–newborn nursing* (5th ed., pp. 37–62). St. Louis, MO: Saunders Elsevier.

Fetal Growth and Development

Advances in knowledge and technology have provided newer methods for assessing fetal well-being and maturity. Improved methods for assessment and diagnosis enable early intervention for improved outcome. See Figure 36-7 for critical periods of fetal growth.

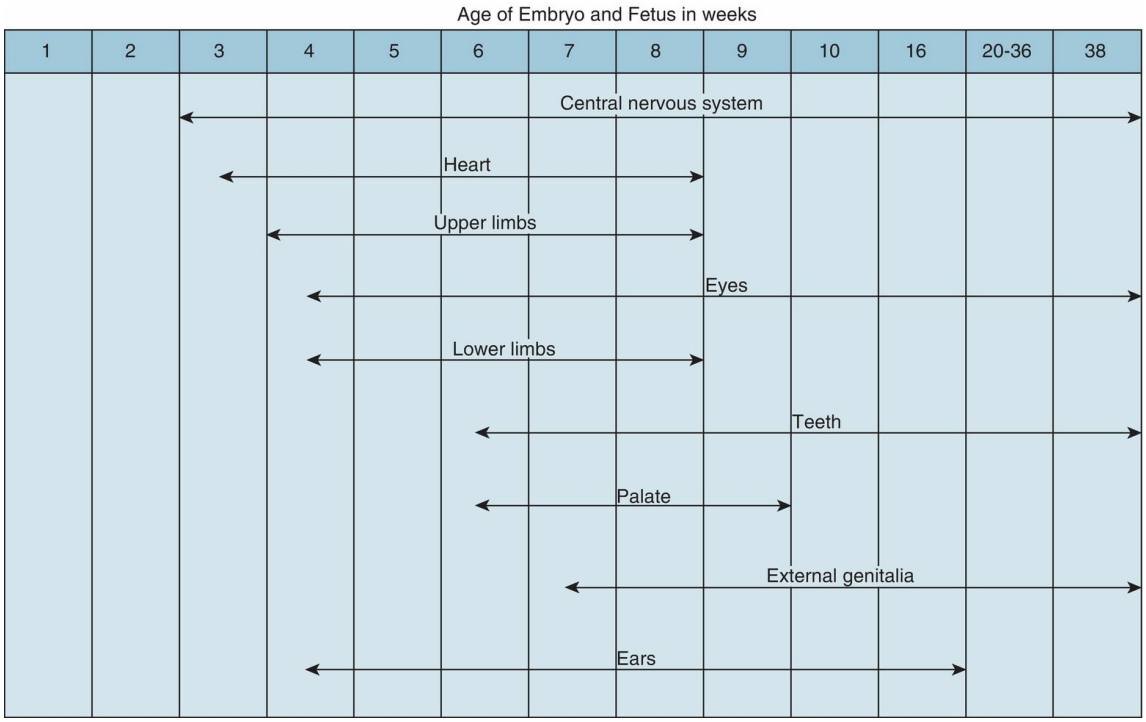

Figure 36-7. Critical periods of fetal growth. (Pillitteri, A. [2013]. *Maternal and child health nursing* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Stages of Growth and Development

The growth and development of the fetus is typically divided into three stages.

Preembryonic Stage: Fertilization to 2 to 3 Weeks

1. Rapid cell division and differentiation.
2. Develop embryonic membranes and germ layers.

Embryonic Stage: 4 to 8 Weeks Gestation

1. Most critical stage of physical development.
2. Organogenesis.

Fetal Stage: 9 Weeks to Birth

1. Every organ system and external structure present.
2. Refinement of fetus and organ function occurs.

Development by Month

First Lunar Month

1. Fertilization to 2 weeks of embryonic growth.
2. Implantation is complete.
3. Primary chorionic villi forming.
4. Embryo develops into two cell layers (trophoblast and blastocyst).
5. Amniotic cavity appears.

Second Lunar Month

1. Three to six weeks of embryonic growth.
2. At the end of 6 weeks of growth, the embryo is approximately ½ inch (1.3 cm) long.
3. Arm and leg buds are visible; arm buds are more developed with finger ridges beginning to appear.
4. Rudiments of the eyes, ears, and nose appear.
5. Lung buds are developing.
6. Primitive intestinal tract is developing.
7. Primitive cardiovascular system is functioning.
8. Neural tube, which forms the brain and spinal cord, closes by the 4th week.

Third Lunar Month

1. Seven to ten weeks of growth.
2. The middle of this period (9 weeks) marks the end of the embryonic period and the beginning of the fetal period.
3. At the end of 10 weeks of growth, the fetus is approximately 2½ inches (6.3 cm) from crown to rump and weighs ½ oz (14 g).
4. Appearance of external genitalia.
5. By the middle of this month, all major organ systems have formed.
6. The membrane over the anus has broken down.
7. The heart has formed four chambers (by 7th week).
8. The fetus assumes a human appearance.
9. Bone ossification begins.
10. Rudimentary kidney begins to secrete urine.

Fourth Lunar Month

1. Eleven- to fourteen-week-old fetus.
2. At the end of 14 weeks of growth, the fetus is approximately 4¾ inches (12 cm) crown–rump length and 3¾ oz (110 g).
3. Head erect; lower extremities well developed.

4. Hard palate and nasal septum have fused.
5. External genitalia of male and female can now be differentiated.
6. Eyelids are sealed.

Fifth Lunar Month

1. Fifteen- to eighteen-week-old fetus.
2. At the end of 18 weeks of growth, the fetus is approximately 6¼ inches (16 cm) crown–rump length and 11¼ oz (320 g).
3. Ossification of fetal skeleton can be seen on x-ray.
4. Ears stand out from head.
5. Meconium is present in the intestinal tract.
6. Fetus makes sucking motions and swallows amniotic fluid.
7. Fetal movements may be felt by the mother (end of month).

Sixth Lunar Month

1. Nineteen- to twenty-two-week-old fetus.
2. At the end of 22 weeks of growth, the fetus is approximately 8¼ inches (21 cm) crown–rump length and 1 pound, 6¼ oz (630 g).
3. Vernix caseosa covers the skin.
4. Head and body (lanugo) hair visible.
5. Skin is wrinkled and red.
6. Brown fat, an important site of heat production, is present in neck and sternal area.
7. Nipples are apparent on the breasts.

Seventh Lunar Month

1. Twenty-three- to twenty-six-week-old fetus.
2. At the end of 26 weeks of growth, the fetus is approximately 10 inches (25 cm) crown–rump length and 2 pounds, 3¼ oz (1,000 g).
3. Fingernails present.
4. Lean body.
5. Eyes partially open; eyelashes present.
6. Bronchioles are present; primitive alveoli are forming.
7. Skin begins to thicken on hands and feet.
8. Startle reflex present; grasp reflex is strong.

Eighth Lunar Month

1. Twenty-seven- to 30-week-old fetus.
2. At the end of 30 weeks of growth, the fetus is approximately 11 inches (28 cm) crown–rump length and

3 pounds, 12 oz (1,700 g).

3. Eyes open.
4. Ample hair on head; lanugo begins to fade.
5. Skin slightly wrinkled.
6. Toenails present.
7. Testes in inguinal canal, begin descent to scrotal sac.
8. Surfactant coats much of the alveolar epithelium.

Ninth Lunar Month

1. Thirty-one- to 34-week-old fetus.
2. At the end of 34 weeks of growth, the fetus is approximately 12½ inches (32 cm) crown–rump length and 5 pounds, 8 oz (2,500 g).
3. Fingernails reach fingertips.
4. Skin pink and smooth.
5. Testes in scrotal sac.

Tenth Lunar Month

1. Thirty-five- to 38-week-old fetus; end of this month is also 40 weeks from onset of last menses.
2. At the end of 38 weeks of growth, fetus is approximately 14½ inches (37 cm) crown–rump length and 7 pounds, 8 oz (3,400 g).
3. Ample subcutaneous fat.
4. Lanugo almost absent.
5. Toenails reach toe tips.
6. Testes in scrotum.
7. Vernix caseosa mainly on the back.
8. Breasts are firm.

Fetal Circulation

Assessment of Fetal Maturity and Well-Being

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2015). Diagnostic tests for birth defects FAQ's 164. Washington, DC: Author.American College of Obstetricians and Gynecologists. (2014, July) (1999/Reaffirmed 2016). Antepartum fetal surveillance (Practice Bulletin #145). Washington, DC: Author.Association of Women's Health, Obstetric, Neonatal Nurses. (2015). *Fetal heart monitoring: Principles and practices* (5th ed.). Dubuque, IA: Kendall Hunt Publishing Company.

Maternal History and Examination

1. Comprehensive family medical history, personal medical history, and reproductive health history including previous pregnancy experience/outcomes and STIs.
2. Comprehensive physical examination, history of current pregnancy, and identified risk factors.
3. Routine prenatal labs.
4. Fetal assessment after first trimester and individualized fetal surveillance, as indicated.

Fetal Heart Tones

Description

Fetal heart tones (FHTs) are representative of the fetal heart rate (FHR) and are an indicator of oxygen perfusion to the fetal brain, heart, and adrenals. The evaluation of FHTs is indicated in routine assessment of fetal well-being, in determining gestational age, and in cases of threatened abortion or other abnormalities. FHTs can be heard using techniques that amplify sound.

1. Doppler at approximately 10 to 12 weeks fetal gestation.
2. Fetoscope (fetal stethoscope) at approximately 18 to 20 weeks fetal gestation.
3. Electronic fetal monitoring testing is usually done when the fetus is considered viable, around 24 weeks gestation.
4. Rate—between 110 and 160 bpm.
5. In latter months of pregnancy, fetal heart sounds found:
    a. Near the woman's midline in fetal occipitoanterior positions.
    b. Lateral to midline in fetal occipitotransverse positions.
    c. In the woman's flank in fetal occipitoposterior positions.
    d. Below the woman's umbilicus in cephalic presentations.
    e. At or above the woman's umbilicus in breech presentations.
    f. Position may affect the ability to clearly hear the heart tones.
6. Failure to hear FHTs at the expected time may be due to maternal obesity, polyhydramnios, error in date calculation, or fetal death.

Nursing and Patient Care Considerations

1. Explain equipment, purpose, and procedure to patient.
2. Assist patient to a sidelying or semi-Fowler position. Perform Leopold maneuvers.
3. Document findings on patient's chart and monitor strip along with date, time, activity level, medications, and other information per your health care facility's guidelines.
4. Discontinue electronic fetal monitoring, as indicated, according to facility guidelines.
5. Document and communicate appropriate information in the patient record to the patient and provider.
6. Monitor tracings become part of the neonate's and mother's chart and are legal documents that may be used in litigation.

Assessment of Fetal Movement

Description

Fetal movement or "kick counts" may be evaluated daily by the pregnant woman to provide reassurance of fetal well-being. Several methods are used in practice but study comparisons do not provide sufficient evidence to influence practice related to the ideal number of kicks or the ideal interval for movement counting. Methods are facility specific, and policy should be standardized for consistently. Testing can be as short as 5 minutes or as long as 2 hours.

Nursing and Patient Care Considerations

1. Instruct patient to lie on her side in a quiet place with no distractions. Have her place her hands on the largest part of her abdomen and concentrate on fetal movement.
2. Instruct patient to use a clock and record the movements felt. Once the tenth movement is felt, the testing is stopped. If fewer than 10 movements are felt in 2 hours or if the time it takes to get the 10 movements takes longer to achieve than earlier testing, she should contact her primary care provider.
3. Instruct patient that fetal movements are best assessed after meals, after or with light abdominal massage, or after short walks, and if she has not smoked for the last 2 hours.
4. Instruct patient that the fetus can sleep for up to 40 minutes.
5. Request patient to explain the procedure so her understanding is ensured.

Alpha-Fetoprotein

Description

Alpha-fetoprotein is produced by the fetus' liver and present in amniotic fluid. Small amounts cross the placenta into the maternal circulation.

1. MS-AFP levels are analyzed at 15 to 20 weeks gestation to identify neural tube defects and Down syndrome (trisomy 21) and may be tested alone or with a triple or quad screening. This testing is not diagnostic, and further diagnostic testing may be indicated for conclusive results.
    a. Elevated MS-AFP levels may be associated with birth defects and chromosomal abnormalities, such as open neural tube defects, open abdominal defects, and congenital nephrosis. Also associated with

Rh isoimmunization, multiple gestation, maternal diabetes mellitus, and fetoplacental dysfunction.

b. Decreased levels have been associated with Down syndrome and other chromosome anomalies (eg, gestational trophoblastic disease) but are not diagnostic.

c. Follow-up for abnormal high or low levels includes ultrasound examination and amniocentesis.

2. Triple marker screening (TMS) can also be used for the evaluation of trisomy 18 and 21 and neural tube defects. This test is costly when compared to MS-AFP; thus, it is limited in its use. The TMS evaluates unconjugated estriol and hCG: Down syndrome shows increased hCG and decreased estriol levels; trisomy 18 shows decreased hCG and decreased estriol levels.

3. The quadruple screen, which includes a measurement of the substance dimeric inhibin A, provides a more sensitive and accurate detection of trisomy 21.

Nursing and Patient Care Considerations

1. Obtain health and pregnancy history, including the date of patient's last menses and risk factors. Accurate dating of the pregnancy is crucial to interpret the results of the serum levels.
2. Explain the purpose and procedure for the test.
3. Explain that the testing is for screening purposes only and not diagnostic. If an abnormal result is detected, further testing may be recommended.
4. Discuss patient's concerns.

Ultrasound and Doppler Studies

Description

Ultrasonography is a noninvasive, safe technique that uses reflected sound waves as they travel in tissue to produce a picture. In the abdominal approach, a clear gel is applied to the woman's abdomen or to the transducer, and the transducer is moved along the abdomen by the examiner. Images are produced onto a screen. During the early weeks of gestation, when the uterus remains a pelvic organ, a full bladder may be necessary to facilitate visualization. In the transvaginal approach, a lubricated transducer probe is inserted (either by the woman or by the examiner) into the vagina. No full bladder is necessary, and this technique is especially useful during the early weeks of pregnancy or when cervical evaluation is important (ie, for assessment of preterm labor). Three-dimensional ultrasonography is a newer technology that is believed to offer improved assessment of fetal growth and weight parameters.

1. Indications for a first trimester (prior to 13 6/7 weeks gestation) ultrasonography:
   a. Early confirmation of intrauterine pregnancy.
   b. To confirm cardiac activity.
   c. Estimated date of confinement.
   d. Estimate gestational age.
   e. To evaluate for an ectopic pregnancy or gestational trophoblastic disease.
   f. Detection of an intrauterine device.
   g. Evaluation of placental location.

h. Diagnosis of a multiple gestation.
i. Guidance for chorionic villous sampling (CVS) between 10 and 13 weeks requiring a small sample of placental tissue for prenatal diagnosis of certain chromosomal abnormalities when early diagnosis is preferred.
j. Nuchal translucency at 11 to 14 weeks to screen for fetal aneuploidy.

2. Indications for second- and third-trimester ultrasonography that may be standard, limited, or specialized as necessary:
   a. Fetal survey for anatomy, growth, weight, gestational age, and anomalies.
   b. Evaluation of the placenta position and attachment.
   c. Evaluation of fetal presentation and position.
   d. Evaluation of fetal viability and cardiac activity.
   e. Biophysical profile (BPP).
   f. Evaluation of amniotic fluid volume.
   g. Guidance for amniocentesis or fetal blood sampling.
3. Doppler flow study, also known as Doppler velocimetry, is a noninvasive way to analyze uteroplacental blood flow within the umbilical, uterine, and cerebral arteries. The use of this technology primarily focuses on placental analysis to identify patients at risk for increased perinatal mortality. Systolic and diastolic ratios are measured within the arteries. If the ratios rise above normal, it means that blood flow to the placenta is decreased.
4. Three- and four-dimensional (3-D and 4-D) ultrasonography evaluates major and superficial vessels of the placenta, including the cord, fetal physiologic development, and fetal behavior. There are a number of advantages to 3-D and 4-D ultrasonography over Doppler velocimetry, such as decreased time of fetal exposure to ultrasound beam (2 to 5 minutes for 3-D vs. 15 to 30 minutes for velocimetry), off-line image processing, and identification of placental anastomoses, to mention a few.

Nursing and Patient Care Considerations

1. Explain the purpose and procedure to patient, emphasizing the need to remain still.
2. Inform patient of the need for a full bladder, if indicated, before the procedure.
3. When indicated, instruct patient to drink three to four glasses of water if the bladder is not full.
4. Instruct patient not to void until the procedure is over.
5. Remove the lubricant from patient's abdomen after the procedure or provide perineal cleaning products, as needed.

Note: Nurse can perform ultrasound if credentialed in limited ultrasound.

Amniocentesis

Description

Amniocentesis is a diagnostic procedure requiring informed consent, in which amniotic fluid is removed from

the uterine cavity by insertion of a needle through the abdominal and uterine walls and into the amniotic sac. The procedure, when performed between 15 and 20 weeks gestation, is used genetic evaluation. In later pregnancy, amniocentesis is performed for the assessment of fetal lung maturity and to treat polyhydramnios. Risks are associated with the procedure such as miscarriage (1:300 to 500 procedures), chorioamnionitis, and preterm premature rupture of membranes. In determination of genetic or metabolic diseases, the procedure is performed between 16 and 18 weeks gestation. It is useful for women age 35 or older, for those with a family history of metabolic disease, a previous child with a chromosomal abnormality, a family history of chromosomal abnormality, a patient or husband with a chromosomal abnormality, or a possible female carrier of an X-linked disease.

1. In determination of lung maturity, the lecithin/sphingomyelin (L/S) ratio of the amniotic fluid is analyzed.
    a. When the L/S ratio is 2:1 or greater, the fetal lung is considered mature and the incidence of respiratory distress syndrome in the neonate is low.
    b. Results may be less reliable with maternal diabetes or if the fluid is contaminated with blood or meconium.
2. The presence of phosphatidylglycerol (PG), one of the last lung surfactants to develop, is the most reliable indicator of fetal lung maturity. PG is not present until 36 weeks gestation and is measured as being present or absent. Unlike the L/S ratio, PG is not affected by hypoglycemia, hypoxia, or hypothermia.
3. In the treatment of polyhydramnios also called hydramnios (2,000 mL amniotic fluid or greater than 25 cm amniotic fluid index [AFI]), amniocentesis may be performed to drain excess fluid and relieve pressure. Polyhydramnios can be associated with specific fetal abnormalities, such as trisomy 18, anencephaly, spina bifida, and esophageal atresia or tracheoesophageal fistula.

Nursing and Patient Care Considerations

1. Reduce anxiety related to the procedure.
    a. Reduce the parents' anxiety by determining their understanding of the procedure and the meaning it holds for them.
    b. Reexplain the procedure before it begins and answer any questions they have. Ensure informed consent is signed.
    c. Provide explanations during the procedure, correct misinformation they may have, and make sure they know when the results will be available and how they may obtain the results as soon as possible.
2. Reduce pain and discomfort related to the procedure.
    a. Reduce discomfort by having patient lie comfortably on her back with her hands and a pillow under her head. Relaxation and controlled breathing may help.
    b. Ensure adequate time between infiltration of local anesthetic and introduction of needle into the amniotic sac.
    c. IV access in accordance with facility policy. Tocolytics such as terbutaline may be administered per

facility policy.

3. Reduce potential for traumatic injury to fetus, placenta, or maternal structures.
    a. Have patient empty her bladder if the fetus is more than 20 weeks gestation to avoid injury to patient's bladder. If the fetus is less than 20 weeks gestation, patient's full bladder will hold the uterus steady and out of the pelvis. The placenta is localized with the use of ultrasound.
    b. Obtain maternal vital signs and a 20-minute FHR tracing to serve as a baseline to evaluate possible complications.
    c. Monitor patient during and after the procedure for signs of premature labor or bleeding.
    d. Tell patient to report signs of bleeding, unusual fetal activity or abdominal pain, cramping, or fever while at home after the procedure.
    e. If woman in Rh negative, may need to administer RhoGAM.

Chorionic Villus Sampling

Description

Chorionic villus sampling (CVS) involves obtaining samples of chorionic villus (placental tissue [fetal origin]) to test for chromosomal (via deoxyribonucleic acid [DNA]) and enzymatic disorders of the fetus. CVS is ideally performed between 10 and 14 weeks gestation.

1. Using ultrasound, a catheter is passed vaginally into the uterus, where a specimen of chorionic villus tissue is removed.
2. Results from CVS are available in 4 days.
3. Complications include rupture of membranes, intrauterine infection, spontaneous abortion, hematoma, fetal trauma, or maternal tissue contamination.
4. Incidence of fetal loss is about 2% to 5%.

Nursing and Patient Care Considerations

1. Obtain maternal vital signs.
2. Instruct patient to void.
3. Offer reassurance and compassionate presence during the procedure.
4. If woman in Rh negative, may need to administer RhoGAM.
5. Inform patient that a small amount of spotting is normal, but heavy bleeding or passing clots or tissue should be reported to provider immediately.
6. Instruct patient to rest at home for a few hours after the procedure.

Percutaneous Umbilical Blood Sampling

Description

Percutaneous umbilical blood sampling (PUBS), or *cordocentesis*, involves a puncture of the umbilical cord (vein) for aspiration of fetal blood under ultrasound guidance.

1. It is used in the diagnosis of fetal blood disorders, infections, Rh isoimmunization, metabolic disorders, and karyotyping.
2. Transfusion to the fetus may be conducted with this procedure.
3. Using ultrasound picture, the provider inserts a needle (guided by ultrasound) into one of the umbilical vessels. A small amount of blood is withdrawn.
4. Can also be used for fetal therapies, such as RBC and platelet transfusion.

Nursing and Patient Care Considerations

1. Explain the procedure to patient.
2. Provide support to patient during the procedure.
3. Monitor patient after the procedure for uterine contractions and the FHR for distress.
4. If woman in Rh negative, may need to administer RhoGAM.

Biochemical Markers

Description

1. *Fetal fibronectin (fFN)* is a protein that is secreted by the trophoblast of the implanted egg. The exact function is unknown; however, this protein is thought to play a key role in placental–uterine attachment. It is considered to be a better marker of women who will *not* go into PTL than those who *will* go into PTL.
   a. Normally present in cervical or vaginal fluid before 20 weeks gestation.
   b. After 20 weeks' gestation, the presence of fFN can indicate a detachment of the fetal membranes and should be evaluated as an early marker for preterm birth.
   c. Specimen is collected no earlier than 24 weeks and no later than 34 weeks and 6 days.
   d. A positive finding for fetal fibronectin alone is not predictive of PTL.

Nursing and Patient Care Considerations

1. Explain the procedure to patient.
2. Collect specimen with a Dacron swab placed in the posterior fornix of the vagina and rotated for 10 seconds. Sexual activity within 24 hours of sample collection, recent cervical examination, and vaginal bleeding may result in a false-positive test.
3. Provide support to patient during the procedure.

EVIDENCE BASE DeFranco, E. A., Lewis, D. F., & Odibo, A. O. (2013). Improving the screening accuracy for preterm labor: Is the combination of fetal fibronectin and cervical length in symptomatic patients a useful predictor of preterm birth? A systematic review. *American Journal of Obstetrics and Gynecology, 208*(3), 233.e1–233.e6.

Nonstress Test

Description

The *nonstress test (NST)* is used to evaluate FHR accelerations that normally occur in response to fetal activity as a measure of uteroplacental function. Accelerations are indicative of an intact central and autonomic nervous system and are a sign of fetal well-being. Absence of FHR accelerations in response to fetal movements may be associated with hypoxia, acidosis, drugs (analgesics, barbiturates), fetal sleep pattern, and some fetal anomalies.

1. Maternal indications include postdates, Rh sensitization, maternal age 35 or older, chronic renal disease, hypertension, collagen disease, sickle cell disease, diabetes, premature rupture of membranes, history of stillbirth, trauma, and vaginal bleeding in the second and third trimesters.
2. There are no contraindications or known adverse effects associated with the NST.
3. Fetal indications include decreased fetal movement, intrauterine growth restriction, fetal evaluation after an amniocentesis, external cephalic version, oligohydramnios, or polyhydramnios.
    a. Criteria for a reactive NST for a fetus greater than 32 weeks gestation include two accelerations within 20 minutes, each lasting at least 15 seconds with an FHR increased by 15 bpm above baseline in response to fetal activity. The quality of the tracing is an important factor in the test interpretation.
    b. Criteria for a reactive NST in a preterm fetus (less than 32 completed weeks gestation) include two accelerations within 20 minutes, each lasting at least 10 seconds with an FHR increased by 10 bpm above baseline in response to fetal activity.
    c. Testing time for the term NST can be as long as 40 minutes. Testing time for the preterm NST can be as long as 60 to 90 minutes.
    d. In a nonreactive NST, the above criteria are not met.
4. Significance/management
    a. Reactive NST—is reassuring and suggests a less than 1% chance of fetal death within 1 week of the NST. However, nonpreventable fetal death for abruptio placentae, sepsis, and cord accidents are excluded.
    b. Nonreactive NST—suggests a fetus that may be compromised and there needs to be further follow-up with a BPP, modified BPP, contraction stress test (CST), or oxytocin challenge test (OCT).

Nursing and Patient Care Considerations

1. Explain the procedure and equipment to the patient. Make sure the patient has had adequate nutrition and fluid intake and, if a smoker, has not been smoking within the past 2 hours.
2. Instruct the patient to void prior to NST for comfort.
3. Assist patient to a semi-Fowler position in bed. Perform Leopold maneuvers, and apply the external fetal and uterine monitors.
4. Event markers do not need to be used unless the fetal movement is not observed on the fetal monitor. If fetal movement not observed, instruct patient to make a mark on the monitor strip each time fetal

movement is felt. The nurse will do this if patient cannot.

5. Evaluate the response of the FHR immediately after fetal activity.
6. Monitor patient's BP and uterine activity during the procedure.

Fetal Acoustic Stimulation Test and Vibroacoustic Stimulation Test

Description

Acoustic (sound) and vibroacoustic stimulation (VAS) are sound plus vibration involving the use of handheld battery-operated devices (usually a laryngeal stimulator) placed over the mother's abdomen near the fetal head. This technique produces a low-frequency vibration and a buzzing tone intended to induce fetal movement along with associated FHR accelerations. The sound stimulus should last for up to 3 seconds. The *fetal acoustic stimulation test (FAST)* and *vibroacoustic stimulation test (VST)* are used as an adjunct following a nonreactive NST; these tests may also be used with fetuses that exhibit a nonreassuring FHR cardiotocographic (CTG) tracing during labor. If no FHR accelerations occur in response to the stimulus, it is repeated at 1-minute intervals up to three times (total of 6 seconds). If the FHR tracing remains nonreactive, further evaluation with BPP or CST is indicated. In the light of advanced ultrasound technology, this test is being used less frequently. However, there are still facilities that do not have the ultrasound capabilities; therefore, this testing is appropriate.

1. It is not known whether the fetus responds more to the sound or to the vibration.
2. Both methods of testing are noninvasive, easy to perform, and yield rapid results.
3. No adverse neurologic or auditory effects noted in the fetus after testing.

Nursing and Patient Care Considerations

1. Explain procedure, equipment, and purpose to patient.
2. Instruct the patient to void prior to NST for comfort.
3. Assist patient to a semi-Fowler position in bed.
4. Apply external fetal monitors to patient.
5. Demonstrate how the stimulus may feel on patient's forearm or leg.
6. Observe for reactivity.

Contraction Stress Test (Oxytocin Contraction Test)

Description

Contraction stress test (CST) or OCT is used to evaluate the ability of the fetus to withstand the stress of uterine contractions as would occur during labor.

1. The test is generally used when a woman has a nonreactive NST or FAST/VST, although in many areas, the CST has been replaced by the BPP.
2. The test is contraindicated in women with third-trimester bleeding, multiple gestation, incompetent cervix, placenta previa, previous classic uterine incision, hydramnios, history of PTL, or premature rupture of membranes.

3. Contractions may occur spontaneously (unusual), or they may be induced endogenously producing oxytocin with nipple or breast stimulation.
4. The OCT utilizes exogenous oxytocin, which is administered by titrated IV infusion with continuous fetal monitoring.

Nursing and Patient Care Considerations

1. Obtain maternal vital signs, especially BP.
2. Instruct patient to void for comfort.
3. Assist patient to a semi-Fowler or sidelying position in bed.
4. Obtain a 20-minute strip of the FHR and uterine activity for baseline data.
5. For CST:
    a. Apply warm packs to the breasts for 10 minutes before the CST.
    b. Instruct patient on nipple stimulation. Instruct patient to brush or roll the nipple, using the palmar surface of the index finger and thumb. The patient can do this through her clothes or skin-to-skin. If using skin-to-skin, provide the patient with some lubricant to use on her fingers to ease stimulation. Stimulation occurs in 4 cycles of 2 minutes *on* and 2 to 5 minutes off *(for ease of memory: 1 cycle = 2 minutes on and 2 minutes off)*. The nipple is stimulated until contractions begin *or* 2 minutes have passed.
    c. If contractions occur during stimulation, instruct the patient to stop the stimulation; she can begin the stimulation again when the contraction is over. If no contractions after four cycles, two different methods can be used:
        i. Let the patient rest for 5 to 10 minutes, then begin bilateral continuous stimulation for 5 to 10 minutes, stopping when contractions begin (have the patient resume stimulation when contraction ends).
        ii. Let the patient rest for 5 to 10 minutes, then begin stimulation again, alternating nipples, stopping when contractions begin (have the patient resume stimulation when contraction ends).
    d. Stop the stimulation if:
        i. Three or more contractions occur within 10 minutes that last more than or equal to 40 seconds.
        ii. Hyperstimulation or tachysystole occurs.
        iii. Unsuccessful nipple stimulation (two rounds of four cycles without contractions). Notify health care provider and prepare for OCT, BPP, or modified BPP.
6. For OCT: Follow steps 1 through 4 above. In addition:
    a. Administer low-dose oxytocin infusion using a pump, as indicated, until three contractions occur within 10 minutes and last ≥40 seconds. Maintain mainline IV fluids in accordance with facility policy.
    b. Discontinue the infusion when:
        i. Criteria are met.
        ii. Maximum dose of 16 milliunits per minute has been achieved.

iii. Hyperstimulation or tachysystole occurs. Prolonged deceleration, bradycardia, or late decelerations are observed.

Interpretation of CST/OCT

1. Negative (normal/reassuring)—absence of late or variable decelerations.
2. Positive (abnormal/nonreassuring)—late decelerations with more than 50% of uterine contractions even if frequency is less than three contractions in 10 minutes; usually associated with absent or minimal variability.
3. Equivocal—intermittent late decelerations (less than 50% of uterine contractions) or significant variables.
4. Unsatisfactory—quality of tracing inadequate to assess or less than three contractions in 10 minutes or contractions less than 40 seconds in duration.
5. Equivocal and unsatisfactory results can be repeated in 24 hours or sooner unless indication for delivery is present.
6. Regardless of the result, if variable decelerations are present, further testing should be done to evaluate for oligohydramnios.

Biophysical Profile

Description

The *biophysical profile (BPP)* uses ultrasonography and NST to assess five biophysical variables in determining fetal well-being. A BPP is performed during a 30-minute time frame by someone credentialed in ultrasonography.

1. For each variable, if the criteria are met, a score of 2 is given. For an abnormal observation, a score of 0 is given.
2. A score of 8 to 10 is reassuring, 6 is equivocal and requires further evaluation, and 4 or less is nonreassuring and requires further evaluation and delivery may be considered.
   a. NST—assessing for FHR acceleration (fetal reactivity) in relation to fetal movements.
   b. AFI volume—assessing for one or more pockets of amniotic fluid measuring at least (2 cm) or more in two perpendicular planes.
   c. Fetal breathing movements—one or more episodes lasting at least 30 seconds within 30 minutes.
   d. Gross fetal body movements—three or more body or limb movements, in 30 minutes.
   e. Fetal muscle tone—one or more episodes of active extension with return to flexion of spine, hand, or limbs within 30 minutes.

Nursing and Patient Care Considerations

1. Explain the purpose and procedure to the patient; provide emotional support.
2. Instruct patient to empty her bladder for comfort.
3. Assist patient onto the examination table and help her to assume a position of comfort.
4. Remove the lubricant from patient's abdomen after the procedure.

5. Assist patient in rising from the examination table.

Modified BPP

Description

The modified BPP is more common today than the BPP. It consists of an NST and an assessment of AFI. The modified BPP performed twice per week provides the same predictive results as the weekly CST.

1. Normal interpretation is a reactive NST with an AFI greater than 5 cm. A normal AFI is 9 to 25 cm with a borderline "normal" being 5 to 8 cm.
2. An abnormal AFI of less than 5 cm of amniotic fluid (oligohydramnios) requires a full ultrasound evaluation, and the fetus is evaluated for functioning renal tissue.

Nursing and Patient Care Considerations

1. Explain NST and AFI check in accordance with previously stated guidelines, as noted in this chapter.
2. Document findings in patient's prenatal record.

Nursing Management During Labor and Delivery

The Labor Process

General Considerations

Nursing Assessment and Interventions

Initiation of Labor

Fetal Heart Assessment

First Stage of Labor: Latent Phase (0 to 3 cm)

First Stage of Labor: Active and Transition Phase (4 to 10 cm)

Second Stage of Labor

Third Stage of Labor: Delivery of the Placenta

Fourth Stage of Labor: Immediate Postpartum

Precipitous Delivery or Delivery in the Absence of Health Care Provider (Nurse-Assisted)

Immediate Care of the Neonate

Special Considerations

Neonatal Resuscitation

THE LABOR PROCESS

The phases of pregnancy, labor, and birth are normal physiologic processes. A pregnant woman typically approaches the birth process with possible concerns of personal well-being, that of her unborn child, and fear of labor pain. Addressing these concerns, minimizing her discomfort, and optimizing patient safety should be of paramount importance to all participants involved in the care of the mother and her fetus during the intrapartum period.

EVIDENCE BASE Lowdermilk, D., Perry, S., Cashion, C., & Alden, K. R. (2016). *Maternity and women's health care* (11th ed.). St. Louis, MO: Elsevier.

Mattson, S., & Smith, J. E. (2016). *Core curriculum for maternal–newborn nursing* (5th ed.). St. Louis, MO: Elsevier.

Prepared Childbirth

Historically, the term *natural childbirth* has evolved to mean (1) delivery outside in nature, (2) home birth, (3) nonhospital birth (birthing center), (4) facility birth—no medical intervention (eg, no intravenous [IV] medications)—and, most recently, (5) facility birth without analgesia or anesthesia. Preparation through education and training prior to labor gives the pregnant woman a method of coping with the discomforts of labor and delivery. This method is known as *prepared childbirth* and incorporates analgesia and anesthesia into the process. The latter method dominates current culture in the United States. Variances in prepared childbirth are outlined.

Psychoprophylactic or Lamaze Method

1. Psychoprophylactic childbirth has a rationale based on Pavlov concept of pain perception and his theory of conditioned reflexes (the substitution of favorable conditioned reflexes for unfavorable ones). The Lamaze method is an example of this technique.
2. The woman learns to replace responses of restlessness, fear, and loss of control with more controlled measures, which can excite the cerebral cortex efficiently to inhibit other stimuli such as pain in labor.
3. The mother learns exercises that strengthen the abdominal muscles and relax the perineum.
4. The mother/partner/support person learns various breathing techniques to help maintain focus and a sense of control during the labor process.

The mother learns to respond with respiratory measures and disassociation or relaxation of the uninvolved muscles while controlling her perception of the stimuli associated with labor.

The Bradley Method of Delivery

1. Commonly referred to as "partner-coached childbirth." A coach may be *any* significant other designated by the mother.
2. Involves the concepts of leading, guiding, supporting, caring, and fostering specific skills and confidence.
3. Coaches attend classes and learn to help the woman prior to labor.
4. The coach serves as a conditioned stimulus using the sound of his or her voice, use of particular words, and repetition of practice.
5. Relaxation is the core component and medications are not encouraged for pain relief. Increased tolerance

to pain is accomplished by decreased mental anxiety and fear, which ultimately decreases the awareness of the pain stimulus. This occurs through cognitive and physical rehearsal.

The Dick-Read Method

1. Dr. Grantly Dick-Read wrote the landmark book, Childbirth without Fear in 1944.
2. Fear is the primary factor that creates tension and therefore increases pain perception.
3. Classes include a detailed explanation of the normal labor process to enhance understanding of the normal physiological changes associated with labor.
4. Women learn strategies such as abdominal breathing to break the fear–tension–pain cycle.

Planned Home Birth

1. Motivations for home delivery:
   a. Increases patient choices and flexibility during the birth process while decreasing patient separation and fear of medical intervention.
   b. Desire to avoid medical intervention such as anesthesia and operative procedures.
2. Contraindications:
   a. High-risk pregnancy such as placental abnormalities, multiple gestation, preeclampsia, and gestational diabetes.
   b. History of premature or postdate delivery in previous or current pregnancy or previous cesarean delivery.
   c. Diagnosed fetal abnormalities.
3. Alternatives to home delivery:
   a. Family-centered hospital setting.
   b. Birthing centers with adequate facilities for emergency care for low-risk women.

NURSING ALERT Women interested in a planned home birth should weigh the risks and benefits for this method of delivery. Current evidence supports that the risk of perinatal death in home births is double that of facility births (however, still low at 1 to 2 per 1,000 births). Additionally, the risk of neonatal seizures or neurologic dysfunction is three times more likely to occur (0.4 to 0.6 per 1,000 births). Nurses working with the maternal–child population should provide women with educational resources that foster informed decision-making.

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2017). *Planned home birth* (Committee Opinion #697). Washington, DC: Author.

Initiation of Labor

EVIDENCE BASE Cunningham, F. G., Leveno, K., Bloom, S., et al. (2014). *Williams obstetrics* (24th ed.). New York: McGraw-Hill.

Parturition is a multifactorial physiologic process and the exact mechanism initiating labor is unknown. The inhibition of labor during pregnancy is maintained by a constant release of progesterone and other uterotonic inhibitors (eg, PgI_2, relaxin, nitric oxide, and parathyroid hormone). Progesterone is the primary hormone of pregnancy, which prevents uterine contractility during the pregnancy. As the pregnancy approaches term, progesterone levels begin to decrease and estrogen levels increase reciprocally stimulating uterine contractility. Labor onset involves both maternal and fetal influences as outlined:

1. Maternal factors:
2. In preparation for labor, prostaglandin (PG) is released as the uterus stretches to accommodate the fetus.
3. The posterior pituitary releases oxytocin because of pressure on the cervix.
4. Oxytocin and PG jointly aid in the inhibition of calcium binding in muscle cells, thus increasing the calcium levels intracellularly causing uterine contractions.
5. Placental and fetal factors:
    a. Placental maturation triggers the onset of contractions.
    b. The concentration of fetal cortisol increases in response to the increase in maternal oxytocin.

Factors Affecting Labor Process

The five Ps: the success of labor and delivery depends on five factors: *passageway (birth canal)*, *passenger (fetus)*, *powers (contractions)*, *position (maternal)*, and *psychological response*.

EVIDENCE BASE Ricci, S. S. (2017). *Essentials of maternity, newborn and women's health nursing* (4th ed.). Philadelphia, PA: Wolters Kluwer Health/Lippincott Williams & Wilkins.

Passageway: Pelvic Dimensions

1. Pelvic inlet (anteroposterior diameter): The obstetric conjugate anteroposterior measurement is typically more than 10 cm. Over 50% of women have a gynecoid-shaped pelvis to accommodate proper descent.
2. Midpelvis (ischial spines): Intraspinous diameter is typically more than 10 cm; protrusion of the spines into the birthing canal may complicate descent.
3. Pelvic outlet (intertuberous diameter + suprapubic arch): Dimensions are estimated as the anteroposterior diameter from the coccyx to the symphysis pubis. This is typically 13 cm in length, but again one must

subtract 1.5 to 2 cm from the calculation because of the thickness of the symphysis. A prominent coccyx may impede descent.

Passenger: Fetal Dimensions

1. Size—assessed via palpation using Leopold maneuvers or ultrasound. Excessive size may lead to inadequate or asynclitic descent, labor dystocia, shoulder dystocia, or postpartum hemorrhage.
2. Attitude—typically, the fetal head and extremities are flexed while the back is rounded. Flexion of the head allows for the smallest diameter (occiput) to present and pass through the birth canal with ease (see Figure 37-1). Nonflexed presentations may increase risk of asynclitic conditions.
3. Lie—constitutes the comparison of the fetal long axis to the long axis of the mother. Variances include transverse, longitudinal, or oblique; 99% of fetuses present as a longitudinal lie parallel to the mother's spine. This improves ease of access into the birth canal.
4. Presentation—the fetal body part presenting into the birth canal first and is felt on vaginal exam (see Figure 37-2).
    a. Cephalic (head)—occiput, sinciput, brow, face, or chin (mentum).
    b. Breech (feet)—frank, complete, or footling (single or double).
    c. Shoulder (transverse).
    d. Compound—two or more parts presenting at the same time.
5. Position—specific landmark of fetal presenting part (occiput, mentum, sacrum, scapula) in comparison to the anterior, posterior, or transverse portion of the woman's pelvis and the maternal left or right side; designated by a three-letter abbreviation.
    a. The first letter L or R represents the side (right or left) in the maternal pelvis the presenting part is facing.
    b. The second letter represents the landmark that is presenting: O for occiput, M for mentum (chin), S for sacrum, and Sc for scapula or shoulder.
    c. The third letter represents the direction (anterior [A], posterior [P], or transverse [T]) the presenting part is facing in the pelvis.
    d. For example, the fetus with the head presenting and facing toward the maternal right anterior pelvis is right–occiput–anterior (ROA).

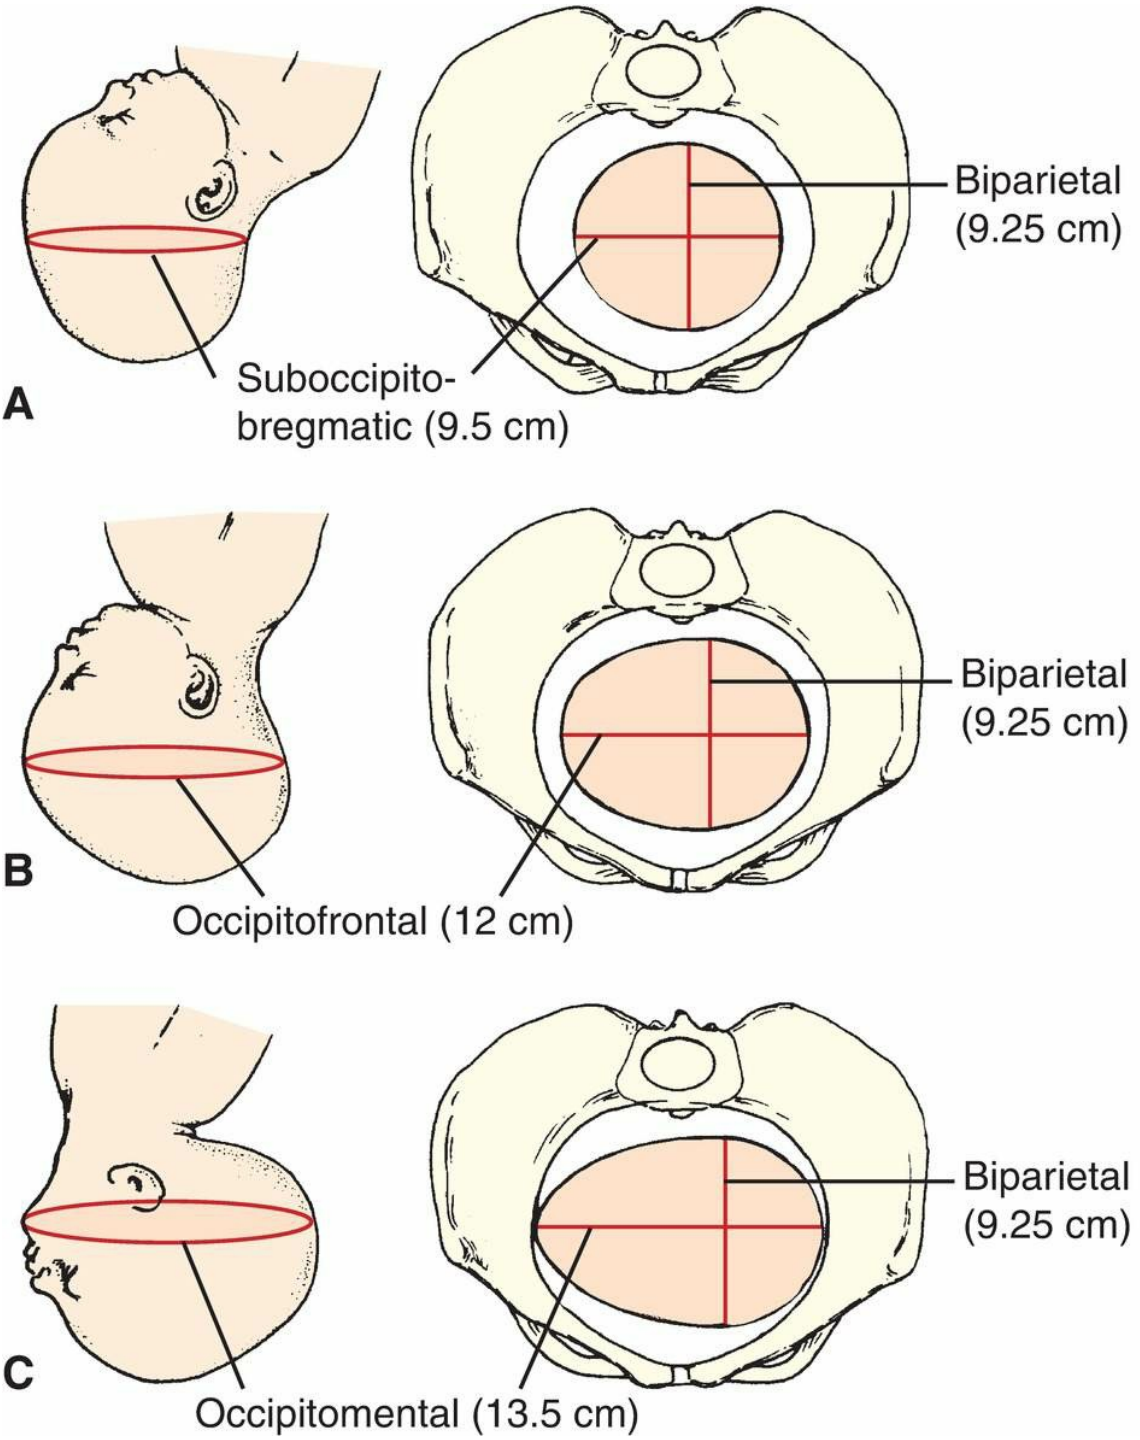

Figure 37-1. **(A)**Complete flexion allows smallest diameter of the head to enter the pelvis. **(B)**Moderate extension causes larger diameter to enter the pelvis. **(C)**Marked extension forces largest diameter against pelvic brim, but the head is too large to enter the pelvis.

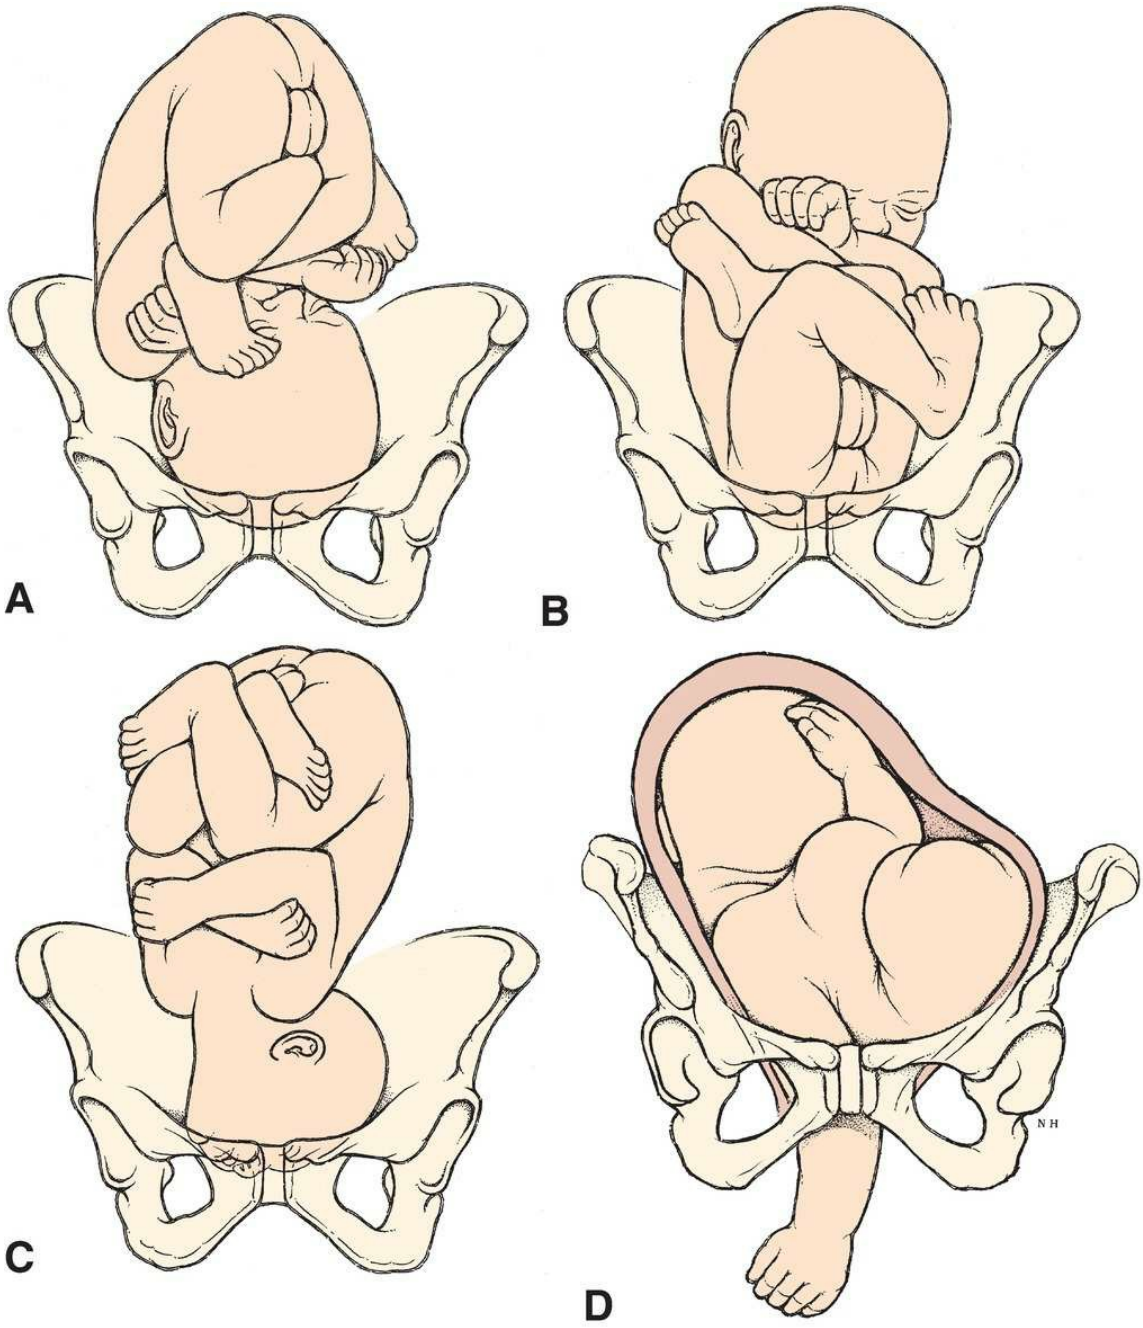

Figure 37-2. Fetal presentations. **(A)** Cephalic; **(B)** breech; **(C)** face; **(D)** transverse.

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2009/Reaffirmed 2016). *Induction of labor* (Practice Bulletin # 107). Washington, DC: Author.

Passenger: Fetal Head (Vertex)

In approximately 95% of all births, the fetal head (vertex) presents first. Sutures and fontanelles provide important landmarks for determining fetal position during a vaginal examination (see Figure 37-3).

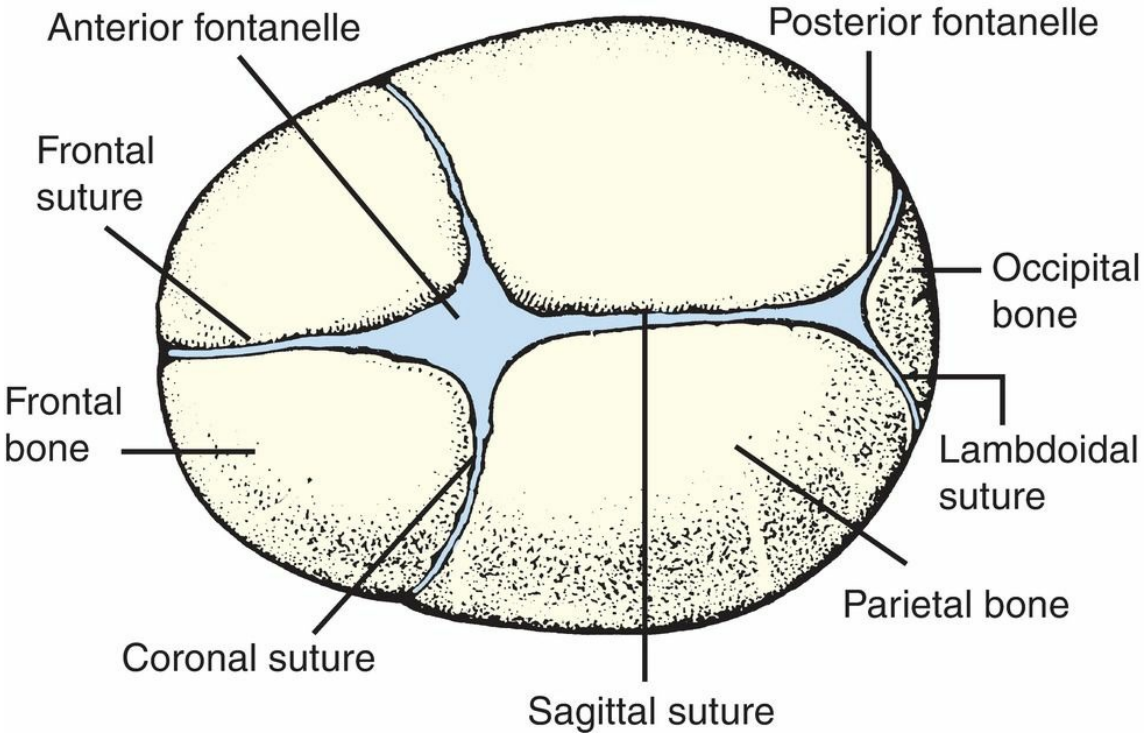

Figure 37-3. Fetal head.

1. Bones of the fetal skull:
   a. One occipital bone posteriorly.
   b. Two parietal bones bilaterally.
   c. Two temporal bones bilaterally.
   d. Two frontal bones anteriorly.
2. Sutures of the fetal skull—membranous spaces between the bones of the fetal skull:
   a. Frontal—between the two frontal bones.
   b. Sagittal—between the two parietal bones.
   c. Coronal—between the frontal and parietal bones.
   d. Lambdoidal—between the back of the parietal bones and the margin of the occipital bone.
3. Fontanelles of the fetal skull—irregular spaces formed where two or more sutures meet. Sutures and fontanelles allow fetal skull bones to overlap to pass through the maternal pelvis.
   a. Anterior—largest fontanelle; junction of the sagittal, frontal, and coronal sutures; closes by age 18 to 24 months; "diamond" shaped.
   b. Posterior—located where the sagittal suture meets the lambdoidal suture (smaller than anterior); closes by 1 year; "triangle" shaped.

Powers: Uterine Contractions

Successful labor depends on regular uterine contractions of adequate intensity that lead to cervical advancement and facilitate fetal descent. The following are characteristics of labor contractions:

a. Uterine contractions typically increase in intensity, frequency, and duration as labor progresses.
b. Uterine contractions may cause vasoconstriction of the umbilical cord leading to potential alterations in the fetal heart rate (eg, variable decelerations).
c. The active upper portion of the uterus (fundus) stimulates activation of contractions during labor (referred to as fundal dominance).
d. At the completion of a contraction, the upper uterine segment retains its shortened, thickened cell size and, with each succeeding contraction, becomes thicker and shorter. As a result, the upper uterine segment never totally relaxes during labor. Cells of the lower uterine segment become thinner and longer with each contraction. This mechanism is greatly responsible for the progress of the fetus through the birth canal.
e. The differentiation point between the upper and lower uterine segment is known as the "physiologic retraction ring."
f. Intrabdominal pressure increases with voluntary maternal pushing efforts during the second stage of labor.

Position (Maternal)

1. The maternal position may influence pelvic size and contour and fetal position and assist fetal rotation.
2. The upright position may facilitate a shortened first and second stage.
3. Allows for the use of gravity for fetal decent.

Psychological Responses

1. A woman's psyche is essential to the labor process in the following ways:
   a. To maintain a sense of well-being and control.
   b. Assists the woman in facing the challenge of labor and sense of accomplishment.

Events Leading to Labor

1. Lightening is the settling of the fetus in the lower uterine segment occurring 2 to 3 weeks before term in the primigravida and typically during labor in the multigravida.
   a. Breathing becomes easier as the fetus falls away from the diaphragm.
   b. Lordosis of the spine is increased as the fetus enters the pelvis and moves more anteriorly. Walking may become more difficult as leg cramping may increase.
   c. Urinary frequency occurs due to pressure on the adjacent bladder.
2. Vaginal secretions may increase due to hormonal changes.
3. Mucus plug may be discharged from the cervix along with a small amount of blood from surrounding capillaries—referred to as "bloody show."
4. The cervix softens and effaces (shortens and thins) and gradually moves from a posterior to an anterior position.
5. Membranes may rupture spontaneously.

6. False labor contractions (Braxton Hicks) may occur (see Table 37-1) in preparation for true labor.
7. Backaches may occur due to fetal size and lightening.
8. Gastrointestinal alterations (eg, diarrhea) and weight loss of 1 to 3 pounds (0.5 to 1.5 kg) may occur with advanced pregnancy.
9. Energy may increase (referred to as "nesting") or decrease in the last few weeks.

Table 37-1 True and False Labor Contractions

TRUE LABOR CONTRACTIONS	FALSE LABOR CONTRACTIONS
Result in progressive cervical dilation and effacement	Do not result in progressive cervical dilation and effacement
Occur at regular intervals	Occur at irregular intervals
Interval between contractions decreases	Interval between contractions remains the same or increases
Frequency, duration, and intensity increase	Intensity decreases or remains the same
Located mainly in the back and abdomen	Located mainly in the lower abdomen and groin
Generally intensified by walking	Generally unaffected by walking
Not easily disrupted by medications	Generally relieved by mild sedation

Stages of Labor

First Stage of Labor (Labor Onset to Full Cervical Dilation and Effacement)

1. Begins with regular and rhythmic true labor contractions and ends with complete effacement (100%) and dilation of the cervix (10 cm).
2. The length of the first stage varies and is almost double in a primiparous patient; this stage of labor consists of three phases:
   a. Latent phase (early):
      i. Dilation from 0 to 3 cm; effacement tends to precede dilation in the primiparous patient.
      ii. At the end of the phase, contractions typically occur regularly every 5 minutes on average and are mild via palpation.
   b. Active phase:
      i. Dilation from 4 to 7 cm; completion of effacement evolves over this period in multiparous patients.
      ii. Contractions are more frequent at every 2 to 5 minutes, lasting 40 to 60 seconds and of moderate to strong intensity by palpation or 60 to 80 mm Hg when an internal uterine pressure catheter (IUPC) is in use. Dilation averages 1.2 cm/hour in the nullipara and 1.5 cm/hour in the multipara.

c. Transition phase: Dilation from 8 to 10 cm with contractions occurring every 2 to 3 minutes, lasting 60 to 90 seconds with strong intensity (nonindentable by palpation or 70 to 90 mm Hg with an IUPC).

Second Stage of Labor (Fetal Expulsion)

1. Begins with complete effacement and dilation ending with delivery of the fetus.
2. The second stage may last from 1 to 4 hours in the nullipara and typically less than 1 hour in the multipara. Variance in time depends on maternal pushing efforts, contraction pattern, anesthesia, and fetal descent and position.

Third Stage of Labor (Placental Expulsion)

1. Begins with delivery of the fetus and ends with delivery of the placenta.
2. The third stage may last from a few minutes to 30 minutes typically. Prolonged periods may be attributable to abnormal placentation (ie, placenta accreta) and may require further evaluation and intervention related to the increased risk of hemorrhage.

Fourth Stage (Immediate Postpartum)

This period lasts from delivery of the placenta until the postpartum condition of the woman has become stabilized. With the increase for improved outcomes related to hemorrhage, the fourth stage of labor lasts at least the first 2 hours and may require further assessment and evaluation based on maternal status.

Seven Cardinal Fetal Movements of Labor

When the biparietal diameter (BPD) of the fetal head has passed through the pelvic inlet, engagement occurs. Once the fetus enters the pelvis, seven "cardinal movements" occur to facilitate passage through the maternal pelvis during labor and birth (see Figure 37-4).

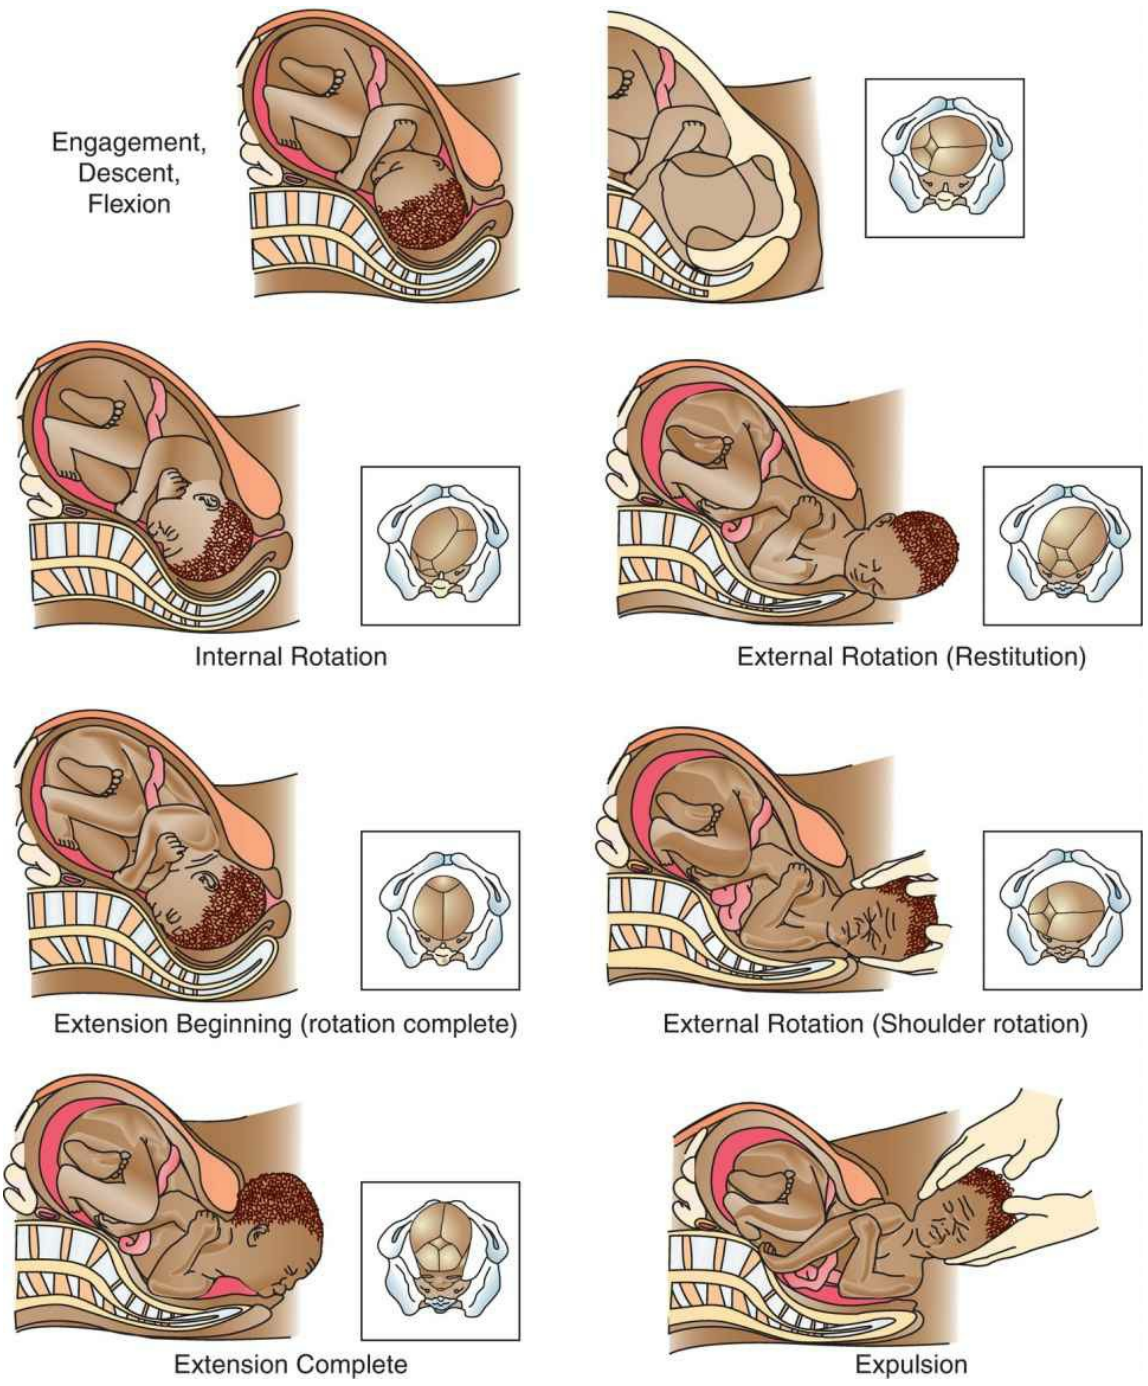

Figure 37-4. Seven fetal cardinal movements of labor (vertex presentation). (Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Descent

1. The downward movement of the fetus through the birth canal is accomplished by the force of uterine contractions and pressure of the amniotic fluid; during second stage of labor, "maternal bearing-down" efforts increase intra-abdominal pressure, thus augmenting effects of uterine contractions.
2. *Station* refers to the relationship of the presenting part to the ischial spines. Subsequently, station has a direct correlation to the degree of descent, as described below (see Figure 37-5):

a. Floating—fetal presenting part is not engaged in pelvic inlet; may be ballotable via cervical exam.

b. Engagement—fetal presenting part enters the pelvis as the BPD passes through the inlet.

c. The pelvis is divided into sections measured in centimeters; a 5-cm scale is used (see Figure 37-6).

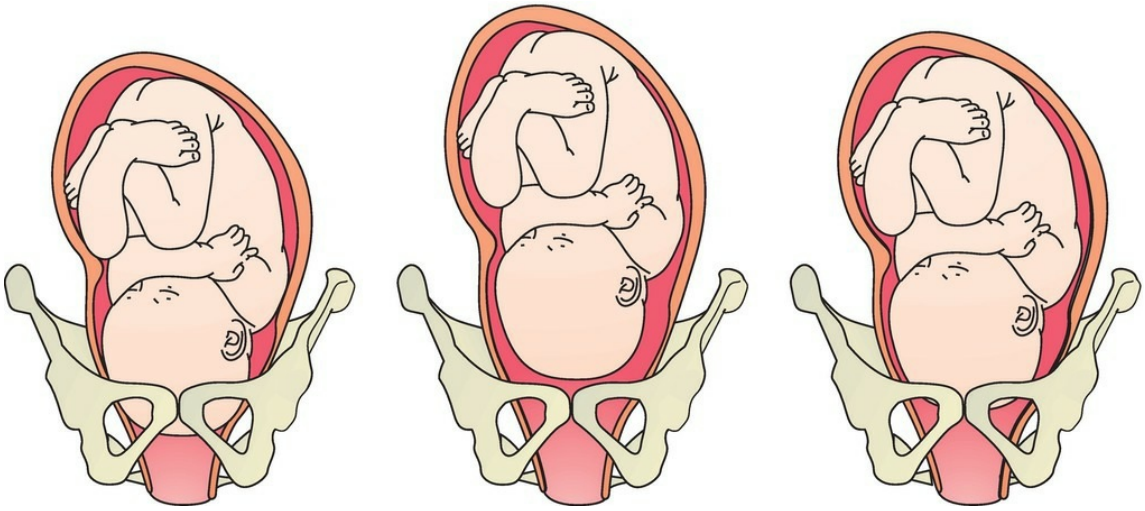

Figure 37-5. Engagement, floating, and dipping.

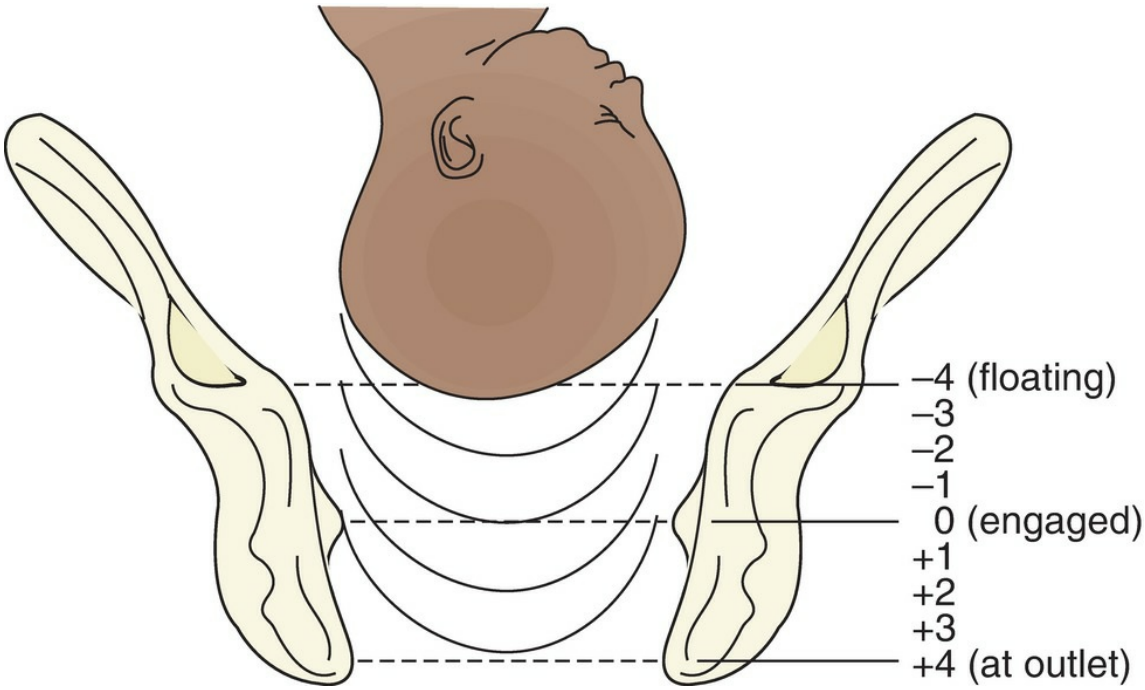

Figure 37-6. Stations of presenting part. The location of the presenting part in relation to the level of the ischial spines is designated station and indicates the degree of advancement of the presenting part through the pelvis. Stations are expressed in centimeters above (minus) or below (plus) the level of the ischial spines (zero). (Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Flexion

Resistance to descent causes the fetal head to flex down, leading to convergence onto the chest.

1. Flexion results in the smallest head diameter, the suboccipitobregmatic, to present through the canal.
2. This position relocates the posterior fontanelle to the center of the cervix, easily palpable on vaginal examination.
3. Flexion begins at the pelvic inlet and continues until the fetal head (or presenting part) reaches the pelvic floor.

Internal Rotation

To accommodate the birth canal, the fetal occiput rotates 45 or 90 degrees from its original position toward the symphysis.

1. The rotation is usually anteriorly, but if the pelvis cannot accommodate the occiput anteriorly because of a narrow forepelvis, it will rotate posteriorly, resulting in an occipitoposterior (OP) position of the fetus.
2. This movement results from the shape of the fetal head and maternal pelvis, as well as the contour of the perineal muscles.
3. The ischial spines project into the midpelvis, causing the fetal head to rotate anteriorly to accommodate the available space.

Extension

1. As the fetal head meets the pelvic floor, it meets resistance from the perineal muscles and is forced to extend up and outward.
2. The fetal head becomes visible at the vulvovaginal ring; its largest diameter is encircled (crowning) and later emerges from the vagina.

External Rotation

1. Initial phase is called *restitution*. Once the fetal head realigns with the shoulders, restitution is complete.
2. The second phase of external rotation occurs as the body rotates so that the shoulders are in the anteroposterior diameter of the pelvis.

Expulsion

1. After delivery of the fetal head and internal rotation of the shoulders, the anterior shoulder resets beneath the symphysis pubis.
2. The posterior shoulder is expelled, followed by the anterior shoulder, leading to total body expulsion.

NURSING ASSESSMENT AND INTERVENTIONS

Initiation of Labor

Nursing responsibilities begin with an initial assessment once a patient presents in labor.

Collection of History and Baseline Data

EVIDENCE BASE Lowdermilk, D., Perry, S., Cashion, C., & Alden, K. R. (2016). *Maternity and women's health care* (11th ed.). St. Louis, MO: Elsevier.

American College of Obstetricians and Gynecologists. (2017). *Emergent therapy for acute-onset, severe hypertension during pregnancy, and the postpartum period* (Committee Opinion #692). Washington, DC: Author.

---

1. Introduce yourself; maintain eye contact as culturally appropriate; ask for name of woman's health care provider; inquire if the provider has been notified that the woman was coming to the facility or birth center; ask about presenting complaints/concerns; orient woman and partner to surroundings and explain the plan of care.
    a. Establish baseline obstetric, medical, and surgical information. Inquire and validate patient information with the prenatal care record, if available. Complete brief review of past medical (including allergies), surgical, and obstetric history.
    b. Obtain a history of the current pregnancy: gravidity, parity, expected date of delivery or confinement, complications, fetal growth, antepartal testing results, sexually transmitted infections, recent travel abroad, and group β streptococcus status if tested.
    c. Inquire about current labor status and validate uterine contraction data with palpation: when did contractions begin, frequency, intensity, and duration; fetal movement; bloody show; have the membranes ruptured, time of rupture, color, consistency, amount of fluid, and any odor?
    d. Assess patient's comfort level.
    e. Inquire about a birth plan, participation in childbirth preparation classes, and pain management plans.
    f. Last oral intake of solids and liquids.
    g. Medications taken—prescription, over the counter, illicit drugs, herbals, or supplements?
    h. Inquire about the woman's support system.
2. Obtain baseline maternal and fetal vital signs.
    a. Temperature—elevation more than 100.0°F (37.8°C) suggests a possible infection or dehydration.
    b. Pulse—elevated over the resting rate during contractions; may be elevated between contractions because of medications, bleeding, or drug use; goal: 60 to 100 bpm.
    c. Respirations—increase as labor progresses; goal: 12 to 24 breaths/minute.

d. Blood pressure (BP)—slight elevation over baseline may be attributed to anxiety and pain.
    i. BP more than 140 diastolic or 90 systolic (mm Hg) may be suggestive of hypertensive disorder of pregnancy and requires further evaluation and notification to primary care provider.
    ii. BP of more than 160/110 requires immediate attention and notification of the primary health care provider because of potential for stroke or seizure (see page 1048).
    iii. Goal: Systolic more than 90 and less than 140 mm Hg; diastolic more than 60 and less than 90 mm Hg; mean arterial pressure (MAP) less than 100.
e. Complete fetal heart rate assessment; if a fetal monitor is to be used, run a 20-to 30-minute strip for baseline data and assessment of fetal well-being.
f. Physical assessment—complete review of systems on admission to include heart and lung sounds and deep tendon reflexes as indicated based on assessment.

3. Obtain a urine specimen—if indicated for symptoms of urinary tract infection or in cases of hypertension to check protein.

Methods for Determining Fetal Presentation

Leopold Maneuvers

The manual manipulation of the maternal abdomen to determine fetal placement in relation to maternal structures (see Figure 37-7).

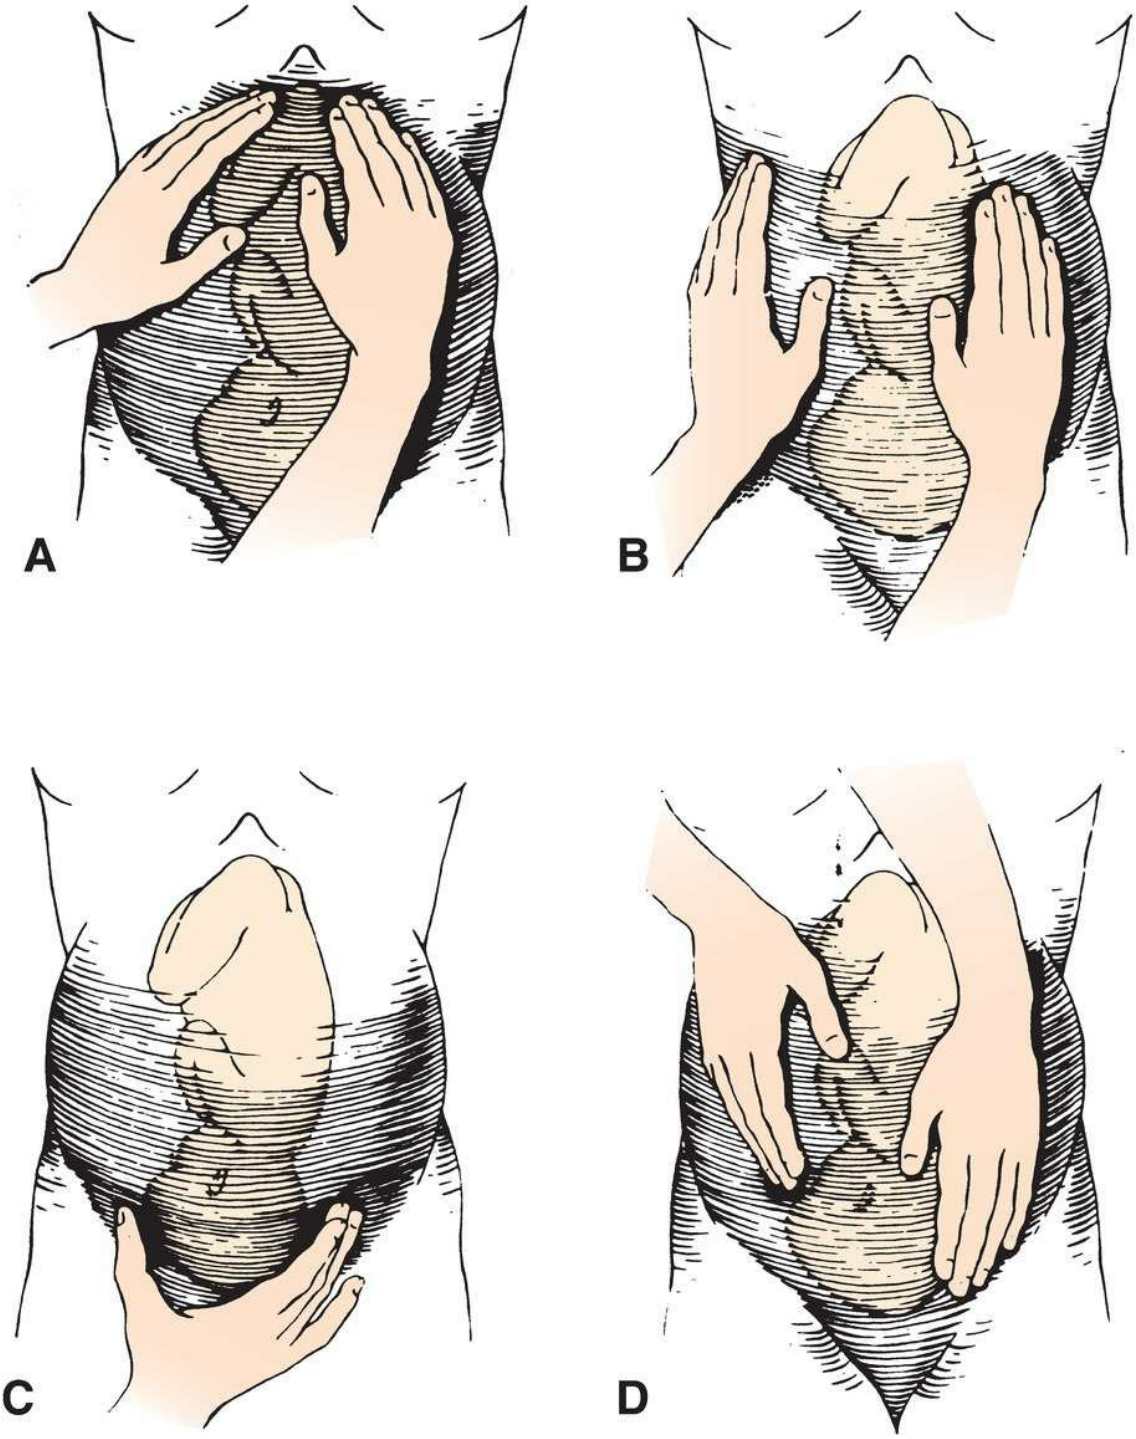

Figure 37-7. Leopold maneuvers.

1. First maneuver (fundal grip) (see Figure 37-7A)—determines fetal parts (fetal head or breech) located in the uterine fundus.
   a. While facing the woman, place both hands laterally on each side of the fundus and palpate; note the size, shape, and consistency.
   b. A head feels smooth, hard/firm, and round, mobile, and ballotable; breech position feels irregular, rounded, soft, and not independently mobile.

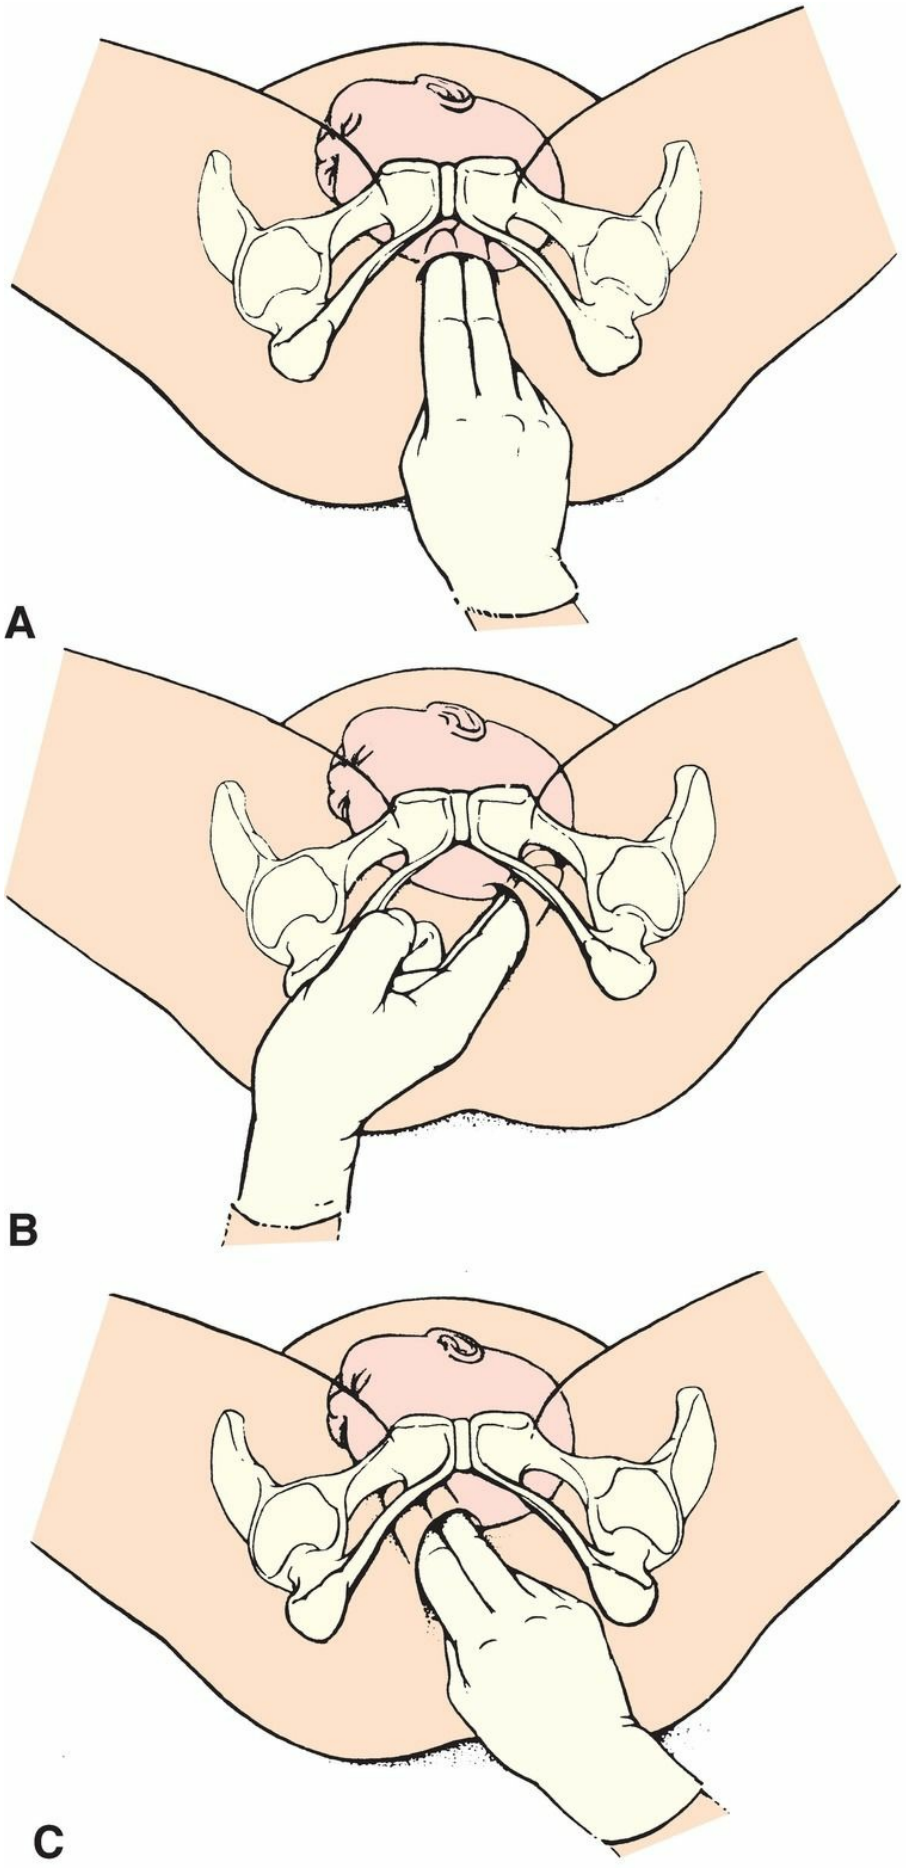
2. Second maneuver (lateral grip) (see Figure 37-7B)—identifies the relationship of the fetal back and the small parts to the front, back, or sides of the maternal abdomen (fetal lie).
    a. In the same position, lower hands bilaterally along the lateral borders of the maternal abdomen.
    b. Select one hand to stabilize one side of the uterus while the opposite hand palpates downward over the opposite side. Repeat on the opposing side.
    c. Determine fetal anatomy by palpated contents: firm, smooth, and a hard continuous structure = fetal back; if small, knobby, irregular, protruding, and moving = fetal extremities.
3. Third maneuver (1st pelvic grip) (see Figure 37-7C)—determines the portion of the fetus that is presenting into the pelvic inlet (fetal presentation). This maneuver is also known as Pallach's maneuver or grip.
    a. Grasp the part of the fetal presenting part situated in the lower uterine segment between the thumb and middle finger of one hand.
    b. Assess contents as described in the first maneuver; findings should be opposite of information found in the fundus.
4. Fourth maneuver (2nd pelvic grip) (see Figure 37-7D)—determines flexion or attitude of the fetal vertex or the greatest prominence of the fetal head over the pelvic brim.
    a. Face woman's feet and place hands on each side of the uterus, below the umbilicus and pointing toward the symphysis pubis.
    b. Press deeply with the fingertips toward the symphysis pubis, locating the cephalic prominence.
        i. If the cephalic prominence is felt on the same side as the small parts, sinciput (fetus' forehead), fetal vertex is flexed.
        ii. If the cephalic prominence is felt on the same side as the back, occiput (or crown), fetal vertex is flexed.
        iii. If the cephalic prominence is felt equally on both sides, military position (common in posterior position), fetal vertex is nonflexed.
    c. As hands move toward the pelvic brim, assess for the following: if the hands converge (come together) around the presenting part, it is floating; if the hands diverge (move apart), the presenting part is either dipping or engaged in the pelvis.

Ultrasonography

See page 985.

Vaginal Examination

See Figure 37-8.



A
B
C

Figure 37-8. Vaginal examination. **(A)** Determining the station and palpating the sagittal suture. **(B)** Identifying the posterior fontanelle. **(C)** Identifying the anterior fontanelle.

1. Explain the procedure to the woman and assist her to a lithotomy position.
2. Keep patient covered as much as possible to maintain privacy.
3. Conduct examination gently using a sterile glove.
4. Perineum—visually assess the perineum for lesions, ulcerations, bruising, discharge, odor, rupture of membranes, or bleeding. If infection is suspected (ie, syphilis or genital herpes) or active bleeding exists, stop the examination and notify the health care provider for further evaluation.
5. Perform manual examination with dominant hand (may use nondominant hand over fundus to stabilize fetal presenting part against the cervix):
   a. Cervical assessment.
      i. Location: Posterior, mid, or anterior (facing the introitus and aligned parallel to the vagina).
      ii. Hard or soft: The cervix softens during latent phase of labor.
      iii. Long or short? As effacement occurs, the cervix shortens and thins. Measured in percentages from 0% to 100%.
      iv. Open or closed: Measure degree of dilation in centimeters from 1 to 10 cm (complete).
   b. Presentation.
      i. Breech, cephalic/vertex face, shoulder, transverse, or compound.
      ii. Caput succedaneum (edema occurring in and under fetal scalp) present (mild, moderate, severe) or absent.
      iii. Station identified: signifies descent in relation to maternal pelvis (−5 to +5).
   c. Position.
      i. Cephalic presentation (in relation to maternal pelvis anterior, posterior, transverse).
      ii. Location of fontanelles.
   d. Membranes—intact or ruptured.
      i. Amount, color, and any odor of fluid.
      ii. Passage of meconium and consistency.

Sterile Speculum Examination

In some situations (eg, premature rupture of membranes, or positive group β streptococcus), a vaginal examination may be deferred and a sterile speculum examination may be required or preferred.

1. Explain the procedure to the woman, ask her to empty her bladder and remove all clothing from the waist down, and give her a sheet to cover herself.
2. Assist the patient into a lithotomy position (place hip roll under one hip to displace the uterus).
3. Drape her legs and abdomen and adjust lighting at the perineum.
4. After selecting a sterile speculum, utilizing sterile technique, open the package.

5. Put on sterile gloves using proper technique.
6. Ask the woman to relax her legs for proper visualization.
7. Explain each step of the procedure to decrease anticipatory anxiety of the patient.
8. With the nondominant hand separating the labia, place two fingers just inside the introitus, and gently press down on the base of the vagina. Next, insert the closed speculum past the fingers at a 45-degree downward angle such that the handle is perpendicular to the introitus.
9. Once the speculum enters the vagina, remove your fingers and turn the blades of the speculum into a horizontal position with the handle now parallel to the introitus; maintain a moderate and constant downward pressure (alleviates pain to the urethra).
10. As the speculum enters the posterior fornix, gently open the blades to visualize the cervix. If you still cannot visualize, close the blades, withdraw the speculum slightly, and move the blades toward the back of the vagina and try again. Once the cervix is in view, tighten the thumbscrew to maintain the blades in an open position. Complete a visual cervical assessment and obtain any samples necessary.
11. When the examination is complete, release the thumbscrew and withdraw in reverse order of placement.
12. Wipe any moisture or discharge from the perineal area and tell the patient the procedure is over; offer her assistance to a comfortable position.

Fetal Heart Assessment

EVIDENCE BASE Association of Women's Health, Obstetric and Neonatal Nurses. (Ed.). (2015). *Fetal heart monitoring principles and practices* (5th ed.). Dubuque, IA: Kendall-Hunt Publishing Co.

Fetal heart rate (FHR) assessment was established in Europe during the 17th century and utilized in the United States by Dr. Edward Hon. As FHR analysis evolved, so too has its purpose.

Providers caring for patients during labor and delivery must be skilled in utilizing correct instrumentation for the current clinical scenario, interpreting FHR characteristics and patterns, applying appropriate interventions, and communicating both routine and critical data to the perinatal team as the patient's (mother, fetus, or both) condition warrants.

Maternal Risk Factors, Fetal/Neonatal Risks, and Fetal Heart Rate Implications

One cannot sufficiently interpret FHR variances without considering the impact of maternal physiology and pathophysiology during gestation. Maternal conditions that may negatively impact oxygenation and perfusion of the mother may lead to oxygen deprivation and hypoxemia in the fetus. The large majority of maternal and fetal couplets tolerate physiologic challenges of pregnancy, labor, and birth without consequence. Under extreme conditions (ie, asthma attack, seizure, hemorrhage), the maternal patient diverts blood and oxygen away from the nonvital uterus to vital organs at the expense of the fetus. Several maternal conditions outlined below explain risk factors to the fetus and subsequent FHR changes possibly witnessed during the intrapartum period.

1. Cardiovascular—acquired or congenital cardiac disease, anemias (sickle cell), or hypertensive disorders.
    a. *Fetal/neonatal secondary risks*: small for gestational age (SGA), intrauterine growth restriction (IUGR), hydrops fetalis, hypoxemia, decreased amniotic fluid volume (AFV), preterm labor (PTL)/birth, and placental abruption.
    b. *Potential FHR alterations*: tachycardia, bradycardia, minimal or absent variability, absent accelerations, late decelerations, variable decelerations, prolonged decelerations, or sinusoidal patterns.
2. Respiratory—*chronic disease*: asthma and smoking; *acute disease*: status asthmaticus, acute respiratory distress syndrome, pulmonary embolus, sickle cell crisis, amniotic fluid embolus, or infections.
    a. *Fetal/neonatal secondary risks*: SGA, IUGR, hypoxemia, PTL/birth, and presence of meconium.
    b. *Potential FHR alterations*: tachycardia, bradycardia, minimal or absent variability, absent accelerations, late decelerations, or prolonged decelerations.
3. Neurologic—*chronic disease*: epilepsy and underlying; *acute disease*: stroke and eclampsia.
    a. *Fetal/neonatal secondary risks*: hypoxemia and PTL/birth.
    b. *Potential FHR alterations*: bradycardia, minimal or absent variability, absent accelerations, late

decelerations, or prolonged decelerations.

4. Renal—*chronic disease*: dialysis and transplant; *acute disease*: acute tubular necrosis, acute renal failure, development of calculi, fluid/electrolyte imbalance, and infection.
    a. *Fetal/neonatal secondary risks*: SGA, IUGR, hypoxemia, decreased AFV, decreased/reversed umbilical blood flow, and PTL/birth. (*Note*: Altered electrolytes may adversely affect the fetus if prolonged.)
    b. *Potential FHR alterations*: tachycardia, bradycardia, minimal or absent variability, absent accelerations, variable decelerations, late decelerations, or prolonged decelerations.
5. Psychosocial and other risk factors—lack of prenatal care, medications, malnutrition/inadequate weight gain, excessive stress, domestic violence, and substance abuse (eg, alcohol, illicit drug use).
    a. *Fetal/neonatal secondary risks*: SGA, IUGR, congenital anomalies, placental anomalies, hypoxemia, decreased AFV, or PTL/birth.
    b. *Potential FHR alterations*: tachycardia, bradycardia, minimal or absent or marked variability, absent accelerations, variable decelerations, late decelerations, or prolonged decelerations.

Fetal Heart Monitoring Instrumentation: External Options

Uterine Contraction Assessment by Palpation

1. Uterine palpation is performed periodically throughout labor to validate labor adequacy and progression; if applicable, palpation is also utilized to validate information received from internal equipment (eg, intrauterine pressure catheter).
2. Intensity may be described as follows (this may be taught to patient and labor coach):
    a. The uterus easily indented: feels like the tip of the nose (mild intensity).
    b. Able to slightly indent the uterus: feels like the chin (moderate intensity).
    c. Unable to indent the uterus: feels like the forehead (strong intensity).
3. Uterine contraction data include:
    a. Frequency: beginning of one contraction to the beginning of the next.
    b. Duration: beginning of one contraction to the end of the same contraction.
    c. Intensity: peak pressure of a contraction.
    d. Resting tone: pressure of the uterus at rest or between contractions.
4. Benefits:
    a. Noninvasive; increases provider–patient interaction; direct assessment; easy to use/teach.
    b. Provides information regarding relative frequency, duration, strength, and resting tone.
    c. Allows freedom of movement and ambulation for woman.
5. Limitations:
    a. Subjective information that leads to potential practitioner variance.
    b. No permanent record for visual comparison analysis or collaboration.
    c. Clinical conditions that may limit or alter data collection: overextended uterus (eg, multiple gestation, polyhydramnios (hydramnios), macrosomia, uterine fibroids) or maternal obesity.

6. Procedure:
    a. Position patient in semi-Fowler or lateral position; place hip roll on one side to displace the uterus; explain the procedure to the patient.
    b. Place the pads of your fingers on the patient's abdomen in the area of the fundus and at the point of maximum intensity (this is not always midline).
    c. Assess uterine contraction frequency, duration, intensity, and resting tone.
        i. Normal findings/intrapartum active phase: frequency, less than or equal to five contractions in 10 minutes, averaged over a 30-minute period; duration, less than 90 to 120 seconds; with IUPC intensity, less than 80 mm Hg; resting tone, less than 20 to 25 mm Hg.
        ii. Abnormal findings—tachysystole, more than five contractions in 10 minutes; hypertonus, intensity. With IUPC intensity, greater than 80 mm Hg; resting tone greater than 20 to 25 mm Hg or Montevideo units (MVUs) greater than 400.

Uterine Contraction Assessment by Tocodynamometer

1. A *tocodynamometer* (TOCO, tocotransducer) detects changes in tension or muscular tone over the fundus on the outside layer of the maternal abdomen. The electronic data are then converted into a number and printed on the lower half of the electronic fetal monitor (EFM) paper. However, proper placement is key for accuracy:
    a. If patient is at term—place over the point of maximum intensity in the fundal region of the maternal abdomen.
    b. If patient is preterm—place over the lower uterine segment below the umbilicus, typically beside the ultrasound device if the fetus is vertex.
2. Benefits:
    a. Noninvasive and easy to use.
    b. Detects relative uterine resting tone, frequency, intensity, and duration of uterine contraction.
    c. Does not require ruptured amniotic membranes.
    d. Generates a tracing for future assessment and permanent record keeping.
3. Limitations:
    a. Nonspecific data are gathered, particularly intensity and resting tone. External uterine monitoring identifies contraction frequency and duration. Contraction intensity is subjectively identified by patient and manual palpation.
    b. Difficult to obtain data in patients with the following conditions: obesity, polyhydramnios, macrosomia, PTL, maternal vomiting, and maternal bearing-down efforts/pushing during second stage or during procedures.
    c. Location sensitive; placement may result in false or inadequate information.
    d. Sensitive to maternal and fetal movement—may be superimposed on contraction waveform.
    e. May limit maternal movement and ambulation during labor.
4. Procedure:

a. Position patient in a semi-Fowler or lateral position; place hip roll on one side to displace the uterus; explain the procedure to the patient and support persons.
b. Palpate the point of maximum intensity over the fundus and secure belt.
c. Press the uterine activity (UA) reference button on the EFM between contractions to set the resting tone between 5 and 15 mm Hg.
d. Palpate the fundus and compare printed data.
e. Reposition the device periodically, as needed, for patient comfort and during labor as the fetus descends.
f. Interpret data and document and communicate findings.

Fetal Heart Rate Assessment by Auscultation

1. *Auscultation* is a FHR counting technique accompanied by a listening device (ie, fetoscope or Doppler). The examiner counts the FHR over a specified time frame (see Table 37-2).
2. Interpretation of data includes FHR baseline rate, rhythm, variability, and accelerations and decelerations in the FHR.
3. Devices for interpretation may include Doptone/Doppler, fetoscope, or Leffscope or Pinard stethoscope.
4. Capabilities of a fetoscope—detects:
   a. Differentiation of fetal and maternal heart rates—eliminates error because of fetal demise and EFM with nonelectrical device (ie, fetoscope).
   b. Verification of FHR dysrhythmias visualized on EFM tracing.
   c. Clarification of halving or doubling (may occur due to dysrhythmia) on the EFM tracing.
5. Benefits:
   a. Neonatal outcomes comparable to the use of EFM, in low-risk populations and with 1:1 nurse–patient ratios.
   b. Noninvasive, easy to use, and most methods require no electricity.
   c. Patient has increased freedom of movement and ambulation.
   d. Patient can be monitored if submerged in water (eg, water/Jacuzzi births).
6. Limitations:
   a. Subjective data collection; variances between practitioners may exist.
   b. Conditions may limit the practitioner's ability to assess the FHR (obesity, increased fetal movement, or amniotic fluid).
   c. Cannot assess FHR variability or periodic/episodic decelerations or accelerations.
   d. Lack of continuous recording from monitor for visual comparative analysis.
   e. Requires education, practice, and skill in auditory assessment.
   f. Requires a 1:1 nurse–patient ratio during intrapartum; therefore, may create need to increase or realign labor and delivery staff.
7. Procedure:

a. Position patient in a semi-Fowler or lateral position; place hip roll on one side to displace the uterus; explain the procedure to the patient and her support persons.

b. Palpate the maternal abdomen to locate the fetal back by using Leopold maneuvers (see page 996). Figure 37-9 outlines FHR locations and corresponding fetal positions.

c. When using Doppler device, apply conduction gel to underside of device.

d. Position the bell of the fetoscope or Doppler on the area of the abdomen where maximum fetal heart sounds can be heard, usually over the back or chest of fetus. If using a fetoscope, use firm pressure. If using Doppler device, avoid friction noises caused by fingers on the abdominal surface area.

e. Assess and compare maternal heart rate (radial pulse) against the FHR; confirm differentiation.

f. Palpate uterine contractions simultaneously and compare with FHR data.

g. Differentiate between fetal heart rate/tone and other abdominal sounds.

   i. FHR—a rapid crisp ticking or galloping sound.

   ii. Uterine bruit—a soft murmur, caused by the passage of blood through dilated uterine vessels; synchronous with maternal pulse.

   iii. Funic souffle (uterine souffle)—a hissing sound produced by passage of blood through the umbilical arteries; synchronous with the FHR.

h. Count the FHR between contractions for at least 30 to 60 seconds (60 seconds per Society of Obstetricians and Gynaecologists of Canada).

i. Interpret findings to include FHR baseline rate, rhythm, and increases or decreases; further evaluation via EFM is indicated if:

   i. Baseline FHR less than 110 or more than 160, irregular rhythm, and abrupt or gradual decreases in FHR during, immediately after, or 30 seconds after a contraction.

j. Document and communicate findings with woman and her support persons.

k. Communicate abnormal findings to primary practitioner immediately.

8. Troubleshooting interventions:

a. Verify placement; utilize Leopold maneuvers to verify fetal position.

b. Assess all four quadrants of the maternal abdomen slowly; fetal malpresentation or demise may exist.

c. Repositioning the patient may reposition the fetus.

d. Reaffirm and compare data to the maternal pulse.

e. Use alternative equipment options (ie, EFM) if unable to assess.

f. Consult with other members of the perinatal team (patient care team) and notify the practitioner as warranted.

g. Multiple gestations require a keen sense of auscultation; each FHR should be documented by location. For example, baby A/#1 = left lower quadrant, 150 beats/minute; baby B/#2 = right upper quadrant, 120 beats/minute. Ultrasound may be warranted to discern two separate FHRs.

Table 37-2 Frequency of Auscultation: Recommended Assessment and Documentation

ORGANIZATION	LATENT PHASE	ACTIVE PHASE	SECOND STAGE
ACOG			
Low risk	—	q30min	q15min
High risk	—	q15min	q5min
AWHONN			
Low risk	—	q30min	q15min
High risk		q15min	q5min
SOGC	Regularly after rupture of membranes or clinically significant change	q15min	q5min when pushing is initiated

Assess fetal heart rate (FHR) before initiation of labor-enhancing procedures, ambulation, administration of medications, administration or initiation of analgesia or anesthesia, and transfer or discharge of patient.

Assess FHR after admission of patient, artificial or spontaneous rupture of membranes, ambulation, recognition of abnormal uterine activity patterns, and administration of medications.

ACOG, American College of Obstetrics and Gynecologists; AWHONN, Association of Women's Health, Obstetric and Neonatal Nurses; SOGC, Society of Obstetrics and Gynecology of Canada.

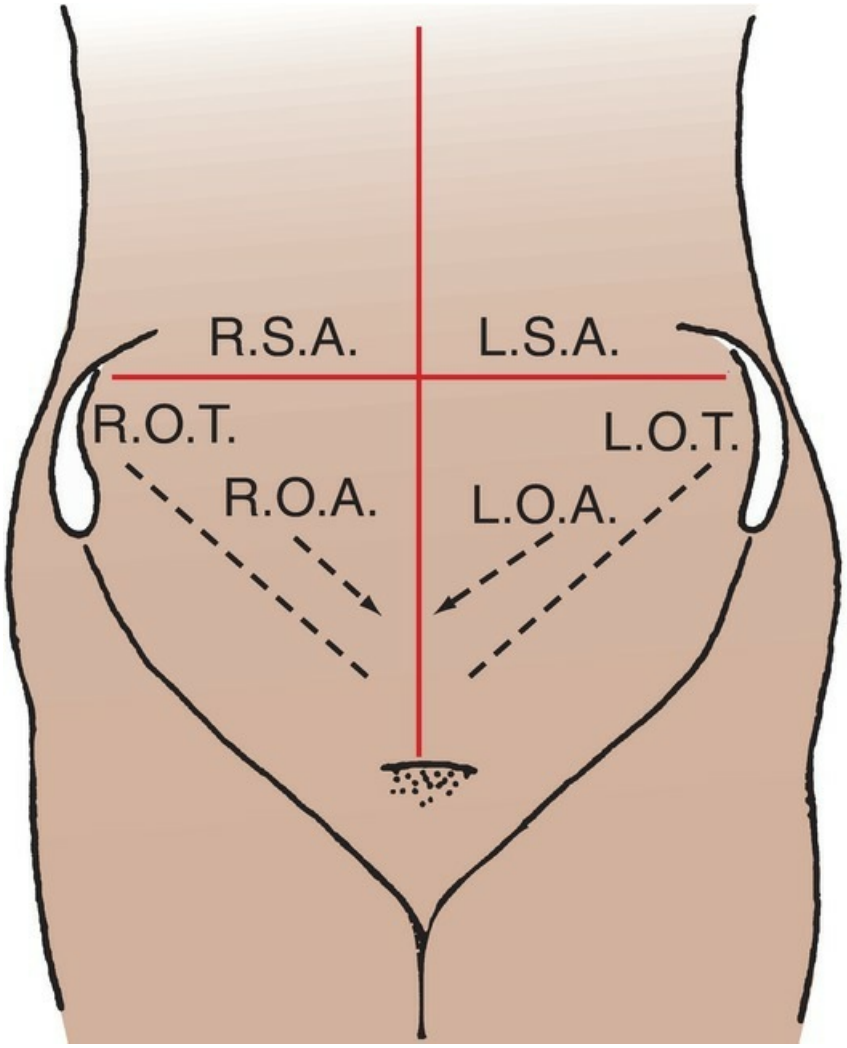


Figure 37-9. Fetal heart tone locations on the abdominal wall indicating possible corresponding fetal positions and the effects of the internal rotation of the fetus.

Fetal Heart Rate Assessment by Ultrasound Transducer

Monitoring the FHR via ultrasound transducer allows detection of the FHR baseline rate, variability, accelerations, and decelerations.

1. Benefits:
    a. Noninvasive.
    b. Rupture of membranes not required.
    c. Provides permanent record for review and collaboration.
2. Limitations:
    a. Signal transmission may be influenced by maternal obesity, polyhydramnios, or anterior placental placement providing a weak, absent, or false signal.
    b. Restricts maternal mobility.
    c. Episodic maternal and fetal movement may interfere with continuous recording.
    d. Half or double counting of FHR may occur, especially with fetal tachycardia or bradycardia.
    e. May document maternal pulse with undiagnosed intrauterine fetal demise; always validate and compare data to maternal pulse.
3. Procedure:
    a. Gather equipment, explain procedure to patient, and perform Leopold maneuvers to locate the fetal back or chest (point of maximum intensity [PMI]).
    b. Lubricate the face of the transducer with a thin layer of ultrasonic gel to aid in the transmission of sounds. Place the transducer over the PMI.
    c. Readjust the device periodically to maximize signal quality. Maintain a constant strip of FHR data as diligently as possible during course of labor.

Fetal Heart Monitoring Instrumentation: Internal Options

Uterine Contraction Assessment by Intrauterine Pressure Catheter

An *intrauterine pressure catheter* (IUPC) is the most objective technique to evaluate all uterine contraction characteristics and patterns. The device may be utilized for amniotic fluid testing and to perform an intrapartum amnioinfusion. IUPCs are either fluid-filled or solid-tipped catheters. Currently, there is no absolute indication for use of the IUPC in labor. Although not required, many practitioners utilize this device during labor of a woman with a previous uterine scar (eg, vaginal birth after cesarean). IUPCs are typically placed by the health care provider.

1. Benefits (fluid-filled and solid-tipped catheters):
    a. Utilized to calculate MVUs. Uterine activity (frequency, duration, intensity, and resting tone) can be calculated and documented using mm Hg and MVUs. MVUs are derived by subtracting the resting tone of the uterus from the peak pressure of the contraction (in mm Hg) for each contraction occurring in a 10-minute period. These numbers are then added together for the total number of MVUs during that 10-minute period. IUPC data should also be periodically checked against manual palpation until delivery.

b. Assists in the interpretation of the FHR (ie, comparison of a variable vs. late deceleration).
c. Tracing generated as a permanent part of the medical record.
d. Offers a portal for amniotic fluid sampling and amnioinfusion.
e. Solid-tipped—easy, quick setup with decreased pressure artifact.
f. Fluid-filled—least expensive; most accurate readings if correctly installed.

2. Limitations (fluid-filled and solid-tipped catheters):
   a. Rupture of membranes (ROM) and adequate cervical dilation are required for insertion.
   b. Invasive procedure.
   c. Increased risk of uterine infection.
   d. Improper insertion can lead to maternal or fetal trauma (ie, uterine perforation, uterine cord prolapse, extraovular placement).
   e. Limits maternal ambulation during labor.
   f. May be contraindicated in presence of vaginal bleeding and infection where ROM is discouraged to prevent maternal–fetal transmissions (eg, human immunodeficiency virus [HIV], herpes, group B strep).
   g. Differences may occur in readings between fluid-filled and sensor-tipped catheters.
   h. Solid-tipped—pressure readings higher than fluid-filled catheters.
   i. Fluid-filled—lengthy setup; may be difficult to maintain with maternal repositioning; may become compressed between the uterine wall and fetus, distorting the waveform.
3. Contraindications: placenta previa, active vaginal or cervical herpes, active hepatitis, or HIV infection, and active vaginal bleeding.

Fetal Heart Assessment by Fetal Spiral Electrode

The use of the *fetal spiral electrode* (FSE) to monitor the FHR allows for detection of FHR baseline rate, variability, accelerations, decelerations, and FHR dysrhythmias. Indications for use during labor include FHR not detected or abnormal findings via an external device.

1. Contraindications:
   a. Face, shoulder, compound, or footling breech presentations.
   b. Unable to identify presenting part.
   c. Presence of placenta previa; active vaginal or cervical herpes; active hepatitis, or HIV infection; active vaginal bleeding; or category III FHR pattern.
2. Benefits:
   a. Ability to detect FHR characteristics to include dysrhythmias and direct FHR variability.
   b. Maternal position change does not alter quality of tracing.
   c. Continuous detection of FHR; permanent recording in health record.
   d. Enhanced maternal comfort with removal of abdominal belt from external device.
3. Limitations:

a. Invasive procedure; requires ROM, cervical dilation, and accessible/appropriate fetal presenting part.
b. Potentially small risk of fetal hemorrhage, injury, or infection.
c. May record maternal heart rate in the presence of fetal demise.
d. Fetal arrhythmias may be missed (not detected) if EFM logic or electrocardiogram activation switch is turned on.
e. A moist environment is necessary for FHR detection.
f. Electronic interference and artifact may occur (ie, may become twisted in fetal hair).

4. Procedure:
   a. Gather equipment and explain procedure to patient.
   b. Perform EFM test if turning on EFM for the first time.
   c. Open FSE package utilizing sterile technique and place sterile glove on dominant hand.
   d. Following completion of a cervical exam, secure hand inside the cervix with second and third fingers pressed against presenting part, avoiding the face, genitalia, and fontanelles.
   e. Press catheter against presenting part and turn clockwise one full turn, pinch locking device at end, remove introducer, and attach to the EFM while securing to maternal abdomen or inner thigh.
   f. Interpret and document data.

Interpretation of Fetal Heart Rate

EVIDENCE BASE Association of Women's Health, Obstetric and Neonatal Nurses. (Ed.). (2015). *Fetal heart monitoring principles and practices* (5th ed.). Dubuque, IA: Kendall-Hunt Publishing Co.

American College of Obstetricians and Gynecologists. (2010/Reaffirmed 2017). *Management of intrapartum fetal heart rate tracings* (Practice Bulletin #116). Washington, DC: Author.

American College of Obstetricians and Gynecologists. (2009/Reaffirmed 2017). *Intrapartum fetal heart rate monitoring: Nomenclature, interpretation, and general management principles* (Practice Bulletin #106). Washington, DC: Author.

The following FHR interpretation criteria meet the current National Institute of Child Health and Human Development (NICHD) terminology and update and guidelines adopted by American College of Obstetricians and Gynecologists and Association of Women's Health, Obstetric and Neonatal Nurses in 2005, as well as management updates by ACOG in 2009 and 2010 and reaffirmed by ACOG 2017.

Fetal Heart Rate Baseline

1. *Fetal heart rate baseline* (FHRB) is the approximate mean FHR rounded to increments of 5 beats/minute during a 10-minute segment and excluding periodic/episodic changes, periods of marked FHR variability, and segments of the baseline that differ by more than 25 beats/minute; interpretation between

contractions is recommended but not required.

2. Documented as a single number.
3. Normal FHRB, 110 to 160 beats/minute; tachycardia, more than 160 beats/minute for 10 minutes or greater; bradycardia, less than 110 beats/minute for 10 minutes or greater.
4. In any 10-minute window, the minimum baseline duration must be at least 2 minutes or the baseline for that period is indeterminate. In this case, one may need to refer to the previous 10-minute segment for determination of the baseline. Two consecutive minutes are recommended but not required.
5. FHRB is calculated by determining the range of FHRV first and then calculating the mean in increments of 5 (if FHRV equals 10 [ie, 140 to 150], mean FHRB = 145; if FHRV equals 15 [ie, 120 to 135], mean = 7.5, round up to FHRB of 130).
6. Variations from the normal baseline rate are tachycardia, bradycardia, and sinusoidal patterns.

Tachycardia

1. Etiology—maternal causes:
    a. Maternal fever.
    b. Maternal infection.
    c. Dehydration.
    d. Hyperthyroidism.
    e. Endogenous adrenaline or anxiety.
    f. Medications.
        i. Sympathomimetics (eg, terbutaline, albuterol, epinephrine, ephedrine).
        ii. Parasympathomimetics (eg, atropine, hydralazine, phenothiazines, hydroxyzine).
        iii. Selected positive inotropic agents (dobutamine and positive chronotropic drugs).
        iv. OTC medications (decongestants, appetite suppressants, and caffeine).
        v. Illicit drugs (cocaine, methamphetamines, and heroin).
        vi. Nicotine, if inhaled (if inhaled, nicotine may increase FHR; if absorbed through a nicotine patch, it may decrease FHR).
        vii. Labor enhancement agents (ie, oxytocin, misoprostol), leading to persistent abnormal uterine contraction patterns.
2. Etiology—fetal causes:
    a. Infection.
    b. Fetal activity or stimulation.
    c. Compensatory response to early/acute hypoxemia.
    d. Fetal hyperthyroidism.
    e. Fetal tachyarrhythmias (supraventricular tachycardia).
    f. Prematurity.
    g. Congenital anomalies—cardiac abnormalities or heart failure.

h. Anemia.

3. Interventions:
    a. Monitor vital signs: maternal temperature and pulse; compare to FHR data.
    b. Assess maternal hydration (initiate or increase IV fluids, as needed).
    c. Decrease maternal temperature, if elevated, via an antipyretic, as ordered.
    d. Decrease maternal anxiety, give explanations for treatment measures, provide comfort measures, and assist with breathing/relaxation techniques.
    e. Assess additional FHR characteristics: if decelerations exist, consider the need to:
        i. Change patient to a lateral position.
        ii. Administer oxygen via face mask (8 to 10 L/minute); prolonged use discouraged.
        iii. Assess medication history and use.
        iv. Assess for tachydysrhythmia.
        v. If auscultating, apply EFM, as needed.
        vi. Notify the primary health care provider and perinatal team.

Bradycardia

Bradycardia in the fetus may result from maternal or fetal conditions and defined as less than 110 bpm for 10 minutes or greater. Severe bradycardia is defined as FHR less than 60 beats/minute. Sudden and sustained bradycardia accompanied by absent FHR variability (FHRV) has the highest risk of fetal and neonatal morbidity or mortality.

1. Etiology—maternal causes:
    a. β-Blocking agents (propranolol).
    b. Connective tissue disease (systemic lupus erythema).
    c. Prolonged maternal hypoglycemia.
    d. Maternal hypotension (r/t supine positioning, hypovolemia).
    e. Hypothermia.
    f. Anesthetics (epidural, spinal, pudendal, or paracervical).
    g. Conditions that may cause acute maternal cardiopulmonary compromise (amniotic fluid embolus, pulmonary embolus, cerebral vascular ischemia, hemorrhage, uterine rupture, trauma).
2. Etiology—fetal causes:
    a. Congenital heart block.
    b. Mature parasympathetic nervous system (post gestation).
    c. Acute hypoxemia.
    d. Cardiac structural defects.
    e. Impaired fetal oxygenation: (eg, umbilical cord occlusion, cord prolapse, uterine rupture, abruptio placentae).
    f. Maternal or fetal sentinel event precipitating hypoxia.

3. Hypoxic causes: umbilical cord prolapse or compression, uterine rupture, maternal hemorrhage, prolonged maternal hypoglycemia, placental abruption, maternal trauma, and persistent abnormal uterine contraction patterns (ie, tachysystole). A FHR category III pattern of lengthy and severe bradycardia accompanied by absent FHR variability may lead to permanent central nervous system (CNS) injury or death in the fetus or neonate.
4. Interventions:
    a. Validate maternal heart rate versus FHR with pulse oximetry if available; validate if fetus has complete heart block.
    b. Perform vaginal examination to assess for umbilical cord prolapse.
    c. Assess maternal vital signs to rule out hypotension; increase fluids.
    d. Assess FHR variability and other FHR characteristics— consider:
        i. Maternal lateral position change.
        ii. Discontinue oxytocin administration or augmentation agents.
        iii. Modify maternal pushing techniques or stop pushing during second stage of labor until FHR resolves.
        iv. Administer oxygen via face mask (8 to 10 L/minute) as necessary; prolonged use discouraged.
    e. If auscultating, apply EFM to assess FHR variability.
    f. Notify the primary health care provider and perinatal team.

Sinusoidal

1. This pattern differs from variability in that it has a smooth, sine wavelike pattern (equal deflections above and below the FHRB) of regular frequency and amplitude and is excluded in the definition of variability; described as *sinusoidal* or *pseudosinusoidal (medication induced)*.
2. Etiology:
    a. Severe fetal anemia: Rh isoimmunization.
    b. Fetal–maternal hemorrhage.
    c. Severe fetal hypoxia or asphyxia.
    d. Maternal opioid administration; may lead to pseudosinusoidal pattern.
3. Interventions:
    a. Lateral positioning.
    b. Administer IV hydration.
    c. Administer oxygen via face mask (8 to 10 L/minute); prolonged use discouraged.
    d. Assess patient for hemorrhage and treat accordingly.
    e. Notify the primary health care provider and perinatal team.
    f. If etiology necessitates, consider:
        i. Kleihauer-Betke test to assess for fetal red cells in maternal blood because of hemorrhage.
        ii. Expeditious delivery.

Fetal Heart Rate Variability

1. *Fetal heart rate variability* (FHRV) is the result of electrical impulses received by the cardiac muscle from the brain stem's medulla oblongata. The medulla oblongata receives information from both the parasympathetic (slow) and the sympathetic (fast) nervous systems; the combined effect leads to a cyclic push and pull of the heart rate over time (heart rates are never static unless permanent CNS damage has occurred). Oxygenation must remain constant for communication to occur between the CNS and cardiac muscle.
2. At the time of observation, variability indicates adequate oxygenation of the fetal CNS.
3. FHRV is defined as fluctuations in the baseline FHR. These fluctuations are irregular in amplitude and frequency and are visually quantified as the *amplitude of the peak-to-trough range* in beats per minute as follows:
   a. Absent FHRV—undetectable.
   b. Minimal FHRV—more than undetectable but less than or equal to 5 beats/minute.
   c. Moderate FHRV—6 to 25 beats/minute.
   d. Marked FHRV—more than 25 beats/minute.
4. Calculation of FHRV range is determined by the mean peak-to-trough range rounded to increments 5 beats/minute (ie, 120 to 135, 115 to 130, 150 to 155); the mean is reported as the FHRB.
5. Absent or minimal variability may be due to preterm gestation (less than 28 to 32 weeks), alteration in nervous system function, medications, abnormal uterine contraction patterns, or inadequate oxygenation.
6. Normal sleep and wake states, medications, alcohol, and illicit drugs that cause fetal neurologic damage; morphine; methadone; anomalies; and previous insults that have damaged the fetal brain can affect the baseline variability.
7. Moderate FHRV, even in the presence of decelerations, is strongly associated (98%) with an umbilical pH more than 7.15 (nonacidemic) or newborn vigor (Apgar score ≥ 7 at 5 minutes).
8. Abnormal findings: prolonged periods of absent, minimal, or marked FHRV; if absent FHRV is accompanied by recurrent decelerations (late, variable, or prolonged), fetal or neonatal morbidity or mortality may result.
9. Interventions for category III pattern: recurrent late, variable, or prolonged decelerations accompanied by absent FHRV (caused by CNS dysfunction, hypoxia, asphyxia):
   a. Notification to primary practitioner and perinatal team for expeditious delivery.
   b. Prepare for expeditious and immediate delivery; route dependent on clinical conditions.
   c. Discontinue oxytocin administration, if applicable.
   d. Assess maternal vital signs (initiate/increase intravenous infusion [IVF], as needed).
   e. Administer oxygen via face mask (8 to 10 L/minute); prolonged use discouraged.
   f. Change maternal lateral position.
10. Interventions for minimal FHRV (caused by sleep state, medications, hypoxia, CNS dysfunction, dysrhythmias):

a. Rule out nonhypoxic causes: sleep state and medications.
b. If minimal FHRV is accompanied by recurrent late, variable, or prolonged decelerations, extended time to complete all interventions outlined in 9a to f (previous paragraph) is afforded.
c. If pattern does not resolve within 60 to 90 minutes, delivery via the most expeditious route is recommended.

11. Interventions for marked FHRV (possibly caused by cord entanglement, excessive release of fetal catecholamines, asphyxia): same as for minimal FHRV.

Periodic/Episodic Fetal Heart Rate Patterns

Periodic or episodic changes are visually apparent increases or decreases in the FHRB in the form of an acceleration or deceleration. Their duration is greater than 15 seconds and less than 2 minutes. After 2 minutes, they are considered prolonged. If duration exceeds 10 minutes, a baseline rate change has occurred. *Periodic* patterns occur simultaneously with contractions and *episodic* patterns occur in the absence of contractions. Periodic and episodic patterns are distinguished on the basis of waveforms, currently accepted as "abrupt" (onset to peak or nadir [lowest point] is less than 30 seconds) or "gradual" (onset to nadir is equal to or greater than 30 seconds). Decelerations are defined as recurrent if they appear with 50% or greater of uterine contractions in any 20-minute period, or intermittent, if they occur with less than 50% of uterine contractions, in any 20-minute period.

1. Acceleration: visually apparent, abrupt increase in the FHR above the baseline rate; calculated from the most recently determined FHRB.
   a. The following criteria reflect gestational age implications:
      i. Term (greater than or equal to 32 weeks): peak of acceleration is 15 or more beats/minute (bpm) above the FHR baseline and 15 seconds or more in duration but less than 2 minutes.
      ii. Preterm (less than 32 weeks): peak of acceleration is at least 10 bpm above the FHR baseline and at least 10 seconds in duration but less than 2 minutes.
      iii. Prolonged: duration 2 minutes or longer but less than 10 minutes.
   b. Etiology: fetal movement, uterine contraction, partial umbilical cord occlusion, breech presentation, occipitoposterior position of the fetal vertex, vaginal examination, fetal scalp stimulation, following application of vibroacoustic stimulator, and application of FSE.
   c. Accelerations are associated with a nonhypoxic fetus and normal fetal pH at the time of observation.
   d. Interventions—none required.
2. Early deceleration—visually apparent usually symmetrical gradual decrease and return of the FHR associated with a uterine contraction; calculated from the most recently determined portion of the FHR baseline. It is coincident in timing, with the nadir of the deceleration occurring with the peak of a contraction. In most cases, the onset, nadir, and recovery of the deceleration occur with the beginning, peak, and end of the contraction, respectively.
   a. Physiology—head compression causing a vagal response. It is a benign pattern and not associated with fetal hypoxemia; may evolve into variable decelerations.

b. Interventions—none required.

3. Late decelerations—visually apparent, usually symmetrical gradual decrease and return of the FHR associated with a uterine contraction. The decrease in FHR is calculated from the onset to the nadir of the deceleration. The deceleration is delayed in timing, with the nadir of the deceleration occurring after the peak of the contraction. In most cases, the onset, nadir, and recovery of the deceleration occur after the beginning, peak, and ending of the contraction, respectively.
   a. Physiology.
      i. Reflex—chemoreceptor stimulation leading to the transient decrease in FHR accompanied by normal FHRB and moderate variability. Prolonged supine positioning may precipitate reflex late decelerations; repositioning patient laterally often resolves pattern.
      ii. Myocardial depression—decreased oxygen transfer at the placental interface may lead to uteroplacental insufficiency (UPI). Prolonged periods of UPI may lead to progressive fetal hypoxia and metabolic acidosis. Metabolic acidosis can directly influence electrical conduction and performance of the fetal heart, causing direct myocardial depression. These late decelerations are "myocardial mediated" and may be accompanied by a change in the fetal heart baseline (tachycardia or bradycardia), absent or minimal variability, and the absence of accelerations, usually indicative of a fetus in metabolic acidemia. A category III FHR pattern of recurrent late decelerations accompanied by absent FHRV requires immediate delivery via the most expeditious route.
   b. Maternal factors that may promote UPI:
      i. Hypotension (may also be associated with reflex late decelerations).
      ii. Severe hypertension.
      iii. Placental changes that may affect uteroplacental gas exchange (ie, postmaturity, premature placental aging, calcification, placental abruption, placenta previa, or placental malformations).
      iv. Physiologic conditions that may be associated with decreased maternal oxygen saturation or hemoglobin levels (ie, asthma attack, cardiopulmonary disease, or trauma).
      v. Persistent abnormal uterine contraction patterns (ie, tachysystole, tetany, or hypertonus).
   c. Interventions—aimed at increasing uteroplacental perfusion by correcting cause.
      i. Alter maternal position: lateral position (right or left) or knee–chest.
      ii. Correct maternal hypotension with hydration and/or medication.
      iii. Discontinue labor stimulation or cervical ripening agents.
      iv. Administer oxygen by face mask at 8 to 10 L/minute via a nonrebreather mask; prolonged use discouraged.
      v. If category III FHR pattern of recurrent late decelerations accompanied by absent FHRV, immediate delivery is warranted by the most expeditious route. Notification of the primary practitioner and perinatal team is indicated. Preparations for emergent delivery are warranted.

4. Variable deceleration—visually apparent abrupt decrease in FHR from the onset of the deceleration to the beginning of the FHR nadir is less than 30 seconds. When variable decelerations are associated with

uterine contractions, their onset, depth, and duration commonly vary with successive uterine contractions. It is important to note that variable decelerations vary in shape, timing, and return to baseline. Severe variable decelerations last more than 60 seconds yet less than 2 minutes and fall more than 70 beats below the FHRB. Therefore, deceleration depth correlates with the degree of academia.

a. Physiology—decreased umbilical cord perfusion, resulting from compression or stretch. Compression may result from maternal positioning, prolapsed cord, cord entanglement, second-stage labor, short cord, and a true knot in the cord.

b. Interventions.

   i. Change maternal position, which may dislodge an occluded cord.

   ii. Perform a vaginal examination to assess for cord prolapse or imminent delivery.

   iii. If prolapse, elevate presenting part off the cord while palpating for an umbilical pulse and FHR.

   iv. Amnioinfusion, if appropriate.

   v. Decrease or discontinue oxytocin, if appropriate.

   vi. Provide oxygen by face mask at 8 to 10 L/minute; prolonged use discouraged.

   vii. Discontinue or alter second-stage pushing technique if repetitive, severe variables occur in second stage.

   viii. If category III FHR pattern of recurrent variable decelerations accompanied by absent FHRV, immediate delivery is warranted by the most expeditious route. Notification of the primary practitioner and perinatal team is indicated. Preparations for emergent delivery are warranted.

5. Prolonged deceleration—visually apparent decrease of FHR of at least 15 beats/minute or more below the baseline and lasting more than 2 minutes but less than 10.

   a. Physiology—causes may reflect similar pathophysiology of late or variable deceleration.

   b. Interventions—if more than 4 to 5 minutes and causes unknown or unresolved, perinatal team should prepare for an emergent delivery.

6. Document all findings and classify patterns as normal (category I FHR), indeterminate (category II FHR), or abnormal (category III FHR) per NICHD guidelines (see Table 37-3).

Table 37-3 Three-Tier Fetal Heart Rate Interpretation System

CATEGORY	FHR PATTERNS
Category I: normal patterns	Baseline rate: 110 to 160 beats/minute Baseline FHR variability: moderate Late or variable decelerations: absent Early decelerations: present or absent Accelerations: present or absent
Category II: indeterminate patterns (includes all tracings not categorized in categories I or III)	Bradycardia not accompanied by absent baseline variability Tachycardia Minimal variability Absent variability not accompanied by recurrent decelerations Marked variability Absence of induced accelerations after fetal stimulation Recurrent variable decelerations accompanied by minimal or moderate variability Prolonged decelerations Recurrent late decelerations with moderate variability Variable decelerations with other characteristics, such as slow return to baseline, overshoots, or "shoulders"
Category III: abnormal patterns	Absent variability plus any of the following: Recurrent late or variable decelerations Bradycardia Sinusoidal pattern

EVIDENCE BASE AWHONN. (2014). *Women's health and perinatal nursing care quality refined draft specifications*. Washington, DC: Author.

TRANSITIONAL CARE ALERT Obstetric units should have comprehensive policies and procedures in place detailing evidence-based labor and delivery supportive practices based on AWHONN and ACOG guidelines. Research supports that maternal–fetal outcomes, hospital readmission rates, and patient satisfaction with the birth experience are improved with continuous nursing support.

First Stage of Labor: Latent Phase (0 to 3 cm)

Nursing Diagnoses

- Deficient Fluid Volume related to decreased oral intake, dietary restrictions, and energy requirement of labor.
- Anxiety related to concern for self and fetus.
- Acute Pain related to uterine contractions, position of fetus, and advancement of labor.
- Knowledge Deficit related to safe and effective use of alternative interventions.

Nursing Interventions

Maintaining Nutrition and Hydration

1. Provide clear liquids and ice chips, as allowed.
2. Initiate IV access and infuse fluids, if ordered.
3. Assess intake and output, and evaluate urine for ketones and glucose, per facility policy.

Relieving Anxiety

1. Establish a relationship with the woman/partner/support persons.
2. Inform the woman/partner/support persons of maternal status, fetal status, and labor progress periodically during the labor process. Ensure appropriate permission for information sharing.
3. Explain all procedures and equipment used during labor; answer questions and offer support.
4. Review birth plan and explain rationales for necessary revisions, if applicable.

Promote partner/support persons' participation in the labor experience.

5. Monitor maternal vital signs as the patient's condition warrants.
    a. Temperature every 2 to 4 hours, unless elevated or membranes ruptured, and then every 1 to 2 hours per facility policy.
    b. Pulse and respirations, as indicated by facility policy, medical condition, or medication administration (eg, oxytocin or magnesium sulfate infusions).
    c. BP is obtained typically every hour unless hypertension or hypotension exists or woman has received pain medication or anesthesia; then, evaluate more frequently based on findings or as indicated.
6. Monitor FHR periodically per facility policy (refer to Table 37-2, page 999).

Promoting Comfort

1. Encourage ambulation and frequent repositioning, as tolerated.
2. Encourage diversional activities, such as reading, talking, watching TV, playing cards, and listening to music.
3. Review, evaluate, and teach proper breathing techniques:
    a. Slow chest breathing (slow paced/)—relax, take one deep cleansing breath, and exhale slowly and

completely. Breathe deeply, slowly, rhythmically throughout the contraction. Average 10 to 12 breaths/minute. Breathe slowly and deeply in through the nose and out through the nose or slightly pursed lips.

b. Modified-paced breathing—used when slow chest breathing no longer effective, typically as labor progresses. Take one deep breath and exhale slowly and completely. As contractions intensify, breathe with more frequent shallow breaths during a contraction. At conclusion of contraction, take a deep breath and exhale slowly. Maintain a pace not to exceed twice the woman's average respiratory rate or less than 24 breaths/minute. Encourage HOOT–HOUT breathing with emphasis on a "crisp T" for exhalation.

c. Patterned-paced breathing (pant–blow breathing)—utilized in later stages of labor as contractions intensify and deep long breaths are not obtainable. Concentrate on breathing in a controlled manner. Take a deep breath and exhale slowly and completely. Then, take four shallow breaths through the mouth, making a "hee" or "heh" sound; maintain steady rhythm. Finish with a deep cleansing breath at the end of contraction. This breathing pattern is most commonly used during transition prior to active pushing.

4. Teach effleurage—light touch and massage over maternal skin, typically the abdomen, with fingertips; can be used with slow chest and modified-paced breathing. Start at the pubic bone and move hands slowly up sides of the abdomen in wide circular sweep; during exhalation, move fingertips down the center of the abdomen. Usually performed by laboring mother, but can be done with one hand if sidelying or coach assisted (see Figure 37-10).
5. Encourage a warm shower or whirlpool, if approved by primary practitioner.
6. Provide comfort measures.
   a. Give back or foot rubs.
   b. Assist the woman to change position. Walking, rocking chairs, squatting, semisitting, hands-and-knees, kneeling, standing, sidelying, or sitting on the toilet assist fetal descent and alleviate pain. Sidelying position or hands-and-knees position will assist to rotate a persistent OP position to an anterior position.

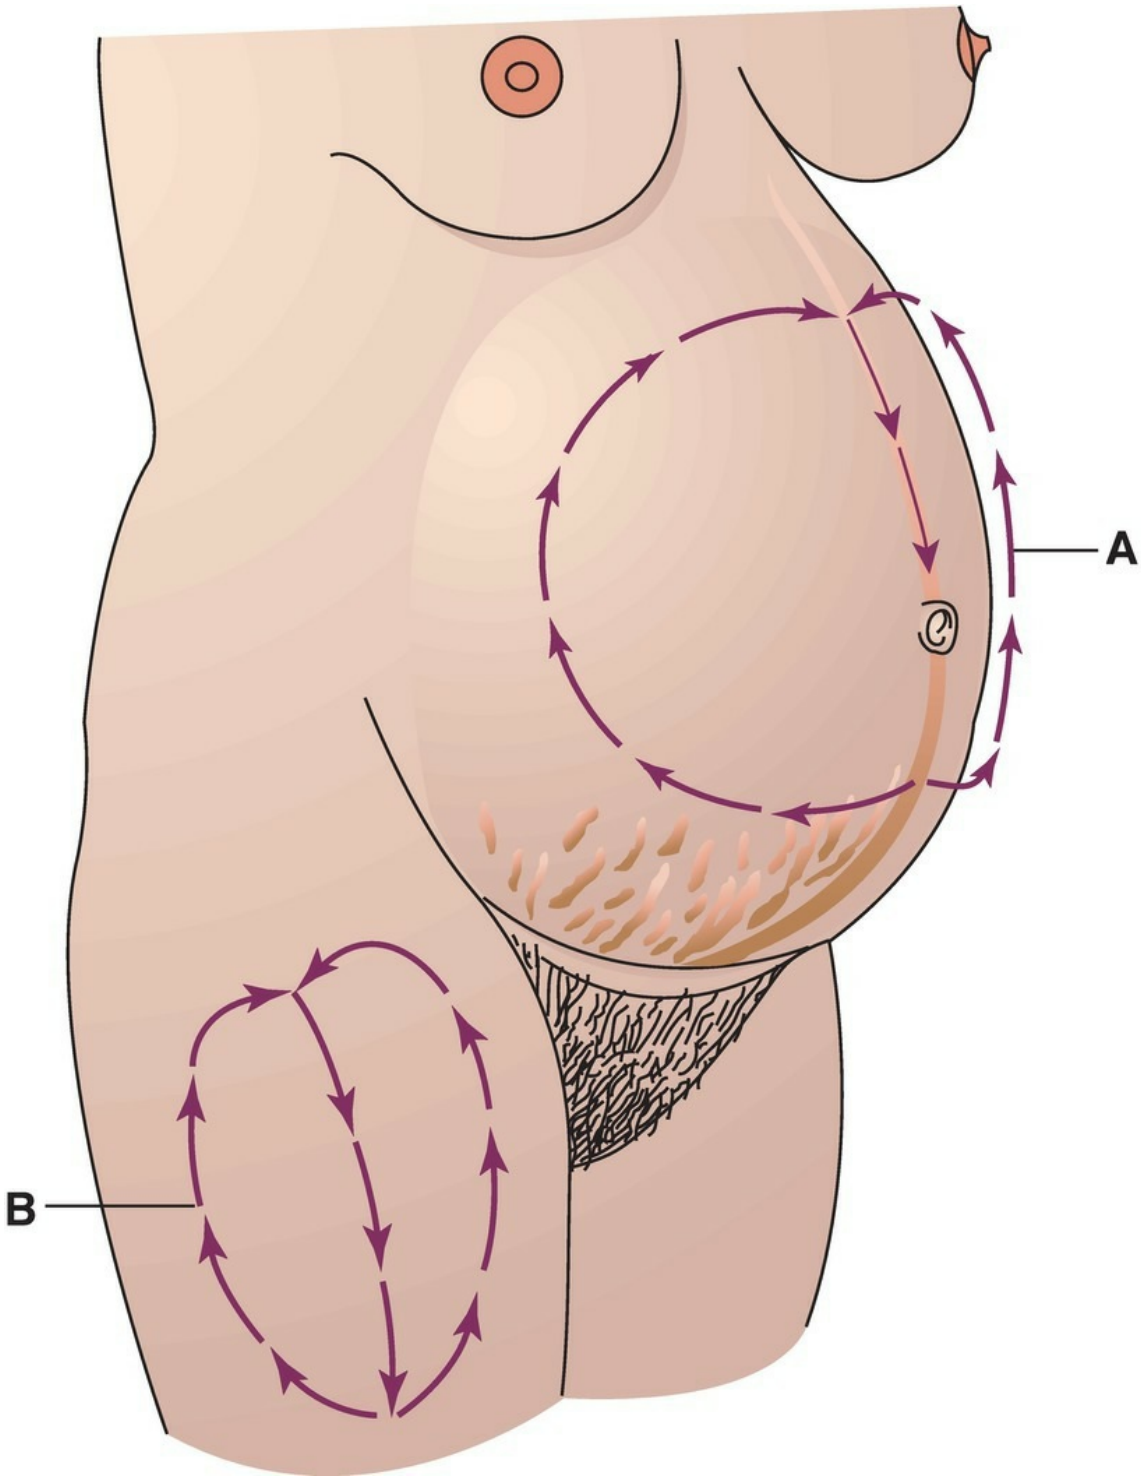

Figure 37-10. Effleurage. **(A)** During uterine contractions, a woman creates the pattern on her bare abdomen with her fingers. **(B)** If electronic fetal monitoring is being used, effleurage may be performed on the thigh. (Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Educate for Safe and Effective Use of Alternative Therapies

Provide information and clear up misconceptions about alternative therapies if patient is interested.

1. Birthing Balls—sturdy inflatable vinyl balls approximately 2½ feet (0.8 m) in diameter. The laboring woman can sit on the ball and sway from side to side, or she may kneel and lean forward resting on the birthing ball to assist in fetal descent.
2. Self-hypnosis—women are trained to rehearse the birth mentally and to control physical reactions to labor, such as BP, pulse, or pain. The American Psychotherapy and Medical Hypnosis Association (*www.apmha.com*) can provide referrals.
3. Acupuncture—although there are no current US studies on acupuncture, this practice is active, and past research findings indicate relief of as much as 90% of the pain in early labor and 60% of the pain during transition. Referrals can be made to the American Academy of Medical Acupuncture (*www.medicalacupuncture.org*).
4. Herbal therapies—although many of the herbs used are not approved by the Food and Drug Administration, they have been researched and found to be effective in laboring women and are documented in myriad medical and nursing references.
    a. Evening primrose oil—rubbed on the abdomen in prelabor to stimulate uterine activity.
    b. Corn silk—stimulates sluggish labor.
    c. Nutmeg—enhances uterine contractions; if added, cayenne and bayberry help to reduce bleeding after delivery.
    d. Nutmeg with yarrow, mistletoe, and corn silk—utilized as a treatment for postpartum hemorrhage.

EVIDENCE BASE Kennedy, D. A., Lupattelli, A., Koren, G., & Nordeng, H. (2016). Safety classification of herbal medicines used in pregnancy in a multinational study. *BMC Complementary and Alternative Medicine, 16*(102), 1–9.

Evaluation: Expected Outcomes

- Tolerates fluids well and urine negative for ketones and glucose.
- Verbalizes positive statements about self and fetus.
- Reports pain decreased from comfort strategies.
- Use of birthing ball and evening primrose oil with provider consent and partner assistance.

First Stage of Labor: Active and Transition Phase (4 to 10 cm)

EVIDENCE BASE Davidson, M. W., London, M. L., & Ladewig, P. W. (2016). *Olds' maternal–newborn nursing and women's health across the lifespan* (10th ed.). Upper Saddle River, NJ: Prentice Hall.

Nursing Diagnoses

- Anxiety related to concern for self and fetus.
- Acute Pain related to uterine contractions, nausea, and vomiting.
- Impaired Urinary Elimination related to epidural anesthesia or from pressure of the fetus.
- Ineffective Coping related to discomfort.
- Risk for Infection related to rupture of the membranes and prolonged labor.
- Impaired Physical Mobility related to medical interventions and discomfort.
- Ineffective Breathing Pattern related to pain and fatigue.

Nursing Interventions

Relieving Anxiety

1. Monitor maternal vital signs every hour if low-risk pregnancy or every 30 minutes if high-risk pregnancy; assess FHR as outlined in Table 37-2, page 999. Reassure mother of her progress and of the well-being of her baby.
2. Provide encouragement and continuous labor support, and involve the patient/partner/support persons in the maternal–fetal plan of care.

Minimizing Pain

1. Encourage frequent position changes for comfort.
2. Assist the woman with breathing and relaxation techniques, as needed.
3. Provide back, leg, and shoulder massage, as needed.
4. Evaluate cervical status as needed to monitor progression. Cervical checks should be kept to a minimum with ROM and positive β-streptococcus status.
5. Assist with preparation for analgesia and anesthesia following patient request (see Table 37-4).
6. Intervene for analgesia as follows:
   a. Confirm known allergies.
   b. Assess and document baseline temperature, BP, pulse, and respiratory rate.
   c. Monitor FHR before and after intramuscular (IM) or IV administration of analgesic medication.
   d. Assess efficacy of analgesics.
   e. Monitor FHR, continuous or intermittent, per facility policy and patient status.

7. Intervene for regional anesthesia as follows:
    a. Communicate maternal health information, laboratory results, labor status, and current obstetric complications with members of the health care team.
    b. Administer IV fluid bolus of lactated Ringer solution (500 to 1,000 mL) as directed, if not contraindicated (ie, severe preeclampsia, pulmonary edema).
    c. Assist anesthesia care provider by helping to position and hold patient for catheter insertion (lateral decubitus or sitting with feet supported, head flexed forward, elbows resting on knees with feet supported on a stool).
    d. Monitor maternal BP, pulse, and respiratory rate after initiation or rebolus of regional anesthesia per facility protocol; typically every 5 minutes for the first 15 minutes.
8. Support patient to comfortable position as labor progresses—lateral or semi-Fowler position, side of bed with legs dangling, or Taylor sitting position with uterine displacement.
9. Intervene for maternal hypotension by assisting to lateral positioning; infusing additional IV fluids, as directed; and administering ephedrine per facility protocol.
10. Monitor for adverse reactions from IV injection of local anesthetic: maternal tachycardia or bradycardia, hypertension, dizziness, tinnitus, metallic taste in the mouth, loss of consciousness, or cardiopulmonary collapse.
11. Monitor for adverse effects of opioids or anesthetics:
    a. Pruritus (itching on the chest, face, and arms), especially during the first hour after medication administration (usually begins within 30 to 60 minutes and decreases during the next hour).
    b. Nausea/emesis—can occur in up to 50% of women; administer medications to help with nausea/emesis, as directed by provider.
    c. Headache (pain in the frontal/occipital regions or radiating to the neck, stiff neck); increases in upright position and may decrease in horizontal position; relieved by abdominal compression; and may be accompanied by nausea/vomiting, ocular symptoms (photophobia, diplopia, difficulty in accommodation), and auditory symptoms (hearing loss, hyperacusis, tinnitus).
    d. Urine retention—observe for bladder distention; may utilize straight or indwelling catheter to empty the bladder if patient loses ability to sense fullness.
12. Assess dermatomes following procedure and periodically as indicated.
13. Periodically evaluate and document maternal pain level on a continuum using pain assessment tools in accordance with facility policy.
14. Evaluate labor progress; anesthetics may slow labor progression; realize that augmentation agents may be necessary.
15. Following delivery, assess neonate for effects of analgesia or anesthesia (neurobehavioral change, such as decreased motor tone and decreased respiratory rate). Initiate neonatal resuscitation, as indicated.

Table 37-4 Obstetric Analgesia and Anesthesia

DRUG	COMMENTS
Analgesics/Parenteral Opioids	
Meperidine Butorphanol Nalbuphine Fentanyl Morphine sulfate	Decreases fear and anxiety, promotes physical relaxation and rest between contractions; may cause nausea and vomiting; respiratory depression is the main adverse effect and is seen primarily in the neonate. Most commonly given via IV line or IM every 3 to 4 hours.
Tranquilizers	
Promethazine Hydroxyzine	May be used in combination with opioids; potentiates opioids; may be used as an antiemetic. Used in latent and first stage of labor to relieve anxiety, increase sedation and rest, and decrease nausea and vomiting.
Sedatives	
Sodium pentobarbital Sodium secobarbital Zolpidem tartrate	Produces sedation and hypnosis. Used for latent stage of labor to decrease anxiety, inhibit uterine contractions, and allow for rest. Does not relieve pain. Given orally or IM.
Regional Anesthesia/Analgesia	
Epidural opioids	Used with a local anesthetic to provide pain relief with a decreased motor block in labor. Used postoperatively to promote long-acting analgesia.
Epidural block	Used for labor to provide a sensory block up to the T10 to T12 level. Medication is given through the epidural catheter. Used for cesarean delivery and postpartum tubal ligation by increasing the level of anesthesia up to T4 to T6.
Subarachnoid block (spinal/intrathecal)	Used for such surgical procedures as a cesarean delivery and postpartum tubal ligation. The procedure is quicker and easier to perform. There is no catheter left in place for the procedure. Medication lasts for a finite period.
Local anesthesia	Used for pain control of the perineal area for an episiotomy or repair during a vaginal delivery.
Pudendal block	Used during the second stage of labor just before delivery to numb the lower vaginal canal, vulva, and the perineum for delivery. May also be used to provide pain relief for a forceps delivery if the woman does not have an epidural and for perineal repair.
General anesthesia	Used for emergency delivery involving cesarean delivery; if the woman refuses regional anesthesia; if regional anesthesia cannot be performed.

Encouraging Bladder Emptying

1. Encourage the woman to void every 2 hours at least 100 mL, if possible.
2. Palpate the lower abdomen; evaluate for a distended bladder periodically throughout labor.
3. Provide privacy to the patient to complete task. Running water or providing a perineal bottle of warm water for the woman to squirt against her perineum may assist success.
4. Catheterize patient if unable to void voluntarily.
5. Monitor intake and output per facility policy, particularly for certain medical conditions or following medication administration of IV oxytocin or magnesium sulfate.

Strengthening Coping with Active Labor and Transition

1. Assist the woman with breathing and relaxation techniques.
2. Encourage partner/support persons to assist with coping strategies.
3. Provide comfort measures, which may include:
    a. Effleurage, back rubs, and leg stroking.
    b. Cool cloth to the face, neck, abdomen, or back.
    c. Ice chips to moisten the mouth.
    d. Peri care and change pads and linens, as needed.
    e. Quiet, calm environment.
    f. Repositioning frequently for comfort with pillow and blanket.

4. Assist patient to pace herself and to encourage her to deal with one contraction at a time.
5. Provide information on the contraction's ascent, peak, and descent; encourage resting between contractions. Anticipatory guidance helps to assist with the patient's ability to tolerate labor.
6. Encourage the woman not to push with feelings of rectal pressure until complete cervical dilation has occurred. Short panting breaths may assist to divert bearing-down sensation.

Preventing Intrauterine Infection

1. Assess temperature every 2 hours if membranes are not ruptured. If ruptured, assess temperature every hour.
2. Periodically change pads and linens when wet or soiled.
3. Provide perineal care after voiding and as needed.
4. Discourage the use of perineal pads or folded towels against the perineum because they create a warm, moist environment for bacteria.
5. Minimize vaginal examinations.
6. Observe for fetal tachycardia and warmth of maternal skin as signs of infection.
7. Assess complete blood count, as indicated and available.

Maintaining Mobility

1. Provide information regarding limitations and opportunities for movement with EFM.
2. Encourage ambulation or sitting in a chair while being monitored, if appropriate.
3. Encourage frequent upright or lateral position changes.

Encouraging Effective Breathing Techniques

1. Assist the woman to alter her breathing and utilize relaxation techniques, as needed, to maintain pain control.
2. Inform the woman that the urge to push is common during transition and occurs as the fetal presenting part meets the perineal floor muscles. Pushing with feelings of rectal pressure before complete cervical dilation should be avoided due to risks of increasing cervical edema and lacerations.
3. Assist the woman to avoid pushing prematurely by:
    a. Maintaining close eye contact during breathing and keeping patient focused.
    b. Breathing with the woman, having her blow out strong, short breaths (pant–blow).

Evaluation: Expected Outcomes

- Verbalizes positive statements about self and fetus.
- Reports pain decreased from comfort strategies and medical interventions.
- The bladder remains nondistended.
- Directs strategies for decreasing discomfort.
- Absence of fever and signs of infection.
- Changes position during labor.

- Utilizes patterned breathing techniques during contractions.

Second Stage of Labor

The second stage of labor is typically the most challenging for both the mother and fetus. As contractions become more frequent and increase in intensity, perineal pressure is heightened as the fetus completes the last few cardinal movements through the birth canal. Breathing techniques and positioning may either help or hinder descent and oxygenation. It is important for each practitioner to assist the maternal–fetal couplet with strategies to optimize oxygenation, encouragement, descent, and patient safety.

Positioning

It is most beneficial for practitioners who offer labor support to encourage the patient to utilize upright positions to facilitate fetal descent. Research supports that the most successful position is the squat; additional options exist (ie, standing, upright kneeling, leaning against a wall). Advanced imaging techniques have verified an increase in the pelvic outlet during squat positioning of approximately 1 to 2 cm. Subsequent findings also conclude that a squat position is accompanied by a shorter second stage, higher Apgar scores, reduced pain, decreased perineal trauma, and decreased need for neonatal resuscitation intervention. With advancements in anesthesia preparations and dosing, patients have increased mobility during anesthetic infusions. Therefore, encouraging and assisting the epidural-induced patient into a squat position is achievable. Additional positions are available to encourage fetal rotation and descent: sidelying, knee–chest, hands-and-knees, and forward lean accompanied by a pelvic tilt or pelvic rocking. Supine positioning is inappropriate during labor—at all stages—as it promotes maternal aortocaval compression syndrome with subsequent deoxygenation and perfusion of the mother and fetus.

Pushing Techniques

For optimum success, pushing techniques should be initiated once the cervix is fully dilated, fetal presenting part is on the pelvic floor (+1, +2, or greater than station), and the patient has a sense to push/bear down (Ferguson reflex). Because of the expanded use and effects of anesthetics during labor and birth, some women lose sensitivity to perineal pressure, requiring guidance and instruction with pushing efforts. Two methods of pushing exist: passive pushing or laboring down and active pushing.

1. Passive pushing (“laboring down”/“rest and descend”)—this technique offers no active participation by the patient or practitioner to facilitate descent; strength of second-stage labor contractions moves the fetus down the birth canal. Reasons that may necessitate the need for this method include the following:
    a. Because of epidural anesthesia/analgesia, the woman does not feel the urge to push.
    b. Maternal clinical conditions such as cardiac disease, respiratory distress, or trauma.
    c. Fetal clinical conditions such as category III FHR or persistent abnormal UA data.
    d. Maternal exhaustion; need for periods of rest during prolonged second stage.
    e. Lack of nursing personnel to provide 1:1 support.
    f. Absence or unavailability of primary practitioner to assist with delivery.
2. Active pushing—this technique involves active participation (breathing techniques and positioning) by the patient and practitioner to assist in fetal descent. It is essential facilitate pushing efforts through

spontaneous pushing and supporting the woman's preferred pushing choice. Closed-glottis (ie, breath holding) is no longer recommended during second stage as it limits oxygenation and encourages CO_2 retention. If prolonged, this technique may negatively impact the fetus and potentially lead to abnormal FHR patterns. Strategies that promote oxygen exchange in the mother include:

a. Open-glottis pushing—this technique allows the woman to maintain a patent airway for gas exchange while enhancing bearing-down efforts with several short, quick breaths over the duration of a contraction (60 to 90 seconds). The method includes several short, quick breaths of 4 to 6 seconds accompanied by bearing-down efforts that utilize muscles in the upper abdomen; improves maternal–fetal oxygenation.
b. Tug-of-war—utilization of a gown or short sheet tied in a knot at both ends. When the mother has the urge to push, she grabs one end of the gown or sheet and pulls as much as she can while the coach or nurse provides resistance by holding the other end (alternative way is to tie knot in one end and tie the other end to squat bar of labor bed); relaxes the perineum and has been found to decrease the second stage of labor by as much as 20 minutes.
c. Birthing aids—birthing balls, squat bars, birthing stools, and cushions may also be utilized to support the woman and her fetus.

Nursing Diagnoses

- Fear or Anxiety related to impending delivery.
- Acute Pain related to descent of the fetus.
- Knowledge Deficit related to the delivery process.

Nursing Interventions

Minimizing Fear and Anxiety

1. Monitor maternal vital signs per facility policy.
2. Assess FHR and contraction every 5 to 15 minutes per facility policy and patient status.
3. Explain procedures, breathing technique, and equipment during the delivery process.
4. Keep the mother informed of her progress and alterations in care plan.
5. Provide frequent, positive encouragement and utilize a mirror to assist the woman to see her progress.
6. Assist with positioning and pushing, as outlined above.

Promoting Comfort

1. Change positions frequently to increase comfort and promote fetal descent.
2. Evaluate bladder fullness and encourage voiding or catheterize, as needed.
3. Evaluate effectiveness of analgesia or anesthesia, as indicated; notify if alterations in dosing are needed to facilitate progression while maintaining pain control.

Facilitating an Uncomplicated Delivery Process

1. Explain delivery process and equipment to patient/partner/support persons.
2. Prepare the delivery equipment maintaining sterile technique, and prepare the delivery area to maximize work area and accessibility of equipment.
3. Prepare the infant resuscitation equipment and preheat radiant warmer; notify pediatric personnel, per facility policy as appropriate; if category III pattern, have two practitioners available to administer neonatal resuscitation, as indicated.
4. Notify necessary obstetric personnel and primary practitioner to prepare for delivery.
5. If delivery room is to be used, safely transfer the patient to the delivery bed before the birth is imminent.
6. If delivering in a birthing room, prepare labor bed for delivery.
7. Position the woman for vaginal birth in a semi-Fowler position (C-position) supported by pillows for her head, back, and shoulders. Positioning may vary by patient preference, practitioner, and facility.
    a. If used, gently place legs in padded stirrups or footrests symmetrically to avoid ligament strain, backache, or injury.
    b. Under buttock drapes are recommended to evaluate blood loss during birth process. Accurate blood loss should be assessed and documented at every birth.
    c. Follow facility protocol or provider preference for cleansing the perineal area.
8. Support and guide the woman step by step during the delivery process. When the birth is imminent, encourage the woman to breath and maintain focus. Controlled pushing may decrease the risk of lacerations, tears, and episiotomy. Evidence-based criteria do not support routine use of episiotomy to facilitate the second stage of labor; however, clinical judgment is the best guide based on individualized patient and fetal status.
    a. An episiotomy may be performed when the fetal head is encircled by the vulvovaginal ring.
    b. Once the head is delivered, the mother is instructed to stop pushing. Mucus is wiped from the infant's face and the mouth and nose. A bulb syringe may be used. Neonatal resuscitation guidelines no longer recommend suctioning of any kind on the perineum for the presence of meconium.
    c. Nuchal cord intervention—loops of umbilical cord found around the neonate's neck are loosened and slipped over the head, whenever possible. If the cord cannot be slipped over the head, it is clamped with two clamps and cut between the two clamps.
    d. Next, the woman is instructed to give a gentle push to assist with delivery of the neonate's body and placed skin-to-skin on the maternal abdomen as the neonatal condition allows.
    e. Cord clamping—depending on the newborn's condition, some providers may delay clamping until the umbilical cord stops pulsating. This is done primarily to increase neonatal weight and hemoglobin and iron stores. The cord is clamped with two cord clamps and cut between the two clamps. It is common for the mother's partner or support person to cut the cord with assistance from the provider.
    f. If color and tone are adequate and accompanied by a vigorous cry, basic neonatal care can be delayed to support skin-to-skin contact and family bonding. If additional resuscitative support is indicated, the baby is passed to the neonatal team for immediate care.

9. Practice standard precautions during labor and delivery.

TRANSITIONAL CARE ALERT Evidence clearly supports the routine implementation of uninterrupted skin-to-skin between the mother and her healthy newborn. Studies demonstrate improved neonatal outcomes with respect to stabilized cardiorespiratory status and blood glucose levels. Maternal benefits include improved breastfeeding, pain management, and reduced anxiety. Nurses should make this a routine process after delivery as the neonate's condition allows. Discharge teaching should include the importance of skin-to-skin contact to facilitate infant comfort, temperature and glucose stability, and bonding.

Evaluation: Expected Outcomes

- Verbalizes positive statements about delivery outcome.
- Reports decreased pain from proper positioning.
- Infant is delivered without complications.

Third Stage of Labor: Delivery of the Placenta

Nursing Diagnoses

- Impaired Tissue Integrity related to placental separation.

Nursing Interventions

Promoting Tissue Integrity

1. Observe for signs of placental separation (see Figure 37-11):
   a. The uterus becomes globular in shape and rises upward in the abdomen.
   b. Umbilical cord lengthens.
   c. Small amount (gush) of blood appears.
2. Once signs of placental separation are observed, instruct the woman to assist delivery of the placenta with gentle bearing-down efforts. Be aware that delivery of the placenta typically occurs within the first 5 to 10 minutes, but may persist past 30 minutes, particularly in preterm gestations.
3. Administer and titrate oxytocin as directed to maintain uterine tone. Once the neonate has been delivered, oxytocin 10 units IM or 10 to 40 units IV per 1,000 mL is often utilized as the first line of treatment to prevent obstetric hemorrhage because of uterine atony.

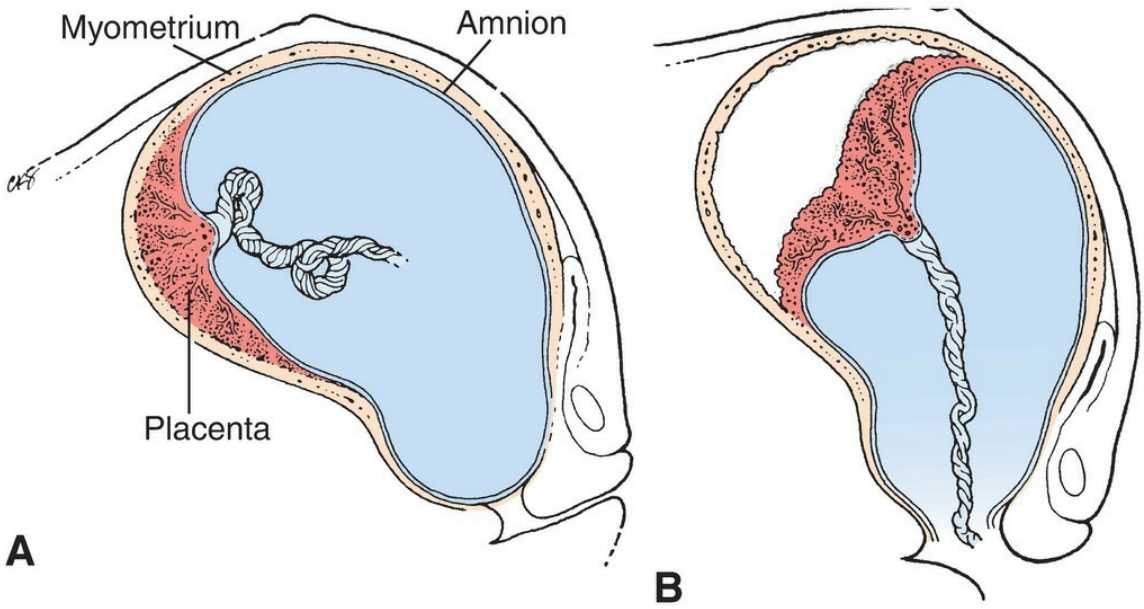

Figure 37-11. Placental separation. (LifeART image.) **(A)** Placenta attached to uterine wall. **(B)** Placenta separated from uterine wall.

NURSING ALERT When oxytocin has been in use for prolonged periods, it may be ineffective in the fourth stage of labor to control hemorrhage. Additionally, high doses of oxytocin can lead to

hypotension. Oxytocin is never administered IV push as it can cause cardiac dysrhythmia and death.

---

1. Inspect the placenta for size, shape, insertion site of cord, and intact cotyledons. The presence of even one cotyledon remaining intact within the uterus may lead to a postpartum hemorrhage. Umbilical cord should be inspected for true/false knots, clots, length, and a three-vessel cord. Abnormalities in the placenta, cord, or foul odor should be documented in the labor record and may necessitate the provider to request the placenta be sent for pathology.

Fourth Stage of Labor: Immediate Postpartum

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2006/Reaffirmed 2011). *Postpartum hemorrhage* (Practice Bulletin #76). Washington, DC: Author.

Nursing Diagnoses

- Risk for Bleeding related to uterine atony and hemorrhage.
- Deficient Fluid Volume related to decreased oral intake, bleeding, and diaphoresis.
- Acute Pain related to tissue trauma and birth process, intensified by fatigue.
- Impaired Urinary Elimination related to epidural or spinal anesthesia and tissue trauma.
- Risk for Injury related to disturbed sensation of lower extremities after regional anesthesia.
- Risk for Impaired Parenting related to inexperience or birth trauma.

Promoting Normal Involution and Controlled Bleeding

Also, see postpartum hemorrhage, page 1073.

1. Monitor BP, pulse, respirations, and oxygen saturation every 15 minutes for 1 to 2 hours and then every half to 1 hour until stable or transferred to the postpartum unit. Vital signs are assessed as the patient's condition warrants; increased frequency during periods of instability is necessary. Take temperature during the first hour postpartum and every 4 hours unless elevated or additional signs of infection present.

NURSING ALERT Hypotension is a late sign of hypovolemia; increased pulse rate is the first indicator.

1. Immediately after delivery of the placenta, assess uterine fundal tone, height, and position every 15 minutes for 1 to 2 hours. Place a hand over the lower uterine segment above the symphysis pubis to inhibit uterine inversion, and gently massage the fundus with the other hand. Visual inspection of the perineum should occur simultaneously to assess lochia.
2. Note that the uterus is firm at or around the level of the umbilicus and midline. If deviated to the side (usually the right side), it is indicative of a full bladder. Assist the mother to void spontaneously or utilize a straight catheter to empty her bladder if anesthesia effects remain.
3. Gently massage uterine fundus at least every 15 minutes for the 1 to 2 hours to promote firmness and expression of clots to decrease the risk of hemorrhage. Also, teach the woman how to massage the uterus. Uterine massage may be performed with a bimanual technique when indicated by a provider.

4. Utilize an under-buttock drape after the placenta is delivered to improve accuracy of blood loss calculation and identify obstetrical hemorrhage.
5. Assess vaginal bleeding (lochia):
    a. Scant—blood only on tissue when wiped or less than 1-inch (2.5-cm) stain on perineal pad.
    b. Small/light—less than 4-inch (10.2-cm) stain on perineal pad.
    c. Moderate—less than 6-inch (15.2-cm) stain on perineal pad.
    d. Heavy—saturated perineal pad.
    e. Clots—note size and frequency; weigh for ABL.
6. Assess the perineum for pain, edema, discoloration, bleeding, odor, or hematoma formation, if excessive perineal pain.
7. Assess episiotomy/lacerations for approximation, drainage, bleeding, or infection.
8. Report and document all assessments.
    a. The woman is stable if the fundus remains firm or firms quickly with massage and moderate amount of lochia for 1 hour and then reduce to small or trace moderate amounts over 2 to 4 hours postpartum.
    b. The woman is unstable if mean arterial pressure (MAP) is less than 60, a systolic blood pressure less than 90, or a 15% drop from normal baseline blood pressure (clinical indicators of obstetrical hemorrhage).
    c. Severe tachycardia (≥120) and severe tachypnea (greater than 30/minute) are signs of impending compromise and require immediate evaluation and intervention by a provider.

Maintaining Fluid Volume

1. Maintain IV fluids as clinical condition warrants. Administer oxytocin as above if not given in the third stage.
2. Maintain accurate measurement of intake and output during the immediate postpartum.
3. Provide oral fluids and a snack or meal, as tolerated, if vital signs are stable and bleeding is controlled.

Relieving Discomfort and Fatigue

1. Apply a covered ice pack to the perineum immediately after delivery and periodically during the first 24 hours for an episiotomy, perineal laceration, or edema.
2. Administer analgesics, as indicated. Excessive perineal pain unrelieved by medications suggests hematoma formation and mandates careful examination of the vulva, vagina, and rectum.
3. Ensure that epidural catheter has been removed by anesthesia provider, if appropriate.
4. Assist the woman in finding comfortable positions.
5. Assist the woman with a partial bath and perineal care. Periodically change linens and pads, as necessary.
6. Allow for privacy and promote rest periods between postpartum checks.
7. Provide warm blankets and reassure the woman that tremors are common during this period because of intravascular fluid shifts.

Encouraging Bladder Emptying

1. Evaluate the bladder for distention.
2. Encourage the woman to void periodically.
   a. Provide adequate time and privacy.
   b. The sound of running water may stimulate voiding.
   c. Gently squirting tepid water on the perineum may facilitate voiding.
3. Catheterize the woman if the bladder is full and she is unable to void.
   a. Birth trauma, anesthesia, and pain from lacerations and episiotomy may reduce or alter the voiding reflex.
   b. Bladder distention may displace the uterus upward and to the right side, impairing tone.

Preventing Injury Pending Return of Sensation

1. Evaluate mobility and sensation of the lower extremities.
2. Evaluate vital signs.
3. Remain with the woman and assist her out of bed for the first time. Evaluate her ability to support her weight and ambulate safely.

Promoting Parenting

1. Once stable, bring neonate to the mother and support person immediately after birth.
2. Encourage the parents to hold infant as soon as possible.
3. Assist and teach parents to hold the neonate close to their faces, about 8 to 12 inches (20.5 to 30.5 cm) to engage neonate.
4. Assist parents to inspect the infant's body to familiarize themselves with their child.
5. Assist with breastfeeding as soon as possible once both mother and newborn are stable. This is typically a period of quiet alert time for the neonate often optimizing successful breastfeeding.
6. Document appropriate and inappropriate bonding; notify primary practitioner and social services if suspect lack of or inappropriate response in mother, father, or any other potential caregiver.

Evaluation: Expected Outcomes

- Vital signs remain stable, vaginal bleeding remains light to moderate, and the uterus remains firm at the midline below the umbilicus.
- Tolerates fluids and food well after delivery.
- Verbalizes decreased perineal pain and feels rested.
- Voids within 2 hours of delivery.
- Ambulates without assistance.
- Interacts with the neonate.

Precipitous Delivery or Delivery in the Absence of Health Care Provider (Nurse-Assisted)

A precipitous delivery is an emergent event. During this event, consider the woman and infant as a unit. Coordination to prevent maternal and fetal infection, injury, and hemorrhage is key.

Interventions

1. Provide reassurance and instruct the woman in a calm, controlled manner. Sustain eye contact and assist the mother to utilize pant–blow breathing until told to push. Do not break down the birthing bed. The lower half of the bed will be utilized as a table and promotes fetal safety.
2. Position patient for comfort and enhance visualization of the perineum.
3. Wash hands, put on gloves, and clean the perineum as time permits.
4. Exert gentle pressure against the head of the fetus, using pads of the thumb, index finger, and middle fingers or cupped palm of the hand, to control progress and prevent precipitous delivery; this prevents undue stretching of the perineum and sudden expulsion through the vulva with subsequent infant and maternal complications.
5. Encourage the woman to pant at this time to prevent bearing down.
6. If membranes are intact at the time of delivery, rupture can be achieved by applying pressure to the membranes
7. Wipe the infant's face and mouth with a clean towel. Suction the mouth and nose with a bulb syringe, if available.
8. Check for nuchal cord and reduce, if possible. If the cord is too tight to permit slipping over the infant's head, it must be clamped in two places and cut between the clamps before the rest of the body is delivered.
9. Allow head to restitute. Place one hand over each ear bilaterally to support the infant's head; gently exert downward pressure toward the floor, thus slipping the anterior shoulder under the symphysis pubis.
10. As soon as the anterior shoulder is delivered, provide upward, outward traction to the head to deliver the posterior shoulder.
11. Support the infant's body and head in the lower hand. As the body is delivered, place skin-to-skin on maternal abdomen.
12. Gentle rubbing of the back may stimulate breathing with warm blankets
13. Cover mother and infant with warm blankets.
14. Watch for signs of placental separation (gush of dark blood from introitus, lengthening of umbilical cord, change in uterine contour). Avoid pulling on the cord, which might break and cause hemorrhage.
15. Clamp and cut cord as outline above.
16. Assess fundal tone and massage the uterus as outlined above. Putting the baby to breast may assist uterine contraction to promote oxytocin release.
17. Place identification bands on both the mother and infant.

18. Offer the patient fluids (IV or by mouth).
19. Teach the woman to massage her fundus.
20. Record the time and date of birth, as well as:
    a. Notifications and preparations for the birth.
    b. Fetal presentation and position.
    c. Presence of nuchal or body cord.
    d. Rupture of membranes: character, color, odor, and amount of amniotic fluid.
    e. Time of placental expulsion.
    f. Placental appearance.
    g. Maternal condition.
    h. Unusual occurrences during birth (ie, shoulder dystocia).
21. Assist and transport as necessary.

Immediate Care of the Neonate

EVIDENCE BASE Ricci, S. S. (2017). *Essentials of maternity, newborn, and women's health nursing* (4th ed.). Philadelphia, PA: Wolters Kluwer Health/Lippincott Williams & Wilkins.

American Academy of Pediatrics & American Heart Association. (2015). *Textbook of neonatal resuscitation* (7th ed.). Elk Grove Village, IL: American Academy of Pediatrics.

Nursing Diagnoses

- Ineffective Airway Clearance related to nasal and oral secretions from delivery.
- Ineffective Thermoregulation related to environment and immature ability for adaptation.
- Risk for Infection related to immature defenses of the neonate.

Nursing Interventions

Promoting Airway Clearance and Transitioning of the Neonate

1. Over 90% of newborns complete intrauterine to extrauterine transition without compromise or assistance. Close observation of all neonates is recommended for a minimum of 4 to 6 hours after birth.
2. Clean mucus from the face, mouth, and nose. Aspirate with a bulb syringe, as necessary.
    a. Neonatal resuscitation protocols no longer require suctioning on the perineum if meconium is present in the amniotic fluid.
    b. A vigorous newborn demonstrating strong respiratory effort, good muscle tone and a heart rate greater than 100 may only require bulb suctioning of the mouth an nose if needed.In the presence of meconium-stained amniotic fluid and a non-vigorous infant, deep suctioning of the mouth and trachea may be necessary to prevent aspiration.
3. Assess neonate's transition using the Apgar scoring system (see Table 37-5) at 1 and 5 minutes after birth. When the 5-minute score is less than 7, scoring continues every 5 minutes up to 20 minutes after delivery. An Apgar score of 0 to 3 at 20 minutes is associated with increased neonatal morbidity. Wear gloves at all times when handling an unbathed newborn and maintain standard precautions.

Table 37-5 Apgar Scoring Chart

SIGN	0	1	2
Heart rate	Absent	Slow (<100)	>100
Respiratory effort	Absent	Slow, irregular	Good, crying
Muscle tone	Flaccid	Some flexion of extremities	Active motion
Reflex irritability	No response	Cry	Vigorous cry
Color	Blue, pale	Body pink, extremities blue	Completely pink

Promoting Thermoregulation

1. Dry the neonate immediately after delivery, remove wet towels, and place skin-to-skin on mother's abdomen if vigorous and cover with a blanket and hat to prevent heat loss. If newborn is nonvigorous, place under a prewarmed radiant warmer for further evaluation. A neonate can lose up to 200 cal/kg/minute through evaporation, convection, conduction, and radiation.
2. Double wrap the neonate in warm blankets, with hat, and return to mother after stabilization.
3. Provide a warm, draft-free environment for the neonate.
4. Assess neonate's axillary temperature—a normal temperature is between 97.7°F and 99.3°F (36.5°C and 37.4°C).

Preventing Infection and Other Complications

1. Prophylactic eye care: Administer a 1-cm ribbon of erythromycin 0.5% or tetracycline 1% ophthalmic ointment to the lower conjunctival sac to prevent ophthalmia neonatorum (gonorrheal or chlamydial). This can be delayed up to 1 hour after birth to facilitate breastfeeding and parental bonding. Ointment may be gently wiped away after 1 minute with a sterile cotton ball.
   a. If the mother has a positive gonococcal or chlamydial culture, the neonate will require further treatment.
   b. Treatment is mandatory in all states.
2. Vitamin K: Administer a single prophylactic dose of vitamin K_1 (phytonadione) 0.5 to 1 mg IM to the vastus lateralis and document site.
   a. Given to prevent a vitamin K–dependent hemorrhagic disease of the newborn.
   b. If the parents decline vitamin K administration, inform the parents that if they desire a circumcision, it may not be performed related to the increased risk of bleeding.
   c. Additionally, inform parents that vitamin K levels will reach their peak (without neonatal injection) at 8 days after birth.
3. Security and Identification: place identical identification bracelets on the mother and the neonate per facility policy. An additional electronic security device may also be secured at this time to prevent infant abduction.
   a. Information on bands may include mother's name, hospital/admission number, neonate's sex, race,

primary practitioner, and date and time of birth and other information specified in the facility's policy.

   b. The father, partner, or other designated person may also wear an identical bracelet matching the mother's and infant's band.

   c. Foot printing and fingerprinting the neonate are not adequate methods of patient identification and may or may not be performed based on facility policy.

   d. Complete all identification procedures before the infant leaves the delivery room.

4. Measurements: Weigh and measure the infant shortly after birth.

   a. Average neonate weight is 5 to 8 pounds (2,500 to 4,000 g).

   b. Average neonate length is 18 to 22 inches (46 to 56 cm).

   c. Head, chest, and abdominal circumferences are also measured (facility dependent).

5. After birth, nursery/mother–baby personnel should evaluate the neonate's status and assess risks of birth trauma or injury.

6. Administer hepatitis B vaccine according to your facility's policy.

   a. Vaccination of all infants born in the United States is recommended regardless of mother's hepatitis status. If the mother's hepatitis B surface antigen (HBsAg) status is negative, the vaccine is given within 12 hours of birth to age 2 months and then again at 1 to 2 months after the initial dose with the final vaccine (#3) given at 6 to 18 months. The vaccine is given for the prevention of acute and chronic hepatitis B infection.

   b. If the mother is hepatitis B positive, the infant will receive hepatitis B immunoglobulin (HBIG) and the HBV vaccine at birth to within 12 hours. Additionally, infants of hepatitis-positive mothers will receive HBV at ages 1 to 2 months and age 6 months.

   c. Neonates born to nonscreened mothers will receive the HBV at birth within 12 hours of birth. If the mother later proves to be hepatitis B positive, the neonate will also receive HBIG (0.5 mL) IM as soon as possible, but no later than 1 week after birth. The infant will also receive HBV at 1 to 2 months and another injection at 6 to 18 months.

Community and Home Care Considerations

1. Issues regarding promoting airway clearance, transitioning, and thermoregulation promotion are essentially unchanged for home births; Apgar scores are not always given at home deliveries.

2. Eye prophylaxis is required using an antimicrobial ointment (ie, erythromycin) to prevent ophthalmia neonatorum.

3. Vitamin K administration is not a requirement for home deliveries. Vitamin K levels naturally increase at 8 days of life. If infant is a boy and parents desire circumcision, the procedure is withheld until after day 8.

4. Make sure attendants are familiar with neonatal resuscitation and that emergency numbers and procedures are readily available.

5. Identification procedures are not required for home births, although required state paperwork must be

completed by the health care provider.

Evaluation: Expected Outcomes

- Neonate transitions appropriately, as evidenced by Apgar score between 7 and 10.
- Temperature remains between 97.5˚F and 99˚F (36.4˚C and 37.2˚C).
- Eye prophylaxis and other procedures completed before leaving delivery room.

SPECIAL CONSIDERATIONS

Neonatal Resuscitation

EVIDENCE BASE American Academy of Pediatrics & American Heart Association. (2015). *Textbook of neonatal resuscitation* (7th ed.). Elk Grove, IL: American Academy of Pediatrics.

Neonatal resuscitation is most effective with an organized and efficient team. At every delivery, there should be at least one person whose primary responsibility is the neonate and who is capable of initiating neonatal resuscitation. Any high-risk delivery (requiring more advanced neonatal resuscitation) requires at least two people to be present to manage the resuscitation—one with complete resuscitation skills (intubation and umbilical catheter placement) and one to assist.

Causes

Perinatal asphyxia is the main cause for neonatal resuscitation. When the infant is deprived of oxygen, an initial period of rapid respirations occurs followed by apnea, decreased heart rate, and decreased neuromuscular tone. This is a period of primary apnea.

Primary Apnea

1. Intrauterine asphyxia may result in passage of meconium, fetal tachycardia, absent variability, recurrent late or variable decelerations, or prolonged bradycardia.
2. Infants born with primary apnea will need sensory stimuli (tactile or positive-pressure ventilation) to initiate respirations.
3. May occur in utero or after birth.

Secondary Apnea

1. Secondary apnea occurs when primary apnea is unresolved. The heart rate continues to drop lower (begins to drop about the same time the infant enters into primary apnea), the BP drops, the infant becomes flaccid, and spontaneous gasps occur.
2. May occur in utero or after birth.
3. At birth, these infants are pale, flaccid, and bradycardia.
4. Anticipation and preparation of neonatal resuscitation should occur at every birth.
5. When the infant is apneic at birth, it is difficult to distinguish between primary and secondary apnea; therefore, one must assume secondary apnea and resuscitation must begin immediately.

Initial Steps in Neonatal Resuscitation

1. A: Airway
2. B: Breathing
3. C: Circulation

How to Achieve Initial Steps

Performing the initial steps should take no more than 30 seconds.

1. Call for assistance, if needed.
2. Place infant on a warm, dry radiant warmer.
3. Dry infant thoroughly with warmed towels, dispose of wet towels, and stimulate infant by rubbing back or slapping soles of feet, if necessary.
4. Assess respirations (rise and fall of the chest, air moving in the lungs) and pulse (heart rate more than 100 bpm).
5. If apnea or the heart rate is less than 100 bpm, begin positive-pressure ventilation (PPV; bag and mask ventilation) and SpO_2 monitoring. Breaths are administered at a rate of 40 to 60 per minute. Resuscitation starts with room air (21%) and increases are made to the concentration of oxygen demonstrated by an uncompromised term neonate.
   a. Observe chest movement and auscultate for air movement in all lung fields.
   b. To prevent air filling, the stomach during PPV, an orogastric tube can be inserted orally.
6. If heart rate is less than 60 bpm, start chest compressions. New recommendations are to intubate infant prior to beginning chest compressions to improve circulation of oxygenated blood. One cycle of events consists of three compressions plus one ventilation, resulting in 120 "events" per 60 seconds or 90 compressions plus 30 breaths.
   a. If the heart rate increases to above 60 bpm, cease chest compressions and maintain ventilation at a rate of 40 to 60 breaths/minute.
   b. Once the heart rate exceeds 100 and spontaneous breathing resumes, gradually decrease rate of PPV.
7. Assist with endotracheal intubation, if needed.
8. Assist with insertion of an umbilical catheter for administration of medications and fluids, if needed. If heart rate remains below 60 bpm for over 60 seconds of PPV and chest compressions, medications (eg, epinephrine) should be considered and administered intravenously via an umbilical catheter or endotracheally.
9. Continue to assess neonate periodically once stabilization is reestablished and transport accordingly.

NURSING CARE OF THE MOTHER

The Puerperium

The *puerperium* is the period beginning after delivery and ending when the woman's body has returned as closely as possible to its prepregnant state. The period lasts approximately 6 weeks. (See Standards of Care Guidelines 38-1, page 1016.)

STANDARDS OF CARE GUIDELINES 38-1

Postpartum Care

- Perform focused assessment regularly using the BUBBLE-HE acronym—breasts, uterus (size and consistency), bladder (distention), bowel elimination, lochia, episiotomy (lacerations), Homans sign, and emotional status/bonding.
- Notify health care provider immediately if abnormalities are present:
  - Increased respiration and pulse, decreased blood pressure, and orthostatic changes may indicate hemorrhage.
  - Excessive vaginal bleeding (saturation of peripad within 1 hour for 2 or more hours), expulsion of large clots, or steady increase in vaginal bleeding, which indicates hemorrhage.
  - Boggy uterine fundus that does not become firm and remain firm with massage, indicating atony.
  - Inability to void and bladder distention, which may displace uterus, leading to uterine atony.
  - Decreased urine output, which may indicate hemorrhage.
  - Elevated temperature, increased pain, swelling, and redness from incisions, indicating infection.
  - Calf tenderness, swelling, redness, or warmth, which may indicate a blood clot.
  - Excessive irritability, crying, moodiness, withdrawal, insomnia, and loss of interest in activities, which may indicate postpartum depression (PPD).
- Encourage rest, nutrition, and bonding with the infant.
- Provide education on feeding, bathing, changing, safety measures, signs of illness, and when to call infants pediatric care provider with questions.

This information should serve as a general guideline only. Each patient situation and facility policy present a unique set of clinical factors and requires nursing judgment to guide care, which may include additional or alternative measures and approaches.

Physiologic Changes of the Puerperium

EVIDENCE BASE Cunningham, F. G., Leveno, K. J., Bloom, S. L., et al. (2014). *Williams obstetrics* (24th ed.). New York: McGraw-Hill.

Mattson, S., & Smith, J. E. (Eds.). (2016). *Core curriculum for maternal-newborn nursing* (5th ed.). St.

1. Uterine and cervical changes.
    a. Uterine involution begins immediately after delivery where the fundus is palpable halfway between the umbilicus and symphysis pubis. At 1 hour postpartum, the fundus is usually level with or slightly below the level of the umbilicus. The fundus is usually midline. Within 12 hours of delivery, the fundus may be ½ inch (1.3 cm) above the umbilicus and, by 24 hours, ¼ inch (1 cm) below the umbilicus. After this, the level of the fundus descends approximately 1 fingerbreadth (or ½ inch) each day; until by the 10th to 14th day, it has descended into the pelvic cavity and can no longer be palpated (see Figure 38-1). At approximately 6 weeks postpartum, uterine involution is complete.
    b. After delivery, *lochia*—a vaginal discharge that consists of fatty epithelial cells, shreds of membrane, decidua, and blood—is red or dark brown with clots (lochia rubra) for approximately 2 to 3 days. It then progresses to a paler pink or more brown-tinged color of serosanguineous consistency (lochia serosa) for 4 to 10 days, followed by a whitish or yellowish color (lochia alba) in the 10th to 14th day. Lochia usually ceases by 2 to 4 weeks, and the placental site is completely healed by the 6th week.
    c. Lochial flow can be scant (less than 2.5 cm stain [1 inch]/hour), light (less than 10 cm stain [4 inches]/hour), moderate (less than 15.2 cm stain [6 inches]/hour), or heavy (one pad saturated within 1 hour). Lochial flow is considered to be "excessive" if the perineal pad becomes saturated in less than 15 minutes (see Figure 38-2).
2. Immediately after delivery of the placenta, the cervix has little tone or resemblance to the prepregnant state.
    a. In approximately 2 to 3 days, the cervix appears more like the prepregnant state and is dilated to 2 to 3 cm. By the end of the first postpartum week, it is approximately 1 cm in diameter.
    b. The cervical opening is more slitlike than the prepregnant dimple and remains that way. (If the cervix has never been dilated, it will remain more prepregnant dimple-like.)
    c. The vaginal walls, uterine ligaments, and muscles of the pelvic floor and abdominal wall regain most of their tone during the puerperium.
    d. Immediately after delivery, the vaginal walls are smooth and swollen because the vaginal rugae are absent. Rugae reappear approximately 3 weeks postpartum.
    e. Postpartum diuresis begins within 12 hours after birth and continues for 2 to 5 days postpartum, as extracellular water accumulated during pregnancy is excreted.
    f. Diuresis may also occur shortly after delivery if urine output was obstructed because of the pressure of the presenting part or if IV fluids were given during labor.
3. Breasts—with loss of the placenta, circulating levels of estrogen and progesterone decrease and levels of prolactin increase, initiating lactogenesis.
    a. *Colostrum*—a thick, yellowish fluid that contains more minerals and protein but less sugar and fat than mature breast milk and has a laxative effect on the infant—is secreted for the first 2 days postpartum.

b. Mature milk secretion is usually present by the third postpartum day but may be present earlier if a woman breast-feeds immediately after delivery. Usually by the end of the 2nd postpartum week, mature breast milk is present.

c. Breast engorgement with milk and venous and lymphatic stasis with swollen, tense, and tender breast tissue may occur between days 3 and 5 postpartum.

4. Endocrine/metabolic function.

a. Human chorionic gonadotropin declines rapidly and is nonexistent by the end of the first postpartum week.

b. Thyroid levels are normal by 4 to 6 weeks postpartum.

c. Glucose levels are low secondary to decreased human placental lactogen, decreased cortisol, decreased estrogen, and decreased growth hormone.

d. Blood glucose levels of women with gestational diabetes mellitus (GDM) may return to normal limits shortly after birth. However, ACOG and the CDC recommend all women with GDM should glucose tested 6 to 12 weeks postpartum and screened for diabetes every 1 to 3 years for early identification of type 2 diabetes mellitus.

5. Ovarian function.

a. Estrogen and progesterone levels decrease rapidly after delivery of the placenta and are usually their lowest by the 7th postpartum day.

b. Estrogen reaches the follicular phase by 3 weeks after birth, as long as the woman is not lactating.

c. Ovulation may occur as early as 27 days after delivery. The average time is 70 to 75 days postdelivery and 190 days postdelivery if breast-feeding.

d. The start of menses after delivery is individualized. Usually, the first menses occurs approximately 7 to 9 weeks after delivery in nonnursing mothers, although breast-feeding women may not start their first menses until as late as 18 months.

6. Urinary function.

a. Mild proteinuria (+1 on urine dipstick) is common for 1 to 2 days after delivery in 40% to 50% of postpartum women.

b. Spontaneous voiding should return by 6 to 8 hours postpartum. Bladder tone returns between 5 and 7 days postpartum.

c. The catabolic process of involution can cause an increase in blood urea nitrogen levels during the postpartum period.

d. Stress incontinence is common during the first 6 weeks postpartum, and Kegel exercises should be encouraged.

e. Hematuria immediately after normal spontaneous vaginal birth can be indicative of bladder trauma. If hematuria occurs after the first 24 hours, it may be indicative of urinary tract infection.

7. Neurologic function.

a. Discomfort and fatigue are common.

Afterpains because of the involution process and discomfort from the delivery, lacerations,

b. episiotomy, and muscle aches are common for the first 2 to 3 days postdelivery.

c. Frontal and bilateral headaches are common and are caused by fluid shifts in the first week postpartum.

d. Non–rapid eye movement (REM) sleep is absent after birth and increases during the next 2 weeks. REM sleep decreases as non-REM sleep increases.

e. Carpal tunnel syndrome (resulting from physiologic edema causing pressure on the median nerve) is usually relieved by postpartum diuresis.

f. Postpartum eclamptic seizures can begin more than 48 hours and less than 4 weeks postdelivery. They are commonly preceded by severe headache or vision disturbances (spots before the eyes, double vision, etc.). Extra care is taken to observe for these symptoms, especially in women with prenatal diagnosis of preeclampsia or hypertension.

8. Cardiovascular function.
   a. Most dramatic changes occur in this system and can take between 6 and 12 weeks to return to the prepregnant state.
   b. Cardiac output decreases to prelabor values within a one hour postpartum and may be dependent on multiple factors including anesthesia use and method of delivery. However, it can remain elevated for as much as 48 hours postpartum. Cardiac output values return to normal by 6 to 12 weeks postpartum.
   c. Blood volume decreases immediately after birth. Average blood loss in a vaginal birth is between 200 to 500 mL and 600 to 800 mL in caesarean deliveries.
   d. Hematocrit increases and increased red blood cell (RBC) production stops.
   e. Leukocytosis (increased white blood cells [WBCs]) is common during the first postpartum week.
   f. A positive Homans sign may indicate thrombophlebitis and should be reported to the primary care provider. The woman should be instructed not to massage her legs.
9. Respiratory function.
   a. Returns to normal by approximately 6 to 8 weeks postpartum.
   b. Basal metabolic rate increases for 7 to 14 days postpartum, secondary to mild anemia, lactation, and psychological changes.
   c. Partial pressure of arterial oxygen (PaO_2), partial pressure of carbon dioxide ($PaCO_2$), and pH usually return to normal by 3 weeks postpartum.
10. GI/hepatic function.
    a. GI tone and motility decrease in the early postpartum period, commonly causing gaseous distention of the abdomen and constipation.
    b. Normal bowel function, including normal bowel movements, returns at about 2 to 3 days postpartum.
    c. Liver function returns to normal approximately 10 to 14 days postpartum.
    d. Gallbladder contractility increases to normal, allowing for expulsion of small gallstones.

e. GI function can be inhibited by surgical intervention, analgesia, anesthesia, and decreased muscle tone.

11. Musculoskeletal function.
    a. Generalized fatigue and weakness are common.
    b. Decreased abdominal tone is common.
    c. Diastasis recti heals and resolves by the 4th to 6th week postpartum. Until healing is complete, usually 1 to 2 weeks postpartum, abdominal exercises are contraindicated.
    d. Joint instability returns to normal between 6 and 8 weeks postpartum.
12. Integumentary function.
    a. Striae gravidarum lighten, and melasma is usually gone by 6 weeks postpartum.
    b. Hair loss can increase for the first 4 to 20 weeks postpartum and then regrowth will occur, although the hair may not be as thick as it was before pregnancy.
13. A good method to remember how to check the postpartum changes is the use of the acronym **BUBBLE-HE**:
    a. **B**—Breast.
    b. **U**—Uterus.
    c. **B**—Bladder.
    d. **B**—Bowels.
    e. **L**—Lochia.
    f. **E**—Episiotomy/lacerations.
    g. **H**—Homans sign/extremities.
    h. **E**—Emotional status/bonding.

---

1. Reva Rubin, the noted nursing theorist, developed the developmental tasks of pregnancy documenting maternal changes and role attainment. After delivery, the woman may progress through Rubin's stages of taking in, taking hold, and letting go.
   a. Taking in (extends over first 24 hours postpartum):
      i. May begin with a refreshing sleep after delivery. Restorative sleep should occur within first 24 hours postdelivery.
      ii. Woman exhibits passive, dependent behavior.

iii. Woman is concerned with sleep and the intake of food, mainly for herself.

b. Taking hold (if not in the first 24 hours postpartum, then between days 2 and 4 postpartum):

i. Woman begins to initiate action and to function more independently. The first sign mother is in this phase is alert interest in her infant.

ii. Woman may require more explanation and reassurance that she is functioning well, especially in caring for her infant.

iii. Openness to teaching on care of self and neonate.

iv. Today, with early hospital discharge, this phase may occur earlier, or it may occur after discharge.

c. Letting go:

i. May begin near the end of the first week; no specific end time noted.

ii. Is influenced by cultural beliefs.

iii. Reestablishment of couple relationship.

iv. As the woman meets success in caring for the neonate, her concern extends to other family members and to their activities.

2. Some women may experience euphoria in the first few days after delivery and set unrealistic goals for activities after discharge.

3. Many women may experience temporary mood swings during this period because of the discomfort, fatigue, and exhaustion following labor and delivery and because of hormonal changes after delivery.

4. Up to 60% to 80% of women may experience a transient period of depression termed postpartum blues. They can last for a few days to 1 to 2 weeks and usually peak at approximately the 5th postpartum day. Women may exhibit irritability, poor appetite, insomnia, tearfulness, or crying. This is a normal reaction to the physiologic shifts that occur postdelivery and temporary.

5. Postpartum depression is a more serious problem affecting as many as 20% of postpartum women. Cultural and ethnic influences may impact the postpartum period; therefore, cultural awareness of pregnancy practices is important to consider when working with postpartum women. A prenatal diagnosis of depression is considered a significant risk factor for PPD. Women may experience an increase in the manifestations listed above as well inability to adequately care for themselves and the baby. These women are at increased risk of suicide and in need of further evaluation (see Chapter 39 Postpartum Depression).

6. Nursing research findings indicate that new mothers commonly identify postpartum needs such as coping with:

a. The physical changes and discomforts of the puerperium, including a need to regain their prepregnancy figure.

b. Changing family relationships and meeting the needs of family members, including the infant.

c. Fatigue, emotional stress, feelings of isolation, and being tied down.

d. A lack of time for personal needs and interests.

Nursing Assessment

EVIDENCE BASE Lowdermilk, D., Perry, S., Cashion, C., & Alden, K. R. (2016). *Maternity and women's health care* (11th ed.). St. Louis, MO: Mosby.

Immediate Postpartum Assessment

The first hour after delivery of the placenta (fourth stage of labor) is a critical period; postpartum hemorrhage is most likely to occur at this time (see page 1073).

Subsequent Postpartum Assessment

1. Check the fundus at regular intervals for tone and location. Perform fundal massage if the uterus is boggy (not firm) (see Figure 38-3).
2. Teach patient self-fundal massage and warning signs to report
   a. Inspect the perineum regularly for bleeding. Note color, amount, clots, and odor of the lochia.
3. Count and/or weigh the number of perineal pads that are saturated as necessary. Assess mother's ability to perform self-care. Provide support and education as needed.
4. Assess vital signs at least twice daily and more frequently, if indicated.
5. Assess bowel and bladder elimination.
6. Evaluate interaction and the new family's ability to provide care to the newborn. Provide support and education as needed.
7. Assess breasts for colostrum, milk production, engorgement, and condition of the nipples if breast-feeding.
8. Assess Homans sign for possible thrombophlebitis.
9. Assess incisions for signs of infection and healing.
10. Assess the perineum using the REEDA acronym. REEDA is based on a 3-point scale. A score of 3 indicates an assessment of very poor wound healing. On the first postpartum day, the REEDA score may range from 0 to 3; by the second postpartum week, the score should be 0 to 1.
    a. **R**—Redness.
    b. **E**—Edema.
    c. **E**—Ecchymosis (purplish patch of blood flow).
    d. **D**—Discharge.
    e. **A**—Approximation or the closeness of the skin edges.
11. If the patient is Rh negative, evaluate her need for Rho(D) immune globulin (RhoGAM). If the newborn is Rh positive, administer the RhoGAM within 72 hours of delivery.
12. If the woman is rubella and/or varicella nonimmune, these vaccinations may be administered at

discharge. During the flu season, the influenza vaccine should also be offered if the mother has not been previously immunized during the pregnancy. Note: If the rubella vaccine is administered at discharge, educate the mother to avoid pregnancy for at least 3 months to minimize fetal risks of congenital defects.

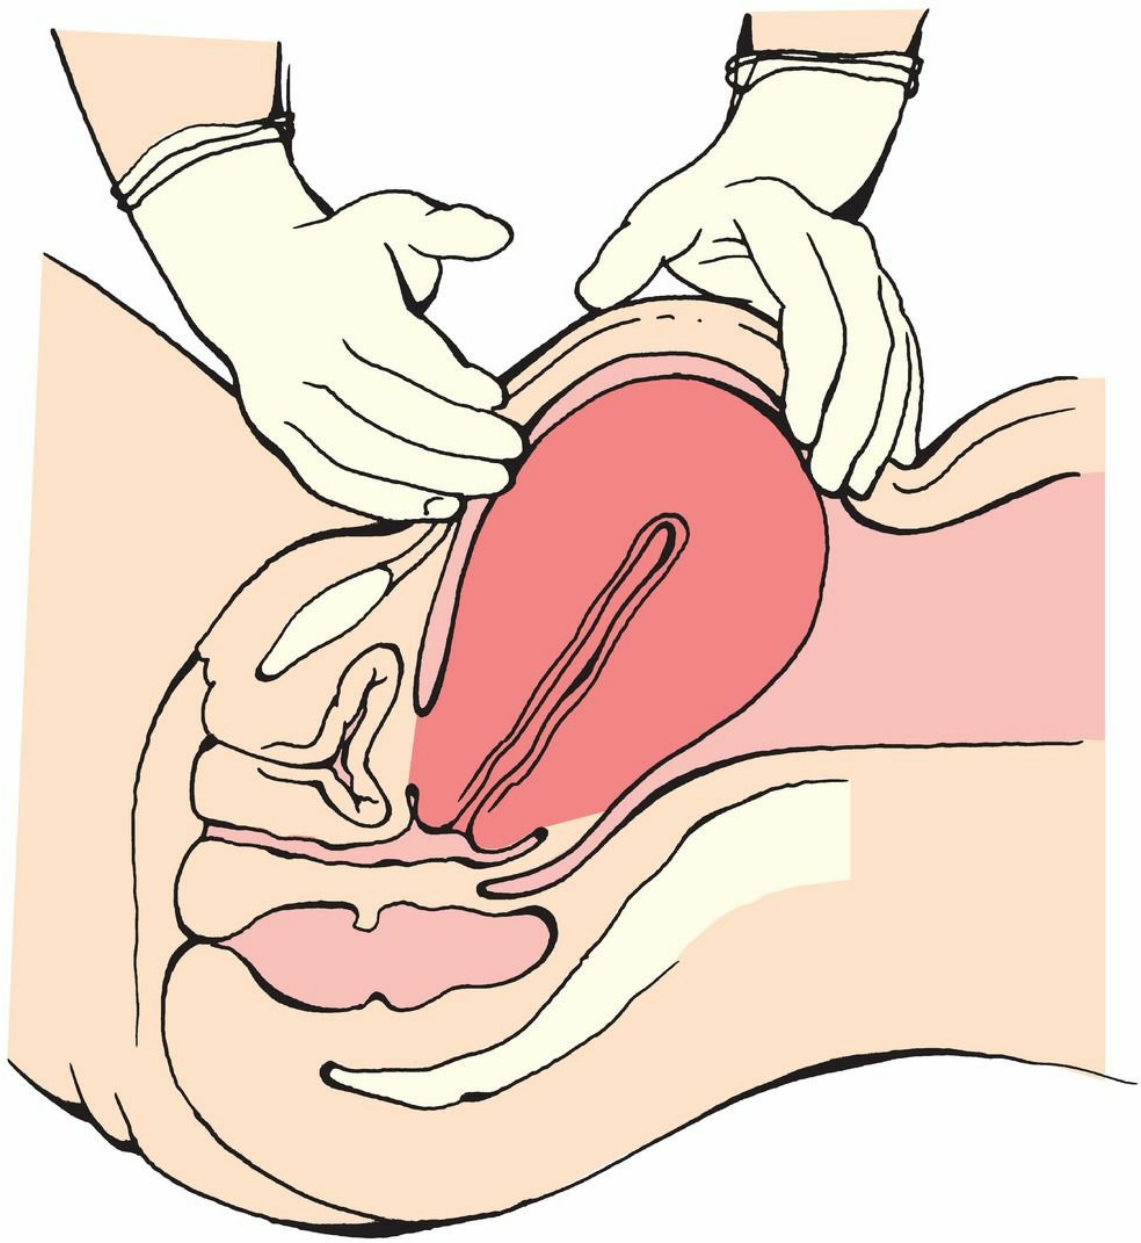

Figure 38-3. Fundal massage. With hands correctly positioned, gentle fundal massage stimulates the uterine muscles to contract, helping to restore normal tone and control bleeding. (Reeder, S., Martin, L., & Koniak-Griffin, D. [1997]. *Maternity nursing: Family newborn, and women's health care* [18th ed.]. Philadelphia, PA: Lippincott-Raven Publishers.)

Nursing Management

EVIDENCE BASE Mattson, S., & Smith, J. E. (Eds.). (2016). *Core curriculum for maternal-newborn nursing* (5th ed.). St. Louis, MO: Saunders Elsevier.

Nursing Diagnoses

- Risk for Deficient Fluid Volume related to blood loss and effects from anesthesia.
- Impaired Urinary Elimination related to birth trauma.
- Constipation related to physiologic changes from birth.
- Risk for Infection related to birth process.
- Fatigue related to labor.
- Acute Pain related to perineal discomfort from birth trauma, hemorrhoids, and physiologic changes from birth.
- Readiness for enhanced self-health management pertaining to postpartum care.
- Breast-feeding: Ineffective related to lack of knowledge and inexperience.

Nursing Interventions

Monitoring for Obstetrical Hemorrhage

1. Monitor vital signs every 4 hours during the first 24 hours and then every 8 to 12 hours or as delineated by facility policy. Observe for the following:
   a. Increased respiratory rate greater than 24 breaths/minute may be caused by increased blood loss, pulmonary edema, or a pulmonary embolus.
   b. Increased pulse rate greater than 100 beats/minute (bpm) may in response to increased blood loss, fever, or pain.
   c. Decrease in blood pressure (BP) 15 to 20 mm Hg below baseline pressures may indicate decreased fluid volume or increased blood loss.
2. Assess the woman for light-headedness and dizziness when sitting upright or before walking.
   a. Assist patient out of bed until stable.
   b. Emphasize to the patient the need for assistance out of bed.
   c. Encourage patient to sit at the bedside prior to ambulating.
3. Evaluate lower extremity sensory function and motor function before ambulation if the woman had regional anesthesia.
   a. Assess regional anesthesia site (epidural/spinal) if applicable.
   b. Evaluate orthostatic BP if symptoms persist.
   c. Have the woman maintain bed rest if symptoms persist.

4. Assess lochia for amount and presence of clots.
5. Maintain IV access and infusion, as ordered.
6. Monitor postpartum hemoglobin levels and hematocrit if ordered.
7. Encourage oral fluids, as tolerated.

Promoting Urinary Elimination

1. Assess for voiding within 6 to 8 hours after delivery.
2. Palpate the abdomen for bladder distention if the woman cannot void or if she complains of fullness after voiding.
   a. Uterine displacement from the midline suggests bladder distention.
   b. Frequent voiding of small amounts of urine suggests urine retention with overflow.
   c. Bladder distention may lead to uterine atony.
3. Utilize a bladder scanner if available to document urine volume.
4. Catheterize the woman with a straight catheter if indicated.
5. Instruct the woman to void every several hours and after meals to keep her bladder empty.

Promoting Bowel Function

1. Teach the woman that bowel activity is sluggish because of decreased abdominal muscle tone, anesthetic effects, effects of progesterone, decreased solid food intake during labor, and opioid use.
2. Inform the woman that pain from hemorrhoids, lacerations, and episiotomies may cause her to delay her first bowel movement.
3. Review the woman's dietary intake with her, and encourage adequate intake of fiber through fresh fruit, vegetables, and at least eight glasses of water daily.
4. Encourage frequent ambulation.
5. Administer stool softeners, as indicated.

Preventing Infection

1. Encourage patient to change peri-pads frequently and use cleansing bottle with warm water.
2. Observe for elevated temperature above 100.4°F (38°C) exclusive of the first 24 hours.
3. Evaluate episiotomy/perineum for REEDA.
4. Assess for pain, burning, and frequency on urination.
5. Assess epidural/spinal site.
6. Administer antibiotics as directed.

Reducing Fatigue

1. Provide a quiet and minimally disturbed environment.
2. Organize nursing care to keep interruptions to a minimum.
3. Encourage the woman to minimize visitors and phone use.

4. Encourage the woman to sleep while the baby is sleeping and specifically to lie down at least 30 minutes/day.

Adequate Pain Management

1. Instruct the woman to apply ice packs to her perineal area for the first 24 hours for perineal trauma or edema and then to apply heat to the area.
    a. Commercial or handmade packs may be used.
    b. Ensure a barrier between the skin and ice.
2. Initiate the use of a warm water sitz baths for 15 to 20 minutes for perineal discomfort after the first 24 hours as needed.
3. Instruct the woman to contract her buttocks before sitting to reduce perineal discomfort.
4. Assist the woman in the use of positioning cushions and pillows while sitting or lying.
5. Encourage frequent perineal cleansing.
6. Provide witch hazel pads or topical creams or ointments for hemorrhoids, as indicated.
7. Administer analgesics as indicated.
    a. Assess for decreased respiratory rate below 12 breaths/minute after receiving opioid analgesics.
8. Assess breasts for signs of engorgement (swollen, tender, tense, shiny breast tissue).
    a. Engorgement in breast-feeding mothers:
        i. Nurse infant on both breasts to ensure adequate emptying of breasts.
        ii. Apply cold packs to breasts after feeding.
        iii. Encourage a warm-to-hot shower water to flow over the breasts to improve comfort, or warm compresses on the breasts may improve comfort.
        iv. Express some milk manually or by breast pump to improve comfort and to make the nipple more available for infant feeding.
        v. OTC analgesics may be used to enhance comfort.
    b. Engorgement in non–breast-feeding mothers:
        i. Instruct the mother to wear a snug and supportive bra at all times and avoid handing her breasts.
        ii. Teach the mother to avoid any stimulation to her breasts including the avoidance of letting warm water fall on her breasts during showers because the heat stimulates milk production.
        iii. Suggest the application of ice or cabbage leaves to the breasts to provide comfort.
        iv. OTC analgesics may be needed to provide comfort.

Promoting Postpartum Health Maintenance

1. **Perineal care:**
    a. Teach the woman to perform perineal care using warm water over the perineum after each voiding and/or bowel movement to promote comfort, cleanliness, and healing.
    b. Promote sitz baths for the same purpose.

c. Teach the woman to apply perineal pads by touching the outside only keeping the side that will touch her perineum clean.

2. **Breasts:**
   a. Assess the condition of the woman's breasts and nipples inspecting nipples for intactness, reddening, ecchymosis, fissures, and pain.
   b. Encourage the mother to ensure an adequate latch and utilize different breast-feeding positions to decrease the risk of sore nipples.
   c. Advise that reddened areas may be improved by expressing colostrum and air-drying nipples.
   d. Commercially prepared lanolin-based creams and ointments may also enhance comfort.
   e. Instruct mother to read labels carefully to determine if ointment needs to be removed before breast-feeding her infant.
   f. Teach the woman to wash her breasts using warm water *without* soap to maintain the protective skin oils and avoid dryness.
   g. Encourage wearing a support bra without underwires for comfort.
3. **Nutrition:**
   a. Instruct mother to eat foods from all food groups with three to four servings of protein, four to six servings of dairy, and four servings each of fruits, grains, and vegetables. Occasional use of caffeine is allowable.
   b. Encourage the woman to continue her prenatal vitamins until her 6-week follow-up appointment.
   c. Increase fluid intake to keep urine pale in color.
   d. Breast-feeding mothers should add 300 to 500 additional calories daily for milk production.
4. **Activity:**
   a. Anatomical and physiologic changes during pregnancy are necessary to consider before beginning an exercise program. Women with uncomplicated pregnancies may resume activity as tolerated to maintain a healthy lifestyle. Women with medical and surgical complications should consult with their provider before doing beginning any exercise program.
   b. Common exercises for all postpartum women may include Kegel exercises, short walks that gradually increase in duration, stationary cycling low-impact aerobics, and modified yoga.

Promoting Breast-Feeding

1. Assist the woman and infant in the breast-feeding process.
   a. Have the mother wash her hands before feeding to help prevent infection.
   b. Encourage the mother to assume a comfortable position, such as sitting upright in the bed or in a chair or side lying.
   c. Have the woman hold the baby so that they are facing each other. Common positions for holding the baby are the cradle hold, with the baby's head and body supported against the mother's arm, with buttocks resting in her hand; the football hold, in which the baby's body and legs are supported under the mother's arm and the head is at the breast, resting in the mother's hand; and side lying with

mother and baby facing each other.

d. Teach the woman to hold the baby close for control and to prevent back, shoulder, and arm strain.
e. Have the woman cup the breast in her hand in a C-position, with bottom of the breast in the palm of her hand and the thumb on top, or the U position, with the fingers and the thumb to the sides of the breast and the breast resting in the palm of the hand.
f. Have the woman place her nipple against the side of the baby's mouth, and when the mouth opens, guide the nipple and the areola into the mouth. The baby should latch on so that as much of the areola as possible is in his or her mouth. If the baby has latched on to the nipple only, break the latch by putting the tip of the mother's finger in the corner of the baby's mouth to break the suction, and then reposition on the breast to prevent nipple pain and trauma.
g. Encourage the woman to alternate the breast with which she begins feeding at each feeding to ensure emptying of both breasts and stimulation for maintaining milk supply.
h. Advise the mother to use each breast at each feeding. Begin with at least 10 minutes at each breast and then increase the time at each breast, allowing the infant to suck until he or she stops sucking actively.
i. Have the mother breast-feed frequently (8 to 12 times/24 hours) to maintain the milk supply. Although there is no time limit on each breast-feeding session, it is recommended to last at least 10 to 15 minutes on each breast.
j. Have the mother express colostrum/milk and apply to nipples; then, air-dry for approximately 15 to 20 minutes after feeding to help prevent nipple trauma.

2. Encourage burping between breasts and at the end of the feeding. Alert the mother that uterine cramping (afterpains) may occur, because of the release of oxytocin needed for milk ejection during feeding. Multiparous women may experience increased discomfort related to decreased uterine tone.
3. Teach the mother to provide for adequate rest periods and nutrition. She should also avoid stress, which can inhibit the let-down reflex and make breast milk less available at feeding.
4. Advise the woman to consult her provider prior to taking any OTC and prescription medications as many substances pass into the breast milk and may also affect milk production or the infant.

Evaluation: Expected Outcomes

- Vital signs within normal limits; decreasing color and amount of lochia.
- Voids freely and without discomfort.
- Lack of constipation; eats high-fiber foods and uses stool softeners.
- Afebrile, no abnormal redness of the perineum, no purulent discharge or foul odor of lochia.
- Verbalizes feeling rested.
- Verbalizes decreased pain.
- Incorporates postpartum care into activities of daily living.
- Demonstrates successful breast-feeding; breasts and nipples intact and without redness or cracks.

Postpartum Patient Education

1. Advise the woman that healing occurs within 2 to 4 weeks; however, evaluation by the health care provider during the follow-up visit is necessary.
2. Inform the woman that intercourse may be resumed when perineal and uterine wounds have healed and when vaginal bleeding has stopped. Inform the woman that normal vaginal secretions may not occur for up to 6 months and use of vaginal lubricants may be helpful. Also, inform the mother that for the first 3 months following delivery, her sexual arousal and desire may be diminished due to infant needs and fatigue. Review methods of contraception. Sexual arousal may cause milk to leak from her breasts; encourage breast-feeding her infant prior to sexual activity. Breast-feeding is not a reliable method of contraception.
3. Inform the woman that menstruation usually returns within 4 to 8 weeks if bottle-feeding; if breast-feeding, menstruation usually returns within 4 months, but may return between 2 and 18 months postpartum. Nursing mothers may ovulate even if they are experiencing amenorrhea. Thus, a form of contraception should be used if pregnancy is to be avoided.
4. Encourage mother to sleep when the baby sleeps and rest when possible. Encourage resuming activities as tolerated and medically indicated (see Activity section). Driving restrictions may be indicated.
5. Counsel the woman to provide quiet times for herself at home and to help her establish realistic goals for resuming her own interests and activities.
6. Encourage the couple to provide times to reestablish their own relationship and to renew their social interests and relationships apart from the infant.
7. Encourage the couple to discuss child care arrangements and return to work plans if appropriate.

NURSING CARE OF THE NEONATE

EVIDENCE BASE American Academy of Pediatrics & American College of Obstetricians and Gynecologists. (2012). *Guidelines for perinatal care* (7th ed.). Washington, DC: Author.

Lowdermilk, D., Perry, S., Cashion, C., & Alden, K. R. (2016). *Maternity and women's health care* (11th ed.). St. Louis, MO: Mosby.

Verklan, M. T., & Walden, M. (Eds.). (2015). *Core curriculum for neonatal intensive care nursing* (5th ed.). St. Louis, MO: Saunders Elsevier.

Physiology of the Neonate

The first 24 hours of life constitutes a highly vulnerable time where the infant must make major physiologic adjustments to extrauterine life. Most neonates transition without difficulty within the first 6 to 10 hours of life.

Transitional Stages

During the period of postnatal transition, six overlapping stages have been identified:

- Stage 1. Receives stimulation (during labor) from the pressure of the uterine contractions and from changes in pressure when the membranes rupture.
- Stage 2. Encounters various foreign stimuli—light, cold, gravity, and sound.
- Stage 3. Initiates breathing.
- Stage 4. Changes from fetal circulation to neonatal circulation.
- Stage 5. Undergoes alteration in metabolic processes, with activation of the liver and GI tract for passage of meconium.
- Stage 6. Achieves a steady level of equilibrium in metabolic processes (production of enzymes, increased blood oxygen saturation, decrease in acidosis associated with birth, and recovery of the neurologic tissues from the trauma of labor and delivery).

Respiratory Changes

Factors Initiating Respiration

1. Mechanical—pressure changes (eg, compression of the fetal chest with delivery) from intrauterine life to extrauterine life produce stimulation to initiate respirations.
2. Chemical—changes in the blood, as a result of transitory asphyxia, include:
    a. Cessation of placental blood flow.
    b. Lowered oxygen level.
    c. Increased carbon dioxide level.
    d. Lowered pH—if asphyxia is prolonged, depression of the respiratory center (rather than stimulation) occurs and resuscitation is necessary.
3. Sensory—light (visual), sound (auditory), olfactory, and tactile stimulation, beginning in utero with uterine contraction and when the infant is touched and dried, contribute to the initiation of respiration by stimulating the neonate's respiratory center in the brain.
4. Thermal—a drop in environmental temperature produced by sudden chilling of the moist infant stimulates the respiratory center in the brain.
5. First breath—maximum effort is required to expand the lungs and to fill the collapsed alveoli.
    a. Surface tension in the respiratory tract and resistance in lung tissue, thorax, diaphragm, and respiratory muscles must be overcome.
    b. First active inspiration comes from a strong contraction of the diaphragm, which creates a high

negative intrathoracic pressure, causing a marked retraction of the ribs and distention of the alveolar space. (Any remaining fluid is reabsorbed rapidly if the pulmonary capillary blood flow is adequate because the fluid is hypotonic and passes easily into the capillaries.)

6. Contributing factors, such as pulmonary blood flow, surfactant production, and respiratory musculature, also increase the respiratory effort of the neonate.

Character of Normal Respirations

1. First period of reactivity occurs immediately after birth. Vigorous, diffuse, purposeless movements alternate with periods of relative immobility/inactivity.
2. Respirations are rapid, as frequent as 80 breaths/minute, accompanied by tachycardia, 160 to 180 breaths/minute.
3. Relaxation occurs and the infant usually sleeps; he or she then awakes to a second period of activity. Oral mucus may be a major problem during this period.
4. Respirations are reduced to 30 to 60 breaths/minute and become quiet and shallow; respiration is carried out by the diaphragm and abdominal muscles.
5. Period of dyspnea and cyanosis may occur suddenly in an infant who is breathing normally; this may indicate an anomaly or a pathologic condition.
6. Pauses in respirations of less than 20 seconds are normal in the neonatal period.

Circulatory Changes

1. Cord clamping causes increased systemic vascular resistance (SVR), an increase in blood pressure, and increased pressures in the left side of the heart.
2. Functional closure of the ductus venosus shunt and anatomic closure the first week of life (see page 984).
3. With the neonate's first breath, the foramen ovale shunt functionally closes. Permanent closure occurs by 3 months of age.
4. Increased SVR, falling pulmonary vascular resistance (PVR), and increased sensitivity to rising arterial oxygen concentrations in the blood = closure of ductus arteriosus shunt. The shunt is completely closed in all infants by 96 hours of age with permanent closure within 3 weeks to 3 months of age.
5. Blood volume can be as high as 300 mL/kg immediately after birth and then decrease to 80 to 85 mL/kg shortly after birth. Factors that influence blood volume:
   a. Maternal blood volume (affected by maternal diseases and iron intake).
   b. Placental function.
   c. Uterine contractions during labor.
   d. Amount of blood loss associated with delivery.
   e. Placental transfusion at birth with delayed cord clamping—increase in blood volume of 60% if cord is clamped and cut after pulsation ceases.
6. Acrocyanosis (cyanosis in hands and feet) is a normal finding related to sluggish peripheral circulation in the first 24 hours after birth.

7. Normal apical pulse rate 110 to 160 bpm; may rise to 180 bpm when the infant is crying or drop to 80 to 110 bpm during deep sleep.
8. Blood pressure in the term newborn ranges from 60 to 80 mm Hg systolic and 30 to 60 mm Hg diastolic at birth and varies with gestational age, weight, activity, and appropriate cuff size (slightly higher in legs).
    a. A systolic BP in the upper extremities that is 20 mm Hg greater than in the lower extremities strongly suggests coarctation of the aorta.
    b. BP measurement is best accomplished with an automated noninvasive blood pressure (NIBP) device while the infant is at rest.
9. Coagulability is temporarily diminished due to a vitamin K deficiency because a sterile gastrointestinal tract. Vitamin K synthesis begins after 5 hours of bacterial colonization in the intestinal tract.
    a. Coagulation time is 5 to 8 minutes (in a glass tubes), 5 to 15 minutes (room temperature), or 30 minutes (silicone tube).
    b. Bleeding time is 2 to 4 minutes.
    c. Prothrombin 50%, decreasing to 20% to 30% (approximately 13 to 18 seconds).
10. Values for blood components in the neonate:
    a. Hemoglobin, 14.5 to 22 g/dL.
    b. Hematocrit, 14% to 72%.
    c. Reticulocytes, 4% to 6%.
    d. Leukocytes, 9,000 to 34,000/mm^3.

Temperature Regulation

1. Temperature instability in the term newborn can be the result of anatomical and physiological factors such as a thin subcutaneous adipose tissue, blood vessels closer to the skin, and larger body surface to body weight ratio.
2. Heat loss in term newborns may occur at birth by radiation, convection, evaporation, and conduction.
    a. Radiation—transfer of heat from neonate to cooler object not in direct contact with the infant.
    b. Convection—transfer of heat when flow of cool air passes over infant's skin.
    c. Evaporation—loss of heat when water on infant's skin is converted to vapor.
    d. Conduction—transfer of heat when neonate comes into direct contact with cooler surface/object.
3. Infants respond readily to environmental heat and cold stimuli and develop mechanisms to counterbalance heat loss.
    a. Vasoconstriction—blood directed away from skin surfaces.
    b. Insulation—from subcutaneous adipose tissue.
    c. Heat production—by nonshivering thermogenesis (brown fat metabolism) elicited by the sympathetic nervous system's response to decreased temperatures; activated by adrenaline.
    d. Fetal position—by assuming a flexed position.

Basal Metabolism

1. Surface area of infant, especially the head, is large in comparison to weight.
2. Basal metabolism per kilogram of body weight is higher than that of an adult.
3. Calorie requirements are high—110 to 130 calories/kg of body weight per day.

Renal Function

Neonatal kidneys have functional deficiency in concentrating urine and coping with fluid and electrolyte fluctuations. Low arterial BP and increased renal vascular resistance lead to the following effects:

1. Decreased ability to concentrate urine because of low tubular resorption rate and low levels of antidiuretic hormone.
2. Limited ability to maintain water balance by excretion of excess water or retention of needed water.
3. Decreased ability to maintain acid–base mechanism; slower excretion of electrolytes, especially sodium and hydrogen ions, results in accumulation of these substances, which predisposes the infant to dehydration, acidosis, and hyperkalemia.
4. Excretion of large amount of uric acid during neonatal period—appears as brick dust stain on diaper.

Hepatic Function

Function limited because of lack of GI tract activity, deficiency in forming plasma proteins, and limited blood supply; consequences include the following:

1. Decreased ability to conjugate bilirubin (rationale for physiologic jaundice).
2. Decreased ability to regulate blood glucose concentration (less glycogen stores) (rationale for neonatal hypoglycemia).
3. Deficient production of prothrombin and other coagulation factors that depend on vitamin K for synthesis (rationale for neonate's predisposition to hemorrhage).

Endocrine Function

Endocrine glands are better organized than other systems: disturbances are most commonly related to maternally provided hormones. This can cause the following:

1. Vaginal discharge (or bleeding [pseudomenstruation]) in female infants.
2. Enlargement of mammary glands (breast engorgement) in both sexes—related to increased estrogen, luteal, and prolactin activity. Milky secretions may be present (witch's milk).
3. Disturbances related to maternal endocrine pathology (eg, mother with diabetes or mother with inadequate iodine intake).

GI Changes

The neonate's intestinal tract is proportionately longer than the adult's; however, elastic tissue and musculature are not fully developed and neurologic control is variable and inadequate.

1. Most digestive enzymes are present, with the exception of pancreatic amylase and lipase. Protein and

carbohydrates are easily absorbed, but fat absorption is poor.

2. Limitations relate primarily to anatomic structures and neutrality of the gastric contents.
3. Limited production of pancreatic amylase leads to inadequate utilization of complex carbohydrates.
4. Immaturity of the cardiac and pharyngoesophageal sphincters and neurological control causes mild regurgitation or slight vomiting.
5. Irregularities in peristaltic motility slow stomach emptying.
6. Peristalsis increases in the lower ileum, resulting in stool frequency—one to six stools per day. No stools within 48 hours after birth may be indicative of intestinal obstruction such as imperforate anus.

Neurologic Changes

Neurologic mechanisms are immature; they are not fully developed anatomically or physiologically. As a result, uncoordinated movements, labile temperature regulation, and poor control over musculature are characteristic of the infant. Reflexes are important indicators of infant neural development (see page 1027).

Nursing Assessment

Delivery of effective neonatal care is enhanced by effective communication of information about the mother and her infant with the interprofessional team.

Pertinent Maternal History

1. Mother's age, socioeconomic status, ethnic or cultural group, educational level, and marital status.
2. Mother's/family's past medical history.
3. Mother's past obstetric history.
4. Mother's prenatal history with current pregnancy includes rubella status, hepatitis B testing, mental health history, domestic violence, or history of previous child abuse or neglect and also includes other maternal test results relevant to neonatal care (ie, human immunodeficiency virus test results and colonization with group B hemolytic streptococci, STIs).
5. Labor and delivery (includes intrapartum maternal antibiotic therapy, along with type and dosage of antibiotics).

Physical Assessment Findings and Physiologic Functioning

Posture

1. Full-term neonate assumes symmetric posture; face turns to side with full mobility; flexed extremities; hands tightly fisted with thumb covered by fingers.
2. Asymmetric posture may be caused by fractures of the clavicle and humerus or nerve injuries (commonly of the brachial plexus).
3. Infants born in the breech position may keep knees and legs straightened or in frog position, depending on the type of breech birth.

Length

Newborn (full-term) length ranges from 18 to 22 inches (46 to 56 cm) with an average of 20 inches (51 cm).

Weight

The weight of a full-term infant ranges from 2,500 to 4,000 g (5 pounds 8 ounces to 8 pounds 13 ounces).

Skin

Infants should be examined under natural light and observed for the following:

1. Hair distribution—term infant will have some lanugo over back; most of the lanugo will have disappeared on extremities and other areas of the body.
2. Turgor—term infant should have good skin turgor (ie, after gently pinching small portion of the skin and releasing it, the skin should return to its original position).
3. Color.
    a. Peripheral cyanosis (acrocyanosis) is bluish discoloration of the hands and feet related to

vasoconstriction and sluggish peripheral circulation. It is a normal finding and may be exacerbated by cold temperatures.

b. Central cyanosis is an indication of reduced arterial oxygen saturation. Persistent central cyanosis requires immediate intervention.

c. Pallor—may indicate cold, stress, anemia, or cardiac failure.

d. Plethora—reddish (ruddy) coloration may be caused by a high level of RBCs to total blood volume from intrauterine intravascular transfusion (twins), cardiac disease, or diabetes in the mother.

e. Jaundice—physiologic jaundice caused by immaturity of the liver is common beginning on day 2, peaking at 1 week, and disappearing by the 2nd week. It first appears in the skin over the face or upper body and then progresses over a larger area; it can also be seen in conjunctivae of the eyes.

f. Meconium staining of the skin, fingernails, and umbilical cord indicates passage of meconium in utero (possibly caused by fetal hypoxia in utero).

4. Dryness/peeling—marked scaling and desquamation are signs of postmaturity.
5. Vernix—in full-term infants, it may be found in skin folds under the arms and in the groin under the scrotum (in males) and in the labia (in females). Increased amounts of vernix may indicate prematurity.
6. Nails—should reach end of fingertips and be well developed in the full-term infant. There should be no evidence of pits, ridges, aplasia, or hypertrophy.
7. Edema—some edema may occur over buttocks, back, and occiput if the infant has been supine; pitting edema may be caused by erythroblastosis, heart failure, and electrolyte imbalance.
8. Ecchymosis—may appear over the presenting part in a precipitous or prolonged delivery; may also indicate infection or a bleeding problem.
9. Petechiae—pinpoint hemorrhages on the skin caused by increased intravascular pressure, infection, or thrombocytopenia; usually resolves within 48 hours.
10. Erythema toxicum (newborn rash)—small white, yellow, or pink to red papular rash that appears on the trunk, face, and extremities.
11. Hemangiomas—vascular lesions present at birth; some may fade, but others may be permanent.
    a. Strawberry (nevus vasculosus)—bright red, raised, lobulated tumor that occurs on the head, neck, trunk, or extremities; soft, palpable, with sharp demarcated margins; increases in size for approximately 6 months and then regresses after several years.
    b. Cavernous—larger, more mature vascular elements; involves dermis and subcutaneous tissues; soft, palpable, with poorly defined margins; increases in size the first 6 to 12 months and then involutes spontaneously.
12. Telangiectatic nevi (stork bites)—flat red or purple lesions most commonly found on the back of the neck, lower occiput, upper eyelid, and bridge of the nose; regress by age 2, although the ones on the neck may persist through adulthood.
13. Milia—enlarged sebaceous glands found on the nose, chin, cheeks, brow, and forehead; regress in several days to a few weeks. They appear as multiple yellow or pearly white papules, approximately 1 mm in diameter. When found in the mouth, they are referred to as Epstein pearls.

14. Mongolian spots—blue-green or gray pigmentation on the lower back, sacrum, and buttocks; common in Blacks (90%), Asians, and infants of southern European heritage; regress by age 4. May be mistaken for signs of child abuse.
15. Café au lait spots—tan or light brown macules or patches. When less than 1¼ inches (3 cm) in length and less than 6 in number, there is no pathologic significance; if greater than 1¼ inches or more than 6 in number, it may indicate cutaneous neurofibromatosis.
16. Harlequin color change—when on side, dependent half turns red and upper half pale; caused by gravity and vasomotor instability.
17. Abrasions or lacerations can result from internal monitoring and instruments used at birth.
18. Cutis marmorata—bluish mottling or marbling of the skin in response to chilling, stress, or overstimulation.
19. Port-wine nevus (nevus flammeus)—flat pink or reddish-purple lesion consisting of dilated, congested capillaries directly beneath the epidermis; does not blanch.

Head

1. Examine the head and face for symmetry, paralysis, shape, swelling, movement.
    a. Caput succedaneum—swelling of soft tissues of the scalp because of pressure; swelling crosses suture lines. May be associated with vacuum-assisted birth or prolonged second stage of labor (pushing).
    b. Cephalohematoma—subperiosteal hemorrhage with collection of blood between the periosteum and bone; swelling does not cross suture lines. May result from vacuum-assisted birth or prolonged second stage of labor.
    c. Molding—overlapping of skull bones, caused by compression during labor and delivery (disappears in a few days).
    d. Examine symmetry of facial movements.
    e. Forceps marks—U-shaped bruising usually on the cheeks following forceps delivery.
2. Measure head circumference—13 to 14 inches (33 to 35.5 cm), approximately ¾ inch (2 cm) larger than the chest. Measure just above the eyebrows and over the occiput.
3. Fontanelles—area where more than two skull bones meet; covered with strong band of connective tissue; also called the soft spot.
    a. Enlarged or bulging—may indicate increased intracranial pressure (ICP).
    b. Sunken—commonly indicates dehydration.
    c. Size—posterior may be obliterated because of molding; generally closes in 2 to 3 months. Anterior is palpable; generally closes in 12 to 18 months.
4. Sutures—junctions of adjoining skull bones.
    a. Overriding—caused by molding during labor and delivery.
    b. Separation—extensive separation may be found in malnourished infants and with increased ICP.

Face

1. Eyes—examine the following:
    a. Color—the sclera in most full-term infants is white; subconjunctival hemorrhages are common from the birth process; blue sclera is indicative of osteogenesis imperfecta. Eye color is usually slate gray, brown, or dark blue; final eye color is evident by 6 to 12 months.
    b. Hemorrhagic areas—subconjunctival hemorrhages may appear as a red band from pressure during delivery; regress within 2 weeks.
    c. Edema—edema of the eyelids may be caused by pressure on the head and face during labor and delivery.
    d. Conjunctivitis or discharge—may be caused by instillation eye prophylaxis or infections from organisms, such as staphylococcus, chlamydia trachomatis, or gonococcus. Tear formation does not usually begin until age 2 to 3 months.
    e. Jaundice—may be seen in the sclera because of physiologic or pathological jaundice.
    f. Pupils—equal in size and should constrict equally in bright light.
    g. Infant can see and discriminate patterns; limited by imperfect oculomotor coordination and inability to accommodate for varying distances.
    h. Red reflex—red-orange color seen when light from an ophthalmoscope is reflected from the retina. No red reflex indicates cataracts.
    i. Brushfield spots—white or yellow pinpoint areas on the iris that may indicate trisomy 21 or even a normal variant.
    j. Abnormal placement of eyes or small eye openings can signify a syndrome or chromosomal anomaly.
    k. Strabismus—cross-eyed appearance that is common; nystagmus (constant, rapid, involuntary movement of the eye) is also common and disappears by age 4 months.
2. Nose—examine the following:
    a. Patency—necessary because infants are obligate nose breathers.
    b. Nasal flaring—abnormal and may indicate respiratory distress. Check for appropriate size and shape of the nose; should be placed vertically midline in the face.
    c. Discharge—stuffiness is normal unless chronic nasal discharge is present; may be caused by possible infection.
    d. Sense of smell—infants will turn toward familiar odors and away from noxious odors.
    e. Septum should be midline; low nasal bridge with broad base may be associated with Down syndrome.
    f. Periodic sneezing is common to clear nasal passages. Excessive sneezing may be an indication of neonatal abstinence syndrome.
3. Ears—Formation: large, flabby ears that slant forward may indicate abnormalities of the kidney or other parts of the urinary tract.
    a. Position in relation to the eye—helix (top of the ear) on the same plane as the eye; low-set ears may indicate chromosomal or renal abnormalities.
    b. Cartilage—full-term infant has sufficient cartilage to make the ear feel firm.

c. Hearing—auditory canals may be congested for a day or 2 after birth; the infant should hear well in a few days. Hearing screening may be performed prior to discharge.

d. Observe for skin tags; preauricular sinus located in front of the ear may be normal or may be associated with genetic disorders.

4. Mouth—examine the following:

a. Size—small mouth found in trisomy 18 and 21; corners of the mouth turn down (fish mouth) in fetal alcohol syndrome. Mucous membranes should be pink.

b. Palate—examine hard and soft palate for closure.

c. Size of the tongue in relation to the mouth—normally does not extend much past the margin of gums. Excessively large tongue seen in congenital anomalies, such as cretinism and trisomy 21.

d. Teeth—predeciduous teeth are found on rare occasions; if they interfere with feeding or pose an aspiration risk, they may be removed.

e. Epstein pearls—small white nodules found on sides of hard palate (commonly mistaken for teeth); regress in a few weeks.

f. Ankyloglossia—thin or thick ridge of tissue running from base of the tongue along undersurface to the tip of the tongue. Most require no intervention, but depending on the extent of ankyloglossia, breast-feeding and speech may be impacted and require further evaluation.

g. Sucking blisters (labial tuberales)—thickened areas on midline of the upper lip that may be filled with fluid or callous; no treatment necessary.

h. Infections—thrush, caused by *Candida albicans*, may appear as white patches on the tongue and/or insides of cheeks that do not wash away with fluids; treated with nystatin suspension.

Neck

1. Mobility—can the infant move the head from side to side; palpate for lymph nodes; palpate the clavicle for fractures, especially after a difficult delivery.
2. Torticollis—observe for spasmodic, one-sided contraction of neck muscles; generally from a shortened sternocleidomastoid muscle; physical therapy may be indicated.
3. Excessive skin folds may be associated with congenital abnormalities such as trisomy 21.
4. Stiffness and hyperextension may be caused by trauma or infection.
5. Clavicle—assess for intactness, fractures, and masses such as cystic hygroma, soft and usually seen laterally or over the clavicle.

Chest

1. Circumference and symmetry—average circumference is 12 to 13 inches (30.5 to 33 cm), approximately ¾ inch (2 cm) smaller than head circumference.
2. Breast.

a. Engorgement—may occur at day 3 because of maternal hormones, especially estrogen; no treatment required. Regresses in 2 weeks.

b. Nipples and areolae—less formed and pronounced in preterm infants.

Respiratory System

1. Rate—normally between 30 and 60 breaths/minute; influenced by sleep–wake status, hunger, medication, and temperature.
2. Rhythm—respirations may be shallow with irregular rhythm.
   a. Respiratory movements are symmetric and mainly diaphragmatic because of weak thoracic muscles. For example, the lower thorax pulls in and the abdomen bulges with each respiration.
   b. Periodic breathing—resumption of respiration after 5- to 15-second period without respiration; decreases with time; more common in preterm infants. Substernal retractions, if accompanied by gasps or stridor, are indicative of upper airway obstruction.
   c. Observe for abnormal respiratory signs.
3. Breath sounds—determined by auscultation.
   a. Bronchial sounds are heard over most of the chest.
   b. Crackles may be heard immediately after birth.
   c. Expiratory grunting may be indicative of respiratory distress.

Cardiovascular System

1. Rate—normal between 110 and 160 bpm (80 to 110 normal with deep sleep); influenced by behavioral state, environmental temperature, and medication; take apical count for 1 minute.
2. Rhythm—common to find periods of deceleration followed by periods of acceleration.
3. Heart sounds—second sound higher in pitch and sharper than first; third and fourth sounds rarely heard; murmurs common; majority are transitory and benign.
4. Pulses—examine equality and strength of brachial, radial, pedal, and femoral pulses; lack of femoral pulses indicative of inadequate aortic blood flow (coarctation).
5. Cyanosis—examine for central cyanosis. Record location of any cyanosis and color changes with time and when crying.
6. Blood pressure—blood pressure in the term newborn ranges from 60 to 80 mm Hg systolic and 30 to 60 mm Hg diastolic at birth and varies with gestational age, weight, activity, and appropriate cuff size. BP is usually higher in the lower extremities than in the upper extremities. BP assessment may not be conducted routinely on healthy neonates. Measurement of BP is essential for infants who show signs of distress, are premature, or are suspected of having a cardiac anomaly.

Abdomen

1. Shape—cylindrical, protrudes slightly, moves synchronously with chest in respiration. Diastasis recti is a common occurrence in the newborn and characterized by a separation of the right and left sides of the rectus abdominis muscle.
2. Distention may be caused by bowel obstruction, organ enlargement, or infection.
3. Palpate the abdomen for masses; palpate the liver and spleen.

a. The liver has decreased ability to conjugate bilirubin (rationale for physiologic jaundice).
b. The liver has decreased production of prothrombin and factors that depend on vitamin K for synthesis (rationale for neonate's predisposition to hemorrhage).

4. Auscultate abdomen in all four quadrants for bowel sounds; usually bowel sounds occur 1 hour after delivery.
5. Kidneys—palpate kidneys for size and shape.
   a. Infant has decreased ability of the kidney to concentrate urine, excrete a solute load, and maintain water and electrolyte balance.
   b. Urine may contain uric acid crystals, which appear on diaper as reddish blotches; uric acid crystals may yield false-positive result when the infant's urine is tested for protein.
6. Umbilical cord.
   a. Normally contains two arteries, one vein; single artery sometimes associated with renal and other congenital abnormalities.
   b. Signs of infection (omphalitis) around insertion into abdominal wall—redness, discharge.
   c. Meconium staining—associated with intrauterine compromise or postmaturity.
   d. By 24 hours, becomes yellowish brown; dries and falls off in approximately 10 to 14 days.
   e. Umbilical hernia—defect in abdominal wall.
7. Genitalia.
   a. Female:
      i. Labia majora cover labia minora and clitoris in full-term female infants.
      ii. Hymenal tag (tissue) may protrude from the vagina—regresses within several weeks.
      iii. Vaginal discharge—white mucus discharge common; pink-tinged mucus discharge (pseudomenstruation) may be present because of the drop in maternal hormones; no treatment necessary.
   b. Male:
      i. Full-term—testes in scrotal sac; scrotal sac appears markedly wrinkled because of rugae.
      ii. Edema may be present in scrotal sac if the infant was born in breech presentation; a collection of fluid in the scrotal sac is a hydrocele—regresses in approximately a month.
      iii. Examine glans penis for urethral opening—normally central; opening ventral (hypospadias); opening dorsally (epispadias); abnormally adherent foreskin (phimosis).
   c. Check for patent anus—infant should stool within 24 hours after delivery.

Back

1. Examine spinal column for normal curvature, closure, and pilonidal dimple or sinus; also for fluid-filled sac, exposed nerves, or other skin abnormality seen with spinal bifida.
2. Examine anal area for position, anal opening, response of anal sphincter (anal wink reflex), and fissures.

Musculoskeletal System

1. Examine extremities for fractures, paralysis, range of motion, and irregular position.
2. Examine fingers and toes for number and separation: extra digits (polydactyly) and fused digits (syndactyly).
3. Examine hips for dislocation—with the infant in supine position, flex knees and abduct hips to side and down to table surface; clicking sound (Ortolani sign) and clunking sound (Barlow sign) indicate dislocation or subluxation. Asymmetrical gluteal folds may also indicate congenital hip dislocation.
4. Examine feet for structural and positional deformities, that is, club foot (talipes equinovarus) or metatarsus adductus (inward turning of the foot).

Neurologic System

1. Neurologic mechanisms are immature anatomically and physiologically; as a result, uncoordinated movements, temperature instability, and lack of control over musculature are characteristic of the infant.
2. Examine muscle tone, head control, and reflexes.
3. Two types of reflexes are present in the neonate:
   a. Protective in nature (blink, cough, sneeze, gag)—remain throughout life.
   b. Primitive in nature (rooting/sucking, Moro, startle, tonic neck, stepping, and palmar/plantar grasp)—either disappear within months or become highly developed and voluntary (sucking and grasping) (see Figure 38-4, page 1027).

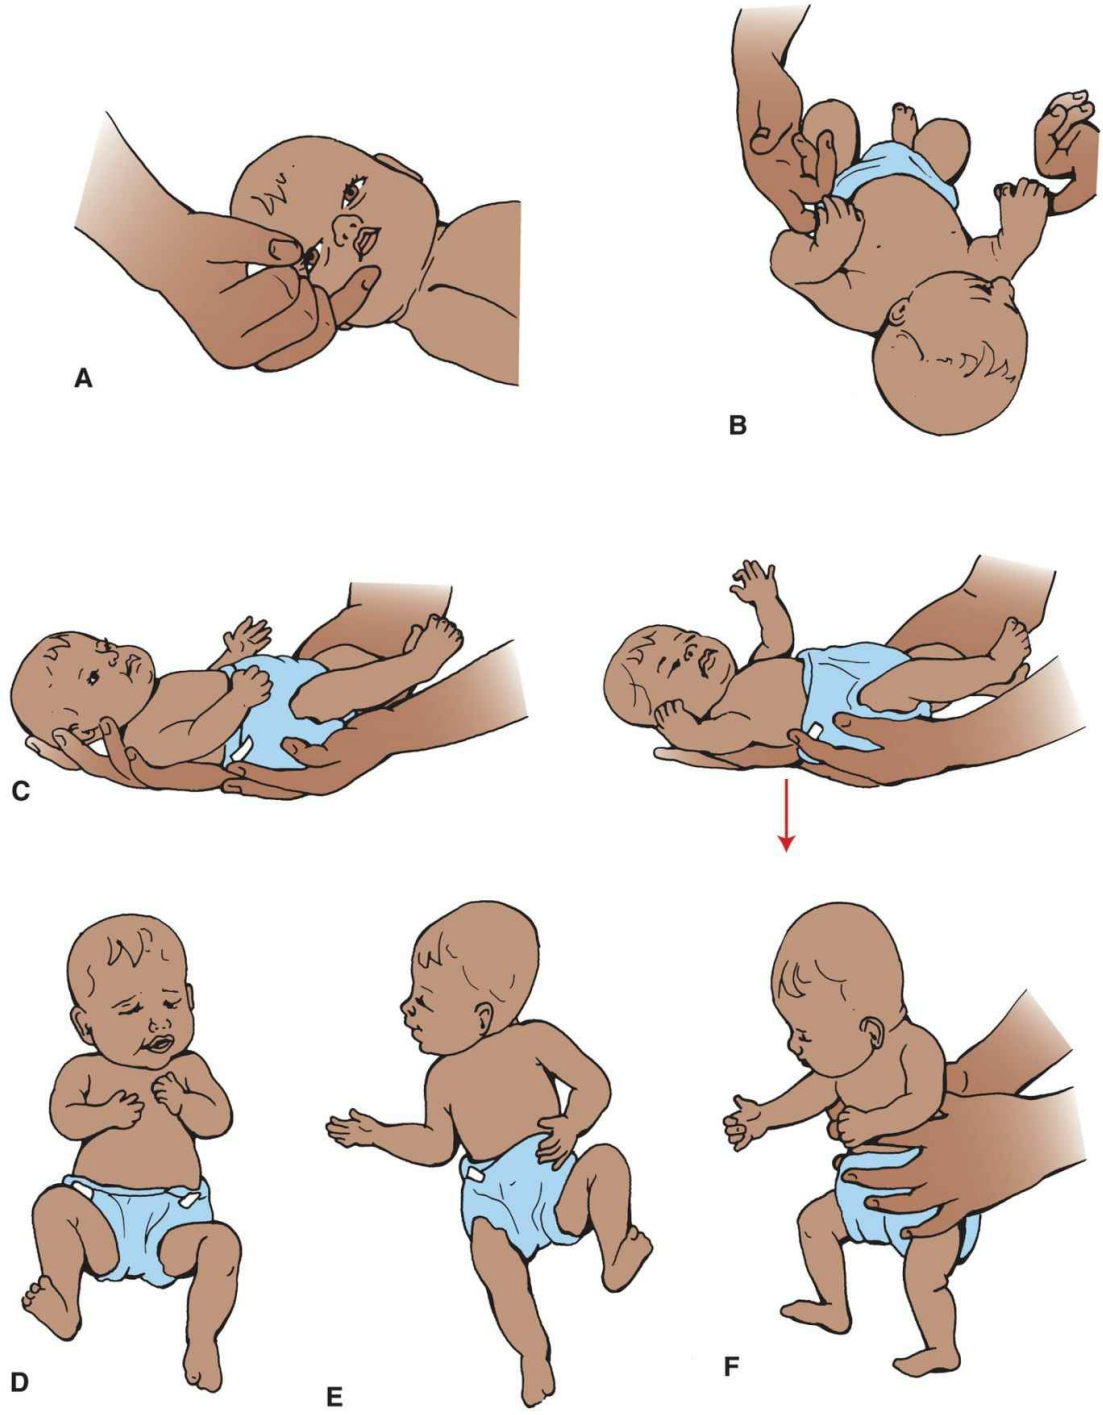

Figure 38-4. Newborn reflexes. **(A)** Rooting. **(B)** Grasp. **(C)** Moro. **(D)** Startle. **(E)** Tonic neck. **(F)**Stepping. (Reeder, S., Martin, L., & Koniak-Griffin, D. [1997]. *Maternity nursing: Family newborn, and women's health care* [18th ed.]. Philadelphia, PA: Lippincott-Raven Publishers.)

Behavioral Assessment

Response to Stimulation

1. Neonates exhibit predictable, directed responses in social interactions with nurturing adults or in

response to attractive auditory or visual stimuli.

2. Neonate responses are influenced by states of consciousness, such as:
    a. Quiet, deep sleep (sleep state)—no spontaneous activity, eyes closed, and respirations regular, with delayed response to external stimuli.
    b. Light, active sleep (sleep state)—random startles, eyes closed, REMs, and frequent change of state with response to stimulation.
    c. Drowsy awake (transitional state)—eyes open or closed, appearing dull and heavy lidded, eyelids flutter, variable activity level, mild startles periodically, and delayed response to stimulation.
    d. Quiet alert (awake state)—eyes open, little motor activity, focuses on source of stimulation. Interacts most with environment; respirations regular.
    e. Alert active (awake state)—eyes open, less bright and attentive, much motor activity, and increase in startles in response to stimulation.
    f. Crying (awake state)—intense crying that is difficult to interrupt with stimulation; increased motor activity and color changes.

Sleeping Pattern

1. Length of sleep cycles (REM, active and quiet sleep) changes with maturation of the central nervous system (CNS).
2. Quiet sleep should increase with time in relation to REM sleep.
3. Neonates usually sleep 20 hours/day.
4. Safe sleep positions should be discussed with families.
5. Prone positioning has been shown to increase the risk of sudden infant death syndrome. The AAP recommends that all healthy infants be positioned supine for sleep.

Feeding Pattern

1. Most breast-fed neonates eat 10 to 12 times per day with 2 to 4 hours between feedings; establish fairly regular feeding patterns in approximately 2 weeks. Formula-fed babies eat every 3 to 4 hours.
2. Caloric requirements are high—110 to 130 calories/kg of body weight daily.
3. Most digestive enzymes are present at birth.
4. Immaturity of the cardiac and pharyngoesophageal sphincters and neurological control causes mild regurgitation or slight vomiting.

Pattern of Elimination

1. Stools.
    a. Meconium is usually passed in 24 to 48 hours.
    b. Passage of meconium (tarry green-black stools) continues for about 72 hours, followed by transitional stools (greenish brown to yellowish brown; thin; may contain milk curds). Milk stools (for breast-fed, yellow to golden; pasty; odor like sour milk; for formula-fed, pale yellow to light brown; firmer; more offensive odor) are passed by day 4 to 5.

c. Neonate has up to six stools per day in the first weeks after birth.

2. Voiding.
   a. Neonate voids within first 24 hours.
   b. After first few days, infant voids from at least six to eight times per day.

Temperature Regulation

1. Infant's body responds readily to changes in environmental temperature.
2. Heat loss at birth may occur through evaporation, convection, conduction, and radiation.
3. Physiologic mechanisms to avoid heat loss include:
   a. Vasoconstriction.
   b. Nonshivering thermogenesis elicited by sympathetic nervous system in response to decreased temperature.
   c. Adipose tissue and brown fat—the latter contains many small blood vessels, fat vacuoles, and mitochondria and is a site of heat production. Brown fat is found between scapulae, around the neck and thorax, behind the sternum, and around kidneys and adrenals.
   d. Flexed position of full-term neonate.

Universal Newborn Screening

EVIDENCE BASE American Academy of Pediatrics. (2015). Hospital stay for healthy term newborn infants. *Pediatrics, 135*(5), 949–953.

Public health law requires newborn screening for disorders caused by inborn errors of metabolism, hemoglobinopathies, infectious diseases, and specific genetic and endocrine disorders. The United States requires testing for 31 core disorders and 26 secondary disorders. In addition, infants are screened for hearing loss, hyperbilirubinemia, and cardiac defects.

1. Blood spot testing—obtain blood by heel stick for the following conditions.
   a. Phenylketonuria—inability of the infant to metabolize phenylalanine; scheduled after 24 hours of protein feedings.
   b. Galactosemia—inborn error of carbohydrate metabolism, in which galactose and lactose cannot be converted to glucose.
   c. Hypothyroidism—thyroid hormone deficiency.
   d. Maple syrup urine disease—inability to metabolize leucine, isoleucine, and valine.
   e. Homocystinuria—inborn error of sulfur amino acid metabolism.
   f. Sickle cell anemia—abnormally shaped RBCs with lower oxygen solubility.
   g. Cystic fibrosis—autosomal recessive genetic disorder affecting the respiratory, endocrine, and

gastrointestinal systems.

h. Human immunodeficiency virus (HIV)—weakens the immune system by reducing CD4 cells (T cells) and increasing the risk for opportunistic infection and acquired immunodeficiency syndrome (AIDS).

2. Hearing screening—screen newborn before discharge using an automated auditory brainstem hearing device or an otoacoustic emission device.
   a. If the infant passes the screening, no further action is needed.
   b. If the infant fails the screening, the testing should be repeated before discharge or on an outpatient basis.
   c. With repeated failed screening, the infant should be evaluated by a pediatric audiologist.
3. Hyperbilirubinemia screening—complete a systematic risk screening for hyperbilirubinemia prior to discharge. Use the serum bilirubin result from the blood spot metabolic screen and plot it on the Hour-Specific Nomogram (*www.bilitool.org*).
   a. A treatment plan should be identified for infants at risk.
   b. Parents should be provided with information on feeding, symptoms of increasing jaundice, and follow-up care.
4. Critical congenital heart disease (CCHD) screening—obtain oxygen saturation by pulse oximetry, according to recommendation by the U.S. Department of Health and Human Services (HHS). Screen after 24 hours of age using pre and post ductal oxygen saturation values taken for 60 seconds.

Discharge Readiness

EVIDENCE BASE American Academy of Pediatrics & American College of Obstetricians and Gynecologists. (2012). *Guidelines for perinatal care* (7th ed.). Washington, DC: Author.

---

1. The American Academy of Pediatrics (AAP established guidelines with suggested criteria for newborn discharge where readiness for discharge is determined in consultation with the maternal and newborn providers and the mother. The following criteria apply to the term newborn (37 0/7 to 41 6/7 weeks' gestation):
   a. Family, environmental, and social risk factors have been assessed for safety.
   b. Physical assessment and clinical course were unremarkable for abnormalities.
   c. The newborn is stable with documented vital signs within normal ranges for 12 hours prior to discharge; temperature 36.5°C to 37.4°C (97.7°F to 99.3°F); respirations below 60 bpm; no signs of respiratory distress; heart rate 100 to 190 while awake.
   d. Pertinent laboratory data have been reviewed and within normal limits for mother and neonate. Cord or infant blood type and direct Coombs results (if required) have been reviewed.

e. Neonate has spontaneously passed at least one stool spontaneously and urinated.
f. Neonate stable, maintaining thermal homeostasis in an open crib, and feeding well with at least two successful feedings with coordinated sucking, swallowing, and breathing. If breast-feeding, the infant latch has been assessed by a qualified caregiver.
g. If circumcised, no excessive bleeding from circumcision site for 2 hours post procedure.
h. All necessary vaccines have been administered to the newborn (eg, hepatitis B) according to current AAP immunization schedules.
i. Maternal immunizations such as Tdap, varicella, rubella, and influenza are administered if not previously immunized. Additionally, any adolescent or adults with close contact to infant should be immunized for Tdap and influenza.
j. Risk assessment for jaundice has been determined with appropriate home management and follow-up according to AAP guidelines.
k. Adequate evaluation for sepsis has been completed according to AAP guidelines.
l. Hearing screening, congenital hip dysplasia screening, newborn metabolic screening, and pulse oximetry for critical congenital heart disease (CCHD) have been completed per facility protocol.
m. The mother's ability to provide appropriate care to her newborn is documented with teaching related to feeding, elimination, infant care, temperature assessment, signs and symptoms of illness, common newborn problems, and infant safety (nicotine-free environment, safe sleep, car seat, and sibling safety).
n. An appropriate car seat for infant's maturity and medical condition is available at discharge.
o. Family members and support persons are available for support.
p. Mother aware of possible complications for self and neonate.
q. Facility has in place mechanisms to address patient questions after discharge.
r. Plan for follow-up medical care is in place. For infants discharged before 48 hours of birth, follow-up should occur within the next 48 hours.
s. Provide mother with lactation support resources.

2. Assess the parents ability to provide daily care of the infant.
   a. Advise the parents to attend or view parenting and baby care classes offered during their stay at the birth facility.
   b. Assess the parents' ability to bathe and diaper the infant, perform circumcision care, and initiate either breast- or bottle-feeding.
   c. Assess bonding and encourage skin-to-skin contact, infant eye contact, and talking to and touching the infant.
3. Assess parents' knowledge of signs of illness and when to notify health care provider.
   a. Fever above 100.4°F (37.8°C).
   b. Loss of appetite for two consecutive feedings.
   c. Inability to awaken the baby to his or her usual activity state.

d. Vomiting all or part of two feedings.
e. Diarrhea—three watery stools.
f. Extreme irritability or inconsolable crying.

4. Assess the parents' technique to properly use an infant car seat in the back seat, facing back.
5. Provide positive reinforcement and reassurance to the parents.
6. Further assess any knowledge gaps and provide written instructions and educational material on discharge.

TRANSITIONAL CARE ALERT Newborn readmission to the hospital increases with primiparity, maternal morbidity, prematurity, operative vaginal delivery, and small for gestational age infants. Discharge readiness should be assessed by the interprofessional team. Discharge instructions should include a thorough discussion of the infant's sleeping, eating, activity, and response patterns for the first month of life. Parents should be alert for signs and symptoms of illness including when to call the provider.

Nursing Management

In caring for the neonate, the nurse establishes an ongoing care plan for the infant and the family until discharge. The nurse's assessment of the neonate includes observing and recording vital signs, daily weight gain or loss, bowel and bladder function, activity and sleep patterns, and thermoregulation. Observation for potential problems in the neonate, ensuring safety, and the prevention of infection are the main goals of nursing care.

Another main component of caring for the neonate is to assist with establishing a healthy family unit. Because so much of the baby's time is spent with parents, the nurse has the opportunity to assist them with promoting health maintenance by teaching feeding methods and by demonstrating baby care techniques, such as diapering, bathing, and circumcision care. The nurse provides health counseling and education and answers questions to enable the parents to gain confidence, control, and satisfaction in caring for their child at home.

PROBLEMS OF THE NEWBORN

See additional online content: Procedure Guidelines 38-1

PROCEDURE GUIDELINES 38-1

Newborn Care

Nursing Action	Rationale
Weight, measurements, temperature, vital signs, blood pressure, and blood glucose—gloves must be worn when handling all unbathed newborns.	
1. Weigh infant and record weight daily. a. Measurements: Head, chest, and abdominal circumferences per facility policy for baseline.	1. Newborn may lose 5% to 10% of birth weight because of minimal intake of nutrients and fluid loss.
2. Take axillary temperature by placing thermometer in axilla and pressing the infant's arm gently but firmly against it until temperature is displayed.	2. Evidence supports the correlation of axillary and rectal temperatures. Minimizes discomfort and the potential risk of perforation.
3. Take blood pressure, if indicated.	3. Hypotension may be present. A mean arterial pressure (MAP) <40 could be an indication of hypovolemia in a term neonate and requires further evaluation.
4. Assess apical pulse and respirations per facility policy.	4. Tachypnea and tachycardia require further evaluation and interventions.
5. Blood glucose testing if indicated according to facility policy.	5. Newborn may be hypoglycemic related to depletion of glycogen stores used during the birth process and require further evaluation and intervention.
Bathing—gloves must be worn when handling all unbathed newborns.	
1. Gather equipment: Cotton balls, washcloths, towels, mild soap (varies with facility), petrolatum for circumcision care and protective ointment if indicated, diaper, wipes, T-shirts, hat, and blankets.	
2. Use a radiant warmer for initial bath to prevent heat loss.	
3. Whenever possible, include parents in bathing demonstration.	3. Increases paternal bonding and confidence.
4. Use cotton balls or soft washcloths to wipe eyes, face, and outer ears without soap. Eyes are wiped from inside corner outward.	4. Moves secretions from cleanest to most soiled area.
5. Use a neutral soap and warm water (98°F to 100°F [37°C to 38°C]) to bathe the infant. Start by washing the infant's head using gentle circular motions.	5. Prevents irritation of skin.
6. Tilt the head back to cleanse the neck.	6. Exposes neck folds for more thorough cleansing.
7. Bathe the torso and extremities quickly.	7. Prevents unnecessary exposure and chilling.
8. Carefully dry each area after washing.	8. Prevents heat loss and maintains thermoregulation.
9. Inspect umbilical cord during sponge bath and with diaper changes. Keep stump clean and dry. Check area for redness, bleeding, or foul odor. Do not cover with diaper. Teach parents to look for sign and symptoms of infection (omphalitis) to report to provider.	9. Minimizes colonization by bacteria. According to the AAP—For deliveries outside the hospital settings and in resource-limited populations (eg, Native American communities), the application of prophylactic topical antimicrobial agents to the umbilical cord remains appropriate.
10. Cleanse the genital area of urine and stool. No need to remove all vernix. For female infants, wipe vulva from front to back direction.	10. Front-to-back cleansing prevents contamination of vagina.
a. Cleanse uncircumcised penis without retracting foreskin, teaching parents to do the same.	a. Edema and constriction of the penis may result if foreskin is retracted.
b. Circumcision care—keep area clean by rinsing area with warm water and avoiding friction. Apply petrolatum to penis for 1 to 3 days during diaper changes with Mogen and Gomco methods of circumcision. Observe for bleeding and signs of infection.	b. Prevents infection and promotes healing. Bleeding can be controlled by pressure. If bleeding persists and signs of infection are present, further evaluation by the provider is required.
11. Bathe buttocks, using a gentle, patting motion. Keep area clean and dry to prevent diaper rash. If rash does occur, protective ointments (zinc oxide or vitamin A & D) may be used. Air drying may be helpful.	11. Area is susceptible to skin breakdown because of exposure to urine and feces.
12. Diaper, cover head with a hat, and rewarm skin to skin with mother.	12. Rewarming skin to skin is effective and preferred by mothers
13. After rewarming, dress in T-shirt and hat and swaddle with blanket per facility policy.	13. Maintains thermoregulation and prevents cold stress.

Nursing Action	Rationale
Elimination	
1. Stool pattern	1. Passage denotes adequate peristalsis.
a. Observe stool pattern—meconium during first 2 to 3 days.	a. Meconium is composed of epithelial and epidermal cells, lanugo, and bile pigments.
b. Transitional stools—change from tarry black to greenish black, to greenish brown to brownish yellow to greenish yellow.	b. Changes reflect intake of milk—stools are composed of meconium and milk stools.
c. Number, color, and consistency are recorded daily.	c. For early identification of abnormalities
	i. No stools within 48 hours indicates an intestinal obstruction.
	ii. Passage of meconium only (without changes) suggests obstruction in the ileum.
	iii. Diarrhea may be caused by overfeeding or gastroenteritis.
	iv. Blood in the stools requires further evaluation.
2. Urinary output	
a. Infant should void within 24 hours of birth and within a few days should void 6 to 8 times per day.	a. Assures renal function.
b. Breast-fed newborns should have at least 3 to 5 voids in a 3- to 5-day period.	b. Exclusively breast-fed infants receive a decreased fluid volume until lactogenesis is established.
Nutritional considerations	
1. Provide for nutritional intake.	1. Nutritional intake is essential for adequate growth and development.
2. Promote feeding method of choice.	2. Although recommendations may be made, family decisions should be respected and continuity of care provided.
3. Breast-feeding—at least 8 to 12 times per day for 10 to 15 minutes per breast and on demand. Instruct mother on football, cross cradle, cradle, and side-lying holds. Observe for proper latch and provide lactation support.	3. Human breast milk supports optimal growth and development with nutritional, immunological, cognitive, psychological, social, economic, and environmental benefits.
4. Bottle-feed ½ to 1 ounce every 3 to 4 hours initially. Teach parents proper preparation of formula and to read labels carefully. Formula can be given at room temperature. Microwaving formula is contraindicated.	4. Commercially prepared formulas offer an alternative to breast milk and provide an acceptable nutrient composition to meet the needs of rapidly growing newborns. Microwaving formula can lead to scalding and the destruction of antimicrobial properties present in formula preparations.
5. Instruct the parent in technique of bottle-feeding	
a. Hold infant in semi-upright position.	a. Gravity assists flow of milk into stomach.
b. Position bottle so that nipple is filled.	b. Prevents the infant from swallowing air leading to abdominal distention.
c. Insert nipple into infant's mouth so that his or her tongue is under nipple and assess suck–swallow–breathing coordination during feeding	c. Sucking and swallowing reflexes are used in feeding.
d. Burp during feeding by holding infant upright every ½ ounce initially.	d. Allows air to escape from stomach, preventing distention and regurgitation. Some regurgitation is normal related to immature cardiac and pharyngoesophageal sphincters in newborns.

Nursing Action	Rationale
Community and home care considerations	
1. Preparation for discharge: Assess for newborn stability and family preparedness to adequately care for infant.	1. Instruction for newborn care is a combined responsibility of the interprofessional team.
a. Provide instruction for infant care, feeding, and safety. Discuss signs and symptoms of common newborn problems and access to health care resources.	
b. Provide breast-feeding mothers with lactation support information.	
c. Consult with social work for home follow-up visits if necessary.	
2. Provide family-centered nursing care, taking every opportunity to teach, demonstrate, and offer support.	2. Family-centered nursing care respects dignity, cultural awareness, and supports parental decision-making and integration of the newborn into the family structure.

Premature Infant

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2013/Reaffirmed 2015). Medically indicated late-preterm and early-term deliveries. (Committee Opinion #560). Washington, DC: Author.

Verklan, M. T., & Walden, M. (Eds.). (2016). *Core curriculum for neonatal intensive care nursing*. St. Louis, MO: Saunders Elsevier.

The *premature neonate* is a neonate born before the completion of 37 weeks' gestation. Other classifications include moderately preterm (32 to 36 weeks), late preterm (34 0/7 to 36 6/7 weeks), early term (37 0/7 to 38 6/7 weeks), and very preterm birth (less than 32 weeks).

A low-birth-weight (weight at birth) neonate is one whose birth weight is less than 2,500 g (5 pounds, 8 ounces), regardless of gestational age.

A very-low-birth-weight neonate is one whose birth weight is below 1,500 (3 pounds, 5 ounces), regardless of gestational age.

An extremely-low-birth-weight neonate is one whose birth weight is below 1,000 g (2 pounds, 2 ounces), regardless of gestational age.

Pathophysiology and Etiology

1. A wide range of maternal factors is associated with prematurity.
2. Possible risk factors associated with prematurity include, but are not limited to:
    a. Chronic health problems, such as hypertension, obesity, or diabetes.
    b. Behavioral and environmental risks, such as late or no prenatal care, smoking, substance abuse, domestic violence, stress, or lack of social support.
    c. Demographic risks, such as non-Hispanic black race, younger than age 17, older than age 35, or low socioeconomic status.
    d. Genetic endowment.
    e. Assisted reproductive technologies (ART).
    f. Medical risks in current pregnancy, such as preeclampsia or gestational hypertension, bleeding, placenta previa or abruptio placentae, uterine or cervical anomalies (incompetent cervix), premature rupture of membranes, preterm premature rupture of membranes, polyhydramnios or oligohydramnios, infection, or periodontal disease.
    g. Changes in delivery practices, concern about postmaturity complications, or risk of stillbirth (late preterm).
3. Fetal factors associated with prematurity include:

a. Chromosomal abnormalities.
b. Anatomic abnormalities, such as tracheoesophageal atresia or fistula and intestinal obstruction.
c. Fetoplacental unit dysfunction.

4. The premature infant has altered physiology because of immature and typically poorly developed systems. The severity of any problem that occurs depends on the gestational age of the infant. Systems and situations that are most likely to cause problems in the premature infant include:
   a. Respiratory system.
   b. Digestive system.
   c. Thermoregulation.
   d. Immune system.
   e. Neurologic system.

Nursing Assessment and Interventions

1. Notice physical characteristics of the premature neonate:
   a. Hair—lanugo, fluffy.
   b. Poor ear cartilage.
   c. Skin—thin; capillaries are visible (may be red and wrinkled).
   d. Lack of subcutaneous fat.
   e. Sole of the foot is smooth.
      i. 36 weeks' gestation—anterior one third of the foot is creased.
      ii. 38 weeks' gestation—two third of the foot is creased.
   f. Breast buds 5 mm.
      i. 36 weeks' gestation—none.
      ii. 38 weeks' gestation—1¼ inches (3 cm).
   g. Testes—undescended.
   h. Labia majora—undeveloped.
   i. Rugae of scrotum—fine.
   j. Fingernails—soft.
   k. Abdomen—relatively large.
   l. Thorax—relatively small.
   m. Head—appears disproportionately large.
   n. Muscle tone poor and possibly weak reflexes.
2. Obtain accurate body measurements.
   a. Head circumference—frontal–occipital circumference one finger above eyebrows, using parallel lines of tape around the head.
   b. Abdominal girth—one finger above umbilicus, mark location.

c. Heel to crown.

d. Shoulder to umbilicus—used to calculate proper length of catheter for umbilical catheter placement.

e. Weight in grams.

3. Assess gestational age (see Figure 38-5) using a tool such as the New Ballard scoring system (recommended by the Committee of Fetus and Newborn of AAP):

   a. Observation of physical and neurologic characteristics that change predictably with growth and maturation. Ideally done in the first 12 to 24 hours of life.

   b. Later, adjusted, or corrected age will be determined once the neonate reaches term (40 weeks after conception). Chronological age is adjusted for prematurity by taking gestational age – 40 + chronologic age = developmental or corrected age. This is the age the neonate would have been if he or she had been born at 40 weeks' gestation.

4. Assist with laboratory testing, as indicated, for blood gases, blood glucose, complete blood count or hemoglobin and hematocrit, electrolytes, calcium, and bilirubin.

5. Monitor closely for respiratory or cardiac complications.

   a. Respirations above 60 per minute and an oxygen saturation below 92% may indicate respiratory difficulty. Expiratory grunting, retractions, chest lag, or nasal flaring should be reported immediately. Respiratory distress syndrome (RDS) is a common complication of prematurity where the etiologic cause is the decreased level of surfactant production.

   b. Watch for cyanosis (other than acrocyanosis—coldness and cyanosis of hands and feet) and other signs of respiratory distress.

   c. Increased (greater than 180 bpm) or irregular heart rate may indicate cardiac or circulatory difficulties.

   d. Muscle tone and activity should be evaluated.

   e. Hypotension, indicated by BP measurement, may be caused by hypovolemia.

   f. Hypoglycemia may result from inadequate glycogen stores, respiratory distress, and cold stress.

6. Institute cardiac monitoring and care for infant in isolette or radiant heater. Defer bathing until infant's temperature has stabilized. Temperature instability is a risk factor for hypoglycemia.

7. Observe for early signs of jaundice and check maternal history for any blood incompatibilities. Also, be aware of maternal factors that can lead to additional complications, such as drug use, diabetes, and infection.

8. Once the infant is admitted to the nursery, be aware that the first 24 to 48 hours after birth is a critical time, requiring constant observation and intensive care management. Assess for the following:

   a. Umbilicus—if umbilical lines are in use, observe for bleeding—apply pressure and notify provider.

   b. Urinary output—first void within 24 hours and monitor every 2 to 4 hours. Stools—abdominal distention and lack of stools may indicate intestinal obstruction or other intestinal tract anomalies. Measure abdominal girth at regular intervals.

   c. Activity and behavior—look for sucking movement and hand-to-mouth maneuver, which can help to

determine oral feeding initiation depending on gestational age.

d. Observe for a tense and bulging fontanelle; palpate suture lines, noting separation or overriding—may indicate intracranial hemorrhage. Be alert to twitching and seizures.

e. Color—cyanosis, jaundice, rashes, paleness, and ruddiness.

f. Carefully monitor, document, and report vital signs to the interprofessional team as necessary.

9. Have resuscitative equipment, oxygen, and suction available.

a. A bulb syringe is used for clearing the mouth and nose.

b. Frequent suctioning of the pharynx may not be necessary and should be used judiciously.

c. May need to assist with intubation for administration of exogenous surfactant depending on the infant's gestational age and clinical presentation.

10. Position to optimize ventilation, with careful attention to maintaining body alignment nesting extremities with blankets.

a. Elevate head and trunk to decrease pressure on the diaphragm from abdominal organs.

b. Change position from side to side.

NURSING ALERT Prone positioning offers some advantage for oxygenation in preterm neonate with respiratory compromise. During the initial phase of illness, these infants are cared for with cardiorespiratory monitoring and may be placed prone according to your facility's policy.

Before discharge, these neonates should be placed supine for sleep with alternating head position. Positioning should be reinforced with the parents.

---

11. Provide humidified oxygen therapy in percentages necessary to maintain appropriate oxygen saturation and/or blood gas values.

a. Continuous oxygen saturation monitoring is recommended when oxygen is in use and until infant is stable.

b. Continuous cardiac monitoring is recommended to assess for apnea and bradycardia episodes.

12. Monitor for apnea (pauses more than 20 seconds) versus periodic breathing (regular repetition of breathing pauses of less than 15 seconds, alternating with breaths of regularly increasing then decreasing amplitude for 10 to 15 seconds). Medications (ie, theophylline and caffeine) may be given to reduce apneic episodes.

13. Protect the infant from infection by maintaining standard and aseptic practices at all times. Follow facility policies related to visitation by family members.

14. Provide meticulous skin care avoiding adhesives and providing adequate hydration.

15. Avoid deformational plagiocephaly (misshapen head) by frequent repositioning and facility-approved devices such as the "cranial cup" or gel pads.

16. Protect the neonate's eyes from bright lights.
17. Continue to provide IV and oral feedings according to neonate's needs. Assist the mother with breast pumping, as needed, and encourage parents to hold and feed infant based on infant status.
18. Continue to monitor for complications, such as hypo/hyperglycemia, respiratory distress syndrome (see page 1186), apnea, pneumothorax, infection, hypocalcemia, cardiac abnormalities, necrotizing enterocolitis (NEC), intracranial hemorrhage, and hyperbilirubinemia. Long-term complications may include retinopathy of prematurity, chronic lung disease, hearing loss, and learning disabilities.
19. Make every effort to include parents in their infant's care and update them frequently on the infant's condition.

Figure 38-5. Ballard assessment of gestational age criteria. (Reprinted from *Journal of Pediatrics*, 119/3, Ballard J. L., Khoury J. C., Wedig K., et al., New Ballard score, expanded to include extremely premature infants, 417–423, Copyright 1991, with permission from Elsevier.)

The Postterm Infant

The postterm newborn infant is one whose gestation is 42 weeks or longer and who may show signs of weight loss with placental insufficiency.

EVIDENCE BASE American Academy of Pediatrics & American Heart Association. (2016). *American Academy of Pediatrics & American Heart Association, Textbook of neonatal resuscitation* (7th ed.). Chicago, IL: American Academy of Pediatrics.

Mattson, S., & Smith, J. E. (Eds.). (2014). *Core curriculum for maternal-newborn nursing* (5th ed.). St. Louis, MO: Saunders Elsevier.

Pathophysiology and Etiology

1. Cause is not known in many cases. Maternal factors associated with postmaturity include nulliparity, a prior postterm pregnancy, carrying a male fetus, and maternal obesity.
2. Anencephaly and placental sulfatase deficiency are disorders associated with postterm delivery.
3. Maternal risks include:
    a. Trauma to the perineum related to possible fetal macrosomia.
    b. Increased risk of infection, hemorrhage, operative vaginal delivery (forceps, vacuum), and cesarean delivery.
    c. Psychological stress and anxiety.
4. Fetal risks include:
    a. Increased risk of mortality and morbidity.
    b. Increased risk of hypoxia related to an aging placenta and decreased amount of amniotic fluid.
    c. Increased risk of meconium aspiration syndrome (MAS).
    d. Increased risk of trauma related to macrosomia and shoulder dystocia.
    e. Increased risk of seizures.
    f. Increased risk of an Apgar score of less than 4 at 5 minutes of life.

Nursing Assessment and Interventions

1. Be alert for the physical appearance of a postterm neonate. The following characteristics are most commonly seen in postterm neonate:
    a. Reduced subcutaneous tissue—loose skin, especially of buttocks and thighs.
    b. Long, curved fingernails and toenails.
    c. Minimal amount of vernix caseosa.
    d. Abundant scalp hair.

e. Wrinkled, macerated skin; possibly pale, peeling skin.
f. Having the alert appearance of a 2- to 3-week-old neonate after delivery.
g. Greenish-yellow staining of the skin, fingernails, or cord may indicate fetal stress in utero.

2. Determine gestational age by physical examination and New Ballard Scale. Measure weight, length, and head circumference.
3. Monitor blood glucose per facility policy; below 40 mg/100 mL indicates hypoglycemia.
4. Assess for asphyxia neonatorum by Apgar score and blood gas analysis.
5. Assess for meconium aspiration; signs include:
   a. Thick meconium in amniotic fluid at delivery.
   b. Tachypnea, increasing signs of cyanosis; difficulty breathing, with need for ventilation.
   c. Tachycardia.
   d. Inspiratory nasal flaring and retraction of the chest.
   e. Expiratory grunting.
   f. Increased anteroposterior diameter of the chest.
   g. Crackles and rhonchi on chest auscultation.
   h. Concomitant cerebral irritation—jitteriness, hypotonia, and seizures.
   i. X-ray—classic coarse, patchy, streaky areas with irregular pulmonary infiltrates ranging in severity.
   j. Additional signs: metabolic acidosis, hypotension, hypoglycemia, and hypocalcemia.
6. Provide supportive care for the prevention of meconium aspiration syndrome (MAS). The consistency of the meconium in the amniotic fluid (thin vs. thick) is no longer used to determine the need for tracheal suctioning.
   a. The indication for *selective* intubation and tracheal suctioning of an infant exposed to meconium in utero includes any infant who is nonvigorous. The neonatal resuscitation program (NRP) defines a nonvigorous infant as an infant who meets one or more of the following conditions: depressed respirations, depressed muscle tone, or heart rate below 100 beats/minute.
   b. A contraindication to *selective* intubation and tracheal suctioning is apparent vigor. The NRP defines a vigorous infant as one with all of the following: strong respiratory effort, good muscle tone, or heart rate above 100 beats/minute.
7. Supportive care measures include:
   a. Warmth—maintain a thermoregulated environment to reduce oxygen and calorie consumption and preserve glycogen stores.
   b. Adequate humidified oxygenation to maintain oxygen saturation of 90% to 95%.
   c. Respiratory support with a ventilator may be necessary.
   d. Adequate administration of calories and fluid.
   e. Accurate monitoring of vital signs and intake and output—to assess possible alteration in kidney function caused by hypoxia.
   f. Administration of antibiotics prophylactically.

8. Provide oral feeding or IV glucose soon after birth to treat or prevent hypoglycemia. If oral feedings are not contraindicated, they can begin 1 to 2 hours after birth. Monitor blood sugar until condition stabilizes per facility policy.
9. Be alert for persistent pulmonary hypertension of the newborn (PPHN)—physiologic disorder characterized by severe, labile cyanosis arising from persistent or return to suprasystemic pulmonary vascular resistance and pressure normally found in the fetus.
    a. Cyanosis, pronounced respiratory distress, murmur, and heart failure.
    b. Treatment is aggressive respiratory support in a tertiary care nursery.
10. Provide psychological support to the parents and encourage participation.

Infant of a Diabetic Mother

A mother may have a diabetes diagnosis prior to pregnancy, overt (unrecognized, preexisting) diabetes or gestational diabetes (GDM). The severity of neonatal problems will depend on the maternal diabetic control of blood glucose prenatally and perinatally. A neonate may be termed infant of diabetic mother (IDM).

Pathophysiology and Etiology

Hyperinsulinemia in utero, secondary to elevated maternal glucose levels, results in the following in the neonate:

1. Macrosomia/large for gestational age (LGA)—increased amount of body fat, not edema.
    a. Total body water is somewhat reduced at birth.
    b. High urine output during the first 2 days of life, probably from freeing of intracellular water.
    c. Large trunk and chest increasing risk of shoulder dystocia.
2. Hypoglycemia (defined as serum glucose less than 40 mg/dL).
    a. In utero, the fetus produces insulin to metabolize glucose independently of maternal endocrine function. With the cessation of maternal glucose transfer at birth, fetal hyperinsulinemia may result in hypoglycemia.
    b. Occurs within first ½ to 12 hours of life; may occur within minutes after birth.
    c. The neonate's response to glucose is excessive (ie, insulin blood level has a slight elevation, will drop, and then peak within 1 hour). This response is probably caused by maternal hyperglycemia.
    d. Neonate may be asymptomatic; therefore, care assessment for hypoglycemia is essential to improve outcomes.
    e. When hypoglycemia is present, symptoms may include the following: lethargy, jitteriness, poor feeding, vomiting, pallor, apnea, irregular respirations, hypotonia, tremors, seizure activity, and high-pitched cry.
3. Hypocalcemia (less than 7 mg/dL).
    a. Associated with prematurity, difficult labor and delivery, asphyxia at birth, and decreased functioning of parathyroid glands.
    b. Generally occurs during the first 24 to 72 hours of life.
    c. Tremors are characteristic and may be secondary to prematurity or stress during pregnancy, labor, and birth.
    d. The infant may also have hypomagnesemia (less than 1.4 mg/dL) resulting from functional hypoparathyroidism because of maternal magnesium loss.
4. Polycythemia and hyperbilirubinemia.
    a. Most likely to occur within 48 to 72 hours after birth.
    b. Immature liver results in inability to conjugate bilirubin.
    c. Hematocrit is higher on the third day after birth and extracellular volume is decreased.
    d. Because of large size, birth trauma may increase risk of cephalohematoma.

e. May be premature or small for gestational age when associated with placental insufficiency in some cases.

f. Respiratory function is similar to that of other premature neonates. Thus, neonate is prone to RDS.

5. Polycythemia.
   a. Venous hematocrit greater than 65% or venous hemoglobin 22 g/100 mL.
   b. Polycythemia increases the risks of occurrence of jaundice, renal vein thrombosis, respiratory distress, hypoglycemia, and hypocalcemia.
6. Congenital anomalies.
   a. Increased incidence of congenital anomalies may be caused by:
      i. Divergent gene pattern.
      ii. High glucose concentrations early in pregnancy.
      iii. Episodes of ketoacidosis in early pregnancy.
   b. Common anomalies are renal, CNS, caudal regression syndrome, small colon syndrome, facial clefts, and cardiac defects such as patent ductus arteriosus, transposition of the great vessels, and ventricular septal defect.
7. Infection.
   a. Prematurity and lowered passive immunity.
   b. Possible maternal UTI and chorioamnionitis.

Nursing Assessment and Interventions

1. Assess for typical appearance of IDM—macrosomia, large chest and shoulders, cardiomegaly, hepatomegaly, large umbilical cord and placenta, plethora, full-face, tendency to be large for gestational age (some may be normal weight or small for gestational age), abundant fat, abundant hair, liberally coated with vernix caseosa, and hypertrichosis pinnae (excessive hair growth on the external ear).
2. Assist with diagnostic evaluation of the infant.
   a. Maternal history of diabetes.
   b. Physical assessment of neonate and determination of gestational age.
   c. Laboratory tests—serum glucose, calcium, phosphorus, magnesium, electrolytes, bilirubin, arterial blood gas analysis, blood hemoglobin, and hematocrit as ordered.
3. Monitor for hypoglycemia.
   a. Monitor serum glucose levels every 30 to 60 minutes beginning immediately after birth for 24 hours and then every 4 to 8 hours until stabilized per facility policy.
   b. May be asymptomatic or may show signs of jitteriness, tremors, convulsions, sweating, cyanosis, weak or high-pitched cry, uncoordinated and/or diminished suck/swallow reflex, hypotonia, apnea, and temperature instability.
4. Hypoglycemia may be prevented or treated by early breast or formula feeding. Persistent hypoglycemia may require an IV infusion of 10% dextrose to maintain serum glucose concentrations above 40 mg/dL.

Facility protocols should be followed.

5. Monitor neonate closely for changes in acid–base status, respiratory distress, temperature instability, hypocalcemia, and sepsis.
6. Observe for hyperbilirubinemia.
   a. IDM infants have a higher incidence of hyperbilirubinemia.
   b. Levels will be elevated 48 to 72 hours after birth.
7. Be aware that the neonate may require phototherapy. An exchange transfusion may also be necessary to prevent kernicterus. Monitor intake and output, ensure adequate fluid intake, and assess for dehydration.
8. Observe for possible cardiac anomalies and secondary heart failure.
9. Observe for other complications, including RDS, renal vein thrombosis, infection, hypermagnesemia or hypomagnesemia, birth injuries (encephalohematomas, facial nerve paralysis, fractured clavicles, brachial nerve plexus injuries), prematurity, asphyxia neonatorum, and organomegaly.
10. Provide supportive care to the family and encouraging full participation in care.

Jaundice in the Newborn (Hyperbilirubinemia)

EVIDENCE BASE American Academy of Pediatrics & American College of Obstetricians and Gynecologists. (2012). *Guidelines for perinatal care* (7th ed.). Washington, DC: Author.

Hyperbilirubinemia (jaundice) in the neonate is an accumulation of serum bilirubin above normal levels. Onset of clinical jaundice is seen when serum bilirubin levels are 5 to 7 mg/100 dL. Jaundice appears first on the face and progresses and serum bilirubin levels increase. Bilirubin levels above 20 mg/100 dL cross the blood–brain barrier.

Kernicterus is the yellow discoloration of specific areas of brain tissue by unconjugated bilirubin and can be confirmed only by death and autopsy. Bilirubin encephalopathy best describes the occurrence of the syndrome and the accompanying neurologic sequela in neonates.

Pathophysiology and Etiology

Causes

1. Increased bilirubin load.
   a. Hemolytic disease—Rh and ABO incompatibility.
   b. Morphologic abnormalities of RBCs.
   c. RBC enzyme defects.
   d. Physiologic jaundice.
   e. Sepsis.
2. Extravascular blood.
   a. Cephalohematoma.
   b. Pulmonary or cerebral hemorrhage.
   c. Any enclosed occult blood.
3. Decrease or inhibition of bilirubin conjugation.
   a. Inherited bilirubin conjugation defect: Crigler-Najjar syndrome (deficiency of glucuronyl transferase needed to conjugate bilirubin).
   b. Acquired bilirubin conjugation defect: breast milk jaundice, Lucey-Driscoll syndrome, IDM, asphyxiated infant with respiratory distress.
4. Increased extrahepatic circulation.
   a. Intestinal obstruction.
   b. Ileus.
5. Polycythemia.
   a. Twin–twin transfusion.

b. Maternal–fetal transfusion.
c. IDM.
d. Infant small for gestational age.

6. Hypothyroidism.
7. Familial, transient—associated with inhibiting factor in plasma.
8. Obstructive disorders (ie, biliary atresia).
9. Intrauterine infection.
10. Postterm infants.

Physiologic Jaundice

1. Increased bilirubin load for conjugation on immature liver cells.
   a. Increased bilirubin production related to rapid hemolysis because of higher level of circulating RBCs per kg of body weight and a shorter RBC life span.
   b. Enterohepatic circulation—reabsorption of unconjugated bilirubin.
2. Decreased clearance of bilirubin from plasma.
   a. Predominant bilirubin-binding protein in liver cells may be deficient in the first days of life.
   b. Glucuronyl transferase enzyme activity may be decreased, resulting in impaired conjugation of bilirubin.
   c. The liver may show decreased ability to excrete large amounts of conjugated bilirubin.
   d. Poor portal blood supply may decrease the liver's capacity to act effectively.
3. Physiologic jaundice occurs 2 to 5 days after birth.
   a. Increase in unconjugated bilirubin levels; levels should not exceed 5 mg/100 dL/day with physiological jaundice.
   b. Full-term infant peak levels are reached 48 to 72 hours after birth; clinical jaundice generally declines in 1 week.
   c. Premature infant peak levels are reached by 5 to 6 days of age; clinical jaundice declines in 2 weeks.
   d. Jaundice progresses in head-to-toe fashion. A yellow hue can be seen on the face and on the abdomen with levels of 10 to 15 mg/dL and on the soles of the feet with levels of more than or equal to 20 mg/dL.
4. Pathologic unconjugated hyperbilirubinemia.
   a. Jaundice usually appears in the first 24 hours of life.
   b. Total serum bilirubin usually increases greater than 5 mg/dL/day; total serum bilirubin greater than 12.9 mg/dL in term infant or 15 mg/dL in preterm infant.
   c. Direct serum bilirubin usually exceeds 1 to 2 mg/dL.

Erythrocyte Destruction

1. Erythroblastosis fetalis (isoimmunization caused by Rh factor or ABO incompatibility).

Immune hemolysis or Rh/ABO blood group incompatibility; the mother's and fetus's blood are
   a. different. Rh factor; different ABO blood groups (see Coombs test, page 976).
   b. Fetal cells frequently cross the placenta and may cause the mother to produce antibodies against the antigen of the fetus's blood.
   c. Antibodies of the mother's blood are in the infant's blood at birth, causing hemolysis of the neonate's RBCs, leading to a rising level of indirect bilirubin.
2. Glucose-6-phosphate dehydrogenase deficiency—nonimmune hemolytic disease (erythrocyte biochemical factor).
   a. Deficiency results in reduced stability to oxidative destruction from substances that act as oxidizing agents (ie, vitamin K, naphthalene, salicylates).
   b. X-linked recessive disease that affects primarily Black and Mediterranean Asian groups.
   c. Screen maternal blood for carrier state and screen neonatal blood in high-risk groups.
3. Other conditions associated with increased erythrocyte destruction:
   a. Infection—bacterial, viral, or protozoan.
   b. Structural abnormal erythrocyte.
   c. Sequestered blood (ie, cephalohematoma, ecchymoses).

Nursing Assessment and Interventions

1. Assess for signs and symptoms of jaundice:
   a. Sclerae appear yellow before the skin appears yellow.
   b. The skin appears light to bright yellow or orange.
   c. Lethargy.
   d. Dark amber, concentrated urine.
   e. Poor feeding.
   f. Meconium stools.
2. Make observations in daylight, sunlight, or white fluorescent light.
   a. Blanch the skin during the observation to clear away capillary coloration: forehead, cheeks, and clavicle sites allow for clear view.
   b. Be alert to the neonate's age in connection with the appearance of jaundice.
   c. With dark-skinned neonates, observing the color of the sclera and buccal mucosa is useful.
   d. If available, utilize the transcutaneous bilirubin (TCB) monitor to trend bilirubin levels.
3. Monitor serum bilirubin levels as ordered.
   a. Utilize the Hour-specific Nomogram for Risk Stratification on the BiliTool Web site (*www.bilitool.org*) to evaluate treatment needs.
4. Assist with treatment.
   a. Fluids—ensure adequate hydration and increase elimination. Encourage frequent feeding of newborn to facilitate excretion of bilirubin. Breast-feeding infants may require supplementation with formula.

b. Phototherapy—uses blue light to convert bilirubin molecules into water-soluble isomers for excretion. Therapy will depend on infant's age in hours, serum bilirubin level, and risk zone (see *www.bilitool.org*).

c. Exchange transfusion—mechanically remove bilirubin.

d. Enzyme induction agent—used in rare cases (Crigler-Najjar syndrome type 1) to reduce bilirubin levels by inducing hepatic enzyme system involved in bilirubin clearance (ie, phenobarbital).

5. Provide nursing care related to phototherapy.

a. Photoisomerization of tissue bilirubin occurs when the neonate is exposed to blue light-emitting diodes. The number of lights used will depend on the clinical presentation of the infant.

b. Check light intensity for therapeutic range daily with a phototherapy radiometer to ensure adequate light intensity.

c. Undress infant to expose maximum skin surface to light. A small diaper may be used to cover genitalia.

d. Keep the neonate's eyes covered with a size-appropriate mask, to protect from constant exposure to high-intensity light, which may cause retinal injury.

e. Develop a systematic schedule of turning neonate so all body surfaces are exposed (ie, every 2 hours).

f. Maintain thermoregulation of infant to prevent cold stress—lights affect the ambient temperature.

g. Obtain bilirubin levels, as ordered. The diminishing icterus (ie, the lowering of unconjugated bilirubin from cutaneous tissue) does not reflect the serum bilirubin concentration. Lights should be turned off when blood is being collected to eliminate false-low bilirubin levels.

h. During feedings, remove the neonate from under the lights, remove eye covers, and encourage parent participation.

i. A fiberoptic blanket (biliblanket), which delivers continuous phototherapy by wrapping light around the neonate's torso, may be used. This method allows the neonate to remain in the mother's room in an open crib. Encourage the mother to remove the infant from the biliblanket and hold for feedings. An eye mask is not required when using the biliblanket.

Septicemia Neonatorum

Septicemia neonatorum (sepsis of the neonate) is a generalized infection that is characterized by the proliferation of bacteria in the bloodstream and commonly involves the meninges (as distinguished from simple bacteremia, congenital infection, septicemia after major diseases or surgery, or major congenital anomalies). Mortality is high.

Pathophysiology and Etiology

1. The distribution of etiologic agents varies from year to year and from facility to facility.
    a. Gram-negative organisms include *Escherichia coli*, *Klebsiella* (Enterobacteriaceae), *Pseudomonas*, *Proteus*, *Salmonella*, and *Haemophilus influenzae*.
    b. Gram-positive organisms include group B beta-hemolytic *Streptococcus*, *Listeria monocytogenes*, *Staphylococcus aureus* (coagulase-negative and coagulase-positive), *Staphylococcus epidermidis*, *Streptococcus pneumoniae*, and *Streptococcus faecalis*.
2. Preterm infants are at increased risk of fungal infections from the organism *Candida albicans* because of immature immune system and diminished integumentary integrity.
3. Predisposing factors include a wide range of maternal perinatal complications; iatrogenic factors, such as use of catheters, oxygen, and resuscitative equipment; and infant complications, such as prematurity, congenital anomalies, RDS, skin infections, and asphyxia.
4. Infection occurs because of a temporary breakdown or depression of the neonate's defense mechanism for an unknown reason.
5. Risk factors for bacterial infection: prematurity, prolonged rupture of membranes (≥18 hours), foul-smelling amniotic fluid, maternal temperature, urinary tract infection with group B *Streptococci*, chorioamnionitis, low socioeconomic status, no or limited prenatal care, or antenatal or intrapartum asphyxia.

Nursing Assessment and Interventions

1. Assess for early signs of sepsis, which are vague and subtle.
    a. Poor feeding; gastric retention; weak sucking.
    b. Lethargy, limpness; weak crying, irritability.
    c. Temperature alteration—generally hypothermia, but infant may have hyperthermia or temperature instability.
    d. Hypoglycemia or hyperglycemia.
    e. Tachycardia (because of inability to change contractility of the heart).
    f. Decreased perfusion and pulses.
2. Assist with diagnostic testing.
    a. Cultures from the blood, urine, cerebral spinal fluid (CSF), skin lesions, nose, throat, rectum, and gastric fluid may be obtained.

b. WBC and differential, hemoglobin, and hematocrit. Be alert for neutrophils less than 5,000 cells/mm^3 or greater than 25,000 cells/mm^3; absolute neutrophil count less than 1,800 cells mm^3; immature/total neutrophils greater than 0.2; platelets less than 150,000.

c. Blood chemistries—glucose, calcium, pH, electrolytes.

d. C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR).

e. Acid–base studies (acidosis).

f. Bilirubin.

g. TORCH (toxoplasmosis–rubella–cytomegalic inclusion virus–herpes–other) detects antibodies against common intrauterine-infective agents.

h. Arterial blood gases.

i. Chest x-ray—may demonstrate pulmonary infection.

j. Urinalysis.

k. CSF: look for protein 150 to 200 mg/L term and 300 mg/L preterm; glucose, 50% to 60% or more of blood glucose level.

3. Assist with treatment.

a. Before the specific organism is identified and after cultures have been obtained, the antibacterial therapy is based on the more common causative agents and their anticipated susceptibilities.

b. Supportive therapy includes observation, standard precautions, hydration, nutrition, oxygen, regulation of thermal environment, blood transfusion to correct anemia and shock, and protection from further infection.

4. Observe for complications, such as meningitis, shock, adrenal hemorrhage, disseminated intravascular coagulation, PPHN, seizures, pneumonia, UTI, and heart failure.

Neonatal Abstinence Syndrome

Maternal abuse of such substances as drugs, alcohol, and tobacco may have an impact on the growth, development, and well-being of her fetus or neonate. According to the National Institute on Drug Abuse, there has been a fivefold increase in opioid use during pregnancy since 2000. Working mechanisms include direct toxic effects on fetal circulation and CNS (heroin/cocaine), indirect toxic and vasoconstrictive effects impacting placental circulation (alcohol and marijuana), and both direct and indirect toxic effects (polydrug use).

Pathophysiology and Etiology

1. Drugs and alcohol cross the placental barrier and enter the fetal circulation. The supply to the neonate is abruptly terminated at delivery, causing withdrawal symptoms.
2. Alcohol is a CNS depressant, and fetal alcohol spectrum disorders (FASD) are caused by direct ethanol toxicity to the developing fetus. Additional effects on the fetus come from maternal malnutrition, maternal hypoglycemia, smoking, and alcohol-induced illness.
3. Cocaine is a CNS stimulant which produces increased norepinephrine levels resulting in vasoconstriction, tachycardia, hypertension, and uterine contractions, which may lead to cerebral hemorrhage. This can result in fetal complications such as decreased uterine blood flow, increased fetal mean arterial pressure, increased FHR, decreased fetal oxygen, and damage to fetal brain transmitters.
4. Opioids are morphine derivatives with three sources of dependence: pain management (misuse of prescribed opioids), an untreated opioid use disorder (heroin addiction), and pharmacologically supported dependence with methadone and buprenorphine. The long-term biologic effects on the neonate of a drug-dependent mother are not fully known.
5. These children will be at risk for:
    a. Abnormal psychomotor development associated with intrauterine growth restriction because of the decreased perfusion/blood flow.
    b. Behavioral disturbances, such as hyperactivity, brief attention spans, temper tantrums, and seizures, because of exposure to large doses of the drug.
    c. Fetal anoxia (because of decreased perfusion) and meconium aspiration, prematurity (because of uterine hypertension and hyperirritability), and a wide variety of complications to include but not limited to limb reduction defects, uterine tract anomalies such as urethral obstruction malformation, prune belly syndrome, or hydronephrosis.
    d. Neurodevelopmental abnormalities because of damage to the fetal brain neurotransmitters; this may be permanent.
6. Infants and children with FASD may develop intellectual impairment, poor fine motor control, difficulty feeding, hyperactivity, delay of gross motor skills, and brain dysfunction.
7. Complications of cocaine abuse include spontaneous abortion, premature labor, abruptio placentae, uterine rupture, meconium staining, congenital anomalies, and neonatal death.

Nursing Assessment and Interventions

Treatment of a newborn with NAS requires a multidisciplinary approach to care and will depend upon the infant's gestational age, clinical presentation, length of exposure, and type of drug abused. Hallmark signs of neonatal withdrawal include excessive high-pitched cry, reduced quality and length of sleep following a feeding, hypertonia, tremors, and convulsions. Autonomic dysregulation may be present with sweating, frequent yawning and sneezing, and increased respirations. Gastrointestinal manifestations with excessive sucking, poor feeding, regurgitation or vomiting, and loose or watery stools may also present.

1. Obtain maternal history of drug, dosage, time of last dose, and length of use. Be alert and assess for onset of symptoms of withdrawal.
    a. Heroin—several hours after birth to 3 to 4 days of life.
    b. Methadone—7 to 10 days after birth to several weeks of life.
    c. Alcohol—3 to 12 hours after birth.
    d. Barbiturates—1 to 14 days after birth with a mean of 4 to 7 days.
    e. Sedative hypnotics—withdrawal can begin as late as 12 days (diazepam) to 21 days (chlordiazepoxide).
2. Assess infant for NAS using the Neonatal Abstinence Scoring System (see Figure 38-6).
    a. Assessment and scoring of the neonate utilizing the NASS tool should be every 2 hours for the first 2 days following birth and then deceased to every 8 hours as long as withdrawal symptoms continue.
    b. A score is awarded based upon observations of the neonates' psychomotor behavior. The use of a scoring tool provides a more objective approach when determining a plan of care.
    c. When a neonate receives a score greater than 8 on three consecutive screenings, and nursing interventions implemented have not assisted in decreasing the neonates' withdrawal behaviors, initiation of medications should be considered.
3. Assess for symptoms of FASD.
    a. Difficulty establishing respirations.
    b. Metabolic problems.
    c. Irritability.
    d. Increased muscle tone, tremulousness.
    e. Lethargy.
    f. Opisthotonos.
    g. Poor sucking reflex.
    h. Abdominal distention.
    i. Seizure activity.
    j. Facial abnormalities.
4. Assess the neonate born to mother of cocaine abuse—does not appear to experience classic neonatal abstinence syndrome because cocaine metabolites are stored in the fetal liver compartment. Symptoms may not occur for several days and the infant may exhibit:

a. Mild tremulousness.
b. Increased irritability and startle response.
c. Muscular rigidity.
d. Difficulty in being consoled.
e. Pronounced state of lability.
f. Tachycardia and tachypnea.
g. Poor tolerance for oral feedings, diarrhea.
h. Disturbed sleep pattern.

5. Collect urine and/or meconium for toxicology screen within 24 hours after birth. Obtain blood gases, blood glucose, and other laboratory tests.
6. Administer medications, as directed.
   a. Opioid antagonist such as naloxone for opioid-induced respiratory depression at birth.
   b. Drug therapy for alleviation of signs of withdrawal. Duration of therapy using decreasing dosages will depend on clinical presentation.
      i. Morphine.
      ii. Tincture of opium.
      iii. Phenobarbital.
      iv. Chlorpromazine.
      v. Diazepam.
      vi. Methadone.
      vii. Lorazepam.
7. Provide nursing care to support infant and to relieve symptoms.
   a. Irritability and restlessness, high-pitched crying.
      i. Swaddle infant with legs flexed.
      ii. Minimize handling.
      iii. Gentle rocking.
      iv. Decrease environmental stimuli (ie, light, noise).
      v. Skin to skin with snug blanket.
      vi. Organize care to allow for periods of uninterrupted sleep.
      vii. Supervised prone positioning may help the infant organize motor movements.
      viii. Give medications with feedings.
   b. Tremors—protect the skin from irritation and abrasions.
      i. Change position frequently.
      ii. Give frequent skin care—keep the neonate clean and dry.
   c. Frantic sucking—use pacifier between feedings; protect the neonate's hands and chin from excoriation.

d. Poor feeding—give small, frequent feedings; maintain caloric and fluid intake requirement for the neonate's desired weight. Higher-calorie formulas may be used.

e. Vomiting/diarrhea—position the neonate to prevent aspiration; provide good skin care to areas exposed to vomitus or stools.

f. Muscle rigidity, hypertonicity.

    i. Change position frequently to minimize development of pressure areas.

g. Increased salivation and nasal stuffiness.

    i. Aspirate nasopharynx as needed; avoid overuse.

    ii. Provide frequent nose and mouth care.

    iii. Note respiration rate and characteristics and infant's color.

h. Tachypnea.

    i. Note onset and severity of accompanying signs of respiratory distress; place the infant on respiratory monitor.

    ii. Position the infant for easier ventilation—semi-Fowler position; tilt head back slightly.

    iii. Minimize handling.

    iv. Have resuscitative equipment available.

i. Tachycardia and hypertension—monitor vital signs closely; cardiopulmonary monitor may be indicated.

8. Provide supportive care to parents to promote bonding and nonjudgmental therapeutic communication is essential. Teaching should include infant care, bathing, and feeding.

NEONATAL ABSTINENCE SCORING SYSTEM															
SYSTEM	SIGNS AND SYMPTOMS	SCORE		A^M						P^M					COMMENTS
CENTRAL NERVOUS SYSTEM DISTURBANCES	Excessive High Pitched (Or other) Cry	2													Daily Weight
	Continuous High Pitched (Or other) Cry	3

Complications of the Childbearing Experience

Antepartum/Obstetric Complications
Ectopic Pregnancy
Gestational Trophoblastic Disease
Spontaneous Abortion
Hyperemesis Gravidarum
Placenta Previa
Abruptio Placentae
Hypertensive Disorders of Pregnancy
Hydramnios
Oligohydramnios
Multiple Gestation
Intrapartum Complications of Labor
Preterm Labor
Premature Rupture of Membranes
Preterm Premature Rupture of Membranes
Induction and Augmentation of Labor
Dystocia
Shoulder Dystocia
Uterine Rupture
Amniotic Fluid Embolism
Umbilical Cord Prolapse
Uterine Inversion
Operative Obstetrics
Episiotomy
Operative Vaginal Delivery: Forceps
Vacuum Extraction
Cesarean Delivery
Postpartum Complications
Postpartum Infection
Postpartum Hemorrhage

Postpartum Hematomas

Postpartum Depression

ANTEPARTUM/OBSTETRIC COMPLICATIONS

NURSING ALERT Many obstetric complications involve the possibility of hemorrhage, requiring blood replacement. Determine the patient's feelings and cultural beliefs regarding the possibility of transfusions, and notify health care providers if transfusion is refused.

Ectopic Pregnancy

Ectopic pregnancy is a gestation that implants outside the uterine cavity. Locations typically include the fallopian tube (96%), ovary, cervix, or abdominal cavity (Figure 39-1). Most tubal pregnancies occur in the distal (ampullary) two thirds of the tube. Some are located in the proximal portion of the extrauterine part of the tube (isthmic).

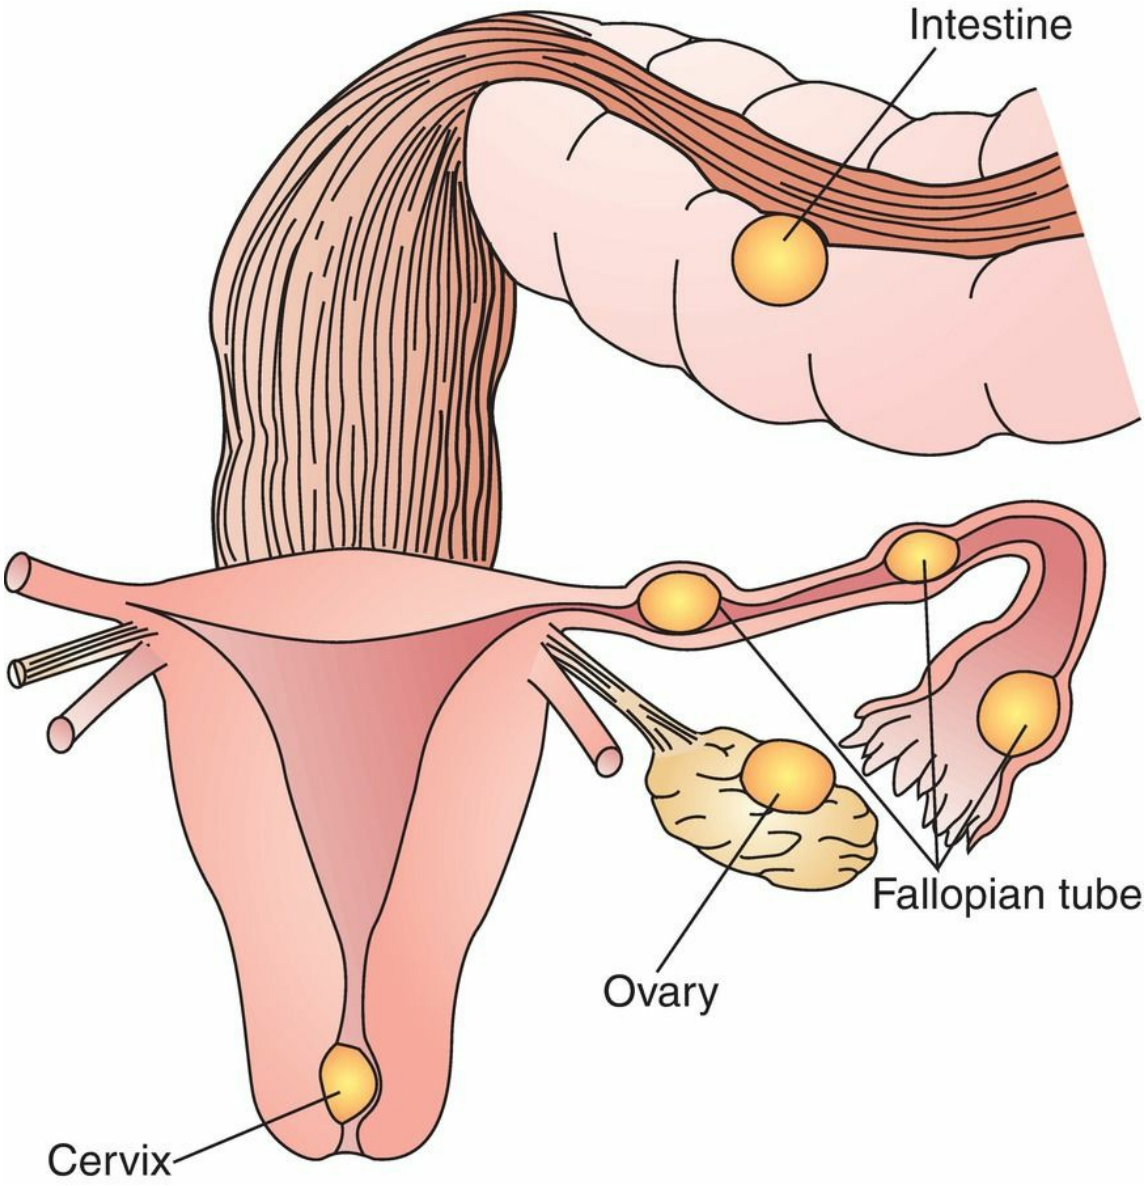

Figure 39-1. Sites of ectopic pregnancy. (From Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

1. Clinical or structural factors that prevent or delay the passage of the fertilized ovum:

a. Pelvic inflammatory disease.
b. History of ectopic pregnancy.
c. Prior tubal surgery and/or ligation.
d. Diethylstilbestrol (DES) exposure.
e. Endometriosis.
f. Increased maternal age.
g. Sexually transmitted infections.

2. Assisted reproduction technologies (ART) especially with multiple embryo transfer.
3. The growing ectopic pregnancy may result in inflammation, rupture, hemorrhage, peritonitis, or death.

Clinical Manifestations

1. Abdominal or pelvic pain (typically unilateral). Pain may become severe if the fallopian tube ruptures; clinical presentation will evolve into shock.
2. Irregular vaginal bleeding—usually scanty and dark (most common).
3. Amenorrhea—75% of the cases.
4. Uterine enlargement: size equates to normally implanted pregnancy.
5. Abdominal tenderness on palpation.
6. Radiating shoulder pain (because of bleeding aggravating nerves in the peritoneal cavity).
7. Increased pulse and anxiety.
8. Nausea, vomiting, faintness, vertigo, or syncope.
9. Pelvic examination may reveal a pelvic mass, posterior or lateral to the uterus, adnexal tenderness, and cervical pain with movement of the cervix.

Diagnostic Evaluation

1. Serial quantitative levels of the beta subunit of human chorionic gonadotropin (β-hCG) can be used in combination with ultrasound in most cases to confirm diagnosis.
   a. Serum β-hCG (produced by trophoblastic cells)—serial evaluations will not show characteristic rise as in intrauterine pregnancy and assists in determining management of care when an ectopic pregnancy is identified through use of ultrasound.
   b. Transvaginal ultrasound—identifies absence of gestational sac within the uterus and is most accurate and rapid method of diagnosis.
2. Serum progesterone—reflects production of progesterone by the corpus luteum stimulated by a viable pregnancy; 97.5% sensitivity if serum progesterone levels are greater than or equal to 25 ng/mL (greater than or equal to 79.5 nmol/L), signifying further testing is warranted; is not a good predictor for diagnosis of an ectopic pregnancy.
3. Culdocentesis—bloody aspirate from the cul-de-sac of Douglas, the posterior fornix of the vagina, indicates intraperitoneal bleeding from tubal rupture.

4. Laparoscopy—abdominal visualization of tubal.
5. Laparotomy—indication for surgery if there is any question about the diagnosis.

Management

Conservative Therapy

1. Conservative therapy is chosen should the patient desire future childbearing and clinical condition is stable.
2. Methotrexate is considered first-line treatment, if applicable.
   a. Hemodynamically stable without active bleeding or signs of hemoperitoneum.
   b. General anesthesia poses a risk.
   c. Patient is unable to return for follow-up care.
3. Contraindications to methotrexate include breastfeeding, immunodeficiency, alcoholism, liver disease, pulmonary disease, peptic ulcer disease, renal dysfunction, or blood dyscrasias.
4. May be single or multiple dosing.
   a. Weight-based, single-dose methotrexate (50 mg/m^2)—may need to be divided into 2 syringes related to volume required for safe intramuscular administration
   b. Multiple dose may be necessary if hCG levels remain elevated and patient is hemodynamically stable.
5. Goal of treatment is to resolve the ectopic pregnancy and preserve tubal patency and reproductive function. Following treatment, absorption of the pregnancy will take approximately 4 to 6 weeks.

Surgical Treatment

1. If methotrexate is not an option based on clinical presentation, surgical intervention is recommended. The surgical procedure depends on the extent of tubal involvement and if rupture has occurred.
   a. The surgery of choice used to preserve future fertility is a salpingostomy (removes conceptus leaving tube intact but may cause adhesions).
   b. Should a woman not desire future fertility, the surgery of choice is salpingectomy (removal of portion of fallopian tube with conceptus).
   c. Other surgeries range from removal of ectopic pregnancy with tubal resection, salpingostomy, and possibly salpingo-oophorectomy (removal of tube and ovary on affected side).
2. Treat shock and hemorrhage accordingly as clinical condition warrants.
3. Administer Rho(D)Immune Globulin (RhIG) if woman is Rh negative.

Complications

1. Infertility.
2. Hemorrhage and death.

Nursing Assessment

Evaluate the following to determine pregnancy status and to monitor for clinical changes in patient, such as

ectopic rupture or hemorrhage:

1. Maternal vital signs.
2. Presence and amount of vaginal bleeding.
3. Amount, type, and evolving intensity of pain.
4. Presence of abdominal tenderness on palpation accompanied by radiating shoulder pain.
5. Date of last menses.
6. Presence of positive pregnancy test.
7. Rh type.

Nursing Diagnoses

- Deficient Fluid Volume relative to blood loss from ruptured fallopian tube.
- Acute Pain related to ectopic pregnancy or rupture and bleeding into the peritoneal cavity.
- Grieving related to loss of pregnancy.

Nursing Interventions

Maintaining Fluid Volume

1. Establish an intravenous (IV) line with a large-bore catheter (16G to 18G) and infuse fluids; blood component therapy may be prescribed.
2. Obtain blood samples for complete blood count (CBC) and type and screen, as directed.
3. Monitor vital signs and urine output as the patient's condition warrants.

Promoting Comfort

1. Administer analgesics, as needed and prescribed.
2. Encourage the use of relaxation techniques.

Providing Support through the Grieving Process

1. Be available to patient and provide emotional support; listen to concerns of patient and significant others.
2. Be aware that patient/family may be experiencing denial or other stages of grief; compassionate presence and empathy are essential.
3. Offer bereavement resources.

Patient Education and Health Maintenance

1. Teach signs and symptoms of ectopic pregnancy to women at risk: increased vaginal bleeding, moderate to severe abdominal pain (typically unilateral and low), shoulder pain, nausea, and vomiting.
2. Instruct woman to report relative signs and symptoms to primary practitioner or emergency department immediately.
3. Encourage grief counseling and supportive care at home.
4. Discuss contraception.

5. If methotrexate is used reinforce that women should not become pregnant for 3 months.

Evaluation: Expected Outcomes

- Vital signs stable.
- Verbalizes pain relief.
- Patient and support person express appropriate grief response.

Gestational Trophoblastic Disease

Gestational trophoblastic disease (GTD) ("molar pregnancy") comprises a myriad of interrelated conditions, originating from anomalous development of the placenta that can be uterine or extrauterine (rare). It is characterized by the conversion of the chorionic villi into a mass of clear vesicles (moles). GTD is observed in 1 in 1,500 pregnancies and 1 in 600 therapeutic abortions. Molar pregnancies are usually diagnosed during the first trimester of pregnancy and may be classified as incomplete (partial) or complete. In a complete GTD pregnancy, the fetus, placenta, and amniotic membranes or fluid are absent. Incomplete molar pregnancies may contain embryonic or fetal parts and an amniotic sac. The majority of women experiencing a molar pregnancy will have nonmetastatic invasive moles; however, 20% will develop a malignancy. The use of chemotherapy will be dependent on presentation and pathology.

Pathophysiology and Etiology

1. GTD occurs due an excess of paternal chromosomes.
    a. Complete homozygous moles are generally the result of abnormal fertilization of an ovum devoid of genetic material (empty egg without DNA) with a single sperm containing a haploid set (single set of unpaired chromosomes) of 23X chromosomes (80%) that duplicates to 46XX.
    b. A heterozygous mole (20% of complete moles) occurs when 2 sperm fertilize an empty egg (46XX/46XY).
    c. Partial moles are triploid and occur due to paternal dispermic fertilization. The mole has a karyotype of 69XXX, 69XXY, or 69XYY.
2. Malignancy results from one of the following: invasive hydatidiform mole (most common), choriocarcinoma, placental trophoblastic tumor, or an epithelioid trophoblastic tumor.
3. Complete moles account for approximately 50% of all choriocarcinomas with the heterozygous mole presenting the greater risk of developing a malignancy.

Clinical Manifestations

1. First-trimester vaginal bleeding.
2. Absence of fetal heart tones and fetal structures.
3. Uterine enlargement greater than dates (size may double if complete mole exists).
4. β-hCG titers greater than expected for gestational age.
5. Expulsion of the vesicles.
6. Hyperemesis gravidarum (severe nausea and vomiting).
7. Early onset of preeclampsia; first half of pregnancy.

Diagnostic Evaluation

1. β-hCG levels—excessive elevations.
2. Ultrasound—diffuse mixed echogenic pattern replacing the placenta. May be described as villous cavitation—clear "grapelike" structures fill the uterine cavity accompanied by an absent fetus or partial

development.

Management

1. Suction curettage is the method of choice for immediate evacuation of the mole with possibility of laparotomy; hysterectomy may be an option but rare.
2. Serial quantitative β-hCG determinations should be performed to confirm resolution to baseline values (less than 5 mIU/mL). Persistent elevations indicate malignant postmolar GTD.
3. Hormonal contraception during β-hCG monitoring.
4. Chemotherapy for patients with a malignant invasive GTD.
5. Administer RhIG per your facility's policy if woman is Rh negative.

Complications

1. Significant blood loss.
2. Malignancy (10% to 20%).
3. Infertility.

Nursing Assessment

1. Monitor vital signs; note symptoms of early-onset preeclampsia (see page 1048).
2. Assess the amount and type of vaginal bleeding; note the presence of other vaginal discharge.
3. Assess for proteinuria (elevated levels of protein in urine).
4. Determine date of last menstrual period (LMP) and date of positive pregnancy test.
5. Measure fundal height, via tape or palpation, and compare to LMP.
6. Evaluate CBC results and Rh type.

Nursing Diagnoses

- Risk for deficient Fluid Volume related to maternal hemorrhage.
- Anxiety related to loss of pregnancy and medical interventions.

Nursing Interventions

Maintaining Fluid Volume

1. Obtain blood samples for type and screen; blood component therapy may be indicated, prepare accordingly.
2. Establish and maintain peripheral IV line; start with a large gauge needle (16G to 18G) to accommodate anticipatory need for transfusion and/or large quantities of fluid.
3. Assess maternal vital signs and evaluate bleeding as patient's condition warrants.
4. Monitor laboratory results to evaluate patient's status.

Decreasing Anxiety

1. Prepare the patient for surgery. Explain preoperative and postoperative care along with intraoperative procedures.
2. Educate patient and family on the disease process—acute and chronic aspects.
3. Allow the family to grieve over the loss of pregnancy and possible infertility.

Patient Education and Health Maintenance

1. Advise the woman on the importance of continuous follow-up care, including weekly evaluation of β-hCG level until levels return to normal and remain normal for 3 weeks, and then monitor once a month for 6 months.
2. Provide reinforcement of follow-up procedures; typically lasts at least 1-year postdiagnosis.
3. Encourage ongoing discussion of care and fertility options with health care provider.

Evaluation: Expected Outcomes

- Vital signs stable; laboratory work within normal limits.
- Verbalizes concerns about self and related procedures; describes follow-up care and its importance.

Spontaneous Abortion

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2005/Reaffirmed 2016). *Medical management of abortion* (Practice Bulletin #143). Washington, DC: Author.

Spontaneous abortion occurs as a natural termination of pregnancy prior to 20 weeks. Variations are outlined in Table 39-1. Medical termination of a pregnancy is known as a *therapeutic* (maternal or fetal indications) accomplished through medication administration or surgical intervention.

Table 39-1 Types of Spontaneous Abortions

CLASSIFICATION	CLINICAL MANIFESTATIONS	MANAGEMENT
Threatened	• Vaginal bleeding or spotting • Mild cramps • Tenderness over uterus, simulates mild labor or persistent lower backache with feeling of pelvic pressure • Cervix closed or slightly dilated • Symptoms subside or develop into inevitable abortion	• Vaginal examination • Bed rest (some clinicians will not limit activity in belief that the embryo will be aborted anyway) • Pad count
Inevitable	• Bleeding more profuse • Cervix dilated • Membranes rupture • Painful uterine contractions	• Embryo delivered, followed by dilatation and evacuation (D&E)
Habitual	• Spontaneous abortion occurs in successive pregnancies (three or more)	• D&E • Treatment of possible causes: hormonal imbalance, tumors, thyroid dysfunction, abnormal uterus, incompetent cervix; with treatment, 70% to 80% carry a pregnancy successfully • Hysterogram to rule out uterine abnormalities, infections • Surgical suturing of the cervix if incompetent cervix is a causative factor
Incomplete	• Fetus usually expelled • Placenta and membranes retained	• D&E
Missed	• Fetus dies in utero and is retained • Maceration • No symptoms of abortion, but symptoms of pregnancy regress (uterine size, breast changes)	• Real-time ultrasound, and if second trimester, fetal monitoring to determine if fetus has died • D&E if early pregnancy • If fetus is not passed after diagnosis, oxytocin induction may be used; retained dead fetus may lead to development of DIC or infection • Fibrinogen concentrations should be measured weekly

Pathophysiology and Etiology

1. Natural causes commonly unknown, yet up to 50% are due to chromosomal anomalies.
2. Exposure or contact with teratogenic agents.
3. Poor maternal nutritional status.
4. Maternal illness with virus, such as rubella, cytomegalovirus, varicella, active herpes, and toxoplasmosis, or specific bacterial microorganisms that put the pregnancy at risk.
5. Endocrine imbalance: Luteal phase defect, insulin-dependent diabetes mellitus, thyroid disease.
6. Systemic lupus erythematosus and other immunologic factors: antiphospholipid antibodies.
7. Smoking, substance abuse, and high caffeine intake.

8. Genetic factors.
9. Morbid obesity.
10. Abnormal uterine development or structural defect in the maternal reproductive system (ie, incompetent cervix, uterine fibroids, bicornuate uterus).
11. Presence of intrauterine device.
12. Environmental factors such as chemicals, radiation, or trauma.
13. Bleeding during first trimester.

Clinical Manifestations

1. Uterine cramping, lower back pain.
2. Vaginal bleeding usually begins as dark spotting and then progresses to frank bleeding.
3. hCG levels may be elevated for as long as 2 weeks after loss of embryo.

Diagnostic Evaluation

1. Ultrasonic evaluation of the gestational sac or embryo.
2. Visualization of the cervix; presence of dilation or tissue expulsion.

Complications

1. Hemorrhage.
2. Uterine infection.
3. Septicemia may occur due to missed/undiagnosed abortion.
4. Disseminated intravascular coagulation (DIC) is rare but may occur with a missed abortion.

Nursing Assessment

1. Determine date of LMP and date of positive pregnancy test.
2. Monitor maternal vital signs: assess for hemorrhage or infection.
3. Evaluate blood loss: initiation, duration, estimated total amount, precipitating factors.
4. Evaluate any blood or clot tissue for the presence of amniotic membranes, placenta, or fetus.

Nursing Diagnoses

- Risk for Deficient Fluid Volume related to maternal bleeding.
- Anticipatory Grieving related to loss of pregnancy, cause of the abortion, future childbearing.
- Risk for Infection related to dilated cervix and open uterine vessels.
- Acute Pain related to uterine cramping.

Nursing Interventions

Maintaining Fluid Volume

1. Draw blood for CBC as well as type and screen, as directed, to assess blood loss and prepare for possible

transfusion.

2. Assess and report to the perinatal team signs of hemorrhage: tachycardia, hypotension, hyperventilation, altered level of consciousness (LOC), diaphoresis, or pallor.
3. Establish and maintain an IV access with large gauge catheter (16G to 18G) for possible transfusion and large quantities of fluid replacement; two IV lines may be warranted.
4. Inspect all expelled tissue and assess for completeness; retained products of conception may lead to further bleedin and, possibly, hemorrhage if not completely expelled.
5. Administer RhIG per your facility's policy if woman is Rh negative.

Providing Support through the Grieving Process

1. Evaluate need for grievance counseling; offer emotional support to mother, partner, and family.
2. Do not minimize the loss by focusing on future childbearing; rather, acknowledge the loss and allow grieving. Every pregnancy, irrelevant to the length of gestation, deserves recognition and respect of acknowledgment.
3. Provide time alone for the couple/family to discuss their feelings and to grieve.
4. Discuss the prognosis of future pregnancies with the patient and support persons.
5. Provide an opportunity for viewing the fetus per patient request.
6. Screen for signs and symptoms of depression.
7. Offer spiritual support and case management opportunities as indicated.

Preventing Infection

1. Evaluate temperature and pulse for signs of infection periodically.
2. Assess vaginal drainage for increased amount and odor; may indicate infection.
3. Educate and encourage perineal care after each urination and defecation to prevent contamination.

Promoting Comfort

1. Instruct patient on the cause of pain to decrease anxiety.
2. Instruct and encourage the use of relaxation techniques to augment analgesics.
3. Administer pain medications, as needed and prescribed.

Community and Home Care Considerations

1. Review symptoms of hemorrhage if a threatened abortion is suspected.
2. Discuss an emergency access care plan with patient and support personnel.
3. Instruct the patient to collect any expelled specimen and to bring to facility for evaluation.

Patient Education and Health Maintenance

1. Provide the names of local bereavement support groups; Resolve Through Sharing (*www.gundersenhealth.org/resolve-through-sharing/*) groups may be available.
2. Discuss with the patient desired method of contraception to be used.

3. Explain the need to wait 2 to 4 months before attempting another pregnancy.
4. Teach the woman to observe for signs of infection (fever, pelvic pain, change in character and amount of vaginal discharge) and advise to report to provider immediately.
5. Provide information regarding genetic testing of the products of conception, if indicated; send the specimen according to facility policy.

Evaluation: Expected Outcomes

- Vital signs remain normal; minimal blood loss.
- Expresses feelings regarding the loss of the pregnancy by demonstrating normal signs of grief and coping.
- No signs of infection, temperature normal, performs perineal care.
- Verbalizes relief of pain and discomfort.

Hyperemesis Gravidarum

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2015 # 153). *Nausea and vomiting in pregnancy* (Practice Bulletin #52). Washington, DC: Author.

Hyperemesis gravidarum is exaggerated and persistent nausea and vomiting that occurs during pregnancy. It is a clinical diagnosis of exclusion based on a typical presentation in the absence of other diseases that could explain the findings, such as GI conditions, metabolic disease, neurologic disorders, drug use, or acute fatty liver or preeclampsia during pregnancy. Early identification and treatment at onset of nausea and vomiting may decrease the incidence of developing hyperemesis gravidarum.

Pathophysiology and Etiology

1. Typically occurs during the first 16 weeks' gestation but may last into the third trimester in severe cases.
2. Etiology is unknown, but two theories prevail: psychosomatic or hormonal stimulus (high levels of β-hCG or estrogen).
3. Accompanied by appetite disturbances that are intractable in nature.
4. Psychological factors, including neurosis or altered self-concept, may be contributory.
5. Seen in molar pregnancies, multiple gestation, and history of hyperemesis in previous pregnancies.
6. Decreased gastric motility often accompanies the condition.
7. Persistent vomiting may result in fluid and electrolyte imbalances, dehydration, jaundice, and elevation of serum transaminase.

Clinical Manifestations

1. Persistent vomiting; inability to tolerate anything by mouth.
2. Dehydration—fever, dry skin, decreased urine output, large ketonuria.
3. Weight loss (up to 5% to 10% of body weight).
4. Severity of symptoms commonly increases as the condition progresses.

Diagnostic Evaluation

1. Tests may be done to rule out other conditions causing vomiting (cholecystitis, appendicitis, pancreatitis, thyroid disease, or hepatitis) or to confirm hyperemesis gravidarum diagnosis.
2. Liver enzymes LDH, AST, and ALT elevated.
3. Serum bilirubin elevated (less than 4 mg/dL).
4. Complete blood count may indicate anemia.
5. Blood urea nitrogen (BUN) and creatinine—may be slightly elevated.
6. Serum electrolytes—may result in hypokalemia, hyponatremia, or hypernatremia; loss of hydrogen and

chloride.

7. Urine may show ketones and elevated specific gravity.
8. Ultrasound may be considered to identify multiple gestation or molar pregnancy.

Management

1. Try withholding food and fluid for 24 to 48 hours or until vomiting stops and appetite returns; then restart small meals.
2. Control of vomiting may require pharmacological treatment with antiemetics and prokinetic agents (benefits to therapy may outweigh the risks of drugs), such as:
   a. Pyridoxine (vitamin B_6) with or without doxylamine—first line of treatment for nausea and vomiting of pregnancy.
   b. Ondansetron (Zofran)—most commonly prescribed parenterally and orally.
   c. Meclizine.
   d. Dimenhydrinate.
   e. Metoclopramide—do not give in combination with phenothiazines.
   f. Methylprednisolone (recently found to be more helpful than promethazine; 16 mg three times per day for 3 days then tapered over 2 weeks).
   g. Over the counter remedies may include ginger capsules of 250 mg taken four times a day.
   h. Aromatherapy, acupressure, and acupuncture have been used.
3. Treat dehydration with IV fluids—typically 1 to 3 L of dextrose solution with electrolytes and vitamins, as needed.
4. Most women respond quickly to restricting oral intake and giving IV fluids, but repeated episodes may occur.
5. Total parenteral nutrition rarely needed.

Complications

1. Hypovolemia and renal insufficiency.
2. Electrolyte imbalance.
3. Malnutrition.
4. Hepatic or renal failure with coma could result from disease progression but rare.

Nursing Assessment

1. Evaluate weight loss pattern; compare to prepregnant weight.
2. Evaluate 24- or 48-hour dietary recall.
3. Evaluate environmental factors that may affect the woman's appetite. Determine if woman is ingesting nonfood substances (pica), such as starch, clay, or toothpaste.
4. Monitor vital signs for tachycardia, hypotension, and fever because of dehydration.

5. Assess skin turgor, mucous membranes, and urine for signs of dehydration.

Nursing Diagnoses

- Risk for Deficient Fluid Volume related to prolonged vomiting.
- Imbalanced Nutrition: Less Than Body Requirements related to prolonged vomiting.
- Anxiety related to threat to self and fetus/infant.
- Fear related to concerns for fetal well-being.

Nursing Interventions

Maintaining Fluid Volume

1. Establish an IV line and administer IV fluids, as prescribed.
2. Monitor serum electrolytes and report abnormalities.
3. Medicate with antiemetics, as prescribed.
4. Maintain nothing-by-mouth status until vomiting has stopped; introduce ice chips slowly and add clear fluids once tolerated; solid food in small amounts introduced later as tolerated.
5. Assess intake and output, urine-specific gravity and ketones, vital signs, skin turgor, and fetal heart rate (FHR), as indicated by condition.

Encouraging Adequate Nutrition

1. Advise the woman that oral intake can be restarted as tolerated.
2. Begin small bland meals (ie, rice and chicken). Avoid greasy, gassy, and spicy foods.
3. Suggest or provide an environment conducive to eating.
4. Administer parenteral calorie replacement if multiple antiemetic treatments and enteral tube feeding have been unsuccessful.
5. Consult with a dietitian, as indicated.

Strengthening Coping Mechanisms

1. Therapeutic communication and compassionate presence allowing patient to verbalize feelings regarding this pregnancy and associated stressors.
2. Refer the patient to social service and counseling services, as needed.

Allaying Fears

1. Explain the effects of all medications and procedures on maternal as well as fetal well-being.
2. Once confirmed, accentuate the positive signs o fetal well-being.
3. Praise and support patient for attempts at following nutritious diet and healthy lifestyle.

Patient Education and Health Maintenance

1. Educate the woman about proper diet, nutrition, and healthy weight gain.

2. Educate the woman on the need to take antiemetics continuously during the nausea phase to alleviate vomiting episodes.
3. Recommend to take prenatal vitamins 3 months prior to pregnancy as may decrease nausea and vomiting in subsequent pregnancy.

Evaluation: Expected Outcomes

- Demonstrates signs of normal hydration with no ketosis; urine output adequate; urine-specific gravity within normal limits; blood pressure (BP) stable.
- Tolerates clear liquids then small, bland diet without vomiting.
- Verbalizes concerns and stresses related to pregnancy.
- Expresses confidence in fetal well-being.

Placenta Previa

Placenta previa is the abnormal implantation of the placenta in the lower uterine segment, partially or completely covering the internal cervical os (Figure 39-2). Classification may change over the course of the pregnancy or during labor as the cervix dilates. Placenta previa occurs in 1 in 200 live births and is associated with intrauterine growth restriction (IUGR) and increased risk for hemorrhage. The improvement in ultrasound technology has increased the accuracy of assessing the placental location and cervical os.

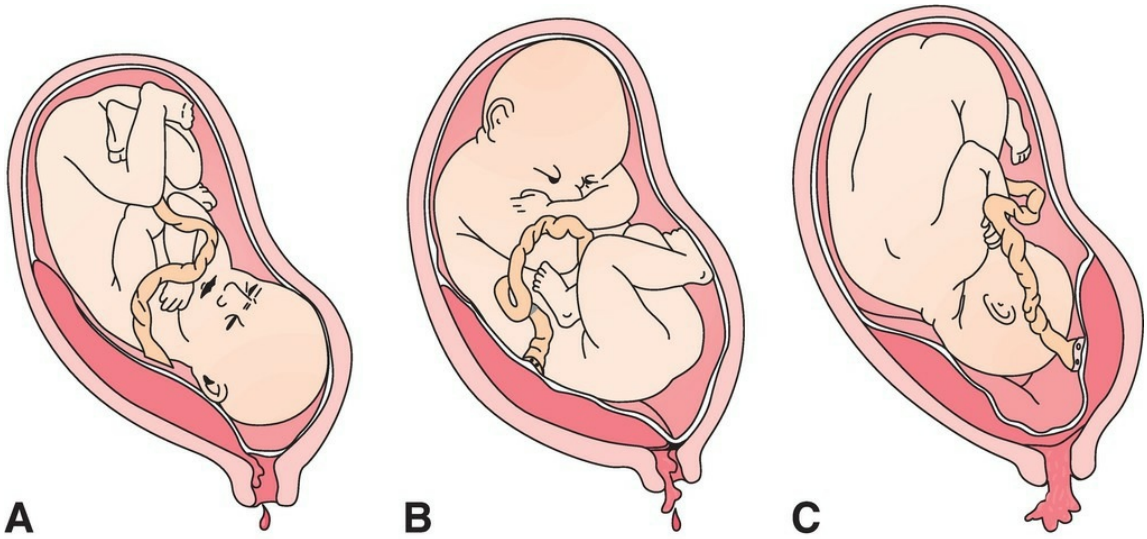

Figure 39-2. Degrees of placenta previa. **(A)** Low implantation. **(B)** Partial placenta previa. **(C)** Total placenta previa. (From Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

1. *Classifications* of placenta previa:
   a. Complete: placenta covers the cervical os completely.
   b. Partial: placenta partially covers the cervical os.
   c. Marginal: placenta lies at the margin of the internal os, but does not cover it.
   d. Low-lying placenta: placental implantation in the lower uterine segment next to the cervical os; the placenta may migrate and be pulled upward as the uterus stretches and grows during the course of the pregnancy.
2. *Causation* is unknown, but risk factors include:
   a. Previous myomectomy.
   b. Endometritis.
   c. Scarred uterus to include vaginal birth after cesarean delivery (VBAC).
   d. Induced or spontaneous abortions involving suction curettage.
   e. Advanced maternal age, multiparity, cigarette smoking.

f. Fetal hydrops fetalis.

g. Previous placenta previa.

Clinical Manifestations

1. Cardinal sign is sudden onset of painless bright red vaginal bleeding during the second or third trimester; some women may not exhibit bleeding until labor starts.
2. Initial episode of bleeding is rarely life-threatening and usually stops spontaneously. Bleeding can be intermittent or continuous.
3. With a complete placenta previa, bleeding typically occurs earlier in the pregnancy.

Diagnostic Evaluation

1. Ultrasound (transabdominal, transvaginal, or translabial) is the method of choice to identify location of placental implantation.

Management

1. Conservative management is usually possible with immature fetus and maternal stability.
2. Avoid vaginal examinations in patients with active vaginal bleeding as this may aggravate the condition.
3. Once viable and fetal lung maturity is established, delivery may be attempted based on maternal–fetal status.
4. If repeated episodes or heavy bleeding, IV access should be established immediately, along with CBC, blood type, screen, and crossmatch, as indicated.
5. Typically, in the medical facility setting, continuous maternal and fetal monitoring may be necessary.
6. Cesarean delivery is usually indicated if maternal–fetal status unstable or complete previa.
7. Vaginal delivery may be attempted in a marginal or low-lying placenta without active bleeding. Operating room and neonatal teams should be available.

Complications

1. Placenta accreta (abnormally adherent placenta difficult to expel); increased incidence if placenta previa exists with maternal history of uterine surgery.
2. Placenta increta (placenta attaches very deeply into muscle layer of uterus) and placenta percreta (placenta grows through the uterus possibly to surrounding organs).
3. Immediate hemorrhage, possible shock, and maternal death.
4. Postpartum hemorrhage.
5. Uterine rupture.
6. Fetal malpresentation.
7. Prematurity.

Nursing Assessment

1. Estimate current episode of blood loss; review history of bleeding throughout current pregnancy.
2. Assess pain in association with the bleeding.
3. Assess maternal and fetal vital signs through electronic fetal monitoring (EFM).
4. Assess for symptoms of labor: preterm or term.
5. Evaluate laboratory data to assess signs of hemorrhage: hemoglobin and hematocrit.

Nursing Diagnoses

- Risk for Ineffective Peripheral Tissue Perfusion: Placental related to excessive bleeding causing fetal compromise.
- Risk for Deficient Fluid Volume related to excessive bleeding.
- Anxiety related to excessive bleeding, procedures, and possible maternal–fetal complications.

Nursing Interventions

Promoting Tissue Perfusion

1. Monitor both the mother and fetus frequently; pulse, respirations, and BP should be taken as the patient's condition warrants; continuous EFM if fetus viable.
2. Administer IV fluids, as prescribed.
3. Prepare for emergency delivery and neonatal resuscitation, as needed.
4. Administer antenatal corticosteroids (betamethasone) if gestational age is between 24 and 34 weeks to enhance fetal lung maturity.

Maintaining Fluid Volume

1. Establish and maintain IV access as indicated; obtain CBC, type and screen/cross for blood replacement, platelets, PT/PTT, and fibrinogen. Repeat periodically as patient's condition warrants.
2. Assess bleeding frequently to note changes in frequency and volume.
3. Activity may be restricted while hospitalized based on mother and fetal condition.
4. If bleeding is profuse and delivery cannot be delayed, prepare for a cesarean delivery.
5. Administer blood transfusion, as necessary.

Decreasing Anxiety

1. Explain all treatments and procedures; answer related questions to patient satisfaction.
2. Offer compassionate presence and emotional support.

Community and Home Care Considerations

1. Home care for patients with placenta previa and other antenatal bleeding disorders can occur if the following criteria are met:
    a. No active bleeding.
    b. No signs and symptoms of preterm labor (PTL).

c. Follow up plan with health care team in place. Emergency support readily available.

2. Teach the woman signs and symptoms of hemorrhage; patient report to labor and delivery immediately if bleeding occurs.
3. Monitor vaginal discharge and bleeding after each urination and bowel movement.
4. Instruct the woman on home uterine activity monitoring, if ordered; use of palpation and electronic telemetry units included.
5. Instruct the woman on performing daily fetal movement counts (kick counts).
6. Antepartum testing may be increased, as indicated periodically; biophysical profile (BPP), nonstress test (NST), and amniotic fluid index (AFI) may be ordered to be conducted weekly.
7. Instruct the woman to have support persons readily available.
8. Instruct patient of the need for vaginal and sexual abstinence; discuss options.

Patient Education and Health Maintenance

1. Educate the woman and her family about the diagnosis, etiology, and treatment of placenta previa.
2. Educate the woman who is discharged from the hospital with placenta previa to avoid intercourse or inserting anything into her vagina, limit physical activity, have an accessible person in the event of an emergency, and report to the hospital immediately if repeat bleeding, more than six uterine contractions per hour, or decreased fetal movement.

Evaluation: Expected Outcomes

- Fetal condition stable.
- Absence of shock, stable vital signs, absence of bleeding.
- Verbalizes concerns and understanding of procedures and treatments.

Abruptio Placentae

Abruptio placentae results from the premature separation of a normally implanted placenta before the birth of the fetus; typically occurs after 20 weeks' gestation. Classifications include partial, complete, or marginal (Figure 39-3). Hemorrhage can be concealed (occult/hidden) or revealed (exposed). During an occult hemorrhage, the placenta detaches from the center, leaving the edges attached; this offers a concealed area for blood to pool behind the placenta. Even though bleeding is not evident at the perineum, concealed hemorrhage is accompanied by constant cramping or general abdominal pain. Prompt intervention is warranted.

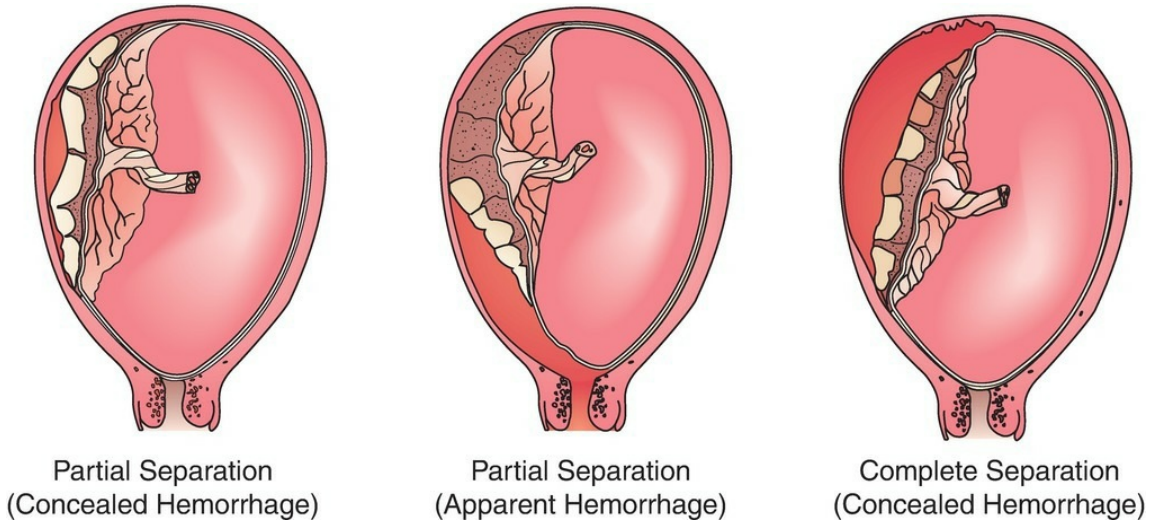

Figure 39-3. Abruptio placentae—premature separation of the placenta. (From Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Pathophysiology and Etiology

1. Typically, the etiology is unknown, but risks include:
   a. History of abdominal trauma, prior cesarean birth, uterine anomalies (fibroids, septum).
   b. Maternal hypertension: 50% of placental abruptions are associated with some form of hypertension.
   c. Cigarette smoking, cocaine, or amphetamine abuse.
   d. Thrombophilias, such as Factor V Leiden or antiphospholipid antibody.
   e. Previous history of abruptio placentae or partial abruption in current pregnancy.
   f. Rapid decompression of the uterus (reduction of fluid with polyhydramnios).
   g. Preterm premature rupture of membranes: less than 34 weeks.
2. Hemorrhage occurs into the decidua basalis behind the placenta and forms a hematoma. This hematoma will expand as bleeding increases; enlargement further detaches the placenta from the uterine wall.

Clinical Manifestations

1. Sudden-onset, intense, constant, generalized abdominal pain/tenderness with (revealed) or without (concealed) vaginal bleeding; approximately 10% of women present with concealed hemorrhage.
2. Uterine contractions are typically low amplitude and high frequency. Uterine baseline resting tone may be elevated over course of evolving abruption.
3. Changes in the FHR may commonly be the first sign of maternal hemodynamic imbalance. Category II or III patterns may present to include tachycardia or bradycardia, recurrent late decelerations with minimal or absent variability. Fetal response depends on amount of blood loss and extent of uteroplacental insufficiency present.
4. Patient may exhibit signs and symptoms of rapid labor progress and delivery.

Diagnostic Evaluation

1. Based on woman's history, physical examination, laboratory studies, EFM data, and signs and symptoms to include vaginal bleeding, abdominal pain, uterine contractions, uterine tenderness, and/or maternal–fetal distress. Presentations vary per patient.
2. Ultrasound is performed to exclude placenta previa, but may not be sensitive enough to diagnose or rule out abruptio placentae; EFM is frequently more accurate.
3. Kleihauer-Betke lab test may be ordered to determine maternal–fetal hemorrhage by assessing maternal blood for the presence of fetal RBCs.

Management

1. Management depends on maternal and fetal status and degree of bleeding. Any viable fetus and patient with suspected abruptio placentae should be admitted immediately and continuous EFM applied.
2. In fetal compromise, severe hemorrhage, coagulopathy, or increasing uterine activity dysfunction, emergent cesarean delivery is highly recommended.
3. If the mother is hemodynamically stable and the fetus is stable (normal FHR/Uterine Activity data) or has an intrauterine fetal demise, vaginal delivery may be recommended.
4. If mother is hemodynamically unstable, she may need stabilization with IV/blood/blood products replacement to maintain urine output and appropriate hematocrit levels. With rapid infusion of fluids, monitor woman for signs/symptoms of pulmonary edema.
5. A neonatal specialty team is necessary at delivery because of prematurity and neonatal complications.

Complications

1. Maternal shock, DIC.
2. Anaphylactoid syndrome of pregnancy (formerly amniotic fluid embolism).
3. Postpartum hemorrhage.
4. Acute respiratory distress syndrome.
5. Sheehan syndrome (postpartum pituitary necrosis).
6. Renal tubular necrosis.

7. Precipitous labor and delivery.
8. Prematurity.
9. Maternal or fetal death.

Nursing Assessment

See Table 39-2.

Table 39-2 Characteristics of Abruptio Placentae and Placenta Previa

CHARACTERISTIC	ABRUPTIO PLACENTAE	PLACENTA PREVIA
Onset	Third trimester	Third trimester (commonly at 32–36 weeks)
Bleeding	May be concealed, external dark hemorrhage, or bloody amniotic fluid	Mostly external, small to profuse in amount, bright red
Pain and uterine tenderness	Usually present; irritable uterus, progresses to boardlike consistency	Usually absent; uterus soft
Fetal heart tone	May be irregular or absent	Usually normal
Presenting part	May be engaged	Usually not engaged
Shock	Moderate to severe depending on extent of concealed and external hemorrhage	Usually not present unless bleeding is excessive
Delivery	Immediate delivery, usually cesarean delivery	Delivery may be delayed, depending on size of fetus and amount of bleeding

1. Determine the amount and type of bleeding along with the presence or absence of pain; labor pain is episodic, whereas placental abruption pain is constant.
2. Monitor maternal and fetal vital signs, especially maternal BP, pulse, FHR, FHR characteristics, and uterine activity data.
3. Palpate the abdomen.
   a. Note presence of contractions and note relaxation between each subsequent contraction.
   b. If contractions are not present, assess abdominal firmness (relaxed or tight).
4. Measure and record fundal height periodically to evaluate accumulation of concealed bleeding.
5. Prepare for possible delivery.

Nursing Diagnoses

Ineffective Peripheral Tissue Perfusion: Placental related to excessive bleeding

- Deficient Fluid Volume related to excessive bleeding.
- Fear related to excessive bleeding, procedures, and unknown outcome.

Nursing Interventions

Maintaining Tissue Perfusion

1. Evaluate amount of bleeding by weight of pads (actual blood loss) and direct visualization, rather than estimated blood loss, particularly if moderate to severe. Monitor CBC results and vital signs.
2. Position in the left lateral position, with head elevated.
3. Administer oxygen via face mask at 8 to 10 L/minute. Maintain oxygen saturation level above 90% to 95%. Limit prolonged use, particularly if delivery is imminent.

4. Evaluate fetal status with continuous external fetal monitoring.
5. Encourage relaxation techniques.
6. Prepare for possible cesarean delivery if maternal or fetal compromise is evident.

Maintaining Fluid Volume

1. Establish and maintain IV access for fluids and blood component therapy, as prescribed.
2. Evaluate coagulation studies and intake and output totals.
3. Monitor maternal vital signs and uterine activity.
4. Monitor vaginal bleeding and evaluate fundal height to detect an increase in bleeding.

Decreasing Fear

1. Inform the woman and her family about maternal–fetal status frequently.
2. Explain all procedures in advance when possible or as they are performed.
3. Answer questions in a calm manner, using simple terms.
4. Encourage the presence of a support person.

Patient Education and Health Maintenance

1. Provide information regarding etiology and treatment for abruptio placentae.
2. Encourage involvement from the neonatal team regarding education related to fetal/neonatal outcome.
3. Teach high-risk women the signs and symptoms of placental abruption.
4. Instruct woman to report to labor and delivery immediately should excessive bleeding or constant pain occur at home.
5. Instruct woman to have emergency plan in place for transport to medical facility. It is important to have support persons aware of procedures as well.

Evaluation: Expected Outcomes

- FHR remains as category I or II with minimal fetal deterioration noted.
- Absence of shock, demonstrated by stable maternal vital signs after initiation of treatment.
- Verbalizes concerns; asks questions.

Hypertensive Disorders of Pregnancy

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2017). *Emergent therapy for acute-onset, severe hypertension during pregnancy, and the postpartum period* (Committee Opinion #692). Washington, DC: Author.

Simpson, K. R., & Creehan, P. A. (2014). *Perinatal nursing* (4th ed.). Philadelphia, PA: Wolters Kluwer/Lippincott.

Hypertensive disorders of pregnancy are considered the most common medical complications of pregnancy, affecting 10% of all pregnancies globally and of the leading cause of maternal deaths in the United States. Classification varies from prepregnancy disease and beyond 12 weeks postpartum.

Classification

Chronic Hypertension

Hypertension is defined as mild, systolic BP ≥ 140 mm Hg *or* diastolic BP ≥ 90 mm Hg, or severe, systolic BP ≥ 160 mm Hg *or* diastolic BP ≥ 110 mm Hg. The condition may be observable before pregnancy, diagnosed before the 20th week of gestation, or persisting beyond 12 weeks postpartum. Condition increases risk of placental abruption.

Gestational Hypertension

1. New onset of hypertension (systolic BP ≥ 140 mm Hg *or* diastolic BP ≥ 90 mm Hg), generally after 20 weeks' gestation in the absence of gestational proteinuria; replaces the term *pregnancy-induced hypertension*.
2. BP typically normalizes to prepregnancy values by 12 weeks postpartum; if it remains elevated past 12 weeks, then a diagnosis of chronic hypertension is confirmed.

Preeclampsia and Eclampsia

1. Preeclampsia—elevated BP after 20 weeks' gestation accompanied by proteinuria.
   a. Gestational proteinuria greater than 300 mg on random specimen or greater than 1+ on dipstick.
   b. Urinary excretion ≥0.3 g protein in a 24-hour specimen (24-hour specimens are recommended for diagnosis).
   c. Both must be present for a diagnosis.
2. Severe preeclampsia: diagnosis considered if preeclampsia evident and at least one of the following is also present: systolic BP ≥ 160 mm Hg; diastolic BP ≥ 110 mm Hg; proteinuria 5 g or greater than 24-hour specimen or 3+ on two or more random urine specimens; oliguria of less than 500 mL/24 hours, cerebral or visual disturbances, pulmonary edema or cyanosis, epigastric or right upper quadrant pain, impaired

liver function (elevated AST/SGOT, ALT/SGPT, or LDH), thrombocytopenia (less than 150,000/mm^3 platelets), or fetal growth restriction.

3. HELLP syndrome—acronym stands for **H**emolysis: microangiopathic hemolytic anemia, **E**levated **L**iver enzymes, and **L**ow **P**latelets; form of severe preeclampsia (refer to Box 39-1).
4. Eclampsia—new onset of seizure activity or coma in a preeclamptic patient that cannot be attributed to any underlying neurologic condition or preexisting disease.

BOX 39-1 HELLP Syndrome

HELLP syndrome—consisting of Hemolysis of RBCs, Elevated Liver enzymes, and Low Platelets (<100,000 mm^3)—is a severe complication with or without preeclampsia.

- These findings are commonly associated with DIC and, in fact, may be diagnosed as DIC.
- The hemolysis of erythrocytes is seen in the abnormal morphology of the cells.
- The elevated liver enzyme measurement is associated with decreased blood flow to the liver as a result of fibrin thrombi.
- The low platelet count is related to vasospasm and platelet adhesions.
- Treatment is similar to treatment for preeclampsia with close monitoring of liver function and bleeding.
- These women are at increased risk for postpartum hemorrhage.
- Complaints range from malaise, epigastric pain, and nausea and vomiting to nonspecific viral syndrome-like symptoms.

Preeclampsia/Eclampsia Superimposed on Chronic Hypertension

1. Diagnosis based on presence of one or more of the following in woman with hypertension and proteinuria prior to 20 weeks' gestation:
   a. New onset of proteinuria.
   b. Sudden increase in proteinuria.
   c. Sudden increase in hypertension.
   d. Development of HELLP syndrome.

Pathophysiology and Etiology

1. The etiology of preeclampsia is unknown; however, inadequate placentation related to inadequate trophoblastic invasion of uterine spiral arteries is characteristic. Additional theories include immunologic, genetic, and endocrine factors. These factors lead to endothelial dysfunction, systemic inflammatory response, and subsequent increased capillary permeability resulting in multisystem organ dysfunction.
2. The disease is more commonly seen in primigravidas.
3. Risk factors—history of preeclampsia, African descent, first pregnancy with a new partner, chronic hypertension, hydatidiform mole, multiple gestation, polyhydramnios, preexisting vascular disease, obesity, and diabetes mellitus. Adolescents (younger than age 19) and women older than age 40 are at higher risk.

Diagnostic Evaluation

1. Evaluate BP with appropriate cuff size and placement.
2. A 24-hour urine for protein-creatinine ratio is recommended to confirm diagnosis of preeclampsia.
3. Serum BUN, serum creatinine, and serum uric acid levels evaluate renal function and glomerular filtration capability, signaling advanced disease.
4. Liver function tests (AST, ALT, LDH); elevations indicative of organ dysfunction and disease.
5. CBC with platelets.
6. Ultrasound assesses fetal growth, amniotic fluid volume, and placental implantation and function.
7. Periodic antepartum testing may be required to assess advanced or evolving disease and maternal–fetal tolerance: nonstress test (NST), oxytocin challenge test (OCT), biophysical profile (BPP).
8. Deep tendon reflexes (DTRs) and clonus evaluation assesses evolving disease and level of medications administered to treat disease.

Management

Treatment for hypertensive disorders of pregnancy focus on stabilization of the mother and pregnancy prolongation while observing for fetal intolerance. Delivery may be necessary for maternal indications, fetal indications, or both.

Expectant Management

Expectant management can be considered if the following maternal and fetal factors are present:

1. Maternal factors:
    a. Controlled hypertension.
    b. Urinary protein not severe; organ function adequate.
    c. Oliguria (less than 0.5 mL/kg/hour) that resolves with hydration.
    d. Liver enzymes not excessive, organ function adequate.
2. Fetal factors:
    a. BPP greater than 6.
    b. Amniotic fluid index (AFI) greater than 2 cm.
    c. Ultrasound fetal weight greater than 5th percentile.

Delivery

Delivery may be considered if any of the following occur:

1. Maternal factors:
    a. Uncontrolled hypertension: persistent greater than 160 systolic or 110 diastolic.
    b. Eclampsia unresolved or controlled.
    c. Thrombocytopenia: platelet count less than 100,000/mm^3.
    d. Compromised liver function.

e. Pulmonary edema.
f. Compromised renal function.
g. Abruptio placentae.
h. Persistent and unresolved severe headache or visual changes.
i. Evidence of hemorrhagic stroke or coma.

2. Fetal factors:
   a. Evolving category II patterns or category III FHR patterns (see page 1004).
   b. BPP less than 4 on two occasions, 4 hours apart.
   c. AFI less than 2 cm.
   d. Ultrasound fetal weight less than 5th percentile.
   e. Reverse umbilical artery diastolic flow.
   f. Evidence of acute placental abruption.

Antihypertensive Drug Therapy

Acute and persistent (greater than 15 minutes) onset of severe preeclampsia, systolic greater than 160 or diastolic greater than 110, is considered a hypertensive emergency warranting prompt medical management. A clinical relationship between severe systolic hypertension and risk of hemorrhagic stroke has been observed in pregnant and nonpregnant adults. Therefore, a systolic BP of 160 mm Hg or greater is widely adopted as the definition of severe hypertension in pregnant or postpartum women. The goal of antihypertensive therapy is not to achieve normotension but to reduce risk of stroke and coma. BP is maintained with a margin of safety (less than 100 mm Hg) without compromising adequate uterine perfusion.

1. Hydralazine—relaxes vascular arterioles and stimulates cardiac output via direct peripheral vasodilation.
   a. Use with caution in women with coronary artery disease.
   b. Dosage: 5 to 10 mg IV push over 2 minutes every 15 to 20 minutes to a maximum dose of 20 mg; dose cautiously and avoid hypotension. Cardiac monitoring is required for IV administration. Oral dosing will depend on clinical presentation.
   c. Onset of action can occur in 10 to 20 minutes, with peak action in 20 minutes; duration of the drug can last 3 to 8 hours.
   d. Monitor BP and pulse closely. If desired response is not obtained after 20 mg, change agents or consider hemodynamic monitoring.
   e. Adverse effects: flushing, headache, maternal and fetal tachycardia, palpitations, uteroplacental insufficiency with subsequent fetal tachycardia, late decelerations, and worsening hypertension (if due to elevated cardiac output). Rebound hypotension is possible if drug is given too rapidly.
2. Labetalol—alpha/beta-adrenergic blocker that decreases systemic vascular resistance without reflex tachycardia; it slows the maternal heart rate.
   a. Contraindicated in women with asthma, heart failure, and/or second-or third-degree heart block.
   b. Administered as 20 mg IV bolus dose, followed by 40 mg if no effect is seen in 10 minutes, then 80 mg every 10 minutes to a maximum dose of 220 mg. Cardiac monitoring is required for IV

administration. Oral dosing will depend on clinical presentation.

c. Onset of action is 1 to 2 minutes, with peak of action at 10 minutes; duration of drug effect lasts 6 to 16 hours.

d. Adverse effects: transient fetal and neonatal hypotension, bradycardia, and hypoglycemia. Small doses excreted in breast milk.

3. Nifedipine—a calcium channel blocker that inhibit calcium reuptake and smooth muscle cell contractility.

a. Administer 10 mg orally.

b. Onset of action is 20 minutes, may repeat ×1 after 30 minutes if necessary.

c. Sublingual route is contraindicated related excessive hypotension and acute myocardial ischemia and death.

Anticonvulsant Therapy

1. Magnesium sulfate is the primary medication for prophylactic treatment of seizure activity precipitated by hypertension; may be given either via IV line or IM, yet IV route is preferred; IM administration is reserved for eclamptic patients without IV access.

a. A 4-g loading dose of 50% magnesium sulfate is usually given via IV line over 15 to 30 minutes followed by a maintenance dose (secondary infusion) of 1 to 2 g/hour.

b. The therapeutic level for magnesium sulfate is a serum level of 4 to 7 mEq/dL. Periodic laboratory analysis of serum levels is required.

c. Actions: decreases neuromuscular irritability and blocks release of acetylcholine at the neuromuscular junction; depresses vasomotor center; depresses central nervous system (CNS) irritability.

d. Signs of magnesium sulfate toxicity (magnesium sulfate levels greater than 8 mEq/dL): loss of DTRs, including patellar reflex, respiratory depression, oliguria, respiratory arrest, and cardiac arrest.

e. Calcium gluconate is maintained bedside (but must remain secure) as a reversal agent for magnesium toxicity; dosage is 1 g (10 mL of 10% solution) by slow IV push.

2. Phenytoin, although proposed for eclampsia prophylaxis, is considered second-line therapy in the United States; preferred for patients with kidney dysfunction.

Complications

Complications of preeclampsia affect many organ systems to include cardiovascular, renal, hematologic, neurologic, hepatic, and uteroplacental.

1. Abruptio placentae.
2. DIC.
3. HELLP syndrome.
4. Maternal or fetal death.
5. Hypertensive crisis, hemorrhagic stroke, or coma.
6. Pulmonary edema; cerebral edema.

7. Oliguria; acute renal dysfunction or failure.
8. Thrombocytopenia; acute liver dysfunction or failure.
9. Postpartum hemorrhage.
10. Blindness; retinal detachment.
11. Fetal intolerance of labor; evolving category II or category III patterns.
12. Hypoglycemia.
13. Hepatocellular dysfunction; hepatic rupture.
14. Prematurity.
15. Growth restriction and placental dysfunction.

DRUG ALERT To improve maternal–fetal outcomes, severe headaches that occur after 20 weeks' gestation, accompanied by visual changes, elevated BP (systolic > 140 mm Hg or diastolic > 90 mm Hg), and proteinuria should be evaluated immediately by the health care provider to decrease associated risk to mother and fetus during pregnancy and prevent hospitalization.

Nursing Assessment

1. Evaluate BP with appropriate cuff size and placement.
2. Assess urine protein and creatinine as ordered.
3. Assess DTRs and clonus on admission and per facility policy.
4. Evaluate fetal status with NST, fetal movement (kick) counts, BPP, contraction stress test (CST) via nipple stimulation or OCT, and continuous EFM, as directed.
5. Evaluate uterine activity for high-frequency, low-intensity uterine contractions; possible signs and symptoms of PTL or placental abruption.
6. Periodically observe for signs and symptoms of advancing disease.
7. Monitor for signs of magnesium sulfate toxicity—absent knee-jerk reflex, respiratory depression, oliguria, absent FHR variability; if evident, discontinue magnesium sulfate and notify health care provider immediately.
8. Monitor serum magnesium serum level based on patient's clinical status and per facility's policy.

Nursing Diagnoses

- Risk for Imbalanced Fluid Volume related to pathophysiologic aspects of disease leading to fluid overload.
- Risk for Decreased Cardiac Tissue Perfusion (Placental) related to altered vascular perfusion caused by vasospasm and thrombosis formation.
- Risk for Injury related to seizures, prolonged bed rest, or other therapeutic regimens.

- Anxiety related to diagnosis and concern for self and fetus.
- Decreased Cardiac Output related to antihypertensive therapy.

Nursing Interventions

Maintaining Fluid Balance

1. Strict intake and output—control IV fluid intake using an infusion pump. Foley catheter with urometer for strict assessment of output may be ordered. Notify health care provider if urine output is less than 25 mL/hour.
2. Monitor vital signs per facility protocol and as the patient's condition warrants.
3. Auscultate breath sounds at admission and periodically; report signs of pulmonary edema (ie, wheezing, crackles, shortness of breath, increased pulse rate, increased respiratory rate, or reduced SpO_2 saturation).

Promoting Adequate Tissue Perfusion

1. Maintain bed rest and position laterally to optimize maternal and placental perfusion.
2. Evaluate NST and continuous EFM, if applicable, to determine fetal status.

Preventing Injury

1. Instruct patient on importance of reporting signs of advancing disease: headaches, visual changes, dizziness, respiratory distress, and/or epigastric pain.
2. Keep the environment quiet and calm as possible, minimizing visitors.
3. Implement seizure precautions with padded side rails and maintain safe environment
4. Hospitalized patients should have oxygen, suction, and emergency medications immediately available for seizure management.
5. Assess DTRs and clonus facility protocol; increase frequency as patient's condition warrants.

Decreasing Anxiety and Increasing Knowledge

1. Explain disease process and care plan including signs and symptoms of evolving disease.
2. Discuss the effects of all medications on mother and fetus.
3. Allow time to ask questions and discuss feelings regarding the diagnosis and treatment plan.

Maintaining Cardiac Output

1. Maintain strict intake and output monitoring.
2. Monitor maternal vital signs and pulse oximetry. Report abnormalities to provider.
3. Assess formation of edema: peripheral and pulmonary. Report pitting edema of +2 or less or evidence of pulmonary edema to primary care provider immediately.

Community and Home Care Considerations

1. Mild preeclampsia, if stable, may be considered for home care at the discretion of the primary practitioner.

2. Ensure patient has access to primary care provider.
3. Periodic home visits by nursing personnel may be warranted.
4. Teach woman signs and symptoms of evolving disease. Home BP and urine output monitoring is recommended.
5. Teach woman to assess daily fetal movement (kick) counts; arrange for weekly NST, if indicated.

Patient Education and Health Maintenance

1. Teach the woman the importance of bed rest, medication use, and lateral positioning.
2. Encourage support of family and friends; suggest diversional activities on bed rest.
3. Include support of the neonatal team for discussion of fetal prognosis with the woman and her family.

Evaluation: Expected Outcomes

- BP and other vital parameters stable.
- Absence of evolving category II or category III FHR patterns.
- No seizure activity.
- Expresses concern for self and fetus.
- No evidence of pulmonary edema; urine output adequate.

Hydramnios

Hydramnios also called poly*hydramnios* is excess amniotic fluid and occurs in 1% to 5% of pregnancies; volume typically exceeds 2 L between 32 and 36 weeks' gestation. Although about 50% of cases result in normal outcomes, hydramnios often leads to preterm delivery, fetal malpresentation, and umbilical cord prolapse.

Pathophysiology and Etiology

1. Amniotic fluid is 98% to 99% water, with the remainder consisting of proteins, carbohydrates, fats, electrolytes, enzymes, hormones, urinary by-products, fetal cells, lanugo, and vernix.
   a. Amniotic fluid volume is influenced by fetal urination and fetal lung liquid production.
   b. Volume facilitates normal lung and neuromuscular maturity.
   c. A fetus near term will produce 500 to 1,200 mL of urine and swallow 210 to 760 mL of amniotic fluid daily.
   d. At 36 weeks' gestation, approximately 1 L of fluid is present with subsequent decreases over the duration of gestation.
2. Polyhydramnios is idiopathic in 60% of women but is associated with multiple gestation, immune and nonimmune hydrops fetalis, chromosomal anomalies such as Down syndrome, and fetal GI–cardiac–neural tube abnormalities.

Clinical Manifestations

1. Excessive weight gain, dyspnea.
2. Abdomen may be tense and shiny.
3. Edema of the vulva, legs, and lower extremities may be evident.
4. Increased uterine size for gestational age; usually accompanied by difficulty in palpating fetal parts or auscultation of the FHR.
5. Possible evolving category II or category III FHR patterns.

Diagnostic Evaluation

1. Ultrasound evaluation: AFI greater than 20 cm or single deepest pocket depth greater than 8 cm or total volume greater than 2 L.
2. Difficult to palpate fetus or auscultate FHR.
3. Fundal height (FH) greater than age of gestation.

Management

1. Treatment is based on severity and underlying conditions; may include direct fetal therapy, amnioreduction, or administration of prostaglandin inhibitors such as indomethacin.
2. Indomethacin decreases fetal urine output through the constriction of the renal arteries. Used cautiously after 30 weeks' gestation to prevent premature closure of the patent ductus arteriosus.
3. Amnioreduction:

a. Accomplished with amniocentesis where fluid is slowly removed under ultrasound-guided needle aspiration; rapid removal can result in a premature separation of the placenta.
b. Usually 500 to 1,000 mL of fluid is removed during one procedure. Fluid should be removed slowly, no faster than 1,000 mL over 20 minutes.

Complications

1. Potential for dysfunctional labor with increased risk for cesarean delivery.
2. Postpartum hemorrhage because of uterine atony from prolonged gross distention of the uterus.
3. Acute fetal hypoxia secondary to prolapsed cord or trauma.
4. Potential for preterm delivery.

Nursing Assessment

1. Evaluate maternal respiratory status; dyspnea may be present as hydramnios increases.
2. Evaluate EFM, to assess fetal status.
3. Inspect abdomen and evaluate uterine height and compare with previous findings.
4. Evaluate for abdominal pain, edema, varicosities of lower extremities, and vulva.

Nursing Diagnoses

- Ineffective Breathing Pattern related to pressure on the diaphragm.
- Impaired Physical Mobility related to edema and discomfort from the enlarged uterus.
- Anxiety related to fetal outcome.
- Risk for Bleeding at delivery and postpartum related to prolonged overdistention of the uterus.

Nursing Interventions

Promoting Effective Breathing

1. Position to alleviate dyspnea.
2. Limit activities and plan for frequent rest periods.
3. Maintain adequate intake and output.

Promoting Mobility

1. Assist the woman with position changes and ambulation, as needed.
2. Advise on alternating activity with rest periods to promote circulation.
3. Instruct the woman to wear loose-fitting clothing and low-heeled shoes with good support.

Decreasing Anxiety

1. Explain probable causes of polyhydramnios, if known.
2. Encourage the patient and family to ask questions and express feelings regarding any treatment or procedure.

3. Prepare patient for mode of delivery that is anticipated and for the expected findings at the time of delivery.
4. Encourage presence and participation of support person in plan of care.

Preventing Hemorrhage During Labor and Postpartum

1. Notify primary care provider of inadequate or abnormal labor curve.
2. Maintain IV access and administer parenteral fluids as ordered (LR).
3. Administer medications (ie, oxytocin, misoprostol) to decrease postpartum bleeding, as necessary.
4. Observe for alterations in vital signs indicating excessive blood loss.

Patient Education and Health Maintenance

1. Instruct the woman to notify her health care provider if she experiences respiratory distress.
2. Teach the woman signs of PTL and hemorrhage and to report them to health care provider.

Evaluation: Expected Outcomes

- Respirations: rate of 18 to 22 and unlabored.
- Verbalizes improved comfort; moves freely.
- Discusses pregnancy outcome realistically; asks questions regarding treatment for self and fetus.
- Labor progresses and involution occurs without hemorrhage.

Oligohydramnios

Oligohydramnios is the marked decrease of amniotic fluid of less than 500 mL in the amniotic sac. It is rarer than hydramnios and is associated with a 43% perinatal mortality risk.

Pathophysiology and Etiology

1. Commonly related to amnion abnormalities, placental insufficiency, severe preeclampsia, premature rupture of membranes, and fetal problems, such as obstruction in the urinary tract, renal agenesis, pulmonary hypoplasia (Potter syndrome), and IUGR (any condition that prevents the formation of urine or the entry of urine into the amniotic sac usually results in oligohydramnios).
2. Commonly seen in postdate pregnancies.

Clinical Manifestations

1. Prominent fetal parts on palpation of the abdomen.
2. Small-for-date uterine size.
3. FHR variable decelerations or repetitive late decelerations may present on EFM tracing.

Diagnostic Evaluation

1. Ultrasound evaluation of the AFI—decrease of amniotic fluid in all four vertical plane quadrants of the uterus of less than 500 mL, single deep pocket depth less than 2 cm, or AFI less than 5 cm at term.

Management

1. Frequent evaluation of fetal status through NST, BPP, CST, or OCT, as indicated.
2. Periodic ultrasound evaluations performed to evaluate fetal renal dysfunction and abnormal fetal growth.
3. Amnioinfusion (the installation of fluid into the amniotic cavity to replace depleted volumes of amniotic fluid) during labor is optional to decrease occurrence and severity of FHR variable decelerations.
4. Delivery may be indicated for such conditions as IUGR or fetal compromise.

Complications

1. Preterm labor.
2. Umbilical cord compression.
3. Passage of meconium.
4. Fetal/neonatal death.
5. Neonatal respiratory distress because of pulmonary hypoplasia related to fetal compression and growth restriction.

Nursing Interventions and Patient Education

1. Evaluate fetal status with EFM.
2. Evaluate maternal vital signs per facility protocol; note signs of infection, especially if oligohydramnios is

secondary to PROM.

3. Assist with an amnioinfusion, as indicated.
4. Inform health care provider of fetal intolerance to labor and treat, as indicated.

Multiple Gestation

Multiple gestation or *multifetal pregnancy* results when two or more fetuses are present in the uterus at the same time. Since 1980, there has been a 76% increase in the frequency of twins and a 400% rise in triplet and high-order multiples because of advanced maternal age and assisted reproductive technology (ART). Multiple gestation is not a complication of pregnancy; rather, it is a condition that presents an increased risk of morbidity and mortality for mother and neonates.

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2014/Reaffirmed 2016). *Multiple gestation: Complicated twin, triplet, and high-order multifetal pregnancy* (Practice Bulletin #169). Washington, DC: Author.

Pathophysiology and Etiology

1. Types of twinning (Figure 39-4): The degree to which structures are shared (amnion, chorion, placenta) is related to the time of zygotic division after conception (within 72 hours).
   a. Monozygotic (identical)—one ovum fertilizes with one sperm, later dividing early in gestation resulting in two embryos. Each embryo has identical genetic makeup and gender identity but may vary in size because of unequal splitting of the cytoplasm; etiology unclear; rarest type of twinning with increased risk of twin-to-twin transfusion syndrome.
   b. Dizygotic, trizygotic (fraternal, nonidentical)—two or more ova are fertilized by two or more separate sperm. The twins do not always share same genetic makeup or gender identity.
2. Artificially induced ovulation, as well as in vitro fertilization with multiple embryos transferred into the uterus, increases risk of multiple gestation.
3. Increasing maternal age and parity increase odds of twinning.
4. Other terminology:
   a. Monochorionic—one chorionic membrane.
   b. Monoamniotic—one amniotic sac.
   c. Dichorionic—two chorionic membranes.
   d. Diamniotic—two amniotic sacs.

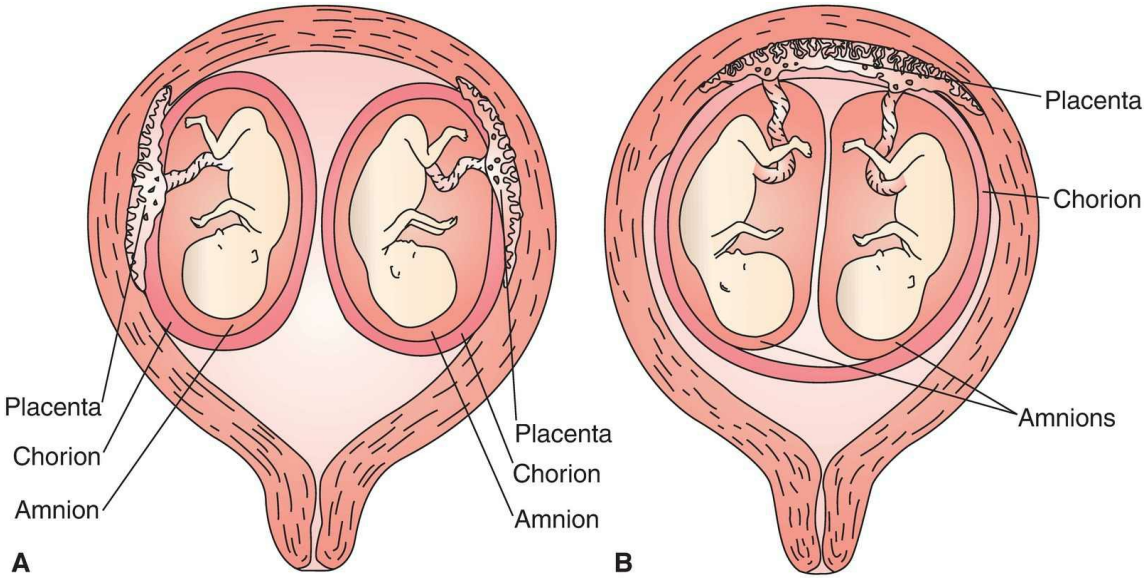

Figure 39-4. Multiple gestations. **(A)** Dizygotic twins showing two placentas, two chorions, and two amnions. **(B)** Monozygotic twins with one placenta, one chorion, and two amnions. (From Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Clinical Manifestations

1. Uterine size is large for gestational age. Fundal height is typically 2 cm larger than normal.
2. Auscultation of two or more distinct and separate fetal hearts may occur with a Doppler late in the first trimester or with a fetoscope after 20 weeks' gestation.
3. Ultrasound is the primary diagnostic tool; used for 95% to 100% of cases. Gestation sacs identified as early as 6 to 8 weeks.
4. High initial quantitative β-hCG is one of the earliest indicators. However, because of the possibility of false-positive results, ultrasound should be used to confirm the diagnosis in the presence of elevated β-hCG levels.

Complications

1. Cardiopulmonary.
   a. Pulmonary edema.
   b. Complications from tocolysis.
   c. Hypertension or preeclampsia.
   d. Aortocaval compression syndrome
   e. Peripartum and postpartum cardiomyopathy.
2. GI.
   a. Acute fatty liver of pregnancy.
   b. Cholestasis of pregnancy.

3. Hematologic—anemia.
4. Obstetric.
    a. PTL or preterm birth.
    b. Incompetent cervix.
    c. Increased incidence of cesarean delivery.
    d. Increased use of tocolysis.
    e. Antepartum and postpartum hemorrhage.
    f. Abruptio placentae.
    g. Uterine rupture.
    h. Gestational diabetes.
    i. Polyhydramnios; oligohydramnios common with twins.
    j. Spontaneous abortion.
    k. IUGR.
    l. Umbilical cord problems, such as entanglement, cord prolapse, or vasa previa.
5. Fetal risks—structural abnormalities, such as congenital heart defects, intestinal tract anomalies, neural tube defects, hydrocephaly, craniofacial defects, skeletal defects, anencephaly, and encephalocele.
6. Conjoined twins.
7. Twin-to-twin transfusion syndrome leads to anastomoses of placental vessels; increased risk with one placenta.

Management and Nursing Interventions

1. Nutrition counseling—increased caloric and protein intake as well as vitamin supplements are needed to meet demands of multiple fetuses.
2. Fetal evaluation—serial sonograms during the pregnancy evaluate growth and development to growth inconsistencies. NST, BPP, and amniocentesis are utilized for detection of fetal lung maturity and fetal tolerance. Percutaneous umbilical cord sampling may be used to establish fetal well-being if twin-to-twin transfusion is suspected.
3. PTL prevention—hospitalization may be necessary for signs and symptoms of PTL.
    a. Encourage bed rest and hydration.
    b. Institute fetal monitoring and assist with tocolytic therapy, if ordered.
4. Mode of delivery—dependent on the presentation of the twins, maternal and fetal status, and gestational age. Cesarean delivery is commonly used for multiples other than twins.
5. Intrapartum management.
    a. Establish IV access.
    b. Provide for EFM for each fetus; triplets and high-order multiples may need serial ultrasounds during labor or preoperatively.
    c. Double setup (vaginal delivery attempted in operating room suite) is recommended for delivery, if

appropriate. Guidelines for vaginal birth of twins:

i. Multiple neonatal teams to care for each newborn.

ii. Surgical suite immediately available.

iii. An obstetrician and assistant experienced in vaginal births of twins at delivery.

iv. Anesthesia of choice: epidural, although alternatives exist; consult with anesthesiologist. Anesthesia provider capable of administering general anesthesia should be immediately available.

d. Pitocin induction/augmentation may be required secondary to hypotonic labor.

e. An increased risk of postpartum hemorrhage exists; prepare accordingly.

6. Emotional support—encourage family to discuss feelings about multiple births and identify ways in which they will need assistance. Refer to resources such as National Organization of Mothers of Twins Clubs (*www.nomotc.org*).

Community and Home Care Considerations

1. Discuss the warning signs of PTL.
2. Home care may include nursing visits and fetal assessments.
3. Ensure provider contact information is available.

INTRAPARTUM COMPLICATIONS OF LABOR

Preterm Labor

Preterm labor (PTL) is defined as regular contractions associated with cervical change between 20 and 37 completed weeks of gestation. PTL is second, only to birth defects, as a leading cause of infant mortality. The preterm birth rate in the United States was 9.6% for 2016. However, neonatal intensive care and technology has advanced to meet the various needs of extrauterine transition of the preterm fetus.

It is important to differentiate PTL from other sequelae to avoid misdiagnosis. For example, uterine irritability without cervical change is not PTL. Likewise, preterm birth (PTB) and low birth weight (LBW) are not synonymous; preterm birth is any birth that occurs before 37 completed weeks of pregnancy, whereas LBW refers to birth weight alone (less than 2,500 g [5½ lb]), regardless of gestational age.

Pathophysiology and Etiology

1. The exact etiology for PTL remains unknown, but may include:
    a. Decidual hemorrhage (placental abruption).
    b. Mechanical factors such as uterine overdistention or cervical incompetence.
    c. Hormonal dysfunction.
    d. Anatomical and structural abnormalities.
    e. Infectious etiology (eg, bacterial vaginosis, group B beta strep).
2. Physiologic alterations occur with onset of spontaneous labor.
    a. Cervical changes occur: softening, shortening, and location.
    b. Oxytocin receptors present in the myometrium respond to circulating levels.
    c. Prostaglandin levels in the amniotic fluid rise.

Risk Factors for PTL

1. Medical/obstetric complications (predating the current pregnancy):
    a. Prior PTB triples risk in current pregnancy.
    b. Multiple abortions.
    c. Low prepregnancy weight for height.
    d. Uterine/cervical abnormalities.
    e. Parity (0 or greater than 4).
    f. Hypertension.
    g. Diabetes.
    h. Obesity.
2. Current pregnancy complications:
    a. Anemia.
    b. Multiple gestation.
    c. Placenta previa.

d. Abruptio placentae.
e. Fetal anomaly.
f. Hydramnios (polyhydramnios, oligohydramnios).
g. Abdominal surgery.
h. Infection.
i. Bleeding in first trimester.
j. Short interpregnancy interval.
k. PROM.
l. Cervical incompetence.
m. UTIs/pyelonephritis.

3. Demographic data:
   a. Maternal age younger than 17 or older than 35.
   b. African American (doubles the risk).
   c. Low socioeconomic status.
4. Behavioral and environmental:
   a. DES exposure.
   b. Smoking (especially if more than 11 cigarettes/day).
   c. Poor nutrition or excessive stress.
   d. Substance abuse.
   e. Late or no prenatal care.
   f. Intimate partner violence.

Clinical Manifestations

1. Uterine cramping (menstrual-like, intermittent, or constant).
2. Uterine contractions occurring at intervals of 10 minutes or less.
3. Low abdominal pain or pressure (pelvic pressure).
4. Dull low backache (intermittent or constant).
5. Increase or change in vaginal discharge.
6. Feeling that baby is "pushing down" or that "something" is in the vagina.

Diagnostic Evaluation

1. Transvaginal cervical ultrasound can predict cervical length and direct internal changes.
2. Fetal fibronectin (fFN): protein produced by fetal membranes and functions as an adhesive to hold membranes against the uterine myometrium. It is normally absent in cervical secretions after 16 to 20 weeks and reappears after 34 weeks. Therefore, a mid-trimester assay with positive fFN is an indicator of risk for PTL/PTB and possible infection. (See Chapter 36.)

Management

Management of PTL is focused on early education, prevention, and limiting neonatal morbidity.

Preconception Care

1. Baseline assessment of health and risks; advise patient to decrease risks attributable to PTL/PTB.
2. Pregnancy planning and identification of barriers to care.
3. Periodontal care.
4. Adjustment of prescribed and over-the-counter medications that may pose a threat to the developing fetus.
5. Nutritional counseling, as needed.
6. Genetic counseling, as indicated.

Antepartum Treatment

1. Educate mother regarding signs/symptoms of PTL.
2. Instruct mother and provide resources for lifestyle modifications:
   a. If applicable, encourage smoking-cessation classes.
   b. Discuss aspects of a healthy diet and adequate maternal weight gain during pregnancy.
3. Early therapy options include bed rest, hydration, and abstention from intercourse and orgasm; effectiveness of each method is uncertain.

Tocolytic Therapy

If antepartum therapy is not successful, tocolytic therapy may be instituted, with no one medication recognized to stop PTL. These drugs should be used only when the potential benefit to the fetus outweighs the potential risk. If tocolytic drugs are used, the choice of drug should be individualized and based on maternal condition, potential drug side effects, and gestational age.

1. Betamimetic—terbutaline: acts on β_2 receptor cells located in smooth muscle, inhibiting uterine contractions. Injectable (subcutaneous) terbutaline should not be used in pregnant women for prevention or prolonged treatment (beyond 48 to 72 hours) of PTL in either the hospital or outpatient setting because of the potential for serious maternal heart problems and death. In addition, oral terbutaline should not be used for prevention or any treatment of PTL because it has not been shown to be effective and has similar safety concerns.
   a. Withhold medication for a maternal pulse greater than 120.
   b. Contraindications: cardiac arrhythmias.
   c. Potential maternal adverse effects: tachycardia, cardiac arrhythmias, pulmonary edema, myocardial ischemia, hypotension, and death.
   d. Potential fetal adverse effects: tachycardia, hyperinsulinemia, hyperglycemia, myocardial or septal hypertrophy, myocardial ischemia.
2. Magnesium sulfate—interferes with smooth-muscle contractility, although its exact mechanism of action

is unknown.

a. Dosage: 4 to 6 g IV piggyback bolus over 15 to 30 minutes and then 1 to 2 g maintenance dose via continuous IV drip.
b. Contraindications: myasthenia gravis and renal disease.
c. Potential maternal adverse effects: flushing, lethargy, headache, muscle weakness, diminished DTR, diplopia, dry mouth, pulmonary edema, and cardiac arrest.
d. Potential fetal adverse effects: lethargy, hypotonia, respiratory depression, and demineralization with prolonged use.
e. Monitor serum magnesium levels.
f. Antidote for magnesium toxicity: calcium gluconate.

3. Prostaglandin inhibitors—Indomethacin: inhibits prostaglandin stimulation of contractions; however, after 34 weeks' gestation, indomethacin may cause premature closure of the fetal ductus arteriosus.
   a. Dosage: loading dose of 50 mg orally and then 25 mg orally every 6 hours for 48 hours maximum.
   b. Contraindications: significant renal or hepatic impairment.
   c. Potential maternal adverse effects: nausea, heartburn, postpartum hemorrhage.
   d. Potential fetal adverse effects: constriction of the ductus arteriosus, pulmonary hypertension, reversible decreased renal function with oligohydramnios, intraventricular hemorrhage, hyperbilirubinemia, necrotizing enterocolitis (NEC).
4. Calcium channel blocker—nifedipine: relaxes smooth muscle by inhibiting the transport of calcium negating contraction formation.
   a. Dosage: 10 to 40 mg oral loading dose and then 30 to 60 mg every 8 to 12 hours for 48 hours maximum.
   b. Contraindications: cardiac disease, use caution with renal disease, maternal hypotension (less than 90/50 mm Hg), avoid concomitant use with magnesium sulfate.
   c. Potential maternal adverse effects: flushing, dizziness, headache, nausea, transient hypotension.
   d. Potential fetal adverse effects: none currently known.
5. Antibiotic therapy: several regimens exist for intrapartum antimicrobial prophylaxis for perinatal group B streptococcal (GBS) disease prevention. Treatment should be started as presumptive positive for GBS.

General Contraindications to Tocolytic Therapy

1. Category III FHR patterns.
2. Intra-amniotic infection.
3. Eclampsia or severe preeclampsia.
4. Fetal demise.
5. Fetal maturity.
6. Maternal hemodynamic instability.
7. Severe bleeding of any cause.

8. Fetal anomaly incompatible with life.
9. Severe IUGR.
10. Cervix dilated more than 5 cm.

Acceleration of Fetal Lung Maturity

1. Corticosteroid administration—betamethasone or dexamethasone.
   a. Given to potential PTL patients between 24 and 34 weeks' gestation.
   b. Betamethasone is given IM in two doses of 12 mg each, 24 hours apart.
   c. Dexamethasone is given IM in four doses of 6 mg each, every 12 hours.
      i. Decreases intraventricular hemorrhage (IVH), NEC, and respiratory distress syndrome (RDS), mortality that may be a result of prematurity.
   d. Timely administration is essential; given before delivery to mother; postponing delivery for administration is an option.
   e. Serial administration of the agents is no longer recommended.
   f. Administered to woman at risk for PTB within the next 7 days.

Complications

1. Prematurity and associated neonatal complications include:
   a. Intraventricular hemorrhage (IVH), necrotizing enterocolitis (NEC).
   b. Respiratory distress syndrome (RDS) because of lung immaturity related to lack of surfactant production.
   c. Patent ductus arteriosus (PDA).
   d. Necrotizing enterocolitis (NEC).

Nursing Assessment

During tocolytic therapy, assess the following:

1. Fetal status and uterine activity (UA) data by EFM.
2. Respiratory status (pulmonary edema is an adverse effect).
3. Muscular tremors.
4. Palpitations.
5. Dizziness/light-headedness.
6. Urine output.
7. Patient education to signs and symptoms of PTL.
8. Patient education to signs and symptoms of infection.

Nursing Diagnoses

- Anxiety related to use of tocolytic drugs and change in role function.

- Risk for Injury to fetus secondary to prematurity.
- Potential Complications of Drug Therapy related to tocolytic therapy.
- Ineffective Coping related to situational crisis.

Nursing Interventions

Decreasing Anxiety

1. Know the contraindications and potential complications of tocolytic therapy.
2. Explain the purpose and common adverse effects of tocolytic therapy.
3. Provide accurate information on the status of the fetus and progressive labor.
4. Allow the woman and her support person to verbalize their feelings.
5. Encourage relationship with other patients who are also experiencing PTL.

Minimizing Injury to Fetus

1. Encourage the woman to assume lateral positions that will enhance placental perfusion.
2. Monitor fetal status and labor progress.
3. Assist with delivery of infant, as needed.
4. Notify the interprofessional team of progressing labor.

Minimizing Risk of Drug-Related Complications

1. Maintain accurate intake and output at least per facility protocol based on tocolytic agent and dosing.
2. Assess maternal vital signs in accordance with facility policy. Notify the primary health care provider if maternal pulse greater than 120 beats/minute.
3. Assess for signs and symptoms of pulmonary edema.
4. Assess DTRs per facility policy noting hyporeflexia because of magnesium sulfate infusion; excessive dosage or poor renal clearance may lead to magnesium toxicity.
5. Discontinue infusion if adverse effects occur; notify health care provider.
6. Educate the woman and partner on tocolytic therapy, explaining the purpose and common adverse effects.

Promoting Maternal–Family Coping

1. Provide support and direction, but also encourage private time for woman and partner.
2. Encourage asking questions and verbalization of feelings.
3. Facilitate social worker referral as needed.

Community and Home Care Considerations

1. Ensure that woman meets the following criteria for home management of PTL:
   a. No evidence of active PTL.
   b. No evidence of infection.

c. Cervical dilatation less than 3 cm.

Patient Education and Health Maintenance

1. Educate the patient about the importance of continuing the pregnancy until term related to improved outcomes with enhanced fetal lung maturity.
2. Encourage compliance with a decreased activity level or bed rest, pelvic rest, adequate nutrition, and hydration.
3. Teach the woman signs and symptoms of infection and to report them immediately.

Evaluation: Expected Outcomes

- Demonstrates concern about treatment and pregnancy outcome.
- No fetal compromise or complications; term delivery.
- Vital signs stable.
- Family focused on maternal–fetal well-being.

Premature Rupture of Membranes

Premature rupture of membranes (PROM) is defined as rupture of the membranes before the onset of labor. PROM is independent of gestational age; when it occurs prior to term it is referred to as preterm PROM. This condition occurs in approximately one third of preterm births and 8% of term pregnancies. PROM increases the risk of variable decelerations in the FHR tracing related to decreased amniotic fluid volume.

Pathophysiology and Etiology

1. Rupture of membranes occurs during the normal course of labor. The exact etiology of PROM is not clearly understood, although nonpathologic causes, such as the combination of stretching of the membranes and biochemical changes, are suspected to contribute; infection has commonly been found to be a primary cause.
2. PROM is manifested by a gush of amniotic fluid or leaking of fluid through the vagina, which usually persists; flow may decrease in the sitting or supine position.

Diagnostic Evaluation

1. Patient history and physical exam.
2. Sterile speculum examination for identification of "pooling" of fluid in the vagina, cervicitis, umbilical or fetal prolapse, and cervical advancement. Collect cultures as appropriate.
3. Nitrazine test—amniotic fluid changes pH paper from yellow–green to blue. False-positives may result when blood, semen, alkaline antiseptics, and bacterial vaginosis are present.
4. Fern test—swab of the posterior vaginal fornix is taken to obtain amniotic fluid. Positive test will reveal arborization or "ferning" (visually appears as a fern leaf) on a slide viewed under a microscope.
5. Ultrasound to assess amniotic fluid volume.

Management (>34 Weeks)

1. When PROM is confirmed, the gestational age, fetal presentation, and well-being will determine if hospitalization is warranted.
2. At any gestational age, a patient with evident intrauterine infection, placental abruption, or evidence of category III FHR pattern is best cared for by expeditious delivery.
3. If immediate delivery is not indicated, cultures of the cervix should be obtained to identify best antibiotic management (chlamydia, gonorrhea, and group B beta-hemolytic *Streptococcus*, if appropriate).
4. Expectant management: offer adequate time for the latent phase of labor to progress (may be as long as hours to days or at the discretion of the primary practitioner) and EFM.
    a. Vaginal examinations are kept to a minimum to prevent infection.
    b. Once the decision to deliver is made, GBS prophylaxis should be initiated based on prior culture results or risk factors.
5. Active management:
    a. Oxytocin induction/augmentation may be initiated at the time of presentation to reduce:

i. Risk of chorioamnionitis.

ii. Postpartum febrile morbidity.

iii. Neonatal antibiotic treatments.

Complications

1. Maternal infection—intrapartum (chorioamnionitis) and postpartum (endometritis).
2. Potential increased rates of cesarean delivery.
3. Fetal or neonatal infection or compromise.

Nursing Assessment

1. Evaluate maternal BP, respirations, pulse, and temperature per facility policy. Temperatures should be done every 2 hours. If temperature or pulse is elevated, continue monitoring more frequently.
2. Monitor the amount and type of amniotic fluid that is leaking. Observe for purulent, foul-smelling discharge that may indicate chorioamnionitis and report immediately.
3. Assess patient periodically for diffuse abdominal pain or pain on palpation, signs of increased infection.
4. Evaluate periodic CBC with differentials results; any shift to the left (ie, increase of immature forms of neutrophils/WBCs) signals infection.
5. Communicate any findings related to signs of infection to the primary practitioner and perinatal team.
6. Evaluate fetal status per facility policy depending on stages of labor; maternal infection is the primary cause of fetal tachycardia.
7. Allow patient activity as clinical status warrants.

Nursing Diagnosis

- Risk for Infection related to ascending bacteria, rupture of amniotic sac.

Nursing Interventions

Preventing Infection

1. Evaluate amount and odor of amniotic fluid leakage.
2. Use sterile gloves with vaginal exams that should be kept to a minimum.
3. Place patient on disposable pads to collect leaking fluid and change pads every 1 to 2 hours or more frequently, as needed.
4. Review the need for good hand-washing technique and hygiene after urination and defecation.
5. Monitor FHR and fetal activity per facility policy, as indicated.
6. Monitor maternal temperature, pulse respirations, BP, and uterine tenderness frequently, as indicated.
7. Administer GBS therapy or antibiotics, as indicated.

Evaluation: Expected Outcomes

- No signs of infection.

Preterm Premature Rupture of Membranes

Preterm premature rupture of membranes (PPROM) is defined as rupture of membranes before 37 completed weeks' gestation without the onset of spontaneous labor. Regardless of management or clinical presentation, delivery within 1 week is the most likely outcome. However, approximately 3% to 13% of patients can anticipate cessation of fluid leakage and possible restoration of normal amniotic fluid volume over remaining course of gestation.

PPROM patients are at high risk for infection during the intrapartum and postpartum phases. Secondary complications include fetal malpresentation, placental abruption, and prematurity. Neonatal complications are respiratory distress syndrome, infection, and death.

Pathophysiology and Etiology

1. Although the exact cause is unknown, PPROM is likely to be either a pathologic intrinsic weakness or related to an extrinsic factor that causes the membranes to rupture prematurely.
2. The primary cause of PPROM is infection, particularly in earlier gestations (amnionitis; group B beta-hemolytic *Streptococcus*).
3. Other causes:
    a. History of PROM/PTB.
    b. Low body mass index (less than 19.8).
    c. Nutritional deficiencies.
    d. Connective tissue disorders.
    e. Maternal smoking.
    f. Cervical conization or cerclage.
    g. Pulmonary disease.
    h. Uterine overdistention.
    i. Amniocentesis.

See PROM, page 1057, and Preterm Labor, page 1054, for management and nursing interventions.

Induction and Augmentation of Labor

EVIDENCE BASE Troiano, N., Harvey, C., & Chez, B. (Eds.). (2013). *High-risk and critical care obstetrics* (3rd ed.). Philadelphia, PA: Lippincott Williams & Wilkins.

Association of Women's Health, Obstetric, Neonatal Nurses. (2011). AWHONN Position statement: Non-medically indicated induction and augmentation of labor. *Journal of Obstetric, Gynecologic, and Neonatal Nursing, 40*, 665–666.

Induction of labor (IOL) refers to utilization of exogenous labor enhancement agents or procedures resulting in rhythmic contractions and spontaneous onset of labor. Cervical ripening utilizes medications and procedures to effect the physical properties (softening and dilation) of the cervix in preparation for labor and delivery. Benefits of induction must outweigh the risks to the maternal–fetal unit. Inductions may be medically indicated or elective. Elective procedures prior to 39 completed weeks of gestation are contraindicated.

Augmentation refers to the administration of uterine stimulants once labor dystocia (dysfunction) ensues. Dysfunctional labor may result for several reasons (outlined in the next section) and remains the number one cause for primary cesarean deliveries. Similar medications are utilized for induction, augmentation, and sometimes cervical ripening.

Indications for Induction

Medically Indicated

1. Abruptio placentae.
2. Chorioamnionitis (intra-amniotic infection).
3. Fetal demise.
4. Hypertensive disorders: chronic, gestational, preeclampsia, or eclampsia.
5. Premature rupture of membranes.
6. Postterm pregnancy.
7. Maternal medical conditions: diabetes mellitus, renal disease, chronic pulmonary disease, or underlying cardiac disease.
8. Fetal conditions: severe fetal growth restriction, anomalies, isoimmunization, evolving category II FHR pattern, or category III FHR pattern, oligohydramnios.

Elective

1. Patient or provider preference.
2. Logistic reasons: risk of rapid labor, distance from hospital.
3. Psychosocial indications.

4. In addition to the other reasons for elective induction, there must also be fetal lung maturity or 39 or more weeks' gestational age determined by one of the following criteria:
    a. Fetal heart tones documented from 20 weeks onward by nonelectronic fetoscope or for at least 30 weeks by Doppler.
    b. Thirty-six weeks or more since a positive serum or urine hCG pregnancy test from a reliable laboratory.
    c. An ultrasound measurement of the crown to rump length obtained at 6 to 12 weeks, which supports a gestational age of at least 39 weeks.
    d. An ultrasound examination between 13 and 20 weeks, confirming at least 39 weeks' gestation as determined by clinical history and physical exam.

Contraindications for Induction

1. Vaginal bleeding, known placenta previa or vasa previa.
2. Abnormal presentation: transverse or funic (cord).
3. Previous transfundal ("classic") uterine incision or extensive myomectomy.
4. Pelvic structural deformities.
5. Active or culture-proven genital herpes infection.
6. Invasive cervical carcinoma.
7. Umbilical cord prolapse.
8. Fetal presenting part above pelvic inlet.
9. Category III FHR pattern.

Indications for Augmentation

1. Uterine hypocontractility.
2. Dystocia (slow, abnormal progression of labor).
3. Augmentation should be considered in the absence of cervical change if the frequency of contractions is less than 3 over 10 minutes or the intensity of contractions is less than 25 mm Hg above baseline with intrauterine pressure catheter or both.

Contraindications for Augmentation

1. Same as induction.

Management

Bishop score refers to a scoring system that documents cervical favorability, giving a score of 0 to 3 for each of five parameters: dilation, position of cervix, effacement, station, and cervical consistency. With a Bishop score of 8 or greater, the likelihood of a vaginal delivery is similar to spontaneous labor. A Bishop score should be documented along with fetal presentation prior to induction.

Cervical Ripening

Cervical ripening is performed if induction is indicated and the cervix is unfavorable. Typically, the cervix is evaluated according to the Bishop pelvic scoring system; if the score is 8 or more, the probability of vaginal delivery after labor induction is similar to that of spontaneous labor.

1. Mechanical methods:
    a. Laminaria digitata—a seaweed preparation that is inserted directly into and dilates the cervix by absorption of water.
    b. Transcervical balloon catheter is inserted through the cervix, balloon is inflated, and gentle traction is applied to dilate the cervix.
2. Prostaglandin E_2 (PGE_2): Dinoprostone is a solid, time-released 10 mg insert placed into the vagina and can be removed.
    a. Requires continuous fetal monitoring as evidenced by manufacturer and research guidelines.
    b. Keep frozen until immediately before use; unstable at room temperature; stable up to 3 years when frozen.
    c. Patient is to remain supine for 2 hours after insertion; may ambulate after 2 hours if EFM telemetry is available for continuous monitoring.
    d. Removal may be required if evidence of uterine tachysystole response or fetal intolerance (evolving FHR category II or category III pattern).
    e. Removal after 12 hours or at onset of labor; oxytocin should be delayed at least 30 to 60 minutes after removal.
    f. Should be administered at or near labor and delivery/birthing suite with continuous EFM to monitor fetal and uterine status and for at least 15 minutes after removal.
3. PGE_2 gel is given via catheter or diaphragm (pessary) in doses ranging from 0.5 to 5 mg.
    a. Unstable at room temperature; store in refrigerator; bring to room temperature just before administration (do not use microwave; warm water, or any other heating method to speed the warming process as the gel is sensitive to heat and may be inactivated).
    b. Patient should stay recumbent for at least 30 minutes. If no response, additional doses may be administered every 6 hours.
    c. Uterine tachysystole is a complication with increased risk of uterine rupture.
    d. Removal may be required if evidence of uterine tachysystole response or fetal intolerance (evolving FHR category II or category III pattern).
    e. Oxytocin should be delayed for 6 to 12 hours after last dose of gel.
    f. Should be administered at or near labor and delivery/birthing suite (to monitor fetal and uterine status—continue monitoring for 30 minutes to 2 hours after administration).

Stripping/Swiping of Membranes

1. Mechanical method of induction.
2. Following a cervical exam, the procedure entails separating the membranes from the lower uterine segment, without rupturing the membranes, to induce labor.

3. Complications include maternal–fetal infection, PPROM, umbilical cord prolapse, precipitous labor and birth, and maternal discomfort.

Amniotomy

1. Mechanical method of induction through artificial rupture of membranes (AROM).
2. Insert amnihook through cervix and perform a slight twisting motion to catch a small area of the membranes. Fluid should be clear or cloudy without odor.
3. Data show when amniotomy is used alone it has unpredictable results with often long intervals before the onset of labor; increasing risk of infection.
4. Utilized with oxytocin at onset, induction to delivery is shorter than with amniotomy alone.
5. Monitor UA and FHR data at periodic intervals.
6. Complications include umbilical cord prolapse or compression and possible maternal or fetal infection.

Pharmacologic Methods of Induction

1. Prostaglandin E_1–misoprostol is not FDA-approved but has off-label use for cervical ripening or labor induction.
   a. Various dosing regimens are available; however, lower doses are associated with less uterine tachysystole; 25 to 50 mcg administered orally or intravaginally—every 4 hours.
   b. Adverse effects include shivering, backache, vomiting, diarrhea, shortness of breath, uterine hypertonus, or uterine rupture.
   c. Redosing is withheld if more than five contractions occur in 10 minutes, adequate cervical ripening is achieved (cervix 80% effaced and 3 cm dilated), the patient is in active labor, or FHR category III pattern.
   d. Patient should be observed for up to 2 hours after spontaneous rupture of membranes. If the cervix remains unfavorable, the uterine activity is minimal, there is absence of category III FHR pattern, and the last dose was given at least 3 hours, redosing is acceptable.
   e. Oxytocin can be initiated 4 hours after the last dose.
   f. Misoprostol should be administered at or near the labor and delivery/birthing suite to allow continuous monitoring of fetal and uterine status.

DRUG ALERT Misoprostol is not recommended for women with a history of prior cesarean delivery or other uterine scarring (myomectomy).

---

2. Oxytocin is naturally produced peptide hormone by hypothalamus and released by the posterior pituitary. Synthetic oxytocin is one of the most common drugs utilized in the United States. Based on pharmacokinetic studies, uterine response begins within 3 to 5 minutes of infusion and reaches a steady state in 40 minutes; however, patient sensitivity varies. Cervical dilation, parity, and gestational age

predict the dose response of oxytocin.

a. Oxytocin infusion is administered as a secondary infusion connected to the lowest port of the primary IV. Solution concentrations vary and may be mixed by pharmacy or on labor and delivery by a staff registered nurse per facility policy. Oxytocin is only given via infusion pump accompanied by constant monitoring of maternal and fetal status with EFM in the inpatient setting.
b. Due to the antidiuretic property of oxytocin, water intoxication may occur, which can lead to heart failure. Symptoms of water intoxification include headache, nausea and vomiting, mental confusion, decreased urine output, hypotension, tachycardia, and cardiac arrhythmia.
c. Dosing requirements adequate for labor vary as low-and high-dose options. Typical starting doses vary from 0.5 to 2 milliunits (mU) and increasing 1 to 2 mU every 30 to 60 minutes until an adequate contraction pattern is achieved.
d. The goal is to establish regular uterine contractions leading to cervical change and fetal descent. Cervical dilation of 0.5 to 1 cm/hour in the active phase of labor—contractions occurring every 2 to 3 minutes lasting 60 to 90 seconds and an intensity of 50 to 70 mm Hg (moderate) or greater than 180 Montevideo units but less than 400. Montevideo units are measures using an intrauterine pressure catheter.

NURSING ALERT Be aware that cervical dilation, effacement, and subsequent fetal descent are the true indicators of adequate labor progression, not uterine activity.

---

e. If oxytocin is discontinued for 20 to 30 minutes, it may be restarted at least below the prior rate of infusion, once reassuring UA and FHR data are established. However, if the oxytocin has been discontinued for over 30 to 40 minutes, it must be restarted at the initial dose.

3. Complications of oxytocin include:
   a. Uterine tachysystole (more than 5 contractions in 10 minutes).
   b. Uterine hypertonus (resting tone greater than 20 to 25 mm Hg, depending on the type of intrauterine pressure catheter; intensity greater than 80 mm Hg).
   c. Contractions longer than 2 minutes in duration.
   d. Increased incidence of cesarean delivery.
   e. Hypotension with rapid infusion.
   f. Uterine tachysystole accompanied by fetal bradycardia may be treated with tocolytics prior to emergent delivery, if indicated.

Nursing Assessment

Prior to Induction of Labor

1. Obtain an NST to assess fetal well-being.

2. Evaluate maternal vital signs, especially BP.
3. Place an IV and evaluate patency prior to initiation.
4. Follow facility policy. Fetal presentation, Bishop score, fetal assessment, and vaginal exam should be documented prior to IOL.

Following Administration of Oxytocin

1. Monitor FHR and uterine activity every 30 minutes and as indicated.
2. Assess maternal vital signs in accordance with facility policy; BP and pulse should be assessed at each dose interval.
3. Limit vaginal examinations, especially after the membranes have ruptured.
4. Maintain intake and output records and watch for signs of water intoxication—dizziness, headache, confusion, nausea and vomiting, hypotension, tachycardia, and decreased urine output.

Nursing Diagnoses

- Anxiety related to medical interventions and maternal fetal outcomes.
- Risk for Impaired Tissue Perfusion: Placental, related to hyperstimulatory uterine response.
- Acute Pain related to uterine activity and evolution of labor and birth process.

Nursing Interventions

Decreasing Anxiety

1. On admission, review hospital policies and protocols for induction with patient and partner.
2. Solicit feedback related to birth plan and cultural preferences.
3. Teach or review the use of relaxation and distraction techniques.
4. Answer questions and offer emotional support.

Enhancing Uteroplacental Oxygenation

1. Assess fetal status and uterine contractions periodically. Assess for signs of uteroplacental insufficiency (minimal-absent variability, abnormal baseline FHR, recurrent or repetitive late or variable decelerations).
2. Place patient in lateral position and assess vital signs; increase IV fluids if hypotension occurs.
3. Administer prescribed oxygen (8 to 10 L/minute by nonrebreather face mask) if nonreassuring FHR characteristics develop (evolving category II or category III FHR pattern) and notify provider.
4. If any persistent hyperstimulatory uterine response (eg, tachysystole or hypertonus) develops, discontinue the augmentation or induction agent, if possible; induce intrauterine resuscitation techniques; and notify health care provider immediately. Administer tocolytics, as ordered, and prepare for emergent cesarean delivery.

Pain Control

1. Encourage use of breathing/relaxation techniques, distraction, positioning, and nonpharmacologic

comfort measures.

2. Encourage active partner participation.
3. Administer analgesia/anesthesia as requested and prescribed.
4. Support mother and partner through the process with presence and empathy.

Evaluation: Expected Outcomes

- Verbalizes understanding of the induction process.
- No evidence of hyperstimulatory uterine response or category III FHR pattern.
- Labor progressing and pain controlled.

Dystocia

Dystocia is characterized by slow, abnormal labor progression typically resulting from abnormal uterine activity patterns or maternal expulsive forces. Dystocia is the leading indication for augmentation and primary cesarean delivery. Causes include power (contractions), passageway (pelvis), or passenger (fetus) abnormalities. (Refer to Chapter 37.)

Pathophysiology and Etiology

Power Abnormalities

1. Inadequate contractions result in poor labor progression and slow fetal descent. Common causes include increased uterine tone, abnormal contraction pressure, hypotonic labor (prolonged latent phase, protracted or arrested active phase, or prolonged second stage of labor), and abnormal contraction pressure.
2. Problems with the force of labor result in ineffective contractions or bearing-down efforts (pushing) during the second stage of labor.
3. Etiology of abnormalities in the force of labor includes:
    a. Early or excessive use of analgesia.
    b. Overdistention of the uterus (hydramnios, macrosomia, multiple gestation).
    c. Excessive cervical rigidity.
    d. Grand multiparity (greater than 6).

Passageway Abnormalities

1. Abnormalities in the passageway may be the result of pelvic or soft tissue anomalies.
2. Pelvic abnormalities that interfere with the engagement, descent, and expulsion of the fetus include:
    a. Size and shape of the pelvis.
    b. Obstruction that may result from soft tissue problems, such as a uterine or ovarian fibromyoma, and obesity.
3. Contractions of the inlet are noted when the anteroposterior diameter is less than 10 cm or the greatest transverse diameter is less than 12 cm. Contracted inlets may be of genetic origin or a result of rickets.
4. Cephalopelvic disproportion (CPD) is a disparity between the size of the maternal pelvis and fetal head that prevents or precludes fetal descent and subsequent vaginal birth; cesarean birth is indicated if unresolved.

Passenger Abnormalities

1. Breech presentations occur in approximately 3% of all deliveries.
    a. This presentation is more common in multiple gestations, increased parity, hydramnios, congenital dislocated hip, placenta previa, and preterm neonates.
    b. Usually, the method of choice for delivery is a cesarean delivery.

2. Shoulder presentation (transverse lie) occurs when the infant lies perpendicular to the maternal spine and cervical os. The infant is delivered by cesarean delivery if external cephalic version (ECV) is unsuccessful.
3. A large fetus increases the risk of trauma, both maternal and fetal; CPD may result.

Diagnostic Evaluation

1. Inadequate progress of cervical effacement, dilation, or descent of the presenting part as determined by vaginal examination.
2. Comparison of serial evaluations of labor progress using Friedman curve criteria, if available.
   a. A prolonged latent phase in the primigravida is greater than 20 hours and greater than 14 hours in the multigravida.
   b. During the active phase, the cervix of a primigravida will normally dilate at a rate of 1.2 cm/hour and a multigravida 1.5 cm/hour. In addition, the fetus should descend at a typical rate of 1 cm/hour in a primigravida and 2 cm/hour for a multigravida.

Management

1. Treatment for contraction abnormalities involves stimulation of labor through the use of labor enhancement medications such as oxytocin (see page 1059); an intrauterine pressure catheter may be utilized for direct assessment of uterine contraction data.
2. Management for maternal passageway or fetal passenger problems involves delivery in the safest manner for the mother and fetus.
   a. If the problem is related to the inlet or midpelvis, a cesarean delivery is indicated.
   b. If the problem is related to the pelvic outlet, an operative vaginal delivery with forceps or vacuum extraction may be performed.

Complications

1. Maternal exhaustion.
2. Infection.
3. Postpartum hemorrhage.
4. Fetal intolerance: evolving category II or category III FHR patterns.
5. Fetal or maternal trauma from operative vaginal delivery.

Nursing Assessment

1. Perform Leopold maneuvers and evaluate fetal presentation, position, and size.
2. Using Friedman labor curve, periodically evaluate progress of labor.
3. Monitor FHR and contraction status periodically per facility policy.

Nursing Diagnoses

- Acute Pain related to physical and psychological factors of difficult labor.

- Anxiety related to threat of possible operative delivery.

Nursing Interventions

Promoting Comfort

1. Review relaxation techniques.
2. Encourage use of breathing techniques learned in prenatal classes.
3. Encourage frequent change of position, especially the use of the upright posture to facilitate descent.
4. Encourage voiding at regular intervals to decompress the bladder.
5. Provide back rubs and sacral pressure, as needed.
6. Offer ice chips and clear fluids as permitted.
7. Provide frequent encouragement to the woman and her support person.
8. Administer pain medication as ordered.
9. Assist with the administration of anesthesia, as requested and indicated.

Decreasing Anxiety

1. Provide anticipatory guidance regarding labor process and progress, the use of medication, equipment, and procedures.
2. Educate the woman regarding augmentation agents: oxytocin.
3. Prepare the family for cesarean delivery, if necessary.

Evaluation: Expected Outcomes

- Verbalizes increased comfort.
- Verbalizes understanding of procedures.

Shoulder Dystocia

Shoulder dystocia is the dysfunctional descent and expulsion of the fetal shoulders, resulting in impaction of the anterior shoulder behind the maternal pubis symphysis or posterior shoulder on the sacral promontory during the second stage of labor. This condition is often relieved with gentle manipulation but may turn into an obstetric emergency within minutes. Approximately 50% of shoulder dystocia incidents have no risk factors.

Pathophysiology and Etiology

1. Antepartum risk factors:
    a. Fetal macrosomia.
    b. Maternal diabetes.
    c. Fetal macrosomia more than 5,000 g or more than 4,500 g with maternal diabetes (women with 2 or more risk factors have highest rate of shoulder dystocia).
    d. Postterm gestation.
    e. Previous history of shoulder dystocia, macrosomia, or postterm pregnancy.
2. Intrapartum factors:
    a. Labor induction.
    b. Epidural anesthesia.
    c. Protraction or arrest of labor.
    d. Prolonged second stage.
    e. Operative vaginal delivery.
3. None of the risk factors noted above individually, or collectively, can predict shoulder dystocia. Facilities should develop interprofessional protocols to effectively manage and anticipate shoulder dystocia at every delivery. Simulation exercises are recommended to enhance team communication and function during this emergency.

Management

1. Compare labor progression to a labor progression model such as the Friedman labor graph per facility policy, and communicate dysfunctional patterns early and prepare accordingly.
2. Prevention is the key because shoulder dystocia is difficult to predict.
    a. Early identification and treatment of gestational diabetes mellitus.
    b. Antepartum glucose control of insulin-dependent diabetes mellitus.
    c. Periodic estimated fetal weight measurements; third-trimester ultrasound measurements are significantly inaccurate.
    d. Avoid postterm deliveries.
    e. Prevent abnormal progression of labor or treat early.
    f. Promote adequate maternal weight gain.
3. Once shoulder dystocia is identified, the following interventions may be indicated based on individual

clinical conditions:

a. Document the time shoulder dystocia is called.
b. Perform appropriate nursing maneuvers and assist with appropriate medical maneuvers, if applicable (see below). Fundal pressure is contraindicated. Performing fundal pressure may further impact the shoulder; utilize other maneuvers to dislodge shoulder.
c. Call for assistance to support maneuvers and to treat immediate postpartum complications.
d. Notify neonatal team.
e. Document delivery time and calculate total time frame from the delivery of the fetal head to the delivery of the infant. List all maneuvers performed during incident, time of application, and individual(s) who performed the intervention(s). Record Apgar scores and neonatal resuscitative interventions, if applicable. Lastly, manage and document any postpartum complications.
f. Perform critical assessment of neonate after delivery, particularly face and upper limbs.

4. Nursing maneuvers; begin with least invasive; no particular order is recommended:
   a. McRoberts maneuver—exaggerated flexion of the mother's legs, simulating a supine squat position. The squat position increases pelvic diameter by 1 to 3 cm.
   b. Suprapubic pressure—place the heel or palm of one hand over the suprapubic area and press down and to the left or right, as directed by the primary practitioner, to assist in dislodging the anterior shoulder under the maternal pubic bone. Have a step stool available to assist position of staff.
   c. Gaskin maneuver—Hands-and-knees position; assist the patient onto her hands and knees in an "all-fours" position; it is suspected the anterior shoulder drops posteriorly in this position, releasing the dystocia and resulting in delivery. This may be difficult but obtainable in the patient with epidural anesthesia.
5. Medical maneuvers:
   a. Episiotomy is no longer routinely recommended and is performed based on clinical presentation.
   b. Rotation of the anterior shoulder to oblique position.
   c. Barnum maneuver-delivery of posterior arm across fetal chest.
   d. Rubin maneuver—displacement of the posterior shoulder anteriorly, with respect to fetus.
   e. Wood screw maneuver—rotation of the shoulders to an oblique position.
   f. Zavanelli maneuver—replacement of the head by reverse cardinal movements into the vagina and delivery by cesarean.

Complications

Fetal

1. Fetal hypoxia and asphyxia; neonatal hypoxic ischemic encephalopathy.
2. Brachial plexus injury.
3. Fractured clavicle or humerus.
4. Facial nerve paralysis.

5. Neuropsychiatric dysfunction or death.

Maternal

1. Postpartum hemorrhage.
2. Vaginal lacerations.
3. Cervical lacerations.

Nursing Assessment

1. Continuously evaluate labor curve for signs of dystocia.
2. Maintain EFM until delivery is successful.
3. Notify all perinatal team members of delivery time frame.

Nursing Diagnoses

- Fear and Anxiety related to inability of fetus to deliver.
- Acute Pain associated with operative and instrumented procedures or uterine manipulation.
- Risk for Injury to fetus or mother secondary to instrumented delivery or manual maneuvers.

Nursing Interventions

Reducing Fear and Anxiety

1. Inform patient of complication and offer support.
2. Limit family members in the delivery room should shoulder dystocia occur, as additional health care personnel may be required.
3. Keep voice calm and controlled during delivery process.
4. Keep patient focused on pushing efforts and positioning.

Decreasing Pain

1. Maintain appropriate anesthesia/analgesia for pain relief during maneuvers.
2. Offer additional anesthesia/analgesia after delivery, as needed or indicated.

Reducing Risk of Injury

See Nursing maneuvers above.

Evaluation: Expected Outcomes

- Verbalizes understanding of situation and is cooperative with plan.
- Verbalizes control of pain.
- No maternal or neonatal injury.

Uterine Rupture

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2010/Reaffirmed 2017). *Vaginal birth after cesarean* (Practice Bulletin #115). Washington, DC: Author.

Uterine rupture is a spontaneous or traumatic tear in the uterus exposing the internal uterine compartment to the peritoneal cavity; extrusion of the umbilical cord, fetus, or fetal parts may occur. *Uterine dehiscence* occurs due to partial separation of an old scar prior to full rupture. Uterine rupture is a rare, catastrophic event with significant risk of maternal, fetal, and neonatal morbidity and mortality.

Pathophysiology and Etiology

Risk factors:

1. Number of prior cesarean births and scar type (vertical uterine incision).
2. Interpregnancy interval (time frame of the end of one gestation to the beginning of the subsequent gestation).
3. Trial of labor after cesarean (TOLAC).
4. Uterine closure technique: single-layer closure has higher risk over double-layer closure.
5. Trauma.
6. Obstetric maneuvers.
7. Uterine abnormalities.

Clinical Manifestations

Clinical manifestations depend on location, size, and duration of rupture. Clinical conditions may evolve acutely (within minutes) or chronically (hours) during the intrapartum period. Signs and symptoms may be absent or present individually or collectively.

1. Constant abdominal pain and tenderness (may be dulled by anesthesia or analgesia).
2. Uterine contractions will usually continue but may diminish in intensity and tone.
3. Vaginal or abdominal bleeding into the peritoneal cavity.
4. Nausea/vomiting.
5. Syncope.
6. Vital sign instability: early (tachycardia, tachypnea, hypertension); late (signs of shock: rapid, weak pulse); hypotension; cold, clammy skin; pale color.
7. Uteroplacental insufficiency as evidenced by evolving category II or category III FHR patterns.
8. Clinical signs of placental abruption or cord prolapse (sudden onset of FHR variable decelerations).

Management

1. Immediate stabilization of maternal hemodynamics followed by emergent cesarean delivery. Anticipatory preparations may require intraoperative blood component therapy.
2. Fetus is delivered expeditiously and neonatal resuscitation is performed, as indicated. The uterus is repaired, if possible; otherwise, a hysterectomy may be indicated.
3. Adequate fluid replacement is maintained.
4. Antibiotic therapy.

Complications

Maternal

1. Urologic injury.
2. Hysterectomy.
3. Concurrent complete or partial abruptio placentae; hemorrhage.
4. Hypovolemic shock.
5. Severe blood loss or anemia, with possibility of transfusion.
6. Bowel laceration, with possibility of peritonitis.
7. Infection.
8. Death.

Fetal

1. Hypoxia leading to fetal acidosis and perinatal asphyxia (occurs 39% to 91%).
2. Hypoxic–ischemic encephalopathy; neonatal brain injury.
3. Death.

Nursing Assessment

1. Continuously evaluate maternal vital signs for clinical triggers of decompensation.
2. Observe for signs and symptoms of impending rupture periodically during labor progression, particularly during VBAC delivery or a history of uterine surgery (see Box 39-2).
3. Assess fetal status by continuous monitoring.
4. Communicate with family and debrief them on event following stabilization of mother and newborn as HIPAA allows.

BOX 39-2 Vaginal Birth After Cesarean

- Selection criteria to identify women eligible for vaginal birth after cesarean (VBAC):
  - One or two low-transverse cesarean births.
  - Clinically adequate pelvis.
  - No other uterine scars or previous rupture.
  - Physician (capable of monitoring labor and performing an emergent cesarean delivery) is immediately available throughout active labor.

    - Anesthesia and surgical team available for emergent cesarean delivery.
- Contraindications for VBAC (because of high risk of uterine rupture):
    - Prior classic or T-shaped incision or other transfundal uterine surgery.
    - Contracted pelvis.
    - Medical or obstetric complication that prevents/precludes vaginal delivery.
    - Inability to perform emergency cesarean delivery because of unavailability of surgeon, anesthesia provider, sufficient personnel, physician capable of performing cesarean delivery, or sufficient facility.

Nursing Diagnoses

- Deficient Fluid Volume related to active fluid loss secondary to hemorrhage.
- Risk for Decreased Cardiac Tissue Perfusion: Maternal and Fetal, related to hypovolemia.
- Fear related to outcome for fetus and mother.

Nursing Interventions

Maintaining Fluid Volume

1. Maintain primary IV line and start a secondary line, as indicated by the patient's condition; if patient is unstable with lactated Ringer solution with rapid infusion.
2. Monitor vital signs frequently to observe for maternal decompensation.
3. Assist with and maintain central venous pressure and arterial lines, as indicated, for hemodynamic monitoring.
4. Maintain bed rest to decrease metabolic demands.
5. Place indwelling urinary catheter and monitor urine output hourly or as indicated.
6. Obtain and administer blood component therapy, per obstetric hemorrhage (OH) guidelines.
7. Monitor for signs of DIC—spontaneous bleeding from IV sites, oral mucous membranes, and vagina; bruising.

Maintaining Maternal Vital Organ and Fetal Tissue Perfusion

1. Administer oxygen using a face mask at 8 to 10 L/minute or as indicated; prolonged use prior to delivery is not recommended unless clinical conditions dictate.
2. Apply pulse oximeter and monitor oxygen saturation, as indicated. Pulse oximeter is unreliable during episodes of severe hemorrhage; therefore, monitor patient closely.
3. Monitor arterial blood gas levels and serum electrolyte levels, as indicated, to assess respiratory status, observing for hypoxemia and electrolyte imbalance.
4. Continually monitor maternal vital signs and FHR and UA data on EFM for clinical triggers of decompensation; rapid deterioration may indicate shock and report any abnormalities to the health care team.

5. Evaluate actual blood loss as determined by weight.

Reducing Fear

1. Offer explanation and answer questions of events and procedures to the patient and her support person.
2. Maintain a quiet and calm atmosphere to enhance relaxation.
3. Remain with the patient during anesthesia administration; offer support, as needed.
4. Update family members on the current situation, while the woman is in surgery, and then again postoperatively. Debrief family with the family about the emergency situation and discuss expected outcomes of mother and newborn.

Patient Education and Health Maintenance

1. Provide information and support regarding the possibility for future pregnancies.
2. Encourage the support of family and friends.
3. Offer dietary options high in iron to improve secondary anemia.
4. Inform patient of the postoperative care to reduce risk for thrombophlebitis, pneumonia, infection, and inadequate pain management.

Evaluation: Expected Outcomes

- Vital signs stable; no evidence of shock.
- Hemoglobin and hematocrit stable.
- Verbalizes concerns about self and her fetus.

Amniotic Fluid Embolism

Amniotic fluid embolism (AFE), also known as *anaphylactic syndrome of pregnancy*, is an unpredictable and unpreventable catastrophic even occurring once amniotic fluid containing fetal cells and debris enters the maternal circulation. Deposits of fluid or debris into the pulmonary arterioles result in rapid onset of respiratory distress, shock, and possible development of DIC. The incidence is 1 in 10,000 to 1 in 80,000 pregnancies with a mortality rate of 60% to 90%.

Pathophysiology and Etiology

1. The exact mechanism or portal of entry is uncertain, yet many researchers have postulated the following theories:
    a. Fluid and debris may enter through small endocervical tears, vessels of the lower uterine segment, or cervical veins.
    b. Diffusion across amniotic membranes.
    c. Once fluid and debris enter the maternal vasculature, the maternal system may stimulate an immunologic (allergic) response to the foreign entity similar to rejection of a transplanted organ or infusion of the wrong blood type; this often stimulates the coagulation system, resulting in DIC (see Figure 39-5).
    d. Debris may be large enough to block the perfusion through the pulmonary artery, leading to pulmonary hypertension and right-sided heart failure; over a short time, subsequent left-sided heart failure ensues, accompanied by hypoxia and acidosis.
2. If prolonged, DIC, shock, and cardiopulmonary collapse may occur.
3. It can occur in the intrapartum or postpartum period.
4. Although AFE is unpredictable, the following conditions have a potentially higher association to AFE.
    a. Intrapartum period.
    b. Multiparous.
    c. Abruptio placentae.
    d. Multiple gestations.
    e. Genetic influences.
    f. Previous cesarean delivery.
    g. Chorioamnionitis.
    h. Hydramnios.

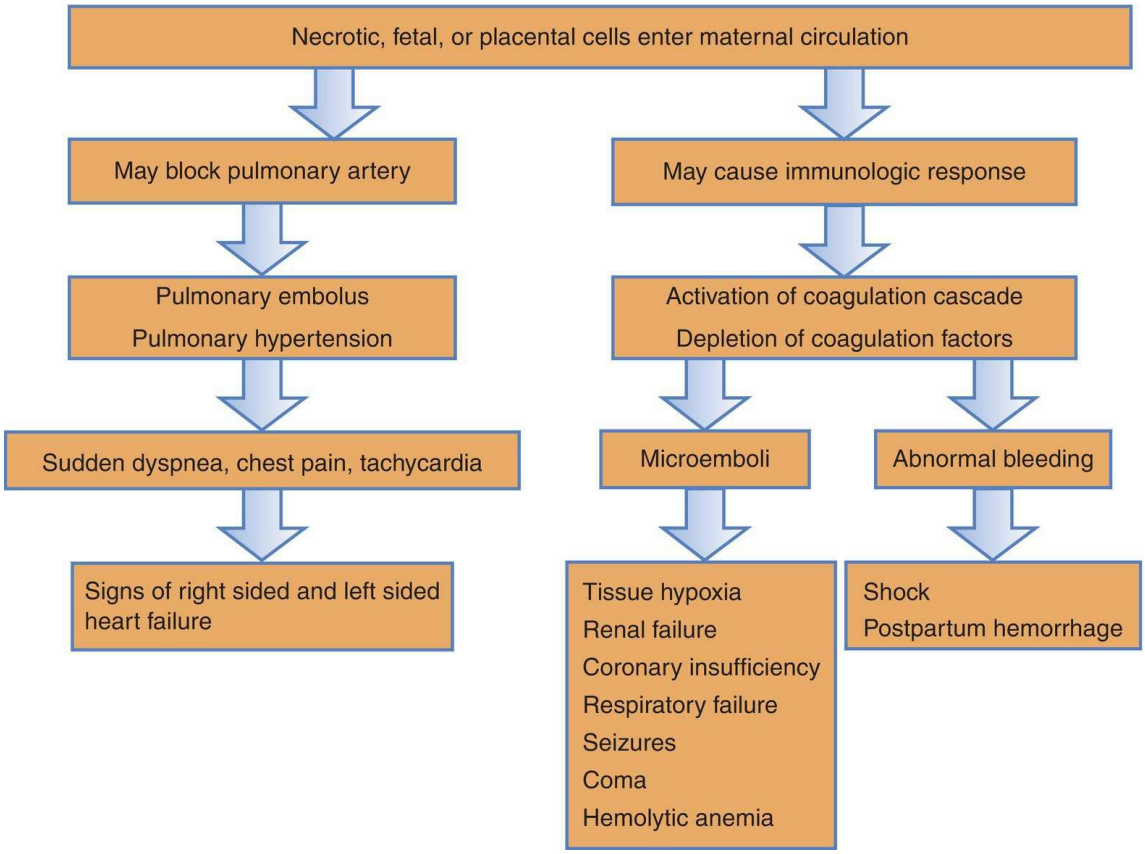

Figure 39-5. Pathogenesis of disseminated intravascular coagulation from amniotic fluid embolism.

Clinical Manifestations

1. Sudden dyspnea and chest pain.
2. Cyanosis, tachycardia.
3. Pulmonary edema.
4. Seizures.
5. Increasing restlessness and anxiety.
6. Feeling of impending doom.
7. DIC.
8. Cardiac dysrhythmias.
9. Cardiopulmonary collapse.

Diagnostic Evaluation

1. Clinical picture of sudden onset of respiratory collapse, shock, and cardiopulmonary arrest.
2. DIC confirmed by coagulation studies (prolonged thrombin time, PT, and PPT; decreased factor V, VIII, X; decreased platelets; increased fibrin split products).
3. Pulmonary aspirate evaluation for fetal cells.
4. Autopsy evaluation to confirm fetal cells and debris intravascularly.

Management

Also see Disseminated Intravascular Coagulation, page 772.

1. Respiratory support with oxygen therapy and intubation, as necessary.
2. Administration of IV crystalloid fluids in the treatment of shock.
3. Administration of blood component therapy to combat hemorrhage, shock, and DIC.
4. Establishment of a pulmonary artery catheter, if appropriate.
5. Cardiopulmonary resuscitation in a wedge position or abdominal displacement if undelivered.
6. Perimortem cesarean delivery within 5 minutes of cardiopulmonary collapse.

Nursing Assessment and Interventions

See page 773 for additional nursing care.

1. Be alert and suspicious to signs and symptoms of potential AFE and patients at risk (see above risk factors).
2. Monitor maternal vital signs to assess for signs of shock.
3. Monitor FHR if undelivered.
4. Administer oxygen to assist respiratory status.
5. Alert the interprofessional team immediately and assist with emergency procedures, such as delivery and cardiopulmonary resuscitation, as needed.
6. Provide information and comfort to the family or support persons as the situation allows.

Umbilical Cord Prolapse

If the umbilical cord precedes the presenting part of the fetus or lies adjacent to the primary presenting part, prolapse has occurred. Types of cord prolapse include:

Complete—the cord completely and significantly precedes the primary fetal presenting part; may be in the vagina or visible outside the introitus.

Occult—the cord is beside or just in front of the presenting part of the fetus (hidden).

Funic—the cord can be felt on vaginal examination through intact membranes preceding the fetal presenting part.

Pathophysiology and Etiology

Predisposing factors include:

1. Rupture of membranes before the presenting part is engaged in the pelvis.
2. More common in abnormal fetal positions, such as shoulder and foot presentations.
3. Prematurity.
4. Polyhydramnios (hydramnios).
5. Multifetal gestation.
6. Cephalopelvic disproportion.
7. Abnormally long umbilical cord.
8. Result of interventions or maneuvers (ie, external cephalic version or amniotomy).
9. Low-lying placenta.

Clinical Manifestations

1. Cord may be seen protruding from vagina or palpated in the vagina or through the cervix.
2. Compression of the cord may cause variable decelerations; prolonged decelerations or bradycardia may develop over time.

NURSING ALERT Prolapsed cord should be suspected with FHR prolonged deceleration or bradycardia resulting immediately after spontaneous or artificial rupture of membranes.

Management

1. Deliver fetus as soon as possible via the most expeditious route.
2. When prolapsed cord is identified, relieve pressure off the umbilical cord by positioning the cord between your two examination fingers and elevating the fetal presenting part up and off the cord.
3. Change maternal positions to potentially alleviate compression (typically knee–chest position or side-lying is adequate).

4. Prepare for emergent delivery.

Complications

Maternal

1. Infection.
2. Risk of increased perineal trauma from emergency operative delivery.

Fetal

1. Prematurity.
2. Hypoxia and perinatal asphyxia.
3. Meconium aspiration.
4. Fetal death if delayed or undiagnosed.

Nursing Assessment and Interventions

1. Observe for variable or prolonged FHR deceleration following spontaneous or artificial rupture of membranes.
2. Perform vaginal exam with sterile gloves; if cord is palpated, call for assistance and prepare for emergent delivery. Keep pressure off the cord as described above. Do not remove hand from vagina (see Figure 39-6). Extreme conditions may include lack of additional staff to assist; if so, remove hand and place patient in a reverse Trendelenburg position or up on all four extremities so that she is supported by knees and elbows to alleviate pressure on the cord while preparing for emergent delivery.
3. A cord exposed to room air may exhibit a reflex constriction of the umbilical blood vessels. These conditions may further restrict oxygen and blood flow to the fetus. Do not pinch or squeeze the umbilical cord as this may cause the cord to spasm, decreasing umbilical blood flow and oxygen to the fetus.
4. Explain procedures as much as possible to the woman during this emergent situation.
5. Administer oxygen at 8 to 10 L/minute via nonrebreather mask.

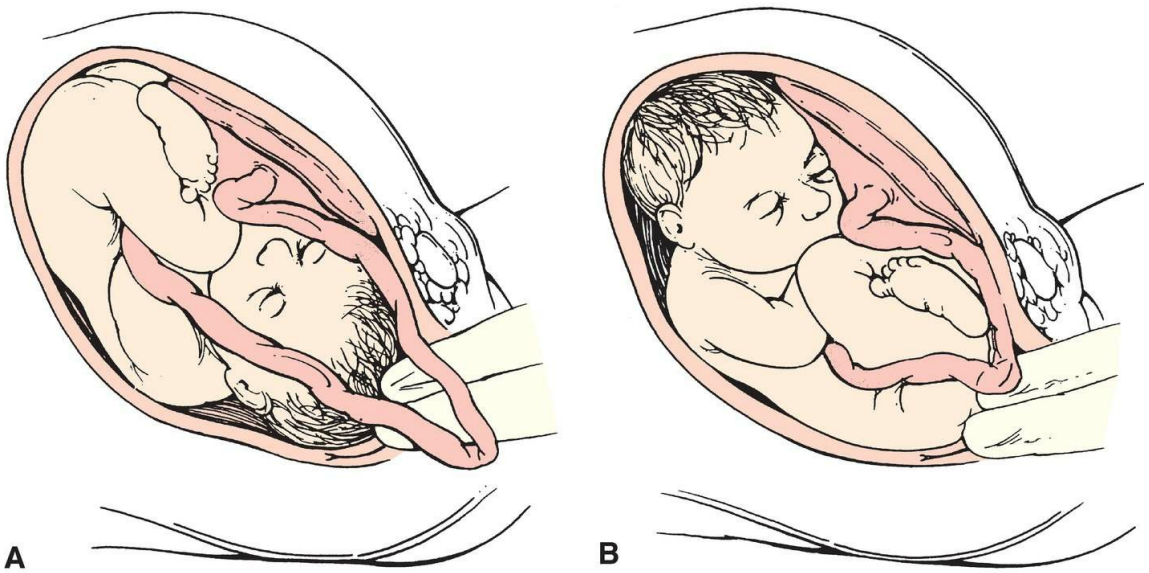

Figure 39-6. Prolapsed cord. Reduction of cord compression using gloved examiner's hand in vagina to elevate presenting part. **(A)** Vertex. **(B)** Breech. (From Reeder, S., Martin, L., & Koniak-Griffin, D. [1997]. *Maternity nursing: Family newborn, and women's health care* [18th ed.]. Philadelphia, PA: Lippincott-Raven Publishers.)

Uterine Inversion

Uterine inversion is a potentially life-threatening complication in which the uterus turns inside out during the third stage of delivery. Uterine inversions may be classified as:

Complete—fundus inverts and passes through the cervical os into the vagina and may prolapse through the introitus.

Incomplete—fundus of uterus partially inverts but not beyond the cervical os.

Pathophysiology and Etiology

1. Excessive traction on the cord while the placenta is still attached.
2. Aggressive fundal pressure.
3. Lax or thin uterine wall.
4. Spontaneous inversion.
5. Abnormally short umbilical cord.
6. Prolonged labor.
7. Uterine atony.
8. Uterine anomalies.
9. Fundal placentation.
10. Abnormally adherent placental tissue (placenta accreta or increta).
11. Fetal macrosomia.

Clinical Manifestations

1. Sudden onset of maternal hemorrhage, shock, and instability accompanied severe pelvic pain (anesthesia may dull pain sensation).
2. Inability to palpate fundus in association with clinical manifestations.
3. Confirmed with bimanual examination.

Management

1. Prevention is the most effective therapy. Proper management of the third stage of labor may prevent most uterine inversions. Immediate identification and interventions essential.
2. Goal is to manually restore the uterus to its normal position.
3. Typically, anesthesia is necessary to complete manual manipulation and to alleviate associated pain.
4. If manipulation is difficult or lengthy. Administer tocolytic therapy (terbutaline or magnesium sulfate) as ordered.
5. Monitor maternal vital signs for signs for deterioration and shock.
6. After the uterus has been restored, oxytocin is administered to alleviate uterine atony.
7. Abdominal or vaginal surgery may be necessary if manual replacement fails.
8. Administer a broad-spectrum antibiotic if ordered.

Complications

1. Infection.
2. Anemia.
3. Hysterectomy.
4. Hemorrhagic shock.
5. Death.

Nursing Assessment and Interventions

Also see page 949 for additional nursing care.

Before Correction of the Inversion

1. Check maternal vital signs and evaluate blood loss.
2. Assist practitioner, as needed, for manual replacement.
3. Administer oxygen, as warranted.
4. Maintain primary IV line and establish a second line with a 16G or 18G catheter for administration of fluids, blood products, and/or medications.
5. Apply a pulse oximeter to determine oxygen saturation.
6. If replacement of the uterus is unsuccessful, prepare the woman and her support persons for surgery.

After Correction of the Inversion

1. Check maternal vital signs, and monitor CBC for signs of bleeding and infection.
2. Administer oxytocin and other uterotonic agents, as ordered.
3. Measure and record accurate intake and output.
4. Evaluate uterine fundus carefully for position and firmness and avoid vigorous massage.
5. Evaluate lochia for amount of blood loss.
6. Evaluate for transfusion reactions (ie, itching, wheezing, anaphylaxis).
7. Administer antibiotics, as ordered, to minimize risk of infection.
8. Provide support to the woman and encourage her to express her feelings.

See additional online content: Procedure Guidelines 39-1

PROCEDURE GUIDELINES 39-1

Sitz Bath

PURPOSE

- A sitz bath aids the healing of the perineum through application of moist heat.

EQUIPMENT

- Sitz bath basin, bag, and tubing
- Towel
- Perineal pad

PROCEDURE

Nursing Action	Rationale
1. Assess patient's condition, pain level, and ability to ambulate to bathroom.	1. Effects of childbirth, pain medication, and lost sleep may make patient light-headed, fatigued, or drowsy, impairing her ability to ambulate and tolerate sitting on toilet without support.
2. Wash hands.	2. Prevents spread of germs onto clean equipment.
3. Fill sitz bath basin with warm water and place on toilet bowl (with toilet seat up). Fill bag with warm water at a temperature of 105°F–110°F (40.6°C–43.3°C), and attach tubing to basin.	3. Warm water is soothing and results in vasodilation to enhance healing but should not create thermal injury.
4. Hang bag overhead so a steady stream of water will flow from the bag, through the tubing, into the basin.	4. Flow of water in the basin continuously replenishes warm water and enhances cleansing and circulation of the perineum, reducing inflammation and enhancing healing.
5. Assist patient with removal of peripad from front to back and positioning on sitz basin.	5. Removal of peripad from front to back prevents rectal contamination of incision.
6. Instruct patient to use clamp on tubing to control water flow. Make sure that she has robe or blanket to prevent chilling and that she can call for assistance, if necessary.	6. Adequate circulation of water enhances comfort and healing, but too brisk a flow will drain water too quickly to achieve benefit. Privacy should be protected.
7. Allow patient to sit for 20 min, then assist her with drying and applying a clean peripad (avoid touching front of pad).	7. Beneficial effects of heat are lost after 20 min due to vasoconstriction. Contamination of front of peripad might result in infection of healing tissue.
8. Assist patient back to bed, noting tolerance of the procedure.	8. Use of warm water and prolonged sitting in one position may result in light-headedness on arising.
9. Document tolerance of procedure, pain, and appearance of the perineal area.	9. Decreased swelling, redness, and drainage and complete healing are the goals

Episiotomy

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2016). *Prevention and management of obstetric lacerations at vaginal delivery* (Practice Bulletin 165). Washington, DC: Author.

An *episiotomy* is a surgical incision of the perineum to increase the vaginal opening for delivery of the fetus during the second stage of labor. In the United States, the rates have episiotomies performed have decreased to about 12% of vaginal births. The common type of episiotomy in the United States is the midline (median) and the mediolateral episiotomy is more prevalent in Europe. Routine episiotomies are not recommended in current practice. Episiotomies are only recommended for such maternal or fetal indications as avoiding severe maternal lacerations or facilitating or expediting difficult deliveries.

Types of Episiotomies

See Figure 39-7.

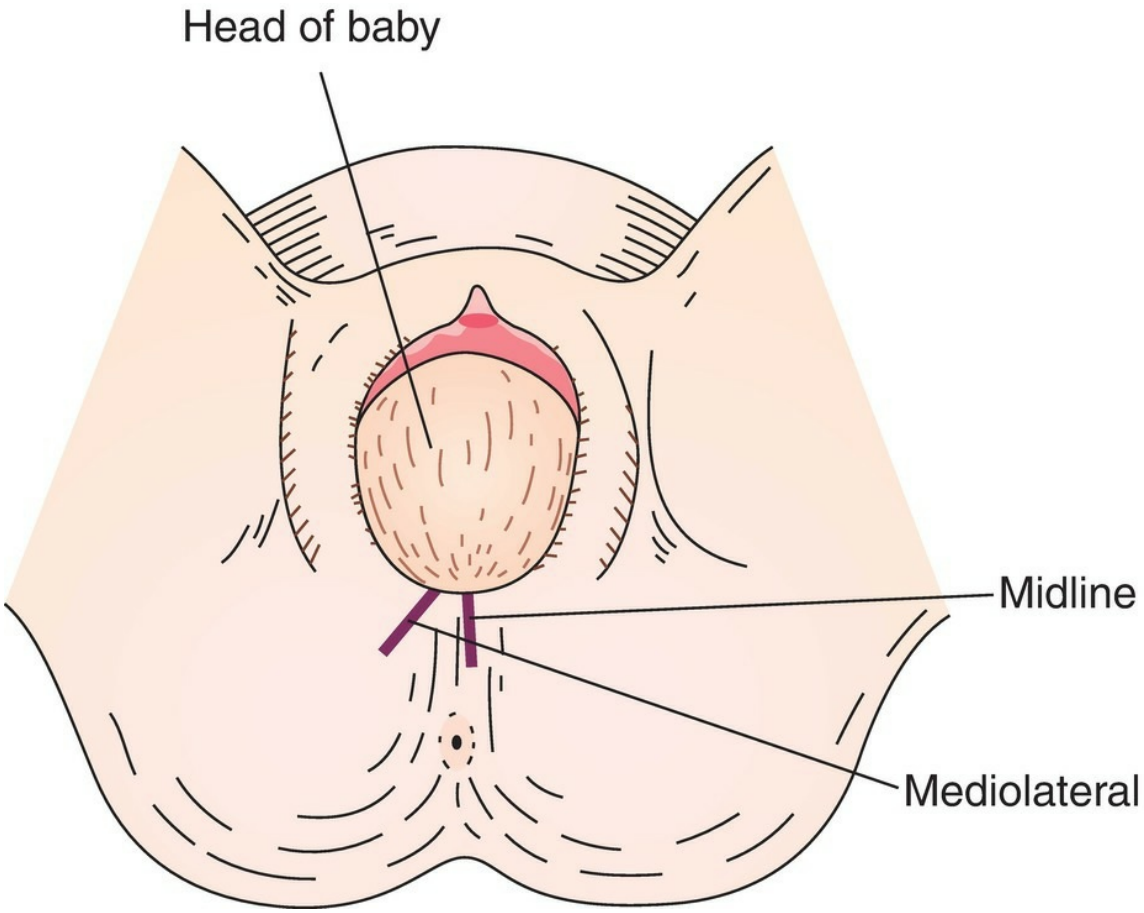

Figure 39-7. Position of episiotomy incision in a woman during second stage of labor. Baby's head is presenting to vaginal outlet (crowning). (From Pillitteri, A. [2013]. *Maternal and child health*

nursing: Care of the childbearing and childrearing family [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Median (Midline)

1. Incision is made midline down the perineum directed toward the rectum.
2. This method is believed to heal with few complications, is more comfortable for the woman during healing, is easy to repair, and is associated with minimal blood loss.
3. Increases risk of third- and fourth-degree lacerations.
4. Decreased postpartum dyspareunia.
5. Most commonly performed in the United States.

Mediolateral

1. Incision 45 degrees or more from the midline.
2. This method avoids the anal sphincter if an extension is needed.
3. Women find it extremely uncomfortable during healing.
4. Difficult to repair.
5. Associated with increased blood loss.
6. Necessitates longer wound healing time.

Management

1. The application of warm compresses to the perineum during the second stage of labor has demonstrated a reduction in third- and fourth-degree lacerations.
2. Pain relief.
    a. The stretching of the perineum and pressure from the fetal head may provide a natural numbing effect.
    b. Local perineal infiltration with lidocaine provides anesthesia for performing and repairing the episiotomy.
    c. A pudendal block provides anesthesia to the lower two thirds of the perineum and vagina using lidocaine injection into the vaginal walls.
    d. Epidural anesthesia provides anesthesia from the level of the umbilicus to the midthigh area.
3. The episiotomy is performed once the fetal head is 3 to 4 cm visible with a contraction.
4. The repair of the episiotomy usually begins after the delivery of the placenta.

Complications

1. Infection.
2. Bleeding.
3. Third- and fourth-degree lacerations.
4. Pain.

5. Hematoma.
6. Dyspareunia (painful intercourse).

Nursing Assessment

During the recovery period, the episiotomy should be evaluated periodically after delivery.

1. Describe and document the degree of healing.
2. Assess for infection; signs and symptoms include edema, redness, purulent drainage at the site, and/or increased temperature.
3. Notify health care provider of signs of infection or excessive bleeding at site, other than slight oozing.
4. Monitor for hematoma formation.
5. Apply ice packs to limit edema and pain.

Nursing Diagnoses

- Risk for Infection related to traumatized tissue.
- Acute Pain related to tissue trauma.

Nursing Interventions

Preventing Infection

1. Instruct the woman to clean the perineum from front to back.
2. Provide instructions on perineal care.
   a. Provide a peri bottle; teach patient to squirt the water gently on her perineum after voiding.
3. Instruct patient to change the perineal pad each time after urination and defecation; dispose of in proper biohazard receptacle.
4. Explain the importance of proper handwashing before and after perineal care.
5. Explain that perineal care should be performed after urination and defecation.
6. Encourage a diet that is high in protein and vitamin C and encourage hydration.

Promoting Comfort

1. Apply covered ice packs to the perineal area for the first 24 hours after delivery. The ice packs should not remain in place longer than 20 minutes at a time to get the maximum benefit from the treatment.
2. Encourage sitz baths with either warm or cool water.
3. Administer pain medication and topical anesthetics, as ordered.
4. Instruct the woman to tighten her buttocks and perineal muscles before sitting in a chair and to release the muscles once seated.
5. Abstain from sexual intercourse until healing is complete, typically 4 to 6 weeks.

Evaluation: Expected Outcomes

- No evidence of infection; afebrile.
- Demonstrates increase in comfort.

Operative Vaginal Delivery: Forceps

Obstetric forceps (see Table 39-3) are used to facilitate delivery of the fetal head during the second stage and expedite a safe vaginal delivery when indicated for maternal and fetal health. Most forceps are placed on each side of the fetal vertex and others are utilized for special considerations (pipers: vaginal breech birth). Forceps consist of two pieces: a right blade, which is slipped into the right side of the mother's pelvis, and a left blade, which is slipped into the left side. Unfortunately, forceps increase the diameter of the presenting part, which may hinder delivery. Special training and skill are required.

Table 39-3 Representative Types of Forceps*

MAJOR CLASSIFICATIONS	USE
Simpson—separated shanks	
(eg, DeLee forceps)	Extract fetus with elongated, molded head; commonly used with nulliparas who have long labors
Elliot—overlapping shanks	
(eg, Tucker-McLean)	Extract fetus with unmolded, rounder heads; commonly used with multiparas who have briefer labors
Specialized Types	
Piper	Deliver aftercoming head in a breech presentation
Kielland	Rotate head from transverse or posterior position to an anterior position; used with women with anthropoid pelves
Barton	Rotate head from transverse to an anterior position; designed for use in women with flat pelves

**There are more than 600 types of forceps.*

Types of Forceps Deliveries

American College of Obstetricians and Gynecologists definitions for obstetric forceps:

Outlet Forceps

1. Scalp is visible at the introitus without separating labia.
2. Fetal skull has reached pelvic floor.
3. Sagittal suture in anteroposterior diameter or right or left occiput anterior or posterior position.
4. Fetal head is at or on perineum.
5. Rotation does not exceed 45 degrees.

Low Forceps

1. Leading point of fetal skull is at station +2 cm or above and not on the pelvic floor.
    a. Rotation is less than 45 degrees (left or right occiput anterior to occiput anterior or left or right occiput posterior to occiput posterior).
    b. Rotation is greater than 45 degrees.

Indications for Forceps Delivery

1. No absolute indication exists. The fetal head must be engaged and the cervix fully dilated.
2. Suspicion of immediate or potential fetal compromise.
3. Shortening of the second stage of labor for maternal benefit.

4. Prolonged second-stage labor.
    a. Nulliparous women: lack of continuing progress for 3 hours with regional anesthesia or 2 hours without regional anesthesia.
    b. Multiparous women: lack of continuing progress for 2 hours with regional anesthesia or 1 hour without regional anesthesia.
5. Category III FHR pattern.
6. Cardiac or neurologic disease.

Contraindications

1. Malpresentations: face or brow presentation.
2. Incomplete dilation of the cervix.
3. Unengaged fetal head.
4. Gestational age less than 34 weeks.
5. Live fetus with bone demineralization.
6. Fetal coagulopathies.
7. Inexperience of practitioner or unavailable operative personnel.

Management

1. The woman is placed in lithotomy position.
2. The bladder should be emptied, and may be done by catheterization.
3. Regional anesthesia may be used.
4. The neonatal staff is in attendance at delivery.
5. An episiotomy should not be routinely performed for an operative delivery.
6. Each blade is placed bilaterally over the fetal ear, avoiding the face.
7. Gentle traction is administered in a downward motion.

Complications

Maternal

1. Perineal trauma: lacerations of the vulva, cervix, vagina, and rectum; coccyx fracture.
2. Extensions of an episiotomy into the rectum: fourth-degree laceration.
3. Bladder trauma, uterine rupture.
4. Postpartum infection, postpartum hemorrhage secondary to uterine atony.
5. Anemia secondary to uterine atony/hemorrhage.
6. Urinary or fecal incontinence; fistula formation.

Fetal

1. Bruising.

2. Cephalohematoma.
3. Nerve injuries.
4. Facial lacerations and facial nerve palsy.
5. Skull fracture.
6. Ocular trauma.
7. Intracranial hemorrhage.

Nursing Assessment

1. After application of forceps, the FHR should be evaluated frequently per facility policy until delivery.
2. Evaluate bladder fullness—bladder should be empty before the application of the forceps.
3. Ensure sterile technique is maintained.

Nursing Diagnoses

- Anxiety related to fetal outcome.
- Acute Pain related to procedures.

Nursing Interventions

Decreasing Anxiety

1. Provide education and support for the woman and her partner when use of a vaginal assisted birth is expected.
2. Explain that a sensation of pressure will be felt.
3. Stay with the woman and provide guidance during the delivery process.

Promoting Comfort

1. Encourage use of breathing and relaxation techniques.
2. Make sure bladder is completely empty.
3. Encourage relaxation between contractions and use of abdominal muscles and pushing with the contractions.
4. Use blankets and pillows for support when positioning the woman for delivery.

Evaluation: Expected Outcomes

- Verbalizes concerns regarding forceps; responds to instructions.
- Demonstrates increased level of comfort.

Vacuum Extraction

Vacuum extraction applies suction to the fetal vertex, which is slowly increased to assist in delivery. Advantages include ease of application with a decrease in intensity to the fetal vertex. It is also associated with less maternal trauma, decreased injuries to fetus, and less need for general or regional anesthesia.

Indications

1. Same as forceps.

Contraindications

1. Same as forceps.

Management

1. Fetus is in vertex presentation.
2. Fetus should not be below 34 weeks' gestation.
3. The woman is in the lithotomy position.
4. The bladder is emptied by catheterization.
5. Pressure is applied during contractions and released between contractions. Fetal descent should occur with each contraction.
6. Anesthesia may be indicated.
7. Unsuccessful extraction is followed by a cesarean delivery.
8. Neonatal staff is in attendance at delivery.

Complications

Complications are usually less frequent and less severe with vacuum extraction than with forceps.

Maternal

1. Lacerations of the cervix or vagina.
2. Pain.
3. Infection.
4. Bladder trauma.
5. Hemorrhage.

Fetal

1. Cephalohematoma.
2. Caput succedaneum (swelling of the scalp) from the vacuum.
3. Intracranial hemorrhage.
4. Retinal hemorrhage.
5. Abrasions and lacerations to scalp.

6. Subgaleal hemorrhage.

Nursing Assessment

1. After application of the vacuum extractor, the FHR should be assessed frequently per facility policy until delivery.
2. Evaluate maternal sensation.
3. Evaluate bladder fullness—bladder should be empty before the application of the vacuum extractor.
4. Make sure sterile technique is maintained.
5. Monitor the vacuum pressure of the equipment according to your facility's protocol and document maternal–fetal response during procedure.
6. Monitor "pop-offs" (vacuum extractor cup pops off the fetal head); if three pop-offs have occurred or greater than 20 minutes have passed, other options should be considered.

Nursing Interventions

Same as for forceps delivery, page 1069.

Cesarean Delivery

Cesarean delivery is the surgical removal of the infant from the uterus through an abdominal and uterine incision. Cesarean births after increasing for more than a decade have begun to decrease from 32.9% to 32%. A decision to perform a cesarean section is for maternal and fetal well-being. It is recommended that prior to performing an elective cesarean section (based upon maternal request) that fetal gestational age of 39 weeks be confirmed.

Types of Cesarean Delivery

Uterine Incisions

Incision choice is based on the clinical scenario and future fertility.

1. Low transverse—transverse incision made across the lower uterine segment.
    a. Incision is made across the thickest section and away from uterine activity (fundus); minimizes blood loss and improves the integrity of the scar, decreasing risk of future dehiscence or rupture.
    b. Incidence of postoperative adhesions and danger of intestinal obstruction are reduced.
    c. First-line choice of incision in most clinical scenarios.
2. Classic or Vertical incision from the fundus down the body of the uterus to the lower uterine segment; may be utilized for emergent or preterm deliveries.
    a. Useful when bladder and lower segment are involved in extensive adhesions.
    b. Surgery of choice with a diagnosed anterior placenta previa, which inhibits the use of the low transverse incision.
    c. Increased blood loss versus low transverse.
    d. Increased risk of uterine rupture in subsequent deliveries.

Indications for Cesarean Delivery

1. Maternal medical complications, such as asthma, chronic hypertension, diabetes, cardiac disease, and active herpes infection.
2. Labor complications: dystocia, malpresentation, CPD, category III FHR pattern, prolonged or arrest of first or second stage of labor, early labor induction prior to cervical ripening.
3. Obstetric complications: placenta previa, breech, elective induction of nulliparous (50% higher risk than spontaneous labor).
4. Possible indications for cesarean hysterectomy:
    a. Ruptured uterus.
    b. Intrauterine infection.
    c. Postpartum hemorrhage: unresponsive to conservative management options.
    d. Laceration of major uterine vessel.
    e. Severe dysplasia or carcinoma in situ of the cervix.

f. Placenta accreta.
g. Gross multiple fibromyomas.
h. Uterine inversion unresponsive to manual replacement.

Management

Preoperative

1. Assess patient's last intake of food; surgery should be delayed for 8 hours following last meal; consult anesthesia.
2. A blood sample should be typed, screened with Rh status, and available to be cross matched, if needed; a CBC is obtained including platelets.
3. Anesthesia, regional or general, depends on indication for surgery.
4. Informed consents signed and witnessed.
5. A large gauge IV is established with Lactated Ringers (LR).
6. Insert indwelling urinary catheter; may wait until after anesthesia placement to minimize discomfort.
7. Administer an antacid; reduces gastric acidity, limiting complications should aspiration occur.
8. Shaving of pubic hair with a razor just prior to the incision is discouraged related to increased risk of SSI. Clipping pubic hair is preferred. Refer to facility guidelines.
9. Cleanse incision area with antimicrobial wash per facility protocol.
10. Antibiotics may be given prophylactically, as directed.

Intraoperative

1. Patient is moved to the operating suite.
2. Application of pneumatic compression devices is recommended.
3. Grounding pad applied per manufacturer's instructions.
4. Assist in application of monitors (cardiorespiratory).
5. Ensure facility verification process is completed prior to beginning of procedure, including "Time Out" Per facility policy.
6. Cleanse lower abdominal area (incision site) with FDA-approved antiseptic agent based on provider preference and facility policy.
7. Perform instrument, needle/knife, and lap pad counts periodically: before, during, and after surgery.
8. Verify that neonatal resuscitation equipment is readily accessible and radiant warmer is preheated.
9. Receive newborn and perform neonatal assessment; maintain asepsis.
10. Provide hand-off communication per facility policy.

Postoperative

In addition to routine postoperative recovery room care (see page 94), fundal checks must be performed as with the fourth stage of labor (page 1010).

Complications

1. Hemorrhage.
2. Endometritis.
3. Paralytic ileus (intestinal obstruction).
4. Pulmonary embolism.
5. Thrombophlebitis.
6. Anesthesia complications.
7. Bowel or bladder injury.
8. Respiratory depression of the infant from anesthetic drugs.
9. Possible delay in mother–infant bonding.

Nursing Assessment

Before Delivery

1. Assess knowledge of procedure.
2. Perform admission assessment.
3. Obtain 20- to 30-minute fetal tracing strip to assess fetal and uterine status.
4. Obtain maternal vital signs.
5. Identify drug allergies; identify other allergies (eg, latex, iodine, tape).

After Delivery (Also See Chapter 37)

1. Assess maternal vital signs every 15 minutes the first 1 to 2 hours or more frequently as the patient's condition warrants.
    a. Respiratory status: airway patency, oxygen needs, rate/quality/depth of respirations, auscultation of breath sounds, oxygen saturation readings.
    b. Circulation: BP, pulse, electrocardiogram monitoring for assessing dysrhythmias, color; assess dressing for drainage.
    c. LOC: orientation and response to verbal/tactile/painful stimulation.
2. Assess mobility and sensation of extremities if regional anesthesia is used.
3. Assess postpartum status (same intervals for assessment): fundal position and contractions, condition of incision and abdominal dressing, maternal–neonatal attachment, lochia (color, amount), neonate condition (if applicable), feeding preferences.
4. Assess hourly intake and output and reestablishment of bowel sounds.
5. Perform pain assessment: evaluate level of anesthesia, medications given (amount/time/results).
6. Assess knowledge and performance of breastfeeding.

Nursing Diagnoses

- Anxiety related to change in childbirth plan.

- Acute Pain related to surgical procedure.
- Risk for Infection related to open abdominal cavity.
- Interrupted family process related to unmet expectations for childbirth experience.

Nursing Interventions

Relieving Anxiety

1. Explain the purpose of all interventions and answer questions.
2. Allow the support person to attend the birth, if appropriate.

Promoting Comfort

1. Encourage use of relaxation techniques after medication has been given for pain.
2. Monitor for respiratory depression up to 24 hours after epidural opioid administration.
3. Monitor and instruct patient on use of patient-controlled anesthesia pump, as applicable.
4. Use a back rub and a quiet environment to promote the effectiveness of the medication.
5. Support and splint the abdominal incision when moving or coughing and deep breathing.
6. Encourage frequent rest periods.
7. To reduce pain caused by gas, encourage ambulation or use of rocking chair.
8. Administer pain medications as ordered. Do not administer parenteral opioids if patient is receiving epidural opioids unless ordered by anesthesia provider.

Preventing Infection

1. Establish protocol to decrease surgical site infections (SSI) per national guidelines.
2. Maintain sterile technique during surgery and use sterile technique when changing dressings postoperatively.
3. Be aware that the most effective method of infection prevention is handwashing.
4. Provide perineal care along with vital signs every 4 hours or as needed.
5. Provide routine postoperative care measures to prevent urinary or pulmonary infection.
6. Utilize incentive spirometer every hour while awake.

Promoting Effective Family Unit

1. Encourage infant bonding as soon as possible.
2. Emphasize the positive outcomes of operative delivery—avoidance of maternal–fetal complications and healthy baby.
3. Provide parent education and family time as tolerated by the mother.
4. Emphasize that adjustments to parenting under any circumstances are necessary and normal.

Patient Education and Health Maintenance

1. Teach and assist the woman with the “football hold” for breastfeeding; alleviates pressure on the

abdominal incision.

2. Teach incisional care per facility policy and instruct to observe for signs of infection (foul-smelling lochia, elevated temperature, increased pain, redness and edema at the incision site) and to report them immediately through 12 weeks' postpartum.
3. Assist the woman in planning for the assistance of friends and family during the period immediately after discharge.

Evaluation: Expected Outcomes

- Verbalizes an understanding of the cesarean delivery procedure and postdelivery care.
- Reports relief of pain.
- Absence of infection.
- Able to care of self and infant by discharge.

POSTPARTUM COMPLICATIONS

Postpartum Infection

Postpartum (puerperal) infection should be suspected if the patient's temperature exceeds 100°F (37.8°C) on two occasions at least 6 hours apart during the first 10 days postpartum exclusive of the first 24 hours postpartum. The infection may remain localized or extend to various parts of the body such as connective tissue by lymphatic dissemination (parametritis). The broad ligament is the main pathway for systemic infection.

Pathophysiology and Etiology

The most common cause is polymicrobial ascent to the uterus from the lower genital tract. Hematogenous bacterial spread may also occur.

1. Types of infection include:
    a. Endometritis: inflammation of the endometrium.
    b. Endomyometritis: inflammation of the endometrium and myometrium.
    c. Parametritis: inflammation of the endometrium and parametrial tissue.
2. Other infections include:
    a. Wound or UTIs.
    b. Pneumonia.
    c. Mastitis.
    d. Pelvic thrombophlebitis.
    e. Necrotizing fasciitis.
3. Risk factors:
    a. Operative birth.
    b. Prolonged labor or rupture of membranes.
    c. Use of invasive procedures (ie, internal monitoring, amnioinfusion, fetal scalp sampling).
    d. Multiple pelvic examinations.
    e. Excessive blood loss.
    f. Pyelonephritis or diabetes.
    g. Socioeconomic and nutritional factors compromising host defense mechanisms.
    h. Anemia and systemic illness.
    i. Smoking.
    j. Mastitis-specific risk factors: infrequent breastfeeding, incomplete breast emptying, plugged milk duct, cracked or bleeding nipples (may be secondary to improper latch-on and removal).

Clinical Manifestations

Endometritis Postpartum

1. Fever occurring around third day postpartum is the most important finding.

2. Uterus usually larger than expected for postdelivery day and tender.
3. Lochia may be profuse, bloody, and foul-smelling.
4. Chills, malaise, and fever occur if lochial discharge is obstructed by clots.
5. WBC greater than 20,000/mm^3 with increased neutrophils.
6. Infection may spread to myometrium (endomyometritis), parametrium, fallopian tubes, peritoneum, and blood.

Parametritis (Pelvic Cellulitis)

1. Chills, fever (38.9°C to 40°C [102°F to 104°F]), tachycardia.
2. Severe unilateral or bilateral pain in lower abdomen.
3. Enlarged and tender uterus.
4. Uterine position may become fixed as it is displaced by the exudate along the broad ligament.
5. Commonly, the result of an infected wound in the cervix, vagina, perineum, or lower uterine segment.

Diagnostic Evaluation and Management

1. Obtain urinalysis and urine culture to rule out UTI.
2. Obtain blood sample for CBC and report results; assess for leukocytosis more than 20,000/mm^3.
3. Antibiotic therapy: obtain cultures to identify causative agent prior to administration of broad-spectrum antibiotics including penicillins, cephalosporins (cefoxitin, cefazolin), clindamycin, and aminoglycosides (gentamicin, tobramycin). Antibiotics are given until the woman is afebrile for 48 hours (maternal response usually occurs within 48 to 72 hours) and may include home therapy.
4. Increase daily fluid intake.
5. Encourage increased intake of 300 to 500 calories if lactating; diet should include a variety of foods, usually high in protein and vitamin C (promotes wound healing).
6. Ensure adequate urine output (30 mL/hour).
7. Supportive therapy is used to control pain and to maintain hydration and nutritional status.
8. Drainage is indicated for abscess development.

Complications

1. Thrombophlebitis may result from postpartum infection spread along the veins or immobility.
    a. Femoral thrombophlebitis—appears 10 to 20 days after delivery as pain in calf, fever, edema; affected leg circumference is 2 cm greater than unaffected leg.
    b. Pelvic thrombophlebitis—infection of the veins of uterine wall and broad ligament usually caused by anaerobic streptococci; presents 14 days after delivery with severe chills and wide range of temperature changes.
    c. Treatment may include bed rest, compression stockings anticoagulants, and antibiotics.
2. Pulmonary embolus may occur—respiratory distress and chest pain.
3. Peritonitis—spread of infection through lymphatic channels.

Nursing Assessment

1. Perform postpartum assessment: note uterine tenderness on palpation and the color, amount, and odor of lochia; assess for proper breastfeeding techniques.
2. Monitor vital signs for signs of infection per facility policy.
3. Assess patient hygienic practices, and encourage frequent handwashing.

Nursing Diagnoses

- Hyperthermia related to infection.
- Risk for impaired attachment because of management of infection.

Nursing Interventions

Restoring Normothermia

Teach proper technique and assist, if necessary.

1. Provide for adequate rest periods.
2. Increase fluid intake to make up for insensible loss.
3. Position in high-Fowler position to promote drainage.
4. Administer antibiotics and analgesics, as ordered.
5. Explain the benefit of perineal washing or sitz baths; assist, as needed.
6. Explain importance of good handwashing technique; proper cleaning (front to back) during voiding or defecation.
7. Assist with perineal pads and medications; encourage changing pads with each voiding, bowel movement, and periodically throughout the day.
8. Observe for signs of septic shock: severe tachycardia, hypotension, tachypnea, changes in sensorium, and decreased urine output. Report to interprofessional team.

Promoting Infant Attachment

1. Encourage minimal separation from the infant and continuation of breastfeeding, as able.
2. Promote good handwashing technique for the mother before contact with the infant.
3. Encourage father/family participation in care of mother/baby unit.

Evaluation

- Afebrile, tolerating antibiotics well, using good hand hygiene.
- Infant bonding time uninterrupted.

Postpartum Hemorrhage

Postpartum hemorrhage, also known as obstetric hemorrhage (OH), reflects a blood loss in excess of 500 mL for a vaginal delivery or greater than 1,000 mL in a cesarean delivery. Early postpartum hemorrhage occurs in the first 24 hours and may be considered late after 24 hours up until 12 weeks after birth. The greatest risk is during the first hour following delivery. Hemorrhage may also be defined as a decrease in hematocrit of at least 10%, but determinations of hemoglobin and hematocrit concentrations may not reflect current hematologic status. The World Health Organization (WHO) found 25% of pregnancy-related deaths in the world were attributed to OH, and it is the single greatest cause of maternal deaths. In the United States, the mortality rate is 13% and on the rise. Worldwide, a woman dies of OH every 4 minutes.

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2006/Reaffirmed 2015). *Postpartum hemorrhage* (Practice Bulletin #76). Washington, DC: Author.

Pathophysiology and Etiology

Excessive bleeding from a point between the uterus and perineum (see Figure 39-8).

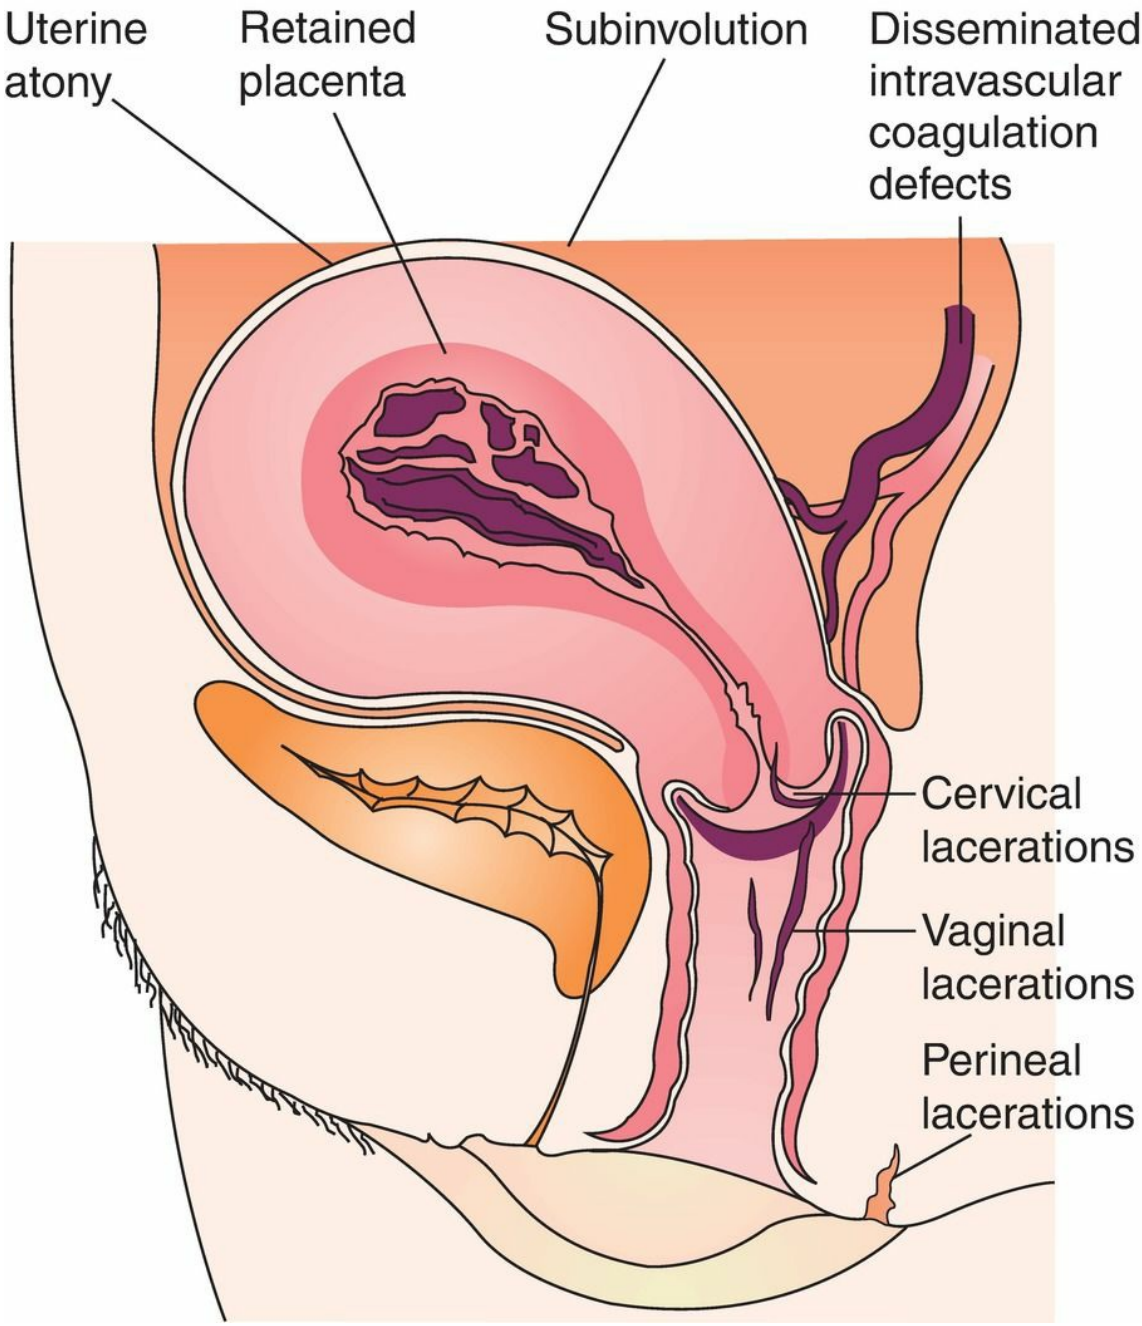

Figure 39-8. Common causes of postpartum hemorrhage. (From Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

Early Postpartum Hemorrhage (the First 24 Hours After Birth)

1. Main cause: uterine atony (80%)—relaxation of the uterus secondary to:
   a. Overdistention of uterus secondary to multiple pregnancy, polyhydramnios, or macrosomia.
   b. High parity (more than six pregnancies).
   c. Prolonged labor.
   d. Medications—oxytocin, magnesium sulfate, tocolytics, anesthetics.

e. Fibroids—prevents uterus from contracting.
f. Retained placental fragments—result from manual removal of placenta, succenturiate (additional) lobe, abnormally adherent placenta (placenta accreta), or spontaneous Duncan placenta delivery (periphery detaches first instead of central detachment).

2. Uterine inversion.
3. Bleeding disorders such as DIC.
4. Trauma, laceration, or hematomas of the vagina, cervix, or perineum secondary to:
   a. Forceps delivery, especially rotation forceps.
   b. Large infant.
   c. Multiple gestation.
5. Difficult third stage of labor (aggressive fundal manipulation or cord traction).
6. Sepsis.
7. Uterine rupture; uterine inversion.
8. Other risk factors include augmented or induced labor, rapid labor, history of postpartum hemorrhage, preeclampsia, or Asian or Hispanic ethnicity.

Late Postpartum Hemorrhage (24 Hours to 6 Weeks Postpartum)

1. Main cause is retained placental fragments.
2. Infection.
3. Subinvolution (delayed healing) of placental site.

Clinical Manifestations

Early Postpartum Hemorrhage

1. With uterine atony, uterus is soft or boggy, usually difficult to palpate, and will not remain contracted; excessive vaginal bleeding occurs.
2. Lacerations of the vagina, cervix, or perineum cause bright red, continuous bleeding even when the fundus is firm.
3. Tachycardia, hypotension, dizziness, pallor, and decreased urine output occur after loss of 10% total blood volume.

Late Postpartum Hemorrhage

1. Uterus is soft or boggy.
2. Slow, reddish oozing or heavy bleeding (first 6 weeks postdelivery).
3. Low persistent backache.
4. Abdominal pain or tenderness.
5. Fatigue.
6. Loss of appetite.

NURSING ALERT Over 50% of deaths because of OH were preventable and the result of ineffective medical management. Early assessment, identification, and intervention in the event of an OH is essential to improving obstetric outcomes.

Management

Goal is to stop hemorrhage by alleviating cause, correct hypovolemia, and return maternal hemostasis. These goals are accomplished through identification of risk factors and early identification and treatment of the underlying cause. Visual estimates of blood loss are frequently imprecise and inaccurate, delaying diagnosis and treatment.

1. Prompt notification and communication to the interprofessional team, which includes anesthesia provider, primary care provider, nursing and operating room personnel, as indicated by the patient's condition.
2. Continue fundal massage and possible bimanual massage if indicated.
3. Maintain IV access with Lactated Ringers infusion and add a secondary line with 16G catheter for severe loss.
4. Obtain ordered lab work (CBC, crossmatch). For each 450 to 500 mL of blood loss, there will be a decrease in the hematocrit of 2% to 4% and a decrease in the hemoglobin of 1 to 1.5 g/dL.
5. Notify blood bank, as indicated; order 4 to 6 units, as needed. When anticipating administration of blood products or transfusions, it is important to recognize that some patients may decline them based on religious beliefs. It is important to identify the patient's cultural and religious practices upon admission and communicate to the interprofessional team.
6. Administer medications, as ordered: for uterine atony—
   a. IV administration of oxytocin, IV or IM (see Chapter 37 stage 4 of labor).
   b. When oxytocin is ineffective to control bleeding, anticipate the need for additional medications to treat postpartum hemorrhage:
   c. Methylergonovine 0.2 mg IM every 2 to 4 hours. (Contraindicated in women with hypertension, Raynaud syndrome, scleroderma).
   d. Misoprostol 800 to 1,000 mcg per rectum (single dose) (may cause fever and tachycardia).
   e. Carboprost tromethamine 0.25 mg IM every 15 to 90 minutes (8 dose maximum)—contraindicated in women with asthma, active cardiac, hepatic, or renal disease; may cause fever, chills, nausea, vomiting, diarrhea).
7. In the presence of continuous bleeding and a firm uterus, notify the provider for evaluation and possible intervention.
   a. Repair of lacerations, transfusion of blood products, dilation and curettage, B-lynch suture, uterine tamponade, and selective arterial embolization.
   b. Intrauterine balloon tamponade using, for example, the Bakri SOS (surgical obstetric silicone) to

control bleeding (see Figure 39-9).

   i. 250 to 500 mL of saline is introduced into the balloon to maintain pressure against the uterine walls. Pooled blood above the balloon is removed through the drainage port of the catheter.

   ii. Vaginal packing is also placed to increase the tamponade effect on the lower uterine segment, and a urinary catheter is placed for bladder drainage.

8. Opioid analgesics may be needed to counter the pain of uterine contractions.
9. Emergency hysterectomy may be necessary.

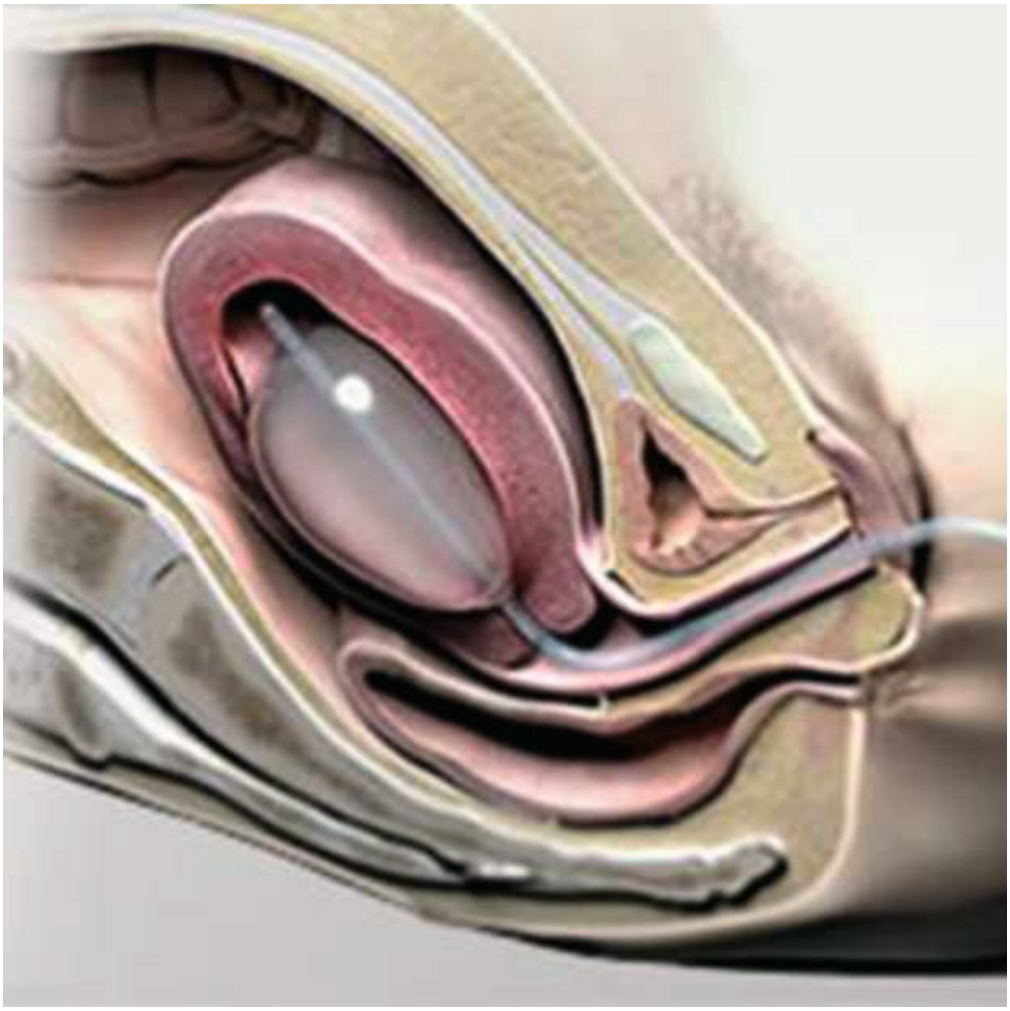

Figure 39-9. The Bakri SOS provides balloon tamponade to stop postpartum hemorrhage.

Complications

1. Hypovolemic shock.
2. Hysterectomy.
3. Death.

Nursing Assessment

1. Assess maternal history for risk factors; plan accordingly and communicate to the perinatal team.

2. Perform ongoing cumulative assessment of blood loss during the entire postpartum period. As the patient changes hands between practitioners and departments, blood loss is commonly estimated only by what one practitioner visualizes over his or her own shift, not taking into consideration what has transpired over the course of the entire postpartum period. Therefore, documentation and communication should reflect a cumulative total and any acute changes relative to the changes in the patient's immediate status. See Box 39-3 for blood loss estimates.
3. Evaluate for presence of clots expelled or passed during voiding; note number of pads saturated in 1 hour or shorter time frame, if applicable. Weigh pads, as necessary, to determine loss.
4. Assess vital signs, pulse pressure, and oxygen saturation per facility policy and increase assessments if the patient shows signs of instability—tachycardia, hypotension, pallor, diaphoresis, altered LOC, tachypnea, nausea and vomiting, feelings of impending doom—all of which may indicate hypovolemic shock.
    a. Normal vital signs are not an indication that the woman is *not* in shock. Traditional signs of hypovolemic shock are not evident until approximately 15% to 20% of total maternal blood volume is lost.
    b. Continuous BP monitor readings may falsely lower diastolic and raise systolic readings. Assessments more frequent than 2 minutes apart may not allow for vessels within the extremity to reperfuse between assessments.
5. Assess intake and output (maintain greater than 25 mL/hour); make sure intake includes a cumulative total to include all labor and delivery infusions as well as any fluids administered during surgery, such as with cesarean delivery. Foley catheter may be used for bladder decompression.
6. Assess location and firmness of uterine fundus.
7. Percuss and palpate for bladder distention, which may interfere with contracting of the uterus.
8. Inspect for intactness of any perineal repair.
9. Because of rapid infusion of fluid during fluid resuscitation, assess breath sounds for signs of pulmonary edema.

Nursing Diagnoses

- Anxiety related to unexpected blood loss and uncertainty of outcome.
- Deficient Fluid Volume related to uterine atony.
- Risk for Infection related to blood loss and vaginal examinations.

Nursing Interventions

Decreasing Anxiety

1. Maintain a quiet and calm atmosphere; provide emotional support.
2. Provide information about the current clinical situation; answer questions.
3. Encourage the presence of a support person.
4. Explain changes to care plan.

Maintaining Fluid Volume

1. Maintain primary IV access and place a second large gauge 16G catheter infusing crystalloids and blood products, as indicated.
2. Monitor and maintain accurate intake and output; use of indwelling urinary catheter provides accurate output measurements.
3. Make sure that cross-matched blood is available; administer per facility protocol when necessary.
4. Provide supplemental oxygen by face mask; monitor oxygen saturation with pulse oximetry.
5. Administer medications, as ordered.
6. Change patient positions to facilitate perfusion to vital organs: elevate legs 20 to 30 degrees.
7. Monitor CBC and additional ordered lab work.

Preventing Infection

1. Maintain standard precautions and asepsis.
2. Evaluate for symptoms of infection: chills, elevated temperature, increased WBCs, uterine tenderness, and odor of lochia.
3. Administer antibiotics, as prescribed.
4. Maintain adequate rest and proper nutrition.

Patient Education and Health Maintenance

1. Educate the woman about the cause of hemorrhage.
2. Teach the woman the importance of eating a balanced diet high in iron-rich options and taking vitamin supplements.
3. Advise the woman she may feel tired and fatigued and to schedule daily rest periods.
4. Teach woman and family signs and symptoms of hemorrhage for home care.
5. Advise the woman to notify her health care provider of increased bleeding or other changes in her status.

Evaluation: Expected Outcomes

- Verbalizes concerns about her well-being.
- Vital signs stable, urine output adequate, hematocrit stable.
- Remains afebrile, WBC count within normal limits.

Postpartum Hematomas

Postpartum hematomas are localized collections of blood in loose connective tissue beneath the skin of external genitalia, beneath the vaginal mucosa, or in the broad ligaments. Usually occurs without laceration of the overlying tissue. Excessive perineal pain unrelieved by medications suggests hematoma formation and mandates careful examination of vulva, vagina, and rectum.

Pathophysiology and Etiology

1. Trauma during spontaneous labor or operative vaginal delivery.
2. Inadequate suturing of an episiotomy.
3. Delayed homeostasis or difficult or prolonged second stage of labor or both.

Clinical Manifestations

1. Complaints of pressure and pain; pain may be verbalized as excruciating.
2. Discolored skin that is tight, full feeling, and painful to the touch.
3. Possible decrease in BP, tachycardia.
4. Decrease or absence of lochia flow if the vagina is impeded.

Management

1. Small hematomas (less than 3 cm) are left to resolve on their own—ice packs may be applied. Sitz baths may also increase comfort.
2. Large hematomas (greater than 3 cm) may require evacuation of the blood and ligation of the bleeding vessel.
3. Analgesics and broad-spectrum antibiotics may be ordered (because of increased chance of infection).

Complications

1. Hypovolemia and shock from extreme blood loss.
2. Anemia, infection.
3. Increased length of postpartum recovery period.
4. Sepsis.
5. Calcification and scar tissue.
6. Dyspareunia (painful intercourse).

Nursing Interventions and Patient Education

1. Inspect perineal and vulvar area for signs of a hematoma periodically postpartum.
2. Inspect vaginal area for signs of a hematoma if woman is unable to void.
3. Monitor vital signs and evaluate for signs of shock.
4. Relieve pain of a hematoma by applying an ice bag to perineal area, medicating with mild analgesics, and

positioning for comfort to decrease pressure on the affected area.

5. Help relieve voiding problems by assisting to bathroom if able to ambulate. If patient is unable to ambulate, then assist her on to a bedpan with legs hanging over side of bed. Provide privacy and run water while the woman is attempting to void.
6. Catheterize patient if unable to void.
7. Teach the woman the importance of eating a balanced diet and to include food high in iron.
8. Encourage the woman to take vitamin supplements and to take medications, as ordered.
9. Instruct the woman in the use of a sitz bath to provide perineal comfort after the first 24 hours and at home.

Postpartum Depression

EVIDENCE BASE American College of Obstetricians and Gynecologists. (2015). *Screening for depression during and after pregnancy* (Committee Opinion #630). Washington, DC: Author.

There is no consensus regarding the classification of postpartum depression. Is it estimated to complicate 13% to 19% of pregnancies. Severity and presenting symptoms vary.

Pathophysiology and Etiology

Social, cultural, physiologic, and psychological factors may contribute to postpartum depression. Predisposing factors include:

1. Stressful life events during pregnancy or the postpartum period.
    a. Loss of loved one (fetus, neonate, partner, or other child).
    b. Illness of loved one.
    c. Financial difficulties.
    d. Loss of job.
    e. Move to new area, home, or job.
    f. Previous mental health history.
2. Poor interpersonal relationships.
3. Inadequate support.
4. History of sexual abuse or domestic violence.
5. High levels of anxiety, neurotic behavior, and depression or emotional distress.
6. Personal or family history of psychopathology, especially depression.

Common Presentations

1. Maternity blues; postpartum blues; baby blues; mother's blues; or 3rd-, 4th-, or 10th-day blues.
2. Postpartum or postnatal depression.
3. Postpartum or puerperal psychosis.
4. Postpartum panic disorder.
5. Postpartum obsessive–compulsive disorder.

Clinical Manifestations

BOX 39-3 Estimation of Blood Loss

Accurate evaluation of blood loss is critical to maternal outcomes. Studies validate the inaccuracy of blood loss estimation with visual inspection. The use of under buttock drapes to collect blood loss during delivery

has been valuable in improving the ability to measure blood loss during childbirth. Estimation by weight using a scale is desirable. Follow these steps:

- Obtain the dry weight (in grams) of commonly used items such as disposable underpad, perineal pad, 4 × 4).
- Weigh the saturated items and subtract the dry weight of the items to determine blood loss.
- 1 gram weight = 1 mL of blood. In the absence of a scale, the following estimations may be utilized:
- Saturated 12-ply surgical sponge (4 × 4 in.) = 5 mL.
- Standard perineal pad 50% saturated = 25 mL.
- Saturated 18 × 18 inch surgical laparotomy pad = 100 mL.
- Clot the size of a golf ball = 50 mL.
- Clot the size of a tennis ball = 140 mL.

1. Confusion.
2. Exaggerated and prolonged periods of irritability, moodiness, hostility, and fatigue.
3. Ineffective coping.
4. Withdrawal and inappropriate response to the infant or family.
5. Loss of interest in activities.
6. Insomnia or sleep disturbances.
7. Headache.
8. Constipation or other gastrointestinal symptoms.
9. Hair loss.
10. Dysmenorrhea.
11. Difficulties with lactation.
12. Decreased sexual responsiveness.

Evaluation and Management

1. Signs and symptoms may be overlooked, making the diagnosis of depression difficult. Several assessment tools, designed to screen for women who may need further evaluation for postpartum depression, are available. The psychosocial screening tool recommended by the American College of Obstetricians and Gynecologists can be used by the nurse or health care provider as a means of communication. Questions should be worded empathically and nonjudgmentally to stimulate an honest response from the mother.
2. Counseling with a mental health professional, medication, and continuous support from family and friends may be helpful in managing the depressed patient. If untreated, the woman may possibly harm the infant, herself, or others.
3. The use of psychotropic medications during breastfeeding remains a controversial issue. All of the major classes of psychotropic drugs are expressed in breast milk. Use will depend on the risk versus benefits of treatment. Consultation with the interprofessional team including lactation consultant is recommended.
4. Any indication of suicide or harm to infant requires immediate intervention to relieve the danger and

referral to mental health professional.

Nursing Interventions and Patient Education

1. Actively listen to the woman regarding her adjustment to role of mother and observe for any clinical manifestations suggesting depression.
2. Teaching related to signs and symptoms should include the mother and her partner.
3. Provide multimedia resources if available.
4. Ask the woman about the infant's behavior. Negative statements about the infant may suggest that the woman is having difficulty coping. Notify the woman's obstetric or primary care provider.
5. Consult or refer woman to health care provider and other resources skilled in postpartum depression, as indicated. Refer patients to Postpartum Support International (*www.postpartum.net*).
6. Provide support and encourage family and friends to support and assist with the infant and mother. Physical support as well as emotional support may be indicated.
7. Educate the woman that treatment may help alleviate her symptoms and allow her to better care for herself and her infant.
8. Encourage the woman to engage in activities that enhance attachment: rooming-in, breastfeeding, and becoming involved in the medical examination of the neonate.
9. Realize that effective attachment behaviors differ from culture to culture and do not necessarily indicate maladaptive parenting behaviors.

Pediatric Growth and Development

Growth and Development

Infant to Adolescent Growth and Development

Developmental Screening

GROWTH AND DEVELOPMENT

Infant to Adolescent Growth and Development

Growth and development begin with birth. As infants and children grow and mature, they pass through predictable stages of development. Knowledge and assessment of growth and development help the nurse provide screening for physical and emotional problems, offer anticipatory guidance to parents and caregivers, develop a rapport with the child to enhance the provision of health care, and provide education to the family to build a healthy lifestyle for the future. For assessment of the neonate, see Chapter 38, page 1023. This chapter covers the beginning of infancy (age 1 month) to adolescence (ages 12 to 14). See Table 40-1.

Table 40-1 Infant to Adolescent Growth and Development

AGE AND PHYSICAL CHARACTERISTICS	BEHAVIOR PATTERNS	NURSING CONSIDERATIONS
Birth to 4 Weeks (1 Month) • Significant neurologic disorganization. • Strong Moro reflex. • Sleep cycle disorganized. • GI system too immature for solid foods.	***Motor development*** • Momentary visual fixation on objects and human face. • Eyes follow bright moving objects. • Lies awake on back. • Immediately drops objects placed in hands. • Responds to sounds of a bell and other similar noises. • Keeps hands fisted. ***Socialization and vocalization*** • Mews and makes throaty noises. • Shows interest in human face. ***Cognitive and emotional development*** • Reflexive. • External stimuli are meaningless. • Responses are generally limited to tension states or discomfort. • Gains satisfaction from feeding and being held, rocked, fondled, and cuddled. • Has an intense need for sucking pleasure. • Quiets when picked up.	***Play stimulation*** • Use human face—smile and talk. • Dangle bright moving object (eg, mobile) in field of vision. • Hold, touch, caress, fondle, and kiss. • Rock, pat, and change position. • Play soft music or have infant listen to ticking clock or sing. • Talk to infant; call by name. ***Parental guidance*** • Begin to expose infant to different household sounds. • Change crib location in the room. • Use brightly colored clothing and linens. • Put infant to sleep on back until old enough to roll. • Keep infant nearby. • Play with infant when awake. • Hold during feeding. **NURSING ALERT** Educate parents about infant sleep stages and putting infant to sleep on back.
4 to 8 Weeks (2 Months) • Crossed extensor reflex disappears. • Tonic neck reflex begins to fade.	***Motor development*** • Reflexive behavior is slowly being replaced by voluntary movements. • Turns from side to back. • Begins to lift head momentarily from prone position. • Shows improved eye coordination. • If a bell is sounded nearby, infant will stop activity and listen. • Eyes more accurately follow vertical and horizontal alignment. Focuses well. ***Socialization and vocalization*** • Begins vocalization—coos, especially to a voice. • Crying becomes differentiated. • Visually looks for sounds. • May squeal with delight when stimulated by touching, talking, or singing. • Begins to smile socially. • Eyes follow person or object more intently. ***Cognitive and emotional development*** • Recognizes familiar face. • Becomes more aware and interested in environment. • Anticipates being fed when in feeding position. • Enjoys sucking—puts hand in the mouth.	***Play stimulation*** • Securely arrange mobile over crib. • Hang wind chimes near infant. • Hang brightly colored pictures on the wall. • Use cradle gym and infant seat. • Use rattles. • Hold infant and walk around the room. • Allow freedom of kicking with clothes off. ***Parental guidance*** • Talk to infant and smile; get excited when infant coos. • Place infant seat on a secure surface (eg, floor, center of a table—never near the edge of the table) near mother's activities. • Put infant in prone position in bed or on floor for supervised periods. • Expose infant to different textures. • Exercise infant's arms and legs. • Sing to infant. • Provide tactile experience during bathing, diapering, and feeding.
8 to 12 Weeks (2 to 3 Months) • Landau reflex appears at 3 to 4 months. • Positive support reflex disappears.	***Motor development*** • When prone, will rest on forearms and keep head in midline—makes crawling movements with legs, arches back, and holds head high; may get chest off surface.	***Play stimulation*** • Encourage socialization, smiling, and laughing. • Place on mat on the floor. • Continue to introduce new sounds.

8 to 12 Weeks (2 to 3 Months) (*Continued*)

- Posterior fontanelle closes.
- Increase in body fluids—real tears appear, drooling and GI juices increase.

Motor development (Continued)

- Indicates preference for prone or supine.
- Discovers hands—bats objects with hands.
- Holds objects in the hands and brings to the mouth.
- Has fairly good head control.

Socialization and vocalization

- Smiles more readily, babbles, and coos.
- Stops crying when parent enters the room or when caressed.
- Enjoys playing during feeding.
- Stays awake longer without crying.
- Turns head to follow familiar person.

Cognitive and emotional development

- Shows active interest in environment.
- Recognizes familiar faces and objects.
- Focuses and follows objects.
- Shows repetitiveness in play activity.
- Is aware of strange situations.
- Derives pleasure from sucking—purposefully gets hand to the mouth.
- Begins to establish routine preceding sleep.

Parental guidance

- Take outdoors with proper clothing (similar warmth as that of adults), hat, and PABA-free sunscreen.
- Bounce on bed.
- Play with infant during feeding.
- Rattles can be used effectively for visual following and for hand play.
- Encourage older siblings to "make faces," sing, and talk to infant.

NURSING ALERT Children of all ages should avoid intense sun exposure, particularly during the middle of the day. PABA-free broad spectrum sunscreen with a sun protection factor of at least 15 (SPF 15) should be used on children of all ages, particularly if sun exposure is longer than 30 minutes with frequent reapplication.

12 to 16 Weeks (3 to 4 Months)

- Moro reflex fades.
- Stepping reflex disappears.
- Rooting reflex disappears.
- By 4 to 5 months, infant's weight approximately doubles birth weight.
- Average weekly weight gain, 4 to 7 ounces (113.5 to 198.5 g).
- Average monthly height gain, 1 inch (2.5 cm).
- Pulse rate slows to 100 to 140 beats/minute.
- Respirations, 20 to 40 breaths/minute.
- Grasp becomes voluntary.
- Sucking becomes voluntary.

Motor development

- Eyes focus on small objects; may pick a dangling ring.
- Holds head up (when being pulled to sitting position).
- Becomes more interested in environment.
- Hand comes to meet rattle.
- Listens—turns head to familiar sound.
- Sits with minimal support.
- Intentional rolling over, back to side.
- Reaches for offered objects.
- Grasps objects with both hands and everything goes into the mouth.

Socialization and vocalization

- Laughs and chuckles socially.
- Demands social attention by fussing.
- Recognizes mother.
- Begins to respond to "No, no."
- Enjoys being propped in sitting position.

Cognitive and emotional development

- Actively interested in environment.
- Enjoys attention; becomes bored when alone for long periods.
- Recognizes bottle.
- More interested in mother.
- Indicates increasing trust and security.
- Sleeps through the night; has defined nap time.

Play stimulation

- Encourage mirror play.
- Provide soft squeeze toys in vivid colors of varying textures.
- Allow infant to splash in bath.
- Infant still enjoys holding and playing with rattles.
- Enjoys old-fashioned clothespins and playing pat-a-cake and peekaboo.

Parental guidance

- Be certain button eyes on toys and other small objects cannot be pulled off.
- Hold rattle and let infant reach and grasp it.
- Secure infant in high chair or infant seat.
- Move mobile out of reach—infant may grab it and cause injury.
- Repeat child's sounds.
- Talk in varying degrees of loudness.
- Begin looking at and naming pictures in book.
- Begin physically active play by both parents.
- Give space in playpen or on sheet on the floor to practice rolling over.
- Place on the abdomen for part of playtime.

16 to 26 Weeks (4 to 7 Months)

- By 5 to 6 months, tonic neck reflex disappears.
- By 6 to 7 months, palmar grasp disappears.

Motor development

- Shows momentary sitting with hand support.
- Bounces and bears some weight when held in standing position.
- Transfers and mouths objects in one hand.

Play stimulation

- Enjoys social games, hide-and-seek with adult, toys, and large blocks.
- Likes to bang objects.
- Plays in bounce chair and walker.

16 to 26 Weeks (4 to 7 Months) (*Continued*)

- Two central lower incisors erupt.
- Spine "C-shaped"—lacks lordotic and lumbar curves
- Eustachian tube short and horizontal, which may be a factor in ear infections
- GI system mature enough for solid foods

Motor development (Continued)

- Discovers feet.
- Bangs objects together.
- Rolls over well.
- May begin some form of mobility.

Socialization and vocalization

- Discriminates between strangers and familiar people.
- Crows and squeals.
- Starts to say "Ma," and "Da."
- Play is self-contained.
- Laughs out loud.
- Makes "talking" sounds in response to others' talking.

Cognitive and emotional development

- Secures objects by pulling on string.
- Searches for lost objects that are out of sight.
- Inspects objects; localizes sounds.
- Likes to sit in high chair.
- Drops and picks up objects.
- Displays exploratory behavior with food.
- Exhibits beginning fear of strangers.
- Becomes fretful when mother leaves.
- Shows much mouthing and biting.

Play stimulation (Continued)

- Enjoys large nesting toys (round rather than square).
- Likes to drop and retrieve things.
- Likes metal cups, wooden spoons, and things to bang with.
- Loves crumpled paper.
- Enjoys squeeze toys in bath.
- Likes peekaboo, bye-bye, and pat-a-cake.

Parental guidance

- Will play as long as you can.
- Let play with extra spoon at feeding.
- Give soft finger foods in small amounts.
- Because infant puts everything in the mouth, use safety precautions.
- Keep small items away from infant, which could choke on them.
- Show excitement at achievements.
- Supply safe kitchen items for toys.

26 to 40 Weeks (7 to 10 Months)

- By 7 to 9 months, develops eye-to-eye contact while talking; engages in social games.
- Four upper incisors erupt around 7 to 9 months.
- By 9 to 12 months, plantar reflex disappears.
- By 9 to 12 months, neck righting reflex disappears.

6 to 12 months

- Average weekly weight gain, 3 to 5 ounces (85 to 141.7 g).
- Average monthly height gain, ½ inch (1.25 cm).

Motor development

- Sits without support.
- Recovers balance.
- Manipulates objects with hands.
- Unwraps objects.
- Creeps.
- Pulls self upright at crib rails.
- Uses index finger and thumb to hold objects.
- Rings a bell.
- Can feed self a cracker and can hold a bottle. Chewing reflex develops.
- Can control lips around cup.
- Does not like supine position.
- Can hold index finger and thumb in opposition.

Socialization and vocalization

- Claps hands on request.
- Responds to own name.
- Is very aware of social environment.
- Imitates gestures, facial expressions, and sounds.
- Smiles at image in the mirror.
- Offers toy to adult, but does not release it.
- Begins to test parental reaction during feeding and at bedtime.
- Will entertain self for long periods.
- Begins fear of strangers, 8½ to 10 months.

Cognitive and emotional development

- Begins to imitate.
- Shows more interest in picture books.
- Enjoys achievements.
- Has strong urge toward independence—locomotion, feeding, and dressing.

Play stimulation

- Encourage use of motion toys—rocking horse and stroller.
- Supervised water play.
- Imitate animal sounds.
- Allow exploration outdoors.
- Provide for learning by imitation.
- Offer new objects (blocks).
- Child likes freedom of creeping and walking, but closeness of family is important.
- Good toys: plastic milk carton; bean-bag for tossing; fabric books; things to move around, fill up, and empty out; pileup and knockdown toys.

Parental guidance

- Protect from dangerous objects—cover electrical outlets, block stairs, and remove breakable objects from tables.
- Have child with family at mealtime.
- Offer cup.
- Talk and sing to infant.

10 to 12 Months (1 Year)

- Develops lordotic and lumbar curves to make walking possible.
- Weight should approximately triple birth weight.
- Two lower lateral incisors appear.
- Four first molars appear by 14 months.

Child development theories

- Freudian: Behavior
  - Birth to 1 year—Oral Stage
- Eriksonian: Emotion/ Personality
  - Birth to 1 year—Sense of Trust vs. Mistrust
- Piagetian: Intellectual Activity (Thought Process)
  - Birth to 2 years—Sensorimotor Period

Motor development

- Cruises around furniture.
- Beginning to stand alone and toddle.
- Turns pages in book.
- Tries tossing object.
- Shows hand dominance.
- Navigates stairs; climbs on chairs.
- Builds a tower of two blocks.
- Puts balls in the box.
- May use spoon.
- Can release objects at will.
- Has regular bowel movements.

Socialization and vocalization

- Uses jargon.
- Points to indicate wants.
- Loves give-and-take game.
- Responds to music.
- Enjoys being center of attention and will repeat laughed-at activities.

Cognitive and emotional development

- Shows fear, anger, affection, jealousy, anxiety, and sympathy.
- Experiments to reach new goals.
- Displays intense determination to remove barriers to action.
- Begins to develop concepts of space, time, and causality.
- Has increased attention span.

Play stimulation

- Ball play.
- Cloth doll.
- Motion objects and toys.
- Transporting objects.
- Name and point to body parts.
- "Put in" and "take out" toys.
- Sandbox with spoons and other simple objects.
- Blocks.
- Music.

Parental guidance

- Allow self-directed play rather than adult-directed play.
- Continue to expose to foods of different texture, taste, smell, and substance.
- Offer cup.
- Show affection and encourage child to return affection.
- Safety teaching: Child gets into everything within reach. Place medications in safe, locked place. Create a safe environment for child. Use stair guards, faucet protectors, and drawer locks. Have poison control center phone number readily available.

12 to 18 Months

- *Note:* Between ages 1 and 3 years, the child is called a "toddler."
- By 12 to 24 months, Landau reflex disappears.
- Anterior fontanelle closes.
- The abdomen protrudes; arms and legs lengthen.
- Large muscles become well developed.
- Four cuspids appear by 18 months.
- Fine muscle coordination begins to develop.
- Average yearly weight gain, 4½ to 6½ pounds (2 to 3 kg).
- Average height gain during second year, 4¾ inch (12 cm).

Motor development

- Walks up stairs with help and creeps downstairs.
- Walks without support and with balance.
- Falls less frequently.
- Throws ball.
- Stoops to pick up toys and looks at bug.
- Turns pages of book.
- Holds and lifts cup.
- Builds three-block tower.
- Picks up and places small beads in a container.
- Begins to use spoon.

Cognitive and emotional development

- Has vocabulary of 10 words that have meanings.
- Uses phrases and imitates words.
- Points to objects named by adult.
- Follows directions and requests.
- Imitates adult behavior.
- Retrieves toy from several hiding places.

Psychosocial development

- Develops new awareness of strangers.
- Wants to explore everything in reach.
- Plays alone, but near others.
- Is dependent on parents, but begins to reach out for autonomy.
- Finds security in a blanket, toy, or thumb-sucking.

Play stimulation

- Allow unrestricted motor activity (within safety limits).
- Offer push–pull toys.
- Child selects favorite toy.
- Child likes blocks, pyramid toys, teddy bears, dolls, pots and pans, cloth picture books with large colorful pictures, telephone, musical top, and nested blocks.

Parental guidance

- Begin to teach toothbrushing to establish good dental habits; however, continue to brush child's teeth with specially formulated pediatric toothpaste.
- Establish limits to give toddler sense of security, but encourage exploration.
- Reinforce safety teaching.

1½ to 2 Years

- Protruding abdomen less noticeable.
- During first 2 years, 14 inches (35 cm) is added to height.
- Slight bowing of legs with a wide-based walk.
- Hand preference may become apparent.

Motor development

- Walks up and down stairs.
- Opens doors; turns knobs.
- Has steady gait.
- Holds drinking cup well with one hand.
- Uses spoon without spilling food (may prefer fingers).
- Kicks a ball in front of him or her without support.
- Builds a tower of four to six blocks.
- Scribbles.
- Rides tricycle or kiddie car (without pedals).

Cognitive development

- Has 200 to 300 words in vocabulary.
- Begins to use short sentences.
- Refers to self by pronoun.
- Obeys simple commands.
- Does not know right from wrong.
- Begins to learn about time sequences.

Psychosocial development

- Uses word "mine" constantly.
- Is possessive with toys.
- Displays negativism—uses "no" as assertion of self.
- Routine and rituals are important.
- May begin cooperation in toilet training.
- Resists restrictions on freedom.
- Has fear of parents leaving.
- Shows parallel play.
- Dawdles.
- Resists bedtime—uses transitional objects (blanket, toy).
- Vacillates between dependence and independence.

Play stimulation

- Shows parallel play, although enjoys having other children around.
- Has very short attention span.
- Enjoys same toys as child of 18 months.
- Likes doll play and balls.
- Imitates parents in domestic activities.
- Likes swing, hammering, paper, and large crayons.

Parental guidance

- Has need for peer companionship (parallel play) although displays immaturity by inability to share and take turns.
- A decrease in appetite normally occurs at this stage.
- Toilet training readiness should be assessed and started if appropriate (each child follows own pattern).
- Begin to have child eat meals with family if not already doing so.
- Begin to read to child; child likes storybooks with large pictures.

2 to 3 Years

- Height approximates one-half adult height.
- Legs are about 34% of body length.
- Begins 5 pounds (2.3 kg) or more weight gain per year until age 5 years.
- At 2½ years, has full set (20) of baby teeth.
- Four second molars appear by 2½ years.
- Height gain, 2⅜ to 3¼ inches (6 to 8 cm).
- Lordosis and protuberant abdomen of toddler disappear.

Child development theories

- Freudian:
  - 1 to 3 years—Anal Stage
- Eriksonian:
  - 1 to 3 years—Sense of Autonomy versus Shame and Doubt

Motor development

- Throws objects overhead.
- Pedals tricycle.
- Walks backward.
- Washes and dries hands.
- Begins to use scissors.
- Can string large beads.
- Can undress him- or herself.
- Feeds himself well.
- Tries to dance.
- Jumps in place.
- Builds tower of eight blocks.
- Balances on one foot.
- Swings and climbs.
- Can eat an ice cream cone.
- Drinks from a straw.
- Chews gum without swallowing it.

Cognitive development

- Shows increased attention span.
- Gives first and last name.
- Begins to ask "why."
- Is egocentric in thought and behavior.
- Beginning ability to reflect on own behavior.
- Talks in short sentences.

Play stimulation

- Plays simple games with other children.
- Enjoys storytelling and dress-up play.
- Plays "house."
- Colors.
- Uses scissors and paper.
- Rides tricycle.
- Reads simple books to child.
- Will assist in developing memory skills, visual discrimination skills, and language.

Parental guidance

- From 2 to 3 years, the child develops a seeming maturity; do not expect more than child is able to do.
- Arrange first visit to the dentist to have teeth checked if not done prior.
- Be aware that negativistic and ritualistic behavior is normal.
- Be consistent in discipline.
- Control temper tantrums.
- Begin to teach stranger, animal and traffic safety.
- Supervise outdoor play.

2 to 3 Years (*Continued*) • Piagetian: • 2 to 7 years—Preoperational Period; shows egocentrism and centering	***Cognitive development (Continued)*** • Uses plurals. • May attempt to sing simple songs. • Has vocabulary of 900 words. • Begins fantasy. • Begins to understand what it means to take turns. • Can repeat three numbers. • Shows interest in colors. ***Psychosocial development*** • Negativism grows out of child's sense of developing independence—says "no" to every command. • Ritualism is important to toddler for security (follows certain pattern, especially at bedtime). • Temper tantrums may result from toddler's frustration in wanting to do everything for self. • Shows parallel play as well as beginning interaction with others. • Engages in associative play. • Fears become pronounced. • Continues to react to separation from parents but shows increasing ability to handle short periods of separation. • Has daytime bladder control and is beginning to develop nighttime bladder control. • Becomes more independent. • Begins to identify sex (gender) roles. • Explores environment outside the home. • Can create different ways of getting desired outcome.	
3 to 4 Years *Note:* Between ages 3 and 5 years, the child is called a "preschooler." May appear "knock-kneed."	***Motor development*** • Drawings have form and meaning, not detail. • Copies a circle and a cross. • Buttons front and side of clothes. • Laces shoes. • Bathes self, but needs direction. • Brushes teeth. • Shows continuous movement going up and down stairs. • Climbs and jumps well. • Attempts to print letters. ***Cognitive development*** • Awareness of body is more stable; child becomes more aware of own vulnerability. • Is less negativistic. • Learns some number concepts. • Begins naming colors. • Can identify longer of two lines. • Has vocabulary of 1,500 words. • Uses mild profanities and name-calling. • Uses language aggressively. • Asks many questions. • May not be abstract enough to understand body parts that cannot be seen or felt. • Can be given simple explanation as to cause and effect. • Thinks very concretely; demonstrates irreversibility of thought.	***Play stimulation*** • Plays and interacts with other children. • Shows creativity. • Likes ring-around-the-rosy. • "Helps" adults. • Likes costumes and enjoys dramatic play. • Toys and games: record player, nursery rhymes, housekeeping toys, transportation toys (tricycle, trucks, cars, wagon), blocks, hammer and peg bench, floor trains, blackboard and chalk, easel and brushes, clay, crayon and finger paints, outside toys (sandbox, swing, small slide), books (short stories, action stories), drum, and scrapbook. ***Parental guidance*** • Base your expectations within child's limitations. • Provide limited frustrations from environment to assist in coping. • Give small tasks to do around the house (putting silverware on table, drying an unbreakable dish). • Expand child's world with trips to the zoo, to the supermarket, to restaurant, etc. • Prevent accidents.

3 to 4 Years (*Continued*)	***Cognitive development (Continued)*** • Immature concept of death—believes it is reversible. • Has beginning understanding of past and future. • Is egocentric in thought. ***Psychosocial development*** • Is more active with peers and engages in cooperative play. • Performs simple tasks. • Frequently has imaginary companion. • Dramatizes experiences. • Is proud of accomplishments. • Exaggerates, boasts, and tattles on others. • Can tolerate separation from mother longer without feeling anxiety. • Is keen observer. • Has good sense of "mine" and "yours." • Behavior still frequently ritualistic. • Becomes curious about life and sex. Often masurbates.	***Parental guidance (Continued)*** • Provide for brief nonthreatening separation from parents and home. • Reinforce correct use of language. • Use opportunities for simple sexual education as child's needs arise. • Accept masturbation as a normal phenomenon to be discouraged in public. • Provide consistent discipline, motivated by love rather than anger. • Consider nursery school/preschool opportunities.

4 to 5 Years
• By 2 to 5 years, adds 9½ inches (25 cm) to height
• At age 4, legs comprise about 44% of body length.
 	
Child development theories
• Freudian:
  • 3 to 6 years—Phallic Stage
• Eriksonian:
  • 3 to 6 years—Sense of Initiative versus Guilt
• Piagetian:
  • 2 to 7 years—Preoperational Period; shows egocentrism and centering
	Motor development
	• Hops two or more times.
	• Dresses without supervision.
	• Has good motor control—climbs and jumps well.
	• Walks up stairs without grasping handrail.
	• Walks backward.
	• Washes self without wetting clothes.
	• Prints first name and other words.
	• Adds three or more details in drawings.
	• Draws a square.
	
	Cognitive development
	• Has 2,100-word vocabulary.
	• Talks constantly.
	• Uses adult speech forms.
	• Participates in conversations.
	• Asks for definitions.
	• Knows age and residence.
	• Identifies heavier of two objects.
	• Knows weeks as time units.
	• Names days of week.
	• Begins to understand kinship.
	• Knows primary colors.
	• Can count to 10.
	• Can copy a triangle.
	• Has a high degree of imagination.
	• Questioning is at a peak.
	• Begins to develop power of reasoning.
	
	Psychosocial development
	• May have an imaginary companion.
	• Has a sense of order (likes to finish what was started).
	• Is obedient and reliable.
	• Is protective toward younger children.
	• Begins to develop an elementary conscience with some influence in governing behavior.
	• Has increased self-confidence.
		Play stimulation
		• Demonstrates gross motor activity—likes to jump rope, skip, climb on jungle gym, etc.
		• Prefers group play and cooperates in projects.
		• Plays simple letter, number, form, and picture games.
		• Plays with cars and trucks.
		• Still likes being read to.
		• Continues to enjoy fantasy play.
		
		Parental guidance
		• Child may no longer require an afternoon nap
		• Prepare child for kindergarten.
		• Tell him or her stories.
		• Provide opportunities and reassurance for group play; have his or her friends visit for lunch and an afternoon of playing.
		• Prevent accidents.
		• Encourage child's participation in household activities.

4 to 5 Years (Continued)

Psychosocial development (Continued)

- Accepts responsibility for acts.
- Is less rebellious.
- Has dreams and nightmares.
- Is cooperative and sympathetic.
- Shows generosity with toys.
- Begins to question parents' thinking.
- Identifies strongly with parent of same sex.

Middle Childhood (5 to 9 Years)

- Growth rate is slow and steady.
- Gains an average of 7 pounds (3.2 kg) per year. Height increases approximately 2½ inch (6.3 cm) per year.
- Among children, there is considerable variation in height and weight.
- Appears taller and slimmer.
- Early lordosis disappears.
- Begins to lose baby teeth; permanent teeth appear at a rate of about 4 teeth per year from 7 to 14 years.
- Neuromuscular and skeletal development allows improved coordination.
- Eyes become fully developed; vision approaches 20/20.
- Handedness should be well developed.

Child development theories

- Freudian:
  - 5 to 9 years—Beginning of Latency Period
- Eriksonian:
  - 5 to 9 years—Industry versus Inferiority
- Piagetian:
  - 5 to 9 years—Enters Stage of Concrete Operations

Motor development

6 years

- Is active and impulsive.
- Balance improves.
- Uses hands as manipulative tools in cutting, pasting, and hammering.
- Can draw large letters or figures.

7 years

- Has lower activity level.
- Capable of fine hand movements; can print sentences.
- Nervous habits, such as nail biting, are common.
- Muscular skills, such as ball throwing, have improved.

8 years

- Moves with less restlessness.
- Has developed grace and balance, even in active sports.
- Has developed coordination of fine muscles, allowing child to write in script.

9 years

- Uses both hands independently.
- Has become skillful in manual activities because of improved eye–hand coordination.

Cognitive development

6 years

- Begins to learn to read. Defines objects in terms of use. Time sense is as much in past as present.
- Is interested in relationship between home and neighborhood; knows some streets.
- Uses sentences well; uses language to share others' experiences; may swear or use slang.
- Distinguishes morning from afternoon.

7 years

- More reflective and has deeper understanding of meanings.
- Interested in conclusions and logical endings. Begins to have scientific interests in cause and effect.
- More responsible in relation to time, more punctual. Sense of space is more realistic; child wants some space of own.
- Knows value of coins.
- Concept of death maturing—includes idea of irreversibility.

8 years

- Thinking is less animistic. Is aware of impersonal forces of nature. Begins to understand logical reasoning, conclusions, and implications.

Parental guidance

- Family atmosphere continues to have an impact on the child's emotional development and future response within the family.
- The child needs ongoing guidance in an open, inviting atmosphere. Limits should be set with conviction. Deal with only one incident at a time. When punishment is necessary, the child should not be humiliated. Child should know that it was the act that the adult found undesirable, not the child.
- Needs assistance in adjusting to new experiences and demands of school. Should be able to share experiences with family. Parents need to have communication with the teacher to work together for the health of the child.
- Convey love and caring in communication. The child understands language directed at feelings better than at intellect. Get down to eye level with the child.
- Focus attention on child's abilities and accomplishments rather than shortcomings and limitations.
- The child is sex-conscious and should be able to discuss questions at home rather than with friends. Requires simple, honest answers to questions.
- Common problems include teasing, quarreling, nail biting, enuresis, whining, poor manners, swearing, lying, cheating, and stealing. These are usually fleeting phases and should not be handled negatively. The causes for such behavior should be investigated and dealt with constructively.
- The child needs order and consistency to help in coping with doubts, fears, unacceptable impulses, and unfamiliar experiences.
- Encourage peer activities as well as home responsibilities and give recognition to child's accomplishments and unique talents.
- Television may stimulate learning in several spheres, but should be monitored.
- Accidents are a major cause of disability and death. Safety practices should be continued. (Refer to section on safety, page 1127.)

Middle Childhood (5 to 9 Years) (*Continued*)	***Cognitive development (Continued)*** • Less self-centered in thinking. Personal space is expanding; goes places on own. Aware of time; plans events of the day. Understands right from left. *9 years* • Intellectually energetic and curious. Realistic; reasonable in thinking. Able to plan in advance. Breaks complex activities into steps. • Focuses on detail. • Sense of space includes the entire earth. • Participates in family discussions. • Likes to have secrets. ***Psychosocial development*** *5 to 9 years* • Still requires parental support, but pulls away from overt signs of affection. • Peer groups provide companionship in widening circle of persons outside the home. Child learns more about self as he or she learns about others. • "Chum" stage occurs at about age 9 or 10. Child chooses a special friend of same sex and age in whom to confide. This is usually child's first love relationship outside of home, when someone becomes as important to him or her as oneself. • Play teaches the child new ideas and independence. Child progressively uses tools of competition, compromise, cooperation, and beginning collaboration. • Body image and self-concept are fluid because of rapid physical, emotional, and social changes. • Latency-stage sexual drive is controlled and repressed. Emphasis is on the development of skills and talent. ***Patterns of play*** *6 to 7 years* • Child acts out ideas of family and occupational groups with which he or she has contact. • Painting, pasting, reading, simple games, watching television, digging, running games, skating, riding bicycle, and swimming are all enjoyed activities. *8 years* • Child enjoys collections; loosely formed, short-lived clubs, table games, card games, books, television, and music.	***Parental guidance (Continued)*** • Exercise is essential to promote motor and psychosocial development. The child should have a safe place to play and simple pieces of equipment. • A school health program should be available and concerned with the child's physical, emotional, mental, and social health. This should be augmented by information and example at home. • Medical supervision should continue with yearly examination to detect developmental delay and disease. Appropriate immunizations should be administered. • The child frequently has "quiet days"—periods of shyness, which should be tolerated as part of growing up and deciding who he or she is. • The child may be subject to nightmares, a situation that requires reassurance and understanding. • Parents, teachers, and health professionals should be available and able to provide information and answer questions about the physical changes that occur.
Late Childhood (9 to 12 Years) • Vital signs approach adult values. • Loses childish appearance of face and takes on features that will characterize individual as an adult.	***Motor development*** • Energetic, restless, active movements such as finger drumming or foot tapping appear. • Has skillful manipulative movements nearly equal to those of adults. • Works hard to perfect physical skills.	***Parental guidance*** • Continue appropriate interventions related to early childhood. • Continue sex education and preparation for adolescent body changes. • Understanding is important.

Late Childhood (9 to 12 Years) (*Continued*)

- Growth spurt occurs and some secondary sex characteristics appear: in girls, between ages 10 and 12 years, and in boys, between ages 12 and 14 years.

Physical changes of puberty

- Increased height and weight, increased perspiration and activity of sebaceous glands; vasomotor instability; increased fat deposition.

Physical changes in girls

- The pelvis increases in transverse diameter; hips broaden; tenderness in developing breast tissue; enlargement of areola diameter; appearance of pubic hair.

Physical changes in boys

- Size of testes increases; scrotum color changes; breasts enlarge, temporarily; height and shoulder breadth increase.
- Appearance of lightly pigmented hair at the base of the penis.
- Increase in length and width of the penis.

Child development theories

- Freudian:
  - 9 to 12 years—Latency Period continues.
- Eriksonian:
  - 9 to 12 years—Industry versus. Inferiority continues.
- Piagetian:
  - 9 to 12 years—Stage of Concrete Operations continues.

Cognitive development

10 years

- Likes to reason and enjoys learning.
- Thinking is concrete and matter of fact.
- Wants to measure up to challenge.
- Likes to memorize and identify facts.
- Attention span may be short. Space is rather specific (ie, where things are).
- Can write for relatively long time with speed.
- Likes action in learning.
- Concentrates well when working competitively.
- Can understand relational terms, such as weight and size.
- Perceives space as nothingness that goes on forever.
- Can discuss problems.
- Can conceptualize symbolically enough to understand body parts.
- Can describe some abstract terms.

12 years

- Enjoys learning.
- Considers all aspects of a situation.
- Motivated more by inner drive than by competition.
- Able to classify, arrange, and generalize.
- Likes to discuss and debate.
- Begins conceptual thinking.
- Verbal, formal reasoning now possible.
- Can recognize moral of a story.
- Defines time as duration; likes to plan ahead.
- Understands that space is abstract.
- Can be critical of own work.

Psychosocial development

- Gang becomes important and gang code takes precedence over nearly everything. Gang codes are typically characterized by collective action against the mores of the adult world. Here, children begin to work out their own social patterns without adult interference. Early gangs may include both sexes; later gangs are separated by sex.
- May strive for unreasonable independence from adult control.
- Usually interested in religion and morality.
- Has increased interest in sexuality.
- May reach puberty; resurgence of sexual drives causes recapitulation of Oedipal struggle.

Patterns of play

- Continues to enjoy reading, TV, and table games.
- More interested in active sports as a means to improve skills.
- Creative talents may appear; may enjoy drawing and modeling clay. By age 10, gender differences in preferred play activities may be more pronounced.
- Occasional privacy is important.
- Begins to have vocational aspirations, may be seemingly unrealistic and frequently changing.

Parental guidance (Continued)

- Encourage participation in organized clubs and youth groups.
- Democratic guidance is essential as child works through a conflict between dependence (on parents) and independence. The child needs realistic limits set.
- Needs help channeling energy in proper direction—work and sports
- Requires adequate explanation of body changes prior to changes appearing. Special understanding is required for the child who lags in physical development compared to peers or to those who develop significantly earlier than peers.
- Continue consistent disciplinary style.

Early Adolescence (12 to 14 Years)

- Phase of development begins when reproductive organs become functionally operative; the phase ends when physical growth is completed.
- Skeletal system grows faster than supporting muscles.
- Hands and feet grow proportionately faster than the rest of the body.
- Large muscles develop more quickly than small muscles.

Girls

- Physical changes include beginning of menarche, growth of axillary and perineal hair, deepened voice, ovulation, and further development of breasts.
- Nutritional need for iron and calcium increases dramatically.

Boys

- Physical changes include growth of axillary, perineal, facial, chest hair, deepening of voice, production of spermatozoa, and nocturnal emissions.

Child development theories

- Freudian:
  - 12 to 14 years—Begins Stage of Sexuality
- Eriksonian:
  - 12 to 14 years—Identity versus Role Diffusion.
- Piagetian:
  - 12 to 14 years—Begins Stage of Formal Operations

Motor development

- Usually uncoordinated; has poor posture.
- Tires easily.

Cognitive development

- Mind has great ability to acquire and use knowledge.
- Abstract thinking is sufficient to learn multivariable ideas such as the influence of hormones on emotions.
- Categorizes thoughts into usable forms.
- May project thinking into the future.
- Is capable of highly imaginative thinking.

Psychosocial development

- Interest in opposite sex increases.
- Often revolts from adult authority to conform to peer–group standards.
- Continues to rework feelings for parent of opposite sex and unravel the ambivalence toward parent of same sex.
- Affection may turn temporarily to an adult outside of the family (eg, crush on family friend, neighbor, or teacher).
- Uses peer–group dialect—highly informal language or specially coined terminology.
- Peer groups are especially important and help adolescent to define own identity, to adapt to changing body image, to establish more mature relationships with others, and to deal with heightened sexual feelings. Cliques may develop.
- Dating generally progresses from groups of couples to double dates and finally single couples.
- Teenage "hangouts" become important centers of activity.
- Begins questioning existing moral values

Parental guidance

- Stresses frequently result from conflicting value systems between generations. The parents may need help to see that the adolescent is a product of the times and that actions reflect what is happening around the adolescent.
- The parents' limits and rules should be realistic and consistent. They should convey the parent's love and concern and should be a source of comfort and reassurance, protecting the child from activities for which he or she is not ready.
- The home should be an accepting, emotionally stable environment.
- Continue sex education, including discussion of ovulation, fertilization, menstruation, pregnancy, contraception, masturbation, nocturnal emissions, and hygiene.
- Adolescents have an increased need for rest and sleep because they are expending large amounts of energy and are functioning with an inadequate oxygen supply.
- Recreational interests should be fostered. Favorite activities include sports, dating, dancing, reading, hobbies, and social media. Socializing via telephone or computer and listening to music are favorite pastimes.
- Adolescent health problems that require preventive education are accidents, obesity, acne, pregnancy, sexually transmitted disease, and drug abuse.
- Allow the adolescent to handle his or her own affairs as much as possible, but be aware of physical and psychosocial problems that may require help. Encourage independence but allow child to seek support and guidance from parents or trusted adults when frightened or unable to attain goals.
- Adolescents with special problems should have access to specialists, such as adolescent clinics and psychologists.
- Requires reassurance and help in accepting a changing body image. Parents should make the most of the child's positive qualities.
- Give gentle encouragement and guidance regarding dating. Avoid strong pressures in either direction.
- Understand conflicts as the child attempts to deal with social, moral, and intellectual issues.

Developmental Screening

Assessment tools have been created to determine the overall developmental age of a child or to detect specific areas of development that are lacking. The most widely used developmental screening tool is the Denver II Developmental Screening Test (Denver II). This tool provides for a quick overview of development in children from birth to age 6 years and identifies areas of strength and weakness relative to age norms. Denver II test forms, and an instruction manual can be obtained from *www.denverii.com*. This test has been criticized for a lack of sensitivity in detecting children with more subtle developmental delays. The American Academy of Pediatrics recommends that developmental surveillance be conducted at all well-child exams and screening tests administered at the 9-, 18-, and 30-month visits; however, they do not recommend a specific test.

Another method for developmental screening involves interviewing the parent or caregiver about attainment of developmental milestones. Persistent deficits or deficits in multiple areas indicate a more serious problem than deficits in a single area (Table 40-2, pages 1092 and 1093).

Table 40-2 Developmental Milestones

AGE	GROSS MOTOR	VISUAL–MOTOR/ PROBLEM SOLVING	LANGUAGE	SOCIAL/ADAPTIVE
1 month	Raises head slightly from prone, makes crawling movements	*Birth:* visually fixes *1 month*: has tight grasp, follows to midline	Alerts to sound	Regards face
2 months	Holds head in midline, lifts chest off table	No longer clenches fist tightly, follows object past midline	Smiles socially (after being stroked or talked to)	Recognizes parent
3 months	Supports on forearms in prone, holds head up steadily	Holds hands open at rest, follows in circular fashion, responds to visual threat	Coos (produces long vowel sounds in musical fashion)	Reaches for familiar people or objects, anticipates feeding
4 months	Rolls front to back, supports on wrists, and shifts weight	Reaches with arms in unison, brings hands to midline	Laughs, orients to voice	Enjoys looking around environment
5 months	Rolls back to front, sits supported	Transfers objects	Says "ah-goo," blows raspberries, orients to bell (localizes laterally)	—
6 months	Sits unsupported, puts feet in the mouth in supine position	Unilateral reach, uses raking grasp	Babbles	Recognizes strangers
7 months	Creeps	—	Orients to bell (localized indirectly)	—
8 months	Comes to sit, crawls	Inspects objects	"Dada" indiscriminately	Finger-feeds
9 months	Pivots when sitting, pulls to stand, cruises	Uses pincer grasp, probes with forefinger, holds bottle, throws objects	"Mama" indiscriminately, gestures, waves bye-bye, inhibits to "no"	Starts to explore environment; plays gesture games (eg, pat-a-cake)
10 months	Walks when led with both hands held	—	"Dada/mama" discriminately; orients to bell (directly)	—
11 months	Walks when led with one hand held	—	One word other than "dada/mama," follows one-step command with gesture	—
12 months	Walks alone	Uses mature pincer grasp, releases voluntarily, marks paper with pencil	Uses two words other than "dada/mama," immature jargoning (runs several unintelligible syllables together)	Imitates actions, comes when called, cooperates with dressing
13 months	—	—	Uses three words	—
14 months	—	—	Follows one-step command without gesture	—
15 months	Creeps up stairs, walks backward	Scribbles in imitation, builds tower of two blocks in imitation	Uses four to six words	*15 to 18 months:* uses spoon, uses cup independently
17 months	—	—	Uses 7 to 20 words, points to five body parts, uses mature jargoning (includes intelligible words in jargoning)	—

18 months	Runs, throws objects from standing without falling	Scribbles spontaneously, builds tower of three blocks, turns two to three pages at a time	Uses two-word combinations	Copies parent in tasks (sweeping, dusting), plays in company of other children
19 months	—	—	Knows 8 body parts	—
21 months	Squats in play, goes up steps	Builds tower of five blocks	Uses 50 words, two-word sentences	Asks to have food and to go to toilet
24 months	Walks up and down steps without help	Imitates stroke with pencil, builds tower of seven blocks, turns pages one at a time, removes shoes, pants, etc.	Uses pronouns (*I, you, me*) inappropriately, follows two-step commands	Parallel play
30 months	Jumps with both feet off the floor, throws ball overhand	Holds pencil in adult fashion, performs horizontal and vertical strokes, unbuttons	Uses pronouns appropriately, understands concept of "1," repeats two digits forward	Tells first and last names when asked; gets self drink without help
3 years	Can alternate feet when going up steps, pedals tricycle	Copies a circle, undresses completely, dresses partially, dries hands if reminded	Uses minimum 250 words, three-word sentences; uses plurals, past tense; knows all pronouns; understands concept of "2"	Group play, shares toys, takes turns, plays well with others, knows full name, age, sex
4 years	Hops, skips, alternates feet going down steps	Copies a square, buttons clothing, dresses self completely, catches ball	Knows colors, says song or poem from memory, asks questions	Tells "tall tales," plays cooperatively with a group of children
5 years	Skips alternating feet, jumps over low obstacles	Copies triangle, ties shoes, spreads with knife	Prints first name, asks what a word means	Plays competitive games, abides by rules, likes to help in household tasks

Pediatric Physical Assessment

History

Obtaining a History

Physical Examination

General Principles

Approach to the Patient

HISTORY

Obtaining a History

A history of the child is obtained to establish a relationship with the child and family, to assess family understanding about the child's health, to formulate an individual care plan, and to correct misinformation the family may have.

Focus on specific topics in the history, depending on the child's age, including:

- Infant—prenatal and postnatal history, nutrition, development.
- Toddler—home environment, safety issues, development, parent's response.
- School age—school, friends, reaction to previous hospitalizations.
- Adolescent—alcohol, drugs, friends, sexual history, relationships with parents, identity.

Identifying Information

Type of Information Needed

1. Date and time.
2. Health care provider's name and telephone number, if known.
3. Insurance data.
4. Patient's name, address, telephone number, birth date.
5. Referring health care source (eg, school, other health care provider, clinic).

Note: Permission from the legal guardian must be obtained to treat a child unless it is an emergency.

Method of Collecting Data

1. Identify the care person in charge of the patient by name and relationship to the patient; obtain a relative's or caregiver's address and home, cell and work telephone numbers, if different from those of the parent.
2. To make the informant feel more at ease, the questions should begin in a friendly, nonthreatening manner. Questions addressed to the parent should be phrased appropriately.
3. Casual, friendly responses or remarks on the part of the interviewer may also help break the ice, such as:
   a. "Whoever takes care of this baby certainly does a good job."
   b. "That is a lovely outfit the baby is wearing." (Remember that families will usually put good clothes on a baby for a visit to a health care agency.)
4. Sometimes, repeat the information to verify data. This will give you a better judgment of the care person's cooperation and reliability.
5. If age appropriate, get some data directly from the child.

Chief Complaint

Method of Recording

1. Record who arrived with child and write an exact description of the complaint.

2. Use quotation marks to clearly indicate that the informant's words are being used. It is helpful to explain:
    a. "I will write it down so there will be no mistake."
    b. "Let me read this back to you to make sure it is correct."
3. Quotation of the care person's exact words may give an indication of how he feels about the symptoms; it may reflect fear, guilt, and defensiveness.

Method of Collecting Information

1. Begin with a helpful, open-ended question. That is the first overture made to this patient:
    a. "How have things been going?"
    b. "Please tell me the reason for your coming here today."
    c. "Do you have any particular worries or concerns about the baby?"
2. Then, proceed to more specific questions.

Duration of Complaint

1. The information obtained may indicate the natural history of the disease, if one is present, and its gradual evolution. Pursue the information with a series of probing questions.
    a. "How long has the baby (child) had this problem?"
    b. If the informant cannot remember, try another route: "When did the child last act well? Before summer vacation? Last Christmas? Did the baby have the trouble then?"
2. Write down the responses; try to assess, as more questions are asked, how accurate the informant's answers may be. Remember, a child that is a reliable historian, may be the most accurate source of information regarding their health history, treatments, and other health needs.

History of Present Illness

Type of Information Needed

For an infant, a preverbal, or nonverbal child, information will consist mainly of what the informant has been able to observe. Having established what the chief complaint is, identify further problems, if any. Obtain the following information for each problem:

1. Body location—of pain, itching, weakness.
2. Quality and quantity of complaint—both type (a burning pain) and severity (knifelike, comes and goes).
3. Degree of symptom—(eg, pain, how severe; cough, day and night; eye drainage, amount).
4. Chronology—indicate time sequence and whether the problem is episodic (lasts for a while and then clears up completely).
5. Environment or setting—where and when the symptoms occur.
6. Aggravating and alleviating factors—what makes the pain worse or better.
7. Associated manifestations or symptoms—accompanied by vomiting, blurred vision.

Importance of Detail

1. Typically, a carefully written description of a symptom will be the source of a future diagnosis and will serve all who are involved in helping the patient.
2. Do not worry about how many notes you have to take at first.
3. You will be able to recheck this information when you do the review of systems.

Family History

1. Family members—parents' age and state of health, siblings-who is at home with you?
2. Family health history:
    a. Eyes, ears, nose, throat—nosebleeds, sinus problems, glaucoma, cataracts, myopia, strabismus, other problems of eyes, ears, nose, throat.
    b. Cardiorespiratory—tuberculosis, asthma, hay fever, hypertension, heart murmurs, heart attacks, strokes, rheumatic fever, pneumonia, emphysema, other problems.
    c. Gastrointestinal—ulcers, colitis, vomiting, diarrhea, other problems.
    d. Genitourinary—kidney infections, bladder problems, congenital abnormalities.
    e. Musculoskeletal—congenital hip or foot problems, muscular dystrophy, arthritis, other problems.
    f. Neurologic—seizures, epilepsy, nervous disorder, mental retardation, emotional problems, comas, headaches, others.
    g. Chronic disease—diabetes, liver disease, cancer, tumors, anemia, thyroid problems, congenital disorder.
    h. Special senses—anyone deaf or blind.
    i. Miscellaneous—other medical problem not mentioned.
3. Family social history:
    a. Residence—apartment or house and size. Yard, stairs, proximity to transportation, shopping, playground, school, safe neighborhood? City or well water?
    b. Financial situation—who works, where employed, occupation, welfare, food stamps.
    c. Primary care person—babysitters, day care center.
    d. Family interrelationships—happy, cooperative, antagonistic, chaotic, multiproblem, violent.

Past History

Prenatal

1. Pregnancy—planned or not; source of care; approximate date of seeking care; birth order of this pregnancy, including miscarriages. This area of the history may be one of great sensitivity. Try to make the questions gentle and supportive:
    a. "Did you plan a baby around this time?"
    b. "When was your first checkup for the pregnancy?"
    c. "Were there any unusual problems related to your pregnancy or delivery?"
2. Maternal health—includes illnesses and dates, abnormal symptoms (eg, fever, rash, vaginal bleeding,

edema, hypertension, urine abnormalities, sexually transmitted disease). Avoid technical words, if possible.

   a. "Were the doctors or nurses worried about your health?"
   b. "Were your rings or shoes tight?"
   c. "Do you know if your blood pressure went up?"
   d. "Did you have trouble with your urine?"

3. Weight gain—validate by trying to get a figure for nonpregnant weight and weight at delivery.
4. Medications taken—for example, vitamins, iron, calcium, aspirin, cold preparations, tranquilizers ("nerve medicine"), antibiotics; use of ointments, hormones, injections during pregnancy; special or unusual diet; radiation exposure; sonography; and amniocentesis.
5. Quality of the fetal movements—when felt?
6. Use of alcohol, tobacco, or drugs during pregnancy.

Natal

1. Expected date of delivery and approximate duration of pregnancy.
2. Place of delivery and name of person who conducted the delivery.
3. Labor—spontaneous or induced, duration, and intensity.
4. Analgesia or anesthesia.
5. Type of delivery—vaginal (breech or vertex presentation); cesarean delivery; forceps delivery.
6. Complications (eg, need for blood transfusion or delay in delivery).

Neonatal

1. Condition of infant.
2. Color (if seen) at delivery.
3. Activity of infant.
4. Type of crying heard.
5. Breathing abnormality.
6. Birth weight and length.
7. Problems that occurred immediately at birth.

Postnatal

1. Duration of hospitalization of the mother and infant.
2. Problems with baby's breathing or feeding.
3. Need of supportive care (eg, oxygen, incubator, special care nursery, isolation, medications).
4. Weight changes, weight at discharge, if known.
5. Color—cyanosis or jaundice.
6. Bowel movements—when.
7. Problems—seizures, deformities identified, consultation required.

8. Hearing—was a hearing screen conducted in the nursery? The United States Preventative Services Task Force recommends universal screening for all newborns using otoacoustic emissions and/or auditory brain stem response testing. The guideline is available online at *www.guideline.gov/summaries/summary/47317/preventive-services-for-children-and-adolescents?q=newborns+otoacoustic*.
9. Mother's contact with the baby and her first impression:
    a. "What was it like when you first saw your baby?"
    b. "What did the baby do when you were first together?"

Nutrition

1. Breast- or bottle-fed? What formula? How prepared?
2. Amounts offered and consumed.
3. Frequency of feeding—weight gain.
4. Addition of juice or solid foods.
5. Food preferences or allergies.
6. Feeding problems—variations in appetite.
7. Age of weaning.
8. Vitamins—type, amount, regularity.
9. Pattern of weight gain.
10. Current diet—frequency and content of meals.

Growth and Development

1. Past weights and lengths, if available.
2. Milestones—sat alone unsupported; walked alone; used words, then sentences.
3. Teeth—eruption, difficulty, cavities, brushing, flossing.
4. Toilet training.
5. Current motor, social, and language skills.
6. Sexual development.
    a. Infant—swollen breast tissue, vaginal discharge, hypertrophy of the labia.
    b. Toddler or school-age child—early development of breasts or pubic hair.
    c. Prepubertal or pubertal child—in girls, time of development of breasts and pubic hair and onset of menstruation. In boys, time of enlargement of testes and penis, development of pubic and facial hair, and voice changes.

Health Maintenance

1. Immunizations—rubella, rubeola, mumps, polio, diphtheria, pertussis, tetanus toxoid, varicella, pneumococcal, bacille Calmette-Guérin, influenza, *Haemophilus influenzae* type b, hepatitis A and B, meningococcal conjugate, human papillomavirus, and rotavirus. Indicate number and dates.

Recommended immunization schedules are available online at *www.cdc.gov/vaccines/recs/schedules/*.

2. Screening procedures—hematocrit or hemoglobin level, urinalysis, tuberculin testing, visual and auditory acuity, color vision, lead testing, cholesterol screening, syphilis testing, HIV testing, gonorrhea and Chlamydia screening.
3. Dental care—source and frequency of care, dental hygienist visits, fillings, extractions, last checkup.

Acute Infectious Diseases

Rubella, rubeola, mumps, chickenpox, group A beta-hemolytic pharyngitis, parvovirus B19 (fifth disease), hepatitis, infectious mononucleosis, sexually transmitted disease, tuberculosis, influenza. Recent exposure to a communicable disease.

Hospitalizations and Surgeries

1. Dates, hospital, health care provider.
2. Indications, diagnosis, procedures.
3. Complications.
4. Reactions to previous hospitalizations.

Injuries

1. Emergency department or urgent care visits-frequency and diagnosis.
2. Fractures, injuries, burns—location and treatment.
3. Ingestions.
4. Ask
5. the parents about provision of a safe environment; for example, cleaning supplies out of reach, electrical outlets with appropriate covers, guns in the house unloaded and kept in a locked room or cabinet, water safety education (bathtub and pools). Ask about use of safety equipment, such as seat belts, bike helmets, childproof safety caps on medications, smoke and carbon monoxide detectors in home.

Medications

1. For general use, such as vitamins, antihistamines, laxatives.
2. Special or fad diets.
3. Recent antibiotics.
4. Herbal or complementary remedies.
5. Routine use of aspirin.
6. Hormonal contraceptives—types, dose, duration.
7. Drugs, opioids, marijuana, hallucinogens, mood elevators, tranquilizers, alcohol.
8. Determine when last dose of medication was taken; is the medication with the patient? How does the child take the medication?
9. Allergy or adverse reaction to medication?

School History

Type of Information Needed

1. Present and past schooling, attendance, grade, and performance.
2. Favored and least-favored subjects.
3. School-related behavior—anxious to go, anxious to stay home.
4. General attitude toward school and career plans.
5. General attitude toward peer groups, attempt to avoid or be included.

Method of Collecting Data

1. Straightforward questions to a child (eg, "What grade are you in?" "Who are your friends?").
2. Three wishes offered to the child:
   a. "If your birthday were here, what would you ask for?"
   b. "If you could be anyone, who would it be?"
   c. "What would be the best thing that could happen to you?"
3. "Do you have friends?," "Who is your best friend?"
4. Questions to parents: "Do you know the friends your child identified?
5. Adolescents—Interviews with older children and teens may start with the parents present, but the child should also be provided with some private time away from the parents to discuss concerns. The parents should also be allowed a brief time away from their child to voice any concerns.
6. Emphasize the positive (eg, "What is your best subject?").

Social History

Type of Information Needed

1. Environment—rural, urban.
2. Housing—type, location, heating, sewage, water supply, family pets, other animal exposure.
3. Parents' occupations (employment) and marital status.
4. Number of individuals living in home, sleeping arrangements.
5. Religious affiliations.
6. Previous utilization of social agencies.
7. Health insurance and usual source of care.
8. After assuring older children of the confidentiality of their answers, inquire about risk-taking behaviors, such as cigarette smoking, alcohol and drug use, drinking and driving, and sexual history.

Method of Collecting Data

Parents are proud, so use tact and diplomacy when asking some questions. Ask permission.

1. "Can you tell me a little bit about your home?"

2. "I need to know more about how you live to help you with your child's problem."

Personal History

Type of Information Needed

1. Hygiene.
2. Exercise.
3. Sleep habits.
4. Elimination habits.
5. Activities, hobbies, special talents.
6. Friends, teacher relationships.
7. Sibling and parent relationships.
8. Expression of emotions.
    a. Blows up easily.
    b. Quiet.
9. Idiosyncratic behavior and habits (eg, thumb-sucking, nail-biting, temper tantrums, head banging, pica, breath-holding, rituals, tics).
10. Emotional issues, such as school avoidance, somatic complaints.

Review of Systems

Type of Information Needed

1. General—activity, appetite, affect, sleep patterns, weight changes, edema, fever, behavior.
2. Allergy—eczema, hay fever, asthma, hives, food or drug allergy, sinus disorders.
3. Skin—rash or eruption, nodules, pigmentation or texture change, sweating or dryness, infection, hair growth, itching.
4. Head—headache, head trauma, dizziness.
5. Eyes—visual acuity, corrective lenses, strabismus, lacrimation, discharge, itching, redness, photophobia.
6. Ears—auditory acuity, earaches (frequency, ages, response to specific medications), infection, drainage.
7. Nose—colds and runny nose (frequency), infection, drainage.
8. Teeth—hygiene practices, frequency of brushing, general condition, cavities, malocclusions.
9. Throat—sore throat, tonsillitis, difficulty swallowing.
10. Speech—peculiarity of or change in voice, hoarseness, clarity, enunciation, stuttering, development of articulation, vocabulary, use of sentences.
11. Respiratory—difficulty breathing, shortness of breath, chest pain, cough, wheezing, croup, pneumonia, tuberculosis or exposure.
12. Cardiovascular—cyanosis, fainting, exercise intolerance, palpitations, murmurs.
13. Hematologic—pallor, anemia, tendency to bruise or bleed.

14. Gastrointestinal—appetite (amount, frequency, cravings), nausea, vomiting, abdominal pain, abnormal size, bowel habits and nature of stools, parasites, encopresis (incontinence of feces), colic.
15. Genitourinary—age of toilet training, frequency of urination, straining, dysuria, hematuria (or unusual color or odor of infant's soiled diaper), previous urinary tract infection, enuresis (age of onset; day or nighttime), urethral or vaginal discharge. Girls and young women: age at menarche, last menses, cramps, changes in interval and duration.
16. Musculoskeletal—deformities, fractures, sprains, joint pains or swelling, limited motion, abnormality of nails.
17. Neurologic—weakness or clumsiness, coordination, balance, gait, dominance, fatigability, tone, tremor, seizures or paroxysmal behavior, personality changes.

PHYSICAL EXAMINATION

General Principles

1. Establish the order of all data collection according to the needs of the patient. For example:
   a. An exhausted parent with a screaming baby will not give a careful, comprehensive history.
   b. Alternative care may not be available for preschoolers when the neonate comes in for his or her first checkup.
2. If the parent has come in with more than one child, try to organize some supervision of the other children so that you can have a little time alone with the parent.
3. Remember that the safest place for a young child is on the parent's lap. Privacy may not be possible when other children are present.
4. Attempt to develop rapport with the young patient from the moment you first see or meet him or her.
5. Explain to the school-age child or teenager what you are looking for as you proceed with the examination and provide feedback.

APPROACH TO THE PATIENT

1. Offer the young child a choice of being examined on the parent's lap or on your "special table."
2. Start with examination of the lungs and heart. You will need to listen to at least 10 heartbeats. Consider the use of a pacifier for a screaming infant.
3. The part to be examined should be completely exposed, but if an apprehensive child objects to having clothes removed, slip your stethoscope under the shirt.
4. After listening to the heart, begin with parts of the body that are already exposed.
5. Start with either the head or the toes and work thoroughly and systematically toward the other end.
6. Gradually remove the child's clothes (may best be done by usual caregiver); look for asymmetry very carefully in the bodies of all children.
7. Develop a pattern appropriate to the patient's age.
   a. With infants, it may be wise to leave the diaper area until last.
   b. Adolescents and school-age children are usually embarrassed at the genital examination—you may want to leave this until last, covering areas already examined.
8. Using a cold stethoscope may result in a frightened and screaming child, so warm and clean the stethoscope before bringing it into contact with the child.
9. Some children are less frightened if allowed to hold the examination equipment first.
10. Show the child the procedure by demonstrating on the parent first.
11. Many young children enjoy listening to their own hearts.
12. Toddlers and preschoolers enjoy blowing your otoscope light out.

Pediatric Physical Assessment

Technique	Findings
VITAL SIGNS 1. Obtain temperature, pulse rate, respiratory rate, and blood pressure as often as necessary, based on the child's condition. 2. Measure core temperature, whenever possible, via rectal or ear route. A mercury thermometer must remain in place 3 to 5 minutes. Alternately, use an electronic thermometer. Avoid taking temperature via oral route following fluid or food intake. 3. Obtain apical pulse rate on an infant or small child; radial, temporal, or carotid pulse may be measured on an older child. Pulse may be counted for 30 seconds and multiplied by 2. 4. Count respirations on an infant for 1 full minute; observe the chest as well as the abdomen. Respirations may be counted for 30 seconds and multiplied by 2 in an older child. 5. Obtain blood pressure by auscultatory method, rather than palpation method, whenever possible. Make sure the cuff covers no less than ½ and no more than 2/3 the length of the upper arm or leg.	**Temperature** *Oral* 97.6°F–99.3°F (36.4°C–37.4°C) *Rectal* 97°F–100°F (36.1°C–37.8°C) *Axillary* 96.6°F–98°F (35.9°C–36.7°C) **Pulse and respiratory rates** Neonate: Pulse 70–170; Respirations 30–50 11 months: Pulse 80–160; Respirations 26–40 2 years: Pulse 80–130; Respirations 20–30 4 years: Pulse 80–120; Respirations 20–30 6 years: Pulse 75–115; Respirations 20–26 8 years: Pulse 70–110; Respirations 18–24 10 years: Pulse 70–110; Respirations 18–24 Adolescent: Pulse 60–110; Respirations 12–20 **Blood pressure** Varies with age, height, and weight of child.

STANDING HEIGHT, HEAD CIRCUMFERENCE, AND CHEST CIRCUMFERENCE

1. Use a tape measure to obtain accurate head circumference. Measure the widest part of head.

2. Measure the chest at the level of the nipples.
3. Record height and weight at each visit. Plot on growth chart.
4. Calculate body mass index (BMI) and plot on appropriate chart.

3. A variety of clinical growth charts on which to record length, head, circumference, BMI, and weight can be downloaded from *https://www.cdc.gov/growthcharts/index.htm*. Trends in growth are as important as the basic measurements.
4. BMI is calculated by following the formula on page 566, or for online pediatric BMI calculator, *https://nccd.cdc.gov/dnpabmi/calculator.aspx*.

GENERAL APPEARANCE

1. Begin your observations with the first contact with the patient, taking into account that there are at least two people to observe (child and parent).
2. The patient's interaction with the caretaker, whether it be the mother, father, a babysitter, an older sibling, or a friend of the family, is vital in the assessment of the child. As you observe for race, sex, general physical development, nutritional state, mental alertness, evidence of pain, restlessness, body position, clothes, apparent age, hygiene, and grooming, remember that many of these things are a measure of the parent's caretaking.

1. If the child is easily distracted or sleepy, it may be nap time.
2. Careful observation of the general state of the child will provide many clues about the child's relationship with the family and its response to the child.

SKIN AND LYMPHATICS

Inspection of the skin is the same as for the adult.

1. Observe for skin color, pigmentation, lesions, jaundice, cyanosis, scars, superficial vascularity, moisture, edema, color of mucous membranes, hair distribution.	1. In young infants, the skin is soft, smooth, and velvety in texture.
2. Describe any variation in color, particularly in children with increased pigmentation. No pigment, or vitiligo, in darker children can be noted.	2. Pigmentations vary in children, depending on race, and will change as the child gets older.
3. Birthmarks of any type are recorded. (May change as child grows older.)	3. A suntan, freckles, and small, light-brown patches or café au lait spots may occur.
4. Bruises or unusual marks, wounds or insect bites, scratch marks, or scars may have particular significance.	4. Bruises are particularly important because of the possibility of reoccurring injury and/or child abuse.
5. Draw a picture of anything unusual such as a scar and measure the dimensions of the lesion when recording the findings.	5. If you have difficulty describing something, use ordinary words rather than inaccurate technical terms.
6. To ascertain suspected jaundice, take the child to the window to get a true picture of the color of the skin. (A room with yellow walls and artificial lighting may create a wrong impression when jaundice is suspected.)	6. Carotenemia, which causes the nose and palms to have a yellowish tinge, may lead the parents to suspect jaundice; however, carotenemia is caused by eating a large amount of yellow vegetables (sweet potatoes, squash, carrots). In carotenemia, the sclerae are clear; this is not the case in jaundice.
7. The skin of neonates will still be covered with vernix caseosa, the oily material that covers the fetus's body while in utero.	7. Swollen sebaceous glands over the nose and chin are commonly seen immediately after birth and are called *milia*.
8. Postmature infants may have scaliness or peeling that persists for several weeks after birth, particularly around the feet. The color of the skin may change as the child gets a little older.	8. The blotchy, pink patches over the eyelid, bridge of the nose, and the back of the neck may persist until the child is almost 2 years of age.
9. Note striae.	9. May indicate rapid weight gain or loss.
10. Dark-skinned children may have Mongolian spots at the base of spine or elsewhere.	10. Important to distinguish from child abuse.

Palpation

1. Use the tips of your fingers to palpate—fingertips are more sensitive.
2. Check the tension of the skin by pinching up a fold of skin—normal skin quickly falls back, but dehydrated skin remains in pinched position.

3. Feel the skin for texture, moisture, temperature, turgor, elasticity, masses, tenderness.
3. Skin that is rough and dry in texture may actually have a discrete rash that can be felt but not seen.

Lymph

1. Observe and palpate for lymph node enlargement in lymph chain areas.
   a. Neck.
   b. Axilla.
   c. Inguinal.
   d. Epitrochlear.
1. May be large or readily palpable, but should be non-tender, mobile, and slightly spongy.
2. Note tenderness, size, and consistency.

Nails

1. Observe for color, shape, irregularities in surface, and general nail care; cleanliness, evidence of biting.
1. Nail beds should be pink, nails convex.
2. Palpate the skin around the fingernails for firmness. Palpate any part that appears inflamed.
2. General care of the child is frequently reflected in good care of nails.

Hair

1. Observe for color and distribution.
   a. Note according to the age of the child and race.
   b. Be aware that tufts of hair over the spine or sacral area may mark an underlying abnormality.
1. *Neonate*: Normally varies from no hair to a thick bush. Infant: lanugo, a soft, downy covering commonly seen over the shoulders, back, arms, face, and sacral area, especially in dark-skinned children; lanugo is present for the first 1 to 2 months, after which it disappears.
2. Note changes in pigmentation.
2. Remember, children may experiment with hair dye or rinse.
3. Palpate the hair for texture and thickness.
3. Texture may be thick or thin, coarse or fine, straight or curly.
4. Examine to see if there are patches on the head where hair is missing.
4. May denote underlying skin infection; however, some children pull their hair out; sometimes, the hair is braided so tightly that it falls out. Infants who sleep consistently on their backs may have thinning or absent hair in the occiput.
5. Separate thick hair on the head to get a good view of the scalp. Check for dandruff or scaliness in older children.
5. Look carefully for broken hairs, for scaliness on the scalp, or cradle cap in infants.
6. Check scalp for signs of lice infestation.
6. Nits (louse eggs) appear on the hair as little white dots. Lice may be seen on the scalp; they move quickly and may jump.
7. Inspect in the axillae and over the pubis and the extremities for hair and its quantity, to gauge the development and level of puberty.
7. The child does not need to be totally undressed at one time, a prepubertal child will usually be embarrassed if all clothes are removed.

HEAD AND NECK

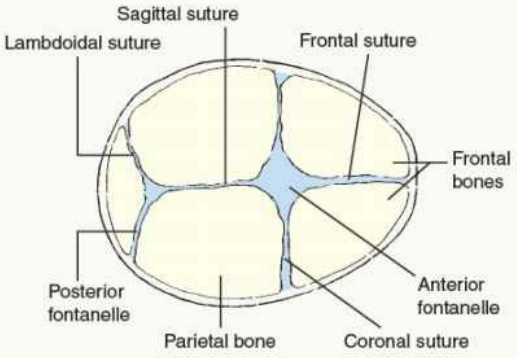
1. Unless specifically requested, examine the eyes and ears last, especially in the younger child.
2. Also, examine the throat toward the end of the examination, unless the child exhibits concern about the "throat stick." It is then best to examine the throat right away to "get it over with." If a child cries or can open mouth widely with encouragement, you may be able to avoid using a tongue blade.
3. To avoid frightening the child when palpating the head, make a game out of it—ask, "Where is your nose?" "Where are your eyes?"

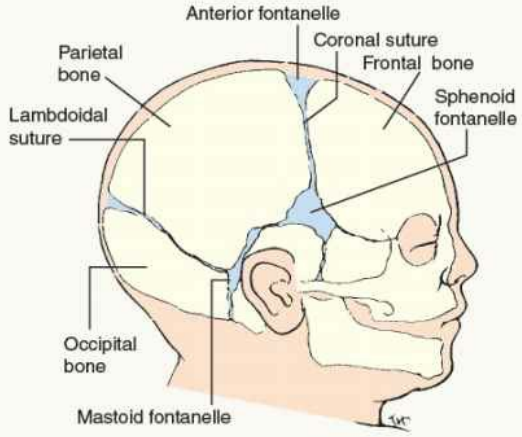
Inspection

1. Observe the face and skull for asymmetry, deformity, and abnormal or limited movements.
   1. An infant's head may be asymmetrical because of pressure during pregnancy and delivery. The rounded head of an infant born by breech delivery contrasts with the long, pointed head of an infant who is a firstborn and whose head was molded during a prolonged labor.
2. Closely observe facial expressions and blinking, if the child is not crying. This may be one of your few moments to see the child when he or she is not crying. If you are examining a crying infant, watch particularly for asymmetry of the face.
   2. In an infant born by forceps delivery, there may be signs of weakness of the facial nerve caused by pressure of the forceps over the front of the ear where the facial nerve emerges. When the infant cries, the involved side will show weakness and downturning of the mouth.
3. Observe the movement of the head on the neck as the infant looks around. When turning an infant over, observe the head for control, position, and movement.
   3. There should be very little head lag after age 3 months.
4. Because an infant's neck is typically short and there are usually several folds of skin under the chin, it is necessary to lift the chin a little to observe the skin completely—to see that it is clear and free from perspiration rash or irritation.
   4. In the back, the neck should be free of webbing or extra folds of skin extending from just beneath the ear toward the shoulder.

Palpation

1. Palpate the skull for the suture lines. Feel the face for masses, noting size, consistency, surface, temperature, and tenderness.
   1. The suture lines of the skull may be felt to override as a result of the pressure applied when contractions occurred during labor. This is usually most marked between the frontal and the parietal bone, where the coronal suture is located.





2. Palpate the anterior and posterior fontanelles.	2. The fontanelles are soft and flat when the child is quiet. Tense or bulging fontanelles may indicate hydrocephalus. Depressed fontanelles are often a sign of dehydration. The posterior fontanelle usually closes by 1 to 2 months; anterior fontanelle by 18 months.
3. Palpate along the lambdoidal suture at the back of the head between the parietal bones and the occipital bone.	
4. Palpate the neck for swollen lymph nodes, noting tenderness, mobility, location, and consistency.	4. Palpation of the lymph nodes may reveal slightly enlarged nodes in the anterior cervical chain secondary to sore throat.
	5. Note that there are other nodes, which are normally not palpable.	5. These include the preauricular and postauricular, the posterior cervical (behind the sternomastoid), the submental and submandibular (under the jaw), the supraclavicular, and the occipital nodes (along the prominence of the occiput).
6. Feel the pulses in the neck for location, strength, and equality.	
7. Check the thyroid for enlargement, position, texture, and tenderness.	
8. Locate the trachea in the suprasternal notch for position in the center of the neck.	
9. Palpate the sternocleidomastoids, making sure they are equal in size.	
Percussion	
1. Percussion of the face may elicit tenderness over the sinuses.	1. Tenderness may be caused by a tooth cavity or by a sinus infection.
2. Percuss over the head and neck directly with the fingertips, usually the middle finger of the right hand.	2. Gentle tapping over the skull elicits a typical sound when the sutures are open and elicits a different sound when the sutures are closed.
3. Percuss over the forehead for tenderness in the sinuses and across the zygoma, or cheek bone.	3. Determines underlying tenderness in the frontal or maxillary sinus.
Auscultation	
Auscultate the skull and carotid arteries in the neck.	To determine bruits.

EYES AND VISION

Inspection

Similar to adult examination; see pages 45 to 46.

1. Pay particular attention to the lacrimal duct and excessive tearing.
1. Discharge from the eyes along the lower lid or from the lacrimal duct can occur as a result of infection or reaction to silver nitrate administered to the neonate.
2. Note the distance between the eyes and the distribution of the eyebrows.
2. Hypertelorism denotes a wider than normal area between the eyes. Excessively long and full eyebrows that meet in the midline and extra-long eyelashes may signify a developmental abnormality from a genetic disorder.
3. Test the eyes for light perception.
3. It is difficult to prevent children from blinking their eyes or closing them when testing light response.
4. Do cover–uncover test.
4. To discover strabismus.
5. Beginning at about age 3 years, a visual acuity screen using an age-appropriate chart should be attempted at every well-child checkup.

Palpation

If the child is old enough, have him or her squeeze the eyes tightly (not possible in younger children) while you try to open them.

Weakness of the muscles around the eyes is difficult to demonstrate in the young child. Muscle strength or weakness can be evaluated when the child cries.

Funduscopic examination

1. Check to see that the child's eyes move in conjugate fashion. Ask the mother if she has noticed signs of squinting, especially when the child is tired.
1. Loss of vision can occur if the eyes are not working together properly. Squinting can indicate vision problems.
2. This is a difficult examination to conduct because children tend to watch the light and stare directly at you, which constricts their pupils. If the child cannot cooperate, it may be necessary to dilate the pupil to see the fundus and this is only infrequently necessary.
2. A picture can be pinned to the wall opposite the child, who is then instructed to look at the picture during the examination. If the child is examined while lying down, a picture can be placed on the ceiling.
3. Start your examination at about 1 foot (0.3 m) from the patient. Look for the red reflex, which should be readily observable.
3. The corneal light reflex and red reflex should be symmetrical.
4. Look for opacities and then slowly approach the patient, turning the ophthalmoscope dial to the smaller plus (+) numbers. Start originally at +8 to +10.
4. The red reflex is diminished if there is something obstructing your view. A cataract or opacity in the retina can cause this, as would a tumor filling the posterior chamber. If there is any paleness in the red reflex or difficulty in identifying it, a consultation should be sought immediately.
5. To help guide your gaze, put your hand on top of the child's head or at the side, with your thumb at the corner of the eye at the outer edge. If you lose the fundus, you can return to your thumb and get your bearings by directing your gaze medial to the tip of your thumbnail.

EARS AND HEARING

Equipment

- Otoscope with insufflator (pneumatic bulb and tubing)
- Varying sizes of ear speculum
- Fresh batteries to ensure a bright light

Inspection

1. When examining the external ear, the auricle, or the pinna, be sure to note the position of the ear.
   1. The top of the ear should cross an imaginary line drawn between the edge of the eye and the back of the occiput. If the ear is positioned more obliquely or is low set, some underlying abnormality, particularly of the genitourinary system, may be present.
2. If you cannot get the child to cooperate by offering an explanation or by playing a game, the child will need to be restrained. Many children will enjoy watching the light on their legs or seeing the red glow of their fingers with the light shining through or blowing the light out. If restraint is needed:
   2. If the child is in a supine position, be sure to remove the child's shoes because some children will kick when frightened.
   a. The child can be seated on the parent's knee, facing the parent, with arms and legs wrapped around the parent. The parent can then use one hand to hold the child's head firmly against the parent's chest and the other hand to hold the child's back.
      a. This allows a good secure hold and provides the child with the security of a "hug."
   b. An older child may be held in a supine position, with the parent controlling the head by holding the child's arms above his head.

Inspection with otoscope

1. Attach the insufflator, a small bulb and tube device, to the otoscope. Hold the otoscope gently with the handle between the thumb and forefinger. This will enable you to control the head of the otoscope while keeping your hand steady on the child's head.
   1. Small children will jerk about, so be careful not to push the speculum into the eardrum. The insufflator allows assessment of mobility of the tympanic membrane.
2. With your free hand, pull the pinna back and slightly upward to straighten the canal. Examine the canal.
   2. Cerumen or wax may interfere with your view of the eardrum. You may need to remove the wax with an ear curette or hydrogen peroxide instillation.
3. Use the insufflator to inspect the eardrum and test for mobility. Do not use an insufflator if there is any suspicion of a perforated eardrum.
   3. The normal eardrum moves slightly when air is introduced into the ear canal.

Palpation

Palpate behind the ear over the mastoid process.

Tenderness behind the ear may denote infection. Sometimes, a lymph node can be felt in this area.

Special testing

1. Most children will be able to respond to a test of gross hearing.
   1. A small bell, such as that found in the Denver kit, can be used to determine hearing ability by noting if the child stops moving when the bell is rung and turns his or her head toward the sound.
2. More specific tests using an electric screening device are used before school age.

NOSE AND SINUSES

Equipment

- Nasoscope
- Small speculum

Inspection

1. Observe for general deformity.
2. With a nasoscope, examine the nasal septum, mucous membranes, and turbinates and observe for discharge and nasal obstruction (see "Adult Physical Examination," page 48).
   2. Dry mucous membranes may bleed and cause clots of blood to form in the nares. Scratches may also occur if the child picks at his or her nose or scratches when itching occurs.
3. Check for the presence of a foreign body. Always remember that a foul odor may indicate a foreign body in the nose, ear, or any other body orifice including the anus or the vagina.
   3. A foreign body in the nose will cause a foul odor, purulent discharge, and possibly cause bleeding.
4. Observe for nasal flaring.
   4. Indicates respiratory distress.

Palpation

Palpate the sinuses, remembering the order of development.

Sinuses develop in a set order; the ethmoid and maxillary sinuses are present at birth. The frontal sinuses begin to develop at about 7 years and are fully formed by adolescence. The sphenoid sinuses develop after puberty.

MOUTH AND THROAT

Equipment

- Penlight
- Tongue blade

Inspection

Note: The child may gag when the tongue blade is placed on the tongue. The use of the tongue blade may be avoided by encouraging the child to open widely, or perform oral inspection if a young child is crying during ear exam (lying in supine position on exam table).

A child may also be allowed to place the tongue blade directly on own tongue while you guide with your hand.

1. Observe the lips, noting the color. (Remember that cyanosis is difficult to detect in a black child.)
   1. *Infants*: There may be a protuberance on the upper lip, the so-called sucking blister.
      Children: May have dry lips and redness around the lips caused by allergy.
2. Count the teeth (see page 1106) and note any extra or missing teeth and any evidence of caries, staining, tartar, and malocclusion.
3. Check the gums for swelling and signs of easy bleeding. Also note mouth odor.
4. Check the tongue for movement, color, and taste buds on the surface. Check to see that the frenulum under the tongue is the proper length.
   4. If the frenulum is too short, the child may be tongue-tied (meaning that he or she cannot advance the tip of the tongue beyond the lips), which may interfere with sucking or speech.
5. As the gag reflex is elicited, note how the palate moves upward and the uvula springs into view.
   5. It should be midline and single, although occasionally, it will be divided or bifurcated.
6. Examine the roof of the mouth.
   6. Whitish lesions, called Epstein pearls, may be noted on the roof of the mouth at the junction of the hard and soft palate and persist through infancy.
7. Inspect the height of the arch of the palate.
   7. With experience, an unusually high arch is easily recognizable.

Inspection (*Continued*)

8. Note the tonsils on each side of the uvula and immediately posterior to it for position, surface, size, equality, and color.
9. As the child cries, note the odor of the breath and any hoarseness of the voice; note difficulty on inspiration, as in croup, or wheezing on expiration.

8. Any coating with pus or ulcers or a pocket or cryptic appearance should be recorded.
9. These signs may indicate throat and chest disturbances.

Palpation

1. Palpate the lips and cheeks manually using a finger cot or glove.
2. Note evidence of swelling.
3. Palpate for submucous cleft.

1. By comparing one side with the other, differences caused by abnormality can be detected.
3. Submucous cleft may indicate a genetic disposition toward cleft palate.

	(Upper)	(Lower)
1 Central incisor	8 to 12 months	5 to 9 months
2 Lateral incisor	8 to 12 months	12 to 18 months
3 Cuspid	18 to 24 months	18 to 24 months
4 First molar	12 to 18 months	12 to 18 months
5 Second molar	24 to 30 months	24 to 30 months

	(Upper)	(Lower)
1 Central incisor	6 to 7 years	7 to 8 years
2 Lateral incisor	7 to 8 years	8 to 9 years
3 Cuspid	9 to 10 years	11 to 12 years
4 First bicuspid	10 to 11 years	10 to 11 years
5 Second bicuspid	11 to 12 years	10 to 12 years
6 First molar	6 to 7 years	6 to 7 years
7 Second molar	11 to 13 years	12 to 13 years
8 Third molar	17 years	17 to 18 years

BREAST

1. Realize that a child may be resistant to examination because of not wanting to remove clothes.
2. The following approaches may help overcome this problem:
   a. Distract the child by having him or her listen to a few heartbeats.
   b. Have the parent (while the child is sitting on parent's knee) remove the underclothing while you stand by.
   c. For an older child entering puberty, provide an examination sheet or gown.

1. Resistance may be due to modesty or fear of being exposed.

Inspection

1. Check to see if there are any small extra nipples present.
2. In the neonate, the nipples appear a little darker than normal and breast tissue underneath may form a small knot with occasional leakage of fluid.
3. In the child, a lump may be found under or near one or both nipples in either males or females, causing parents to worry about cancer.
4. Occasionally, the breasts begin to develop earlier than normal, at about age 5 or 6 years.

1. These would appear along a line extending from the anterior axillary line through the normal nipple down toward the symphysis pubis.
2. This leakage is a secondary effect of the hormone level in the mother; instruct the mother not to try to express the fluid because of the danger of infection.
3. Such lumps are almost always secondary to hormone stimulation and occur toward puberty or during the neonatal period.
4. This may indicate the need for referral to an endocrinologist.

THORAX

Inspection

1. Observe the entire thorax as the child breathes; note symmetry and equal expansion of both sides as the lungs inflate.	1. Diaphragm excursion is more marked than intercostal expansion in infants (especially an infant lying on the parent's knee) and young children. Thus, the abdomen goes up and down more than the chest expands.
2. Confirm the respiratory rate as you observe the child with shirt off.	
3. Observe for substernal, suprasternal, and intercostal retractions.	3. Indicates respiratory distress.

Percussion

Percussion of the child's chest is difficult. Because the underlying structures are crowded, little information is gathered. The heart edge is difficult to outline.	Light percussion is necessary; a hyperresonant note may be elicited over air, particularly of a stomach bubble that projects up into the left side of the chest.

Palpation

1. Use warmed hands as you palpate the shape and angle of the sternum. Note if there is depression of the sternum.	1. The shape of the sternum may vary, although a large depression of the sternum (funnel sternum) may cause subsequent trouble because of pressure on underlying structures.
2. Palpate the costochondral junctions for tenderness and enlargement.	2. May suggest an underlying inflammatory response.
3. As you palpate, vibration may be felt through your hands as the child cries.	3. Normal inspiration and expiration do not give a sensation under the fingers, except for the expansion of the chest.
4. Vocal fremitus is difficult to elicit in the smaller child since it is difficult to have him or her make repetitive sounds on command.	4. In the older child, it is worth trying to obtain transmission of sound through the lung tissue (see page 55).

Auscultation

1. Try to examine the child before crying begins.	1. Note, however, that crying increases lung expansion.
2. Warm the stethoscope before using by rubbing it between your hands.	2. A cold stethoscope will startle the child.
3. Be aware that breathing is louder in younger children with slightly increased length of inspiration, almost to the point of bronchovesicular breathing in the adult.	3. Bronchial breathing with equal inspiration and expiration is very loud and easy to hear in children with respiratory tract infections.
4. Crackles (discontinuous; interrupted, explosive sounds) may be heard more easily in children.	4. Added coarse-quality sounds in the chest are commonly associated with mucus in the trachea or in the back of the nose and usually clear with cough.
5. Wheezes.	5. Recurrent wheeze is an important finding in children.

HEART

Inspection

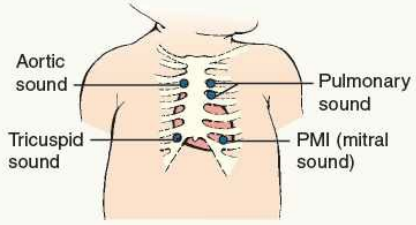
In thin children, the apical beat or the point of maximal impulse can easily be seen, particularly if you look obliquely across the chest wall.	Measurement and documentation of the distance from the midline and the exact rib space are worth noting.

Palpation

The apical beat may be felt in the 6th intercostal space about 2 inches (5 cm) from the midline in the school-age child. It is more difficult to feel in the infant, particularly a plump child, and would not be so far out toward the anterior axillary line.	The apical beat will be deviated to the left with cardiac enlargement or a collapsed lung on that side. The apical pulse could be pushed toward the right by a tumor or a collapsed lung on the right. Pneumothorax under tension will push the heart away from the side of the increased pressure.

Auscultation

1. Identify the first heart sound (S_1) (occurs during systole).	1. Consists of the "lub" portion of the "lub–dub" heart sound.
a. Locate the apical beat (closing of the mitral valve) by placing the stethoscope over the maximum impulse area, concentrating on the first heart sound. (As the ventricle on the left contracts, pushing the blood up into the aorta, the sound of the mitral valve closing is heard.)	
b. That sound can be identified by placing the thumb on the carotid pulse of the neck, which will coincide very closely with the heart sounds.	
2. Identify the second heart sound (S_2).	2. Represents the "dub" portion of the "lub–dub" heart sound.
a. Move the stethoscope up toward the sternum and to the left.	
b. At the base of the heart, both over the aortic and pulmonic areas, S_2 is louder than S_1.	b. In a child, S_2 can be heard as two heart sounds because the two valves in the aorta and pulmonary vessels do not close at the same time. This split will increase with inspiration and decrease with expiration.
3. Move the stethoscope in small jumps from the apical area medially toward the sternum. Go up to the left side of the sternum, listening at each interspace next to the sternum.	3. Represents the area of maximum intensity of sound of the pulmonary vessels.
4. Move next to the child's right second intercostal space—again next to the sternum.	4. It is at this area that you will hear the aortic sound best.
5. Listen to only one sound; concentrate on that to the exclusion of all others. Can you identify this sound? Is it clear? Compare it with your own heart sound or that of the parent.	5. The child will enjoy this comparison if allowed to listen.
6. If there is question of a heart murmur or added sounds, refer to the health care provider.	
7. As you listen to the heart sounds, you are also listening to the rhythm to confirm your findings on pulse.	7. The typical rhythm of a child is called *sinus arrhythmia*. As the heart speeds up, the child is breathing in; the heart slows down on expiration.
a. If the child breathes in and out deeply, a sinus arrhythmia may be detected.	
b. If the child holds his or her breath, the sinus arrhythmia will disappear.	
8. Be sure to note a rapid heart rate that is present even when the child is at rest and quiet.	8. This may be indicative of a tachycardia that requires further investigation.
9. In the infant, heart sounds are just a series of taps; they occur so fast that it may be very difficult to determine which sound is S_1.	9. In the infant, the S_1 and S_2 are equal in intensity.



ABDOMEN

1. For examination of the abdomen, the child should be lying down, relaxed, and not crying. Placing a small child, particularly those between ages 1 and 3, on a high table on cold paper can be frightening; as a result, his or her abdomen will not be relaxed.	1. The abdomen needs to be relaxed to palpate abnormal masses or enlarged liver or spleen as well as to auscultate for abnormal sounds.
2. Infants up to age 1 do not seem to be perturbed and will usually lie down and play nicely as long as they can see the parent, who should be stationed at the head of the child while you examine the abdomen.	
3. Having the child lie across the parent's knees with the legs dangling on one side and the head cradled in his or her arms will enable you to feel the abdomen quite well.	
a. You may find that with the infant's head in the parent's left arm, you can use your left hand to examine the infant's abdomen on the right, feeling up under the right costal margin and into the right hypochondrium.	
b. You may need to turn the infant around and use your right hand to examine the left side of the infant's abdomen.	

Inspection

1. Observe the abdomen for contour and any markings while the child is standing and when lying down. As you inspect, you may see some abdominal movement with respiration. (Remember that the diaphragm, as it goes up and down, will move the contents of the abdomen.)
2. Check for early signs of puberty as evidenced by pubic hair over the symphysis pubis.
3. Carefully inspect the umbilicus for cleanliness and the presence of scar tissue.

1. Sometimes superficial veins are seen on the abdomen, particularly in a very blond infant. Striae are commonly noticed on the flank following rapid loss or gain of weight.
2. Early pubic hair in younger children (ages 8 to 10 years) may appear long and silky. This will ultimately become curly toward the onset of puberty.
3. A deep umbilicus may be difficult to keep clean. Immediately after the cord has dropped off, a granuloma may occur.

Auscultation

1. Because percussion and palpation will stimulate the small bowel and increase bowel sounds, auscultation should precede these two techniques.
2. To obtain the child's cooperation, you can conduct a running commentary as you listen, saying such things as, "I can hear the Cheerios in there."

1. Bowel sounds are heard as tinkling, irregular sounds that indicate that fluid is moving from one section of the bowel to the next.
2. In a quiet infant who has just eaten, not many bowel sounds will be heard. In a hungry child, noisy bowel sounds can be heard, even without a stethoscope.

Percussion

1. On the right side, percuss for the liver. Confirm on palpation.
2. Percuss over the left upper quadrant (LUQ).
3. Percuss the lower abdomen, particularly above the symphysis pubis.

1. Liver dullness can frequently be outlined to determine size of the liver.
2. Percussion over a gas-filled bowel or stomach results in a high-pitched, hollow sound.
3. Above the symphysis pubis, a filled bladder can produce a duller sound, as does a pregnant uterus. (A mass in the abdomen of a female over age 10 years may be a fetus.)
   a. The liver is frequently felt about $^{3}/_{8}$ inch (1 cm) below the right costal margin and in some instances as low as ¾ inch (2 cm). This is a common finding in the neonate and through the early school-age years.

Palpation

1. Divide the abdomen into imaginary quadrants, palpating each with the fingertips.
2. In the right upper quadrant, palpate for the liver edge.
   a. Although the liver is easily palpable in many children, you may have to press quite firmly.

3. In the LUQ, palpate for the spleen. Less resistance is encountered as you feel up under the left costal margin.

3. Typically, only the tip of the spleen can be felt in the outer LUQ in the early months of life and in very thin children of preschool age.

4. In the upper quadrants, also try to palpate for the kidneys. Deep palpation for both kidneys should routinely be a part of the examination to make sure there is no enlargement of the kidney. Normally, the kidney is not palpable.	4. Kidney palpation is difficult, but during the neonatal period, the lower pole of the right kidney may be felt and sometimes the left as well. (This applies to the period immediately after delivery, when the neonate's abdomen is relaxed and the bowel is not distended.)
5. In the iliac fossa or the left lower quadrant, palpate for the descending bowel.	5. The descending colon can be felt, particularly if it's filled with firm stool and the child is quiet. It may be slightly tender, but it should not cause severe pain on gentle palpation.
6. Palpate on the right lower quadrant (RLQ) where the appendix is located.	6. In the RLQ, usually, the only sensation is that of gas-filled bowel. Tenderness in this area could be related to an inflamed appendix.
7. If the child has pain in any area or has pointed to the umbilicus when asked to show where the pain is, avoid the area demonstrated and leave it until last. Note whether the pain is with pressure or rebound.	7. If the painful area is palpated first, the child may tense up when the other areas of the abdomen are examined.
8. Palpate around the umbilicus for any masses that may indicate a hernia, especially in preterm and black children. As you press over the protruding hernia, you can feel the sensation of gurgling under your fingers as the bowel returns to the abdomen.	8. Most of these hernias heal naturally by age 6 years. A hernia above the umbilicus can be revealed by asking the child to lift his or her head from the table. (*W*idening of the muscles above the umbilicus is called *diastasis recti*.)

RECTUM AND ANUS

1. Rectal examinations are rarely necessary in infants and young children.
2. If the child will be examined by another health care provider, it is not necessary to duplicate this part of the examination.
3. Rectal examinations are embarrassing and uncomfortable for most children. Explain the procedure before performing the examination.
4. Positioning for a rectal examination:
   a. Infants can be placed on their abdomens, sides, or backs with their legs raised to their chests.
   b. Young children and teenagers can be positioned on their sides.

Inspection

1. When examining an infant or toddler, place the child on a flat surface so that the weight is evenly distributed on the front of the pelvis. As the infant moves about on the abdomen, observe the entire back, the lower back, the upper thigh, and the tightening of the buttocks.	1. If one buttock is larger than the other, you will see that side projected above the other. Weakness of one side will be obvious as the infant moves around, although a child in the early stages of crawling will tend to use one knee as a predominant leader, dragging the other.
2. Check particularly the lower part of the back for hairiness or a mass.	2. This may indicate an underlying abnormality of the vertebrae in spina bifida.
3. As the child moves away, part the buttocks and look at the cleft between them.	3. A pilonidal dimple or sinus may be seen over the lower back. This is a common finding, but parents should be told about it for cleaning purposes. Make sure there is no drainage.
4. Pay careful attention to the outer appearance of the anus and the perineum, the underside of the scrotum in the male, and the labia majora in the female.	4. The anus is inspected for blood, fissures, or splitting in the external tissue, redness, swelling, or pads of extra flesh. On occasion, small white pinworms may be seen adhering to the anal skin.

Palpation

1. Consider the child's age and feelings; ask the mother to assist, if necessary. This part of the examination is not always needed.	
2. Start by parting the buttocks with the left hand and introducing a well-lubricated finger (with finger cot) into the anus.	2. When an infant is being examined, the small finger should be used.
3. Gently apply pressure on the anal sphincter to allow the muscles to relax and the fingertip to slide into the rectum.	3. Apply pressure with pulp of the finger rather than jab at the anus with the fingertip.
4. Gently palpate the inner ring, feeling for areas of thickening and tenderness and simultaneously judging the sphincter tone.	4. As the perianal area is pressed on from the inside, tenderness will be elicited if a deep fissure exists or if an infection has occurred around a fissure.
5. If the rectum is full of stool, it will be impossible to feel any other mass.	5. In a young child, particularly an infant, dilation provided by the finger may result in a bowel movement. In an older child, a suppository or even an enema may be required.
6. Palpate the walls of the rectum.	6. The mucosal walls should be smooth, and deep palpation should elicit mild tenderness and no acute pain.
7. In the adolescent male, gently turn your finger through 180 degrees and feel the posterior surface of the prostate. Note size, consistency, tenderness, and contour.	
8. In the female, perform a bimanual examination and palpate the cervix.	

EXAMINING MALE GENITALIA

1. This part of the examination requires a direct, matter-of-fact approach. Acknowledge that it is normal to feel embarrassed during an examination of the genitals. Explain what you are looking for as you proceed through the examination with a teenager.	
2. Reassure the child after the examination that his genitals are normal. This decreases anxiety.	
3. When examining the testes in a young boy, you may need to block the canals to prevent them from retracting into the abdomen.	

Scrotum and Testes

Inspection

1. Before touching the child, determine by observation of the testes whether they are in the scrotum.	1. Retraction of the testes into the abdomen occurs frequently in young children; the development of the scrotum depends on the presence of the testes.
2. Observe the skin over the scrotum for color and surface appearance, noting the presence of wrinkles, or rugae.	2. The skin over the scrotum varies in color, being a darker brown to black in the more pigmented races and reddish in children with light complexions. The wrinkles, or rugae, are more developed as the child grows older.

Palpation

1. Check the scrotum wall for swelling or sensitivity. Gently feel the testes, palpating across the upper pole and feeling for the epididymis. (Remember the scrotum is extremely sensitive to pressure.)	1. The epididymis is a ridge of soft, bumpy tissue extending from the superior pole and running down and behind the testis.
2. Estimate the size of the testes and identify the spermatic cord, tracing it from the testis up toward the groin.	2. The spermatic cord, with the vas deferens, feels firm and is accompanied by softer nerves, arteries, veins, and a few muscle fibers.
3. Make a special effort to locate the testis in a young child whose testes may be retracted into the abdomen via a hyperactive cremasteric reflex. You may need to have the child in a sitting or standing position. Occasionally, you may need to ask a parent to check at home with the child sitting in a warm bathtub.	3. Ascertaining the presence of the testes in the scrotum is vital in older infant or toddler. Nondescent of the testes requires further evaluation.

a. If the testes cannot be felt in the scrotum, gently run the skin of the upper scrotum between your fingers, moving superiorly and approaching the external inguinal ring.
b. Try to milk the testis down toward the scrotum from above with your hand.
c. If this fails, have the child sit cross-legged to abolish the reflex of the cremaster muscle.

a. During this period, the testis is about ½ to ¾ inch (1.5 to 2 cm) in length. In the quiescent period before puberty, the male genitalia remain fairly infantile.

4. When examining a boy in the early stages of puberty, it is important to note the size of the testis as well as the greater number of rugae on the scrotum and the appearance of pubic hair around the penis. If appropriate, discuss importance of self testicular exam.

4. In early puberty, the testes start to grow. Onset of puberty varies, occurring between the ages of 10 and 14 years. In most teenagers, the findings are similar to those in adults.

Penis

1. Evaluate the penis on all sides by lifting up the shaft.

1. The shaft of the penis contains the urethra on the under, or ventral, surface and is easily palpable.

2. If the child is not circumcised, partially retract the foreskin to observe the glans and meatus.

2. The foreskin may adhere to the glans for the first few years of life. It is not necessary for the parent to "stretch" the foreskin by retraction.

3. Observe the position of the meatus and evert the lips of the meatus to reveal an adequate orifice.

3. The meatus may be positioned off center. If the meatus is located on the dorsal or ventral surface of the shaft, the child should be evaluated by a pediatric urologist.
Whitish discharge around the glans under the foreskin is normal and not a sign of infection. The foreskin should completely encircle the glans.

4. In the older child, inspect the penis for ulcers, sores, or discharge from the meatus.

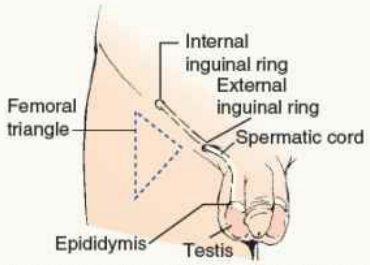
4. Consider sexually transmitted infections in children of all ages; the possibility of sexual abuse must be considered.

Inguinal Area

Palpation

1. Palpate for a hernia over the external inguinal ring. Have the child cough to enhance your observation.

1. Having the child stand with the parent either holding him or placing him against the parent's knee will help you in locating a hernia in the inguinal area.



2. An increased cough reflex or swelling in the area should be checked by carefully placing a finger on the scrotal skin and invaginating the skin over your fingers toward the external ring. You are trying to follow the course of a hernia that would descend into the scrotum while you feel the external ring from below. A hernia in the inguinal region presents as a bulge that can be either seen or felt from below by placing the finger in the scrotum pointing up toward the external inguinal ring.

3. Also palpate for the inguinal lymph nodes.

3. The inguinal lymph nodes in an infant are palpable as small and "shotty." Anything more than this should alert you to possible infection because the perianal area drains into the superficial inguinal lymph nodes. For example, diaper rash may explain enlargement of the lymph nodes, which should be noted and reported.

Femoral Area

Palpation

Palpate the femoral triangle carefully for a hernia and for lymph nodes.

In the femoral area, a swelling that can be reduced with a gurgling sound is an unusual finding.

Auscultation

If you are trying to reduce a mass, listen over the scrotum to determine if there is a gurgling sound.

This will locate the bowel and confirm a hernia.

Transillumination

1. To locate the testis, darken the room and shine a bright light from behind the scrotum. In a normal child, the testis will stand out as a darker area.
2. Transilluminate any suspicious mass to help locate a hernia.

1. A scrotal sac that is swollen by fluid (hydrocele) will transilluminate. Fluid around the testes or cord must be differentiated from a hernia.
2. Any mass in this area must be reported to a health care provider immediately.

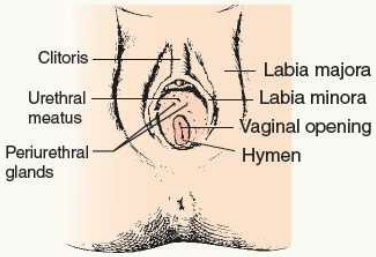
EXAMINING FEMALE GENITALIA

1. If the child will be examined by a health care provider, it is not necessary to duplicate this part of the examination.
2. Place the infant or toddler on the table or on her parent's knee while the parent holds the child's knees in an abducted and flexed position.
3. A preschool child can be allowed to lean over her parent's knee. However, remember that the structures are being visualized upside down.
4. The older child or teenager should be draped as an adult would and should be placed in a lithotomy position with the aid of stirrups.

Equipment

- Disposable gloves
- Speculum
- Light source

1. Carefully inspect the perineal area for cleanliness, inflammation, and abnormality.



1. This includes the mons pubis, clitoris, labia, urethra, and perineum. The labia minora are seen as two slender folds of tissue inside the labia majora. In some instances, adhesions of the labia minora occur because of the lack of natural hormones.

2. If the mother of a neonate has noted a bloody discharge from the infant's vagina during the first few days of life, reassure her that this is not an uncommon occurrence; the discharge will disappear, as will swelling of the labia majora and clitoris and enlargement of the infant's breasts.
3. Note the vaginal opening, which may vary in size because of the presence of a thin membrane, the hymen. The hymen varies in appearance according to the child's age.
4. In the young child, it is usually unnecessary to examine inside the vagina. If a young child requires an extensive vaginal exam, it is frequently done under sedation.

2. Hormone stimulation from the mother's body accounts for this occurrence. The discharge usually stops after the hormones are excreted. The bloody appearance on the diaper may be confused with the presence of urates, which are also orange-red and appear normally in urine.
3. The lack of an opening into the vagina may result in the retention of menstrual fluid when the child reaches puberty. In the sexually active adolescent, vestigial remains on the hymen may appear as small particles (caruncles) at the fringe of the vagina.
   The possibility of sexual abuse should always be considered and, if necessary, the child referred to a specialist in sexual abuse.
4. A foreign body or sexually transmitted infection may be suspected if there is a vaginal discharge, bleeding, or odor.

MUSCULOSKELETAL SYSTEM

1. Evaluation of the musculoskeletal system can be done both in an informal manner, while watching the child at rest and at play, and in a formal manner as specific findings are methodically checked.
2. In the neonate, observe the position of the extremities during sleep and the quality of movement when the child is awake.
3. Various aspects of size, shape, and movement are evaluated as the child is observed pushing up on his or her arms and turning his or her head toward the mother.
4. A child in the early stages of walking offers many opportunities for evaluation of muscle strength and movement.
5. At the same time, rapport with the mother can be reinforced by your admiring the child's ability and by inquiring if she is concerned about the manner in which the child is walking.
6. A more mobile child can be evaluated as you watch him or her play and explore the room.
7. Having the older child reach for crayons, run after a ball, or walk around the room enables you to evaluate the musculoskeletal system and the child's sense of balance.

Upper Extremities

1. In the infant, evaluate the status of the clavicles when examining the skull and neck.	1. During a difficult delivery, the clavicle that has been exposed to traction may snap. A lump can be felt on the bone at about age 3 weeks.
2. Carefully examine the hands to note the shape of the hand, shape and length of the fingers, changes in the nails, and creases on the palms.	2. Variation in the hands or unusual length of the fingers should be noted. An incurved little finger or low-set thumb with the single simian crease may reflect Down syndrome.

Lower Extremities

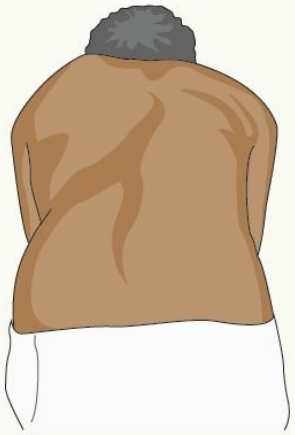
1. Examine the appearance of the infant's foot, noting arch formation.	1. The foot of an infant is usually flat and appears broad because the arch on the inside of the foot is covered by a fat pad. Parents may need reassurance about this.
2. Inspect the angle of the foot and lower leg and then manipulate the ankle to evaluate the range of motion.	2. Full flexibility of the foot (plantar flexion) rules out underlying abnormality. The foot should return to the neutral position after manipulation. Typically, the foot will turn in, or adduct. Such a finding should be recorded.
3. Place the legs together and see how far the ankles and knees are separated.	3. Toddlers typically have external hip rotation and internal knee rotation, which results in a "bowed" appearance. The preschooler has a normally knock-kneed walk, but with knees touching, ankles should be no more than two fingerbreadths apart.
4. Evaluate the child's ability to walk, noting the appearance of his or her legs and foot placement. Remember to look at the child's shoes and see which side of the sole is worn down.	4. Infants commonly appear to be bowlegged when they first start to walk because the feet are kept wide apart and turn slightly in. The ankles appear curved when viewed from behind.

Hip

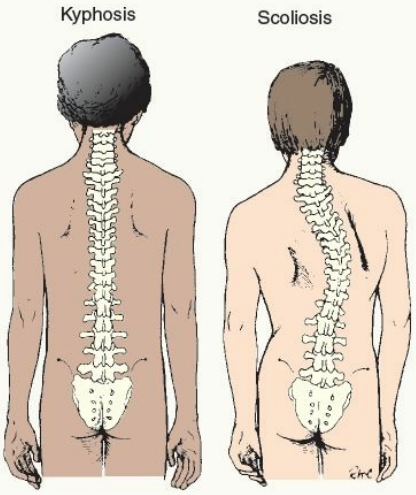
When examining children under age 1, check for signs of hip dislocation. See page 1424.

Spine

1. Check the spine for signs of abnormal curvature.
2. Observe the child from the side and back in the standing position to see forward curving of the shoulders.
3. Have the child bend forward with the arms hanging down. A unilateral rib prominence will be seen in children with scoliosis.



1. The normal young child has a curve inward at the lumbar region (lordosis), but this should not be exaggerated. It is normally more exaggerated in black children.
2. These appear most commonly during school-age years and adolescence.



Kyphosis: Forward curvature of the shoulders.

Scoliosis: Side-to-side curvature of the spine.

NEUROLOGIC EXAMINATION

1. The neurologic system at birth is different from that in an infant age 3 months. There is an even greater contrast between the infant and children and adults.
2. The central nervous system at birth is underdeveloped and the functions tested are below the level of the cortex.

Equipment

- Flashlight
- Ophthalmoscope
- Tuning fork
- Noisemaker
- Tongue depressor

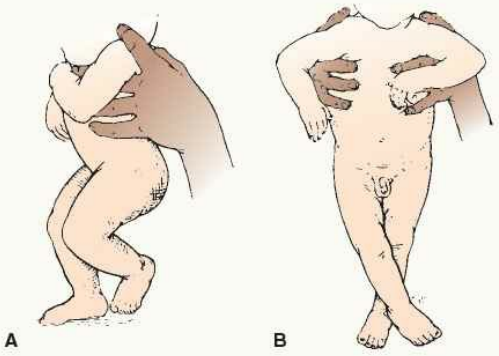
Procedure for the neonate and young infant

1. Observe the neonate for general appearance, positioning, activity, crying, and alertness. Take note of the posture—including head, neck, and extremities.
2. Note the pitch, volume, and character of his or her cry.
3. Observe the infant's facial expression and the symmetry of his or her face when crying or sucking.
4. Most of the cranial nerves are difficult to check at this early age.

1. Stiffness of the neck or marked extension of the head will cause a position of opisthotonos and necessitates referral.
2. The high-pitched cry of the infant who has intracranial irritation is distinctive.
3. Poor sucking, with dribbling, is abnormal. Transient weakness of the mouth caused by cranial nerve VII paralysis is commonly seen as a result of a forceps delivery in which the forceps is pressed on the facial nerve where it emerges from the ear.

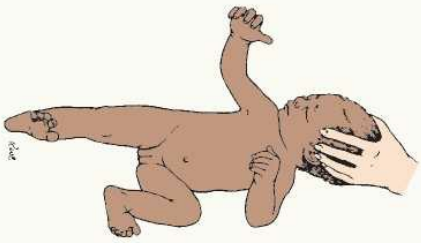
Automatic Reflexes

1. *Blinking reflex because of loud noise* Clap your hands or produce a loud clicking noise. Be careful not to clap near the infant to prevent a wave of air from causing a blinking of the eyes.	1. Lack of a blink in response to a loud noise may indicate deafness.
2. *Blinking reflex because of bright light* Shine a bright light into the infant's eyes to elicit the blinking reflex.	2. Failure to blink may indicate blindness.
3. Cranial nerve X can be checked by using a tongue blade to gag the infant.	3. Palate moves upward.
4. *Palmar grasp reflex* Place your fingers across the infant's palm from the ulnar side. The infant needs to be in a relaxed position with head in a central position. Reinforcement may be offered by having the infant suck on a bottle at the same time.	4. Both hands will flex and can be compared for strength. Weakness on one side may be indicated by a failure to grasp when the palm is stimulated.
5. *Rooting reflex* Touch the edge of the infant's mouth.	5. The infant's mouth will open and the head will turn toward the side stimulated. This reflex is marked during the early weeks of life.
6. *Incurving of the trunk (Galant reflex)* Hold the infant horizontally and prone in one arm while using the other hand to stimulate one side of the infant's back from the shoulders to the buttocks. The trunk curves toward the stimulated side as the shoulders and pelvis move toward the stroking hand (persists until the infant is about age 2 months).	
7. *Vertical suspension position* Place your hands under the infant's axillae with thumbs supporting the back of the head and hold the infant upright.	7. The legs flex at the hips and knees (persists for about 4 months).
8. *Stepping response* Hold the infant under its axillae with thumbs supporting the back of the head. Allow the infant's foot to touch a firm surface.	8. Normally, the infant responds by lifting one knee and hip into a flexed position and moving the opposite leg forward—making a series of stepping movements (see 8A). a. Difficulty with the stepping reflex and stiffness or spasticity connected with crossing of the feet and scissoring (see 8B) is indicative of spastic paraplegia or diplegia. b. It should be noted that the stepping response may be affected by breech delivery. (It may also be affected by weakness.) c. The stepping response is evident toward the end of the first week after birth and persists for a variable time.



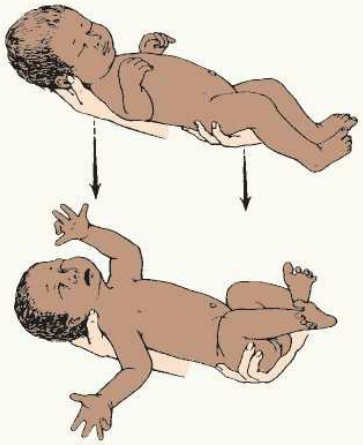
A B

9. Tonic neck reflex
Hold the infant in a supine position with the head turned to one side and the jaw held in place over the shoulder.



9.
a. The arm and leg on the side to which the head is turned will extend, whereas those on the other side will flex (the so-called fencing reflex).
b. This reflex persists for about 5 to 6 months; it may be present at birth or delayed until the infant is age 6 or 8 weeks.
c. Persistence beyond 6 months suggests major cerebral damage.

10. *Mass reflexes* (Moro or startle reflex)
Hold the infant along your arm with the other hand below the lower legs. Lower the feet and body in a sudden motion.



10. The arms will spring up and out, abducting and extending; the fingers are also extended. The arms then return forward over the body with a clasping motion. At the same time, the legs flex slightly and the hips abduct.
   a. The Moro reflex is present at birth and disappears at approximately the end of the third month. Persistence beyond 6 months is significant.
   b. Asymmetrical response may be caused by paralysis of the arm after difficult delivery, tension and injury to the brachial plexus, or a fracture of the clavicle or humerus. A dislocated hip would produce an asymmetrical response in the lower extremities.

11. *Perez reflex*
Hold the infant in a prone position along your arm; place the thumb of the other hand on the sacrum and move it firmly toward the head, along the entire length of the spine.

11. The head and spine will extend and the knees will flex upward.

Summary

1. Some of the jerking and shaking movements seen in neonates are normal, but they should be rechecked frequently during the first few weeks of life.
2. Variants in the findings caused by the infant's sleepiness or hunger should be taken into account and reevaluations should be carried out under different conditions.
3. Severe neurologic damage may be completely asymptomatic and impossible to detect during the first few weeks of life.

Procedure for the toddler and early school-age child

1. The neurologic examination for the toddler and the early school-age child is similar to that for the adult (see page 66).
2. The Draw-A-Person Test and the Denver Developmental Assessment are both well-accepted methods for testing areas in the development of the child.
3. Beyond the neonatal period, specific gross and fine motor coordination testing, accompanied by appropriate evaluation of the Denver test, will assist in assessing the child's level of development.
4. 4. These tests also assess social and language development and are important screening devices.
5. Interview techniques can also be useful in assessing development in the preschool child.

2. See *www.denverii.com* for instructions and findings of the Denver Development Assessment.

PATIENT EDUCATION GUIDELINES 42-1

Breast-Feeding

1. Breast-feeding is the best possible source of nutrition for your infant. It provides an immunologic boost for the infant, protects against breast cancer, hastens postpartum healing, and serves as a wonderful bond between the infant and mother.

2. You should begin breast-feeding in a quiet, comfortable place that is free from interruption. You may need a pillow to help support the infant and a footstool to use to elevate your leg.

3. Make sure that the infant is awake and dry before the feeding is started. If awake and comfortable, the infant will settle down and feed better. The infant should also be hungry.

4. Dress the infant appropriately so that the infant is not too warm or too cool during the feeding. If too warm, the infant may fall asleep after the first few sucks of milk. A sleepy infant will not nurse well. If too cool, the infant may be fussy and restless.

5. Position infant at the breast by placing the infant in a semisitting position with face close to the breast and supported by one of your arms and hand. A pillow may be used under the infant for support. The breast should be supported with your other hand. This makes the nipple more easily accessible to the infant's mouth and prevents obstruction of nasal breathing. Proper positioning will provide the infant with comfort and make it easier for the infant to suck and swallow.

6. When the feeding is to start, let the breast touch the infant's cheek. Do not hold the cheek, but try to help the infant find the nipple. The rooting reflex will take over and the infant will turn head toward breast with mouth open. If you touch the cheek, the infant will become confused, perhaps turning toward your hand.

7. The infant's lips should be out over the areola and not just around the nipple before beginning to suck. Because

8. the nipple is so small, suction cannot be achieved merely by grasping it. The areola must be in the infant's mouth to establish suction and make the suck effective. Check to make sure that the lips are not curled in, as this may cause pain and irritation to the breast tissue.

9. You may notice the "(let-down)" reflex during the nursing period. Milk flowing from the other breast during nursing is quite normal.

10. The length of feeding time may vary from 5 to 30 minutes. Let the infant nurse until satisfied. When the infant is satisfied and has nursed well, the infant is relaxed and usually falls asleep. The infant will stop sucking.

11. Burp the infant during and at the end of the feeding to prevent abdominal distention or regurgitation from air swallowed during the feeding.

12. One or both breasts may be used at each feeding. It makes no difference as long as the infant is satisfied at the end of the feeding, and one breast is completely emptied at the feeding. If both breasts were used, the second breast is not usually emptied and should be used first at the next feeding. Regular and complete emptying of the breast is the only stimulation for the production of milk.

13. When the infant has stopped sucking, the infant typically likes to cling to the breast. To break this suction, insert a finger to the corner of the infant's mouth and gently pull.

14. When the infant has finished feeding, change the diaper if it is wet or soiled. Position the infant on their back in bed. Note whether the infant appears satisfied or still seems to be hungry.

15. To continue successful breast-feeding, get adequate rest, nutrition, and fluid intake.

16. For information and support, contact La Leche League International, 957 N. Plum Grove Rd., Schaumburg, IL 60173, (800) 525-3243, www.illi.org; or read their publication The Womanly Art of *Breast-feeding* (8th ed.).

PROCEDURE GUIDELINES 42-1

Bottle Feeding

EQUIPMENT

- Sterile nipple and bottle (can be washed in dishwasher or in hot soapy water and rinsed well)
- Formula or breast milk (prepared according to manufacturer's directions)

PROCEDURE

Nursing Action	Rationale
Preparatory phase	
1. Infant should be awake and hungry. Change wet or soiled diaper.	1. A sleepy infant will not feed well. A dry diaper will provide comfort so that the infant will settle down and feed more easily.
2. If using new bottle and nipple, boil for 5 minutes immersed in a covered pan. Remove bottle and nipple and place upside down on a clean towel to cool and dry. Commercial sterilizers may also be used.	2. Prevent possible contamination by bacteria or other particles.
3. Check formula for proper type and amount. Prepare according to manufacturer's instructions.	
a. For babies up to 6 months, mix concentrated or powdered formula with water that has been boiled (unless commercially prepared water is marked as sterile).	a. Boiling water kills bacteria in the event of contaminated water supply.
b. If using tap water, run the faucet for 2 minutes to flush out any lead or other impurities before boiling.	b. Running the tap removes impurities that standing water may pick up from the plumbing.
c. Boil water vigorously for 1–2 minutes, let cool, and add to formula.	
4. Use cold formula, if tolerated, but some infants prefer warmed formula.	4. Infants may prefer cold formula if started on it from the beginning.
a. Warm bottle by holding it under very warm running water for a few minutes or putting the bottle in a pan of warm water (away from the heat source). Commercial bottle warmers may be used. Shake bottle vigorously after warming.	a. Overheating must be avoided to prevent burns to the infant's sensitive mouth. Shaking will distribute fluid temperature evenly. Do not use a microwave to heat formula.
b. Test formula temperature by squirting some on your inner wrist before feeding.	b. The inside of the wrist is more sensitive to test temperature than other areas of the skin.
5. Sit in a comfortable chair. Cradle the infant with one hand and arm, while supporting the infant against your body or lap.	5. Proper position will provide the infant with comfort and security and will make it easier to suck and swallow. Holding the infant will enhance bonding and provide sensory stimulation.
Performance phase	
1. Let the infant root for the nipple by touching the corner of the infant's mouth with the nipple.	
a. When the infant's mouth opens, insert the nipple.	a. Rooting is a natural reflex.
b. Suction will be created when the infant sucks if the nipple is positioned properly in the mouth.	b. Position the nipple on top of the tongue and far enough into the mouth so suction can be created.
2. Hold the bottle at an angle to completely fill the nipple with fluid.	2. Prevents the infant from sucking and swallowing excessive air.
3. Never prop the bottle or leave the infant unattended during feeding.	3. This is unsafe. Should vomiting occur, aspiration is more likely.
4. Handle the bottle carefully so as not to contaminate the nipple or fluid.	4. Contamination will increase the risk of GI disturbances.
5. Feed until the infant stops sucking; varies from 10 to 25 minutes.	5. Feeding time is individual, based on age, size, how vigorously the infant sucks

Nursing Action	Rationale
6. Burp the infant after every 2–3 ounces during the feeding and at the end of the feeding.	6. Most infants swallow some air with feeding. These positions aid in expelling air and thus prevent abdominal distention, discomfort, and regurgitation. Vigorous handling or patting may result in the infant spitting up or regurgitating fluid.
a. Place the infant in a sitting position in your lap, tilt slightly forward, and gently rub or pat the back.	
b. Place the infant in a prone position on your shoulder or in your lap and gently pat or rub the back.	
Follow-up phase	
1. After final burping, keep the infant in an upright position for 10–15 minutes (longer if the infant has reflux). If restless, burp the infant. Note if any spitting up occurs.	1. Prevents regurgitation, but it is not abnormal to bring up small amounts of formula.
2. Throw away any leftover formula in the bottle after the feeding.	2. Avoids bacterial contamination.
a. Discard any formula that has been left out unrefrigerated for 2 hours.	
b. Refrigerate extra bottles after mixing formula; discard if not used in 24 hours.	
c. Do not reuse the bottle for a subsequent feeding (refill and reuse) without properly cleaning.	

NURSING ALERT When feeding a premature infant, the infant will tire more easily and fall asleep. Allow frequent rest periods and use a soft, fast flow nipple so that less energy is needed to suck. To stimulate the premature infant to suck, the nurse can brush the infant's cheek with her or his finger, place the thumb or finger under the infant's chin, or move the nipple slowly back and forth in the infant's mouth. Feeding time should not exceed 30 minutes. Keep the infant warm during feeding.

EVIDENCE BASE Infant Nutrition Council. (2013). *Safe preparation, storage and handling of powdered infant formulas*. Available: http://infantnutritioncouncil.com/safe-prep-and-handling/

Pediatric primary care includes health promotion and disease prevention interventions that will positively affect the well-being of children and their families. The goal of pediatric primary care is to achieve physical, emotional, and developmental health for all children. Primary prevention—through immunizations, proper nutrition, and safety counseling—is an essential component of pediatric health care.

Immunizations

Disease prevention through immunizations has significantly reduced childhood morbidity and mortality from infectious diseases. However, despite effective immunization availability, vaccine-preventable diseases are still present in the United States and continue to pose significant public health problems. The rate of immunization in the United States exceeds 90% for children aged 19 to 35 months for poliovirus vaccine; measles, mumps, rubella (MMR); hepatitis B, and varicella vaccine. However, rates vary by state and decrease after this age. Rates of immunization for routine vaccines for adolescents aged 13 to 17 have risen over the past 10 years from 26.7% to 41.7% (human papillomavirus vaccine) and 84.7% to 86.7% (Tdap vaccine).

Nurses are in a vital position to promote child health by assessing, recommending, and administering immunizations. Also, nurses are frequently asked to provide documentation (to parents or caregivers) of the immunizations that have been administered to facilitate children's enrollment in day care, school programs, and summer camp participation. A review of immunizations and administration of needed vaccines should be done at every health care visit.

EVIDENCE BASE Centers for Control Disease and Prevention. (2016). National and state vaccination coverage among children aged 19–35 months—United States, 2015. *Morbidity and Mortality Weekly Report, 65*(39), 1065–1071.

Barriers to Vaccination

EVIDENCE BASE Carpiano, R., & Fritz, N. (2017). Public attitudes toward child undervaccination: A randomized experiment on evaluations, stigmatizing orientations, and support for policies. *Social Science & Medicine*, 185, 127–136.

Rutten, L., St. Sauver, J., Beebe, T., et al. (2017). Clinician knowledge, clinician barriers and perceived parental barriers regarding human papillomavirus vaccination: Association with initiation and completion rates. *Vaccine, 35*(1), 164–169.

There are many reasons that parents or caregivers may give to refuse vaccinations for their children.

1. Safety concerns, such as concerns that the child may develop learning disabilities. Information about vaccine safety can be obtained from the Centers for Disease Control and Prevention (CDC) at *www.cdc.gov/vaccinesafety/Concerns/Index.html*.
2. Concern for the pain inflicted on the child.
3. Because of success of vaccine programs for many years, many parents have no memory or knowledge of the serious vaccine-preventable illnesses that have been near eradicated.

4. Unfortunately, many parents may be influenced by high-impact negative media information regarding vaccinations despite the fact that most is not supported by evidence.

NURSING ALERT Nurses can be instrumental in assisting caregivers in discerning factual information from myths and erroneous information that may be presented in the media.

General Considerations

Requirements of National Childhood Vaccine Injury Act (Effective 1988)

1. This act mandated providers to notify all patients and parents about the risks and benefits associated with vaccines.
2. The patient, parent, or legal guardian should be informed about the benefits and risks of immunizations. Before administration of the vaccine, they must be provided with the current Vaccine Information Statement (VIS), developed by the CDC. Health care providers must record the name of the VIS publication (eg, polio), date of VIS publication, and the date the VIS was given to the patient or his or her family on the child's medical record.
3. Federal law mandates that all health care providers must record the following information in the patient's permanent medical record: month, day, and year of administration; vaccine or other biologic administered; manufacturer, lot number, and expiration date; and name, address, and title of the health care provider administering the vaccine.
4. In addition, the site and route of administration should be documented in the patient's record.
5. Health care providers are required to report selected events occurring after vaccination to the Vaccine Adverse Events Reporting System, part of the CDC Immunization Safety Office, which monitors and investigates possible vaccine adverse effects.

Routine Vaccinations for Children in the United States

The Advisory Committee on Immunization Practices (ACIP) annually develops written recommendations for the CDC regarding the routine administration of vaccines, along with schedules detailing the appropriate timing, dosage, and contraindications for children and adults in the civilian population in the United States. The most recent recommendations are reviewed below, but complete immunization schedules can be found at *www.cdc.gov/vaccines*.

Childhood-recommended vaccines (ages 0 to 6 years) include diphtheria, tetanus toxoid, acellular pertussis (DTaP); inactivated poliovirus vaccine (IPV); MMR; *Haemophilus influenzae* type b (Hib) vaccine; hepatitis B vaccine (HBV); *Varicella*; pneumococcal conjugate vaccine (PCV7 and PCV13); rotavirus (Rota); hepatitis A (HepA); and meningococcal vaccine (MCV4). An influenza vaccine is recommended to be given annually for healthy children aged 6 months to 19 years old. In many areas of the United States, influenza vaccine is a requirement for day-care attendance.

The recommended immunization schedule for persons ages 7 to 18 years includes tetanus toxoid, diphtheria, and acellular pertussis (Tdap); human papillomavirus vaccine (HPV); MCV4; pneumococcal polysaccharide vaccine (PPV)—to certain groups at high risk; annual influenza vaccine (trivalent inactivated influenza vaccine [TIV]); HepA—for certain groups of children; HBV; MMR; *Varicella*; and IPV, if necessary, to equal a total of four doses. While not required by schools, the HPV is recommended to start by age 9 years, but can be given until age 26 years. If the child receives the vaccine before age 14 years, he or she only needs a two-dose vaccine series; after age 14 years, three doses of the vaccine are required.

Immunization Schedules

1. Routine immunizations are started in infancy. However, if a child is not immunized in infancy, immunizations may be started at any age and a slightly different schedule may be followed, depending on the child's age and the prevalence of specific diseases at that time.
2. Usually, an interrupted primary series of immunizations does not need to be restarted; rather, the original series should be resumed regardless of the length of time that has elapsed.
3. In special circumstances involving some cancer treatments and severe immunologic disorders, immunization schedules will require adjustment.
4. The immunoresponse is limited in a significant proportion of infants, and the recommended booster doses are designed to ensure and maintain immunity.
5. Current recommended immunization schedules can be found at *www.cdc.gov/vaccines/*.
6. When using a combination vaccine, if there is a contraindication to any of the components, do not vaccinate.

Contraindications and Precautions

It is important to read the manufacturer's insert for each vaccine before administration.

1. Contraindications to all vaccines:
   a. Anaphylactic reaction to a vaccine or a vaccine constituent.
   b. Moderate or severe illnesses with or without a fever. Children with moderate or severe illnesses, with or without fever, can be vaccinated as soon as they are recovering and no longer acutely ill.
2. All live virus vaccines (live oral poliovirus vaccine [OPV], MMR, *Varicella*) are contraindicated in pregnancy, immunosuppression or immunodeficiency, and household or close contact with those who are immunosuppressed or immunodeficient.
   a. MMR vaccine should be considered for all symptomatic human immunodeficiency virus (HIV)–infected persons who do not have evidence of severe immunosuppression or evidence of measles immunity.
   b. *Varicella* vaccine should be considered for asymptomatic or mildly symptomatic HIV-infected children.
3. Diphtheria, tetanus, and pertussis (DTP)/DTaP—encephalopathy within 7 days of administration of previous dose of DTP/DTaP.
   a. Infants and children with stable neurologic conditions, including well-controlled seizures, may be

vaccinated; however, such vaccination should be decided on an individual basis.

4. IPV—anaphylactic reaction to neomycin, streptomycin, or polymyxin B.
5. MMR and *Varicella*—anaphylactic reactions to neomycin or gelatin.
6. Influenza—anaphylactic reaction to eggs or egg protein. Persons with asthma, reactive airway disease, or other chronic pulmonary or cardiovascular disorders should not receive LAIV.
7. HBV—anaphylactic reaction to baker's yeast.
8. Meningococcal vaccines—can be given to pregnant women; should not be administered with other vaccines for children with sickle cell disease or those without a functioning spleen.

Misconceptions Concerning Vaccine Contraindications

1. Some health care providers and parents inappropriately consider certain conditions or circumstances to be contraindications to vaccination. Conditions most commonly regarded as such include the following:
   a. Mild acute illness with low-grade fever or mild diarrheal illness in an otherwise well child.
   b. Current antimicrobial therapy or the convalescent phase of illness.
   c. Reaction to a previous DTaP dose that involved only soreness, redness, swelling in the immediate vicinity of the vaccination site, or temperature of less than 105°F (40.5°C).
   d. Prematurity.
   e. Person using aerosolized steroids, short course of oral steroids (less than 14 days), or topical steroids.
   f. Pregnancy of mother or other household contact.
   g. Recent exposure to an infectious disease.
   h. Breast-feeding.
   i. History of nonspecific allergies or relatives with allergies.
   j. Allergies to penicillin or other antibiotic, except anaphylactic reactions to neomycin or streptomycin.
   k. Allergies to duck meat or duck feathers.
   l. Family history of seizures in people considered for pertussis or measles vaccination.
   m. Family history of sudden infant death syndrome in children considered for DTaP vaccination.
   n. Family history of an adverse event, unrelated to immunosuppression, after vaccination.
   o. Malnutrition.
2. In most cases, children with the above conditions can still be immunized.

Vaccine Administration Considerations

1. Strict adherence to the manufacturer's storage and handling recommendation is vital. Failure to observe these precautions and recommendations may reduce the potency and effectiveness of vaccines.
2. Health care personnel administering vaccines should be immunized against MMR, hepatitis B, influenza, tetanus, pertussis, and diphtheria. *Varicella* vaccine is recommended for health care providers with no serologic proof of immunity, prior vaccination, or previous disease. Gloves should be worn when administering vaccines. Good hand-washing technique is mandatory before and after vaccine administration.

3. Sterile, disposable needles and syringes should be discarded promptly in appropriate biohazard containers. Do not recap needles.
4. Parenteral vaccines should be administered in the anterolateral aspect of the upper thigh in infants and in the deltoid area of the upper arm in older children and adolescents. Recommended routes of administration are included in the package inserts of vaccines.
5. Before administering a subsequent dose of any vaccine, question patients and parents about adverse effects and possible reactions from previous doses.
6. Routine vaccines can be safely and effectively administered simultaneously in most healthy children.

Specific Immunizations

DTaP

1. Administered IM.
2. A time lapse of 8 weeks is recommended between the first three DTaP injections for desirable maximum effects.
3. Administration of acetaminophen at the time of immunization and at 4 and 8 hours after immunization decreases the incidence of febrile and local reactions.
4. Tdap is recommended for children over age 7 years. As of 2006, vaccination guidelines recommend that Tdap be routinely used in adolescents 11 to 18 years of age and single doses for adults 19 to 64 years of age in attempts to control recent pertussis outbreaks.
5. For contaminated wounds, a booster dose of tetanus should be given if more than 5 years have elapsed since the last dose.
6. For infant pertussis protection, ACIP has recommended that Tdap be given during each pregnancy between 27 and 36 weeks of gestation to maximize the maternal antibody response and passive antibody transfer to the infant.

Tuberculin Skin Test

1. It is recommended that, if indicated, the tuberculin test be given before or at the time of the MMR vaccine. The measles vaccine may temporarily suppress tuberculin reactivity for 4 to 6 weeks, so result may not be accurate during that time frame.
2. The frequency of repeated tuberculin testing depends on the following:
   a. Risk of tuberculosis exposure to the child.
   b. Prevalence of tuberculosis in the population group.
   c. Presence of underlying host factors in the child (immunosuppressive conditions or HIV infection).
3. Children who have immigrated or been adopted from another country may have received an immunization for tuberculosis (BCG vaccine). It is not recommended in the United States because of low effectiveness.
   a. BCG may cause a false-positive tuberculosis (TB) skin test; however, screening for tuberculosis should still occur.

b. Interferon-gamma release assays (IGRAs) are the preferred method of testing for tuberculosis in those immunized with BCG. An IGRA measures how strong a person's immune system reacts to TB bacteria by testing the person's blood in a laboratory.

c. Chest x-ray confirms pulmonary disease.

EVIDENCE BASE Fry, S., Barnabas, S., & Cotton, M. (2018). Update on trends in childhood tuberculosis. *Current Opinion in Pediatrics*, 30(1), 152–160.

Measles Vaccine

1. Usually given between ages 12 and 15 months, but should be given at 12 months in high-risk areas. Second dose is recommended between ages 4 and 6 years.
2. Administered subcutaneously.
3. During an outbreak, infants as young as age 6 months can be immunized. A second dose should be given between ages 12 and 15 months and again at school entry.
4. Mild postimmunization symptoms include transient skin rashes and fever up to 2 weeks after vaccination.
5. Immunoglobulin preparations will interfere with the serologic response to measles vaccine; therefore, wait the specified time after administration for vaccination.

Meningococcal Vaccine

1. Usually given between the ages of 11 and 12 years, with a booster dose at age 16 years for healthy children. Is administered earlier (minimum age of 9 months) for some children with underlying conditions or children who are resident or travel to countries with epidemic disease.
2. Administer the MPSV4 vaccine subcutaneously into the fat of the arm. The MCV4 vaccines are given IM.
3. Mild postimmunization symptoms such as local discomfort may occur. A small percentage of those who receive the vaccine may develop a fever. Severe reactions (such as an allergic reaction) are very rare.

Mumps Vaccine

1. Usually administered in combination with measles and rubella vaccine between ages 12 and 15 months.
2. Second dose administered as MMR is important because a substantial number of cases have occurred in people with previous immunizations.
3. Important to immunize susceptible children approaching puberty, adolescents, and adults.

Rubella Vaccine

1. Two doses of rubella vaccine are recommended to avoid consequences such as congenital rubella syndrome; usually administered in combination with mumps and measles.

2. Important to immunize postpubertal individuals, especially college students and military recruits.
3. Women should avoid pregnancy within 3 months of vaccine because of the theoretical risk to the fetus.

Polio Vaccine

1. Two types of trivalent vaccine have been developed—OPV and IPV (given IM or subcutaneously). Both are effective in preventing poliomyelitis; however, as of 2000, both the ACIP and CDC recommend exclusive use of IPV for infants and children in the United States, to reduce the risk of vaccine-induced polio from OPV.
2. Because live OPV is excreted in the stool for up to 1 month after vaccination, vaccine-induced polio is a risk to both the nonimmune child and any immunosuppressed contact.

Haemophilus Influenzae Type B Vaccine

1. Incidence of invasive disease caused by Hib has declined dramatically since the introduction of the conjugate vaccine.
2. Several different types of Hib vaccines are available. Different vaccines have different schedules.
3. Minimal adverse reactions (pain, redness, or swelling at immunization site for less than 24 hours).

Hepatitis B Vaccine

1. There are two schedules for this vaccine. Infants born to hepatitis B surface antigen (HBsAg)–negative mothers should receive the routine schedule. Infants born to HBsAg-positive mothers should be on an accelerated vaccination schedule.
2. Recommended for all infants born to HBsAg-negative mothers. Three-dose schedule is initiated in neonatal period or by age 2 months; the second dose is given 1 to 2 months later; the third dose, 6 to 18 months later.
3. All infants born to HBsAg-positive mothers, including premature neonates, should receive hepatitis B immunoglobulin and HBV within 12 hours after birth. The second dose is given between ages 1 and 2 months; the third dose is given at age 6 months.
4. Preterm neonates weighing less than 2,000 g may have lower seroconversion rates. Initiation of HBV should be delayed until just before hospital discharge if the infant weighs 2,000 g or more or until about age 2 months when other routine immunizations are given.
5. All children and adolescents who have not had HBV should be immunized.
6. Administered IM.

Pneumococcal Vaccines

1. There are two types of pneumococcal vaccines:
   a. PCV7/Prevnar (must be administered IM).
   b. 23-valent PPV/Pneumovax (may be given IM or subcutaneously).
2. Since 2000, the pneumococcal has been included in the recommended childhood vaccines for all children ages 2 to 23 months and for certain children ages 2 to 5 years.

3. Efficacy for the vaccine is 97%, and the adverse effects are mild (fever and localized tenderness and redness at the injection site).
4. PPV is recommended for children ages 2 to 5 years in certain high-risk groups (sickle cell disease, functional or anatomic asplenia, nephrotic syndrome, chronic renal failure, immunosuppressive disorders, HIV infection, and cerebrospinal fluid leak).

Influenza Vaccine

1. The influenza vaccine known as TIV or LAIV contains three virus strains and is changed yearly, based on predictions of predominate strains expected to circulate in the upcoming influenza season. LAIV was approved for use in those ages 2 through 49 years in the United States in 2003 and is administered intranasally. TIV is available in both pediatric and adult formulations and is administered IM.
2. The influenza vaccine should be given annually to children ages 6 months through 18 years. The "Recommended Immunization Schedule" provides more specifics.
3. This vaccine is given annually, before flu season, usually in October, November, or December.
4. In children ages 8 years and younger, the first time influenza vaccine is administered, two doses should be given 1 month apart. In subsequent years, only one dose is needed.
5. TIV should be used for children with asthma, children 2 to 4 years who had wheezing in the past 12 months, or children who have any other underlying medical contraindications to the LAIV.
6. In recent years, LAIV has been less effective than the TIV, and therefore, many providers have chosen not to offer it to patients.

Rotavirus Vaccine

1. In 2006, a live, oral vaccine—RotaTeq—was licensed. In the United States, routine vaccination of infants—with three doses of rotavirus vaccine administered at 2, 4, and 6 months—is recommended.

Varicella Virus Vaccine

1. Varicella virus vaccine contains live, attenuated virus; approved for children 12 months and older and for adults.
2. Administered subcutaneously at 12 to 15 months; second dose at 4 to 6 years (or at least 3 months after first dose).
3. May be given to older children and adults who do not have immunity. In those older than age 13, the second dose may be delayed only 4 weeks following first dose.

NURSING ALERT Millions of children travel overseas every year, risking exposure to infectious diseases not covered by routine immunizations. Refer families to their local public health department or retail travel clinic for special immunizations and malaria prophylaxis.

Nutrition in Children

The nutritional status of the child is an important aspect of health maintenance. A balanced diet influences child growth and psychosocial development. Feeding provides emotional and psychological benefits in addition to nutritional needs. In the United States, obesity in childhood has become a major problem, and in developing countries, undernutrition—due to scarcity of nutrient-rich foods—leads to malnutrition and illness. In addition, anorexia, bulimia, and other dietary restrictions may place children and adolescents at risk for serious health consequences. Good eating habits, nutrient-rich foods, and physical activity introduced early in life can help foster good nutrition practices into adulthood. Nurses can be instrumental in providing factual information to both parents and children on typical nutritional needs and those required for specific sport participation. Table 42-1 presents nutritional guidelines based on age and developmental maturation.

Table 42-1 Nutrition in Children

AGE AND DEVELOPMENTAL INFLUENCE ON NUTRITIONAL REQUIREMENTS AND FEEDING PATTERNS	FEEDING PATTERN AND DIET	NURSING CONSIDERATIONS AND PARENTAL GUIDANCE
Neonate		

Birth–4 weeks
• Neonate's rapid growth makes infant especially vulnerable to dietary inadequacies, dehydration, and iron deficiency anemia.
• Feeding process is basis for infant's first human relationship, formation of trust.
• Neonates require more fluid relative to their size than do adults.
• Sucking ability is influenced by individual neuromuscular maturity.
	• Breast milk or formula is generally given in 6–8 feedings per day, spaced 2–4 hours apart.
	• Feeding schedules should be individualized according to infant's needs.
	• Breast-fed infants should receive 400 IU of supplemental vitamin D daily, beginning in the first few days of life. Supplementation should continue until baby is weaned to at least 1 qt (1 L) of whole milk per day. Whole milk should not be used until after 12 months of age.
	• Human milk contains little iron, so infants who are exclusively breast-fed are at increased risk of iron deficiency after 4 months of age. It is recommended that infants be given 1 mg/kg/day of a liquid iron supplement until iron-containing solid foods are introduced at about 6 months of age.
	• Infant formula should be iron fortified to prevent anemia.
	• All formulas sold in the United States have at least 400 IU/L of vitamin D; if baby is drinking at least 32 ounces of formula, vitamin D supplementation is not needed.
		• Provide information to help parents make decision concerning breast- or bottle-feeding.
		• Support parents in their decision.
		Breast-fed infant:
		• Help mother assume comfortable and satisfying position for self and baby.
		• Help mother to determine schedule, timing, and when infant is satisfied.
		• Provide specific information about:
		  • Feeding technique: position, "bubbling/burping"
		  • Care of breasts
		  • Manual expression of milk from breast
		  • Maternal diet
		Bottle-fed infant:
		• Provide specific information about:
		  • Type of formula
		  • Preparation of formula: measuring and sterilization
		  • Equipment—types of bottles and nipples
		  • Sterilization of equipment
		  • Technique of feeding: position, "bubbling/burping"
		• Help mother to determine when infant is satisfied; develop schedule for feeding.
		• Provide information about normal characteristics of stools, signs of dehydration, constipation, colic, milk allergy.
		• Discuss need for prescribed supplements and how to administer (by dropper).
		• Discuss need for additional fluids during periods of hot weather and with fever, diarrhea, and vomiting.
		• Observe for evidence of common problems and intervene accordingly:
		  • Overfeeding
		  • Underfeeding
		  • Difficulty digesting formula because of its composition
		  • Improper feeding technique; holes in nipples too large or too small; formula too hot or too cold; uncomfortable feeding position; failure to "bubble/burp"; improper sterilization; bottle propping
		  • Bottles should never be given to infants to take to bed.

Infant		
3 months–1 year overview • Increased neuromuscular development allows infant to make transition from a totally liquid diet to a diet of milk and solid foods as well as to more active participation in the feeding process. **3–6 months** • Sucking reflex becomes voluntary and chewing action begins; infant can approximate lips to rim and cup and may begin drinking from cup at 6 months.	• Number of feedings per day decreases through the first year. • By ages 4–6 months, generally ready to begin strained foods. The usual sequence of foods is cereal followed by vegetables and fruits. Meats may be started between 8 and 9 months. Sequence may vary according to preferences of the family and health care provider.	• The person feeding should be calm, gentle, relaxed, and patient in approach. • When first offered puréed foods with a spoon, the child expects and wants to suck. The protrusion of the tongue, which is needed in sucking, makes it appear as if the child is pushing the food out of the mouth. This response should not be interpreted as dislike for the food; it is a result of immature muscle coordination and surprise at the taste and feel of the new food. • The baby foods selected should be high in nutrients without providing excessive calories. Personal and cultural preferences should be considered. Iron-fortified formulas and cereals are needed to prevent physiologic anemia. • New foods should be offered one at a time and early in the feeding while the infant is still hungry. Allow 3–5 days between new foods to assess for any allergic reaction.

6–12 months

- Loses maternal iron stores at 6 months; first tooth erupts between ages 6 and 9 months; eyes and hands can work together; infant can sit without support and has developed grasp; can feed self a biscuit; bangs objects on table; able to hold own bottle between ages 9 and 12 months; can "pincer" grasp food; able to be weaned from bottle as child becomes developmentally able to take sufficient fluids from the cup.
- Food provides the infant with a variety of learning experiences; motor control and coordination in self-feeding; recognition of shape, texture, and color; stimulation of speech movement through use of mouth muscles.
- Mealtime allows the infant to continue development of trust in a consistent, loving atmosphere. The infant is forming lifetime eating habits; it is therefore important to make mealtime a positive experience.
- Mashed table foods or junior foods are generally started between ages 6 and 8 months, when infant begins chewing action.
- Infant begins to enjoy finger foods between ages 10 and 12 months.
- The transition from iron-fortified formula or breast milk to cow's milk is usually advised at about age 12 months.
- By age 1 year, most infants are satisfied with three meals and additional fluids throughout the day.
- Infants should be observed for allergic reactions when new foods are added. Common allergies are to citrus juices, egg whites, and cow's milk. These foods should be avoided until age 12 months. New research has shown early introduction of peanuts into the diet of infants at high risk of peanut allergy can play a role in the prevention of peanut allergies. Health care providers may recommend introducing peanut containing products into the diets of infants between ages 4 and 11 months.
- Honey should be avoided until age 12 months because of the risk of infantile botulism.
- Finger foods should be selected for their nutritional value. Good choices include teething biscuits, cooked vegetables, bananas, cheese sticks, and enriched cereals. Avoid nuts, raisins, and raw vegetables, which can cause choking.
- Parents can be taught to prepare their own strained or junior foods using a commercial baby food grinder or blender.
- Weaning is a gradual process.
  - Assist parents to recognize indications of readiness.
  - Do not expect the infant to completely drop old pattern of behavior while learning a new one; allow overlap of old and new techniques.
  - Evening feedings are usually the most difficult to eliminate because the infant is tired and in need of sucking comfort.
  - During illness or household disorganization, the infant may regress and return to sucking to relieve his or her discomfort and frustration.

NURSING ALERT Obtain a thorough nursing history for the hospitalized infant that includes feeding pattern and schedule; types of foods that have been introduced; likes and dislikes; breast- or bottle-fed, type of bottle; and temperature at which infant prefers foods and fluids.

Toddler

1–3 years

- Growth slows at the end of the first year. The slower growth rate is reflected in a decreased appetite.
- The toddler has a total of 14–16 teeth, making him or her more able to chew foods.
- Increased self-awareness causes the toddler to want to do more for self. Refusal of food or refusal of assistance in feedings are common ways in which the toddler asserts self.
- Because body tissues, especially muscles, continue to grow quite rapidly, protein needs are high.
- Transition from a bottle to a cup before, or at the age of 1 is recommended to prevent tooth decay.
- Appetite is sporadic; specific foods may be favored exclusively or refused from time to time.
- Child may be ritualistic concerning food preferences, schedule, and manner of eating.
- Diet should include a full range of foods: milk, meat, fruits, vegetables, breads, and cereals. Iron-fortified dry cereals (rice, barley) are an excellent source of iron during the second year of life.
- Provide foods with a variety of colors, textures, and flavors. Toddlers need to experience the feel of foods.
- Offer small portions. It is fun for the child to ask for more. It is more effective to give small helpings than to insist that he or she eat a specific amount.
- Maintain a regular mealtime schedule.
- Provide appropriate mealtime equipment:
  - Silverware scaled to size
  - Dishes—colorful, unbreakable; shallow, round bowls are preferable to flat plates
  - Plastic bibs, placemats, and floor coverings permit a relaxed attitude toward child's self-feeding attempts
  - Comfortable seating at good height and distance from table
- Adults who help toddlers at mealtime should be calm and relaxed. Avoid bribes or force-feeding because this reinforces negative behavior and may lead to a dislike for mealtime. Encourage independence, but provide assistance when necessary. Do not be concerned about table manners.

Toddler (*Continued*)	• Older toddler can be expected to consume about one half the amount of food than an adult consumes. • Whole milk is recommended up to age 2 years.	• Avoid the use of soda or "sweets" as rewards or between-meal snacks. Instead, substitute fruit or cereal. • Toddlers who show little interest in eggs, meat, or vegetables should not be permitted to appease their appetite with carbohydrates or milk because this may lead to iron deficiency anemia. Milk should be limited to ~16 ounces a day and should be offered after solid foods. **NURSING ALERT** Nursing history for the hospitalized toddler should include feeding pattern and schedule; food likes and dislikes; food allergies; special eating equipment and utensils; whether child is weaned; and what child is fed when ill.

Preschooler
3–5 years
• Increased manual dexterity enables child to have complete independence at mealtime.
• Psychosocially, this is a period of increased imitation. The preschooler identifies with parents at the table and will enjoy what parents enjoy.
• Additional nutritional habits are developed that become part of the child's lifetime practices.
• Slower growth rate and increased interest in exploring his or her environment may decrease the preschooler's interest in eating.
• Eating assumes increasing social significance. Mealtime promotes socialization and provides the preschooler with opportunities to learn appropriate mealtime behavior, language skills, and understanding of family rituals.
 	
NURSING ALERT Consider cultural differences. Allow parents to bring in favorite foods or eating utensils from home for the hospitalized preschooler. Encourage family members to be present at mealtime.
	• Appetite tends to be sporadic.
	• Child requires the same basic four food groups as the adult, but in smaller quantities.
	• Generally likes to eat one food from plate at a time.
	• Likes vegetables that are crisp, raw, and cut into finger-sized pieces. Often dislikes strong-tasting foods.
		• Emphasis should be placed on the quality rather than the amount of food ingested.
		• Foods should be attractively served, mildly flavored, plain, as well as separated and distinctly identifiable in flavor and appearance.
		• Nutritional foods (eg, crackers and cheese, yogurt, fruit) should be offered as snacks.
		• Desserts should be nutritious and a natural part of the meal, not used as a reward for finishing the meal or omitted as punishment.
		• Unless they persist, periods of overeating or not wanting to eat certain foods should not cause concern. The overall eating pattern from month to month is more pertinent to assess.
		• Frequent causes of insufficient eating:
		  • Unhappy atmosphere at mealtime
		  • Overeating between meals
		  • Parental example
		  • Attention-seeking.
		  • Excessive parental expectations
		  • Inadequate variety or quantity of foods
		  • Tooth decay
		  • Physical illness
		  • Fatigue
		  • Emotional disturbance
		• Measures to increase food intake:
		  • Allow child to help with preparations, planning menu, setting table, and other simple chores.
		  • Maintain calm environment with no distractions.
		  • Avoid between-meal snacks.
		  • Provide rest period before meal.
		  • Avoid coaxing, bribing, threatening.
		• Place children in small groups, preferably at tables during mealtime. Use nursing history to determine likes and provide simple foods in small portions. Peanut butter and jelly sandwiches are often favorites. Allow and encourage children to feed themselves. Do not punish children who refuse to eat. Offer alternative foods.

School-Age Child

- Slowed growth rate during middle childhood results in gradual decline in food requirements per unit of body weight.
- The preadolescent growth spurt occurs about age 10 in girls and about age 12 in boys. At this time, energy needs increase and approach those of the adult. Intake is particularly important because reserves are laid down for the demands of adolescence.
- The child becomes dependent on peers for approval and makes food choices accordingly.
- The child experiences increased socialization and independence through opportunities to eat away from home (eg, at school and homes of peers).

- By this time, food practices are generally well established, a product of the eating experiences of the toddler and preschool period.
- Many children are too busy with other affairs to take time out to eat. Play readily takes priority unless a firm understanding is reached and mealtime is relaxed and enjoyable.

- Nutrition education should help the child to select foods wisely and to begin to plan and prepare meals.
- Parental attitudes continue to be important as the child copies parental behavior (eg, skipping breakfast, not eating certain foods, consuming fast foods frequently).
- Most children require a nutritious breakfast to avoid lassitude in late morning.
- Mealtime should continue to be relaxed and enjoyable. Diversions, such as television, should be avoided.
- Calcium and vitamin D intake warrant special consideration. They must be adequate to support the rapid enlargement of bones.
- Parents and health care professionals should be alert to signs of developing obesity. Intake should be altered accordingly.
- Table manners should not be overemphasized. The young child typically stuffs mouth, spills food, and chatters incessantly while eating. Time and experience will improve habits.
- Provide some companionship and conversation at the child's level during meals. Peers should be invited occasionally for meals.

NURSING ALERT Nursing history of the hospitalized child should include food preferences; mealtime patterns and snacks; food allergies; and food preferences when ill. Provide opportunities for children to eat in small groups at tables. Consider cultural differences. Allow parents to bring in favorite foods from home. Allow child to order his or her own meal.

Adolescent

11–17 years

- Dietary requirements vary according to stage of sexual maturation, rate of physical growth, and extent of athletic and social activity.
- When rapid growth of puberty appears, there is a corresponding increase in energy requirements and appetite.
- Menstruating teen is particularly susceptible to iron deficiency anemia.

- Previously learned dietary patterns are difficult to change.
- Food choices and eating habits may be quite unusual and are related to the adolescent's psychological and social milieu.
- Generally, a significant percentage of the daily caloric intake of the adolescent comes from snacking.

- Continue nutrition education, with emphasis on:
  - Selecting nutritious foods high in iron
  - Nutritional needs related to growth
  - Preparing favorite "adolescent foods"
  - Foods and physical fitness
- Informal sessions are generally more effective than lectures on nutrition.
- Special problems requiring intervention:
  - Obesity
  - Excessive dieting
  - Extreme fads—eccentric and grossly restricted diets
  - Anorexia nervosa and bulimia
  - Adolescent pregnancy
  - Iron deficiency anemia
- Provide nutritious foods relevant to the adolescent's lifestyle.
- Discourage cigarette smoking, which may contribute to poor nutritional status by decreasing appetite and increasing the body's metabolic rate.

NURSING ALERT Allow hospitalized adolescent to choose own foods, especially if on a special diet. Provide a refrigerator in the recreation room for snacks or utilize a snack cart. Serve foods that appeal to adolescents. Use a nursing history similar to that for the school-age child.

EVIDENCE BASE Lewis, E., Richard, C., Larsen, B., & Field, C. (2017). The importance of human milk for immunity in preterm infants. *Clinics in Perinatology, 44*(1), 23–47.

Breast-Feeding

1. Breast-feeding is the natural and ideal nourishment that will supply an infant with adequate nutrition as well as immunologic and anti-infection properties. With breast milk being at the proper temperature, it may prevent other GI disturbances as well. The development of allergies is reduced in breast-fed babies.
2. Breast-feeding is recommended solely for infants up to 6 months of age. As the infant grows and develops, the breast milk properties change in respect to amounts of fat, carbohydrates, and protein as well as physical properties such as pH needed for the respective age of the infant.
3. Breast-feeding provides psychological and emotional satisfaction for the infant and mother and can promote bonding. The physical closeness may also provide comfort after a frightening or painful procedure.
4. Breast-feeding can be continued through most illnesses and hospitalizations of the infant. In times of stress, the infant may cope with breast-feeding better than bottle-feeding. Because breast milk is more easily and quickly digested, shorter periods without food preoperatively and postoperatively may be necessary. Attempts should be made to maintain the breast-feeding bond and routines of the child and mother.
    a. Supplemental artificial formula can be given to the infant if the mother is not available.
    b. The mother can pump her breasts so that milk can be given to the infant by way of bottle when she is not available.
    c. Breast milk can be frozen for up to 6 months (check the facility's specific policy).
    d. Thaw frozen breast milk for use in tepid water. Do not use a microwave, which may destroy vitamins and nutritional properties as well as result in extreme overheating of portions of the breast milk.
5. Stress of new motherhood or illness in the infant or mother may decrease the mother's milk supply and inhibit her "let-down" reflex, as well as increase or decrease the infant's desire to suckle. Pumping may be initiated to help stimulate the mother's milk supply. An electronic pump may be necessary if prolonged pumping is expected or if manual pumping is not successful.
6. Education and encouragement should be offered to all new mothers and those having difficulty or concerns about breast-feeding.

Bottle-Feeding

1. Bottle-feeding is a method of supplying nutrition to the infant by oral feedings, using a bottle and nipple setup.
2. Bottle-feeding can supplement breast-feeding with formula or water or can be the sole means of nutritional intake for the infant.
3. Bottle-feeding can also provide intermittent feedings of expressed breast milk when the mother cannot be present at the time of the feeding.
4. Bottle-feeding can be a time of bonding between the mother and infant. The father or other capable members of the family should be taught bottle-feeding technique as well.
5. Some mothers may have chosen bottle-feeding for a variety of reasons, ranging from poor milk production, discomfort (psychological or physical) with breast-feeding, or drug treatment not compatible

with breast-feeding. It is important that health care providers offer mothers information on all methods of feeding, but not be judgmental when the mother chooses one method over another.

Safety

Safety is an important aspect of child health and well-being. Injuries are the leading cause of death for children in the United States. Additionally, injury is a significant cause of childhood morbidity. Although childhood deaths from other causes have decreased, deaths from injuries remain constant.

Role of the Nurse

1. Identify environmental hazards and act to reduce or eliminate them.
2. Identify behavioral characteristics of individual children that may be related to accidental liability and caution parents accordingly. Pay particular attention to children who show the following:
   a. Characteristics that increase exposure to hazards, such as excessive curiosity, inability to delay gratification, hyperactivity, and daringness.
   b. Characteristics that reduce the child's ability to cope with hazards, such as aggressiveness, stubbornness, poor concentration, low frustration threshold, poor impulse control, and lack of self-control.
3. Provide anticipatory guidance about child development as it relates to accidents. Direct preventive teaching toward the intended audience, be it individuals or groups, children or adults.
4. Participate in policy setting for accident prevention, with great emphasis on effective public health measures.

Principles of Safety

1. The type of accident likely to occur is influenced by the child's age and developmental level. Parents who have knowledge of their own child's typical behavior patterns may foresee potential accident situations.
2. Children are naturally curious, impulsive, and impatient. The young child needs to touch, feel, and investigate. Consistent adult supervision will enable children to learn in a safe environment.
3. Children copy the behavior of their parents and absorb parental attitudes. Parents and other adults should be a role model for using proper and safe methods.
4. Children become less careful and less willing to listen to warnings and to observe routine safety precautions when they are tired or hungry.
5. An estimated 90% of all accidents are preventable.

General Areas of Adult Responsibility for Child Safety

Motor Vehicle

EVIDENCE BASE Evidence Base American Academy of Pediatrics. (2017). Car seats: Information for families. Available: *https://healthychildren.org/English/safety-prevention/on-the-go/Pages/Car-Safety-Seats-Information-for-Families.aspx*.

---

1. Automobiles should be in good mechanical condition.
2. Use properly fitted and installed car seats and seat belts. Be aware of the guidelines for restraints based on the child's age, weight, and height.
    a. Rear-facing car seat until age 2, or if child has outgrown the manufacturer's recommendation for maximum height and weight.
    b. Front-facing car seat from age 2 until the child has outgrown the manufacturer's recommendation for maximum height and weight.
    c. Belt-positioning booster seat until the vehicle seat belt fits properly, typically when the child has reached 4 feet, 9 inches in height, between 8 and 12 years of age.
3. All children younger than 13 years should be restrained in the rear seats of vehicles (when the vehicle has a rear seat with lap and shoulder belts) for optimal protection. The center rear seat is the safest seat for a child.
4. The driver should look carefully in front and back of the car before getting into the car.
5. Lock all car doors.
6. Never leave young children in a car alone.
7. Do not place heavy or sharp objects on the same seat with a child.

Sports and Recreation

1. Keep equipment in good condition and proper working order.
2. Ensure that children are aware of the correct use of sports equipment.
3. Encourage the routine use of bike helmets (see Figure 42-1).
4. Wear appropriate clothing and safety equipment for the activity (see Figure 42-2).
5. Do not attempt activities beyond one's physical endurance.
6. Keep firearms and ammunition locked in different locations.

Figure 42-1. Use of bike helmets by all children for safety.

Figure 42-2. Use of appropriate pads and helmets for safety.

Electrical and Mechanical Equipment

1. Only underwriter-approved devices should be installed; they should be inspected periodically.
2. Dry hands before touching appliances. Keep radios, transportable heaters, and hair dryers out of the bathroom.
3. Disconnect appliances after each use and before attempting minor repairs.
4. Keep garden equipment and machinery in a restricted area. Teach proper use of the equipment as soon as the child is old enough.
5. Avoid overloading electrical circuits.
6. Discourage children from playing with or being in area where appliances or power tools (eg, washing machine, clothes dryer, saw, lawn mower) are in operation.

Prevention of Falls

1. Keep stairs well lit and free from clutter.
2. Use gates at tops and bottoms of stairways where toddlers have access.
3. Provide sturdy railings.

4. Anchor small rugs securely.
5. Use rubber mats in the bathtub and shower.
6. Use only sturdy ladders for climbing.
7. The American Academy of Pediatrics and the National Association of Children's Hospitals and Related Institutions have recommended that baby walkers be banned as most injuries using these walkers will occur even when adults are present (rolling down stairs, burns, drowning, reaching unsafe objects because of greater stability provided by walkers).

Poisonings and Ingestions

1. Do not mix bleaches with ammonia, vinegar, and other household cleaners.
2. See section on ingested poisons and pediatric poisoning (see page 1133).
3. Label poisonous household materials, and keep them out of child's reach.
4. Become familiar with the telephone number for poison control centers where available. Post local poison control phone number in easily accessible location (eg, refrigerator door).

Fire

1. Maintain an adequate fire escape plan and routinely conduct home fire drills. Teach children escape routes as soon as they are old enough.
2. Keep a pressure-type, handheld fire extinguisher on each floor. Regularly check expiration or necessary inspection dates. Consider additional units in areas where there are higher risk of fires (kitchen, laundry room, garage). Instruct all family members who are old enough in its use.
3. Fit fireplaces with snug fireplace screens.
4. Store gasoline and other flammable fluids in tightly covered containers that are clearly labeled, away from heat and sparks, and out of reach.
5. Dispose of paint- and oil-soaked cloths promptly.
6. Use flame-retardant sleepwear.
7. Mark children's rooms so they are obvious to firefighters.
8. Teach children about the danger of smoke inhalation.
9. Teach children to stop, drop, and roll if their clothing catches fire.
10. Maintain smoke and carbon monoxide detectors in working order.
11. Keep lighters and matches out of the reach of children.
12. Keep children away from heated oven, stovetop, and outdoor grill.

Swimming Pools

1. Completely enclose pool with a fence that complies with local regulations. The gate should be self-closing and have a lock.
2. Indicate water depth with numbers on the edge of the pool. Place a safety float line where the bottom of the slope begins to deepen.

3. Install at least one ladder at each end of the pool. Ladders should have handrails on both sides, and the diameter of the rails should be small enough for a child to grasp.
4. Use nonslip materials on ladders, deck, and diving boards.
5. If the pool is used at night, install underwater lighting as well as outdoor lights.
6. Install a ground fault circuit interrupter on the pool circuit to cut off electrical power and thus prevent electrocutions should electrical fault occur.
7. Instruct children about safety rules, such as not swimming alone, need for adult supervision, not running around the pool, and not pushing others. Avoid using radios or other electrical appliances around the pool.
8. Warn children not to attempt to walk on any remaining pool water after the season—frozen water or pool-covering equipment.
9. Keep essential rescue devices and first-aid equipment close to the pool.

Emergency Precautions

1. Record emergency telephone numbers in an obvious and easily accessible place.
2. Keep a well-stocked first-aid kit immediately available for emergencies. It is helpful to also carry a small first-aid kit in family vehicles.
3. Give instruction in principles of first aid to all family members who are old enough.
   a. Responsible adults should enroll in first-aid courses offered by the American Red Cross and adult education programs.
   b. Be aware of first-aid procedure for the following conditions: burns, electric shock, poisoning, bites and stings, wounds, near drowning, fractures, cardiopulmonary arrest.
   c. Teach children safety precautions concerning bicycles, answering the telephone or door, strangers outside the home, and street safety.
4. Know the location of gas, water, and electrical switches and how to turn them off in an emergency.
5. Teach children their addresses and telephone numbers and how to dial 911 in case of emergency.

Miscellaneous

1. Take advantage of preventive health care.
   a. Obtain recommended immunizations.
   b. Have regular physical and dental examinations.
2. Seek immediate treatment of all diseases and health problems.
3. Balance periods of work, rest, and exercise in daily living.

PEDIATRIC CARE TECHNIQUES

Nursing Management of the Child with Fever

EVIDENCE BASE Peetoom, K., Sits, J., & Ploum, L. (2017). Does well-child care education improve consultations and medication management for childhood fever and common infections: A systematic review. *Archives of Disease in Childhood*, 102, 261–267.

Fever is an abnormal elevation of body temperature. Prolonged elevation of temperature above 104°F (40°C) may produce dehydration and harmful effects on the central nervous system (CNS).

General Considerations

1. Consider basic principles related to temperature regulation in pediatric patients.
   a. Usually, an infant's temperature does not stabilize before age 1 week. A neonate's temperature varies with the temperature of the environment.
   b. The degree of fever does not always reflect the severity of the disease. A child may have a serious illness with a normal or subnormal temperature.
   c. Febrile seizures may occur in some children when the temperature rises rapidly.
   d. The range for normal temperature varies widely in children. A common explanation for "fever" is misinterpretation of a normal temperature reading.
   e. A child's temperature is influenced by activity and by the time of day; temperatures are highest in late afternoon.
2. Temperature interpretation depends on accurate temperature measurement in a child. The mode should be appropriate for the child's age and condition, and the thermometer should be left in place for the required time period. Parents or caregivers should be taught the appropriate assessment of temperature as the child grows.

Causes of Fever in Children

1. Infection.
2. Inflammatory disease.
3. Dehydration.
4. Tumors.
5. Disturbance of temperature-regulating center.
6. Extravasation of blood into the tissues.
7. Drugs or toxins.

Nursing Assessment

1. Assess history of present illness for source of fever.

a. Age of the child.
b. Pattern of the fever.
c. Length of the illness.
d. Change in normal patterns of eating, elimination, and recreation.
e. Other symptoms—poor feeding, cough, earache, diarrhea, vomiting, and rash.
f. Exposure to any illness.
g. Recent immunizations or drugs.
h. Treatment of fever and effectiveness of treatment, including appropriate dosing of antipyretic medications.
i. Previous experiences with fever and its control.

2. Assess the general appearance of the child.
3. Perform a systematic physical assessment.
   a. Inspection of the skin for rashes, sores, or flushed appearance.
   b. Inspection of eyes, ears, nose, and throat for redness and drainage.
   c. Auscultation of the lungs for abnormal sounds.
   d. Neurologic observation for changes in state of consciousness, pupillary reaction, strength of grip, abnormal muscle movement, or lack of movement.
   e. Inspection of external genitals for redness and drainage.
   f. Presence of abdominal or flank tenderness.
4. Assist with laboratory tests, as indicated. Initial tests typically include complete blood count; urinalysis; cultures of the throat, nasopharynx, urine, blood, and spinal fluid; and chest x-ray.
5. Attempt to identify the pattern of the fever. Take the child's temperature by the same method every hour until stable, then every 2 hours until normal, then every 4 hours for 24 hours.

Nursing Measures to Reduce Fever

Fever does not necessarily require treatment. The presence of fever should not be obscured by the indiscriminate use of antipyretic measures. However, if the child is uncomfortable or appears toxic because of fever, an attempt should be made to reduce it by any of the following nursing measures or by a combination of these measures:

1. Increase the child's fluid intake to prevent dehydration.
2. Expose the skin to the air by leaving the child lightly dressed in absorbent material. Avoid warm, binding clothing and blankets.
3. Administer antipyretic drugs, as prescribed. Avoid aspirin/acetyl salicylic acid as its use is known to result in Reye syndrome (encephalopathy, fatty degeneration of the liver with associated hypoglycemia) in some children. Children ages 4 to 12 years with a viral illness are at greatest risk for Reye syndrome.
4. Use a tepid tub or sponge bath or a hypothermia blanket. Do not allow the child to shiver, as that may increase the body temperature.

Administering Medications to Children

Administration of medication can be traumatic for children. The proper approach to administration can facilitate the process and enhance the child's understanding of the importance of taking medications.

Important Considerations

1. The manner of approach should indicate that the nurse firmly expects the child to take the medication. This manner usually convinces the child of the necessity of the procedure.
2. Establishing a positive relationship with the child will allow expression of feelings, concerns, and misconceptions regarding medications.
3. Explanation about medication should be directed to the child's level of understanding (ie, through play or comparison to something familiar).
4. The nurse must mask her or his own feelings regarding the medication.
5. Always be truthful when the child asks, "Does it taste bad?" or "Will it hurt?" Respond by saying, "The medication does not taste good, but I will give you some juice as soon as you swallow it," or "It will hurt for just a minute."
6. It is typically necessary to mix distasteful medications or crushed pills with a small amount of carbonated drink, cherry syrup, ice cream, or applesauce. After mixing, monitor to ensure that the child finishes the preparation.
7. Never threaten a child with an injection when refusing oral medication.
8. Do not mix medications with large quantities of food or with any food that is taken regularly (eg, milk).
9. Avoid giving medications to a child at mealtime unless specifically prescribed.
10. For each medication administered, the nurse should know the common use, safe dosage based on the child's weight, contraindications, adverse effects, and toxic effects.
11. The child must be accurately identified before medication is given.
12. When preparing IM injections, draw 0.2 cc of air into the syringe, in addition to the correct amount of medication. This clears the medication from the needle on injection and prevents backflow and the depositing of medication in subcutaneous fat when the needle is withdrawn.
13. Physical intervention (through swaddling, side or stomach position, shushing, swinging, sucking) and oral sucrose administration have been shown through research to reduce pain reactions in infants ages 2 and 4 months during vaccine injections.

EVIDENCE BASE Saleh, E., Swamy, G., Moody, A. & Walter, E. (2017). Parental Approach to the Prevention and Management of Fever and Pain Following Childhood Immunizations. *Clinical Pediatrics*, 56(5), 435–442.

Calculating the Pediatric Dosage

General Principles

1. The nurse is responsible for knowing the safe dosage range for the medication she administers.
2. Factors determining the amount of drug prescribed include the following:
   a. Action, absorption, detoxification, and excretion of the drug are related to the maturity and metabolic rate of the child.
   b. Neonates and premature neonates require a reduced dosage because of:
      i. Deficient or absent detoxifying enzymes.
      ii. Decreased effective renal function.
      iii. Altered blood–brain barrier and protein-binding capacity.
   c. Dosage recommendations based on age groups are not satisfactory because a child may be much smaller or larger than the average child in the age group.
   d. Dosages based on child's weight are more accurate; however, these calculations have limitations.
3. Consult drug references for recommended dosage and other information, and be alert for prescription that would be inappropriate for a child.
4. Advise parents not to save unused medications that are unneeded or outdated, and do not give one child's prescription to another child.

Calculating by Body Surface Area

The following formulas are used to estimate the pediatric dosage based on the child's body surface area (BSA). BSA calculations are generally preferred because many physiologic processes in the child (eg, blood volume, glomerular filtration) are related to BSA.

1. Surface area in square meters × dose per square meter = approximate child dose.
2. Surface area of child/surface area of adult × dose of adult = approximate child dose.
3. Surface area of child in square meters/1.75 × adult dose = child dose.

Calculating by Clark Rule

Clark rule may be used as an estimate of the pediatric dosage based on the child's weight in respect to the adult dose of the drug:

Child's weight in pounds/150 × Adult dose = Approximate dose for child

---

NURSING ALERT Ensure proper identification of all patients via the identification bracelet before administration of medication.

Oral Medications

Infants

1. Draw up medication in a plastic dropper or disposable syringe.
2. Elevate the infant's head and shoulders; depress chin with thumb to open mouth.
3. Place dropper or syringe on the middle of the tongue and slowly drop the medication on the tongue.
4. Release thumb and allow the child to swallow.
5. When the correct amount of medication has been measured, it can be placed in a nipple and the infant can suck the medication through the nipple.
6. If the nurse feels comfortable managing the infant in her or his lap, it is acceptable to hold the infant for medication administration.

Toddlers

1. Draw up liquid medications in a syringe or measure into medicine cup. Medications may be placed in a medicine cup or spoon after being measured accurately in a syringe.
2. Elevate the child's head and shoulders.
3. Squeeze the cup and put it to the child's lips or place the syringe (without needle) in the child's mouth, positioning the syringe tip in the space between the cheek mucosa and gum, and slowly expel the medicine. Child may prefer using a familiar teaspoon.
4. Allow the child time to swallow.
5. Allow the child to hold the medicine cup if able and to drink it at his or her own pace. (This may be a more agreeable method.) Offer a favorite drink as a "chaser," if not contraindicated.
6. The small, safe medicine cups can be given to the child for play.

School-Age Children

1. When a child is old enough to take medicine in pill or capsule form, teach the child to place the pill near the back of the tongue and immediately swallow fluid such as water or fruit juice. If swallowing of the fluid is emphasized, the child will no longer think about the pill.
2. Always give praise after a child takes medication.
3. If the child finds it particularly difficult to take oral medications, express understanding and offer help.

Subcutaneous and Intramuscular Medications

General Considerations

1. After the medication to be given IM is drawn from the vial, draw up an additional 0.2 to 0.3 cc of air into the syringe, thus clearing the needle of medication and preventing medication seepage from the injection site.
2. When injecting less than 1 mL of medication, use a tuberculin syringe for accuracy.
3. Clean site thoroughly, using friction with an antiseptic solution; let site dry.
4. Establish anatomic landmarks and prepare to position the needle at a 45-degree angle for subcutaneous (SC) injection and a 90-degree angle for IM injection (see Figure 42-3). Alternate injection sites and

keep record at bedside or on medication card.

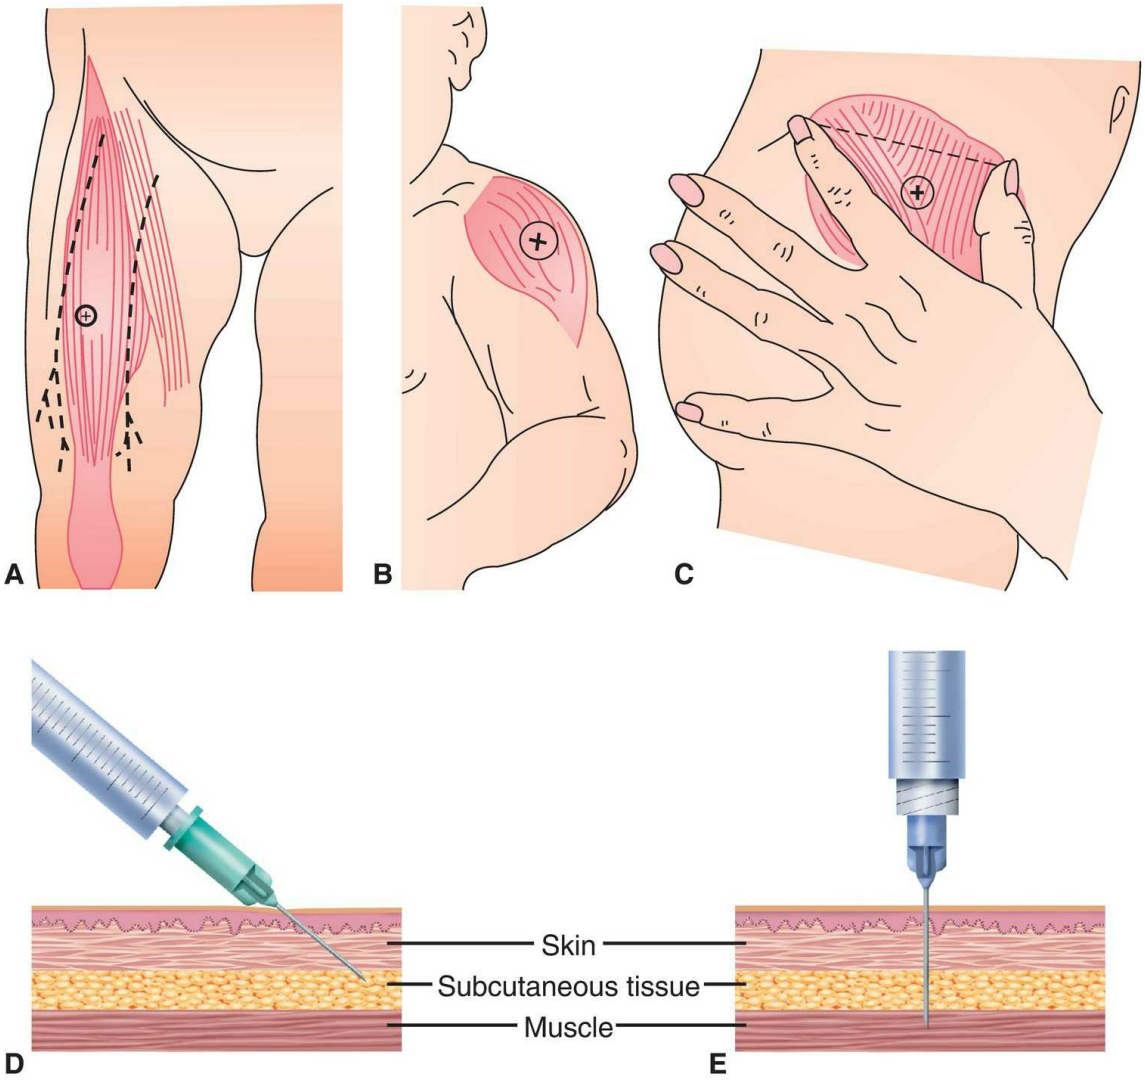

Figure 42-3 IM and subcutaneous injections in children. Sites for IM injections: **(A)** rectus femoris, **(B)** deltoid, **(C)** ventrogluteal, **(D)** subcutaneous, and **(E)** IM. (From Pillitteri, A. [2013]. *Maternal and child health nursing: Care of the childbearing and childrearing family* [7th ed.]. Philadelphia, PA: Lippincott Williams & Wilkins.)

5. With IM injections, after penetrating site, aspirate to check for blood vessel puncture. If this occurs, withdraw the needle, discard the medicine, and start again.
6. After injection, massage site (unless contraindicated). When multiple injections are being administered, such complications as fibrosis and contracture of the muscle can be diminished by massage, warm soaks, and range-of-motion exercises to disrupt and stretch immature scar tissue.

Infants

1. Acceptable sites for IM injections include the rectus femoris (anterior thigh, middle third), vastus lateralis (lateral thigh, middle third), or ventrogluteal, as these sites are relatively free from major nerves and blood vessels. The gluteus maximus and deltoid muscles are underdeveloped in the infant and use of these sites can result in nerve damage.

2. Rectus femoris injection.
    a. Place the child in a secure position to prevent movement of the extremity.
    b. Do not use a needle longer than 1 inch.
    c. Bunch the muscle between your thumb and forefinger.
    d. Insert needle at 90-degree angle or slightly toward the knee.
3. Vastus lateralis injection.
    a. Place the child in a prone or supine position.
    b. Area is a narrow strip of muscle extending along a line from the greater trochanter to lateral femoral condyle below.
    c. Insert needle at 90-degree angle, ¾ to 1½ inches (2 to 4 cm) deep.
4. Ventrogluteal injection.
    a. This site provides a dense muscle mass that is relatively free from the danger of injuring the nervous and vascular systems.
    b. The disadvantage is that the injection site is visible to the child.
    c. Administration.
        i. Position the child supine.
        ii. Place the index finger on the anterosuperior spine.
        iii. With the middle finger moving dorsally, locate the iliac crest; drop finger below the crest. The triangle formed by the iliac crest, index finger, and middle finger is the injection site.
        iv. Inject needle perpendicular to the surface on which the child is lying.
5. After administration of medication, hold and cuddle the infant.
6. Administer subcutaneous injection in the fatty tissue over the anterolateral thigh.

Toddlers and School-Age Children

1. Posterogluteal injection—upper outer quadrant for IM injection.
    a. Gluteal muscles do not develop until a child begins to walk; they should be used only when the child has been walking for 1 year or more. Complications include sciatic nerve injury or subcutaneous injury (because of medication being injected) and poor absorption.
    b. Upper outer quadrant of the young child's buttock is smaller in diameter than that of an adult; thus, accuracy in determining the area constituting the upper outer quadrant is essential.
    c. Administration.
        i. Do not use a needle longer than 1 inch.
        ii. Position the child in a prone position.
        iii. Place thumb on the trochanter.
        iv. Place middle finger on the iliac crest.
        v. Let index finger drop at a point midway between the thumb and middle finger to the upper outer quadrant of the buttock. This is the injection site.

vi. Insert needle perpendicular to the surface on which the child is lying, not to the skin.

2. Ventrogluteal injection for IM injection.
   a. May be used for the older child who is difficult to restrain.
   b. See description given above.
3. Deltoid injection for IM injection.
   a. May be used for older, larger children.
   b. Inaccurate site injection can result in damage to the radial nerve or brachial artery.
   c. Determine injection site by palpating the acromion process of the shoulder and placing two fingers down from the acromion process.
   d. Inject needle at 90-degree angle or slightly toward the shoulder.
4. Lateral and anterior aspect of the thigh for IM injection.
   a. Do not use a needle longer than 1 inch.
   b. Use the upper outer quadrant of the thigh.
   c. Insert needle at 45-degree angle in a downward direction, toward the knee.
5. Administer subcutaneous injection in the fatty tissue over the anterolateral thigh or outer aspect of upper arm.
6. Nursing support of toddlers and older children.
   a. Prepare all equipment before approaching the child.
   b. Explain to the child where you are going to give the injection (site) and why you are giving it.
   c. Allow the child to express fears.
   d. Carry out the procedure quickly and gently. Have needle and syringe completely prepared and ready before contact with the child.
   e. Numb the site of injection by rubbing the skin firmly with cleaning swab or with ice (older children may assist with this). Minimize pain of an IM injection by injecting the needle into the muscle with a quick, darting motion.
   f. Always secure the assistance of a second nurse or a family member to help immobilize the child and divert his or her attention as well as to offer support and comfort.
   g. Praise the child for behavior after the injection. Allowing the child to assist with applying an elastic bandage will give some feeling of comfort.
   h. Also encourage activity that will use the muscle site of the injection, this promotes dispersal of medication and decreases soreness. This can also be done by firmly massaging the muscle after injection, unless contraindicated.
   i. Accurately record the injection site to ensure proper site rotation.

Intravenous Medications

1. Intravenous (IV) administration of medications may be done through a variety of techniques, including piggyback or through a heparin lock, volume control set, or implantable port. See pages 71 to 74 for

information on these techniques.

2. Prepare mixtures aseptically (laminar flow hood) and use sterile technique when accessing the IV line. (Sepsis is a constant threat when a child is receiving IV medications.)
3. Be aware that an exaggerated pharmacologic effect may exist with IV medications. As with any medication, know the use, adverse effects, and toxic effects of the drug as well as the pharmacologic effect on the body.
4. Dilute IV medications and inject slowly—never less than 1 minute (this allows peripheral blood flow through the entire circulating system to dilute the medication and prevent high concentrations of the drug from reaching the brain and heart).
5. Be knowledgeable about compatibilities of drugs, electrolytes in IV solutions, and the fluid itself.
6. Observe the IV site frequently. Restrain the child, as needed, to prevent infiltration. Infiltration of fluids containing medications can cause rapid and severe tissue necrosis.

SPECIAL CONSIDERATIONS IN PEDIATRIC PRIMARY CARE

Acute Poisoning

Exposure to poisons can occur by ingestion, inhalation, or skin or mucous membrane contact. This section focuses on the most common poisoning, toxic ingestions. Poisoning by ingestion refers to the oral intake of a harmful substance that, even in a small amount, can damage tissues, disturb body functions, and, possibly, cause death. The substances may include such medications as acetaminophen and iron, household products, and plants.

Children are at risk for acute poisoning. Every day, over 300 Children in the United States ages 0 to 19 years of age are treated in an emergency department and two will die as a result of being poisoned. The most common agents ingested by children younger than age 6 include cosmetics and personal care products; however, cleaning products, analgesics, plants, pesticides, vitamins, and cough and cold medications also pose risk.

Pathophysiology and Etiology

1. Improper or dangerous storage of potentially toxic substances.
2. Poor lighting—causes errors in reading.
3. Human factors:
    a. Failure to read label properly.
    b. Failure to return poisons to their proper place.
    c. Failure to recognize the material as poisonous.
    d. Lack of supervision of the child.
    e. Purposeful use of poison.
4. Toxin is ingested and may have limited local effects or continue to a stage of absorption and interference with metabolic processes and organ function.
5. Typically occurs in children younger than age 6, with a peak incidence between 12 and 24 months.
6. Acute poisoning may result in arrhythmias or permanent multiorgan damage due to initial loss of airway, breathing, and circulation (ABCs) and specific organ toxicity.

Poisoning with Acetaminophen

Acetaminophen is a common drug poisoning agent in children because of its replacement of salicylates and the pleasant taste of the preparations developed to facilitate administration. Ingestion by adolescents is frequently intentional. Acetaminophen is toxic to the liver, resulting in cell necrosis and, possibly, cell death.

Clinical Manifestations

Phase I (first 24 hours after ingestion):

1. May be asymptomatic.
2. Anorexia.
3. Nausea and vomiting.

4. Diaphoresis.
5. Malaise.
6. Pallor.

Phase II (24 to 48 hours after ingestion):

1. Symptoms of phase I diminish or disappear.
2. Right upper quadrant pain due to liver damage.
3. Liver enlargement with elevated bilirubin and hepatic enzymes and prolonged prothrombin time.
4. Oliguria.

Phase III (days 3 to 5 after ingestion):

1. Signs of hepatic failure, such as jaundice, hypoglycemia, coagulopathy, and encephalopathy.
2. Peak liver function abnormalities.
3. Anorexia, nausea, vomiting, and malaise may reappear.
4. Renal failure and cardiomyopathy may occur.

Phase IV:

1. Associated with recovery or progression to complete liver failure and death.

Diagnostic Evaluation

1. Serum acetaminophen level 4 hours after ingestion.
2. Serial liver function tests.
3. Urine and serum chemistry studies for renal function.

Management

1. Activated charcoal should be given if treatment is instituted within 6 to 8 hours after ingestion; if treatment is begun after this time frame, activated charcoal is not used unless another toxic substance was ingested.
2. *N*-Acetylcysteine as an antidote given orally or via IV line. This is the most extensively studied regimen for acetaminophen overdose.
3. As with all poisons, ABCs and treatment of shock are always the priority in management.

Iron Poisoning

Iron poisoning occurs frequently in childhood because of the prevalence of iron-containing preparations. The severity of iron poisoning is related to the amount of elemental iron absorbed. The range of potential toxicity is between 50 and 60 mg/kg.

Clinical Manifestations

1. Thirty minutes to 2 hours after ingestion:
    a. Local necrosis and hemorrhage of GI tract.

b. Nausea and vomiting, including hematemesis.
c. Abdominal pain.
d. Diarrhea, usually bloody.
e. Severe hypotension.
f. Symptoms subside after 6 to 12 hours.

2. Six to twenty-four hours—period of apparent recovery.
3. Twenty-four to forty hours:
   a. Systemic toxicity with cardiovascular collapse, shock, hepatic and renal failure, seizures, coma, and, possibly, death.
   b. Metabolic acidosis.
4. Two to 4 weeks after ingestion:
   a. Pyloric and duodenal stenosis.
   b. Hepatic cirrhosis.

Diagnostic Evaluation

1. Measurement of serum-free iron.
   a. Total serum iron.
   b. Total serum iron-binding capacity.
2. Abdominal x-ray to visualize iron tablets; limited use for visualizing liquid toxins.

Management

1. Gastric lavage may be of some benefit because iron is not absorbed by activated charcoal; however, wide lumen must be used, which may not be possible in small children.
2. Whole-bowel irrigation reduces the absorption of iron and sustained-release drugs.
3. Administration of deferoxamine for severe cases—iron-chelating agent that binds with iron and is excreted in urine (urine will be bright red).

Primary Assessment in Acute Poisoning

1. Initial assessment should include evaluation of ABCs, level of consciousness, vital signs, and neurologic assessment.
2. Assess for symptomatic effects of poisoning by systems.
   a. GI—common in metallic acid, alkali, and bacterial poisoning. These may include nausea and vomiting, diarrhea, abdominal pain or cramping, and anorexia.
   b. CNS—may include seizures (especially with CNS depressants, such as alcohol, chloral hydrate, barbiturates) and behavioral changes. Dilated or pinpoint pupils may be noted.
   c. Skin—rashes; burns to the mouth, esophagus, and stomach; eye inflammation; skin irritations; stains around the mouth; lesions of the mucous membranes. Cyanosis may be visible, especially with cyanide and strychnine.

d. Cardiopulmonary—dyspnea (especially with aspiration of hydrocarbons) and cardiopulmonary depression or arrest.

e. Other—odor around the mouth.

3. Identify the poison when possible.

a. Determine the nature of the ingested substance from the child's history or by reading the label on the container. Nursing intervention may need to be implemented immediately after this assessment.

b. Call the nearest poison control center or toxicology section of the medical examiner's office to identify the toxic ingredient and obtain recommendations for emergency treatment. The United States toll-free number is (800) 222-1222.

c. Save vomitus, stool, and urine for analysis when the child reaches the hospital.

NURSING ALERT It may be necessary to initiate emergency respiratory and circulatory support at this time. If needed, obtain venous access, maintain safety during seizure activity, and treat shock. Otherwise, continue with assessment.

Primary Interventions

Assisting the Family by Telephone Management

1. Calmly obtain and record the following information:

a. Name, address, and telephone number of caller.

b. Evaluation of the severity of the ingestion.

c. Age, weight, and signs and symptoms of the child, including neurologic status.

d. Route of exposure.

e. Name of the ingested product, approximate amount ingested, and time of ingestion.

f. Brief past medical history.

g. Caller's relationship to victim.

2. Instruct the caller about appropriate emergency actions or refer to (800) 222-1222.
3. Direct the patient to the nearest emergency department. Dispatch an ambulance, if necessary.
4. Instruct the caller to clear the child's mouth of any unswallowed poison.
5. Identify what treatments have already been initiated.
6. Instruct the parents to save vomitus, unswallowed liquid or pills, and the container and to bring them to the hospital as aids in identifying the poison.
7. Identify whether other children were involved in the poisoning to initiate treatment for them also.

DRUG ALERT Do not administer household neutralizing foods or products (unless recommended by poison control specialist) because the heat generated by the chemical reaction could result in a burn (or exacerbation of an existing burn).

Intervention Related to the Patient's Condition

Support ABCs, as needed.

Removing the Poison from the Body

1. If the poison is nonpharmaceutical, have the child drink 100 to 200 mL of water if told to do so by Poison Control. If a medication was ingested, do not dilute with water, as this may speed absorption.
2. For skin or eye contact, remove contaminated clothing and flush with water for 15 to 20 minutes.
3. For inhalation poisons, remove from the exposed site.
4. Administer gastric lavage if the toxin is not bound by charcoal (most effective within 50 minutes after ingestion).
5. Follow lavage with a cathartic and activated charcoal to hasten removal of the poison from the GI tract. Use cautiously with young children.
6. Be aware of the dangers associated with lavage.
    a. Esophageal perforation—may occur in corrosive poisoning.
    b. Gastric hemorrhage.
    c. Impaired pulmonary function resulting from aspiration.
    d. Cardiac arrest.
    e. Seizures—may result from stimulation in strychnine ingestion.
7. Follow lavage (if performed) with activated charcoal (preferably within 1 hour after ingestion) to hasten removal of the poison from the GI tract.
    a. Charcoal poorly absorbs most electrolytes, iron, lithium, mineral acids and bases, alcohols, cyanide, most solvents, and hydrocarbons.
    b. Administer 30 to 50 g for an adolescent, in 6 to 8 ounces (180 to 240 mL) of water with sweetener.
    c. It is sometimes easier to administer in an opaque beverage container as some children are hesitant to drink the charcoal because of its unusual dark color.
